Title: Understanding the role of 16p11.2 CNV genes in human cerebral corticogenesis

Authors: *S. MORSON, Y. YANG, D. J. PRICE, T. PRATT
The Univ. of Edinburgh, Edinburgh, United Kingdom

Abstract: The process of the brain developing from a single fertilised cell to the most sophisticated known organ requires precise spatial and temporal control to produce the required brain size and architecture. A particular region of interest is the cerebral cortex, responsible for higher functions such as language, reasoning and conscious thought. Its expansion in size and complexity from smaller mammals (such as mice) to humans is thought to give rise to our higher functions. However a caveat of this increased complexity is the increased challenge of generating such a complex structure, and the potential for subtle changes during neurodevelopment to manifest in neurodevelopmental disorders, such as Autism Spectrum Disorders (ASD).
The 600kbp 16p11.2 CNV encompasses 29 genes and its heterozygous duplication (dup) or deletion (del) is implicated in around 1% of ASD cases, with many patients suffering macrocephaly (del) or microcephaly (dup) indicating early neural proliferation defects. Given the vast heterogeneity of ASD this is a significant proportion making this region a promising area of study to understand how genetic dysregulation during critical pre-natal neurodevelopment can contribute to the ASD phenotype.
Using *in silico* analysis of human fetal scRNA-seq data to identify candidate genes we present highly novel data showing the *in vivo* expression pattern of genes enriched during neural proliferation during human corticogenesis. We describe their role in regulating proliferation to understand how their dysregulation may underlie the patient phenotype.
In parallel, we show data from our studies using hiPSCs derived from 16p11.2 del patients to elucidate the complex molecular changes early in neurogenesis that may underlie the phenotype of this CNV, with the long term goal of culturing cerebral organoids. This allows us to test our hypothesis that the 16p11.2 CNV genes play a vital role in human neurogenesis.

Title: Ogt regulates adult hippocampal neurogenesis and cognition

Authors: *C. W. WHITE, III[1], X. FAN[2], E. WHEATLEY[1], G. BIERI[3], S. A. VILLEDA[2]
[1]Developmental and Stem Cell Biol., [2]Anat., Univ. of California, San Francisco, San Francisco, CA; [3]Stanford Univ., Menlo Park, CA

Abstract: Adult hippocampal neurogenesis, the process by which new neurons are generated in the adult hippocampus, provides a significant source of cellular plasticity in the adult brain. Within the dentate gyrus subregion, neural progenitor cells (NPCs) undergo rounds of division and maturation, ultimately giving rise to functional neurons that integrate into existing hippocampal circuitry. Decreased adult neurogenesis is commonly observed alongside impaired cognitive function, in conditions such as neurodegenerative disease and aging. Given the prevalence of these conditions, it is critical to understand the mechanisms regulating the self-renewal and differentiation of adult NPCs. One potential mediator of these processes is the post-translational modification O-linked β-N-acetylglucosamine (O-GlcNAc). Previously implicated in the context of regulation of gene expression in embryonic stem cells, the catalytic enzyme responsible for addition of this modification, O-GlcNAc transferase (Ogt), has also been shown to be essential for both embryonic stem cell and neuronal survival. Interestingly, the roles of O-GlcNAc and Ogt have not yet been explored in NPCs. Here we report that Ogt regulates adult hippocampal neurogenesis, and associated cognitive processes. Using an in vitro lentiviral-mediated RNAi approach, we demonstrate that abrogating Ogt expression in primary NPCs impairs self-renewal and proliferation. Using a complementary in vivo lentivirus-mediated RNAi approach resulted in a marked decrease in NPC proliferation following Ogt knockdown in the adult dentate gyrus. To gain further mechanistic insight at a cell-type specific level in vivo, we utilized a temporally controlled adult NPC-specific conditional knockout mouse model. Loss of Ogt in adult NPCs resulted in decreased levels of adult neurogenesis accompanied by impairments in spatial learning and memory, and associative fear memory. Taken together, this work identifies Ogt as a novel regulator of adult NPC function, and posits O-GlcNAcylation as a

potential therapeutic target for ameliorating neurodegenerative- and age-related loss of neurogenesis and associated cognitive decline.

Title: HDAC3 differentially regulates the proliferation of two progenitor pools by Wnt/β-catenin signaling in the developing tectum

Authors: *W. SHEN[1], J. GAO[2], Z. GUO[1], L. ZHENG[1], N. DING[1], Y. LIAO[1]
[1]Col. of Life and Envrn. Sci., [2]Hangzhou Normal Univ., Zhejiang, China

Abstract: It is known that radial glial cells (RGs) are one of the major progenitor cells in the developing Xenopus tectal brain. Our previous data have shown that a majority of BLBP-positive RGs are BrdU+ progenitor cells. Visual experience-dependent proliferation of RGs is selectively mediated by histone deacetylase 1/3 (HDAC1/3) but not HDAC2 in the developing brain. However, the classification of progenitor cells is not fully determined in the developing optic tectum. We immunostained the whole tectal brain at different developmental stages and find that SOX2+ and BLBP+ progenitor cells are specifically distributed along the ventricles. In particular, we first find that there is a large cluster of SOX2+ and BLBP- cells located in the pretectum, which are SOX6- and SOX9- at stage 47. We previously have shown that RGs are BrdU+ progenitor cells by bath incubation of BrdU. Interestingly, the SOX2+ cells in pretectum can only be labeled by brain injection of BrdU. These data indicate that there are two distinct progenitor pools existed in the developing tectal brain. The SOX2+ progenitor cells in pretectum and ventricle may play different roles in the brain development. To determine whether HDAC is involved in the proliferation of SOX2+ cells, tadpoles were exposed to a HDAC inhibitor (VPA). The number of SOX2+ cells is greatly increased in the ventricular layer while significantly decreased in the pretectum at stage 49 tadpoles. The histone of H3 acetylation at lysine 9 and H4 acetylation at lysine 12 were consistently increased. To determine whether SOX2+ cells are regulated by visual experience, tadpoles were exposed to visual deprivation (VD) for 2 days. We find that the proliferation of SOX2+ cells are dramatically decreased by VD in the pretectum while gradually increased in the ventricle. Furthermore, the expression of SOX2 cells in the

pretectum is significantly decreased in response to visual deprivation by Western blot. In particular, SOX2 are colocalized with β-catenin only in the pretectum but not in the ventricle. Knockdown of SOX2 decreases the expression of HDAC3 and β-catenin while knockdown of β-catenin also decreases the expression of HDAC3 and SOX2. These data suggest that visual experience dependent proliferation of SOX2+ cells is differentially regulated by SOX2, β-catenin and HDAC3 signaling.

Title: Dlx1/2 promote olfactory bulb interneuron generation through activating Sp8/9 expression

Authors: *T. GUO, H. DU, Z. YANG
Fudan Univ., Shanghai, China

Abstract: Generation of olfactory bulb (OB) interneurons requires neural stem/progenitor cell proliferation, specification and differentiation, and interneuron migration and maturation. Here, we show that the homeobox transcription factors *Dlx1/2* are required for the generation of all OB interneurons. In *Dlx1/2* constitutive null mutants, GSX2-expressing (+) and $ASCL1^{+}$ progenitors in the dorsal lateral ganglionic eminence (dLGE) fail to generate $Sp8/9^{+}$ OB interneurons, whereas they appear to transform toward immature undifferentiated medium spiny neuron-like cells. In adult *Dlx1/2* conditional mutants (hGFAP-Cre; $Dlx1/2^{F/-}$), $GSX2^{+}$ and $ASCL1^{+}$ neural progenitors in the subventricular zone generate neuroblasts that fail to express SP8 and SP9. Overexpression of DLX1/2 in neural progenitors of the E14.5 mouse neocortex led to generation of immature OB interneurons in the E18.5 cortex that express *Sp8/9*, *GAD1*, *Arx*, *Etv1*, *Pbx3*, *Tshz1* and *Prokr2* expression. Thus, we propose that DLX1/2 promote OB interneuron development mainly through activating the expression of *Sp8/9*. This study, in combination with earlier studies, presents a transcriptional regulatory network that controls the multistep process of OB interneuron development.

Abstract: Subcortical heterotopia (SH) is a cortical malformation characterized by the presence of mis-localized neurons beneath the normal cortex within the white matter. This pathology is associated with intellectual disability and epilepsy. The microtubule-associated protein EML1/Eml1 was found mutated in three families presenting this disorder (Kielar et al., 2014, Shaheen et al., 2017), as well as in the heterotopic cortex (*HeCo)* mouse, which is a model for SH. At early stages of corticogenesis, abnormally positioned neuronal progenitors were found cycling outside the proliferative ventricular zone (VZ) of the mutant cortex in the region where the heterotopia develops. In order to elucidate the mechanisms leading to ectopic progenitors, we study the *HeCo* VZ, focusing on apical radial glia (aRG) in this zone, the source of all other cortical progenitors. The *HeCo* mouse is hence a good model to study key features influencing neuronal progenitor behavior while shedding light on patho-mechanisms contributing to the heterotopia phenotype.
Using a variety of approaches (genetic tools, confocal and electron microscopy) we identified centrosome and primary cilia defects in *HeCo* aRG endfeet, which are also larger and less numerous at the mutant ventricular surface. Our data reveals that in Eml1 mutant conditions, primary cilia are shorter and often fail to protrude towards the ventricle, remaining basally

oriented. Ciliary anomalies associated with Eml1 mutations are supported by studies in patient fibroblasts, which also show a decrease in number and length of these organelles. Our converging data suggest an unprecedented role for Eml1 in primary cilium formation. Additionally, mass spectrometry (MS) analyses for Eml1 interacting partners point towards ciliary proteins. This combined approach followed by biochemical experiments has led us to confirm the interaction of Eml1 with the basal body-ciliary protein Rpgrip1l. Gene ontology analyses of MS data are guiding ongoing experiments to dissect the intracellular mechanisms by which primary cilia fail to properly form in Eml1 mutant conditions.

Title: Microglia interface with the mitotic neural precursor cells that line the surface of the lateral ventricles

Authors: *S. C. NOCTOR[1,2], H. SHEPHERD[7], J. KEITER[3], N. BARGER[1], A. KREUTZ[4], A. F. TARANTAL[5,6,8]
[1]Psych & Behavioral Sci., [2]MIND Inst., UC Davis, Sacramento, CA; [3]Ctr. for Neurosci., [4]Neurosci. Program, UC Davis, Davis, CA; [5]Pediatrics, UC Davis, Sacramento, CA; [6]Cell Biol. and Human Anat., UC Davis, Davis, CA; [7]Biol., Brigham Young Univ. - Idaho, Rexburg, ID; [8]Ctr. for Fetal Monkey Gene Transfer for Heart, Lung, and Blood Dis., California Natl. Primate Res. Ctr., Davis, CA

Abstract: Microglia contribute to the development of axonal pathways, synapse formation, cortical layer formation, and cell genesis. Yet, microglial cell functions in the prenatal brain are not fully understood. Microglia begin to colonize the cerebral cortex during prenatal development: in rat by embryonic day (E)13, and in rhesus monkey during the first trimester prior to 50 days gestation. Microglia do not initially distribute evenly throughout the cortex, as found in healthy adult cortex, but instead populate a few specific regions such as the cortical

proliferative zones. Furthermore, prenatal microglia in the cortex do not display the 'resting' morphology characteristic of healthy adult cortex, but exhibit distinct 'activated' morphological phenotypes that correlate with cell location in the proliferative zones. Microglia in the subventricular zone (SVZ) tend to exhibit an 'amoeboid' morphology - larger cell bodies with a few short, thick processes, while periventricular microglia have smaller soma and extend longer, thinner processes. We have found that microglia make extensive contacts with neural precursor cells (NPCs) throughout the proliferative zones. To shed light on microglial function in the proliferative zones we quantified the frequency and type of interactions between microglia and NPCs undergoing division at the surface of the ventricle, and NPCs dividing in the SVZ of prenatal rats and rhesus monkeys. In E19 rats fewer than 50% of NPCs dividing at the ventricle were contacted by periventricular microglia, but all periventricular microglia contacted multiple dividing NPCs. Periventricular microglia were more likely to contact the pial process of prophase and metaphase NPCs, and were more likely to contact the soma of anaphase and telophase NPCs. Similar interactions were observed in the gestation day 90 monkey, but a larger proportion of mitotic NPCs interacted with microglia in the rhesus monkey. Microglia interfaced with dividing NPCs in the SVZ of both species, but the number of microglia in the monkey SVZ was significantly higher. NPCs divide at the surface of the ventricle during forebrain development of all vertebrates, but the number of NPCs that divide away from the ventricle and in the SVZ varies significantly and is largest in species such as primates. Our data suggest that the number of periventricular and SVZ microglia across species correlates with the number of NPCs in the SVZ and that the distinct morphology of periventricular and SVZ microglia reflects different functional roles for these cells.

Title: Rac is required for the survival of cortical neurons

Authors: *K. KATAYAMA[1], Y. ZHENG[2]
[1]Dept. of Mol. Cell Biol. and Mol. Med., Wakayama Med. Univ., Wakayama, Japan; [2]Div. of Exptl. Hematology and Cancer Biol., Cincinnati Children's Hosp. Mrdical Ctr., Cincinnati, OH

Abstract: Rac1 is a member of Rho family small GTPases, and previous studies have shown that it plays important roles in various steps of neural development including neurogenesis, neuronal migration and neuritogenesis. However, these functions are mainly deduced from studies using cultured cells and its physiological roles in neural development still remain unclear. Previous studies showed that deletion of Rac1 in early neurodevelopmental stages caused severe microcephaly due to defective neurogenesis. In the present study, we deleted Rac1 using GFAP-Cre mice, which induces Cre/loxP recombination in neuronal cells from E13.5 to investigate the roles of Rac1 in later neurodevelopmental stages. Although cerebral cortices of Rac1;GFAP-Cre conditional knockout mice were slightly smaller than those of control mice, they grew up almost normally. To exclude the possibility that Rac3, a close homolog of Rac1 expressed in the nervous system, compensates the function of Rac1, we also deleted Rac1 in Rac3-null background. At birth, overall morphology of the Rac1/Rac3-deleted cerebral cortex was almost normal. However, soon after birth, cortical neurons lacking both Rac1 and Rac3 began to die by apoptosis. The cerebral cortex of Rac1;Rac3;GFAP-Cre conditional knockout mice became thinner as they grew up and the mice died before 3 weeks of age. Existence of either one allele of Rac1 or Rac3 could protect cortical neurons from apoptotic cell death. These results suggest that Rac plays a critical role in the survival of cortical neurons.

Title: Leukemia inhibitory factor signaling and STAT3 phosphorylation at Ser727 in fetal mouse brain development

Authors: *T. TSUKADA[1,2], H. SAKAGAMI[1], H. SHIMADA[1,3], S. TAKATA[2], H. SAKATA-HAGA[1], H. SHOJI[4], H. IIZUKA[2], T. HATTA[1]
[1]Anat., [2]Neurosurg., [3]Med. Sci., [4]Biol., Kanazawa Med. Univ., Ishikawa, Japan

Abstract: Leukemia inhibitory factor (LIF) in the fetal cerebrospinal fluid (CSF) may have a role in neural progenitor pool expansion and corticogenesis in the fetal rodent brain. Generally, LIF binds to specific receptors, LIFR and gp130, and subsequently signal transducer and activator of transcription 3 (STAT3) is activated by Janus kinase 2-mediated phosphorylation of

the Tyr705 site. It has been believed this activated STAT3 has an essential role in LIF–STAT3 signaling. STAT3 is known to have another phosphorylation site, Ser727, although the contributions of STAT3 phosphorylation at Ser727 to neurogenesis are unclear. In this study, the expression of LIF-related signal molecules and the phosphorylation of STAT3 were examined in the dorsal fetal mouse brain. Fetuses from C57BL/6J mice were collected during mid-gestational days. The concentration of LIF in the fetal CSF was measured using enzyme-linked immunosorbent assay and stained sections of fetal brain using antibodies for LIFR, gp130, and phosphorylation of STAT3 at Tyr705 and Ser727. The levels of phosphorylation of STAT3 at Tyr705 and Ser727 were also examined by Western blotting. The highest level of LIF in the fetal CSF was observed between 12.5 and 14.5 days post coitum (dpc). At 13.5 dpc, LIFR was expressed and gp130 was phosphorylated in the fetal brain. Sections indicated the phosphorylation of STAT3 at Ser727 but not that of STAT3 at Tyr705. In addition, Western blotting revealed phosphorylation of STAT3 at Ser727 but not at Tyr705 in the fetal brain. Considering the previous reports on the role of LIF in expanding neural progenitor pool, these results suggest that the phosphorylation of STAT3 at Ser727 plays a role in LIF-mediated neurogenesis independent of the phosphorylation of STAT3 at Tyr705 in fetal mouse brain.

Title: Cx43 as a marker gene of ependymal cells in the spinal cord of zebrafish embryo

Authors: *J. KIM, I.-H. JUNG
Chonnam Natl. Univ. Hosp., Gwangju, Korea, Republic of

Abstract: Objective: Ependyma is the simple ciliated epithelium that lines the ventricular surface of the central nervous system, and consists primarily of ependymal cells, one type of glial cells. Ependymal cells have cilia and microvilli, and are involved in the absorption of the cerebrospinal fluid (CSF). Defect in ependymal cells leads to hydrocephalus. As such, I sought to determine molecular mechanism underlying development of ependymal cells using a zebrafish model.
Methods: Spinal cords of zebrafish larvae were examined for the presence of ependymal cells by electron microscopy, and for a specific marker gene for ependymal cells by in situ RNA hybridization. Antisense oligonucleotide morpholino (MO) against cx43 was injected into zebrafish embryos to determine a loss-of-function phenotype of cx43, and Sonic hedgehog (Shh)

mutant embryos were subjected to in situ hybridization with cx43 riboprobes to check if Shh signaling is involved in the development of ependymal cells. In addition, in situ hybridization with cx43 riboprobes was performed on larvae treated with cyclopamine, a Shh signaling inhibitor, to confirm the finding obtained from Shh mutant larvae. Finally, Quantum dot was injected into the ventricle of larvae and the diffusion rate of the Quantum dot into the central canal was assessed.
Results: In situ hybridization with cx43 riboprobes revealed that cx43 was specifically expressed in the ependymal cells in the developing spinal cord. In addition, ependymal cells in the human spinal cord were shown to specifically express Cx43, as demonstrated by immunohistochemistry with anti-connexin43 antibody and anti-acetylated tubulin antibody. Cx43 morphants showed defect in ependymal cell development, which was rescued by microinjection of mouse cx43 RNA. Defect in ependymal cell development was observed in Shh mutant embryos and cyclopamine-treated embryos. cx43 morphants exhibited slower rate of diffusion of Quantum dot, which was injected into the ventricle of larvae, into the central canal than did control larvae.
Conclusion: cx43 is a marker gene for ependymal cells both in zebrafish and human, and plays an important role in ependymal cell development. Furthermore, Shh signaling is involved in the ependymal cell development.

Title: Fubp1 controls neural stem cell differentiation through cooperation with notch

Authors: *D.-Y. KIM[1], M. KANG[1], I. HWANG[2], T.-J. KIM[1], J. SUNG[1], J. PAIK[2]
[1]Dept of Pharmacology, Sch. of Dent., Kyungpook Natl. Univ., Daegu, Korea, Republic of;
[2]Dept. of Pathology and Lab. Med., Weill Cornell Med., New York, NY

Abstract: Neural stem cells (NSCs) are pluripotent self-renewing cells, which can give rise to new neurons and glial cells. As candidates of cell therapy for central nervous system injury or degenerative diseases, massive progress toward understanding NSCs has been made in recent decades. However, stem cell-based therapies still showed several problems such that the grafted NSCs maintain the undifferentiated states and fail to differentiate into appropriate neurons, or

that the grafted cells are developed into tumor cells. Therefore, characterization of NSCs fate decision mechanisms and identification of key factors regulating NSCs differentiation should be critical pre-requisites for NSC-based therapies. Here, we demonstrate that Fubp1 is highly expressed in proliferating neural stem/precursor cells (NSPCs) and Fubp1 expression is gradually reduced in the early phase of NSPC differentiation. We also showed that modulation of Fubp1 level influences NSPC fate regulation. We propose that functional interaction between Fubp1 and Notch pathway contributes to the maintenance of NSPC homeostasis.

Title: GLI2 promotes cell proliferation and migration through transcriptional activation of ARHGEF16 in human glioma cells

Authors: *L. CHEN[1], L. XU[2], D. HUANG[2], Y. WANG[2], M. CHENG[2], W. SHI[2], H. XIONG[2], D. ZALLI[3], S. LUO[2]

Abstract: The Hedgehog (Hh) signaling pathway plays critical roles in modulating embryogenesis and maintaining tissue homeostasis, with glioma-associated oncogene (GLI) transcription factors being the main mediators. Aberrant activation of this pathway is associated with various human malignancies including glioblastoma, although the mechanistic details are not well understood. We addressed this question in the present study by performing a microarray analysis of genes that are differentially expressed in glioblastoma U87 cells overexpressing GLI2Arelative to the control cells. We found that *Rho guanine nucleotide exchange factor* (*ARHGEF*)*16* mRNA level was upregulated in U87 cells overexpressing GLI2A—the active form of GLI2—relative to control cells. The results of chromatin immunoprecipitation and dual-luciferase assays revealed that GLI2 binds to the *ARHGEF16* promoter and activates gene transcription. U87 and U118 cells overexpressing ARHGEF16 showed enhanced migration and proliferation relative to control cells, as determined by transwell migration and soft-agar colony

formation assays, respectively. A yeast two-hybrid assay revealed that ARHGEF16 interacts with cytoskeleton-associated protein (CKAP)5 and that this association is important for the stimulatory effects of ARHGEF16 on glioma cell migration and proliferation. These results suggest that therapeutic strategies
targeting the GLI2/ARHGEF16/CKAP5 signaling axis could inhibit glioma progression and recurrence.

Title: The small regulatory cytokine, Midkine-a, mediates stem cell proliferation and microglial phagocytosis during photoreceptor regeneration in zebrafish

Authors: *M. NAGASHIMA, P. F. HITCHCOCK
Univ. of Michigan, Ann Arbor, MI

Abstract: Midkine (Mdk) is a small, heparine-binding cytokine/growth factor that has multiple roles in neural development, repair and disease. During retinal development in zebrafish, *midkine-a*/Mdka, one of two paralogous *midkine* genes, functions to govern elements of the cell cycle. To explore the role of Mdka during regenerative neurogenesis, we generated mutant zebrafish using CRISPR-Cas9 gene editing and compared the death and regeneration of photoreceptors in wildtype and mutant animals. In Mdka mutants, the intrinsic retinal stem cells respond to the selective death of photoreceptors by dedifferentiating, characterized by increased expression of stem cell-associated genes, such as Rx1 and Sox2, however, reentry cell into the cell cycle is significantly diminished, resulting in reduced number of regenerated photoreceptors. This result indicates that Mdka is required for the intrinsic stem cells to enter the cell cycle, a result that is consistent with the role of Mdka in governing cell cycle kinetics during retinal development. In addition, in Mdka mutants, microglia respond abnormally to the apoptotic death of photoreceptors. Although the photoreceptor death follows a time frame observed for wildtype animals, microglia fail to phagocytose the dying photoreceptors, resulting in the persistence of apoptotic nuclei and the accumulation of reactive microglia in the photoreceptor layer. These results suggest that Mdka also plays a role in orchestrating inflammatory events following neuronal death and mediates the interaction between microglia and dying photoreceptors.

Abstract: Proteins of the major histocompatibility complex class I (MHC I), previously known mainly for antigen presentation in the immune system, have recently been shown to be necessary for both developmental neural refinement and adult synaptic plasticity. However, their roles in non-neuronal cell populations in the brain have yet to be investigated. Our study identifies classical MHC I molecule H2-K^b as a negative regulator of proliferation in neural stem cells (NSCs), a cell type conferring inherent regenerative capacity to the brain. Adult animals with a genetic deletion ($K^{-/-}$) or acute knockdown of H2-K^b in the dentate gyrus exhibit enhanced cell division and an increased number of adult-born neurons in the hippocampus. This proliferative phenotype is recapitulated in cultured $K^{-/-}$ NSCs devoid of influences from the neurogenic niche or systemic environment, suggesting the effects are cell type specific. Subsequent transcriptomic analysis of $K^{-/-}$ and wild type NSCs further revealed that endogenous H2-K^b molecules inhibit NSC proliferation by dampening growth factor receptor signaling pathways, through a physical interaction with fibroblast growth factor receptor 1. These findings identify H2-K^b as a potential therapeutic target in neurodegenerative disorders or aging, where neurogenic dysfunction is a hallmark.

Abstract: Introduction. 5 Bromo 2 Deoxyuridine (BrdU) is a marker of neurogenesis widely used in animal models[1]. To date, it is unknown if the systemic administration of BrdU has a cytotoxic effect. In this study, we evaluated the physiological impact that multiple intraperitoneal administrations of BrdU, over 384 h, has in the liver of male and female Wistar rats. **Methodology.** This study was carried out with 21 rats divided in groups by sex and into subgroups (n=3). The male rats were distributed into the subgroups: 1) Control (intact), 2) 30% hepatectomy (HP) without receiving administration of BrdU (HP - BrdU), 3) HP + BrdU, and 4) incision at muscular level (Sham). The female rats were distributed into the subgroups: 1) Control (intact), 2) HP + BrdU and 3) Ovariectomized (24 h previous) + HP + BrdU. BrdU (50 mg/kg) was administered intraperitoneally. The volume corresponding to the weight of each rat was prepared in 250 μL of 0.1 M PBS, starting from a stock diluted in 50 μL of DMSO. The administrations of BrdU were applied at 12, 24, 48, 96, 144, 192 and 384 h post HP. Sham subgroup was euthanized the same day. The rest of the subgroups were euthanized at 384 h. **Results**. There was a survival rate of 96.7% and the animals showed dynamism similar to control groups. Liver function was assessed at a biochemical level. Total protein content, albumin, AST and LDH showed no significant difference in regard to the controls, between treatments (or sexes).As for total and conjugated bilirubin, only the group of male rats that did not receive BrdU showed significant increase (5.07x and 6.19x vs control respectively). The alkaline phosphatase content showed no significant difference between the BrdU group and the controls. The incorporation of rats with previous ovariectomy did not evidence significant differences with their control. However, the administration of BrdU induced the increase of 1.68x the levels of ALT in regard to control in male rats. **Discussion**. HP induces alteration in bilirubin and alkaline phosphatase levels demonstrated in the hepatic regenerative process. Ovariectomy does not affect the levels of analytes studied, which implies a component of susceptibility due to sex. An incision at muscular level induces an increase in ALT levels. Therefore, the observed increase in ALT levels in the BrdU group is due to the surgery and the mechanical stimulation due to injection[2,3]. **Conclusion.** Repeated administrations of BrdU (50 mg/kg) over 384 h in male and female Wistar rats did not induce significant alteration in the liver function tests. Title: MicroRNA expression in brain exosomes is altered in a Kainate model of chronic Temporal Lobe Epilepsy

Authors: *D. GITAI[1,2], Y. DOS SANTOS[1], R. UPADHYA[2,3], M. KODALI[2,3], A. K. SHETTY[2,3]

Abstract: Temporal lobe epilepsy (TLE), the most common type of epilepsy, is often medically intractable. An initial precipitating injury to the brain resulting from a variety of causes underlies TLE in most cases, as such injury leads to the development of multiple epileptogenic changes in the hippocampus and the establishment of chronic epilepsy typified by spontaneous seizures. Precise mechanisms underlying the transformation of the injured hippocampus into an epileptic hippocampus are still unclear. We hypothesize that brain exosomes released from neurons and glia play an important role in epileptogenesis and the maintenance of chronic epilepsy. This premise is based on the ability of exosomes to facilitate the cross-talk between different types of neurons and neurons and glia through the release of their cargo (miRNAs, proteins, and lipids). These interactions can modulate function through activation or repression of multiple pathways. In this study, we compared the miRNA profile of brain exosomes in naïve and chronic epilepsy conditions using a Kainate-model of TLE. Brain exosomes were isolated by ultracentrifugation, characterized using Nanosight, electron microscopy and western blotting for CD63, and then processed for RNA-Seq. The exosomes from chronically epileptic brains displayed downregulation of 3 miRNAs (miR-187-5p, miR-346 and miR-331-3p) and upregulation of 4 miRNAs (miR-490-5p, miR-376b-3p, miR-493-5p and miR-124-5p) with fold changes ranging from 1.5 to 2.4 ($p<0.0006$; FDR<0.05). Bioinformatic analyses using microT-CDS and TargetScan tools retrieved a list of predicted target genes. Pathway analysis was performed by KEEG database to determine the biological significance of these targets and evaluate their representation. For some miRNAs, we observed overrepresentation of signaling pathways that are linked to molecular mechanisms underlying spontaneous seizures and chronic epilepsy, such as GABA-ergic synapses (miR-346 targets), spliceosomes (miR-331-3p targets) and gap junctions (miR-493-5p targets). Validation of the differential expression of identified miRNAs

and their targets in the epileptic brain through RT-qPCR and western blotting assays are underway. The results suggest that certain miRNAs in brain exosomes participate in maintaining a chronic epileptic state, which may be important for understanding the pathophysiology of TLE as well as developing promising therapeutic targets.

Title: Intranasal administration of exosomes from human iPSC-derived NSCs enhances neural stem/progenitor cell proliferation and neurogenesis in the normal adult hippocampus

Authors: *A. K. SHETTY[1,2], R. UPADHYA[1], S. ATTALURI[1], M. PINSON[1], J. XU[1], B. SHUAI[1]

Abstract: Exosomes are tiny extracellular vesicles secreted by cells. They carry a cargo of miRNAs, proteins, and lipids and are involved in cell-cell communication as well as transmission of disease. Conversely, exosomes derived from stem cells such as mesenchymal stem cells and neural stem cells (NSCs) have neuroprotective and antiinflammatory properties. Such exosomes may also have neurogenic properties. The use of stem cell-derived exosomes for enhancing brain function in normal and disease conditions is attractive as they can be harvested, characterized and banked for prolonged periods. Their small size makes them particularly amenable for administration to the brain via relatively non-invasive intranasal (IN) and intravenous routes. The use of EVs also avoids several potential safety hazards linked with cells such as the risk for tumors. Our previous study has shown that IN administered exosomes can enter virtually all regions of the forebrain and get incorporated into neurons and microglia (Castro et al., SFN abstracts, 2017). Here, we examined the neurogenic property of exosomes generated from human induced pluripotent stem cell (hiPSC)-derived NSCs. We generated NSCs from hiPSCs using standardized methods and then expanded NSCs in adherent cultures. The conditioned media containing NSC-derived exosomes was next processed for a concentration step followed by ion exchange chromatography (Kim et al., PNAS, 2016). The exosomes were further concentrated using 100kDa ultrafiltration columns. Nanosight analysis revealed that the

size of exosomes varied from 50-120 nm (average size, 103 nm). hNSC-derived exosomes also expressed the exosome marker CD63. We administered these exosomes intranasally to mildly-anesthetized adult (6 months old) male rats (~62.5 billion exosomes/nostril, ~125 billion/rat) and examined NSC behavior and neurogenesis in the subgranular zone (SGZ) of the hippocampus 14 days after administration. Measurement of Ki-67 expressing cells in the SGZ revealed the proliferation of increased numbers of putative NSCs in animals receiving IN exosomes, in comparison to animals receiving IN vehicle ($p<0.01$). Moreover, Ki-67+ cell clusters in the SGZ of exosome treated animals were larger, more frequent and comprised a higher number of cells per cluster ($p<0.01$). Doublecortin (DCX+) immunostaining also revealed increased numbers DCX+ clusters containing higher numbers of immature neuroblasts ($p<0.05$). Additional analyses of neurogenesis are underway. Thus, hiPSC-NSC derived exosomes have neurogenic properties. These exosomes may be suitable as biologics for enhancing hippocampal neurogenesis in conditions such as aging and disease.

Title: Status epilepticus leads to increased concentration of neuron-derived exosomes in the blood with downregulation of mir-363-5p, mir-322-3p, and mir-320-3p

Authors: *M. LEELAVATHI NARAYANA[1], R. UPADHYA[1,2], S. ATTALURI[1], B. SHUAI[1,2], M. KODALI[1,2], D. GITAI[1], A. K. SHETTY[1,2]
[1]Inst. For Regen Med, Texas A&M Univ. Coll Med., College Station, TX; [2]Olin E. Teague Veterans' Med. Center, CTVHCS, Temple, TX

Abstract: Status epilepticus (SE) causes neurodegeneration and neuroinflammation in the brain when seizures are not extinguished quickly. An episode of SE may lead to temporal lobe epilepsy (TLE) typified by partial complex seizures and cognitive dysfunction. Yet, the progression of SE into TLE is difficult to envisage as it depends on the extent of the injury, neuroinflammation, and epileptogenic changes. Hence, finding blood biomarkers that predict whether a particular SE episode would result in TLE has importance. Exosomes released from neurons and glia into the bloodstream have promise as biomarkers of SE-induced TLE because

the composition of exosomes (microRNAs, lipids, and proteins) is likely altered after injury. As exosomes express specific markers, it is also possible to track them to the cell of origin. We developed methods to isolate neuron-derived exosomes (NDE) and astrocyte-derived exosomes (ADE) in the blood. We induced SE via Kainate injections, terminated seizures through a diazepam injection at 2h after SE onset, and collected blood at 24h after SE. We first segregated exosomes from the serum using ExoQuick kit (Systems Bio) and then separated NDE and ADE using biotinylated antibodies for CD171 (a marker of NDE) and glutamine aspartate transporter (a marker of ADE), and streptavidin-based resin. Analyses using Nanosight revealed a decreased number of total exosomes but increased numbers of NDE and ADE in the blood after SE ($p<0.05$). NDE and ADE were similar in size (64-83 nm) but were smaller than the average size of all blood exosomes (115-125 nm). All exosomes expressed the membrane marker CD63. miRNA-sequencing revealed that the top 10 abundant miRNAs in NDE and ADE were similar in both control and SE conditions. However, 4 miRNAs displayed differential expression between NDE and ADE in naïve animals. Importantly, 3 miRNAs (miR-363-5p, miR-322-3p, and miR-320-3p) in NDE were downregulated after SE. These miRNAs are involved in regulation of neurite outgrowth (miR-363-5p, Quan et al., Neurochem Res, 2017), neoangiogenesis (miR-322-3p, Altintas et al., Neurological Res, 2016), apoptosis, IGF-1 signaling, and depressive phenotype (miR-320-3p, Camkurt et al., J Psychiatr Res, 2015). Bioinformatic analyses to retrieve a list of predicted target genes is underway. Thus, isolation of NDE and ADE from the blood is feasible for biomarker discovery in neurodegenerative conditions through RNA-Seq studies. Increased NDE and ADE in the blood after SE is likely linked to neuronal hyperactivity and astrocyte reactivity. Downregulation of 3 specific miRNAs in NDEs after SE may be linked to epileptogenic processes that ensue after SE.

Title: MHCI molecules regulate cell proliferation of central nervous system during embryonic period stage

Authors: *P. LI[1], Y. SHEN[2], Y. HU[1], J. ZHANG[2]
[1]Inst. Of Life Sciences, Southeast Univ., Jiangsu, China; [2]Med. School, Southeast Univ., Jiangsu, China

Abstract: Background: Classical major histocompatibility complex class I (MHCI), first identified in the immune system, are well known for their role in the vertebrate adaptive immune response. Recent studies have shown that major histocompatibility complex (MHCI) proteins are expressed in postnatal central nervous system (CNS) where they play important roles in neuron development and synaptic plasticity. We reported that MHCI protein was widely expressed by neural progenitors in the subventricular zone where neurogenesis take place. In addition, MHCI proteins were co-expressed with the nestin-positive cells in telencephalon during E10.5. However, the functions of MHCI molecules during the initial development of CNS still remain unknown. **Methods and results:** In the present study, we attempt to determine whether MHCI molecules have effects on neurogenesis in mouse CNS at embryonic stage using littermate wild type and H2-DbKb Knock out (KO) mice. Littermate mice were injected BrdU at E15.5 and E17.5, then brain tissue were collected 20 minutes later. Immunofluorescence staining showed cell numbers that positively stained with proliferation marker PH3, BrdU and Ki67-positive decreased in H2-DbKb KO mice, suggesting the proliferation of progenitor cells reduced in KO mice. Besides that, cell numbers of double immunostaining of GFP and the BrdU were found to be elevated by overexpression of H2-Db-GFP in wild type mice from E15.5 to E16.5 by in utero eletroporation. In contrast to that, when we knocked down non-classical MHCI molecules H2-M3 using GFP expression plasmid with shRNA targeting H2-M3, the number of double positive cell decreased. **Conclusions:** Although the development of H2-DbKb KO mice was reported to be normal, our results showed that both classical and non-classical MHCI molecules have an effect on neuronal proliferation in the embryonic period. As we reported before, the expression of non-classical MHCI molecules were increased in H2-DbKb KO mice, which might compensate for loss of classical MHCI molecules. Moreover, we are exploring the effect of MHCI molecules on neuronal migration and differentiation during embryonic development. In conclusion, this study will extend previous findings by suggesting a novel role on neuronal MHCI molecules during neurogenesis.

Abstract: A number of studies have highlighted the connection between infections during pregnancy and increased risk for autism leading to the view that maternal immune activation (MIA) is a significant contributor to autism spectrum disorder (ASD) incidence. Cytokines produced maternally can cross the placenta to affect the developing brain. However, it is not clear how these cytokines alter the trajectory of neural development. In our studies on the effects of inflammation on the cells of the subventricular zone (SVZ), we have established that one of the key cytokines implicated in ASD, interleukin-6 (IL-6) directly affects the neural stem cells and progenitors that reside in this region. SVZ neural stem cells and progenitors express both the IL-6 receptor and GP130 and 30 minutes following addition of 5 ng/mL IL-6 to neurosphere cultures, STAT-3 phosphorylation increases 10-fold and STAT-1 phosphorylation increases 4-fold, but phosphorylated ERK and AKT are unchanged. When neurospheres are maintained in culture for 6 days in IL-6 supplemented medium, sphere self-renewal and tripotentiality are enhanced. However, this is due to an increase in the proportion of PDGF/FGF2 responsive multipotent progenitors (PFMPs) with a decrease in the proportion of neural stem cells; and can be attributed to increased PFMP proliferation. To studythe effects of systemically increased IL-6 on SVZ cells and brain development,40 ng IL-6 was injected i.p., which doubled the circulating concentration of IL-6, similar to that documented for ASD patients. When postnatal day 4 male Swiss Webster mice were administered 3 doses of IL-6 every 12 hours followed by a single injection of EdU, the proportion of EdU+ PFMPs (but not other progenitors) was increased 2-fold compared to PBS injected controls. Altogether, these studies show that IL-6 alters the proportion of multipotential progenitors and stem cells in the SVZ, which may have important consequences for brain development and function. Title: Extracellular matrix-associated CYR61 maintains neural stem cells during forebrain development

Authors: *J. ZHENG[1,2,3], S. QI[1,2,3], J. WU[1,2,3], Q. SHEN[2,3]
[1]Dept. of Basic Med., Tsinghua Univ., Beijing City, China; [2]Col. of Life Sci. and Technol., Tongji Univ., Shanghai City, China; [3]Brain and Spinal Cord Innovative Res. Ctr., Tongji Hosp., Shanghai City, China

Abstract: Neural stem cells (NSCs) are capable of self-renewal and differentiation into multiple neural cell types. NSCs and their progeny reside in microenvironment called stem cell niches, which consist of extracellular matrix (ECM), soluble factors, and neighboring cell types are functional components of NSC niche. Here, we investigate the role of an extracellular matrix associated signaling protein, cysteine-rich angiogenic inducer 61 (*Cyr61*) during the development of NSCs in the forebrain. *Cyr61* belongs to the CCN family, also known as CCN1 or insulin-like growth factor binding protein 10 (IGFBP10). By *in situ* hybridization, we found that *Cyr61* specifically expressed in radial glial cells (RGCs) in the embryonic forebrain, enriched in the apical side along the ventricular surface. The expression of *Cyr61* becomes restricted to ependymal cells at postnatal stages. In a binding assay applying recombinant CYR61 human Fc (CYR61-huFc) protein to NSC culture or forebrain wholemount culture, we found that CYR61 only bound to Nestin+ radial glial cells but not Tuj1+ neurons both *in vitro* and *ex vivo*. Overexpression of *Cyr61* through *in utero* electroporation (IUE) at embryonic (E) 12.5 to E14.5 increased Sox2+ neural progenitors in the lateral ganglionic eminence (LGE). Moreover, prolonged overexpression of CYR61 in the dorsal cortex from E14.5 to postnatal day 7 maintained neural progenitors in cortical germinal zones. We found that overexpression of *Cyr61* by IUE in the dorsal cortex resulted in up-regulation of genes related to neural stem cell identity, including Pax6, Sox2, and VCAM1 by RNA-seq analysis of fluorescence-activated cell sorted (FACS) *Cyr61*-overexpressing cortical cells. Additionally, we demonstrated that IGF2 interacted with mouse CYR61 by co-immunoprecipitation in transfected 293FT cells. Ongoing studies are to identify CYR61-interacting proteins in the embryonic forebrain *in vivo* using pull down assay followed by mass spectrometry analysis. We are investigating the phenotypes of $Nestin^{cre}/Cyr61^{fl/fl}$ mice to characterize the role of *Cyr61* during early neural development. Our study will help us understand the role and working mechanisms of NSC niche factors such as *Cyr61* in NSC maintenance and differentiation.

Title: Resolving cellular equipotency of developing optic vesicles

Authors: *B. XU, H. WANG, J. YAN, J. HE
Inst. of Neuroscience, CAS, Shanghai City, China

Abstract: In the CNS development, symmetric proliferation characterizes the initial stages, where individual progenitors produce two daughter progenitors. The assumption of cellular equipotency of these progenitors is fundamentally important, but has not been tested in-vivo. To test this, we analyzed progenitors of developing optic vesicles in zebrafish. Modeling of clonal dynamics revealed that PP progenitors exhibit the unified cell-cycle dynamics. Further clonal analysis at consecutive lineage stages and heterochronic transplantation showed that as lineage progresses, PP progenitors are equivalent in proliferative potentials, change in which counts on environmental cues but not cell division. Furthermore, stochastic absence of individual retinal fates from sister clones of PP progenitors suggested no fate restriction. Surprisingly, single-cell RNA-seq demonstrated that stochastic gene expression characterizes this cellular equipotency. This study provides the framework to assess cellular equipotency and demonstrates the stochastic mitosis of equipotent progenitors as the major cellular mechanism driving the early CNS development.

Title: Mechanisms of selective autophagy-mediated regulation of neuronal differentiation during nervous system development

Authors: *A. LEE[1], K. ZARBALIS[2], L. N. BORODINSKY[1]
[1]Univ. of California Davis, Sacramento, CA; [2]Dept. Pathology/IPRM, UC Davis/Shriners Hosp. for Children, Sacramento, CA

Abstract: The autophagy factor Wdfy3 is critical for mouse and human brain development. In humans, *WDFY3* genetic mutations are associated with autism, macrocephaly, or familial microcephaly and intellectual disability. In mice, *Wdfy3* loss-of-function has been shown to alter the transition from neural stem cell to intermediate neuronal progenitor and to cause axonal outgrowth defects. However, the precise mechanisms by which Wdfy3 regulates these processes remain unclear.
Using *Xenopus laevis* and mouse, we aim to determine the mechanisms of Wdfy3-dependent regulation of neurogenesis and axonal outgrowth. We hypothesize that Wdfy3 regulates neural stem cell proliferation, neuronal differentiation and axonal outgrowth through autophagic removal of ubiquitinated proteins. Reverse transcriptase PCR indicates *wdfy3* is expressed during different stages of *Xenopus laevis* development. Fluorescent immunohistochemistry staining shows that Wdfy3 is present in the frog tadpole spinal cord, and brain. Wdfy3 protein appears enriched in neurons compared to neural stem cells, and is present in neurites.
To assess the function of Wdfy3 in *Xenopus laevis* nervous system development, we injected a Wdfy3 translation-blocking morpholino at 2-cell stage embryos and performed EdU cell proliferation assays followed by immunostaining for the neural stem cell marker Sox2. Results show that the number of Sox2-immmunopositive cells in the forebrain increases when Wdfy3 is knocked down, suggesting an increase in neural stem cell expansion in the affected brain. Moreover there are fewer Wdfy3-morpholino-containing cells with highest EdU-labeling compared with the wild type counterparts, suggesting a higher rate of cell division in Wdfy3-deficient neural cells.
Wdfy3's effect on *Xenopus laevis* axonal outgrowth was assessed by morpholino-induced knockdown. Wdfy3 deficiency decreases the axonal density in brain commissures and in the axial musculature.
Further understanding of autophagy's role during neural development could lead to new treatments for neurodevelopmental and neurodegenerative disorders.

Title: Aspm knockout ferret reveals an evolutionary mechanism governing cerebral cortical size

Authors: *B.-I. BAE[1], M. B. JOHNSON[2], A. KODANI[2], R. BORGES-MONROY[2], K. IM[3], J. F. ENGELHARDT[4], C. A. WALSH[2]

Abstract: The human cerebral cortex is distinguished by its large size and abundant gyrification, or folding. However, the evolutionary mechanisms that drive cortical size and structure are unknown. Although genes that are essential for cortical developmental expansion have been identified from the genetics of human primary microcephaly (a disorder associated with reduced brain size and intellectual disability), studies of these genes in mice, which have a smooth cortex that is one thousand times smaller than the cortex of humans, have provided limited insight. Mutations in abnormal spindle-like microcephaly-associated (*ASPM*), the most common recessive microcephaly gene, reduce cortical volume by at least 50% in humans, but have little effect on the brains of mice; this probably reflects evolutionarily divergent functions of *ASPM*. Here we used genome editing to create a germline knockout of *Aspm* in the ferret (*Mustela putorius furo*), a species with a larger, gyrified cortex and greater neural progenitor cell diversity than mice, and closer protein sequence homology to the human ASPM protein. *Aspm* knockout ferrets exhibit severe microcephaly (25-40% decreases in brain weight), reflecting reduced cortical surface area without significant change in cortical thickness, as has been found in human patients, suggesting that loss of 'cortical units' has occurred. The cortex of fetal *Aspm* knockout ferrets displays a very large premature displacement of ventricular radial glial cells to the outer subventricular zone, where many resemble outer radial glia, a subtype of neural progenitor cells that are essentially absent in mice and have been implicated in cerebral cortical expansion in primates. These data suggest an evolutionary mechanism by which ASPM regulates cortical expansion by controlling the affinity of ventricular radial glial cells for the ventricular surface, thus modulating the ratio of ventricular radial glial cells, the most undifferentiated cell type, to outer radial glia, a more differentiated progenitor.

Title: Role of Hippo signalling in adult neural stem cell homeostasis

Authors: *W. FAN[1], J. JURADO ARJONA[1], S. PÉRON[1], C. BERGER[2], B. BERNINGER[1]
[1]Univ. Med. Ctr., Johannes Gutenberg Univ. Mainz, Mainz, Germany; [2]Inst. of Genet., Johannes Gutenberg Univ., Mainz, Germany

Abstract: Adult neural stem cells (aNSCs) residing in the subgranular zone (SGZ) of the dentate gyrus (DG) are finely regulated to precisely control the adult generation of newborn neurons. Quiescence is essential for long-term maintenance of aNSCs. Intrinsic factors, as well as extrinsic niche signals, orchestrate the balance between activation and quiescence of aNSCs but the mechanisms are still not completely understood.
Here we show that changes in Hippo signaling pathway affects the quiescence and activation of aNSCs in mice. We found that Yap1, one of the most important effector components in Hippo pathway, is specifically expressed in mouse aNSCs and astrocytes in SGZ, but not in other cell types such as neurons and oligodendrocytes. Moreover, levels of nuclear Yap1 significantly decrease in induced quiescent aNSCs. In vitro, overexpression of constitutively active Yap1 (5SA) induces the transition from quiescence to activated state of aNSCs. This effect is exerted through TEAD interaction, thereby, constitutively active version of Yap1 with a mutation in TEAD binding site (5SA/S94A) fails to activate quiescent aNSCs. In addition, pharmacological disruption of YAP1-TEAD complex decreases proliferation of aNSCs. These results indicate that Yap1-TEAD interaction is very important for aNSCs activation and proliferation. In vivo, overexpression of constitutively active Yap1 driven by hGFAP promoter, increases proliferation of aNSCs dramatically at 7 dpi in DG. Moreover, overexpression of Yap1 can also block differentiation of aNSCs and maintain them at progenitor stage (Sox2 positive) at 30 dpi. Collectively, we uncover a new mechanism which can regulate aNSCs development and exhibit the key role of Hippo signaling in aNSCs homeostasis.

Title: Dissecting the roles of store-operated calcium entry during development of the cerebral cortex

Authors: *A. ARJUN[1,2,3], S. LAUNER[2], J. TONG[2], R. I. PETROVA[1,2], Y. KHAN[2], G. PANAGIOTAKOS[1,2,3,4]

Abstract: Calcium signaling has been reproducibly implicated in a variety of developmental processes in the embryonic brain, including neural induction, neural progenitor cell (NPC) proliferation, neuroblast migration and differentiation. Mutations in genes encoding calcium signaling proteins have also been associated with neurodevelopmental disorders like autism spectrum disorders and intellectual disability, further highlighting key roles for calcium signaling during the development of the cerebral cortex. In the embryonic rodent cortex, agonist-induced calcium waves, mediated by the release of intracellular calcium stores, propagate through the germinal zones and modulate aspects of NPC proliferation. It is unclear, however, how internal calcium stores are regulated in cortical NPCs and how they are linked to the regulation of NPC function. Store operated calcium entry (SOCE), a mode of calcium influx tied to depletion of intracellular ER calcium stores, has been shown to regulate calcium influx and proliferation of NPCs *in vitro*, but its role in the embryonic cortex remains unexplored. Here, utilizing a combination of pharmacology and *in utero* gain- and loss-of-function approaches, we interrogate specific roles for SOCE in the embryonic cortex. We have found that functionally distinct isoforms of the STIM family of endoplasmic reticulum (ER) calcium sensors are dynamically regulated during neuronal differentiation, such that an inhibitory isoform of Stim2 is upregulated in young neurons. This observation is in line with previous work demonstrating that robust SOCE responses in NPCs *in vitro* are abolished upon differentiation into neuroblasts. We have also found that manipulating the levels of Stim2 variants using *in utero* electroporation at embryonic day 13 (E13) bidirectionally regulates cell cycle exit in dividing cortical NPCs. We are further exploring this observation using live imaging approaches, single cell RNA sequencing, and a variety of molecular and biochemical assays. Collectively, our data sheds light

on roles for the molecular mediators of SOCE in the regulation of proliferation and differentiation in the developing cortex.

Title: The long noncoding RNA lncNSPC is required for the maintenance of neural stem and progenitor cell (NSPC) potential

Authors: *S. QI[1,2,3], J. ZHENG[1,2,3], Q. BAI[2,3], Q. SHEN[2,3]

Abstract: Neocortical development involves cell proliferation, differentiation, migration and synaptic connection. This complex yet highly organized process is regulated by multi-layered mechanisms including transcriptional, epigenetic and environmental controls. Among various regulatory factors, long non-coding RNAs (lncRNAs) emerge as important epigenetic players during cortical development. Numerous lncRNAs have been identified in the developing brain. However, functions of these transcripts remain unexplored or elusive, especially at the early stage of neurogenesis. To identify lncRNAs that are differentially expressed in embryonic cortical neural stem and progenitor cells (NSPCs) versus in differentiating neurons, we performed a transcriptome analysis of early NSPCs and differentiating neurons by RNA-seq. We found that a poorly characterized lncRNA, which we called *lncNSPC* is specifically expressed in NSPCs in the embryonic cerebral cortex. In situ hybridization (ISH) on brain sections from E11 to E16 mouse embryos verified that *lncNSPC* is enriched in the germinal zone of the developing forebrain. Using subcellular fractionation and fluorescence in situ hybridization (FISH) assays, we revealed that *lncNSPC* is present in the cytoplasma of Neuro2a (N2a) cell lines or primary NSPCs. To investigate the roles of *lncNSPC* in NSPCs, we electroporated shlncNSPC or shluciferase (control) construct into neural stem cells in the embryonic cerebral cortex at E14.5. Two days later, we found that depletion of *lncNSPC* promotes cell cycle exit of NSPCs, accompanied by decreased TBR2 positive progenitor cells as well as increased neuronal differentiation when we co-electroporated a NeuroD1-GFP vector. Notably, we discovered that

partial deletion of the promoter and exon1 regions in *lncNSPC* locus by CRISPR/Cas9 does not affect the RNA levels of its neighboring coding genes in N2a cell lines. Using RNA pulldown assay, we identified potential binding partners of *lncNSPC* including RNA binding proteins. Therefore, *lncNSPC* , as a lncRNA, may participate in the regulation of neurogenesis through multiple mechanisms. We are further evaluating the target genes affected by *lncNSPC* and its binding partners in order to elucidate mechanisms of altered NSPC potential by reduced *lncNSPC*. This work will provide insights in regulatory roles of lncRNAs in the context of neural differentiation.

Title: PDK1 regulates the transition of APs to BPs during the cortical neurogenesis

Authors: *Y. WEI[1], X. HAN[2], C. ZHAO[2], J. GAO[3]
[1]Inst. of Life Science,Southeast Univ., Jiangsu, China; [2]Southeast Univ., Jiangsu, China; [3]Nanjing Med. Univ., Jiangsu, China

Abstract: Abstract The mammalian neocortex consists of hundreds of neuron subtypes arising from two specific classes of neural stem cells (apical progenitors, Aps) and fate-restricted basal progenitor cells (BPs) during embryonic development. APs dividing at the ventricular zone (VZ) mainly give rise to deeper cortical neurons and BPs, while BPs undergoing mitosis at the subventricular zone(SVZ) mainly produce upper layer neurons. The timing of the transition from APs to BPs is critical for corticogenesis. However, the regulation of the transition is poorly understood. In this study, we first identified a peak expression level of the phosphoinositide-dependent protein kinase 1 (PDK1) during the period of E14.5-16.5, the time window when superficial neurons produced, suggesting a possible role for PDK1 regulating the balance between deeper and superficial neurogenesis. By crossing $PDK1^{fl/fl}$ mice with *Emx1*-Cre line, PDK1 was conditionally ablated in the dorsal cortex. We have found the overall neural output as well as the number of deeper neurons was increased with no obvious changes on superficial neurons at P0. Further studies show the transition from Aps to BPs is severely delayed after PDK1 deletion, and results in overproduction of deeper neurons. We have found the length of the G1 phase of AP cell cycle is shortened from E14.5 onwards and accompanied with impaired

interkinetic nuclear migration at ventricular zone. The division planes of PDK1-deficient APs are significantly more vertical than that of controls. In cell culture, NPCs display the tendency to take proliferative division instead of neurogenic division after PDK1 deletion, consistent with that observed in vivo. We have also demonstrated that by inhibiting activated atypical PKC (aPKC), the PDK1-aPKC pathway coordinating with Notch signaling to regulate the transition of Aps to Bps. Our findings provide new sight into cortical neurogenesis.

Abstract: ABSTRACT
Control of neuronal precursor cell proliferation is essential for normal brain development, and deregulation of this fundamental developmental event contributes to brain diseases. Typically, neuronal precursor cell proliferation extends over long periods of time during brain development. However, how neuronal precursor proliferation is regulated in a temporally specific manner remains to be elucidated. Here, we report that conditional knockout of the transcriptional regulator SnoN in granule neuron precursors in the mouse cerebellum robustly inhibits the proliferation of these cells and promotes their cell cycle exit specifically at later stages of cerebellar development in the postnatal brain. In gene profiling studies, SnoN regulates the expression of a program of cell proliferation genes in granule neuron precursors, whose pattern of expression and gene promoter-associated histone marks correlate temporally with SnoN-regulation of granule neuron precursor cell proliferation. In behavior analyses, conditional knockout of SnoN impairs cerebellar-dependent learning in a delayed eye-blink conditioning paradigm, suggesting that SnoN-regulation of granule neuron precursor proliferation bears

functional consequences at the organismal level. Our findings define a novel function for the major transcriptional regulator SnoN in the temporal control of granule neuron precursor proliferation in the mammalian brain.

Title: A novel mechanism for ephrin reverse signaling in the control of neuronal migration

Authors: *P. F. COPENHAVER, C. BATES, A. D. RAINHA, C. KAWAMOTO, H.-J. LEE
Cell & Developmental Biol., Oregon Hlth. and Sci. Univ., Portland, OR

Abstract: Bidirectional signaling by Ephrins and Eph receptors can regulate many aspects of cell migration in the developing nervous system, but the mechanisms controlling these responses are only partially understood. Ephrin ligands stimulate conventional “forward” signaling by activating Eph receptors, but Eph receptors also induce “reverse” signaling via their cognate Ephrins. Investigating the mechanisms underlying these responses in vertebrates has been complicated by evidence that neurons often co-express multiple Ephrins and Eph receptors that can interact promiscuously. In contrast, the hawkmoth Manduca sexta expresses only one type-A Ephrin (GPI-linked MsEphrin) and one corresponding Eph receptor (MsEph). In previous work, we showed that reverse signaling via MsEphrin plays an essential role in regulating neuronal migration within the embryonic enteric nervous system (ENS). During ENS development, a population of ~300 neurons (EP cells) migrate along pre-formed visceral muscle bands while avoiding adjacent midline regions. The migratory neurons express GPI-linked MsEphrin, while MsEph receptors are confined to the midline muscle cells. Manipulations in embryo culture demonstrated that blocking endogenous MsEphrin-MsEph interactions resulted in ectopic midline crossing by the neurons, whereas forward signaling (via MsEph receptors) played no role in this process. We also showed that MsEphrin reverse signaling was transduced by a specific Src family kinase (Src42A): activating MsEphrin signaling significantly increased Src42A activity in the EP cells and inhibited their motility, whereas inhibiting Src42A activity precluded reverse signaling and caused midline crossovers (similar to blocking MsEphrin-MsEph interactions). We also showed that activation of Src42A induced RhoA-dependent

retraction responses away from the midline, defining the effector pathway underlying this response. In a screen for MsEphrin-interacting proteins that might directly activate Src42 during reverse signaling, we recently identified RACK1 (Receptor of Activated Protein Kinase C), a reciprocal regulator of Src family kinase (SFK) activity. We now have found that MsEphrin requires RACK1 to activate Src42, while Src42 is required for the inactivation of RACK1 during MsEphrin signaling. These results support the model that a "Src-RACK rheostat" plays a central role in the transduction of Ephrin-A reverse signaling. We are currently testing candidate co-receptors that may couple MsEphrin to the RACK1-Src42 complex, with the goal of understanding how Ephrin-A reverse signaling regulates neuronal migration during embryonic development.

Title: Cell-autonomous and non-autonomous mechanisms controlling projection neuron migration

Authors: *A. H. HANSEN[1], J. RENNO[1], C. STREICHER[1], S. LAUKOTER[1], F. M. PAULER[1], L. ANDERSEN[2], T. RUELICKE[2], S. HIPPENMEYER[1]
[1]IST Austria, Klosterneuburg, Austria; [2]Inst. of Lab. Animal Science, Univ. of Vet. Med., Vienna, Austria

Abstract: Concerted radial migration of newly born cortical projection neurons, from their birthplace to their final target lamina, is a key step in the assembly of the cerebral cortex. The cellular and molecular mechanisms regulating the specific sequential steps of radial neuronal migration *in vivo* are however still unclear. Recent evidence suggests that distinct signaling cues act cell-autonomously but differentially at particular steps during the overall migration process. Functional MADM (Mosaic Analysis with Double Markers) analyses in comparison to global knockout also indicate a significant degree of cell-non-autonomous and/or community effects in the control of cortical neuron migration. Cell-non-autonomous effects may differentially affect cortical neuron migration in distinct compartments and thus regulate critical steps in the migration process. It is therefore not only essential to determine the nature of the interplay of

cell-autonomous and cell-non-autonomous mechanisms but also how they control cortical neuronal migration. Here we established a MADM-based experimental strategy for the analysis of cell-autonomous versus non-autonomous gene function and/or community effects. We pursued subtractive phenotypic analysis of genetic mosaics (wild-type/heterozygote background) with conditional and/or global knockout (mutant background), both coupled with sparse fluorescent MADM-labeling of homozygous mutant neurons, to trace the sequential steps of migration in 4D. Using these experimental paradigms we define so far unknown cell-autonomous functions of candidate signaling pathways intersecting with cell-non-autonomous effects to coordinate radial neuron migration.

Title: Human forebrain endothelial cells: New avenue for interneuron-based therapy of neuropsychiatric disorders

Authors: *D. DATTA, S. SUBBURAJU, S. KAYE, A. VASUDEVAN
Dept. of Psychiatry, Harvard Med. Sch., Belmont, MA

Abstract: Abnormalities in GABAergic interneurons are implicated in the pathology of severe brain disorders like schizophrenia and epilepsy, for which effective treatments are still elusive. Transplantation of human stem cell-derived interneurons is a promising cell-based therapy for treatment of these disorders. In mouse xenograft studies, human stem cell derived-interneuron precursors could differentiate in vivo, but required a prolonged time (up to seven months) to migrate from the graft site and integrate with the host tissue. This poses a serious roadblock for clinical translation of this approach. For transplantation to be effective, especially for very sick or severe patients, grafted neurons should migrate to affected areas at a faster rate. Our group has previously discovered in mouse that endothelial cells of the periventricular vascular network act as physical substrates, and provide valuable guidance cues for migrating GABAergic interneurons in the developing forebrain. In this study we translated this discovery into human, with significant therapeutic implications. We generated human periventricular endothelial cells, using human pluripotent stem cell technology. We validated molecular, cellular and functional

properties of the derived cells using microarray profiling and cell-based assays. Co-culture of human periventricular endothelial cells with human interneurons showed a significant increase in rate of interneuron migration in vitro. Co-transplantation of human periventricular endothelial cells with human interneurons in adult mouse brain led to faster migration and wider distribution of grafted interneurons, compared to neuron-only transplants. These results establish that human periventricular endothelial cells are critical for long distance migration of human GABAergic interneurons, and pave the way for a novel strategy for effective interneuron transplantation. Co-delivery of human periventricular endothelial cells with human interneurons will accelerate the migration of grafted neurons in diseased brain, leading to faster and effective brain repair. This strategy will facilitate the advancement of interneuron-based cell therapy into a clinical setting and open new avenues for cure of serious neuropsychiatric disorders.

Title: Reelin- and dab1-expressing superficial dorsal horn neurons co-express lmx1b and migrate together during development

Authors: *G. METTA YVONE, C. L. CHAVEZ-MARTINEZ, P. E. PHELPS
Integrative Biol. and Physiol., UCLA, Los Angeles, CA

Abstract: In the canonical Reelin-signaling pathway, the binding of secreted Reelin to its two receptors, ApoER2 and Vldlr, induces the phosphorylation of the intracellular protein Disabled-1 (Dab1). Phosphorylated Dab1 then activates pathways that regulate neuronal positioning during development. Mice that lack Reelin, both of its receptors, or Dab1 have neuroanatomical defects and exhibit thermal (heat) hyperalgesia and mechanical insensitivity. Previously we found that Reelin and Dab1 neurons are concentrated in nociceptive areas of the adult dorsal horn, specifically laminae I-II, lateral lamina V, and lateral spinal nucleus (LSN). 70% of the Dab1 neurons co-express Lmx1b and therefore are excitatory. Many of the Dab1-Lmx1b neurons are incorrectly positioned in *Reln*$^{-/-}$ mice. Here we examine the Reelin-positive dorsal horn neurons in adult and developing spinal cord. Our data show that most Reelin neurons in the adult laminae I-II co-express Lmx1b and thus are also excitatory. Furthermore, we show that Reelin- and Dab1-positive neurons are discrete subsets of Lmx1b neurons and together account for almost

50% of the adult Lmx1b-labeled superficial dorsal horn neurons. Interestingly, the locations of Reelin and Dab1-positive neurons are both affected by disruption of the Reelin-signaling pathway. We found more Reelin-Lmx1b neurons within IB4-positive area and fewer within the lateral lamina V and LSN of adult *dab1*$^{lacZ/lacZ}$ compared to *dab1*$^{+/+}$ mice. We also characterized the migration of Reelin and Dab1 neurons during development in *dab1*^{lacZ} and *Reln*^{rl} mice, respectively. We found that Reelin- and Dab1-expressing neurons fated for the dorsal horn shared a nearly identical migratory pathway. Although the migration of Reelin cells appeared normal in *dab1*$^{lacZ/lacZ}$, we observed mispositioned Dab1 neurons during embryonic development of *Reln*$^{-/-}$ dorsal horn. Our finding that Reelin- and Dab1-expressing neurons share the same neurotransmitter phenotype is unique and supports a role for Reelin-signaling in specific pain modalities.

Title: The role of the microRNA 122 in the migration and maturation of superficial cortical neurons

Authors: *U. TOMASELLO[1], L. DE VEVEY[2], E. KLINGLER[3], J. PRADOS[2], M. NIQUILLE[2], D. JABAUDON[2], V. BORRELL[4], A. DAYER[2]
[1]Univ. De Geneve, Geneve, Switzerland; [2]Univ. of Geneva, Geneva, Switzerland; [3]Basic Neurosci., Univ. of Geneva, Geneve, Switzerland; [4]Inst. of Neuroscience, CSIC, San Juan de Alicante, Spain

Abstract: The cerebral cortex is built by sequential waves of neurogenesis, giving rise to deep and superficial layer neurons. Superficial layer neurogenesis is evolutionarily the most recent and could require a more complex transcriptional control, possibly by non-coding RNAs such as microRNAs. This hypothesis is supported by the fact that a variety of microRNAs are expressed in pallial progenitors domain in gyrencephalic species. However, their specific role in regulating transcriptional dynamics of superficial layer neurogenesis is largely unknown. Among potential key players, microRNA-122 is predicted to regulate essential pathways of projection neuron development like Wnt1, Cux1 and MeCP2. Here we investigated the role of miR 122 in the development of superficial layer projection neurons (PNs) by a gain-of-function approach in the mouse model, using *in utero* electroporation. We targeted the dorsal pallium at E14.5 and

overexpressed miR 122 in dorsal progenitors. Its impact on cell cycle dynamics and migration was analysed at several subsequent embryonic time points. Our results indicate that progenitor proliferative and neurogenic programs are largely unaffected by miR 122 overexpression. In contrast, miR 122 overexpression alters the migratory dynamics and the positioning of PNs within the cortical plate. Moreover, the small fraction of neurons that reached their correct laminar position partially lose their superficial layer molecular identity. Ongoing transcriptomic analysis of single-cells overexpressing miR 122 at embryonic and postnatal stages are underway in order to identify the molecular mechanisms through which miR 122 controls neuronal migration and identity.

Abstract: Mitochondrial diseases are best recognized in a variety of muscle disorders; however mitochondrial dysfunction is increasingly being recognized in a host of common neurological disorders affecting the cerebral cortex including neurodevelopmental disorders such as autism and some forms of epilepsy. Given this association with neurodevelopmental disorders, understanding the role mitochondria play in early cortical development, an unexplored area, is necessary to understand the pathogenesis of these disorders. Recent studies have suggested that the intracellular localization of mitochondria influence non-neural cell migration. Our published data indicate this is also true for migrating cortical neurons. In this study, we examined the localization pattern of mitochondria in migrating excitatory neurons and inhibitory neurons and assessed the importance of a mitochondrial trafficking GTPase, Miro1, during neuronal migration. We performed *ex vivo* electroporation to label mitochondria in excitatory and inhibitory neurons in embryonic day (E) 14.5 mouse brains. Additionally, we expressed knockdown plasmids to disrupt mitochondrial trafficking and assessed the resulting impact on excitatory and inhibitory neuronal migration. Our data suggest that excitatory neurons and inhibitory neurons have similar but distinct patterns of mitochondrial localization. Mitochondria

in excitatory neurons predominately localize anterior to the cell body. In contrast, mitochondria are highly dynamic as inhibitory neurons migrate, moving from the rear of the cell to the leading process and back. Further, our data suggests that a knockdown for Miro1 disrupts mitochondrial trafficking and specifically perturbs inhibitory neuron migration, branching dynamics, and mitochondrial localization. Currently, the connection between mitochondria localization and neuronal migration is poorly studied. Our data indicate that impaired mitochondrial localization may impact embryonic brain development, specifically neuronal migration. This, at least in part, may underlie the pathogenesis of mitochondrial-related neurodevelopmental disorders.

Title: Erythropoietin signaling regulates neuronal migration in the developing neocortex

Authors: P. E. CONSTANTHIN, A. CONTESTABILE, V. PETRENKO, P. SALMON, *J. Z. KISS
Univ. of Geneva, Dept. of Neurosciences, Geneva, Switzerland

Abstract: Erythropoietin (EPO) is a cytokine hormone that is required for erythroid differentiation and has been proved neuroprotective in both animal experiments and clinical trials. EPO and its receptor (EPOR) have been detected in the developing brain and their expression appears to be timely and spatially regulated. However, apart from a potential effect on neurogenesis, the role of endogenous EPO signalling in brain development remains unknown. Here, we report that EPO as well as EPOR is expressed in the developing somatosensory cortex of the rat during the period of radial migration and that their expression is temporally and spatially regulated. We demonstrate using constitutive and conditional genetic strategies that downregulation of EPOR in late generated layer IV excitatory neurons results in mispositioning and accumulation of these cells in the intermediate zone. While most control cells in this zone exhibited a bipolar shape, knocking down EPOR expression by forced expression of shEPOR significantly increased the number of multipolar cells with branched processes. In addition, a large proportion of shEPOR-overexpressing cells displayed a disoriented Golgi apparatus and a decreased number of cells were exiting the intermediate zone. Confocal time-lapse imaging also showed that downregulating EPOR expression results in an increased proportion of cells with

numerous highly dynamic processes and decreased migratory speed. Together, these observations support the hypothesis that EPO signaling is required for the proper polarization and orienting neurons for radial migration. Knockdown of EPOR during radial migration leads to permanently misplaced cells that fail to integrate correctly in the cortical network. Animals with these migration defects exhibited abnormal somatosensory behaviors later in life. Finally, forced expression of extracellular signal-regulated kinase (ERK), a well-known downstream regulator of EPO signaling, restored the normal migratory phenotype and rescued the behavioral phenotype.
Together, these results show for the first time that appropriate activity of intrinsic EPO signaling is required for proper radial migration of neocortical excitatory neurons.

Abstract: Zinc finger E-box binding homeobox 1 (*Zeb1*) is a key regulator of epithelial-mesenchymal transition and cancer metastasis. Mutation of *Zeb1* is associated with human genetic eye diseases and defective brain development. Here we show that *Zeb1* is expressed in the embryonic cortical neural progenitor cells (NPC) and turned off upon neuronal differentiation to allow proper differentiation and migration of neuronal progeny. We found that altering *Zeb1*'s expression in cortical cells in vivo by in utero electroporation (IUE) affected neuronal differentiation and migration. Surprisingly, overexpression of *Zeb1* did not increase NPC proliferation, but disrupted multipolar-to-bipolar transition and the correct positioning of NPCs and differentiating neurons, leading to severe migration defects and heterotopia bands in the white matter at postnatal stage. By high-throughput sequencing we found that *Zeb1* regulates a

cohort of genes involved in cell differentiation and migration, including *NeuroD1* and *Unc5d*. Interestingly, by IP-MS, we identified that ZEB1 binds to CTBP2 in the embryonic cortex. Binding to CTBP2 is required for ZEB1 to elicit the effect on multipolar-to-bipolar transition but not suppression of *NeuroD1*. These findings provide insights for understanding the complexity of transcriptional regulation during neuronal differentiation.

Abstract: During cortical circuit formation, spontaneous Ca^{2+} transients are believed to occur even before sensory inputs stimulate neuronal firings, and preceding studies showed Ca^{2+} signaling regulates several aspects of neuronal development in the embryonic brain. Consistent with these findings, we previously reported that distinct limbs of the CaMKK-CaMKI cascade were specifically implicated in determining the extent of either dendritic or axonal growth. To further study the involvement of Ca^{2+} signaling in cortical circuit formation, we investigated whether Ca^{2+} signaling regulates radial migration of excitatory neurons in the embryonic cortex. At first, we identified CaMKIα as a key regulator for radial migration. CaMKIα was necessary for radial migration, whereas excess CaMKIα kinase activity drastically decelerated migration rate. We also observed spontaneous Ca2+ transients in migrating neurons and inverse correlation between the intracellular Ca^{2+} event frequency and migration rate from GCaMP6s based Ca^{2+} imaging studies. Furthermore, pharmacological studies revealed intracellular Ca^{2+} transients are L-type VDCC dependent. L-type VDCC was necessary for radial migration, whereas L-type

VDCC with Timothy syndrome mutation (G406R), which causes excess Ca^{2+} influx, induced a severe radial migration defect. Finally, chelation of intracellular free Ca^{2+} using EGTA-AM that blocked intracellular Ca^{2+} transients and impaired radial migration. Taken together, these results suggest appropriate temporal pattern of Ca^{2+} transients facilitates radial migration via Ca^{2+} dependent signaling molecules.

Abstract: Histone deacetylase inhibitors (HDACIs) have emerged as potential anticancer agents for the treatment of solid and hematopoietic cancers. Several HDACIs delay cell growth, induce differentiation, or activate apoptosis in multiple types of tumors, including glioblastomas. In the present study, we showed that the mercaptoacetamide-based HDACI W2 inhibits cell migration and invasion in monomorphic malignant human glioma cells. W2 treatment significantly decreased the activity and expression levels of matrix metalloprotease-2 in malignant A172 cells but not in U373MG cells. Key signaling pathways involved in cell migration and invasion, including PI3K-AKT, ERK-JNK-P38, and FAK/STAT3, were examined to identify the mechanism of action of W2. W2 increased the phosphorylation of AKT and altered cell migration and invasion in an AKT-independent manner. W2 inhibited the phosphorylation of FAK/STAT3, and treatment with a FAK/STAT3 inhibitor significantly suppressed cancer cell migration and MMP-2 activity in the presence of W2. In addition, W2 significantly inhibited the nuclear translocation of phospho-STAT3. Taken together, our results suggest that W2 suppresses cancer cell migration and invasion by inhibiting FAK/STAT3 signaling and STAT3 translocation to the nucleus in monomorphic malignant human glioma cells.

Title: The role of a novel BICD2 mutation in brain development and lissencephaly

Authors: *H.-Y. CHENG[1], F.-S. NIAN[1], M.-H. TSAI[2], J.-W. TSAI[1]
[1]Inst. of Brain Sci., Natl. Yang-Ming Univ., Taipei, Taiwan; [2]Dept. of Neurol., Kaohsiung Chang Gung Mem. Hosp., Kaohsiung, Taiwan

Abstract: During cerebral cortex development, radial glia cells undergo interkinetic nuclear migration (INM) and proliferate at the ventricular zone. The progeny cells differentiate into neurons followed by radial migration along radial glia fibers to form the organized cerebral cortex. Previous studies have shown that nuclear position during INM requires BicD2, an adapter protein linking dynein motor complex to the nuclear envelope (NE) through binding to a nucleoporin, RAN binding protein 2 (RanBP2). Although BICD2 mutations in humans were associated with spinal muscular atrophy (SMA) but not brain developmental disorders, we recently found a novel BICD2 mutation in a patient with lissencephaly. To understand the role of this mutation in cortical development, we used in utero electroporation to knockdown BicD2 or overexpress wild type (WT) or mutant BicD2 in neural progenitors in mouse embryos and observed the cell distributions several days later. We found that knockdown of BicD2 using shRNA mildly inhibited neuronal migration. Surprisingly, we observed a severe blockage of neuronal migration upon overexpression of our BicD2 mutant while overexpressing WT or three other reported SMA-associated mutations did not affect neuronal migration. Hence our mutation may cause lissencephaly through a dominant negative effect. Furthermore, pulldown assay also showed that our mutation disrupted its interaction to RanBP2, thus interrupting the NE recruitment of Dynein motor complex. Therefore, our BICD2 mutation may cause lissencephaly by disrupting nuclear migration during neuronal migration. Our findings elucidated the novel roles of BicD2 in neuronal migration and lissencephaly pathogenesis and discovered a novel etiology of this severe developmental disorder.

Title: Functions of KBP in neural development and its role in causing Goldberg-Shprintzen syndrome

Authors: *H.-Y. CHANG, C.-W. HUANG, J.-W. TSAI
Inst. of Brain Sci., Natl. Yang-Ming Univ., Taipei, Taiwan

Abstract: Kinesin-binding protein (KBP; KIF1BP; KIAA1279) functions as a regulator of a subset of kinesins, many of which play important roles in neural development. Previous studies have shown that KBP is expressed in nearly all tissue with cytoplasmic localization. Autosomal recessive mutations in *KIAA1279* causes a rare neurological disorder, Goldberg-Shprintzen syndrome (GOSHS), characterized by microcephaly, polymicrogyria, intellectual disability, axonal neuropathy, thin corpus callosum and peripheral neuropathy. Most *KIAA1279* mutations found in GOSHS patients are homozygous nonsense mutations that result in KBP loss of function. However, the mechanism of KBP dysfunction in causing these defects remains not fully understood. Here we used *in utero* electroporation (IUE) to express KBP shRNA with green fluorescent protein (GFP) in radial glial progenitors in embryonic day (E) 14 mice and collected brain slices at different developmental stages. By immunostaining of neuronal lineage markers, we found that neural differentiation process is not affected. However, four days after IUE, KBP knockdown led to many cells arrested in the intermediate zone (IZ) where neural progenitors undergo multipolar-bipolar transition before they start radial migration. Moreover, at postnatal day (P) 6, about one thirds of the cells, which have become mature neurons, remained ectopically in the white matter. For those cells that have reached Layer II/III of the cortex, neurite outgrowth and axon projection was impaired. Our findings indicate that loss of KBP function leads to defects in neuronal migration and morphogenesis, which may be responsible for brain phenotypes observed in GOSHS.

Title: The role of a novel mutation in forkhead box domain protein in brain development and focal cortical dysplasia

Authors: *C. LIU[1], Y.-T. LIU[2], C. CHEN[2], K.-P. CHANG[3], Y.-H. SHIH[2], S.-Y. KWAN[2], H.-H. CHEN[2], J.-W. TSAI[1]

Abstract: Focal cortical dysplasia (FCD) is a heterogeneous form of neurodevelopmental disorders characterized by local cortical malformation. Using next generation sequencing (NGS), we identified a novel gene mutation of Forkhead box (FOX) protein in a family with FCD. This transcription factor contributes to the regulation of cell cycle, proliferation and differentiation. However, the function of this FOX protein in cortical development is unexplored. In this study, we hypothesize that this FOX may play important roles in cortical development through regulating neural progenitor cell proliferation, differentiation and/or migration. We used *in utero* electroporation (IUE) of the FOX shRNA or cDNA into embryonic mouse brains to knock down or overexpress the FOX protein in neural progenitor cells. Neuronal proliferation, differentiation, and migration patterns were then examined later by immunostaining of cell cycle and cell fate markers under a fluorescence confocal microscope. We found that knocking down this FOX protein at embryonic day 14.5 (E14.5) led to a migration delay with more neurons located in the intermediate zone (IZ) 4 days after IUE. At postnatal day 6 (P6), we observed a layer of neurons arrested in deep cortical layer. Interestingly, the percentage of cells positive to the progenitor cell marker Pax6 was increased, suggesting a delay in neuronal differentiation. Furthermore, the cell exit index decreased in the knockdown group, implying this FOX protein might be a possible factor in neurogenesis regulation. Our findings indicate that the dysfunction of this FOX protein impairs the differentiation and migration of neural progenitor cells, which may lead to characteristic abnormal neurons found in FCD lesions.

Title: Delayed GABAergic interneuron migration through impaired actin remodelling in a mouse model with deletion of the autism gene MYO9B

Authors: *L. EID[1,2], P. K. R. PEDABALIYARASIMHUNI[1,2], L. MARCOUX[1], X. JIANG[1,2], A. LUPIEN-MEILLEUR[1,2], L. TOUSSAINT[1,2], M. LACHANCE[1], J.-C. LACAILLE[2], G. HICKSON[1,3], E. ROSSIGNOL[1,4]
[1]Ctr. de Recherche du CHU Sainte-Justine, Montreal, QC, Canada; [2]Neurosci., [3]Pathology and Cell. Biol., [4]Neurosci. and Pediatrics, Univ. de Montréal, Montréal, QC, Canada

Abstract: Autism spectrum disorders (ASD) are genetically heterogeneous. Recent data suggest that a subset of genetically-determined ASD result from defects in the development of inhibitory GABAergic interneurons (INs), leading to aberrant enhancement of cortical excitability. *De novo* mutations in the *MYO9B* gene, encoding a non-muscular myosin with a RhoA-specific RhoGAP domain, have recently been associated with ASD. *Myo9b* regulates dendritogenesis in pyramidal cells (PCs) and is involved in cell motility in other cellular populations, including osteoclasts and dendritic immune cells. However, its roles in brain development, including in the migration and maturation of INs, are unknown. Given the central role of RhoA in actin remodeling and in IN maturation, and the implication of IN pathologies in ASD, we hypothesized that *Myo9b* might be a central regulator of IN development. We thus generated *Nkx2.1^{Cre};Myo9b$^{c/c}$* mutant mice, carrying a conditional deletion of *Myo9b* in MGE-derived INs. We find that the morphology of migrating INs is disrupted at e13.5 in mutant mice, with excessively elongated and branched processes, resulting in a delay in tangential migration that persists at P3 but resolves by P21. Furthermore, time-lapse imaging of F-actin (*Lifeact*) in INs migrating from MGE explants reveals an increased meandering, with slower and infrequent nukleokinesis, resulting in reduced net displacement of mutant INs. Also, we note a more diffuse F-actin distribution in the soma of mutant INs, suggesting a reduction in actin turnover. Immunostaining and western blot analyses

indicate that this is in part attributable to an increased phosphorylation of cofilin, the actin-severing enzyme downstream of RhoA. Altogether, our data suggest that *Myo9b* is a critical player regulating IN development, possibly through its repression of RhoA signaling, and that its loss prevents actin remodeling and perturbs IN migration. In turn, this delay in tangential migration might impact the establishment of neuronal networks during early post-natal ages and lead to socialization deficits and other cognitive impairments seen in patients with *MYO9B*-associated ASD.

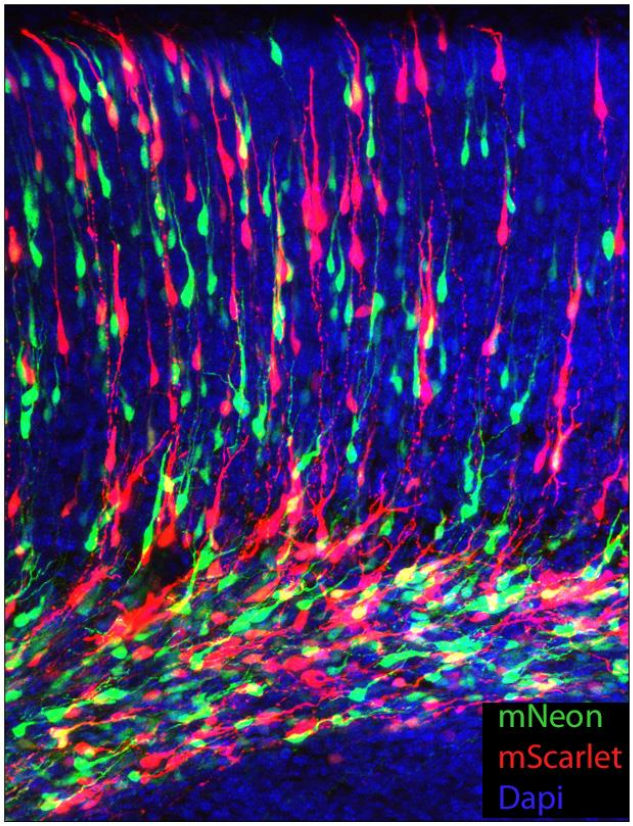
Title: Determining the role of neurite initiation *in vivo* using a novel labeling approach to *in utero* electroporation

Authors: *R. J. TAYLOR[1], K. L. TAYLOR[2], J. CARRINGTON[2], M. MCDERMOTT[2], K. RICHTERS[2], E. W. DENT[2]
[1]Univ. of Wisconsin Madison, Madison, WI; [2]Neurosci., Univ. of Wisconsin, Madison, WI

Abstract: Neurite initiation from a newly born neuron is a critical step in neuronal differentiation. We have previously described the unique role of Cdc42-Interacting Protein 4 (CIP4) in the inhibition of neurite initiation *in vitro*. However, the role of CIP4 in neuronal migration and neurite initiation *in vivo* have not yet been evaluated. Within the prenatal cortex CIP4 protein levels track directly with neuronal migration. CIP4 is expressed highly prenatally, during the period of active neuronal migration in cortex, but decreases to undetectable levels just after birth, when neurons have ceased migrating. To determine the role of CIP4 in cortical neuron migration and neurite initiation we have developed a novel approach for labeling both control and knockdown/overexpressing neurons after *in utero* electroporation (IUE). This technique results in internal controls and experimentally manipulated neurons to be generated in a single brain, obviating the need for separate control and experimental IUEs and subsequent matching of brain sections. Using this new labeling approach, termed Double UP, we have both prematurely decreased CIP4 expression and artificially maintained CIP4 expression beyond

when it would normally decrease. Preliminary experiments indicate that decreasing CIP4 expression causes precocious migration, while maintaining CIP4 expression at high levels delays cortical neuron migration, neurite initiation and axonal extension across the midline. Implementation of this powerful labeling technique will allow for more accurate comparison between experimental and control conditions and requires fewer experiments, saving time and resources.



In Utero Electroporation of Double UP
Cortical section through an embryonic brain of an e17.5 mouse, which recieved Double UP and limiting amounts of Cre plasmid at e14.5.

Title: The effects of mutant Pea3 on cell invasion and cell migration

Authors: *M. USTUN, I. KURNAZ
Gebze Tech. Univ., Kocaeli, Turkey

Abstract: ETS domain transcription factors that contain specific common purine rich DNA sequence in all family members regulate numbers of cellular genes being critical for many celular process. Pea3/ETV4 transcription factor which is ETS family member known to be regulated by many growth factors through MEK/ERK (MAPK) signal transduction cascade during neural development. In this study, our goal is to understand the effects of putative Pea3 phosphorylation sites on cell invasion and cell migration under the conditions of several growth factors. Mimicking and silencing mutations on putative MAPK phosphorylation sites on mPea3 were created by SiteDirected Mutagenesis. The mutant mPea3 plasmids were transfected into the SHSY5Y human neuroblastoma cells and their protein expression levels were analyzed by Western Blot Analysis, transfected cells were also induced with diverse growth factors by cell culture techniques and the protein expressions were checked. Finally, morphological analysis of growth factor induced cells that include mutant mPea3 have been proceed by Immunofluorescence. Various growth factors are known to regulate Pea3 members at the different stages of development. Studies also show that Pea3 leads to dendritic arborization of motor neurons and retinal ganglion cells in response to diverse growth factors. As supported with our experiments, Pea3 induces axonal growth in various neural model cells, and the protein expression pattern of mutant mPea3s with/without growth factors was diverse. The elucidation of Pea3 activation would be contributed to understand of neuroregeneration mechanism after axonal injuries or nerve crush injuries which trigger the retrograde signaling for proper regeneration.

Title: Developmental and physiological defects in a mouse model of cobblestone lissencephaly

Authors: *W. WONG[1], Y. C. WONG[1], C. R. JONAK[3], D. K. BINDER[3], E. ZAGHA[2], M. M. RICCOMAGNO[1]
[1]Molecular, Cell, and Systems Biol., [2]Psychology, Univ. of California, Riverside, Riverside, CA; [3]Biomed. Sci., Univ. of California, Riverside Sch. of Med., Riverside, CA

Abstract: We aim to identify the role of a family of adaptor proteins during neocortical lamination and cortical circuit establishment. During neocortical development, migrating neurons must accurately interpret signaling cues to laminate properly. The Crk-associated substrate (*Cas*) family of cytosolic signaling adaptor proteins mediates cellular responses to neural guidance cues, making them good candidates to integrate multiple signaling pathways. Cas adaptor proteins show strong and specific expression in the cortical plate and white matter, in a manner consistent with playing a role in radial migration and stratification during neural development. We used a conditional gene targeting approach to inactivate neocortical expression of three embryonically expressed Cas proteins (p130Cas, CasL, and Sin). Cas triple conditional knockout (*CasTcKO*) mice display severe cortical phenotypes resembling cobblestone lissencephaly. A hallmark of the debilitating neurodevelopmental disorder in our mouse model includes ectopic clusters of neurons migrating beyond the marginal zone and invading the meninges. *CasTcKO* brains have L1+ axon bundles innervating these ectopias and display mispositioned deep layer and superficial layer neurons. These findings support the notion that Cas adaptor proteins play essential roles during neural migration and circuit formation. To explore the physiological correlates of these lamination defects, we performed electroencephalography (EEG) recordings and trained mutant and control animals in a Go/No-Go somatosensory detection task. EEG analysis revealed the presence of epileptiform activity in the frontal and somatosensory cortices of *CasTcKO* mutant mice, which are absent in control animals. Furthermore, *CasTcKO* animals performed poorer in the detection task. Intriguingly, mutant mice demonstrated long periods of disengagement during the task, which may correlate with the electroencephalographic abnormalities. Our study provides unique and significant mechanistic insight into how the neocortex forms and how neurodevelopmental disorders may arise.

Title: Prenatal exposure to opioids and neurodevelopmental toxicity in the developing chicken embryo model

Authors: *M. HADERA[1], J. M. ANDERSEN[1,2], R. E. PAULSEN[1]
[1]Dept. of Pharmaceut. Biosci., Univ. of Oslo, Sch. of Pharm., Oslo, Norway; [2]Dept. of Forensic Sci., Oslo Univ. Hosp., Oslo, Norway

Abstract: Introduction: Methadone is used in opioid maintenance therapy during pregnancy, though reports indicate potential for long-term neurodevelopmental deficits in exposed children. The mechanisms by which it influences neurodevelopment is not yet known but opioid systems appear early in neurogenesis and are believed to play roles during the neurodevelopment process. The developing chicken embryo is an attractive model system with potential for nonclinical safety studies of pharmaceuticals. The ontogeny of the opioid system is well characterized in this model and reflects the development in rodents as well as humans. In this study we aimed to explore the effect of methadone and morphine on some markers that are known to represent aspects of the neurodevelopment in the cerebellum. **Methods:** On embryonic day (ED) 13 (single exposure) or ED13 and 16 (repeated exposure), methadone and morphine at 20 mg/kg dose were injected onto the chorioallantoic membrane of chicken (*Gallus gallus*) embryos. On ED17, embryos were anesthetized by hypothermia, hatched, decapitated and then the cerebellum harvested. Protein expression of PAX6, MMP9, NR2B (neuronal migration markers) and PCNA (proliferation marker) was analyzed using western blotting. We also studied the effect on PAX6 promotor activity in primary cultures of cerebellar granule neurons from E17 chicken. We included both untreated control as well as vehicle (saline) controls in all the experiments. The data is obtained from 6-9 independent observations and results represent average effects on male and female cerebellum. **Results:** There were no significant differences between the untreated and saline treated groups. We observed reduced levels of PAX (30%; One-way ANOVA, P=0.005) and MMP9 (40%; P=0.04) in the methadone treated compared to the control in the ED13 injected embryos. Though not significant, a 25% reduction in level of NR2B was also observed in the same comparison. Methadone injection on ED13 did not affect PCNA expression. We did not see statistically significant changes in any of the markers in the morphine treatment in the ED13 protocol. None of the treatments showed effects in the ED13 and ED16 repeated injection protocol. Neither morphine nor methadone affected PAX6 promotor activity. **Conclusion**: The developing chicken embryo is a promising alternative animal model for testing of effects by medications on neurodevelopment. Methadone appears to affect molecular markers of migration

of cerebellar granule neurons in this model and it will be interesting to explore histologic changes associated with the observed effects.

Title: Metabolic regulation and glucose sensitivity of cortical radial glial cells

Authors: *B. G. RASH[1], N. MICALI[1], A. J. HUTTNER[1], Y. M. MOROZOV[1], T. L. HORVATH[2], P. RAKIC[3]

Abstract: The primary stem cells of the cerebral cortex are the radial glial cells (RGC)s, and disturbances in their operation lead to myriad brain disorders in all mammals from mouse to human. Yet, their physiology and metabolic sensitivities are not well understood. Here we found in mice that maternal gestational obesity and hyperglycemia can delay RGC neurogenesis and impair neuronal migration to the cortical plate. Using optogenetic approaches we found that Ca^{2+} signaling regulates mitochondrial transport and is crucial for metabolic support in RGC fibers. Cyclic intracellular Ca^{2+} discharge from localized RGC fiber segments detains passing mitochondria and ensures their proper distribution and enrichment at specific sites such as endfeet. Impairment of mitochondrial function caused an acute loss of Ca^{2+} signaling, while hyperglycemia decreased Ca^{2+} activity and impaired mitochondrial transport, leading to degradation of the RGC scaffold. Our findings therefore uncover a novel physiological mechanism indicating pathways by which gestational metabolic disturbances can interfere with brain development. Furthermore, we found that elevated slow-wave Ca^{2+} activity is a feature of cortical neural stem cells (NSCs), but not human induced pluripotent stem cells. Our data support the hypothesis that multiple types of Ca^{2+} activity regulate NSC function and neurogenesis during cortical development, but other stem cell types utilize different regulatory mechanisms for cell type differentiation.

Abstract: Human cerebral cortex consists of billions of neurons distributed across dozens of functional areas. Using unbiased single cell capture and RNA sequencing, we sought to characterize the diversity of molecular programs underlying the differentiation of specialized cell types in the developing human forebrain. We uncover a highly conserved neuronal differentiation signature shared across forebrain regions, as well as specialized signatures characteristic of ventral and dorsal telencephalon. Within the cortex, we discover an unexpected diversity of excitatory pyramidal neuron lineages that relates strongly to cortical area of origin, but poorly reflects adult cortical layer signatures. By relating these area specific signatures to differentiation states our analysis reveals a limited number of transcriptomic differences among progenitor cells cascades into robust typological differences among maturing excitatory neurons. By analyzing the molecular diversity of radial glia progenitor cells, we discover the molecular signatures related to classical radial glia, characterized by the expression of proneural transcription factors, and outer radial glia, and a distinct signature of radial glia at the ventricular zone which emerges mid-way through neurogenesis. We investigated the emergence of this cell type in primary tissue samples by labelling their morphology and found an unexpected transition from classical pial surface-contacting radial glia to shorter, "truncated" morphologies that coincide with the emergence of this transcritomic state. This transcriptomic-based classification of radial glia in the human cerebral cortex suggests a revised model of cortical development as it applies to primates. The model accounts for the transformation of the radial glia scaffold from a physically continuous to the physically discontinuous structure, and accounts for the disproportionate expansion of the supragranular layers in primate species.

Title: Temporal specific regulation of neural differentiation by Foxg1 in the developing cerebral cortex

Authors: Q.-R. BAI[1], *Q. SHEN[2]
[1]Tongji Univ., Shanghai, China; [2]Sch. of Life Sci. and Technol., Tongji Univ., Shanghai City, China

Abstract: Neural stem cells in the embryonic mammalian brain are located in the germinal zones along the ventricular surface and play fundamental roles in generating diverse cell types on a precisely timed schedule. Understanding the intrinsic timing mechanism is important for directed differentiation of neural stem cells to obtain desired cell types for therapeutic use. Previous studies have shown that Foxg1, a forebrain specific transcription factor, regulates the timing sequence of cortical neuron generation, however its molecular mechanism is still not clear. Here using chromatin-immunoprecipitation followed by sequencing analysis we performed genome-wide mapping of Foxg1 binding sites in FACS-selected cortical neural progenitor cells at different stages during embryonic development. We found that Foxg1 is dynamically distributed in the genome of neural stem and progenitor cells, binding to different targets at different developmental stages. In combination with RNA-seq analysis of stage-specific gene expression of FACS-purified neural progenitor cells, we identified putative Foxg1-regulated gene networks. We are confirming potential targets regulated by Foxg1 through analyzing changes in gene expression profile after conditional deletion of Foxg1 in cortical progenitor cells. Furthermore, we found that Foxg1 binding motifs are highly associated with other transcription factors that are important for neural differentiation, and confirmed their interactions in cell lines. Our findings suggest that Foxg1 acts as a master regulator of the timing mechanism controlling neural stem cell differentiation during cortical development.

Title: The roles of tri-methylation of histone h3 lysine 27-mediated pathways in neurodevelopment

Authors: *C. LIU, P.-P. LIU, Y.-J. XU, G.-B. TANG, H.-Z. DU, S.-K. DAI, Z.-Q. TENG

Abstract: Histone H3K27 exists in three methylation states, monomethylated (H3K27me1), dimethylated (H3K27me2), and trimethylated (H3K27me3), a mark of transcriptionally silent chromatin. Evidence shows that polycomb repressive complex 2 (PRC2) localizes with H3K27me3 and has histone methyltransferase activity and primarily trimethylates histone H3 on lysine 27 (H3K27me3). Reduction of H3K27me3 can be accomplished by active H3K27me3 demethylation mediated by H3K27me2/3 demethylases in mammals. These enzymes include UTX /KMD6A (lysine demethylase 6A) and JMJD3/KDM6B, both of which contain a JmjC (Jumonji) catalytic domain for de-methylation of H3K27me3. What's more, Clinical data and sequencing information show that constitutional loss-of-function defects in PRC2 components (EZH2, EED) and UTX cause Weaver syndrome and Kabuki syndrome separately, which are both characterized by moderate-to-severe congenital anomaly/mental retardation. To investigate the mechanism underlying these diseases, we systematically studied the roles of H3K27me3-mediated signalings in neural development. Firstly, we show that miR-203 is repressed by PRC2 in both embryonic and adult in neural stem/progenitor cells (NSPCs). MiR-203 negatively regulates the proliferation of NSPCs. One of PRC1 components, Bmi1, is a downstream target of miR-203 in NSPCs. this study provides the first evidence for coordinated function of the EZH2-miR-203-Bmi1 regulatory axis that regulating the proliferation of NSPCs(Liu, Tang et al. 2017). We also found that EED (embryonic ectoderm development), the core component of PRC2, is necessary for maintenance of the NSPC pool, especially during neurogenesis in the early postnatal DG, which established a critical role of EED in hippocampal DG development (in revision). To our surprise, our results demonstrate that deletion of UTX in the brains of both developing and adult mice results in increased anxiety-like behaviors and impaired spatial learning and memory. Loss of Utx in the hippocampus leads to reduced long-term potentiation (LTP), amplitude of miniature excitatory postsynaptic currents (mEPSCs), aberrant dendrite development, and defective synapse formation(Tang, Zeng et al. 2017). Therefore, we hypothesized that PRC2 has emerging roles in the central nervous system(Liu, Xu et al. 2017). Taken together, our results suggest that H3K27me3 signaling and its related enzymes have

critical roles in mediating neural and behavioral plasticity in mice. EZH2, EED and UTX deficiency leading to neural stem cell and cognition deficits may provide the basis for underlying intellectual disability in Weaver Syndrome or Kabuki syndrome.

Title: 3D bioengineered neural tissue to mitigate acute cerebral inflammation after brain transplantation in rats

Authors: *V. LIAUDANSKAYA[1], D. JGAMADZE[2], A. N. BERK[1], D. J. BISCHOFF[1], B. J. GU[2], H. HAWKS-MAYER[1], M. J. WHALEN[3], H. I. CHEN[2], D. L. KAPLAN[1]
[1]Biomed. Engin., Tufts Univ., Medford, MA; [2]Neurosurg., Univ. of Pennsylvania, Philadelphia, PA; [3]Neurosci. Ctr. at Massachusetts Gen. Hosp., Charlestown, MA

Abstract: Introduction: Cancer, stroke and other neurodegenerative diseases lead to neural tissue loss, and disrupted neuronal signaling. Current approaches of dissociated stem cell transplantation showed promising results, however has limits for the treatment of large size defects. Thus alternative methods are needed, such as implantation of engineered neural tissues. However, inflammation is a prominent concern in neuronal grafting studies. Neuroinflammation is a critical defense mechanism of the brain, and also modulates tissue regeneration in the diseased state. Thus, a fine balance is required to modulate the inflammatory responses for optimal graft integration and survival. The goal of this study was to design a brain implant to control the local environment in order to mitigate acute inflammation post-implantation *in vivo* to improve graft survival. We pursued rat motor cortex implantation of 3D engineered brain constructs (later in text referred to as implants) loaded with corticosteroid and studied the effect of acute inflammation on graft survival.
Methods: Implants were prepared by seeding E18 rat GFP cortical neurons on silk fibroin scaffolds, followed by embedding in a fibrin hydrogel with/out methylprednisolone (MP, 8.7mM). Constructs were implanted into a motor cortex cavity created by aspiration (2x2mm)

and covered with a fibrin gel +/- MP (Tufts IACUC, M2015-28; University of Pennsylvania IACUC, 805600). Three days post-implantation (3 dpi), animals were perfused, and brains were extracted for analysis of graft viability and inflammatory response.
Results and discussion: MP-loaded implants showed increased survival compared to controls (without MP) 3dpi. Increased survival correlated with decreased levels of pro-inflammatory cytokines (IL-1β, IL-6, TNFα, CCL2 and TIMP1) and a shift of immune cells from a pro-inflammatory towards an anti-inflammatory state with upregulation of CD163, IL-4 and IL-10 expression. CCL2 was a critical contributor to neuronal death during acute inflammation, regulated through the NF-κB pathway and STAT transcriptional factors. Finally, the co-activation of Notch1, STAT3, and NF-κB pathways in MP implants suggested the presence of reactive astrocytes at the site of injury. Overall, we achieved improved survival of MP-loaded implants during the acute phase of inflammation through downregulation of upstream targets for many inflammatory cytokines.

Title: Connectivity of human organoid-derived retinal tissue transplanted into subretinal space of a large-eye animal (cat)

Authors: *I. O. NASONKIN[1], R. K. SINGH[1], L. OCCELLI[2], O. CUZZANI[1], F. BINETTE[1], G. S. HOGGE[1], S. PETERSEN-JONES[2]

Abstract: The conceptual approaches to restoring vision impacted by degenerative retinal diseases or trauma have been enriched by the introduction of 3-dimensional (3D) retinal tissue idea a patch idea, which brings incremental improvements in restoring vision. Compared to Retinal Pigment Epithelium (RPE) layer, which serves an important supportive role in visual process and can benefit from a simple cell suspension-based delivery into the subretinal space, neural retina is a multilayered sensory tissue, which vitally depends on preserving structure and photoreceptor directionality to carry out visual function. To develop bioprosthetic approaches to neural retina repair, we derived 3D human retinal tissue (retinal organoids) from human

embryonic stem cells (HESCs) and investigated delivery, survival and integration of laboratory-grown retina in a large-eye animal model. Human embryonic stem cell-derived retinal tissue was introduced into the subretinal space of wildtype cats using a transvitreal approach following a pars plana vitrectomy (n=7 eyes). *Per os* (orally introduced) prednisone was given at an anti-inflammatory dose for the duration of the study. Cats received either no systemic cyclosporine immunosuppression (n=3 grafts) or continuous systemic cyclosporine (n=4 grafts) starting from seven days before transplantation and then continuously. Eyes were examined by fundoscopy and spectral domain optical coherence tomography (SD-OCT) for adverse effects due to subretinal graft presence or/and surgical procedure and monitored regularly by fundoscopy and SD-OCT. Cats were euthanized 5 weeks following grafting, and immunohistochemistry of retinal sections performed using human-specific antibodies (HNu, Ku80, SC121), axonal, synaptic, retinal cell type-specific markers and lymphocyte, microglia/macrophage markers. We report substantial improvement in the survival of xenogenic retinal tissue grafts in cat subretinal space with systemic immunosuppression protocol and evidence of structural and axonal/synaptic integration. Specifically, we observed SC121-positive, CALB2-positive human axons emanating from the grafts and migrating past the photoreceptor layer of the recipients and ending up in cat's inner nuclear layer and ganglion cell layer. Further refinement of the surgical delivery approaches coupled with improved design of bioprosthetic retina is expected to incrementally improve methods of retinal tissue replacement enabling development of more realistic approaches of restoring vision.

Title: Precocious deposition of perineuronal nets on parvalbumin inhibitory neurons transplanted into adult visual cortex

Authors: *D. FIGUEROA VELEZ[1], K. BRADSHAW[2], M. HABEEB[2], S. P. GANDHI[3]
[1]Neurobio. & Behavior, Univ. of California, Irvine, Irvine, CA; [2]Univ. of California Irvine Dept. of Neurobio. and Behavior, Irvine, Irvine, CA; [3]Neurobio. and Behavior, Univ. of California Irvine Dept. of Neurobio. and Behavior, Irvine, CA

Abstract: The end of the critical period for primary visual cortex (V1) coincides with the deposition of perineuronal nets (PNN) onto Parvalbumin (PV) inhibitory neurons. Recently, we found that transplantation of embryonic inhibitory neurons into adult V1 reinstates a new critical period. Here we used Wisteria Floribunda Agglutinin (WFA) staining to compare the deposition of PNNs onto neurons during normal development and following transplantation at equivalent cell ages. In accord with previous findings, PV and PNN expression increases from negligible levels at postnatal day 14 (P14) to mature levels by P70. In contrast to P14, PNNs are found on transplanted neurons by 21 days after transplantation. Moreover, PNN levels remain stable from 21 to 105 days after transplantation. This precocious deposition was specific to PV neurons and excluded transplanted neurons expressing Somatostatin. Notably, the onset of PV expression in transplanted inhibitory neurons follows the timing of PV expression in juvenile V1. Moreover, transplantation has no discernible effect on host PNNs. The precocious deposition of PNNs onto transplanted PV neurons suggests that PNN expression identified by WFA does not reflect neuronal maturity and may be an inaccurate marker for transplant-induced plasticity of cortical circuits.

Title: Transplanted neural progenitor cell survival and development in a jaundiced rat model of kernicterus

Authors: *F.-C. YANG[1], J. VIVIAN[2], S. M. SHAPIRO[3], J. A. STANFORD[1]
[1]Dept. of Mol. and Integrative Physiol., [2]Dept. of Pathology & Lab. Med., Univ. of Kansas Med. Ctr., Kansas City, KS; [3]Pediatrics, Children's Mercy Hosp. & Clinics, Kansas City, MO

Abstract: Neonatal hyperbilirubinemia targets specific brain nuclei and can lead to kernicterus. The most debilitating symptom of kernicterus is dystonia, caused by bilirubin toxicity in GABAergic neurons of the globus pallidus (GP). We believe that targeting GP with neuronal stem cells is a promising therapeutic approach to treat dystonia in kernicterus. We have reported greater neuronal progenitor cell (NPC) survival in brains of jaundiced (jj) than non-jaundiced (Nj) Gunn rats. The goal of the current study was to further determine NPC survival and development in a more severe condition of bilirubin toxicity that closely resembles kernicterus in human cases. For this purpose, we modified the model by injecting sulfadimethoxine (sulfa, 50 or 70mg/kg) to jj rats at postnatal day 10 (P10). These rats and their Nj littermates then received inhibitory medial ganglion eminence neuron-like (MGE-like) NPCs grafted unilaterally to the GP at P21. Immunosuppressant cyclosporine A was given after transplantation throughout the experiment. Animals were allowed to survive 3 weeks or 7 weeks after the surgery. Brain sections were processed with immunohistochemical analyses to identify cell survival, cell properties and fiber outgrowth. Our preliminary data suggests: 1. Even after hyperbilirubinemia exacerbation (sulfa treatment), jj rat brains (7 weeks or 3 weeks) still had greater graft cell survival than Nj rat brains. 2. There were more mature graft cells in brains of 7-week group than in 3-week group. 3. Overall, necrotic tissue was relatively low all groups, maybe due to immunosuppressant, which we did not use in our previous studies. We observed fewer necrotic cells in brains of 7-week group compared to 3-week group. Interestingly, Nj brains had more necrotic tissue than jj brain. 4. Abundant fiber outgrowth was identified in all cases. Fibers distributed widely from the injection site. While a type of short, parallel fibers were concentrated near the core of the graft, many long fibers projected ventromedially from the GP. 5. PENK (proenkephalin)-ir graft cells exited from the graft site, but they were few and immature. 6. We

previous reported that NPC graft induced strong PENK expression in certain cells (possibly astrocytes) surrounding the graft in the host brain. In this experiment we found the PENK expression was much weaker 7 weeks after transplantation in both jj and Nj brains. In conclusion, MGE-like NPCs were able to survive and generate various types of fibers in more severely bilirubin-damaged brains, supporting the feasibility of stem cell therapy in kernicterus.

Title: Functional recovery after the systemic administration of mesenchymal stem cells in a rat model of neonatal hypoxic-ischemia

Authors: *T. SAKAI[1,2], M. SASAKI[2], Y. KATAOKA-SASAKI[2], S. OKA[2], M. NAKAZAKI[2], S. FUKUMURA[2], M. KOBAYASHI[2], H. TSUTSUMI[2], J. D. KOCSIS[3], O. HONMOU[2]
[1]Tomakomai City Hosp., Tomakomai / Hokkaido, Japan; [2]Sapporo Med. Univ., Sapporo / Hokkaido, Japan; [3]Neurosci. Res., Yale Univ. Sch. Med., West Haven, CT

Abstract: ***Objective:*** Children who have experienced neonatal hypoxic-ischemic encephalopathy often develop cerebral palsy. Although many treatments have been performed, few effective therapies are available. In this study, we tested the hypothesis in rats with hypoxia-ischemia (HI) injuries that the systemic infusion of mesenchymal stem cells (MSCs) would result in functional improvement by facilitating neural compensation in the contralesional cortex.
Methods: Postnatal (P) day 7 (P7) rats that had undergone unilateral hemisphere hypoxia-ischemia (modified Rice-Vannucci model) were randomly assigned to MSC-infused or vehicle-infused groups. MSCs (1.0×10^6/200 μL) or vehicle were intravenously infused at P10. Brain volume was measured using *in vivo* magnetic resonance imaging (MRI) on P8 and P35. On P35, the rats were sacrificed after their behavior was evaluated using a beam walk test, and their brains were then prepared for histological analyses.
Results: The MSC-treated group had less slips on the beam walk test compared to those in the vehicle group ($p = 0.041$). MRI was used to measure the volumes of the whole brain, contralesional brain (hemisphere), and residual brain regions of interest, and the

results indicated increased brain volume after the intravenous MSC infusions. The histological analyses revealed increased thicknesses of the contralesional cortex and corpus callosum in the MSC group compared with those in the vehicle group ($p = 0.021$, $p = 0.019$), which confirmed the volume increases. In the contralesional cortex, the MSC-treated group exhibited significant increases in the numbers of NeuN-positive cells ($p = 0.004$) and synaptic puncta ($p = 0.000$) compared with those in the vehicle group.
Conclusions: The intravenous infusion of MSCs resulted in improvements in functional outcome, increased brain volume, and enhanced synaptogenesis in HI rats.

Title: Human neural progenitor cells reverse symptoms and extend longevity in a rat model of ataxia

Authors: *W. M. TIERNEY[1], B. ORTEGA[1], A. LEMUS[1], T. L. UHLENDORF[1], J. OCHOA[2], W. VAN TRIGT[2], A. KOPYOV[2], O. V. KOPYOV[2], R. W. COHEN[1]
[1]California State University, Northridge, Northridge, CA; [2]Celavie Biosciences, LLC, Oxnard, CA

Abstract: The spastic Han Wistar (sHW) rat serves as our model for human ataxia presenting symptoms of motor deterioration, decreased weight and a shortened lifespan. Correspondingly, sHW rats show progressive loss of Purkinje cells starting at 30 days. Past experiments in our lab revealed that human neural progenitor cells (NPCs) have been effective in this ataxic rat model, including significant improvements in behavioral assays and human cell survival 20 days post-transplantation. Here, we examined the longer-term effectiveness and fate of human NPCs in this ataxic rat. For this experiment, rats were placed into four treatment groups (equal mix of male and female rats): an untreated normal control group (n=10), an untreated mutant rat control (n=10), a mutant group that received an injection of dead NPCs (n=9), and a mutant group that received live NPCs (n=10). Bilateral cerebellar injections of 500,000 of either live or dead NPCs were performed on mutant sHW rats at 40 days of age, and motor activity (via open field and rotarod assays) was tested twice per week henceforth. All mutant rats started to decline in open

field testing around day 35. However, at day 45, the live NPC-treated mutants began to exhibit improved motor activity while dead NPC-treated and untreated mutants continued to display decreased motor abilities. Starting at day 60 (20 days post-transplantation), live NPC-treated mutant's motor behavior was statistically similar to normal rats, and this trend continued until the end of the experiment. Cerebellar decline was tested via the rotarod test. Live NPC mutants were statistically similar to normal rats; yet, dead NPC and untreated mutants showed significant decreases in rotarod performance. All rats were perfused with 4% paraformaldehyde, their brains removed and sliced for histological staining. While immunohistochemistry revealed few surviving human NPCs in the cerebellums of 100 day old NPC-treated mutants, cresyl violet staining revealed that live NPC-treated mutants had significantly more surviving Purkinje neurons as compared to mutants that were untreated or received dead NPCs. Implantation of live NPCs alleviated the symptoms of ataxia, acting as a neuroprotectant for the remaining Purkinje neurons, but paradoxically did not survive 60 days post-transplantation.

Title: Transplanting immortal orexin neurons in narcolepsy

Authors: *S. K. PINTWALA[1], J. CHALMERS[2], J. FRAIGNE[1], D. BELSHAM[2], J. PEEVER[1]
[1]Cell and Systems Biol., [2]Physiol., Univ. of Toronto, Toronto, ON, Canada

Abstract: Narcolepsy is a sleep disorder caused by loss of orexin neurons in the lateral hypothalamus. This results in symptoms such as excessive daytime sleepiness and cataplexy, a sudden and involuntary loss of muscle tone during wake. The objective of cell transplantation is to treat disease by reinstating lost transmission, but is dependent on the availability of cells with phenotype of those lost. The aim of this study is to investigate the physiology of a novel, immortal orexin cell line and to perform cell transplants using a mouse model of narcolepsy. To do this, we used an immortal cell line isolated from transgenic mice (m) expressing green fluorescent protein (GFP) in orexin (ORX) neurons, isolated from the adult (A) hypothalamus (Hypo)—the mHypoA-ORX/GFP4 cell line. First, we performed immunocytochemistry against

GFP, the fluorescent marker which denotes these cells, and orexin-A to confirm the phenotype. Next, we performed a live cell secretion assay, coupled with enzyme immunoassay, to confirm the ability of these cells to secrete orexin. Finally, we performed transplant surgeries in a mouse model of narcolepsy (orexin-knockout) to determine cell survival. Cells were bilaterally injected into the prefrontal cortex (AP: 1.8/ ML: 0.4/ DV: 1.5, approx. 2000 cells/hemisphere). Cells were visualized using immunohistochemistry.
All (100%) of neurons in the mHypoA/ORX-GFP4 (#cells=379; n=3) cell line expressed orexin-A and GFP antigens. Using a live cell assay we detected orexin-A secretion at baseline (0.276±0.030ng/ml; n=3; 5.0mM glucose media). To probe orexin-A release, cells were challenged with a hypoglycemic condition (0.2mM glucose media) and found a significant increase in orexin-A release (0.337±0.031ng/ml; t-test; n=3; $p<0.01$). Finally, cells were transplanted to the brains of narcoleptic mice. GFP+ cells were found at 2 (#cells=731±382; n=4), 14 (#cells=1186±603; n=6) and 30 days (# cells=963±192; n=6) post-transplant.
This experiment highlights the potential of cell replacement therapy as a novel therapeutic strategy for narcolepsy, and the potential for using immortal cells to accomplish this.

Title: Neovascularization for optimal survival of neural transplants

Authors: *J. E. KRZYSPIAK[1], B. GALINSKI[1], P. J. LITUMA[1], J. YAN[1], S. G. KEE[2], S. ZUKIN[1], D. WEISER[1], P. CASTILLO[1], K. KHODAKHAH[3], J. M. HEBERT[1]

Abstract: The transplantation of neural stem cells holds great promise for improving function after various forms of brain damage and disease. Days or weeks after transplantation, however, transplant-derived cells can be greatly reduced in numbers. The loss of transplanted cells has been attributed in part to immunorejection. However, there is growing evidence in the field that supporting cell types may be required to facilitate the success of a transplant in contrast to

transplanting pure populations of cells. Specifically, there is evidence that neovascularization may also be critical for transplant cell survival. As in the fetus where vascularization must match the physiological demands of each growing tissue, vascularization of neural cell transplants might also need to occur rapidly to promote optimal neuron survival, differentiation, and function. Our preliminary studies with transplants of cortical precursorsembryonic forebrain cells into the adult neocortex of a stroke affected mouse suggest that vascular endothelial precursors may be required in the transplant cell population for efficient survival of the neural precursors and the neurons they generate. We observe that within transplants on the stroke affected side, blood vessels primarily develop from donor-derived cells, in contrast to the control side, and appear to fuse with the host vasculature. Moreover, our early findings suggest that other cell types, such as microglia, might play critical roles in transplant neovascularization.
To show that donor-derived vessels are integrating with the host circulation, we are using an intravenous fluorescent dye to confirm bona fide fusion with host vessels. To determine the requirement of vascular precursor cells for enhanced cell survival, we are currently experimenting with two mixes of cell types for transplantation: one that contains the complete heterogeneous population of cells harvested from mouse embryonic cortices and one that lacks specifically the vascular precursor cells. To show that donor-derived vessels are integrating with the host circulation, we are using an intravenous fluorescent dye to confirm bona fide fusion with host vessels.Future studies will be using human embryonic stem cell derived neural stem cells and human umbilical cord derived endothelial cells to test if this phenomenon to is applicable to cultured human cells. These studies are directly relevant to the effective use of neural cell transplants in future clinical trials.

Title: Development of murine/human microglia chimeras to study neurological disease

Authors: *M. A. COBURN, J. HASSELMANN, D. X. FIGUEROA, A. MCQUADE, C. H. TU, J.-P. CHADAREVIAN, H. DAVTYAN, S. GANDHI, M. BLURTON-JONES

Abstract: Microglia are strongly implicated in the pathogenesis of Alzheimer's Disease (AD) and recent GWAS studies have identified several microglia-enriched genes that influence AD risk. Yet the impact of these genetic variants on microglial function remains unclear. Our lab recently developed a fully-defined approach to differentiate induced pluripotent stem cells (iPSCs) into microglia (iMGLs), providing an important tool to study human microglia *in vitro*. However, microglial function is dramatically influenced by other cell types and pathologies within the brain, underscoring the need to also examine human microglial function *in vivo*. Lineage tracing studies reveal that microglia originate from primitive hematopoietic progenitors (HPCs) within the yolk-sac that migrate into the developing brain. We therefore reasoned that transplantation of HPCs into postnatal immune-deficient mice with humanized CSF-1 would allow us to recapitulate this developmental program and generate murine/human microglia chimeras. Transplanted HPCs readily differentiated into human microglia, exhibiting typical microglial markers and morphology. In addition, HPCs also differentiated into three other CNS macrophages (perivascular, meningeal, and choroid plexus macrophages), all of which can be derived from yolk sac HPCs. Our protocol thereby reproduces microglial ontogeny, allowing transplanted HPCs to proliferate and differentiate appropriately in response to extrinsic cures within the developing rodent brain. To further establish the utility of this approach we have performed experiments to examine the impact of systemically induced neuroinflammation though lipopolysaccharide (LPS) stimulation on human microglial morphology and gene expression, validated through histology, two-photon live imaging, and RNA sequencing. Additionally, analysis of focal laser damage under a two-photon microscope allows us to assess the effect of localized damage response and infiltration of transplanted microglia. Together our data suggests that this approach can be used to produce a novel and informative humanized mouse model of neuroinflammation.

Title: Psychophysical assessment of tactile sensory functions in microsurgical rat models

Authors: *S.-H. WU[1,4], C.-J. WEN[1,4], J.-J. HUANG[5,4,1], Y.-C. PEI[5,1,4], C.-H. LIN[1,4,2,3], H.-Y. CHENG[1], Z.-L. PENG[1,2,3], H.-Y. YANG[6], F.-C. WEI[1,4,3]

Hosp., Taoyuan City, Taiwan; [6]Dept. of Electronic Engin., Natl. Taipei Univ. of Technol., Taipei City, Taiwan

Abstract: Vascularized composite allotransplantation (VCA) is a powerful tool for human body reconstruction, which allows severe limb and facial defects to be reconstructed by genetically non-identical tissues. The functional outcome is one of major concerns for VCA. However, the lack of the rigorous method for quantifying the postoperative function makes the assessment of the long-term recovery difficult. Therefore, developing an appropriate animal model, which can systematically assess the functional recovery, will help scientists discover more potential treatments to improve the nerve reinnevation in VCA. The mystacial pad flap, also known as the whisker system, is a suitable animal model for VCA studies because its function is easily to be monitored by the whisking-related behavior. Here we designed a two-alternative forced-choice tactile discrimination task to evaluate the whisker sensory function in *Lewis* rats. In this task, the rat had to use its whisker to discriminate the target texture from two tactile stimuli presented simultaneously to get the reward (6% sucrose solution). The proportion of correct decision (Pc) would be calculated after 60 sequential trials in one session, and each rat would repeatedly perform 4-5 sessions in each week. Our rats were able to acquire the skill, i.e. the proportion of correct decision greater than 75%, within 1.5 months. Next, we manipulated the infraorbital nerve, which is responsible for tactile sensation in the mystacial pad flap, on the well-trained rats by microsurgical technique. We found that rats' Pc sharply dropped down to the chance level (50%) after we cut off their infraorbital nerve, but the decrease of the Pc did not occur in the subjects who received the sham surgery. Furthermore, we cut the infraorbital nerve first and then sutured it back. Rats' Pc also had dropped down in the first postoperative week, but it gradually recovered to the baseline around the second to third postoperative week. This result suggests that our tactile discrimination task is able to quantify the whisker sensory function after the surgical operation. Compared with the traditional behavior paradigms, such as the pain or thermal test, our psychophysical task provides a more reliable and repeatable way for long-term monitoring. In addition, the action of rats' active discrimination is similar to rehabilitation, so this paradigm has the potential to serve as the animal model for rehabilitation. Our future work will focus on VCA rat models, and try to combine this behavior task with the brain image technique to study the mechanism of the nerve reinnvervation after VCA.

Title: Optimizing the survival of transplanted engineered neural tissue grafts using necrostatin-1 and methylprednisolone

Authors: *G. MAN[1], D. JGAMADZE[1], B. GU[1], J. LIM[1], V. LIAUDANSKAYA[2], D. L. KAPLAN[2], H.-C. I. CHEN[1]
[1]Neurosurg., Univ. of Pennsylvania, Philadelphia, PA; [2]Biomed. Engin., Tufts Univ., Medford, MA

Abstract: Introduction: Transplantation of three-dimensional neural tissue constructs emulating features of native neural tissue could effectively replace large brain defects and restore circuit function. An obstacle to this strategy is cell death after transplantation, especially in the context of acute injury or ischemia. In a rat model of motor cortex aspiration injury, we assessed the effect of inhibiting necroptosis and inflammation on the survival of human cortical neurons derived from induced pluripotent stem cells (iPSC) seeded on a silk sponge scaffold. Methods: Human cortical neurons were differentiated from iPSC lines. The phenotype of these neurons was characterized over the course of 80 days by standard immunocytochemistry. Neurons differentiated from GFP+ iPSC lines (day 30) were seeded on a silk sponge scaffold and embedded in a fibrin hydrogel with and without necrostatin-1, a necroptosis inhibitor, and methylprednisolone (MP), a corticosteroid. These silk constructs were transplanted into the primary motor cortex of adult male Sprague-Dawley rats after an aspiration lesion had been created. Three days after surgery, the animals were sacrificed, the brains extracted for immunohistochemistry. Results: iPSC-derived cells seeded on silk scaffolds consisted of a mixture of neurons (68% βIII-tubulin+) and neural progenitors (43% Pax6+). Most cells expressed the forebrain marker Foxg1 (72%). Animals were transplanted with silk constructs containing necrostatin-1 and MP (n=3) or with silk constructs lacking these agents (n=3). Qualitatively, there was considerably more survival in the former group compared to the latter group. Preliminary quantification of GFP+ area as a percentage of injury cavity size supported this qualitative finding (0.51 ± 0.18 versus 0.27 ± 0.06, $p=0.02$). The majority of the GFP+ cells within the graft were Tuj1+, indicating a neuronal phenotype. Initial quantification of CD68+ inflammatory cells per injury area suggested no difference between the two groups ($p=0.35$).

Conclusion: We have demonstrated that the local presence of a necroptosis inhibitor and corticosteroid improves the survival of transplanted 3D constructs consisting of iPS-derived human cortical neurons seeded on a silk scaffold. Ongoing studies are evaluating graft survival at later time points and more thoroughly examining the inflammatory response. These results indicate that pharmacological interventions can have a significant impact on the survival of transplanted neurons, which could greatly facilitate studies of the anatomical and functional integration of engineered neural tissues with the brain.

Abstract: The damaged mammalian central nervous system (CNS) has a limited ability to regenerate making the treatment of CNS injury and diseases difficult. Cell transplantation strategies are currently under extensive investigation as a potential approach for CNS repair. However, transplanted cells often have a low survival rate and poor host integration. To overcome these limitations, biocompatible materials can provide structural support and physical cues to direct cell growth and differentiation. In the present study, we aim to use zebrafish as an *in vivo* model system to study biomaterial-based cell delivery systems. Zebrafish provide an ideal vertebrate model as they have an innate immune system that is similar to mammals, develop *ex utero,* and are optically transparentas larvae, enabling implant and transplantation studies to be followed *in vivo*. To test whether biocompatible materials can improve cell viability and integration, *Xenopus* retinal glial (XR1) cells were labeled with fluorescent dyes to distinguish them from host tissues, and seeded onto polymer scaffolds. Unlike mammalian cells, *Xenopus* and zebrafish-derived cell lines have the advantage of being cultured at room temperature, supporting cell survival in a zebrafish. GFAP:GFP transgenic zebrafish larvae were used to follow the host glial response to the XR1-polymer implants. Implants were performed into the brain and eye of the zebrafish and the CNS microenvironment was examined by monitoring changes in brain morphology post implantation. Further, the larvae were time lapse-imaged

overnight, whole-mount imaged and sectioned post implantation to further characterize the glial response. Our results demonstrate that *in vitro*, XR1 cells attach and proliferate on the scaffolds. Secondly, scaffolds were successfully implanted into zebrafish, and that at least 4 days post implant the scaffolds are retained. This approach may provide a means for rapid screening of biocompatible materials in support of cell transplantation for *in vivo* delivery for CNS repair following injury.

Abstract: The diagnostic criteria for Autism Spectrum Disorder (ASD) includes two domains: social communication impairments and restricted, repetitive behaviors and interests. However, individuals with ASD commonly experience cognitive deficits. One possible mechanism of cognitive deficits in ASD is the shortening of telomeres. Telomeres are repetitive non-coding DNA nucleotides that protect genes by capping chromosome ends. Recently, two reports introduced preliminary evidence associating shortened telomere length with ASD or familial relation. Further, shortened telomeres have been associated with age-related cognitive decline. While it has been demonstrated that telomere length is not related to core symptoms of ASD, the relationship between telomere length and cognitive function in ASD has not been investigated. Using blood leukocyte-derived DNA, we investigated the association between relative telomere length (RTL) and ASD in males (ASD [mean age: 8.7±8.4], n = 116; typically developing [TD, mean age: 7.1±2.3], n = 71). We used an established quantitative polymerase chain reaction method, and designed telomere and single-copy reference gene primers as controls. We assessed

RTL between groups using ANCOVA with age as a covariate. Additionally, we hypothesized that shorter telomere length would be associated with lower levels of cognitive function as measured by the Stanford-Binet Intelligence Scale-5, but not core symptoms (i.e. Autism Diagnostic Observation Schedule and Social Responsiveness Scale) or sensory symptoms (i.e. Sensory Profile). We replicated previous findings that individuals with ASD have shortened RTL, compared to TD individuals ($p<0.001$). There were no significant associations between shortened telomere length and level of cognitive functioning, core ASD symptoms, or sensory symptoms. Taken together, these evidence strongly suggest that telomere length is affected in individuals with ASD, but the behavioral consequences remain unknown.

Title: Investigating the DNA methylation signature of the brain in Rett syndrome patients

Authors: *M. RASTEGAR[1], D. KROFT[2], K. SHEIKHOLESLAMI[4], S. AMIRI[2], V. SIU[5], T. PEMBERTON[2], M. DEL BIGIO[3]
[1]Dept. of Biochem. and Med. Genet., [2]Biochem. and Med. Genet., [3]Pathology, Univ. of Manitoba, Winnipeg, MB, Canada; [4]Med., Univ. of Toronto, Toronto, ON, Canada; [5]Biochem., Western Univ., London, ON, Canada

Abstract: Rett Syndrome (RTT) is an X-linked progressive neurodevelopmental disorder that is caused by *MECP2* gene mutations. RTT is one of the leading causes of mental disability in young females and has no cure or effective treatment. Individuals with RTT develop normally during their first 6-18 months of life, but then start to exhibit symptoms that include developmental regression, mental disability, seizers, speech problems, anxiety, and autistic characteristics. We have previously shown the expression of MeCP2 isoforms E1 and E2 to vary temporally and regionally during brain development and in the adult mouse brain. Moreover, we found that MeCP2E1 and E2 are differentially controlled by DNA methylation and that specific types of DNA methylation regulate MeCP2 homeostasis. Thus, genome-wide patterns in DNA methylation might be perturbed to varying extents in different regions of RTT brains. Here, we

explore genome-wide DNA methylation patterns in human post-mortem RTT brains using genomic DNA extracted from the cortex, hippocampus, amygdala, and cerebellum of RTT patients with confirmed *MECP2* gene mutations and age-/sex-matched controls. Global DNA methylation patterns were determined using Illumina's Infinium MethylationEPIC BeadChip, while global levels of different types of DNA methylation were studied by dot blot analysis. Comparative analyses of global 5mC and 5hmC as well as MethylationEPIC data in RTT patients and controls identified clear differences in the methylation patterns of specific gene promoter regions across different brain regions. Additional permutation-based significance tests identified marginally significant ($p < 0.10$) differentially methylated regions between RTT patients and controls in cortex, amygdala, and cerebellum. Our results support existence of a distinctive DNA methylation signature in the human RTT brain, providing important new insights into how molecular abnormalities at the cellular levels may lead to compromised brain function in RTT patients.
Control brain tissues and some RTT brain regions were obtained through NIH NeuroBioBank Program (neurobiobank.nih.gov). Additional RTT brains were donated to the Rastegar lab by patient family members with proper consent for research. Research with human brain tissues was reviewed and approved by the University of Manitoba Bannatyne Campus research ethics board.

Title: Reducing noise in spit and brain: Multi-tissue deconvolution analysis reveals epigenetic differences in young children diagnosed with autism spectrum disorder

Authors: *B. S. MULLIGAN, J. M. STEPHEN[1], E. L. BEARER[2,3]
[1]Mind Res. Network, Albuquerque, NM; [2]Dept. of Pathology, UNM Sch. of Med., Albuquerque, NM; [3]Div. of Biol., Caltech, Pasadena, CA

Abstract: Autism Spectrum Disorder (ASD) refers to a range of mental conditions present from childhood characterized by difficulty with communicating, developing/utilizing social skills, and understanding abstract concepts. 1 in 59 Americans aged 8 have been diagnosed with ASD, with

presence in all demographics across ethnicity, sex, and socio-economic status. No cure nor unifying cause are known. Current diagnosis is behavioral assessment beginning at 18 months of age. A minority of children (42%) are diagnosed by 36 months, though it is known that early diagnosis is key to the effectiveness of interventions. In order to diagnose more quickly diverse groups of children, the biological mechanisms related to ASD must be discovered. We propose that a possible biological mechanism of ASD is global epigenetic change. We believe that changes in methylation impact the development of the neural system in a child with ASD that will be detectable across multiple tissues. To test this, children with ASD and non-ASD control children aged 1-4 were recruited for interviews and sample collection. From these children, 11 individuals' saliva (6 control and 5 ASD) were analyzed with Illumina HumanMethylation450 BeadChip. Control and ASD brain samples from a separate study were used for cross comparison. After initial processing yielded little variation between ASD and control global epigenetic patterns, saliva composition was found to be 62.42% (± 6.59 , SD) keratinocyte (K) in ASD saliva samples and 57.64% (± 9.14) K in control samples, with a total average composition of 59.48% (± 7.85) K. After correction, ASD-driven global variation was detectable across the saliva samples. Gene expression modified related to axonal guidance, neurogenesis, and similarly neural-focused functions. Similar corrections were made in the brain samples for relative contributions of neuronal versus glial cells, and then the saliva and brain sites were compared again, identifying sites and genes commonly altered in both brain and saliva. Methylation in the original cohort was confirmed by pyrosequencing and validated in a new cohort. These genes' role in neural development and maintenance provides targets for future exploration into a mechanism by which developing brains are or become autistic, and gives hope for earlier detection.

Title: *In vivo* Perturb-Seq: Finding common ground for heterogeneous variants in autism spectrum disorder

Authors: *X. JIN[1], M. KO[1], S. SIMMONS[3], J. LEVIN[3], F. ZHANG[3], P. ARLOTTA[2]
[2]Stem Cell and Regenerative Biol., [1]Harvard Univ., Cambridge, MA; [3]Broad Inst., Cambridge, MA

Abstract: Autism Spectrum Disorder (ASD) comprises a broad collection of brain developmental and functional disorders with highly heterogeneous genetic contributions.

Hundreds of risk genes have been identified by whole exome sequencing of patients with ASD and intellectual disability. The rare de novo variants found in these genes have large effect sizes and are highly penetrant, but very little is known about how they contribute to ASD pathology. Challenges in the field remain: 1) systemic, causative genetic studies of hundreds of ASD risk genes are needed, but generating knockout mice for individual genes is time-consuming and costly; 2) although ASD appears to have a developmental origin, it is not known whether different risk variants affect shared brain cell types and/or developmental pathways.
I propose to develop tools to systematically study a subset of these de novo ASD risk genes, aiming to uncover shared cellular mechanisms that give rise to common ASD phenotypes. To achieve this, I will build on the Perturb-Seq platform, to use in vivo genome editing in rodent progenitor cells of the cortex in utero to generate mutations in ASD risk genes, and use high-throughput single-cell transcriptomics to find common cell types altered by these perturbations. Working with human geneticists, I will select a panel of ~40 ASD risk genes, and investigate their function with the Perturb-Seq platform. I expect to identify the neuronal and nonneuronal substrates altered by each of these ASD risk variants, and identify the developmental stages of their manifestation. By combining human genetics and neurobiology in a more scalable approach, I will be able to investigate many ASD risk genes in parallel to gain a broader understanding of how diverse genetic changes give rise to a shared pathology.

Title: Altered brain-wide neural dynamics in mouse models of autism

Authors: D. GUTIERREZ-BARRAGAN[1], M. A. BASSON[2], S. PANZERI[1], *A. GOZZI[3]
[1]Inst. Italiano di Tecnologia, Rovereto, Italy; [2]King's Col. London, London, United Kingdom; [3]Fondazione Inst. Italiano Di Tecnologia, Genova, Italy

Abstract: Aberrant or disrupted brain functional connectivity is a hallmark feature of autism spectrum disorders (ASDs). When measured with neuroimaging techniques such as functional MRI in the resting state (rsfMRI), changes in interregional connectivity are typically mapped under the assumption that functional connectivity remains static over time. However, mounting experimental and theoretical work has implicated disrupted large-scale neural dynamics as a key

contributor to aberrant network activity. Here we applied a novel computational framework to probe the presence of altered neural dynamics in mouse lines harboring autism-associated mutations (*Chd8*$^{+/-}$, *Shank3B*$^{-/-}$ and *Cntnap2*$^{-/-}$) as measured with rsfMRI. By using a whole-brain clustering analysis of spontaneous rsfMRI activity, we could reliably classify, both at the group and single-subject level, a restricted set of brain-wide functional brain states, each characterized by a rich spatial structure that can be mapped with voxel-resolution. Importantly, we show that the dynamics of the rsfMRI states varies from state to state according to coupled oscillatory dynamics. Finally, we document that patterns of over- (*Chd8*$^{+/-}$) and under- (*Shank3B*$^{-/-}$, or *Cntnap2*$^{-/-}$) functional connectivity reflect the engagement of non-canonical brain states, characterized by regionally-altered patterns of spontaneous fMRI activity, as well as altered coupling among the oscillatory dynamics of each state. Collectively, our results offer a novel framework to interpret and model the emergence of aberrant functional connectivity in ASDs, and suggest that autism risk mutations lead to disrupted network activity via brain-wide alterations in spontaneous neural dynamics.

Title: Cell type-specific disruption of cortico-striatal circuitry drives repetitive and perseverative behaviors in fragile X syndrome model mice

Authors: *F. LONGO[1], S. ARYAL[1,2], J. TABOR[1], F. ALBANESE[1], J. D. ZHU[1], E. SANTINI[3], E. KLANN[1]
[1]Ctr. for Neural Sci., New York Univ., New York, NY; [2]Dept. of Biochem. and Mol. Pharmacol., New York Univ. Sch. of Med., New York, NY; [3]Dept. of Neurol., Columbia Univ. Med. Ctr., New York, NY

Abstract: A significant proportion of individuals (15-50%) diagnosed with fragile X syndrome (FXS), the most common form of inherited intellectual disability, exhibit a variety of behaviors emblematic of autism spectrum disorders (ASD), including self-injury, stereotypy, and impaired social interaction (Penagarikano et al., 2007). These aberrations severely disrupt the health, safety, and quality of life of patients with FXS and ASD, and their families. Despite the clinical impact of these motor disturbances, relatively little is known about the underlying neurobiology of these features in comparison with other aspects of autism. Evidence from both clinical and preclinical studies suggests that the basal ganglia contribute to the pathophysiology of ASD (Hardan et al., 2003). It has been proposed that ASD symptoms such as cognitive inflexibility and impulsive/compulsive behavior might be generated by abnormalities in the striatum and in cortico-striatal circuits, as well as within striatal circuitry itself (Qiu et al., 2010). Consistent with this idea, FXS model mice display distinct repetitive/perseverative behaviors that are likely striatal-based, a brain area mostly unexplored in ASD. Altered protein synthesis may be a shared molecular anomaly that underlies the synaptic and behavioral impairments associated with ASD. Consistent with this hypothesis, a high proportion of patients with FXS, which is characterized by disrupted *de novo* protein synthesis, also suffer from autism. We hypothesized that the aberrant repetitive and perseverative behaviors exhibited by FXS individuals is due to a net increase in cap-dependent translation at cortico-striatal synapses and in particular in striatal medium spiny neurons (MSNs) and that alters the activity of direct and indirect pathways, causing changes in behavior. To dissect out the contribution of D1- versus D2- expressing MSNs in the dorsal striatum to repetitive and perseverative behaviors in FXS, we used a broad array of biochemical and genetic techniques and a newly developed RNA-sequencing technology, which allowed us to interrogate cell-type specific translatomes of the FXS mouse striatum at a genome-wide resolution. Our preliminary findings are consistent with the hypothesis that enhanced cap-dependent translation via increased eIF4E-eIF4G interactions contributes to repetitive behaviors displayed by FXS model mice that are likely cortico-striatal in nature and provide critical information concerning potential therapeutic treatments for synaptic and behavioral dysfunction not only FXS, but also in ASD.

Title: Perineuronal nets are increased on parvalbumin+ interneurons of the dorsomedial striatum in three mouse models of autism spectrum disorder

Authors: *B. A. BRIONES[1], M. N. PITCHER[2], A. D. ZYCH[2], A. E. HAYE[1], S. MURTHY[2], E. GOULD[1]
[1]Dept. of Psychology & Neurosci. Inst., [2]Princeton Neurosci. Inst., Princeton Univ., Princeton, NJ

Abstract: Autism spectrum disorder (ASD) is a heterogeneous neurodevelopmental disorder commonly associated with impaired social interactions and maladaptive repetitive behaviors, functions linked to the basal ganglia. Numerous studies have implicated basal ganglia and interneuron pathology in ASD, and furthermore that cortico-striatal dysfunction contributes to social impairment and repetitive self-injurious behaviors (Peca et al., 2011). In addition, a previous study reported that the disruption of fast-spiking parvalbumin (PV) + interneurons in the dorsal striatum of C57 mice produced impaired social interactions and stereotyped behavior (Rapanelli et al., 2017). In the striatum, PV+ interneurons receive direct pathway cortical and nigrostriatal input, project onto MSNs almost exclusively, and form synapses on their proximal dendrites. These findings might suggest that brain region-specific differences in interneuron plasticity contribute to the formation and learning of repetitive compulsive behaviors. Striatal PV+ interneurons are ensheathed by perineuronal nets (PNNs), extracellular matrix structures shown to be important for plasticity, and GWAS studies have shown abnormalities in extracellular matrix genes associated with ASD. No previous studies have investigated whether PNNs differ in the striatum of ASD mouse models compared to controls. To address this question, we stained for PV interneurons and PNNs with immunohistochemistry for PV and histochemistry for the PNN-binding lectin *Wisteria floribunda*, in the dorsomedial striatum (DMS) and dorsolateral striatum (DLS) of two genetic mouse models of ASD, Cntnap2$^{-/-}$ and Shank3ΔC$^{+/-}$, and one idiopathic model, BTBR compared to C57 controls. We found that a greater percentage of PV+ interneurons have PNNs in the DMS of all three mouse models of ASD compared to controls, this was not true for the DLS. We did not find any differences in dorsal striatum volume compared to controls, however the number of PV+ interneurons was

significantly decreased in the DMS of BTBR mice. These results suggest that enhanced PNNs in the DMS may reduce plasticity, thus increasing behavioral rigidity in ASD mouse models.

Title: Cortical hyperexcitation in early development results in autistic behavioral phenotypes

Authors: *W. E. MEDENDORP[1], A. PAL[2], U. HOCHGESCHWENDER[3]
[1]Neurosci., [2]Central Michigan Univ., Mount Pleasant, MI; [3]Neurosci., Central Michigan Univ., Mt Pleasant, MI

Abstract: Early development is marked by spontaneous neuronal activity that occurs without the input of sensory experience. This spontaneous activity has been demonstrated to refine foundational neural circuits before sensory input. By manipulating this activity in genetically-targeted pyramidal neurons within the cortex, we can interfere with the normal formation of specific neural circuits. Many psychiatric disorders are thought to be neurodevelopmental, stemming from malformation of neural circuits in early development. Autism disorders in particular have been associated with increased cortical excitation leading to a cortical imbalance of excitation to inhibition. Early disruptions to cortical activity may result in behavioral changes that correlate with psychiatric phenotypes typical of disorders such as autism.
Using optogenetics, we can manipulate neuronal activity using light. Due to the young age of the animals used in this study, a non-invasive light source must be used. Our laboratory has created mice that conditionally express a luciferase protein, sbGLuc, tethered to a channelrhodopsin, VChR1. This luminescent opsin, or luminopsin (LMO3), produces light, and thus a neuronal response, in the presence of the substrate coelenterazine (CTZ), which can be delivered intraperitoneally (IP). Lox-Stop-Lox LMO3 mice were crossed with Emx1-Cre transgenic mice, thus limiting expression of LMO3 to cortical pyramidal neurons. By delivering CTZ IP during

post-natal days 4-14, a hyperexcitation can be induced in the cortical pyramidal neurons of developing mouse pups. During adulthood, mice are tested behaviorally, and assessed for morphological and electrophysiological changes. Behavioral results indicate behavioral phenotypes consistent with autism behaviors. Electrophysiology indicates strongly increased excitation to inhibition and a lack of synchrony in the cortex. The results of this research will provide insight into the effect of altered developmental activity and its relationship to psychiatric disease.

Title: Auditory processing deficits in Cntnap2-knock-out rats: Implications for neurodevelopmental disorders

Authors: *S. SCHMID[1], K. E. SCOTT[1], B. L. ALLMAN[2]
[2]Anat. and Cell Biol., [1]Univ. of Western Ontario, London, ON, Canada

Abstract: The mammalian auditory system undergoes considerable development and experience-dependent plasticity in early life. This normal maturation, however, is perturbed in individuals with neurodevelopmental disorders, such as autism spectrum disorder (ASD). These maturational differences may lead to impairments in auditory processing, and ultimately underlie the communication deficits and altered reactivity to sensory stimuli associated with ASD. For example, individuals with mutations in the autism-linked gene, contactin-associated protein-like 2 (CNTNAP2), experience language processing deficits, yet the contribution of CNTNAP2 to auditory function remains unknown. We addressed this question with a recently-developed rat model, using the neural measures of hearing sensitivity, auditory responsivity and speed of transmission, and behavioural measures of acoustic reactivity, sensory filtering and sensory-motor gating to allow a broad understanding of auditory system dysfunction across development and the behavioural consequences thereof. The auditory brainstem response (ABR), *in vivo* electrophysiological recordings from the primary auditory cortex, and manipulation of the acoustic startle response (ASR) were conducted in young (<P42) and adult (>P70) male and

female homozygous knockout (*Cntnap2*$^{-/-}$), heterozygous knockout (C*ntnap2*$^{+/-}$), and wildtype Sprague Dawley rats. Ultimately, we found the knockout rats to have typical hearing sensitivity but reduced neural responsivity in both the brainstem and cortex. Acoustic information was also transmitted slower throughout the brainstem auditory pathway in young *Cntnap2*$^{-/-}$ rats compared to age-matched wildtype controls; however, this *Cntnap2*-related delay was no longer present in adulthood. In contrast, the adult auditory cortex revealed a prolonged latency to the response onset and longer response duration. Behaviorally, while a short-term habituation deficit improved with age, the *Cntnap2*$^{-/-}$ rats displayed a heightened acoustic reactivity and sensory-motor gating deficit when young that worsened with age. To our knowledge, this study represents the first investigation into the role of *Cntnap2* in the development of auditory processing impairments which are found in individuals with neurodevelopmental disorders. Overall, these results provide insight into the altered maturation of the different levels of the auditory system and point to potential targets for intervention. Abstract: Brain development and function rely on vascular features that ensure adequate supply of oxygen and nutrients from the blood stream. These features consist of a well-established vascular network, a functional blood-brain barrier, as well as cerebral blood flow regulation.

Early life impairments in these features can lead to neurodevelopmental defects. Very few studies have considered the contribution of the brain vasculature to Autism Spectrum Disorders (ASD). A recent postmortem study suggested a possible impairment in angiogenesis (i.e. process through which new vessels are formed) in the young ASD brain. A possible link between ASD and altered cerebral perfusion has also been suggested. Yet, contribution of cerebrovascular deficits to ASD physiopathology remains elusive, and a detailed analysis of these deficits is needed. ASD are viewed as neurodevelopmental conditions associated with genetic origins. Mutations identified as a possible cause for ASD include the common 16p11.2 deletion, which leads to haploinsufficiency of 26 conserved genes. We are using a multidisciplinary approach in order to decipher the cerebrovascular underpinnings of ASD in a mouse model of the 16p11.2 deletion syndrome. We have identified functional and structural cerebrovascular deficits during postnatal development in constitutive 16p11.2+/- mutants. In particular, we evidenced in 16p11.2+/- mice a significant decrease in microvascular branching and density in the cerebral cortex at P14 ($p<0.01$; $n=12$), as well as a significant increase in microvascular branching and density at P50 ($p<0.05$; $n=12$) when compared to age-matched WT littermates. In addition, P50 16p11.2+/- mice display a collection of functional abnormalities when compared to WT mice, such as altered neurovascular coupling *in vivo* and altered vascular reactivity *ex vivo*. In particular, we demonstrate a defective endothelium-dependent vasodilation in 16p11.2+/- mice, while smooth muscle function is unaffected. Furthermore, we generated mice with endothelial-specific 16p11.2 haploinsufficiency (Ve-Cad-Cre;16p11.2flox/+) in order to dissect the endothelial contribution to ASD phenotypes. These mice underwent behavioral testing to assess whether they display ASD-related characteristics. We demonstrate that mice harboring the endothelial-specific 16p11.2 deletion show home cage hyperactivity, as well as motor coordination deficits in the rotarod test, both characteristics linked to the human 16p11.2 deletion syndrome. Altogether, our research program provides insight into how the vasculature controls critical features of brain development, and investigates ASD from a novel angle.

Title: Pro social effects of Oxytocin agonist in a PFC circuit model

Authors: *M. BENEKAREDDY[1], P. JANZ[2], C. GRUNDSCHOBER[3], F. KNOFLACH[4]
[1]Neuroscience, Ophthalmology & Rare Dis. (NORD) Translational Area, Roche Pharma Res. & Early Development, Roche I, Basel, Switzerland; [2]Fac. of Biol., Univ. of Freiburg, Freiburg, Germany; [3]Neurosci. Discovery and Biomarkers Roche Innovation Ctr. Basel, Roche Innovation Ctr., Basel, Switzerland; [4]Neurosci. Discovery and Biomarkers Roche Innovation Ctr. Basel, F. Hoffmann-La Roche Ltd, Basel, Switzerland

Abstract: Impaired social behavior is a major symptom in neurodevelopmental diseases such as autism spectrum disorders and schizophrenia. Previous studies show that the medial prefrontal cortex (PFC) is critically involved in governing social behavior (Yizhar et al., *Nature*, 2012; Benekareddy et al., *Biol Psychiatry*, 2017), and that acute hyperactivity in the PFC impairs social information processing and thereby social behavior. However, the cellular and circuit mechanisms that might be responsible for long-term social dysfunction remain poorly understood. We hypothesized that perturbing PFC circuit homeostasis over longer timescales would lead to social impairments in rats. DREADDs are ideally suited to ask this question as recent data has shown the effectiveness of clozapine-N-oxide (CNO) in activating DREADDs even after chronic application (Urban et al., 2016). To test the effect of chronic increase in PFC excitability on social behavior, we used AAVs to transduce CamKII-positive neurons with the activatory DREADD hM3D and treated the rats chronically with CNO before testing their social preference. Sociability was assessed in a 3-chamber task, following chronic CNO treatment. In a set of parallel experiments, acute PFC slices were prepared to perform electrophysiological recordings. Our data shows that chronic PFC hyperactivity leads to a persistent decrease in social interaction, associated with long-term PFC dysfunction. Field potential recordings in PFC slices revealed persistent alterations in synaptic transmission. Whole-cell patch clamp recordings from retrogradely-identified cortico-thalamic projection neurons demonstrated that the excitability of these neurons is altered. Further, to address the effect of Oxytocin agonist in this circuit model, we treated rats undergoing chronic PFC activation with the selective peptidic oxytocin agonist, RO6958375. Data from social behavior experiments and physiological characterization reveal an effect of RO6958375 in correcting the circuit and behavioral dysfunction caused by the disruption of the PFC network. Taken together this study highlights the role of the PFC network in dysfunctional social behavior and points to a circuit mode of action for the pro-social effects of oxytocin.

Abstract: Autism is a neural developmental disorder that in children manifests itself as a spectrum of behavioral alterations between 2 and 3 years of age. Although the number of studies in this regard increases annually, significant physiological manifestations that allow to make laboratory diagnoses are still unknown. To date, autism continues to be diagnosed only on the basis of the subject's behavior. This is why it is relevant to find approaches that allow physiologicals determinations of the disorder. It is known that one of the structures invariably altered in autistic subjects is the cerebellum. Therefore, in this work we proposed the encephalographic record of this structure could serve as a basis for spectrum´s physiological analysis. To do this, a posnatal autistic model was used in Wistar rat by the posnatal injection of a daily dose of 150 mg / kg of valproic acid to pups from day P6 to P12. Four groups, Controls (Ct) in standard (SE) and enriched environment (EE), and Autistic (At) in SE and EE were used. All of them had a multi-unit registry of the cerebellar vermis, specifically lobes VI and VII . The results showed that EE impact on the amplitude response by different ways in all groups, but the At in SE presented a significant increase in the amplitude compared with Ct-SE, which was reduced when they were submitted to EE. Thus, we first observe that it is possible to identify encephalographic variations characteristic of autism in the cerebellum cortex, and that these increased variations can return to a level close to Ct after the subject is submitted to an environmental enrichment program. The significance of this amplitude in the discharge of the cerebellar cortex requires further studies. Conacyt Scholarship No. 574809 (OECM); Academic Body of Neurosciences (UV-CA-28).

Title: Network based brain transcriptome analysis in Down syndrome

Authors: *S. SEOL[1], J. KWON[1], J.-S. HAN[2], H. KANG[1]
[1]Life Sci., Chung-Ang Univ., Seoul, Korea, Republic of; [2]Biol. Sci., Konkuk Univ., Seoul, Korea, Republic of

Abstract: Down syndrome (DS) (also known as Trisomy 21) is the most common genetic disorder causing intellectual disability. DS patients showed altered brain developmental characteristics that cause abnormal brain structure and function compared with normal subjects. To further investigate the underlying mechanisms of observed differences between DS and euploid controls at the system level, we performed weighted gene co-expression network analysis (WGCNA) using previously published transcriptome data set (GEO's GSE 59630). For analysis, we chose three regions, dorsolateral prefrontal cortex (DFC), cerebellar cortex (CBC) and primary visual cortex (V1C), which have the high coverages in developmental periods from mid-fetal to adult. The function of these three regions are also known to be related with Down syndrome phenotypes (cognition, motor coordination and vision, respectively). Principal component analysis showed that the samples from DS and controls are mainly clustered by more developmental stages and regions than disease status. From WGCNA, 49 modules were detected and the modules' eigengenes showed diverse correlation patterns with traits like developmental stages, regions and disease status of the samples. After defining modules, we conducted cell type enrichment analysis in each module using human and mouse brain RNA-seq database. Genes in some modules are enriched in distinct cell types and they also have unique gene expression patterns affected by regions, developmental stages, and disease status of the samples. We annotated these modules and analyzed Gene Ontology and KEGG pathways using DAVID. We built intramodular gene networks in each module and selected hub genes which have higher module membership. Through these analyses, we have created gene modules displaying unique gene expression patterns, and the annotations of these modules provide insights needed to discover relationship between genes and cell type-related phenotypes.

Title: Characterization of early communicative behavior in mouse model of Down syndrome Ts65Dn and its response to pharmacological treatment using the NMDA-receptor antagonist memantine

Authors: *B. ZAMPIERI[1], M. W. JOHNSON[1], A. C. COSTA[2]
[1]Dept. of Pediatrics, [2]Departments of Pediatrics and Psychiatry, Case Western Reserve Univ., Cleveland, OH

Abstract: Down syndrome (DS) is the most prevalent chromosomal cause of intellectual disability. Language development is delayed in children with DS and many areas of speech are known to be impaired, yet the causal mechanisms of these deficits are not well understood. Isolation-induced ultrasonic vocalizations (USV) have been a commonly used behavioral measurement to assess developmental delays and communication deficits in mouse models of neurodevelopmental disorders. Here we investigated communication by means of isolation-induced pup USV from postnatal day (P) 3 to 21 in the Ts65Dn mouse model for DS. We also assessed the impact exerted on USVs emission by the inhibition of NMDA-receptor function with the antagonist memantine. In total, 36 untreated Ts65Dn, 22 treated Ts65Dn, 40 untreated euploid pups and 33 treated euploid pups were tested for USV recording. Memantine combined with NIH31 formula mouse diet (TestDiet, St. Louis, MO, USA) was administered orally at the doses of 200 mg/kg from P1 to P2, 500 mg/kg from P3 to P18 and 200 mg/kg from P19 to P21 of food for chronic memantine treatment. USVs were recorded every other day for 5 min inside a sound-attenuating chamber (SonoTrack SMART Chamber, Metris). Data were recorded at 250 kHz using a Sonotrack system (Metris). Acoustical analysis was performed using Avisoft Bioacoustics SasLab Pro software (Version 5.2.09) and IGOR Pro 6 (WaveMetrics). Spectrograms were generated with a Fast Fourier Transform (FFT)-length of 512 and a Flat top window with 87.5% overlap using Avisoft whistle detection algorithm and post-processed in IGOR Pro. Overall, we found differences between genotypes in both spectral and temporal properties of USVs emitted by untreated mice. In particular, Ts65Dn mice displayed a developmental delay in their emission rate of USVs with a peak in call number at P7 compared

to P5 for wild-type mice. A genotype-dependent difference was found in the total number of USVs when all ages were combined for the untreated groups (t test, $p < 0.0019$). Preliminary results show that the delay on the peak of USVs rate was not restored after administration of memantine. However, no difference in the total number of calls between untreated wild-type and treated Ts65Dn mice was observed. Memantine showed no or little effect on the qualitative parameters of USVs emitted by Ts65Dn pus mice. The impairment in ultrasonic communication during early development observed here is consistent with other behavioral phenotypes exhibited by Ts65Dn mice and mimics the atypical communication pattern observed in DS. The effect of memantine on the emission pattern of USV in Ts65Dn mice is being further investigated in our laboratory.

Abstract: Down syndrome (DS) is caused by the triplication of human chromosome 21 (Hsa21) and is the leading genetic cause of intellectual disability. Dual-specificity tyrosine-phosphorylated regulated kinase 1A (DYRK1A), included on Hsa21, regulates several key pathways in cell proliferation and differentiation, and its triplication is thought to contribute to aberrant developmental process that lead to neurodevelopmental deficits, intellectual disability, and bone and craniofacial abnormalities. Limited information exists regarding regulation of DYRK1A expression across key periods of brain development and none exists concerning potential sex differences. Drug development efforts have used putative DYRK1A inhibitors in preclinical studies and in clinical trials to determine therapeutic potential to improve neurobehavioral phenotypes in individuals with DS. However, these studies are hampered by the lack of information about the expression and activity of DYRK1A protein during brain

development in mouse models of DS.
Ts65Dn is the most commonly used mouse model of DS and contains three copies of approximately half of the ~300 genes on Hsa21, including DYRK1A. We tested the hypothesis that expression of Dyrk1a from the late prenatal period through the first postnatal month of development in this DS mouse model will show temporal and spatial variation in the extent of overexpression in the developing brain, and that differences between the sexes may be apparent. Using Western blot analysis, Dyrk1a protein concentrations were quantified in the hippocampus, cerebral cortex, and cerebellum from embryonic day 18.5 to postnatal day 24 in euploid and trisomic male and female mice. Our data suggest that males and females have different patterns of Dyrk1a dysregulation, but also share some commonalities in time and brain region of Dyrk1a expression between euploid and trisomic mice. Identifying developmental periods of greatest elevation of Dyrk1a protein expression in specific brain regions, including the differences in temporal patterns between males and females, provides key information to inform new studies of mechanisms by which excessive Dyrk1a alters regional brain development and produces neurodevelopmental deficits characteristic of DS phenotypes.

Title: Young adults with Down syndrome show smaller hippocampal subfields measured with high-field MRI

Authors: *K. A. KOENIG[1], S.-H. OH[2], M. STASKO[3], E. LISSMORE[3], E. ROTH[3], A. BIRNBAUM[3], T. SCHEIDEMANTEL[4], H. TAYLOR[4], N. ROIZEN[4], S. RUEDRICH[4], A. C. COSTA[3]

Abstract: Introduction: Down syndrome (DS) is the most common non-inherited genetic cause of developmental disability, leading to a range of well-described cognitive and physiological characteristics, including an increased incidence of dementia. Neuroanatomical features related to DS have been fairly consistently described, and generally include a decrease in the size of the

hippocampus. Here we report a comparison of hippocampal subfield volumes in young adults with DS and age-matched healthy controls. A more complete understanding of structural changes of the hippocampus has the potential to increase our understanding of the pathophysiology of DS. **Methods**: 13 young adults with DS (mean age 20.5 ± 5.6, 8 males) and 8 age-matched controls (mean age 20.6 ± 5.0, 4 males) were scanned in an IRB-approved protocol on a Siemens 7T Magnetom. Scans included a whole-brain anatomical MP2RAGE (0.75mm^3 isotropic voxel size) and a high-resolution GRE scan focusing on the hippocampus (0.375 x 1.0 x 0.375mm^3). Hippocampal subfield segmentation was performed using the Automated Segmentation of Hippocampal Subfields (ASHS) software and manually corrected if necessary. Subfield volumes were calculated and corrected for intracranial volume (ICV). Unpaired Student's t-tests with a correction for multiple comparisons were used to compare controls and those with DS. In participants with DS, subfield volumes were correlated with cognitive performance. **Results:** Groups did not differ in age ($p < 0.970$). ICV-corrected whole-brain grey and white matter volumes were smaller in those with DS ($p < 0.05$). Figure 1 shows a representative segmentation at the head of the hippocampus. Bilateral CA1, CA3, dentate gyrus, and total hippocampal volumes were smaller in those with DS (Table 1). Subfield volumes were not correlated with cognitive performance. **Discussion:** This work represents the first assessment of hippocampal subfield volume in DS at ultra-high field strength. We find that hippocampal subfield volumes are decreased bilaterally in those with DS, in agreement with reports of decreased myelin density.[1] A larger sample size may be needed to identify any relationship between cognitive performance and volume measures. 1. Title: Interferon signaling in Down syndrome

Authors: *K. SULLIVAN[1], K. SMITH[1], D. EVANS[1], H. LEWIS[1], A. PANDEY[1], A. HILL[1], A. RACHUBINSKI[1], K. WOLTER-WARMERDAM[2], F. HICKEY[2], T. BLUMENTHAL[1], J. M. ESPINOSA[1]
[1]Linda Crnic Inst. for Down Syndrome, Aurora, CO; [2]Children's Hosp. Colorado, Aurora, CO

Abstract: Trisomy 21 (T21) is the most common chromosomal abnormality in the human population, occurring in approximately 1 in 700 live births. The extra copy of chromosome 21 (chr21) impacts human development in myriad ways across every major organ system, causing the condition known as Down syndrome (DS). One of the most intriguing biomedical aspects of T21 is that it causes a novel disease spectrum in the DS population, protecting these individuals from some conditions (e.g. solid tumors), while strongly predisposing them to others (e.g. Alzheimer's disease, cognitive deficits, autoimmune disorders). In order to identify dysregulated molecular pathways that could contribute to the phenotypes associated with DS, we performed complementary transcriptome and proteome analysis from age- and sex-matched cohorts of individuals with T21 and euploid controls.
Transcriptome analysis revealed that T21 activates the interferon (IFN) transcriptional response in nine pairs of fibroblast and lymphoblastoid cell lines, and this observation was confirmed in freshly isolated circulating monocytes and T cells from 17 individuals, 10 with DS. The gene expression signature caused by T21 cells is dominated by induction of interferon-stimulated genes (ISGs) as well as decreased expression of ribosomal proteins and translation factors and is likely due to the fact that four of the six IFN receptors are located on chr21. Accordingly, T21 cells are hypersensitive to IFN ligands and show significant overexpression of ISGs in response

to IFN treatment. Furthermore, we show that pharmacological inhibition of JAK kinases, which function downstream of IFN receptors, reduces expression levels of ISGs and rescues growth defects in T21 cells.
Employing a cohort of 263 individuals, 165 with T21, we performed a plasma proteomics study that confirmed massive immune dysregulation in people with Down syndrome, including changes in many immune-modulatory factors that could be explained by chronic IFN hyperactivation. For example, levels of IL6, TNFα, MCP1, and IL22, are all increased in individuals with T21, while the levels of numerous components of the complement cascade are decreased.
These data are consistent with the observations that: 1) nearly 30% of individuals with T21 are affected by one or more autoimmune conditions and 2) brain tissue from people with T21 shows obvious signs of neuroinflammation across their lifespan, even in neonates. We hypothesize that chronic interferon activation is central to these autoimmune and autoinflammatory phenotypes, and that interferon antagonists may, therefore, have therapeutic benefits in DS.

Title: Quantitative analysis of retinal function during development by electroretinography in the Ts65Dn, a mouse model of Down syndrome

Authors: *J. J. SCOTT-MCKEAN[1], A. C. S. COSTA[1,2]
[1]Dept. of Pediatrics, [2]Dept. of Psychiatry, Case Western Reserve Univ., Cleveland, OH

Abstract: Down syndrome (DS) results from an extra copy of chromosome 21 (trisomy 21) and is the most common genetically defined cause of intellectual disability. There are an estimated 83,000 children, out of an overall population of over 300,000 individuals, living with DS in the US. Visual system deficits have been associated with DS, affecting academic performance in

school age children, which can negatively impact their cognitive development and daily life. The electroretinogram (ERG) provides information about the electrical activity of various retinal cell populations in response to light stimuli, and is a useful tool for assessing various retinal diseases, including retinal degeneration. In this study, we utilized the Ts65Dn mouse model of DS, which mimics many phenotypes seen in persons with DS, including impaired visual function. Flash, full-field (Ganzfeld) ERGs were used to track basic retinal function in Ts65Dn mice at three different stages of development (young (17 day old), early adult (35 day old), and mature adult (3-5 month old)). Mice were anesthetized with 20% urethane (8.0 ml/kg, intraperitoneally (i.p.)). A Ganzfeld ERG system was used to evoke and record flash ERGs using the following protocol (green light: 504nm; flash duration: 1 ms; interstimulus intervals of 0.7 s for stimulus intensities -4.7 to -2.0 log (cd s/m^2) and 10 s for stimulus intensities -1.7 to 2.2 log (cd s/m^2); and an average of 5-20 flashes per recording). We found that adult Ts65Dn mice displayed abnormal ERGs when compared to euploid littermate control mice. Specifically, under urethane anesthesia, these mice exhibit deficits in A-wave amplitude, and larger maximum oscillatory potentials (OPs), when compared to control mice. However, there was no difference in B-wave amplitude in Ts65Dn mice when compared to control mice. We than assessed whether memantine could rescue retinal function differences in Ts65Dn mice. Memantine (5 mg/kg, i.p.) was injected 15 min prior to the start of ERG recordings, and all experiments lasted no longer than 20 min. In adult Ts65Dn mice, memantine significantly increased A-wave amplitudes to levels similar to those seen in control mice. However, memantine did not decrease OP amplitudes in Ts65Dn mice. Together, these results show that retinal activity is abnormal in Ts65Dn mice, and memantine can at least partially rescue retinal function. The data presented here provides a basic information about the development of retinal function in the Ts65Dn mouse, which may lead to a better understanding of sensory deficits in children with DS and guide the development of pharmacotherapies aimed at improving the quality of life of this vulnerable population.

Title: Neurogenesis deficits in Down syndrome: Testing recovery with GABAα5 negative allosteric modulator, β2 adrenergic agonist and IGF-1 in Ts65Dn mice

Authors: *M.-C. POTIER[1,2], C. ALBAC[1,2], F. STAGNI[3], M. GRILLI[4], E. SALVALAI[4], R. BARTESAGHI[3]
[1]CNRS INSERM UPMC, Paris, France; [2]ICM, Paris, France; [3]Dept. of Biomed. and Neuromotor Sci., Univ. of Bologna, Bologna, Italy; [4]Dept. Pharm. Sci, Un. Piemonte Orientale, Novara, Italy

Abstract: Down syndrome (DS), induced by trisomy of human chromosome 21 is the most common genetic cause of mental retardation. Cognitive deficits are a hallmark of the syndrome, both in individuals with DS and in mouse models such as the Ts65Dn. Neurogenesis impairment is present in Ts65Dn mice, starting at embryonic stages and extending to adulthood in the hippocampal dentate gyrus (Contestabile *et al.* 2007). Neurogenesis can be recovered after treatment with several molecules such as lithium, fluoxetine (Stagni *et al.* 2015) and TrkB agonist (Stagni *et al.* 2017). Here we tested three additional drugs selected for their ability to restore neurogenesis or cognitive deficits: i) a negative allosteric modulator selective for α5-containing $GABA_A$ receptors (α5IA, 5mg/Kg, Braudeau *et al.* 2011); ii) an agonist for the β2 adrenergic receptor (salmeterol, 1mg/Kg) that came out of a screen for FDA approved drugs reversing proliferation deficits in neural progenitors from Ts65Dn mice; iii) the neurotrophin IGF-1 1 (50 or 250µg/Kg, Castro *et al.* 2014).
Ts65Dn and WT neonates were treated daily from post-natal day 3 (P3) to post-natal day 15 (P15), then received BrdU (150mg/Kg), and were sacrificed 2 hours later. After cryoprotection and freezing, the brains were cut at 30µm and immunohistochemistry was conducted. BrdU positive cells were counted manually. For the salmeterol treated mice half brains were treated for Golgi staining using FD Rapid GolgiStain Kit (FD NeuroTechnologies).
We showed reduced number of BrdU positive cells in the dentate gyrus at P15 in Ts65Dn mice as compared to WT ($p= 0.013$). Treatment with α5IA from P3 to P15 did not correct neurogenesis deficits in Ts65Dn dentate gyrus ($p= 0.9054$) and had no effect in WT mice. Unexpectedly, the neurotrophin IGF-1 at 250µg/Kg decreased neurogenesis in WT mice ($p=0.0001$) but did not significantly improve Ts65Dn mice. At 50µg/Kg IGF-1 had no significant effect on neurogenesis in WT and Ts65Dn mice. Finally, salmeterol treatment is currently being analyzed both on neurogenesis and on the number of dendritic spines.
Our study showed no significant effect of α5IA on neurogenesis when administered during postnatal period (P3 to P15) at a procognitive dose, suggesting that GABAergic neurons might have different maturation in Ts65Dn mice as compared to WT. IGF-1 treatment that provided beneficial effects on mouse model of Rett syndrome that have reduced levels of IGF-1, did not increase neurogenesis in the Ts65Dn mice suggesting that IGF-1 levels in these mice might not be altered. Finally, we will present the results obtained on neurogenesis and dendritic spines following postnatal treatment with salmeterol.

Title: Discovery and characterization of novel selective NKCC1 inhibitors for Down syndrome and brain disorders with depolarizing GABAergic transmission

Authors: *A. SAVARDI[1,5], M. BORGOGNO[2,6], J. ORTEGA MARTÍNEZ[2], R. NARDUCCI[1], G. LA SALA[2], M. SUMMA[3], R. BERTORELLI[3], S. BERTOZZI[4], A. ARMIROTTI[4], A. CONTESTABILE[1], M. DE VIVO[2], L. CANCEDDA[1,7]

Abstract: Proper GABAergic transmission trough Cl-permeable $GABA_A$ receptors is fundamental for physiological brain development and function. Indeed, defective GABAergic signaling -due to a high ratio of expression of the Cl importer NKCC1 and Cl exporter KCC2- has been implicated in several neurodevelopmental disorders (e.g., Down syndrome, DS). Interestingly, NKCC1 inhibition by the FDA-approved diuretic bumetanide reverts cognitive deficits in the TS65Dn mouse models of DS and core symptoms in a number of models of other neurodevelopmental disorders. However, the required chronic treatment with bumetanide is burdened by its diuretic side effects caused by the antagonization of the kidney Cl importer NKCC2, which leads to hypokalemia and jeopardizes drug compliance. Crucially, these issues would be solved by selective NKCC1 inhibitors, thus devoid of the diuretic effect. Starting from bumetanide's structure, we applied a computational ligand-based approach to design new molecular entities that we tested *in vitro* for their capacity to selectively block NKCC1. Among the 3 newly-identified and highly promising NKCC1 inhibitors, one showed excellent solubility and metabolic stability *in vitro* and it was predicted to better penetrate the blood-brain barrier compared to bumetanide. Moreover, analysis of wild type mice systemically treated with this NKCC1 inhibitor revealed no diuretic effect. Finally, our novel, selective NKCC1 inhibitor was able to rescue cognitive deficits in Ts65Dn mice in four different memory tasks. Thus, a selective NKCC1 inhibitor devoid of the diuretic effects could represent a suitable and solid therapeutic strategy for the treatment of Down syndrome and all the brain disorders with depolarizing GABAergic transmission.

Title: Overeating in a mouse model of Down syndrome is associated with a dopaminergic deficit in the prefrontal cortex

Authors: *M. FRUCTUOSO CASTELLAR[1,2], I. DE TOMA[2,3], K. LANGOHR[4,5], J. DAIROU[6], N. JANEL[6], M. DIERSSEN[2,3,4,7]

Abstract: Individuals with Down syndrome (DS) present high obesity prevalence that has been traditionally attributed to endocrine issues such as leptin resistance or thyroid gland dysfunction and deficient exercising. However, poor eating habits could also be a main contributor since individuals with DS consume regularly big amounts of energy-dense foods. As a matter of fact, DS brains show reduced volume and decreased functional connectivity of prefrontal cortex (PFC), a brain region implicated in reward and behavioral control. Here we hypothesized that the PFC impairment in DS individuals may increase their risk of overeating in environments with easy availability of sweet or fatty foods. To address this question, we characterized obesity development, meal pattern and food preferences in wild-type (WT) and Ts(1716)65Dn (Ts65Dn) mice, a DS mouse model, given both standard rodent chow and an energy- dense diet. Upon 8

weeks of free choice feeding, we investigated the appearance of compulsive and inflexible behaviors using stand-alone tests. Ts65Dn mice showed higher preference for energy-dense diets than WT mice and scored higher in compulsivity and inflexibility tests (limited access to energy-dense food and food adulteration with quinine hydrochloride). Both abnormal behaviors are associated with alterations in PFC function which depend, among other signals, on monoamines. Thus, we characterized the diet-induced changes in monoamine levels in prefrontal cortex and striatum, regions related to the reward-driven control of feeding, by high performance liquid chromatography (HPLC) that revealed reduced levels of dopamine in Ts65Dn mice that were PFC region-specific. Our results suggest that overeating of energy-dense foods might be more detrimental for behavioral control (e.g. flexibility, impulsivity management) in Ts65Dn mice and therefore, overeating might be a relevant contributor of obesity in DS.

Title: Cognitive decline in young and adults with Down syndrome

Authors: *O. GARCIA[1], E. M. RAMOS GALICIA[2], N. ARIAS TREJO[3]
[1]Facultad de Psicologia, UNAM, Mexico, D.F., Mexico; [2]Psicobiologia y Neurociencias, Facultad de Psicologia, UNAM, Ciudad de Mexico., Mexico; [3]Facultad de Psicologia, UNAM, Ciudad de Mexico, Mexico

Abstract: Down syndrome (DS) or trisomy 21 (Ts21) is the most common genetic cause of intellectual disability (ID). In addition, people with DS show an abnormally slow development in childhood and, subsequently, premature aging in adulthood accompanied by a cognitive decline and neuropathological characteristics of Alzheimer's disease (AD). However, most of the studies on aging in DS have focused on people over 40 years of age. Therefore, the objective of this work was to identify patterns of cognitive decline that could be indicators of accelerated aging in DS. Neuropsychological batteries CAMCOG-DS and Neuropsy Attention and Memory, were used to evaluate cognitive functions and detect mild degrees of cognitive impairment. Thirty individuals with DS with an age range of 10-30 years old divided into two groups of 10-20 years and 20-30 years participated in the study. We result show that people with an age range of 10-20

years have a good receptive language and expressive language, however, after 20 years show a decrease in expressive language and up to 30 years decreases the receptive language. The tests related to memory and learning and abstract thought show deficiencies from 20 years old. These results suggest that cognitive deficiencies can start from 20 years of age, with receptive language being one of the functions that can remain without apparent changes. The results of this work could contribute to design clinical strategies for evaluation and diagnosis of cognitive deterioration associated with aging in young population with Ts21.

Title: Effects of mild-to-moderate physical training on the gait dynamics of young Ts65Dn mice: A mouse model for Down syndrome

Authors: *M. STASKO[1], J. CHU[1], I. BASTEN[4], A. C. S. COSTA[2,3]
[2]Dept. of Pediatrics, [3]Dept. of Psychiatry, [1]Case Western Reserve Univ., Cleveland, OH; [4]Dept. of Child and Adolescent Psychiatry, Univ. Hosp. Brussels, Brussels, Belgium

Abstract: Delayed motor development and gait abnormalities have been observed in human beings with Down syndrome (DS), as well as in the Ts65Dn mouse model for DS. The immediate aim of this research was to test the development of gait dynamics in Ts65Dn mice using a DigiGait Apparatus (Mouse Specifics, Inc.). The device consists of a treadmill with a transparent belt in which gait dynamics can be quantified by analyzing images of the underside of the mice captured by high-speed video (181 frames/s). The image is rendered from the frame by software, and the areas of the paws are identified, vectorized, and used to calculate multiple variables of the gait. Here, performed longitudinal studies of 17 trisomic and 17 euploid mice, every other day, from 17 days until 35 days of age. Mice were allowed 5 minutes to acclimate, then practiced walking at four speeds (8, 12 ,16, and 18 cm/s) for 5 seconds each, with a short rest in between. After training, mice ran at belt speed of 18 cm/s for 30 seconds while video was recorded. Mice practiced at five higher speeds (22, 26, 30, 34, and 36 cm/s) for 5 seconds each with short rest intervals. Mice ran at belt speed of 36 cm/s for 30 seconds while video was

recorded. The following parameters were measured: duration and percent of swing, brake, propel, stance, and stride; and stride length, absolute paw angle, and stance width. For each of the parameters, two forelimb and two hindlimb values were averaged. Two-tailed T-tests were used to compare the means for each parameter between the two genotypes (Ts65Dn and euploid control). The main finding from these experiments was that Ts65Dn mice presented a 6-day delay in reaching the maximal speed of 36 cm/s when compared with euploid control littermates. However, when gait dynamics of the two groups of mice were compared by assessing gait characteristics at 35 days of age, we found no significant differences between genotypes. This result contrasted with our previous finding showing various DS-like alterations in gait dynamics in Ts65Dn mice (Hampton at al., Physiol Behav 82:381-389, 2004). Therefore, we hypothesized that, by exposing them to intervals of moderate physical training from an early age, Ts65Dn mice were able to reach euploid control-level performance by 35 days of age. We are currently testing this hypothesis by testing naïve Ts65Dn and control mice at 21, 29, and 35 days of age. Preliminary data collected from 35-day old naïve mice, did reproduce our previous findings and showed that even every-other-day, mild-to-moderate degree of physical training can significantly increase stride length and decreased stride frequency in Ts65Dn mice.

Abstract: Down syndrome, caused by trisomy of the 21st chromosome, leads to lifelong cognitive impairment. Efforts to understand this disorder first require an understanding of the genes encoded on the 21st chromosome (HSA21). While progress has been made using traditional mouse models, the tiny nematode *C. elegans* represents a complementary model to uncover the in vivo function of genes. We analyzed all 213 predicted protein-coding genes on HSA21 and found that, excluding the keratin genes, approximately half had orthologs

represented in worm. Using RNAi and loss-of-function mutants, we systematically investigated the role of all orthologs in viability and neuronal function. Overall, we identified ten HSA21 orthologs that are required for neuromuscular behaviors: *cle-1* (*COL18A1*), *cysl-2* (*CBS*), *dnsn-1* (*DONSON*), *eva-1* (*EVA1C*), *mtq-2* (*N6ATM1*), *ncam-1* (NCAM2), *pad-2* (*POFUT2*), *pdxk-1* (*PDXK*), *rnt-1* (*RUNX1*), and *unc-26* (*SYNJ1*). We also found that three of these genes are required for normal release of the neurotransmitter acetylcholine. This includes a known synaptic gene unc-26 (*SYNJ1*), as well as uncharacterized genes *pdxk-1* (*PDXK*) and *mtq-2* (*N6ATM1*). Furthermore, we found that the glutamine methyltransferase MTQ-2 localizes to cholinergic synapses where it appears to regulate neurotransmission via methylation of a Gα/o signaling protein. As the first systematic functional analysis of HSA21 orthologs, our study may serve as a platform to understand genes that underlie phenotypes associated with Down syndrome.

Title: Spinogenesis impairment can be rescued by neonatal treatment with a beta 2-adrenergic agonist in a mouse model of Down syndrome

Authors: *F. STAGNI[1], M. SALVALAI[2], B. UGUAGLIATI[1], M. EMILI[1], S. GUIDI[1], A. GIACOMINI[1], V. BORTOLOTTO[2], M. GRILLI[2], R. BARTESAGHI[1]

Abstract: Down syndrome (DS) is a relatively high-incidence (1:700/1000) genetic condition due to triplication of chromosome 21. The intellectual disability (ID) that characterizes DS is attributable to impairment in the processes of neurogenesis and spinogenesis. It ensues that drugs that are able to increase the number of neurons and/or spine density may be regarded as possible strategic tools to improve brain ID in DS. The goal of this study was to establish whether it is possible to pharmacologically improve brain development in DS by exploiting the Ts65Dn mouse, the most popular model of DS. We recently screened two libraries of FDA-approved drugs in neural progenitor cells (NPCs) derived from Ts65Dn mice for a drug-repurposing project. Among the tested drugs, we found that the beta 2-adrenergic agonist clenbuterol increased neurogenesis and favored neuron maturation. We then progressed to *in vivo* experiments and examined the effect of treatment on the hippocampal dentate gyrus, a region that is fundamental for declarative memory and that largely develops in the early postnatal period. Ts65Dn and euploid pups received clenbuterol (10 µg/kg, 0.5 mg/kg, 1 mg/kg or 2

mg/kg; s.c. daily injections) from postnatal day 3 (P3) to P15. On P15 mice received an injection of BrdU, in order to label NPCs, and were killed 2h later. We found that in Ts65Dn mice all doses of clenbuterol caused a large increase in the density of dendritic spines of the principal neurons of the dentate gyrus that became even larger than in untreated euploid mice. While the three lower doses of clenbuterol did not affect proliferation, the highest dose was able to increase the number of BrdU-positive cells, although in a marginally significant manner. This study provides novel evidence that treatment with the beta 2-adrenergic agonist clenbuterol is able to fully restore spinogenesis in the hippocampal dentate gyrus. The finding that this effect took place with a low dose of clenbuterol appears of relevance from a translational viewpoint because the use of low doses may reduce the probability of effects on beta 1-adrenergic receptors. The effect of clenbuterol on neurogenesis took place with the highest tested dose only, suggesting that it may not be a drug of choice for restoration of neurogenesis in DS. On the other hand, various drugs with a safe profile have been shown to be able to restore neurogenesis in the Ts65Dn model of DS. Taken together, these data suggest that co-treatment with clenbuterol and a drug that restores neurogenesis may represent a strategy for the improvement of the two major defects of the DS brain: hypocellularity and spine hypotrophy.

Title: Developmental alterations in the subiculum of fetuses with Down syndrome and in the Ts65Dn model of Down syndrome

Authors: *S. GUIDI[1], F. STAGNI[1], A. GIACOMINI[1], M. EMILI[1], B. UGUAGLIATI[1], M. BONASONI[2], R. BARTESAGHI[1]
[1]DIBINEM - Dept. Biomed. and Neuromotor Sci., Bologna Univ., Bologna, Italy; [2]Pathology Unit, Azienda Unità Sanitaria Locale, IRCCS, Reggio Emilia, Italy

Abstract: Intellectual disability (ID) is an invariable hallmark of Down syndrome (DS), a genetic condition due to triplication of chromosome 21. Accumulating evidence suggests that ID is attributable to widespread neurogenesis impairment during critical windows of prenatal development. Consequently, children with DS are impaired in various cognitive domains, including explicit memory. Consistently with memory alterations, fetuses with DS exhibit neurogenesis impairment in the hippocampus, a region fundamental for long-term explicit

memory. While the hippocampus is involved in memory formation and consolidation, recent evidence suggests that the subiculum plays a unique role in memory retrieval, a process that also appears to be altered in DS. While much attention has been devoted to the hippocampus, there is a striking lack of information regarding the subiculum of individuals with DS and DS models. In order to fill this gap, in the current study we examined the subiculum of fetuses with DS, with the goal to establish whether it exhibits developmental alterations that may account for the damage of subiculum-dependent memory functions in children with DS. We additionally examined the subiculum of the Ts65Dn mouse, a widely-used model of DS, in order to obtain comparative information. Fetal brains (17-21 weeks of gestation) were obtained according to procedures approved by the Ethical Committee of the St. Orsola-Malpighi Hospital, Bologna, Italy. We found that the subiculum of DS fetuses had a reduced size and a reduced number of cells. An evaluation of the number of neural progenitor cells (NPCs) in the ventricular zone of the subiculum showed that fetuses with DS had a reduced number of NPCs, which can account for the subicular hypocellularity. An evaluation of the phenotype of the cells populating the subiculum showed that fetuses with DS had a reduced percentage of neurons and an increased percentage of astrocytes, indicating impairment in the acquisition of a neuronal phenotype. In addition, fetuses with DS had an increased percentage of cells immunopositive for calretinin, a calcium-binding protein expressed by inhibitory interneurons. Similarly to fetuses with DS, the subiculum of neonate Ts65Dn mice was reduced in size, had a reduced number of neurons and a reduced number of proliferating cells. Results suggest that the developmental defects in the subiculum of DS fetuses may underlie impairment in recall memory and possibly other functions played by the subiculum. The finding that the subiculum of the Ts65Dn mouse exhibits neuroanatomical defects resembling those seen in fetuses with DS further validates the use of this model for preclinical studies.

Title: Altered motor function and perseverative behaviors in a mouse model of a human gain-of-function mutation in the GRIK2 kainate receptor gene

Authors: *E. BINELLI[1], T. NOMURA[2], W. P. NOBIS[3], J. R. STOLZ[1], A. CONTRACTOR[4], G. T. SWANSON[1]
[1]Pharmacol., [2]Physiol., [3]Neurol., Northwestern Univ., Chicago, IL; [4]Physiol., Northwestern Univ. Dept. of Physiol., Chicago, IL

Abstract: Kainate receptors (KARs) are a family of ionotropic glutamate receptors with diverse roles in the central nervous system. Missense mutations in GRIK genes, which encode KAR subunits, can lead to profound neurodevelopmental disorders if they result in aberrant or reduced receptor function. To gain insight into the synaptic and circuit disruptions that occur in children with KAR genetic variants, we generated a mouse model for a gain-of-function GRIK2 mutation in a child with developmental delay, ataxia, and profound language deficits. The mutation results in a threonine substitution for alanine at position 657 in the GluK2 subunit, which profoundly alters the gating properties of KARs incorporating the mutant subunit. Here we report the initial behavioral and synaptic phenotypes of the GluK2(A657T) mouse model.
We generated the GluK2(A657T) knock-in mouse line using CRISPR/Cas9 gene editing. Heterozygous mice displayed early onset ataxia with otherwise grossly normal development. Homozygous mice were not viable. Behavioral tests were performed on wild type and heterozygous littermates in order to test motor function, social interaction, anxiety, and perseverative behaviors. Juvenile GluK2(A657T)+/- mice performed significantly worse in tests of motor coordination when compared to wildtype littermates and did not exhibit typical perseverative behaviors such as nestlet shredding and marble burying. In contrast, wildtype and heterozygous mice showed no differences in open field and zero maze tests. We confirmed that the mutant GluK2(A657T) subunit was incorporated into functional KARs in whole cell recordings from mossy fiber-CA3 pyramidal cell synapses; KAR-EPSCs in GluK2(A657T)+/- neurons decayed with a significantly slower time course compared to those in wildtype littermates (mean $\boldsymbol{\tau}$; of 172.4 ms ± 30.9 ms and 35.3 ms ± 1.3 ms, n=5 and 3, respectively). The longer time course of KAR activation suggests that integrative properties of CA3 pyramidal neurons will differ in the mutant mice. Additional behavioral, synaptic and circuit analysis are underway. In summary, these results suggest that the GluK2(A657T) mouse successfully models several aspects of the patient's syndrome and identify at least one potentially pathological synaptic dysfunction.

Title: Genomic aberrations in embryonic neural progenitor cells may underlie cellular pathologies of lysophosphatidic acid induced hydrocephalus in mice

Authors: *W. S. MCDONALD, J. CHUN
Sanford Burnham Prebys Med. Discovery Inst., La Jolla, CA

Abstract: Fetal post-hemorrhagic hydrocephalus (PHH) is a rare but devastating disease that's associated with debilitating neurodevelopmental disorders and infant mortality. The etiology of fetal PHH remains unclear and there are no curative therapies, with major treatments limited to palliative, surgical approaches. Our research group has identified the involvement of lysophosphatidic acid (LPA), a bioactive and blood-derived lysophospholipid, through its G protein-coupled receptor LPA1, in PHH pathogenesis. Our LPA-induced model of PHH recapitulates many pathological features of hemorrhagic injury identified in clinical hydrocephalus including cortical cell loss, neural progenitor cell (NPC) lineage changes (including ependymal cell loss), ciliary dysfunction and/or loss, choroid plexus dysfunction and intracranial fluid imbalances (1). Moreover, we also observed alterations in genomic content, at the cellular level, in our model of PHH. Genomic abnormalities (i.e. aneuploidies) have also been identified 8-16% of congenital hydrocephalus cases and predict a higher risk of poor clinical outcomes as well as comorbid neurological disorders (i.e., schizophrenia, and Down syndrome) (2-7). Approach: To assess the potential genomic component of fetal PHH, fetal mice received intraventricular injections of LPA or vehicle (HBSS). DNA content by flow cytometry and cytogenetics approaches were used to determine genomic changes in embryonic cortices during fetal and early post-natal development. To assess the link between genomic aberrations and functionality of NPCs, we performed microelectrode array (MEA) recording during differentiation of neurons harvested from cortices of vehicle and LPA-exposed embryos. Results: Our results show acute changes in chromosomal content in cortical progenitor cells after LPA exposure. Prolonged aberrations in the genomes of neural progenitor cells are also observed, by flow cytometric genomic content analysis. Our MEA data suggests that LPA exposure prolongs network formation. The results indicate that LPA exposure during embryonic development alters function of progenitor cells and these changes are linked to prolonged genomic abnormalities in NPCs. LPA signaling may be a molecular initiator of genomic and cellular pathologies in murine hydrocephalus.

Title: Conserved role of DNM1in circadian rhythm control in humans and *Drosophila*

Authors: *F. V. BOLDUC[1], R. HE[2], C. ROSENFELT[2]
[1]Div. Pediatric Neurosci, [2]Univ. of Alberta, Edmonton, AB, Canada

Abstract: Background: Dynamin-1 (DNM1) is a conserved, large guanosine triphosphatase (GTPase) essential to synaptic vesicle recycling via clathrin-mediated endocytosis. De novo missense mutations in the *DNM1* gene have been identified in patients with severe epileptic encephalopathy and more recently, intellectual disability. However, the role of *DNM1*in sleep has not been reported before. Considering the importance of sleep on memory formation and the significant impact of sleep disorders on quality of life for individuals and their families, we sought to explore this further. Methods: We used whole exome sequencing (WES) in individuals with developmental delay and seizure to identify disorder causing variants. Standardized cognitive testing was used. Sleep questionnaires were used to identify sleep issues. Next, we used Drosophila temperature sensitive alleles of the gene identified via (WES) to assess the functional effect of the gene in various behaviors. Results: We identified two novel cases of *DNM1* mutations associated with a seizure disorder and intellectual disability, but also sleep disturbances. Whole exome sequencing revealed a previously reported de novo missense mutation c.709C>T (p.Arg237Trp) in one patient, while the other patient with a similar but less severe phenotype was found to have an in frame deletion c.647_655del (p.Asp215_Arg217del) in exon 5 of *DNM1*. Intragenic deletions in *DNM1* have not been previously reported. Those patients presented both with sleep dysregulation. Importantly, using a well-established locomotor assay for circadian activity, we also identified significant disturbance of circadian behavior in the *Drosophilamelanogaster* ortholog mutant of *DNM1*, *shibire*. Employing a pathway analysis approach we further identified potential genetic networks that could underlie both the seizure and circadian defects observed in individuals and flies with *DNM1* variation. Conclusions: Together, our results show that *DNM1*needs to be considered as a candidate gene for patients with a wide range of seizure severity, intellectual disability but also sleep and circadian disturbances.

Title: Subconvulsive stimulation in early postnatal life reduces NeuN and parvalbumin antigenicity while increasing interneuronal activity within the dentate gyrus and amygdala cortical complex in juvenile rats

Authors: *L. K. FRIEDMAN[1], B. A. KAHEN[1], J. E. HOFFMAN[2]
[2]Cell Biol., [1]New York Med. Col., Valhalla, NY

Abstract: Although select genes have been identified in cases of severe ASD, they do not yet account for the mild and more functional ASD cases that are not pervasive until years after birth. We hypothesized that continuous subconvulsive activity in early postnatal life may contribute to the development of autistic pathologies. To establish a valid ASD model, daily subconvulsive step-up doses of kainic acid (KA) were administered subcutaneously to rat pups for 15 days beginning on postnatal (P) day 6. At 24 h after the last subconvulsive treatment, a single convulsive dose of KA was administered to ASD (ASD+KA) and naïve rat pups (1xKA) to compare cellular consequences of subconvulsive vs. convulsive activity in early postnatal life. Brains were histologically evaluated with cresyl violet, NeuN, *cfos* and parvalbumin (PV) immunohistochemistry. The ASD group had increased numbers of hyperbasophilic neurons within the amygdala cortical complex (AMG/Cx) that correlated with reduced NeuN antigenicity revealing an increased average gap width extending from the BLA/BSTA to the piriform and entorhinal cortices, but in the absence of cell loss (142 ± 5 µm vs. 216 ± 8 µm, $p<0.01$). Serial hippocampal sections were devoid of injury in contrast to juveniles with 1xKA. Few cells were *cfos*$^+$ in control AMG/Cx, whereas the ASD group had many scattered *cfos*$^+$ cells within the AMG/Cx and dorsal blade of the dentate gyrus (DG), presumably GABAergic interneurons (2.33 ± 1.8 vs. 34.3 ± 4.4, $p<0.001$). A prominent *cfos*$^+$ cluster was also observed within the BSTA (45.5 ± 1.5, $p<0.002$). After ASD+KA, extremely dark *cfos* expression was apparent within large cells of the hilus, resembling GABAergic mossy cell distribution. Eosinophilia was also detected deep within the hilus, but belonged to a different cell population. Interneurons expressing PV were dramatically reduced in number and immunodensity but only in ASD and ASD+KA treated groups. Data suggest that continuous subconvulsive stimulation of high density low-affinity KA receptors of AMG/Cx in early postnatal life results in persistent or delayed elevations in activity within certain GABAergic interneurons of the AMG/Cx and DG. A progressive hyperactive state in early life due to a steady loss of PV interneuronal inhibition in these regions could lead to autistic pathologies. Accordingly, lack of NeuN antigenicity appears to reflect changes in metabolic activity rather than neuronal cell loss which may be sufficient to produce a mild and functional ASD syndrome.

Title: Postnatal-induced autism impairs social behavior and hovering in juvenile rats

Authors: *B. A. KAHEN, L. K. FRIEDMAN
New York Med. Col., Valhalla, NY

Abstract: The overall diagnosis of autism spectrum disorder (ASD) varies widely from very mild to severe social and cognitive impairments. We hypothesized that subconvulsive activity in early postnatal life may contribute to the development of autistic behavior. To induce a subconvulsive postnatal ASD model, daily step-up doses of kainic acid (KA) were administered subcutaneously to rat pups for 15 days beginning on postnatal (P) day 6 to elevate early life neuronal hyperactivity. Handling, open field, elevated plus maze, social interaction, object recognition and several hovering tests were examined 24 h after the last subconvulsive treatment. Within 5 days, increased exploratory and escape behavior in the handling test were observed in both sexes. On testing day P21, ASD females were more active in the elevated plus maze. In contrast, the social interaction test revealed that the ASD males spent more time and visits to the novel object and less time and visits with the stranger compared to controls (12.56s ± 3.97 vs. 17.09s ± 6.32, $p = 0.037$). The female ASD group was more active but otherwise similar to controls. To evaluate group dynamics, a novel hovering test was developed whereby rat pups from same groups and different groups were allowed to socialize in a small rectangular, large rectangular, or circular environment. Control pups hovered quickly and more frequently in all three environments whether they socialized with littermates or with other age-matched controls from a different litter (onset of hovering, 75s vs. 105s). In the circular environment, the ASD pups failed to group in large numbers. There was also an increased latency to hovering in the ASD group when tested with littermates in the large rectangular environment, but when a second ASD group was introduced to the first ASD group, wild running occurred and much less grouping was observed. In the spontaneous alternating T-Maze test, males exhibited more repetitive behavior. The object recognition test showed that only the ASD males spent less time with both old and new objects (4.09s ± 1.85 vs. 11.82s ± 2.85, $p= 0.038$). These findings suggest that continuous excitation of low-affinity KA binding sites in early postnatal life leads to increased hyperactivity and an ASD phenotype in the juvenile period. Males were more susceptible to developing autistic behaviors and cognitive pathologies, validating our postnatal model for autism.

Title: Silencing of *Drosophila* ortholog of TCF4 leads to behavioural impairment

Authors: *L. TAMBERG, M. JAAGO, A. SHUBINA, T. TIMMUSK, M. PALGI
Tallinn Univ. of Technol., Tallinn, Estonia

Abstract: Pitt-Hopkins syndrome (PTHS) is a rare intellectual disability syndrome characterized by specific facial features, severe mental retardation, lack of speech, and breathing problems. PTHS is caused by haplo-insufficiency of Transcription factor 4 (TCF4). TCF4 is one of the three human class I basic helix-loop-helix transcription factors also called E-proteins. In *Drosophila* there is a sole E-protein Daughterless (Da). We have previously shown that Da is the functional homolog of TCF4, that human TCF4 can replace Da in fly nervous system development and that the same homologous PTHS associated mutations cause similar effects in TCF4 and Da. We have used CRISPR-Cas9 technology for introducing FLAG tag to Da locus undisturbing the protein function , which allows us to study Da expression, since there is no good available antibodies for Da. Our new data demonstrates that lowered levels of Da in the nervous system of *Drosophila* larvae impair appetitive olfactory learning or in the adults affect negative geotaxis. These phenotypes can be used as a model for screening potential treatments for PTHS. Our latest results will be presented.

Title: CHD7 controls cerebellar development and granule cell differentiation

Authors: *N. REDDY[1], S. MAJIDI[1], C. J. FERGUSON[1], J. V. GOODMAN[1], T. YAMADA[1], A. BONNI[2]
[1]Washington Univ. in St. Louis, Saint Louis, MO; [2]Dept. of Neurosci., Washington Univ. in St. Louis, Sch. of Medi, Saint Louis, MO

Abstract: Proper brain development and neuronal differentiation are the result of precise temporal control of gene expression. Additionally, neurodevelopmental disorders and diseases, as well as premature death, are often due to genetic perturbations affecting gene expression programs. In particular, homozygous chromatin remodeling protein mutations tend to be embryonically lethal, while heterozygous mutations resulting in haploinsufficiency cause disease. Specifically, de novo mutations in CHD7, a member of the chromodomain helicase DNA-binding (CHD) family of ATP-dependent chromatin remodeling proteins, lead to CHARGE (coloboma of the eye, heart defects, atresia of the choanae, retardation of growth/development, genital and ear abnormalities) syndrome. Interestingly, CHD7 haploinsufficiency has also been shown to cause cerebellar hypoplasia and/or foliation defects in CHARGE patients. These phenotype suggests a critical role of CHD7 in multiple aspects of granule cell developmental programs, yet the distinct roles of CHD7 behind these phenotypes remains to be revealed.
In order to answer these questions, we have conditionally knocked out CHD7 in granule cell precursor cells of the mouse cerebellum. We aim to characterize the cellular phenotypes that result from the knockout of CHD7 in granule cell precursors. To better understand the mechanistic role of CHD7 and gene programs that CHD7 regulates we will intersect changes in the epigenetic state and transcriptional environment of immature granule cells in the presence and absence of CHD7. The described experiments will lend insight to the underlying developmental disruptions caused by CHD7 knockout, the multiple roles of CHD7 in granule cell development, and the mechanism by which CHD7 orchestrates these developmental and transcriptional programs.

Title: Paternal ethanol exposure prior to conception impacts offspring brain and behavioral development

Authors: *K. E. CONNER[1], R. T. BOTTOM[1], K. J. HUFFMAN[1,2]
[1]Interdepartmental Neurosci. Program, [2]Dept. of Psychology, Univ. of California, Riverside, CA

Abstract: Ethanol exposure *in utero* can cause cognitive, behavioral, and sensorimotor deficits in offspring. Past research has predominantly focused on prenatal ethanol exposure (PrEE) from maternal consumption of alcohol during pregnancy. However, little is known about how paternal ethanol exposure, prior to conception, may impact offspring development. Ethanol can alter epigenetic profiles of sperm, presenting a potential mechanism for impacting offspring development via paternal ethanol consumption. Our laboratory recently documented transgenerational transmission of stable genetic and neuroanatomical phenotypes in neocortex, as well as behavioral effects, resulting from PrEE (Abbott et al., 2017). Because our transgenerational model passes epigenetic modifications via male sperm, we hypothesized that paternal ethanol exposure before conception (PatEE) may impact neocortical development in offspring. Thus, we generated a PatEE mouse model where experimental male mice were given 25% ethanol in water for 15-23 days prior to mating. Offspring of males exposed to either ethanol (PatEE) or water (control) were examined at postnatal (P) day 0 for brain phenotypes. There were no differences between control and PatEE mice in measures of brain weight or neocortical length. Neuroanatomy was analyzed via Nissl staining which revealed no significant differences in cortical thickness between the two offspring groups. RNA *in situ* hybridization was used to investigate expression of two genes, *Id2* and *RZRβ,* which are critical to patterning the connections of the neocortex, in control and PatEE brains. Laminar-specific patterns of gene expression were found in both groups, where *Id2* was expressed rostromedially and *RZRβ* rostrolaterally. However, expression boundaries were shifted laterally in *Id2* and medially *RZRβ* in PatEE mice. Lipophilic dyes were used to observe intraneocortical (INC) development in putative somatosensory and visual cortices of control and PatEE P0 brains. Abnormal, overlapping labeling of INCs from the two distinct cortical regions was seen at the somatosensory-visual boundary in PatEE but not control mice. This region corresponded to the area of shifted neocortical gene expression. Finally, two subsets of pups were raised to ages P20 and P30 and tested on behavioral assays. PatEE mice exhibited increased motor deficits and

hyperactivity compared to controls, as assessed by Suok and Rotarod tests. Overall, these findings suggest that ethanol exposure in males prior to conception may induce long-lasting changes in brain and behavior of their offspring.

Title: Neuro-behavioral effects of prenatal ethanol exposure in pre-pubescence: A transgenerational mouse model of FASD

Authors: *R. T. BOTTOM[1], O. O. KOZANIAN[2], D. J. ROHAC[2], K. J. HUFFMAN[2,1]
[1]Neurosci., [2]Psychology, Univ. of California, Riverside, Riverside, CA

Abstract: Ethanol consumption during pregnancy results in detrimental developmental outcomes in offspring which often persist into adulthood. Fetal alcohol spectrum disorders (FASD) is an umbrella term that describes the range of developmental outcomes caused by prenatal ethanol exposure (PrEE). Children and adults with FASD may have neurobiological, cognitive and behavioral deficits that can potentially be transmitted across generations to unexposed offspring. The cognitive and behavioral deficits present in FASD have led researchers to generate hypotheses centering around dysfunction of the neocortex, as it is the primary structure responsible for complex, higher-order functions. Recently, our laboratory generated a transgenerational mouse model of FASD and demonstrated the transmission of PrEE-related phenotypes, such as ectopic intraneocortical connectivity and altered gene expression in the neocortex of newborn, postnatal day (P) 0 mice and adverse behavioral outcomes in peri-pubescence (P30), to the unexposed third generation (Abbott et al., 2017). The current study extends this work by examining whether PrEE-related brain phenotypes observed in newborn PrEE mice are maintained throughout 'childhood' (to age P20) and whether these phenotypes pass to subsequent generations. Specifically, we investigated if ectopic intraneocortical connections (INCs) found in first generation (F1) PrEE newborns (El Shawa et al., 2013) persist into pre-pubescence (P20) and whether these phenotypes are present at P20 transgenerationally. We found that PrEE-induced ectopic cortical connectivity observed in newborn F1 mice is rescued by P20, and is not present in F2 or F3 P20 animals. *In situ* hybridization for *Id2* and *RZRβ* was employed to assess gene expression in the neocortex, where layer and region specific patterns were observed in all groups of mice. Lastly, using a battery of behavioral assays, we

found that PrEE mice of F1, F2 and F3 generations continue to show significant behavioral deficits at P20 including poor motor coordination, sensorimotor integration, and depression-like behavior. These results indicate the persistence of PrEE-induced developmental outcomes into pre-pubescence, as well as their ability to be transmitted across generations. Results from this study will help identify long-term neurobiological and behavioral effects resulting from prenatal ethanol-exposure related brain dysfunction in humans with FASD and their kin.

Title: A spontaneous marmoset model of dysgenesis of the corpus callosum

Authors: D. SZCZUPAK[1], C. LIU[1], C. C. YEN[1], R. LENT[3], F. F. TOVAR-MOLL[3], *A. C. SILVA[2]

Abstract: Dysgenesis of the corpus callosum (DCC) is a unique condition caused by a congenital malformation in this structure. It can vary from complete, to partial dysgenesis or simply hypoplasia. This variety of phenotypes result in several different clinical presentations. While some of these patients are perfectly normal and cognitively well preserved, most have a subnormal IQ coefficient, with a subset of those being severely compromised and needing caretakers' assistance. The underlying mechanisms that cause the symptoms in a portion of these patients are still unknown. Many mouse models have been used to study this pathology, but rodents' brain anatomy and function are very different from humans. To evaluate more cognitive tasks to understand how the underlying anatomy contributes to the cognition, a better suited animal model is needed. Here we present the characterization of the first case of spontaneous corpus callosum hypoplasia in a non-human primate, the common marmoset (Callithrix jacchus). Using *in vivo* diffusion tensor MRI with 2 shells (b=1000/2000 s/mm2, 64/128 directions respectively), blip up and blip down, isotropic spatial resolution = 0.5mm, we were able to reconstruct the entire brain connectivity and see abnormal formation of the corpus callosum in one male marmoset 6.5 years old (Figure 1). These abnormalities were also observed in 3D T1- and T2-weighted MRI of the same animal. We then proceeded to retrospectively search MRI

scans from relatives of the affected marmoset, and we found 1 other with similar malformations in the same lineage, confirming that the congenital defect has an inheritable cause. Our results indicate that marmosets are a promising animal model for spontaneous presentations of malformation s of the corpus callosum.

Title: Binge-like alcohol produces long-lasting epigenetic marks on the stress axis only during the prenatal to prepubertal period but not after puberty

Authors: G. BERGER[1], L. CHASTAIN[1], O. GANGISETTY[1], V. MURUGAN[1], M. CABRERA[1], *D. K. SARKAR[2]
[1]Endocrinol. and Animal Biosci. Grad. Program, Rutgers Univ., New Brunswick, NJ; [2]Rutgers, SUNJ, New Brunswick, NJ

Abstract: Alcohol exposure during prenatal and postnatal periods can impact developmental pathways resulting in lasting structural and regulatory changes that predispose individuals to diseases including hyper-responsiveness to stress with exaggerated circulating glucocorticoids and enhanced anxiety like behaviors. Recently, it has been shown that alcohol exposures during the adolescent periods similarly predisposes individuals to adulthood stress abnormalities and enhanced anxiety. This raises the question of developmental timing: when does alcohol programming of stress axis to hyper-response cease? To address this issue, we fed young rats at various stages of reproductive development (postnatal period 2-7 days of age; juvenile periods, 15-20 days of age; prepubertal period 23-28 days of age; or post-pubertal period 50-55 days age) with a liquid diet containing 11.34% alcohol to raise blood alcohol levels to a range of 150-200mg/dl. Control animals were pair-fed an isocaloric volume of maltose dextrin. These rats were maintained in the animal house and challenged with restraint stress around 65 days of age. The stress challenge was conducted in both sexes. For females, the stress study was conducted on diestrus. Several days after the stress response, animals were sacrificed and the hypothalamic tissue samples were obtained and used for measurements of gene expression and methylation or left alone until PD 90, when animals underwent open field behavioral testing to measure anxiety and locomotor activity. Plasma glucocorticoid levels after restraint demonstrated an enhanced response to restraint stress in adult male and female rats who were given alcohol either on postnatal, juvenile or prepubertal period but not after pubertal period. Among pre-pubertal time groups, males displayed increased hyperactivity defined by increased distance moved and increased time mobile across pre-pubertal age groups when compared to pair-fed controls. Females displayed increased anxiety-like behaviors defined by decreased central tendency and increased avoidance behavior when compared to pair-fed controls. Since proopiomelanocortin*(Pomc)* is known to be an inhibitory regulator of the stress axis, we measured the expression of *Pomc* mRNA and DNA methylation levels and found reduced expression of *Pomc* but increased methylation of *Pomc*gene in rats treated with alcohol on postnatal, juvenile or prepubertal period but not after pubertal period. These results identify a critical period for alcohol programming of the stress regulatory gene during the developmental period that causes stress hyperresponse and increases anxiety-like behaviors via epigenetic mechanisms.

Title: Cranial nerve abnormalities in fetal alcohol spectrum disorders

Authors: *N. K. BAER[1], B. M. BJORKE[2]
[2]Biol. Dept., [1]Carleton Col., Northfield, MN

Abstract: Prenatal alcohol exposure is the leading preventable cause of neurodevelopmental disorders. Those most effected display cognitive, structural, and motor defects and are diagnosed with fetal alcohol spectrum disorders (FASD). The teratogenic effects of alcohol on the avian embryo parallel those found in mammals including defects to cardiac function and alterations to neural crest migration influencing later craniofacial development. Previous research demonstrates that prenatal alcohol exposure significantly reduces Sonic hedgehog (Shh) signaling. A critical role of Shh is to act as a morphogen to inform the differentiation of motor neurons. Perturbation of Shh signaling during development may therefore explain the motor defects described in FASD. However, an examination of whether motor neuron development is altered following alcohol exposure is lacking.
We examined growth and guidance of the cranial nerves following early embryonic ethanol exposure in the avian model system. Chick eggs were exposed to 9 mM of ethanol, a physiologically relevant concentration that mimics persistent exposure to alcohol. Embryos were collected at time points following early nerve development and immunolabeled against beta-tubulin. The growth and guidance of the oculomotor and facial nerves were compared to PBS-injected and no-injection controls. Preliminary findings suggest a reduction in cranial nerve fiber density following ethanol exposure, which may indicate a decrease in the number of motor neurons. Subsequent research will focus on quantifying this reduction in motor neuron density and count.

Title: Perinatal exposure to low doses of ethanol induces changes in cerebral areas analyzed at early postnatal days, which could be involved in characteristic adult behaviour

Authors: *H. A. BRUSCO, N. M. VILLALBA, C. MADARNAS, L. A. NOVAK, D. B. SORIANO, L. R. CALTANA, V. N. SANCHEZ
IBCN (UBA-CONICET) Facultad De Medicina UBA, Buenos Aires, Argentina

Abstract: Different animal models have been used to analyze the effect of ethanol (EtOH) during brain development and its consequences in adulthood. One of the most characteristic effects of *in utero* EtOH exposure is infant locomotor hyperactivity. However, studies on adult rats prenatally exposed to EtOH have rendered controversial results. Some authors have reported an increase in locomotor activity, while others have found no hyperactivity. In addition, previous studies found that adolescent mice and infant rats exhibit EtOH-induced locomotor activation. In view of these contrasting results, the aim of this work was to analyze adult behavior in CD1 mice perinatally exposed to low doses of EtOH (PEE) during gestation and lactation, and correlating it with morphological changes observed in their early postnatal brain. Primiparous CD1 female mice were exposed to EtOH 6%v/v intake for four weeks previous to mating. Pregnant mice drank EtOH 6%v/v during pregnancy and lactation. At the end of lactation, EtOH was eliminated and male pups were fed with food and water *ad libitum*. At P0 (postnatal day 0) and P17 pups were fixed and brain sections were stained. Morphometric parameters and nuclear characteristics were analyzed in hippocampus, cerebral premotor cortex and callosum. At P60, open field test were performed and locomotor activity, latency, time spent in periphery, time spent in central square and travelled distance were analyzed. In this PEE model, no differences were observed in weight gain in pregnant mice and in the number of offspring compared to the control group. Female mice consumed 0.261±0.08 ml EtOH/g/day, and yielded a BEC (blood EtOH concentration) of 73.29±8.69 mg/dl at the end of lactation. In PEE pups, BEC at P17 was 155.09±28.25 mg/dl and 101.56±5.21mg/dl at P21. There was a reduction of CA1 hippocampal area thickness in PEE pups at both P0 and P17; while a reduction of cerebral premotor cortex and the callosum thickness was found at P17. No morphological changes in nuclei were found. In adult PEE mice, behavioral estudies showed an increase in latency and a decrease in distance travelled compared to control animals. These results could be related with the alterations found in the studied brain areas.

Title: Single-day binge early postnatal alcohol exposure causes region-specific patterns of short- and long-term damage in prefrontal-thalamic circuitry of rat

Authors: *Z. GURSKY, E. C. SPILLMAN, A. Y. KLINTSOVA
Dept. of Psychological & Brain Sci., Univ. of Delaware, Newark, DE

Abstract: Fetal alcohol spectrum disorders constitute significant public health concern. Both human and animal studies link severity of prenatal alcohol-related brain damage to the timing and dose of alcohol to which the fetus is exposed. Previous findings in our lab indicate that behaviors dependent on mPFC - but not OFC - are impaired in a rodent model of human third trimester alcohol exposure (AE). The current study examined the impact of a single-day early postnatal binge AE on cell death and cell number in medial prefrontal cortex (mPFC), orbitofrontal cortex (OFC), and the thalamic nucleus required for mPFC-hippocampal interactions (reuniens, Re). To test the hypothesis that AE restricted to postnatal day (PD) 7 selectively damages Re and mPFC, but not OFC, male and female Long Evans rat pups were either administered 5.25 g/kg/day of ethanol via intragastric intubation (AE group), intubated without liquid (sham-intubated, SI), or left undisturbed (suckle control, SC). Brain tissue was fixed and extracted on either PD7 (12 hours after experimental manipulation), PD11, or PD72. Brains were serially sectioned coronally at 40µm and sections were stained with cresyl violet. Unbiased stereological estimation of apoptotic cell number (PD7), total cell number (PD11, PD72), and volume (PD7, PD11, PD72) were performed for Re, mPFC, and OFC in each animal. All 3 regions displayed a significant 10-to-20-fold increase in apoptosis in AE animals on PD7, while levels of apoptosis in both SI and SC groups were very low and did not differ from each other. There was a main effect of postnatal treatment (but not age nor a significant interaction between factors) on cell number in Re, indicating that AE animals showed cell loss at both the PD11 and PD72 timepoints. A significant interaction between postnatal treatment and age was observed for mPFC cell number, due to a loss of cells at the PD11 timepoint in AE animals compared to both SI and SC, but no differences between treatments at PD72. In contrast, no significant differences were detected in OFC due to postnatal treatment, but an increase in cell number on PD72 relative to PD11. These data indicate that Re, mPFC, and OFC are differentially vulnerable to AE on PD7. While all 3 regions display increased cell death in response to alcohol on PD7, Re cell loss is present within 4 days from the insult and persists into adulthood, while mPFC cell deficits which are present short-term do not persist into adulthood, and OFC appears to be unaffected at PD11 or 72. The findings add to previous research presented by our lab indicating that PD4-9 AE targets Re within thalamus and selectively impairs mPFC-dependent behaviors among PFC-dependent behaviors.

Title: Polygenic contributions of general transcription factors, Gtf2i and Gtf2ird1, in Williams Beuren syndrome critical region to cognitive phenotypes

Authors: *N. D. KOPP[1], J. D. DOUGHERTY[2]
[2]Genet., [1]Washington Univ. Sch. of Med., Saint Louis, MO

Abstract: Williams Beuren syndrome (WS) is a neurodevelopmental disorder caused by a deletion of 26 genes on chromosome 7q11.23. Hemizygosity of these 26 genes results in a constellation of phenotypes including cardiovascular abnormalities, craniofacial dysmorphology, a unique cognitive profile, and gregarious personality. Human and mouse studies have implicated two transcription factors in the cognitive and social phenotypes, *Gtf2i* and *Gtf2ird1*. While single gene knock out studies in mice suggest that both of these genes individually contribute to social and cognitive phenotypes, we do not know if these paralogous transcription factors have additive effects or synergistic effects on behaviors. Further, we do not know how much of the phenotype caused by hemizygosity of the 26 genes can be explained by haploinsufficiency of *Gtf2i* and *Gtf2ird1*. CRISPR/Cas9 was used to generate mice lines that are haploinsufficient for either *Gtf2i* or *Gtf2ird1*. Crossing the two single haploinsufficient mouse lines allows us to compare the double haploinsufficient animals to single haploinsufficient and wild type littermates, so we can test single gene, additive, or epistatic genetic models. We tested these mouse lines in a battery of battery of motor, cognitive, and social behaviors in mice. Experimenters were blinded to genotype and for each task we aimed to test 15-24 animals per genotype and included both males and females. Behaviors such as activity levels and time spent in the center of an arena show additive effects; pre-pulse inhibition, contextual and cued fear show single gene effects; and balance and marble burying deficits are caused by an interaction between the two genes. Given the evidence for different genetic models, we test if haploinsufficiency of these two genes is sufficient to replicate the phenotypes in mice that lack all 26 genes typically deleted in WS. We cross a mouse line that is haploinsufficient for both *Gtf2i* and *Gtf2ird1* to a mouse line that is hemizygous for the genes deleted in WS, the complete deletion mouse (CD). We test the offspring of this cross on the same battery of behaviors. We see that the CD mice have a more severe phenotype than mice that are haploinsufficient for *Gtf2i* and *Gtf2ird1*, suggesting that there are contributions from other genes in the region to behavioral

phenotypes in mice. These studies provide evidence that *Gtf2i* and *Gtf2ird1* act additively as well as interact to affect behaviors. Further, these two genes alone are not sufficient to replicate the phenotype caused by hemizygosity of all the genes typically deleted in WS.

Abstract: A causal relationship has been established between congenital Zika virus (ZIKV) exposure and microcephaly and other neurological disorders. However, long-term consequences

of perinatal infection are largely unknown. Herein, we evaluated acute and late neuropathological and behavioral consequences of ZIKV infection in neonatal wild-type mice. ZIKV showed brain tropism, causing post-natal microcephaly and several behavioral deficits in adulthood. During the acute phase of infection, mice developed frequent epileptic seizures, which were consistently reduced by TNF-α neutralization. Although adult animals recovered from spontaneous seizures, they were significantly more susceptible to chemically-induced crises. ZIKV replication persisted in brains of adult mice, which exhibited marked brain necrosis and calcifications. Altogether, the results reveal the risk for the development of late neuropathological and behavioral complications caused by congenital or neonatal ZIKV exposure, and suggest the early inhibition of TNF-α-mediated neuroinflammation as a potential therapeutic strategy to prevent long-term neurological sequelae in ZIKV-infected infants.

Title: Chorioamnionitis induced by group B streptococcus serotype III: Intrauterine growth retardation and motor impairments in male rats

Authors: *M.-J. ALLARD[1], M.-E. BROCHU[2], J. BERGERON[2], M. SEGURA[3], G. SEBIRE[1,2]
[1]McGill Univ., Montreal, QC, Canada; [2]Univ. de Sherbrooke, Sherbrooke, QC, Canada; [3]Univ. de Montréal, Saint-Hyacinthe, QC, Canada

Abstract: INTRODUCTION: Chorioamnionitis is a polymicrobial infection - most often due to ascending genital bacteria - characterized by acute maternofetal inflammation. Chorioamnionitis is a major risk factor for intrauterine growth retardation (IUGR), associated with premature birth and brain injuries, which may result in cerebral palsy and other long-term neurologic deficits. However, the causal link between chorioamnionitis and IUGR has not been demonstrated yet. The pathogen(s) involved in this sequence of perinatal morbidities remain unknown. Common isolates in women with chorioamnionitis include group B Streptococcus (GBS) serotypes Ia and

III. Serotype III GBS is considered more virulent than serotype Ia, and is associated with worse clinical outcomes. We aimed to compare the impact of end-gestational exposure to serotype Ia and III, considering GBS serotype-specific virulence asset. METHODS: Dams were injected every 12 h from gestational day 19 to 22 with saline, inactivated GBSIa or GBSIII, as previously described (Bergeron JD et al., 2013). The open field apparatus was used to evaluate spontaneous locomotion, exploratory behavior and thigmotaxis in a novel environment. RESULTS: End-gestational exposure to GBSIa and GBSIII and subsequent chorioamnionitis impacted negatively the maternal weight gain, without leading to increased mortality rate in the progeny. No premature delivery was noticed in any group, *i.e.* all dams gave birth naturally on G23/P0 GBSIII - but not GBSIa - induced chorioamnionitis impacted negatively the pups' weight at birth, suggesting an IUGR, and this growth retardation was still present at P40. At P25, GBSIII-exposed males - but not females - displayed an impaired motor behavior in the open field apparatus, but no anxiety-like behavior or impaired exploratory behavior was observed. GBSIII-exposed males - but not females - had a thinner primary motor cortex than controls at P40, which was correlating with the total distance travelled in the open field. CONCLUSIONS: Our results showed for the first time that end-gestational exposure to GBS lead to serotype-specific and sex-specific neuromotor impairments. These results validate the pertinence to further investigate whether GBSIII triggers a differentiated inflammatory response from GBSIa, and subsequently leads to worst neurodevelopmental impacts associated with motor and/or cognitive deficits.

Title: Behavioral analysis of the progeny of rats exposed to the toxoplasma gondii extract

Authors: *E. ROMERO NUÑEZ, B. PINEDA[1], A. JIMENEZ-ANGUIANO[2], S. MUÑIZ HERNÁNDEZ[3], D. F. GONZÁLEZ ESQUIVEL[1], C. RÍOS[1], V. PÉREZ DE LA CRUZ[1]
[1]Inst. Nacional de Neurología y Neurocirugía, Ciudad de México, Mexico; [2]Univ. Autonoma Metropolitana-Iztapalapa, Mexico City, Mexico; [3]Inst. Nacional de Cancerología, Ciudad de México, Mexico

Abstract: Toxoplasmosis is a parasitic infection caused by the protozoan *Toxoplasma gondii* whose prevalence is estimated as 30% of the world population. Generally, the infection is considered asymptomatic, although recently it has been associated with some behavioral alterations in the host. In the case of maternal infection, *T. gondii* has been recognized as a risk factor for abnormal brain development in the fetus because it can invade the central nervous

system, but even in the absence of perinatal transmission, infection during the pregnancy could play an important role in the neurological development of the offspring. The aim of this work is to evaluate behavioral changes in the progeny of rats immunized with *T. gondii* antigens. Female wistar rats were injected with the *T. gondii* lysate or PBS three times (once per week) prior to gestation. In the progeny was evaluated Memory and learning, locomotor activity in the open field and social interaction at 60 postnatal days. In the locomotor activity test, the progeny of mothers previously immunized with the *T. gondii* lysate showed a decrease (26%) in the total distance traveled, compared with the control group. In the object recognition test, the progeny of mothers previously immunized with the *T. gondii* lysate showed a lower preference (67%) for the novel object, compared to the control group. Regarding the social interaction test, the progeny of mothers previously immunized with the *T. gondii* lysate showed less interest (58%) in interacting with another rat either known or unknown, compared to the control group showing greater preference for interacting with the novel rat. These results suggest that the progeny of mothers previously immunized with the *T. gondii* lysate presents behavioral and social impairment possibly as a result of immune maternal system alteration by *T. gondii* antigens.

Abstract: Tideglusib, a glycogen synthase kinase β inhibitor, is predicted to alleviate autism-related symptoms, increase neurogenesis and memory formation (Guo et al.2012, Hermida et al. 2017). In this study, we treated five different autism mouse models with Tideglusib to characterize the effects on the behaviour and neuranatomy of the mice. The five mouse models chosen represent either single-gene disorders related to autism (like Fragile X Syndrome) or common mutations present in the autism population: Fmr1 and NHS hemizygous knockout models, the CHD8 and Arid1b heterozygous deletion models, and the Shank3 homozygous knockout model.

Mice were administered 5mg/kg I.P. Tideglusib five days a week, for four weeks, starting at 5 weeks of age. On the final week of treatment, a battery of behavioural assessments were conducted to assess sociability, memory, anxiety, and hyperactivity. Magnetic resonance imaging (MRI) was used to assess the effects of treatment on neuroanatomy at three *in vivo* and one *ex vivo* timepoints.

A significant effect of Tideglusib treatment was found in the behaviour of the Shank3 mouse model, with treatment normalizing a memory deficit in Ymaze but exacerbating O-maze hyperactivity and decreasing anxiety past wildtype levels (the figure shows mean and 95% confidence intervals for all strains on the Ymaze memory test). No treatment effect was found in the *ex vivo* neuroanatomy of any of the mouse models, nor on the behaviour of any of the other strains, although some trends were seen in the Chd8 and NHS mice.

These results indicate that though Tideglusib is beneficial for the memory deficits of the Shank3 mouse model, it may have harmful side effects in other behaviours, and therefore may not be a suitable treatment for humans. Tideglusib also showed no effect on the neuroanatomy, although comparison to baseline and the longitudinal effect of Tideglusib on structural anatomy remains to be determined. In conclusion, the effect of chronic treatment with Tideglusib may be more subtle than originally anticipated.

Title: Origin and function of directionality in spontaneous retinal waves

Authors: *X. GE, A. GRIBIZIS, M. C. CRAIR
Neurosci., Yale Univ., New Haven, CT

Abstract: Before the onset of visual experience, spontaneous retinal waves are the main source of activity in the developing superior colliculus (SC), thalamus and primary visual cortex in the mammalian visual system. Genetic and pharmacological manipulations of this spontaneous retinal activity suggest a causal link between retinal waves and circuit refinement. Previous studies found that Stage II (around the first week after birth in mice) spontaneous waves exhibit a strong directional bias. However, it remains unclear how this bias emerges, whether it changes over development and whether this spatiotemporal feature of spontaneous waves is critical for circuit refinement and the development of functional circuit properties. Here, we describe experiments that investigate the role and origin of spontaneous wave directionality during visual system development. We used wide-field Ca^{2+} imaging of retinal ganglion cell (RGC) projections in the SC *in vivo* and optogenetic or light stimulation of the retina to examine spontaneous and stimulus induced wave direction bias. We observe that the directional bias emerges at the end of Stage II (~P8) waves and vanishes before the time of eye opening (~P12). The biased direction (temporal to nasal) is consistent between P8 and P12. The averaged wave propagation direction distribution resembles the optic flow pattern in the retina generated by forward motion. To understand the origin of wave directional bias *in vivo*, we used selective optogenetic stimulation of starburst amacrine cells (SACs), or light stimulation after the onset of light response (~P10), to initiate waves at various locations in the retina. Our experiments suggest that starting from around P10, stimulated retinal waves propagate in a direction consistent with intrinsic waves, regardless of their nucleating sites. This suggests a biased retinal circuit that favors the propagation of waves in a specific direction on the retina. In addition, we show that pharmacological blockade of inhibition *in vivo* diminished wave directional bias. This result suggests that inhibition plays an especially important role in establishing the strong directional bias of spontaneous retinal waves. In summary, these results suggest a specific developmental stage in which spontaneous retinal waves exhibit a strong directional bias, and that this bias is a result of intrinsic asymmetry in the retinal circuit. This bias could potentially affect visual circuit refinement in the retina and other parts of the developing visual system.

Title: Spontaneous thalamic waves regulate cortico-thalamic innervation in the visual system

Authors: *V. MORENO-JUAN, G. LOPEZ-BENDITO
Inst. de Neurociencias UMH/CSIC, San Juan de Alicante, Spain

Abstract: Understanding how do cortical areas acquire their functional identity is a central question that has been studied for many years. To determine how the brain adapts to the sensory lost might help to better decipher the role of extrinsic and intrinsic mechanisms in cortical development. We have recently demonstrated an unpredicted role of the prenatal thalamus in shaping cortical territories after input deprivation, which depends on the propagation of spontaneous calcium waves across the different thalamic sensory nuclei (Moreno-Juan et al., 2017). Now, we have evidences that suggest that spontaneous thalamic activity is crucial for the correct development of the corticothalamic projections in the visual system. Here we have shown that consistent to what was published before, in embryonically bienucleated (embBE) mice, corticothalamic axons (CTAs) prematurely invade the dorsal lateral geniculate nucleus (dLGN) at P4 and thus suggesting that retinal axons have a pivotal role in the control of the CTAs segregation and synapses maturation in the dLGN. However, it is still possible that the role of the retinal axons in controlling the innervation of the CTAs is indirect by modulating the thalamic intrinsic activity. Indeed, the thalamic calcium waves in the dLGN persist in absence of retinal input and moreover, their frequency is increased. So it is possible that CTAs invasion is controlled by thalamic calcium waves rather than purely by the presence or absence of retinal axons. We have performed several experiments in retinal or thalamic silenced mice using specific drug injections or transgenic modified animals in order to better characterize the mechanisms that control the corticothalamic innervation in the visual thalamus. Moreover, it is possible that thalamic spontaneous activity controls the expression pattern of genes in the dLGN that might be important for CTA targeting. We have performed a microarray assay in which the dLGN genetic profile of the embBE mice was analyzed. Thus, we have a powerful suitable dataset in which to look for specific activity-dependent genes involved in controlling the entrance of the CTAs. Altogether these results contribute to elucidate the role of the thalamus in cortical development.

Title: Embryonic thalamic calcium waves control barrel map formation through the developmental regulation of cortical excitability

Authors: N. ANTÓN-BOLAÑOS[1], A. SEMPERE-FERRÀNDEZ[1], F. MARTINI[1], L. PÉREZ SAIZ[1], H. GEZELIUS[1,2], A. FILIPCHUK[1,3], A. ESPINOSA[1], M. A. VALDEOLMILLOS[1], *G. LOPEZ-BENDITO[1]

Abstract: Sensory periphery systems are represented in cortical primary sensory areas of the brain, organized in anatomical and functional maps. For instance, the whisker pad representation in the barrel field of S1 in rodents. Several intrinsic and extrinsic factors have been proposed to shape sensory maps during early development. Thalamic spontaneous calcium waves which propagate from the thalamus to the cortex during perinatal stages, might influence sensory map development. To test this possibility, we developed a mouse model in which the pattern of spontaneous thalamic activity is modified due to the specific abolishment of the calcium waves in this structure. In this mouse (Th^{kir}), thalamic neurons are hyperpolarized due to the overexpression of Kir2.1. *Ex vivo* calcium imaging in postnatal acute slices showed that at P2-P3, VPM stimulation generates a cortical propagating activity in the Th^{Kir}, in contrast to the pre-columnar restricted domains generated in control animals before barrel formation. Moreover, our data shows that the cortex of Th^{kir}mice remains hyper-reactive throughout the first postnatal week, as indicated by the higher frequency of spontaneous cortical activity in comparison with control mice. The change in this pattern of thalamic activity and therefore the cortical excitability lead to the complete lack of the somatosensory map representation in S1. Remarkably, thalamocortical axons (TCAs) reach their cortical target layer 4 but do not segregate in cortical barrel-like patches as observed in control mice, lacking their characteristic point-to-point refined organization. In sum, our results demonstrate a crucial role of the prenatal thalamic calcium waves in the acquisition of cortical sensory maps in the somatosensory system by the postnatal regulation of cortical excitability.

Title: LDB1 is required for the early development of the dorsal telencephalon and the thalamus

Authors: V. KINARE[1], S. PAL[2], *S. P. TOLE[3]
[1]Sophia Col. for Women, Mumbai-400, 005, India; [2]Tata Inst. of Fundamental Res., Mumbai, India; [3]Tata Inst. of Fundamental Res., Mumbai-400, 005, India

Abstract: LDB1 is a protein cofactor that participates in several multiprotein complexes with transcription factors that regulate forebrain development. Since Ldb1 null mutants display early embryonic lethality, we used a conditional knockout strategy to examine the role of LDB1 in early forebrain development, using multiple Cre lines. Loss of Ldb1 using Foxg1Cre caused a disruption of midline boundary structures in the dorsal telencephalon. While this Cre line gave the expected pattern of recombination of the floxed Ldb1 locus, unexpectedly, standard Cre lines that act from E10.5 (Emx1Cre) and E11.5 (NesCre) did not show efficient or complete recombination in the dorsal telencephalon by E12.5. Intriguingly, this effect was specific to the Ldb1 floxed allele, while three other lines including floxed Ai9 and mTmG reporters, and a floxed Lhx2 line, each displayed the expected patterns of recombination. Furthermore, the incomplete recombination of the floxed Ldb1 locus using NesCre was limited to the dorsal telencephalon, while the ventral telencephalon and the diencephalon displayed the expected loss of Ldb1. This permitted us to examine the requirement for LDB1 in the development of the thalamus. We report that the somatosensory VB nucleus is profoundly shrunken upon loss of LDB1. Our findings highlight the unusual nature of the Ldb1 locus in terms of recombination efficiency, and also report a novel role for LDB1 during the development of the thalamus.

Title: Genetic mechanisms in early cortical progenitors control thalamocortical innervation

Authors: *S. PAL, G. GODBOLE, T. PRAMANIK, S. TOLE
Dept. of Biol. Sci., Tata Inst. of Fundamental Res., Mumbai, India

Abstract: Sensory information from the periphery is presented to the cerebral cortex in a highly ordered manner, providing a topographic representation of the external world. In the mouse, sensory information from the whiskers is spatially represented via maps in the brainstem and thalamus from where it enters the somatosensory cortex to form whisker-specific “barrels.” We have discovered a genetic tool that allows us to examine how the innervation of the cortex by thalamocortical afferents is regulated. Using a cortex specific and progenitor-specific conditional mutant of transcription factor Lhx2, we discovered that the cortical barrels do not form. Therefore, the Lhx2 deficient cortex causes a non-cell-autonomous disruption of incoming thalamocortical innervation. This disruption is seen at very early stages, suggesting mechanisms in operation that have not previously been reported. The cortex-specific Lhx2 conditional mutant offers new insights into the problem of thalamocortical guidance.

Title: Development of coherent orientation selective responses to monocular and binocular stimuli in ferret visual cortex

Authors: *J. T.-Y. CHANG, D. E. WHITNEY, D. FITZPATRICK
Max Planck Florida Inst. for Neurosci., Jupiter, FL

Abstract: In the mammalian primary visual cortex, neurons form networks that are characterized by selectivity to visual features such as orientation, a property known to emerge during early postnatal life. While orientation preferences for each eye are matched in the mature visual system, we recently demonstrated that at the onset of visual experience orientation tuning through the two eyes is initially mismatched at both the cellular and network-level, and only later becomes reconciled with exposure to a week of patterned visual experience. However, the process and factors that drive toward a coherent representation of orientation tuning remain poorly understood. For example, one possible outcome is a winner-take-all approach where the orientation preference of the dominant eye drives the remapping of orientation preference of the non-dominant eye.
Here we use longitudinal functional imaging of GCAMP6s over the first week of patterned visual experience to assess orientation selective responses to either the monocular or binocular presentation of drifting gratings. Surprisingly, we find that patterns of cellular and network level responses evoked by binocular stimulation are distinct from those of monocular stimulation at eye-opening, and not merely predicted as a simple weighted sum of monocular responses. Furthermore, we demonstrate that metrics of ocular dominance and reliability fail to predict the experience-dependent shifts in monocular orientation preferences. Indeed, most cortical neurons remain highly binocular during this developmental epoch, suggesting that the shift in orientation preferences cannot merely be accounted for by increases in monocularity or changes in ocular dominance. Instead, our imaging data show that responses evoked by binocular stimulation remain relatively stable over the first week of visual experience and monocular responses shift progressively to match the binocular response. Thus, we propose that a stable binocular response is the template for remapping monocular responses, and anchors the final representation of orientation tuning in primary visual cortex.

Title: V1 pyramidal neurons lose dendritic inhibition and somatic disinhibition across critical period closure

Authors: *C. E. YAEGER[1], D. L. RINGACH[2], J. T. TRACHTENBERG[1]
[1]Neurobio., [2]Neurobio. & Psychology, UCLA, Los Angeles, CA

Abstract: During development, long-lasting changes in neural circuitry are rapidly induced by sensory exposure. The mechanisms of sensory-dependent plasticity are not understood, nor is it known how plasticity rules shift with maturation. Here we show a microcircuit unique to the developmental critical period in mouse primary visual cortex, in which behavioral state and inhibition converge to alter compartmentalized dendritic responses and somatic excitability. Using 2-photon microscopy to measure GCaMP6 fluorescence in awake mice viewing natural movie scenes, we find that sister dendrites of L2/3 pyramidal cells are strongly decorrelated during movement in young mice but not in adults. Locomotion also strongly activates a population of interneurons that innervate pyramidal cell dendrites-- somatostatin-expressing (SST) interneurons-- but only prior to critical period closure. Whole-cell recordings in slice indicate that SST cells lose cholinergic responsivity across developmental time points. These changes in SST-mediated inhibition also affect parvalbumin-expressing (PV) interneurons and their primary target, pyramidal cell somas. During the critical period, PV interneurons are inhibited during locomotion and cholinergic release, subsequently removing inhibitory drive onto pyramidal cell somas. Optogenetic stimulation of SST cells in adult cortex restores both branch-specific dendritic responses and somatic disinhibition in pyramidal neurons. Thus, cholinergic sensitivity of SST cells affects dendritic and somatic excitatory processing through direct and indirect means. We propose that the age-dependent inversion of inhibition along the somato-dendritic axis alters local plasticity rules and contributes to the closure of critical periods.

Title: Modeling the development and binocular matching of orientation preferences of binocular neurons in layer 2/3 of V1

Authors: *X. XU[1], H. RIECKE[2]
[2]Engin. Sci. and Applied Mathematics, [1]Northwestern Univ., Evanston, IL

Abstract: Information about the world reaches the brain via multiple sensory information channels. This variety of inputs needs to be merged in a coherent fashion to provide meaningful information. The mouse visual system is an excellent model system to investigate such merging. At eye-opening (P13-P15) binocular cells in V1 have already developed significant orientation tuning, but the preferred orientations for input from the left and from the right eye typically differ significantly. With normal visual experience during a critical period (P19-P30) these orientations shift and eventually become well matched [1]. Recent experiments have shown that the binocular matching process, which is completely blocked by monocular deprivation spanning the entire critical period, can be rescued by environmental enrichment to the level seen in normal mice [2].

To gain insight into the matching process, we developed a computational model of a cortical cell in L2/3 that receives - via monocular cells in L4 - oriented inputs from the two eyes via synapses that exhibit voltage-based spike-timing dependent plasticity. Employing a monocular stage of development followed by a binocular one, our model captured the experimentally observed matching of the orientation preferences, the dependence of the matching process on the ocular dominance of the cell, and the inverse relationship between the resulting binocular orientation selectivity and the mismatch. Moreover, our model puts forward testable predictions regarding the interplay of ocular dominance, orientation selectivity, and the matching of preferred orientations. Two different routes of matching are predicted depending on the initial degree of the mismatch.

We expect that these results provide insight more generally into the development of systems that integrate inputs from multiple sources in order to generate normal neuronal functions.

Title: Function of vasoactive intestinal peptide (VIP)-expressing interneurons in the developing auditory cortex

Authors: *J. HU[1], J. BIGELOW[3], R. J. MORRILL[2], J. L. RUBENSTEIN[5], A. R. HASENSTAUB[4]
[1]Dept. of Psychiatry, [2]Univ. of California, San Francisco, San Francisco, CA; [4]Otolaryngology / Ctr. for Integrative Neurosci., [3]UCSF, San Francisco, CA; [5]Nina Ireland Lab. Dev Neurobiol, Univ. of California San Francisco, San Francisco, CA

Abstract: In adult mice, distinct cortical interneuron subtypes uniquely process sensory information. However, their roles during postnatal development of the sensory cortex are poorly understood. Transcription factors direct the development and function of cortical interneurons in a subtype-specific fashion. Among these is *Coup-TF2 (Nr2f2)*, an orphan nuclear receptor whose expression is restricted to a few interneuron subtypes. We analyzed the effect of conditionally removing *Coup-TF2* in vasoactive intestinal peptide (VIP)-expressing interneurons during early postnatal development. We found a ~40% reduction in VIP+ interneuron density that first occurred at age P3 through cell death. We then examined the consequences of this reduction on sensory processing through extracellular *in vivo* recordings in the adult primary auditory cortex. We observed frequency tuning curves with smaller bandwidths and perturbed tonotopic map. These effects were associated with changes in layer-specific firing responses, altered spike waveform duration and response onset (peristimulus time histogram (PSTH)) in fast-spiking cells, and changes in post-stimulus firing (PSTH) in regular-spiking cells. Altogether, our data support a specific role in VIP+ interneurons during the development of circuits that process auditory stimuli.

Title: Developmental regulation of top-down inputs onto L1 neurons in the Primary Auditory Cortex

Authors: *L. A. IBRAHIM[1], N. YUSUF[1], R. MACHOLD[2], G. J. FISHELL[1]
[1]Dept. of Neurobio., Harvard Med. Sch., Boston, MA; [2]NYU Langone Med. Ctr. Neurosci. Inst., New York, NY

Abstract: Information processing in a sensory cortex is determined not only by 'bottom-up' sensory experience, but by feedback from higher cortical areas, modulation by subcortical systems, as well as cross-modal modulation by other sensory cortices. Many of these projections exist to create an internal representation that predicts the incoming stimuli to react faster and draw conclusions based on limited information. How this develops and is achieved in sensory cortices is not well understood. It is likely that L1 interneurons might play a role. They receive both strong cortico-cortical inputs from higher order cortices, as well as bottom up thalamic inputs, and their inhibitory nature puts them in a suitable position to modulate sensory processing. Our preliminary rabies data suggests that in the primary auditory cortex (A1), the thalamic inputs onto the 'neuron derived neurotrophic factor' (NDNF) interneurons, the largest subset of L1 interneurons, while decreasing during development, persist into adulthood. We hypothesize that this initially large bottom up sensory input might be important in establishing long rage top-down inputs onto L1 neurons and impart important functions to these neurons in sensory processing. Previous work in our laboratory has shown that Prox1, a homeobox transcription factor is required for the specification and integration of CGE (Caudal ganglionic eminence) derived interneurons. Whether this is also an important factor in establishing long range connectivity is still not known. Our preliminary data shows that removal of Prox1 affects connectivity of these interneurons; a decrease in local, long range as well as cholinergic inputs was observed. It is possible that this effect might be due to a broad role of Prox1 in maintaining CGE identity; hence, identifying specific molecules that are regulated by Prox1 action is important in determining the molecular basis of top-down input establishment in A1.

Title: Neural dynamics in the developing piriform cortex

Authors: *Z. ZHANG, D. C. COLLINS, J. X. MAIER
Neurobio. and Anat., Wake Forest Sch. of Med., Winston Salem, NC

Abstract: Revealing the mystery of cortical development can help us understand how cortical circuits learn to process information. Previous work has focused on how cortical computations are shaped by sensory input during the critical period. However, recent work on the visual and somatosensory systems has shown that cortex learns to process information already in the absence of sensory input, during the pre-critical period. For example, before maturation of the retina, spontaneous retinal waves trigger 10 Hz spindle oscillations in the thalamo-cortical loop that drive initial patterning of visual cortex.In contrast, nothing is known about the development of piriform olfactory cortex—a 3-layer paleocortex that lacks thalamic relay and receives natural sensory input from birth. These odd features, in combination with an evolutionary history that is shared with neocortex, make piriform cortex a unique model for studying cortical development. Here, we ask whether the same activity patterns observed during development of neocortex are observed in piriform cortex. We recorded local field potential activity in the piriform cortex of urethane-anesthetized rats across development, from postnatal day 0 days to adulthood. Odor and clean air were presented for 5 s with 30-45 s intervals. Respiration was recorded with a pressure sensor.Our results show that immediately after birth, respiration drives 10 Hz odor-evoked spindle oscillations in piriform cortex. These oscillations increase in frequency during the first two weeks of life until they reach adult values of ~20 Hz. The transformation from spindle to beta oscillation is not gradual but occurs suddenly around 15 days of age. At the same time, spontaneous activity undergoes a dramatic increase in structure. These findings indicate that early developmental dynamics observed in piriform cortex activity are highly similar to those previously observed in neocortical sensory areas, despite major differences in circuits, systems and peripheral input. This suggests that the principles underlying cortical development are evolutionarily conserved, and that sensory cortical development is coordinated across the brain. Ongoing work focuses on characterizing spiking activity, as well as developmental activity patterns in awake rats.

Title: The development of multisensory integration is influenced by network correlation and sensory experience

Authors: *T. L.-S. TRUSZKOWSKI[1], J. BLEIER[2], S. COHEN[2], C. D. AIZENMAN[1]
[1]Neurosci., [2]Brown Univ., Providence, RI

Abstract: The interaction of sensory information from multiple senses provides crucial information to the brain. Previously, we have used the Xenopus tadpole optic tectum to show that multisensory integration is sensitive to stimulus interval and shows inverse effectiveness. These are dependent on maturation of inhibition and NMDAR activation respectively. However, these studies raise the question of how single cell activity could give rise to behavior and how that process could be manipulated with experience. First, we investigated the interactions among cells in the optic tectum using in vivo calcium imaging. The optic tectum has a subset of cells that are highly correlated with a large number of other cells in response to both multisensory and unisensory stimuli. This may indicate the presence of a few highly connected cells in the optic tectum that may act as network influencers to coordinate multisensory responses across the tectum. Younger tadpoles have more of these highly correlated cells, suggesting that correlation decreases over development. This may indicate a mechanism by which a subset of cells provide sensory input that is processed differently by a variety of functional cell types. Our data provides novel insight into how cells process multisensory information as a functional group. Furthermore, we showed that temporally disparate multisensory experience changes the multisensory responses behaviorally and in single cells. In particular, single cell spike responses are shifted towards a conditioned temporal interval and tadpoles show increased behavioral responses to the conditioned interval. Together, these data provide a robust, multi-faceted assessment of the development of multisensory integration in the Xenopus tadpole.

Title: Experience dependent development of prey capture performance in larval zebrafish

Authors: *K. LAGOGIANNIS, M. MEYER
King's Col. London, London, United Kingdom

Abstract: Hunting in larval zebrafish is an innate behaviour that emerges early during their development. These larvae rely on sensorimotor coordination in order to visually track down and capture moving prey. The developmental mechanisms that lead to the rapid emergence of such robust sensorumotor loops are not known. We have developed a behavioural tracking system that permits detailed analysis of hunting routines and are using this to examine the role of hunting experience in the development of hunting behaviour. Our data suggest that hunting success improves with prior experience while not affecting the probability of engaging in hunting behaviour. These findings provide a basis for probing how the reward associated with the consumption of prey and/or exposure to a natural sensory stimulus (prey) contribute to the development of visuomotor circuits optimized for hunting.

Title: Multiple body maps in newborn macaques

Authors: *M. J. ARCARO, P. F. SCHADE, M. S. LIVINGSTONE
Neurobio., Harvard Med. Sch., Boston, MA

Abstract: Like the visual and auditory systems, somatosensory and motor systems exhibit substantial postnatal plasticity. We previously reported that the entire visual system of neonatal macaques is organized into a series of retinotopic maps that we proposed act as a proto-organization for subsequent postnatal experience-dependent plasticity (Arcaro & Livingstone, 2017, eLife). Here we explored the organization of the neonatal somatosensory system.
We used fMRI of alert infant monkeys to measure responses to tactile stimulation starting as early as 11 days through two years of age. To map representations of the body, we applied tactile stimulation to the face, hands, legs, and body. To map representations of individual fingers, we applied tactile stimulation to each digit.
Even at the earliest timepoint measured, 11 days, somatosensory and motor regions already

comprised several topographically organized representations of the body. Body maps were identified within primary and secondary somatosensory cortex (SI & SII), supplementary motor area (SMA), primary motor (M1), pre-motor (F5), the insula, the putamen, the globus pallidus, and the ventral posterior nucleus of the thalamus. An additional representation of the face was found in posterior parietal cortex within anterior parts of the ventral intraparietal area (VIP). Representations of individual fingers could be mapped in SI and SII. The extent and organization of these body maps were comparable to the organization found in juveniles and older monkeys. We propose that the body-map organizations of the somatosensory and motor systems are present at birth and are the result of self-organizing mechanisms. We speculate that this early architecture provides a scaffolding that supports and constrains the development of neural circuits promoting complex movements and fine tactile abilities.

Title: Neural correlates of dynamic human visual search in cerebral visual impairment using virtual reality simulation

Authors: *C. R. BENNETT[1,2], E. S. BAILIN[1,2], T. K. GOTTLIEB[1], C. M. BAUER[1,2], P. J. BEX[3], L. B. MERABET[1,2]
[1]Massachusetts Eye and Ear Infirmary, Boston, MA; [2]Harvard Med. Sch., Boston, MA; [3]Northeastern Univ., Boston, MA

Abstract: *Background*:
Human visual search of a dynamic visual scene (e.g. finding a person in a crowd) involves many higher-level visual processing brain regions. Developmental complications can impair the function of these visual processing regions and thus impact visuospatial performance. Evidence suggests that individuals with cerebral visual impairment (CVI) often report difficulties identifying an individual in a crowd, particularly at higher crowd densities. However, the neural correlates of impaired dynamic human visual search in this population remain unclear. To investigate this, we developed a virtual reality (VR) environment and fMRI protocol to probe which brain regions may be responsible for impaired visual search performance in CVI.
Methods:

The virtual simulation invokes dynamic visual search by having participants find a target person among varying levels of distractors (i.e. 1 to 30 people) walking throughout a hallway scene. A cohort of individuals with CVI (ages 16-25, M = 19.5) and typically sighted controls (ages 14-28, M = 19.3) underwent behavioral testing and scanning. Behavioral testing was completed using desktop VR and the Tobii 4c eye-tracking system. Functional MRI data were acquired on a 3T Philips Achieva System for each participant.
Results:
Behavioral performance showed marked differences between the control and CVI groups for reaction time and quantified gaze data spread. Individuals with CVI: (1) took longer to identify the correct target, (2) had notably wider search patterns, and (3) exhibited even further impairment of visual search under conditions of higher task complexity, when compared to controls. Imaging data revealed that compared to controls, individuals with CVI demonstrated reduced functional activation in the fusiform face area (FFA), fusiform body area (FBA), intraparietal sulcus (IPS), and other higher visual processing areas. In particular, individuals with CVI show similar activation of the aforementioned visual areas regardless of task complexity, while controls showed increased activation with higher crowd densities. Additionally, a pattern of increased frontal activation was observed for the CVI group at both task complexities compared to controls.
Conclusions:
Current results suggest that individuals with CVI have difficulty performing a dynamic human visual search task. Increasing visual search demands (i.e. greater crowd size) had a more detrimental effect in the CVI group. Functional activation within higher order visual processing areas reflected the observed behavioral deficits. The aggregate of behavioral and imaging outcomes match reported real-world behaviors in the CVI population.

Title: Associations between white matter microstructure alterations and sensorimotor performance in adolescents with prenatal alcohol exposure

Authors: *K. A. UBAN[1], S. BODISON[3], E. KAN[1], E. R. SOWELL[2]
[2]Pediatrics, [1]Children's Hosp. Los Angeles, Los Angeles, CA; [3]Occup. Sci. and Occup. Therapy, USC, Los Angeles, CA

Abstract: Fetal alcohol spectrum disorder (FASD) is completely preventable, yet remains among the top 3 known causes of intellectual disability. Sensorimotor processing is impaired by prenatal alcohol exposure (PAE), and involves neurocircuitries that process sensory input, and then integrate with neurocircuitries to produce motor output. Very little is known about how PAE-related brain alterations relate to sensorimotor impairments with FASD. The present study aimed to fill this gap through examination of white matter microstructure and a sensorimotor battery. Diffusion tensor imaging (DTI) measures restriction of water diffusion known as fractional anisotropy (FA). We hypothesized that PAE would be associated with reduced FA in key sensorimotor circuitries, and would relate to poor sensorimotor performance. 30 directional DTI images were obtained in adolescents with PAE (boys: n=8, mean=11.7±2.5 years; girls: n=5, mean=13.6±2.6 years) and age- and sex-matched non-exposed peers as Controls (n=11) as part of the Collaborative Initiative on Fetal Alcohol Spectrum Disorders at Children's Hospital Los Angeles. Along-tract statistics were utilized to investigate integrity of white matter at specific points along key tracts for sensorimotor processing [bilateral corticospinal tract (CST), Forceps major (Fmaj) and Forceps minor] across boys and girls, controlling for multiple Point by Tract comparisons at $p<0.05$. Sensory processing abilities and fine and gross motor skills were assessed with the Bruininks-Oseretsky Test of Motor Proficiency (BOT-2) and the Sensory Profile 2 Questionaire. Associations between sensory and motor summary measures were examined with summary FA measures of key white matter tracts using Pearson correlations. Mean FA of the left CST ($p<.03$) and Fmaj ($p<.04$) were significantly associated with lower sensory and motor performance in adolescents with PAE, but not Controls. Follow-up analyses demonstrated that mean FA of was significantly associated with poorer balance and bilateral motor control in adolescents with PAE compared to Controls. Results provide preliminary evidence that poorer sensorimotor performance observed among individuals with FASD may relate to alterations in underlying white matter microstructure, specifically within tracts that integrate circuitry across the left and right hemispheres, and coordinate brain-spinal integration. Increased understanding of PAE-related alterations in sensorimotor neurocircuitries could inform future FASD-specific interventions targeted at improving sensorimotor integration in adolescents.

Title: Development of sensory competition in the visual cortex: An fMRI study in school-aged children

Authors: *N. KIM, M. P. PINSK, S. KASTNER
Princeton Univ., Princeton, NJ

Abstract: The visual system is constantly bombarded with too much information to process at once. When multiple stimuli are present at the same time, they are not processed independently, but interact with one another to compete for sensory representation in the visual system (Desimone and Duncan, 1995). The neural mechanisms underlying sensory competition have been extensively studied in nonhuman primates and adult humans, but it remains unclear how such sensory interactions occur in the developing visual system. Here, we investigated competitive interactions among multiple objects in the visual cortex of adults and children (age 6 to 12) by using fMRI in the conceptual framework of biased competition theory. The amount of sensory competition was measured by comparing BOLD responses to multiple stimuli presented either simultaneously or sequentially in the periphery of the visual field. The spatial distance between the objects was also varied in order to modulate the amount of sensory competition as a function of receptive field (RF) architecture across the visual system. In adult participants, competitive interactions were scaled to RF sizes across the visual processing hierarchy, thereby corroborating previous findings. In contrast, in children, we found sensory competition effects in extrastriate areas beyond the RFs, thus including the extra-RF surrounds. These results suggest that, unlike adults, suppressive interactions from the extra-RF surrounds may contribute during development to mediate competition interactions among multiple objects that are simultaneously presented. Since selective attention operates on competitive interactions to filter out distracter information in the adult brain, this sort of filtering mechanism may be implemented quite differently in the developing brain. Future studies will be needed to address this issue.

Title: Signatures of auditory brain maturation and their relation to attention and response inhibition

Authors: *S. VAN BIJNEN[1], T. PARVIAINEN[2]
[1]Univ. of Jyväskylä, Jyväskylä, Finland; [2]Ctr. For Interdisciplinary Brain Res., Jyväskylä, Finland

Abstract: The sequence of brain responses to auditory stimulation are strikingly different in children compared to adults. In short, whereas the adult waveform is typically dominated by the short lived P1-N1-P2 responses, the child waveform is characterized by a peak around 100ms (referred to as P1 in EEG and P1m in MEG recordings) and one robust peak around 250ms after stimulus presentation (N250/N250m or N2/N2m). In primary school children (~6-11y), the emerging N1(m) overlaps in space and time with both the P1(m) and the N250(m). This complicates the separation and extraction of neurophysiological signatures that reflect distinct (auditory) processes, emphasizing the need to include source information in order to study the development trajectory and functional significance of these auditory responses. In this combined M/EEG and MRI study, we recorded auditory responses evoked by sine-wave tones in both active and passive tasks of 6-15 year old children. Source analysis was used to isolate the auditory responses. In the passive task, children were asked to ignore a standard (1 KHz) and deviant tone (1.5 KHz). The active tasks were divided in a detection task (press for deviant tone) and an auditory go/no-go (press for standard tone). Based on previous research we hypothesized an emergence of N100m with age accompanied by a decrease in P50m and N250m. We further anticipated increased N100m and decreased N250m responses in the active tasks compared to passive tasks. The results showed a decrease in P1m and N250m and an increase in N100m with age, as has been found in previous studies. This maturational trajectory is most clear in the right hemisphere; typically the dominant hemisphere for pure-tone processing in adults. Furthermore, in the inhibition task all except the youngest age group show a decrease in right-hemisphere N250m when it signals a need to inhibit your response, compared to the passive task. Conceivably, this neural inhibition can also be achieved by making the processing of the sound relevant for response inhibition. These results suggest that the functional significance of these signatures of auditory brain maturation extend beyond sensory sound analysis to include a broad range of cognitive processes important for everyday functioning.

Title: Effect of in ovo sound stimulation on the development of auditory cortex and hippocampus of neonatal chicks

Authors: *P. KATHPALIA[1], T. C. NAG[1], M. BHAT[1], T. S. ROY[1], S. WADHWA[2]
[1]All India Inst. of Med. Sci., New Delhi Delhi, India; [2]Anat., North Delhi Municipal Corp. Med. Col., Delhi, India

Abstract: Sound exposure during development affects the Central Nervous System at multiple levels. There is an increase in neuronal number and size in brainstem auditory nuclei, auditory cortex and hippocampus in response to *in ovo* rhythmic sound stimulation at 110 dB in chicks. Chicks exposed to *in ovo* rhythmic/arrhythmic sound stimulation at the same sound intensity of 110 dB also show differences in their performance on a spatial memory task. Brain-derived Neurotrophic Factor (BDNF) levels have been found to be altered in central auditory system and hippocampus of the neonatal chicks, but in depth mechanisms are still not clearly known. To understand one such possible underlying mechanism in detail, we decided to study the epigenetic regulation of BDNF in these regions.
Eggs of fertilized white Leghorn chicks (*Gallus g. domesticus*) were exposed to rhythmic (sitar music frequency ranging from 100-4000Hz, serving as enriched environment) /arrhythmic (traffic noise, 30-3000Hz with peak frequency at 2700 Hz) sound stimulation at 110 dB from embryonic day 10 (E10) until hatching. At posthatch day 1, tissue samples were taken from brainstem auditory nuclei, auditory cortex and hippocampus for protein and RNA isolation and for Chromatin Immunoprecipitation (ChIP) to quantify levels of acetylated histone H2B and H4 at the Bdnf promoter region.
In auditory cortex, an increase in the levels of acetylated Histone H4 at the Bdnf promoter was observed in chicks exposed to *in ovo* rhythmic sound, but no changes w.r.t epigenetic marks on the Bdnf promoter were seen in the hippocampus. We further performed a Microarray analysis (Gene Expression Microarray by Agilent Technologies) of hippocampal RNA to look at differential gene expression, and found a total of 65 genes to be up regulated and 117 genes to be down regulated (analysis done by GeneSpring, Agilent Technologies), in the rhythmic sound stimulation group in comparison to the arrhythmic sound stimulation group in the neonatal hippocampus. The GO enrichment analysis revealed genes with GO terms for metabolic

processes, development, differentiation, cell communication, regulation of transcription, and morphogenesis.
Thus, *in ovo* sound stimulation affects epigenetic regulation of a growth factor in the auditory cortex that could explain the increased neuronal number and size. The effect on hippocampus would need to be further elucidated by a systemic evaluation of the results obtained from the microarray data. Further, it is essential to understand the auditory cortex and hippocampus circuitry and connectivity during the development of CNS to gain insights into the effect of *in ovo* sound stimulation on spatial memory.

Title: Xenoplastic transplantation of inner ears reveals conserved afferent targeting and circuit formation in hindbrain vestibular networks

Authors: *C. GORDY[1], B. FRITZSCH[2], H. STRAKA[3]
[1]Dept. Biol. II, Ludwig-Maximilians-University Munich, Planegg, Germany; [2]Dept. of Biol., Univ. of Iowa, Iowa City, IA; [3]LMU Munich - Biocenter Martinsried, Planegg, Germany

Abstract: A major step in the developmental formation of vestibular circuitries is the establishment of specific afferent connections between inner ear organs and functionally matching sets of central vestibular neurons. The diversity and segmental arrangement of the different vestibular phenotypes during ontogeny depends on the combinatorial expression of developmentally regulated genes along the rhombomeric scaffold. This genetic and cellular patterning also promotes and influences the target finding of developing vestibular afferents. Given the genetic conservation of inner ear and hindbrain patterning during vertebrate ontogeny, such connectivity specification might be conserved across distant species. Thus, inner ear afferents from different species should be able to connect, if presented with foreign hindbrain environments. Here, we experimentally tested an adequate establishment of connections between inner ears and the vestibular nuclei following unilateral xenoplastic inner ear transplantations between two distant amphibian species, *Xenopus laevis* and *Ambystoma mexicanum* (Axolotl).

Single inner ear vesicles from both species were removed and reciprocally transplanted to replace the removed ear at comparable embryonic stages. This ear vesicle swap method therefore generates *Xenopus* embryos (stage 33) with a grafted inner ear from an Axolotl (stage 38) donor, and *vice versa*. Following transplantation, manipulated embryos of both species were reared until reaching early larval stages to assess the development of VIIIth nerve afferents and their innervation of the vestibular nuclei. Injections of lipophilic neuronal tracer (NeuroVue) into native and transplanted ears were used to label afferent vestibular projections. Following dye diffusion for 17 hours, bundles of afferent fibers from transplanted and control ears were labeled in both Axolotl and *Xenopus*, respectively. Afferent fiber bundles from grafted and native ears entered the hindbrain in rhombomere 4, bifurcated rostrally and caudally, and innervated the entire longitudinal extent of the vestibular nuclei. This now allows testing the establishment of functional connections between xenoplastic afferents and central vestibular neurons by recording vestibulo-ocular reflexes during natural stimulation at later developmental stages. These results suggest the presence of ubiquitous and species-independent genetic/molecular guidance cues that provide an ontogenetic environment for vestibular afferents that is shared in all vertebrates and allows formation of adequate connections between inner ear organs and central neuronal circuits.

Title: Quantification and localization of carbohydrate sulfotransferase (Chst15) in developing hypothyroid cochlea

Authors: *M. C. TOMPACH[1], D. FORREST[2], D. S. SHARLIN[1]
[1]Biol. Sci., Minnesota State University, Mankato, Mankato, MN; [2]NIDDK, NIH, Bethesda, MD

Abstract: Thyroid hormone (TH) is necessary for proper auditory system development and hearing. The greater epithelial ridge (GER), a transient cochlear structure important in tectorial membrane formation, is remodeled in the early postnatal cochlea and timing of GER remodeling is influenced by TH. In developing hypothyroid cochlea, regression of the GER is delayed which leads to sustained secretion of tectorial membrane proteins and altered tectorial membrane structure. Although it is clear that TH controls GER remodeling, the TH responsive genes that contribute to this phenotype are largely unknown. Through a transcriptional screen performed on

isolated GER cells, carbohydrate sulfotransferase 15 (Chst15) was identified as a potential TH responsive gene in the GER. Chst15 is a type II transmembrane glycoprotein that acts as a sulfotransferase to transfer sulfate to the C-6 hydroxal group of chondroitin sulfate. Interestingly, several studies have localized chondroitin 6-sulfate proteoglycan epitopes to the tectorial membrane. Moreover, Chst15 has been implicated in the deafness associated with headbobber (*hb*) mutant mouse line. Chst15 is one of three genes deleted as a consequence of the insertional mutation. The *hb/hb* mice have a number of inner ear abnormalities including an abnormal tectorial membrane and disorganized hair cell stereocilia. Considering this, we hypothesize that Chst15 is a TH responsive gene and its expression is misregulated in the developing hypothyroid cochlea contributing to the deafness associated with low TH. To test this, hypothyroidism was induced in timed-pregnant dams starting at embryonic day 12.5 (E12.5). Untreated euthyroid dams served as controls. Cochlea from pups were harvested at E16.5, postnatal day (P)1, P5, P10, and P15. Chst15 mRNA was quantified by qRT-PCR and its tissues distribution was mapped using *in situ* hybridization. Our results indicate that Chst15 is developmentally regulated with expression decreasing as development proceeds. Additionally, hypothyroidism delayed the decrease in Chst15 mRNA observed in euthyroid controls. This observation is consistent with the known effect of hypothyroidism on GER remodeling. *In situ* hybridization demonstrated that the expression of Chst15 mRNA is largely restricted to the GER with low levels observed in the other cochlear regions. Based on the reported function of Chst15, these results suggest that Chst15 may play an important role in sulfonating tectorial membrane proteins. Additionally, these results provide some insight in to the cochlear abnormalities associated with low TH.

Title: Early developmental expression of $P2X_2$ and $P2X_3$ purinergic receptors in cephalic tissues of opossums Monodelphis domestica

Authors: *A. BEAUVAIS, J.-F. PFLIEGER
Sci. Biologiques, Univ. de Montreal, Montreal, QC, Canada

Abstract: The P2X cation-channels are a family of ATP-gated purinergic receptors, comprising seven identified subtypes, that are distributed throughout the nervous system. Little is known of their physiological roles in nervous system ontogenesis, such as in mammalian sensorimotor

development. Given its immature state at birth which compares to that of a 13 day rat embryo, we use the opossum *Monodelphis domestica*, a marsupial, as a model to investigate the ontogenesis of sensorimotor systems. A previous study using *in vitro* preparations of newborn opossums has shown that PPADS, a non-specific P2 purinoceptors antagonist, decreases the intensity of forelimb motor responses induced by mechanical stimulations of the face. This suggests that some purinergic receptors may be involved in early sensorimotor transmission. We have used immunofluorescence to investigate the developmental expression of $P2X_2$ and $P2X_3$ in cephalic tissues of opossums aged from one day after birth (P1) to P14. These two receptors were targeted since they are expressed in the brain of embryonic rats and are the most common subtypes on sensory neurons in mature rodents. We found that $P2X_2$ labeling appeared only at P5 in opossums. At this age, it was observed in a small number of cells in the trigeminal ganglia and in several nerve fibers at the periphery of the brainstem. $P2X_2$ labeling remained sparse after P5. In contrast, $P2X_3$ labeling was present in the facial skin (including the ears pinnae) of P1 opossums, where it was observed in the dermis and around growing hairs. Its intensity increased afterwards. Moreover, diffuse $P2X_3$ labeling was present throughout the trigeminal ganglia at all ages studied. In the central nervous system, the whole brainstem showed a strong background labeling at P1 and P5, preventing identification of individual cells. At P9 the labeling was less intense and cells could be identified in some brainstem nuclei and in the cerebral cortex. Our findings suggest that $P2X_3$ purinergic receptors could potentially be involved in physiological mechanisms underlying early sensorimotor functions in opossums, but this is doubtful for $P2X_2$. Pharmacological experiments will be undertaken to better characterize the role of the $P2X_3$ receptors.

Title: Distribution of the mechanically activated channel Piezo2 in the facial skin of developing opossums, Monodelphis domestica

Authors: *J. LAFORGE, J.-F. PFLIEGER
Sci. Biologiques, Univ. de Montreal, Montreal, QC, Canada

Abstract: Marsupials such as opossums of the species *Monodelphis domestica* are born very immature. The newborns use their forelimbs to crawl on the mother's belly and attach to her

nipples to pursue their development. Sensory cues are needed to sustain the locomotor behavior, guide the newborn to the nipple and trigger the attachment. We have demonstrated the presence of numerous nerve fibers from the trigeminal nerve in the facial skin in the newborn and that mechanical pressures exerted on the facial skin provokes forelimb movements, indicating that trigeminal nerve fibers have mechanosensory properties. The stimuli employed may be have been sensed by mechanosensory or nociceptive free endings, and/or by Merkel cells, the latter being epidermal mechanoreceptors. To pursue further this line of study, herein we look at the distribution of Piezo2 in the facial skin of newborn opossums. Piezo2 is a stretch-gated cationic channel that has been shown to be involved in mechanotransduction by Merkel cells and their innervating fibers, at least in mature mammals. 9 opossums aged from one day after birth (P1) to P14 were used for the present study. Each animal was anesthetized by hypothermia until it was unresponsive to stimulation. It was then decapitated and its head fixed by immersion in 4% paraformaldehyde. The head was sectioned transversally with a cryostat and the sections were processed for immunofluorescence using a rabbit polyclonal anti-Piezo2 (Sigma-Aldrich) as a primary antibody. They were then incubated with a secondary antibody, which was conjugated to a fluorophore, and were observed using a microscope equipped for fluorescence. No labeling was found in the facial skin at P1 and P7. At P13-14, labelled cells were observed in the root sheath of numerous hair follicles on the cheeks and the snout, but not in control sections of the same specimens processed without the primary antibody. Labeling was not seen in the cephalic ganglia or the brainstem. From these results we conclude that Piezo2 cannot be involved in the mechanosensory responses of the newborn opossum. The labelled cells expressing Piezo2 in older postnatal opossums may be Merkel cells, which are present on hair follicles in mammals, but this needs to be verified.

Abstract: Dynamic changes in the expression of several neuropeptides during (mouse) brain development have previously been reported, including CCK, NPY and vasopressin. Moreover, several neuropeptides were found to affect typical events in neuronal development, such as mitosis, neuronal survival, sprouting and differentiation, classifying them as neurotrophic factors. However, some caution is warranted when interpreting these data: as the neuropeptides were almost exclusively administered exogenously either *in vivo* or *in vitro*, the observed receptor response may not have been physiological. Still, these early results pointed at a potential role of several neuropeptides as neurotrophic factors. Interestingly, many neuropeptide null mouse lines have demonstrated behavioral changes and even loss of specific neuronal populations, although the absence of a neuropeptide does not necessarily lead to a serious or lethal phenotype, possibly because of redundancy in neuropeptide signalling. In the Galanin-Cre::Tomato mouse we found, surprisingly, Galanin-Tomato^{+} cell bodies in the ventrobasal complex of the thalamus (VB) from P4 onwards, which was confirmed by CUBIC clearing in the adult mouse brain. To confirm endogenous galanin expression we carried out histochemical analyses in the VB. Using radioactive riboprobe and *in situ* hybridization we found low preprogalanin mRNA levels at E18, increased levels at P7, and no expression in the adult, indicating transient expression of preprogalanin mRNA. With immunohistochemistry we detected galanin peptide (and galanin message-associated peptide, GMAP) in cell bodies in VB from P4-14. From P21, only a few galaninergic fibers were found randomly dispersed throughout the VB. In the Galanin-Cre::Tomato mouse, Tomato^{+} fibers were present in barrel cortex, seemingly following the pattern of barrel formation. Weak galanin (and GMAP) labelling was detectable in barrels from P4-14. From P21, galanin was present in scattered fibers throughout the cortex. AAV-GFP injections into VB of Gal-Cre::Tomato mice at P7 showed that galaninergic cells in the VB project towards the barrel cortex. Taken together, our findings indicate a role for galanin in the development of the somatosensory system.

Title: Type III Neuregulin 1 potentiates TrkA signaling in sensory neurons through activation of src family kinases

Authors: *S. LONCAR[1], L. W. ROLE[2], D. A. TALMAGE[3]
[2]Neurobio. & Behavior, [3]Pharmacol. Sci., [1]Stony Brook Univ., Stony Brook, NY

Abstract: During development, nociceptive sensory neurons depend on the neurotrophin nerve growth factor (NGF) for survival. NGF is produced by peripheral target fields of sensory axons and by activating the receptor tyrosine kinase, TrkA, sends a survival signal to the neuronal soma in the dorsal root ganglia (DRG). In the absence of either NGF or TrkA, these neurons undergo axon degeneration and then apoptosis. Genetically blocking apoptosis prevents neuronal cell death, but not axon degeneration. Type III Neuregulin 1 (Nrg1) is also required for the survival of $TrkA^{+}$ sensory neurons. When apoptosis is blocked in Type III $Nrg1^{-/-}$ mice, sensory neuron central projections to the spinal cord are maintained while peripheral projections reach their target fields but eventually retract and degenerate: a phenotype highly reminiscent of NGF and TrkA mutants, as well as mutants lacking the ERK1 and ERK2 in sensory neurons. Based on the similarities between NGF, TrkA, and Type III Nrg1 mutants, I hypothesized that Type III Nrg1 was necessary to achieve optimal levels of NGF-TrkA signaling. In this study, I demonstrate that Type III Nrg1 participates in NGF-TrkA signaling via regulation of Src family kinases (SFKs). I find that DRG neurons from Type III $Nrg1^{-/-}$ embryonic mice have lower levels of active SFK and of ERK1/2 in the absence of and in response to NGF compared to wild type littermates. I show that in embryonic DRG neurons, SFK activity is required for maximal NGF-TrkA activation of the MAP kinase pathway. The convergence of SFK and TrkA signaling on the MAP kinase pathway enhances axon outgrowth. I further demonstrate that Type III Nrg1 forms a complex with Src via a proline-rich SH3 ligand and that Type III Nrg1 can be tyrosine phosphorylated by Src. I show that re-expression of Type III Nrg1 in mutant sensory neurons rescues deficits in axon outgrowth as well as SFK and ERK1/2 activation but expression of a mutant Type III Nrg1 that fails to interact with Src does not rescue these deficits. These results demonstrate for the first time that Type III Nrg1 regulates SFK activity and that regulation by Type III Nrg1 is critical for NGF-TrkA signaling in nociceptive sensory axons during development. Results are from 3 independent experiments and axon measurements were made while blind to genotype.

Title: Onecut transcription factors control the development of sensory neurons in the dorsal root ganglia

Authors: *G. MASGUTOVA, A. HARRIS, F. CLOTMAN
Lab. of Neural Differentiation, Univ. Catholique De Louvain, Brussels, Belgium

Abstract: Without sensory neurons, one could perceive neither touch, cold, limb movements or spatial position nor pain. Three major classes of sensory neurons, in cranial or dorsal root ganglia (DRG), enable to sense and distinguish these stimuli. Their differentiation is characterized by the early expression of tyrosine kinase receptors for neurotrophic factors (Trk). Small diameter TrkA+ neurons are activated by noxious stimuli, medium diameter TrkB+/C+ neurons are mechanoreceptors and large diameter TrkC+ neurons convey proprioceptive information. Transcription factors of the Onecut family, namely OC-1 and OC-2, are present in sensory neurons during embryonic development. To assess the roles of these factors during DRG development, we phenotypically analysed mouse embryos mutant for the Onecut genes from embryonic day e10.5 to e16.5.
We observed that DRG sensory neurons devoid of Onecut factors showed a decrease in the number of TrkA+ sensory cells at developmental day e10.5. However, the number of TrkA+ cells rapidly normalized, suggesting a delay in TrkA expression onset. In addition, we observed an increase in TrkB+/TrkC+ coexpression resulting from a higher proportion of TrkB+ cells. From e14.5, this imbalanced expression of TrkB/C normalized and reached a distribution similar to that of control littermates. To identify the cause of these defects, we assessed cell proliferation and death in the developing DRG. Our preliminary data suggest alterations of proliferation and of apoptosis of sensory neurons in Onecut mutant embryos. Hence, our observations demonstrate that Onecut proteins are involved in the differentiation of sensory neurons and may control the onset of Trk expression.

Title: Mapping function-related epigenomes in mouse dorsal root ganglia neurons

Authors: *C. QIAN[1], Q. LI[2], X. WANG[3], C. ZHANG[3], T. LIN[3], A. KOSANA[3], B. C. DONG[1], F.-Q. ZHOU[4]
[1]Orthopedic Surgery, JHMI, Baltimore, MD; [2]Orthopedic Surgery Dept., Johns Hopkins Hosp., Baltimore, MD; [3]Neurosci., Johns Hopkins Univ., Baltimore, MD; [4]Orthopedic surgery and Neurosci, Johns Hopkins Univ. Sch. Med., Baltimore, MD

Abstract: The mammalian sensory neurons with somas in the dorsal root ganglia (DRG) branch axons into CNS and PNS. DRG neuron serves as a prevailing model for studies of neurodevelopment, neuropathy and particularly axon regeneration. The peripheral branch of DRG neurons can regenerate axons after injury, but the CNS end cannot. Intrinsic regenerative capacity related to gene transcription has garnered growing interest after a study showing that preconditioning PNS-end lesion can promote axon regeneration at the CNS end. In fact, early studies using microarrays and recent whole-genome sequencing at the single-cell level revealed that various genes especially some regeneration-associated genes (RAGs) changed in DRG neurons after sciatic nerve axotomy. These RAGs are associated with cellular functions including metabolism, protein synthesis, axonal trafficking and cell death. Such widespread transcriptional alterations suggest that the axon regeneration in the PNS is coordinated by various categories of genes. In addition, even though developed DRG neurons in adult mammalians can reactivate axon regeneration after injury, DRG neurons still show a developmental decline in the regenerative capacity, which suggests a step-wise closure of regenerative transcriptional programs along the developmental stages. All of these suggest that the intrinsic capacity of DRG neuron axon regeneration is a reflection of specific favorable chromatin architecture that allows a whole set of RAGs to be accessed and transcribed. Indeed, emerging evidence has demonstrated the role of histone posttranslational modification and DNA methylation in DRG neuron axon regeneration. For next step of the study, several unbiased deep-sequencing-based epigenome mapping techniques are suitable for further dissecting the mechanisms in detail. However, the heterogeneity of cells in the DRG challenges such study. The non-neuronal DRG cells (>50%), particularly the satellite glia tightly adhering to somas of DRG neurons and migrated macrophages have been shown to undergo epigenetic alterations as indirect responses to nerve injury. With the elimination of these interferences, we are analyzing how TFs, histone markers and regulators influence the widespread transcriptional programs in DRG neurons during processes including but not limited to neurodevelopment, nerve injury and axon regeneration. These data will help to obtain insights into some unique and useful properties of DRG neurons regarding the epigenetic regulation. With the full potential of such method, we should be able to obtain some knowledge regarding the intrinsic properties of various subtypes of DRG neurons.

Title: Morphological and electrophysiological development of rat spinal substantia gelatinosa neurons

Authors: *J. WU[1], S.-C. PENG[1], H.-X. KUANG[1], D.-Y. ZHANG[2], L.-M. CHEN[1], L.-L. XU[1], T. LIU[2]

Abstract: Aim:Spinal lamina II, also known as substantia gelatinosa (SG), consists of a heterogenous population of neurons that process incoming sensory signals before information ascending to the brain. Previous study shows developmental changes in electrophysiological properties of superficial dorsal horn neurons from P0-5 and P24-45 mice (Tadros et al., 2012), but the neuroanatomical basis for these changes is not known. Moreover, the prevalence of many types of chronic pain peaks in midlife (Gagliese et al., 2000), suggesting the necessity to expand the ages to middle-aged animals in developmental research. Methods:Four age groups of male and female Sprague-Dawley (SD) rats were recruited: neonate (aged 7 days), juvenile (aged 3 weeks), young adult (aged 6-8 weeks) and middle-aged (8-12 months). Whole-cell patch-clamp recordings were performed to record the electrophysiological properties of SG neurons from acute parasagittal lumbar spinal cord slices. Morphological properties of neurobiotin-filled SG neurons were observed under a confocal microscopy. Results:Altogether, 381 SG neurons from neonate (n = 129 cells), juvenile (n = 124 cells), young adult (n = 94 cells) and middle-aged (n=34 cells) rats were used for morphological analysis. Four major cell types based on their morphology were identified: islet, central, radial, and vertical cells. The proportions of islet and central neurons were significantly increased in young adult group compared to neonatal rats. However, we observed a decrease of them in middle-aged group compared to young adult group. In contrast, the percentages of vertical and radial neurons were dramatically decreased in middle-aged group compared to neonatal group. Furthermore, the densities of spine and bouton exhibit highest level in juvenile and adult groups, respectively. Based on the electrophysiological data, seven firing patterns of SG neurons were observed: tonic-firing, delayed-firing, single-spike, initial-burst, phasic-bursting, gap-firing, and reluctant-firing. The percentage of tonic-firing was

highest in neonates compared to other age groups. In addition, the proportion of sub-threshold currents, such as hyperpolarization-activated inward currents (I_h) and A-type potassium currents (I_A), were highest in juvenile and adult groups, respectively. Conclusions:Our results demonstrate age-dependent morphological and electrophysiological changes in SG neurons. These structural and functional differences may have important implications that contribute to age-related pain behaviors.

Title: Hypothalamic inflammatory and barrier changes in rodent offspring born of females following surgical weight loss

Authors: *R. A. SPANN, C. A. ZAMARRIPA, N. ARAVINDAN, B. DUNCAN, B. E. GRAYSON
Univ. of Mississippi Med. Ctr., Jackson, MS

Abstract: Surgical weight loss has a positive impact on reproductive capabilities of women in addition to effectively treating obesity and diabetes. Despite improvement in maternal health, offspring of mothers who have had bariatric surgery may be born small-for-gestational age and are consequently at a much greater risk of metabolic disease as adults. The etiology of this relationship remains unknown. We have previously shown in a maternal rat model of vertical sleeve gastrectomy (VSG) greater permeability of the placental barrier, elevated inflammatory signaling, and higher incidence of apoptosis in the placenta. In the present study, we investigate outcomes in postnatal day (PD) 22 and 110 pups, measuring molecular and cellular changes in the hypothalamus. Here there is an increase in hypothalamic interleukin 1 beta mRNA (IL1B) expression in PD22 pups born to VSG dams when compared to pups from sham operated dams. Immunohistochemical detection of IBA1 positive microglia in the paraventricular nucleus of the hypothalamus shows reduced staining density in VSG pups with no impact on astrocyte density. We also report reductions in endothelial marker, RECA, in the arcuate nucleus of the hypothalamus in VSG pups in comparison to controls suggestive of altered capillary density. Finally, these are accompanied by reductions in TJP (tight junction protein) mRNA and increased claudin 5 mRNA expression in PD22 hypothalamus of VSG offspring. In PD110 female VSG offspring, we report increased expression of hypothalamic IL1B and IL6 mRNA in comparison to Sham offspring; these mRNA changes were not evident in male VSG offspring.

These results show that maternal VSG has effects early postnatal and long-term inflammatory and barrier function of the hypothalamus. Future work will determine if these changes are responsible for impaired metabolic control and weight gain.

Title: A comparative analysis of the visual system in two whale species

Authors: *M. A. SMITH[1], E. S. PLYLER[1], J. C. GEORGE[4], J. THEWISSEN[2], S. D. CRISH[3]
[2]Anat. and Neurobio., [3]Pharmaceut. Sci., [1]Northeast Ohio Med. Univ., Rootstown, OH; [4]Dept. of Wildlife Mgmt., North Slope Borough, Barrow, AK

Abstract: The whale visual system is a product of unique selection pressures, yet relatively little is known about it across taxa. We examined the general organization of retinas and optic nerves from beluga and bowhead whales in comparison to related terrestrial animals. The beluga retina presents with thinner synaptic and nuclear layers compared to the bowhead and other artiodactyls. While this “compression” could be attributed to a reduced density of cells and synaptic connectivity in most layers, the thin photoreceptor layer in the beluga is directly attributed to short outer segments. In the bowhead whale, previous reports indicate the absence of cone outer segments retina, we have histological data suggesting that a population of cone photoreceptors retain their outer segment. Comparing the ganglion cell layers, both the beluga and bowhead reveal smaller cell density in this layer with large, often displaced retinal ganglion cells predominating. Optic nerve analysis further reveals a greater density of larger caliber axons in these animals. These unique anatomical features will be discussed as it relates to particular challenges in whale vision.

Title: Novel role for mineralocorticoid receptors in the development and maintenance of hippocampal area CA2 pyramidal cell phenotype

Authors: K. E. MCCANN, D. J. LUSTBERG, K. E. CARSTENS, *S. FARRIS, E. K. SHAUGHNESSY, M. ZHAO, G. M. ALEXANDER, S. M. DUDEK
NIEHS/NIH, Research Triangle Park, NC

Abstract: In the brain, glucocorticoid (GR) and mineralocorticoid (MR) receptors mediate behavioral and physiological responses to stress. In the adult mouse hippocampus, the distribution of GRs and MRs is subregion-specific, with the highest MR:GR mRNA ratio being in area CA2 ($F(3,8)=40.51$, $p<0.0001$). In addition to the striking MR:GR ratio, CA2 pyramidal neurons exhibit a unique pattern of gene expression that tightly regulates synaptic plasticity, further distinguishing it from its hippocampal neighbors. MRs are expressed in the embryonic hippocampus and may be one of the earliest markers for CA2. Although much is known about MR function in stress response, the biological significance of this early and concentrated MR expression in CA2 remains unknown. Thus, the goal of the current study was to investigate the role of MRs in the development and maintenance of CA2 molecular and cellular identity, including its distinct plasticity phenotype. Using immunofluorescence, we assessed whether CA2 pyramidal cell phenotype was changed by neuronal MR deletion. Indeed, we found that the expression of several of the molecules that make CA2 molecularly distinct, including RGS14, PCP4, and NECAB2, were reduced, regardless of whether MR deletion occurred embryonically (Nestin-Cre; whole brain neuronal MR knockout), postnatally, after postnatal day 4 (Amigo2-Cre; CA2-specific MR knockout), or in adulthood (virally expressed Cre in CA2). Interestingly, several CA1 markers, such as GR and WFS1, increased in the CA2 region after MR deletion, indicating that not only did the CA2 molecular phenotype disappear, but that CA2 took on a CA1-like phenotype. These results indicate that the genes that make CA2 molecularly distinct are under direct or indirect transcriptional control of MR. In addition, mRNA analysis of whole hippocampal extractions confirmed the results from our protein analysis and further revealed several stress-related genes that were also differentially expressed between Cre-negative and Cre-positive animals, including *Fkbp5*, which is normally highly expressed in CA2. Lastly, this loss of MR, and/or the resulting disruption of CA2 gene expression, enabled synaptic potentiation of the normally LTP-resistant synaptic currents in CA2 stratum radiatum. Together,

these results indicate MRs are critical for the development and maintenance of CA2 cellular phenotype. This novel role of MRs provides additional insight into their potential role in regulating CA2-mediated stress responses, including social behavior and aggression.

Informatics and Clin. Epidemiology, Oregon Hlth. Sci. Univ., Portland, OR; [8]Marcus Autism Ctr., Atlanta, GA; [9]Dept. Psychiatry, Univ. of North Carolina, Chapel Hill, NC

Abstract: Primate infants develop critical social and emotional regulatory skills as they transition from dependence on their mothers to increased exploration and social interactions with peers during weaning. However, we still do not understand the underlying neurobiological processes. The goal of this study was to characterize the developmental changes of brain networks underlying socioemotional regulation, focusing on the structural and functional maturation of the amygdala (AMY) and its functional connectivity (FC) with prefrontal cortex (PFC) in infant rhesus monkeys. Structural and resting-state functional MRI (rsfMRI) scans were acquired longitudinally (at 2, 4, 8, 12, 16, 20 and 24 weeks - equivalent to 2 years in humans) in 16 male infant macaques living with their mothers in complex social groups. Structural T1- and

T2-MRI, and BOLD contrast sensitive rsfMRI scans were acquired using a 3T MRI scanner under isoflurane anesthesia. Developmental volume growth of AMY and PFC (gray + white matter) in relation to total brain growth (measured as intracranial volume -ICV-), and changes in AMY-PFC FC were analyzed throughout infancy using repeated measures ANOVA and network analysis. The potential confounding effect of anesthetics on FC was controlled for by adding anesthetic levels as covariates in the statistical models. Our results indicate that AMY volume sharply increases between 4-8 and again between 16-20 weeks, whereas the PFC volume sharply increases up to 4 months of age. After correcting the data with ICV, the proportion of the AMY increased, but the PFC decreased by age. The fast structural growth of AMY could support the sharp increase in positive FC between AMY and dorsolateral PFC regions (dlPFC: BA9, BA46), which contrasts with increased negative coupling between AMY and orbitofrontal cortex (OFC: BA11, BA13) observed after 8 weeks of age. Interestingly, AMY and medial PFC (mPFC: BA14, BA24, BA25, BA32) FC remained unchanged during the first 6 months of life, with some areas, such as the anterior cingulate (BA24), already showing positive FC with AMY soon after birth. Network analysis confirmed the PFC region-specific FC developmental patterns. Thus, AMY and PFC undergo drastic changes during the first 6 months of life and AMY-PFC circuits critical for social and emotional regulation become more strongly connected during infancy, with PFC region-specific developmental trajectories. These dynamic maturational changes in structure and AMY-PFC FC during the first 6 months of life probably tune the development of cortical brain regions and drive the transition to independence from the mother towards social interactions with other members of the group.

Title: The role of kainate receptors in the development of amygdala internal glutamatergic circuit in neonatal rats

Authors: *M. RYAZANTSEVA[1], J. E. ENGLUND[2], A. SHINTYAPINA[2], S. E. LAURI[2]
[1]Helsinki Univ., Helsinki, Finland; [2]Univ. of Helsinki, Helsinki, Finland

Abstract: Kainate-type glutamate receptors (KAR) have been linked to several developmentally originating CNS disorders related to dysfunction of the limbic areas, including mood and anxiety disorders, autism and schizophrenia. Despite the prospective clinical importance, nothing is known on the physiological functions of KAR in the developing amygdala. Here, RT-qPCR and in situ hybridization measurements were performed to characterize the expression pattern of KAR subunits in the amygdala during early postnatal development. The data obtained demonstrate KAR subunits and in particular, GluK1, GluK2 and GluK5 are highly expressed in the BLA and CeA during the first week of life in rodents. Whole-cell patch-clamp recordings of miniature EPSCs at different stages of postnatal development demonstrate that this time period coincides with an abrupt increase in functional glutamatergic inputs to basal and central amygdala. The contribution of KAR to transmission at the immature glutamatergic synapses was studied using selective pharmacological tools to manipulate KAR function during electrophysiological recordings. The synapses development was analyzed with confocal imaging of spines in amygdaloid nuclei at different ages. In addition, shRNA knock-down of KARs in the lateral amygdala was performed in vivo to investigate the role of KAR in the development of glutamatergic circuits between amygdaloid nuclei. The data obtained support that tonically active presynaptic KARs regulate glutamate release and development of the intra-amygdaloid connectivity during early postnatal development. Additional experiments with whole-cell recordings and pharmacological manipulations with signalling molecules demonstrated that KARs regulate presynaptic function by affecting activity of voltage-gated calcium channels.

Abstract: The amygdala has an essential role in emotional learning. Abnormal development of this region has been linked to autism, mood and anxiety disorders. The paralaminar amygdala contains multiple nuclei with a high density of cells and is prominent in primates including humans but not present in rodents. It has been hypothesized that the paralaminar nuclei have postnatal plasticity and possibly continued neurogenesis. We studied the development of this region in postmortem and intraoperative human brain samples from fetal, infant, childhood, adolescent, and adult ages. At fetal stages, a high density of young neurons was present in this region of the amygdala, next to the caudal ganglionic eminence. In early postnatal samples (birth to 5 months) we found dividing Ki-67+SOX2+ and Ki-67+OLIG2+ cells within the paralaminar amygdala. After 2 years of age, Ki-67+ cells within this region were rare. Most of the DCX+PSA-NCAM+ neurons within the paralaminar amygdala had round nuclei and multiple long processes and none were Ki-67+. The density of cells within the paralaminar amygdala decreased progressively between 5 months and 77 years of age with a parallel increase in neuropil. The percentage of small DCX+PSA-NCAM+ neurons decreased in this region with age whereas the percentage of large mature NeuN+DCX- neurons increased with age. Interestingly, some small neurons in this region continued to express DCX and PSA-NCAM at 67 and 77 years. Although Ki-67+ cells were rare in the paralaminar amygdala after 2 years of age, DCX+PSA-NCAM+ neurons were observed in all ages studied. This protracted neuronal maturation in the human paralaminar amygdala may be a substrate for plasticity and emotional development in children and adults.

Abstract: The Medial Amygdala (MeA) regulates innate and social behaviors involved in reproduction and defense, essential for survival and the preservation of the species. These behaviors are largely hardwired across species. Here, we are investigating the developmental programs for establishment of innate behavioral circuits, focusing on MeA formation and function. Our previous results showed that different embryonic progenitor pools of cells contributing to the developing MeA can be identified by the non overlapping expression of the transcription factors *Dbx1*, *Foxp2* and *Otp* (Hirata et al., 2009; Carney et al., 2010; Lischinsky et al., 2017). We further found that the embryonic identity of these progenitor populations predicted neuronal identity and innate behavioral activation patterns in adult mice. We are currently exploring the identity of Foxp2 and Dbx1 cell subpopulations across developmental time and in males and females and the mechanisms by which they may regulate innate behaviors. Using FACs sorting and RNA-seq of Foxp2 and Dbx1 positive cells in the MeA at different embryonic stages in mice, we identified differential sets of co-expressing genes. We further find that these developmentally defined subpopulations respond to different neuromodulators and neurohormones. We are further investigating social and innate behaviors in Foxp2 mutant mice. Thus, Foxp2 and Dbx1 neuronal subpopulations in the amygdala may activate different biological pathways to regulate social and innate behaviors, which may also shed light on understanding amygdala-linked developmental disorders such as autism.

Abstract: Chronic psychosocial stress is associated with psychopathology in children and comorbid with consumption of highly caloric diets that pose a cumulative risk factor for obesity. It is not well understood, though, how neurobehavioral alterations caused by social stress emerge during development and interact with other risk factors, such as obesogenic diets. Here we examined the potential synergistic impact of social stress and an obesogenic diet on infant and juvenile brain development longitudinally and the biological mechanisms involved, using a translational macaque model of social subordination stress. Thirty-eight socially-housed rhesus monkey mother-infant pairs (n=19 dominant (DOM), n=19 subordinate (SUB)) were randomly assigned to either a low-calorie diet (LCD) condition, or had access to both LCD and high-calorie diet (HCD) from birth (Choice). Food intake was recorded continually using automatic feeders and radio-frequency identification (RFID) chips implanted in subjects' wrists. Brain structural MRI data was collected during infancy (2 wks, 6 mo) and in the juvenile period (16 mo). Morning plasma and hair cortisol were analyzed at the same ages to examine stress- and diet-induced activations of neuroendocrine stress systems.
At both 6 and 16 mo, subjects with access to the obesogenic diet showed greater cumulative Kilocalorie consumption and larger overall brain (ICV) volumes, which by 16 months was driven by increases in both white matter and gray matter, but not CSF, volumes. Interestingly, higher Kcal consumption did not predict bigger brain volumes, suggesting that the differences between the Choice and LCD juveniles may be better explained by qualitative differences in the nutrient composition between both diets.
Regarding the effects of social status, by 6 months SUB animals had larger amygdala and hippocampus volumes and these effects persisted at 16 mo, suggesting that early neurodevelopmental effects of social subordination are already detected during infancy and are long-lasting. The only SUB effects detected in prefrontal cortex were smaller CSF volumes at 16 mo.
With respect to cortisol concentrations, animals in the Choice diet condition showed higher levels than those in the LCD condition at 6 mo, which predicted larger right amygdala volumes. Ongoing analysis of the 2-wk data will provide a baseline from which to further examine the longitudinal volumetric effects of diet and social status during development.
These findings suggest that exposure to social subordination and obesogenic diets early in life impacts primate infant structural brain development, resulting in region-specific, not synergistic effects.

Title: Amygdala nuclei composition across adolescence using a high-resolution probabilistic atlas

Authors: *C. E. CAMPBELL[1], A. F. MEZHER[1], J. TYSZKA[2], W. M. PAULI[3], B. J. NAGEL[4], M. M. HERTING[1]

Abstract: The amygdala is a hormone receptor dense heterogeneous structure that functionally connects to the striatum, hippocampus, and prefrontal cortex to regulate affective emotion and cognitive function. Current non-invasive studies are trying to understand the relative volume of theses nuclei and the role each play in the amygdaloid complex. The goal of this study was to examine how age, sex, body mass index (BMI), and pubertal stage relates to the relative volume fraction (RVF) of 9 nuclei regions of interest (ROIs) in the amygdala. Whole-brain T1-weighted magnetic resonance imaging scans were acquired on typically developing youths (N=438), age 10-17 years. Probabilistic amygdala labels were generated per hemisphere for each subject, using a new in vivo high-resolution amygdala atlas (CIT168). Probabilistic volumes were calculated, and RVF to total amygdala volume were computed for each ROI. Generalized additive models were used to assess how age, sex, BMI, pubertal stage, and their interactions were associated with amygdala composition. They were corrected for multiple comparisons (Bonferroni $p < 0.0027$). Results showed that females have a larger proportion of their amygdala dedicated to the left central nucleus (CEN) and bilaterally to the amygdalostriatal transition area (ASTA) (R^2 = 4.64-9.71%). In addition, males show bilaterally larger basolateral ventral and paralaminar (BLVPL) subdivision and amygdala transition areas (ATA) (R^2 = 9.35-13.8%) at age 10, but sex differences converge at age 17. Associations with BMI and pubertal stage were observed in select regions, but did not survive multiple comparison corrections. The ASTA projects to the striatum and may be involved with emotional motor reflexes, whereas the adjacent CEN is a primary recipient of internal amygdala connections and - projects to the brainstem, bed nucleus

of the stria terminalis and hypothalamus, to regulate autonomic responses to emotional stimuli. Our finding of a larger CEN in females is consistent with previous research showing females to have a greater physiological response to negative stimuli than males. After receiving afferents from the lateral nucleus and hippocampus, the BLVPL gradually merges with the periamygdaloid cortex (included in the ATA ROI). Moreover, the number of immature neurons in the PL increases with age across postnatal development and is hypothesized to be involved in fear learning. Thus, more research is needed to determine if the current BLVPL and ATA findings may relate to the development of other emotional regulation processes, such as the functional coupling of the amygdala and medial prefrontal cortex that also begins to develop around age 10.

Title: Structural differences in amygdalae nuclei in children with classical congenital hyperplasia

Authors: *M. M. HERTING[1], M. CANALES[1], A. MEZHER[1], M. PARKER[2], M. E. GEFFNER[3], M. S. KIM[3]

Abstract: Naturally occurring clinical neuroendocrine conditions are vital in bridging knowledge between animal models and healthy humans regarding the role of hormones in amygdala development. Classical Congenital Adrenal Hyperplasia due to 21-hydroxylase deficiency (CAH) is a primary adrenal disorder in which children cannot make adequate amounts of cortisol and aldosterone, yielding excess testosterone during fetal development. Previous research suggests that, compared to matched controls, children with CAH have smaller total amygdalae volume. Although the amygdala is comprised of multiple nuclei with heterogeneous functions and distinct histology, it remains unknown which amygdalae nuclei are distinctly altered in CAH affected youth. The aim of the current study was to examine group differences in

amygdala subnuclei in 9 children with classical CAH (4 female, age 10.62±1.44) compared to 10 age- and sex-matched controls (3 female, age 10.36±1.82). Using T1 and T2 3D structural MRI scans, FreeSurfer v6.0 and amygdala segmentation module were used to quantify total amygdala volumes, as well as volumes of bilateral nuclei including the lateral nucleus, basal nucleus, accessory basal nucleus, anterior amygdaloid area, medial nucleus, cortical nucleus, cortico-amygdaloid transition, and paralaminar nucleus. ANCOVAs were used to examine group and hemisphere differences in total amygdala volumes, while controlling for intracranial volume (ICV). A linear mixed effect model was then performed to investigate group differences in nuclei, with subject as the random factor and controlling for ICV. A significantly smaller total amygdala volume was seen in CAH patients compared to controls [F (1/16)=10.37, p=0.005; partial eta^2=0.23], as well as group differences in amygdala subregions (Likelihood Ratio=34.26, p=0.0001), with CAH children having significantly smaller basal (t=2.88, p=0.0045) and lateral (t=3.45, p=0.0008) nuclei. This study not only replicates previous findings of smaller total amygdala volumes in children with CAH vs controls, but also extends these findings to suggest that basal and lateral nuclei of the amygdalae are smaller in CAH children. Together, the basal and lateral subregions are known to be vital to acquisition and extinction of emotional learning, and thus, may be related to reported alterations in amygdala activity and greater internalizing and externalizing problems in children with CAH. Ongoing research is examining how these structural differences may be associated with hormone imbalances inherent to CAH and/or its glucocorticoid treatment.

Title: For adolescent rats, periodic environmental enrichment affects hippocampal c-FOS expression evoked by an acute enriching experience

Authors: *M. PAVELKA[1], S. L. SANTIAGO[2], P. M. CLAYTON[2], E. B. TURNER[2], M. R. WOOD[2], C. T. FENNELL[2], M. C. ZRULL[2]

Abstract: The opportunity for unsupervised interaction with novel objects and same-sex conspecifics in a unique setting, which is often known as environmental enrichment (EE), can have a lasting impact on brain and behavior. More specifically, EE can alter neural activity across hippocampal formation (HF) circuits affecting spatial learning and memory as well as

promoting other informal learning and memory consolidation. We investigated the extent of evoked activity among HF neurons following periodic and/or acute EE exposure in adolescent rats. Twelve Long-Evans rats were exposed to periodic EE between postnatal days (pnd) 25 and 48 and 12 controls were not. During 90-min, daily EE sessions, same-sex enriched rats were placed into enclosures with ramps, platforms, and objects, which were changed each day. Control rats were not enriched but were handled, and all rats lived in same-sized, same-sex groups. Prior to sacrifice on pnd 49, 6 enriched (EE+EE) and 6 control (No+EE) rats experienced a final, acute EE session and other rats did not (EE+No, No+No, n=6 each). Brain tissue was processed using floating section immunohistochemistry to visualize the neural activity marker c-FOS, and activated neurons were quantified in HF regions using digital microscopy and stereological technique. For rats without EE history, a final, acute EE exposure produced more c-FOS+ neurons in dentate gyrus (DG, +103%), a major input region of the HF, internal processing regions, CA3 (+172%), CA2 (+136%), and CA1 (+183%), and in subiculum (Sub, +164%), a major output region of the HF (all $p<.02$). Periodic EE exposure lessened the effect of an acute EE session on evoked neural activity: DG, -17%, CA3, -43%, CA2, -47%, CA1, -64%, and Sub, -41% (all $p<.02$ except DG, $p>.30$). HF neural activity did not differ between rats with and without periodic EE exposure without a final EE session. The data suggest a history of EE experiences does not necessarily alter input available to the HF, via DG activation, during an acute enriching experience. However, periodic EE during adolescence does appear to reduce activation evoked by acute EE as neural signal moves sequentially through the HF. While periodic enrichment during adolescence may or may not habituate animals to novelty, it may make processing of current information by the HF more efficient and impact other opportunities that require learning and memory formation

Title: For adolescent rats, acute, but not periodic, environmental enrichment affects c-FOS expression in the amygdala

Authors: *C. FENNELL[1], C. A. PEGGS[2], C. E. GAILLARD[3], A. PEREZ[2], S. L. SANTIAGO[2], M. C. ZRULL[2]
[2]Psychology, [3]Interdisciplinary Studies, [1]Appalachian State Univ., Boone, NC

Abstract: Adolescent rats like many mammals, exhibit greater response to novelty and are more likely to engage in risky behavior than adults. For adolescents, environmental enrichment (EE) can provide sensory and motor stimulation as well as opportunity to interact with same-sex conspecifics. An EE experience can evoke behavioral responses to an emotionally arousing situation, which impacts brain development of adolescents who often make decisions based on emotions and novelty. In this study, we examined how periodic and/or acute EE might evoke neural activity in lateral (LA) and basolateral amygdala (BLA) given the relative importance of these structures in learned and unlearned emotional response as well as the evaluation of social cues. Eleven Long-Evans rats were exposed to periodic EE between postnatal days (pnd) 25 and 48 and 10 controls were not. During 90-min, daily EE sessions, same-sex enriched rats were placed into enclosures with ramps, platforms, and objects, which were changed each day. Control rats were not enriched but were handled, and all rats lived in same-sized, same-sex groups. Prior to sacrifice on pnd 49, 6 enriched (EE+EE) and 5 control (No+EE) rats experienced a final, acute EE session and other rats did not (EE+No, No+No, n=5 each). Brain tissue was processed using floating section immunohistochemistry to visualize the neural activity marker c-FOS, and activated neurons were quantified in LA and BLA using digital microscopy and stereological technique. Regardless of periodic EE history, an acute EE session evoked 68% more c-FOS+ neurons in LA and 40% more c-FOS+ neurons in BLA of rats than observed in brains of animals without a final acute EE experience (both $p<.05$). For rats not experiencing a final EE exposure (i.e., EE+No vs. No+No), a history of periodic EE did not produce differences in neural activation in LA or BLA (both $p>.25$). More evoked activity was observed in posterior BLA (pBLA, 70%) than anterior BLA (aBLA, 30%) in all groups except the EE+EE group in which about 50% of c-FOS+ neurons were observed in both pBLA to aBLA. As expected, the data suggest that novelty exposure and emotional response elicited through an EE experience enhances amygdala activity as compared to a baseline. The greater discrepancy between EE-evoked and baseline activation of LA neurons in comparison to BLA neurons may be due to the former's role as the primary target for converging amygdala inputs and acquisition of emotional memory in comparison to the output and behavior-directing role of BLA. Finally, less evoked activity in BLA may also reflect the social behavior inherent to the enriching experience provided in this study.

Title: Epigenetic transmission of enhanced response to nicotine in the neonatal quinpirole model of schizophrenia

Authors: *W. D. GILL[1], M. J. CHANDLEY[2], L. J. HERNANDEZ[3], W. S. WHICKER[1], C. L. KAESTNER[2], K. C. BURGESS[2], R. W. BROWN[2]
[2]Biomed. Sci., [3]Psychology, [1]East Tennessee State Univ., Johnson City, TN

Abstract: Schizophrenia is a neurological disorder found in approximately 1% of the population. It is estimated that as many as 88% of individuals diagnosed which schizophrenia smoke tobacco, a rate which is increased compared to the general population. Delineation of the biomolecular mechanisms which result in a higher propensity for smoking in vulnerable population may lead to new treatment options. This study investigated the effects of nicotine in an epigenetic transmission model of schizophrenia. Rats were ip administered quinpirole (dopamine D2/D3 agonist) from postnatal days (P)1-21, which results in an increase of D2 receptor sensitivity, and this rodent model has been established to demonstrate face, content, and predictive validity towards schizophrenia. These neonatally treated rats were then bred to produce pups which were not neonatally treated to investigate whether schizophrenia-like symptoms, such as enhanced responding to nicotine, would be transmitted to the untreated offspring of the quinpirole-treated parents. To examine the effects of nicotine in this f1 generation, the rats that were the offspring of animals neonatally treated with quinpirole were behaviorally tested on either a nicotine behavioral sensitization or a nicotine conditioned place preference (CPP) paradigm during adolescence. Following behavioral testing, brain tissue was analyzed for brain-derived neurotrophic factor (BDNF) in the nucleus accubmens, a brain area that is critical to dopaminergic activity that underlies behavioral sensitization and CPP. Additionally, PCR was performed to examine genetic expression of rgs9, a protein that regulates D2 signaling, in the nucleus accumbens. Results revealed that these offspring demonstrated a heightened behavioral sensitization to nicotine, enhanced CPP to nicotine as well as increased accumbal BDNF protein and altered expression of accumbal rgs9 RNA following nicotine administration if at least one parent rat was neonatally treated with quinpirole. These results show that the offspring of rats neonatally treated with quinpirole likely have altered dopaminergic systems in the brain which may indicate a vulnerability to addiction.

Title: Tumor necrosis factor-alpha modulation results in alleviation of prepulse inhibition deficits and reduction in microglial cell activation produced by neonatal polyinosinic:polycytidylic acid treatment in rats

Authors: *H. W. SHELTON[1], W. D. GILL[1], K. C. BURGESS[1], P. GABBITA[2], R. W. BROWN[1]
[1]Dept. of Biomed. Sci., East Tennessee State Univ., Johnson City, TN; [2]P2D Biosci., Blue Ash, OH

Abstract: Schizophrenia (SZ) is a debilitating neurocognitive disorder that is treated through the use of antipsychotic medications. However, antipsychotic treatment leads to severe dose-dependent side effects. Therefore, there is a need for new adjunctive drugs that reduce the required effective dose of antipsychotics. Previous studies have shown increased neuroinflammation localized in the prefrontal cortex (PFC) and hippocampus (HPC) in individuals diagnosed with SZ. This is largely due to the interaction the pro-inflammatory cytokine tumor necrosis factor-alpha (TNFα) and microglia, which are resident central nervous system defense cells. The purpose of this study was to evaluate a novel small molecule TNFα modulator for improving behavioral deficits and decreasing neuroinflammation in the polyinosinic:polycytidylic acid (Poly I:C) rodent model of SZ. Poly I:C is an immunostimulant that mimics infection in humans, and neonatal infection during pregnancy has been shown to increase the prevalence of SZ later in life. Groups were neonatally treated with saline or Poly I:C (2 mg/kg) from postnatal day (P)5-7 and administered control diet or compound (10 mg/kg) in the diet from (P)30 until (P)67. During adolescence (P)45-46 and in adulthood (P)60-67, rats were behaviorally tested on auditory sensorimotor gating as measured through prepulse inhibition (PPI). Importantly, results revealed that in both adolescence and adulthood, Poly I:C resulted in PPI deficits, and treatment with the TNF modulator significantly improved PPI performance. After (P)67, animals were sacrificed and microglial activation via IBA-1 was evaluated by immunohistochemistry (IHC). Brain tissue was analyzed using confocal microscopy, and images were quantified using NIH ImageJ software. Of the three parameters of analysis, (cell count, sampled cell body fluorescence, and overall image fluorescence) microglia activation in the Neonatal Poly I:C/TNFα group was significantly reduced and was similar to controls when compared to Neonatal Poly I:C/Control group. These results indicate our TNF modulator is successful in improving known behavioral deficits and reducing neuroinflammation associated with SZ and provides a novel pharmacotherapy for the treatment of SZ.

Title: Establishing a model of post-traumatic stress disorder in adolescent rats

Authors: *E. WRIGHT[1], M. RUYLE[2], J. MERCADO[2], B. CHELINE[2], T. E. KOELTZOW[1]
[1]Psychology, [2]Bradley Univ., Peoria, IL

Abstract: Diagnostic criteria for Post-traumatic Stress Disorder (PTSD) in adolescents emphasize the need to better understand the behavioral and physiological impact that trauma might elicit during development. The single prolonged stress (SPS) rat model of PTSD reliably produces an enhanced fear response to traumatic cues and disrupted cortisol regulation in adult rats similar to that typically observed in humans with PTSD (Wang et al., 2008; Knox et al., 2012). The purpose of the present study was to determine the long-term impact of SPS (n=10) on adolescent (postnatal day 32-35), male, Sprague Dawley rats compared to controls (n=4). A second aim of the present experiments is to identify individual differences that may confer predict vulnerability to the effects of SPS. Dependent variables included spontaneous locomotor activity as well as responses to an open field (OF), black/white chamber (BW), and an elevated plus maze (EPM).

Data indicate that exposure to SPS elicited persistent alterations in the behavior of adolescent rats (n=10) compared to controls (n=4). The SPS rats tended to exhibit hyperactivity compared to controls in locomotor activity measures 2 weeks post-SPS, as indicated by RMANOVA analysis of total ambulations during a one-hour test (F (1,12) = 0.840, p = 0.19; Cohen's d = 1.27). Similar trends were observed in SPS rats when tested 4 weeks later (F (1,12) = 0.20, p = 0.20; Cohen's d = 0.47). The results of the behavioral anxiety data were more complex. For example, center time in the OF tended to be lower among SPS rats (F (1,12) = 1.25, p = 0.14; Cohen's d = 0.77) when tested two weeks post-inductions, and this trend was present 4 weeks later (F (1,12) = 0.069, p = 0.069; Cohen's d = 0.74). By contrast, no meaningful trends were observed in the BW chamber in terms of black time 2 weeks post-SPS (F (1,12) = 0.429, *n.s*; Cohen's d = 0.37), but when tested 4 weeks later, SPS rats exhibited a strong preference to the black side compared to controls (F (1,12) = 2.740, p = 0.052; Cohen's d = 0.93). Finally, when exposed to the EPM, SPS rats exhibited statistically significant hypoactivity compared to control rats in terms of open arm entries 2 weeks post-SPS (F (1,12) = 4.578, p = 0.027; Cohen's d = 1.3). At 4 weeks post-SPS, a similar trend was observed (F (1,12) = 2.954, p = 0.056; Cohen's d = 0.86). Despite the limited sample size, these results indicate that adolescent rats may be highly susceptible to stress.

On-going research aims to validate these preliminary findings with additional subjects and to identify potential variables that can predict risk versus resilience to the long-term consequences of SPS.

Title: Single Prolonged Stress elicits robust behavioral effects in adolescent Wistar Kyoto rats

Authors: M. T. RUYLE, E. B. WRIGHT, J. A. MERCADO, B. C. CHELINE, *T. E. KOELTZOW
Psychology Dept, Bradley Univ., Peoria, IL

Abstract: The single prolonged stress (SPS) model has been utilized in recent years to produce key features of Post-traumatic Stress Disorder (PTSD) in rats. For example, SPS has been reported to reliably produce enhanced fear responses to traumatic cues and disrupted cortisol regulation in adult rats similar to that typically observed in humans with PTSD (Wang et al., 2008; Knox et al., 2012). A key feature of PTSD is that not everyone that is exposed to trauma develops symptoms, indicating that individual differences may serve as a biomarker for vulnerability. Wistar Kyoto (WKY) rats are an inbred strain that have been suggested to be at risk for a variety of affective disorders, including depression and anxiety. The purpose of the present study was to determine whether male, adolescent (postnatal day 33-35) WKY are differentially sensitive to the effects of SPS compared to Sprague-Dawley rats. In addition, a second objective of the current study was to assess the impact of SPS 24 hours after induction in order to determine whether individual differences present shortly after SPS are sufficient to predict long-term consequences to SPS. Dependent variables included spontaneous locomotor activity as well as responses to an open field (OF), black/white chamber (BW), and an elevated plus maze (EPM). Adolescent WKY rats (n=6) were subjected to SPS (two hours of restraint stress, 20 minutes of forced swim, and CO2-induced loss of consciousness) or served as controls (n=12). 24 hours after SPS, rats were subjected to a one-hour locomotor activity test. RMANOVA with one between-groups factor (SPS vs Control) and 12 levels of the within groups factor (5 minute intervals) revealed a statistically significant main effect of condition ($F_{(1,14)} = 6.28$, $p = 0.023$), and a statistically significant Time x Condition interaction ($F_{(11,176)} = 3.07$, $p = 0.001$). These data indicate that exposure to SPS elicits robust hypoactivity inn WKY 24 hours after SPS induction. Ongoing research seeks to determine the potential persistence of these

effects in adulthood, the effect size relative to Sprague-Dawley rats (e.g., see Wright et al., 2018), and to identify behavioral features that may predict individual differences in the magnitude of responses.

Title: Adolescent ketamine pre-exposure does not alter cocaine preference in adult female mice

Authors: *I. GARCIA[1], A. R. ZAVALA[2], S. D. IÑIGUEZ[1]
[1]Psychology, Univ. of Texas at El Paso, El Paso, TX; [2]Psychology, California State Univ., Long Beach, CA

Abstract: Major Depressive Disorder (MDD) is a prevalent illness that affects females at a higher rate than their male counterparts. Unfortunately, close to 60% of MDD patients do not receive treatment, and when they do, nearly half of them are unresponsive to traditional antidepressants, like fluoxetine. As such, alternative pharmaceutical treatments for MDD are being explored, particularly for juvenile patients - given that the first incidence of MDD is usually reported during this period of development. Recently, ketamine, a non-competitive N-methyl-D-aspartate (NMDA) receptor antagonist, has shown promising antidepressant efficacy in adolescent treatment-resistant MDD patients. Nevertheless, the possible long-term effects of ketamine exposure during early development have not been assessed. Although there has been some progress in breaching our understanding of how ketamine works by using preclinical models, a limitation of this approach is that most of this work has been done using males as subjects. Thus, we examined whether exposure to ketamine during adolescence results in long-lasting changes in sensitivity to the rewarding properties of cocaine in adulthood using female C57BL/6 mice. Specifically, mice received either ketamine (20 mg/kg) or saline (VEH) for 15 consecutive days during adolescence (Postnatal Day [PD] 35-49). Twenty-one days after ketamine exposure, once mice reached adulthood (PD70), we assessed their behavioral responsivity to cocaine (0, 5, 7.5 mg/kg) using the conditioned place preference (CPP) test. Our results show that adult female mice spent significantly higher time in the cocaine-paired side, as a function of cocaine dose ($p<0.05$). However, juvenile ketamine pre-exposure during adolescence did not influence the magnitude of preference for environments previously paired

with the stimulant, when compared to VEH pre-treated controls, at the same doses of cocaine ($p>0.05$, respectively). Together, our findings suggest that exposure to ketamine during adolescence does not alter sensitivity to the rewarding properties of cocaine in adulthood, in female C57BL/6 mice.

Title: Extracellular-regulated kinase 2 in the lateral habenula regulates reactivity to stress in adolescent male rats

Authors: *L. F. PARISE, O. K. SIAL, A. M. CARDONA, E. L. VIEREGG, P. N. SKANSI, C. BOLAÑOS-GUZMAN
Texas A&M Univ., College Station, TX

Abstract: Approximately 13% of individuals aged 12-17 are diagnosed with major depressive disorder (MDD). Early-life MDD is highly debilitating, andthe World Health Organization reports suicide as a leading cause of death among adolescents and young adults. Althoughtreatments for MDD are available, they are only partially effective, and a large portion of adolescents are non-responsive,suggesting that there is much left to be understood about the underlying neurocircuitry that mediates symptoms of MDD. Stress is a primary factor in precipitating MDD thus necessitating assessment of how it alters neural signaling of mood-related genes during developmental periods prior to adulthood. To this end, adolescent (postnatal day 35) male rats were exposed to 4 weeks of chronic unpredictable stress (CUS), then tested in behavioral assays designed to assess stress-reactivity, and tissue was subsequently collected for biochemical analysis. After CUS exposure, rats were tested in the elevated plus maze (EPM), forced swim test (FST), and for sucrose preference. Stress-exposed rats spent less time in the open arms of the EPM, indicative of an anxiogenic response, while also showing increased total immobility in the FST (i.e., behavioral despair) and had reduced sucrose consumption (i.e., anhedonia). We have previously shown that extracellular regulated kinase 2 (ERK2) activity in mesolimbic structures, such as the ventral tegmental area (VTA), is a key mediator of stress- and antidepressant-responding. The VTA receives regulatory input from the lateral habenula (LHb), however, knowledge of whether ERK2 is regulated in the LHb after stress is lacking. To this end, rt-PCR and western blot were performed, revealing that both mRNA and protein levels of

ERK2 in the LHb were decreased after CUS exposure. To assess whether direct ERK2 modulation could buffer CUS-induced behavioral deficits, naïve adolescent rats received microinfusions of wtERK2, to increase ERK2 expression within the LHb, and then exposed to the EPM and FST. Increasing ERK2 within the LHb promoted more time in the open arms of the EPM and less time immobile in the FST (i.e., antidepressant-like effects). A separate group of CUS-exposed rats received LHb infusions of wtERK2 prior to behavioral testing. Similar to naïve rats, increasing ERK2 within the LHb was sufficient to promote antidepressant-like responses in the EPM and the FST, when compared to the GFP-treated controls. These results suggest that increasing ERK2 in the LHb promotes resilience to stress and can reverse a depressive-like phenotype. Overall these findings highlight the importance of LHb second-messenger signaling in mediating resilience to stress.

Title: Juvenile combination treatment with fluoxetine and aripiprazole does not alter cocaine-seeking behavior in adulthood

Authors: *S. A. CASTILLO[1], A. R. ZAVALA[2], S. D. IÑIGUEZ[3]
[1]Biol. Sci., [2]Psychology, The Univ. of Texas At El Paso, El Paso, TX; [3]California State Univ., Long Beach, CA

Abstract: Major depressive disorder (MDD) is a highly debilitating illness that affects millions of people across the globe. Interestingly, the first reported incidence of MDD occurs during the adolescence stage of development. Because fluoxetine (FLX) is the only antidepressant medication approved by the Food and Drug Administration (FDA) for the treatment of pediatric MDD, the prescriptions rates of this antidepressant are very high within populations younger than 20 years of age. Unfortunately, FLX does not alleviate MDD symptoms in most patients - with close to 50% being resistant to this pharmacotherapeutic treatment. An alternative approach for treatment resistant-MDD is the prescription of FLX in combination with the atypical antipsychotic aripiprazole (ARI). This is surprising, given that the long-term consequences of this combination treatment (FLX+ARI) have not been thoroughly assessed at either the clinical or preclinical level. Thus, the purpose of this study is to examine for potential long-term

consequences of juvenile combination therapy with FLX+ARI on sensitivity to drugs of abuse in adulthood. To achieve this, adolescent (postnatal day [PD] 35) male C57BL/6 mice were administered with either vehicle (DMSO) or FLX (10 mg/kg) with aripiprazole (0.03 mg/kg) for 15 consecutive days (PD35-49). Twenty-one days later, once the mice reached adulthood (PD70), they were tested for cocaine (5 mg/kg) sensitivity using the conditioned place preference test (CPP). The results of this experiment show that when tested in adulthood, animals pretreated with FLX+ARI during adolescence do not differ in the time spent in the cocaine-paired side when compared to VEH-treated controls. Together, our results suggest that no long-lasting reward-related deficits become apparent in male C57BL/6 mice exposed to FLX+ARI during the adolescent stage of development.

Title: Neonatal caffeine does not disrupt locomotor activity in adolescence but attenuates the expression of locomotor sensitization to methylphenidate

Authors: *R. MEHTA, B. SORTMAN, C. GERAGHTY, C. J. RICHARD, A. R. ZAVALA
California State University, Long Beach, Long Beach, CA

Abstract: Chronic neonatal caffeine exposure, depending on the age of initial treatment, has been shown to produce hyperactivity in adolescent and adult rats exposed to a novel environment. This caffeine-induced hyperactivity has only been demonstrated in rats that are pretreated during postnatal days (PDs) 7-11, but not if given between PD 13-17. The present experiment studied whether neonatal caffeine exposure produces hyperactivity and whether neonatal caffeine exposure affects the development of methylphenidate sensitization in adolescent rats. Rats were pretreated with either saline or caffeine (20 mg/kg) on PD 7 for seven consecutive days (i.e., PD 7-13) and horizontal locomotor activity was assessed from PD 25-28. For five consecutive days thereafter, rats were pretreated with saline or methylphenidate (2.5 or 5 mg/kg). A methylphenidate challenge was then conducted on PD 34, during which rats received saline or methylphenidate (2.5 mg/kg). Unlike previous findings, neonatal caffeine exposure did not produce hyperactivity in adolescent rats. However, the development of methylphenidate

sensitization was attenuated in rats that received neonatal caffeine. Specifically, neonatal caffeine pretreated male rats did not increase their locomotor response across the five days of pretreatment with methylphenidate (5.0 mg/kg) compared to controls, which exhibited an increase in locomotor activity across the five methylphenidate pretreatment days. Moreover, during the methylphenidate challenge, neonatal caffeine pretreated female rats exhibited an attenuated sensitized response when challenged with methylphenidate (2.5 mg/kg) compared to controls. These findings suggest that neonatal caffeine exposure during PD 7-13 may have a long-lasting disruption of dopaminergic systems that persist into adolescence.

Title: The effects of early-life ketamine administration on the rewarding effects of alcohol in male and female adolescent sprague dawley rats

Authors: *D. FRANCO[1], E. NUNEZ LARIOS[1], R. A. CABRERA[1], S. D. INIGUEZ[2], A. R. ZAVALA[1]
[1]Psychology, California State Univ. Long Beach, Long Beach, CA; [2]Psychology, Univ. of Texas at El Paso, El Paso, TX

Abstract: Although the prevalence of major depressive episodes (MDEs) in juvenile populations has significantly increased in recent years, treatment with fluoxetine, a selective serotonin reuptake inhibitor (SSRI), has failed to adequately manage depressive symptoms in more than one-third of children and adolescents. As a result, there is a critical need for novel therapeutic agents with the ability to effectively and efficiently treat depression. Recently, a single low-dose of ketamine, a non-competitive NMDA receptor antagonist, has been shown to produce rapid and effective antidepressant effects in clinical and preclinical models. However, the long-term effects of early and prolonged ketamine administration in juvenile populations are unclear. Specifically, because ketamine is also a drug of abuse, early ketamine exposure may inadvertently alter the developing brain reward systems, and thereby increase the abuse potential of other drugs of abuse (e.g., alcohol). Thus, we examined whether early ketamine administration

increases the rewarding effects of alcohol in adolescent rats using the conditioned place preference (CPP) paradigm, a validated animal model of reward. Periadolescent male and female Sprague-Dawley rats received daily ketamine injections from postnatal day (PD) 21-30. One day after the last ketamine injection, rats were assessed for alcohol-induced CPP on PD 31 using a 10-day CPP procedure. On days 1 and 10, rats were tested for their preconditioning and postconditioning place preference, respectively, for 15-minute sessions. On days 3-8, rats were conditioned 15 minutes a day with either alcohol (0.0, 0.125, 0.5, 2.0 g/kg) or saline on alternating days. Results show that early ketamine administration modulates the rewarding effects of alcohol in adolescence. Specifically, the degree of alcohol-induced CPP is shaped by previous ketamine exposure. Overall, the results demonstrate that early life ketamine administration alters the rewarding properties of alcohol during adolescence. Consequently, ketamine use in clinical trials involving juvenile populations should be carefully evaluated.

Title: Social stress during adolescence followed by western-style diet leads to physiological dysregulation, depressive phenotype, and decreases in reward sensitivity in adulthood

Authors: *O. K. SIAL, L. F. PARISE, P. N. SKANSI, A. M. CARDONA, E. L. VIEREGG, T. GNECCO, C. A. BOLAÑOS-GUZMÁN
Psychology, Texas A&M Univ., College Station, TX

Abstract: The prevalence of major depressive disorders (MDD) and obesity in adolescence has steadily increased over the last decade. This comorbidity has been reported by clinicians and a relationship between depression- and anxiety-like states with cardiac and metabolic dysfunction has also been demonstrated in rodents. Conversely, western-style high fat diet (HFD) has been linked to the development of metabolic syndrome and mood dysregulation. While much has been elucidated about the neural basis of depression and obesity, how they converge is unknown. It is unclear whether chronic stress induces physiological and neurobiological changes associated with metabolic dysfunction or vice versa, thus understanding potential mechanism(s) and/or directionality is paramount. To this end, adolescent (postnatal day [PD]30) male C57bl/6J mice were exposed to HFD either before or after chronic social defeat stress (CSDS), and then tested

for behavioral and physiological dysregulation. Mice were given free access to HFD for 14 days (PD30-44) prior to CSDS exposure (10 days; 10 minutes/day), and subsequently tested for sucrose preference. Mice did not show changes in caloric intake or total body weight regardless of diet. However, those in the HFD condition showed a significant decreased in preference for sucrose (i.e., increased anhedonia) when compared to the NC-exposed mice. A separate group was given access to HFD alone for 4 weeks and tested in the conditioned place preference (CPP) paradigm to assess for changes in drug reward. Mice pretreated with HFD did not develop preference to the side compartment paired with morphine (1.0 mg/kg), which promoted CPP in the NC-exposed mice. Combined, these results demonstrate that pre-exposure to HFD blunts responses to both natural and drug reward. A separate group of mice was exposed to CSDS before the introduction of the HFD. There was no change in calories consumed, but a significant increase in body weight after only 10 days of HFD was observed. After 1 month of NC or HFD consumption, the mice were re-tested for social avoidance. The NC-exposed mice showed significant recovery in social interaction whereas the HFD-exposed mice showed profound social avoidance suggesting that pre-exposure to stress alters the physiological response to HFD and promotes a depression-like phenotype. Together, these findings indicate that exposure to HFD during adolescence blunts reward sensitivity, and that stress exposure followed by consumption of HFD induces neurobiological changes that lead to physiological and mood related deficits which could lead to the development of maladaptive behaviors and negative health outcomes in adulthood.

Title: Fluoxetine pre-exposure decreases cocaine and sucrose preference in female mice

Authors: *F. J. FLORES RAMIREZ[1], M. ARENIVAR[1], A. THEMANN[1], M. RODRIGUEZ[1], O. LIRA[1], J. PRECIADO-PINA[1], A. R. ZAVALA[2], S. D. IÑIGUEZ[1]
[1]Psychology, Univ. of Texas At El Paso, El Paso, TX; [2]Psychology, California State Univ., Long Beach, CA

Abstract: Preclinical literature indicates that exposure to antidepressant medications, during early stages of development, results in long-term altered behavioral responses to drugs of abuse

(Iñiguez et al., 2015, Sci Rep, 5:15009). However, to date, these studies have been conducted in male subjects primarily. This is surprising, given that females, when compared to males, are more likely to be diagnosed with mood-related disorders, and thus, be prescribed with antidepressants. Therefore, the objective of this study is to assess whether exposure to the selective serotonin reuptake inhibitor fluoxetine (FLX) results in long-lasting alterations in sensitivity to the rewarding properties of cocaine and sucrose, using female mice as a model system. To do this, adolescent (postnatal day [PD]-35) and adult (PD70) female C57BL/6 mice were exposed to FLX (in their drinking water, 250 mg/l) for 15 consecutive days. Twenty-one days later (PD70+ and PD105+, respectively), mice were assessed on behavioral responsivity to cocaine (0, 2.5, 5, 7.5 mg/kg) using the conditioned place preference paradigm, or their sensitivity to a 1% sucrose solution using the 2-bottle choice test. Our results indicate that female mice pre-exposed to FLX during adolescence or adulthood displayed reliable conditioning to the cocaine-paired compartment, in a dose-dependent manner. However, when compared to respective age-matched controls, antidepressant pre-exposure decreased the magnitude of conditioning at the 5 ($p<0.05$, $R^2= 0.21$) and 7.5 mg/kg ($p<0.05$, $R^2= 0.51$) cocaine doses. Similarly, independent of age of antidepressant pretreatment, FLX-pretreated mice also displayed a decrease in sucrose preference ($p<0.05$, $R^2= 0.62$), without altering total liquid intake ($p>0.05$). Collectively, our results suggest that exposure to FLX, in adolescent and adult female C57BL/6 mice, leads to prolonged decreases in sensitivity to the rewarding properties of both drug- and natural-rewards. This data further highlight the need for investigations assessing the potential enduring neurobiological side effects that may arise later in life, as a result of antidepressant exposure, in a sex dependent manner.

Title: Alprazolam exposure during adolescence dysregulates reward sensitivty and second messenger signalingin adulthood

Authors: A. M. CARDONA, L. F. PARISE, O. K. SIAL, E. L. VIEREGG, J. P. ROZOFSKY, *C. A. BOLANOS-GUZMAN
Psychological and Brain Sci., Texas A&M Univ., College Station, TX

Abstract: Benzodiazepines are prescribed widely as anxiolytics, hypnotics, muscle relaxants, and anticonvulsants. However, their utility is limited by unwanted side effects such as abuse liability and the potential for dependence. Benzodiazepine-related emergency room visits have increased in the US within the past two decades and despite concerns surrounding their use, there has been a substantial increase in benzodiazepine's prescription rate. Benzodiazepines are commonly abused concurrently with opioids, resulting in greater psychopathology and increased comorbidity. There is evidence of increased use and abuse of benzodiazepines during adolescence, yet most available neurobiological evidence has been based on studies using adult organisms. This study was designed to investigate whether exposure to alprazolam during adolescence also potentiates the behavioral and biochemical effects of opiates such as morphine. Adolescent C57BL/6J male mice were treated with alprazolam (0.25, 0.5 and 1.0 mg/kg)or saline, once daily from postnatal days 35-49. Changes in behavioral responsiveness to morphine (0.5, 1.0 and 5.0 mg/kg), using the conditioned place preference paradigm (CPP), and gene expression changes within the ventral tegmental area (VTA), using qPCR,were assessed both 24 h and one-month after the end of drug treatment.Our results show that pretreatment with alprazolam during adolescence potentiates the effects of morphine as measured in the CPP paradigm: the alprazolam pre-treated mice developed strong preference to the compartment paired with a threshold dose of morphine (0.5 mg/kg), and this effect was still present a month after alprazolam exposure. We then measured whether extracellular signal-regulated kinase 1/2 (ERK)-signaling would be affected by alprazolam pretreatment, given ERK's role in mediating drug-induced behaviors. Preliminary results show a decrease in GSK3β and ERK2 gene expression when compared to controls 24 h after alprazolam treatment. Ongoing studies are currently assessing expression of other transcription factors such as CREB, BDNF cFos, and zif268.Overall, these findings suggest that exposure to alprazolam during adolescence potentiates the rewarding effects of opiates such as morphine, and that alprazolam exposure during this period result in persistent changes of ERK-signaling within the VTA, a brain region implicated in both drug-reward and mood-related disorders, in adulthood.

Title: The role of glucagon-like peptide 1 receptors on the rewarding effects of oxycodone in male and female adolescent rats

Authors: *Y. C. BROWN, C. J. RICHARDS, A. R. ZAVALA
Psychology, California State University, Long Beach, Long Beach, CA

Abstract: Available treatments for drugs of abuse are limited. Preclinical studies show activation of Glucagon-like peptide-1 receptors (GLP-1R) reduces the rewarding effects of alcohol and cocaine through the modulation of dopamine release in the mesolimbic pathway, suggesting GLP-1R may be a good pharmacotherapeutic target. However, the role of GLP-1R in modulating opioid reward has not been examined. This study is examining whether Exendin-4 (EX-4), a GLP-1R agonist, will reduce the rewarding effects of oxycodone, an opioid receptor agonist, in adolescent male and female adolescent rats. The rewarding effects of Oxycodone were assessed using the Conditioned Place Preference (CPP) paradigm-an animal model of reward. CPP involved a 10-day procedure. On days 1 and 10, rats were tested for their preconditioning and postconditioning place preference, respectively, for 15-minute sessions. On days 3-8, rats were conditioned 30 minutes a day with either oxycodone (0.0, 0.01, 0.1, 1.0, or 9.0 mg/kg) or saline on alternating days. During oxycodone conditioning sessions, rats were pretreated with EX-4 (2.4 ug/kg) or saline 10 min before being conditioned with oxycodone. Results indicated that Ex-4 attenuated oxycodone-induced CPP in male and female adolescent rats. Overall, this study adds to a growing body of literature that suggests GLP-1R may be a target in reducing the abuse of various drugs of abuse.

Title: Differential consequences of post-natal and post-weaning environment on the relative playfulness of F344 and Lewis rats

Authors: *S. M. SIVIY, C. M. CAMPBELL, J. A. GENTES, L. GUSTAFSON
Dept Psychol, Gettysburg Col., Gettysburg, PA

Abstract: Previous work from our lab has shown that the Fischer 344 (F344) rat is consistently less playful than other strains and while the overall level of playfulness in F344 and Lewis (LEW) rats is fairly resistant to cross-fostering, how this urge is titrated by motivational factors

in the two strains may be differentially sensitive to early postnatal experiences (*Physiol Behav*, 2017, 116, 147). To further understand the dynamic interplay between genotype and postnatal experiences, we assessed the effects of neonatal handling on rough-and-tumble play in LEW and F344 rats when allowed to play with a standard Sprague-Dawley (SD) partner. Handled litters experienced brief daily periods (15 min) of separation during the first 2 postnatal weeks and then remained undisturbed until weaning at 21 days of age. When play was assessed after weaning and compared to rats from non-handled control litters, F344 rats were less playful overall but handled LEW and F344 rats were both more likely to respond to playful nape contacts with complete rotations to supine, suggesting that handling increased playful responsiveness to a comparable extent in both strains. SD rats paired with handled inbred rats responded by directing more nape contacts to the inbred partner than those paired with non-handled rats, perhaps reflecting the contagious nature of play, but only when assessed after 4 hours of isolation when overall playfulness was at a sub-maximal level. This was, in turn, countered with more nape contacts by handled LEW rats but not by handled F344 rats. These data suggest that early postnatal handling may be having a differential impact on how motivational state modulates the ebb and flow of a play bout in F344 and LEW rats. In a separate experiment, the consequences of differential housing after weaning were assessed by housing F344 and LEW rats with either 2 rats of the same strain or 2 SD rats immediately upon weaning. When play was assessed between 35 and 40 days of age F344 rats solicited less play than LEW rats and play solicitation in both strains was unaffected by cross-housing. While playful responsiveness in LEW rats was unaffected by housing condition, F344 rats housed with SD rats for 2 weeks were more likely to respond to playful solicitations with a complete rotation than those housed with other F344 rats and did not differ from the playful responsiveness of LEW rats. Taken together, these data suggest that different components of social play, such as playful solicitation and responsiveness, may be differentially sensitive to pre- and post-weaning social experiences and the exact impact on play may depend somewhat on the genetic platform that these experiences are acting on.

Title: Individual differences in social play behaviour in rats: How do they affect adult social behaviour and reward sensitivity?

Authors: *M. ACHTERBERG, H. M. B. LESSCHER, L. J. M. J. VANDERSCHUREN
Fac. of Vet. Med., Utrecht, Netherlands

Abstract: Social play behaviour is a characteristic form of social behaviour displayed by the young of many mammalian species, including rats and humans. Being a rewarding activity, the performance of social play depends on its pleasurable and motivational properties. Importantly, social play behaviour is modulated through neural systems that also mediate the rewarding and motivational effects of other rewards such as food, sex and substances of abuse. Social play behaviour is thought to have an important role in socio-emotional and cognitive development. This is supported by experiments in which rats were deprived of social play, by housing them in isolation during the period in which this behaviour is most abundant (postnatal day 21 to 42). This play deprivation makes rats unable to respond appropriately to social and cognitive challenges in adulthood. Next to that, play-deprivation leads to enhanced sensitivity for cocaine self-administration, amphetamine and alcohol place preference and alcohol consumption in adulthood. Since play-deprivation profoundly affects brain and behaviour, individual differences in playfulness may have long-term implications as well. To investigate this, we characterized young rats on the expression of social play behaviour and subsequently tested them on their motivation to play, adult social behaviour, impulsivity and operant responding for sucrose and alcohol. In addition, expression of relevant genes was assessed in brain regions involved in social play, reward processes and executive functioning. Preliminary data indicate that individual differences in social play expression predict the motivation for social play as well as reward sensitivity and gene expression.

Abstract: Neuromodulation plays two separate essential roles at different ages: during early fetal age in cell development, and later in adulthood in altering neural dynamics and plasticity. Neuromodulatory tone is present in the brain between these two developmental stages, but its role during adolescence, when circuit formation occurs, is less extensively explored. The prefrontal cortex (PFC) experiences protracted development that extends through adolescence during which inputs from local PFC and distal brain regions are integrated into circuits that interface sensory and cognitive information to support complex cognitive behaviors. To what extent neuromodulatory mechanism contributes to this late developmental process is not known. Here, we examine the role of neuromodulation in circuit development of evolutionarily conserved PFC top-down neurons projecting from dorsal anterior cingulated cortex and secondary motor cortex to primary visual cortex (PFC->VIS) in mice. Rabies input mapping identified robust basal forebrain cholinergic inputs onto top-down PFC->VIS projection neurons established by adolescence. However, electrophysiological recording reveals decreased nicotinic ACh response in adult PFC->VIS projection neurons compared to adolescence, as the projection neurons undergo a shift in cell-autonomous suppression of nicotinic signaling through expression of a nicotinic brake, Lynx1. Bidirectional viral manipulations of Lynx1 expression within PFC->VIS projection neurons revealed that adolescent, and not adult, Lynx1 expression is necessary and sufficient to develop adult attentional performance on the 5 choice serial reaction time task. Exploration of Lynx1-dependent changes in connectivity onto PFC->VIS projection neurons revealed that Lynx1 facilitates a selective reduction in heightened local connectivity onto top-down projections through the suppression of excessive dendritic spine formation that shifts the balance of local/long-range inputs in adulthood. Our study reveals that adolescent cell-autonomous molecular control over nicotinic neuromodulatory transmission is essential for prefrontal top-down projection neurons to shift the connectivity balance of local and long-range inputs to establish adult attentional control.

Abstract: Social isolation during developmental critical windows could be highly detrimental to proper functioning of mature prefrontal cortex (PFC) and establishment of appropriate adult behaviors. However, the specific circuits that undergo social experience-dependent maturation to regulate social behavior development are poorly understood. Here we show that juvenile social isolation in mice leads to reduced intrinsic excitability and input drives of adult parvalbumin-positive interneurons (PVIs) in medial PFC (mPFC), suggesting juvenile social experience is required for their proper activation in adulthood. *In vivo* imaging of mPFC-PVI activity by fiber photometry demonstrated that adult mPFC-PVIs are preferentially activated by social signals. Acute chemogenetic suppression of mPFC-PVI activity revealed that normal social behavior requires physiological mPFC-PVI activity. Conversely, chemogenetic restoration of mPFC-PVIs activity in the adult animal selectively rescued juvenile isolation-induced social deficits but not increased anxiety. Therefore, PVI development in the juvenile mPFC is critically linked to long-term impacts on social behavior.

Abstract: Attention is a goal-directed cognitive process that facilitates the detection of task-relevant sensory stimuli from our dynamic environment. Attention deficits are frequently observed in several psychiatric disorders; including autism spectrum disorders, schizophrenia, and depression, yet the underlying neural circuits that regulate attentional behavior are not well understood. Across species, previous studies have demonstrated that the frontal cortex—particularly the anterior cingulate cortex (ACC) — contributes to "top-down" control of sensory processing in the visual cortex (VIS). Here, we aim to investigate the contribution of these evolutionarily conserved, long-range ACC->VIS projecting neurons in top-down control of visual attention behavior. We achieve this by integrating cutting-edge circuit-based techniques to monitor and manipulate selective top-down neural activity in mice performing freely moving attention behavior with a translational automated touchscreen system. Our study has shown that selective chemogenetic suppression of ACC->VIS projections impairs attentional performance in the 5-choice serial reaction time task without disrupting additional detectable readouts of decision-making capacity, motivational state, motor activation, impulsivity, and compulsivity. *In vivo* calcium imaging of projection-specific top-down neurons using fiber photometry in behaving mice points to a key role of top-down projections in integrating sustained attention and visual processing. Direct optogenetic modulation of the projection further reveals temporal- and frequency-dependent bidirectional change in attentional performance. Collectively, our data demonstrate that long-range frontal-sensory projections are a key enactor of top-down control of attentional behavior. Our findings may provide circuit-based insight into the pathophysiology and neuromodulation intervention strategies for impaired visual attention in neuropsychiatric disorders. Our ongoing study aims to rescue attention deficits in mice with risk genes for neurodevelopmental disorders through the modulation of frontal-sensory projections.# equal first authors (Norman and Koike)

Institute, Icahn Sch. of Med. at Mount Sinai, New York, NY; [5]Friedman Brain Institute, Icahn Sch. of Med. at Mount Sinai, New York, NY

Abstract: Juvenile social isolation (jSI) during a two-week window (p21-35), but not a later window leads to decreased social investigation in adult mice, suggesting the juvenile period as a critical period for adult social behavior. However, the specific circuitry that is vulnerable to jSI is unknown. We assessed the effect of jSI in adult medial prefrontal cortex (mPFC) including anterior cingulate cortex and prelimbic cortex by patch clamp recordings from fluorescently labeled excitatory and inhibitory neurons of jSI and group housed (GH) mice. We found that jSI causes a lasting reduction in intrinsic excitability in adult mPFC neurons projecting to midline limbic thalamus but not in neurons projecting to Nucleus accumbens, nor to contralateral mPFC. We next patched from mPFC inhibitory neurons in mice whose Parvalbumin-interneurons (PVI) or Somatostatin-interneurons (SSTI) are fluorescently labeled. SSTI are further divided into three subtypes based on firing patterns, low-threshold spike (LTS), quasi-fast spiking (QFS) and adapting (AD). Of note, layer II/III SSTI overwhelmingly are of the AD subtype. We found that adult mPFC SSTI-QFS neurons showed comparable excitability in jSI and GH mice. In striking contrast, adult mPFC SSTI-AD neurons both in upper and lower cortical layers and PVI show markedly decreased excitability after jSI compared to GH. In contrast, adult LTS-type SSTIs from jSI mice showed elevated intrinsic excitability. Collectively, our study demonstrates that selective sub-population of excitatory and inhibitory neurons in mPFC require proper juvenile social experience to establish normal intrinsic excitability in adulthood. Given that social processing deficits are a common dimension of many neurodevelopmental and psychiatric disorders, identification of the specific circuits sensitive to experience-dependent modulation will point toward therapeutic targets that allow amelioration of social deficits shared across of range of disorders.

Title: Developmental and sex differences in kappa opioid receptor activity in limbic brain areas

Authors: *S. J. CROSS[1], D. BE[1], C. CARMONA[1], F. M. LESLIE[1,2]
[1]Anat. & Neurobio., [2]Pharmacol., Univ. of California Irvine, Irvine, CA

Abstract: The kappa opioid receptor (KOR) and its endogenous ligand, dynorphin, are widely distributed in the brain, including in regions involved in motivation and reward, executive function, and stress responsiveness. Activation of KORs has been shown to induce a compensatory decrease in reward state that is thought to be mediated by inhibition of dopaminergic and serotonergic signaling. However, KOR function and KOR modulation of drug-associated behaviors often differs between males and females. Furthermore, although present early in development, increasing evidence suggests that KORs undergo functional maturation during adolescence, a sensitive developmental period associated with major reorganization of brain regions critical for reward processing. Our lab has previously shown that the reinforcing properties of concurrent nicotine and alcohol (Nic+EtOH) are enhanced in adolescent males, but not females or adult males, likely due to differential activation of KORs. To test the hypothesis that KOR activity differs across development and by sex to differentially modulate Nic+EtOH reinforcement, brain tissue from drug naïve adult and adolescent rats was processed for U69,593-stimulated [^{35}S]GTPγS binding to determine functional KOR activity. KOR activity was found to differ across age and sex, with adolescent males having greater KOR activity in the ventral tegmental area (VTA) and median raphe (MR) compared to adult males. Adolescent males also showed greater KOR activity than adolescent females in the basolateral amygdala (BLA). In contrast, adult females had higher KOR activity than adult males in all subregions of the amygdala, while adolescents did not differ between sexes. These data demonstrate that while males show developmental decreases in KOR function in the VTA and MR, females show increases in KOR function in the amygdala. Our findings highlight the sex-dependent functional maturation of KORs in limbic brain areas important for reward, reinforcement, and stress responses.

Br., NIH/National Inst. of Mental Hlth., Bethesda, MD; [8]Section on Translational Endocrinol., NIH/National Inst. of Diabetes and Digestive and Kidney Dis., Bethesda, MD

Abstract: Abnormalities of hypothalamic-pituitary-adrenal (HPA) axis are frequent accompaniments of mood and anxiety disorders. Adolescence (and puberty) are associated with both an increased onset of mood/anxiety disorders, as well as the emergence of sex differences in the risk for these conditions (i.e., a 2-fold increased life-time risk in women compared with men). Finally, sex differences in HPA axis response to a range of stressors are documented in both rodents and humans. We employed the awakening cortisol response (ACR) to evaluate the HPA axis in a sample of normally-developing pre and post pubertal children. We studied 60 prepubertal children (23 girls, 37 boys) and 29 post pubertal children (13 girls,16 boys). Pubertal stage (PS) was assessed by a trained clinician: in boys based on testicular volume (TV) using the Prader orchidometer; in girls based on breast development. All children (and 1st degree relatives) were free of any past/current psychiatric disorder (as determined by structured diagnostic interview); all children were medically well, medication free, had a BMI within the 15th -85th percentile, normal bone age, and normal IQs. ACR tests were analyzed from the first visit in the prepubertal cohort and from the PS 5 visit in the older cohort. Salivary cortisol was measured by chemiluminescent enzyme immunoassay on Siemens Immullite1000 analyzer. The ACR area under the curve (AUC) and individual time points (0, 30, 45 and 60 minutes) were analyzed by ANOVAs. In the AUC cortisol there was a significant main effect of sex ($F_{1,88}$=6.0; p=0.02) but no main or interactive effects of PS (p=0.2 and p=0.3, respectively). Similarly, the individual timepoints showed significant main effects of sex (ANOVA-R: $F_{1,88}$=4.2, p=0.04) and time ($F_{1,87}$=19.4, p<.001), but no main effects of PS, nor any between-subjects interactive effects (p=ns, all comparisons). In summary, we found no effects of pubertal stage on the ACR and that sex differences in the ACR occurred independently of pubertal stage. Therefore, our findings suggest (albeit preliminarily) that sex differences in HPA axis appear prior to gonadarche. These findings are analogous to previous adult data from our group (Roca, et al. 2005) in which sex differences in HPA axis responsivity were observed after men and women were made hypogonadal by leuprolide treatment, such that hypogonadal men developed greater ACTH and cortisol responses to either exercise or corticotropin releasing hormone (CRH) stimulation compared with women.

(A*STAR), Singapore Inst. for Clin. Sci., Singapore, Singapore

Abstract: The *DCC* receptor directs growing axons to appropriate targets and plays a critical role in prefrontal cortex (PFC) maturation in adolescence. *DCC* haploinsufficiency in humans leads to altered mesocorticolimbic connectivity and *DCC* single nucleotide polymorphisms (SNPs) associate with depression and schizophrenia. Here, we created a polygenic score, which takes into account that genes operate in coherent networks, and investigated how variations in genes co-expressed with *DCC* in the PFC are involved in healthy human development. We postulated that genetic variation in the *DCC* gene network will unfold discrete differences in behavior and brain morphology in a cohort of Canadian children (MAVAN project).
Followed from birth to 12 years of age with multiple behavioral measures (n=260; 131 females), 64 of the children (n=64; 33 females) underwent MRI and had genetic data collected (Psychchip/Psycharray). First, we obtained genes highly co-expressed with *DCC*, with brain region (PFC) and age (1.5 to 11 y.o.) specificity, from human postmortem gene expression and genotype databases. Then, we used the gene expression slope coefficient, derived from the GTEx regression model, to weigh the SNPs located in these genes. The polygenic score is thus created

by combining the estimated effects of SNPs for the alleles that each subject carries.
Based on Euclidean matrix of gene expression from postmortem data, we find that genes co-expressed with *DCC* exhibit pronounced clusters of upregulated and downregulated expression during the childhood period. However, this expression pattern dissipates in adolescence, coinciding with the dramatic developmental changes that are ongoing in the PFC during this time. We also find that the *DCC* polygenic score in PFC predicts brain volume in healthy individuals. Children with high polygenic score have significantly smaller brain volumes, when adjusted for age, sex and ethnicity. Furthermore, volumetric thalamus measures are smaller in children with high *DCC* co-expression scores, with substantial variance among boys. Finally, measures of behavioral impulse control reveal that high polygenic score group exhibits lower response inhibition.
Our pioneering study reveals that the differential expression of the prefrontal cortex *DCC* gene network can predict brain volume in healthy children and could serve as a powerful identification of developmental differences and possible vulnerabilities to disorders.

Title: Cognitive control networks and related vulnerabilities for alcohol abuse in adolescents with childhood trauma

Authors: S. SILVEIRA[1], K. B. NOONER[3], B. J. NAGEL[4], S. TAPERT[2], M. D. DEBELLIS[5], *J. MISHRA[2]
[1]Psychiatry, Univ. of California San Diego, San Diego, CA; [2]Psychiatry, Univ. of California San Diego, La Jolla, CA; [3]Psychology, Univ. of North Carolina Wilmington, Wilmington, NC; [4]Psychiatry & Behavioral Neurosci., Oregon Hlth. and Sci. Univ., Portland, OR; [5]Psychiatry, Duke Univ. Med. Ctr., Chapel Hill, NC

Abstract: Individuals with childhood trauma are vulnerable to adverse life outcomes and show elevated risk for alcohol and substance abuse, which emerges during adolescence. This is also a critical time period when cognitive control, a fundamental cognitive capacity of the human brain that allows us to select and maintain goal-relevant information, while ignoring goal-irrelevant distractions, is developing. Two distinct cognitive control brain networks have previously been identified, the fronto-parietal network (FPN) and the cingulo-opercular network (CON). While

the FPN has been ascribed to enabling moment-to-moment task control, the CON is associated with sustained task control. Notably, CON and FPN are not distinctly segregated during childhood. Adolescence marks the critical period during which the key cognitive control hub in the dorsal anterior cingulate cortex (dACC) segregates from FPN to form the CON. In the current study, we investigate the maturation and segregation of cognitive control brain networks in N = 388 adolescents with varying levels of trauma severity in the multisite NCANDA (National Consortium on Alcohol & Neurodevelopment in Adolescence) cohort. We analyze functional network connectivity using blood oxygen level dependent signal time course correlations of resting state functional magnetic resonance imaging (fMRI) data with the dACC as a seed region of interest. In a regression model, we analyze the relationship between mean functional connectivity network strength from the baseline rs-fMRI scans and childhood trauma scores as measured by the Childhood Trauma Questionnaire-2 (CTQ-2). Trauma-impacted functional network connectivity outcomes are used in a linear mixed effects model to test prediction of variance in binge drinking as measured by the Customary Drinking and Drug Use Record (CDDR) collected at baseline and at 1- and 2-year follow-up assessments. All analyses control for participants' sex, age, socioeconomic status, and study site MRI scanner type (GE vs. Siemens). In line with our preliminary findings, we hypothesize that FPN and CON functional network segregation will be modulated by the severity of trauma. Further, we specifically hypothesize that the maturing functional connectivity of the dACC node that segregates to form the CON, will be hampered by childhood trauma, and that this will predict higher levels of binge drinking. Results from this study will significantly advance the understanding of how functional network development during adolescence contributes to alcohol and substance abuse. This research also has the potential to inform network-targeted therapeutics for individuals with childhood trauma.

Abstract: Introduction. Exposure to stress during critical periods of development can lead to enduring changes in functioning of the brain and body that can impact physical and mental health. **Objective**. Examine the role of chronic stress during puberty on the future development of stress-related psychopathologies such as depression, anxiety and suicidal ideation. **Method**. Observational, retrospective, descriptive and transversal study. In this project, participants were chosen between 18-40 years from Veracruz Institute of Mental Health Doctor Rafael Velasco Fernandez (IVSM) who presented a diagnosis of anxiety, depression and/or presence of suicidal ideation, also a control group was chosen. We applied Beck's anxiety and depression inventories and a questionnaire about the factors associated with chronic stress in adolescence. This project was approved by the ethics and research committee of the IVSM. The statistical analysis included descriptive statistic and chi square test in SPSS program. **Results:** 227 participants, 58% were women and 42% men. The prevalence of moderate or severe anxiety was 48% for women and 41% for men, for moderate or severe depression, it was 30% for women and 24% for men, for suicidal ideation it was 30% for women and 21% for men. We found significant differences ($p \leq 0.05$) in the results of women group who presented moderate and severe anxiety (ANS), moderate and severe depression (DEP), suicidal ideation (SI) and high prevalence of physical variables and the control group. The statistical significant differences for ANS were in the following evaluated symptoms: nausea, diarrhea, back pain, dizziness, headache, weakness, chest pain, shortness of breath, heart palpitations, abuse and type of abuse. The statistical differences for DEP were in nausea, back pain, shortness of breath, heart palpitations and abuse. For SI the statistical significant differences were in dizziness, weakness, chest ache, abuse and type of abuse. We found significant differences ($p \leq 0.05$) in the results of men group who presented moderate and severe anxiety (ANS), moderate and severe depression (DEP) and high prevalence of physical variables and the control group. The statistical significant differences for ANS were in weakness, abuse and type of abuse. The statistical differences for DEP were in headache, chest pain, abuse and type of abuse. **Conclusions**. Chronical stressful experiences in adolescence could have the potential to make a person vulnerable to experiencing endocrine and affective disorders that could harm health.

Title: Adolescent levels of circulating miR-218 predict susceptibility to chronic social defeat stress in adult mice

Authors: *A. TORRES BERRIO[1,2], A. MORGUNOVA[2], C. FLORES[3]
[1]Neurosci., Icahn Sch. of Med. At Mount Sinai, New York, NY; [2]Integrated Program in Neurosci., [3]Dept. of Psychiatry, McGill Univ., Montreal, QC, Canada

Abstract: Adolescence is a period of Increased vulnerability to psychiatric disorders including depression. However, there is still the need of discovering novel biomarkers to identify those individuals who are at the highest risk. The microRNA, miR-218, mediates susceptibility to depression by targeting the guidance cue receptor gene, *Dcc* (Deleted in colorectal cancer) in the prefrontal cortex (PFC). Furthermore, circulating levels of miR-218 correlate with depression-like behaviors in adult mice, following the chronic social defeat stress (CSDS) paradigm. Here, we assessed whether (1) the PFC expression pattern of miR-218 and *Dcc* varies across postnatal neurodevelopment, (2) miR-218 expression in blood changes throughout life, and (3) circulating miR-218 during adolescence predicts susceptibility to CSDS in adulthood. We show that miR-218 expression in the PFC increases drastically from early adolescence to adulthood, whereas *Dcc* mRNA expression decreases in the exact opposite manner. In fact, miR-218 and *Dcc* mRNA levels correlate negatively across postnatal life. Circulating miR-218 increases from adolescence onward, paralleling those changes observed in the PFC. Importantly, high circulating levels of miR-218 during adolescence are strongly associated with vulnerability to CSDS in adulthood. In fact, adult susceptible mice display "adult-like levels" of miR-218 in blood during adolescence. Downregulation of miR-218 in the PFC specifically during adolescence prevents vulnerability to CSDS in adulthood. These results show that the pattern of postnatal expression of miR-218 in the PFC is dynamic and reproduced when measured in blood. Furthermore, miR-218 levels in the PFC appear to maintain *Dcc* expression in this region from adolescence to adulthood. We propose that circulating levels of miR-218 might indicate vulnerability to stress throughout life.

Title: Environmental cues alter the timing of adolescent neural development in Siberian hamsters

Authors: *D. HOOPS[1], R. F. KYNE[4], A. HE[2], K. C. SCHATZ[5], L. LIN[6], C. FLORES[3], M. J. PAUL[7]

Abstract: Siberian hamsters (*Phodopus sungorus*) are seasonally-breeders that restrict reproduction to spring and summer, when conditions are favourable for offspring survival. Those born early in the breeding season enter puberty during the summer, while those born late delay puberty over the winter months. Hamsters use changes in day length to detect the time of year, and therefore, summer and winter pubertal phenotypes can be reproduced in the lab by rearing hamsters in long, summer-like photoperiods or short, winter-like photoperiods. We recently found that photoperiod impacts the development of some adolescent behaviours, such as novelty seeking, but not others, such as the transition from juvenile play to adult aggression. In the present experiment, we test whether photoperiod impacts neural changes associated with adolescence. The dopamine innervation to the prefrontal cortex is one of the most striking hallmarks of adolescent development, as axons grow long distances to innervate this region during adolescence. Hamsters were reared under a long or short photoperiod and sacrificed as pre-adolescents, young adults, or old adults. Dopamine innervation to the prefrontal cortex was visualized using immunohistochemistry, and innervation was quantified as the density of dopamine varicosities. Paired testes and uterine weights were recorded to confirm reproductive responsiveness to photoperiod. As expected, puberty, as measured by increases in paired testes and uterine weights, was delayed in short photoperiod-reared hamsters compared to those reared under a long photoperiod. Paralleling sex organ development, dopamine innervation was also delayed in hamsters reared under a short photoperiod. To our knowledge, this is the first demonstration that the timing of the adolescent development of mesocortical dopamine input can be plastic in response to environmental cues. In combination with previous behavioural experiments, this experiment demonstrates how this seasonal-species approach can used to dissect out the neural and endocrine mechanisms that regulate adolescent development.

Title: Cannabinoid exposure in adolescence dysregulates genes that orchestrate dopamine development and enhances cocaine-motivated behavior

Authors: *N. E. ZLEBNIK[1], S. CUESTA[4], S. KUMMER[6], D. NOUEL[4], J. M. WENZEL[2], C. FLORES[5], J. F. CHEER[3]
[2]Anat. & Neurobio., [3]Anat. and Neurobio., [1]Univ. of Maryland Sch. of Med., Baltimore, MD; [5]Dept of Psych, [4]McGill Univ., Verdun, QC, Canada; [6]Univ. of Pompeu Fabra, Barcelona, Spain

Abstract: Initiation of drug use during adolescence is a strong predictor of both the incidence and severity of addiction throughout the lifespan. Among adolescents, marijuana is the most commonly abused illicit drug, and excessive use of cannabinoids in this population is associated with the development of psychiatric conditions, including drug addiction. Adolescence is a critical period for the refinement and organization of neuronal connectivity, especially within the mesocorticolimbic dopamine circuity. We have shown, in male mice, that exposure to high doses of amphetamine in early adolescence (PND21-32) disrupts the development of mesocorticolimbic dopamine connectivity, leading to alterations in cognitive processing in adulthood. Importantly, this effect is mediated by amphetamine-induced downregulation of the guidance cue receptor gene, *Dcc*, in ventral tegmental area (VTA) dopamine neurons. DCC receptors orchestrate the development of the mesocorticolimbic dopamine system in adolescence by determining the spatiotemporal targeting of dopamine axons. Here, we examined whether exposure to the synthetic CB1/2 receptor agonist WIN-55,212-2 (WIN) in adolescence regulates *Dcc* mRNA expression in the VTA and induces, in turn, adult alterations in cocaine-related behaviors and in dopamine function in adulthood. We treated early adolescent mice (PND21-32) with repeated intraperitoneal injections of saline or WIN, using 3 different doses (0.5, 2, 4 mg/kg). Mice received one injection every other day for a total of 5 times. We find that exposure to WIN strongly attenuates *Dcc* mRNA expression in the VTA one week later. Remarkably, exposure to the same WIN regimen in early adolescence results in enhanced cocaine seeking in adulthood as measured using a mouse intravenous self-administration paradigm. We are currently examining phasic dopamine release in brains of adult mice exposed to WIN or saline in adolescence. These findings show that repeated exposure to a CB1/2 receptor agonist in adolescence impacts vulnerability to drug addiction later in life and that *Dcc*-mediated disruption of mesocorticolimbic dopamine maturation might be at play.

Title: Effects of adolescent WIN exposure on perineuronal net emergence in PFC

Authors: *E. JACOBS-BRICHFORD[1], H. CHEN[3], A. W. LASEK[2], J. D. ROITMAN[4]
[2]Psychiatry, [1]Univ. of Illinois At Chicago, Chicago, IL; [3]Psychiatry, UIC, Chicago, IL; [4]Psychology, Univ. of Illinois at Chicago, Chicago, IL

Abstract: A hallmark of adolescent brain development is the establishment of a finely-tuned excitatory-inhibitory (E-I) balance in the prefrontal cortex (PFC). This balance, which comes online as inhibitory signaling is refined, helps regulate neuron activity and is essential for the acquisition of cognition in adulthood. In PFC, E-I balance is established over a protracted period of development, with remodeling of inhibitory signaling extending into late adolescence/early adulthood. The brain is particularly vulnerable to environmental insult during this time, including drugs of abuse. Indeed, exposure to cannabis - the most commonly used illicit drug among adolescents - during this time has been linked to memory impairment, increased risk for addiction, and heightened risk of psychosis or schizophrenia in individuals with a predisposition. Cannabis use during adolescence is also known to alter PFC neural activity in adulthood, but little is known about the effects of cannabis on the PFC *during* its development.
To address this gap in our knowledge, we investigated the effect of cannabinoid treatment on the structural development of PFC. Specifically, we examined how exposure to WIN 55, 212-2 (WIN) from postnatal day 35-45 affected the maturation of perineuronal nets (PNNs), lattice-like structures that wrap around cells and regulate their excitability. In the PFC, they are predominantly found on parvalbumin-expressing interneurons (PV), a population of inhibitory cells that develop during adolescence and regulate pyramidal cell excitability. PNN formation is known to be influenced by drug exposure, and we hypothesized that exposure to cannabinoids may disrupt their formation around PV cells, therefore altering the ability of PV cells to regulate pyramidal cell output. We used immunohistochemistry to analyze the fluorescence intensity of two extracellular components of PNNs, brevican and neurocan, as well as *Wisteria floribunda* agglutinin (WFA), a plant lectin that often colocalizes with PNNs. Additionally, we double-labeled brevican, neurocan, and WFA with PV cells in order to determine if any changes in expression are due to a change in the number of cells covered by PNNs or simply a change in intensity of expression.

Title: Chronic intermittent ethanol exposure produces long-lasting changes in immune function and corticosterone sensitivity when experienced during adolescence, but not in adulthood

Authors: *A. S. VORE, T. M. BARNEY, J. E. MONDELLO, T. DEAK
Binghamton Univ., Binghamton, NY

Abstract: Adolescence represents a time of heightened vulnerability to many of the neurotoxic effects of ethanol, yet previous studies have shown cytokine gene expression was substantially reduced/impaired during early adolescence, regardless of what type of challenge was imposed (LPS or ethanol). Interestingly, adolescent exposure to chronic intermittent ethanol (CIE) led to sexually dimorphic outcomes, with male rats exhibiting impaired cytokine gene expression in adulthood. In contrast, females displayed no alteration in cytokine reactivity and instead exhibited sensitized CORT release to later challenges in adulthood, an effect that was absent in males. The goal of the present study, therefore, was to test whether these sexually dimorphic effects of adolescent CIE were unique to the adolescent period, or a more general response to ethanol that would also be observed in adult CIE-exposed rats. To test this, Sprague Dawley rats were given daily 4.0 g/kg intragastric (i.g.) ethanol exposures for three consecutive days followed by two days of abstinence/withdrawal. This "cycle" was repeated for a total of four "cycles" spanning postnatal day (P) P70-P90 and then left undisturbed for an equivalent amount of time as our prior work in adolescents (~20-30 days). At P110, all rats received a one-hour restraint stress challenge and cytokine gene expression and CORT were measured. Female rats with a history of adolescent CIE displayed increased CORT release 60 minutes into restraint challenge. As expected, restraint increased circulating CORT in both male and female rats, and neither sex showed changes in CORT release as a consequence of adult ethanol history. Although adult female rats with an adult history of CIE displayed significantly reduced IL-1β expression, this difference was not observed in any other target gene examined (IL-6, TNF-α, IκBα). Male rats displayed no effects of adult CIE on any of these targets. These data suggest that our previously documented effects reflect adolescent-specific changes in immune and HPA-axis function, and that adult rats given an identical pattern of binge-like ethanol exposure display

mostly stable cytokine expression in response to restraint challenge later in life. It is perhaps worth noting that adult female rats with a history of i.g. intubations (relative to non-intubated controls) displayed altered basal IL-1 & IκBα expression. This may reflect a unique vulnerability of female rats to procedural stress. These data contribute to a growing body of work demonstrating that the unique sensitivity of adolescents to alcohol use alters immune and neuroimmune sensitivity later in life, even after long periods of abstinence.

Title: Neuroimmune and epigenetic mechanisms underlying the adolescent binge ethanol-induced loss of basal forebrain cholinergic neurons: Restoration with anti-inflammatory drugs and voluntary exercise

Authors: *R. P. VETRENO[1], J. P. BOHNSACK[2], S. C. PANDEY[3], W. LIU[4], F. T. CREWS[5]

Alcohol, Chapel Hill, NC

Abstract: Binge drinking and alcohol abuse are common during adolescence. Using the preclinical adolescent intermittent ethanol (AIE; 5.0 g/kg, i.g., 2-day on/2-day off from postnatal day [P]25 to P55) model of human adolescent binge drinking, we find reductions of basal forebrain cholinergic neuron populations that persist from late adolescence (P56) into adulthood (P220), an effect that we observed in the post-mortem human alcoholic basal forebrain. However, the mechanism underlying the persistent loss of cholinergic neurons remains to be elucidated. We tested the hypothesis that voluntary exercise and/or anti-inflammatory drug treatment would restore the AIE-induced loss of basal forebrain cholinergic neurons. We report

here that wheel running from P56 (24 hr after the conclusion of AIE) to P95 restored the AIE-induced cholinergic neuropathology as well as the increase of proinflammatory pNF-κB p65 in the adult (P95) basal forebrain. Further, AIE induced dimethylation of H3K9 on both the ChAT and TrkA genes as well as DNA methylation on the ChAT promoter CpG Island, which were reversed with exercise exposure. Exercise also recovered the AIE-induced behavioral flexibility impairments on the Morris water maze in adulthood. Administration of the anti-inflammatory drug indomethacin during AIE blocked the AIE-induced loss of cholinergic markers and concomitant increase of pNF-κB p65. Together, these data implicate a novel neuroplastic process involving neuroimmune and epigenetic mechanisms resulting in the phenotypic loss of basal forebrain cholinergic neurons following AIE. Further, these data reveal that AIE does not cause immediate cholinergic neuron degeneration highlighting the potential for the development of therapeutics. Supported by the NADIA of the NIAAA.

Title: The effects of amphetamine exposure in adolescence on Netrin-1 receptors, dopamine development, and cognitive maturation are sex-specific

Authors: *L. M. REYNOLDS[1,2], S. ISRAEL[1,2], S. CUESTA[2], M. WODZINSKI[2], M. HE[2], C. FORTIN-CLAES[2], C. FLORES[2]

Abstract: Drug use in adolescence increases later vulnerability to addiction. In male mice, repeated exposure to amphetamine (AMPH) during early adolescence downregulates the expression of the Netrin-1 receptor DCC in dopamine neurons, disrupting the development of mesocortical dopamine connectivity and leading to deficits in prefrontal cortex-dependent behaviors that persist into adulthood. However, the effects of this drug regimen on females remain unknown. Here, we treated male and female mice with an intraperitoneal regimen of

AMPH (4 mg/kg, producing peak plasma levels similar to human recreational use) or saline during early adolescence (PND 22±1-31±1). We assessed DCC expression in the ventral tegmental area (VTA) one week after treatment in females, as we have previously in males. In contrast to our previous findings in males, AMPH did not alter VTA DCC expression in female mice one week after treatment, indicating that AMPH exposure regulates VTA DCC expression not only in an age-dependent (Yetnikoff et al; 2007, 2011, 2013), but also in a sex-specific manner. We then measured behavioral inhibition, motivation, and risk-taking-like behavior in separate cohorts of adult male and female mice exposed to the same AMPH or saline regimen in adolescence. When compared to their saline-treated littermates, adult males that were exposed to AMPH during early adolescence showed impairments in behavioral inhibition, increased risk taking-like behavior, and an inability to adapt to changing reward contingencies. However, we observed no behavioral differences between adult females exposed to AMPH or saline in early adolescence. In males, AMPH exposure in early adolescence disrupts the development of mesocortical dopamine connectivity in a *Dcc*-dependent manner. We are currently assessing the effects of the AMPH or saline regimen on dopamine connectivity in females. Our data show that, in male mice, AMPH exposure in early adolescence downregulates VTA DCC expression and leads to cognitive alterations in adulthood that are associated with addiction vulnerability. Strikingly, the exact same AMPH regimen does not lead to these molecular and behavioral changes in female mice.

Title: Opposite effects of low versus high doses of amphetamine in adolescence on dopamine development and behavior

Authors: *J. RESTREPO[1,3], S. CUESTA[2,3], L. M. REYNOLDS[1,3], C. POPESCU[1], S. HE[1], C. FORTIN[3], J. EPELBAUM[1], S. SILVESTRIN[3], C. FLORES[2,3]

Abstract: The guidance cue receptor DCC plays a critical role in the development of the mesocortical dopamine system in adolescence. Furthermore, repeated exposure to an amphetamine regimen of 4 mg/kg (a dose that reaches plasma levels similar to those achieved by abused doses in humans) during early adolescence, induces downregulation of DCC expression in ventral tegmental area (VTA) dopamine neurons by recruiting the *Dcc* microRNA repressor, miR-218. In turn, this amphetamine regimen leads to disruption of mesocortical dopamine connectivity and deficits in cognitive processing in adulthood, including reduced behavioral control. Whether, exposure to low doses of amphetamine, comparable to those used in therapeutic settings, disrupts miR-218/DCC signaling and mesocortical dopamine development, needs to be established. In this study, we treated male early adolescent C57BL/6 mice (from PND 22 ± 1 to PND 31 ± 1) with saline or with low doses of amphetamine (0.5 mg/kg i.p.) every other day, for a total of 5 injections. One week after the last injection, we measured levels of miR-218, *Dcc* mRNA, and DCC protein in the VTA. We then allowed a separate group of mice to reach adulthood (PND 75 ± 15), to assess behavioral control using the Go/No-Go task. Finally, we performed stereological analysis to estimate the span of the innervation of dopamine axons in the prefrontal cortex and the number/density of their presynaptic sites. We found that: (1) in contrast to the high-dose regimen, low doses of amphetamine in adolescence do not alter *Dcc* mRNA or miR-218 expression in the VTA, but *upregulate* DCC protein levels in this region, one week later; (2) there are no discernable differences in prefrontal cortex dopamine input volume or in the number/density of mesocortical dopamine presynaptic sites between adult mice treated with the saline or low amphetamine dose regimen in early adolescence; (3) strikingly, adolescent exposure to the low dose amphetamine regimen does not lead to impaired behavioral inhibition in adulthood. Instead, this drug treatment induces an overall increase in the rate of correct responses in the Go/No Go task, in comparison to saline-treated groups. These results show that low doses of amphetamine in adolescence lead to different, even opposite dopamine and behavioral effects in adulthood, compared to high doses. These differences may result from the opposite regulation that these doses exert on miR-218/DCC signaling in the VTA.

Title: Locus coeruleus glutamatergic synapses experience divergent forms of plasticity during the adolescence to adulthood transition

Authors: *A. LOCARNO[1], I. MISEVICIUTE[1], F. PAPALEO[2], G. MARSICANO[3], B. LUTZ[4], F. E. GEORGES[5], R. TONINI[1]
[1]Neuromodulation of Cortical and Subcortical Circuits Lab., [2]Genet. of Cognition Lab., Fondazione Inst. Italiano Di Tecnologia, Genova, Italy; [3]Neurocentre Magendie, INSERM U1215, Bordeaux, France; [4]Univ. Med. Ctr. Mainz, Mainz, Germany; [5]IMN-UMR-CNRS-5293, Bordeaux, France

Abstract: The adolescent and adult brains respond differently to psychological stressors, which are encoded at the level of the prefrontal cortex (PFC) and amygdala (Amyg) circuits. This raises the possibility that unbalanced activity between PFC- and Amyg output pathways may contribute to the higher emotional reactivity and stress-related behavior observed during adolescence. The PFC and Amyg send excitatory afferents to the Locus Coeruleus (LC) nucleus, the major source of norepinephrine for the entire forebrain. This neuromodulatory nucleus has been associated with attention, arousal, emotional learning, and stress response. Whether glutamatergic inputs to LC neurons undergo experience-dependent synaptic plasticity and whether this plasticity differs between adulthood and adolescence remains to be established. To address these questions, we investigated spike-timing dependent plasticity (STDP) at excitatory LC synapses. In adult mice (P45-P60), glutamatergic inputs to LC neurons express a Hebbian form of timing-dependent LTD (t-LTD) that relies on CB1 receptor activation, and which is lost in response to social stress. In young mice (P23-P28), we found inverted STDP rules. Furthermore, plasticity in young animals requires the release of Corticotropin Releasing Factor, likely by Amyg projections to the LC. By showing post-natal functional remodeling of LC glutamatergic synapses, our results identify synaptic substrates for some of the different adrenergic-mediated behavioral responses between adolescent and adult subjects.

Title: Sex determines the behavioral and biochemical impact of dopaminergic dysfunction in the DAT Val559 mouse model

Authors: *A. STEWART[1], R. GOWISHANKAR[1,4,5], R. PEART[2], K. SPIESS[1], G. L. DAVIS[1,4], M. K. HAHN[1,3], R. D. BLAKELY[1,3]
[1]Biomed. Sci., [2]Wilkes Honors Col., [3]Brain Inst., Florida Atlantic Univ., Jupiter, FL; [4]Neurosci. Grad. Program, [5]Intl. Scholars Program, Vanderbilt Univ., Nashville, TN

Abstract: Dopaminergic dysfunction has been implicated in multiple neuropsychiatric disorders with a demonstrated sex bias including Attention-Deficit/Hyperactivity Disorder (ADHD), Autism Spectrum Disorder (ASD) and Bipolar Disorder (BPD). The dopamine (DA) transporter (DAT, *SLC6A3*) mutation Val559 exhibits spontaneous DA efflux (ADE) and has been identified in patients with ADHD, ASD, and BPD suggesting that ADE may be a shared etiological factor driving neuropsychiatric disease risk. We now show that sex influences the phenotypic manifestation of tonically elevated extracellular DA in mice. Male DAT Val559 animals display blunted amphetamine- (AMPH) and methylphenidate (MPH)-induced hyperactivity and completely lack a locomotor response to cocaine (COC). In contrast, while COC-induced locomotion was also absent in female DAT Val559 animals, the response of DAT Val559 females to AMPH and MPH was indistinguishable from that of WT mice. When the rewarding properties of COC were assayed, both male and female DAT Val559 mice acquired cocaine conditioned place preference (CPP), with females exhibiting overall higher preference scores. However, male DAT Val559 animals displayed delayed extinction as compared to their WT littermates whereas COC CPP extinction was accelerated in DAT Val559 females. The observed behavioral resilience of female DAT Val559 mice to alterations in psychostimulant responses may stem from a differential impact of the mutation on DAT function. For example, in synaptosomes isolated from the striatum of male mice, we observed a significant rightward shift in potency for AMPH, but not COC, whereas shifts in the potency of DA uptake inhibition were not observed in DAT Val559 females. Further, *in vivo* chronoamperometry revealed an attenuation in dorsal striatal DA clearance in male DAT Val559 mice whereas a similar impact of the mutation was not seen in females. Together these data provide evidence for a sex-dependence to the penetrance of molecular, physiological and behavioral effects of the DAT Val559 variant, underscore the importance of *in vivo* models interrogating the functional impact of DAT mutations, and indicate that the DAT Val559 mouse model offers opportunities to delve into the influence of sex on molecules, neurons, circuits and behaviors that link DA to neuropsychiatric disorders.

Abstract: Aberrations in dopaminergic neurotransmission have been linked to multiple neuropsychiatric disorders. Given the possibility that this overlapping mechanism is rooted in shared genetic insult(s), the Blakely lab conducted a genetic screen for patients harboring rare, functional coding variation in the dopamine (DA) transporter (DAT) gene, identifying the Ala559Val substitution in two male siblings with Attention-Deficit Hyperactivity Disorder (ADHD) that has also been identified in subjects with Autism Spectrum Disorder (ASD) and Bipolar Disorder. DAT Val559 exhibits a phenotype of basal DA leak, leading to elevations in extracellular DA in DAT Val559 knock-in mice. Previous work in the lab has demonstrated that these animals exhibit waiting impulsivity, which appears to be driven by a heightened motivational state. In addition, the animals exhibit a habitual checking behavior in operant tasks whereby they will continue to seek reward even following reward devaluation, possibly indicative of compulsive perseveration. Here, we evaluate the impact of the DAT Val559 mutation on reversal learning, using a pairwise discrimination paradigm. Initial findings indicate that the DAT Val559 mutant mice do not differ significantly from wild-type (WT) littermates in task acquisition. Ongoing studies are examining changes in the rate by which WT and DAT Val559 animals reverse their activity to select a previously non-rewarded option. Given the presence of habitual behaviors in other operant behavioral tasks, we predict that the mutant mice would fail to inhibit past learned behaviors once the rewarded stimulus is reversed. As deficits in cognitive flexibility are characteristic of children with both ADHD and ASD, disorders in which the DAT Val559 mutation has been identified, DAT Val559 mice could, then, be used as a model to investigate the circuit-level and neurochemical basis for disease-associated cognitive inflexibility.

Title: Screening the *C. elegans* million mutation project library to identify regulators of dopamine signaling

Authors: *O. REFAI[1], P. RODRIGUEZ[1], R. D. BLAKELY[1,2]
[1]Florida Atlantic Univ., Jupiter, FL; [2]FAU Brain Inst., Jupiter, FL

Abstract: Dopamine (DA) is a catecholamine neurotransmitter in both vertebrate and invertebrate nervous systems, including the nematode *C. elegans*. DA modulates a wide variety of behaviors including movement, attention, learning and reward. In humans, disruption of DA levels and signaling is associated with multiple brain disorders such as Bipolar Disorder, Parkinson's disease, Schizophrenia, Attention Hyperactivity Disorder (ADHD), and addiction. The DA transporter (DAT) regulates the spatial and temporal dynamics of extracellular DA. In *C. elegans*, DA is produced by eight neurons in the hermaphrodite (4 CEP, 2 ADE, 2 PDE). Proteins that support DA biosynthesis, DA vesicular packaging and release and DA reuptake are highly conserved across phylogeny. Indeed, a wild-type form of the human DAT can rescue the knockout phenotype of *C. elegans dat-1* mutants, indicating the functional conservation between human and nematode DAT proteins. Thus, the simple *C. elegans* dopaminergic system presents an ideal model to study DA signaling. Mutation in the DA transporter protein (DAT-1) results in a phenotype that we termed Swimming-induced paralysis (Swip), which we used previously to identify novel *dat-1* alleles and genetic determinants of DA signaling (Hardaway et al 2012; 2015; Bermingham et al, 2017). Here, we extend our screening efforts to the *C. elegans* Million Mutation Project (MMP) Library. The MMP Library represents a bank of mutant strains that possess pre-sequenced mutations, usually missense point mutations. We screened 300 MMP lines and identified 38 strains that exhibited a SWIP phenotype. Lines were tested for their locomotion behavior on plates to identify animals with otherwise normal movement. Mutants were then prioritized based on their paralysis strength, with 50% or greater Swip by 10 minutes selected for further analysis. We used the antipsychotic drug and DOP-3 receptor blocker azaperone to validate DA-dependence of Swip in these lines. In this effort, 10 strains showed significant reversal of SWIP paralysis, similar to that of *dat-1* mutants treated with azaperone. Subsequently, strains were outcrossed to an N2 wild-type background at least four times, while monitoring the Swip phenotype, to remove background mutations. To further validate candidate mutants, we have acquired and tested other alleles to validate gene selection, and are validating azaperone results using crosses to *dop-3* and the DA synthesis enzyme *cat-2*, which we previously showed to suppress the SWIP of *dat-1* mutants. Ongoing efforts, using cell-specific gene rescue strategies, are aimed at determining whether these genes exert their effects within DA neurons or act indirectly.

Title: Epigenetic effects of amphetamine in dopamine transporter regulation: Insights from *C. elegans*

Authors: *S. M. SOSSI[1], K. R. KUDUMALA[1], G. AMBIGAPATHY[2], L. CARVELLI[1]
[1]Brain Inst. and Harriet Wilkes Honors Col., Florida Atlantic Univ., Jupiter, FL; [2]Dept. of Biomed. Sci., Univ. of North Dakota Sch. of Med. & Hlth. Sci., Grand Forks, ND

Abstract: Amphetamine (AMPH) is a psychostimulant that is addictive in nature. Use and abuse of this drug have serious side effects. Nevertheless, it is also used to alleviate symptoms in Attention Deficit Hyperactivity Disorder (ADHD). One well-known mode of action of AMPH is to compete with dopamine (DA) to bind to the dopamine transporter and affect reuptake of extracellular DA as well as by stimulating efflux of intracellular DA. Long-term exposure to this drug may contribute to long-lasting epigenetic changes leading to alterations in gene expression. However, the exact mechanisms that mediate these effects at the genomic level are poorly understood. The nematode *C. elegans* has 8 dopaminergic neurons and the genes involved in the dopaminergic signaling pathway are conserved between the worms and humans. With its amenable molecular, cellular, and genetic tools as well as its short life cycle, *C. elegans* is advantageous for studying heritable alterations caused by drug exposure across multiple generations. Exposure to AMPH results in a behavioral phenotype termed Swimming Induced Paralysis (SWIP) in young adult worms, which has been previously determined to be largely mediated by the dopamine transporter, DAT-1. Here, we took advantage of SWIP phenotype to test the long-term effects of AMPH exposure across generations. We found that adult (F0) worms that were exposed to AMPH during development had a higher AMPH-induced SWIP compared to control-treated animals. Moreover, the F1 and F2 progeny originating from AMPH treated parental worms also showed an elevated SWIP response. Thus, our results show that chronic AMPH exposure during development sensitizes adult worms and their progeny to AMPH, suggesting that AMPH causes heritable alterations in gene expression. Recent studies indicate a major role of epigenetic mechanisms, such as chromatin modifications, in addiction and hence we investigated the role of histone modifications on DAT-1 gene. Using Chromatin Immunoprecipitation (ChIP) assays, we found that animals exposed to AMPH showed significant alterations of specific histone markers at the promoter region of DAT-1 in both adults and progeny. Taken together, our results indicate a potential role for epigenetics in the

mechanism of action of AMPH and provides insights into the regulation of dopamine transporter in normal and pathological states.

Title: Investigating the behavioral impact of regulated dopamine transporter endocytosis in *Drosophila melanogaster*

Authors: *R. R. FAGAN[1,2,3], C. G. SWEENEY[1,2,3], P. EMERY[1,3], H. E. MELIKIAN[1,2,3]

Abstract: Dopamine (DA) is a critical regulator of movement, sleep, reward, and cognition. The presynaptic dopamine transporter (DAT), clears released DA, and thereby significantly impacts DA signaling and homeostasis. Psychostimulants including methylphenidate (Ritalin), cocaine, and amphetamine (AMPH), are competitive DAT inhibitors and substrates that enhance extracellular DA. Genetic DAT ablation in mice and invertebrates results in behavioral defects including hyperactivity, reduced sleep, and altered psychostimulant responses. Multiple DAT coding variants identified in attention-deficit/hyperactivity disorder (ADHD), infantile parkinsonism-dystonia, and autism spectrum disorder probands, support that DAT plays a vital role in maintaining DA homeostasis. DAT surface expression is not static under basal conditions; DAT constitutively recycles to and from the plasma membrane, and protein kinase C (PKC) activation significantly stimulates DAT internalization, which decreases DAT surface levels and function. We previously reported that the neuronal GTPase, Rin (RIT2), binds directly to DAT and is required for PKC-stimulated DAT internalization. While considerable progress has been made to define the mechanisms underlying PKC-dependent DAT surface regulation, it is unclear how DAT trafficking impacts DA-dependent behaviors and signaling. Here we leveraged the model organism, *Drosophila melanogaster*, to directly test how DAT trafficking dysregulation impacts DA-dependent locomotion and sleep. To perturb DAT trafficking *in vivo,* we used the GAL4-UAS system in two ways: 1) we manipulated the DAergic expression and function of Ric, the *Drosophila* Rin ortholog, which is required for PKC-mediated *Drosophila* DAT (dDAT) downregulation in cell lines, and 2) we expressed DAT trafficking-mutants, including the ADHD coding variant R615C, on the dDAT null background. Overexpressing constitutively active Ric

in DA neurons significantly decreased total sleep in adult flies. These flies also exhibited increased DA uptake measured in intact *ex vivo* brains, demonstrating that Ric activity in DA neurons correlates with altered DA-dependent behavior. Ongoing experiments will use RNAi to test whether Ric expression in DA neurons is required for locomotion or sleep. Moreover, we will directly test whether DAT trafficking-dysregulated mutants impact DA-dependent behaviors, including locomotion, sleep, and reward, using *Drosophila* strains that express WT or trafficking-dysregulated human DAT constructs on the dDAT null background. Taken together, these studies will illuminate the role that DAT trafficking imposes on DA-dependent behaviors.

Title: Presynaptic Gq-coupled receptor activation drives D2-dependent, biphasic dopamine transporter surface trafficking

Authors: *P. J. KEARNEY, H. E. MELIKIAN
Neurobio., UMASS Med. Sch., Worcester, MA

Abstract: Dopamine (DA) is a modulatory neurotransmitter critical for behaviors such as movement and reward, as well as cognitive functions including learning and memory. Aberrant DAergic transmission is implicated in multiple neuropsychiatric disorders including ADHD, Parkinson's disease, and addiction. The presynaptic DA transporter (DAT) spatiotemporally controls DA signaling by rapidly clearing released DA. Given that DAergic signaling is highly sensitive to DAT function, understanding the molecular mechanisms that control DAT function and availability is critical for understanding DA neurotransmission and dysfunction in DA-related disorders. DAT constitutively internalizes and recycles to the plasma membrane, and acute protein kinase C (PKC) activation with phorbol esters stimulates rapid DAT internalization and functional down-regulation. Although considerable progress has been made to define the molecular mechanisms governing basal and PKC-regulated DAT trafficking, it is unclear how DAT is regulated in response to endogenous presynaptic receptors that are activated upstream of PKC, such as Gq-coupled receptors, and how the complex signaling stemming from Gq receptor activation integrate to control DAT surface expression and function. In this study, we conditionally expressed the chemogenetic DREADD (Designer Receptors Exclusively Activated

by Designer Drugs), hM3Dq, in mouse DAergic neurons, and tested the impact of presynaptic Gq activation on DAT surface expression in *ex vivo* striatal slices. Gq activation drove biphasic DAT surface trafficking, with a significant increase in DAT surface expression within 5 minutes in both the dorsal and ventral striatum with a return to baseline in dorsal striatum and a net downregulation in ventral striatum by 10 and 30 minutes. Pharmacological DA depletion and D2 receptor (D2R) inhibition studies revealed that Gq-mediated DAT insertion was dependent upon DA release and D2R activation. Furthermore, activating the endogenous Gq-coupled muscarinic receptor 5 (M5) resulted in similar increases in DAT surface expression within 5 minutes in the ventral striatum in *ex vivo* slices. These studies suggest that DAT surface expression is rapidly modulated in response to presynaptic Gq activation and that a combination of presynaptic signaling and autoreceptor activity impacts DAT surface expression through multimodal trafficking mechanisms. Ongoing studies will leverage pharmacological and novel *in vivo* gene silencing approaches to specifically determine the mechanisms required for Gq-mediated biphasic DAT trafficking, and will test whether Gq-stimulated DAT trafficking impacts DA signaling.

Title: PKC-stimulated dopamine transporter internalization: Interdependent roles of Rin, Ack1 and transporter amino- and carboxy termini

Authors: *H. E. MELIKIAN, C. G. SWEENEY, B. S. ALEJANDRO, L. C. O'CONNOR, R. R. FAGAN

Abstract: The neurotransmitter dopamine (DA) is critical for movement, motivation, and reward. Synaptic DA availability is spatially and temporally limited by presynaptic DA clearance, mediated by the DA transporter (DAT). DAT coding variants in patients with DA-related neuropsychiatric disorders clearly illustrate that DAT is vital for DA homeostasis and DA-related behaviors. DAT surface stability is highly plastic, and PKC activation stimulates rapid DAT internalization that acutely diminishes DAT surface levels. The neuronal GTPase, Rin, binds to DAT and is required for PKC-stimulated DAT endocytosis. PKC-stimulated DAT

internalization also requires inactivation of the non-receptor tyrosine kinase, Ack1. However, it is unknown whether Rin and Ack1 are functionally linked to promote PKC-stimulated DAT internalization, nor is it known whether PKC regulates a functional Rin/Ack1/DAT complex. We used GTPase mutants and knockdown to test the mechanistic linkage between Rin, Ack1 and DAT, and used a chimeric transporter approach to test which DAT domains are required for stimulated DAT endocytosis and DAT/Rin interactions. PKC-mediated Ack1 inactivation requires Rin, placing Rin upstream of Ack1 in the PKC-stimulated DAT regulatory pathway. Ongoing studies will examine how Rin knockdown impacts PKC-stimulated Ack1 inactivation and DAT internalization. Given that the DAT intracellular terminal domains are crucial sites for regulating transporter function, surface stability, and protein-protein interactions, we further hypothesized that the Rin- and Ack1-dependent endocytic mechanisms synergistically require the DAT N- and C-termini. To test this possibility, we used a transporter chimera approach in which DAT intracellular termini were replaced with the cognate serotonin transporter (SERT) domains. We found that the DAT N-terminus, but not the C-terminus, is required for PKC-mediated internalization, but not internalization in response to Ack1 inactivation. In contrast, both DAT N- and C-termini are required for stimulated DAT internalization in response to Ack1 inactivation. Preliminary pulldown studies using an extracellular bungarotoxin binding site in DAT suggest that PKC activation decreases the wild-type DAT/Rin association, and that PKC-stimulated DAT/Rin dissociation may require the DAT N-terminus. Taken together, these studies will further elucidate the interplay between two known signaling pathways that control DAT surface expression, and test whether the intracellular termini synergistically coordinate for DAT internalization in response to these signaling events.

Abstract: Monoamines are often regarded as neurotransmitters that are released from vesicles at axon terminals. However, recent work has demonstrated that intracellular, non-vesicular monoamines can be covalently added to glutamine (Q) residues on proteins (i.e., post-translationally) via tissue transglutaminase 2 (TGM2) and affect a variety of biological processes. We have previously demonstrated that histone H3Q5 is a potent substrate for monoaminylation and we have uncovered roles for brain H3Q5 serotonylation and dopaminylation in depression- and drug-related behavior. However, H3Q5 histaminylation remains to be explored. Given that brain histamine levels are largely rhythmic across circadian cycles, we sought to explore the role of H3Q5 histaminylation in regulating circadian behavior. We used specific antibodies to detect H3Q5 histaminylation (i.e., H3Q5his) at several time points across 24 h in mouse tuberomammillary nucleus (TMN), the source of brain histamine, using Western blot. We then reduced levels of H3Q5his in the mouse TMN using a lentivirus that mutates the Q5 into an alanine (i.e., LV-H3Q5A) and tested circadian and anxiety-related behavior. Across the 24-h zeitgeber, TMN H3Q5his expression exhibited a rhythmic pattern, where levels appear to rise and fall during the transitions into active (i.e., night) and inactive (i.e., day) periods, respectively. Upon H3Q5his knockdown in the mouse TMN, circadian locomotor was altered compared to controls and the LV-H3Q5A group also exhibited reduced anxiety-like behavior. H3Q5 histaminylation appears to be regulated differentially across circadian periods and itself regulate circadian and anxiety-like behavior in mice. In order to investigate the mechanism for these effects, we performed isothermal titration calorimetry (ITC) to examine binding efficiencies of known epigenetic regulator proteins onto H3Q5his. Interestingly, we found that WDR5 (a WD40-repeat protein involved in depositing methyl groups onto H3K4) tolerates binding to H3Q5 serotonylation, but has significantly reduced binding (~5 fold) onto H3Q5his. Future studies will utilize ChIP-seq for H3Q5his, WDR5, and H3K4me3 in order to identify enriched loci across 24 h in the TMN, coupled with transcriptional profiling using RNA-seq. These experiments may reveal a novel mechanism of how H3Q5 histaminylation influences circadian gene expression and behavior.

Purdue Univ. at Indianapolis Dept. of Biol., Indianapolis, IN

Abstract: Down syndrome (DS) is the most common genetic cause of intellectual disability worldwide resulting from triplication of chromosome 21 (HSA21) in humans. Despite much progress in understanding the genetics of DS, the genes encoded on HSA21 that directly contribute to intellectual disability, as well as their associated molecular mechanisms, remain incompletely understood. BRWD1 is an uncharacterized, brain enriched chromatin effector protein encoded within the DS critical region 2 on HSA21. BRWD1 is believed to act as a transcriptional activator via its proposed interactions with the SWI/SNF chromatin remodeling complex; however, its roles in the contexts of neurodevelopment and in DS have yet to be studied. Consistent with previous gene expression analyses in human DS brain, we observe that Brwd1 expression is significantly elevated in Ts65Dn mice–a well established model of DS–as well as in neurons derived from hiPSCs from DS subjects. Select histone posttranslational modifications (PTMs), some of which we have already shown to directly interact with BRWD1, are also altered in their expression. We recently demonstrated that genetic re-normalization of Brwd1 expression in Ts65Dn mice significantly rescues deficits in trisomy associated transcription, hippocampal LTP and cognition. Furthermore, exogenous Brwd1 overexpression–via viral-mediated transduction of adult dorsal hippocampal neurons in wildtype animals–also leads to deficits in both contextual and spatial memory. It is therefore our working hypothesis that BRWD1 trisomy in DS brain results in aberrant interactions between BRWD1 and the epigenetic landscape, thereby contributing to transcriptional dysplasticity and cognitive deficits. We are now testing this hypothesis in the following ways: 2) Investigating the mechanistic impact of Brwd1 triplication on gene expression in DS-like brain. We are performing unbiased, epigenome-wide analyses of Brwd1 enrichment–along with associated histone PTMs–in Ts65Dn (+/- rescue) brain, followed by overlay comparisons with gene expression profiles obtained using RNA-seq; and 2) Exploring the impact of Brwd1 triplication on recruitment and activity of specific SWI/SNF chromatin remodeling complexes in Ts65Dn mouse brain using biochemical and genome-wide assessments. These experiments will allow us to mechanistically dissect the

functional consequences of abnormal patterns of chromatin regulation in DS brain and will aid in our understanding of the neuroepigenetic processes associated with brain plasticity.

Abstract: Drug abuse is characterized by loss of control over drug intake, as well as persistent drug-seeking behaviors, despite negative consequences to both the drug abuser and those directly affected by their behavior. Given that drug addicts continue to crave and pursue drugs of abuse following extended periods of abstinence and/or treatment indicates that there must be life-long changes that occur in brain to promote these behavioral phenotypes. Persistent changes in neuronal gene expression are known to promote physiological alterations implicated in drug addiction. More recently, cell-type and brain region specific epigenetic mechanisms have also been demonstrated to regulate transcriptional programs contributing to addiction-like behaviors; however, our understanding of how these mechanisms mediate life-long addiction remains

limited. Dopaminergic neurotransmission in the central nervous system plays a critical role in psychostimulant-induced neural plasticity, with alterations in dopamine (DA) production/function being implicated in both the development and treatment of substance abuse disorders. Although packaging of DA by the vesicular monoamine transporter is essential for numerous aspects of reward, recent data have demonstrated the additional presence of 'reserve' pools of extravesicular monoamines in the nucleus of monoamine producing neurons. Our lab has shown that DA can form covalent bonds with histone proteins catalyzed by the tissue Transglutaminase 2 enzyme, specifically on histone 3 glutamine 5 (H3Q5dop). We have demonstrated that chronic withdrawal from extended access to cocaine in rodents, results in high levels of DA accumulation in the nucleus of neurons in the VTA, as well as a robust increase in H3Q5dop. Furthermore, we have shown that inhibition of H3Q5dop in VTA represses DA release following cocaine SA and subsequently represses cocaine-seeking behaviors. Interestingly, we have also observed increased amounts of nuclear DA, as well as accumulation of H3Q5dop, in NAc neurons, a non-DAergic producing projection region of VTA, in extended access cocaine animals following a short (24 hr) withdrawal period. Additionally, blocking H3Q5dop in NAc similarly results in decreased cocaine-seeking behaviors following prolonged withdrawal suggesting a circuit-based phenomenon for H3Q5dop in regulating addictive and relapse associated phenotypes. Taken together, these potentially paradigm-shifting studies promise to aid in our understanding as to how monoamines, specifically DA, function in brain to regulate neurotransmission-independent neuronal plasticity and cocaine-mediated behaviors.

Title: Histone serotonylation and its dynamic effects on DNA methylation

Authors: *L. FARRELLY[1], S. ZHAO[2], R. THOMPSON[3], Y. LU[1], L. SHEN[1], A. RAMAKRISHNAN[1], T. MUIR[3], H. LI[2], I. MAZE[1]

[1]Neurosci., Dept. of Neurosci., New York, NY; [2]Tsinghua Univ., Beijing, China; [3]Princeton Univ., New Jersey, NJ

Abstract: Dynamic changes in histone modifications often precede *de novo* DNA methylation and can affect the overall rate of DNA methyltransferase (DNMT) activities. Moreover, aberrant alterations in these epigenetic processes have been demonstrated to result in various disease states. recently identified a novel chromatin modification in eukaryotic organisms, histone serotonylation, which mediates permissive gene expression in mammalian adult and embryonic brain, as well as in models of serotonergic neuronal differentiation. Furthermore, we have defined its biophysical activities as a putative co-regulator of general transcription factor complex (specifically TFIID) recruitment to H3K4me3 marked chromatin.
Our recent data have provided further evidence that histone serotonylation may have consequential effects on DNA methylation *in vivo* that is reflected by differential DNMT3A activity in the presence of serotonylated histones. Stemming from our observation that histone serotonylation is increased in its enrichment in gene bodies of highly permissive loci, this novel modification may act to recruit DNMT3A to accessible chromatin, thereby potentiating its activity and antagonizing the recruitment of repressive complexes, such as PRC2. Recruitment of DNMT3A may link gene body DNA methylation with differentiation-induced alternative splicing, as H3Q5serotonyl is also involved in the recruitment of various subunits of the Splicesome to regions of permissive chromatin.
These mechanisms may be of critical importance, as histone serotonylation likely directs the activities of DNMTs that may be necessary for maintaining chromatin states of genes implicated in normal neurodevelopment, and perhaps even in adulthood neural plasticity. A multitude of DNA methylation assessments, both in culture and in brain, using genome-wide platforms, such as bisulfite sequencing, will assess the interplay between histone serotonylation and DNA methylation, both in developmental and disease models. The importance of assessing specific genomic locations displaying altered DNA methylation in the presence of histone serotonylation will greatly advance our knowledge of this novel histone modification, as well as provide insights into its aberrant regulation in neurological disease states.

Abstract: The field of neuroepigenetics has grown rapidly over the past few decades and has recently implicated chromatin phenomena in the etiology of several psychiatric disorders including major depressive disorder (MDD). While it has been demonstrated that dysregulation of histone posttranslational modifications (PTMs) may be involved in the deleterious transcriptional processes that promote physiological maladaptations in MDD, the field still has only a limited understanding of the underlying mechanisms contributing to this disorder. While it is clear that serotonergic signaling in brain, or aberrations thereof, plays a critical role in the pathophysiology and treatment of MDD, new data from our laboratory suggest potential alternative mechanisms of action for monoamines-so-called histone serotonylation-whereby, for example, the presence of serotonin in the nucleus of dorsal raphe (DRN) neurons may directly mediate transcriptional responses related to various forms of serotonergic plasticity, and the subsequent mediation of mood. Our preliminary data indicate that histone serotonylation is significantly altered in both postmortem DRN tissues from MDD subjects and in chronically stressed rodents, phenomena that appear to be reversed by antidepressant treatments. Furthermore, potentiation of such alterations in a rodent model of MDD (e.g., chronic social defeat stress, CSDS) induced various molecular and circuit level adaptations throughout the DRN. Our studies provide a causal link between these molecular changes and the persistence of depressive-like phenotypes.
While a myriad drugs exist that target monoaminergic dysfunction in brain, antidepressant treatments are only effective for ~1/3 of individuals with MDD. Therefore, it is important to establish novel approaches that specifically target histone PTMs in a cell-type specific manner *in vivo* to better understand their direct contributions to disease states for the development of future pharmacological interventions. Thus, we have developed novel intein-based chemical methodologies to synthesize specific histone PTMs to more directly assess a functional role for histone serotonylation in depressive-like behaviors.

Title: Epigenetic profiling of chromatin accessibility in MDD identifies glial dysfunction in reward-processing cortex

Authors: *S. L. FULTON[1], J. FULLARD[2], J. BENDL[2], K. GLEASON[3], A. LEPACK[4], C. A. TAMMINGA[6], P. ROUSSOS[2], I. S. MAZE[5]

Ctr. at Dallas, Dallas, TX

Abstract: Throughout neurodevelopment and into adulthood, precisely coordinated spatiotemporal regulation of chromatin accessibility and nucleosome dynamics dictates the complex transcriptional programs required for neuronal maturation and function. Recently, our laboratory described a novel mechanistic role for histone turnover in regulating transcriptional plasticity. We found that the H3.3 histone variant accumulates in neuronal chromatin with age, remaining highly dynamic over time. Critically, H3.3 deposition into nucleosomes is required for activity-dependent gene expression, synaptic connectivity and cognition. We now extend these findings to investigate the role of chromatin accessibility and H3.3 dynamics in the neuropsychiatric disease state of Major Depressive Disorder (MDD).
In the Chronic Social Defeat Stress (CSDS) mouse model of depression, we observed increased H3.3 turnover in the prefrontal cortex (PFC) of susceptible, but not resilient, mice. Furthermore, disrupting H3.3 turnover via miRNA KD of H3.3 in the PFC resulted in a pro-resilient phenotype indicating that higher levels of turnover in this region may reflect an aberrant stress response. Interestingly, in the orbitofrontal cortex (OFC), a key cortical region affected in MDD in human clinical cohorts, we found increased H3.3 turnover to be highly cell-type specific; in FAC-sorted tissues, we identified a significant increase in H3.3 only in non-neuronal cells suggesting that glial dysfunction may be a driving force behind MDD-related transcriptional abnormalities. Thus, to profile genome-wide nucleosomal deposition patterns and chromatin accessibility in cell-type specific manner, we used ATAC-seq (*A*ssay for *T*ransposase-*A*ccessible *C*hromatin coupled to next generation sequencing) on FACS-isolated neurons and glia. We identified many differentially accessible open chromatin regions (OCRs) associated with MDD, but only in the non-neuronal cell population. We then investigated the upstream transcription

factors that may bind to these cis-regulatory OCRs and are thus establishing the OFC chromatin signature in MDD, as well as the downstream targets of these OCRs to discover important molecules and pathways involved in the MDD pathophysiology. The current study will greatly advance understanding of how chromatin structural organization in non-neuronal cells affects nucleosome dynamics and gene expression in the context of MDD, and may also identify novel mediators of depression for future therapeutics development.

Title: Treatment of drug-resistant seizures with chloride extrusion enhancer CLP257

Authors: *V. I. DZHALA, K. STALEY
Dept. of Neurol., Massachusetts Gen. Hosp., Charlestown, MA

Abstract: Neuronal chloride concentration ($[Cl^-]_i$) is an important determinant of post-synaptic $GABA_A$-R mediated signaling and cell volume regulation. Altered Cl^- equilibrium results in cell swelling, accumulation of $[Cl^-]_i$, and GABA depolarizing responses, which foster seizures and anticonvulsant resistance. Cl^- equilibrium is mediated by a Donnan system in which the cation-chloride co-transporters (CCCs) KCC2 (Cl^- exporter) and NKCC1 (Cl^- importer) comprise the requisite cation and Cl^- membrane permeability. Under pathological conditions, this permeability may limit the rate at which Cl^- equilibrium and GABA signaling can be restored. We investigated whether altering CCC activity affects $[Cl^-]_i$ in injured neurons, and the downstream effects on GABAergic inhibition and seizures. We tested the mechanism of action and specificity of the putative KCC2 up-regulator CLP257, and KCC2 inhibitors VU 0240551 and VU 0463271 in the organotypic hippocampal slice *in vitro* model of epileptogenesis. Extracellular field potential recordings and two-photon imaging of the transgenic chloride fluorophore Clomeleon were used to monitor neuronal network activity, $[Cl^-]_i$ and neuronal cell volume. We found that: (i) CLP257 improved $[Cl^-]_i$ homeostasis and reduced seizure activity in a concentration-dependent manner; (ii) the $GABA_A$-R antagonist SR95531 (10 μM) prevented the anticonvulsant action of CLP257 (30 μM), and the NKCC1 and KCC2 blocker bumetanide (10 and 200 μM) reduced the anticonvulsant action of CLP257 and the rate of Cl^- reduction; (iii) the VU KCC2 antagonists reduced the frequency of ictal-like discharges but strongly increased the frequency

and power of interictal epileptiform discharges and corresponding Cl^- transients in a dose-dependent manner; (iv) VU 0240551 (10 μM) pro-convulsant actions and corresponding Cl^- transients were not affected by block of CCCs with bumetanide (10 and 200 μM); (v) sodium channel blocker TTX (1 μM) abolished VU 0240551 (10 μM) induced epileptiform discharges and corresponding Cl^- transients without affecting E_{Cl}. Our results indicate that: 1) the anticonvulsant actions of high dose CLP257 (30 μM) are likely partially mediated by increased KCC2 activity; 2) the pro-epileptic action of VU and corresponding Cl^- transients are not mediated by CCC modulation. Our data validate CLP257 as a promising target of investigation for antiepileptic therapies, and highlight the ongoing need to develop more specific activators and inhibitors of KCC2 co-transport.

Title: Characterization of neuronal chloride microdomains

Authors: *N. RAHMATI, K. NORMOYLE, J. GLYKYS, K. STALEY
Harvard Med. Sch. & Massachusetts Gen. Hos, Boston, MA

Abstract: Abstract. Cytoplasmic chloride plays an essential role in the regulation of the polarity of ligand-gated anion channels. Differences in the intracellular chloride concentration ($[Cl^-]_i$) of neurons lead to oppositely directed chloride flow, GABA signaling, and anticonvulsant effects. Therefore, understanding the mechanisms underlying $[Cl^-]_i$ regulation is critical for unraveling the variability in GABA reversal potential (E_{GABA}) and the effects of anticonvulsants. Electrophysiological estimates of cytoplasmic neuronal chloride concentrations are notable for the variance between neurons and also between different compartments of the same neuron. We have confirmed our previously published studies by demonstrating that cytoplasmic chloride concentration varies both in different brain regions (e.g. in cortical vs. subcortical neurons) and in different neurons from the same region. Utilizing multiphoton microscopy and transgenic chloride-sensitive fluorophores, we now demonstrate differences in chloride concentrations in different subcellular cytoplasmic milieus, including cell bodies, dendrites and different segments of the same dendrites both *in vitro* and *in vivo*.
If $[Cl^-]_i$ differs in these microdomains, and this underlies the variance in electrophysiological estimates of the reversal potential for $GABA_A$ receptor-mediated Cl^- currents (E_{GABA}), then the

local E_{GABA} should be predictable from the fluorophore data. To test this hypothesis, we have embarked on characterizing the Cl^- microdomains using both microscopic analysis of the high-sensitivity Cl^- fluorophore SuperClomeleon, and electrophysiological measures of the local E_{GABA} in organotypic slice cultures and dissociated cultured neurons of murine hippocampus. Our data demonstrate that $[Cl^-]_i$ varies in different segments of dendrites, and that the borders of these microdomains are highly stable over a course of an hour. In addition, we show that there is a highly significant correlation between the dendritic $[Cl^-]_i$ calculated by SuperClomeleon and the local E_{GABA} measured by gramicidin-perforated patch-clamp recordings. These studies will shed light on neuronal chloride homeostasis and the existence of functionally significant neuronal Cl^- microdomains.

Title: Comparing phasic dopamine dynamics in the striatum, nucleus accumbens, amygdala, and medial prefrontal cortex

Authors: *Z. R. HOLLOWAY, T. FREELS, J. COMSTOCK, H. NOLEN, H. J. SABLE, D. B. LESTER
Psychology, Univ. of Memphis, Memphis, TN

Abstract: Midbrain dopaminergic neurons project to and modulate multiple highly-interconnected modules of the basal ganglia, limbic system, and frontal cortex. Dopamine regulates behaviors associated with action-selection in the striatum, reward in the nucleus accumbens (NAc), emotional processing in the amygdala, and executive functioning in the medial prefrontal cortex (mPFC). The multifunctionality of dopamine likely occurs at the individual synapses, with varied amounts of phasic dopamine release acting on different receptor populations. Using in vivo fixed potential amperometry in anesthetized mice and electrical stimulation of the medial forebrain bundle, the current study provides a comprehensive, systematic examination of phasic dopamine dynamics in the 4 predominant neural output regions of the nigrostriatal and mesocortical pathways. Amperometric recordings revealed that the striatum (1.86 uM) and NAc (2.03 uM) have significantly greater stimulation-evoked dopamine release than the the amygdala (0.19 uM) and mPFC (0.05 uM). Heterogeneity was also seen in the dopamine half-lives, i.e. the time dopamine remained in the synapse, of these sites. Again, no differences were found in the dopamine half-lives between the striatum and NAc (0.40 and 0.43 sec, respectively), but the half-life of the amygdala (0.85 sec) was twice as long and that of the

mPFC (2.12 sec) was over 5 times as long as the NAc and striatum. These results suggest that dopaminergic innervation and kinetics varies between these systems. Accordingly, when examining overall dopamine supply via a 3 min continuous stimulation, the striatum (11070 uM) and NAc (8157 uM) had increased dopamine available for release than the amygdala (5097 uM) and mPFC (4004 uM). Recordings were confirmed to be dopamine via injections of dopamine, norepinephrine, or serotonin reuptake blockers. The current findings improve understanding of regional differences in dopamine transmission and can lead to more efficient treatments for disorders related to dopamine dysfunction.

Title: The relationship between neuronal extracellular matrix, intracellular cytoskeleton, and mobile chloride

Authors: *K. P. NORMOYLE[1,2], K. J. STALEY[2,1]
[1]Neurology, Div. of Child Neurol., Massachusetts Gen. Hosp., Charlestown, MA;
[2]Massachusetts Gen. Hosp., Boston, MA

Abstract: The cytoplasmic concentration of chloride ($[Cl^-]_i$) is actively managed by neurons. $[Cl^-]_i$ varies both developmentally and spatially along the dendrites of neurons. Because $[Cl_i]$ is maintained by equilibrative transporters, variance in $[Cl^-]_i$ raises the possibility of corresponding variance in extracellular chloride concentration $[Cl^-]_o$. Small changes in transmembrane chloride gradient may profoundly affect the response to GABA-A receptor ($GABA_AR$) activation and thus affect the principle mechanism of many anti-epileptic drugs (AEDs). While the action of cation-chloride cotransporters (CCCs) NKCC1 and KCC2 and their differential expression during early development is surely important, data from multiple laboratories now demonstrate that CCCs do not set E_{GABA}. Rather, $[Cl_i]$ and $[Cl_o]$ are determined by a Donnan system of which the CCCs comprise the membrane permeability. Cytoplasmic perimembranous proteins and extracellular glycoproteins comprise the fixed charges of the Donnan system. We propose that this Donnan system determines $[Cl_i]$ and $[Cl_o]$. Importantly, such a system would also be influenced by osmotic forces because the CCCs cotransport water with cations and chloride. As the neuron integrates signals through multiple pathways to regulate cytoskeletal proteins (e.g. actin and microtubules) and extracellular matrix on multiple distinct time scales (tens of seconds to minutes to days/weeks), the Donnan potential both driving chloride flow across open

$GABA_A$Rs and contributing to CCC activity is adjusted dynamically. Differential rates of intracellular and extracellular remodeling of electrically and/or osmotically active species would result in adjustments to $[Cl^-]_i$ and $[Cl^-]_o$, which we measure directly using the genetically encoded ratiometric reporter Super-Chlomeleon (SClm) and the extracellular fluorescence lifetime imaging (FLIM) reagent SBiQ, respectively. Here we present our work studying the relationship between 'fixed' anionic and osmotically active moieties inside and outside the cell and their relationships with $[Cl^-]_i$ and $[Cl^-]_o$.

Title: Autoreceptor inhibition of dopamine release in the nucleus accumbens is altered by D2 antagonism and dopamine transporter inhibition

Authors: N. PAIGE[1], *H. J. SABLE[1], D. B. LESTER[2]
[1]Dept. of Psychology, [2]Psychology Dept., Univ. of Memphis, Memphis, TN

Abstract: The mesolimbic dopamine pathway has an established role in disorders such as addiction, ADHD, and schizophrenia. This pathway consists of dopamine cell bodies in the ventral tegmental area (VTA) that project to the nucleus accumbens (NAc), which is classically divided into 2 compartments, core and shell. NAc dopamine transmission is continually being regulated via dopamine autoreceptors (DARs) and dopamine transporters (DATs). D2 dopamine receptors have a well-established role as DARs. D3 receptors have also been suspected to function as DARs, although this is debated in the literature. Less is understood about the interaction of DARs and DATs. The present study aimed to distinguish the regulatory role of D2 and D3 receptors on VTA stimulation-evoked dopamine release in the NAc core and shell using in vivo fixed potential amperometry in anesthetized mice. Stimulation parameters specifically designed to assess DAR functioning were applied during dopamine recordings before and after local infusions of D2 or D3 receptor antagonists. To assess the impact of DAT functioning on DAR-mediated inhibition, DAR tests were also employed before and after a systemic injection of the DAT inhibitor nomifensine (10 mg/kg, i.p.). In both the NAc core and shell, infusing a D2 receptor antagonist significantly decreased DAR functioning compared to vehicle infusions, whereas infusions of the D3 receptor antagonist made no differences in DAR-mediated inhibition relative to vehicle infusions. Furthermore, DAR-mediated inhibition was increased following DAT blockade by nomifensine in both the NAc core and shell. Overall, the results indicate no differences between the NAc core and shell in the measured properties of DAR functioning.

Overall, findings indicate D2 receptors but not D3 receptors function as DARs, and DAR functioning is heightened without functional DATs suggesting a potential compensatory relationship. Determining the specific receptor types that serve as DARs and the interplay between DARs and DATs is crucial for understanding disorders related to dopamine dysfunction, especially given that DARs may serve as a therapeutic target for such disorders.

Title: High-fat vs. vegan diet: Effects on nucleus accumbens dopamine release in mice

Authors: *M. K. ESTES, J. BLAND, K. ECTOR, D. B. LESTER
Psychology, Univ. of Memphis, Memphis, TN

Abstract: Natural rewards, such as food, and drugs of abuse, such as psychstimulants, are known to increase mesolimbic dopamine activity; however, less is known about the long-term effects of diet on this reward pathway and its response to psychostimulants. In the present study, 3 diets were compared: a high-fat diet (Western Diet), a low-fat vegan diet (Daniel Fast), and a control diet (standard lab chow). C57BL/6J mice began the diet at 7 weeks old, and open field tests were conducted 4, 8, and 12 weeks post diet initiation. Following the 12-week diet period, *in vivo* fixed potential amperometry was used to measure real-time stimulation-evoked dopamine release in the nucleus accumbens of anesthetized mice before and after a drug challenge of the dopamine reuptake blocker nomifensine (10 mg/kg i.p.). The Western Diet mice weighed significantly more than the other diet groups starting 6 weeks post diet initiation. Open field tests revealed the Western Diet mice had decreased locomotor activity relative to the other diet groups (Western Diet = 622 cm, Daniel Fast = 734 cm, and control = 748 cm; $p = 0.04$ and 0.03, respectively), but only on the 4 week testing day. Western diet mice had reduced baseline (pre-drug) dopamine release compared to the other diet groups (Western Diet = 0.32 uM, Daniel Fast = 0.47 uM, and control = 0.54 uM; $p = 0.05$ and 0.01, respectively) and a reduced dopaminergic response to the nomifensine drug challenge (Western Diet = 220%, Daniel Fast = 261%, and control = 291%; $p = 0.01$ and 0.10, respectively). These results indicate that a high fat diet can reduce mesolimbic dopamine functioning as well as this reward pathway's response to a psychostimulant. These findings may be of importance to individuals suffering from and/or seeking treatment for dopamine-related disorders, such as addiction and ADHD.

Title: SUVN-502, a pure 5-HT_6 receptor antagonist potentiates the effects of donepezil or memantine on electrophysiological activity in rat hippocampus

Authors: *R. V. NIROGI, G. BHYRAPUNENI, V. S. BENADE, S. DARIPELLI, T. BANDYALA, P. ACHANTA, S. KESHARI SARAF
Suven Life Sci., Hyderabad, India

Abstract: SUVN-502 is a pure and potent 5-HT_6 antagonist being developed for the symptomatic treatment of Alzheimer's disease. SUVN-502 is orally bioavailable and has excellent brain penetration. SUVN-502 exhibited pro-cognitive properties when tested in various rodent models. When administered alone, SUVN-502 increased acetylcholine levels in brain regions involved in learning and memory, providing the neurochemical basis for the pro-cognitive effects in rodent models. Effect of SUVN-502 in combination of donepezil or memantine was evaluated using electroencephalography (EEG) for the modulation in power density of stimulation induced theta in hippocampus. Effect on the hippocampal theta activity was tested after administration of SUVN-502 (1 mg/kg, i.v.) in combination with donepezil (0.3 mg/kg, i.v.) or memantine (0.3 mg/kg, i.v.). Hippocampal theta activity was elicited by electrical stimulation of Nucleus Pontis Oralis in urethane anesthetized male Wistar rats. SUVN-502 produced significant potentiation in the donepezil or memantine evoked theta power in hippocampus. These results provide the electrophysiological evidence that SUVN-502 in combination donepezil or memantine may be beneficial in the treatment of cognitive deficits associated with Alzheimer's disease.

Title: Metabolism of ^{13}C-labeled glucose reveals altered neuronal oxidation and glutamate-glutamine cycling in UCP2$^{-/-}$ mice

Authors: *G. M. CHOWDHURY[1], Y. JU[2], T. HORVATH[3], G. SANACORA[4], D. L. ROTHMAN[5], K. L. BEHAR[4], G. HERMES[6]
[1]MRRC & Psychiatry, [2]1Department of Psychiatry and Magnetic Resonance Res. Ctr., [3]Dept. of Comparative Med., [4]Dept. of Psychiatry and Magnetic Resonance Res. Ctr., [5]Diagnos. Radiology, Magnetic Resonance Res. Ctr., [6]Dept. of Psychiatry, Yale Univ. Sch. of Med., New Haven, CT

Abstract: Deficits in mitochondrial energy production represent a common thread in the pathologies of numerous brain disorders including major depressive disorder, schizophrenia and Parkinson's Disease. Mitochondria are therefore emerging as markers for disease progression and targets for therapeutic intervention. The mitochondrial uncoupling protein 2 (UCP2), is a key mitochondrial protein contributing to central regulation of energy metabolism and has been linked to physiological processes underlying neurodegenerative disorders and metabolic syndrome in humans and in animal models. Alterations in brain energy metabolism, including reduced glucose utilization and mitochondrial respiration, are observed with impaired UCP2 expression and in the mouse knockout model UCP2-/-. Here, we apply new experimental tools to broaden the search for the role of mitochondrial UCP2 in disease states. Magnetic Resonance Spectroscopy (MRS) offers one such tool, which has been applied recently in individuals with polymorphisms of UCP2 and UCP2 knockout mice. MRS can be readily adapted to measure metabolic pathway flux by use of ^{13}C-labeled substrates. In this study we measured the flow of ^{13}C label into brain glutamate, glutamine and GABA in 12~14 week old UCP2 het (UCP2-/-, n=12), and non-carrier control (UCP2 +/+, n=12) mice following timed (8 min) intravenous infusions of [1,6-$^{13}C_2$] glucose (neuronal and glial substrate) to determine whether dynamic turnover of the major amino acids linked to brain energy metabolism and neurotransmission (glutamate, GABA and glutamine) is altered in the UCP2 mice. Following euthanasia by focused-beam microwaves, brain tissues (hippocampus, HP and pre-frontal cortex, PFC) were dissected and extracted using ethanol and the brain concentrations and ^{13}C enrichments of amino acids determined using ^{1}H-[^{13}C] MRS at 11.74T. We found that in UCP2-/- mice, ^{13}C labeling of glutamate, GABA, and glutamine was significantly lower in PFC (Glu-C4, *$p<0.01$; GABA-

C2, *$p<0.001$* and Gln-C4, *$p<0.001$*) and HP (Glu-C4, *$p<0.01$;* GABA-C2, *$p<0.01$* and Gln-C4, *$p<0.001$*) compared to wild type mice. These findings indicate that the activities of the tricarboxylic acid cycles in glutamatergic and GABAergic neurons and neuron-astroglial neurotransmitter cycles were reduced, suggesting impaired neuronal energy metabolism and neuron-astrocyte substrate cycling. These physiological changes could underlie pathology associated with UCP2 impairment and may provide targets for novel drug development.

Title: Ovariectomy reduces the suppression of excitatory synaptic transmission induced by physostigmine in layer II of the entorhinal cortex

Authors: *A. A. BATALLAN BURROWES[1], I. A. IASENZA[2], F. CARTER[3], W. SHAMS[4], C. CHAPMAN[5]
[1]Psychology, Concordia Univ., Montréal, QC, Canada; [2]Concordia Univ., Montreal, QC, Canada; [3]Concordia Univ., Montréal, QC, Canada; [4]Psychology, Concordia Univ., Montreal, QC, Canada; [5]Psychology, Concordia Univ., Concordia University, QC, Canada

Abstract: Estrogens are thought to contribute to cognitive function in part through interactions with basalforebrain cholinergic neurons which project to the hippocampus and adjacent cortical regions includingthe entorhinal cortex. Reduced availability of estrogens is associated with a decline in cognitive function,and it is possible that this may be due in part to a resulting impairment in the function of cholinergicinputs to the hippocampal region. Layer II of the entorhinal cortex, which receives strong cholinergicinnervation, contributes importantly to cognitive and mnemonic functions of the hippocampal region byproviding the hippocampus with its main source of cortical sensory input. Acetylcholine results in asuppression of glutamate release at excitatory synapses in the entorhinal cortex. In the present study, weassessed the effects of loss of estrogens on the function of cholinergic terminals indirectly, by comparingeffects of the cholinesterase inhibitor physostigmine (i.e., eserine) on excitatory synaptic transmission inbrain slices obtained from intact and ovariectomized rats. Physostigmine was used as an agonist becauseits effects depend upon amplifying the impact of the endogenous

release of acetylcholine. Ovariectomy wasconducted at ≈60 days of age, and recordings were obtained at 10 to 12 weeks of age. Horizontal acutebrain slices were obtained and field excitatory postsynaptic potentials (fEPSPs) in layer II of theentorhinal cortex were evoked by stimulation of layer I. After baseline recordings in normal aCSF,physostigmine (10 µM) was applied for 15 min. Physostigmine caused a reduction in the peak amplitudeof fEPSPs that persisted during 30 min washout in normal aCSF. However, the application ofphysostigmine caused a smaller reduction in responses in ovariectomized rats (89.5 ± 3.0% of baseline,n=12) relative to intact control rats (80.0 ±3.1% of baseline, n=8; t 18 =-2.12, p<0.05). Subsequentapplication of the muscarinic receptor blocker atropine (1 µM, 15 min) reversed the suppression offEPSPs to above baseline levels in both groups. The blunting of the suppressive effect of physostigmineon evoked excitatory responses in ovariectomized rats may be a result of reduced function in cholinergicterminals in the entorhinal cortex. This is consistent with the idea that loss of estrogens may lead toreduced cognitive function in part through disruption of cholinergic transmission within the entorhinalcortex.

Title: Dietary large neutral amino acids suppress kynurenic acid production in rat brain

Authors: *T. FUKUWATARI, A. KUSUMOTO, A. SEKINE, A. MARUYAMA, M. SANO, N. MORI, K. SHIBATA
Dept. of Nutr., The Univ. of Shiga Prefecture, Hikone, Japan

Abstract: At endogenous brain concentrations, the tryptophan metabolite kynurenic acid (KYNA) is a preferential antagonist of the α7 nicotinic acetylcholine receptor. Animal experiments show that elevated KYNA levels reduce glutamate and dopamine levels, and contribute cognitive dysfunction. Patients with schizophrenia show elevated KYNA levels in the brain and cerebral spinal fluid, suggesting the involvement of KYNA in the pathophysiology of schizophrenia. Kynurenine (KYN), the immediate precursor of KYNA, is transported into astrocytes via large neutral amino acid transporters (LATs). We have reported that high tryptophan diet increased KYNA production and reduced dopamine release in rat brain (*J Neurochem* 2011;118:796), that several LATs substrate amino acids reduce KYN uptake and

KYNA production in rat brain *in vitro* (*SpringerPuls* 2015;4:48), and that inhibition of LATs suppresses KYNA production via inhibition of KYN uptake in rodent brain (*Neurochem Res* 2016;41:2256). In the present study, we investigated the effect of large neutral amino acids diets on KYNA and KYN contents in rat brain. Rats were given 1.5% tryptophan supplemented diet with 3% valine, 3% leucine, 3% isoleucine, 1% methionine, 3% phenylalanine or 5% tyrosine for 7 days. The tryptophan supplemented diet increased brain KYNA and KYN contents, and serum KYN concentration to 2.1-, 2.4- and 1.8-fold, respectively. Additional amino acids except for valine suppressed increase of high tryptophan-induced brain KYNA and KYN contents to 0.5-0.8-fold, and failed to affect serum KYN concentration. These results suggest that intake of large neutral amino acids except for valine competitively inhibit KYN uptake by astrocytes via LATs, and thus suppress the increase of KYNA production in the brain. Dietary manipulation of KYNA formation in astrocytes may provide useful approach for the treatment of glutamate and dopamine related disorders.

Title: Ethanol modulates kynurenic acid synthesis - in an *in vitro* study

Authors: *H. BARAN, B. KEPPLINGER
Karl Landsteiner Res. Inst. Mauer, Amstetten-Mauer, Austria

Abstract: Background Ethanol interacts at one of the major sites associated with $GABA_A$ receptors. Ethanol exerts antidepressant properties and anti-dementia action is suggested. The study evaluates the action of various physiological and toxic/lethal doses of ethanol on the activity of enzymes synthesizing kynurenic acid (KYNA) kynurenine aminotransferases I, II and III (KATI, KATII and KATIII) in the rat brain and post mortem human brain, in an *in vitro* study.
Material and Methods Human post mortem samples of frontal cortex from the Boltzmann Institute, Institute of Neurobiology, General Hospital Lainz, Vienna, Austria (N = 5) were obtained. Sprague Dawley rats 3 months old male were used (N = 4). The study was performed according to the ethical regulations of the government of Austria. KATs determination performed according to method (H. Baran and B. Kepplinger, Eur. Neuropsychopharmacol., 2014).
Results Ethanol at concentration between 1.05 – 34.5 mM, respectively 0.062 - 2 ‰ lowered

slightly but significantly the activity of KAT II, KAT I and KAT III (between 10 and 15 % of control; $P<0.05$) in the homogenate of human frontal cortex. Moderate effect of ethanol on KAT II and KAT III activities was seen in rat brain homogenate, too. Higher doses of ethanol (non physiological / lethal) (34.5 - 345 mM) reduced doses dependently and significantly the activity of KAT II and KAT III in the rat brain and in the human brain homogenate (between 15 and 30 % of control, $P<0.05$).
Conclusion The present study for the first time demonstrates the ability of ethanol to lower moderately KYNA formation in rat and human brain homogenates. Modulation of KYNA formation by ethanol is interesting and a notable observation, since moderate lowering of KYNA content would constantly try to increase the dopamine neurotransmission which in fact is already affected by alcohol alone causing dependences event. We suggest that modulatory effect of alcohol on KYNA synthesis might be in part involved in the alcohol's action as an antidepressant and likely as an anti-dementia acting putative ligand. The mechanism of ethanol action on KATs activities needs to be further elaborated. All authors have no conflict of interest. Study supported by Sene*Cura* Austria.

Title: Nicotinic cholinergic receptors in VTA glutamate neurons modulate excitatory transmission

Authors: *Y. YAN[1], C. PENG[1], M. C. ARVIN[1], X. JIN[1], V. J. KIM[1], M. D. RAMSEY[1], Y. WANG[1], S. BANALA[2], D. L. WOKOSIN[1], J. MCINTOSH[3], L. D. LAVIS[2], R. M. DRENAN[1]
[1]Northwestern Univ., Chicago, IL; [2]Janelia Res. Campus, Howard Hughes Med. Inst., Ashburn, VA; [3]Univ. of Utah, Salt Lake City, UT

Abstract: The ventral tegmental area (VTA) is divided into lateral and medial subnuclei. Lateral VTA is mainly composed of dopaminergic and GABAergic neurons. Lateral VTA dopaminergic transmission contributes to reward, addiction, and other psychiatric disorders. Afferent glutamatergic neurons modulate these effects via presynaptic α7 nicotinic acetylcholine receptors (nAChRs). Although vesicular glutamate transporter 2 (VGLUT2+)-expressing neurons in the medial VTA are involved in optically stimulated reward or aversion in rodents, the expression pattern and function of nAChRs in these cells are poorly understood. In this study, we used

molecular, physiological, CRISPR gene editing, and optogenetic techniques to address these questions. Medial VTA neurons are responsive to acetylcholine released from cholinergic axons triggered by presynaptic photostimulation. Medial VTA VGLUT2+ neurons express mRNA and protein subunits known to comprise heteromeric nAChRs. Electrophysiology, coupled with 2-photon microscopy and laser flash photolysis of photoactivatable nicotine, showed nAChR functional activity in the somatodendritic subcellular compartment of VTA VGLUT2+ neurons. Finally, optogenetic isolation of intrinsic VTA glutamatergic microcircuits along with gene editing techniques demonstrated that nicotine potently modulates excitatory transmission within the VTA via heteromeric nAChRs. These results indicate that VTA glutamate neurons are modulated by cholinergic mechanisms and participate in the cascade of physiological responses to nicotine exposure.

Title: Nicotinic acetylcholine receptors mediate and modulate cholinergic circuit activity in mouse myenteric ganglia

Authors: J. F. MARGIOTTA, A. KALINOSKI, A. PERRIN, *M. J. HOWARD
Dept Neurosciences, UT Hlth. Sci., Toledo, OH

Abstract: Cholinergic nicotinic acetylcholine receptors (nAChRs) mediate a significant component of transmission in myenteric ganglia, making them critical components of enteric circuitry producing rhythmic, reciprocal activation of intestinal longitudinal and circular muscles. To probe cholinergic myenteric circuits *in-situ*, colon strips from mice engineered to express GCaMP6f in cholinergic neurons were challenged with nAChR specific agonists and antagonists. The resulting changes in GCaMP6f mediated Ca^{2+} fluorescence ($\Delta F/F$) were captured by rapid cell imaging and used to assess agonist sensitivity as well as spontaneous and

induced circuit activity. The pan-specific nAChR agonist DMPP reliably induced increases in both neuronal ΔF/F and in the frequency of ΔF/F fluctuations; both were inhibited by the pan-specific nAChR antagonist D-tubocurarine. nAChRs composed of α7-subunits (α7-nAChRs) are known to mediate and modulate transmission at some autonomic neuron synapses, and RNAseq findings reveal expression of α7-subunit transcripts in myenteric ganglia. Indicative of α7-nAChR participation in myenteric circuits, application of an α7-nAChR selective agonist (GTS-21) increased both ΔF/F levels and fluctuations. Confocal analysis of colon strips treated with Alexa Fluor 488-conjugated α-bungarotoxin (an α7-nAChR-specific neurotoxin) reveals specific labeling on myenteric neuron somas and processes. These findings are consistent with a major role for nAChRs in mediating and modulating transmission at myenteric synapses. They further indicate that functional α7-nAChRs are present in myenteric ganglia and may regulate transmission at some myenteric neuron synapses.

Title: Cholinergic interneurons facilitate disinhibition of pyramidal neurons in the rat cerebral cortex

Authors: *K. KANEKO[1], S. MATSUMURA[2], Y. OI[3], M. KOBAYASHI[4]
[1]Dept. of Anesthesiolosy, [2]Dept. of Pediatric Dent., Nihon Univ. Sch. of Dent., Tokyo, Japan; [3]Dept. of Anesthesiol., Nihon Univ. Sch. of Dentisitry, Tokyo, Japan; [4]Dept. of pharmacology, Nihon Univ. Sch. Dent., Chiyoda-Ku, Japan

Abstract: The cerebral cortex involves cholinergic interneurons in addition to cholinergic projections from the basal forebrain (BF). Cortical cholinergic interneurons (CCN) are immunopositive for vasoactive intestinal peptide (VIP), and are distributed principally in layers II/III with a bipolar somatic morphology. Several studies have reported that CCN do not exert direct inhibitory postsynaptic response in neighboring pyramidal neurons (Pyr), but indirectly increase spontaneous EPSCs in adjacent Pyr. It is also reported that cortical VIP-immunopositive interneurons are activated by cholinergic inputs from BF, and project to the somatostatin (SST)-immunopositive interneurons and parvalbumin (PV)-immunopositive interneurons, both of which inhibit Pyr. Therefore, it is likely that cholinergic inputs from BF disinhibit excitatory

neurons by exerting VIP-immunopositive interneurons-induced suppression of SST/PV-immunopositive interneurons. However, little information is available in terms of the cellular mechanisms of neuromodulation by CCN. Here, we performed whole-cell patch-clamp recording from CCN (ChAT-tdTomato- and VGAT-Venus-positive) and adjacent GABAergic interneurons and Pyr in the rat insular cortex (IC). CCN rarely projected to Pyr but principally project to low threshold spike (LTSN) or fast-spiking GABAergic neurons (FSN), which frequently induced unitary IPSCs in Pyr. In addition, CCN often mutually connected to other CCN via chemical and electrical synapses, and their repetitive spike firings were often synchronized. GABAergic projections from CCN to LTSN/FSN were attenuated by application of atropine. These results suggest that CCN disinhibit Pyr via GABAergic interneurons. Indeed, simultaneous recording from CCN, other GABAergic interneurons, and Pyr under current clamp condition demonstrated that bath application of acetylcholine induced repetitive spike firing in CCN and this spike firing was followed by enhancement of spontaneous IPSCs in the GABAergic interneurons and reduction of spontaneous IPSCs in Pyr. These effects were mimicked by nicotine. Thus, it is likely that CCN disinhibit Pyr via nicotinic and muscarinic receptors.

Title: A novel aspect of cholinergic transmission in central nervous system

Authors: *I. MURAMATSU, T. MASUOKA, M. NISHIO, T. ISHIBASHI
Dept. of Pharmacology, Sch. of Med., Kanazawa Med. Univ., Uchinada, Ishikawa, Japan

Abstract: In the central nervous system, acetylcholine (ACh) is an important neurotransmitter related to higher brain functions and some neurodegenerative diseases. It is released from cholinergic nerve terminals and acts on presynaptic and postsynaptic ACh receptors (AChRs). Following release, ACh is rapidly hydrolyzed and the resultant choline is recycled as a substrate for new ACh synthesis. However, this classical concept of cholinergic transmission is currently being reevaluated due to new evidence. Quantum release of ACh from striatum cholinergic neurons is reduced by an increase in stimulus frequency, showing an inverse correlation between release probability and neuronal excitability. ACh release is negatively regulated by presynaptic M2/M3- but not M4-muscarinic receptor subtypes. ACh esterase inhibitors including anti-

Alzheimer's disease drugs have bidirectional influences on synaptic ACh concentrations: an increase by inhibition of ACh hydrolysis and a decrease following activation of presynaptic autoreceptors. Synaptic concentrations of ACh are also regulated by uptake of ACh itself. Therefore, ACh acts on surface and intracellular M1-muscarinic AChRs, both of which are independently involved in cholinergic facilitation of long-term potentiation (LTP) in the hippocampus. Choline for ACh synthesis in cholinergic nerve terminals may be mainly supplied from choline at relevant concentration levels present in the extracellular space, rather than recycled from ACh-derived choline. Our study reveals complex mechanisms of ACh release from cholinergic terminals and initiates a new stage in cholinergic transmission and therapeutic strategies for Alzheimer's disease.

Title: Cell-type specific cholinergic modulation of the claustrum

Authors: *A. NAIR[1,2], M. GRAF[2], G. J. AUGUSTINE[2]
[1]Fac. of Sci., Natl. Univ. of Singapore, Singapore, Singapore; [2]Lee Kong Chian Sch. of Med., Nanyang Technological Univ., Singapore, Singapore

Abstract: Neuromodulatory input from acetylcholine (ACh) is known to drive selective attention (Neuron 97: 769). We characterized cholinergic modulation of neurons in the claustrum, a poorly understood brain region hypothesized to be involved in directing attention (TINS 38: 486). Whole-cell patch clamp recordings were used to measure neuronal responses to photostimulation of cholinergic inputs in brain slices prepared from a ChAT-ChR2 transgenic mouse line. We found that all types of claustrum neurons, classified based on their intrinsic electrophysiological properties, exhibited polysynaptic responses to cholinergic input. However, these responses differed according to neuron type: while projection neurons were both excited and inhibited by cholinergic input, interneurons were only excited. Although polysynaptic responses were found in 86% of claustrum neurons, a remarkably small fraction of these neurons (11%) exhibited monosynaptic responses to cholinergic input (measured in the presence of glutamate and GABA receptor blockers). This monosynaptic input was exclusively excitatory and was present in only 3 of the 6 subtypes of claustrum neurons, namely amplitude-adapting and strongly frequency-adapting projection neurons as well as VIP interneurons. This excitatory input was blocked by mecamylamine and, thus, is mediated by nicotinic ACh receptors. Our results show that the claustrum receives excitatory cholinergic input in a cell-type specific

manner and that local circuits further transform the nature of this input. Rapid nicotinic input to the claustrum may improve the signal-to-noise ratio between different cortical inputs received by the claustrum, thereby enhancing processing of task-relevant input and contributing to selective attention.

Title: Decreased synaptic physiological properties in aged central cholinergic neurons

Authors: *S. GRIGORYEV, Y. BESSONOVA, H. LAWAL
Dept. of Biol. Sci., DSU, Dover, DE

Abstract: Decline in acetylcholinergic (ACh) neurotransmission is a key characteristic of aging across different animal species. And this decline is correlated with deficits in cholinergic linked behaviors such as locomotion and learning. However, the precise contribution of cholinergic signaling remains poorly understood. We are interested in determining the contribution of the cholinergic release process to aging through the study of the vesicular acetylcholine transporter (VAChT). VAChT mediates the transport of ACh into synaptic vesicles is essential for synaptic transmission in ACh neurons. Here, our goal is to use the *Drosophila* model to determine how aging alters the synaptic physiology of Projection Neurons (PNs) in the brain. PNs are the principal neurons of the antennal lobe, and they are almost all cholinergic. They release acetylcholine from both their axonal arbors in higher brain regions and from their dendrites in the antennal lobe. These neurons receive direct excitatory synaptic inputs from olfactory receptor neurons (ORNs) which in turn receive odor stimuli from the external environment. Each type of ORN projects to a discrete glomerulus in the antennal lobe and defines an identifiable type of postsynaptic PN. Using whole cell patch clamp recordings, we characterized electrophysiological properties, including action potential generation and neuronal excitability, in the PNs in young and old flies.. We report that some but not all WT PNs fire action potentials at baseline, and that injection of varying levels of current causes a corresponding increase in AP generation. Moreover, our preliminary data show that neuron firing and neuronal excitability are markedly reduced in the old flies. These findings demonstrate that key synaptic physiological properties of

cholinergic projection neurons are altered during aging; and could provide a platform for efforts to develop interventions against the decline observed in neuronal function as organisms age.

Title: Differential involvement of distinct types of interneurons in cholinergic-induced oscillations in the basolateral amygdala

Authors: *J. X. BRATSCH-PRINCE, J. W. WARREN, G. C. JONES, A. J. MCDONALD, D. D. MOTT
Dept. of Pharmacology, Physiology, and Neurosci., Univ. of South Carolina Sch. of Med., Columbia, SC

Abstract: Acetylcholine (ACh) has been implicated in attention, learning, and memory through its modulatory action in brain areas such as the hippocampus and cortex. One of the proposed mechanisms underlying ACh's actions is the induction of synchronized oscillations that can couple brain regions. In areas of the hippocampus and cortex these oscillations are driven by muscarinic acetylcholine receptor (mAChR)-mediated activation of cholecystokinin (CCK) and somatostatin (SOM)-containing interneurons. The basolateral amygdala (BL) is a brain region important in emotional processing and memory that receives dense cholinergic projections, providing an anatomical basis for cholinergic effects in this region. Despite this dense cholinergic innervation, little is known about cholinergic modulation of BL circuits. This study explores the mechanism of cholinergic-induced rhythmic oscillations in the BL. Using whole-cell recordings, we found that focal puff application of 10mM ACh on BL pyramidal cells (PNs) induced a burst of gamma frequency (30-100 Hz) IPSCs followed by rhythmic theta frequency (4-12 Hz) IPSCs that could entrain synchronized PN firing. Both sets of IPSCs were blocked by bicuculline, but not glutamate receptor antagonists, suggesting direct cholinergic activation of interneurons (INs). The nicotinic antagonist mecamylamine blocked the gamma frequency IPSCs, suggesting they were driven by nicotinic ACh receptors. In contrast, selective blockade of M3, but not M1 mAChRs blocked the theta frequency IPSCs and rhythmic PN firing. Recordings from parvalbumin (PV)-positive, but not SOM-positive INs, revealed ACh-induced currents, suggesting a selective role of PV INs in driving the oscillations. This differs from hippocampal area CA1 and prefrontal cortex where CCK and SOM INs play a prominent role in generating

cholinergic oscillations. Interestingly, while a majority of PV INs showed an M3-sensitive depolarizing response to ACh, some exhibited a hyperpolarizing or biphasic response, suggesting that theta frequency IPSCs are driven by a subset of these PV INs. Collectively, these studies indicate that mAChRs induce theta rhythm in BL through a mechanism different than that in areas of the hippocampus and cortex.

Abstract: Cholinergic neurons of the basal forebrain project to cortical and subcortical structures and release acetylcholine (ACh), a neuromodulator critical for attention and learning. Interestingly, cholinergic neurons of the basal forebrain project most densely to the basolateral amygdala (BLa), where ACh is necessary for processing sensory inputs and forming emotional memories. However, the mechanisms underlying this processing are poorly understood. In cortical circuits, ACh facilitates afferent input while suppressing intrinsic transmission, but whether ACh exerts a similar tuning of information processing in the BLa is not known. To investigate this, we used a combination of optogenetics and slice electrophysiology to examine cholinergic modulation of afferent prelimbic (PL), thalamic (THAL), ventral subicular (VS) inputs and intrinsic recurrent projections to BLa pyramidal neurons. We optogenetically released endogenous ACh from the basal forebrain of ChAT-Cre mice, while recording field and whole-cell electrophysiological responses to determine the mechanisms of cholinergic regulation of afferent and intrinsic input to the BLa. Unlike cortex, we found that endogenous ACh significantly inhibited afferent cortical transmission to the BLa, but did not suppress intrinsic transmission. This inhibition of cortical input was blocked by bath application of the muscarinic

antagonist atropine (5 µM), indicating a role for muscarinic acetylcholine receptors (mAChRs) in modulating afferent inputs to the BLa. These results suggest fundamental differences in cholinergic regulation of information processing in cortex and amygdala. To further investigate cholinergic modulation of distinct afferent inputs, experiments using muscarinic agonists and optogenetically released glutamate demonstrated that mAChRs differentially suppress PL, THAL, and VS inputs to the BL, with greatest inhibition of PL and VS inputs and lesser inhibition of THAL inputs. Muscarinic suppression of PL and VS inputs was augmented by the M4 mAChR positive allosteric modulator VU0467154 (3µM), indicating an M4-mediated inhibition of PL and VS pathways. However, when these inputs were stimulated at gamma frequency (40Hz), mAChR-mediated inhibition failed, indicating frequency-dependent filtering by M4 mAChRs. While M4 receptors inhibited THAL input to the BL, there was also a modest inhibition of THAL input by M1 receptors, indicating mechanistic differences in mAChR regulation at this pathway. Together, these findings suggest mAChRs regulate information processing to the BL in an input-specific and activity-dependent manner that is different from that in the cortex.

Title: Cholinergic modulation of excitability of pyramidal neurons of the basolateral amygdala

Authors: *T. ANDERSON-SIEG, N. VU, J. X. BRATSCH-PRINCE, M. E. LONG, G. C. JONES, J. W. WARREN, A. J. MCDONALD, D. D. MOTT
Pharmacology, Physiology, and Neurosci., Univ. of South Carolina Sch. of Med., Columbia, SC

Abstract: Compelling evidence supports a role for cholinergic signaling in attending to and remembering salient experiences, but the precise role of acetylcholine (ACh) in mnemonic processing of these events is not yet fully understood. In the cortex, pyramidal neurons (PNs) are a prominent target of cholinergic input, but are not uniformly regulated by ACh. In this region, ACh acting through M1 muscarinic acetylcholine receptors (mAChRs) can have opposing effects on pyramidal cell excitability in different cortical layers. During a behavioral task, these opposing effects of ACh may be important in confining action potential output to selected neurons, thereby enhancing the signal-to-noise in relevant cortical circuits. Neurons in the

basolateral amygdala (BL) play an essential role in the cellular processes that underlie emotional memory. BL neurons receive very dense cholinergic innervation from basal forebrain, suggesting that acetylcholine plays a central role in regulating BL function. Indeed, pharmacological activation of mAChRs in BL enhances formation and consolidation of fear memories, whereas blockade of these receptors prevents memory consolidation. Despite the importance of mAChRs in emotional learning, the role of these receptors in modulating PNs in distinct BL circuits is poorly understood. In this study we used confocal immunofluorescence, brain slice electrophysiology and tract tracing to investigate cholinergic modulation of excitability of PNs in behaviorally relevant circuits. BL PNs in appetitive and aversive circuits were identified by injection of the retrograde tracer cholera toxin b into nucleus accumbens, ventral hippocampus and infralimbic cortex. We found that nucleus accumbens projecting PNs most densely clustered in the ventrolateral portion of the intermediate BL, while the ventral hippocampal and infralimbic projecting PNs tended to most densely populate the posterior BL. To determine if ACh uniformly depolarizes these projection PNs, whole-cell electrophysiology was used to record responses to ACh. During blockade of glutamate and GABAergic transmission, focal puff application of 10mM ACh onto BL PNs evoked a monophasic depolarizing response in 75% of recorded cells. In contrast, in the remaining cells ACh application evoked a biphasic response, consisting of an initial transient hyperpolarization followed by a prolonged depolarization. These cells did not differ in resting membrane potential or input resistance. Overall, these findings indicate that BL PNs can be segregated based on projection target and suggest differential cholinergic modulation of these cells.

Title: Recruitment of a basal forebrain cholinergic engram in conditioned fear

Authors: *P. M. RAJEBHOSALE[1], D. A. TALMAGE[2], L. W. ROLE[3]
[1]Ctr. for Nervous Syst. Disorders, State Univ. of New York At Stony Brook, Stony Brook, NY; [2]Pharmacol. Sci., [3]Neurobio. & Behavior, Stony Brook Univ., Stony Brook, NY

Abstract: We previously demonstrated that cholinergic signaling in the basolateral amygdala (BLA) is essential for the proper acquisition and retention of fear memories. How the fear

learning process engages basal-forebrain cholinergic neurons (BFCNs) and the circuit mechanisms that might underlie their recruitment are questions that remain unanswered. First, to understand the contribution of BFCNs to fear learning and recall, we asked whether BFCNs are active during fear recall. To do this, we developed viral tools for activity-dependent (AD), Cre dependent (CD), temporally controlled, and permanent labeling of neurons (ADCD). Upon recall of a fear memory, we discovered cholinergic neurons in the nucleus basalis/substantia innominata (nbM/SI) are labeled by ADCD, and that the number of ADCD+ cholinergic neurons was directly related to the animal's behavioral performance. We next asked whether the ADCD+ cholinergic neurons labeled during recall were a result of de-novo activity or if they represented an ensemble recruited and engraphed during the acquisition of the fear memory. To answer this question, we used the ADCD permanent marker to label neurons during fear acquisition and a transient activity marker (cfos-GFP) during fear recall. We observe that nbM/SI cholinergic neurons have higher reactivation in animals who received tone-shock pairings as opposed to either tone alone or homecage controls. We also observe that tone-shock pairing leads to preferential recruitment of the learning-activated cholinergic ensemble during subsequent recall. Based on these observations, we suggest the establishment of a cholinergic engram in conditioned fear. Given these activity patterns of the nbM/SI cholinergic neurons, we investigated the functional consequences of disrupting the cholinergic inputs to the BLA during different phases of fear conditioning. Inhibiting acetylcholine release in the BLA during fear acquisition significantly reduces freezing behavior during tone recall. Additionally, this manipulation alters c-fos induction in the BLA during recall. Inhibiting acetylcholine release in the BLA during fear recall preserved the freezing response to the tone, but dramatically reduced freezing behavior upon termination of the tone. Ongoing studies examine the possible circuit mechanisms engaged by the cholinergic engram including cell type-specific monosynaptic input mapping to BLA excitatory vs. inhibitory neurons and systematic mapping of the density of nbM/SI cholinergic synapses along the anterior-posterior axis of the BLA.

Title: Yin and yang of cholinergic modulation in the hippocampus

Authors: *R. SHARMA[1], S. NADKARNI[2]
[1]Biol., IISER-PUNE, Pune, India; [2]Indian Inst. of Sci. Educ. and Res. Pune, Pune, India

Abstract: Acetylcholine is a crucial neuromodulator in the hippocampus which can activate both presynaptic as well as postsynaptic signaling cascades and influence a large number of synaptic functions including receptor sensitivity, plasticity and genetic modifications. Pharmacological blocking of cholinergic receptors in the hippocampal formation impairs encoding of new memories and working memories. Acetylcholine, via the differential effects on a family of metabotropic(muscarinic) receptors, can have a paradoxical impact of suppressing synaptic transmission and enhancing the activity of hippocampal neurons over a range of time scales. Expression of acetylcholine receptors, in various parts of the brain, has been classified and molecular cascades that allow diversity of downstream signals have been elucidated in a variety of cells and in-vitro. However, how heterogeneous and concurrent expression of these receptors in the hippocampus modify synaptic transmission and plasticity remains unknown. Both M1 and M4 muscarinic acetylcholine receptors are highly expressed in hippocampal neurons. M1 expression has been reported in soma, dendrites and spines of CA3 and CA1 pyramidal cells. Their activation is seen to cause increased neuronal excitability and enhanced LTP induction. It can also lead to suppression of membrane potassium currents, thereby causing depolarization and suppression of adaptation. M4 is seen to be mainly localized in the presynaptic terminal and is seen to reduce EPSP amplitude at the Schaffer collateral terminals. We develop a multi-compartment model of CA3 and CA1 neurons that include detailed descriptions of the ion channels on the cell membrane. We model activity of M1 and M4 receptors with biophysical realism along with their downstream signaling. This paradigm allows for the investigation of changes in electrical excitability associated with M1 receptors and its effect on calcium signaling for a range of plasticity protocols. It has been suggested that information in the complex graded voltage signals experienced by the soma is not lost in binary form of synaptic transmission (release or no release) at the CA3-CA1 synapse but encoded by presynaptic short term plasticity. Our results show how differential action of M1 and M4 expression and its modulation of electrical excitability couples to synaptic calcium and neuronal excitability to influence synaptic plasticity and transmission at CA3-CA1 synapses.

Title: Role of cholinergic signaling in fear memory

Authors: *L. JIANG[1], D. A. TALMAGE[2], L. W. ROLE[3]
[1]Dept. of Neurobio. and Behavior, [2]Pharmacol. Sci., [3]Neurobio. & Behavior, Stony Brook Univ., Stony Brook, NY

Abstract: The amygdala is a key structure in encoding of fear learning. The Basolateral Amygdala (BLA) receives a massive cholinergic innervation from the basal forebrain including the nucleus basalis of Meynert/ substantia innominata (NBM/SI). With both optogenetic and chemogenetic techniques, we have shown that altering endogenous ACh release effects animal fear behaviors and induces synaptic plasticity in the BLA. In recent work, we used genetically encoded activity probes to map fear memory related circuits. In the BLA, we find that fear conditioned mice have increased numbers of activated (c-fos+) neurons than home cage sibling controls. c-fos GFP positive BLA neurons had higher baseline synaptic inputs but less synaptic plasticity upon acute nicotine challenge. Using an Activity Dependent and Cre Dependent (ADCD) viral tool that we developed, we also examined behavior dependent changes in activity in cholinergic neurons. Combining the transient c-fos GFP labeling and the permanent ADCD labeling, we tested the role of NBM/SI cholinergic neurons in fear memory. Specific clusters of NBM/SI cholinergic neurons are labeled by both fear conditioning and recall. Fear activated cholinergic NBM/SI neurons display increased firing frequency that drops back to control levels within days. Current studies examine fear memory “engram” in both BLA and NBM/SI and further examine changes in electrophysiology properties with engram enrollment.

Title: Cholinergic modulation of reverberatory activity in cultured neuronal networks

Authors: *X. LI, P. LAU, G.-Q. BI
USTC, Anhui, China

Abstract: Reverberatory activity in neuronal cell assemblies has been theoretically considered as neural process underlying short-term memory. Acetylcholine as a neuromodulator in the brain influences neuronal excitability and synaptic transmission thus changes the state of neuronal networks. We have shown previously that small networks of cultured hippocampal neurons

could elicit rhythmic persistent activity following a single brief stimulus, and thus could be used as an in vitro model system to study network reverberation. We found that acetylcholine reduced occurrence probability of the evoked reverberation while enhanced the duration of spontaneous activities in the same network. This opposite effects of acetylcholine on evoked and spontaneous activities were completely rescued by muscarinic antagonist atropine and scopolamine, but not by nicotinic antagonist mecamylamine, suggesting that cholinergic modulation of network activity in this system were primarily through muscarinic receptor signaling. Further study shows that acetylcholine decreased only excitatory but not inhibitory postsynaptic current, suggesting that its inhibition of evoked reverberation was through acetylcholine suppression of excitatory neurotransmission. Meanwhile acetylcholine increased neuron excitability, probably underlying the enhanced spontaneous network activation. The effects of acetylcholine on excitatory synaptic transmission and neuron excitability also could be rescued by muscarinic antagonist scopolamine. These results provide experimental evidence for cholinergic modulation of reverberation and may give insight into basic regulatory mechanism of short-term memory.

Title: Autaptic cultures of single neurons for studying autonomic synaptic transmission

Authors: *S. KANG[1], C.-K. LEE[4], S. KIM[2], S.-W. JEONG[3]
[1]Dept. of physiology, [3]Dept. of Physiol., [2]Yonsei Univ. Wonju Col. of Med., Wonju, Korea, Republic of; [4]Max PlankIinstitute Exptl. of Medizin, Gottingen, Germany

Abstract: Autaptic synapse (called “autapse”) is a self-synapse that is a functional connection between a neuron and itself, and anatomically identified in a variety of brain regions although its functional significance remains little known. On the other hand, many studies have proved that autaptic cultures of the central neurons are experimentally valuable for studying synaptic transmission. Unlike central synapses, basic mechanisms underlying synaptic transmission and plasticity have been poorly elucidated. In the present study, we generated autaptic cultures of single neurons for studying autonomic synaptic transmission. In this regard, the sympathetic neurons were enzymatically dissociated from the superior cervical ganglia or stellate ganglia of neonatal rats (P0-P2), and plated onto agarose-coated culture dishes with microdots of growth-permissive substrates or glial feeder layers. We tested different culture media containing

different types of serum for optimizing culture conditions. Nerve growth factor and ciliary neurotrophic factor were supplemented to the culture media for a long-term culture and induction of cholinergic phenotype, respectively. The neurite growth and formation of autapse were promoted in the L15 and DMEM/F12 containing rat serum. Electrical measurements were performed under whole-cell ruptured configuration of the patch-clamp recording techniques. To evoke synaptic currents, a single neuronal soma was stimulated by a 2 ms depolarizing step from a holding potential of -60 mV to 0 mV. Hexamethonium-sensitive excitatory postsynaptic currents (EPSCs) were observed from four days in culture, which indicates the formation of cholinergic autapse. Interestingly, however, the EPSCs were not completely abolished in the presence of the hexamethonium, suggesting non-cholinergic neurotransmitter release at the autapses. The EPSCs and the readily releasable pool of vesicles increased time-dependently and reached the maximum size around 12-14 days in culture. The spontaneous miniature EPSCs were observed in the presence of tetrodotoxin. The autaptic cultures also exhibited short-term plasticity as demonstrated with a paired pulse stimulation. Taken together, we successfully generated the autaptic cultures of autonomic neurons which exhibit the previously reported characteristics of cholinergic synaptic transmission.

Title: Acetylcholine release indirectly inhibits Schaffer collateral inputs onto CA1 pyramidal neurons via an increase in inhibitory interneuron excitability and the activation of postsynaptic $GABA_B$ receptors

Authors: P. GOSWAMEE, *R. MCQUISTON
Dept Anat/Neurobiol, Virginia Commonwealth Univ., Richmond, VA

Abstract: Activation of muscarinic acetylcholine (ACh) receptors achieved by bath application of muscarinic receptor agonists has been repeatedly shown to presynaptically inhibit both Schaffer collateral (SC) and perforant path (PP) glutamatergic inputs onto hippocampal CA1 pyramidal neurons. Although ACh release has been shown to contribute to synaptic plasticity at the SC input, fewer studies have examined the direct effect of ACh release on glutamatergic transmission at these synapses. Moreover, indirect effects of cholinergic activation of inhibitory

interneurons on glutamatergic synaptic transmission have not been explored. Therefore, we examined the effect of optogenetically released ACh on both SC and PP inputs in hippocampal CA1 pyramidal neurons of genetically modified mouse brain slices. To optogenetically stimulate the release of ACh, we crossed a choline acetyl transferase (Chat) Cre driver mouse line to a ReaChR Cre-reporter mouse line that resulted in the selective expression of ReaChR in cholinergic neurons of the medial septum and diagonal band of Broca complex. To examine glutamatergic synaptic efficacy, we used paired-pulse electrical stimulated of the SC or PP and measured synaptic responses in CA1 pyramidal neurons using whole cell patch clamp methods. Our results showed that optogenetic activation of ACh release prior to paired pulse electrical stimulation of SC inputs significantly reduced the paired-pulse amplitude (P2/P1) ratio measured from individual CA1 pyramidal neurons (n= 30 cells from 11 animals). The reduction of SC paired-pulse ratio could be blocked by atropine (5 μM), CGP 52432 (2 μM), or the inclusion of GDP-β-S in the intracellular patch clamp solution. These observations suggest that ACh release decreased the SC paired-pulse ratio through a muscarinic receptor driven increase in the excitability of inhibitory interneurons that activate $GABA_B$ receptors on CA1 pyramidal cells. In contrast, ACh release resulted in a suppression of synaptic amplitudes and an increase in the PP paired-pulse ratio that was blocked by atropine (5 μM) but not CGP 52432 (2 μM). The PP data suggests that ACh release directly inhibits PP terminals via muscarinic receptor activation independent of inhibitory interneuron activity (10 cells from 6 animals). Thus, our data indicate that ACh release differentially modulates glutamatergic neurotransmission in SC and PP synapses and provides new insights into the diverse mechanisms by which cholinergic modulation affects hippocampal function.

Title: GABA cotransmission from cholinergic neurons in the cortex and basal forebrain

Authors: *A. J. GRANGER[1], B. L. SABATINI[2]
[1]Harvard Med. Sch., Boston, MA; [2]Neurobio., Harvard Med. Sch. Dept. of Neurobio., Boston, MA

Abstract: Acetylcholine is a major neuromodulator in the brain, important for maintaining alertness, directing attention, promoting learning, and detecting salient sensory cues. While acetylcholine has a net excitatory effect on downstream neurons, we have recently shown that all cholinergic neurons have the potential to package and release the inhibitory neurotransmitter GABA. The purpose of cholinergic neurons releasing two neurotransmitters with apparently contradictory post-synaptic effects is unknown. To answer this question, we have studied the functional role and developmental time-course of GABA corelease from two different populations of cholinergic neurons: cortically projecting neurons of the basal forebrain, and local cortical cholinergic interneurons. Our hypothesis is that both of these neuron populations differentially release GABA and ACh onto different post-synaptic targets to maintain a net excitatory effect on cortical activity.

Title: Inhibitory role of peripheral GABA receptors on salivation

Authors: J. LEE[1], *D. R. GIOVANNUCCI[2]
[1]Neurosciences, [2]Univ. of Toledo/College of Med., Toledo, OH

Abstract: Autonomic neural activity closely regulates the production and composition of saliva critical for oral health via sympathetic and parasympathetic input from the superior cervical (SCG) and otic (OG) ganglia, respectively. The discovery of peripheral gamma-aminobutyric acid (GABA) and its receptors in the salivary glands, and the observation that treatment of patients with benzodiazepines can induce severe xerostomia, hints at an unexplored mechanism for peripheral regulation of salivary gland function. In the current study, immunofluorescence, electrophysiology, and live-cell calcium imaging were used to elucidate the GABAergic system in the mouse parotid gland and define its effect on acinar cell regulation. Immunofluorescence analysis of SCG and OG indicated GABA-containing nerve fibers and cell bodies, a subset of which colocalized with retrogradely labeled parotid-projecting neurons injected with Fast Blue (FB) tracer. Whole-cell and gramicidin-perforated patch clamp of FB-labeled neurons revealed depolarizing GABAA receptor-evoked currents that inhibited action potential generation and frequency. In addition, RT-PCR showed the expression of multiple GABA receptors in parotid tissue. However, both live-cell calcium imaging and whole-cell recordings of dispersed acinar cells showed no direct impact of GABA treatment to evoke acinar cell currents or calcium signals. In contrast, calcium imaging of parotid tissue slices demonstrated that GABA reduced

calcium signaling evoked by a depolarizing stimulus that this diminishment was blocked by picrotoxin. Our data suggest GABA has no direct effect on parotid acini but may depress salivation by inhibition of autonomic neural inputs. This may be achieved through decreased neuronal excitability at autonomic ganglia via a shunting effect and presynaptically via reduced neurotransmitter release in the parotid gland.

Title: Reducing inhibition improves E/I balance and hippocampal circuit function in PGC-1α null mice

Authors: *D. BHATTACHARYA, A. F. BARTLEY, Q. LI, L. E. DOBRUNZ
Neurobio., Univ. of Alabama at Birmingham, Birmingham, AL

Abstract: Alterations in the excitation/inhibition (E/I) balance are thought to contribute to dysfunction in neuropsychiatric and neurodevelopmental brain disorders such as schizophrenia and autism. E/I imbalance can be caused by dysfunction of GABAergic interneurons, leading to enhanced or reduced GABAergic inhibition. As a result, pharmacological modulation of $GABA_A$ receptors could potentially normalize E/I function. Because E/I imbalances can be frequency dependent due to synaptic short-term plasticity, it is not clear whether the same dose that rescues baseline synaptic function would also normalize the E/I balance at higher frequencies. Our lab has previously shown alterations in E/I ratio and hippocampal circuit function in a mouse model of interneuron transcriptional dysregulation. We use mice with deletion of PGC-1α (peroxisome proliferator activated receptor γ coactivator 1α), a transcriptional co-activator that in hippocampus is localized to GABAergic interneurons. Loss of PGC-1α reduces the expression of the calcium binding protein parvalbumin, which mimics molecular aspects of some complex brain disorders. We have previously shown that there is enhanced inhibition, reduced E/I balance, and impaired CA1 circuit function in PGC-1α null mice. Importantly, the E/I imbalance and circuit dysfunction are frequency-dependent, in that the magnitude of the effects are reduced by paired-pulse stimulation at short intervals. Here we tested the extent to which reducing inhibition can restore the dynamic E/I balance and rescue the deficits in circuit function. We used acute CA1 hippocampal slices from young adult PGC-1α wildtype and null mice, and reduced inhibition by partially blocking $GABA_A$ receptors with a low concentration of bicuculline (BIC).

Surprisingly, we found that low dose BIC rescued the E/I balance during paired-pulse stimulation as well as at baseline. BIC also increased the paired pulse ratio of disynaptic inhibition in PGC-1α null slices, suggesting that it is altering interneuron recruitment. BIC improved CA1 output in slices from PGC-1α null mice to levels comparable to wildtype, as measured by E-S coupling. Our results show that modulation of $GABA_A$ receptors can potentially rescue E/I imbalances even when they are frequency-dependent.

Abstract: The hippocampus has a diverse collection of inhibitory neurons distinguished by their electrophysiological, morphological, and molecular properties. Previous research has laid a substantial foundation for our understanding of inhibitory neurons in the hippocampus; however, recent advancements in tools to selectively target and manipulate neurons allow continued advances in our understanding of inhibitory neuron diversity. Here we report a population of cells appearing to lack prior characterization, which we refer to as LINCs (long-range inhibitory neuronal nitric oxide synthase expressing cells). Our data suggest that LINCs are unique in that they i) provide powerful inhibition to the hippocampus, targeting both deep and superficial pyramidal cells, ii) are capable of producing both postsynaptic GABAA and GABAB receptor-mediated responses, and iii) have long-range projections to several distinct regions of the brain including the tenia tecta. Together, our data suggest that LINCs are a novel and remarkably powerful inhibitory cell type in the hippocampus that may be capable of orchestrating network-wide activity.

Title: Effect of alterations in the vesicular acetylcholine transporter on acetylcholine-linked behaviors in *Drosophila*

Authors: *S. WILLIAMS[1], H. O. LAWAL[2]
[1]Biol. Sci., Delaware State Univ., Wilmington, DE; [2]Biol., Delaware State Univ., Dover, DE

Abstract: The proper functioning of the cholinergic neurotransmission system is critical for essential organismal functions such as movement, and learning and memory. Accordingly, a balance in acetylcholine (ACh) levels is important in the regulation of locomotion and cognitive performance. Although reports have shown that increases or deficits in ACh release results in deficits in behavioral and cognitive functions, however, the mechanism through which this occurs is not well understood. *Drosophila Melanogaster* is a useful model for studying acetylcholine-linked behaviors due to it's ability to perform complex cognitive functions such as locomotion and courtship learning. Here we are using the vesicular acetylcholine transporter (VAChT) which mediates the packaging and transport of ACh for subsequent exocytotic release to manipulate ACh release. Specifically, we are measuring the effect of both reduced and increased levels of VAChT expression on locomotion and learning behaviors. We report that reduced *Vacht* expression causes a deficits in locomotion behavior in at least three locomotion assay paradigms measured. Moreover, we also report preliminary data on our assay for the effect of altered *Vacht* expression on courtship learning and memory. Taken together, these data provide evidence for a role for central cholinergic release in the mediation of key neuronal functions and sets the stage for a more detailed behavioral analysis and would inform functional studies in cholinergic neurons.

Title: Role and function of a5-$GABA_A$Rs in the neocortex: A molecular signature of dendritic synapses from Martinotti cells?

Authors: *J. ZORRILLA DE SAN MARTIN[1], C. DONATO[1], A. AGUIRRE[1], C. CABEZAS[1], A. BARBERIS[2], M.-C. POTIER[1], A. BACCI[1]
[1]Inst. Du Cerveau Et De La Moelle Epinière (ICM), PARIS, France; [2]Plasticity of ihibitory networks Lab, Fondazione Inst. Italiano di Tecnologia, Via Morego 30, Genova Italy, Genoa, Italy

Abstract: The neocortex is the site where all sensory information is integrated to generate complex behavior and sophisticated cognitive functions. This is accomplished through the concerted, synchronous, and rhythmic activity of intertwined cortical networks formed by highly heterogeneous neuronal populations. In particular, locally-projecting, inhibitory GABAergic interneurons encompass a vast number of cell subclasses. Some interneurons are specialized in targeting dendrites, whereas others, known as basket cells, innervate the perisomatic region of cortical principal cells (PNs). Here we studied the α5 subunit of the $GABA_AR$, which is believed to contribute significantly to tonic inhibition. We found that, in L 2/3 PNs of mouse somatosensory cortex, α5 provides a negligible contribution to tonic inhibition. Conversely, we found that α5 is specifically expressed at synapses between the dendrite-targeting interneurons Martinotti cells (MCs) thus indicating that GABAergic transmission through α5-containing $GABA_AR$ subtypes is important for synaptic dendritic inhibition. Moreover, our preliminary results revealed the presence of the α5 subunit onto MC dendrites. Using multiple patch-clamp recordings between MCs and different cortical neuron types, our preliminary results suggest that the expression of α5 is always present at synapses made by MCs, regardless of the postsynaptic target. Altogether, these experiments contribute to better define the role of α5 subunit in somatosensory cortex and help understanding if α5-$GABA_ARs$ can be considered as a molecular signature of dendritic synapses from inhibitory circuits involving MCs.

Title: GABA and glutamate co-release from hippocampal VGluT3-expressing interneurons

Authors: *K. A. PELKEY, D. CALVIGIONI, C. FANG, G. VARGISH, R. CHITTAJALLU, C. J. MCBAIN
NICHD/LCSN, NIH, Bethesda, MD

Abstract: Cholecystokinin expressing interneurons (CCK-INTs) are positioned to powerfully influence hippocampal information processing by providing strong feedforward and feedback inhibition to principal cells (PCs). However, despite a wealth of information describing intricate synaptic details of CCK-INTs (eg. depolarization induced suppression of inhibition (DSI)/asynchronous release (AR)), their network functions remain enigmatic. This relates to the fact that, beyond common developmental origins and CCK expression, CCK-INTs comprise a heterogeneous cohort with unique postsynaptic target preferences and molecular signatures. Interestingly, one subset of CCK-INTs, vesicular glutamate transporter 3- (VGluT3) expressing perisomatic targeting CCK basket cells (VGluT3$^+$CCKBCs), was recently shown to critically regulate theta oscillations and spatial information coding of place cells. Initial reports of VGluT3 expression within this subpopulation prompted speculation that VGluT3$^+$CCKBCs subserve unique computational roles based on their ability to co-release GABA and glutamate. Indeed, in contrast to Dale's principal of "one neuron, one transmitter" recent studies have described a variety of central neurons that utilize more than one classical neurotransmitter including GABA/glutamate co-releasing neurons in subcortical circuits. However, detailed investigation into the functional properties of a pure VGluT3$^+$ CCK-INT cohort, including glutamate release, is currently lacking. Here we demonstrate GABA/glutamate co-release from hippocampal VGluT3$^+$ interneurons using both paired recording and optogenetic approaches. Under baseline conditions the glutamate component of VGluT3$^+$INT-PC transmission is approximately 1/16th of the GABA mediated conductance and is dominantly mediated by AMPA receptors with minimal NMDA receptor contribution. Glutamate release from VGluT3$^+$CCK-INTs exhibits the same hallmark features as GABA release including cannabinoid sensitivity (DSI) and AR during high frequency firing. Surprisingly, we found that the VGluT3 expressing population of hippocampal INTs extends beyond VGluT3$^+$CCKBCs, also comprising subsets of dendrite targeting INTs including minority populations of somatostatin expressing cells such as subsets of O-LM interneurons. Preliminary optogenetic evaluation also supports functional glutamatergic output

from these dendrite targeting interneurons. Further investigations will aim to uncover physiological, and potential pathological, roles for glutamate release from VGluT3$^+$ INTs in local circuit processing.

Abstract: Trisomy (TS) 21 is a human condition produced by the triplication of chromosome 21 and is characterized by mild to severe cognitive deficits. This condition has been successfully modeled in mice; notably, Ts65Dn, the most widely studied model generated so far, reproduces the cognitive deficits observed in humans, and shows marked reduction of synaptic plasticity (LTP) both in vivo and in vitro. Interestingly, it was shown that both features can be recovered by selective block of the α5 subunit of the $GABA_AR$, corroborating the hypothesis of over-inhibition as an underlying mechanism of TS-related cognitive deficits. However GABAergic interneurons are highly diverse and specialized in inhibiting different compartments of principal cortical neurons, and specific alterations of inhibitory sub-circuits in TS mice remain unknown. Here we found that in cortical layer 2/3, α5-$GABA_ARs$ are expressed selectively at synapses between dendrite-targeting, somatostatin-positive Martinotti cells (MCs) and pyramidal neurons (PNs). This was demonstrated in dual whole-cell recordings using X98 mice expressing GFP specifically in MCs, and the use of a specific α5 inverse agonist (α5IA). Interestingly, α5-$GABA_ARs$ had a negligible contribution to tonic inhibition onto layer 2/3 PNs.
This finding prompted the question whether this cortical GABAergic sub-circuit is specifically altered in DS. We first confirmed that α5-$GABA_ARs$ are expressed at MC-PN synapses also in

TS mice. Importantly, however, we found a 2-fold increase at unitary MC-PN GABAergic connections in TS, as compared to WT. This was accompanied by a decrease of paired pulse ratio, suggesting a presynaptic alteration of dendritic inhibition from MCs. Furthermore, glutamatergic recruitment of MCs by PNs was also increased by near 2-fold. We are in the process of determining the mechanisms underlying this enhanced MC-PN-MC circuit loop in TS mice, and test if it is specific for this GABAergic interneuron subclass. Altogether, these results confirm the presence of α5 at MC-PN synapses and show that dendritic inhibition from MCs is specifically affected in TS, indicating this inhibitory loop as a potential therapeutic target for this condition.

Title: Optical measurements of anesthetic action on GABA exocytosis

Authors: *I. A. SPEIGEL, H. C. HEMMINGS, Jr
Anesthesiol., Weill Med. Col. of Cornell Univ., New York, NY

Abstract: General anesthetics are powerful psychoactive drugs that produce therapeutic as well as dangerous neurological effects. Although they have been in use for over 170 years, we do not fully understand how these drugs disrupt neural function to cause loss of consciousness, amnesia, and immobility. Volatile anesthetics such as isoflurane disrupt synaptic transmission and inhibit the vesicular release of neurotransmitters, with GABA release from interneurons being significantly less sensitive than glutamate release. The molecular basis for this difference remains unknown. Identifying the responsible presynaptic features would uncover fundamental determinants of anesthetic sensitivity, but a direct comparison of anesthetic actions on glutamatergic versus GABAergic synaptic physiologies and neurotransmitter release mechanisms is limited without a means to selectively measure and manipulate GABAergic exocytosis.
To identify isoflurane's effect on GABAergic synaptic vesicle exocytosis at the level of the individual neuron, we are performing live-cell imaging of GABA release using pHluorin-based optical biosensors expressed in transgenic primary hippocampal neuron cultures, wherein GABAergic interneurons are distinguished by the expression of genetically-encoded fluorescent

markers. We expect that these optical exocytosis measurements will enable interneuron-specific analysis of anesthetic action, and reveal potential variance in isoflurane sensitivity, yielding novel observations of isoflurane's effects on GABAergic signaling. This information is critical to further the understanding of the cellular and behavioral effects of anesthetics, as interneurons modulate nearly every aspect of neuronal excitability and network function, with specialized subpopulations serving distinct roles in circuit function.

Title: Action of $G_{i/o}$ DREADDson GABAergic projections within the basal ganglia

Authors: *D. M. LOVINGER[1], L. VOYVODIC[2], K. P. ABRAHAO[2]
[1]Chief, Lab. Integrative Neurosci, [2]Lab. Integrative Neurosci, Natl. Inst. on Alcohol Abuse and Alcoholism Rockville Office, Rockville, MD

Abstract: Chemogenetic neuromodulation mediated by the hM4Di designer receptor exclusively activated by designer drug (DREADD) has been shown to involve G protein-coupled inwardly-rectifying potassium (GIRK) channels. However, Gi/o-coupled receptors influence other effectors including voltage-gated calcium channels and adenylate cyclase. In addition, *in situ* hybridization studies indicate that GIRK channels are not expressed in the medium-sized striatal projection neurons (MSNs). Nonetheless hM4Di-mediated chemogenetic modulation of striatal direct and/or indirect pathways alters behaviors. Thus, it is important to assess the cellular mechanisms involved in DREADD alteration of striatal projection pathways. To this end, we examined effects of hM4Di DREADD activation on MSN excitability and synaptic transmission onto neurons within the basal ganglia using transgenic mice, optogenetics and whole-cell patch-clamp recording. Activation of the hM4Di receptors with the otherwise pharmacologically inactive agonist clozapine n-oxide (CNO; 10 µM) inhibited GABAergic opto-evoked inhibitory postsynaptic currents (oIPSCs) in the substantia nigra pars reticulata resulting from activation of striatonigral MSNs. In contrast, CNO did not inhibit oIPSCs at synapses on MSNs made by hM4Di-expressing pallidostriatal projecting (arkypallidal) neurons. These results indicate hM4Di G_i-coupled DREADDs are able to inhibit neurotransmitter release in neuronal populations in a

GIRK channel-independent manner. We are now studying the mechanisms underlying this effect and we also examine the effect of other putative DREADD agonists.

Title: A comparison of botulinum toxin A light chain and heavy chain gene fragments in adenoviral vector-mediated gene-based synaptic inhibition

Authors: *L. DI, Y. KIM, M. S. TORA, O. P. KEIFER, Jr., Y. H. CHEN, P. HANNIKAINEN, A. DONSANTE, B. J. MADER, N. M. BOULIS

Abstract: Introduction: Botulinum toxin, the standard of care for a variety of peripheral nervous system disorders, suffers from its transient effects and central nervous system toxicity. Vector-mediated gene transfer has the potential for cell-specific, sustained neural inhibition through botulinum toxin gene expression. Here, we tested the adenoviral vector-mediated transfer of select botulinum toxin/A (serotype A) gene fragments in focal neural inhibition without cytotoxicity.
Methods: Adenoviral vectors encoding different botulinum toxin/A domains - light chain, light chain and receptor binding domain, and light chain and translocation domain - were injected into rat spinal cords at 4×10^4 transforming units to test their neural inhibitory effects. To assess for dosage dependency, vectors were also tested at 4×10^5 and 4×10^6 transforming units. Pre-surgical baseline and post-operative motor function was measured by Basso-Beattie-Bresnahan open-field locomotor scoring, grip strength, and rotarod performance. After 3-weeks of postoperative behavioral testing, rats were euthanized, and spinal cords were immunostained and counted for neuronal nuclei to assess cytotoxicity from transgene expression. Prior to injection, vectors were tested *in vitro* in HEK293 cells to control for differences in transduction efficiency.
Results: Animals injected with adenoviral vectors containing genes for the light chain and receptor binding domain displayed the most consistent and sustained deficits in open-field assessment, grip strength, and rotarod performance. Rats injected with adenovirus containing light chain showed spontaneous recovery at 16 days post-injection, coinciding with the cessation of adenoviral gene expression. Spinal cord neuron counts revealed no signs of cytotoxicity between treatment groups and controls at injection titers of 4×10^4 and 4×10^5 but not at 4×10^6 transforming units. *In vitro* testing showed no difference in transduction efficiency between

vectors and there were no differences in neuron density compared to controls.
Conclusion: These results suggest that vector-mediated gene transfer of botulinum toxin light chain and receptor-binding domain is most effective at synaptic inhibition without cytotoxicity. This gene-based approach at focal neuromodulation may hold future applications in the treatment of neurological disease and the study of neural circuitry. Furthermore, these data suggest that the heavy chain may play a role in the characteristic persistence of botulinum neurotoxin/A synaptic inactivation that is yet unexplained.

Title: Mechanisms of presynaptic suppression of GABA release by opioid receptors in the hippocampus

Authors: *X. J. HE[1], M. R. BANGHART[2]
[1]Biol. Sci., Univ. of California San Diego, LA Jolla, CA; [2]Neurobio., Univ. of California San Diego, La Jolla, CA

Abstract: Opioid receptors are prominent in interneurons of the hippocampus where they modulate GABAergic inhibition onto pyramidal cells. Mu opioid receptor (MOR) activation is known to suppress GABA release from parvalbumin (PV) basket cells in the CA1 region, which positions opioids to affect spike timing, oscillations, and synchronization of neuronal populations in the hippocampus. Although the delta opioid receptor (DOR) is also prominent in the hippocampus, its functional role in distinct interneuron classes has not been established, nor have the molecular mechanisms that underlie MOR and DOR-mediated suppression of synaptic transmission. Using a combination of electrophysiology and optogenetics, we discovered that both MOR and DOR strongly inhibit GABA release from PV+ basket cells in a mutually-occlusive manner. Although both receptors appeared to utilize a presynaptic mechanism, they were differentially prone to desensitization. We further characterized the molecular mechanisms of opioid receptor-mediated suppression using two-photon calcium imaging and pharmacology

and found evidence for modulation of processes downstream of voltage-gated calcium channel activation. Our results suggest a previously unappreciated role for DOR in modulating perisomatic inhibition in the hippocampus and reveal the molecular mechanisms by which both MOR and DOR regulate GABA release from PV basket cells in CA1.

Title: CAPS1 finely regulates the exocytosis of synaptic vesicles in calcium- and/or synapse type-dependent manners, affecting on learning and memory

Authors: *C. ISHII[1], Y. SHINODA[2], T. SADAKATA[3], Y. SANO[1], Y. ISHII[1], N. SHIBANO[1], Y. KATO[1], M. YAMAZAKI[1], A. YAMATO[1], T. FURUICHI[1]

Abstract: Presynaptic exocytosis of synaptic vesicles (SVs) is a fundamental event in the synaptic transmission. Although various kinds of synaptic molecules have been shown to regulate synaptic exocytosis, a more subtle and fine-tuning mechanism remains unclear as an elaborate cellular device for neural information processing. Recent studies have demonstrated that Calcium-dependent activator protein for secretion 1 (CAPS1) is involved in the exocytosis of SVs as well as that of dense-core vesicles (DCVs). In this study, we analyzed the involvement of CAPS1 in the basic transmission and plasticity of hippocampal synapses. Besides, we evaluated the impact of CAPS1-mediated SV exocytosis on learning and memory in mice. To address these issues, we utilized Emx1-Cre-mediated forebrain-specific CAPS1 conditional knockout (cKO) mice because of the neonatal lethality of CAPS1 conventional knockout mice. Electrophysiological recordings revealed that basal synaptic transmission was severely suppressed at both CA3-CA1 and dentate gyrus (DG)-CA3 synapses which are respectively high and low presynaptic expression of CAPS1 protein. Intriguingly, long term potentiation (LTP) was not impaired at CA3-CA1 synapses but greatly inhibited at DG-CA3 synapses. In addition, SypHy-based live cell imaging using cultured hippocampal neurons acutely deleted CAPS1 gene showed that synaptic release from CAPS1-deleted neurons was significantly suppressed. However, increased $[Ca^{2+}]_i$ rescued SV release in these neurons. These physiological results

suggest that CAPS1 regulates SV exocytosis differently at least two synapses of the hippocampal trisynaptic circuit and in a Ca^{2+}-dependent manner. Consistent with this inference, behavioral tests revealed that CAPS1 cKO mice showed significant impairments in only some but not all of hippocampus-related tasks, indicating that CAPS1-mediated heterogeneous mechanisms between DG-CA3 and CA3-CA1 synapses underlie hippocampus-dependent learning and memory. Taken together, we conclude that CAPS1 is critical to regulating SV exocytosis, specifically to initiate the priming of SV with low $[Ca^{2+}]_i$. Moreover, the contribution of CAPS1 to the synaptic release depends on synapse types of the trisynaptic circuit, presumably because of molecular diversity from synapse to synapse, reflecting the task-dependent memory impairments. Our results suggest CAPS1 is a unique cellular device for information processing in the hippocampus.

Title: Modulation of synaptic transmission: Quantitative analysis of Gbg specificity to a_{2a} adrenergic receptor and SNARE

Authors: *Y. YIM[1], K. BETKE[2], W. MCDONALD[4], R. GILSBACH[5], Y. CHEN[6], K. HYDE[2], Q. WANG[6], L. HEIN[5], H. E. HAMM[3]
[1]Pharmacol., [3]Dept. of Pharmacol., [2]Vanderbilt Univ. Sch. of Med., Nashville, TN; [4]Vanderbilt Univ., Nashville, TN; [5]Univ. of Freiburg, Freiburg, Germany; [6]Univ. of Alabama at Birmingham, Birmingham, AL

Abstract: Modulation of neurotransmitter exocytosis by activated $G_{i/o}$ coupled G-protein coupled receptors (GPCRs) is a universal regulatory mechanism used both to avoid overstimulation and to influence circuitry. One of the known modulation mechanisms is Gβγ interaction with soluble N-ethylmaleimide-sensitive factor attachment protein receptor (SNARE). There are 5 Gβ and 12 Gγ subunits, but specific Gβγs activated by a given GPCR and the specificity to effectors *in vivo* are not known. Presynaptic α_{2a}-adrenergic receptors (α_{2a}ARs)

in both adrenergic (auto α_{2a}ARs) and non-adrenergic neurons (hetero α_{2a}ARs) inhibit neurotransmitter release and affect various physiological functions such as anesthetic sparing and working memory enhancement. With a quantitative MRM proteomic analysis of neuronal Gβ and Gγ subunits to detect neuronal Gβ and Gγ subunits, several mouse models including transgenic Flag-α_{2a}ARs, knock-in HA-α_{2a}ARs, and other biochemical techniques such as co-immunoprecipitation, we investigate the specificity of Gβ and Gγ subunits to α_{2a}ARs in both adrenergic (auto α_{2a}ARs) and non-adrenergic neurons (hetero α_{2a}ARs), and SNARE in presence of epinephrine. $G\beta_2$, $G\gamma_2$, $G\gamma_3$, and $G\gamma_4$ preferentially interact with activated auto α_{2a}ARs while $G\beta_4$ and $G\gamma_{12}$ preferentially interact with activated hetero α_{2a}ARs. We also detect a subset of Gβ and Gγ subunits interacting with SNARE upon auto α_{2a}ARs activation. Further understanding of Gβγ specificity on its downstream signaling, especially Gβγ-SNARE interaction, offers new insights into the normal functioning of the brain and lead to identification of potential pathophysiological states in which the Gβγ-SNARE interaction may be dysregulated. These studies yield additional insights into $G_{i/o}$-coupled GPCR-mediated regulation of exocytosis.

Abstract: Organization of mammalian inhibitory synapses is thought to be crucial for normal brain functions, but its molecular mechanisms have been largely undefined. IQSEC3, a guanine nucleotide exchange factor for ADP-ribosylation factor (ARF-GEF), is a GABAergic synapse component that directly interacts with gephyrin. Here, we show that IQSEC3 acts in a synaptic activity-dependent manner to regulate GABAergic synapse development *in vivo*. GABAergic synapse-specific transcription factor Npas4 directly binds to the promoter of *Iqsec3* and regulates its transcription. Moreover, IQSEC3 functions downstream of Npas4 in orchestrating GABAergic synapse development in both dendritic and somatic compartments. Strikingly, a

variety of activity-altering regiments inducing Npas4 upregulation concurrently increased the IQSEC3 expression levels, prominently in somatostatin-positive GABAergic interneurons in hippocampal CA1 stratum oriens, which were compromised in Npas4 knockout (KO) mice. Furthermore, expression of wild-type (WT) IQSEC3, but not the ARF-GEF-inactive mutant (dominant-negative; DN), normalized altered GABAergic synaptic transmission in both dendrites and soma of Npas4-deficient CA1 pyramidal neurons. Collectively, our results demonstrate that IQSEC3 is a key GABAergic synaptic component organized by Npas4 activity- and ARF activity-dependent gene programs to coordinate functional excitation-to-inhibition balance *in vivo*.

Title: Adulthood ErbB4 is critical for normal GABA release and behaviors

Authors: *H. WANG[1], F. LIU[2], W. CHEN[3], X. SUN[4], W. CUI[1], Z. DONG[1], K. ZHAO[2], H. ZHANG[1], E. FEI[3], B.-X. PAN[3], B.-M. LI[3], W.-C. XIONG[1], L. MEI[1]

Abstract: Neurotrophic factor Nrg1 and its receptor, ErbB4, play critical roles in neurodevelopment. Meanwhile, studies suggest their expression and regulation in synaptic transmission in adult brain. In agreement with their roles in neurodevelopment, Nrg1 and ErbB4 are susceptibility genes of schizophrenia, which has been treated as a developmental disorder. However, it is not clear whether E/I imbalance at adult stage contributes to the deficits in Nrg1-ErbB4 signaling-deficient mice, which cannot be addressed by routine genetic strategy. In this

study, we generated the iKO and rKO mice to temporally control the deletion or expression of ErbB4. We found adult ErbB4 deletion in iKO mice caused behavioral deficits and GABA release deficiency, recapitulating phenotypes in ErbB4 null mice. In contrast, morphological deficits observed in ErbB4 null mice was not induced after adult ErbB4 deletion. In rKO mice, we found the behavioral deficits caused by ErbB4 loss-of-function during development could be mitigated by restoring ErbB4 expression at adult stage. The mitigation effect might be due to the rescued GABA release probability but not morphological attenuations. These findings suggest that the ErbB4 signaling at adult stage is both necessary and sufficient for maintaining the normal behaviors and synaptic transmission, and targeting to Nrg1-ErbB4 signaling might benefit post-development treatment of relevant schizophrenia.

Title: Loss of STEP61 couples BDNF-driven loss of inhibition to NMDAR potentiation in rodent and human spinal pain processing

Authors: *C. M. KANDEGEDARA[1,2], A. DEDEK[1,2], J. XU[3], E. C. TSAI[2], P. J. LOMBROSO[4], M. E. HILDEBRAND[1]
[1]Carleton Univ., Ottawa, ON, Canada; [2]Neurosciences, Ottawa Hosp. Res. Inst., Ottawa, ON, Canada; [3]Connecticut Mental Hlth. Ctr., New Haven, CT; [4]Yale Univ. Sch. Med., New Haven, CT

Abstract: Chronic pain is a debilitating condition with few safe and effective treatments. To develop novel therapeutics, we must identify the molecular determinants of pathological pain. However, the majority of pre-clinical pain research relies exclusively on rodent models of pain. Thus, proof-of-concept human tissue studies are urgently needed to bridge the rodent to human translational divide. Runaway excitability within the spinal dorsal horn is a critical mediator of chronic pain. Using the rodent nerve injury model of neuropathic pain, we have previously

shown that BDNF-mediated loss of inhibition (disinhibition) gates the potentiation of excitatory GluN2B NMDAR responses at lamina I dorsal horn synapses (Hildebrand *et al*, 2016, Cell Reports). However, what links these two distinct pathological pathways and whether this mechanism underpins other pathological pain states remain unknown. Here, we show that KCC2-dependent disinhibition is coupled to increased GluN2B-mediated synaptic NMDAR responses in the rodent CFA injection model of inflammatory pain, with an associated downregulation of the phosphatase $STEP_{61}$. We find that decreased activity of $STEP_{61}$ is both necessary and sufficient to prime subsequent phosphorylation and potentiation of GluN2B NMDARs by BDNF at lamina I synapses. Blocking disinhibition reversed the downregulation of $STEP_{61}$ as well as inflammation-mediated behavioural hypersensitivity. Through patch clamp recordings on viable human lamina I neurons, we show for the first time that GluN2B-containing receptors dominate NMDAR responses at human lamina I synapses. We subsequently developed a human *ex vivo* BDNF model of chronic pain using spinal sections from "neurological determination of death" organ donors 1-2 hours following aortic cross clamping. We found that BDNF downregulates KCC2 and $STEP_{61}$ and upregulates phosphorylated GluN2B at human dorsal horn synapses. Our results demonstrate that $STEP_{61}$ is the molecular brake downstream of KCC2-dependent disinhibition that is lost to drive the potentiation of excitatory GluN2B NMDAR responses in rodent and human models of pathological pain. The *ex vivo* human BDNF model may thus form a translational bridge between rodents and humans for identification and validation of novel molecular pain targets.

Title: MAPK-dependent presynaptic potentiation in the LHb is responsible for depressive behaviors

Authors: *H. PARK, H. RYU, S. ZHANG, S. KIM, C. CHUNG
Konkuk Univ., Seoul, Korea, Republic of

Abstract: Emerging evidences suggest that the lateral habenula (LHb), recently proposed to be involved in depressive disorders, is a part of clock system in our brain. Disrupted circadian

patterns are one of commonly observed symptoms in human patients with depression. Recently, we reported that synaptic transmission in the LHb is temporally variable. Here, we showed that temporal variation no longer exists in the LHb of a well-established rodent model of depression. Either exposure to a stressor or incubation with corticosterone abolishes the presynaptic temporal variation of synaptic transmission in the LHb. We also found that altered mitogen-activated protein kinase (MAPK)-dependent signaling upon the activation of glucocorticoid receptors (GRs) mediates the abolishment of temporal variations in the LHb. The selective inhibition of MAPK kinase (MAPKK, MEK) activity in the LHb restores the temporal variations of synaptic transmission of the LHb even after the exposure to stressors. Moreover, the blockade of MAPK signaling before exposure to stress successfully prevents depressive symptoms including behavioral despair and helplessness in the acute learned helpless animal model of depression. Our study delineates the cellular and molecular mechanisms responsible for previously reported abnormal presynaptic enhancement of LHb neurons in animal models of depression, which critically participate in mediating depressive behaviors.

Title: Sex differences in endocannabinoid-modulation of neurotransmission during adolescence

Authors: A. FERRARO, P. WIG, *C. G. REICH
SSHS/Psychology, Ramapo Col. of New Jersey, Mahwah, NJ

Abstract: Work in our lab demonstrated that hippocampal CB1 receptor (CB1R) levels are lower in female adolescent animals compared to males (Reich et al., 2009). Following 21 day exposure to chronic mild stress, CB1 increased in females while decreasing in males; thus suggesting that hippocampal CB1 responds differentially to stress depending on sex. Several other lines of converging evidence clearly indicate a functional sex difference in the endocannabinoid system and behavioral reactions to exogenous cannabinoids in both humans and animals (Rubino and Paralaro, 2011). However, there remains a paucity of data how these sex differences are manifested physiologically. We, therefore, investigated adolescent sex differences in rat endocannabinoid function. Field excitatory post-synaptic potentials were recorded from CA1 in Sprague-Dawley rat (40-60 days old) hippocampal slices. All drugs were

bath applied after a 10 min baseline with appropriate positive and negative drug controls as necessary. All sample sizes were greater than n=5, the size needed for 80% statistical power. Our studies show that exogenous activation of CB1 (CB1 agonist, WIN 55-212-2) enhances excitatory neurotransmission (fEPSPs) in the CA1 area of female hippocampal slices, while it classically decreases excitatory transmission in males. The latter is due to a CB1-mediated suppression of glutamate release. In females, we now provide evidence that CB1-modulation of excitatory neurotransmission results from enhanced CB1-mediated suppression of GABAergic neurotransmission (inhibitory). Further observations suggest that the following contribute to the mechanism for augmented suppression of inhibition in females: 1) constitutive CB1 activity at GABAergic synapses, 2) enhanced tonic eCB output and 3) Estrogen receptor α. These results clearly demonstrate sex differences in the dendritic layer of CA1 and further extend data on sex differences in the CA1 perisomatic layer.

Title: SUVN-G3031, H3 receptor inverse agonist modulates brain neurotransmitters with role in the treatment of narcolepsy

Authors: *V. BENADE, V. KAMUJU, S. GANDIPUDI, G. BHAYRAPUNENI, P. JAYARAJAN, K. BOJJA, K. KANDUKURI, S. MANCHINEELLA, R. NIROGI
Suven Life Sci. Ltd, Hyderabad, India

Abstract: Numerous studies have demonstrated that brain histamine plays a crucial role in maintenance of wakefulness, attention, learning and other cognitive processes. SUVN-G3031, a potent H3 receptor inverse agonist (hKi of 8.7 nM with more than 100 fold selectivity against the related GPCRs) is being developed for the treatment of narcolepsy and other sleep related disorders. SUVN-G3031 exhibited desired pharmacokinetic properties and brain penetration. First in human, Phase 1 studies are completed under US IND and SUVN-G3031 has shown drug-like properties with desirable pharmacokinetic profile, safety and tolerability in healthy human volunteers. In the current study, SUVN-G3031 was evaluated in brain microdialysis for evaluation of neurotransmitters like acetylcholine, histamine, dopamine and norepinephrine in male Wistar rats. Additional neurochemical studies were carried out to evaluate the in vivo functional nature of the test compound and its effect on the tele- methylhistamine as a possible biomarker for clinical studies. SUVN-G3031 blocked R-α-methylhistamine induced water intake and produced dose dependent increase intele-methylhistamine levels in rat and mice brain and

cerebrospinal fluid. A single oral administration of SUVN-G3031 produced significant increase in acetylcholine, histamine, dopamine and norepinephrine levels in the cortex. SUVN-G3031 produced no change in the dopamine levels of striatum and nucleus accumbens indicating that SUVN-G3031 may not have addiction liabilities. Results from the current studies and electroencephalographic (EEG) studies provide a strong evidence for the potential utility of SUVN-G3031 in treatment of narcolepsy and other sleep related disorders.

Title: Cannabidiol regulates mesolimbic dopamine system transmission through peroxisome proliferator-activated receptor gamma signaling in the nucleus accumbens

Authors: *T. D. JUNG, W. J. RUSHLOW, S. R. LAVIOLETTE
Anat. and Cell Biol., Western Univ., London, ON, Canada

Abstract: Cannabis contains two compounds that produce opposite effects. Delta-9-tetrahydrocannabiol (THC), the main psychotropic component of cannabis, has been shown to induce anxiety and schizophrenia-like symptoms. In contrast, cannabidiol (CBD), the non-psychotropic component, demonstrates potential as a promising treatment for both anxiety and schizophrenia. Although the precise mechanisms underlying the effects of THC and CBD are unclear, evidence suggests that the mesolimbic dopamine (DA) system is implicated in their effects. The mesolimbic DA system includes DA projections from the VTA to the NAc. The inhibitory GABA projections from the NAc regulates VTA DA release. The mesolimbic DA

system is carefully regulated through the endocannabinoid system which consists of endocannabinoid type 1 receptors (CB1R). Through CB1R signaling, endogenous cannabinoids modulate the excitatory glutamate and inhibitory γ-aminobutyric acid (GABA) inputs onto VTA DA cells. The phytocannabinoid THC binds to CB1R and disrupts the endocannabinoid system to amplify VTA DA signaling. It is believed that this amplification of VTA DA transmission underlies THC's ability to induce anxiety and schizophrenia-like behaviours. In contrast, CBD produces its therapeutic effects through the attenuation of VTA DA transmission. Unlike THC, CBD has a weak affinity for CB1R and it is unclear which receptors mediate the effects of CBD. One type of receptor that binds CBD is the peroxisome proliferator-acitvated receptor gamma (PPARγ). PPARγ is a nuclear transcription factor that colocalizes with GABA neurons. A past study by de Guglielmo et al. reported that PPARγ activation in the rostromedial tegmental nucleus (RMTg) decreases VTA DA release to the NAc. The RMTg contains a high density of GABA neurons that inhibit VTA DA release and it was found that the attenuation of VTA DA activity by PPARγ activation was mediated through GABA signals from the RMTg. Given that PPARγ is highly expressed in the NAc which also projects GABA neurons to the VTA, we hypothesized the following: PPARγ activation in the NAc will similarly decrease VTA DA release through the augmentation of NAc GABA signaling. Using in-vivo electrophysiology, we report that intra-NAc CBD infusions decreased VTA DA activity. The co-infusion of CBD with a selective PPARγ antagonist blocked the effect of CBD alone. In addition, the combination of a subthreshold dose of CBD with a selective PPARγ agonist synergistically decreased VTA DA signaling. These results demonstrate a novel potential nuclear receptor mechanism through which CBD produces its effects in the mesolimbic DA pathway.

Title: Corticosterone rapidly inhibits vagal afferent to NTS signaling via cannabinoid subtype 1 receptors

Authors: F. J. SHAFFER, J. E. M. LINDBERG, I. N. KARATSOREOS, *J. H. PETERS
Dept. of Integrated Physiol. and Neurosci., Washington State Univ., Pullman, WA

Abstract: Centrally, vagal afferent terminals release the excitatory neurotransmitter glutamate (GLU) onto neurons in the nucleus of the solitary tract (NTS) and integrate direct gastrointestinal

signals with ongoing NTS activity and circulating hormones. Glucocorticoid levels increase rapidly in response to stress, fasting, as well as exhibit a diurnal rhythm; all conditions that impact feeding. In this project we investigated the rapid, membrane delimited effects of corticosterone on GLU and GABA signaling in the NTS using patch-clamp electrophysiology on acute brainstem slice preparations containing the NTS and central vagal afferent terminals. Brainstem slices were isolated from adult male C57BL/6 mice and recorded for 3-4 hours following isolation. We found that bath application of CORT rapidly suppressed both presynaptic GLU and GABA release onto NTS neurons. We observed a large decrease in the frequency of spontaneous GLU release as well as an inhibition of action-potential evoked release. While the effect on spontaneous GABA release was rapidly reversed, the inhibition of glutamate was much more prolonged. The effect of CORT was blocked by mifepristone, localized intracellular G-protein inhibition, and phenocopied by dexamethasone; consistent with rapid glucocorticoid receptor (GR) mediated signaling. To elucidate a potential mechanism of these fast effects, we investigated the contribution of the retrograde endocannabinoid (eCB) signaling system, which has been reported to transduce non-genomic GR signals. Pharmacological blockade of the cannabinoid type 1 (CB1) receptor (AM251 or AM4113) blocked CORT induced suppression of GLU release, as did genetic deletion of CB1 receptors. These results demonstrate that fast GLU and GABA signaling can be suppressed in the NTS via GR mediated eCB signaling with distinct time courses. The net impact on NTS signaling will be a function of the balance between GLU and GABA signaling. This provides a plausible mechanism whereby the NTS may integrate circulating endocrine signals with fast neurotransmission to control food intake.

Title: Effects of chronic intermittent ethanol exposure on excitatory inputs onto cerebellar purkinje neurons

Authors: *P. A. ZAMUDIO-BULCOCK[1], J. J. WOODWARD[2]
[2]Neurosciences, [1]Med. Univ. of South Carolina, Charleston, SC

Abstract: Chronic alcohol exposure is associated with morphological and structural changes in the cerebellum, yet little is known about its effects on synaptic transmission, plasticity, and excitability of Purkinje neurons, the sole output of the cerebellar cortex. Purkinje neuron dendritic spines and climbing fiber terminals show structural alterations in rats chronically exposed to alcohol and in alcohol-dependent humans, eyeblink conditioning, a cerebellar-dependent task associated with Purkinje neuron plasticity, is impaired. These findings suggest that repeated exposures to alcohol impacts synaptic transmission at inputs onto Purkinje neurons. To study this, we used a vapor inhalation model of chronic intermittent ethanol exposure (CIE) and treated adult C57Bl6J mice with four cycles of ethanol vapor. Each cycle was composed of four daily 16 hr episodes of ethanol vapor inhalation followed by an 8 hr withdrawal period. Whole-cell patch-clamp recordings were performed 72 hours following the last ethanol exposure. As CIE is known to affect the expression of NMDARs and to disrupt NMDAR-mediated forms of synaptic plasticity in other brain regions, we first evaluated the effects of CIE on parallel fiber NMDAR-dependent long term potentiation (PF-LTP). PF-LTP was induced by trains of PF stimulation (5 pulses at 200 Hz) repeated 300 times at 1 Hz. In control animals, the amplitude of PF-EPSCs measured 20 minutes after the induction protocol was significantly increased (133.2 ± 8.77 % of baseline) and a similar increase (132.7 ± 11.28 % of baseline) was observed in slices from CIE animals. Responses evoked by PF stimulation at different intensities also did not differ between control and treated animals (p=0.21, n=5-7). However PF-evoked firing threshold was decreased in CIE mice (-60.24 ± 1.69 mV in CIE vs -52.21 ± 2.55 mV, *p=0.0454*, n=4), suggesting that PC excitability is increased after CIE. We then evaluated the amplitude of NMDAR-mediated currents at climbing fiber to Purkinje neuron synapses. Following CIE exposure and withdrawal, the amplitude of these currents was enhanced (-106 ± 30.7 pA in CIE vs -51.17 ± 25.91 pA in controls, *p=0.045, n=5-8*), suggesting an upregulation of NMDARs at this synapse. This effect of CIE on NMDA receptor function is consistent with findings previously reported in other brain regions. Together, these results suggest that excitatory synaptic transmission onto cerebellar Purkinje neurons is affected by CIE treatment and may contribute to deficits in cerebellar-mediated behaviors observed following chronic exposure to ethanol.

Title: Alcohol-induced neuroadaptation of IL-1 signaling at GABAergic synapses in the mouse prelimbic cortex

Authors: *F. P. VARODAYAN[1], M. Q. STEINMAN[1], T. D. DAVIS[2], S. A. WOLFE[1], T. NADAV[1], S. E. MONTGOMERY[1], W. B. KIOSSES[3], M. D. BURKART[2], A. J. ROBERTS[1], M. BAJO[1], M. ROBERTO[1]

Abstract: The interleukin-1 (IL-1) system has emerged as a key regulator of the brain's response to alcohol. IL-1β expression is elevated in the brains of human alcoholics and ethanol-dependent rodents, and exogenous IL-1β treatment in rodents regulates inhibitory transmission in key addiction-related brain regions, promotes alcohol-induced neuroinflammation and potentiates withdrawal-induced anxiety. Moreover, the IL-1β neuroinflammatory response of ethanol-dependent rodents is associated with significant cognitive deficits. Therefore, here we investigated the mechanisms underlying alcohol-induced neuroadaptation of IL-1 signaling at GABAergic synapses in the prelimbic region of the medial prefrontal cortex, an area responsible for drug-seeking behaviors. We induced ethanol dependence by exposing C57BL/6J mice to the chronic intermittent ethanol vapor/2 bottle choice paradigm (CIE-2BC) and used whole-cell voltage-clamp electrophysiology to record spontaneous inhibitory postsynaptic currents in prelimbic cortex layer II/III pyramidal neurons. We found that IL-1β (50 ng/mL) reduced inhibitory input onto these cells in naïve mice, but enhanced it in ethanol-dependent mice. To uncover potential neuroadaptive mechanisms, we next examined whether these effects are sensitive to acute ethanol. In naïve mice, ethanol (44 mM) alone had no effect on GABA transmission, but IL-1β in the presence of acute ethanol increased GABA release (similar to the effects of IL-1β alone in dependent mice). Importantly, a 15 min washout of the acute ethanol application restored the ability of IL-1β to decrease GABA release in naïve mice. These interactions between the IL-1 system and acute and chronic ethanol involve both the PI3K/Akt and MyD88 intracellular cascades; Akt (200 nM MK-2206) or PI3K inhibition (50 µM LY294002) produced an IL-1β-induced increase in GABA release in naïve mice, while in dependent animals IL-1β's potentiation of GABA release was blocked by a MyD88 mimetic (AS-1, 50 µM) that prevented MyD88 recruitment to the IL-1 receptor complex. Potential chronic ethanol-induced changes in the expression of IL-1 signaling molecules and these two intracellular cascades are currently being assessed. Collectively, our results indicate that acute alcohol interacts with the IL-1 system, most likely by shifting its recruitment between the PI3K/Akt and MyD88 intracellular cascades, to regulate GABAergic synapses in the mouse prelimbic cortex, and that alcohol dependence produces neuroadaptation leading to a more persistent recruitment bias.

Title: Acute osmotic stress produces differential effects on synaptic vs. paracrine signaling in oxytocinergic magnocellular neurons in the mouse paraventricular nucleus

Authors: *W. SHENG, S. W. HARDEN, C. J. FRAZIER
Dept. of Pharmacodynamics, Col. of Pharm., Univ. of Florida, Gainesville, FL

Abstract: Acute hypernatremia promotes natriuresis in part by increasing activity of oxytocinergic magnocellular neurons (OT-MCNs) in the hypothalamus that promote synaptic release of oxytocin (OT) from axon terminals in the neurohypophysis. Peripheral hypernatremia also blunts stress-induced activation of the hypothalamic-pituitary-adrenal axis via a mechanism that we believe is likely to depend on central paracrine (rather than synaptic) release of OT from magnocellular dendrites. Interestingly, prior work from other groups indicates that peripheral hypernatremia produces an increase in the concentration of circulating OT significantly more rapidly than it creates an increase in the concentration of central OT. The current project was designed to develop a better understanding of the underlying cellular mechanisms through which osmotic stressors may plausibly modulate both synaptic and paracrine release of OT from the same population of osmosensitive hypothalamic neurons, but with distinctly different temporal dynamics. Towards that end, we used the Cre-LoxP system to generate OT-reporter mice that express tdTomato in oxytocinergic neurons. Two-photon calcium imaging revealed that the dendrites of OT-MCNs are passive conductors, with robust activity dependent dendritic calcium influx that diminishes substantially with increasing distance from the soma. Further work revealed that acute osmotic stress (AOS) increases action potential frequency as observed in the soma via whole cell patch clamp recordings, and yet also substantially diminishes activity dependent calcium influx as observed in the distal dendrites. Indeed, we report that the effect of AOS on activity dependent calcium influx into distal dendrites is TTX insensitive, cell type (and compartment) specific, and bidirectional. Finally, we find AOS also reduces impact of distal glutamatergic inputs as observed in the soma, and suggest that other modulators may similarly regulate activity dependent dendritic release of oxytocin by modulating dendritic input resistance. Collectively, these results provide new insight into how osmotic stress differently

modulates synaptic vs. paracrine OT release from OT-MCNs in the mouse paraventricular nucleus.

Biol. and Geriatric Med., Univ. of Oklahoma Hlth. Sci. Ctr., Oklahoma City, OK

Abstract: Long noncoding RNAs (lncRNAs) are transcripts with lengths of >200 nucleotides that have been associated with numerous cellular processes, including X-chromosome inactivation, carcinogenesis and a wide range of developmental processes. The high incidence of lncRNAs in large genomes has been suggested to reflect the complexity of the underlying regulatory networks. Synaptic transmission is the quintessential example of a biological process that requires complex regulatory networks, and neurons express a large variety of lncRNAs. While several lncRNAs have been described in the nervous system, their molecular function in synaptic transmission has not been thoroughly explored. Thus, we designed a screening strategy based on a pHluorin assay to test the role of lncRNAs in synaptic vesicle exo-endocytosis. After an initial bioinformatic selection of lncRNAs, we tested the ten most promising candidates in our assay and found some of them to significantly affect neurotransmitter release. We termed the most interesting one among these “NeuroLnc”. NeuroLnc has a nuclear localization, it is highly neuron-specific and its expression is developmentally controlled. We used adeno-associated viruses to overexpress or downregulate NeuroLnc in hippocampal neurons, and found that its overexpression enhances calcium currents and favors neurite elongation, while its

downregulation produces the opposite effects. Moreover, *in utero* downregulation of NeuroLnc impairs the migration of neurons in developing mouse cortices. Using mass-spectrometry we identified several NeuroLnc interactors which included RNA-binding proteins as well as molecules implicated in neuropathology. We also studied the changes that NeuroLnc elicits at the transcriptome level and found several key changes in pathways related to neuronal development and transmission, suggesting that this lncRNA has pleiotropic effects on neuronal physiology. Our results reinforce the idea that molecules which are rapidly synthetized and degraded, such as RNAs, can contribute to the fine-tuning of neurons and underline the importance of lncRNAs for the regulation of the neuronal physiology.

Title: Examining the role of *Drosophila* synaptotagmin 7 in synaptic transmission

Authors: *M. C. QUINONES-FRIAS[1], Z. GUAN[1], Y. AKBERGENOVA[1], T. LITTLETON[1,2]
[1]Picower Inst., [2]Biol. Dept., MIT, Cambridge, MA

Abstract: Synaptic communication dependents on proteins that sense calcium and drive SNARE-dependent exocytosis. Initially, release is rapid and synchronized with the action potentialand is mediated by the calcium sensor Synaptotagmin 1 (Syt1). This is followed by a slower calcium-dependent phase of release that occurs through a Syt1-independent mechanism. Recent evidence suggests the asynchronous release calcium sensor may be another member of the Synaptotagmin family, Syt7. However, Syt7 has also been suggested to mediate synaptic facilitation, synaptic vesicle recycling, and lysosomal fusion. It is unclear if Syt7 mediates multiple roles in neurotransmission or if one function may underlie the host of defects that have been identified in mouse models. To examine conserved roles of Syt7 in neurotransmission, we used the CRISPR-Cas9 system to generate null mutations in the *Drosophilasyt7*locus and to tag the endogenous gene with GFP. Endogenous GFP-tagged Syt7 was observed in both the pre- and post-synaptic compartment and found at multiple subcellular locations within synapses. One pool of Syt7 localized near active zones, while other pools of Syt7 co-localized with the membrane trafficking markers Arl8 (lysosomes) and Rab11 (endosomes). Mutants in *syt7*were fully viable and displayed no obvious motor defects. The most robust synaptic defect recorded at

neuromuscular junctions (NMJs) in *syt7*mutants was a 50% increase in evoked neurotransmitter release in response to single action potentials. In contrast, overexpression of Syt7 reduced evoked release, indicating Syt7 acts endogenously to suppress synchronous neurotransmission. *syt7*mutants also displayed reduced paired-pulse facilitation. During high frequency stimulation, evoked responses in *syt7*mutants depressed faster than controls, but maintained a larger recycling synaptic vesicle pool and a faster recovery of the pool following stimulation. Surprisingly, *syt1*/*syt7*double null mutants were viable through the larval stages and actually displayed more neurotransmitter release than *syt1*mutants alone, indicating there must be other calcium sensors for asynchronous release at *Drosophila*NMJs. Electron microscopy did not reveal any robust defects in synaptic vesicle distribution at synaptic boutons. Overall, our data indicate Syt7 is likely to act in several pathways that alter synaptic vesicle release and recycling that control vesicle availability during stimulation. In addition, other calcium sensor(s) must be present that trigger the residual release in the absence of both Syt1 and Syt7.

Title: Reintroduction of synapsin II in knockout mice using neonatal viral injections

Authors: *R. SCHWARK, R. ANDRADE, M. BYKHOVSKAIA
Wayne State Univ. Sch. of Med., Detroit, MI

Abstract: The synapsins (Syn) are a family of presynaptic phosphoproteins that modulate neurotransmitter release via reversible association with synaptic vesicles. Deficiency in synapsins I or II results in an epileptic phenotype in mice. By employing whole-cell recordings from hippocampal slices, our lab has previously shown that CA1 pyramidal neurons of SynII-KO mice exhibit increased frequency of spontaneous excitatory currents (sEPSCs), and a lower threshold of epileptiform activity produced by the epileptogenic agent 4-aminopyridine (4-AP). Here we utilize neonatal viral injections to balance the neuronal hyperexcitability in SynII-KO mice via the expression of SynII. We took advantage of injections at P0, when the ependymal lining of the ventricles is immature and permeable to adeno-associated viruses (AAVs), and cerebrospinal fluid can disseminate AAVs throughout the entire brain. Neonatal SynII-KO pups were anesthetized and injected with AAV1-*Syn2-EGFP* into the lateral ventricles in order to induce brain-wide rescue of Syn II. Expression of SynII-GFP was confirmed using epi-fluorescence microscopy in brain slices obtained from two and three-week old mice. Using whole-cell recordings from hippocampal slices derived from injected mice, we show that SynII

transfection significantly reduced sEPSC frequency in CA1 pyramidal neurons to the level observed in wild-type slices. These results demonstrate that global re-expression of SynII at P0 can robustly reduce synaptic hyperexcitability. This approach opens the avenue for employing neonatal injections to investigate the molecular and cellular pathways that govern hyperexcitability in the SynII-deficient brain.

Title: Effects of general anesthesia on cortical neuronal activity in adults and neonates

Authors: *D. P. AKSENOV, M. MILLER, C. DIXON, A. WYRWICZ
NorthShore Univ. HealthSystem, Evanston, IL

Abstract: Volatile general anesthetics are used commonly in adults and children, but the dynamics of single unit firing throughout the anesthesia process have not been well studied *in vivo*. The process of general anesthesia comprises three main phases: the initial induction of decreased neuronal activity, the sustained plateau phase and the recovery phase. Characterizing the activity of single units throughout these phases requires stable, continuous recording of single neurons in the awake, anesthetized and recovery states, which represents a challenge for most animals models. Developing a better understanding of the neuronal changes that underlie the anesthesia process is important for comparing the effects of different anesthetics and the mechanisms through which they interact with the brain. Here we investigate how different anesthetics and their concentrations impact cortical single unit activity in adult and neonate rabbits. Neonate (6 days old) or adult Dutch-Belted rabbits were chronically implanted with electrodes in the whisker barrel cortex. The multiple signals from the microwires were fed through a miniature preamplifier to a multichannel differential amplifier system (Neuralynx Inc, Bozeman, Montana, USA). The signals were amplified, band-pass-filtered (300Hz to 3 kHz), and digitized (32 kHz/channel) using a Neuralynx data acquisition system. Unit discrimination was performed offline using threshold detection followed by a cluster analysis of individual action potential wave shapes using Neuralynx analysis software. Single unit firing was recorded continuously before, during and after delivery of two commonly-used volatile general anesthetics: isoflurane or sevoflurane. As anesthesia protocols often involve delivery over a wide range of hyperoxic mixtures, delivery of volatile anesthetics was tested in air as well as in

combination with 80% oxygen. Our results indicated that the single unit activity decreased during anesthetic delivery in a concentration-dependent manner. Although sevoflurane and isoflurane belong to the same class of general anesthetics, they produced considerably different levels of neuronal suppression during anesthesia as well as different rates of neuronal recovery. Furthermore, their effects were different in neonates and adults. Our results highlight how characterizing the temporal behavior of single units before, during and after anesthesia can provide detailed information about the impact of anesthetics on neuronal activity in specific brain regions.

Title: Subanesthetic-dose ketamine induces sustained cortical disinhibition through downregulation of neuregulin-1/ErbB4 signaling

Authors: *X. QIAO, C. NGUYEN, X. XU
Dept. of Anat. and Neurobio., Univ. of California Irvine, Irvine, CA

Abstract: Ketamine is a non-competitive antagonist of N-methyl-D-aspartate receptors and has been used for anesthesia. A finding is that a single low dose of ketamine can elicit a rapid antidepressant action with sustained effects lasting for 10 - 14 days. Ketamine can modulate circuit excitation and inhibition in the cortex and alter the neurochemistry of parvalbumin (PV)-expressing neurons. Ketamine may mediate its behavioral effects through neural plasticity processes. As Neuregulin-1 (NRG1) and its receptor ErbB4 are involved in visual cortical plasticity (Sun et al., 2016), we hypothesize that ketamine treatment may activate visual cortical plasticity through NRG1 signaling in PV neurons. We study the effects of subanesthetic-dose ketamine (10 mg/kg) on synaptic circuit connections of excitatory neurons and PV neurons in layer 2/3 of mouse visual cortex and test whether NRG1/ErbB4 signaling is involved in this process. Electrically evoked inhibitory postsynaptic currents (IPSCs) recorded in excitatory neurons in adult C57/B6 mice without ketamine treatment (666 ± 165 pA, n=9 cells) were stronger than those recorded in ketamine treated mice at 24 hours after systemic injection (401 ± 60 pA, n=12 cells) and PV-Cre; ErbB4$^{flx/flx}$ mice with and without ketamine treatment (226 ± 31 pA, n=10 cells and 268 ± 38 pA, n=13 cells, respectively). Bath applied NRG1 increased IPSCs in excitatory neurons from mice at 24 hours after ketamine injection (NRG1/baseline ratio: 1.97

± 0.22, n=12 cells), but not in excitatory neurons from wild-type mice without ketamine treatment (NRG1/baseline ratio: 0.97 ± 0.06, n=9 cells) or in PV-Cre; ErbB4$^{flx/flx}$ mice with and without ketamine treatment (NRG1/baseline ratio: 1.04 ± 0.05, n=10 cells and 0.99 ± 0.04, n=13 cells, respectively). We mapped local excitatory inputs to PV neurons by laser scanning photostimulation via glutamate uncaging. Photostimulation-induced excitatory postsynaptic responses are not significantly influenced by bath applied NRG1 in PV neurons from PV-Cre; Ai9 mice without ketamine treatment. However, in ketamine treated PV-Cre; Ai9 mice at 24 hours, 48 hours and 72 hours after systemic injection, bath applied NRG1 significantly increased excitatory postsynaptic responses of PV neurons, supporting ketamine-induced downregulation in PV neuronal NRG1/ErbB4 signaling. Together, our results indicate that ketamine treatment modulates NRG1/ErbB4 signaling and reduces excitatory inputs to local PV neurons, which in turn decreases PV inhibitory inputs to excitatory neurons. These findings suggest subanesthetic-dose ketamine can alter circuit excitation / inhibition in adult cortex to better treat amblyopia.

Title: Effects of ketamine and its metabolite 2R,6R-hydroxynorketamine on synaptic transmission and dendritic properties in dorsal CA1 neurons

Authors: *C. KIM, D. JOHNSTON
The Univ. of Texas At Austin, Austin, TX

Abstract: The limbic system is an integral brain region that underlies the action of depression and antidepressants. Growing evidence suggests that glutamatergic and GABAergic dysfunction may contribute to major depressive disorders. A sub-anesthetic dose of ketamine, a rapid and sustained antidepressant, is known to increase glutamine/glutamate and gamma-aminobutyric acid (GABA) releases within 30-40 min in the medial prefrontal cortex of depressed patients. We previously demonstrated that reduced expression of the HCN1 (Hyperpolarization-activated, Cyclic nucleotide gated, Non-selective cation) subunit of h-channels in the dorsal CA1 region leads to anxiolytic- and antidepressant-like effects in normal rats. When rats are exposed to chronic unpredictable stress (CUS), expression of HCN1 and I_h are upregulated in the perisomatic region of dorsal, but not ventral CA1 region/neurons of the hippocampus. We,

therefore, tested whether ketamine counteracts the shunting effects of I_h in dorsal CA1 neurons. We found a significant increase in synaptically evoked excitatory and inhibitory postsynaptic potentials (eEPSPs and eIPSPs) in the soma and dendrites of dorsal CA1 neurons following ketamine or 2R,6R-hydroxynorketamine (HNK) application. We also found that dendritic, but not somatic, h-measurements (R_{in} and f_R) were significantly changed at depolarizing membrane potentials (ranging from -68 mV to -83 mV) following ketamine or 2R,6R-HNK application (in the presence of AP5). These effects of ketamine on h-measurements suggested a reduction in I_h, which was distance-dependent along the somatodendritic axis of dorsal CA1 neurons. These findings represent NMDA-independent action of ketamine or 2R,6R-HNK on synaptic transmission and dendritic properties in dorsal CA1 neurons.

Title: Human induced pluripotent stem cell (hiPSC) - derived motor neurons co-cultured with primary astrocytes exhibit functional network sensitivity to botulinum neurotoxin

Authors: *B. J. BLACK, J. J. PANCRAZIO
The Univ. of Texas At Dallas, Dallas, TX

Abstract: Botulinum neurotoxin (BoNT) is the most toxic protein known to man. BoNTs act presynaptically to prevent neurotransmitter release, causing sustained paralysis, and, at sufficiently high doses, death by asphyxiation. Currently, there are no proven clinically effective treatments for reversing intoxication. The gold standard method for BoNT quantification is based on the mouse lethality assay which low-content, and incurs high animal burdens. These disadvantages have driven the development of alternative molecular, cellular, and tissue-based approaches. Substrate-integrated microelectrode arrays (MEAs) enable long-term non-invasive interrogation of phenotypic network activity in vitro. Recent technological advances have enabled more rapid neurotoxicological assessments via elecrtrophsyiological measures, but this approach is still limited due to the availability of physiologically relevant cells. Here, we report exploratory studies regarding BoNT/A sensitivity using a commercially available hiPSC motor neuron (hiPSC MN) - astrocyte co-culture model.
Methods: Astrocytes were isolated and sub-cultured from primary embryonic whole-brains at a density of 50,000 cells/cm2. hiPSC MNs were provided by BrainXell, Inc. and cultured as specified by the vendor. hiPSC MNs were seeded at 100,000 cells/cm2 on astrocyte feeder layers three days following astrocyte culture. Spontaneous network activity was monitored using the

Axion Maestro multi-well MEA recording system. Extracellular action potentials were defined as band pass filtered (300 - 5000 Hz) continuous data crossings of a 5.5σ adaptive threshold. Network activity was quantified as a combination of network bursting rates and cross-channel synchrony. 100 ng/ml BoNT/A was added on DIV 16 and recordings were collected every 24 hours following BoNT/A addition.
Results: ChAT staining of homogeneous hiPSC MN cultures confirmed a highly purified homogeneous motor neuron population. Dual GFAP and β-III tubulin staining of astrocyte cultures confirmed high purity of GFAP positive astrocytes (>95%). Network activity, consistent with formation of functional synapses, emerged following 7 DIV. No network activity was observed in homogeneous control cultures of hiPSC MNs. BoNT/A (100 ng/ml) induced significant reduction in network bursting rate and synchrony following 24 h incubation. This reduction in network activity persisted at least 7 days following BoNT/A washout. No modulation of intrinsic spontaneous activity was observed in homogeneous control cultures of hiPSC MNs.

Title: Characterization of the nociceptin system in neural circuits underlying highly palatable food intake as a model of reward

Authors: J. A. HARDAWAY[1], K. BOYT[2], W. J. MARTIN[3], T. L. WALLACE[3], *T. KASH[4]
[1]Pharmacology, Ctr. for Alcohol Studies, Univ. of North Carolina at Chapel Hill, CHapel Hill, NC; [2]UNC Chapel Hill, Chapel Hill, NC; [3]Blackthorn Therapeut., San Francisco, CA; [4]UNC-Chapel Hill, Chapel Hill, NC

Abstract: Nociceptin/orphanin FQ (N/OFQ) and its receptor (NOP) are widely distributed in cortical and subcortical brain regions and are involved in multiple functions including stress modulation and reward processing. Previous studies from our group and others have shown that antagonists for NOP can specifically reduce consumption of highly palatable food, while maintaining overall food intake, highlighting the role of the N/OFQ system in mediating rewarding processes involved in feeding behavior. In the current study, we examined the

mechanism of action of a novel and selective NOP antagonist, BTRX-246040, and aimed to confirm and extend these earlier findings by characterizing the neural substrates and circuitry underlying palatability-induced hyperphagia. We first assessed target engagement using a whole cell slice physiology approach in C57BL/6J mice. Our initial studies were focused in the Central Nucleus of the Amygdala (CeA), as we recently found that pre-pronociceptin (gene precursor for N/OFQ) expressing neurons in the CeA play a key role in regulation of palatable food intake. Consistent with previous studies, we found that bath application of N/OFQ, the endogenous peptide agonist for NOP, led to a reduction in evoked GABAergic transmission in the CeA using whole cell electrophysiology. The reduction in GABAergic neurotransmission was blocked by pre-application of BTRX-246040 further demonstrating the specificity of this effect to NOP. We then sought to identify brain-wide neural circuits that drives preference for palatable food consumption, and the impact BTRX-246040 may have on them using a whole-brain c-fos imaging and analysis approach, iDISCO-CLEARMAP. In these experiments, we aim to identify differential brain activity patterns associated with the consumption of highly-palatable food and regular chow, and to investigate the effects BTRX-246040 has on these patterns. Furthermore, we will examine how NOP antagonism alters the activity of both pre-pronociceptin containing neurons and NOP-containing neurons using genetically engineered mouse lines coupled to confocal imaging. The results of these studies will highlight the circuit mechanisms by which BTRX-246040 alters consumption of highly palatable food and provide insight into the role of the N/OFQ system in reward processes underlying obesity and binge eating disorder.

Title: Modulation of ventral tegmental area (VTA) neurons by the nociceptin/orphanin fq (N/OFQ) system

Authors: *J. R. DRISCOLL[1], E. B. MARGOLIS[2], T. L. WALLACE[3], W. J. MARTIN[4]
[1]Univ. of California San Francisco, San Francisco, CA; [2]Neurol., UCSF, San Francisco, CA; [3]BlackThorn Therapeut., San Francisco, CA; [4]Blackthorn Therapeut., San Francisco, CA

Abstract: Nociceptin/Orphanin FQ (N/OFQ) is a non-opioid, stress-induced neuropeptide that has been associated with disorders involving altered reward processing and motor function. One hypothesis for the broad emotional and behavioral influence of N/OFQ is through the modulation of dopamine signaling. N/OFQ and its cognate receptor, OLR1, are highly enriched in mesocortical and mesolimbic pathways, and intracerebroventricular injections of N/OFQ result in the inhibition of dopamine in the striatum, nucleus accumbens, and the ventral tegmental area (VTA). To better understand how N/OFQ may influence physiological mechanisms of dopamine signaling in cortical and limbic brain regions we use whole cell electrophysiology in acute midbrain slice preparations from rat to characterize the synaptic actions of N/OFQ on VTA neurons. In this study, neurons were maintained in voltage clamp mode at -60 mV and changes to membrane current in response to N/OFQ (1 nM to 10 M) were measured in both tyrosine hydroxylase (TH)+ and TH- neurons sampled throughout the VTA. Consistent with the literature, we found that N/OFQ was inhibitory, causing outward currents, in both TH+ and TH- VTA neurons. We did not observe a significant difference in the concentration response curves between TH+ and TH- neurons. The resulting dose response curve for N/OFQ yielded an EC_{50} < 5 nM, substantially lower than concentrations used in previous behavioral experiments in rodents. We also observed that repeated application of high dose N/OFQ (> 100 nM) was associated with a marked decrease in current response, a result that is consistent with desensitization. In contrast, repeated application of low dose N/OFQ (10 nM) consistently induced a similar current response. To test the specificity of responses to N/OFQ (10 nM), we bath applied a selective OLR1 antagonist, BTRX-246040 (100 nM), to confirm N/OFQ-responsive neurons. BTRX-246040 consistently blocked the inhibitory outward current activated by N/OFQ (n=6, $p<0.01$). The data from these studies provide an electrophysiological characterization of the inhibitory effect of N/OFQ on VTA neurons and demonstrate the selective antagonist activity of BTRX-246040 in this population of cells. These results extend our understanding of the involvement of N/OFQ within key circuits implicated in many neurobehavioral disorders and support the development of N/OFQ antagonists as novel therapeutics.

Title: Histamine significantly increases ASIC-1a contribution to excitatory synaptic transmission at the calyx of Held

Authors: *O. D. UCHITEL, C. GONZALEZ-INCHAUSPE
IFIBYNE UBA CONICET, Buenos Aires 1428, Argentina

Abstract: Acid-sensing ion channels (ASICs) regulate synaptic activities and play important roles in neurodegenerative diseases. We found that homomeric ASIC-1a channels are expressed in neurons of the medial nucleus of the trapezoid body (MNTB) of the auditory system in the CNS. During synaptic transmission, acidification of the synaptic cleft, presumably due to the co-release of neurotransmitter and H^+ from synaptic vesicles, activates postsynaptic ASIC-1a channels, generating synaptic currents (ASIC-SCs) that add to the glutamatergic excitatory postsynaptic currents (EPSCs). Here we report that neuromodulators like histamine (0.1-1mM) potentiate ASIC-SCs up to 84 ± 4 % and that natural products like lactate and spermine potentiate ASIC-SCs in an additive form up to 221 ± 18 %, such that excitatory ASIC synaptic currents as well as the associated calcium influx became significantly large and physiologically relevant. We show that potentiated ASIC currents by endogenous neuromodulators are capable of supporting synaptic transmission in the absence of glutamatergic EPSC. Furthermore, at high frequency stimulation, ASIC-SCs contribute to diminish short term depression (STD) and their contribution is even more relevant at early stages of development. Since ASIC channels are present in almost all type of neurons and synaptic vesicles content is acid, the participation of protons in synaptic transmission and its enhancement by endogenous substance could be a general phenomenon across the central nervous system.

Title: Effects of thyroid hormone, pregnenolone sulfate and pH on function of nicotinic acetylcholine receptors

Authors: S. X. MOFFETT, E. A. KLEIN, G. BRANNIGAN, *J. V. MARTIN
Ctr. for Computat. & Integrative Biol., Rutgers Univ., Camden, NJ

Abstract: Historically, thyroid hormones were thought to have exclusively genomic actions in adults, with no short-term signaling effects, but recent evidence contradicts this. The thyroid hormone 3, 3',5-triiodothyronine (T3) localizes in adult brain noradrenergic centers and projection sites. T3 affects sleep after microinjection into the median preoptic nucleus of adult male rats. It has neurotransmitter-like, inhibitory effects on the GABA-A receptor, a pentameric ligand-gated ion channel (pLGIC). The neurosteroid pregnenolone sulfate (PS) has a similar size and structure to T3, and inhibits activity of the GABA-A receptor as well. Another pLGIC, the nicotinic acetylcholine receptor (nAChR), is highly concentrated in the sea ray *Torpedo californica*'s electric organ. We extracted *Torpedo* nAChRs and reconstituted functional channels in asolectin (soybean) lipids. We injected resuspended nAChRs into *Xenopus* oocytes and performed two-electrode voltage clamping (TEVC) studies to demonstrate modulatory effects on nAChR response to acetylcholine due to T3/PS binding or different pH environments. Here we show an inhibitory effect on ion flux through the nAChR with increasing concentration of co-administered T3, similar to the inhibitory effect of PS. We also show a direct relationship between positive modulation of the nAChR channel and increasing pH in perfusion solutions (n=3, per condition). Finally, we show that this pH relationship has complex effects on desensitization when the channel is inhibited by T3 or by PS. The effect due to pH, the inhibitory effects due to T3 and PS, and the differing relationship between the pH and each of the ligands' effects may implicate charged residues within the transmembrane domain of the nAChRs in both ligand binding and channel conductance.

Title: Global transcriptome analysis reveals genes and signaling pathways regulated by lactate in cortical neurons

Authors: *M. B. MARGINEANU, H. FIUMELLI, P. J. MAGISTRETTI
BESE, King Abdullah Univ. of Sci. and Technol., Thuwal, Saudi Arabia

Abstract: Lactate, a product of aerobic glycolysis in astrocytes, is required for memory formation and consolidation, and has recently emerged as a signaling molecule for neurons and various cell types of peripheral tissues. In particular lactate stimulates mRNA expression of a few plasticity-related genes. Here, we describe a RNA-Seq study that unravels genome-wide transcriptomic responses to this energy metabolite in cortical neurons. Our results show that mRNA expression of 4999 genes was modulated after 1h, 6h, and 24h of lactate treatment (FDR<0.05). Among these, the expression of 20 immediate-early genes involved in the MAPK signaling pathway and in synaptic plasticity was increased following 1h of lactate stimulation.

This effect was dependent on NMDA receptor activity since it was prevented by pre-treatment with MK-801. Comparison with published datasets showed that a significant proportion of genes modulated by lactate were similarly regulated by a synaptic NMDA receptors activation protocol known to result in upregulation of pro-survival and downregulation of pro-death genes. Remarkably, transcriptional responses to lactate were reproduced by NADH suggesting a redox-dependent mechanism of action. Longer-term gene expression changes observed after 6h and 24h of lactate treatment, affected genes involved in regulating neuronal excitability, glutamatergic transmission and genes coding for proteins localized at synapses. Gene set enrichment analyses performed with ranked lists of expressed genes revealed effects on molecular functions involved in epigenetic modulation, and on processes relevant to sleep physiology and behavioral phenotypes such as anxiety and hyperactivity. Overall, these results strengthen the notion that lactate effectively regulates activity-dependent and synaptic genes, and highlight new signaling effects of lactate in plasticity and neuroprotection.

Sci. and Engin. Div., King Abdullah Univ. of Sci. and Technol. (KAUST), Thuwal, Saudi Arabia

Abstract: Intracellular metabolic cascades triggered by stimulation of second messenger-coupled cell membrane-bound receptors are responsible for numerous biological functions including the regulation of energy supply to the brain. This complex network of biochemical

reactions including cAMP-dependent enzymes, glycogenolysis, glycolysis, and other downstream processes are regulated at various points. Using an atlas-based, data-driven computational model of the biochemical reactions contained within the neuro-glio-vascular ensemble (NGV), we demonstrate that the chain reaction of enzymes and metabolites forms a dynamical system, the components of which may exhibit hysteretic trajectories and shift phases in a concentration-dependent manner. The various metabolites and enzymes may also display non-linear, dose-dependent interdependencies. These cascade profiles can be tuned by adjusting individual components such as metabolite concentrations or enzyme kinetics and optimized for a desired outcome. We propose that "cascade tuning" with a broad diversity of previously unexploited regulatory options could be important to cellular functions, as well as a useful research tool for studying cell metabolism.

Title: Contribution of astrocytic Connexin 43 in energy homeostasis

Authors: *F. GUILLEBAUD, K. POIROT, B. LEBRUN, M. DALLAPORTA, S. RAMI, J.-D. TROADEC
Aix Marseille Univ., Marseille, France

Abstract: The metabolic syndrome, which comprises obesity and diabetes, is a major public health issue and consequently the understanding of energy homeostasis control remains an important worldwide concern. The homeostatic regulation of energy balance is under the control of specific neuronal networks, located mainly in the hypothalamus (hypth) and the dorsal vagal complex (DVC). These structures integrate nutritional, humoral and nervous information arising from the periphery. Glial cells contribution to balance regulation has been poorly studied until recently and the role of gliotransmitters in these mechanisms warrants further investigations. In the present study, we sought to evaluate the involvement of astrocytic Connexin 43 (Cx43) hemichannels and the release of subsequent gliotransmitters in energy balance regulation. We showed that Cx43 is strikingly expressed in the hypth and DVC while Cx43 was mostly found in close apposition to synapses located through pre-synaptic Bassoon presence. Then, we used intracerebroventricular injection of TAT-Gap19, a peptide that specifically blocks Cx43 hemichannels activity. We reported a strong decrease of food intake upon TAT-Gap19 treatment, without further alteration of energy expenditure. Moreover, TAT-Gap19 induced the activation

of prototypic anorexigenic neurocircuitries as attested the expression of the immediate early gene c-Fos. Altogether, these results suggest a tonic delivery of orexigenic molecules associated with astrocytic Cx43 hemichannel activity. To further decipher the role of astrocytic Cx43 in energy homeostasis, we generated a mouse line exhibiting a conditional deletion of Cx43 gene in astrocytes of hypth and/or DVC. The deletion of Cx43 in astrocytes was achieved by crossing Cx43 floxed mice with mice harbouring the Cre transgene under the control of GFAP transcriptional elements. The Cre activity was dependent on ERT2 receptor and induced in adult mice by endoxifen administration. Endoxifen was administered within the 3rd and/or 4th ventricle(s) to target the hypth and/or the DVC respectively. The validity of this approach was confirmed by using td-Tomato knock-in mice and local quantification of Cx43 gene expression after Cre recombinase induction. Food intake, energy expenditures and locomotor activity were recorded on this unique Cx43 specific KO model to characterize the whole influence of Cx43 in energy homeostasis. The susceptibility of the conditional KO mice to high fat diet-induced obesity is under investigation. Collectively, these results suggest that glial Cx43 is essential for homeostatic regulation of energy balance and could open new therapeutic avenues.

Title: Metabolic changes in astrocytes: Implications for psychiatric disorders

Authors: *Y. JOUROUKHIN, A. V. SHEVELKIN, L. NUCIFORA, C. TERRILLION, O. MYCHKO, F. NUCIFORA, M. PLETNIKOV
Dept. of Psychiatry and Behavioral Sci., Johns Hopkins Univ. Sch. of Med., Baltimore, MD

Abstract: Metabolic alterations and mitochondrial dysfunction have been described in patients with major psychiatric disorder. Astrocytes provide metabolic support for neurons and regulate synapse formation and neurotransmission. We studied the role of *NPAS3* (Neuronal PAS domain protein 3), a transcriptional factor highly expressed in astrocytes, in regulation of mitochondria functions. We evaluated cognitive outcomes using trace fear conditioning test; quantified the density of parvalbumin- and glutamate decarboxylase-positive pre-synaptic boutons on

pyramidal neurons of the frontal cortex layer 2/3 as well as performed RNA-seq analyses of hippocampal samples of mice with astrocyte-specific deletion of Npas3 (Npas3 KO). In addition, we evaluated mitochondrial function and measured glutamate and lactate production in Npas3 KO primary astrocytes. Our results show that learning and memory deficit in mice with astrocyte-specific deletion of *Npas3* accompanied by decreased density of parvalbumin-positive inhibitory neurons in prefrontal cortex. Moreover, we found that parvalbumin-positive neurons have reduced glutamate decarboxylase - immunoreactivity in their presynaptic boutons on pyramidal excitatory neurons. Remarkably, *Npas3* deletion was also associated with a 40-fold decrease in expression of the *Solute Carrier Family 25, Member 18* (*Slc25a18*) and decreased levels of its protein product, the mitochondrial glutamate carrier 2 (GC2). Reduced expression of GC2 resulted in decreased mitochondrial respiration and elevated secretion of glutamate by *Npas3* KO astrocytes. Our findings suggest a previously unknown role for *Npas3* in regulation of glutamate metabolism in astrocytes abnormalities in which could affect functioning of cortical inhibitory neurons, leading to cognitive impairment relevant to major psychiatric disorders.

Abstract: Compartmentation in the metabolism of tricarboxylic acid (TCA) cycle intermediates, glutamate and GABA in mammalian brain has been established in the last two decades. The heterogeneity of expression of multiple enzyme systems in neurons and glial cells constitute one mechanism underlying the brain metabolic compartmentation. By contrast, the metabolic compartmentation of dorsal root ganglion (DRG) neurons and Schwann cells in the peripheral nervous system (PNS) is still inadequately defined. Three energy-metabolizing enzymes (lactate, glutamate, and malate dehydrogenases (LDH, GDH, and MDH)) were employed to investigate our hypothesis that metabolic differences between DRG neurons and Schwann cells exist. Activities of these enzymes were therefore studied employing the Clark and Lai assays.

Consistent with our hypothesis, the activities of these enzymes differed between the two cell types. GDH and LDH activities were much higher in Schwann cells than in DRG neurons while MDH activity was slightly higher in DRG neurons than in Schwann cells. Because our findings may have physiological/pathophysiological implications in normal and disease conditions in the PNS, further characterization of the metabolic properties of these PNS neural cells is warranted.

Title: The effect of BDNF signaling in VMH astrocytes on energy and glucose balance control

Authors: *D. AMEROSO, C. DULLA, M. RIOS
Neurosci., Tufts Univ. Sackler Sch. of Grad. Biomed, Boston, MA

Abstract: Central neural circuits critically regulate energy and glucose homeostasis. Neural networks within the hypothalamus receive and integrate peripheral energy status signals and respond by altering feeding behavior and energy expenditure to meet the nutritional demands of the animal. Brain-derived neurotrophic factor (BDNF) signaling in the ventromedial hypothalamus (VMH) is an essential component of these complex regulatory mechanisms. BDNF expression in the VMH is robustly induced in the fed state and activation of its receptor tyrosine receptor kinase B (TrkB) increases activity of VMH neurons and the anorexigenic tone and mediates glucose homeostasis. Importantly, reduced BDNF signaling in both mouse models and humans is associated with severe obesity and impaired glycemic control. In addition to its significant effects facilitating neuronal synaptic plasticity, BDNF has been shown to regulate astrocyte morphology and calcium signaling through activation of the TrkB splice variant TrkB.T1 in other brain regions. It is unclear whether VMH astrocytes are an essential substrate for actions of BDNF influencing metabolic function. Astrocytes are in contact with the blood supply and reciprocally communicate with neurons to regulate their activity. Thus, they are an excellent yet understudied candidate for sensing peripheral metabolic signals to accordingly shape the appropriate neuronal and metabolic responses. We hypothesize that VMH astrocytes are key regulators of energy and glucose balance, and that BDNF signaling in this cell population is critical for these effects. In support, preliminary data indicate that BDNF and energy status

dynamically regulate function and structural plasticity of VMH astrocytes to influence neuronal activity. Additionally, results show that VMH astrocytes exclusively express TrkB.T1 and that this receptor is required for proper energy balance control. As the VMH is a sexually dimorphic region, ongoing studies will assess whether these effects are influenced by sex. To ensure scientific rigor, all of the experiments involved appropriate use of controls, power analysis to determine cohort size and statistical analysis to determine significant differences. In total, our findings inform novel mechanisms involved in the regulation of central feeding circuits and provide a stepping-stone for identification of potential therapeutic targets in treating obesity and metabolic disorders.

Title: Reduced astrocyte-oligodendrocyte gap junction coupling in the anterior cingulate cortex of depressed suicides

Authors: *A. TANTI, G. TURECKI, N. MECHAWAR
Douglas Mental Hlth. Univ. Inst., McGill Group For Suicide Studies, Montreal, QC, Canada

Abstract: Imaging studies have shown widespread changes in white matter integrity and brain connectivity in patients with major depressive disorder. This is in agreement with reports of altered oligodendrocyte densities and impaired myelin ultrastructure in human post-mortem studies as well as animal models of depression. Myelination of axons by oligodendrocytes is tightly regulated, notably by astrocytes, which establish gap junctions with oligodendrocytes through heterotypic coupling of astrocyte-specific (Cx30 and Cx43) and oligodendrocyte-specific (Cx32 and Cx47) connexins, allowing metabolic support to oligodendrocytes. Because decreased expression of astrocyte-specific connexin genes has been previously observed in the prefrontal cortex of depressed suicides, we ought to investigate if changes in myelin integrity associated with depression could be linked to abnormal oligodendrocyte-astrocyte coupling. Using well-characterized post-mortem samples from depressed suicides and matched controls, we used immunofluorescence and confocal microscopy to map and quantify the expression of Cx30 in oligodendrocytes and myelinated fibers, as well as along blood vessels of the anterior

cingulate cortex (ACC) grey matter. RNAseq data was used to screen for gap junction-related changes in gene expression and validated by quantitative PCR. We found that in the ACC, depressed suicides show a decreased expression of Cx32 and Cx47, both connexins involved in oligodendrocyte-astrocyte gap junction coupling, as well as decreased expression of several key mediators of gap junction assembly. These changes were associated with decreased Cx30 puncta mapping to oligodendrocytes, suggesting overall that depressed suicides display lower gap junction channel coupling between astrocytes and oligodendrocytes in the ACC grey matter. This may ultimately affect oligodendrocyte function and myelination within this brain area known to be critical for the regulation of mood and emotions. Given that glial pathology is a major hallmark of depression and suicide, understanding how glia-glia interactions shape oligodendrocyte function in health and disease may prove useful in understanding the neurobiological basis of mood disorders.

Title: Nrf2 function in oligodendrocyte development and injury responses

Authors: *D. VERDEN[1], M. C. NEAL[1], C. SCHROEDER[2], P. S. HERSON[2], W. B. MACKLIN[1]
[1]Cell & Developmental Biol., [2]Pharmacol., Univ. of Colorado Anschutz Med. Campus, Aurora, CO

Abstract: White matter injury is a crucial component of ischemic stroke pathophysiology. In addition to local neuronal death, ischemia damages oligodendrocytes, the myelin-producing cells of the central nervous system. Myelin loss drives inflammatory responses and causes secondary damage to myelinated axons connecting brain regions, inhibiting tissue recovery and increasing the scope of circuit dysfunction. Stroke susceptibility varies with age, and the juvenile period is characterized by greater stroke recovery than in neonates or adults. Previous work from our lab has shown that in juvenile mice, oligodendrocytes and myelin are resistant to ischemic injury. The juvenile period is the peak of central nervous system myelination, during which oligodendrocytes have increased metabolism demands that generate reactive oxygen species (ROS) byproducts. Active myelination requires increased antioxidant capacity, which we hypothesize may provide protection from ischemic injury in juvenile oligodendrocytes. RNA-

sequencing of acutely isolated juvenile and adult oligodendrocytes uncovered differential regulation of Nrf2, a master transcriptional regulator of oxidative stress response. Nrf2 is protective for several cell types following ischemia, and is known to protect oligodendrocytes from reactive oxygen species in other contexts, revealing a capacity for Nrf2-mediated ROS management in oligodendrocytes. We therefore investigated a potential dual role of Nrf2 both in oligodendrocyte development and ischemic response. Analysis of juvenile and adult brains revealed increased expression of Nrf2 in juvenile oligodendrocytes, and Nrf2 protein is upregulated during oligodendrocyte differentiation in primary oligodendrocytes. Preliminary evidence from an oligodendrocyte-specific Nrf2 knockout indicates that loss of Nrf2 causes reactive responses by NG2 cells. These results indicate that Nrf2 is developmentally regulated by oligodendrocytes and may play a role in oligodendrocyte lineage function. Additional characterization will determine the effect of Nrf2 on oligodendrocyte ROS management, as well as myelin production and maintenance.

Title: TRPA1 channels regulate oligodendrocyte intermodal potassium conductance during ischaemia

Authors: *N. B. HAMILTON[1], M. CORNILLOT[2], M. KHARAGHANI[2], C. LA MACHE[2], K. KOLODZIEJCZYK[3], D. ATTWELL[4]
[2]Wolfson Ctr. for Age-Related Dis., [1]King's Col. London, London, United Kingdom; [3]Cardiac Services BC, Vancouver, BC, Canada; [4]Univ. Col. London, London, United Kingdom

Abstract: Oligodendrocytes wrap myelin around axons to speed neuronal transmission, provide trophic support and syphon away excess K^+ during burst firing of action potentials. These functions are crucial to normal brain function, and oligodendrocyte electrical conductance has the potential to limit or enhance action potential size and speed, as well as to limit the excitability of neurons. We have recently shown that raised extracellular K^+ concentrations that occur in ischaemia, can activate TRPA1 in oligodendrocytes (Hamilton et al., 2016). We now find that

TRPA1 activity can regulate internodal K^+ conductance through modulation of K^+ channel phosphorylation states and therefore the capacity for myelinating internodes to sequester K^+ from the axonal space during spontaneous action potentials. TRPA1-mediated inhibition of K^+ channels occurs during ischaemia, and can be prevented by blocking TRPA1 channels with HC 030031, ruthenium red or genetically removing TRPA1. These results suggest that oligodendrocyte TRPA1 channels may have an important role in regulating K^+ syphoning in the white matter and that this mechanism may play a role in ischaemia-evoked white matter changes.

Title: Changes of myelin morphology and development in early stage of Alzheimer's disease mouse model

Authors: *Y. WU[1,2]
[1]Beijing City, China; [2]Inst. of Mental Hlth., Peking Univ., Beijing, China

Abstract: Alzheimer's disease (AD) is the most common cause to dementia and predicted to affect more than 35 million people by the end of 2050. In this study, we discovered alterations of myelin morphology in brain tissues of 2-month-old APP/PS1 mouse. Myelin sheath was thicker and distance between two nodes of Ranvier was shorter in APP/PS1 mouse. Oligodendrocytes, which was differentiated from oligodendrocytes progenitor cells (OPCs) and responsible for formation and maintenance of myelin sheath in central nervous system (CNS), was found developed in disordered in 2-month-old APP/PS1 mouse. Neuregulin-1 type III, which was critical for both oligodendrocytes development and central nervous system myelination, was found up-regulated in APP/PS1 mouse by western blots. Given together, this study indicated the changes of myelin sheath morphology and oligodendrocytes development in early stage of APP/PS1 mouse.

Title: Deep learning for cell-specific high-throughput quantification of oligodendrocyte ensheathment

Authors: *Y. XU[1], D. CHITSAZ[2], R. A. BROWN[2], J. P. ANTEL[3], T. E. KENNEDY[4]
[1]Neurol. and Neurosurg., Montreal Neurolog. Institute, McGill Univ., Montreal, QC, Canada; [3]Dept Neurol & Neurosurg., [2]McGill Univ., Montreal, QC, Canada; [4]Neurol. & Neurosurg., Montreal Neurolog. Inst., Montreal, QC, Canada

Abstract: Reducing myelin injury and enhancing myelin repair are central therapeutic objectives in reversing the progression of demyelinating diseases. Despite the unique structure of myelin, elaborated by oligodendrocytes (OL), quantifying the injury and repair responses of OLs on a large-scale still poses a significant methodological challenge to researchers. The lack of high-throughput systems capable of extracting cell-specific morphological information has impeded the screening and development of therapeutics for myelin diseases. In the present study, we established deep learning and classic algorithmic approaches that resolve this quantitative challenge by eliminating the time for image acquisition and analysis, while successfully matching human analytic quality. We first generated a classic algorithmic approach that used the basic morphological characteristics of OL ensheathments to assess the myelinating potential of OLs in nanofiber cultures. Next, we attempted to improve on this classic approach by combining automated imaging with deep learning techniques. Our deep learning approach employed a convolutional neural network that followed a "UNet" architecture to learn cell-specific information. During training, the UNet was presented with images appended to single nuclei masks so that the network could learn to associate ensheathments to specific cell nuclei rather than identify ensheathments globally. Through validation on cell-specific and whole-image levels, we demonstrate that both approaches could match the accuracy of human segmentations on several parameters, including length distributions and number of sheaths formed per cell. Overall, the combination of automated imaging and analysis has the potential to eliminate weeks of manual labor while offering a 5- and 20-fold increase in whole-well analytic speed for the UNet and classic algorithmic approaches respectively. Furthermore, since the task is highly parallelizable, the speed of analysis can be enhanced nearly indefinitely by employing additional computing workstations. By enhancing analytic speed without sacrificing analytic quality we

have developed a high-throughput system capable of quantifying single-cell ensheathments. This new technology permits the detection of nuanced differences associated with injury induction and repair to accelerate the development of therapeutics for myelin diseases.

Title: Antisense oligonucleotides (ASOs) efficiently target glial cells and provide a novel therapeutic platform for demyelinating disorders

Authors: *B. POWERS[1], T. HAGEMANN[2], C. MAZUR[1], F. RIGO[1], A. MESSING[2], E. SWAYZE[1]
[1]Neurosci. Drug Discovery, Ionis Pharmaceuticals, Carlsbad, CA; [2]Dept. of Neuropathology and Waisman Ctr., Univ. of Wisconsin-Madison, Madison, WI

Abstract: Antisense oligonucleotide (ASO)-based therapeutics hold much promise for the treatment of neurodegenerative diseases. ASOs are chemically modified DNA oligomers that distribute widely throughout the CNS when dosed into the cerebral spinal fluid. They bind RNA and can be designed to halt or increase the production of proteins. SPINRAZA was recently approved by the FDA for the treatment of spinal muscular atrophy and we have several other antisense programs in clinical trials for Huntington's, Alzheimer's, and ALS. Here, we demonstrate that ASOs not only efficiently target neurons, but also oligodendrocytes (OLs), oligodendrocyte progenitor cells (OPCs), and astrocytes. First, using in situ hybridization (ISH), we find robust reduction of target RNA in white matter tracts throughout cynomolgus monkey CNS after an intrathecal injection of ASO targeting the non-coding RNA Malat1. Second, we show >90% reduction of target RNA in mouse CNS eight weeks after an intracerebroventricular (ICV) injection of ASO targeting OL-specific proteolipid protein 1 (Plp1), indicating that ASOs efficiently target OLs. Third, using double fluorescent ISH we demonstrate target RNA reduction in PDGFRa+ OPCs within lysolecithin lesions in the corpus callosum of mice dosed with Malat1 ASO. This indicates that OPCs are efficiently targeted by ASO in a demyelination context. Finally, we demonstrate near total reduction of transcript and protein in rodent astrocytes using

GFAP-targeted ASOs. Importantly, we have performed proof of concept studies in mouse and rat models of Alexander disease, a rare and fatal leukodystrophy driven by toxic accumulation of mutated GFAP, which forms Rosenthal fibers in astrocytes. GFAP-targeted ASOs markedly reduce target mRNA and protein in rodents, even within the context of the models' high overexpression. Within 2-4 weeks post-treatment, Rosenthal fibers degrade and the underweight animals gain weight and limb strength. These exciting results indicate that ASOs are a promising new platform for the treatment of Alexander disease and potentially additional myelin-related disorders such as other leukodystrophies, multiple sclerosis, traumatic injuries, and stroke.

Title: The therapeutic potential of fingolimod against ischemia-induced suppression of oligodendrocyte differentiation

Authors: *K. YASUDA[1], T. MAKI[1], S. SAITO[3], Y. YAMAMOTO[3], H. KINOSHITA[1], K. NATSUE[2], M. IHARA[3], R. TAKAHASHI[1]
[1]Neurol., [2]Neurosurg., Kyoto Univ., Kyoto city, Japan; [3]Natl. Cerebral and Cardiovasc. Ctr., Suita, Japan

Abstract: [Background]Subcortical ischemic vascular dementia (SIVD) is the most common subtype of vascular dementia. SIVD is defined by evidence of subcortical white matter lesions in human. Injury of myelin/oligodendrocytes (OLGs) after chronic cerebral ischemia results in an abundant loss of myelin sheaths and axonal degeneration, which eventually lead to functional

disabilities. The failure to regenerate myelin due to impairment of oligodendrocyte precursor cell (OPC) differentiation is one of crucial pathomechanisms underlying ischemia-induced white matter damages. Therefore, the enhancement of OPC differentiation should be a promising therapeutic target for SIVD. Fingolimod, known as a drug used to treat multiple sclerosis, binds to the sphingosine 1-phosphate (S1P) receptor which is expressed not only on lymph nodes but also on neuronal, glial, and vascular cells in the brain, exerting various effects beside immunomodulation.[Object]The purpose of present study was to investigate whether fingolimod and related compounds exert positive effects on OPC function and regeneration under chronic ischemic condition.[Methods] For *in vitro* experiments, we prepared primary culture of OPCs and OLGs obtained from neonatal rats. To induce prolonged hypoxic conditions, OPCs were incubated with non-lethal concentration of $CoCl_2$ and were treated with or without fingolimod. Western blot analysis and immunocytochemistry were performed to examine the effect of fingolimod on OPC differentiation under ischemic condition. For *in vivo* experiments, we used a mouse model of prolonged cerebral hypoperfusion and white matter ischemic lesions generated by bilateral common carotid arteries stenosis (BCAS). Fingolimod was administered intraperitoneally to the BCAS-operated mice. On day 28 after surgery, mice were euthanized and western blot analysis and immunohistochemistry were performed.[Results]In vitro studies demonstrated that low concentration of fingolimod directly rescued ischemia-induced suppression of OPC differentiation via PI3K-Akt pathway, as shown by western blot and immunocytochemistry. Western blot analysis of *i*n vivo studies revealed that fingolimod treatment significantly ameliorated the decreased levels of myelin basic protein expression in the BCAS-operated mice. Immunohistochemistry showed that the number of newly generated mature OLGs in the corpus callosum was increased in fingolimod-treated mice on day 28 after BCAS.[Conclusion]The present study indicated that fingolimod can promote oligodendrogenesis under prolonged ischemic condition and the modulation of S1P signaling is a potential therapeutic target for SIVD.

Title: Enhancing oligodendrocyte myelination rescues synaptic loss and improves functional recovery after chronic hypoxia

Authors: F. WANG[1], J. Y. YANG[1], N. YANG[2], J. X. CHEN[2], S. P. FANCY[3], L. XIAO[2], J. R. CHAN[3], *F. MEI[1]

Abstract: White matter injury (WMI) in the brains of preterm infants leads to long-term functional neuronal impairment without any available clinical therapies. Although hypomyelination and arrested development of oligodendrocyte precursor cells (OPCs) are prominent in WMI, it is still unclear whether enhancing myelination represents a promising strategy to achieve functional recovery. As hypomyelination accompanies a number of pathological changes in WMI, determining the functional significance of myelination requires oligodendroglial-specific genetic manipulation. To address the significance of enhancing myelination for functional recovery after WMI, we characterized the hypomyelination deficit after chronic hypoxia, accompanied by structural and functional deficits of excitatory cortical synapses and a prolonged motor behavior deficit. To demonstrate the specific effect of hypomyelination on these features, we induced the oligodendroglial-specific deletion of the transcriptional factor Olig2, and demonstrate that a delay in myelination phenocopies the synaptic and functional deficits observed in adolescent mice after hypoxia, suggesting that functional developmental progression necessities proper spatiotemporal deposition of myelination. Additionally, these data suggest that myelin may even facilitate excitatory presynaptic innervation. As a gain of function, we induced oligodendroglial-specific deletion of the muscarinic receptor 1 (M1R), a negative regulator for oligodendroglial differentiation. The M1R deletion in OPCs enhances oligodendrocyte myelination and subsequently promotes the functional recovery and rescues the synaptic loss after chronic hypoxia. In line with this evidence, drug-based myelination-therapies also result in accelerated recovery of myelination and functional recovery after chronic hypoxia. Taken together, our data indicates that the loss of synapses and the functional deficits resulting from chronic hypoxia may be specifically and directly attributed to hypomyelination and that myelination-enhancing strategies represent a promising approach for functional recovery against WMI.

Title: Glutathione antioxidant system is transiently upregulated in juvenile oligodendrocytes: Implications for development and ischemic response

Authors: *M. NEAL[1], D. VERDEN[2], W. B. MACKLIN[3]
[1]Cell and Developmental Biol. Dept., CU Anschutz, Aurora, CO; [2]UC Denver Anchutz Med. Campus, Aurora, CO; [3]Dept Cell & Dev Biol., Univ. Colorado Med. Sch., Aurora, CO

Abstract: Oligodendrocytes are the cells of the central nervous system (CNS) that wrap axons with myelin, which allows for the fast transduction of electrical signals. Oligodendrocytes rapidly produce myelin during development, entering a myelin maintenance stage once myelination is complete. The process of myelination generates reactive oxygen species (ROS) byproducts; however the mechanism by which myelinating oligodendrocytes mitigate oxidative stress is unknown. Because we have previously seen resistance to oxidative stress induced by ischemic/reperfusion (I/R) injury in juvenile oligodendrocytes, we are investigating the differences in antioxidant activity, specifically glutathione (GSH) metabolism, between juvenile and adult oligodendrocytes in both healthy and stroked tissue. GSH is a common antioxidant across many cell types that is known to be expressed at a low level in oligodendrocytes, but it may be required during active myelination to mitigate ROS by-products. Comparison of gene expression in oligodendrocytes acutely isolated from juvenile or adult striatum by qPCR revealed increased levels of GSH-regulating genes in juvenile oligodendrocytes relative to adult cells, along with an upregulation of GSH-related genes in response to I/R injury in juvenile oligodendrocytes. Furthermore, immunohistochemical (IHC) analysis of juvenile and adult striatum revealed increased expression of glutathione-synthesizing proteins, as well as maintenance of these proteins after stroke injury in juvenile oligodendrocytes. These results indicate that juvenile oligodendrocytes utilize the antioxidant GSH pathway during the process of active myelination, and that this pathway may provide for their protection from stroke injury.

Title: A reliable method for isolation and culture of different glial cells from adult pig brain

Authors: *G. K. TANTI[1], R. SRIVASTAVA[2], S. R. KALLURI[2], C. NOWAK[2], B. HEMMER[2,3]
[1]Dept. of Neurol., Tech. Univ. Munich, Munich, Germany; [2]Dept. of Neurol., Klinikum rechts der Isar, Tech. Univ. Munich, Munich, Germany; [3]Munich Cluster for Systems Neurol. (SyNergy), Munich, Germany

Abstract: Primary culture of glial cells is an important tool for basic and translational neuroscience research. Glial cell cultures are usually generated from rodent brain although considerable differences exist between human and rodent glia. Because many translational research projects aim to identify mechanisms that eventually lead to diagnostic and therapeutic approaches to target human diseases, glia cultures are needed that better reflect human glia. Pig brain is easily accessible and in many aspects close to the human brain. We have established an easy and cost-effective method to isolate and culture different primary glial cells from adult pig brain. Oligodendrocyte, astrocyte, and microglia primary cell cultures were generated from the same brain tissue and grown for 6-8 weeks. Primary oligodendrocyte cultures had a purity of 95%, showed the typical morphology and were O4, Olig2, MBP and MOG positive. Primary microglia cultures were 90% pure and expressed CD11b and Iba1. Astrocyte cultures showed the typical morphology with 60% of cells expressing GFAP. Human sera from patients with Neuromyelitis Optica containing AQP4 antibodies exerted a specific cytotoxic effect on astrocyte but not other glial cell cultures. In summary, we established a new method for primary oligodendrocyte, microglia and astrocyte cell cultures from the pig brain suitable for functional assays.

[1]Tohoku Univ., Sendai-Shi, Japan; [2]Dept. Neuropharmacol / Univ. Yamanashi, Yamanashi, Japan

Abstract: Remodeling the brain by clearance of unnecessary network and debris is thought to be essential for the maintenance of brain function and microenvironment. Emerging evidence has shown that not only microglia but astrocytes also contribute to the remodeling under pathological conditions via phagocytosis. Here, we show that astrocytes, other type of glia, also show highly phagocytic phenotype after stroke with different spatiotemporal patterns of microglia. Following transient brain ischemia, phagocytic astrocytes are observed within the ischemic penumbra region during the later stage of ischemia. However, phagocytic microglia are mainly observed within the ischemic core region during the earlier stage of ischemia. Phagocytic astrocytes upregulate ABCA1 and its pathway molecules, MEGF10 and GULP1, which are required for phagocytosis, and upregulation of ABCA1 alone is sufficient for enhancement of phagocytosis. Disrupting ABCA1 in reactive astrocytes result in fewer phagocytic inclusions after ischemia. Together, these findings suggest that astrocytes are transformed into a phagocytic phenotype as a result of increase in ABCA1 and its pathway molecules and contribute to recovery or remodeling of damaged tissues and penumbra networks.

Title: AAV mediated trans-synaptic tagging of astrocytes: A novel tool for studying neuron-astrocyte interactions

Authors: *L. GEORGIOU, B. KUHN
Okinawa Inst. of Sci. and Technol. (OIST), Onna-son, Japan

Abstract: One of the most exciting modern hypothesis is that astrocytes respond to neuronal signals with calcium transients that in turn can influence neuronal activity. However, it is controversial whether astrocytes respond reliably to neuronal signals *in vivo.* Our objective was to develop a novel method to study neuron-astrocyte interactions *in vivo.* We show that recombinant adeno associated viruses (rAAVs) have trans-synaptic properties that can be exploited to reliably label axon-astrocyte pairs at high contrast and record their activity simultaneously *in vivo*. To confirm the trans-synaptic properties of rAAVs to astrocytes we used different combinations of vectors injected in the thalamus and cortex of adult (1-3-month-old), male and female mice (n > 100). rAAV injections labelled neurons densely at the injection site and sparsely astrocytes and neurons at the anterograde projection sites. Additionally, we find virus capsid proteins using immunohistochemistry in the labelled cells anterograde to the injection site. Now, we use this method combined with genetically encoded calcium indicators to study axon-astrocyte interactions with two-photon microscopy through a chronic cranial window in awake, head fixed mice. We show that astrocytes in the somatosensory cortex of awake mice exhibit fast calcium signals at the microdomains. We also show that astrocytes are in contact with thalamocortical axons. Exploratory correlation analysis of cortical astrocytes and contacting neurite calcium concentration recordings suggests that astrocytes do not respond to axon activity. We conclude that rAAVs have trans-synaptic properties and can infect both neurons and astrocytes anterogradely. This property of rAAVs can be used to study circuit specific axon-astrocyte interactions. Furthermore, the results challenge the spatial specificity of rAAVs and if cortical astrocytes reliably respond to neuronal activity *in-vivo.*

Abstract: Astrocyte dysfunction emerges early in Alzheimer's disease (AD) and may contribute to its pathology and progression (Verkhratsky et al. 2011; Zhao et al. 2011; Couturier et al. 2016). Recently, the voltage gated potassium channel $K_V3.4$ subunit, which underlies the fast-inactivating K^+ currents, has been recognized to be relevant for AD pathogenesis and is emerging as a new target candidate for AD (Angulo et al. 2004; Pannaccione et al. 2007). In the present study, we investigated both in in vitro and in vivo models of AD the expression and functional activity of $K_V3.4$ potassium channel subunits in astrocytes. In primary astrocytes biochemical, immunohistochemical, and electrophysiological studies demonstrated a time-dependent upregulation of $K_V3.4$ expression and functional activity after exposure to amyloid-β (Aβ) oligomers. Consistently, astrocytic $K_V3.4$ expression was upregulated in the cerebral cortex, hippocampus, and cerebellum of 6-month-old Tg2576 mice. Further, confocal triple labeling studies revealed that in 6-month-old Tg2576 mice, $K_V3.4$ was intensely coexpressed with Aβ in nonplaque associated astrocytes. Interestingly, in the cortical and hippocampal regions of 12-month-old Tg2576 mice, plaque-associated astrocytes much more intensely expressed $K_V3.4$ subunits, but not Aβ. More important, we evidenced that the selective knockdown of $K_V3.4$ expression significantly downregulated both glial fibrillary acidic protein levels and Aβ trimers in the brain of 6-month-old Tg2576 mice. Collectively, our results demonstrate that the expression and function of $K_V3.4$ channel subunits are precociously upregulated in cultured astrocytes exposed to Aβ oligomers and in reactive astrocytes of AD Tg2576 mice.

Title: The effect of γ-synuclein treatment on adult human cortical astrocyte proliferation and BDNF expression

Authors: T. LE[1], C. L. WINHAM[1], E. C. WILKIE[1], E. R. JELLISON[2], *A. O. KOOB[1]

Abstract: γ-Synunclein (γ-syn), a member of the synuclein protein family implicated in neurodegenerative disease, is expressed by astrocytes in the human nervous system, and increased extracellularly in the cerebrospinal fluid of individuals diagnosed with Alzheimer's disease and Dementia with Lewy Bodies. Upregulation of γ-syn has also been shown in glioblastomas and other cancers. In order to better understand the function of extracellular γ-syn, astrocytes from adult human cortex in tissue culture were treated with 100 nM γ-syn for 3, 6 and 24 hours. Western blot analysis revealed endogenous expression of γ-syn in controls as well as uptake of extracellular γ-syn by astrocytes at 3 and 6 hours, with a further increase at 24 hours. Brain derived neurotophic factor (BDNF), a growth factor released by astrocytes, was increased intracellularly over time with γ-syn treatment, but not in controls, and coincided with elevated extracellular BDNF release at 6 hours. However, after 24 hours of treatment, extracellular BDNF was decreased after γ-syn treatment compared to controls. Astrocytes labeling with proliferation marker 5-bromodeoxyuridine (BrdU) were increased at 3 hours as well as 6 hours after γ-syn treatment, but not at 24 hours. Additionally, after cell synchronization in G_0/G_1, cells were released back into the cell cycle and treated with BrdU and 50, 100 and 150 nM of γ-syn for 24 and 48 hours. Analysis of BrdU and propidium iodide through flow cytometry 24 hours after release revealed an increase in G_2/M phase of the cell cycle in cells treated with 100 nM γ-syn compared to controls. This effect was no longer seen at 48 hours. However, BDNF release was increased after 100 nM and 150 nM γ-syn treatment at 48 hours, with no difference from controls after 24 hours. These results suggest γ-syn treatment initially causes upregulation of the cell cycle and subsequent BDNF release in human cortical astrocytes. Since stimulation of reentry into the cell cycle by non-neuronal cells is shown in neurodegenerative disease, dysregulation of endogenous γ-syn in the aging brain could potentially contribute to this process.

Title: Direct effects of polychlorinated biphenyls and synuclein on astrocyte function

Authors: *M. S. MCCANN[1], K. MAGUIRE-ZEISS[2]
[1]Georgetown Univ., Washington, DC; [2]Neurosci. & IPN, Georgetown Univ. Med. Ctr., Washington, DC

Abstract: Synucleinopathies are diseases characterized by the accumulation of oligomeric α-synuclein (syn) where the central nervous system (CNS) is the primary organ system affected. While the etiology of synucleinopathies remains elusive, evidence suggests that the intersection of environmental stressors and genetic predispositions result in neurodegeneration. The accumulation of polychlorinated biphenyls (PCBs), a class of hazardous organic chlorines once widely used for industrial purposes, is correlated with increased nigral cell death in Parkinson's disease (PD) patients. Astrocytes have a critical role in maintaining brain homeostasis and do so through their robust antioxidant profiles. Here, we hypothesize that syn and PCB act as a 'dual hit' in inciting disease pathogenesis, for which astrocyte dysfunction is a critical component. We found that PCBs and syn individually cause significant lipid peroxidation and increased expression of specific Nrf2 antioxidant genes in primary murine astrocytes. To investigate whether these compounds serve as a 'dual hit' in inciting astrocytic dysfunction, we co-treated astrocytes with PCBs and syn and found significant astrocytic release of monocyte chemoattractant protein-1 (MCP-1). Overall, this study suggests that syn and PCBs have a synergistic effect *in vitro*, and future work will use an *in vivo* dual hit model.

Title: Astrocyte specific expression of TDP-43 alters memory and anxiety

Authors: *C. M. KHALID-JANNEY, S. DAVIS, D. CARTER, M. A. GITCHO
Biol. Sci., Delaware State Univ., Dover, DE

Abstract: TAR DNA binding protein 43 (TDP-43) functions as a heterogeneous nuclear ribonucleoprotein that regulates gene expression, RNA stability, and localizes to the cytoplasm as a stress response protein. Glial Fibrillary Acidic Protein (GFAP) is an intermediate filament protein found primarily in astrocytes that increases expression when astrocytes are activated. TDP-43 predominantly resides in the nucleus except under pathological conditions it accumulates in the cytoplasm. In this study, we selectively and conditionally express TDP-43 with a defective nuclear localization signal (ΔNLS) under control of the human GFAP promoter in astrocytes utilizing a doxycycline inducible system to investigate pathological outcomes and non-cell autonomous effects associated with TDP-43 expression. We hypothesize that age-dependent selective TDP-43ΔNLS expression in astrocytes alters memory and anxiety through in a mechanism of non-cell autonomous neuronal degeneration.
At two months of age, GFAP/TDP-43ΔNLS mice displayed functional changes in anxiety and memory, which may be associated with the changes in non-cell autonomous neuronal degeneration. In addition, primary cortical neuron/astrocyte co-cultures expressing TDP-43ΔNLS exclusively in astrocytes showed a significant decrease in neuronal viability compared with littermate controls.
Mice were tested via a battery of behavioral tests across multiple time points (8/12/16 weeks), consisting of anxiety tests (Light/Dark Box, Open Field, Hole Board, Elevated Plus Maze), memory tests (8-Arm Radial Maze (ARM), Y Maze), motor tests (Rotarod, Elevated Beam), and a sociability test (3-Box/Resident Intruder), in differing combinations at each time point. Additionally, primary cortical neuron/astrocyte (~90%/~10%) cultures comparing GFAP and GFAP/TDP-43ΔNLS mice were examined for viability, immunofluorescence, Western blot, and mitochondrial bioenergetics. Pathology and biochemistry in the brain and was also evaluated at the three behavioral time points (8/12/16 weeks). This relationship of non-cell autonomous degeneration may expand our knowledge of astrocyte dysfunction associated with neurodegeneration.

Title: Astrocytes are target of a-synuclein oligomers: Implications for astrocyte reactivity and synapse formation in Parkinson's disease model

Authors: *L. P. DINIZ[1], I. MATIAS[2], M. GARCIA[2], A. P. B. ARAUJO[2], S. V. ALVES-LEON[2], J. M. SOUZA[2], D. FOGUEL[2], C. P. FIGUEIREDO[2], C. BRAGA[2], L. F. ROMÃO[2], F. C. A. GOMES[2]

Abstract: Parkinson's disease (PD) is characterized by selective death of dopaminergic neurons in the substantia nigra, alterations in the basal ganglia circuit, increase of glutamatergic synapses in the striatum and aggregation of α-Synuclein. Evidence suggest that oligomeric species of α-Synuclein (αSO) are the genuine neurotoxins of PD. Whereas several studies support the direct neurotoxic effects of αSO on neurons, their effects on astrocytes have never been directly addressed. Astrocytes are essential to synapse formation and function, including maintenance of neurotransmitters levels in the synaptic cleft in homeostatic condition. However, the role of reactive astrocytes in synaptic regulation in neurodegenerative diseases is unclear. Here, we evaluated the effects of αSO on astrocyte reactivity and regulation of striatal glutamatergic synapses. We showed that αSO increases the expression of complement component 3 (C3), the proinflammatory cytokines tumor necrosis factor alpha (TNF-α), interleukin-1 beta (IL-1β) and interleukin-6 (IL-6), in addition to regulate the nitric oxide levels in astrocyte cultures. Additionally, we observed that αSO enhanced the synaptogenic capacity of astrocytes by increasing the levels of the known synaptogenic molecule, transforming growth factor beta 1 (TGF-β1). Moreover, intracerebroventricular injection of αSO in mice increased the number of astrocytes, the density of excitatory synapses, as well as TGF-β1 levels in the caudate-putamen of injected animals. Inhibition of TGF-β1 signaling impaired the synaptogenesis effect of the astrocyte conditioned medium on glutamatergic synapses *in vitro;* whereas addition of purified TGF-β1 protected dopaminergic neurons against synapse loss triggered by αSO. Together, our data suggest that αSO have important effects on astrocytic functions, and describe TGF-β1 as a new endogenous astrocyte-derived molecule involved in the increase of striatal glutamatergic synaptic density present in early stages of PD.

Title: Differential gene expression in reactive mouse astrocytes and astrocytes from the $SOD1^{G93A}$ mutated ALS model

Authors: *R. D. PÉREZ, L. LEYTON
ICBM, Fac. Medicine,University of Chile, Santiago, Chile

Abstract: When activated by brain damage (e.g. Amyotrophic Lateral Sclerosis, ALS), astrocytes undergo hypertrophy, proliferate and migrate to the damaged zone. Altogether, this process is known as “reactive gliosis” or "astrogliosis", and although required to protect the brain, astrogliosis represents a major obstruction to nerve regeneration. Such lack of repair is due to the presence of inhibitory molecules, including proteins secreted by these reactive astrocytes. In addition, reactive astrocytes undergo changes at the subcellular level and rearrange the expression and localization of cell surface proteins; however, changes in gene expression levels of signaling pathways involved in astrogliosis remain unclear. We analyzed using bioinformatics approaches different datasets (GSEs) to explore and identify changes in the expression of molecules from reactive astrocytes as compared to astrocytes from the normal rat brain and primary astrocytes obtained from the ALS mouse model (animals with $SOD1^{G93A}$ mutated). *In silico* analysis was validated using primary cultures of astrocytes, and from the ALS mice, to test levels of expression of the most relevant genes by western blotting. The bioinformatic analysis revealed that signaling pathways such as regulation of actin cytoskeleton and focal adhesion were those that showed most significant alterations in gene expression in reactive and ALS astrocytes compared with normal astrocytes. β3-integrin, a cell adhesion molecule important in cytoskeleton regulation and focal adhesion formation, as well as the glial fibrillary acidic protein (a marker of astrocyte reactivity), were found to be elevated in reactive astrocytes and ALS-derived astrocytes compared to their respective controls. Bioinformatics analysis provided us with relevant information regarding genes involved in crucial signaling pathways that are altered in astrogliosis. Importantly, expression of some identical genes was similarly affected in the ALS condition.

Title: Using mild uncoupling in mitochondria of astrocytes to rescue spatial memory in Alzheimer's disease

Authors: *N. ROSENBERG[1], A.-B. ROCHER[1], L. RESTIVO[1], Y. BERNARDINELLI[2], M. BRIQUET[1], J.-Y. CHATTON[1]
[1]Univ. of Lausanne, Lausanne, Switzerland; [2]Neonomia, Geneva, Switzerland

Abstract: Oxidative stress has been associated with apoptosis and cell death in neurodegenerative diseases such as Alzheimer's disease (AD). It has been shown *in vitro* that mitochondrial uncoupling proteins (UCPs) endogenously expressed by astrocytes decrease peroxide production from astrocytes, increase glycolysis and lactate release, and enhance survival rate of neurons. Lactate exerts beneficial effects in cerebral ischemia and has a non-metabolic modulatory effect on neuronal activity. Furthermore, in neurons, lactate is involved in the potentiation of NMDA receptors that are key players in synaptic plasticity and in long-term memory consolidation. We therefore hypothesize that overexpression of astrocytic UCP4 *in vivo* will provide support to neurons facing AD-associated injuries. Adeno-associated virus (AAV) containing UCP4 alone, or UCP4 in combination with mCherry as a fluorescent reporter under the GFAP promoter were stereotaxically injected in the CA1-CA3 of the dorsal hippocampus of wild-type (WT) and 3xTg-AD (3xTg) mice. We assessed the cognitive status in a first set of 3 month-old and 7 month-old mice. The viral construct designed had no effect on the exploratory behavior in both groups. While 3 month-old WT mice react to the spatial change, 3xTg mice fail to selectively explore the displaced object. Overall, uncoupling mitochondria of astrocyte appear to rescue spatial memory deficits. Whether this effect is due to long term mitochondrial uncoupling has to be confirmed. In parallel, we are assessing the electrophysiological properties of CA1 pyramidal cell of the same animals, by using the patch-clamp technique. Further experiments will allow us to tackle the question of whether astrocytic UCP4 influences lactate and ROS production *in vivo* and alters the function and health of vulnerable neurons of AD-associated pathologies.

Abstract: Astrocytes are multifunctional cells, which play essential roles in the brain development, physiology and pathology. The age-related morphological changes and loss of normal astrocyte functions may contribute to the onset and progression of various neurodegenerative pathologies and dementia.
Here, we have focused on age-related changes in astrocyte functioning, predominantly on astrocyte ability to regulate their volume in response to pathological stimuli. The volume changes of hippocampal astrocytes were quantified using three-dimensional confocal morphometry in acute brain slices isolated from 3M, 9M, 12M and 18M old GFAP/EGFP mice. The slices were exposed either to 20-minute hypoosmotic stress or to severe hyperkalemia (50mM K+). Under the exposure to hypotonic solutions the astrocyte swelling was maximal in 3M old mice, where the volume increased by 30%, and the extent of their swelling continually decreased during aging. Interestingly, the exposure to high K+ concentration evoked similar swelling in 3M and 12M old animals (by 65-70%), while in 9M and 18M old animals the swelling was markedly smaller (by 35-40%).
In addition, a single cell RT-qPCR profiling was carried out to reveal possible differences in the expression levels of ion channels/transporters that participate in maintaining ionic and neurotransmitter homeostasis and contribute to the astrocyte swelling and their volume regulation. Based on the Self-organizing map analysis, a single cell RT-qPCR revealed the presence of three astrocytic subpopulations, of which incidence significantly differed during aging.

Title: Normal aging induces A1-like astrocyte reactivity

Authors: *L. CLARKE[1], S. A. LIDDELOW[2], C. CHAKRABORTY[1], A. E. MUNCH[1], M. HEIMAN[3], B. A. BARRES[1]
[1]Neurobio., Stanford Univ., Stanford, CA; [2]Alexandria Ctr. for Life Sci., NYU Neurosci. Inst., New York, NY; [3]Brain and Cognitive Sci., MIT, Cambridge, MA

Abstract: The decline of cognitive function occurs with aging, but the mechanisms responsible are unknown. Astrocytes instruct the formation, maturation, and elimination of synapses, and impairment of these functions has been implicated in many diseases. These findings raise the question of whether astrocyte dysfunction could contribute to cognitive decline in aging. We used the Bac-Trap method to perform RNA sequencing of astrocytes from different brain regions across the lifespan of the mouse. We found that astrocytes have region-specific transcriptional identities that change with age in a region-dependent manner. We validated our findings using fluorescence in situ hybridization and quantitative PCR. Detailed analysis of the differentially expressed genes in aging revealed that aged astrocytes take on a reactive phenotype of neuroinflammatory A1-like reactive astrocytes. Hippocampal and striatal astrocytes up-regulated a greater number of reactive astrocyte genes compared with cortical astrocytes. Moreover, aged brains formed many more A1 reactive astrocytes in response to the neuroinflammation inducer

lipopolysaccharide. We found that the aging-induced up-regulation of reactive astrocyte genes was significantly reduced in mice lacking the microglial-secreted cytokines (IL-1α, TNF, and C1q) known to induce A1 reactive astrocyte formation, indicating that microglia promote astrocyte activation in aging. Since A1 reactive astrocytes lose the ability to carry out their normal functions, produce complement components, and release a toxic factor which kills neurons and oligodendrocytes, the aging-induced up-regulation of reactive genes by astrocytes could contribute to the cognitive decline in vulnerable brain regions in normal aging and contribute to the greater vulnerability of the aged brain to injury.

Title: *In vivo* multiphoton astrocytic imaging in the APPswe/PS1dE9 mouse model of Alzheimer's disease

Authors: *P. KELLY, S. S. HOU, M. CALVO RODRIGUEZ, S. J. VAN VELUW, B. J. BACSKAI
Mgh/Harvard Med. Sch., Boston, MA

Abstract: While synaptic dysfunction is a strong pathological correlate of memory dysfunction in Alzheimer's disease (AD), the causative mechanisms are unknown which limits the clinical management of individuals living with AD. Astrocytes critically support synaptic structure and function but undergo a series of complex morphological and functional alterations in AD. Our working hypothesis is that the astrocytic alteration in AD contributes to neurodegeneration and is a potential therapeutic target. Aged wild-type and APPswe/PS1dE9 (APP/PS1) transgenic mice each received a 3 μL bihemispheric intracortical injection of the ratiometric genetically encoded calcium indicator, Yellow Cameleon 3.6 (YC3.6) under the regulation of GFA2 promoter followed by the surgical removal of a 6-8 mm circular skull portion above the somatosensory cortex. Animals were provided with post-operative care and given at least 21 days to recover from surgery prior to being habituated to awake multiphoton *in vivo* imaging at 12 months of age. The astrocyte specific expression of fluorescent proteins resulted in the full delineation of astrocytes throughout hundreds of microns of intact murine cortex at high resolution. The intracellular astrocytic calcium transients in awake animals were heterogeneous and occurred

with less frequency within the soma when compared to the proximal, perisynaptic and perivascular processes. There was a trend towards increased baseline calcium levels within the astrocytes of awake 12-month old APP/PS1 mice when compared to age-matched wild-type animals. These preliminary data are in agreement with earlier findings from our laboratory that revealed a global elevation in astrocytic calcium activity within anesthetized 6-8 month old APP/PS1 mice when compared to age-matched wild-type mice and collectively implicate the role of aberrant astrocytic calcium homeostasis in the neurodegeneration in AD.

Title: Role of insulin-like growth factor 1 in astrocytic regulation of learning and memory in aging

Authors: *D. PRABHU[1], J. MARSHALL[1], K. BLACKBURN[1], N. M. ASHPOLE[2]
[1]Univ. of Mississippi, Oxford, MS; [2]Univ. of Mississippi, University, MS

Abstract: Advancements in healthcare have increased the average life span of people all over the world, thereby making them susceptible to disorders of aging. Aging of the brain is associated with a decline in learning, memory and cognition, affecting the ability to lead an independent life and posing an enormous economic burden. However, we still do not have an effective therapy for treating cognitive impairment. Insulin-like Growth Factor (IGF)-1, known to promote learning and memory, decreases with age. Majority of the studies have focused on the effects of IGF-1 on neurons, and not on astrocytes, despite the fact that it is the astrocytes that are the predominant cell type in the brain. One of the key functions of astrocytes is regulation of the glutamate-glutamine cycle. IGF-1 is known to influence some of the key proteins involved in this cycle. This project aims at investigating the effects of IGF-1 on the ability of astrocytes to release and recycle signaling molecules that transmit messages to nearby neurons as well as astrocytes.
We have measured the amount of glutamate released by cultured rat astrocytes under basal and stimulated conditions, in response to exogenous IGF-1 or PPP- which is an antagonist of IGF-1, with short-term and long-term treatments, using the Amplex red glutamate assay. Additionally, we have measured the changes in gene and protein expression of several key transporters

associated with the transport of glutamate in astrocytes, with qPCR and Western blotting respectively. Furthermore, we will look at the amounts of ATP released in response to IGF-1 and PPP, under basal and stimulated conditions, using a luminescence ATP measurement assay kit. Our results indicate that IGF-1 is critical for glutamate handling by astrocytes. We have observed that the amount of glutamate released into the media by astrocytes increases when treated with an inhibitor of IGF-1. We are currently measuring the gene and protein expression levels of key glutamate transporters.
In the future we plan to examine the same endpoints after genetic ablation of IGF-1 receptor using Cre-Lox recombination technology. Overall, this project will help uncover the role of IGF-1 in astrocytic regulation of learning and memory.

Title: EphrinB/EphB forward signaling in Müller cells causes apoptosis of retinal ganglion cells by increasing tumor necrosis factor alpha production in rat experimental glaucomatous model

Authors: *Z. WANG, S.-T. LIU, S.-M. ZHONG, X.-Y. LI, F. GAO, F. LI, M.-L. ZHANG, Y. MIAO, X.-L. YANG
Fudan Univ., Shanghai, China

Abstract: It was previously shown that EphB/ephrinB reverse signaling in retinal ganglion cells (RGCs) is activated and involved in RGC apoptosis in a rat chronic ocular hypertension (COH) model. In the present study, effects of ephrinB/EphB forward signaling in Müller cells were explored in the rat COH model. Treatment of cultured Müller cells with ephrinB1-Fc, an EphB1 activator, or intravitreal injection of ephrinB1-Fc in normal rats induced an increase in phosphorylated EphB levels in these cells, indicating the activation of ephrinB/EphB forward signaling, similar to that in COH retinas. The above treatment did not induce Müller cell gliosis, as evidenced by unchanged GFAP expression, but significantly up-regulated mRNA and protein levels of tumor necrosis factor-α (TNF-α) in Müller cells, thereby promoting RGC apoptosis. Production of TNF-α induced by the activation of ephrinB/EphB forward signaling was mediated by the NR2B subunit of NMDA receptors, which was followed by a distinct PI3K/Akt/NF-κB

signaling pathway, as pharmacological interference of each step of this pathway caused a reduction of TNF-α production, thus attenuating RGC apoptosis. Functional analysis of forward and reverse signaling in such a unique system, in which ephrin and Eph exist respectively in a glial element and a neuronal element, is of theoretical importance. Moreover, our results also raise a possibility that suppression of ephrinB/EphB forward signaling may be a new strategy for ameliorating RGC apoptosis in glaucoma.

Title: GLAST regulates its own mRNA levels

Authors: D. HERNÁNDEZ-MELCHOR[1], M. ESCALANTE[2], L. CID[2], *E. LOPEZ-BAYGHEN[3], A. ORTEGA[2]
[1]Toxicology, Cinvestav-IPN, Toxicology, Mexico City, Mexico; [2]Toxicology, Cinvestav-IPN, Toxicology, Ciudad de Mexico, Mexico; [3]Toxicology, Cinvestav-IPN, Dept. De Toxicología, Ciudad DE Mexico, Mexico

Abstract: Glutamate removal from synaptic cleft is carried out by transporter systems such as GLAST, a high affinity Na^+-dependent glutamate/aspartate transporter. GLAST regulation is under transcriptional glutamate-dependent control through PKC. The time-dependent reduction of H^3-labeled D-Aspartate (D-Asp) uptake and lack of effect when selective glutamate receptor agonists were used prompted us to explore the plausible transcriptional self-regulation of GLAST using the established model of cultured cerebellar Bergmann glia cells (BGCs) which present a predominant expression of GLAST. *chglast* is down-regulated in a dose- and time-dependent manner when BGCs were exposed to D-Aspartate (D-Asp). A 50 % decrease in GLAST mRNA was detected after 12 h of 150 µM D-Asp stimuli, this effect continues until 24 h of treatment. Similarly, 24 h exposure to 150 and 1000 µM of D-Asp diminished *chglast* in about 50%. In every condition cellular viability was unaltered. Interestingly, D-Asp enhances in 20% the effect of the transportable glutamate inhibitor PDC (trans-4-Carboxy-L-proline) over *glast*, reducing its expression to 50 %. Moreover, D-Asp reverts the effect of TBOA (DL-threo-β-Benzyloxyaspartic acid), a selective non-transportable inhibitor of EAATs, and diminishing

chglast expression to 70 % when compared to an untreated control. The use of D-Asp instead of glutamate guarantees that the observed effects are no related to receptor activation, but to the transporter itself. This results suggest that GLAST self-regulation is under transcriptional control via PCK.

Title: Real-time imaging of activity-driven synapse-microglia interaction *in vitro*

Authors: *M. ANDOH, R. KOYAMA, Y. IKEGAYA
Grad Sch. Pharma Sci, Univ. Tokyo, Tokyo, Japan

Abstract: Synaptic remodeling is fundamental for the refinement of neural circuits. Accumulating evidences have suggested that the brain-resident immune cells microglia are executors of synaptic remodeling. Microglia tend to engulf less active synapses during development, while activity-dependent microglial touch to spines has been shown to result in spine growth in adulthood. However, it remains unclear how microglia detect the difference of neuronal activity and modulate synapses. To answer the question, we established a live imaging system of microglia-synapse interactions *in vitro* in which neuronal activity can be modulated. We cultured neurons with both microglia and astrocytes, which allowed microglia to exhibit ramified morphology. For performing real-time imaging, glial cocultures were prepared from $CX3CR1^{GFP/+}$ mice whose microglia express GFP and neurons were transfected with synaptophysin-RFP. Using this coculture system, we successfully captured an actual moment of synaptic pruning by microglia and are now investigating whether neuronal activity affects synaptic remodeling by microglia, using the DREADD system.

Title: Noradrenergic modulation of microglial dynamics and synaptic plasticity

Authors: *R. STOWELL[1], G. O. SIPE[2], A. K. MAJEWSKA[3]
[1]Univ. of Rochester, Rochester, NY; [2]MIT, Cambridge, MA; [3]Univ. of Rochester Med. Ctr., Rochester, NY

Abstract: Microglia, the innate immune cells of the central nervous system (CNS), respond rapidly and dynamically to homeostatic perturbations of the CNS milieu. In the healthy unperturbed brain, microglial processes make frequent contacts with neurons at synapses, impacting synaptic remodeling and turnover of dendritic spines. However, it remains unclear what receptors and signaling pathways govern microglial surveillance and synapse monitoring. Noradrenaline is a powerful signal that can affect many aspects of synaptic function and plasticity. Because microglia express high levels of β_2 adrenergic receptors (ARs) compared to other cell types in the brain, we asked whether noradrenergic tone could alter microglial behavior with respect to synapses through β_2 AR signaling. To test this hypothesis we have manipulated β_2 AR signaling pharmacologically using the following agents: Nadolol (blood brain barrier (BBB) impermeant β AR antagonist), Clenbuterol (BBB permeant β_2 AR agonist), and ICI 118-551 (BBB permeant β_2 AR antagonist). We paired nadolol with clenbuterol to stimulate β_2 ARs centrally without concomitant peripheral stimulation. We then evaluated changes in basic microglial physiology through a combination of *in vivo* two-photon microscopy and immunohistochemical staining for Iba-1, a microglia-specific protein. We have found that stimulation of β_2 AR signaling *in vivo* reduces microglial motility and pseudopodia formation and causes microglia to assume a less ramified morphology. We also found that stimulation of β_2 ARs leads to impaired microglial responsiveness to focal tissue injury. These experiments show that β_2 AR signaling can affect microglial physiology and immune responses. We next examined whether these changes in basic microglial function could impact microglial interactions with neurons and functional experience-dependent plasticity. Using intrinsic optical signal imaging we have shown that pharmacological manipulation of β_2 AR signaling impairs ocular dominance plasticity in the visual cortex during the visual critical period in mice. We have shown that

microglia are directly involved in this impairment through cre-mediated excision of β_2 AR specifically in microglia, which eliminates the effect of AR signaling on plasticity. Based on our results we believe that β_2 AR signaling serves important roles in modulating microglial physiology in the context of synaptic refinement. These results and future findings will improve our understanding of the signaling mechanisms that govern microglial interactions with synapses and how they impact activity-dependent synaptic modifications.

Title: Cellular localization of lysophosphatidic acid receptor 1 in the mouse brain

Authors: *N. KAJITANI[1], M. OKADA-TSUCHIOKA[1], H. ABE[1], W. OMORI[1,2], K. ITAGAKI[1,2], M. TAKEBAYASHI[1,2,3]

Abstract: [Background] Lysophosphatidic acid (LPA) is a bioactive lysophospholipid that acts as an extracellular signaling molecule through six different G-protein-coupled receptors (LPA1-6). LPA signaling has many roles in the central nervous system that influence neural development, function, and behavior. Among LPA receptors, LPA1 is abundantly expressed in the brain. LPA1 deficient mice exhibit emotional dysregulation, impaired hippocampal-dependent memory and dysfunctional coping in response to chronic stress. Antidepressants have been reported as activating LPA1 signaling (Kajitani et al., 2016). Such findings indicate that LPA1 may be a potential therapeutic target for neuropsychiatric disorders. However, the cellular localization of LPA1 is not completely understood because of the lack of validated antibodies against LPA1. Here, we evaluated the cellular localization of LPA1 in the brain using LPA1 heterozygous mice that integrate a lacZ-reporter-tagged deletion allele. [Method] Current study used adult (> 6 week old) male Lpar1<tm1b(EUCOMM)Wtsi> mice, which contained a lacZ-reporter-tagged deletion allele in which the critical exon had been removed by Cre/loxP

mediated excision. LacZ (β-galactosidase) activity in a brain section was detected by X-Gal staining. Cellular localization of LPA1 in the brain was evaluated by double fluorescent immunostaining of antibodies against β-galactosidase and several cell markers (NeuN, DCX, GFAP, S100β, Olig2, Iba1, and CD31). [Results] X-Gal staining revealed that LacZ activity was observed in myelinated areas such as the corpus callosum. The distribution of LacZ activity was similar to a previous report that examined activity in situ through a LPA1 binding assay. Fluorescent immunostaining revealed that β-galactosidase-positive cells were enriched in the corpus callosum, but were sparsely observed in the whole brain area. The majority of β-galactosidase-positive cells expressed Olig2. The remaining β-galactosidase-positive cells expressed S100β, GFAP, and CD31. NeuN, DCX, and Iba1-positive cells hardly expressed β-galactosidase. [Conclusion] Several types of glial cells (oligodendrocytes and astrocytes), ependymal cells, and vascular endothelial cells express LPA1. LPA1 signaling may be involved in various activities of the brain network, including glial function and regulation of tissue fluids (blood and cerebrospinal fluid).

Title: The cystine/glutamate antiporter system x_c^- as modulator of corticostriatal neurotransmission

Authors: *A. MASSIE[1], E. BENTEA[2,1], A. VILLERS[3], C. MOORE[4], A. FUNK[2], S. M. O'DONOVAN[2], L. VERBRUGGEN[1], E. DEPASQUALE[2], M. J. CHURCHILL[4], H. SATO[5], L. RIS[3], C. K. MESHUL[6,4], R. E. MCCULLUMSMITH[2]

Abstract: The cystine/glutamate antiporter system x_c^-, with xCT as specific subunit, is mainly located on glial cells and couples the import of cystine with the export of glutamate. As such, system x_c^- contributes substantially to ambient extracellular glutamate levels in various regions of the brain, including the striatum and hippocampus. However, the physiological function of system x_c^- in the central nervous system remains poorly understood, despite its high expression in the brain. As a source of glial extrasynaptic glutamate, system x_c^- can affect synaptic neurotransmission as a mechanism of neuro-glial communication. In the current study, we

investigated how system x_c^- regulates transmission at corticostriatal synapses, one of the two major types of striatal excitatory synapses. Electrophysiological recordings identified a significant decrease in the amplitude of striatal field excitatory postsynaptic potentials in mice genetically lacking xCT ($xCT^{-/-}$ mice) following stimulation of corticostriatal fibers. Further, using electron microscopy, we observed depletion of glutamate immunogold labeling from corticostriatal terminals and their corresponding dendritic spines in $xCT^{-/-}$ mice. Genetic deletion of xCT did not, however, affect the morphology of corticostriatal synapses, the density of cortical innervation or spine density. Proteomic analysis of the striatum of $xCT^{-/-}$ mice revealed decreased expression of a wide range of proteins involved in regulating presynaptic neurotransmitter release, including synaptophysin, VGLUT1, and members of the synapsin, septin, and syntaxin families. In addition, kinome profiling identified changes in striatal serine/threonine kinase activity, highlighting ERK signaling as a possible node of kinase dysregulation in $xCT^{-/-}$ mice. Finally, in the marble burying test, a paradigm sensitive to changes in corticostriatal function, we measured a significant increase in repetitive digging behavior in $xCT^{-/-}$ mice. Together, our findings shed new light on the role of system x_c^- in controlling synaptic transmission. We hypothesize that the corticostriatal circuit deficits present in $xCT^{-/-}$ mice are a consequence of depletion of presynaptic glutamate stores, deficits in the presynaptic glutamate release machinery and/or aberrant ERK signaling, avenues we are currently exploring. As a novel modulator of corticostriatal transmission, system x_c^- may be relevant to neuropsychiatric disorders characterized by corticostriatal dysfunction and repetitive behavior, such as obsessive-compulsive behavior and autism.

Title: Neuronal-Müller glial signaling in the developing retina

Authors: *J. M. TWORIG, M. B. FELLER
Univ. of California Berkeley, Berkeley, CA

Abstract: Müller glia are specialized radial astrocytes that are the predominant glial type of the vertebrate retina. Müller glia extend through each retinal layer and display fine filopodia-like

processes in synaptic layers. Prior to eye opening in the mouse, Müller glia respond to acetylcholine and glutamate released during retinal waves by undergoing calcium transients (Rosa et al, *J Neurosci*, 2016). Retinal wave-evoked glial calcium transients are compartmentalized to Müller glial stalks and processes in the inner plexiform layer, suggesting that the transients play a specific role in synaptic development or function.
Here, we address the mechanisms and function of Müller glial calcium transients during retinal development. First, we identify signaling pathways mediating wave-evoked calcium transients in Müller glia using simultaneous two-photon calcium imaging and electrophysiology. Blockade of M1 muscarinic acetylcholine receptors with pirenzepine (5 μM) or depletion of internal calcium stores with thapsigargin (5 μM) significantly reduced the proportion of Müller glia undergoing wave-evoked calcium transients. Second, we describe Müller glial process motility using two-photon volumetric imaging of fluorescently labeled Müller glia in the double reporter mouse line *GLAST-CreER;mTmG* (Wang et al, *J Comp Neurol*, 2017). We found that prior to eye opening, Müller glial lateral processes in the inner plexiform layer undergo bouts of extension and retraction, yet they are largely stable in the adult retina. We will test the hypothesis that acetylcholine or glutamate released during retinal waves modulates the outgrowth and/or motility of Müller glial processes.

Title: Microglial derived matrix metalloproteinases (MMPs) in synuclein mediated neuroinflammation

Authors: *K. SANCHEZ[1], K. A. MAGUIRE-ZEISS[2]
[1]Biol., Georgetown Univ., Washington, DC; [2]Neurosci., Georgetown Univ. Med. Ctr., Washington, DC

Abstract: Matrix metalloproteinases (MMPs) are a family of endopeptidases that remodel the extracellular matrix and play an important role in synaptic plasticity. While MMPs have been evaluated in the context of synucleinopathies, their role in α-synuclein mediated neuroinflammation remains to be further characterized; specifically, in the context of glial-neuronal interactions. α-Synuclein is a 140-amino acid protein highly expressed in presynaptic

terminals that is also associated with Lewy body pathology found in Parkinson's (PD) patients. We and others have shown that α-synuclein is a damage-associated molecular pattern (DAMP) eliciting a microglial proinflammatory response through activation of pattern recognition receptors (PRRs). Furthermore, PD patients display increased expression of proinflammatory cytokines such as tumor necrosis factor-alpha (TNF-α) and interleukin-1beta (IL-1β) as well as MMP-9.
Here we demonstrate that the expression of MMP-9 and MMP-13 are increased following exposure of microglia to mutant A53T α-synuclein. This increased MMP expression is associated with increased release of TNF-α and NF-κB nuclear translocation. The impact of MMP-13 and -9 on neurons remains to be further studied. Since MMPs are known to impact neuronal structure and survival, it is hypothesized that the release of MMP13 can impact neuronal structural plasticity. Future investigations will explore the impact of microglial-derived MMP13 on neurons and its cleavage targets such as PAR1. Specifically, we are interested in how dendritic complexity and cell viability of neurons is impacted by MMP-13.

Title: Transient plasticity of perisynaptic astrocyte processes during reinstated heroin seeking

Authors: *A. KRUYER[1], M. D. SCOFIELD[2], P. W. KALIVAS[3]
[2]Neurosci., [1]Med. Univ. of South Carolina, Charleston, SC; [3]Neurosci. Res., Med. Univ. S Carolina, Charleston, SC

Abstract: Repeated drug use, but not repeated exposure to natural rewards, disrupts glutamate homeostasis within corticofugal projections to the ventral striatum in response to reward-associated cues and contexts. Exposure to different classes of addictive drugs also results in downregulation of the principal glutamate transporter GLT-1, contributing to synaptic glutamate spillover and conferring relapse vulnerability. Synaptic proximity of perisynaptic astrocyte processes (PAPs) that contain GLT-1 affects the rate and efficiency of glutamate uptake, adding another measure of control over synaptic glutamate diffusion. We labeled astrocytes in the nucleus accumbens core (NAcore) with a membrane-targeted fluorescent tag. Using confocal microscopy, we measured synaptic proximity of PAPs via their colocalization with the pre-

synaptic marker Synapsin I. Using this strategy, we previously found that synaptic proximity of PAPs is reduced during extinction from cocaine self-administration. We found similar reductions in synaptic proximity of PAPs during extinction from heroin self-administration. We also observed rapid and reversible structural plasticity of NAcore astrocytes during 15-minutes of cued reinstatement, measured as reductions in volume and surface area, increased synaptic proximity of PAPs, and increased surface expression of GLT-1, despite reduced levels overall following heroin self-administration. These adaptations were restored to extinction levels by 120 minutes of reinstatement, when active drug seeking had ceased, and were not observed in NAcore astrocytes during reinstated sucrose seeking. Our findings suggest that NAcore astrocytes play a dynamic role in shaping glutamatergic transmission during cued drug seeking.

Title: Microglial motility and interaction with dendritic spines is elevated in the hippocampus of awake mice due to increased neuronal activity

Authors: *F. C. NEBELING, S. POLL, L. C. SCHMID, J. STEFFFEN, K. KEPPLER, M. FUHRMANN
DZNE German Ctr. for Neurodegenerative Dis., Bonn, Germany

Abstract: Microglia, the resident immune cells of the CNS, actively survey their environment while interacting with other brain cells and structurally shaping the CNS. Yet, the mechanisms underlying microglial motility and their significance for structural plasticity, especially in adult organisms, remain widely unresolved. Here we investigated the impact of neuronal activity on microglia motility and its implication for synapse formation and survival in the hippocampus. Therefore, we implanted a chronic hippocampal-window in CX3CR1-GFP::Thy1-YFP-H transgenic mice. By applying two-photon microscopy, we were able to study microglia synapse interaction *in vivo* in adult mice. We recorded 3-D time series of microglia and synapses in the same mice sequentially under anesthesia and awake conditions. We found elevated microglia motility in awake compared to anesthetized mice. Furthermore, upon topical application of tetrodotoxin (TTX) in awake mice, microglial motility decreased below levels observed in anesthesia, indicating a relationship between neuronal activity and microglia motility. These findings were confirmed by injecting an inhibitory DREADD into CA3 and CA1, which enabled us to pharmacologically block neuronal activity in the *stratum radiatum* of awake mice. Chemogenetic inhibition of neuronal activity significantly reduced microglial motility in awake

mice. Thus neuronal activity seems vital for microglia motility. On the subcellular level, microglia showed increased synapse interaction in awake mice. We also observed elevated microglia motility around newly formed or eliminated dendritic spines compared to stable ones. Additionally, synapse turnover was more likely to be anatomically clustered in regions with high microglial contact rates. Overall, these findings suggest a neuronal-activity dependent regulation of synapse homeostasis in the hippocampus via microglia.

Title: Vascular compartmentalization of functional hyperemia from the synapse to the pia

Authors: *R. L. RUNGTA, E. CHAIGNEAU, B.-F. OSMANSKI, S. CHARPAK
Lab. of Neurophysiol. and New Microscopies, INSERM U1128, Paris, Paris, France

Abstract: Functional hyperemia, a regional increase of blood flow triggered by local neural activation, is used to map brain activity in health and disease. Despite its vast importance for functional imaging, the spatial-temporal dynamics of functional hyperemia, as well as its site of initiation remain unclear. Here, we exploit the unique neural-vascular anatomy of the olfactory bulb and two-photon imaging in NG2-creERT2;GCaMP6f mice to investigate Ca^{2+} signaling and hemodynamics of functional hyperemia, from juxta-synaptic capillaries back to the upstream pia. We first show that activation of oligodendrocyte precursor cells (OPC) is a reliable marker of synaptic input and precedes (by ~300 ms) a synchronous Ca^{2+} drop in upstream pericytes and smooth muscle cells enwrapping the vessels that feed the activated synapses. Despite this simultaneous activation of mural cells, the resulting hemodynamics varied dramatically but precisely in terms of timing, amplitude and direction according to the vascular compartment. The most rapid dilation occurs with indistinguishable onset at the parenchymal arteriole and proximal first-order capillary and is paradoxically associated with a local decrease or delayed increase in blood velocity. In contrast, a slower dilation associated with a rapid velocity increase occurs in the upstream pial arteriole and downstream capillaries. Proportionally, the largest velocity

increase occurs in juxta-synaptic capillaries. These results establish the precise temporal and spatial dynamics of blood volume and velocity changes essential for the interpretation of blood flow based imaging techniques such as BOLD-fMRI.

Title: Acute manganese exposure increases glutamate uptake in Bergmann glial cells

Authors: *M. ESCALANTE LOPEZ, L. C. R. HERNÁNDEZ KELLY, A. ORTEGA
Cinvestav, Mexico City, Mexico

Abstract: Even though manganese (Mn) is required as an essential trace element for humans, more public health concerns are focused on the adverse health impacts upon manganese exposure. Specifically, a cognitive and movement disorder, referred to as manganism. To date, Mn is reported to cause neurons as well as many other cell types functional impairments. Astrocytes, accounting for approximately 50% of the neuronal cells in the central nervous system and maintain glutamate homeostasis, are sensitive to neurotoxicity induced by Mn exposure. The fine regulation of extracellular glutamate in the brain is accomplished by two major glutamate transporters – GLT-1 and GLAST – that are predominantly expressed in astrocytes. Excitotoxic neuronal injury has been highlighted as a critical mechanism in Mn neurotoxicity and is also involved in the pathological signs of multiple neurodegenerative diseases including Amyotrophic Lateral Sclerosis, Alzheimer's disease and Parkinson’s disease.
Recent evidences demonstrate that Mn accumulates in different brain regions, including the cerebellum. Bergmann glial cells (BGC) are radial glial cells prevalent in the adult cerebellum and represent the most abundant non-neuronal population of this structure. This characteristic localization is related to their involvement in neurotransmitter uptake and turnover, K^+ homeostasis, lactate supply and pH regulation. Despite these well-known facts, little or null attention has been drawn to studying the role of BGC in Mn neurotoxicity.
To this end, in this contribution we focused in the molecular mechanisms induced by Mn that affect GLAST in BGC. A time and dose-dependent increase in GLAST activity was found upon acute Mn exposure. Moreover, Mn apparently modifies the amount of GLAST molecules in the plasma membrane, suggesting an alteration in its trafficking. In contrast to the reported findings

regarding GLAST regulation by Mn in cortical cell models, the kinetics of the Mn effects in neurogenic radial glia are faster and mediated through different signal transduction pathways. These results strengthen the notion of the critical involvement of radial glial cells in glutamatergic neurotransmission.

Title: In silico modeling of astrocytes and neuron-astrocyte interactions

Authors: *T. MANNINEN[1], A. SAUDARGIENE[2], R. HAVELA[1], M.-L. LINNE[1]
[1]BioMediTech Inst. and Fac. of Biomed. Sci. and Engin., Tampere Univ. of Technol., Tampere, Finland; [2]Neurosci. Inst., Lithuanian Univ. of Hlth. Sci., Kaunas, Lithuania

Abstract: Astrocytes have been shown to modulate information transmission and plasticity in several brain areas (Araque et al., 1999; Haydon and Nedergaard, 2015; Bazargani and Attwell, 2016). The mechanisms by which this modulation is orchestrated are however not understood (Fiacco and McCarthy, 2018; Savtchouk and Volterra, 2018). One reason for partially contradictory results is the lack of selective pharmacological tools for astrocytes (Bazargani and Attwell, 2016). In silico studies are one way to help solve the challenges related to experimental neuron-astrocyte interactions. In our previous studies (Manninen et al., 2017, 2018a-c), we have characterized and categorized a hundred computational models of astrocytes and neuron-astrocyte interactions as well as evaluated reproducibility and comparability of several models. Often new in silico models are published without explaining how they differ from the hundreds of previously published models and without giving all the model details. In addition, model implementations are rarely given in the online model repositories. All these make extension of models difficult. Models should be defined using common description formats in publications, implemented using easily accessible and expandable model description languages, and be downloadable via online model repositories. In this study, we extend our previously published neuron-astrocyte synapse model (Havela et al., 2017) with the description of presynaptic

terminal and gather the state-of-the-art experimental and computational knowledge of neuron-astrocyte interactions to help guide the future research of tripartite synapses. The here modeled presynaptic neurotransmitter release can induce elevated astrocytic calcium concentration, similarly to experimental in vitro data. Moreover, the elevated astrocytic calcium concentration can induce exocytosis of chemical substances from astrocytes which can modulate vesicle release from the presynaptic terminal. In addition to calcium signaling, we also address the endocannabinoid (eCB) signaling and explore the ability of the in silico model to modulate the presynaptic vesicle release by postsynaptic eCB system in contrast to astrocytic modulation. One of our future goals is to develop both detailed and reduced models of neuron-astrocyte interactions for different brain areas. With integration of both in vivo and in vitro data with corresponding in silico models, we might be able to explain which astrocytic mechanisms are important and how they contribute to brain information processing and plasticity. This will hopefully clarify the controversies in experimental data.

Council, Rome, Italy; [5]San Raffaele Pisana, IRCCS, Rome, Italy

Abstract: Astrocytes play several functions in the brain: they give structural and metabolic support to neurons and modulate synaptic transmission by the release of gliotransmitters including ATP. Here we asked whether astrocytes also have a “dark side”, specifically contributing to HSV-1 infection of neurons. HSV-1 (1 MOI) was applied for 1 h (adsorption time) to co-cultures of mouse cortical neurons and astrocytes to allow virus binding and entry into cells. After 24 h, infection was assessed by immunocytochemistry and Western blot analysis of viral proteins. We observed that astrocytes were more susceptible than neurons to HSV-1

infection, in agreement with our finding that astrocytes exhibit 4-fold greater expression of Heparan Sulfate Proteoglycans (binding sites for viral glicoproteins C and B) than neurons ($p<0.05$). The probability to find HSV-1-infected (HSV-1^+) neurons was significantly higher in proximity (<100 µm) of virus-infected astrocytes. At such distance about 78±6% of neurons were HSV-1^+ vs. only 11±6% of neurons far from HSV-1^+ astrocytes ($p<0.05$). When co-cultures were challenged with HSV-1 after metabolic inhibition of astrocytes by fluorocitrate (FC, 200 µM), neither astrocytes nor neurons were HSV-1^+, thus suggesting that the presence of functional astrocytes is necessary for neuronal virus infection. HSV-1 binding to astrocytic plasma membrane triggered IP3-dependent intracellular Ca^{2+} transients followed by ATP release, whose concentration in the culture medium, assessed by HPLC, was up to 4-fold higher than that of control cultures (44.1±11.3 vs. 10.3±1.2 nM; $p<0.05$). ATP released from astrocytes diffused locally and activated purinergic P2 receptors (P2R) on neurons and astrocytes themselves that sustained and amplified Ca^{2+} transients. Application of the P2R blocker suramin (200 µM) during the adsorption time prevented HSV-1 infection, thus suggesting that ATP released from astrocytes and the consequent P2R-dependent Ca^{2+} transients are necessary for virus infection of both astrocytes and neurons. Accordingly, if exogenous ATP (100 µM) was applied to FC-treated co-cultures during the adsorption time more than 70% of neurons was HSV-1^+ after 24 h. ATP-induced P2R-mediated Ca^{2+} transients caused activation of the Glicogen Synthase Kinase (GSK)-3 by phosphorylation at Y216 in both astrocytes and neurons, and GSK-3 inhibition by SB216763 (10 µM) during the adsorption time completely prevented HSV-1 infection. In conclusion, we found that ATP released from astrocytes after HSV-1 binding diffuses locally and causes P2R-dependent activation of GSK-3 in both neurons and astrocytes, likely involved in HSV-1 infection.

Title: Octopus glia: Identification of glia-specific molecular markers in cephalopods

Authors: *G. C. WINTERS[1], H. E. WEBER[2], C. J. BOSTWICK[1], L. L. MOROZ[1]
[1]Neurosci., Univ. of Florida Whitney Lab. for Marine Biosci., Saint Augustine, FL;
[2]Transylvania Univ., Lexington, KY

Abstract: Cephalopods (*Octopus*, Squid, Cuttlefish, and *Nautilus*) exhibit a degree of behavioral flexibility comparable to that of many mammals. The intricate neural circuits responsible for this behavioral complexity have evolved in parallel to arthropod and chordate nervous systems. The independent emergence of sophisticated brains in distinct lineages has produced a natural subject of investigation to understand physiological, anatomical, and molecular constraints of nervous system evolution. Despite diverse interdisciplinary efforts to characterize *Octopus* brain circuitry, little is known about the enigmatic support cells of the nervous system: glia. Although glia-like cells have been recognized based on anatomical position and morphology in *Octopus* brains and peripheral neural tissues, no molecular markers for cephalopod glia have been identified. There has been no evidence for sequences encoding mammalian glial markers such as GFAP and vimentin in any available cephalopod transcriptomes. We constructed, sequenced, and analyzed *Octopus bimaculoides* transcriptomes of 85 tissues (neuronal and peripheral) to identify conserved and novel molecules expressed in *Octopus* neurons and glia. Abundant transcripts from neuronal transcriptomes were anatomically validated using *in-situ* hybridization. Of the 167 transcripts we investigated, seven were expressed in cells morphologically resembling glia. Two of these putative glial molecules were enzymes associated with neurotransmitter synthesis or metabolism (glutamate decarboxylase and glutamine synthetase- a molecule that also labels mammalian glia), and five were novel predicted secretory molecules. Aside from a conserved eukaryotic glycoprotein, each of the putative glial secretory molecules is either mollusc-specific or unique to cephalopods. Cellular expression maps of each marker vary by distribution, density, and reveal four different morphologically distinct types of glia-like cells. The combination of evolutionarily conserved and cephalopod-specific genes, which are uniquely expressed in *Octopus* glia suggests three possible scenarios for glia specification: (1) independent recruitment of conserved proteins (glutamine synthetase) in novel cephalopod cell types, (2) development of novel secretory molecules in evolutionary conserved glial-like cell lineages, and/or (3) multiple origins of cephalopod glial sub-populations.

Title: Forebrain GABAergic neurons regulate astrocyte gene expression through the morphogen sonic hedgehog

Authors: *W. T. FARMER[1], S. CHIERZI[1], G. CHEN[2], J.-F. THÉROUX[2], C. ERNST[2], K. K. MURAI[1]

Abstract: Astrocytes are a heterogeneous population of cells that are critical for maintaining the precise environmental conditions required for optimal neuronal activity. To faithfully fulfill diverse roles across the central nervous system, astrocytes display a complex range of specialized physiological and molecular phenotypes. Despite the importance of astrocyte specialization for nervous system function, the processes responsible remain poorly understood. Previously, we have shown that the morphogen Sonic Hedgehog (Shh) is secreted by neurons to regulate the expression of the inward rectifying potassium channel Kir4.1/KCNJ10 in forebrain astrocytes. To further our understanding of astrocyte specialization in the adult forebrain, we aimed to identify the genes regulated by the Shh pathway as well as the specific neuron populations that are responsible for Shh release in both the hippocampus and the medial septum/diagonal band complex (MSBD). To reveal genes that are regulated by the Shh pathway, we performed RNA-seq on control hippocampi and hippocampi containing astrocytes with the Shh pathway constitutively-activated. Differential gene expression analysis revealed that the Shh pathway regulates a cohort of ~500 genes, many of which are ion channels and neurotransmitter transporters known to influence neural activity including the GABA transporter Slc6a11/GAT3. Interestingly, the cohort of genes regulated in the hippocampus is distinct from the genes previously identified in the cerebellum. To identify Shh-expressing cells, we utilized an inducible Cre-dependent Shh expression reporter system. In the adult hippocampus and MSBD, reporter expression was detected predominantly in mixed populations of GABAergic neurons. To evaluate the contribution of GABAergic neurons to both Shh expression levels and astrocyte gene expression, we utilized the GAD2-Cre allele to specifically knock out Shh from GABAergic neurons (GAD2 cKO). Quantitative PCR and immunofluorescence on GAD2 cKO knockout brains revealed a robust reduction of Shh message and significant changes in the expression of Shh-responsive genes in both the hippocampus and MSBD. These results show that GABAergic neurons are responsible for regulating specific aspects of astrocyte gene expression through the release of Shh. Furthermore, neuron-astrocyte communication through Shh appears to be widely used across the brain to fine-tune the molecular properties of astrocytes in a region-specific manner.

Title: Characterization of the initial stages of myelination in the medial nucleus of the trapezoid body

Authors: *D. T. HELLER[1,2], D. KOLSON[1], A. BRANDEBURA[2], J. WAN[4], J. QIAN[5], P. MATHERS[3], G. A. SPIROU[6]
[1]Otolaryngology, West Virginia Univ., Morgantown, WV; [2]Otolaryngology, [3]Biochem., West Virginia Univ. Sch. of Med., Morgantown, WV; [4]Indiana Univ. Sch. of Med., Indianapolis, IN; [5]Johns Hopkins, Baltimore, MD; [6]Otolaryngology, West Virginia Univ. Sch. Med., Morgantown, WV

Abstract: Glial cells play a major role in regulating synaptogenesis, cell proliferation and differentiation, and myelination during neural circuit formation and maturation. Myelination is a complex process involving the targeted compartmentalization of several myelin-associated proteins resulting in the wrapping of axons. Astrocytes play a functional role in myelination by regulating oligodendrocyte proliferation and differentiation, providing lipids for myelin synthesis, and promoting myelination in response to electrical activity. Several studies have shown that astrocytes promote myelination, but the exact functions associated with astrocyte-axonal interactions remains elusive. The medial nucleus of the trapezoid body (MNTB) is used as a model system for studying neural circuit formation and maturation. The large presynaptic nerve terminals onto MNTB neurons, the calyces of Held, grow very quickly between postnatal day (P)2 and P6 and are mostly refined to mono-innervation within the first postnatal week. Furthermore, the astrocytes and oligodendrocytes in the MNTB increase in number and begin to exhibit morphological maturation within the same time window, allowing for a detailed study of the coordinated role of astrocytes and oligodendrocytes in myelination. Limitations associated with the resolution of fluorescence microscopy hamper detailed structural analysis of the myelin sheath and the extent of myelination. For this study, an extensive collection of serial block-face electron microscopy (SBEM) data sets from the mouse MNTB at P2, P4, P6, and P9 were used. These volumes allowed for the detailed investigation of individual calyceal axons, which elucidated ultrastructural characteristics of the onset and progression of axonal wrapping and myelin compaction during early development. Many of the calyceal axons were receiving single glial wraps by P4 with compaction of the myelin sheath beginning at P6, after most MNTB

principal neurons are mono-innervated. From the analysis of our SBEM volumes, we find that the early axonal wrapping at P4 originate from astrocyte-like cells while oligodendrocytes do not begin wrapping until P6. Gene expression profiles from our microarray study of the MNTB between P0-P14 provide a temporal sequence of expression onset for myelination-related genes, with expression profiles turning on four to six days before compaction of myelin. This study provides a genetic and structural basis for future research investigating the coordinated roles of glial cells in myelination.

Title: Aloe vera colon fermentation compounds suppresses the substance P-induced production of IL-6 and IL-8 by human U373MG glioblastoma/astrocytoma cells

Authors: *A. TORNERO
Inst. Politecnico Nacional, Ciudad de Mexico, Mexico

Abstract: Introduction: In recent years there has been an increased incidence of neurodegenerative diseases around the World. Functional food has demonstrated beneficial effects against some pathological markers of brain degeneration, such as neuroinflammation. Aloe vera is a plant rich in polysaccharides (PA) with proven anti-inflammatory properties in vivo and in vivo studies, resulting in an improved health status in diseases associated conditions. Moreover, A. vera presents well known neuroprotective activities. PA are avidly taken up by gut microbiota (GM) that metabolize them, and release potent anti-inflammatory compounds, such as short-chain-fatty acids (SCFAs). However, the neuroprotective effects of SCFAs produced from A. vera fermentation has not been reported. **Methods:** In the present study we incubated human faecal samples with homogenates of inner gel and the PA fraction of A. vera. An in vitro digestion method, was followed by fermentation during 48 hrs. We collected fermented samples every 2 hours to determine the anti-oxidant activity and the presence of SCFAs (acetate, propionate,butyrate). Thereafter, those fermented fractions were added to human astrocytoma cell line, U373MG activated with neuropeptide substance P (SP). The U373MG cells were plated into 12-well tissue culture plates at a density of 2x105 cells/well and incubated in MEM supplemented with 10% FBS for 12 h, followed by incubation in MEM supplemented with 0.5% FBS for 12 h at 37℃. Subsequently, the cells were incubated with the different digested fraction of (0.1 and 1 mM) for 60 min, and then stimulated with SP (100 nM) for 10 min or 24 hr. We

used western-blot analysis for quantification of ERK1/2, p38 MAPK and NF-κB proteins. Analysis and IL-6 and IL-8 levels was done by use of Cytometric Bead Array Human Inflammatory Cytokine kit (BD Biosciences). **Results:** We observed that a higher anti-oxidant activity in the inner gel compared to PA fraction. However, the digested PA fraction presented a potent anti-inflammatory effect on U373MG cells, associated with an increased abundance of SCFAs that increases along the fermentation period. **Conclusion:** This study demonstrates that A. vera neuroprotective properties may be associated with GM´s fermentation of polysaccharides and subsecuente release of SCFAs with strong anti-inflammatory effects.

Title: Effects of microglia elimination in the spinal cord on glial plasticity observed following peripheral axon injury

Authors: *J. HUTCHINSON[1], J. GOINS[1], V. RAJATHI[2], L. G. ISAACSON[3]
[1]Biology, Ctr. for Neurosci. and Behavior, [2]Cell, Mol. and Structural Biol., [3]Biology, Ctr. for Neurosci. and Behavior, Cell, Mol. and Structural Biol., Miami Univ., Oxford, OH

Abstract: Our lab has previously shown that transection of preganglionic axons of the cervical sympathetic trunk (CST) in the periphery results in robust activation of glial cells within the intermediolateral cell column (IML) of the spinal cord near the vicinity of the injured cell bodies. One week post injury, activated microglia are observed within the IML, characterized by increased expression of Iba1, cellular aggregation, and amoeboid like morphology. Because microglia-derived cytokines signal to nearby glial cells, we aimed to eliminate microglia in the mouse spinal cord to investigate their role in oligodendrocyte (OL) lineage cell and astrocyte plasticity as well as in cytokine expression following peripheral axon injury. We previously reported that use of the PLX5622 diet (Plexxikon), which contains colony stimulating factor-1 receptor (CSF-1R) inhibitor, successfully eliminated approximately 90% of microglia in young adult C57BL/6 mice spinal cord. Oligodendrocyte progenitor cells (OPCs) were increased in Sham+PLX group (vs Sham+Cont), suggesting that microglia influence baseline OPC proliferation. In addition, elimination of microglia reduced the typical increase in OPCs observed

post injury, indicating that microglia positively influence OPC plasticity. The absence of microglia did not affect CC1 or Olig2 cells, indicating no changes in mature oligodendrocyte populations. GFAP immunofluorescence revealed that microglia elimination did not affect the typical astrocyte activation observed post injury. Western blot analysis revealed no change in GFAP protein in Sham+PLX compared with Sham+Cont and did not detect an increase post injury in the control group. However, GFAP protein expression in the IML was increased by approximately 37% in the Inj+PLX group compared to Sham+PLX, indicating a more robust response to peripheral axon injury in the absence of microglia, and suggesting that microglia regulate astrocyte activation post injury. Interleukin-1ß (IL-1ß) was expressed by astrocytes in the mouse spinal cord. Following injury, IL-1β in the spinal cord was upregulated in Inj+Cont mice, yet this increase was blunted when microglia were eliminated, suggesting a role for microglia in the upregulation of pro-inflammatory cytokines in astrocytes at 1 week post injury. These findings indicate that microglia play an important role in the regulation of OL lineage cells and astrocytes in the mouse spinal cord. Overall, these results lead to a better understanding of the influences of microglia within the spinal cord microenvironment in the intact animal as well as following peripheral axon injury.

Title: Sequential analysis of glial cell plasticity in the spinal cord following peripheral axon injury

Authors: *V. RAJATHI[1], S. BHATI[1], S. P. BROWN[2], J. GOINS[3], J. HUTCHINSON[3], L. G. ISAACSON[4]
[1]Cell, Mol. and Structural Biol., [2]Biol., [3]Biology, Ctr. for Neurosci. and Behavior, [4]Biology, Ctr. for Neurosci. and Behavior, Cell, Mol. and Structural Biol., Miami Univ., Oxford, OH

Abstract: Following transection of the cervical sympathetic trunk (CST), we have previously reported robust glial cell plasticity in the intermediolateral (IML) cell column of the spinal cord in close proximity to the injured parent cell bodies. At 7 days following CST transection, we observe increased numbers of activated microglia and astrocytes, as well as an increase in oligodendrocyte lineage cells in the IML and adjacent white matter (WM). Both microglia and

oligodendrocyte precursor cell (OPC) proliferation contribute to this glial cell plasticity. However, the sequence of events that takes place in the IML and WM during the 7 day post injury period remains unclear. The objective of this study was to compare glial cell activation and proliferation in the rat spinal cord at 3 days and 7 days post injury. Starting on the day of the CST transection or sham surgery, young adult female Sprague Dawley rats were given daily ip injections of bromodeoxyuridine (BrdU; 20mg/ml in sterile saline solution) for either 3 or 7 days and sacrificed 24 hours after the last BrdU injection. The IML and WM of the upper thoracic spinal cord were analyzed, using immunofluorescence, for changes in microglia activation and proliferation. In the IML similar increases in the number of $Iba1^+$ cells, $BrdU^+$ cells, and $BrdU^+/Iba1^+$ cells, were observed at 3 days and 7 days post injury (vs respective shams), indicating that microglia proliferation in the IML was similar at the two post injury time points. However, in the WM, the number of $BrdU^+$ cells and $BrdU^+/Iba1^+$ cells, while unchanged at 3 days post injury, was significantly increased at 7 days post injury (vs respective shams), suggesting that changes in glial cell plasticity in the WM take place after day 3 of the post injury survival period. Cytokine analysis of cores taken from IML and adjacent WM of rat spinal cord at 3 days or 7 days post injury revealed similar increases in ciliary neurotrophic factor (CNTF) and CXCL7 (vs sham). However, a two-fold increase in the expression of intercellular adhesion molecule-1 (ICAM-1; CD54) was observed at 7 days with no change observed at 3 days post injury (vs sham). The increase in ICAM-1 at 7 days post injury may reflect the additional plasticity taking place in the WM late in the 7 day survival period. Further investigation will indicate whether sequential changes occur in the OPCs between 3 and 7 days post injury. Together our results will provide evidence regarding the timing of proliferation and cell signaling events that take place in the spinal cord following peripheral axon injury, and may provide important clues to how glial plasticity ultimately impacts neuronal survival.

Title: Effects of minocycline administration on the superior cervical ganglion following transection of the cervical sympathetic trunk

Authors: *R. SNYDER[1], M. POWELL[2], J. GOINS[2], L. G. ISAACSON[3]
[1]Biol., [2]Biology, Ctr. for Neurosci. and Behavior, [3]Biology, Ctr. for Neurosci. and Behavior, Cell Mol. and Structural Biol., Miami Univ., Oxford, OH

Abstract: The transection of distal axons in the cervical sympathetic trunk (CST) leads to robust retrograde neuronal and glial plasticity in the upper thoracic spinal cord. One week post injury the parent sympathetic preganglionic neurons housed in the intermediolateral cell column (IML) exhibit transient plasticity, including decreased expression of choline acetyltransferase (ChAT), and the nearby microglia, astrocytes, and oligodendrocyte (OL) lineage cells in the IML increase in number and show robust activation. Previously we reported that dampening microglia activation using the antibiotic minocycline (Mino) reversed the typical decrease in ChAT expression in young adult Sprague-Dawley rats, and also reduced the number of astrocytes and OLs in the IML typically observed at one week post injury. In a second group of rats examined four months post injury, fewer ChAT neurons were present in the IML of the Inj+Mino group, suggesting that dampened glial activation and reduced neurotransmitter plasticity by the injured neurons during the one week post injury contributed to long-term neuronal loss. Here we examined the superior cervical ganglion (SCG), the sole target of the transected CST axons, at one week and 4 months post injury to assess whether minocycline administration during the first week post injury affected peripheral macrophages in the ganglion or long term reinnervation of the SCG. Starting on the day of surgery Sprague-Dawley rats received daily ip injections of Mino (50mg/kg for 2 days; 25mg/kg for 5 days) or vehicle (VEH; saline; 2ml/kg) for one week following bilateral CST transection or sham surgery. Rats were examined at one week (Sham+VEH, n=4; Inj+VEH, n=3; Sham+Mino, n=4; Inj+Mino, n=2) and 4 months post injury (Sham+VEH, n=8; Inj+VEH, n=9; Sham+Mino, n=8; Inj+Mino, n=10). At one week post injury the number of macrophages (Iba1+) as well as macrophages per neuron (labeled with NeuN) were increased in the Inj+VEH group (vs Sham+VEH). However these increases were blunted in the Inj+Mino group (vs Sham+Mino), suggesting that minocycline treatment reduced the number of peripheral macrophages in the SCG following injury. Additionally, both ChAT and synaptophysin were virtually eliminated in the SCG in both injury groups at one week and no changes in NeuN+ neurons were observed. At 4 months post injury SCGs from both Inj+VEH and Inj+Mino groups showed approximately 50% ChAT and 76% synaptophysin reinnervation, indicating that Mino treatment did not affect the reinnervation of the SCG. We conclude that minocycline administration can impact both microglia and peripheral macrophages. However, these changes did not impact long term reinnervation of the SCG.

Title: Aging and an immune challenge interact to potentiate activation of hippoccampal microglia in a rodent model with features of delirium

Authors: *N. SALLA, K. C. ESSLINGER, L. M. DEFLITCH, N. TANAKA, S. L. PATTERSON
Dept. of Biol., Temple Univ., Philadelphia, PA

Abstract: Aging increases the risk of an abrupt cognitive decline, sometimes called delirium, following an injury or illness. Although little is known about why aging brains are more vulnerable to immune stressors, research has shown that the immune and central nervous systems communicate extensively. Data drawn from rodent models suggest that microglia, cells of the innate immune system, become primed (sensitized) with age, responding more vigorously to signals from the peripheral immune system and other parts of the brain. Fischer Brown Norway (F344xBN) rats display no significant physical or cognitive impairments at 24 months. However, in response to a single intraperitoneal injection of *E. coli*, microglial production of proinflammatory cytokines is potentiated and prolonged in the aged (24 months) rats compared to production in their younger (3 months) counterparts. We have previously demonstrated that these aged animals have deficits in hippocampus-dependent long-term memory and memory-related synaptic plasticity that mirror the elevations in proinflammatory cytokines. We are now more closely examining the involvement of microglial dysregulation in these aging-associated, immune-challenge driven cognitive deficits. We are using immunohistochemistry for IBA1, a microglial membrane protein, to compare microglial numbers, distribution, and morphological changes triggered by a peripheral immune challenge in old and young animals with or without a recent history of *E. coli* infection. Preliminary findings indicate that IBA1 labeling is increased in the aged compared to young animals, and this trend is more pronounced following infection. In addition, there appear to be distinctive morphological profiles associated with microglia in the infected vs. saline groups and aged vs. young groups. We are also examining IBA1 expression in different subregions of the hippocampus and at different times after infection. Analysis of microglial phenotypes over time allows us to assess potential changes in microglial phenotypes. Prolonged activation is consistent with the idea that the dysregulation of the immune system may play a significant role in an abrupt cognitive decline and possibly in progression to dementia. We are developing novel algorithms for quantitative analysis of microglial numbers and morphology in specific pixel ranges. By comparing the number of microglia in each differing pixel ranges, we are investigating the relative distributions of IBA1 cluster sizes across treatment groups. Through these distributions we are attempting to categorize morphological profiles of microglia across these treatment groups.

Title: Aging and an immune challenge result in increased activation of microglial complement proteins in the rat hippocampus

Authors: *A. S. ARNOLD, C. R. FITZGERALD, L. G. RODRIGUES, J. D. WEIR, N. TANAKA, S. L. PATTERSON
Biol., Temple Univ., Philadelphia, PA

Abstract: Aging significantly increases brain vulnerability to negative life events. Cognitive function in older individuals often declines precipitously after events (surgery, infection, or injury) that trigger activation of the immune system. This impairment is often temporary, but its occurrence is associated with a greatly increased probability of eventually developing Alzheimer's disease or other forms of dementia. Very little is known about the underlying mechanisms. However, since the immune and central nervous systems communicate extensively, it seems likely that dysregulation of brain immune cells (particularly microglia) may contribute to immune-challenge evoked cognitive impairment.

Aging is known to sensitize microglia to signals triggered by immune challenges, resulting in an exaggerated production of pro-inflammatory cytokines like IL-1β. Aged (24-month-old) Fischer Brown Norway (F344xBN) rats are generally healthy, with no significant physical or cognitive impairments. However, in response to a single i.p. injection of *E. coli*, production of IL-1β is potentiated and prolonged in the aged (24 months) rats compared to production in their younger (3 months) counterparts. We have previously demonstrated that these aged animals have deficits in hippocampus-dependent long-term memory and memory-related synaptic plasticity that mirror the elevations in proinflammatory cytokines.

In addition to producing chemical mediators of immune function like IL-1β, microglia can also act as phagocytes, engulfing foreign invaders. Intriguingly, they have also been shown to play a role in developmental synaptic pruning and remodeling. Proteins of the complement cascade interact with pathogens, or with inappropriate or under performing synapses to mark them for destruction by phagocytes. We have now begun to explore the possibility that microglia may also play a more direct role in immune-challenge driven cognitive impairment.

Using immunohistochemistry, we are investigating the presence and interactions of proteins associated with phagocytic activity, including those within the complement cascade (e.g. C3 and C1q). Our preliminary data suggest that C3 labeling is increased in rats with a recent history of

infection, and this trend is more pronounced in aged animals. We are also examining distribution and expression levels of these proteins in different hippocampal regions. A time-course study will be conducted to determine if changes in the expression of these immune markers persist in parallel with deficits in synaptic plasticity.

Title: Specific MHCI overexpression in astrocytes induces behavioral and neuropathological abnormalities in mice

Authors: *K. HADA[1], A. SOBUE[1], B. WULAER[1], N. ITOH[1], A. NAKAJIMA[1], T. NABESHIMA[2,3], T. NAGAI[1], K. YAMADA[1]

Abstract: Major histocompatibility complex class I (MHCI) molecules play an important role in the adaptive and innate immune responses, and MHCI genes are polygenic and highly polymorphic. Classical MHCI α-chains in humans are encoded by three genes, HLA-A, B, and C, while their homologues are H-2K, D, and L in mice. The unique roles of MHCI molecules have been demonstrated in the central nervous system. Association studies have also implicated MHCI genes in several neuropsychiatric disorders such as Parkinson's disease, Alzheimer's disease and schizophrenia. However, the pathophysiological role of astroglial MHCI in neuropsychiatric disorders remains unclear. We have previously reported that polyriboinosinic-polyribocytidylic acid (polyI:C) treatment in neonatal mice results in impairments of neurodevelopment accompanied by schizophrenia-like behaviors in adulthood. Neonatal polyI:C treatment in mice increased MHCI H-2K and H-2D mRNA levels mainly in astrocytes but not neurons in the medial prefrontal cortex (mPFC). Moreover, we have previously demonstrated the localization and secretion of MHCI/H-2D and its soluble form (sH-2D) as exosomes in cultured astrocytes. To clarify the role of MHCI in astrocytes, we developed a mouse model expressing MHCI molecules in astrocytes of mPFC, using an adeno-associated virus vector (AAV) that expresses the transgene under the control of glial fibrillary acidic protein (GFAP) promoter. Behavioral and neuropathological analyses were carried out 3 weeks after the AAV injection. The MHCI-expressing mice showed impaired sociability and cognitive function. Additionally,

the number of Iba1-positive microglial cells was significantly increased in the mPFC of MHCI-expressing mice compared with control mice. Astroglial expression of MHCI decreased the number of parvalbumin-positive cells and reduced the dendritic spine density of pyramidal neurons in the mPFC. Furthermore, repeated treatment of neutral-sphingomyelinase inhibitor GW4869 ameliorated these abnormal behaviors and neuropathological changes observed in MHCI-expressing mice. These results suggest that the exosomal MHCI derived from astrocytes affects the microglial proliferation as well as neuronal number and spine density, thereby leading to behavioral dysfunctions in mice.

Title: Novel astrocyte-secreted factor promotes synapse maturation and limits plasticity through GluA2-AMPAR clustering

Authors: *E. BLANCO SUAREZ, T. LIU, A. KOPELEVICH, N. J. ALLEN
MNL, Salk Inst. For Biol. Studies, La Jolla, CA

Abstract: Astrocytes are the most abundant glial cells in the mammalian brain. Among their various functions, astrocytes secrete factors that affect the number and strength of synapses. Some of these factors regulate the subunit composition of AMPA glutamate receptors (AMPARs), the main transducers of fast excitatory neurotransmission in the mammalian brain. AMPARs are di-heteromers composed of GluA1-4 subunits, which vary in subunit composition depending on the stage of development. GluA1-containing AMPARs are extensively expressed at the synapses in early stages of development, clustered by glypican 4 and 6, astrocyte-secreted factors previously identified by our lab. They are subsequently replaced by GluA2-containing AMPARs in order to promote synaptic maturation in the mouse brain. However, the mechanism behind this switch remains unknown. Identifying the astrocytic factor that promotes the expression of GluA2 at the synapse has important implications for normal synapse formation, maturation and synaptic plasticity. By biochemical screening, we identified a novel astrocyte-secreted factor that is sufficient to enrich synaptic levels of GluA2, increase synapse number and enhance synaptic function between neurons *in vitro*. This novel astrocyte factor has

heterogeneous temporal and regional expression in the mouse brain, but is enriched in the visual cortex at the time of synapse maturation. KO mice for the astrocyte-secreted factor showed decrease in GluA2 and altered kinetics of synaptic transmission *in vivo*. These are features of immature synapses that promote higher brain plasticity. Experience-dependent plasticity in the visual cortex of the KO mice was enhanced, in both critical period and later when the visual cortex circuitry is fully developed and stable. These results indicated that the astrocyte-secreted factor is key to limit plasticity, and its role is not restricted to development and synapse maturation, but throughout life. Understanding astrocyte-secreted factors in the context of synaptic formation and plasticity in the brain will help to define the role of astrocytes in synapse formation, and synaptic maturation, but also to elucidate new avenues to manipulate synaptic plasticity, especially at later stages in life when it greatly declines.

Title: Contribution of astrocytic purinergic signalling in serotonin neuromodulation

Authors: *C. A. WOTTON, L. K. BEKAR
Pharmacol., Univ. of Saskatchewan, Saskatoon, SK, Canada

Abstract: It is well established that serotonin (5HT) plays a critical role in shaping cortical network activity by affecting inhibition. However, we call in to question the mechanism through which this is thought to occur. Previous literature claims that 5HT is having its effects via direct action on interneurons. While this may occur, limitations in neuromodulator diffusion, such as degradation and uptake, would limit the ability of 5HT to have rapid actions on these inhibitory networks. We propose that astrocytes, which possess 5HT receptors, the means to influence inhibitory networks via purinergic signaling, and are each in contact with over 100,000 synapses are the ideal intermediary to aid 5HT in rapidly modulating cortical inhibition. In addition, 5HT has the ability to alter cellular metabolism which may occur in astrocytes and result in release of purinergic gliotransmitters. Previous results indicate 5HT is affecting cortical inhibition via purinergic and GABAergic mechanisms. This study sought to narrow down those mechanisms and establish a role for astrocytes in the 5HT effects on inhibition. We used both whole-cell patch-clamp technique (neurons/astrocytes) and extracellular field recordings in acutely isolated mouse brain slices. A paired-pulse paradigm was used in field recordings to indirectly assess

whole network changes in inhibition, while whole-cell recordings allowed for direct observation of changes in inhibitory currents. Results thus far indicate that adenosine A2A and ATP P2Y receptors, which are both previously established to depolarize interneurons, are playing a role in the 5HT effect on cortical networks. In patch recordings, we see that antagonists at the P2Y and A2A receptors block the 5HT increase in spontaneous inhibitory currents. Alternatively, using agonists at these same receptors produces an effect similar on inhibition to 5HT in field recordings. Finally, a known antagonist of astrocyte metabolism, iodoacetate, was also found to attenuate 5HT effects on inhibition in both field and patch recordings. These results suggest the importance of the largely unacknowledged existence of astrocytic output in aiding neuromodulatory shaping of the flow of information in the cortex.

Title: Astroglial activity during gamma oscillations in acute hippocampal slices

Authors: *H. JAKOBI[1], T. HONDRICH[1], P. GESCHWILL[2], J. SCHNEIDER[3], E. KIRSCHBAUM[4], F. HAMPRECHT[4], O. KANN[3], M. BOTH[2], R. SPRENGEL[1]

Neurophysiol., Inst. of Physiol. and Pathophysiology, Heidelberg University, Germany; [4]Heidelberg Collaboratory for Image Processing, University Heidelberg, Germany

Abstract: Gamma oscillations and sharp wave ripples complexes (SWR) in the hippocampus are thought to be associated with memory acquisition and consolidation during slow wave sleep. Both these oscillatory neuronal activities can be measured *in vivo* and in hippocampal slice preparations. Since recent studies measuring Ca^{2+} activity in astrocytes suggested a relay function of astrocytes on activity states of large neuronal circuits and since the existence of the bi-directional astrocyte-to-neuron communication is well documented, we analyzed a potential role of astrocyte activity and SWR and gamma oscillations in acute ventral hippocampal slices and hippocampal slice cultures. Therefore, we simultaneously monitored SWR with a multi-electrode array and astrocytic Ca^{2+} transients with confocal microscopy in acute hippocampal slices, infected with GCaMP6f-expressing recombinant adeno-associated virus (rAAV). In six slices of two rAAV injected C57BL/6 mice we could not detect any correlation between the

occurrence of SWR and astrocyte Ca^{2+} signaling. In another approach we measured astrocyte Ca^{2+} signals after gamma oscillation induction in hippocampal slice cultures. Here we observed in 10 slices, a statistically significant increase in total astrocyte Ca^{2+} activity upon onset of gamma oscillation.
Conclusion: Our results show that astrocytes respond to the induction of gamma oscillations in hippocampal slice culture but show no specific Ca^{2+} response when SWR are observed in acute hippocampal slice. It remains to be elucidated if astrocytes follow the neurons in their activity increase, lead or merely independently accompany the neurons during the onset of gamma oscillations. This work was supported by the German Research Foundation (SFB1134).

Abstract: Tumor necrosis factor (TNF) is a pleiotropic cytokine implicated in key physiologic and pathologic processes in the central nervous system (CNS). These range from modulating synaptic plasticity, thereby regulating memory and cognitive function, to participating in the pathophysiology of neurologic disorders such as multiple sclerosis, Alzheimer's disease, stroke, etc. TNF exists in two forms, transmembrane (tmTNF) and soluble (solTNF), whose functions are mediated by TNFR1 and TNFR2. The signals activated by the two receptors are often opposite: TNFR1 mediates apoptosis and inflammation, while TNFR2 mediates cell survival, immunity and myelination. Studies with knockout mice have implicated TNFR2 in the regulation

of cognitive function in non-inflammatory physiological conditions. However, the cell type that contributes to this effect is still unknown. Given that astrocytes are key players in synaptic function and they express TNFR2, we sought to investigate whether astroglial TNFR2 could be implicated in regulating cognition and memory. To do so, we generated conditional knockout mice to selectively ablate TNFR2 in GFAP expressing astrocytes (GFAPcre^{ERT2}:Tnfrsf1b$^{fl/fl}$ mice). We found that astroglial TNFR2 ablation impairs memory and cognition, measured with the novel object recognition test, and spatial memory recognition, measured with the Morris water maze test. Ablation of TNFR2 in astrocytes also resulted in anxiety-like behaviors determined with the light-dark transition test. Furthermore, GFAPcre^{ERT2}:Tnfrsf1b$^{fl/fl}$ mice displayed astrogliosis and microgliosis in the hippocampus, shown by increased numbers of GFAP^{+} and Iba1^{+} cells. Taken together our data point at a role for astroglial TNFR2 in cognition, memory and anxiety, as well as hippocampal homeostasis. Further studies are warranted to better understand the mechanisms of these effects, and whether they are maintained under CNS disease conditions.

Title: Olfactory bulb astrocytes modulate activity-dependent sensory processing and map refinement

Authors: *K. UNG[1], B. R. ARENKIEL[2], B. TEPE[3], E. HANSON[4], C. K. MCCLARD[3], G. LIU[3], B. DENEEN[3]

Abstract: Despite important roles astrocytes play in synaptic plasticity, how astrocytes function towards processing sensory information remains largely unexplored. Exploiting the anatomy and experimental tractability of the mouse olfactory system, here we test the hypothesis that local astrocytes play essential roles in sensory circuit processing, and the maintenance of odor response maps in the olfactory bulb. By genetically targeting both astrocytes and neurons for simultaneous *in vivo* imaging of Ca^{2+} responses, we found that astrocytes exhibited an odor-response map that overlapped with excitatory neuronal activity. Furthermore, we observed that stimulating or inhibiting astrocyte intracellular Ca^{2+} signaling inversely modulated odor-evoked neuronal activity, suggesting that activation of olfactory bulb astrocytes inhibits neuronal odor responses. Moreover, this inhibitory effect was mediated by calcium-dependent vesicular release, and was critical in maintaining neuronal sensory domains. Finally, behavioral analysis showed that astrocyte activity manipulations affected both odor detection threshold and olfactory discrimination, supporting an active role for astrocytes in information processing within olfactory sensory circuits. Together, these data support functional roles astrocytes play in sensory processing, highlighting a dynamic neuron-glia mechanism to sculpt and maintain sensory maps. Uncovering novel functional roles for astrocytes toward sensory processing and circuit function may not only better inform us of proper brain development, but may also help explain how defects in astrocytes contribute to brain circuit dysfunction or disease.

Title: Investigating neuron-astrocyte functional interactions using a bioengineered 3D coculture platform

Authors: *C. CVETKOVIC, N. BASU, R. KRENCIK
Houston Methodist Res. Inst., Houston, TX

Abstract: The manner in which human astrocytes respond and contribute to developing neuronal circuits is not widely understood. It especially remains unclear how their response is altered during neuromodulation approaches such as drug intervention or electrical stimulation (ES). We hypothesize that enhancement of neuronal activity in turn stimulates astrocytes to secrete neuroregenerative factors previously identified[1]. We aim to utilize this knowledge in future preclinical studies to test whether regulation of astrocyte extracellular signaling can promote neuroregeneration after injury and disease.

Human astrocytes have distinct morphological and functional attributes which may lead to dissimilar responses from non-human cellular models; as such, we utilize tissue generated from human pluripotent stem cells. We also sought to recapitulate the complexity of human astrocytes and their intimate synaptic associations with improved culture conditions. Thus, we devised an efficient method to systematically and rapidly bioengineer 3D coculture spheres containing human neurons and astrocytes using organoid technologies[2] (*Fig 1*). To modulate neuronal activity, we introduced direct ES of 100Hz with 10 mV square wave pulses, then assessed how coculture and enhanced neural activity affected cellular maturation with gene expression profiling, immunohistochemistry and multielectrode array recordings. We found that the presence of astrocytes accelerated neuronal circuit formation, while neuronal stimulation led to dramatic morphological changes in astrocytes. Surprisingly, astrocytes respond directly to ES suggesting there may be a combination of neuronal signals and cell autonomous results.
In summary, we report an optimized coculture system to stimulate and measure the responses of neuron-astrocyte signaling and are conducting further characterization to elucidate the specific signaling factors involved. As a preclinical platform, this system may be effective to define the impact of ES on astrocyte signaling. (Krencik et al, [1]*Sci Transl Med* 2015; [2]*Stem Cell Rep* 2017)

Title: Developmental analysis of astrocytes and astrocyte-derived synapse promoting proteins in the mouse visual cortex *in vivo*

Authors: *I. FARHY TSELNICKER, C. DOWLING, N. J. ALLEN
The Salk Inst. For Biol. Studies, LA Jolla, CA

Abstract: Astrocytes, a major type of glial cells, are crucial regulators of neuronal synapse development and function. In the rodent cortex neurons are arranged in 6 layers, each with stereotyped synaptic connectivity between layers and with neurons outside the cortex. The correct establishment of these synapses during development is crucial for the proper function of the brain. Astrocytes produce several proteins that promote synapse formation and function, however, whether cortical astrocytes differentially regulate formation of synapses in different layers is unknown. Furthermore, the developmental time line of expression of astrocyte synaptogenic cues in the different cortical layers, and whether expression is regulated by neuronal activity, is unknown. Here we use mouse visual cortex to study the development of astrocytes, astrocyte-derived synapse promoting proteins glypicans and thrombospondins, and neuronal synaptic proteins Vesicular Glutamate transporters (VGlut1, 2) and AMPA receptor subunits GluA1, 2. We perform our analysis at 4 different stages of cortical astrocyte and synapse development: 1) Postnatal day (P) 0-4: astrocytes are at early stages of generation and proliferation; synapses have not yet formed, 2) P7 - astrocytes are immature, continue to proliferate; synapses begin to form, 3) P14 - peak of synaptogenesis, beginning of synapse maturation 4) P21-P28 end of synaptogenesis; astrocytes and synapses are mature. Through a combination of immunohistochemistry and in situ hybridization methods we quantify the developmental changes in astrocyte numbers within each of the 6 neuronal layers, and ask whether the expression of astrocyte-derived synapse-promoting genes is segregated by layers, and how their expression patterns and localization change with development. Furthermore, we ask whether perturbing development of thalamo-cortical innervation of the visual cortex alters the expression levels and/or localization of astrocyte-derived synapse promoting factors. Our findings constitute an important frame work for future studies of astrocyte and synapse development in the cortex, as well as provide insight into neuron-astrocyte interaction as it occurs at the level of the distinct cortical connections during synapse development.

Title: The neuropeptide PACAP orchestrates glutamate signaling between astrocytes and neurons in the nucleus accumbens core: implications for cocaine seeking

Authors: *E. M. HESS[1], S. KASSEL[1], L. KONG[4], N. RADDATZ[1], E. VAN NEWENHIZEN[2], E. AFREEN[1], E. BARDONNER[1], D. KORPICS[1], Q.-S. LIU[5], A. GEURTS[6], J. R. MANTSCH[1], S. CHOI[3], D. A. BAKER[3]

Abstract: Dysregulation of glutamate signaling is observed in humans abusing cocaine, opiates, and other drugs. A challenge in revealing the glutamatergic basis of addiction is that it signals via an elaborate network of receptors, transporters, and release mechanisms expressed by neurons and astrocytes. Preclinical studies have revealed that cocaine dysregulation of glutamate signaling stems from disrupted function of neurons and astrocytes. Glutamate signaling across these cells is likely to be highly coordinated. In support, cocaine, which targets neuronal monoamine transporters, impairs the astrocytic cystine-glutamate antiporter system x_c^- (Sxc) in the nucleus accumbens core (NAcc). Hence, the NAcc may contain an unidentified molecule capable of coordinating glutamate signaling across neurons and astrocytes. Here, we hypothesize that the neuropeptide pituitary adenylate cyclase-activating polypeptide (PACAP) is a previously unrecognized component of glutamate signaling in the NAcc that integrates signaling between neurons and astrocytes. To test this, we used adult male rats to examine whether PACAP and PACAP receptors are expressed in the NAcc. To do this, we fluorescently labelled NAcc afferents, efferents, and astrocytes. Subsequently, the use of fluorescence activated cell sorting followed by PCR enabled the detection of PACAP mRNA in NAcc afferents and PACAP receptor mRNA in NAcc efferents and astrocytes. Regarding the role of PACAP signaling in astrocytes, we found that PACAP decreased the apparent K_m of Sxc-mediated cystine-glutamate exchange. In neurons, PACAP signaling was found to promote NMDA receptor activation, an effect that may be due to altered phosphorylation of the GluN1 subunit at S897. The net impact of promoting glutamate release from astrocytes and regulating neuronal NMDA receptors was inhibition of AMPA receptor function in NAcc efferents to the substantia nigra. The relevance of these findings to drug addiction was established by our finding that PACAP micro-injections into the NAcc dose-dependently reduced cocaine-primed reinstatement of extinguished cocaine seeking. Moreover, micro-injection of a PACAP receptor antagonist promoted cocaine-primed reinstatement, which indicates that this neuropeptide may be an endogenous factor protecting against compulsive drug seeking. These findings suggest that the neuronal factor PACAP is a key integrator of the glutamate network in the NAcc that enables a neuron-astrocyte signaling pathway promoting control over drug-induced behavior.

Title: A neuron-glia co-culture model system to study neuroinflammation

Authors: *N. M. TAYLOR, S. HAKIM, A. BHATTACHARYA, Y. HE
Janssen, San Diego, CA

Abstract: Astrocytes and microglia are major glial cell types in the brain and play fundamental roles in association with neuronal networks in the central nervous system. Inflammation or dysfunction of either contribute to neurologically associated disorders and diseases. To investigate the involvement of astrocytes and microglia in health and diseases and identify potential therapeutic targets, it is critical to establish reliable isolation methods for individual cell types as well as co-culture glial-neuronal systems. Here we explored neuronal, microglial, and astrocyte purification and co-culture methods. Furthermore, we assessed the effects of glia and LPS-stimulated glia on neurite length and neuronal activity. As a result, we found: 1) a method to obtain pure neurons; 2) Brainbits media maintained microglia in a relatively quiescent state; 3) neurite length was suppressed by LPS-induced microglia but not LPS-induced astrocytes; 4) neuronal activity was enhanced by astrocyte co-culture. Our study provides a useful tool as a co-culture system to mimic the *in vivo* brain environment, which can be applied for further compound testing and mechanism studies.

Title: An astrocyte-neurons model of emergent spatial modulation of synapses mediated by endocannabinoid

Authors: Y. NAKAHAMA, *O. ARAKI, T. URAKAWA
Tokyo Univ. of Sci., Tokyo, Japan

Abstract: We focused on the interactions between an astrocyte and neurons through endocannabinoid (ECB). ECB transmitted retrogradely from an active postsynaptic neuron to presynaptic neurons has been reported to decrease the probability of release (PR) of neurotransmitter at synaptic cleft. This inhibitory effect is called Depolarization-induced Suppression of Excitation (DSE). On the other hand, when a microdomain of astrocyte also receives the ECB, the inositol trisphosphate (IP_3) is generated in the astrocyte. Then, calcium waves induced by IP_3 increase PR by glutamate release from the astrocyte. This phenomenon is referred to as endocannabinoid-mediate Synaptic Potentiate (e-SP). Further, it has been reported that DSE occurs in the shorter range of distance (< 60 μm) from the electrically stimulated cell, while e-SP occurs at the longer range of distance (Navarrete et al., 2010). The mechanism underlying this distance dependency remains unclear. Using a computational model, we attempted to verify the hypothesis that ECB release and IP_3 diffusion in astrocyte play an important role in such spatial modulation of synapses. Our model consists of three parts as follows: (Part 1) membrane potentials of neurons, (Part 2) intracellular calcium wave with IP_3 in an astrocyte (Li-Rinzel, 1994, De Pitta et al., 2009), and (Part 3) ECB release among the astrocyte and neurons (Naeem et al., 2015). We used the adaptive exponential integrate-and fire model (Destexhe, 2009) as a model neuron. Part 2 of our model was set to make the dynamics of Ca^{2+} stored in endoplasmic reticulum (ER) and its release from ER, which depend on IP_3 concentration. We assumed 100 x 100 neurons arranged on the grid points in a 2D plane and one astrocyte interacting with all of them. When one neuron fires, it releases ECB around it. Then, DSE occurs in the presynaptic neurons which receive the ECB. On the other hand, if the astrocyte receives ECB, IP_3 is generated. If $[Ca^{2+}]$ exceeds a threshold depending on IP_3 concentration, e-SP occurs. Here, we uniquely introduced the spatial IP_3 diffusion model which follows a diffusion equation in the astrocyte aiming for the distance-dependent DSE and e-SP. Our computational simulation showed a circular area of decreased PR within about 30 μm from the stimulated neurons and increased one from there to 150 μm apart. The results were almost consistent with the actual experimental data (Navarrete et al., 2010). In addition, no distance-dependent modulation was observed without IP_3 diffusion. The present results support our hypothesis that IP_3 diffusion in astrocyte is involved in spatial modulation of synapses.

Title: Optogenetic stimulation of astrocytic Gq signaling differentially alters synaptic transmission in hippocampal CA1 and layer V of sensorimotor cortex

Authors: *C. SOBIESKI[1,2,3], N. M. WOJNOWSKI[2,3], C. RAMAKRISHNAN[4], R. A. DEFAZIO[5], K. DEISSEROTH[4], C. A. CHRISTIAN[2,3]

Abstract: Appreciation of active roles for astrocytes in shaping central nervous system function is growing. While astrocytes can detect synaptic signaling through G-protein linked receptors, the subsequent effects of this response on synaptic function are less understood. It is also unclear how these effects may differ across brain areas. These questions have been difficult to address due to limited availability of tools that selectively activate G-protein signaling pathways in astrocytes. Here we investigated how the activation of Gq signaling in astrocytes modulates synaptic transmission in hippocampal CA1 and layer V of sensorimotor cortex. C57BL/6J mice were injected with adeno-associated virus (AAV8) to express either a light-sensitive Gq-linked alpha1 adrenergic receptor and GFP (optoa1) or control GFP alone under the astrocyte promoter GFAP. Successful targeting of opsin/GFP to astrocytes was confirmed by histology. At least two months after virus injection, we used whole-cell patch clamp electrophysiology in acute brain slices to measure spontaneous inhibitory postsynaptic currents (sIPSCs) or excitatory postsynaptic currents (sEPSCs) while delivering 1 mW, 5 mW, or 10 mW blue laser light (473 nm) to the slice via an optical fiber at 0.5 Hz for 90 s. Biocytin filling of recorded cells confirmed localization near GFP-expressing astrocytes. While there was little effect on sPSC kinetics at 1 mW and 5 mW light intensities for either optoa1 or GFP-expressing slices, in hippocampal CA1 pyramidal cells we found that sIPSC decay time was increased when optoa1 was stimulated at 10 mW compared to baseline recordings (N=8 cells, $p<0.0001$, K-S test). We did not observe this effect in GFAP-GFP controls (N=10 cells GFP; $p=0.1150$, K-S test). We also found that light pulses increased sEPSC amplitude in GFP controls (N=10 cells; $p<0.0001$, K-S test), but not in slices expressing optoa1 (N=9 cells; $p=0.1845$, K-S test). Compared to CA1, preliminary results from pyramidal neurons in layer V sensorimotor cortex show decreased sIPSC decay time following optoa1 stimulation (N= 5 cells; $p=0.0048$, K-S test). These initial data suggest that acute activation of Gq G-protein signaling in astrocytes has differential effects on sIPSC kinetics in hippocampus vs. cortex.

Title: Astrocytic excitatory amino acid transporters (EAATs) differentially regulate metabotropic glutamate receptor (mglur) activation in normoxia and chronic intermittent hypoxia (CIH)

Authors: *D. MARTINEZ, E. M. HASSER, D. D. KLINE
Biomed. Sciences/Dalton Cardiovasc. Res. Ctr., Univ. of Missouri, Columbia, MO

Abstract: The nucleus tractus solitarii (nTS) is the first central integration site for visceral reflexes including the chemoafferent reflex. Sensory afferent signals are transmitted to nTS neurons via release of Glutamate (Glu). EAATs in the nTS restrain extracellular Glu, ionotropic Glu receptor activation, and thus modulate neuronal activity and synaptic transmission. We have shown that EAAT block (EAAT-X) with the general antagonist DL-threo-β-Benzyloxyaspartic acid (DL-TBOA) depolarized nTS neurons and increased the frequency of spontaneous excitatory postsynaptic currents (sEPSC); yet reduced the amplitude of afferent (TS)-evoked EPSCs (TS-EPSCs). Interestingly, CIH, a model of obstructive sleep apnea, produces similar synaptic and neuronal responses as EAAT-X. EAATs in the nTS may modulate synaptic and neuronal excitability via mGluR activation, as iGluR blockers did not fully eliminate EAAT-X effects. Group I mGluRs are found on nTS neuron somas; their activation leads to depolarization and increased excitability. Group II/III are found presynaptically; their activation decreases TS-EPSC amplitude. We sought to determine the influence of EAATs on a) CIH-induced changes, and b) mGluRs in CIH responses. Male Sprague-Dawley rats (3-6 wk) underwent 10d normoxia (Norm, 21% O_2) or 10d CIH (alternating 21% O_2 and 6% O_2, 8h/day). Horizontal brainstem nTS slices were generated and sEPSCs, TS-EPSCs, and holding currents (I_{hold}), were recorded from monosynaptic nTS neurons. Electrophysiological properties were examined in aCSF, EAAT-X (TFB-TBOA, 500 nM) alone, and during EAAT-X and block of either Grp I (LY367385 160 μM) or Grp II/III (eGLU and MSOP 200 μM). As a time control, some neurons were exposed to a second EAAT-X (EAAT-X2). In Norm, EAAT-X increased both I_{hold} (depolarized V_m) and sEPSC frequency (indicating an increase in network activity), yet decreased the amplitude of TS-EPSCs. EAAT-X2 enhanced all of these effects. mGluR-I-X eliminated the enhancement of I_{hold} and sEPSC frequency seen with EAAT-X2. Conversely, mGluR-II/III-X attenuated TS-EPSC depression seen in EAAT-X2. In CIH, EAAT-X increased I_{hold} and sEPSC frequency but less than in Norm. CIH decreased TS-EPSC amplitude compared to NORM, yet EAAT-X increased

TS-EPSC amplitude. EAAT-X2 enhanced these effects. In contrast to Norm, mGluR-I-X further increased sEPSC frequency and I_{hold} to EAAT-X2. mGluR-II/III-X decreased the TS-EPSC amplitude to EAAT-X2. These data suggest in Norm that EAATs regulate network activity and I_{hold} through mGluR I, and TS-EPSCs through mGluR II/III. CIH reduces EAAT influence on synaptic and neuronal activity, and mGluRs contribute differentially.

Title: Astrocyte volume changes associated with cortical seizures *in vivo*

Authors: *T. R. MURPHY[1], T. A. FIACCO[2], D. K. BINDER[1]
[1]Div. of Biomed. Sciences, Sch. of Med., [2]Dept. of Molecular, Cell and Systems Biol., Univ. of California, Riverside, Riverside, CA

Abstract: Epilepsy is a large spectrum of recurrent seizure disorders which collectively afflict over 65 million people worldwide. The mechanisms underlying seizure generation remain largely unknown, and current therapies which target neurons alone often fail to control seizures. More specific targets require a more fundamental understanding of the factors driving neuronal hyperexcitability and seizure susceptibility. One intriguing, often-overlooked factor in neuronal excitability is the size of the extracellular space (ECS). ECS shrinkage (reflecting cell/tissue swelling) has been repeatedly demonstrated to augment tissue excitability and seizure susceptibility, and seizures in multiple models are preceded by ECS reductions. Conversely, a dilated ECS (cell/tissue shrinking) produces the opposite effect. ECS volume changes likely reflect those of astrocytes, which facilitate brain water movements and rapidly change volume under osmotic gradients and facilitate brain water movement through aquaporin-4 (AQP4) water channels. Swollen astrocytes can also volume regulate under certain conditions, releasing neurotransmitters in the process and potentially further increasing neuronal excitability. We have previously observed rapid astrocyte swelling prior to excitability increases in hippocampal slices, and preliminary work indicates that reactive astrocytes in epileptic mice are even more susceptible to swelling. To date, however, the exact relationship between astrocyte volume change and neuronal excitability *in vivo* remains unknown. Using *in vivo* two-photon imaging alongside cortical EEG recording, we have begun to directly examine the temporal relationship between astrocyte volume changes and cortical seizures in awake, behaving animals. Rapid

(1/minute) z-stack images of layer 2/3 cortical astrocytes were acquired continuously before, during and after acute generalized seizure (induced by pentylenetetrazole) in Aldh1L1-eGFP mice to obtain astrocyte volume measurements over time. In agreement with previous findings, we have observed rapid astrocyte swelling occurring minutes before seizure initiation, reaching a peak of nearly 8% above baseline volume, before dropping precipitously just prior to seizure. Preliminary results indicate that GFP-expressing neurons do not show similar volume changes. These data suggest that astrocyte volume changes may specifically promote seizure initiation. Ongoing experiments include the use of a focal (4-aminopyridine) seizure model and specific manipulations of astrocyte volume to more specifically determine the influence of astrocyte swelling on hyperexcitability.

Title: Regulation of excitatory and inhibitory synapses through astrocytic ephrin-B1 in developing and adult hippocampus

Authors: *A. Q. NGUYEN[1], J. KOEPPEN[1], S. HANNA[1], A. VENGALA[1], A. OBENAUS[3], I. M. ETHELL[2]
[2]Sch. of Med., [1]Univ. of California, Riverside, Riverside, CA; [3]Dept Pediatrics, Loma Linda Univ., Loma Linda, CA

Abstract: Synapses undergo structural and functional modifications during development, which is regulated by astrocytes. Astrocyte dysfunctions are also implicated in synapse pathologies associated with neurodevelopmental disorders such as autism and intellectual disabilities. Astrocytes can regulate both formation and elimination of functional synapses during development. In addition, astrocytes can regulate synapse maintenance and plasticity in the adult brain. We propose that astrocytic ephrin-B1 may negatively influence synapse growth by mediating pruning of existing synapses or suppressing new synapse formation through the interactions with neuronal EphB receptors. To test this hypothesis, we first examined whether the deletion of astrocytic ephrin-B1 during early postnatal development (P14→P28) or in adulthood (P90) would result in excessive formation of synapses in the hippocampus. Deletion was achieved using ERT2-Cre^{GFAP}*ephrin-B1*$^{flox/y}$ mouse model; P14 or adult *ephrin-B1*$^{flox/y}$ (WT) and Cre^{GFAP}*ephrin-B1*$^{flox/y}$ (KO) male littermates were intraperitoneally injected with tamoxifen

(0.5mg in 5mg/ml of 1:9 ethanol/sunflower seed oil) once a day for 5 or 7 days, and analyzed 2 weeks after first tamoxifen injection. Astrocytic ephrin-B1 deletion in adult male mice resulted in significant increase in dendritic spine density and pre-synaptic vGlut1 puncta with no changes to GAD65 puncta in stratum radiatum (SR) of CA1 hippocampus. Interestingly, we found an increased proportion of immature dendritic spines with small heads along with a two-fold decrease in synaptic AMPAR levels. We also observed an overall decrease in postsynaptic firing of CA1 hippocampal neurons in KO mice following stimulation of Schaffer Collaterals. In contrast, early postnatal deletion of astrocytic ephrin-B1 resulted in significantly increased postsynaptic fEPSPs and postsynaptic firing of CA1 hippocampal neurons. Our results suggest that astrocytic ephrin-B1 may regulate the development of hippocampal circuits by suppressing excitatory synapse formation or by influencing excitatory-inhibitory balance.

Title: Noradrenergic enhancement of antidepressant-induced LPA_1 signalling in astrocytes

Authors: *P. ONALI, S. DEDONI, M. C. OLIANAS
Univ. of Cagliari, Dept.Biomedical Sci., Monserrato, Italy

Abstract: Antidepressants are considered to exert their therapeutic effects by enhancing monoaminergic neurotransmission. However, there is evidence that these drugs have additional molecular targets, including G protein-coupled receptors. We have recently shown that in different cell types distinct classes of antidepressants activate the lysophosphatidic acid (LPA) receptor LPA_1. In cultured astrocytes antidepressant-induced LPA_1 activation triggers growth factor receptor transactivation, ERK1/2 phosphorylation and protection from oxidative stress. However, it is not known whether in astrocytes monoamines can affect antidepressant-induced LPA_1 signalling. We found that in C6 glioma cells and in cultured rat cortical astrocytes prolonged exposure to either noradrenaline or the selective β-adrenergic agonist l-isoproterenol enhanced the stimulation of ERK1/2 phosphorylation elicited by either amitriptyline, mianserin or LPA. The noradrenergic potentiation was mimicked by the adenylyl cyclase stimulator forskolin, the cyclic AMP analogue dibutyryl-cAMP and PDE4 inhibitor rolipram, implying the involvement of a cyclic AMP-dependent mechanism. These data suggest that the enhancement of β-adrenergic transmission elicited by certain antidepressants may potentiate the action of these drugs as stimulators of LPA_1-mediated signalling in astrocytes.

Title: Optogenetic manipulation of preBötzinger complex astrocytes modulates activity of inspiratory rhythm-generation circuits

Authors: *S. SHEIKHBAHAEI[1,2], H. KOIZUMI[1], R. ZHANG[1], A. V. GOURINE[2], J. C. SMITH[1]
[1]Cell. and Systems Neurobio. Section, Natl. Inst. of Hlth. (NIH)- NINDS, Bethesda, MD; [2]Univ. Col. London, London, United Kingdom

Abstract: Astrocytes, the electrically silent CNS cells, have been proposed to modulate neuronal network activity, including vital brainstem respiratory rhythm-generating circuits of the preBötzinger complex (preBötC), although such a modulatory function at the level of preBötC circuits has not been directly demonstrated. We employed transgenic mice expressing Cre recombinase under control of the human glial fibrillary acidic protein (hGFAP-cre) promoter for astrocyte-specific expression of Channelrhodopsin-2 (ChR2) or archaerhodopsin (ArchT) and applied optogenetic techniques to manipulate activation of preBötC astrocytes in rhythmically active neonatal medullary slice (*in vitro*) and in adult perfused brainstem-spinal cord preparations (*in situ*). Activation of ArchT in preBötC astrocytes via laser (593 nm, 2-10 mW, *in vitro*), decreased the frequency and amplitude of hypoglossal nerve activity, while laser activation of ChR2 (473 nm, 0.5-5 mW) in preBötC astrocytes increased the frequency of hypoglossal (*in vitro*) and phrenic nerve (*in situ*) activities. Our experimental results have confirmed the capability of astrocytes to modulate the activity of preBötC rhythm-generating circuits. Identifying the astrocytic signaling mechanisms involved remains an important problem.

Title: Increased endoplasmic reticulum stress and gliosis in a model of high altitude retinopathy and CNS hypoxia

Authors: *L. A. MESENTIER-LOURO, A. CAMARGO, V. KUMAR, M. A. SHARIATI, R. DALAL, A. J. OH, Y. J. LIAO
Dept. of Ophthalmology, Stanford Univ., Palo Alto, CA

Abstract: Vision and CNS changes are well described after acute high-altitude exposure, sometimes also called high altitude cerebral edema (HACE) or high-altitude retinopathy. This is primarily attributed to hypoxia as a result of hypobaria. Hypoxia leads to rapid energy failure, cessation of oxidative phosphorylation, and cell death, likely via intrinsic or extrinsic mechanisms. Surprisingly little has been done to study the impact of hypoxia on the retina and optic nerve in the setting of high altitude disease, although hypoxia is thought to be a common mechanism of vision loss in retinopathies and optic neuropathies, including in stroke, glaucoma, ischemic optic neuropathy, diabetic retinopathy, and retinopathy of prematurity. In this study, we used in vivo optical imaging and histology to assess the impact of hypoxia on the retina and optic nerve in a mouse model of acute high-altitude exposure and assessed the impact of treatment with the chemical chaperone 4-phenylbutyric acid (4-PBA).We induced systemic hypoxia in adult (6-8 weeks old) C57BL/6 female mice using a hypoxia chamber, where animals are acclimated over 20 min from 21% oxygen to 6-12% oxygen for 24h or 48h. We performed serial in vivo imaging of the retina using optical coherence tomography, and sacrificed animals at different time points for immunohistochemistry analysis of the retina and optic nerve using antibodies to label different components of the neuron-glia-vascular unit, including C/EBP homologous protein (CHOP; ER stress), Brn3A (retinal ganglion cells), glial fibrillary acidic protein (GFAP; astrocytes and Müller cells), Olig2 (oligodendrocytes) and Iba1 (microglia). To investigate whether ER stress was responsible for hypoxia-induced changes, we treated animals with intraperitoneal injections of 4-PBA (40 mg/kg; ER stress blocker) or vehicle (PBS). Optical coherence tomography showed that hypoxia for 24-48h led to a small but significant reduction in retinal thickness (P=0.0158), which was improved after treatment with 4-PBA. Within 24-48h of hypoxia, we found a profound increase of proapoptotic transcription regulator CHOP, a marker

of ER stress, in the retina (ganglion cell layer and inner nuclear layer) and optic nerve oligodendrocytes. There was also marked gliosis with increased expression of GFAP in the Müller glia, optic nerve head astrocytes and optic nerve astrocytes, and increased $Iba1^+$ microglia in the optic nerve. We showed that CNS hypoxia for 24-48h led to rapid and dramatic activation of ER stress and gliosis in the retina and optic nerve. Reduction of ER stress may be a promising novel treatment for vision changes in high altitude disease and hypoxia.

Title: Astrocytes as orchestrators of long-range synchronization and hippocampal sharp wave ripple generation

Authors: *S. BERRY[1,2], C. LEWIS[1], F. F. VOIGT[1,2], F. HELMCHEN[1,2], U. GERBER[1,2]
[1]Brain Res. Inst., Univ. of Zurich, Zuerich, Switzerland; [2]Neurosci. Ctr. Zurich, Zurich, Switzerland

Abstract: Network oscillations and neuronal synchronization in several brain regions are believed to be key components of memory formation. Traditionally, these processes have been considered the exclusive work of neurons. However, increasing evidence suggests that astroglia can mediate coincident neuronal activity and may even facilitate oscillations in certain brain regions. Here we show that the astrocytic syncytium harbors the ability to synchronize the full hippocampal network, independent of action potentials. Furthermore, we provide *in vitro* and *in vivo* evidence that glia activity is correlated with the generation of sharp wave ripples (SWRs), which are compressed neuronal replay events necessary for memory consolidation. In acute mouse hippocampal slices, we find that the application of K^+ channel antagonists engenders large slow inward currents (SICs) throughout the full neuronal circuit that persist in the presence of tetrodotoxin (TTX). Whole-cell electrophysiological recordings combined with neuronal calcium or glutamate imaging revealed events initiating in CA3c followed by activity in distal CA1 approximately 50 ms later. Astrocytic imaging revealed circuit-wide calcium elevations coincident with neuronal SICs. Manipulations to suppress glial glutamate release inhibited these events. Interestingly, when applied briefly and in the absence of TTX, the K^+ channel antagonists induced persistent SWRs. Considering that this manipulation facilitates both gliotransmission

and SWRs, we explored a potential role for astrocytes as orchestrators of these endogenous hypersynchronous events. Using *in vivo* fiber photometry, we found that astrocytic Ca^{2+} rises are correlated with the occurrence of SWRs in awake mice. Moreover, pharmacological and optogenetic inhibition of gliotransmission abolished endogenous SWRs *in vitro*. Our results reveal novel mechanisms involved in large-scale hippocampal synchronization and the generation of SWRs, indicating that astrocytes may play a previously unappreciated role in memory formation.

Abstract: Myelinated axons, which account for approximately half the volume of the human brain, are a major factor enabling the dense, rapid, and efficient signal transmission that lies at the heart of human cognitive capacities. The insulating myelin sheath, created by a complex interaction between neuronal and glial cell, keeps axonal impulse propagation velocity high and energy consumption low, while allowing very small overall fiber diameters. Recently, we showed that a large fraction of myelin in mouse neocortex ensheathes axons of inhibitory neurons, specifically of parvalbumin (PV) basket cells (1). These inhibitory myelinated axons differ significantly from the excitatory axons in structural organization (length of nodes of

Ranvier and internodes), and in biochemical composition (axonal cytoskeleton and protein content of myelin). Using samples of surgically-excised brain tissue, we now show that many of the characteristic features of mouse cortical myelinated axons are also present in human, despite 100 million years of evolutionary isolation. As in mouse, many human myelinated inhibitory axons originate from PV interneurons and have distinctive features, including high neurofilament and low microtubule content, short nodes of Ranvier, and high content of myelin basic protein in their myelin sheath. The implications of these differences will require further study, but we speculate that they have direct functional significance. We further show that the inhibitory myelinated axons in both human and mouse cortex have more mitochondria, as well as more 2',3'-cyclic nucleotide 3'-phosphodiesterase, a protein enriched in the myelin cytoplasmic channels thought to provide access for trophic support from ensheathing oligodendrocytes. This is consistent with the high energy demands of fast-spiking PV interneurons and suggests that, in addition to influencing conduction velocity, the myelination of inhibitory axons is likely beneficial for managing their energy consumption by increasing the efficiency of action potential propagation, and providing trophic support. The distinctive features of myelinated inhibitory axons in human cortical grey matter may have important implications for neurological disorders that involve pathologies of myelinated axons. The similarities in structural and biochemical characteristics of mouse and human myelinated inhibitory axons supports the mouse as a good model system to study disease-related changes of cortical myelin.

Title: Astrocyte depolarizations modulate astrocytic glutamate clearance in a Kir4.1 dependent manner

Authors: *M. ARMBRUSTER[1], C. G. DULLA[2]
[1]Neurosci., Tufts Univ., Boston, MA; [2]Neurosci., Tufts Univ. Sch. of Med., Boston, MA

Abstract: Astrocytes abundantly express the voltage dependent glutamate transporters GLT-1 and GLAST, which rapidly remove glutamate from the extracellular environment following synaptic activity, and restrict the temporal and spatial extent of glutamate signaling. We previously showed that neuronal activity slows glutamate clearance in a local, stimulus number dependent, and glutamate independent manner. We hypothesize that this modulation is due neuronally induced astrocytic depolarizations by changes in extracellular K+, which are then cleared by the inward rectifying potassium channel Kir4.1. Somatic electrophysiology recordings from astrocytes show only limited and slow depolarizations of astrocytes. However, imaging new genetically encoded, astrocytically targeted, fluorescent voltage sensors in the adult mouse cortex reveals faster stimulus induced membrane depolarizations. In order to perturb the stimulus induced astrocytic changes; we have turned to the astrocytic potassium channel Kir4.1. Neuronal activity is thought to increase extracellular K^+, which is then cleared/buffered by astrocytes through Kir4.1. Kir4.1 expression and mutations have been associated with hyperexcitability and epilepsy. Through viral overexpression and pharmacological blockade of Kir4.1 in the adult mouse cortex, we have investigated how Kir4.1 levels and function modulate astrocytic glutamate clearance, as a proxy for peripheral depolarizations. Using NMDA current readouts of glutamate clearance, we show that Kir4.1 levels and function can bidirectionaly modulate the stimulus number dependent slowing of glutamate clearance (increased Kir4.1 = reduced slowing of glutamate clearance). These experiments use novel techniques and highlight new glial-neuron interactions, new mechanisms of modulating synaptic signaling, and new insights into astrocyte biology.

Title: The role of astrocytic ephrin-B1 in activity dependent synapse remodeling during memory formation

Authors: *S. WOODRUFF, J. KOEPPEN, A. NGUYEN, I. ETHELL
UC Riverside, Riverside, CA

Abstract: Astrocytes are glial cells known to regulate the formation, pruning, and maintenance of synapses. However, signals that facilitate astrocyte-mediated synaptic pruning are still unknown. Previous work in our lab suggest ephrin-B1 signaling in astrocytes mediates pruning of synapses through interactions with neuronal EphB receptors. Synaptosome engulfment by primary astrocytes is significantly impaired after inhibition of ephrin-B1 signaling in astrocytes or deletion of neuronal EphB receptors *in vitro*. Previous studies *in vivo* show deletion of astrocytic ephrin-B1 increases the number of excitatory synapses in the CA1 hippocampus and increased contextual recall. Our lab has also shown that overexpression of astrocytic ephrin-B1 results in reduced contextual recall, suggesting astrocytic ephrin-B1 may inhibit memory formation by eliminating excitatory synapses. This study looks at the differences in excitatory synapses in the CA1 hippocampal neurons activated during contextual recall in proximity to normal astrocytes and astrocytes overexpressing ephrin-B1 using adeno-associated viral (AAV) approach. Given the role of astrocytes and ephrin signaling in neurodevelopmental disorders and neurodegenerative diseases, this project has potential for future therapeutic clinical applications.

Title: Reorganization of perineuronal nets and astrocyte phenotype in the rat's Medial Preoptic Area

Authors: *J. NOGUEIRA BORDE[1], D. MÉNDEZ[1], M. M. FERREÑO, 11600[2], N. URIARTE[2]
[1]Facultad de Medicina Univ. De La República, Montevideo, Uruguay; [2]Facultad de Ciencias, Univ. de la República, Montevideo, Uruguay

Abstract: Perineuronal nets (PNNs) are aggregations of extracellular matrix associated to specific neuronal populations in the CNS, suggested to play key roles in neural development, synaptogenesis, neuroprotection and experience-dependent synaptic plasticity. PNN remodeling during natural plastic processes in adults and its potential regulatory role in neuro-glia interaction

are poorly understood. Pregnancy and lactation are characterized by a remarkable increase in neuroplasticity, however it is unknown how PNNs remodeling occurs at maternal circuits during these periods. We analyzed the PNN expression and astrocyte associated phenotype remodeling in a key nucleus of the maternal circuit, the medial preoptic area (mPOA). Brains of female rats were obtained during estrous cycle (di-por-estrous, n=7), pregnancy (Gestation Day (GD) 10, GD14, GD21, n=7) and postpartum period (Postpartum Day (PPD) 2, PPD14 and PPD 22, n=7). mPOA containing slices were processed with a) *Wisteria floribunda* lectin (WFA) for labeled chondroitin sulphate glycosaminoglycan (an structural PNN component), and b) Cy3 coupled anti-GFAP (Glial fibrillary acidic protein) forto analyze astrocyte phenotype. Neither PNNs nor diffuse extracellular matrix expression was detected on mPOA of virgin rats. At GD10 few neurons started to express PNN at the soma and dendrites simultaneously, with almost no interneuronal diffuse extracellular matrix. The number of PNN expressing neurons increases reaching a maximum at GD21. PNN dissipate post partum in an orderly manner, first dendrites (PPD2) then soma (PPD14), with a concurrent increase of interneuronal diffuse extracellular matrix expression (PPD14-18). Interestingly, preliminary results show an increase in GFAP expressing astrocytes associated to PNN assembly (GD 10, 14, 21 n=2) that persists at PPD2, gradual returning to basal level during lactation (PPD 14, 22, n=2). The different organization of PNNs is associated with changes in the plasticity of the mPOA, most likely underlying the dynamics of maternal behavior and physiological adaptations to lactation. Assembly and disassembly showed different dynamics, and were accompanied by astrocyte phenotype remodeling, suggesting the plasticity of neuro-astrocyte interactions.

Title: Processing of afferent information at the level of NTS: Astrocytic ATP release evoked by afferent stimulation modulates baroreflex sensitivity

Authors: *S. MASTITSKAYA[1], P. S. HOSFORD[1], N. MARINA[1], S. KASPAROV[2], A. G. RAMAGE[1], A. V. GOURINE[1]

[1]Neuroscience, Physiol. and Pharmacol., Univ. Col. London, London, United Kingdom; [2]Univ. of Bristol, Bristol, United Kingdom

Abstract: Astrocytes play an important role in cardiovascular reflex integration at the level of the nucleus of the solitary tract (NTS, Lin et al., 2013, *J Neurosci*. 33:18608-17), but underlying mechanisms remain poorly understood. ATP, a prototypical gliotransmitter, excites GABAergic interneurons to increase synaptic inhibition in various CNS areas (Bowser and Khakh, 2004, *J Neurosci*. 24:8606-20; Torres et al., 2012, *J Sci Signal.* 5(208):ra8). In this study we investigated the role of NTS astrocytes and ATP, acting though P2Y1 receptors, in the modulation of baroreceptor reflex pathway. Astrocytic vesicular release mechanisms were disrupted in the NTS by expression of dnSNARE driven by adenoviral vector under the control of an enhanced GFAP promoter. Arterial blood pressure and heart rate were recorded using biotelemetry (DSI). Baroreceptor reflex gain (sBRG) was determined from spontaneous changes in blood pressure and pulse interval during normal behavior. In α-chloralose-anaesthetized rats, baroreflex sensitivity was determined following norepinephrine infusion (1 μg/kg, i.v.) to activate the depressor reflex. P2Y1 receptors in the NTS were blocked by topical application of a selective antagonist MRS-2500 (5 μM). In animals transduced to express dnSNARE in the NTS astrocytes (n=5), the sBRG significantly increased when assessed on day 7 after viral injections (1.7±0.1 bpm/mmHg) compared to baseline values (1.0±0.1 bpm/mmHg, $p<0.01$) and sBRG recorded in animals transduced to express eGFP in the NTS (controls, 1.2±0.1 bpm/mmHg, $p<0.05$). Activation of baroreflex in anaesthetized rats (n=4) was associated with increase in mean arterial pressure of 45±5 mmHg and a decrease in HR of 51±7 bpm (BRG 1.1±0.1 bpm/mmHg). Blockade of NTS P2Y1 receptors augmented the degree of bradycardia induced by baroreceptor activation with systemic norepinephrine (BRG 1.5±0.3 bpm/mmHg, $p<0.05$). These data demonstrate that blockade of vesicular release in the NTS astrocytes increases baroreflex sensitivity. We hypothesize that in response to incoming afferent information NTS astrocytes release ATP which restricts the expression of baroreflex via activation of P2Y1 receptors on local inhibitory interneurons.

Title: Disrupted astrocyte interneuron communication in astrocytes lacking fibroblast growth factor receptor 1

Authors: *K. M. SMITH[1], N. A. ESTEVE[1], N. M. DUNN[2], M. A. HENDRICK[2], D. J. ROGERS[3]
[2]Biol., [1]Univ. of Louisiana At Lafayette, Lafayette, LA; [3]Biol., Univ. of Louisiana at Lafayette, Lafayette, LA

Abstract: Fibroblast Growth Factor Receptor 1 (FGFR1) plays important roles in central nervous system development, and is highly expressed within cortical astrocytes. Neuron-astrocyte communication is vital to the proper functioning of the central nervous system. We have previously demonstrated that Cocultures of GABAergic interneurons grown on *FGFR1Flox/Flox;HGFAPCre+* knock out cortical astrocytes displayed smaller soma size, fewer number of neurites, and a more immature phenotype. Changes in neuronal growth may reflect the lack of FGFR1 or may be influenced by dysfunctional neuron-astrocyte communication from impaired astrocytes. FGFR1 kinase signaling initiates many intracellular signaling pathways involving cell differentiation, cell proliferation, and calcium signaling, interruption of this pathway may inhibit the effective function of the astrocyte in its communication with GABAergic interneurons. Comparing astrocyte cultures to GABAergic interneuron-astrocyte cocultures using cortical astrocytes from *FGFR1Flox/Flox;NestinCre+* and control p2-4 mice, calcium imaging of physiological responses were studied. Genotype had no effect on number of spontaneous calcium waves duration, while the intensity of calcium waves was significantly increased in astrocytes lacking Fgfr1 (p=0.0001). Treatment of cultures with 25μM Glutamate increased the frequency (p=0.004) and intensity (p=0.032) of calcium waves in controls and FGFR1 KO astrocytes. When GABAergic interneuron-astrocyte cocultures were treated with 25μM Glutamate, a decrease in calcium wave frequency (p=0.035) and duration (p=0.022) occurred in Fgfr1 KO astrocytes (p=0.035), while no difference was observed in control astrocytes. The decreased signaling in response to 25μM Glutamate in astrocytes may be due to GABA signaling from the interneurons. This will be confirmed through testing with GABA and the GABAergic antagonists; Bicuculline and CGP36216. We will further examine if the effects of Glutamate stimulation on the co-cultures is mediated by ionotropic *versus* metabotropic glutamate receptors.

Title: Pyridazine-derivatives enhance structural and functional plasticity of tripartite synapse via activation of local translation in astrocytic processes

Authors: *J. B. FOSTER[1], F. ZHAO[1], X. WANG[1], C. C. ASKWITH[1], K. J. HODGETTS[2], C.-L. G. LIN[1]
[1]Neurosci., The Ohio State Univ., Columbus, OH; [2]Brigham and Women's Hosp. and Harvard Med. Sch., Cambridge, MA

Abstract: Excitatory amino acid transporter 2 (EAAT2) is primarily located in perisynaptic astrocytic processes (PAP) where it plays a critical role in synaptic glutamate homeostasis. Dysregulation of EAAT2 at the translational level has been implicated in a myriad of neurological diseases. We previously discovered that pyridazine analogs can activate EAAT2 translation. Here, we sought to further refine the site and mechanism of compound action. We found that *in vivo*, compound treatment increased EAAT2 expression only in the PAP of astrocytes where EAAT2 mRNA also was identified. Direct application of compound to isolated PAP induced *de novo* EAAT2 protein synthesis, indicating that compound activates translation locally in the PAP. Using a screening process, we identified a set of PAP proteins that are rapidly up-regulated following compound treatment and a subset of these PAP proteins may be locally synthesized in the PAP. Importantly, these identified proteins are associated with the structural and functional capacity of the PAP, indicating compound enhanced plasticity of the PAP. Concomitantly, we found that pyridazine analogs increase synaptic protein expression in the synapse and enhance hippocampal long-term potentiation. This was not dependent upon compound-mediated local translation in neurons. This suggests that compound enhances the structural and functional capacity of the PAP which in turn facilitates enhanced plasticity of the tripartite synapse. Overall, this provides insight into the mechanism action site of pyridazine-derivatives as well as the growing appreciation of the dynamic regulation and functional aspects of the PAP at the tripartite synapse.

Title: The role of hippocampal astrocytic swelling on neuronal hyperexcitability in conditions of elevated potassium

Authors: *E. M. WALCH[1], N. CUVELIER[2], T. R. MURPHY[5], D. DAVILA[2], A. VENKATESH[6], I. M. HOLMAN[3], C. KHACHATUROVA[2], T. A. FIACCO[4]
[1]Univ. of California Riverside, Moreno Valley, CA; [3]Neurosci., [4]Cell Biol. & Neurosci., [2]UC Riverside, Riverside, CA; [5]Div. of Biomed. Sciences, Sch. of Med., [6]Neurosci., Univ. of California, Riverside, Riverside, CA

Abstract: Pathological hyperexcitability of neurons has been linked to both cellular swelling and increased extracellular potassium ($[K^+]_o$). However, the identity of the swelling cells and the effects of cell-type specific swelling on neuronal excitability in elevated $[K^+]_o$conditions are poorly understood. Astrocytes regulate $[K^+]_o$ by selective uptake through astrocyte-specific K^+ channels, and are thus likely candidates for high $[K^+]_o$ induced cell swelling and subsequent reduction of the extracellular space (ECS). Our work suggests that $[K^+]_o$ in the range of 6.5 - 26 mM produces selective swelling of astrocytes, and this swelling increases proportionally with increasing $[K^+]_o$ concentrations. Neuronal volume is almost completely unaffected by elevated $[K^+]_o$ and actually shrink slightly in hyperosmolar 26 mM $[K^+]_o$ (elevated $[K^+]_o$ not balanced by equiosmolar reduction of $NaCl_2$).. Pharmacological experiments using barium chloride suggest that astrocyte swelling is independent of inwardly rectifying potassium channels, which are thought to be key for astrocytic regulation of extracellular $[K^+]_o$. These channels are thought to function in tandem with the astrocyte-specific aquaporin 4 (AQP4) channel, but genetic knockout of AQP4 also revealed that high $[K^+]_o$ induced astrocyte swelling is independent of AQP4. Further experiments are underway in attempt to define the mechanism of astrocyte-specific swelling in high $[K^+]_o$, including targeting leak 2-pore K^+ channels, the Na^+/K^+ ATPase, the sodium-bicarbonate cotransporter (NBC), and the NKCC/KCC cotransporters. Additional experiments are ongoing to explore the effects of high $[K^+]_o$ induced astrocytic swelling on excitability of CA1 pyramidal neurons in TTX conditions to prevent direct depolarization-induced increases in neuronal firing. Last, we have also begun to develop optogenetic approaches to swell astrocytes selectively by generating an osmotic gradient to draw water into astrocytes coupled to nonselective cation influx. These experiments are expected to shed light

onto the mechanisms underlying selective astrocyte swelling in high $[K^+]_o$ and the impact of high $[K^+]_o$ -induced astrocyte swelling on neuronal excitability.

Title: Molecular mechanisms of astrocyte-neuron interactions in the development of synchronized activity in neuronal networks

Authors: G. GUEVARA, K. R. SANCHEZ, J. SUN, M. A. HARRINGTON, *M. TEMBURNI
Biol., Delaware State Univ., Dover, DE

Abstract: Synchronous oscillations are necessary for establishing functional neuronal networks in normal vertebrate brain development - however, the mechanisms of neuronal synchronization are not fully understood. Existing models of synchronous activity assume that it is intrinsic to neurons. Astrocytes have been shown to modulate oscillatory activity in networks of neurons possibly by releasing like glutamate and ATP. We have established pure and mixed (astrocyte and neuronal) cultures from the developing chicken brain (optic tectum) and recorded neuronal network activity using two different the multi-electrode array systems, MED64 and Axion. Our preliminary results indicate that astrocytes are necessary for synchronous activity of neurons in culture. Mixed neuron and astrocyte cultures on multi-electrode arrays (MEAs) show random spiking activity which synchronizes over time whereas astrocyte-free neurons only show random activity without synchronization. Our results validated that the physical presence of astrocytes is required to properly establish synchronized activity in neuronal networks. To further dissect the molecular pathways involved, we targeted the metabotropic glutamate receptor (mGluR) pathway within astrocytes as crucial for communication with neurons. Our model predicts that glutamate sensing at tripartite synapses via mGluRs elevates local calcium within astrocyte processes. With sufficient activation, the localized calcium elevation crosses a threshold causing a global calcium release within the astrocyte leading to the exocytosis of glutamate. We proposed to test this model by disrupting the mGluR pathway within astrocytes using a truncated mGluR subunit (mGluR DN) which acts as a dominant negative blocking downstream signaling.

Astrocytes expressing the mGluR DN are expected to have reduced or no calcium elevation upon mGluR stimulation. We have generated astrocyte lines expressing the mGluR dominant negative (mGluR DN) along with the calcium sensor GCaMP5G and the glutamate sensor iGluSnFR. With these tools a more comprehensive molecular model for astrocyte involvement in the generation of neuronal synchrony can be developed.

Title: Effects of heroin on neuron-astrocyte interaction

Authors: *M. D. SCOFIELD
Neurosci., Med. Univ. of South Carolina, Charleston, SC

Abstract: Addiction is commonly associated with modification of communication between the prefrontal cortex (PFC) and the nucleus accumbens. This drug-induced alteration, among others, is thought to contribute to the persistent relapse vulnerability that characterizes addiction. One unique aspect of how drug exposure alters synaptic plasticity in the nucleus accumbens is that several of the molecular adaptations that contribute to the altered synaptic communication described above, occur specifically in astroglia. As the study of astrocyte biology in the context of drug addiction progresses, these astrocytic cellular processes impacted by drug abuse and drug cues may serve as candidates for biological mediators of relapse vulnerability and also as potential targets for therapeutic intervention. Indeed, drugs like N-acetylcysteine (NAC) which act to reverse drug-induced molecular alterations in NAcore astroglial glutamate systems, serve as potent inhibitors of cued relapse in animal models. In parallel to the recent advancements in our understanding of the connection between dendritic spine morphology and the synaptic plasticity underlying relapse in the NAcore, we are beginning to see the study of the morphological properties of astrocytes in the context of drug addiction provide similar insights. Using AAV5-GFAP-LCK-GFP labeled astrocytes, Synapsin I immunolabeling and confocal microscopy, we have recently shown that accumbens astrocytes withdrawal from NAcore synapses following extinction of heroin seeking, an effect that likely exacerbates drug-induced deficits in astroglial glutamate clearance linked to relapse vulnerability. Here we explore the association of astrocytes with synapses in the prelimbic cortex following heroin exposure and

after NAC treatment using the same strategy. As an extension of these analyses, we have also examined astrocyte-dendritic spine proximity in cortical neurons that project to the NAcore, using AAV-based retrograde viral labeling of neurons and AAV5-GFAP-LCK-GFP labeling of astrocytes following extinction of heroin self-administration. Taken together our data suggest that the alterations in the association of astrocytic processes with synapses caused by exposure to drugs of abuse may serve an emerging crucial mediator of relapse biology.

Title: Mixed lineage kinase domain-like protein MLKL breaks down myelin following nerve injury

Authors: *C. PAN, Z. YING, S. CHEN, Z. JIANG, F. WANG, X. WANG
Natl. Inst. of Biol. Sciences, Beijing, Beijing City, China

Abstract: Myelin breakdown happens in demyelinating diseases as well as in nerve injury. In demyelinating diseases, aberrant myelin loss is caused by genetic deficiency, infection or autoimmune responses, resulting in reduced transduction efficiency of action potential and axon degeneration. In response to nerve injury, myelin needs to be cleared in time to facilitate axon regeneration. The exact mechanism of the execution of myelin breakdown is unclear in both cases. Unleashing the mechanism of myelin breakdown is crucial for understanding the pathologic mechanism of demyelinating diseases and the regulation of nerve regeneration.
In the current work, we used a model of peripheral sciatic nerve injury to study the mechanism of myelin breakdown. We found that the mixed lineage kinase domain-like protein (MLKL), a protein previously reported to execute necroptosis, executed myelin breakdown following sciatic nerve injury. MLKL expression is induced in Schwann cells after the injury. The rate of myelin breakdown of sciatic nerve in *Mlkl* knockout mice is significantly slower than in wild-type mice. In the presence of nerve injury signal, MLKL is activated through a phosphorylation event on a serine residue in its pseudokinase domain, then inserts into myelin sheath membrane via binding with sulfatide, and finally breaks down the myelin. This MLKL mediated myelin breakdown is necessary for axon regeneration. *Mlkl* knockout mice have a poorer regeneration capability compared with wild-type mice. Overexpression of MLKL in sciatic nerve of wild-type mice can accelerate its functional recovery after injury.

Title: Schwann cell-specific deletion of phosphatidylinositol 4-kinase type IIIα (PI4KA) alters actin dynamics contributing to severe myelination defects in mice

Authors: *A. ALVAREZ-PRATS, Y. KIM, T. BABA, D. ABEBE, T. BALLA
Section on Mol. Signal Transduction. Program for Developmental Neurosci., Eunice Kennedy Shriver NICHD, NIH., Bethesda, MD

Abstract: Myelination is a complex physiological process carried out by specialized Schwann cells (SCs) in the peripheral nervous system (PNS), and several human neuropathies, such as Charcot-Marie-Tooth Disease, show myelination impairment within the PNS. Myelin is composed of a defined mixture of proteins and phospholipids but how SCs regulate and execute their lipid synthetic and distribution programs during myelination are poorly understood. Recent studies have highlighted the critical role of phosphatidylinositol 4-phosphate (PI4*P*) gradients in controlling the non-vesicular transport of several key phospholipids between cellular membranes. Moreover, PI4P, made in the plasma membrane (PM) by phosphatidylinositol 4-kinase type IIIα (PI4KA), also serves as the precursor of the important signaling phospholipids PI(4,5)P_2 and PI(3,4,5)P_3. Both of these lipids are known to regulate cellular movements via controlling actin dynamics, and up-to-date studies have shown that actin plays a crucial role during myelination. We have recently showed that SC-specific deletion of PI4KA in mice affects myelination within the PNS through a mechanism that affects PI4*P* synthesis and transport but appears to spare PI(4,5)P_2 generation and PI(3,4,5)P_3 signaling. Here, we show that deletion of PI4KA in SCs has a major impact on the development of important actin-based structural features of peripheral nerves, including malformation of Schmidt-Lanterman incisures (SLIs) and nodes of Ranvier. Experiments performed in a mouse SC line showed that prolonged inhibition (16 h) of PI4KA with a selective small molecule inhibitor caused a major disruption of actin stress fibers with significant accumulation of the cortical actin cytoskeleton. Remarkably, this phenomenon started to take place as soon as 15 min after the addition of the inhibitor. Genetic inactivation of the kinase, using MEF cells isolated from embryos of our pi4ka-flox mice, also showed major disruption of actin stress fibers and significant accumulation of the cortical actin cytoskeleton. PI4KA inhibition also affected the migration of cultured SCs toward

serum containing media without alteration of the PI3K pathway. Altogether, these data suggest a close direct connection between the activity of PI4KA, actin homeostasis, and myelination of the PNS. To our knowledge, this is the first study to reveal a direct role for PI4KA and PI4*P* in the control of cellular actin dynamics. Ongoing studies are aimed at understanding the molecular basis of the actin regulatory defect and delineating the mechanism by which changes in cortical actin on the expense of stress fibers alter the progression of myelination within the PNS.

Title: The mechanism of central nervous system (CNS) remyelination promoted by circulating TGF-beta

Authors: *H. MACHIKA[1], R. MURAMATSU[1,2], T. YAMASHITA[1]
[1]Mol. Neurosci., Osaka Univ., Suita, Japan; [2]Mol. Pharmacol., Natl. Inst. of Neuroscience, Natl. Inst. of Neurol. and Psychiatry, Kodaira, Japan

Abstract: Remyelination, the reconstitution of myelin sheaths in the CNS, is a process to restore salutatory conduction and promote functional recovery after demyelination. Although remyelination requires oligodendrocyte differentiation, how oligodendrocyte differentiation is promoted is not fully clarified. It is known that blood brain barrier disrupted around the demyelinated lesion sites and circulating blood components leaked out from the vasculature into the CNS. Therefore, in this study, we focused on the circulating blood components as the candidate molecules promoting oligodendrocyte differentiation.
We cultured oligodendrocyte precursor cells (OPCs) obtained from postnatal mice brain in the medium containing adult mice serum and quantified myelin basic protein (MBP) expression which is the constituent protein of myelin. We found that serum increase the MBP expression and assumed that some factors promoting oligodendrocyte differentiation is involved in the adult mice serum. By pharmacological screening, we found that TGF-beta1 in the serum drives MBP expression. Then, we identified that TGF-beta receptor was expressed in mature oligodendrocyte, but not in precursor cells and that TGF-beta receptor deficit from oligodendrocyte suppressed remyelination. We also found that specific depletion of circulating TGF-beta suppressed remyelination. These data suggest that TGF-beta from systemic environment effects on mature oligodendrocytes and promotes remyelination. Furthermore, we observed TGF-beta receptor expression in human oligodendrocytes using the autopsied brain of

multiple sclerosis patients. To confirm whether human oligodendrocytes have TGF-beta sensitivity, we supplied TGF-beta to human oligodendrocytes and then the expression of some myelin related genes were facilitated. Hence, TGF-beta might be common signal in oligodendrocytes differentiation between rodents and human.

Title: Neuroinflammation causes changes to the nodes of Ranvier in multiple sclerosis normal appearing white matter

Authors: *P. GALLEGO DELGADO[1], R. REYNOLDS[1], A. A. FAISAL[2], J. MENG[3], R. JAMES[3], E. BROWNE[3]
[1]Imperial Col. London, London, United Kingdom; [2]Imperial Col. London, London, United Kingdom; [3]Imperial Col., London, United Kingdom

Abstract: In addition to the focal demyelinating lesions that are characteristic of multiple sclerosis (MS), both imaging and neuropathological analyses have demonstrated the presence of a more diffuse pathology in both the white and grey matter, including changes to the structure of nodes of Ranvier in the normal appearing white matter (NAWM). The presence of the tight axo-glial glial junctions of the myelin end loops and the proper clustering of sodium channels (Nav) at the node and potassium channels (Kv1.2) at the juxtaparanode are crucial for fast action potential conduction. In order to study the functional consequences of these nodal changes and to investigate the role of inflammation, we have examined the spatial expression of Caspr1, NF155, Nav, Kv1.2 and SMI32 in NAWM areas from post-mortem progressive MS brains (n=20 cases comprising 34 blocks with 340 NAWM areas) compared to non-neurological controls (n=10 cases comprising 16 blocks with 160 WM areas). To determine axo-glial abnormalities, intensity profiles were measured for each nodal parameter. This axo-geometrical data was then integrated into a computational model of an axon, which was developed with NEURON incorporating published electron-microscopy data from human and macaque brains. To test our hypothesis, rats were injected into the cerebral subarachnoid space with lentiviral vectors for lymphotoxin-α and interferon-γ and nodal changes examined 3 months later. The paranodes in the MS NAWM tissue were 21.7% longer on average than in the control, and associated with stressed axons and

activation of microglia. Moreover, the MS paranodes longer than 5µm were 76.28% more frequent than in the control tissue. In addition, we found a higher proportion of axons in MS NAWM with Kv 1.2 channels dislocated towards the paranode, which correlated with paranodal elongation. When these changes were inserted into the computational model, assuming that the observed increment of paranodal length corresponded to an increment in the peri-axonal space of the paranodal and juxtaparanodal compartments, we observed an exponential decrease in conduction velocity as the paranodal peri-axonal space increases. Furthermore, we predicted a potential conduction failure when the peri-axonal space at the juxtparanode and paranode is increased up to a certain threshold in axons less than 1µm of diameter. The same changes in paranodal length and Kv channel dislocation were observed in the corpus callosum of rats with meningeal inflammation and chronic microglial activation, which points to microglia/astrocyte secretion of cytokines, glutamate and ROS as possible factors that could trigger these changes.

Title: An astrocytic membrane protein, MLC1 inhibits cell motility for stable cell communication

Authors: *J. HWANG, H.-H. LIM
KBRI, Daegu, Korea, Republic of

Abstract: Megalencephalic leukoencephalopathy with subcortical cysts (MLC) disease is a rare type progressive leukodystrophy in children. Mutation of MLC1 mainly lies behind of this disorder leading vacuolation of myelin and astrocyte, subcortical cysts, brain edema, and macrocephaly. Recent studies indicate that functional interactions between MLC1, GlialCAM, and ClC-2 channel is important to regulate neuronal, glial, and vascular homeostatic interactions, however, the physiological role of MLC1 on the cellular communication is poorly understood. Thus, we have been trying to reveal the molecular function of MLC1 on the cell to cell interaction. Expression of MLC1 drastically altered cell morphology; disappearance of lamellipodia and increase in filopodia. Moreover, wound healing assay and live cell time-lapse imaging revealed that cell motility was significantly suppressed by MLC1. These changes in cell morphology and motility seemed to be correlated with altered cellular actin dynamics.

Interestingly, patient-derived MLC1 mutants did not affect cell morphology and motility and the expression pattern of mutants were mainly accumulated in the intracellular organelles. These data suggested that expression of MLC1 on the plasma membrane might change actin dynamics, cell shape and cell motility. Indeed, we found that MLC1 shows heteromorphic intracellular distribution patterns during the course of expression. Plasma membrane-localized MLC1 (PM-MLC1) induced stationary movement, however, intracellular organelle-localized MLC1 (IO-MLC1) showed normal cell motility. These results indicate that MLC1 is important to regulate cell motility and stabilizing cell-cell interaction. In MLC disease patients, misallocation of mutant MLC1 could related with unstable cell communication resulting in disturbed homeostasis of neuro-glia-vascular interaction.

Title: NAA depletion rescues myelin degeneration in the Canavan disease mouse model Aspa^{nur7} but results to hypomyelination and lethality

Authors: *M. TRAKA[1], M. BARNEY[2], B. PARDO[3]
[1]Anat., Midwestern Univ., Downers Grove, IL; [2]Neurol., Univ. of Chicago, Chicago, IL; [3]Mol. Biology, Ctr. for Mol. Biol. Severo Ochoa UAM-CSIC, Autonomous Univ. of Madrid, Madrid, Spain

Abstract: Canavan disease (CD) is a rare autosomal recessive leukodystrophy that is caused by mutations of the aspartoacylase gene (*ASPA*). ASPA is highly expressed in mature oligodendrocytes, where it catalyzes the hydrolysis of the most abundant amino acid in the brain, N-acetyl-aspartate (NAA) to acetate and aspartic acid. ASPA deficiency in CD results in high levels of NAA in the CSF and the urine of the CD patients. The disease pathology is characterized by severe spongiform degeneration of the myelin throughout the CNS that is manifested early postnatally. We previously described the identification of the ENU-induced nonsense mutation, Q193X, in the mouse *Aspa* gene that results in the absence of detectable ASPA protein expression in *Aspa^{nur7}* homozygous mutant mice, which display severe spongy degeneration (vacuolation) throughout the CNS, strikingly resembling CD. Similarly to CD, NAA is increased in the CNS of *Aspa^{nur7}* mutants. New evidence from our lab and others using

the *Aspa*^{nur7} mutants has shown that the mechanism of CD pathogenesis implicates the high NAA levels as a main cause of the myelin degeneration in CD. According to this hypothesis, the CD pathogenesis is caused by ASPA deficiency in mediating NAA clearance in the CNS and thereby protecting myelin and/or oligodendrocytes from NAA damage. This contradicts the other main hypothesis for CD that suggests a role of ASPA in supplying the NAA-derived acetate for myelin lipid synthesis. We generated ASPA-deficient mice that cannot synthesize aspartate and NAA due to a null mutation in the *Aralar/AGC1* transporter gene, the *Aspa*$^{nur7/nur7}$;*Aralar*$^{-/-}$ mice. Although NAA reduction rescues myelin degeneration in the CNS of the double mutants, these mice suffered from a severe, lethal neurological phenotype that is associated with CNS hypomyelination. Our data suggest that although NAA exerts a toxic effect on myelin and/or oligodendrocytes when present at high levels in Canavan disease, it may also play a critical role in supporting CNS myelination during development. To further understand the mechanism of CD pathogenesis, we are currently exploring the molecular pathways that are affected in the CNS of the *Aspa*^{nur7} homozygous mutant mice.

Title: Semaphorin4a causes oligodendrocyte cell death and demyelination

Authors: *B. CHIOU[1], E. LUCASSEN[2], A. KALLIANPUR[3,4], J. R. CONNOR[1]
[1]Neurosurg., [2]Neurol., Penn State Col. of Med., Hershey, PA; [3]Genomic Med., Cleveland Clinic/Lerner Res. Inst., Cleveland, OH; [4]Mol. Med., Cleveland Clin. Lerner Col. of Med., Cleveland, OH

Abstract: Dysregulated myelin production, demyelination, or hypomyelination by oligodendrocytes can lead to a variety of neurological defects, including both motor and cognitive deficits stemming from compromised action potential transmission. One of the primary reasons for irregular myelin deposition may revolve around the direct death of oligodendrocytes, however the causes for this death have yet to be discovered. Deficiency of trophic factors relating to the survival of oligodendrocytes, combined with direct interactions with the immune system, are favored paradigms that are increasingly implicated in demyelinating diseases of the central nervous system. Emerging members of immune-related molecules that have immune-mediated disease properties are proteins of the semaphorin family, such as Semaphorin4A (Sema4A). Implicated in diseases such as rheumatoid arthritis and asthma, the semaphorin family has been shown to be a key component of immune disease progression. We have

previously demonstrated that Sema4A is cytotoxic to rodent and human oligodendrocytes *in vitro*, signaling through the T-cell immunoglobulin and mucin domain (Tim-2) receptor in rodents and Tim-1 in humans. We also demonstrated that H-ferritin, the ubiquitous iron storage and delivery protein, also signals through Tim-1 and can be used to block Sema4A-mediated cytotoxicity. In our current work we demonstrate that intracranial infusion of Sema4A into the corpus callosum of wild-type mice causes robust demyelination coupled with decreased mature oligodendrocytes and increased microglia. These findings suggest Sema4A causes a direct cytotoxic effect *in vivo* on mature oligodendrocytes and that local microglia are responsive to this demyelination as well. Building upon our previous study, we assay for Sema4A in a significantly larger CSF cohort, again demonstrating significantly elevated Sema4A levels in the CSF of patients with altered white matter profiles. Taken together, our current work paired with our published work demonstrates Sema4A to be a significant mediator in the pathogenesis of demyelination and identifies a novel therapeutic targets in the treatment of demyelinating disorders.

Title: Oligodendroglial TNFR2 regulates neuroinflammation and remyelination following CNS disease

Authors: *H. DESU[1], P. MADSEN[3], P. ILLIANO[4], M. PLASTINI[5], J. SHI[5], R. BRAMBILLA[2]
[2]The Miami Project to Cure Paralysis, Dept. of Neurosurg., [1]Univ. of Miami Miller Sch. of Med., Miami, FL; [3]Univ. of Rochester Med. Ctr., Rochester, NY; [4]Miami Project to Cure Paralysis, [5]Univ. of Miami, Miami, FL

Abstract: Tumor Necrosis Factor (TNF) is a pleiotropic cytokine involved in physiological and pathological processes. Among those, TNF has been implicated in the pathophysiology of various neurological disorders, including multiple sclerosis (MS). TNF exists in two forms, transmembrane (tmTNF) and soluble (solTNF), whose cellular effects are dependent upon which

receptor TNF binds to. Due to differing binding affinities, solTNF preferentially binds to TNF receptor 1 (TNFR1) and mediates detrimental processes such as apoptosis and chronic inflammation, while tmTNF preferentially binds to TNF receptor 2 (TNFR2) and mediates protective processes such as cell survival, regulation of inflammation, and remyelination. Our lab has significantly contributed to elucidating the complex role of TNF in CNS autoimmunity. By ablating TNFR2 from all oligodendrocyte lineage cells (CNP-cre:$TNFR2^{fl/fl}$ mice), we showed that TNFR2 promotes remyelination following EAE. Furthermore, CNP-cre:$TNFR2^{fl/fl}$ mice showed exacerbation of the acute phase of EAE, which is mainly driven by immune cell infiltration, suggesting that TNFR2 might play a role in regulating the immune-mediated neuroinflammatory response as well (Madsen et al., 2016). To elucidate the mechanisms through which oligodendroglial TNFR2 regulates remyelination and, possibly, neuroinflammation, we generated PDGFRα-cre^{ER}:$TNFR2^{fl/fl}$:EYFP mice to conditionally ablate TNFR2 in oligodendrocyte precursor cells (OPCs) and induce concomitant expression of EYFP. In the cuprizone model of demyelination, TNFR2 ablation in OPCs resulted in reduced numbers of newly formed myelinating oligodendrocytes once mice were restored to normal diet. This suggests that TNFR2 is important for OPC differentiation into mature oligodendrocytes. Furthermore, in the MOG_{35-55} EAE model of MS ablation of TNFR2 in OPCs resulted in earlier EAE onset and earlier peak disease, suggesting that oligodendroglial TNFR2 may be mediating the process by which peripheral immune cells infiltrate the CNS. Overall, our data point at oligodendroglial TNFR2 signaling as an important pathway in the modulation of neuroinflammation and remyelination in CNS disease, supporting the idea that TNFR2 could be a promising new target for MS therapy.

Title: Role of mitochondrial dysfunction in oligodendrocytes in the etiopathogenesis of multiple sclerosis

Authors: *M. PLASTINI[1], P. MADSEN[3], H. DESU[4], P. ILLIANO[2], C. MORAES[1], R. BRAMBILLA[5]
[2]Miami Project to Cure Paralysis, [1]Univ. of Miami, Miami, FL; [3]Univ. of Rochester Med. Ctr., Rochester, NY; [5]The Miami Project To Cure Paralysis, Dept. of Neurosurg., [4]Univ. of Miami Miller Sch. of Med., Miami, FL

Abstract: While neuronal mitochondrial dysfunction has been clearly implicated in the pathophysiology of multiple sclerosis (MS), the role of mitochondrial dysfunction in oligodendrocytes in MS has not been explored. To investigate this question we generated a mouse model where mitochondrial DNA (mtDNA) double-strand breaks (DSB) can be specifically induced in myelinating oligodendrocytes via the expression of the mitochondrial-targeted endonuclease mtPstI (PLP:mtPstI mice). Using this model, we previously showed that induction of mtDNA DSB causes impairments consistent with an MS-like phenotype, including demyelination and axonal damage (Madsen et al., 2017). Importantly, we demonstrated that mtDNA damage caused oligodendrocytes to undergo cell death. Our current studies are aimed at understanding the mechanisms by which oligodendrocytes die as a consequence of mtDNA damage. Specifically, we are evaluating whether this is directly dependent on impairment of the OXPHOS system or if other mechanisms, such as oxidative damage, are indirectly involved.To assess whether oxidative damage by reactive oxygen species, accumulated due to impaired OXPHOS, is responsible for oligodendrocyte death, we treated mice with the antioxidant N-Acetyl Cysteine (NAC), administered in the drinking water. Preliminary data show that, after 3 months of NAC exposure, treated PLP:mtPstI mice show a trend toward mild locomotor improvement compared to untreated mice. This suggests that oxidative stress might be contributing, at least in part, to oligodendrocyte death.Furthermore, to better characterize the pathological hallmarks of our PLP:mtPstI model, we performed flow cytometric studies to quantify the presence of immune cells in the CNS of induced PLP:mtPstI mice at 2 and 6 months of age. We observed an increased presence of B cells, neutrophils and macrophages in the spinal cord and cerebellum of PLP:mtPstI mice at 2 months. At 6 months B cells were still elevated in the CNS of PLP:mtPstI mice. This indicates that primary oligodendrocyte death elicits a secondary immune response, which can in turn participate in further damaging the CNS, in line with the “intrinsic hypothesis” of MS. As a result, our PLP:mtPstI mouse model not only can help shed light on the consequences of mitochondrial dysfunction in oligodendrocytes, but also proves a useful tool to model chronic demyelinating disease, hence serving as a platform for testing remyelinating therapies.

Title: A molecular characterisation of meningeal inflammatory infiltrates in progressive multiple sclerosis

Authors: *R. REYNOLDS[1], L. FUENTES-FONT[1], C. GLOVER[2]
[1]Imperial Col. London, London, United Kingdom; [2]MedImmune PLC, Cambridge, United Kingdom

Abstract: The presence of lymphoid-like immune cell aggregates in the leptomeninges is suggested to promote damage to the cerebral cortex and play a role in accumulating disability in multiple sclerosis. To explore the molecular mechanisms that drive their formation, cryosections were cut from five cortical blocks per case from 55 SPMS and 14 control brains. Meningeal tissue was dissected and RNA extracted. Affymetrix HTA 2.0 GeneChips were used to obtain the meningeal transcriptome and gene expression determined using R package Limma. Differentially expressed genes with FC>2 and FDR>0.05 were used to perform gene set enrichment analysis using WebGestalt and gene networks constructed using R package WGCNA. When comparing controls with highly inflamed MS cases, alterations were mainly found in expression of homing chemokines and receptors and in cytokines that enhance B cell survival, proliferation and antibody and IFNγ production, such as IL10, IL18, PPBP, CXCR4, HSPA7, XBP1, CS1 and CD27. Modifications in genes involved in the development of lymphatic vessels (LYVE1) and cell motility, survival and antigen presentation (HLA-B) were prominent. Functional pathway analysis identified significant involvement of pathways associated with *Th17, Th1/Th2 cell differentiation, haematopoietic and lymphoid organ development, cell adhesion and leukocyte migration.* Gene network analysis revealed 5 network modules whose eigengenes were highly correlated with disease status and lymphocytic infiltration. Functional enrichment yielded a list of functions, including cell adhesion, protein folding and pro-inflammatory processes. Subsequent to microarray data analysis a panel of 55 inflammatory genes was chosen for validation by TaqMan OpenArrays. Highly significant, strong and moderately strong, correlations were found between the TaqMan and Affymetrix data for most individual genes, providing robustness to our meningeal transcriptomics data. We have identified molecular cues that are likely to mediate meningeal inflammation in MS that suggest a dysregulation of pathways that are critical for B-cell trafficking and recruitment into the CNS.

Title: Pericyte deficiency leads to fibrin(ogen)-dependent white matter demyelination and axonal degeneration

Authors: *A. M. NIKOLAKOPOULOU[1], A. MONTAGNE[2], Z. ZHAO[3], A. P. SAGARE[4], D. LAZIC[2], Y. WANG[5], B. V. ZLOKOVIC[6]

Abstract: White matter damage is a characteristic of a plethora of neurodegenerative diseases, such as Alzheimer's disease (AD) and Multiple Sclerosis (MS). Pericytes play an important role in sustaining blood brain barrier (BBB) permeability and cerebral blood flow (CBF), while they participate in the clearance of toxic byproducts. Pericyte loss has been implicated in BBB breakdown, neuronal degeneration, cognitive impairment, inflammation, synaptic loss and has negative effects on CBF. In this study, we used *Pdgfrβ*$^{F7/F7}$ mice to examine the effects of pericyte deficiency on white matter integrity, and more specifically, in the corpus callosum. Our data show that pericyte deficiency leads to early BBB leakage, which precedes demyelination and axonal degeneration; at very early stages in adulthood (4wks old) animals present accumulation of blood byproducts (IgG and fibrin), however they show no defects in myelin and axonal integrity yet. Adult *Pdgfrβ*$^{F7/F7}$ mice (12-16wks old) exhibit a decrease in myelin thickness, as shown by electron microscopy, and a reduction in axonal and myelin-related protein expression, both of which deteriorate with aging. Furthermore, these animals exhibit behavioral deficits related to white matter damage. Previous studies have shown that hypoxia can

induce coagulation and thus the formation of fibrin deposits, events that are responsible for oligodendrocyte death. Our in vitro oligodendrocyte studies show that fibrin accumulation causes autophagy-induced mature oligodendrocyte death, hence implying that the events following BBB leakage are responsible for myelin destruction. To strengthen our results, we show that fibrinogen depletion can restore myelin integrity and reverse axonal damage. Taken together, our results show that pericyte deficiency causes BBB leakage at very early stages, followed by myelin destruction and axonal degeneration, thus emphasizing the importance of the neurovascular unit in health and disease.

Title: The expression and role of CCN3 during central nervous system development and remyelination

Authors: *N. DE LA VEGA GALLARDO[1], R. G. PENALVA[1], J. FALCONER[1], J. MOFFAT[1], M. NAUGHTON[1], Z. LIN[2], B. PERBAL[3], R. INGRAM[1], D. C. FITZGERALD[1]
[1]Queen's Univ. Belfast, Belfast, United Kingdom; [2]Emory Univ. Sch. of Med., Atlanta, GA; [3]Univ. Côte d'Azur, Nice, France

Abstract: Multiple sclerosis is a demyelinating disease of the central nervous system (CNS) usually diagnosed in young adults and is characterised by immune-mediated destruction of myelin-producing oligodendrocytes. Whereas there is a plethora of disease modifying therapies to reduce relapses, there are currently no available treatments to boost myelin repair. Regulatory T cells (Treg) are necessary for murine remyelination to occur efficiently *in vivo*. Treg-secreted CCN3 promotes oligodendrocyte differentiation and developmental myelination in murine brain slice cultures and is expressed in both the rodent and human brain. These findings identify CCN3 as a candidate of interest in CNS development and regeneration and therefore we aim to investigate the expression and role of CCN3 during these processes.
CCN3 was detected in murine CNS tissue at a range of ages during postnatal development of C57BL/6 mice. CCN3 did not co-localise with $GFAP^+$ astrocytes or $Olig2^+$ cells of the oligodendrocyte cell lineage but did co-localise with NeuN, identifying neurons as the main

source of CCN3 in these studies. Major sites of CCN3 expression in the forebrain included the cerebral cortex, hippocampus and the suprachiasmatic nuclei. To investigate CCN3 expression during demyelination and remyelination, 11 week old, C57BL/6, male mice were fed with the demyelinating agent cuprizone. In addition to described CCN3 expression patterns in healthy adults, CCN3 was also detected in the septal nuclei during demyelination as well as concurrent and subsequent remyelination. To date, it is unknown whether CCN3 is actively involved in myelin regeneration in this model or whether this expression was a response to stress. Furthermore, the cellular or structural source of this CCN3 is currently unknown and under investigation. To study the role of CCN3 in spinal cord remyelination, 10 week old, $CCN3^{-/-}$ and $CCN3^{+/+}$, male mice were injected with lysolecithin toxin in the ventral white matter of the spinal cord. Crucially, there was no difference in the mean lesion size between genotype groups. This demonstrates a comparable burden of damage to resolve in these groups, validating this as a suitable system to study the effects of CCN3 on oligodendrocyte differentiation and remyelination in the spinal cord *in vivo*. Ongoing work is examining whether CCN3 is required for efficient remyelination in the CNS, and whether lack thereof affects myelin wrapping both in the brain and spinal cord. These studies could hold promise for the development of CNS regenerative therapeutics as well as advancing knowledge in the fields of myelin biology and CCN proteins.

Abstract: Background and Objective:
Contactin-1 is a glycosylphosphatidylinositol (GPI)-anchored neuronal surface glycoprotein, which is located at the axonal side of the paranode and belongs to the immunoglobulin superfamily. The protein interacts with the contactin associated protein 1 (Caspr) on the axonal

side and with neurofascin-155 (NF155) on the glial side of the nerve fiber. The complex of these three proteins is required for the proper formation of the paranodal junction, which separates nodal voltage-gated sodium channels from juxtaparanodal voltage-gated potassium channels. In the last few years, autoantibodies to contactin-1 have been reported in some patients with inflammatory neuropathies. They all showed common clinical features like acute symptom onset, predominantly motor involvement and relapsing-remitting disease progression. This form of neuropathy is often associated with sensory ataxia and tremor. As binding of autoantibodies to dorsal root ganglia (DRG) neurons may cause sensory ataxia, we investigated the effects of contactin-1 autoantibodies on sodium currents of DRG neurons in order to study their pathogenesis.

Methods:

Primary neurons were isolated and cultivated from DRGs of adult mice. After one day in culture, currents of voltage-gated sodium channels were measured by patch clamp recordings in a whole-cell configuration mode. Following an incubation of the DRG neurons with serum of patients harboring autoantibodies to contactin-1 in comparison to serum of healthy controls, effects of this treatment on sodium currents were analyzed. Performing immunocytochemical stainings after each measurement ensured the binding of patients' autoantibodies to the primary neurons.

Results:

Immunocytochemistry showed strong and specific binding of patients' autoantibodies to DRG neurons. By contrast, no specific binding to DRGs was detected in binding assays with sera of healthy controls. Regarding electrophysiological measurements, first results indicate that DRGs which were treated with serum of patients who harbor autoantibodies to contactin-1 show lower sodium current densities in comparison to neurons which were incubated with serum of healthy controls.

Conclusions:

Preliminary results showed decreased sodium currents of DRG neurons that were treated with autoantibodies to the neuronal surface protein contactin-1. This indicates a pathogenic effect of the autoantibodies. In summary, our data will help to understand the biological mechanism of contactin-1 autoantibodies in patients with inflammatory neuropathies.

Title: Glial cell responses in CNS demyelination and myelin repair

Authors: *G. SAMTANI[1], D. R. MICHAUD[2], K. KONGANTI[3], S. J. KIM[2], J. LI[2]
[1]Texas A&M Inst. for Neurosci., College Station, TX; [2]Dept. of Vet. Integrative Biosci., Texas A&M Univ., College Station, TX; [3]Texas A&M Inst. for Genome Sci. and Society, College Station, TX

Abstract: Myelin, the lipid-enriched sheath enwrapping axons, is critical for the normal function of the nervous system. Loss of myelin or myelin-producing oligodendrocytes in the central nervous system (CNS) contributes to neurological disorders and age-related neurological decline. The promotion of remyelination and axon protection via oligodendrocyte precursors in the adult CNS presents an attractive therapeutic strategy, as these cells persist throughout the lifespan. However, our understanding of the myelin repair process after a demyelinating insult remains limited. In this study, we utilized an autoimmune-independent experimental mouse model of CNS demyelination to investigate glial cell functions during myelin repair. To facilitate direct visualization of myelin, transgenic mice expressing membrane-anchored EGFP in mature oligodendrocytes (CNP1-mEGFP) were used. Adult mice were fed 0.2% cuprizone diet for 2, 5, and 12 weeks, representing the early, acute, and chronic phases of demyelination. Remyelination was investigated in mice returned to normal diet for 1-2 weeks after 5 weeks of cuprizone intoxication or 4-8 weeks after 12 weeks of intoxication. Cuprizone intoxication induced oligodendrocyte apoptosis, microglial activation, astrogliosis and demyelination in a temporal and spatial fashion in the adult brain. After cuprizone withdrawal, spontaneous remyelination ensues rapidly after acute demyelination. Although remyelination was less efficient after chronic demyelination, significant remyelination was achieved following 4-8 weeks of recovery in both the corpus callosum (CC) and cortex. Myelin debris, determined by neural lipid staining, was abundant in chronic demyelinating lesions and disappeared as remyelination progressed. Immunohistochemical analysis revealed many autophagy conjugate LC3-II-decorated vesicles in the CC after chronic demyelination. While some LC3-II vesicles were EGFP+ and colocalized to microglia, many were not and were EGFP-, suggesting aberrant autophagy activities in axons. Immunostaining of non-phosphorylated Neurofilament H showed significant axonal damage that persisted even after 8 weeks of recovery. Transcriptome profiling of the corpus callosum at early phases of demyelination and remyelination revealed activation of multiple immune and signaling pathways, including extracellular matrix, actin cytoskeleton remodeling, and cell adhesion for myelin repair. Together, our data demonstrate dynamic glial responses during demyelination and remyelination, and also suggest that persistent axonal damage due to chronic demyelinating insults may underlie remyelination failure.

Title: Remodeling of GABAergic innervation may contribute to cortical hyperexcitability and seizures in chronically demyelinated mice

Authors: *A. S. LAPATO[1], C. R. JONAK[2], K. LAUDERDALE[2], D. K. BINDER[3], S. K. TIWARI-WOODRUFF[4]
[1]Univ. of California Riverside Sch. of Medic, Riverside, CA; [2]Univ. of California Riverside, Riverside, CA; [3]Univ. of California Riverside Div. of Biomed. Sci., Riverside, CA; [4]Univ. of California Riverside Sch. of Med., Riverside, CA

Abstract: Background Epileptic seizures are estimated to be up to six-fold more prevalent among multiple sclerosis (MS) patients than the population overall. However, while seizures are more common in MS patients and predict significant morbidity & mortality, epileptogenesis in MS remains poorly understood. Objective To identify functional and cytoarchitectural changes potentially etiologic to demyelination-induced seizures using the cuprizone (CPZ) diet model of MS. Methods 8-week-old male C57BL/6 mice were fed 12 weeks of 0.2% CPZ diet (12wkCPZ; n=8) or standard chow (normal; n=7). *Multielectrode array (MEA) EEG:* 30-channel MEA probes were positioned bilaterally over the dorsal surface of the skull and oscillation frequency power was analyzed. *Immunohistochemistry:* myelination, axon pathology, and GABAergic cells were assessed in sagittal sections at ~ ML +1.5 mm. *Electrophysiology:* field inhibitory postsynaptic currents (fIPSCs) were recorded in the presence of NBQX and AP5. Results 12wkCPZ mice displayed generalized seizures and increased EEG power vs normal mice. Medial areas demonstrated the most dramatic increase across multiple frequency bands and was the only cluster to exhibit greater power in the 30-100 Hz range. Along with significant loss of myelin, SMI-32+ varicosities were observed in commissural fiber tracts. Cortical GAD65/67+ area was reduced in 12wkCPZ mice, while GAD65/67+ staining was increased in rostral white matter, suggesting GABAergic remodeling. 12wkCPZ mice displayed numerous parvalbumin (PV)+ projections between the cortex and striatum that were not seen in normal mice. Cortical fIPSCs were reduced in slices from 12wkCPZ mice while stimulation of striatal PV+ projection fibers evoked altered fIPSCs in 12 wk CPZ mice. Conclusions Neural excitability, pathology of white matter commissural axons, plasticity of PV+ innervation, and aberrant GABAergic transmission between cortical and subcortical areas likely contribute to demyelination-induced

seizures. Planned longitudinal MEA recordings will help expose pathophysiology leading to initiation of seizures and its associated changes to regional connectivity, remodeling of inhibitory circuitry, and attending cellular/molecular substrates.

Title: Cortical cell-type differences at baseline in the presence of Cx deficiency

Authors: *S. KEIL[1], M. FREIDEN[1], C. ABRAMS[2]
[2]Neurol. and Rehabil., [1]Univ. of Illinois Chicago, Chicago, IL

Abstract: Glial cells of the central nervous system (CNS) express several different connexins (Cx). These connexins are integral membrane proteins that form gap junction channels and provide a low resistance pathway for the diffusion of small molecules and ions between coupled cells. The mutation or deficiency of oligodendrocytic Cx32 and Cx47 has been linked to the disease states X-linked Charcot-Marie-Tooth disease (CMT1X) and Pelizaeus-Merzbacher-Like disease 1 (PMLD1), respectively. With recent data suggesting this deficiency effects both inflammatory and immune response pathways, this experiment investigates how the disruption of Cx32 and Cx47 effects the central nervous system, with the goal of parsing out potential differences in microglial populations. Utilizing immunolabeling we examined presence of oligodendrocytes, astrocytes and microglia in Cx32KO, Cx47KO, and mutant mice when compared to wild-type controls. The results continue to support and highlight the critical role connexins play within the central nervous system and implicates further investigation into therapeutic targets.

Title: Region specific changes in gliosis following reduced extracellular vesicle release in the twitcher mouse model of Krabbe disease

Authors: *C. R. REITER[1], D. WOZNIAK[3], J. MARSHALL[2], G. SCESA[2], I. GIVOGRI[2], E. R. BONGARZONE[2]

Abstract: Here we have studied the potential of extracellular vesicles (EVs) released within the Twitcher mouse brain to induce pathology, considering whole brain cellular interactions and individual cell type contributions. Krabbe Disease (KD) is a monogenetic lysosomal storage disorder caused by mutations in the gene encoding galactosylceramidase (GALC). Loss of this lysosomal enzymatic activity causes accumulation of a toxic sphingolipid, galactosylsphingosine (psychosine). Accumulation of psychosine has long been hypothesized to drive the observed pathology in KD patients, which includes oligodendrocyte and Schwann cell cytotoxicity, astrogliosis, microglial activation and the presence of abnormal globoid cells throughout diffusely demyelinating white matter. Extracellular vesicles (EVs) are secreted by most all mammalian cells to facilitate intercellular communication in healthy and pathologic states. Release of vesicles occurs by traditional exocytotic machinery (exosomes) or membrane shedding events (microvesicles). EVs have been shown to provide a vast array of communication signals via membrane proteins and lipids, as well as nucleic acid cargos such as microRNA. We have found EVs with elevated levels of psychosine in the Twitcher (Twi) mouse model of KD; this study aims to understand the pathologic role of psychosine-laden EVs. We hypothesize that EVs contribute to the observed pathology in KD by two intertwined mechanisms; vesicular release serves as a mechanism to preserve individual cell survival by unloading excess lipid, and these EVs induce pathology in distant cells through the spread of psychosine toxicity. To test these hypotheses, we optimized a treatment regimen utilizing a Sphingomyelinase 2 inhibitor (GW4869), which has been demonstrated to reduce exosome and microvesicle release by depleting ceramide pools. The inhibitor or DMSO vehicle were injected intraperitoneally every other day from postnatal day (P) 10 until P20 or P40 in 6 total mice per treatment group, each comprised of 3 males and 3 females. Disease scores were tracked during the treatment period and showed increased severity in treated mice. EV populations were reduced in treated mice and consequently more psychosine was associated with cellular fractions. Immunohistochemical analysis identified region specific increases in astrocytosis and microglial activation. *In vitro* cultures of each glial subtype have been established to determine which cellular populations release and/or receive EVs. These findings will elucidate which cell types lead to psychosine-induced pathology and highlight the contributions of vesicles to observed cytotoxicity.

Title: A co-ultramicronized palmitoylethanolamide/luteolin composite mitigates clinical disability score and disease-relevant molecular markers in a mouse model of experimental autoimmune encephalomyelitis

Authors: *S. D. SKAPER, G. CONTARINI, L. FACCI, M. BARBIERATO, D. FRANCESCHINI, M. ZUSSO, P. GIUSTI
Pharmaceut. & Pharmacol. Sci., Univ. of Padua, Padua, Italy

Abstract: Multiple sclerosis (MS) is the prototypical inflammatory disease of the CNS, whose defining feature is destruction of myelin. MS is the most frequent cause of chronic neurological impairment in young people. The autoimmune nature of the disease has led to the development of therapeutic strategies based on immunosuppressants, immunomodulators, and monoclonal antibodies. In spite of the noteworthy gains in treating MS, these agents do not necessarily ensure repair or target oligodendrocytes (OLs), the myelin-producing cells of the CNS. MS lesions are characterized by a pool of undifferentiated oligodendrocyte precursor cells (OPCs) which fail to mature into myelin-producing OLs. A co-ultramicronized composite of N-palmitoylethanolamine (PEA) and the flavonoid luteolin (co-ultraPEALut, 10:1 by mass), which possesses analgesic, anti-inflammatory, and neuroprotective is efficacious in improving outcome in several CNS injury models. Co-ultraPEALut also promotes OPC differentiation in vitro. Experimental autoimmune encephalomyelitis (EAE), based on active immunization with myelin oligodendrocyte glycoprotein (MOG35-55) in female C57BL/6 mice was used to study the effects of co-ultraPEALut on clinical outcome and expression of disease-relevant markers. Co-ultraPEALut, given intraperitoneally daily starting on day 11 post-immunization (initiation of disease onset) dose-dependently improved clinical score over the range 0.1-5 mg/kg. Cerebellar signs/symptoms and cognitive dysfunction contribute to MS clinical disability. Further, medulla oblongata volume is considered a valid biomarker of spinal cord damage/disability in MS. For gene expression profiling in medulla oblongata and cerebellum, mice were treated daily with 5 mg/kg co-ultraPEALut starting the second day post-immunization. We observed time-dependent increases over a 21-day period in markers for inflammation cytokines, chemokines, serum amyloid A, inducible nitric oxide synthase and the NLRP3 inflammasome, along with glial cell activation. Markers characteristic of immune system activation in MS (CD4, MCP-1, CD137)

were also elevated. Timing varied as a function of the gene studied, with values generally being low at 7 days, and either peaking at 14 days and/or remaining elevated through 21 days post-immunization. Treatment with co-ultraPEALut reduced the enhanced expression of a number of these genes. Strategies intended to promote remyelination in MS should focus on both enhancing long-term survival of OPCs and stimulating these cells to differentiate into remyelinating OLs. Within this context, co-ultraPEALut may represent a novel pharmacological approach.

Title: Selective estrogen receptor modulators significantly enhance remyelination in an estrogen receptor-independent manner

Authors: *K. RANKIN[1,1], F. MEI[1], Y.-A. SHEN[1], S. R. MAYORAL[1], C. DESPONTS[2], D. LORRAIN[2], C. CORDANO[1], S. BARANZINI[1], A. GREEN[1], J. R. CHAN[1], R. BOVE[1]

Abstract: Multiple Sclerosis is a neurologic disease characterized by widespread demyelination with subsequent degeneration of axons. Remyelination of these axons has been widely proposed as a key therapeutic target to reverse clinical disability associated with disease progression. Utilizing the screening technique binary indicant for myelination using micropillar arrays (BIMA), we identified selective estrogen receptor modulators (SERMs) as a cluster that enhances oligodendrocyte precursor cell (OPC) differentiation and subsequently promotes remyelination. In particular, we have identified Bazedoxifene (BZA) as a potent agent of OPC differentiation and subsequent remyelination. BZA stands out, as not only is it FDA-approved, but has proven extremely tolerable in clinical trials.
When administered to both human and rat OPCs, BZA significantly enhanced OPC differentiation *in vitro*. In co-cultures, BZA promoted OPC differentiation and myelination of

axonal substrates. Across multiple models of demyelination, we found that BZA significantly enhanced remyelination and accelerated the kinetics of repair. As a SERM, BZA was developed to differentially agonize/antagonize the nuclear estrogen receptors α and β (ERα and ERβ). Based on conflicting results of various SERMs on OPC differentiation, we sought to validate BZA's target. To this end, OPCs from total ERα and ERβ knockouts, as well as double ER-knockouts were isolated and cultured. We measured significantly enhanced OPC differentiation across all knockout models, suggesting that in contrast to the existing literature, nuclear ERs are not necessary for BZA, as well as other SERMs, to promote differentiation. In a focal demyelination model in wild-type and ER-double knockout mice, all mice treated with BZA displayed significant improvements in remyelination when compared with vehicle-treated mice. Using an exciting new bioinformatics method, we have identified potential candidate targets for SERMs' robust effects on OPC differentiation and remyelination, and work to narrow down the receptor is well underway.

Title: Overcoming CSPG-mediated inhibition of remyelination by targeting PTPσ in experimental models of multiple sclerosis

Authors: *S. R. BADEA[1], H. SUN[2,4], J. HUANG[1,3], W. WU[5,1]
[1]Sch. of Biomed. Sci., The Univ. of Hong Kong, Hong Kong, Hong Kong; [2]Sch. of Biomed. Sci., The Univ. of Hong Kong, Hong Kong SAR, China; [3]State Key Lab. of Brain and Cognitive Sci., The Univ. of Hong Kong, Hong Kong, Hong Kong; [4]Zhujiang Hosp. Dept. of Neurosurg., Southern Med. Univ., Guangzhou, China; [5]GHM Inst. of CNS regeneration, Jinan Univ., Guangzhou, China

Abstract: Introduction: Changes in chondroitin sulphate proteoglycans (CSPGs) following neural injury or as part of a neurodegenerative process lead to the inhibition of myelin repair**.** Multiple sclerosis (MS) is an autoimmune disease of the central nervous system (CNS) characterized by inflammation-induced destruction of the myelin sheath that surrounds axons, with focal demyelinated lesions distributed across multiple locations throughout the CNS. In MS,

CSPGs are deposited at the border of active and expanding demyelinating lesions, and may create a barrier for migration and repopulation by oligodendrocyte progenitor cells (OPCs). CSPG inhibition of axonal regeneration is partially mediated by the protein tyrosine phosphatase sigma (PTPσ) receptor. PTPσ is also the main player of CSPG inhibition of oligodendrocyte (OL) outgrowth and myelination. Intracellular sigma peptide (ISP), a newly developed membrane permeable peptide binds to PTPσ and relieves CSPG-mediated inhibition has been used to promote regeneration after spinal cord injury. Identification of PTPσ as a functional receptor for CSPGs in oligodendrocytes presents a promising avenue of investigation to rescue OL activity and promote recovery in demyelinating lesions.
Aim: We hypothesize that *in vitro* CSPG-mediated inhibition of OPCs can, at least partially, be overcome by blocking receptor PTPσ, leading to improved remyelination and functional recovery.
Methods: OL precursor cells were seeded on coverslips spotted with CSPGs. Cytotoxicity was determined using LDH assay, whereas proliferation was quantified by population doubling. Different stages of the oligodendroglial lineage, as well as CSPG presence, OL migration in the inhibitory zone and PTPσ expression, were determined using immunocytochemistry. Experimental autoimmune encephalomyelitis was induced in female C57BL/6J mice and functional recovery was assessed following daily ISP (10μM) injection over 28 days. Remyelination was assessed by histological staining and electron microscopy.
Results: ISP did not cause significant cell death, but at higher concentrations affected cell adhesion and led to cell detachment. Proliferation and differentiation were not inhibited. ISP treatment of OPCs led to increased migration and proliferation in the CSPG-coated areas. ISP-treated mice showed a decreased microglial presence, reduced cellular infiltrates and increased remyelination and functional recovery, without influencing the expression of CSPGs.

Abstract: Diffusion tensor imaging (DTI) can detect white matter microstructural changes, the pathological nature of which can be validated by histological assessments. As most clinical trials use brain imaging parameters to assess therapeutic success, we wanted to investigate the ability of DTI to resolve remyelination and neuroprotection following estrogen receptor β ligand Indazole chloride (Ind-Cl) treatment in the cuprizone (CPZ) diet model of MS. Adult C57BL/6J male and female mice received 9 weeks of normal diet (normal), 9 weeks CPZ diet (9wkDM), 9 weeks CPZ with 2 weeks normal diet + vehicle (RM+V), or 9 weeks CPZ with 2 weeks normal diet + Ind-Cl (RM+Ind-Cl). *In vivo* and *ex vivo* DTI data were acquired to derive quantitative tissue microstructure measures in the corpus callosum (CC). Fractional anisotropy (FA), axial and radial diffusivity (AD and RD) were compared to immunohistochemistry (IHC). A decrease in FA and an increase in RD, but not AD in DM groups was observed in both *in vivo* and/or *ex vivo* DTI as compared to normal mice. An increase in FA and a decrease in AD and RD was observed in RM+Ind-Cl as compared to RM+V groups reflective of remyelination and improved axonal health only *ex vivo*. In conclusion, DTI imaging is sensitive to demyelination and remyelination and can serve as a valuable translational tool to assess MS pathophysiology. However, standard DTI acquisitions may not be sufficiently sensitive to measure demyelination and remyelination changes as observed with immunohistochemistry, necessitating the utilization of advanced imaging methods.

Abstract: Multiple sclerosis (MS) is characterized by demyelination and axonal injury/degeneration. Demyelinated axons are thought to be more susceptible to degeneration, due to exposure to the inflammatory environment and metabolic stress. Promoting remyelination therefore is a promising therapy, as it might mitigate axonal loss. As opposed to pharmacological therapies, diet-based treatments have fewer side-effects. Ketogenic diet (KD) (high in fat, adequate in protein, while very low in carbohydrates) increases ketone body production and decreases inflammation, which is thought to facilitate remyelination. KD is currently being used clinically for some treatment-resistant epilepsy, but its efficacy in MS models is unknown. Our objective is to assess the effects of KD on remyelination efficacy and oligodendrocyte differentiation in the cuprizone/rapamycin (cup/R) model of demyelination. We hypothesize that KD will promote oligodendrocyte differentiation and increase remyelination as compared to standard diet (SD). We bred transgenic mice carrying membrane-bound green fluorescent protein (mGFP) under the tamoxifen-inducible platelet-derived growth factor receptor α (PDGFRα) promoter (PDGFRα-CreER^{T2}::ROSAmT/mG) (to label new myelin). Demyelination was induced by feeding the mice 0.3% cuprizone (in the diet) for 6 weeks which was accompanied by rapamycin injections 5 times a week (6w-cup/R). The treatment group received ketogenic diet (KD) throughout, while the control group received standard diet (SD). Rotarod behavioral analysis was conducted throughout. Animals were sacrificed at 9 days after cessation of 6w-cup/R and immunohistochemical analysis was conducted. KD improved rotarod recovery and caused an increase in CC1 expression (indicative of increased oligodendrocyte differentiation). Tissue samples are currently being analyzed for new myelination (i.e. mGFP+ sheaths) and myelin pathology (i.e. demyelination, myelin decompaction, etc.) as well as mitochondrial function and axonal survival.

Title: Overexpression of glutathione S transferase 4 alpha regulates OPC proliferation, differentiation and their capacity to remyelinate

Authors: *K. CARLSTROM, F. PIEHL, 17176
Dept. of Clin. Neurosci., Stockholm, Sweden

Abstract: Demyelination is a process in which axon-surrounding myelin is lost due to genetic, toxic or inflammatory mechanisms. In Multiple sclerosis (MS), this is a cause of an autoimmune reaction against the myelinating oligodendrocytes. Following degradation of myelin, oligodendrocyte precursor cells (OPCs) will differentiate into myelin producing cells and remyelinate intact axons. Glutathione S transferase 4 alpha (Gsta4) have an essential role in clearance of 4-hydroxynonenal (HNE), a highly reactive and toxic aldehyde. HNE is generated from unsaturated lipids during oxidative stress, where oligodendrocytes are particularly vulnerable due to their high lipid content and the increased oxidative pressure during their differentiation and remyelination. In this study we have examined the effect of introducing an overexpression construct containing the Gsta4 gene. We show that Gsta4 will influence downstream genes involved in oligodendrocyte differentiation and regulate differentiation of OPCs *in vitro*. We show that Gsta4 is also important in a clinically relevant disease model of MS; experimental autoimmune encephalomyelitis, where overexpressing animals recover faster and show less demyelination in spinal cord compared to wt. Further, we detected greater number of differentiated oligodendrocytes in Gsta4 overexpressing animals compared to wt after lysolecithin injections, causing transient demyelination in the corpus callosum. No differences in OPC proliferation were seen. Histological and electron microscopy analysis after injections confirmed a higher degree of remyelination in overexpressing animals versus wt. Phenotyping with RNAseq of intermediate oligodendrocytes suggest crucial signaling pathways are affected by Gsta4 and levels of HNE. As an example Gsta4 overexpressing OPCs have altered Wnt-signaling key players such as Axin2 and Tankyrase, suggesting that they are more prone to differentiate compared to wt OPCs. In conclusion, we provide evidence that Gsta4 and oxidative mechanisms could be of importance for OPCs' capacity to proliferate, differentiate and for their ability to remyelinate, both in an inflammatory and non-inflammatory disease model.

Title: Loss of Schwann cell connexin32 regulates iNOS and tyrosine nitration

Authors: *M. FREIDIN[1], F. QARNI[2], C. K. ABRAMS[3]
[1]Neurol., Univ. of Illinois At Chicago, Chicago, IL; [3]Neurol. & Rehabil., [2]Univ. of Illinois at Chicago, Chicago, IL

Abstract: X-linked Charcot–Marie–Tooth disease (CMT1X) is an inherited peripheral neuropathy associated with mutations in GJB1, the human gene for Connexin32 (Cx32). Defects in gap junction communication alone does not appear to fully account for the role of Cx32 in myelinating glial cells. Recent studies demonstrate roles for connexins in the regulation of cell growth, apoptosis, and cellular stress signaling that are independent of functional gap junction channels. Microarray studies from our lab comparing gene expression in sciatic nerves from wild-type (WT) and Cx32-knockout (Cx32KO) identified significant regulation of genes in the mitochondrial inflammatory/stress pathways. Preliminary data show elevation of NO and mitochondrial stress in Cx32KO Schwann cells (SCs) compared to WT along with increases in downstream protein (tyrosine) nitration. We hypothesize that loss or mutation in Cx32 predisposes SCs to dysregulation of mitochondrial stress pathways, resulting in activation of nitric oxide. We examined the regulation and relative levels of NOS isoforms (NOS1-3) in WT and Cx32KO SCs and sciatic nerves. NOS2 (iNOS) levels were increased in Cx32KO samples, along with labeling for nitro-tyrosine (nitro-Tyr). Cx32 has been shown to confer resistance to cellular injury and cell death under toxic conditions where gap junctions played no part. Stimulation of cellular stress by treatment with H2O2 upregulated iNOS and nitro-Tyr in WT but had limited effects in Cx32KO SCs; further suggesting that loss or disruption of Cx32 activates a self-reinforcing positive feedback loop involving dysregulation of NOS and mitochondrial stress pathways.

Title: Involvement of astrocyte monocarboxylate transporter 1 in mouse models of demyelination

Authors: *T. PHILIPS[1], J. D. ROTHSTEIN[2]
[1]Dept. of Neurology, Brain Sci. Inst., [2]Brain Sci. Inst., Johns Hopkins Univ., Baltimore, MD

Abstract: In the CNS, astrocytes provide trophic support to neighboring neurons, eg by ion and glutamate buffering and promoting axonal outgrowth during neuronal development. Upon neuronal injury, astrocytes become ‘reactive’: they express a whole plethora of neuro-immunomodulatory factors that will either have benign or detrimental influences on the surrounding neurons. One of the trophic functions exerted by astrocytes is the release of lactate through so-called monocarboxylate transporters (MCTs) of which MCT1 and MCT4 are expressed by astrocytes. MCTs allow the transfer of lactate from cells to the extracellular space from which neurons can take up lactate through their MCT subtype MCT2. Neurons will then use lactate as an energy metabolite to fuel their own ATP demands. It has been suggested that this astrocyte derived lactate is essential for long term memory formation in rats and could promote recovery upon ischemic injury in mice. In these studies, the true glial source of lactate remained elusive as lactate could also be provided by other glial cells. In fact, a role for MCT1 in oligodendrocytes has been suggested as loss of oligodendrocyte MCT1 leads to axonal injury. In order to fully understand the cell specific importance of MCT1 under normal physiological conditions as well under conditions of CNS injury, we have generated conditional MCT1 null mice in which MCT1 exon2 is inserted in between two loxP sites. Upon crossing with GFAP-Cre mice, we obtained very efficient knock-out of MCT1 specifically in astrocytes but not in oligodendrocytes or neurons. To our surprise, loss of MCT1 in astrocytes was well tolerated with no significant pathological or behavioral changes observed in these animals up to the age of one year. Motor skills as well as different learning skill paradigms were unaffected upon knock-out of MCT1 in astrocytes. Interestingly, MCT1 expression was significantly upregulated in mouse models of neuro-injury that were characterized by astrogliosis. MCT1 upregulation was not a consequence of non-specific upregulation of common astrocyte markers, eg GFAP, nor was it affected by a pro-inflammatory astrocytic reaction (A1-astrocytosis). Astrocyte MCT1 upregulation was concomitant with injury to the myelin sheath that enwraps axons to ensure fast action potential conduction. MCT1 upregulation was most notable during the late stages of demyelination while remyelination is ongoing. This striking upregulation of MCT1 in models of demyelination now sheds light on an exciting and novel role of MCT1 in neuro-injury, which could be a novel target for future oligodendrocyte and neuronal repair upon demyelinating injury.

Title: Hyperdirect pathway activation by DBS: An intraoperative ECoG study using paired pulses

Authors: *H. C. WALKER[1], M. AWAD[2], B. L. GUTHRIE[2], A. NAKHMANI[4], C. L. GONZALEZ[2], Z. T. IRWIN[3]
[1]Neurol., UAB, Birmingham, AL; [3]Neurol., [2]Univ. of Alabama at Birmingham, Birmingham, AL; [4]Electrical & Computer Engin., Univ. of Alabama At Birmingham, Birmingham, AL

Abstract: Directional DBS shows great promise for Parkinson's disease (PD) and other neuropsychiatric disorders; however, the increased number of stimulation contacts greatly complicates device activation and adjustment. Our previous EEG findings suggest that DBS evokes both short and long latency neural oscillations in sensorimotor cortex and that different patterns of cortical activation might distinguish effective versus ineffective stimulation sites within an individual. Here we sought to spatially localize these potentials and validate their neural origin with electrocorticography (ECoG) during DBS surgery. In five PD subjects, we placed an ECoG strip across the central sulcus during subthalamic DBS surgery and delivered bipolar stimulation at therapeutic settings. Stimulation was delivered in paired pulses with 90 different inter-stimulus intervals ranging from 0.18 to 30 ms to examine the latency, spatial distribution, and absolute and relative refractory periods of putative cortical activation by DBS. Similar to prior EEG studies, we observed robust short (R1) and long latency (R2/R3) cortical activation over both M1 and S1. R1/R2/R3 collectively displayed absolute and relative refractory periods of 0.59 ± 0.20 ms and 1.70 ± 1.02 ms, respectively (mean ± SD). At our level of statistical power, there were no significant differences between M1 and S1 in R1 latency (0.43 ± 0.15 versus 0.60 ± 0.26 ms, p = 0.29, unpaired t-test) or amplitude (3.5 ± 1.9 versus 3.6 ± 3.8 μV, p = 0.98), though amplitudes were more consistent in M1 versus S1 across subjects. Similarly, there were no significant differences in R2/R3 onset latency (1.9 ± 0.6 versus 3.3 ± 2.4 ms; p = 0.30), but R2/R3 amplitude was significantly larger in M1 versus S1 (11.5 ± 5.9 versus 3.1 ± 2.6 μV; p = 0.04). Our ECoG findings validate the neural origin of cortical potentials elicited by STN DBS and suggest that they involve at least M1 and S1 ipsilateral to the DBS electrode. Stimulus-evoked activity shows considerable promise as a predictive biomarker to guide both directional and closed loop DBS and to better understand systems-level interactions between DBS and cortical motor circuits in humans.

Title: Investigation of non-invasive predictors for outcome during DBS surgery for PD

Authors: *M. AWAD[1], C. L. GONZALEZ[2], A. NAKHMANI[3], Z. IRWIN[2], B. L. GUTHRIE[4], H. C. WALKER[2]
[1]Electrical Engin., Univ. of Alabama at Birmingham, Hoover, AL; [2]Neurol., [3]Electrical Engin., [4]Neurosurg., Univ. of Alabama at Birmingham, Birmingham, AL

Abstract: Background: Although deep brain stimulation (DBS) improves motor symptoms, we lack fundamental knowledge about how it modulates brain circuits. Better understanding the electrophysiology of DBS could guide surgical targeting, postoperative programming, and closed loop stimulation. Our goal was to contrast stimulus-evoked electrophysiology elicited by subthalamic nucleus (STN) DBS at effective versus ineffective stimulation contacts, and to evaluate whether stimulus-evoked activity might serve as a biomarker to inform targeting during "asleep" DBS surgeries.
Materials and Methods: We examined event-related potentials (ERPs) elicited by STN DBS in 11 participants. As part of routine care, patients underwent electrode targeting while awake followed by pulse generator connection one week later under total intravenous anesthesia (TIVA). Stimuli were delivered in a randomized block design from the DBS lead during both surgical procedures with an external pulse generator with a range of voltages between 0 and 8.0 V in 0.5 V increments. ERPs were recorded using EEG electrodes placed on the scalp around the sterile field. Relevant clinical outcomes including UPDRS change and therapeutic window were correlated with the stimulus-evoked scalp electrophysiology.
Results: DBS elicits scalp ERPs regardless of the anesthesia state with both short (R1) and longer (R2 and R3) latency potentials. R1 was preserved to a greater extent under TIVA versus the later components of the response (R2 & R3). Regardless of anesthesia state, we found especially short R1 latencies at motor-adverse corticospinal tract stimulation sites (~500 μsec). Long latency responses under TIVA were often markedly attenuated (present in only 5/11 participants, 45.4%) or delayed (40.7 ± 1.0 versus 30.8 ± 0.7 ms, $t=7.87$, $p<0.001$) versus awake. Receiver operating characteristic (ROC) curves indicate that R1 latency can predict postoperative motor side effects versus sites without motor side effects (AUC = 83.6% awake and 75.6% under sedation).
Conclusions: Regardless of anesthesia state, DBS at adverse corticospinal / corticobulbar

stimulation sites elicits shorter latency R1 responses, whereas stimulation at clinically effective sites elicits more delayed, variable R1 timing. These findings suggest that stimulus evoked scalp electrophysiology can detect clinically meaningful interactions between DBS and specific motor sub-circuits within inidividuals. Given its resilience to sedation, short latency cortical activation shows promise as a predictive biomarker to guide DBS targeting under general anesthesia.

Title: Anodic stimulation misunderstood: Application of anodic stimulation for preferential activation of fiber orientations in deep brain stimulation

Authors: *D. N. ANDERSON[1], G. DUFFLEY[2], J. VORWERK[3], A. D. DORVAL[2], C. R. BUTSON[3]
[2]Dept. of Bioengineering, [3]Scientific Computing & Imaging Inst., [1]Univ. of Utah, Salt Lake City, UT

Abstract: Classically, extracellular cathodic stimulation has been used in deep brain stimulation (DBS) for therapeutic benefit. It is widely agreed that cathodic stimulation causes activation of passing axons, however the role of anodic stimulation on activation of axons is less understood. We hypothesize that anodic stimulation can preferentially target neurons based on fiber orientation and anodic stimulation can be used for therapeutic benefit.
We used bioelectric field models and multicompartment NEURON models to explore preferential activation of neurons using anodic and cathodic stimulation. We explored neuron activation trends based on fiber orientation in a clinical scenario, DBS for Parkinson's disease. Tractography for the hyperdirect pathway, associated with clinical benefits, and internal capsule, associated with side effects, was generated using Diffusion Tensor Imaging (Fig. 1A).
We found that the hyperdirect pathway (oriented orthogonal to lead) was activated by anodic stimulation at lower thresholds than by cathodic stimulation. Activation thresholds of the internal capsule (vertically passing the lead) were increased with anodic stimulation (Fig. 1B). In this clinical scenario, anodic stimulation widened the therapeutic window of DBS as fiber pathways

associated with clinical benefit had 50% lower activation thresholds while activation thresholds for fiber pathways associated with side effects increased. Anodic stimulation preferentially activates fibers approaching or leaving the electrode at lower thresholds.

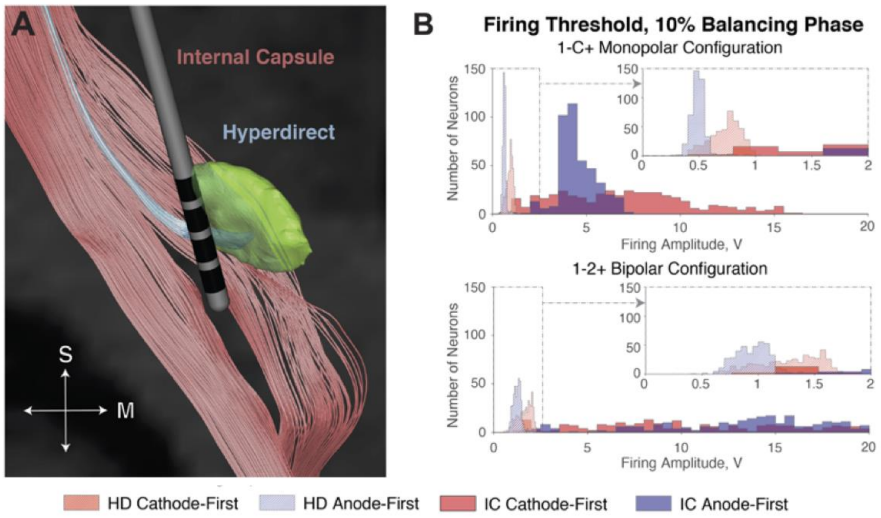

Figure 1. **a.** Visualization of the hyperdirect and internal capsule with respect to the DBS lead. **b.** Firing threshold histograms for hyperdirect and internal capsule tracts given cathodic and anodic stimulation. Anodic stimulation reduces the threshold voltage of orthogonally oriented fibers (hyperdirect), but increases the threshold of passing fibers (internal capsule), which widens the therapeutic window.

Title: Effect of deep brain stimulation (DBS) on spinal cord circuitry in Parkinson's disease

Authors: J. ANDREWS[1], F. ROY[1], *T. SANKAR[2], F. BA[3], R. B. STEIN[4]
[1]Surgery, [2]Neurosurg., [3]Neurol., Univ. of Alberta, Edmonton, AB, Canada; [4]Physiol., Univ. Alberta, Edmonton, AB, Canada

Abstract: Parkinson's disease (PD) is a progressive neurodegenerative disorder of the central nervous system affecting up to 10 million people worldwide. Much has been published on changes in cortical motor areas in PD, including the relationship between these changes and the cardinal PD symptoms of bradykinesia, tremor, rigidity, and postural instability. Relatively few studies have focused on pathways within the spinal cord in PD, a key area of output from cortical/supraspinal centers. For the present study, we focused on the effect of descending input from transcranial magnetic stimulation (TMS) on inhibitory reflex circuits within the spinal cord in 9 people with PD being treated with both parkinsonian medication and Deep Brain Stimulation (DBS). We compared these results to 10 age-matched controls. A subthreshold TMS pulse was used to condition a soleus Hoffmann (H)-reflex, an electrically evoked analog of the stretch reflex, to look for potential alterations in reflex mechanisms. Testing was completed under four different treatment conditions 1) OFF treatment (i.e., without medication and DBS turned off); 2) ON medication only; 3) ON DBS only, and 4) ON medication/ON stimulation (i.e., with both treatments active). Motor symptoms in each condition were quantified using Part III of the Unified Parkinson Disease Rating Scale (UPDRS) and correlated with electrophysiological measures. In control subjects, the inhibition of an H-reflex when conditioned by subthreshold TMS delivered 2 ms after peripheral nerve stimulation, was maximal and the H-reflex was reduced to 76 ± 6% of an unconditioned test H-reflex. Note that at this interval, the descending input from TMS would precede the segmental input to the motor neuron pool, thus providing a conditioning effect on the H-reflex. In contrast, in PD OFF treatment, inhibition was reversed, and the H-reflex reached 128 ± 22% of a test response ($P < 0.05$), with the decrease in inhibition correlated with an elevated (i.e., worse) UPDRS-III motor score ($r = 0.68$; $P < 0.05$). When both treatments were ON, inhibition was maximally restored toward control levels (82 ± 11%; $P = 0.67$), and motor symptoms were similarly diminished relative to OFF treatment ($P < 0.05$). The reappearance of inhibition suggests a cumulative effect of both treatments, which tended to be stronger than when medication (90 ± 10%; $P = 0.27$) or DBS (93 ± 13%; $P = 0.29$) were applied separately**.** This research may contribute to improved understanding of changes in spinal cord circuitry that accompany treatment in PD. In particular, these objective neurophysiological measures may help to optimize medication and DBS therapy aimed at countering motor disability in people with PD.

Title: The subthalamic nucleus is differentially modulated by vocalization and limb movement

Authors: *R. KELLEY[1], K. TJADEN[2], D. M. CORCOS[3], J. D. GREENLEE, M.D.[4]
[1]Univ. of Iowa, Iowa City, IA; [2]Univ. at Buffalo, Buffalo, NY; [3]Dept. of Physical Therapy/Human Movement, Northwestern Univ., Chicago, IL; [4]Dept Neurosurg, Univ. Iowa, Iowa City, IA

Abstract: Deep brain stimulation of the subthalamic nucleus (STN-DBS) exacerbates Parkinson's disease-related vocal motor deficits in select patients. The mechanism behind this is unclear. Few studies have directly compared the role of the STN in vocalization and limb motor activity. To address this question, we recorded neuronal activity form 44 dorsolateral STN single units in 13 intraoperative STN-DBS patients as they performed vocal and limb motor tasks. Patients were instructed to either repeatedly vocalize a syllable (/ɑ/ or /tɑ/) or tap their index finger on the side ipsilateral to an STN recording electrode. Neuronal modulation during vocalization and limb movement was significantly different around both the start ($p = 0.0045$) and end ($p = 0.018$) of performance blocks. Electrode depth and laterality within the dorsolateral STN did not significantly correlate with neuronal modulation. Electrode position along the anterior-posterior axis showed a slight trend towards significance ($p = 0.19$). Differential patterns of neuronal modulation can be detected in intraoperative STN-DBS patients and may help predict susceptibility to STN-DBS-induced vocal motor impairment. These findings aim to address a major complication in STN-DBS for Parkinson's disease.

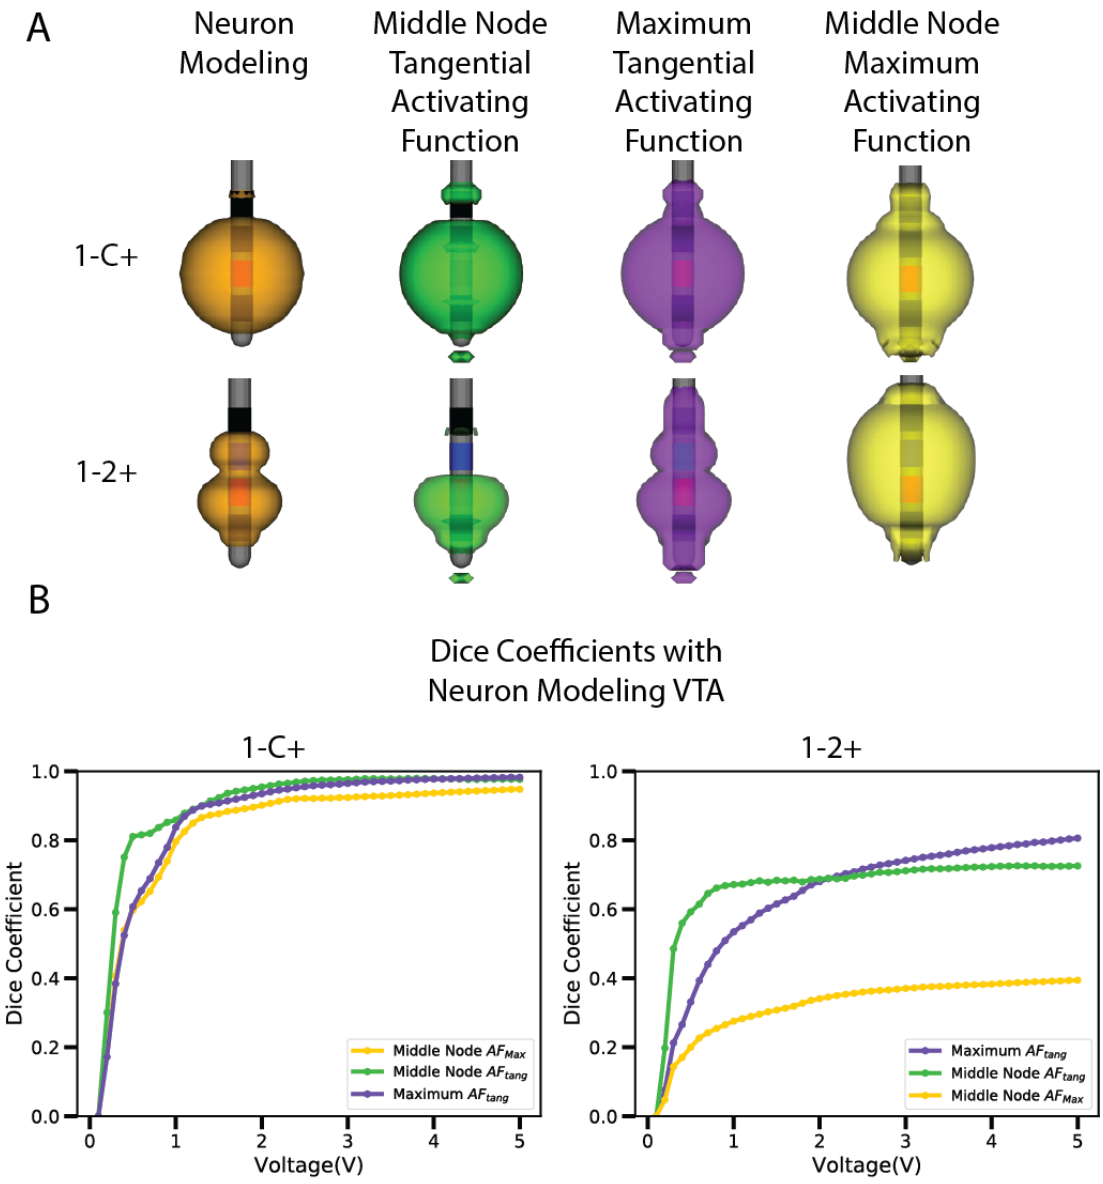
Title: The activating function based volume of tissue activated: An axon orientation and projection independent method for predicting neural activation by deep brain stimulation

Authors: *G. DUFFLEY[1], D. N. ANDERSON[2], J. VORWERK[2], A. D. DORVAL[3], C. R. BUTSON[4]
[1]Bioengineering, [3]Dept. of Bioengineering, [4]Scientific Computing & Imaging Inst., [2]Univ. of Utah, Salt Lake City, UT

Abstract: The volume of tissue activated (VTA) is the spread of activation caused by deep brain stimulation. Computational models of the VTA have been used for a variety of clinical and research applications. Classically, the VTA is calculated by determining activation thresholds for a grid of multicompartment axon models tangential to the electrode in response to electric potential derived from bioelectric field models. The activating function, which is the second spatial derivative of extracellular voltage along an axon, is a known predictor of neuronal activation. In this study, we will demonstrate how the matrix of second spatial derivatives of extracellular potential, the Hessian matrix, can be used to calculate the VTA without the orientation and projection bias of the standard method.
We compared the activation volumes from the standard VTA to three activating function based metrics: middle node tangential activating function, maximum tangential activating function, and middle node maximum activating function, as derived from the primary eigenvalue of the Hessian matrix. We used NEURON models to establish the relationship between the activating function and axon activation. We used our calculated threshold values to create volumes of our three metrics for comparison with the standard VTA (Fig 1A).
All three of our methods matched the standard VTA for monopolar stimulation, but only the maximum tangential activating function matched for bipolar. The maximum tangential activating function matches the NEURON models because it considers the off-centered nodes that are the sites of action potential initiation of the NEURON models located near the anodic contact. In bipolar stimulation, the middle node maximum activating function predicts a much larger volume because it considers all orientations of fibers, some of which are much more excitable compared to the tangential fibers used in the standard VTA. The maximum activating function, as derived from the Hessian, better predicts activation because it considers all possible fiber orientations.



A) Surfaces generated by our four methods for the Medtronic 3389 DBS electrode at 3.0V amplitude, 90µs pulse width, and medium impedance. B) The dice coefficients of overlap between the NEURON modeling results and the three Hessian-based metrics. Overall, all monopolar simulation methods have high overlap. With bipolar stimulation, maximum tangential activating function performs best, and maximum activating function predicts a larger volume of activation.

Title: Hand movement and therapeutic deep brain stimulation differentially modulate cross regional pallidocortical phase amplitude coupling in Parkinson's disease

Authors: *M. MALEKMOHAMMADI[1], N. AUYONG[2], A. O'KEEFFE[2], N. POURATIAN[2]
[1]Los Angeles, CA; [2]UCLA, Los Angeles, CA

Abstract: ***Introduction:*** Multiple lines of evidence suggest that beta band (13-25 Hz) hypersynchrony, including pallidocortical coherence and cortical phase amplitude coupling (PAC), contribute to the pathophysiology of Parkinson disease (PD) and are suppressed by therapy; such as deep brain stimulation (DBS). In our previous work, we have shown that in addition to local cortical PAC, subcortical-cortical PAC (between thalamus and cortex) exists and encodes functional connectivity. In this work, we aimed to explore the pallidocortical PAC to better understand network synchrony. Our working hypothesis is that this hypersynchronized state results in basal ganglia binding and thereby inhibiting normal motor cortical function. ***Methods:*** We recorded local field potentials (LFPs) from pallidum and ipsilateral sensorimotor cortices through a non-penetrating electrocorticography (ECoG) strip in twenty-two subjects with PD undergoing pallidal DBS implantation surgery. Data was recorded during DBS-OFF condition while subjects alternated between a 30-second block of rest and contralateral hand movement (finger tapping). In a subset of nine subjects, similar recordings were obtained during DBS-ON condition. We measured effects of movement and stimulation on interregional beta-broadband gamma (50-200 Hz) PAC. ***Results:*** Pallidocortical beta-broadband gamma PAC was statistically significant across the cohort and is spatially specific to the motor cortex. This coupling was maximal at 22.64±6.74 Hz (high beta) and correlated with symptoms of rigidity and bradykinesia (Rho = 0.68 P= 0.02). Contralateral hand movement and pallidal stimulation significantly suppressed the pallidocortical PAC (P=0.015 and 0.03, respectively). With movement, the frequency of maximal coupling remained unchanged (P=0.1). However, with therapeutic stimulation, the frequency of maximal coupling shifted to the low beta range (18.21±5.38 Hz). While movement related suppression of PAC was correlated with changes in local pallidal beta power (R2 = 0.7, P=0.03), stimulation did not demonstrate this correlation (R2 = 0.03, P=0.6). ***Conclusions:*** Pallidal (phase)- motor cortical (amplitude) PAC in the high beta range reflects the severity of bradykinesia and therapeutic stimulation suppresses this coupling

independently of changes in local pallidal power. These findings provide further evidence of the role of high beta rhythms in exaggerated network level synchrony in PD.

Title: Longitudinal relationships between deep brain stimulation electrode impedances and local field potential recordings in the subthalamic nucleus

Authors: *A. KOVACH-BRINDA[1], A. DOYLE[2], L. WILMERDING[3], J. KRIEG[3], M. JOHNSON[3]
[2]Neurosci., [3]Biomed. Engin., [1]Univ. of Minnesota Twin Cities, Minneapolis, MN

Abstract: Physiological features of local field potentials (LFPs) recorded through deep brain stimulation (DBS) leads hold promise for both identifying therapeutic stimulation configurations and driving neural feedback for closed-loop DBS applications. Studies leveraging LFPs in these contexts have performed these measurements intraoperatively, in an acute phase within days of DBS lead implantation, and in a chronic setting after the electrode-tissue interface surrounding the DBS lead has stabilized. In this study, we tracked the longitudinal dynamics of resting-state LFP signals in the subthalamic nucleus (STN) following implantation of an STN-DBS lead in a non-human primate (macaca-mulatta, 17 yo, female). In conjunction with these recordings conducted over a two-week post-implant period, electrochemical impedance spectroscopy measurements were also collected in parallel. Electrode site impedances significantly decreased from a few hours of implantation to 24 hours post-implant (paired, two-sided Wilcoxon signed-rank test, p=0.03, n=6). Despite these impedance changes, there were non-significant changes in the spectral power of beta band LFP oscillatory activity. Between time periods of putative vasogenic edema (e.g. days 1-2) and putative cellular edema (e.g. day 7-9), DBS electrode site impedances significantly increased in magnitude (paired, two-sided Wilcoxon signed-rank test, p=0.03, n=6) . Over this period, beta band oscillation peak spectral power significantly increased (Mann-Whitney U, p=0.04, n=6). These results suggest that the spectral power of beta-band oscillations is relatively weak in the peri-implant stage as compared with the chronic, post-

implant stage in which electrode site impedance magnitude has significantly increased. The results also suggest that while site impedances and LFP spectral power may not correlate, explicitly, electrochemical impedance spectroscopy can be helpful in relating electrode-tissue interface dynamics to interpretation of LFP recordings.

Abstract: Deep brain stimulation (DBS) is a well-established therapy for the motor symptoms of advanced Parkinson's disease (PD) and other neurological disorders. The subthalamic nucleus (STN) is a widely used DBS target and has been proven clinically effective. However, the mechanisms underlying the therapeutic effects of STN-DBS for PD remain less understood. Here we used an opsin (Chronos) with ultrafast dynamics that is able to follow high-frequency DBS, expressed under the control of calcium/calmodulin-dependent protein kinase II (CaMKII) promoter packaged into an adeno-associated virus serotype 5 (AAV5) to generate local cell specific expression in the STN in our rat model of PD. We quantified the behavioral effects of optogenetic DBS of the STN on parkinsonian motor symptoms including circling behavior and forelimb adjusting steps. We recorded single unit activity and local field potential to evaluate changes of neural circuit activity during cell specific optical stimulation in the STN of urethane anesthetized rats (1.2g/kg, subcutaneous). We found that optogenetic stimulation of STN local cells at 130Hz reduced pathological circling behavior, in contrast to previous results with the much slower channelrhodopsin-2 opsin. Importantly, optogenetic DBS of STN exhibited a strong dependence on stimulation frequencies; high frequency DBS (75, 100, 130Hz) relieved ipsilateral turning while low frequency (5Hz and 20Hz) DBS was not effective. In addition, optogenetic DBS at 130Hz in the STN corrected the bias for using the unimpaired forepaw in

forelimb stepping, while low frequency (20Hz) DBS was not effective. High frequency (130Hz) optogenetic stimulation transiently increased or decreased the neural activity in the STN, globus pallidus externa (GPe) and substantia nigra pars reticular (SNr), with more neurons activated in STN and more neurons inhibited in SNr. As well, high frequency stimulation disrupted beta band oscillatory activity in the STN. Together, our results indicated that high frequency optogenetic stimulation of STN local cells was more effective than low frequency stimulation at reducing pathological rotational behavior and improving abnormal stepping. High frequency optical stimulation resulted in modulations of neuronal firing patterns in the STN-associated neural circuit.

Title: Evaluating the robustness of fiber pathway activation with deep brain stimulation directional and multiple-electrode designs

Authors: *A. JANSON[1], D. N. ANDERSON[2], C. R. BUTSON[3]
[1]Scientific Computing and Imaging Inst., Salt Lake City, UT; [3]Scientific Computing & Imaging Inst., [2]Univ. of Utah, Salt Lake City, UT

Abstract: Clinical outcomes for patients with DBS are highly variable and two critical factors underlying this variability are where and how stimulation is applied. Variability in lead placement for the same target across a patient cohort has also been observed along with computational modeling that has demonstrated how minor variations in lead location and the shape of the electric field can lead to drastic variations in the effects of stimulation. The objective of this study was to evaluate the ability of new directional electrode designs and multielectrode configurations to robustly activate target fiber pathways, with computer simulations, in order to gain insights about how DBS targeting can be improved to handle uncertainty. Our hypothesis is that the use of new directional-steering electrodes or multiple electrodes can compensate for the observed variability in lead placement with respect to the intended target and provide more robust control over fiber activation compared to current cylindrical electrode designs. This means an electrode design or configuration is robust if it is able to provide acceptable stimulation from its contacts to maximally activate the target fiber pathway in scenarios where its location with respect to the target may vary. We found no major

differences in the ability to activate the target fiber bundle for any of the single lead geometries as the lead was placed farther away from the target, but that the use of two DBS leads in close proximity was able to maintain a higher percentage of fiber activation. We anticipate this study will create a framework to assess the benefit of new stimulation technologies and how they can be used to compensate for the observed variability in lead locations.

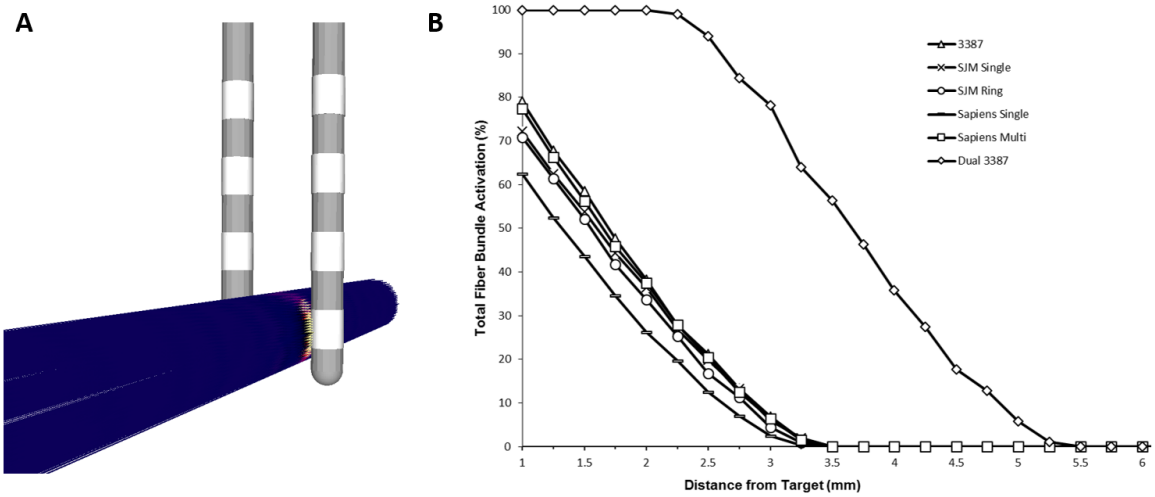

Figure 1. **(A)** Simulation setup with two Medtronic 3387 DBS leads spaced 3.75 mm apart surrounding the target fiber bundle. **(B)** Evaluation of percent fiber bundle activation as lead location distance from target is varied for several DBS lead geometries and the dual lead configuration with amplitude held constant at 1 V.

Abstract: In Parkinson's disease (PD), subthalamic nucleus beta band oscillations are decreased by therapeutic deep-brain stimulation (DBS) and this has been proposed as important to the mechanism of therapy. The globus pallidus is a common alternative target for PD with similar motor benefits as subthalamic DBS, but effects of pallidal stimulation in PD are not well studied, and effects of pallidal DBS on cortical function in PD are unknown. Here, in 20 PD and 14 isolated dystonia human patients of both genders undergoing pallidal DBS lead implantation, we recorded local field potentials from the globus pallidus and in a subset of these, recorded simultaneous sensorimotor cortex ECoG potentials. PD patients had elevated resting pallidal low beta band (13-20 Hz) power compared with dystonia patients, whereas dystonia patients had elevated resting pallidal theta band (4 - 8 Hz) power compared with PD. We show that this results in disease-specific patterns of interaction between the pallidum and motor cortex: PD patients demonstrated relatively elevated phase coherence with the motor cortex in the beta band and this was reduced by therapeutic pallidal DBS. Dystonia patients had greater theta band phase coherence. Our results support the hypothesis that specific motor phenomenology observed in movement disorders are associated with elevated network oscillations in specific frequency bands, and that DBS in movement disorders acts in general by disrupting elevated synchronization between basal ganglia output and motor cortex.

Abstract: High frequency (≥ 130 Hz) deep brain stimulation (DBS) of the subthalamic nucleus (STN) is an effective treatment for motor symptoms of Parkinson's disease (PD), but is limited by stimulation-induced side effects and partial efficacy. There is a need for an approach which more selectively targets pathological activity while using less electrical current. Exaggerated oscillatory activity in the beta frequency range (12-30 Hz) that can be detected in single basal ganglia neurons and local field potentials (LFPs) has been found to correlate with akinetic/rigid motor symptoms. Importantly, the ability of DBS to reduce pathological beta oscillations is predictive of its effectiveness at reducing these symptoms. We hypothesized that stimulating at a specific phase of the beta oscillation would reduce the amplitude of the oscillation, potentially improving efficacy and efficiency. To test this, low amplitude stimulation (0.5 – 2 mA) near the peak beta frequency was delivered, while recording STN unit activity, LFPs, and EEG simultaneously, in ten patients undergoing surgery for implantation of DBS leads. A novel recording setup, where stimulation was delivered dorsal to the STN, resulting in modulatory effects within the STN as well as the cortex, allowed us to better resolve signals without significant corruption by stimulus artifacts. By analyzing the natural drift in the timing between the stimulation and the ongoing beta oscillation, we demonstrate that for each patient there is a specific phase relationship that, if maintained over multiple cycles (> 2), favors suppression of the local oscillation amplitude, unit beta synchronization and cortico-subthalamic synchronization. After five consecutive pulses at this suppressing phase, the beta amplitude was reduced by 47%, similar to the 50% reduction seen previously using high frequency stimulation (130 Hz). However, in comparison to high frequency stimulation, amplitude suppression was achieved by delivering a stimulus pulse every 50-67 milliseconds instead of every 8 milliseconds and using lower stimulus amplitudes. Unlike phase dependent suppression, amplification was not dependent on the number of consecutive pulses, and resulted in weaker effects (4.7-35.5% amplification). Stimulation pulses led to variable multiphasic responses in STN neurons, suggesting that oscillations were suppressed in the absence of a consistent excitatory or inhibitory effect on spiking. Our findings provide the first evidence for phase dependent suppression of beta oscillations in PD and suggest stimulation timed to the ongoing oscillation could reduce pathophysiological activity with greater selectivity.

Title: Fractional anisotropy within the subthalamic nucleus: An imaging biomarker for early Parkinson's disease? A high-resolution 7Tesla magnetic resonance imaging study

Authors: *R. PATRIAT[1,2], J. KAPLAN[2], J. NIEDERER[2], S. A. HUFFMASTER[3], M. PETRUCCI[3], N. HAREL[2], C. D. MACKINNON[3]

Abstract: The search for imaging biomarkers of Parkinson's Disease (PD) has predominantly been focused on measures of the substantia nigra (SN), often with mixed or contradictory results. Few studies have investigated the subthalamic nucleus (STN). The STN is a small basal ganglia structure that is difficult to visualize using a common MRI scanner (1.5T or 3T). Most researchers only have access to "one-size-fit-all" templates, which is a particularly inadequate model for small and varying structures, such as the STN. This could explain why no study has reported fractional anisotropy (FA) differences between PD patients and controls within the structure. 7Tesla (7T) MRI enables viewing the boundaries of the STN, thus making possible analysis at the individual level.
In this study, we used high-resolution 7T MRI to study whether characteristics of the STN, such as its volume and FA, can be used as a biomarker for PD. 7T MRI data were acquired for 30 subjects with early PD (age=64±7yr, 13F, disease duration=2.1 ± 2.0yr) and 22 healthy controls (age=55±16yr, 7F). T2 images (400μm in-plane resolution) were used to manually segment the STN of each subject. Further, diffusion images (1.25mm isotropic) were corrected for distortion, motion, and eddy current effects and FA maps were generated. Finally, FA values were averaged over the left and right STN of each subject separately (STN-FA). The STN volumes and FA values were analyzed between groups and post-hoc analyses were performed within the PD group.

No significant differences in the number of male and female participants were found between the two groups (p=0.60) but a significant difference was found in age between the two groups (p=0.02). Across all subjects, the STN volumes were 116 ± 23 mm^3 for the left STN and 117 ± 24 mm^3 for the right STN, which is consistent with those reported in the literature. STN volume was significantly smaller in PD patients compared to controls ($p<0.05$). In PD patients, smaller STN volumes were associated with higher the UPDRS motor scores ($p<=0.05$). An ANOVA analysis, controlling for STN volumes, showed that the PD group had decreased FA values in the left and right STN compared to controls (corrected $p<=0.01$).
This abstract reports novel findings including a correlation between motor symptoms and STN volume as well as a significant decrease in STN-FA bilaterally compared with controls. Taken together, the volume and FA changes suggest that neurodegenerative changes in the structure of the STN can occur early in disease and the extent of the change impacts the expression of motor impairment.

Title: Closed-loop algorithm for optimizing deep brain stimulation in parkinson's disease using an objective measure of rigidity

Authors: *K. H. LOUIE[1], M. N. PETRUCCI[2], P. J. TUITE[2], T. I. NETOFF[1], C. D. MACKINNON[2], S. E. COOPER[2]
[1]Biomed. Engin., [2]Neurol., Univ. of Minnesota, Minneapolis, MN

Abstract: Background: Deep brain stimulation (DBS) of the subthalamic nucleus (STN) or globus pallidus (GP) can dramatically improve the cardinal motor signs of Parkinson's disease (PD). Programming of stimulation settings is done through a trial-and-error process that is time-consuming and it is often uncertain if optimal settings have been attained. The process is further impeded by the use of somewhat subjective clinical ratings to assess the severity of motor signs. In this project, we explored the feasibility and efficacy of a closed-loop strategy that used a Bayesian optimization algorithm in combination with an objective measure of rigidity to rapidly converge upon the stimulation frequency that optimally reduces rigidity.
Materials and Methods: Rigidity was measured in five participants with GP (n = 2) or STN (n = 3) stimulators at stimulation frequencies between 10-185 Hz (increments of 5 Hz) while keeping the contact, amplitude, and pulse width at their clinical optimized settings. The participant's forearm was passively moved through pronation and supination for 20s by a robotic manipulandum to quantify rigidity. Data at each tested frequency was used post-hoc in a simulation of the Bayesian optimization algorithm. Feasibility and efficacy of the Bayesian optimization algorithm was evaluated through two comparisons: the number of frequencies to test and the minimum rigidity found.
Results: Preliminary data suggest that the algorithm can converge to a frequency within 12-15 iterations as opposed to 36 iterations (the necessary amount of iterations to explore all frequencies). The Bayesian optimization algorithm converged to the minimum rigidity measured in 4 of the participants. In one participant, the algorithm converged to a rigidity value that was 103% of the minimum rigidity measured.
Conclusions: The data suggest that the time to achieve optimization of one DBS parameter may be reduced by 60% with the Bayesian optimization algorithm. Ultimately, this approach could significantly decrease the amount of time spent optimizing multiple DBS parameters and lead to a more immediate improvement of quality of life for PD patients.

Title: Effects of dietary amino acids on parkinson's disease-related phenotypes in a LRRK2 *Drosophila* model

Authors: *V. G. CHITTOOR, I. MARTIN
Neurosci., Oregon Hlth. and Sci. Univ., Portland, OR

Abstract: Parkinson's Disease (PD) is a neurodegenerative disease which affects locomotor abilities from the loss of dopamine neurons in the brain. Mutations in LRRK2 (leucine-rich repeat kinase 2) are a common cause of familial PD and a subset of sporadic cases. The most common pathogenic G2019S mutation enhances the kinase activity of LRRK2 leading to an increase in bulk protein translation in the brains of *Drosophila melanogaster*. This aberrant protein translation contributes to the age-related loss of dopaminergic neurons and locomotor deficits observed in G2019S LRRK2 transgenic flies. Protein translation is critically regulated by dietary amino acids, through the TORC1 (target of rapamycin complex 1) pathway. To test if mutant LRRK2-associated phenotypes can be modulated through amino acids, transgenic flies were fed throughout adulthood with synthetic diets comprising of different amino acid levels. Here we found that low and high amino acid diets, within a defined range, result in better retention of dopamine neurons and motor function in aged G2019S LRRK2 flies. Concomitantly, there is a reduction in protein translation in mutant LRRK2 flies on these altered diets. Thus, our study shows a clear correlation between dietary amino acids modulation and mutant LRRK2-associated PD-phenotypes, using a fly model.

Col. of Med., Seoul, Korea, Republic of

Abstract: Abnormal deposition of a-synuclein and neuroinflammation are key contributors to the pathogenesis of Parkinson’s disease (PD) and other synucleinopathies such as Dementia with Lewy bodies and Multiple system atrophy. In PD and related disorders, α-synuclein aggregates

are released from neurons inducing activation of microglia, a brain resident immune cell through TLR2, thereby increased cytokine production, proliferation, nitric oxide (NO) production, and intracellular reactive oxygen species production (iROS). However the molecular mechanisms as to how extracellular α-synuclein-mediated triggers such pro-inflammatory microglial responses. Here, we show a role of Leucine-rich repeat kinase 2 (LRRK2), a PD-associated gene in the signaling of extracellular α-synuclein-mediated microglial activation. Exposure to extracellular α-synuclein (released from neuronal cells) increased the phosphorylation of LRRK2 and its kinase activity in the mouse primary microglia through TLR2. In contrast, genetic depletion or pharmacological inhibition of LRRK2 selectively reduced extracellular α-synuclein-mediated microglial responses. Among the series of responses, inhibition of LRRK2 only reduced microglial proliferation and expressions of TNFα and IL-6 while other responses, such as expression of IL-1β were not affected by LRRK2 inhibition. We also demonstrated that activation of microglial LRRK2 by extracellular α-synuclein increased nucleus translocation of Nuclear factor of activated T-cells (NFAT1), a selective transcription factor. The level of nucleus NFAT1 was increased in the microglia of PD mouse model, while it was clearly reduced by administration of functional LRRK2 inhibitor. Furthermore, LRRK2 functional inhibition significantly reduced neurotoxicity, deposition of α-synuclein, and some of cytokine expression, such as TNFα and IL-6. Hence, we propose that modulation of LRRK2 and its downstream signaling mediator NFAT1 will be a novel therapeutic strategy for Parkinson's disease and related synucleinopathies.

Title: Pathogenic LRRK2 alters endolysosomal trafficking through impairing Rab8a function

Authors: *P. RIVERO-RÍOS[1], J. MADERO-PÉREZ[1], A. P. THOMAS[2], E. GREGGIO[3], S. HILFIKER[1]

[1]IPBLN-CSIC, Granada, Spain; [2]New Jersey Med. Sch. Rutgers, Newark, NJ; [3]Univ. of Padova, Padova, Italy

Abstract: Mutations in leucine-rich repeat kinase 2 (LRRK2) are the most common genetic cause of Parkinson´s disease (PD). LRRK2 regulates various intracellular trafficking pathways in a kinase activity-mediated manner, including endolysosomal degradative events as measured by epidermal growth factor receptor (EGFR) trafficking. Recent studies have revealed a subset of Rab proteins involved in secretory and endocytic recycling events as *in vivo* LRRK2 kinase substrates. However, the effects of such phosphorylation events on endolysosomal membrane trafficking remain unknown. Here, we report that expression of wildtype or phosphodeficient, but not phosphomimetic Rab8a variants rescues the LRRK2-mediated effects on endomembrane trafficking. Similarly, upregulation of the Rab11-Rabin8-Rab8a cascade to activate Rab8a reverts these deficits. In contrast, loss of Rab8a mimicks the effects of LRRK2 on endolysosomal trafficking. Pathogenic LRRK2 expression or loss of Rab8a interferes with EGFR degradation by causing its accumulation in a Rab4-positive endocytic compartment. Taken together, these findings provide a mechanism by which pathogenic LRRK2 deregulates endomembrane transport through impairing Rab8a function.

Title: The combined use of pathogenic and protective variants as a tool to explore the role of LRRK2 in autophagy and calcium signalling

Authors: *S. AZEGGAGH, D. C. BERWICK, K. P. S. J. MURPHY, S. A. ALLMAN
Sch. of Life, Hlth. and Chem. Sci., The Open Univ., Milton Keynes, United Kingdom

Abstract: Parkinson’s disease (PD) is the second most common neurodegenerative disease worldwide, affecting 3% of individuals of >75 years of age. The disease is relentless and incurable and the need to understand the causes of PD and develop new treatments is overwhelming. The first events in PD aetiology – the deregulated processes that lead to α-synuclein accumulation and neurodegeneration – remain a mystery. Mutations in the *LRRK2* gene encoding the leucine-rich repeat kinase 2 protein (LRRK2), are the most common cause of familial late-onset Parkinson’s disease (PD) and strongly influence the risk of sporadic PD. LRRK2 pathogenic mutations have been linked to a range of biological processes, including

autophagy, lysosomal activity and intracellular calcium signalling, which notably regulates autophagy. The current study investigates the impact of pathogenic and protective LRRK2 variants on autophagy and calcium signalling. The aim is to gain insight into LRRK2's involvement in the mechanism of autophagy and investigate at which step LRRK2 acts. To do so, we are using cells expressing wild-type or mutated LRRK2 protein and pharmacological inhibitors of LRRK2 kinase and GTPase activities, with autophagy induction monitored by quantification of autophagosomes and western blot. We are confident that our study will yield new and important data about the processes impaired by LRRK2 mutations, and the aetiology of late-onset PD.

Title: Mechanism of G2019S LRRK2-induced neurodegeneration *in vivo*: Role of kinase and GTPase enzymatic activities

Authors: *A. TRAN NGUYEN[1], N. LEVINE[1], E. TSIKA[2], D. MOORE[1]
[1]CNS, Van Andel Res. Inst., Grand Rapids, MI; [2]Brain Mind Inst., Swiss Federal Inst. of Technol. (EPFL), Lausanne, Switzerland

Abstract: Mutations in the *leucine-rich repeat kinase 2* (*LRRK2*, OMIM 607060) gene cause late-onset, autosomal dominant Parkinson's disease (PD) and represent the most common cause of familial PD. Genome-wide association studies suggest that common variation at the *LRRK2* genomic locus also contributes to the risk of idiopathic PD. LRRK2 is a large, multi-domain protein and possesses two distinct enzymatic activities, GTPase and kinase. *LRRK2* familial mutations enhance kinase activity or decrease GTPase activity but commonly induce neuronal toxicity in culture via a kinase-dependent mechanism. While increased kinase activity of LRRK2 has been associated with cell death, the contribution of GTPase activity to neuronal toxicity is poorly understood. Recent findings with *bona fide* kinase substrates of LRRK2 (i.e. RAB10) indicate that familial mutations in the GTPase domain can enhance substrate phosphorylation,

suggesting a critical interplay between the GTPase and kinase domains in mediating the pathogenic effects of LRRK2. However, the role of these enzymatic activities in mediating neurodegeneration in rodent LRRK2 models are incompletely understood. In the present study, we have comprehensively dissected the role of kinase and GTPase activities in regulating neurodegeneration induced by human G2019S LRRK2 in the rat brain. Using adenoviral-mediated gene transfer technology to induce expression of full-length human LRRK2 variants in the rat nigrostriatal dopaminergic pathway, we find that expression of G2019S LRRK2 induces the progressive degeneration of nigral dopaminergic neurons. Interestingly, we demonstrate that the neurotoxic effects of G2019S LRRK2 in this model are rescued by the simultaneous introduction of a kinase-inactive mutation (K1906M). Importantly, we also find that introduction of a GTPase-enhancing mutation (R1398L) or a GTP-binding-deficient mutation (T1348N) significantly attenuate neurodegeneration induced by G2019S LRRK2. Our results demonstrate that G2019S LRRK2 induces neurodegeneration via a mechanism that is dependent on kinase activity as well as GTPase activity in this rat model. Collectively, our study provides important insight into the pathophysiological mechanisms underlying familial *LRRK2* mutations and validates inhibition of kinase activity and modulation of GTPase activity as potential therapeutic strategies for attenuating LRRK2-dependent neurodegeneration in PD.

Abstract: A field-wide challenge in Parkinson’s disease (PD) research is a general lack of availability for high-quality, reproducible, and readily accessible preclinical research tools. To address these challenges, The Michael J. Fox Foundation for Parkinson’s Research (MJFF) has developed a growing resource of preclinical tools for the PD research and drug development communities that endeavors to provide researchers with easy access to rigorously validated, research-enabling preclinical tools for molecular biology studies. An important aspect of MJFF’s

preclinical tools portfolio are monoclonal antibodies that target PD-relevant proteins. In collaboration with academic experts and in partnership with Abcam and BioLegend, MJFF has sponsored the custom generation and independent validation of several monoclonal antibodies targeting both total and phosphorylated PD-relevant Rab proteins. The Rab superfamily of proteins function generally in membrane trafficking, and a subset of Rab family members have been identified as key phosphorylation substrates of LRRK2 and PINK1 kinase activity. The ability to detect and visualize these proteins under endogenous conditions would provide us with the opportunity to understand the role of Rabs in PD biology and test their utility as PD-relevant biomarkers. Herein we discuss the general MJFF antibody generation strategy and provide characterization data for ongoing custom antibody development projects, as well as antibody pipeline updates and commercial launch timelines for MJFF's cumulative Rab antibody collection. Ultimately, these MJFF-sponsored antibody projects aim to address field-wide challenges in the PD preclinical tools and reagents landscape and to overall accelerate Parkinson's disease research.

Title: LRRK2 phosphorylation of auxilin mediates synaptic defects in dopaminergic neurons from patients with Parkinson's disease

Authors: *M. NGUYEN, D. KRAINC
Neurol., Northwestern Univ., Chicago, IL

Abstract: Recently identified Parkinson's disease (PD) genes involved in synaptic vesicle endocytosis, such as DNAJC6 (auxilin), have further implicated synaptic dysfunction in PD pathogenesis. However, how synaptic dysfuction contributes to the vulnerability of human dopaminergic neurons has not been previously explored. Here, we demonstrate that the commonly mutated, PD-linked leucine-rich repeat kinase 2 (LRRK2) mediates the phosphorylation of auxilin in its clathrin-binding domain at Ser627. Kinase activity-dependent

LRRK2 phosphorylation of auxilin led to differential clathrin binding resulting in disrupted synaptic vesicle endocytosis and decreased synaptic vesicle density in LRRK2 patient-derived dopaminergic neurons. Moreover, impaired synaptic vesicle endocytosis contributed to the accumulation of oxidized dopamine that in turn mediated pathogenic effects such as decreased glucocerebrosidase activity and increased α-synuclein in mutant LRRK2 neurons. Importantly, these pathogenic phenotypes were partially attenuated by restoring auxilin function in mutant LRRK2 dopaminergic neurons. Together, this work suggests that mutant LRRK2 disrupts synaptic vesicle endocytosis leading to altered dopamine metabolism and dopamine-mediated toxic effects in patient-derived dopaminergic neurons. The work from this project expands the range of proteins for therapeutic intervention to those located at the synapse, potentially leading to the development of targeted treatments for patients with Parkinson's disease.

Title: Investigation of the role of LRRK2 in murine macrophage RAW264.7 cells

Authors: I. NAZISH[1], *R. BANDOPADHYAY[2]
[1]Mol. Neurosci., Reta Lila Weston Institute, UCL Inst. of Neurol., London, United Kingdom; [2]Inst. of Neurol., London, United Kingdom

Abstract: Introduction: Pathogenic mutations and polymorphisms in the LRRK2 gene are linked to familial and idiopathic Parkinson's disease (PD) as well as to two inflammatory conditions, leprosy and Crohn's disease. LRRK2 is expressed strongly in microglia and macrophages indicating its potential role in innate immunity, however, how LRRK2 dysfunction causes PD remains ambiguous. LRRK2 protein harbours two critical enzymatic activities, the kinase and the GTPase making it a highly druggable target for potential PD therapies. Herein, we aimed to establish a link between LRRK2 dysfunction and signalling mechanisms in the murine macrophage cell line (RAW264.7) and the pathological processes in PD.
Materials and Methods: Using WT, T1348N-LRRK2 (this mutation prevents GTP binding) and LRRK2-KO RAW264.7 cell lines, we studied LRRK2 phosphorylation dynamics and TNFα release following treatment with LPS (a proinflammatory mediator) and after treatment with four specific LRRK2 kinase inhibitors. LRRK2 phosphorylation at four specific phospho-sites was monitored using standard immunoblotting and secreted TNFα levels were measured using

ELISA. Statistically significant differences were analysed using ANOVA and T-test using Graph-PAD prism.
Results: LRRK2 phosphorylation significantly upregulated at Ser935/Ser955 residues with LPS (100ng/ml) treatment from 2h-24h in RAW264.7 cells. Kinase inhibition decreased baseline LRRK2 phosphorylation at 4h with LPS treatment reversing the effect. TNFα secretion upregulated following LPS stimulation in both WT and GTPase-deficient cells for both 24h and 48h. However, no significant difference in the basal secretion between the cell lines was seen.
Conclusion: LPS most significantly stimulated phosphorylation of LRRK2 in RAW264.7 WT and GTPase-deficient cells at 4h. Specific LRRK2 kinase inhibitors acted to decrease LRRK2 phosphorylation at Ser935 residue which is a readout of LRRK2 kinase activity. Our preliminary data of TNFα release with LPS treatment appeared to be independent of T1348N mutation.

Abstract: Parkinson’s disease (PD) is the second most common neurodegenerative disorder accompanied by progressive loss of dopaminergic neurons from the substantia nigra. The exact cause of the disease is unknown and currently there is no cure or treatment to stop the disease progression. PD patients remain asymptomatic in pre-clinical phase and lack of biomarkers for early detection poses a major challenge for testing new treatments. PD is mostly sporadic yet, about 10% of patients report first-degree relative with PD. The G2019S substitution in LRRK2 is the most common cause of autosomal dominant PD and it has been associated with sporadic cases as well. The mutation results in toxic gain of function in LRRK2 kinase activity and gives rise to a phenotype that is clinically indistinguishable from sporadic PD. Thus, understanding LRKK2 function is expected to reveal common pathological mechanisms. We established a

phosphoproteomic screen to identify substrates for LRRK2. This screen revealed several regulators of a key cellular process as novel substrates for LRRK2. Inhibition of LRRK2 kinase activity using LRRK2-IN1, GSK2578215A and MLi-2 stimulated this process in neurons as well as in non-neuronal cells, thus identifying a repressive role for LRRK2. To evaluate if LRRK2 regulated this process in PD, we used fibroblasts cells derived from G2019S and sporadic PD patients. We found that compared to healthy individuals, the process was repressed in fibroblasts from both sporadic and G2019S patients and treatment with LRRK2 kinase inhibitor MLi-2 restored activity to normal levels. In summary, our results identify that LRRK2 regulates a key cellular function and provides a unifying mechanism in familial and sporadic PD. Further evaluation of the underlying mechanisms may provide grounds for early diagnosis and potential new drug targets for treatment of PD.

Title: Role of leucine-rich repeat kinase 2 in Parkinson’s disease levodopa-induced dyskinesia

Authors: *R. MARONGIU[1], L. VELAZQUEZ[1], J. L. JOYCE[1,2], M. G. KAPLITT[1]

Abstract: The gold standard for treatment of Parkinson's disease (PD) motor symptoms is the restoration of dopamine transmission with administration of the dopamine precursor levodopa. However, approximately 80% of patients develop motor complications, levodopa-induced dyskinesia (LID), which constitute a major cause of disability and limit therapeutic efficacy. Evidence from in vitro and in vivo studies suggest that when substantia nigra dopaminergic neurons degenerate, levodopa treatment can cause LID by altering DA metabolism, gene expression, and neuroplasticity within the dorsal striatum. Recent data suggest that Leucine-Rich Repeat Kinase 2 (LRRK2) protein may be important for striatal response to dopaminergic therapy in PD. LRRK2 has been associated with several key regulators of striatal medium spiny neuron (MSN) function that are involved in LID. LRRK2 mutations were shown to increase membrane presentation of dopamine receptor D1 (Drd1) and downstream signaling cascades. Furthermore, overexpression of wild type (wt) LRRK2 has been reported to negatively regulate PKA activity in MSNs in response to Drd1 activation, while LRRK2 knockdown induced a significant increase of PKA levels in striatal dendritic spines. We hypothesize that disruption of LRRK2 levels via either PD-associated G2019S LRRK2 mutation or inhibition of endogenous LRRK2 with short-hairpin RNA (shRNA) interference will promote LID in the unilateral 6-hydroxydopamine (6OHDA) mouse model of PD. To test the influence of G2019S LRRK2 on LID, we 6OHDA lesioned transgenic mice overexpressing either human wt or G2019S LRRK2 and, two months post-surgery, upon quantifying the lesion efficiency, we induced LID by administering a daily levodopa treatment (6 mg/kg). We scored locomotor, axial, limb and orolingual LID for 3 weeks and found that mice overexpressing either wt or G2019S LRRK2 had no difference in development of LID compared with non-transgenic littermates. Secondly, we generated AAV vectors to inhibit mouse LRRK2 (AAV-sh.LRRK2) and control vector (AAV.sh.Luciferase), and injected it unilaterally into the dorsal striatum of 6OHDA lesioned C57Bl/6 mice. Upon induction of LID as reported above, we surprisingly found that inhibition of striatal LRRK2 expression significantly increased LID scores by 40% compared with control mice suggesting that endogenous striatal LRRK2 may be a key regulator of the LID response to dopaminergic pharmacotherapy. Notably, our data raises questions about the potential unintended effects of experimental therapies targeting LRKK2 inhibition on striatal function, and specifically on the response to dopamine replacement therapy in patients with PD.

Title: Role of ArfGAP1 phosphorylation and expression in LRRK2 induced neurodegeneration

Authors: *M. ISLAM, D. MOORE
Van Andel Res. Inst., Grand Rapids, MI

Abstract: Mutations in the *leucine-rich repeat kinase 2* (*LRRK2*) gene cause late-onset, autosomal dominant Parkinson`s disease (PD). *LRRK2* encodes a multi-domain protein containing functional GTPase and kinase domains, and familial mutations located within these domains influence enzymatic activity (i.e. R1441C and G2019S). ArfGAP1 was identified as a GTPase-activating protein (GAP)-like protein for LRRK2 that enhances its GTPase activity and ArfGAP1 also serves as a robust substrate of LRRK2-mediated phosphorylation. Importantly, ArfGAP1 is critically required for neuronal toxicity induced by G2019S LRRK2 in primary cultures. We sought to explore the contribution of ArfGAP1 phosphorylation to regulating its function and LRRK2-related neurotoxic pathways. Using ArfGAP1 deletion mutants, we find that the major sites of phosphorylation by LRRK2 are located within residues 252-359 and mass spectrometric analysis of phosphorylated ArfGAP1 identifies three major sites (Ser284, Thr291 and Thr292). Null mutations at all three ArfGAP1 phosphorylation sites (S284A/T291A/T292A) are required to inhibit LRRK2-mediated phosphorylation. ArfGAP1 overexpression robustly induces the vesicular dispersal of the Golgi complex in neural cells and blocking phosphorylation at S284, T291 and T292 in combination markedly attenuates this Golgi phenotype. We further find that ArfGAP1 overexpression in primary cortical neurons robustly inhibits neurite outgrowth, and preventing phosphorylation (S284A/T291A/T292A) reduces the neurotoxic effects of ArfGAP1. Our data suggest that phosphorylation of ArfGAP1 at S284, T291 and T292 is required for Arf1-mediated Golgi dispersal and inhibition of neurite outgrowth. To determine whether ArfGAP1 is required for mutant LRRK2-induced neurodegeneration *in vivo*, we used *Drosophila* with a heterozygous deletion of ArfGAP1 combined with the transgenic expression of human R1441C LRRK2. We find that reducing ArfGAP1 expression improves survival and attenuates motor deficits in the R1441C LRRK2 flies. Our data establish the contribution of ArfGAP1 phosphorylation and expression in mediating LRRK2-induced neuronal damage, and further support ArfGAP1 inhibition as a therapeutic target for attenuating mutant LRRK2.

Title: Alpha-synuclein and LRRK2 cooperation in mitochondrial dysfunctions in Parkinson’s disease

Authors: *G. LIOT, C. GARDIER, N. CRESTO, M.-C. GAILLARD, N. DUFOUR, A. BEMELMANS, E. BROUILLET
Neurodegenerative Dis. Lab. UMR 9199, CEA MIRCen, Fontenay aux Roses, France

Abstract: Parkinson’s Disease (PD) is the most frequent neurodegenerative disease after Alzheimer’s Disease. It is characterized by the selective loss of dopaminergic (DA) neurons in the substantia nigra *pars compacta* (SNpc) and the formation of Lewy bodies, composed primarily of aggregates of α-synuclein (α-syn). Familial forms of PD are due to the duplication/triplication of the gene encoding α-syn, or to certain point mutations, such as the A53T mutation which can accelerate α-syn aggregation. Another gene, encoding the Leucin-Rich Repeat Kinase 2 (LRRK2), also shows automosal dominant mutations linked to PD. Among these, the G2019S mutation is the most frequent leading to familial forms of PD and these patients cannot be clinically distinguished from idiopathic patients. It has also been suggested that α-syn and LRRK2 act in concert in the pathogenesis of PD, and this hypothesis is supported by the *in vivo* results of our laboratory. Indeed, we demonstrated that the AAV-mediated overexpression of $LRRK2^{G2019S}$ in the SNpc of rats increases the dopaminergic cell death induced by the AAV-mediated overexpression of $\alpha\text{-syn}^{A53T}$. Now, our goal is to determine how these two proteins, α-syn and LRRK2, can potentiate neuronal cell death. We focused on the cellular mechanisms linked to mitochondria, as this organelle has been shown to be implicated in the pathogenesis of PD. Moreover, α-syn and LRRK2 have both been found to induce mitochondrial defects. For this purpose, we use a model of rat primary cortical neurons infected with lentiviral vectors in order to overexpress the wild type or mutant forms of α-syn and

LRRK2. We characterize the effect of co-expressing these two proteins on mitochondrial physiology by different biochemical (ATP and ROS production) and imaging methods (mitochondrial morphology) and on cell viability. Preliminary results support the existence of an interplay between α-syn and LRRK2 in the cellular response to a rotenone-induced mitochondrial toxicity.Our long term objective is to find the main pathways impacted by α-syn and LRRK2 to identify new molecular targets and thereafter develop new therapeutic strategies for the treatment of PD.

Title: The association of LRRK2 and GBA1 in Parkinson’s disease pathogenesis

Authors: *D. YSSELSTEIN, D. KRAINC
Neurol., Northwestern Univ., Chicago, IL

Abstract: Parkinson’s disease (PD) is a neurodegenerative disorder that affects millions of individuals around the world. Mutations in the genes encoding for leucine rich repeat kinase 2 (LRRK2) and glucocerebrosidase (GCase) are strongly associated with onset of PD. The mechanism through which these mutations lead to dopaminergic cell loss in PD is unclear. Recent genetic studies have identified patients with concurrent mutations in the genes for LRRK2 and GCase that develop PD at an earlier age or onset than of patients with just a single mutation in either LRRK2 or GCase. This observation highlights the possibility that mutations in these genes operate synergistically to cause dysfunction in PD patients. Identification of a convergent pathway associated with GCase and LRRK2 mutations could have important therapeutic implications in PD. Using midbrain dopaminergic neurons differentiated from patient-derived induced pluripotent stem cells (iPSCs) containing the LRRK2 mutations, we examined the effect of different LRRK2 mutations on lysosomal GCase activity. We found that neurons containing LRRK2 G2019S or R1441C mutations display reduced lysosomal GCase activity relative to neurons derived from healthy control patients. To further study this, we used CRISPR to create isogenic controls with corrected LRRK2 sequences. We found that these isogenic controls displayed significantly increased GCase activity relative to the corresponding LRRK2 mutant cells. Lastly, we found that treatment of LRRK2 mutant neurons with LRRK2

kinase inhibitors significantly increased lysosomal GCase activity to levels observed in the isogenic control lines. Altogether, these results highlight a potential convergence of LRRK2 and GCase mutations in PD pathogenesis by identifying a possible role for reduced GCase activity in LRRK2-associated PD pathogenesis. These observations suggest that emerging therapies targeted towards GCase activation could also have therapeutic benefits in LRRK2 patients.

Title: Alpha-synuclein-induced dopaminergic neurodegeneration is attenuated by AAV2-TOM20 overexpression

Authors: *B. R. DE MIRANDA, E. M. ROCHA, S. CASTRO-SCHEIRER, J. T. GREENAMYRE
Univ. of Pittsburgh, Pittsburgh, PA

Abstract: Both mitochondrial dysfunction and α-synuclein accumulation are implicated in the pathogenesis of idiopathic Parkinson’s disease (PD), and they share a bidirectional relationship; mitochondrial dysfunction results in post-translational modifications that increase α-synuclein toxicity, and α-synuclein accumulation impairs mitochondrial function. Recently, we observed that posttranslationally modified species of α-synuclein directly bind to mitochondrial protein import machinery at the translocase of the outer membrane (TOM)-20 protein, which prevents its association with co-receptor TOM22, and the import of protein into the mitochondria. *In vivo* overexpression of monomeric α-synuclein within the substantia nigra results in progressive dopaminergic neuron death that mirrors a parkinsonian phenotype in animal models of PD. Based on these findings, we postulated that overexpression of TOM20 within dopaminergic neurons of the substantia nigra would be protective against α-synuclein-induced cell death. To investigate this, we generated three adeno-associated 2 viral vectors (AAV2) for infusion into the adult rat brain; (1) AAV2-α-synuclein (2) AAV2-TOM20 and (3) AAV2-GFP (control vector). Unilateral, stereotactic co-injections of AAV2-α-synuclein/GFP, AAV2-α-synuclein/TOM20 or AAV2-TOM20/GFP (control) were performed on adult (7-9 month), male Lewis rats followed by a 12-week incubation period. Histopathological analysis revealed significant loss of dopaminergic neurons from the substantia nigra in animals receiving the AAV2-α-synuclein/GFP vector, however, this neurodegeneration was attenuated in animals co-expressing

AAV2-α-synuclein/TOM20. Neuroprotection against α-synuclein toxicity correlated with a significant preservation of the protein NDUFS3 (NADH:Ubiquinone Oxidoreductase Core Subunit S3), a core subunit of the mitochondrial electron transport chain (complex I), which is imported through the TOM20 presequence receptor. Importantly, we observed that overexpression of AAV2-TOM20 did not result in decreased total α-synuclein protein expression driven by the AAV2-α-synuclein vector. Together, these data implicate that mitochondrial dysfunction caused by α-synuclein plays a central role in the death of dopaminergic neurons, and selective targeting of mitochondrial protein import may be a novel therapeutic strategy to mitigate neurodegeneration in PD.

Abstract: Parkinson’s disease (PD) is a common neurodegenerative disease that results in motor impairment, cognitive and psychiatric symptoms and autonomic dysfunction. Despite the numerous gene mutations responsible for familial PD, about 90% of cases are “idiopathic” (iPD). Missense mutations in leucine-rich repeat kinase 2 (LRRK2), the most common cause of autosomal dominant PD, account for about 3% of cases overall; however, the role of wildtype LRRK2 in iPD is unclear. There is growing consensus that certain LRRK2 mutations increase autophosphorylation at Ser1292, conferring to the enzyme an aberrantly enhanced kinase activity

strongly implicated in PD pathogenesis.
LRRK2 kinase activity state under various conditions and LRRK2/14-3-3 proteins interaction – a biochemical event that modulates LRRK2 activity – have been generally assessed using proteomic approaches, limiting the anatomical or cellular resolution. This constitutes a critical barrier to understanding the role of LRRK2 in PD. We have developed and validated novel proximity ligation (PL) assays with excellent anatomical resolution that can rapidly provide information regarding activation state, cellular localization and physiological regulators of LRRK2.
Using this and other assays, we provide evidence that LRRK2 kinase activity is aberrantly increased in vulnerable dopamine neurons of individuals with idiopathic PD. We also show that LRRK2 kinase activity (i) can be oxidatively increased by mitochondrial impairment or α-synuclein overexpression, (ii) modulates the phosphorylation levels of the Rab GTPase Rab10, (iii) causes endo-lysosomal dysfunction and (iii) accumulation of phosphorylated α-synuclein. Overall, our work shows that, independent of mutations, wildtype LRRK2 plays a key role in idiopathic PD. LRRK2-directed therapeutics may therefore be useful for most people with PD.

Abstract: The primary clinical motor symptoms of Parkinson's disease (PD) result from loss of dopaminergic (DA) neurons in the substantia nigra with autophagy dysfunction being closely linked to this disease. Autophagy is a cellular process responsible for degradation of organelles, macromolecules, and protein aggregates. In PD, characteristic toxic protein aggregates of primarily alpha-synuclein are believed to be substrates for autophagic removal and clearance by autophagy improves preclinical model outcomes. Therefore, modulation of autophagy may be an effective strategy to combat PD. Recently, a PD-causing mutation in VPS35 (D620N) was reported to block autophagy. However, preliminary investigation by other groups into a causal mechanism was limited to canonical VPS35 protein interactors in a cervical cancer cell line. To overcome these limitations, we performed an unbiased screen using RNA sequencing (RNA seq) to identify key pathways affected in a widely used cellular model of PD. We have identified alterations indicative of perturbed extracellular matrix (ECM)-receptor interaction as well as aberrant AKT signaling, a downstream pathway known to regulate the induction of autophagy. Hyaluronic acid (HA) is the major component of brain ECM and signals via CD44, an ECM receptor identified as a top hit by our RNA Seq screen, to the autophagy regulating AKT-mTOR pathway, making this axis a prime candidate for mediating VPS35 D620N autophagy blockade. Additionally, VPS35's well-established role in the retromer complex suggests that altered trafficking of CD44 by the VPS35 mutant may be responsible for the observed repression of autophagy. Our hypothesis is that VPS35 D620N blocks autophagy through dysregulated hyaluronic acid-CD44 signaling by altered trafficking of CD44. Supporting this hypothesis, we find that HA represses autophagy in dopaminergic cells. Furthermore, we report that VPS35 mutant cells exhibit heightened sensitivity to HA signaling suggesting that this might be the mechanism underlying autophagy dysfunction in these cells.

Title: Mitochondria and nadph oxidase 2 interplay: Relevance in Parkinson's disease

Authors: *M. T. KEENEY[1], E. HOFFMAN[1], J. MCCOY[1], P. J. PAGANO[2], J. T. GREENAMYRE[1], R. DI MAIO[1]

Abstract: Oxidative stress has been described as a major cause of nigrostriatal degeneration in familial and idiopathic Parkinson's disease (PD). Moreover, NADPH oxidase 2 (NOX2) and the mitochondrial electron transport chain, the major enzymatic sources of reactive oxygen species (ROS) in neural cells, appear intimately related in a redox regulatory pathway recently termed *"ROS-induced ROS production"*. While there is some evidence that NOX2 inhibitors may protect dopaminergic neurons against degeneration, these studies have generally been hampered by lack of highly specific inhibitors and an inability to assess the activation state of NOX2 under experimental or pathological conditions with a cellular level of resolution. We now report testing of a novel and highly specific NOX2 inhibitor, NOX2ds-tat, and development of a new proximity ligation (PL) histological assay to detect NOX2 activation. By utilizing this novel histological PL assay and NOX2ds-tat, for the first time, we characterized the nature of the interplay between NOX2 and mitochondria in PD pathogenesis. Specifically, we found that neuronal NOX2 is hyperactive in idiopathic PD brains and in 2 rat models of the disease, rotenone and AAV2-α-synuclein overexpression. Our findings support the hypothesis that in PD, neuronal mitochondrial dysfunction can elicit NOX2 hyperactivity that, in turn, may cause post-translational modifications and accumulation of α-synuclein. This event can initiate a pathogenic cycle that further affects mitochondrial integrity (via impaired protein import) and contributes to the initiation and progression of the disease. Overall, the data suggest that targeting NOX2 may constitute a therapeutic approach in prevention of PD progression.

Title: Pharmacological inhibition of LRRK2 prevents rotenone-induced neurodegeneration and endolysosomal dysfunction

Authors: *E. N. ROCHA, B. R. DE MIRANDA, R. DI MAIO, S. CASTRO-SCHEIRER, M. T. KEENEY, J. L. MCCOY, J. T. GREENAMYRE
Neurol., Univ. of Pittsburgh, Pittsburgh, PA

Abstract: Missense mutations in leucine-rich repeat kinase 2 (LRRK2) are a leading cause of familial Parkinson's disease (PD). Despite consensus that *LRRK2* mutations confer a toxic gain-of-function that results in increased LRRK2 kinase activity, the role of LRRK2 in PD remains unclear. In addition to individuals who inherit a LRRK2 mutation, our laboratory recently demonstrated that increased LRRK2 kinase activity is detected in nigral dopaminergic neurons of sporadic PD-patients. LRRK2 can localize to vesicular structures including endosomes and autophagosomes. It is thought to play a role in vesicular trafficking and autophagy-lysosomal degradation through phosphorylation of various Ras Analog in Brain (Rab) GTPases. At baseline, LRRK2 is a rather low-abundance protein, and sustained LRRK2 activation likely has pathological consequences. Therefore, we aimed to determine whether inhibition of LRRK2 kinase activity can prevent neuropathological abnormalities using an environmentally relevant rodent model of PD. Daily exposure of rats to the mitochondrial complex I inhibitor rotenone for 10-14 days caused many of the pathological features observed in sporadic PD, including dopaminergic degeneration, accumulation of endogenous α-synuclein, and increased LRRK2 kinase activity. These hallmark deficits correlated with impaired endolysosomal trafficking. Rab5, a known LRRK2 kinase substrate and key regulator of early endosomal trafficking, accumulates in dopaminergic neurons in rats treated with rotenone and LRRK2 kinase activity is significantly increased in the same neurons. This accumulation of Rab5 (and our previous report of pRab10 accumulation) may explain how rotenone causes endolysosomal dysfunction and accumulation of undegraded α-synuclein. We hypothesize that LRRK2 contributes to the pathogenesis of PD by disrupting endolysosomal trafficking through excessive phosphorylation of Rabs, including Rab5. In support of this, a specific brain-penetrant LRRK2 kinase inhibitor not only prevented rotenone-induced neurodegeneration but also prevented accumulation of Rab5 and lysosomal dysfunction. These data suggest that specific LRRK2 kinase inhibitors may have broad applicability and be useful for all PD patients. Title: Sex differences in sensitivity to rotenone reflect male-to-female ratios in human Parkinson's disease incidence

Authors: *J. T. GREENAMYRE, E. M. ROCHA, B. R. DE MIRANDA
Neurol., Univ. of Pittsburgh, Pittsburgh, PA

Abstract: The male to female odds ratio for incidence of Parkinson's disease (PD) is about 1.5 - 2, indicating that sex differences likely play a role in the pathogenesis of the disease. Many animal models of PD however, do not include sex as a biological variable, possibly overlooking important etiological factors. In male rats, rotenone, an organic pesticide and prototypical mitochondrial complex I inhibitor, reliably reproduces parkinsonism, including motor behavioral deficits of postural instability, rigidity, and bradykinesia at a dose of 2.8 mg/kg/d (i.p.). In addition, rotenone causes the selective neurodegeneration of dopamine neurons in the substantia nigra (SN) and their terminal projections in the striatum (ST), endogenous wildtype α-synuclein accumulation, microglial activation, and changes in iron metabolism. However, our pilot studies in adult female Lewis rats using the same dose of rotenone (2.8 mg/kg/d) did not yield equivalent motor behavioral changes nor dopamine neuron loss or brain pathology. Therefore, we postulated that female rats may be less vulnerable to rotenone-induced neurodegeneration, thus requiring increased exposure to produce an equivalent parkinsonian phenotype to that seen in male rats. To test this, we generated a dose-response using 2.8 mg/kg/d, 3.2 mg/kg/d, or 3.6 mg/kg/d (once daily i.p. injection) of rotenone in female Lewis rats, with one additional group receiving BID dosing (1.6 mg/kg BID = total 3.2 mg/kg/d) of rotenone. Female rats receiving 3.2 mg/kg, 1.6 mg/kg (BID), and 3.6 mg/kg rotenone had a significant loss of dopamine neurons within the SN as assessed by stereology, accompanied by a loss of tyrosine hydroxylase-positive terminals in the ST. Significant microglial activation within the SN was observed in only the 1.6 mg/kg BID and 3.6 mg/kg groups, compared to a marked activation of microglia in male rats receiving 2.8 mg/kg. In addition, following rotenone-treated female animals displayed disparate expression of markers for iron homeostasis, α-synuclein accumulation, and endolysosomal trafficking dysfunction in comparison to male animals. Taken together, these data indicate that female rats display a higher threshold for rotenone-induced pathogenic processes and

neurodegeneration - an effect that parallels human data of higher PD incidence and prevalence in males. This work was supported by the American Parkinson Disease Association and grants from the NIH (1R01 NS095387 and 1R01 NS100744).

Title: Neurodegeneration induced by dysregulation of dopamine sequestration is rescued by restoration of vesicular packaging

Authors: *M. L. BUCHER[1], C. W. BARRETT[2], A. D. MORTIMER[2], C. J. MOON[3], J. T. GREENAMYRE[2], T. G. HASTINGS[3]
[2]Neurol., [3]Neurosci., [1]Univ. of Pittsburgh, Pittsburgh, PA

Abstract: Within dopaminergic (DAergic) neurons, dysregulation of vesicular dopamine (DA) packaging results in increased cytosolic DA, which is susceptible to oxidation and degradation: two processes that generate reactive metabolites and reactive oxygen species. There is significant evidence that deficits in vesicular packaging of DA contribute to the pathogenesis of Parkinson’s disease (Miller et al. 1999, Pifl et al. 2014), and animal models have demonstrated toxic consequences following dysregulation of vesicular DA packaging (Caudle et al. 2007, Chen et al. 2008). We have generated a viral vector (AAV2-shVMAT2) that dysregulates vesicular DA packaging by small-hairpin ribonucleic acid (shRNA) interference of rat vesicular monoamine transporter 2 (VMAT2) expression. Unilateral viral-mediated knock-down of VMAT2 results in increased cytosolic DA, as evidenced by increased DA oxidation (27.5%) and turnover (64.6%) (paired t-test, $n=4$, $p<0.05$). Dysregulation of DA packaging resulted in a 38.7% loss of DAergic neurons in the substantia nigra and a corresponding 29.8% loss of tyrosine hydroxylase (TH) intensity in the terminals (paired t-test, $n=5$, $p<0.05$). These data suggest that dysregulation of DA sequestration is sufficient to induce neurodegeneration. To verify that the neurodegeneration was specific to dysregulation of DA, and not an off-target effect of the AAV2-shVMAT2 itself, we developed a viral vector (AAV2-muVMAT2) that expresses human VMAT2 with silent mutations resulting in VMAT2 transcript resistant to the shRNA-VMAT2. The mutant VMAT2 (muVMAT2) construct was first tested *in vitro* in a DAergic neuronal cell line derived from the midbrain of adult rat. Co-expression of muVMAT2 with the shVMAT2 construct decreased the

endogenous rat VMAT2 mRNA but resulted in exogenous human VMAT2 mRNA and an overall increase in VMAT2 protein expression. After cell culture verification, the AAV2-muVMAT2 virus was made for *in vivo* experiments. When co-injected, reintroduction of VMAT2 by AAV2-muVMAT2 restores VMAT2 protein and prevents neurodegeneration compared to a VMAT2 knock-down control that lost 36.17% of VMAT2 protein in transduced neurons (One-way ANOVA, $p<0.001$) and lost 28.00% of DAergic neurons in the substantia nigra (One-way ANOVA, $p<0.05$). These data confirm that neurodegeneration resulting from AAV2-shVMAT2 is specific to VMAT2 knock-down, and further implicate the necessity of DA sequestration to maintain neuronal health in DAergic neurons.

Title: Pharmacogenomic repression of alpha-synuclein with beta2 adrenoreceptor agonist is protective in a new rotenone model of delayed, progressive Parkinson's disease

Authors: *A. D. VAN LAAR[1], M. T. KEENEY[1], A. ZHARIKOV[2], S. MITTAL[3], C. SCHERZER[4], J. T. GREENAMYRE[1]
[1]Neurol., Univ. of Pittsburgh, Pittsburgh, PA; [2]Neurol., Univ. of Pittsburgh Sch. of Med., Pittsburgh, PA; [3]Celegene, Cambridge, MA; [4]Neurol., Brigham and Women's Hosp., Boston, MA

Abstract: Excess alpha-synuclein production is a known etiology for some familial forms of Parkinson’s disease (PD), and alpha-synuclein accumulation is a core pathologic feature of idiopathic PD. These findings suggest a central role of alpha-synuclein in PD pathogenesis and have led to speculation that reduction of alpha-synuclein could alter the disease course for idiopathic PD. Our lab has demonstrated that brief exposure of rats to rotenone (2.8mg/kg daily, i.p.) for only 5 days results in a delayed onset, then slowly progressive parkinsonian behavioral phenotype occurring over a period of months. This temporally remote administration of rotenone also causes a gradual increase in alpha-synuclein levels within dopaminergic (DAergic) nigral

neurons, associated with the formation of insoluble Lewy body-like inclusions at later time points. Rats also exhibit a loss of DAergic neurons and increased markers of neuroinflammation in the substantia nigra. Here we examined the effects of pharmacogenomic alpha-synuclein reduction in our new progressive parkinsonian model. We utilized clenbuterol, a brain penetrant β2-adrenoreceptor agonist and asthma medication that has been shown to reduce transcription of alpha-synuclein, and has been epidemiologically linked to a reduced risk of PD. In this study, we pretreated aged Lewis rats (12 months old) with clenbuterol (5mg/kg) in drinking water for 10 days before, then during and after 5 days of rotenone administration. No further rotenone was administered and rats were monitored over 4 months for the development of a parkinsonian phenotype, which emerged spontaneously around 80 days after rotenone. We found that treatment with clenbuterol β2-agonist prevented the progressive parkinsonism seen in the rotenone treated animals without agonist. Exposure to clenbuterol also prevented rotenone-associated DAergic neuron loss (reduced to baseline levels), and reduced alpha-synuclein burden within DAergic cells by -24% as compared to vehicle treated animals receiving rotenone as seen by immunohistochemistry. Down regulation of alpha-synuclein mRNA expression (-52%) was also detected by qPCR in midbrain of agonist-treated compared to vehicle-treated animals triggered with rotenone. β2-adrenergic receptors are also present on microglia, and we found that microglia activation (indicated by IBA1 + CD68 dual labeling) was markedly reduced by clenbuterol treatment. These findings show that lowered alpha-synuclein protein levels in dopaminergic cells prevent the neuropathological cascade following rotenone exposure, further demonstrating its potential as a pharmacotherapy for PD.

Title: Target identification and lead discovery for autophagy factors by lipidomic screening

Authors: *A. D. SOTO, B. MORRISON
Boise State Univ., Boise, ID

Abstract: Parkinson’s disease(PD) is the most common motor disease and the second most common neurodegenerative disease. Key hallmarks of the disease are the loss of dopaminergic

neurons in the substantia nigra and autophagy dysfunction. Autophagy is a cellular process responsible for the degradation of organelles, macromolecules, and, toxic protein aggregates. In the case of PD, toxic alpha-synuclein aggregates build up and are the substrate for autophagic degradation. As a result, modulation of autophagy could prove to be an effective target for the treatment of PD. Significant effort has been focused on the identification and characterization of important protein-signaling pathways to regulate autophagy; as a result, considerable progress has been made on this front. However, to date, there have been no clinical treatments that harness autophagy for therapeutic benefit. Therefore, we seek to identify endogenous small lipid molecules that act as signaling mediators for autophagy. In order to accomplish this goal, we have performed an unbiased lipidomic screen using the intracellular lipid chaperone protein FABP5 as "bait". In this study we propose the validation of identified lipid compounds as autophagy modulators in cell culture. We also propose to investigation the molecular mechanisms of action for identified autophagy-regulating lipids using RNA sequencing and subsequent proteomic validation.

Abstract: Mutations in the *LRRK2* gene represent a major genetic risk factor for both sporadic and familial Parkinson's disease (PD). However, the mechanistic link between LRRK2 variants and PD-related neurodegeneration remains unclear. We utilized Berg's proprietary Interrogative Biology® methodology to compare primary fibroblasts (FBs) from PD patients harboring the $LRRK2^{G2019S}$ mutation, idiopathic PD patients, and their matched mutation-negative controls (generous gifts from the PI). This study led to identification of the quinone oxidoreductase, PIG3, mechanistically linking $LRRK2^{G2019S}$ to PD pathology. FBs from LRRK2-PD patients demonstrated elevated steady-state PIG3 protein expression that correlated with upregulated MKK3 activity, p38 MAPK phosphorylation, and accumulation of p53. Human dopaminergic SH-SY5Y cells treated with rotenone and 6-hydroxydopamine (6-OHDA) exhibited an increase

in PIG3 expression that correlated with apoptosis. Forced overexpression of PIG3 also compromised cell viability and elevated intracellular oxidative stress in the SY5Y model. Conversely, conditions that attenuate PIG3 expression significantly reduced rotenone- and 6-OHDA- induced cell death in SH-SY5Y cells. These include: siRNA directed against *PIG3,* and small molecule inhibitors of LRRK2 and p38 MAPK (LRRK2-IN-1 and SB203580 respectively). We have also uncovered a direct interaction between PIG3 and catalase in neurons that may modulate redox homeostasis and apoptosis induction. To further examine the role of PIG3 in human PD models *in vitro*, we have reprogrammed fibroblasts from control- and $LRRK2^{G2019S}$-PD donors to generate patient-specific iPS cells. The resulting iPSCs and iPSC-derived neurons (iPSC/Ns) demonstrate *PIG3* transactivation by 6-OHDA and rotenone, supporting observations from the SY5Y cell line. Consistent with their fibroblast counterparts, steady state PIG3 remains elevated in the $LRRK2^{G2019S}$ iPSCs and iPSC/Ns. Subsequently, we utilized the CRISPR/Cas9-system to delete the *PIG3* locus in these patient-specific iPSCs to better understand the contribution of PIG3 in these models. Relative to their isogenic counterparts, $PIG3^{-/-}$ iPSCs and iPSC/Ns exhibit attenuated molecular apoptotic signatures in response to pro-apoptotic stimuli. Here, we also describe the effects of both genetic and neurotoxin-induced PIG3 modulation on neuronal activity *in vitro* using iSPC/Ns. Taken together, our findings reveal that PIG3 contributes to apoptosis in neuronal models of PD and may advance our understanding of the mechanisms behind $LRRK2^{G2019S}$- mediated hypersensitivity to environmental neurotoxins, and neuronal dysfunction.

Title: Altered cellular and metabolomic phenotypes observed in LRRK2^{G2019S} patient-specific iPSC-derived neurons are partially rescued in PIG3-deficient cells

Authors: *R. ROESSLER[1], I. D. MAJUMDAR[1], K. HA[1], A. KITAYEV[1], J. RANJAN[1], C. HILL[1], J. CHAUFTY[1], S. GESTA[1], B. SCHUELE[2], V. K. VISHNUDAS[1], P. P. NARAIN[1], R. SARANGARAJAN[1], M. KIEBISH[1], N. R. NARAIN[1]
[1]Berg LLC, Framingham, MA; [2]Parkinson's Inst. and Clin. Ctr., Sunnyvale, CA

Abstract: Parkinson’s disease (PD) is a neurodegenerative disorder that primarily and most severely affects midbrain dopaminergic neurons. A variety of cellular and molecular events, such as increased reactive oxygen species, increased protein aggregation and altered neurotransmitter production have been associated with the disease and contribute to loss of function over time. In order to evaluate deteriorating function of LRRK2^{G2019S} patient-specific iPSC-derived neurons, we analyzed electrophysiological and metabolomic profiles in terminally differentiated dopaminergic (DA) neurons. Interestingly, PD neurons showed different activity patterns in a multi-electrode array analysis as well as altered neurometabolomic profiles assessed by our LC-MS platform. More specifically, we analyzed neuronal firing rates, burst frequencies and network synchrony in LRRK2^{G2019S} DA neurons versus unaffected control DA neurons. In our neurometabolomic analysis we performed an untargeted profiling in order to achieve maximal metabolite coverage as well as profiling focused on dopamine pathway metabolites. In this context we were able to profile components of phenylalanine, tyrosine and tryptophan

metabolism, as well as the antioxidant glutathione. Using BERG's proprietary Interrogative Biology® platform we identified quinone oxidoreductase, PIG3, as a novel molecular candidate associated with the $LRRK2^{G2019S}$ mutation. In the current study, we set out to assess this potential mechanistic link by interrogating the cellular and metabolomic profiles in CRISPR/Cas9 mediated PIG3-deficient isogenic iPSC pairs. Strikingly, we observed partial reversals of the assessed phenotypes in homozygous PIG3 knockout cells compared to isogenic ($PIG3^{+/+}$) $LRRK2^{G2019S}$ patient-specific iPSC-derived DA neurons. Our preliminary findings support the notion that PIG3 might serve as valuable and novel therapeutic target in PD-specific pathologies.

Title: Differential ultrastuctural reorganization of thalamo-cortical and cortico-cortical glutamatergic innervation in the primary motor cortex of MPTP-treated parkinsonian non-human primates

Authors: *R. M. VILLALBA[1], J.-F. PARE[1], Y. SMITH[1,2]
[1]Yerkes Resch Ctr. and Udall Ctr. of Excelence For Parkinson's Disease, Emory Un, Atlanta, GA; [2]Dept. of Neurol., Emory Univ. Sch. of Medicine. Dept Neurol., Atlanta, GA

Abstract: The loss of dopaminergic neurons in the substantia nigra results in major functional changes of various component nuclei of the basal ganglia-thalamocortical network in Parkinson's disease (PD). However, little is known about the state of connectivity between the basal ganglia-receiving motor territory of the thalamus and motor cortical regions in parkinsonian condition. In a previous study, we have shown a profound reorganization of thalamo-cortical synaptic inputs (vGluT2-positive) in the primary motor cortex (M1) of parkinsonian monkeys (Villalba et al., 2014). In the present study, we analyzed the overall pattern of synaptic connections of cortico-cortical terminals (vGluT1-positive) in layers II-III and Vb of M1 in control and MPTP-treated parkinsonian monkeys, and compared these results with those previously obtained for the thalamo-cortical inputs. Light microscopy analysis has shown an extensive vGluT1 immunostaining in M1 without major differences between layer II-III and Vb in both control and parkinsonian animals. Quantitative ultrastructural results indicate that vGluT1-positive terminals form asymmetric synapses mainly with dendritic spines (55%-65%) in layers II-III and Vb of control and parkinsonian monkeys. The analysis of the post-synaptic densities (PSDs) at both axo-dendritic and axo-spinous synapses revealed a slight increase (less than 10% in layer II-III and layer V) in the percentage of macular synapses in parkinsonian animals. A similar analysis for vGluT2-positive terminals in M1 of parkinsonian monkeys has shown a drastic reduction of thalamo-cortical innervation of layer Vb, and a differential ultrastructural reorganization of thalamo-cortical synapses between layer II-III and Vb. In layer II-III, the proportion of axo-spinous synapses increased from 55% in control animals to almost 70% in parkinsonian monkeys, while in layer Vb, axo-spinous synapses decreased from 90% to almost 70% in the parkinsonian state. Both macular and perforated axo-spinous synapses decreased by 10-12% in layer II-III, and by 5% (macular) and 10% (perforated) in layer Vb in parkinsonian animals,

while macular and perforated axo-dendritic synapses increased by ~10% in layer II-III. However, in layer Vb, the proportion of macular axo-dendritic synapses increased by 15%, while perforated axo-dendritic synapses decreased by ~5% in parkinsonian monkeys. These results help us better understand neuroplastic changes in the microcircuitry of thalamo-cortical and cortico-cortical glutamatergic connections, and increase our knowledge of the cortical pathophysiology in the state of parkinsonism.

Title: Ultrastructural features of single pallidothalamic terminals in control and MPTP-treated Parkinsonian monkeys visualized using 3D electron microscopic reconstruction approaches

Authors: *A. J. SWAIN[1,2], H. KELLY[1,2], Y. SMITH[1,2,3]
[1]Yerkes Natl. Primate Res. Ctr., Atlanta, GA; [2]Udall Ctr. of Excellence for Parkinson's Dis. Res., Emory Univ., Atlanta, GA; [3]Dept. of Neurol., Sch. of Med., Atlanta, GA

Abstract: In primates, the internal globus pallidus (GPi) is a main source of basal ganglia GABAergic afferents to the ventral motor thalamus. Functional models of the basal ganglia-thalamocortical circuitry predict that the loss of nigrostriatal dopamine results in an increased GABAergic pallidal outflow to the thalamus in Parkinson’s disease (PD). However, our understanding of the pathophysiology of this increased pallidothalamic activity remains limited. Electrophysiological studies have reported complex changes in firing rates, firing patterns, and oscillatory firing properties of thalamocortical neurons in animal models of parkinsonism and in PD patients. In the striatum and subthalamic nucleus, altered neuronal activity generated in the state of parkinsonism is associated with pre- and post-synaptic structural changes of GABAergic and glutamatergic synapses. The GPi gives rise to large GABAergic terminals that form multiple synapses with single dendrites in the ventral motor thalamus. Based on functional data gathered from structurally-similar terminals in other brain regions, it has been shown that the multi-synaptic morphology of GPi-like terminals creates favorable conditions for inter-synaptic spillover of GABA among the multiple synapses of single terminals. This, in turn, may enable tonic inhibition, even under conditions of high presynaptic firing rates, as is the case in the

parkinsonian state. Thus, an understanding of the plasticity of the ultrastructural features of individual pallidothalamic terminals, such as the number and size of synapses, and volume of terminals, will aid in understanding the impact of altered GPi outflow onto thalamocortical neurons in the state of parkinsonism. To address this issue, we used a Single Block Facing/Scanning Electron Microscopy (SBF/SEM) high resolution 3D electron microscopic approach to quantitatively analyze the morphometry of single GPi terminals in the motor thalamus of control and MPTP-treated parkinsonian monkeys. Preliminary results suggest that the following structural changes take place in parkinsonian animals: 1) the volume of the pallidothalamic terminals is enlarged, 2) the average number of synapses per GPi terminal is decreased, and 3) the flat and surface areas of synapses formed by GPi terminals are increased. These findings suggest that pallidothalamic terminals are endowed with a high level of structural plasticity that may contribute to their increased tonic regulation of thalamocortical outflow in PD.

Title: Metabotropic glutamate receptor 5 (mglur5) in the monkey motor thalamus: Subsynaptic association with corticothalamic and cerebellothalamic glutamatergic afferents

Authors: *G. M. JEYARAJ[1], J.-F. PARE[1], Y. SMITH[1,2]
[1]Yerkes Natl. Primate Res. Center, UDALL Cen, Atlanta, GA; [2]Dept. of Neurology, Emory Univ., Atlanta, GA

Abstract: Metabotropic glutamate receptors (mGluRs) are widely distributed throughout the basal ganglia-thalamocortical system, and have been recognized as potential therapeutic targets for Parkinson’s disease. Our understanding of the role and subsynaptic localization of thalamic mGluRs remains limited. Because of its therapeutic relevance, the localization and function of mGluR5 in the basal ganglia has generated significant interest over the past decade. To better understand the potential regulatory role of mGluR5 upon the basal ganglia-related thalamic regions, a deeper understanding of the localization of mGluR5 in the primate motor thalamus is needed. To address this issue, we undertook a detailed electron microscopic analysis of the cellular, subcellular and subsynaptic localization of mGluR5 in the basal ganglia-receiving

regions of the ventral anterior/ventral lateral (VA/VL) and centromedian (CM) nuclei of adult rhesus monkeys, and compared these findings with those gathered from the cerebellar-receiving region of VA/VL. At the light microscopic level, both regions of VA/VL and the CM displayed strong neuropil staining in which laid some mGluR5-positive cell bodies. At the electron microscopic level, mGluR5 immunoreactivity was primarily expressed postsynaptically in dendrites of projection neurons and interneurons (recognized by their content in synaptic vesicles) in the three thalamic nuclei. Occasional immunoreactivity was also encountered in glial processes and putative axonal profiles. Pre-embedding immunogold labeling in VA-VL and CM dendritic profiles of projection neurons and interneurons revealed that 80-85% of gold particles were bound to the extrasynaptic domain of the plasma membrane, whereas 15-20% was intracellular. From the pool of plasma membrane-bound gold particles, a large proportion was found at the edges of the post-synaptic densities of asymmetric synapses formed by putative corticothalamic and cerebellothalamic terminals. The sources of the pre-synaptic boutons was confirmed in double-immunostained tissue for mGluR5 and either vesicular glutamate transporter type 1 (VGluT1-specific marker of cortical terminals) or vesicular glutamate transporter type 2 (VGluT2-specific marker of cerebellar terminals). These findings highlight the widespread expression of mGluR5 in projection neurons and interneurons of the motor thalamus, and provide a solid foundation for the mGluR5-mediated modulation of cortical and cerebellar glutamatergic synapses in the primate motor thalamus.

Title: Altered excitatory input to GABAergic interneurons in the ventral motor thalamus of MPTP-treated parkinsonian nonhuman primates

Authors: *J.-F. PARE[1], D. ALBAUGH[2], T. WICHMANN[3], Y. SMITH[4]
[2]Yerkes Natl. Primate Res. Ctr., [1]Emory Univ., Atlanta, GA; [3]Dept Neurol, Emory Univ. Sch. Med., Atlanta, GA; [4]Yerkes Natl. Primate Res. Ctr., Udall Ctr. Excel. For Parkinson's Dis. and Dept. of Neurol., Atlanta, GA

Abstract: GABAergic interneurons comprise nearly one third of all neurons in the primate motor thalamus, while they are almost non-existent in the rodent motor thalamus. Despite their abundance in primates, little is known about their synaptic connectivity and functional role in

thalamic processing. Defining the source(s) of their afferent inputs is a prerequisite to a deeper understanding of the mechanisms through which they integrate and regulate the thalamic microcircuitry. Although there is evidence for dysregulation of motor thalamic activity in MPTP-treated parkinsonian monkeys and Parkinson's disease patients, the substrate of these changes remains poorly understood. One potential source of pathological activity changes in the parkinsonian motor thalamus may be altered excitatory inputs to this region. Indeed, unpublished data from our group suggests that the total number of small terminals forming asymmetric synapses (likely corticothalamic terminals) is reduced in the motor thalamus of MPTP-treated parkinsonian monkeys, yet such terminals also tend to form complex multisynaptic contacts onto both thalamocortical and interneuron dendrites in the motor thalamus of parkinsonian monkeys, but not healthy controls. Taken together, these data hint that there may be a selective enhancement of cortical inputs to GABAergic interneurons in the parkinsonian state. To more directly address this question, we have now used electron microscopy to quantify the proportions of asymmetric synapses formed by VGLUT1-positive (ie of cortical origin) terminals onto GABA-labeled dendrites in the motor thalamus of healthy and MPTP-treated parkinsonian monkeys. We analyzed tissue of three healthy and three MPTP-treated monkeys, focusing separately on the basal ganglia- and cerebellar-receiving motor thalamic territories. Remarkably, in both territories, the proportions of asymmetric synapses that involved VGLUT1+ terminals in contact with GABA+ dendrites was markedly enhanced (nearly doubled), further suggesting enhanced corticothalamic innervation of interneurons in the parkinsonian state. For comparison, we also examined, in the same monkeys, the proportion of asymmetric synapses established by vGluT2-positive (ie of cerebellar origin) terminals on GABA+ dendrites in the cerebellar-receiving motor thalamic territory, and did not find obvious differences between healthy and parkinsonian animals. Collectively, these findings strengthen our hypothesis that cortical inputs to motor thalamic GABAergic interneurons are remodeled in the parkinsonian state, which may contribute to the dysregulated activity patterns observed in this region.

Title: Does drug-induced dyskinesia affect voluntary movements of patients with Parkinson's disease?

Authors: *C. DUVAL[1], E. GOUBAULT[2], K. LEBEL[3], S. BOGARD[4]
[1]UQAM, Montreal, QC, Canada; [2]Sci. of Physical Activity, Univ. of Quebec at Montreal, Montreal, QC, Canada; [3]Médecine dentaire, Uniersité de Montréal, Montréal, QC, Canada; [4]Sci. of Physical Activity, Univ. of Quebec At Montreal, Montreal, QC, Canada

Abstract: Introduction. Managing dyskinesia associated with Parkinson's disease (PD) is mainly achieved through medical regimen adjustments, sometimes leading to an increase in PD cardinal symptoms. In that case, it is important to objectively determine i) which cardinal symptom(s) is already present in a patient with PD having dyskinesia, ii) which symptom(s) is problematic in performing activities of daily living (ADL), and iii) which symptom(s) will have an influence on patients' daily tasks and quality of life (QoL). **Methods.** Patients with PD known to experience dyskinesia were recruited for this study. They were equipped with a suit containing 17 inertial sensors that recorded movements during the performance of ADL. The levels of dyskinesia, tremor, bradykinesia and freezing were objectively measured by the sensors. Levels of postural stability and muscle rigidity were assessed by clinical evaluations. Cognitive decline and depression symptoms were calculated by questionnaires MMSE and GDS-15, respectively. Patient's engagement level in daily tasks and the number of activities affected were assessed by the Activity Card Sort test (ACS). The SF12 was used to assess QoL. The threshold for symptomatology detection and abnormal ADL performance were set using data from an age-, gender-matched control group comprised of 69 participants. Logistic regression was used to identify symptoms affecting ADL performance, while ROC curves and Youden indices identified the critical moment (symptomatology level) where performance decreased. The engagement level and QoL of patients experiencing dyskinesia were compared to control participants and non-dyskinetic patients. Then, Spearman correlations and multiple regressions were performed to understand their relationship. **Results.** In a first study with 89 patients, some of those exhibiting dyskinesia also had rest, postural and kinetic tremor (12,7%, 37,1%, et 15,9% respectively), bradykinesia (28,6%), rigidity (55,6%), postural instability (71,4%) and freezing (9,5%). In a second study with 121 patients with PD (some of them participated in the first study), multivariate analysis showed that dyskinesia was not associated with lower performance in ADL, nor with the level of engagement in daily tasks or QoL. In fact, it is the cardinal symptoms of PD such as tremor, postural instability, bradykinesia, rigidity, depression or cognitive symptoms that had negative impacts. **Conclusion.** These results show that PD symptoms can be concomitantly present with dyskinesia, that they are more problematic for ADL performance, and have a greater influence than dyskinesia on QoL or on the participation in daily tasks .

Title: Development of high affinity D_2 receptor agonists as PET imaging agents for Parkinson's and schizophrenia: Preclinical studies

Authors: *S. SUBBURAJU[1], A. W. SROMEK[2], P. SEEMAN[4], J. L. NEUMEYER[3]
[1]Program in structural and Mol. Neurosci., McLean Hosp., Belmont, MA; [3]Medicinal Chem. Program, [2]McLean Hospital/Harvard Med. Sch., Belmont, MA; [4]Pharmacol. and Psychiatry, Univ. of Toronto, Toronto, ON, Canada

Abstract: The D_2^{high} receptor is thought to be the functional form of the D_2 receptor to which endogenous dopamine (DA) binds. Elevation of D2high receptors has been demonstrated in various neurological disorders in which the dopaminergic system is affected. In Parkinson's disease (PD), the loss of dopaminergic neurons causes a shift of remaining D_2 receptors into the high affinity state. Evidence for this is supported by the fact that medications used to treat PD have been shown specifically to target the D_2^{high} receptor. In schizophrenia, a higher proportion of D_2 receptors are in the high-affinity state, evidenced by the fact that schizophrenic patients are behaviorally supersensitive to dopamine agonists.
We recently reported the synthesis and receptor binding for D_1^{high}, D_{1low}, D_2^{high},D_{2low}, and D_3^{high} receptors of a series of fluorinated aporphines, and identified two highly promising high affinity D_2^{high} ligands as potential tritiated radioligands for applications in in vitro receptor binding assays and autoradiography studies, MCL-524 and MCL-536. These agonists exhibited no affinity or low affinity for other receptors tested, including serotonin, alpha and beta-adrenergic, benzodiazepine, GABAA, muscarinic, sigma, kappa, and mu opioid receptors, as well as dopamine, serotonin, and norepinephrine transporters and translocator protein.
We evaluated the radioligands [^{3}H] MCL-524 and [^{3}H] MCL-536 in saturation binding studies and competition binding studies using human D_{2long} expressed in CHO cells. In a competition binding assay with the agonist R-(-)-N-n-propylnorapomorphine (NPA) as the competing ligand, NPA had a K_i binding affinity of 0.16 nM. When [^{3}H] MCL-524 was used, NPA was found to have a Ki value of 0.9 nM. Co-incubation with guanylylimidodiphosphate abolished binding to D_2^{high}. We evaluated radioligands [^{3}H] MCL-524 and [^{3}H] MCL-536 for biodistribution in brain

and peripheral tissues in rats. Peak radioactivity levels were detected in the striatum vs. cerebellum between 15-30 minutes post-administration.
In summary, the radioligands [^{3}H] MCL-524 and [^{3}H] MCL-536 display high binding affinity to human D_{2long} and have proven to be superior radioligands for in vitro evaluation in receptor binding assays. Biodistribution studies indicate both radioligands have rapid uptake and selectivity for the striatum. This unique profile makes radiolabeled MCL-536 a versatile tool for diagnostics and therapeutics, and may quantify D_2^{high} sites in schizophrenia and Parkinsonian patients in vivo.

Title: Clinical trial to evaluate the feasibility and neuroprotective potential of photobiomodulation therapy on Parkinson's disease

Authors: *C. MORO[1], J. MOLET[1], D. AGAY[1], N. TORRES[1], S. CHABARDES[1], C. CHABROL[1], S. RENAULT[1], A. POIZAT[1], O. FAIVRE[1], J. MITROFANIS[2], A.-L. BENABID[1]
[1]Cea-Grenoble, Leti-Clinatec, Grenoble, France; [2]Univ. Sydney, Sydney, Australia

Abstract: Parkinson’s disease (PD) is a degenerative disorder that affects movement, due to the progressive death of dopaminergic cells in the midbrain substantia nigra pars compacta of the basal ganglia. Unfortunately, the progression of this cell death has proved difficult to slow and impossible to reverse. The “gold standard” treatments for most patients with PD (dopamine replacement drugs with or without surgery) are effective at attenuating the motor signs, at least initially, but they do not reliably slow the progression of the disease. Thus, there is a large need for new therapeutic strategies for treatment, particularly those that offer neuroprotection against PD insults. Photobiomodulation (λ=600-1070nm) has also been reported to be effective in several diseases, and some studies showed that photobiomodulation therapy improves locomotor activity associated with a neuroprotective effect as determined by rescue dopaminergic cells in mouse and non-human primates models of PD. These data confirm a real potential for the development of light therapy as a novel neuroprotective strategy. To this aim, we developed and qualified and intracranial implantable device delivering near infra-red light into the brain. This device and intracranial photobiomodulation therapy will be evaluated for their feasibility and safety on a clinical trial, and neuroprotective potential of this innovative technic will be also assessed on parkinsonian patients.

Global Ctr. for Med. Engin. and Informatics, Suita, Japan; [5]Neurorehabilitation Res. Inst., Morinomiya Hosp., Osaka, Japan

Abstract: Background:
Gait impairment including the freezing of gait (FOG) is the one of distinctive features of the patients with Parkinson's disease (PD) and has detrimental effect on their activities of daily living (ADL). Previous studies suggested the cortical and cortico-subcortical network dysfunction may contribute gait disturbance in PD patients including FOG. Among various cortical areas, the dorsomedial portion of motor cortex including the supplementary motor area (SMA) is suggested to play an important role in balance and gait control in human. Based on these findings, we hypothesized that SMA facilitation using functional near infrared spectroscopy mediated neurofeedback system (fNIRS-NFB) might help to improve gait impairment in PD patinets.
Objective:
To investigate the safety and efficacy of the fNIRS-NFB targeting the SMA activity combined with mental practice for the gait disturbance in PD patients through a randomized clinical trial. In this RCT, we are planning to include 40 PD patients with gait disturbance. To exclude the possible detrimental effect of the sham neurofeedback or fNIRS-NFB itself, we performed the interim analysis.
Methods:

Clinically established PD patients (N = 17, 7 males, Age : 75.0 ± 5.0, 6.2 ± 4.6 years from clinical onset) with written informed consent have participated. In addition to the usual inpatient rehabilitation up to 80min/day for two weeks, they participated 6 sessions of mental practice with motor imagery of gait and postural related task concurrent with neurofeedback of the SMA activation. Clinical measures including MDS-UPDRS, Hoehn-Yahr stage, and mini-mental state examination (MMSE), are assessed as baseline characteristics. Gait and balance measures including Timed Up-and-go test (TUG), Freezing of gait questionnaire (FOGQ), Berg Balance Scale (BBS), and Gait speed are also assessed before and after 2 weeks of intervention. Subjects are randomly assigned to 2 groups (REAL and SHAM). Neither patients nor physicians did not recognize which group they were assigned (double blinded).
Results:
Baseline clinical characteristics were comparable between two groups. There was non-significant trend for interaction between group and TUG time with more improvement in the REAL group (time×group interaction :$F_{2,14}$=2.58, p=0.096. TUG gain: t_{15}= 1.89, p=0.086). SHAM group did not show any detrimental effect on TUG (95%CI for immediate effect: -24.7sec to 7.9 sec, t_7=-1.22, p=0.26), and here was no adverse effect associated with fNIRS-NFB in both groups.
Conclusion:
This interim analysis confirmed the safety of fNIRS-NFB in PD patients and suggested the beneficial effect on gait disturbance in PD patients.

Abstract: Gait automaticity is known to be reduced in patients with Parkinson's disease (PD) due to impaired habitual control. Robot-assisted gait training (RAGT) has been suggested to improve gait speed and balance in these patients. The aim of this pilot study was to investigate the effect of RAGT on gait automaticity as well as gait speed and balance in patients with PD. Patients with idiopathic PD (H&Y stage 2.5 or 3) received 12 sessions of RAGT, 45-min, 3 days a week, for 4 weeks using an exoskeleton-type gait robot with partial body weight support (Walkbot_S; P&S Mechanics, Seoul, Korea). Primary outcome was the percentage of dual-task interference measured by 10 meter walking test (10MWT) under single- and dual-task conditions. Cognitive dual-task walking was measured using Wechsler Forward Digit Span, and physical dual-task walking was measured with a tray with two cups of water. Patients were also evaluated with Berg Balance Scale (BBS) and Korean version of the Falls Efficacy Scale-International. All outcomes were measured before (T0), after (T1) and 1 month post-treatment (T2). Eleven patients with idiopathic PD were participated (Table 1). Cognitive dual-task interference was significantly increased at T1 (p=.026), but not at T2. No significant changes were found for physical dual-task interference at T1 and T2 (Table 2). Single-task gait velocity was significantly increased at T1 (p=.041), but not at T2 (p=.445). On the other hand, there were no significant changes in dual-task 10MWT. A significant improvement was also found on the BBS at T1 and T2 (p=.004 and p=.024, respectively). In this study, the gait automaticity in patients with PD was not improved by RAGT using an exoskeleton-type gait robot despite improvement in walking speed and balance. Additional therapeutic components may be needed to improve gait automaticity using RAGT in patients with PD.

Table 1. Patients' demographics and baseline characteristics (N=11)

Male/female (n)	5/6
Age (yr)	66.46 ± 5.66
Disease duration (mo)	112.91 ± 50.19
Hoehn & Yahr stage 2.5/3 (n)	8/3
MMSE-K (score)	28.55 ± 0.93

Mini Mental State Examination-Korea; MMSE-K

Table 2. Changes in percentage of dual-task interference (%)

		T0 (n=11)	T1 (n=11)	T2 (n=10)	Within-group comparisons (changes)	
					T1 - T0	T2 - T0
Gait velocity	Dual task (cognitive)	-15.78 (7.78)	-.21.50 (7.62)	-20.75 (6.40)	.026*	.203

	Dual task (physical)	-21.23 (7.42)	-21.10 (5.79)	-23.51 (12.55)	.929	.646

Percentage of dual-task interference; (dual-task performance – single-task performance)/single-task performance , T0; Before treatment, T1; After treatment, T2; 1 month post-treatment, †Mean (SD), *p<.05 by Wilcoxon signed-rank test

Title: Abnormal motor cortex plasticity induced by transcranial static magnetic field stimulation in dyskinetic patients with Parkinson’s disease

Authors: M. DILEONE[1], C. AMMANN[1], V. CATANZARO[1], I. OBESO[1], A. OLIVIERO[2], J. A. OBESO[1], *G. FOFFANI[1,2]

Abstract: Levodopa-induced dyskinesias (LIDs) represent a common motor complication in Parkinson’s disease, but their pathophysiological mechanisms and even the exact brain circuits involved in their generation remain unclear. The aim of the present study was to test whether the primary motor cortex is just a ‘passive integrator’ of subcortical and cortico-cortical abnormalities, or it also plays an active role in the pathophysiology of LIDs. To address this issue, we adopted a new perturbation strategy, by applying transcranial static magnetic field stimulation (tSMS) of the motor cortex (Oliviero et al., J Physiol 2011; Dileone et al., Sci Rep 2017; Dileone et al., Brain Stimul 2018) in dyskinetic (n=22) and non-dyskinetic (n=17) patients with Parkinson’s disease. Crucially, all patients were studied off medication, after overnight withdrawal of dopaminergic therapy, when LIDs are absent in both groups. We assessed both corticospinal and intracortical tSMS-induced plasticity, using the amplitude of motor evoked potentials (MEPs) elicited by single-pulse transcranial magnetic stimulation (TMS) and short-interval intracortical inhibition (SICI) to paired-pulse TMS. In non-dyskinetic patients, 10-min-

tSMS induced MEP depression and increased SICI. In dyskinetic patients, conversely, 10-min-tSMS induced MEP potentiation and did not significantly modulate SICI. These results suggest that abnormal motor cortex plasticity may contribute to the pathophysiology of LIDs.

Title: Does high-cadence cycling promote changes in inhibitory brain circuits in Parkinson's disease?

Authors: *A. L. RIDGEL[1], Y.-C. CHUNG[2], J. HERSHBERG[3], C. BROWN[2], B. E. FISHER[3]
[1]Exercise Physiol., Kent State Univ., Kent, OH; [2]Keck Sch. of Med. of USC, Los Angeles, CA; [3]Div. of Biokinesiology and Physical Therapy, USC, Los Angeles, CA

Abstract: There is significant evidence for the benefits of exercise on motor symptoms in Parkinson’s disease (PD) and it has been suggested that exercise exerts its beneficial effects, at least partially, through changes in the brain. However, the exact nature of these alterations is not known and few studies have linked these changes in motor behavior with alterations of the brain. Transcranial magnetic stimulation (TMS) studies have documented both a decrease in cortical silent period duration (CSP) and short-interval intracortical inhibition (SICI) as common pathophysiological features in PD. Importantly, greater cortical inhibition after medication, as evidenced by an increase in CSP and SICI, has been associated with behavioral improvement. We have previously demonstrated that high-velocity treadmill training lengthened CSP and promoted improvements in gait in PD. We have also shown that high-cadence cycling increased brain activation as measured by fMRI and reduced motor symptoms in PD. These findings suggest that the high velocity component of these training paradigms may be the driver of these brain changes. However, it is not known if the velocity of movement drives the exercise-induced effects on motor performance by altering inhibitory circuits in the PD brain. In this exploratory study, individuals with mild-moderate PD were randomly assigned to either a high-cadence or a low-cadence dynamic cycling intervention, in which the pedaling rate varied around the target cadence. Participants cycled on a motorized stationary bike that maintained the identified cadence parameters 2-3 times per week for 3 months. At baseline and following the 3-month

intervention, single and paired pulse TMS was completed to determine the effect of cadence on CSP and SICI. TMS was applied to the more-affected motor cortex over the representational areas of tibialis anterior and first dorsal interosseous muscle. Preliminary analysis of the data showed no pre-post change in CSP in any of the participants. Interestingly, SICI was increased in all subjects regardless of cycling cadence. These results suggest that exercise facilitates beneficial brain changes in PD by modulating the inhibitory circuits, and that other components of dynamic cycling may be the key ingredients for enabling these changes. Future studies need to examine the role of cadence variability and rider motivation and consistent effort in identifiable brain changes after exercise.

Title: Comparison of deep brain stimulation lead impedance between Medtronic and St.Jude Medical/Abbott systems during the perioperative period

Authors: *E. L. HARGREAVES[1], N. A. BUCKLEY[2], D. O. CONNOLLY[2], D. L. CAPUTO[3], S. F. DANISH[4]
[1]Robert Wood Johnson Med. Sch. -- Rutgers Univ., New Brunswick, NJ; [2]Neurosurg., [3]Neurol., Robert Wood Johnson Med. Sch. - Rutgers Univ., New Brunswick, NJ; [4]Neurosurg., Cancer Insitute of New Jersey - Rutgers Univ., New Brunswick, NJ

Abstract: We measure stimulating lead impedance at final placement during Stage I implantations, again following connection of extensions and the neurostimulator during the Stage II implantations 7 days later and at the beginning of the contact screen prior to activation and every other programming session. The Medtronic Activa PC 37601 or ENS 37022 impedance measurements used endogenous parameters of 3.0V, 80µs, and 100Hz; 14 pulses per monopolar (against the neurostimulator case) or bipolar contact combination. The St.Jude Medical/Abbott (SJM) Infinity IPG models 6660 and 6662 and the ENS 6599 model used endogenous impedance parameters of 30µs, 250Hz, and 500µa cycling as necessary to 163µa, with one or two pulses. Individual contact impedance is measured against the aggregate of remaining contacts. The annular contacts of the both the Medtronic 3389 and 3387 leads and the annular contacts of the SJM 6172 and 6173 leads are 1.5mm in height by 1.27mm in diameter, composed of an 80/20

platinum/iridium mix. The Medtronic connecting wires are an identical alloy, embedded in a polyurethane insulation, whereas the SJM connecting wires are composed of a nickel cobalt alloy, embedded in ethylene tetrafluoroethylene, covered with Bionate hypo tubes (Michmizos et al., 2017). 52 leads from 26 individuals with Medtonic systems were compared to 15 leads from 8 individuals with SJM systems. Analysis of the monopolar contact impedances indicated that the Medtronic impedances (1002.22) were higher than the SJM impedances (627.24) for the Stage II ($F_{(1,353)}$=62.01; p=.0005) and Contact Screen (Medtronic 1381.20, SJM 1205.69; $F_{(1,353)}$=3.83; p=.051). No Left/Right or Dorsal/Ventral differences or interactions were observed.The SJM impedances decreased from Stage I to II then dramatically increased to the contact screen in a quadratic trend, regardless of the annular or segmented leads being tested ($F_{(1,52)}$=125.06; p=.0005). The Medtronic bipolar impedances exhibited the same quadratic pattern ($F_{(1,317)}$=84.84; p=.0005). The segmented contacts of the SJM recorded a higher impedance then their annular contacts (ann: 929.89 seg: 1672.43; $F_{(1,52)}$=215.85; p=.0005). Analogously, the bipolar contacts of the Medtronic system recorded a higher impedance than their annular contacts (ann: 1212.54 bi: 2017.27; $F_{(1,608)}$=473.70; p=.0005). Our initial analyses indicate that the perioperative impedances of both systems exhibit the same pattern across time, but that the SJM monopolar impedances are consistently less than the Medtronic monopolar impedances. This likely has to do with the impedance return anode using either the case versus the aggregate of the remaining contacts.

Abstract: Surgical planning and post-operative programming of deep brain stimulation (DBS) for Parkinson disease (PD) with motor fluctuations has changed relatively little over the past two decades and relies heavily on microelectrode recording and trial-and-error settings, respectively. Using probabilistic Diffused Tension Imaging (DTI) tractography followed by scheletonization and Tract-based spatial statistics (TBSS) we identified the connections of DBS leads in individual patients who underwent DBS surgery for Parkinson disease. We use these connections and clinical outcome data to predict characteristics associated with a favorable and unfavorable clinical response.
All subjects (n = 35) had MRI images as part of the surgical planning including FLAIR, contrasted T1,T2 and DTI images (64 directions) on a 3T Phillips scanner. Images were merged with the postoperative CT scan to identify the exact electrode placement. Following reconstruction, manual tracing of ROIs (involving the DBS lead active contacts) was performed on nonsegmented high resolution T1 images coregistered into T2 space with the post-op CT using BRAINLAB software (Feldkirchen, Germany). Images were realigned using the plane containing the anterior and posterior commissures and the sagittal sulcus to correct head tilt, and resampled into isotropic voxels (0.9375 mm3). Fractional anisotropy (FA) for each voxel was calculated for each volume. We developed a Generalized Factorization Method (GFM) to identify biclusters (i.e., subsets of subjects associated with a subset of particular characteristics, such as low FA in connections attached to each lead). Using the GFM, we identified characteristics associated with a favorable and unfavorable clinical outcome from DBS and programming data. The robustness (high/low FA values) and the destination of the white matter fibers (location) in the region of the active electrode are associated with favorable (high UPDRS-III scores) and unfavorable outcomes (low UPDRS-III) scores. The identification of patient clusters based on these characteristics allows response prediction and future treatment optimization.
o maximize efficacy and minimize the side effect profile for patients undergoing DBS surgery for Parkinson disease, DTI connectivity data can be used to predict and optimize clinical outcomes in future DBS lead placement and programming.

Title: Quantitative analysis of pneumocephalus-related brain shift in deep brain stimulation patients

Authors: *P. M. LAURO[1], A. M. ALDRIDGE[2], W. F. ASAAD[3]
[1]Dept. of Neurosci., [3]Neurosurg., [2]Brown Univ., Providence, RI

Abstract: Deep brain stimulation (DBS) is a therapy for movement disorders such as Parkinson's disease. Successful DBS outcomes depend on the precise placement of stimulating electrodes. When the skull is opened during the surgical procedure, CSF exiting the skull can be replaced by air. Resulting pneumocephalus can deform and shift the brain in a non-linear manner, potentially affecting the electrode placement accuracy and DBS clinical outcomes. Because movement disorders patients can be older, we also investigated the effect of age-related brain atrophy on pneumocephalus and resulting brain shift.

Thirty DBS patients received the following scans: preoperative T1-weighted (T1w) MR images, an intraoperative CT scan, and postoperative T1w MR images. All scans underwent linear skull-to-skull registration using a mutual information algorithm. Preoperative T1w images were segmented using Freesurfer. The resulting whole-brain volume was divided by the total intracranial volume. We then calculated an "atrophy index" by subtracting this ratio from 1. Voxels within CT images were segmented into different categories (blood, air, tissue) by Hounsfield values. The volume of "air" voxel clusters within the skull were calculated as the pneumocephalus volume. Finally, postoperative T1w images underwent nonlinear registration to preoperative T1w images. The resulting warp-field deformations in the medial-lateral, anterior-posterior, and dorsal-ventral axes were interpreted as "pre to post shift." The warp values in each dimension were collapsed into a single "vector shift" value, and each patient's "shift" value was an average of all "vector shift" voxels within the brain.

Pearson correlation of patient age and atrophy index revealed a non-statistically significant direct relationship ($r = 0.271$, $p = 0.147$). Patient atrophy index and pneumocephalus demonstrated a non-significant relationship ($r = -0.155$, $p = 0.414$). Similarly, pneumocephalus demonstrated a non-significant relationship with whole-brain shift ($r = 0.195$, $p = 0.301$). However, age and atrophy demonstrated statistically significant inverse relationships with whole brain shift ($r = -0.442$, $p = 0.014$; $r = -0.566$, $p = 0.001$).

While pneumocephalus does not appear to impact brain shift, increasing age and brain atrophy seem to decrease brain shift. This unexpected result may point to age-related changes in brain tissue compliance which are not measured with neuroimaging.

Title: Effects of group singing on stress and motor symptoms in persons with Parkinson's disease

Authors: *E. L. STEGEMOLLER[1], A. F. ZAMAN[2], E. SHIRTCLIFF[1]
[1]Iowa State Univ., Ames, IA; [2]Kinesiology, Iowa State Univ. Dept. of Kinesiology, Ames, IA

Abstract: Research has revealed that group singing is an effective treatment strategy to improve respiratory control and muscle activity associated with swallow in persons with Parkinson's disease (PD). Moreover, singing groups can be enjoyable for participants and offer a way to relieve stress, have fun, and improve other motor symptoms. Thus, the purpose of this study was to examine the acute effects of group singing on stress and clinical measures of PD motor symptoms in persons with PD. Seventeen participants with PD (mean age = 76 ± 7 years; 47% male; disease duration = 7 ± 5 years) that engage in weekly group singing completed the study. Participants were tested on medication and had been singing in the group for a mean of 2.4 ± 1.4 years. Self-report and physiological data were collected prior to and after 1 hour of therapeutic group singing. The Unified Parkinson's Disease Rating Scale (UPDRS) was collected to assess the clinical motor symptoms and later scored by a trained rater blinded to pre/post collection. Subjective measures anxiety, sadness, happiness, and anger were also collected to measure emotion and affect. Heart rate, blood pressure, and salivary cortisol provided an index of physiological stress. Saliva samples were frozen within 1 hour of collection and stored at -80^{o}C. Saliva was thawed and assayed in duplicates using a commercially-available enzyme-immunoassay (Salimetrics, LLC). Results revealed that participants subjectively felt less anxious (p = 0.05) and less sad (p = 0.002) after the singing group. There were no significant differences in happiness or anger. Heart rate, blood pressure, and cortisol levels were also reduced, but did not reach significance. Lastly, motor symptoms significantly improved (p = 0.026), which was driven mostly by improvements in upper extremity bradykinesia, tremor, and walking. These results suggest that singing may have benefits beyond improving respiratory control and swallow in persons with PD, improving mood and motor symptoms as well as reducing physiological indicators of stress. Thus, group singing holds promise as an alternative treatment strategy for persons with PD that has a broad impact on motor symptoms, stress, and quality of life.

Title: A retrospective analysis of chronic STN LFP beta signals recorded by the Medtronic Activa® PC+S implanted in Parkinson subjects

Authors: M. CASE[1], S. STANSLASKI[1], V. VASOLI[1], J. XIAO[1], S. GOETZ[1], T. DENISON[1], *R. S. RAIKE[2]
[1]Medtronic, Minneapolis, MN; [2]Medtronic Inc, Minneapolis, MN

Abstract: Deep brain stimulation (DBS) is an approved therapy for treating the motor symptoms of Parkinson disease (PD). Several long-term follow-up studies demonstrate the safety and efficacy of subthalamic nucleus (STN) DBS for PD, though improvements could facilitate increased adoption among eligible patients. Closed loop or adaptive DBS algorithms are emerging as a promising approach for individualizing and optimizing the therapy. Perhaps the most commonly-used control signals promising chronic accessibility for adaptive DBS (aDBS) are local field potentials (LFPs), representing oscillations in neuronal network activity adjacent to the recording electrode. LFP beta band (13-30 Hz) power can be associated with different PD patient states, including symptom, therapy and disease progression. For example, PD bradykinesia, rigidity and gait freezing are associated with high-amplitude, long-duration STN LFP beta oscillations, which are distinct from the beta activity associated with normal movements. Both PD medication and DBS therapies suppress pathological LFP beta band power while improving both bradykinesia and rigidity but not tremor. Furthermore, a growing body of evidence from independent research groups suggests potential efficacy, side-effect and efficiency benefits to LFP-beta controlled STN aDBS in studies of akinetic-rigid PD subjects. However, the broad translational potential of LFP beta aDBS is still debated, particularly with respect to general accessibility of sufficient control signals. Critically, LFP signals have been demonstrated to be chronically accessible and stable for years when recorded with the same DBS electrodes that deliver therapy. Although some single-center studies report high rates of success detecting robust LFP beta signals within the PD STN, replicability of this result is an important question. Therefore, we conducted a retrospective analysis of chronic STN LFP beta signals recorded from a large multi-center cohort of PD subjects implanted with the Medtronic Activa® PC+S, which is an investigational device capable of both delivering standard electrical stimulation therapy and recording LFP data through DBS therapy leads. The relationship between LFP beta signal strength and DBS lead location within the brain and PD phenotype (tremor dominant, akinetic-rigid or mixed) will be explored.

Title: Pilot study on the interaction between exercise, medication, and Parkinson's disease symptoms

Authors: *S. L. HOWARD, C. A. KNIGHT
Univ. of Delaware, Newark, DE

Abstract: Motor symptoms of Parkinson's disease (PD) include tremor, bradykinesia (slow movement), rigidity and impaired postural control. Symptoms are treated with dopamine replacement therapies (DRT) and it has been shown that exercise helps slow disease progression and improve mobility. In studies involving rapid isometric contractions, some have reported abnormally segmented force production that could impair multiple aspects of mobility. There has been little development of segmentation measures. Aim 1 was to explore the interaction between single bouts of speed-based exercise and DRT in the management of bradykinesia during the later-day 'wearing-off' phase when DRT doses sometimes have diminished efficacy. Grip strength, timed up and go (TUG) and isometric force pulses were measured before and after three treatment conditions: 1) no exercise, DRT only; 2) no DRT and a 30-minute high-speed low resistance (HS-LR) bicycling session; and 3) DRT plus HS-LR bicycling session in nine subjects with PD (Hoehn-Yahr $\leq$ 3.0). It was hypothesized that the medication plus exercise condition would cause the greatest improvement in function. Aim 2 was to evaluate test-retest reliability of force segmentation and time to peak force (tPF) measures. Paired t-tests did not support any treatment effects (all p>.186). T-statistics were greatest in the medication-only condition for grip strength (t=1.39, p=.202) and force segmentation (t=1.447, p=.186), in the direction of improvements. Delaying an afternoon dose of medication was more challenging for some subjects. Individual exercise responses varied considerably. Segmented force pulses were observed in most subjects and the mean segmentation was strongly correlated with tPF on all three visits (r=.879-.961) suggesting that slowing in force production is related to a disruption, rather than a reduction, in neural drive. ICCs supported favorable test-re-test reliability of mean

segments (r=.83) and tPF (r=.82) relative to ICCs of .96 and .82 for grip strength and TUG, respectively. The methodological approach to Aim 1 would likely require a larger sample size and better control of confounding variables to determine, with adequate power, whether afternoon exercise can boost function alone or with medication. Results related to Aim 2 are promising in that mean segmentation has similar reliability to TUG, which is already accepted in rehabilitation research. Furthermore, strong correlations between segmentation and tPF support further inquiry into the role of disrupted neural drive in bradykinesia.

Title: Tractography-based machine learning algorithm for prediction of acute stimulation-induced side effects in DBS for Parkinson's disease

Authors: *S. C. NANIVADEKAR[1], P. TAYLOR[2], D. EHRLICH[1], C. LUNGU[1], S. G. HOROVITZ[1]
[1]NINDS, [2]NIMH, NIH, Bethesda, MD

Abstract: Deep Brain Stimulation (DBS) is an invasive treatment that improves motor symptoms in Parkinson disease. Certain DBS settings can lead to acute side effects like paresthesia, facial pulling, or speech difficulty, and need to be avoided. Using diffusion tensor imaging (DTI) and clinical data, we have developed a tractography-based algorithm to classify SideEffect (SE) vs. non-SideEffect (nSE) DBS settings. We included neuroimaging and clinical data from 33 Parkinson’s patients with subthalamic nucleus DBS and 6 patients with globus pallidus DBS. T1-, T2-, and Diffusion- weighted images were collected pre-Operatively and T2w images and CT scans were collected post-Operatively. Diffusion data was preprocessed in TORTOISE[1]. We modeled patient-specific volumes of tissue activated (VTA) using DBSproc[2] for the stimulation parameters on each contact that produced clinical benefit (entry) and acute sensorimotor side effects (exit). We performed probabilistic tractography to determine the white matter connectivity between the grey matter ROIs defined from Freesurfer segmentation plus subcortical areas in the ventral diencephalon. We identified tracts that intersected with the VTA at the entry and exit voltages, and computed a binary connectivity vector (intersects with a given tract or not). Each contact and setting had an associated label (SE or nSE). We then used a logistic regression-based single-layer neural network to train the algorithm to classify an

unlabeled connectivity vector into one of the two output classes. The percent error of the training dataset was 37.61% and the testing dataset was 28.72%. The ranked weight vector of the hidden layer in the classifier provided us with the tract features that were most important to determining the output class of the connectivity pattern. Tracts emanating from the L. thalamus to the brainstem, amygdala and putamen were most important in being able to classify the groups. We also performed a voxel-wise t-test on the connectivity maps to find differences between the symptom-producing contacts and the non-symptomatic contacts. Areas in the L. thalamus, putamen and brainstem showed significant ($p<0.005$) differences, providing empirical validation for our learning algorithm. Hence, we developed an effective algorithm that can predict, for a contact and stimulation setting, the probability of side effect occurrence based on the connectivity profile of the stimulation. This learning algorithm allows us to identify biologically relevant tracts that, if selectively stimulated, may generate undesirable side effects.

Title: Alterations in the control and coordination of grasping forces in Parkinson’s disease following aerobic exercise

Authors: *J. L. ALBERTS[1], A. PENKO[2], A. E. JANSEN[2]
[1]Biomed. Engin., [2]Dept. of Biomed. Engin., Cleveland Clin., Cleveland, OH

Abstract: For individuals with PD, motor control impairments may have a substantial impact on overall dexterity and consequently on activities of daily living. Aerobic exercise has been shown to be a beneficial adjunctive therapy to standard clinical care for individuals with Parkinson’s disease (PD), and has resulted in global motor function improvements. However, the effects of lower extremity exercise on the control and coordination of grasping forces during bimanual dexterous actions is unknown. The aim of this project was to determine the effects of high-intensity aerobic exercise on changes in bimanual force coordination patterns in individuals with PD. A total of 26 PD patients completed a supervised eight week (3x per week) high intensity

aerobic exercise intervention. Grasping forces and torques were measured during the completion of a bimanual dexterity task in which one limb served to stabilize the object while the other limb performed a manipulation action. Dexterity assessments were completed at baseline both “on” and “off” PD medications, end of treatment (EOT), and EOT + 8 weeks (EOT+8). Overall, the participants were compliant with the prescribed exercise protocol. Results from the dexterity task indicated that, compared to baseline off conditions, following exercise there was an improvement in total task time. Improvements in task time were likely the result of improved rate of grip force production, improved bilateral onset of grip and load forces and enhanced coordination of grip-load coupling. Enhanced bimanual dexterity in PD patients, following aerobic exercise, suggest that exercise may be altering the mode of force control as PD patients may be shifting from a reliance on feedback to feedforward control patterns. An improvement in the specification of upper extremity forces, following a lower extremity exercise intervention, indicates high intensity aerobic exercise results in a global improvement in central nervous system functioning.

México, Mexico; [6]Div. of Neurosciences., Occidental Biomedical Research Centre, Social Secu, Mexico

Abstract: Oxidative stress (OS) constitutes one of the earliest alterations of Parkinson’s disease (PD) and recent data suggest that dietary intake influences the risk of developing this disease. Thus, studies about the nutrient intake and its relationship to OS in PD may provide information that will help to make nutritional recommendations. We evaluated food intake, OS markers and antioxidant activities of patients in early stages of PD. A cross-sectional, descriptive, and comparative study in early-stage PD patients and controls was conducted. A sample of 22 adults

with an age range of 43-88 years was included in order to match controls and PD patients. All participants received detailed information about the study and signed a letter of informed consent. This investigation was performed according the Declaration of Helsinki and the Regulations of the General Health Act of Mexico. Methodological procedures were approved by the Ethics and Research Committee of the of the Health Department in Jalisco. Additionally, the integrity and security data of PD patients and adults without neurodegeneration included in the study were protected. Anthropometric measurements, food consumption, lipid peroxidation products, carbonylated proteins, total antioxidant capacity and enzymatic activities of catalase, superoxide dismutase and glutathione peroxidase were assessed. The blood sampling and analyses were performed in coordination with the Regional Hospital of Ciudad Guzman in Jalisco, Mexico. Descriptive statistics including the mean and standard deviation were used in patients' sociodemographic characteristics and food consumption frequency. To determine statistically significant differences in biochemical indicators between patients and the control group, a student-T test and distribution was used. For the chemical variables, the Kolmogorov-Smirnov test was used to confirm the normality. PD patients showed a higher intake of monounsaturated and saturated fatty acids ($p<0.05$) than controls; in addition, levels of lipid peroxidation products and catalase activity were increased in PD patients compared to controls ($p<0.05$). These results together with the low intake of antioxidant vitamins A, E and folic acid, suggest alterations in oxidative status in PD patients; however, further studies are required with a larger sample of patients including patients with other stages of PD.

Title: Burden and caregiving in Parkinson's disease due to apathy

Authors: *J. G. AVILA-LORETO[1], M. ARROYO-MEDRANO[2], T. VILLASEÑOR-CABRERA[2]
[1]Univ. De Guadalajara, Guadalajara, Mexico; [2]Univ. de Guadalajara, Guadalajara, Mexico

Abstract: Background: It has been shown that the risk of burden in caregivers of people with Parkinson's disease (PD) is increased when affective symptoms predominate. The most studied are related to depression, however the relationship between the burden of the caregiver and the

levels of apathy of the patient is unknown. Objective: This study aims to evaluate the burden and associated factors on caregivers of people with PD who show apathy. Methods: An observational, cross-sectional study was carried out with 25 pairs of caregivers and their patient from the Clinic of Abnormal Movements and Neurodegenerative Disorders from the Fray Antonio Alcalde Civil Hospital. They were assessed using the Zarit burden inventory (ESCZ) and the Starkstein Apathy Scale (AS) respectively. The overall proportions of each scale were analyzed with Student's T for independent samples and Pearson correlation. Results: Preliminary, 50 participants, 25 caregivers (mean age 52.6 ± 13 years) and their patients (65.1 ± 11 years) were enrolled. The majority of caregivers were providing assistance to the patient for ≥ 4 years, caregiving 12 h a day. Most caregivers were spouses. Female caregivers were more overburdened (56%) than male caregivers (22%). Overall score in ESCZ was correlated with the presence of apathy in patients with PD (p= 0.372) mainly in the domain of caregivers personal and social life deterioration. Conclusions: The levels of burden in caregivers correlate with levels of apathy in patients with PD. We also found that they are more women who are responsible for care and have a higher level of overload than men.

Title: Effects of the manipulation of an artwork on time perception in Parkinson’s disease patients

Authors: *J. O. BUENO[1], M. R. MOTTA[2], V. TUMAS[3]
[2]Psychology, [3]Neurosci. and Behavior, [1]Univ. São Paulo, Ribeirao Preto, Brazil

Abstract: Introduction: Different situations and conditions can alter the temporal perception of individuals, for instance, the artworks appreciation by Parkinson’s disease (PD) patients. It is known that PD is characterized by a dysfunction of the dopaminergic system that is considered involved in temporal processing and motor function. The appreciation of artworks through manipulation can alter the perception of the time of people with this disease. Objective: Examine how the manipulation of artworks affects time perception in PD patients. Methods: The research ethics committee of the University of São Paulo approved the study and the informed consent

was collected from all participants prior to the test. Ten participants with PD and 10 healthy subjects were required to manipulate two reproductions of artworks from the series “Bichos” by Lygia Clark (1960) with different number of piece (six piece: less complex-LC; ten piece: more complex-MC). After that, they performed a verbal estimation about the temporal duration of their manipulations. The behaviors were recorded and then transcribed and analyzed. The data were analyzed by Shapiro-Wilk, Mann-Whitney U and Wilcoxon tests. Results: All participants overestimated the manipulation time of the artworks. However, participants with PD showed less overestimation than healthy subjects. The manipulation time of the artworks to PD patients was shorter than to the healthy subjects and PD patients showed a lesser time of manipulation of the MC artwork. Four behavioral categories were analyzed: Touch, Move, Change of the artwork’s placement and Release the piece of art. The analysis of the exploratory activity of the participants showed that those with PD touched and released the stimulus more often and, in contrast, they moved and dislocated it less than the participants without the disease. PD participants presented a greater proportion of touches to MC artwork and lesser frequently of movement to LC artworks than to healthy subjects. Conclusion: PD patients showed altered perception of artwork manipulation time. This suggests that exploratory behavior influenced temporal estimation. In addition, it is possible that patients with PD had decreased ability to manage attention during the task, that interfered in the cognitive reconstruction of its duration. These considerations indicate that, as a result of cognitive and motor changes, patients with PD present impaired temporal information processing. The involvement of exploratory behavior facilitated the understanding of these results and processes in terms of timing operations of the basal-talocortical ganglion system.

Title: A personalized neuromechanical simulation of hand pronation and supination task in persons with parkinson’s disease: Effects of tonic dopamine levels and disease progression

Authors: *L. ZIEGELMAN[1], Y. HU[2], R. SUN[3], M. E. HERNANDEZ[2,1]

Abstract: This study aimed to create a neuromechanical simulation of hand pronation and supination. This was accomplished by combining an adapted Matsuoka oscillator and torque-based equations to model the kinematics of the desired motion. In addition to the exploration of changes in neural and biomechanical conditions due to age and presence of a neurodegenerative disorder such as Parkinson's Disease, this model aims to accurately simulate changes in a patient's ability to pronate and supinate their hand based off their access to medication and disease progression. Healthy young adults (HYA), healthy older adults (HOA), and patients with Parkinson's Disease (PD) performed 5 trials of repeated pronation and supination for 30 seconds while wearing an InertiaCube BT. This experimental data was used to validate the position output of the model. This simulation shows marked decreases in amplitude and frequency of movement with the progression of PD as well as during the off-medication phase. This simulation is the first to recreate pronation and supination kinematics based on changes in descending or tonic input due to disease progression.

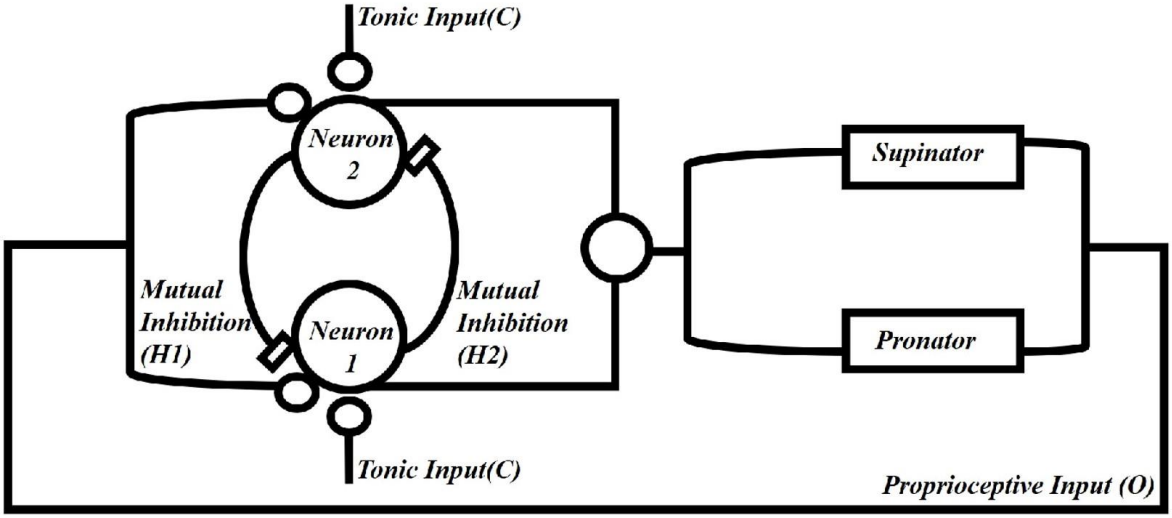

Fig. Representation of the model proposed for hand pronation and supination. This model includes two mutually inhibitory neurons forming a central pattern generator that results in pulses to the supinating and pronating muscles of the hand. The tonic input received by each neuron represents the descending input from the brain, altered by the severity of Parkinson's Disease and the medication state of the individual. Proprioceptive input from the hand is received by the central pattern generator when the hand pronates or supinates past its natural range of motion.

Abstract: Huntington’s Disease (HD) is a rare autosomal dominant neurodegenerative genetic disorder, resulting in abnormal movements of the limbs, along with cognitive deficits and psychiatric symptoms. The underlying cause of the disease is a genetic mutation of the *huntingtin* gene (m*HTT*), which codes for the huntingtin protein (HTT), whereby the poly-glutamine (CAG) repeat domain is extended to more than 35 CAG repeats. Though exact mechanism of the HD pathology is not known, several studies reported abnormal mitochondrial dynamics in HD patients, HD mouse models, and cell lines that express mutant Htt. CRISPR-Cas9 plasmid was constructed to target the DNA at untranscription region (UTR) upstream to the open reading frame (uORF) that resulted in 79 percent decrease in the mutant mHTT protein in the bone marrow derived mesenchymal stem cells (BM MSCs) extracted from YAC128 that carry human mutant huntingtin protein. CRISPR-Cas9 editing leads to indel mutations (random addition / deletions of nucleotides) at the targeted site. This enabled us to obtain single cell clones that expressed different levels of mutant huntingtin protein. The goal of this study was to unravel the link between toxicity exerted by mutant huntingtin and mitochondrial dysfunction. We have observed that blocking the mHTT by CRISPR-Cas9 increased the cell survival of the BM MSCs and restored abnormal mitochondrial bioenergetics involved in HD progression.
Key Words: Huntington’s Disease, CRISPR-Cas9, gene-silencing, mitochondrial bioenergetics.

Title: Comparison of the effects of PHP.eB vectors encoding truncated or point-mutated EAAT2 isoforms as opposed to wild-type EAAT2 in single striatal astrocytes of Q175 heterozygote mice

Authors: *S. HIRSCHBERG[1], A. DVORZHAK[1], S. ANGELOV[1], P. KOVERMANN[2], R. GRANTYN[1]
[1]Einstein Ctr. for Neurosciences, Charité Univ. Med. Berlin, Berlin, Germany;
[2]Forschungszentrum Jülich, Institute of Complex Systems, Germany

Abstract: Neurodegenerative diseases such as Huntington's disease (HD), Alzheimer's disease and ALS are often associated with a reduced expression of the astrocytic glutamate transporter EAAT2 (GLT1 in rodents) and, consequently, ineffective clearance of glutamate from the perisynaptic space. This may contribute to excitotoxic damage. Earlier attempts in our lab to restore normal glutamate uptake by treatment with the transcription activator ceftriaxone or by intravenous injection of AAV9/PHP.B gfaABC1D-GLT1-P2A-Tomato in the Q175 mouse model of HD failed to produce substantial benefits with regard to the respective motor symptoms. The aim of the present study in symptomatic Q175 heterozygotes (15-18 months at sacrifice) was to determine the effects of 3 new PHP.eB-EAAT2 vectors with regard to the achieved levels of EAAT2 immunofluorescence, glutamate uptake activity and motor performance (escape latency). All vectors are stereotaxically injected into the dosal striatum at a concentration of 10 ^ 12 gc/ml. Astrocytes are specifically targeted by using the gfaABC1D promoter. Transduced astrocytes are identified by YFP fluorescence. We compare the expression and effects of the full-length EAAT2 sequence, a C-terminal-truncated EAAT2-sequence and a sequence with point mutations of lysine residues (K517R, K526R, K550R, K570R) that prevent ubiquitin-mediated internalization. Using confocal optics, the level of EAAT2 protein is determined within the territory of individual transduced astrocytes (YFP+) and in the immediate neighborhood of vGluT1+ and vGluT2+ presynaptic terminals within the YFP+ territory. Glutamate uptake activity is elicited by single-cell glutamate uncaging and recorded by SBFI imaging of respective sodium transients in transduced astrocytes. Animals injected with identical vectors but lacking the EAAT2 sequence served as controls. As a result of our current work in progress, we should be able to determine whether PhP.eB constructs containing the truncated or point-mutated EAAT2 isoforms can outperform vectors with the wild-type EAAT2.

Title: Evidence for the axonal transport of a HTT-RAB4 vesicle complex which is disrupted in Huntington's disease

Authors: *S. GUNAWARDENA[1,2], J. WHITE[2], H. HOFMAR-GLENNON[2], C. THANT[2], K. ZIMMERMAN[2], G. IACOBUCCI[2]
[1]Dept. of Biol. Sci., SUNY at Buffalo, Buffalo, NY; [2]The State Univ. of New York at Buffalo, Buffalo, NY

Abstract: The Huntington's disease (HD) protein, HTT associates with molecular motors, however, the cargo complex that HTT moves within axons remains elusive. Previously, we found that HTT differentially regulated the motility of a sub-set of small GTPase Rabs. While Rabs are restricted to particular cellular compartments, the localization of one of these HTT-mediated Rabs, Rab4 is unknown. Here, we tested the hypothesis that a synaptic HTT-Rab4 moving complex exists *in vivo* and that scaffolding proteins present on this complex mediate associations between this complex and motors during axonal transport. Simultaneous dual-view imaging in larval axons revealed that HTT and Rab4, and Rab4 and SYNT/SYNB co-migrate within axons. Co-localization analysis showed that Rab4, HTT and motors co-localize in *Drosophila* and human neurons. Intriguingly reduction of the huntingtin interacting protein 1 (HIP1) and a known Rab effector, Rip11, perturbed both HTT and Rab4 motility *in vivo*. In both mouse and human neurons, Rab4 and HIP1 were present on membranes, while kinesin and HIP1 co-IPed on Rab4 membranes. RIP11 and Rab4 were also co-localized within larval axons, indicating that HTT-Rab4-HIP1-RIP11 and motors likely form a complex during axonal transport. Strikingly, Rab4 motility was disrupted during HD in both Drosophila and human neurons differentiated from HD patients. Larvae expressing polyQ HTT or neurons derived from HD patients exhibited axonal blockages that contained HTT, Rab4 and motors. Collectively, our observations suggest that a moving HTT-Rab4 complex exists and that HIP1 and Rip11 function as scaffolding proteins to link this complex to motors for proper axonal transport. Our findings have important implications for how defects in Rab4 motility contribute to HD.

Title: Investigating the role of aging in Huntington's disease pathogenesis

Authors: *E. MACHIELA[1], M. SCHMIDT[3], N. S. CARON[4], S. MEHTA[5], V. B. MATTIS[6], A. L. SOUTHWELL[2]
[1]Burnett Sch. of Biomed. Sci., [2]Col. of Med., Univ. of Central Florida, Orlando, FL; [3]Neurosci., Univ. of British Columbia, Vancouver, BC, Canada; [4]Med. Genet., Ctr. for Mol. Med. and Therapeut., Vancouver, BC, Canada; [5]Cedars-Sinai, Los Angeles, CA; [6]Board of Governors Regenerative Med. Inst., Cedars-Sinai, West Hollywood, CA

Abstract: Huntington’s disease (HD) is an autosomal dominant disease caused by a CAG repeat expansion in exon 1 of the huntingtin gene. HD is characterized by loss of voluntary movement, neuropsychiatric abnormalities, and cognitive decline. There are currently no disease-modifying therapies for HD. While age of onset negatively correlates with CAG repeat tract length, this only accounts for some of the variation in age of onset of disease. Many other genetic and environmental factors play a role in disease onset. Apart from juvenile-onset HD, which is caused by very long expansions of the CAG repeat tract, carriers of the mutation that causes HD live asymptomatically until mid-life, begging the question of how the aging process may contribute to onset of disease. Accelerated markers of aging such as DNA methylation have been shown to be present in brains of patients with HD. Additionally, cellular functions that decline during the aging process, such as the stress response and functions of the proteasome and mitochondria undergo rapid decline in HD, further supporting the hypothesis that aging contributes to HD pathology.
To investigate the role of aging in HD, we will useare using induced pluripotent stem cell (iPSC)-derived neurons from HD patients as well as healthy controls. One hurdle in the development of disease-relevant iPSC models of HD is the fact that during cellular reprogramming, cells lose markers of age. Further supporting the notion that aging plays an active role in HD pathogenesis, iPSC-derived adult onset HD neurons exhibit very mild phenotypes and no spontaneous neurodegeneration. To overcome this, we will treat HD and control cells with progerin, a truncated protein created by alternative splicing of the *LMNA* gene. Accumulation of progerin causes Hutchinson-Gilford progeria, a disease of rapid aging. Progerin has also been found in healthy tissues during the aging process and has been linked to cellular senescence. Additionally, iPSC-derived neurons treated with progerin exhibit markers of aging, suggesting a role for progerin in physiologic aging. Treating iPSC-derived HD neurons with progerin can unmask cellular phenotypes of HD related to the aging process. In doing this, we

can compare cellular phenotypes in HD neurons that are physiologically “young” and “old” but chronologically identical, to determine the role of physiologic aging in the cellular toxicity of HD. Ultimately, this work will shed light on aging-associated factors that contribute to HD pathogenesis to uncoverand whether anti-aging treatments that may be beneficial for HD patients.

Title: HTT lowering-mediated changes in cerebrospinal fluid mutant huntingtin concentration: What does it mean?

Authors: *A. L. SOUTHWELL[1], N. S. CARON[2], C. YANICK[1], Y. XIE[1], S. E. SMITH[3], J.-J. SONG[4], I. SEONG[5], B. R. LEAVITT[2], M. R. HAYDEN[2]
[1]Col. of Med., Univ. of Central Florida, Orlando, FL; [2]Ctr. for Mol. Med. and Therapeut., Univ. of British Columbia, Vancouver, BC, Canada; [3]Ctr. for Integrative Brain Res., Seattle Childrens Res. Inst., Seattle, WA; [4]Korea Advanced Inst. of Sci. and Technol., Daejeon, Korea, Democratic People's Republic of; [5]Molec Neurogenetics, Massachusetts Gen Hosp, Boston, MA

Abstract: The first huntingtin (HTT) lowering Phase I/2a clinical trial was recently completed, demonstrating dose-dependent reduction of CSF mutant (mt)HTT protein in response to treatment. However, there is very little known about CSF mtHTT; where it comes from or how it enters CSF. Thus, interpretation of these treatment-induced changes is not straightforward. We are using our ultrasensitive immunoprecipitation and flow cytometry (IP-FCM) mtHTT detection assay to better understand what this exciting new data tells us about therapeutic activity in the brain. The source of CSF mtHTT is unknown. The agent under trial is expected to be most active in regions in close contact with the CSF. If these regions are also the major sources of CSF mtHTT protein, then predictions of HTT lowering in deeper structures based on CSF findings

may not be accurate. Conversely, if regional contributions to CSF mtHTT protein are similar in deep and superficial structures, then changes in CSF mtHTT level could be used to infer changes to basal ganglia mtHTT. Thus, we are interrogating the source(s) of CSF mtHTT protein using BACHD HD model mice (floxed mtHTT exon 1) crossed to brain region and cell type-specific cre mice. These crosses generate mice with selective inactivation of mtHTT to enable evaluation of the contribution of the different brain regions or cell types to the pool of CSF mtHTT protein. Additionally, we do not know how mtHTT enters CSF. If it is released passively from dying cells, any neuroprotective therapy would be expected to reduce CSF mtHTT, and the treatment-induced changes observed in the current trial may represent a combination of HTT lowering and neuroprotection. Conversely, if active clearance is primary mechanism of mtHTT release to CSF, then treatment-induced changes may only represent HTT lowering. We have previously shown that mtHTT is not detected in CSF of all premanifest HD mutation carriers and that acute brain injury causes a transient increase in CSF mtHTT, suggesting that mtHTT is passively released from dying cells. However, we have observed mtHTT in the CSF of mice without neurodegeneration and reduced CSF mtHTT in BACHD mice lacking astrocytic mtHTT, suggesting that there may be both passive and active clearance mechanisms involved. We are ectopically delivering intracellular and extracellular mtHTT with or without inhibitors of secretion and glymphatic clearance to investigate the mechanism(S) of mtHTT release to CSF. Delineating the source and mechanism(s) of entry of CSF mtHTT protein will greatly enhance interpretation of this promising HD biomarker.

Abstract: Huntington's disease (HD) is a neurodegenerative disease caused by an expanded CAG repeat in the *Huntingtin* (*HTT*) gene. Induced pluripotent stem cell (iPSC) models of HD provide an opportunity to study the mechanisms underlying disease pathology in disease-relevant patient tissues. Murine studies have demonstrated that HTT is intricately involved in corticogenesis, and mutant (mt) HTT cannot compensate for the loss of wild-type HTT. However, the effect of mtHTT in human corticogenesis has not yet been thoroughly explored. This examination is critical, due to inherent differences in cortical development and timing between humans and mice. We therefore differentiated HD and non-diseased iPSCs into functional cortical neurons. While HD patient iPSCs can successfully differentiate towards a cortical fate in culture, the resulting neurons display altered transcriptomics, morphological and functional phenotypes indicative of altered corticogenesis in HD.

Title: Huntington's disease phenotypes and disrupted corticostriatal connectivity observed in a novel human iPSC-derived *in vitro* co-culture model

Authors: *C. CASEY[1], Y. QUI[2], M. P. BENTHAM[2], E. SMITH[1], G. LIGNANI[2], S. SCHORGE[2], G. BATES[1], G. SCHIAVO[2], R. ANDRE[1], A. WOOD-KACZMAR[1], S. J. TABRIZI[1]
[1]Huntington's Dis. Res. Ctr., [2]Inst. of Neurol., Univ. Col. London, London, United Kingdom

Abstract: The corticostriatal (CS) pathway, comprising layer V cortical projection neurons (CPN) and medium spiny neurons (MSN), is one of the first brain pathways to succumb to Huntington's disease (HD) pathology. As a result, disrupted CS connectivity is evident and contributes to the motor and cognitive symptoms experienced by HD patients. Most studies to date elucidating the cellular drivers and mechanisms behind disrupted CS connectivity have originated from HD mouse models and human imaging data. There have been no investigations into the CS pathway using a purely human tissue-derived *in vitro* system. This project utilizes two iPSC lines derived from two closely related individuals; the control line, with 20/20 HTT CAG repeat lengths (20Q), and a juvenile HD line, with 20/73 CAG repeats (73Q). These lines

were differentiated in parallel to either MSNs or CPNs, and co-cultured in microfluidic chambers to physically recapitulate the human CS pathway.
The co-culture platform was constructed using either 20Q or 73Q iPSC-derived neurons, enabling comparisons between 'healthy' and 'diseased' pathways at a cellular level. Alternatively, crossed co-cultures, where 20Q CPNs synapse onto 73Q MSNs and vice versa, enabled the dissection of neuron-specific pathology and its impact on the CS pathway. High-resolution fluorescence microscopy has revealed the formation of CS synapses within MFC co-cultures, complimented by live cell imaging with calcium binding dye Fluo4, which demonstrates the successful transmission of calcium between neuronal populations within MFCs. Taken together, these data validate this platform as a reliable model of the CS pathway. Moreover, CPN cultures show an HD phenotype in their cytoskeletal dynamics, as axon projection efficiency is drastically reduced in 73Q CPNs compared to 20Q.
Furthermore, 73Q MSNs are more susceptible to BDNF-withdrawal induced cell death compared to 20Q cultures. Finally, the intrinsic membrane properties of iPSC-derived MSNs also differ with disease state, as 73Q MSNs are hyper-excitable, with an extended latency to fire and extended refractory period when compared to 20Q MSNs. These results provide a novel insight into the human CS pathway and suggest subtle differences in both the development and function of the CS pathway in HD.

Title: Investigating the role of the innate immune system in HD

Authors: *G. O'REGAN, R. ANDRE, J. POCOCK, S. J. TABRIZI
Univ. Col. London, London, United Kingdom

Abstract: Huntington's disease (HD) is a devastating neurodegenerative disease. It is caused by the presence of an expanded trinucleotide repeat in the *HTT* gene, resulting in expression of expanded polyglutamine-containing mutant HTT throughout the body. HD patients display a dysfunctional peripheral immune system up to sixteen years before disease onset. This is also

shown in HD animal models, where immune system dysfunction is found both in the periphery and CNS. This work aimed to assess the CNS component of the innate immune system, microglial cells, in a human HD model for the first time.
In order to achieve this, a unique cohort of iPSC lines from related individuals with varying expansion lengths (20Q, 56Q, 67Q, 73Q) were differentiated to microglia and subjected to a battery of functional tests, to assess the performance of HD microglia with increasing CAG lengths relative to controls.
Our results suggest that HD microglia display altered phenotypes compared to control microglia in a polyglutamine-length-dependent manner. Specifically, we found a hyper-reactive cytokine response profile upon stimulation with an immune challenge, increased production of ROS, elevated levels of phagocytosis upon stimulation, and reduced viability in the presence of an autophagy inhibitor.
This work represents this first assessment of HD microglia in a human HD model. We have shown that human HD microglia display the same dysfunction found in animal models of HD and in the peripheral immune cells of patients. Further research is now being conducted to characterise how these dysfunctional HD microglia may affect the health and function of neuronal cell types known to be affected in HD, to ascertain the impact of this dysfunction on disease pathology and progression.

Title: Allele-specific gene editing for Huntington's disease mediated by a self-inactivating CRISPR/Cas9 system

Authors: *S. REGIO, G. VACHEY, M. REY, N. DEGLON
CHUV Pavillon 3, Lausanne, Switzerland

Abstract: Huntington’s disease (HD) is a fatal neurodegenerative disorder caused by CAG expansion in the *huntingtin* (*HTT*) gene. Considering that the mutation is a toxic gain-of-function, a promising approach would be to decrease the expression level of the mutant *HTT*. This can be achieved with genome-editing technologies, in particular the recently characterized CRISPR/Cas9 system. In a previous work, we described the kamiCas9, a self-inactivating CRISPR/Cas9 system designed for the transient expression of the Cas9 protein. We

demonstrated the high editing efficiency of WT and mutant HTT *in vitro* and *in vivo* with an important reduction of the off-target frequency. However, a selective editing of mutant HTT, using an allele-specific approach, represents the safest way to preserve WT HTT expression and functions. We thus developed more complex strategies to discriminate mutant and wild-type HTT genes by using single-guide RNA targeting sequences containing Single Nucleotide Polymorphism (SNP) in the HTT gene. A first *in vitro* screening, allow us to discriminate the two best candidates to trigger the cleavage of the mutant HTT respectively in the promoter and intron 1. Through this approach the exon 1 of the mutant *HTT*, which is the region containing the CAG expansion, could be selectively removed. This strategy has then been validated in human embryonic kidney 293T (HEK- 293T) cells and is currently tested in HD mouse models. These results demonstrate the potential of the self-inactivating CRISPR/Cas9 editing for applications in the context of neurodegenerative diseases and a proof of principle of allele-specific disruption of the human HTT gene.

Title: Cell type specific adenosine modulations in the mouse model of Huntington's disease

Authors: *Y. CHANG[1,2], C.-P. CHANG[1], H.-M. CHEN[1], Y. CHERN[1]
[1]Inst. of Biomed. Sciences, Academia Sinica, Taipei, Taiwan; [2]Taiwan Intl. Grad. Program in Interdisciplinary Neuroscience, Natl. Yang-Ming Univ. and Academia Sinica, Taipei, Taiwan

Abstract: Huntington’s disease (HD) is an autosomal dominant neurodegenerative disease caused by the expansion of CAG repeats in the exon 1 of *huntingtin* gene with no effective treatment. Adenosine is an important modulator in the brain. We have previously shown that the homeostasis and metabolism of adenosine are disrupted in HD. In addition, augmentation of adenosine in the brain caused protective effects on HD progression. Accumulated evidences suggest that different brain cells (including neurons, astrocytes and microglia) might contribute differently to the pathological regulation of adenosine in HD. We used an affinity- purified method to isolate mature neurons, astrocytes and microglia from the cortex of a HD mouse model (R6/2) at their presymptomatic and symptomatic stage (7 and 10.5 weeks old, respectively). The transcription levels of genes involved in adenosine homeostasis (including ecto-nucleotidases, adenosine deaminase, adenosine kinase and equilibrative nucleoside transporters) were examined. Our data showed that these adenosine homeostasis genes were distinctively regulated in different brain cells during HD progression. Further investigations

would provide important insights into understanding the dysregulation of adenosine homeostasis in HD and pave the way for the possible therapeutic intervention in the future.

Title: The role and function of microglia in synaptic loss in Huntington's disease

Authors: *J. C. SAVAGE[1,2], M.-K. ST.-PIERRE[1,2], H. EL-HAJJ[1,2], M. G. SANCHEZ[1,2], F. CICCHETTI[1,2], M.-E. TREMBLAY[1,2]

Abstract: Huntington’s disease (HD) is a dominantly inherited neurodegenerative disorder that affects cognitive and motor abilities by primarily targeting the striatum and cerebral cortex. HD is caused by a mutation elongating the CAG repeats within the *Huntingtin* gene, resulting in HTT protein misfolding. The severity and age of onset are correlated with the number of excess CAG repeats, with more repeats resulting in earlier disease onset. Although the genetic cause of HD has been established, the specific susceptibility of neurons within various brain structures has not been explained. Furthermore, there have been relatively few studies on the role of glial cells in HD, even though they express mutated HTT. We therefore set out to study the maturation and dysfunction of microglia, the brain’s resident macrophages, within the R6/2 model of HD. This transgenic model, which presents with 120+/-5 CAG, displays progressive motor deficits beginning at 6 weeks, with full incapacitation by 13 weeks. We studied microglial morphology, phagocytic capacity, and synaptic contacts and used focused ion beam-scanning electron microscopy (FIB-SEM) to reconstruct dendrites and count the number of synapses per micron in the striatum of R6/2 vs. wild-type littermates at various ages. At 3 weeks of age, prior to motor deficits or synaptic loss, microglia in R6/2 animals have a smaller morphological index, consistent with a mature ramified phenotype. By 10 weeks of age, microglia from R6/2 mice demonstrate increased phagocytosis, as revealed by light microscopy and immunoEM. Putative phagocytosis was confirmed using FIB-SEM in a subset of processes. Ultrastructural analysis indicated that microglial cell bodies from 3 or 10-week old R6/2 animals were more likely to perform extracellular degradation and contain phagocytic material than control. Furthermore, microglial processes in 10-week old R6/2 mice were less likely to make contact with synaptic

elements, while processes in 3-week old R6/2 mice were more likely to contact synapses. These preliminary findings indicate that microglia play an intimate role in HD pathogenesis and may be a target for therapeutic intervention.

Abstract: Huntington's disease (HD) is a fatal neurodegenerative disorder that affects approximately 1 in 10,000 people in the United States. HD is characterized by involuntary movements that often cause difficulty walking, talking, and swallowing. HD is inherited in an autosomal dominant manner and is caused by a CAG trinucleotide expansion in the first exon of the huntingtin gene (*HTT*). The CAG expansion in HD causes an abnormally long polyglutamine tract in the HTT protein that leads to protein misfolding, eventually resulting in neuronal cell death. CRISPR-dCas9 could provide a mechanism to specifically target and silence the mutant allele in HD. dCas9 lacks endonuclease activity while still retaining its DNA binding capabilities, allowing it to be used along with effector domains to modulate gene expression. Effector domains have an innate ability to modulate the heterochromatin structure and can be

fused to the dCas9 protein to decrease transcription of the target gene. Patient-derived stem cells that have naturally occurring disease-associated single nucleotide polymorphisms (SNPs) were used to validate mutant allele specific gRNAs.
In this study, the ability of dCas9 fused to different repressive domains to silence the mutant HTT allele in patient-derived neurons was assessed. HD patient-derived induced pluripotent stem cells (hiPSC) were differentiated into neuron-like cells in order to model the disease in a 2D culture system. The neuronal-like HD cells were evaluated using immunocytochemistry to confirm expression of MAP2 and Tuj1. Disease related phenotypes were assessed within patient derived neurons using a well-regarded published BDNF withdrawal assay. From the HD patient derived cells, SNPs within the regulatory regions of HTT were identified using SMRTseq. Allele-specific gRNAs were designed to target the identified disease-associated SNPs and delivered with a dCas9 fused to KRAB, Fog1, or DNMT3A in HD hiPSCs and the hiPSC-derived neurons . The ability of CRISPR-dCas9 to silence mutant HD allele was evaluated by KASP transcriptome analysis and Western Blotting to examine mutant HTT transcript and protein levels respectively. We hope this work will be a step toward developing a new therapeutic using the dCas9 system as a gene therapy for HD patients.

Abstract: Compensation accounts for the dissociation between pathology and the absence of behavioural change during the premanifest and early stages of neurodegenerative disease. Despite neuronal loss, individuals with neurodegenerative disease function at a level similar to that of a healthy population until pathology overwhelms compensatory mechanisms and causes functional deterioration. The neural mechanisms underlying such compensation, however, are generally poorly understood due to the lack of an operational definition of compensation. Here, we describe both the first example of the modelling and empirical testing of compensation in neurodegenerative disease. Our operationalisation is based on both theoretical models of compensation in healthy ageing and Alzheimer's disease; and the hypothesis that compensation occurs where increased brain activation is required to maintain normal levels of behaviour until pathology becomes too severe. This compensatory relationship is characterized by non-linear longitudinal trajectories of brain activity and behavior with disease load increasing linearly over time across three sequential phases of disease progression. HD is an ideal model to test for such compensation as disease progression can be monitored many years prior to clinical diagnosis. We tested our model of compensation in a large cohort of premanifest and early HD gene-carriers from the TrackOn-HD study. Focusing on both cognitive and motor networks, brain activity was measured using task and resting-state fMRI, volumetric loss by structural MRI and behavior by task performance. Multivariate linear mixed models were fitted for each variable and trajectories tested. Maintained global cognition was associated with increased effective connectivity between the left and right dorsolateral prefrontal cortex, a central region in cognitive processing, while maintained motor performance was associated with increased connectivity between the left and right premotor cortex. Our empirical findings demonstrate theoretically-defined compensation in HD in networks central to the HD phenotype and can now be used to test both cross-sectional and longitudinal compensation in other neurodegenerative disease with similar patterns to HD.

Title: Cortical axon secretion of BDNF in the striatum is disrupted in a knock-in mouse model of Huntington's disease

Authors: *H. PARK[1,2]
[1]Korea Brain Res. Inst. (KBRI), Daegu, Korea, Republic of; [2]Dept. of Mol. and Cell Biol., Univ. of California, Berkeley, CA

Abstract: Deficient BDNF signaling is known to be involved in neurodegenerative diseases such as Huntington's disease (HD). Mutant huntingtin (mhtt)-mediated disruption of either BDNF transcription or transport is thought to be a factor contributing to striatal atrophy in the HD brain. Whether and how activity-dependent BDNF secretion is affected by mhtt remains unclear. In the present study, we provide evidence for differential effects of mhtt on cortical BDNF secretion in the striatum during HD progression. By two-photon imaging of fluorescent BDNF sensor (BDNF-pHluorin and -EGFP) in acute striatal slices of HD knock-in model mice, we found deficient cortical BDNF secretion regardless the HD onset, but antisense oligonucleotide (ASO)-mediated reduction of htts only rescues BDNF secretion in the early HD brain before the disease onset. Although secretion modes of individual BDNF-containing vesicle were not altered in the pre-symptomatic brain, the full-fusion and partial-fusion modes of BDNF-containing vesicles were significantly altered after the onset of HD symptoms. Thus, besides abnormal BDNF transcription and transport, our results suggest that mhtt-mediated alteration in activity-dependent BDNF secretion at corticostriatal synapses also contributes to the development of HD.

Abstract: In early studies, mitochondrial dysfunction had been linked to Huntington's disease (HD) pathology. However, in recent years, a growing number of investigators reported the lack of overt detrimental effects of mutant huntingtin (mHtt) on mitochondria. In our previous studies with isolated brain mitochondria and cultured striatal neurons from YAC128 and R6/2 mouse models of HD, we demonstrated that mHtt does not deteriorate mitochondrial function or glycolytic activity (1-4). In the present study, we used human striatal neurons derived from inducible pluripotent stem cells from an unaffected individual and an HD patient with a HTT gene containing 72 CAG repeats. It is known that the induction of stemness and pluripotency resets the biological age of cells. Consequently, the newly generated neurons were considered young and pre-symptomatic. The human neurons were thoroughly characterized and were shown to express MAP2, DARPP32, GABA, and synapsin. In neurons derived from the HD patient, mHtt and wild-type huntingtin (Htt) were expressed in a 1:1 ratio. The sum of mHtt and Htt expression in cells from the HD patient was comparable to the level of Htt expression in cells from the unaffected individual. The human neurons were assessed for mitochondrial mass, mitochondrial membrane potential, mitochondrial ROS production, the levels of ADP and ATP, and for respiratory and glycolytic activity. All these parameters appeared to be similar in human neurons from the unaffected individual and the HD patient. On the other hand, in electrophysiological experiments, human neurons from the HD patient appeared to have a lower threshold for action potential generation compared with neurons from the unaffected individual. Thus, our results strongly argue against mitochondrial dysfunction as a factor in HD pathogenesis, in accordance with our earlier rodent studies, and suggest that mHtt may increase excitability of human striatal neurons.

Title: Early synaptic dysfunction in the hippocampus of Q175FDN Huntington's disease mice

Authors: A. S. RAVALIA, J. Y. LAU, J. G. QUIRION, *M. P. PARSONS
Biomed. Sci., Mem. Univ., St John's, NL, Canada

Abstract: Huntington Disease (HD) is an inherited neurodegenerative disease caused by a CAG repeat expansion in the gene encoding the huntingtin protein. The resultant polyglutamine-expanded mutant huntingtin (mHtt) protein triggers a myriad of synaptic disturbances. Interestingly, many of these synaptic defects can be detected prior to the onset of an overt behavioral phenotype, suggesting that presymptomatic therapeutic intervention may be required for maximal efficacy. The bulk of research on the early synaptic deficits in HD is conducted in the striatum, and while the striatum is the most vulnerable brain region in HD, HD is now recognized as a brain-wide disease and extrastriatal pathology contributes substantially to disease progression and severity. Relatively little is known regarding the early effect of mHtt on extrastriatal brain regions. Here, we studied various synaptic properties, including spine morphology, N-methyl-D-aspartate receptor (NMDAR) subcellular localization and downstream signaling, as well as activity-dependent synaptic plasticity in the hippocampus of Q175FDN heterozygous HD mice. All experiments were performed at 3 months of age, prior to the emergence of an HD-like behavioral phenotype in this model, and we focused on the hippocampus due to its undisputed involvement in cognitive function and the debilitating cognitive symptoms described by many HD patients. We found a dramatic shift in the spine maturity profile in the CA1 region of the Q175FDN hippocampus, with Q175FDN mice having significantly more immature spines (thin) and significantly less mature (mushroom) spines in comparison to wild-type littermates. Multi-electrode array recordings of synaptic connectivity reveled subtle impairments in activity-dependent synaptic plasticity, and we also observed clear NMDAR mislocalization and enhanced caspase-3 signaling downstream of NMDAR activation in the Q175FDN hippocampus. In all, our data demonstrate clear detrimental effects of mHtt expression on hippocampal function in presymptomatic HD. The identified synaptic deficits are likely to contribute, at least in part, to the emergence of debilitating cognitive symptoms associated with HD.

Title: Rescue of homeostatic plasticity in YAC128 cortical neurons by pridopidine through modulation of Sigma1R and BDNF signaling

Authors: *A. I. SMITH-DIJAK[1], W. NASSRALLAH[1], L. ZHANG[1], M. GEVA[2], M. R. HAYDEN[2], L. A. RAYMOND[1]
[1]Psychiatry, Univ. of British Columbia, Vancouver, BC, Canada; [2]Teva Pharmaceut. Industries, Ltd, Even Yehuda, Israel

Abstract: Homeostatic plasticity is a key mechanism for maintaining stability in neural circuits throughout the brain. Even as individual synapses undergo long-term potentiation or depression, homeostatic synaptic scaling preserves the relative weighting of synaptic strength and numbers locally, while adjusting the overall magnitude of synaptic input to maintain the neuronal firing rate in a physiological range. This is thought to be important for maintaining capacity for new learning and mental flexibility - cognitive functions that are impaired early in Huntington disease (HD). Previous work in rodent cortical neurons has shown that blockade of action potentials for 24-48h by treatment with tetrodotoxin (TTX) results in up-scaling of excitatory glutamatergic synapses, mediated by reduced activity-dependent release of Brain-Derived Neurotrophic Factor (BDNF). Since the mutant huntingtin protein reduces BDNF transcription and transport in cortical neurons, we hypothesized that cortical neurons from the YAC128 HD mouse model would already have a deficit in BDNF signaling and therefore reduced capacity to respond to TTX with synaptic up-scaling. In addition, we postulated that pridopidine, suggested to stabilize total functional capacity (TFC) in a recent clinical trial (PRIDE-HD) and also shown to upregulate BDNF signaling in rodents (Geva M et al., Hum Mol Genet 25:3975, 2016), could rescue a deficit in homeostatic plasticity in YAC128 cortical neurons. To test this, we made electrophysiological recordings from YAC128 and wild-type mouse cortical neuronal cultures to measure function of excitatory glutamatergic synapses in control conditions vs. after 48h exposure to TTX. Wild-type cortical neurons responded to action potential silencing by increasing the frequency and amplitude of miniature excitatory synaptic currents (mEPSCs; which reflect the strength of synapses onto a neuron), whereas there was no response for either measure in YAC128 cortical neurons. In contrast, pre-treatment with pridopidine restored synaptic up-scaling in YAC128 neurons after a subsequent 48h exposure to TTX. We will also present data regarding the role of BDNF in the synaptic scaling which we observed and its rescue by pridopidine. In addition, we will present evidence for the involvement of the sigma-1 receptor, which has been hypothesized to be the primary site of action of pridopidine in its treatment of HD, in this rescue. Our results shed new light on mechanisms by which pridopidine may slow the progressive decline in functional capacity in HD, and suggest a role for this drug in ameliorating cognitive deficits associated with the prodromal and early stages of disease.

Title: Characterization of neurodevelopmental delays in iPSC-derivede striatal cultures from patients with Huntington's disease

Authors: *P. P. MATHKAR, D. SURESH, J. DUNN, V. B. MATTIS
BOG Regenerative Med. Institute, Cedars Sinai, Beverly Hills, CA

Abstract: Abstract: Huntington’s Disease (HD) is a fatal neurodegenerative disorder characterized by progressive neural atrophy, causing the atrophy and loss of the majority of neurons within the striatum in particular. HD is caused by CAG repeat expansion in *Huntingtin* (*HTT*) gene. Previous studies using human induced pluripotent stem cells (hiPSCs), or somatic cells reprogrammed to a pluripotent state, from HD patients have demonstrated a delayed developmental phenotype upon differentiation towards a striatal fate, including increased expression of nestin during the differentiation process, a type VI intermediate filament specific to neural progenitor cells. It was therefore hypothesized that a delayed striatal maturation in HD results in development abnormalities which adversely affects the neuronal homeostasis leading to the downstream degeneration of striatal neurons. This study was designed to further characterize a HD model using human iPSC to further characterize the decrease in neuronal/glial maturation caused by the expanded HTT repeats, and to elucidate the mechanism of such delayed maturation. 5 HD and 4 control lines were hence differentiated towards striatal fate and characterized for the expression of adult and progenitor neuronal and glial markers at different time points. Additionally, we investigated if the similar phenotype is recapitulated *in vivo* using an HD mouse model. In conclusion, this study challenges the traditional notion of HD as an adult onset neurodegenerative disorder by possibly implicating alterations in neurodevelopment.

Title: Characterizing neurodevelopmental deficits in corticogenesis in Huntington's disease using 3D organoid models

Authors: *S. MEHTA, V. MATTIS, P. MATHKAR
Cedars-Sinai, Los Angeles, CA

Abstract: Huntington disease (HD), is a dominantly inherited disorder caused by a CAG expansion mutation in the huntingtin (HTT) gene. The adult form of HD exhibits a late onset of symptoms, nonetheless, there is also a long pre-symptomatic stage which has been increasingly studied and acknowledged as important for disease development. Furthermore, children at a higher risk of HD exhibit symptoms like a smaller head size or lower BMI, which suggest neurodevelopmental deficits. Evidence from recent stem cell studies supports the idea that mutant HTT-dependent changes may be detected early, such as impaired neural rosette formation or increased susceptibility to growth factor withdrawal, even at the naïve pluripotent cell stage. Therefore, it is important to elucidate the pathogenesis of HD along its differentiation pathway in order to identify the early processes relevant to developmental defects and disease onset. Data from iPSC derived 2D HD cultures as well as brain region specific abnormalities found in in vivo murine and human samples suggests that artificial culture systems may be inefficient in studying the complete effect of mutant HTT or identifying therapeutic targets. 3D organoid culture systems may have the potential to recapitulate conditions more similar to in vivo, thereby providing a more viable model to study disease onset and progression. This innovative approach will use patient cells to examine and highlight key HD-specific differences in corticogenesis, which will elucidate novel disease mechanisms for therapeutic intervention targeting.

Title: Modelling the trajectory of cortical atrophy in Huntington's disease

Authors: *E. JOHNSON[1], G. ZIEGLER[2], W. PENNY[3], G. E. REES[1], S. J. TABRIZI[1], R. I. SCAHILL[1], S. GREGORY[1]

Abstract: Huntington's disease (HD) is a neurodegenerative disease typically characterised by early striatal atrophy extending to the cortex as the disease progresses. Despite histological evidence of widespread grey matter atrophy by end-stage-disease, the progression of cortical atrophy in HD has yet to be fully characterised. Here, we have used a novel approach to map cortical atrophy during the transition from premanifest to motor clinical diagnosis of manifest HD, modelling both non-linear and linear atrophy in a large cohort of participants, with MRI data spanning 6 years before and 5 years after clinical diagnosis.
Structural MR images from 49 HD gene-carrier participants were included in the analysis, collected as part of the longitudinal, multi-site TRACK-HD and TrackOn-HD studies. Participants underwent yearly 3T MRI scans, with up to 7 visits, along with clinical examination and cognitive testing. Participants were classified as premanifest at recruitment with subsequent diagnosis as manifest HD occurring at a later time-point during the study. Each set of images for each participant underwent longitudinal registration and were segmented using MALP-EM, with cortical and subcortical volumes calculated. A hierarchical dynamical model was applied at the individual (first-) level to map individual trajectories. A group (second-) level model was then used to estimate group-wise change, accounting for the effects of covariates. This approach was used to measure gross atrophy, linear rate of atrophy and non-linear accelerations in atrophy.
Over the time period examined, atrophy was highest in frontal and motor regions, particularly the supplementary motor cortex (11.66% per decade) with greatest linear rates of atrophy in the frontal cortex and greatest acceleration of atrophy in the motor cortex at the point of clinical motor diagnosis.
This study provides the most complete characterisation of cortical atrophy in HD presented to-date. The results suggest that the degree of atrophy occurring in the cortex around time of HD diagnosis is much higher than previously reported, and a number of regions show accelerations in atrophy around motor diagnosis. These findings have important implications for the understanding and treatment of HD and other neurodegenerative conditions.

Title: Microglia responses to lipopolysaccharide are likely primarily directed towards vasculature and are exacerbated by pronounced and prolonged hypothermia at high doses

Authors: *J. F. BOWYER[1], K. M. TRANTER[1], S. M. LANTZ[1], S. SARKAR[1], J. P. HANIG[2], J. N. HESS[1]

Abstract: For the past two years, we have been conducting histological studies to determine how microglia in adult female BALBc mice respond to systemic administration of lipopolysaccharide (LPS), one of the original compounds shown to evoke neuroinflammation in the brain. Antibodies to allograft inflammatory factor (Aif1, a.k.a. Iba1) and integrin alpha (Itgam, a.k.a. Cd11b) were used to track morphological changes in microglia. Platelet/endothelial cell adhesion molecule 1 (Pecam1, a.k.a. Cd31) was used to visualize vasculature in the forebrain. Doses of 1, 2 and 3 mg/kg LPS were administered either subcutaneously (s.c.) or intraperitoneally (i.p.) and the resulting neurotoxicity was evaluated at 6 h to 2 weeks later. LPS did not cause neurodegeneration at 1 mg/kg (s.c. or i.p.) and 2 mg/ kg s.c. Also, 2 mg/kg LPS i.p., did not cause neurodegeneration in most cases. Neuroinflammation/activation was determined by increased size of Iba1 immunoreactive microglia and their increased close association with Cd31 immunoreactive vasculature. Microglial activation, with minimal or no increase in number, was detectable within 12 h after LPS and pronounced within 24 h, with the effect waning after 3 days. Activation in the hippocampus and somatosensory cortex was most pronounced while activation in the thalamus was less. Within 24 h, almost all of the microglia soma in the hippocampus and cortex were closely associated with vasculature, not neurons, and had increased more than 2-fold in size. Macrophages entered the vasculature and vascular morphology was adversely affected in the few cases where the higher doses of LPS (≥2 mg/ kg i.p. or 3 mg/kg s.c.) produced prolonged hypothermia. It is not clear whether neurodegeneration would have eventually occurred in these mice. Prolonged hypothermia has been shown by other investigators to cause blood-brain barrier leakage, and this may be the reason for the increased vascular toxicity at the higher doses. We hypothesize that immune signals (possibly Ccl2, Ccl7 and Ccl20) from vascular endothelium adversely affected by LPS are triggering the aggregation of the microglia around vasculature.

Abstract: Microglia - the resident immune cells of the brain - are activated after lesions to the brain such as cerebral ischemia and polarize towards a classic “M1” pro-inflammatory or an alternative “M2” anti-inflammatory phenotype following characteristic temporo-spatial patterns, contributing either to secondary tissue damage or to regenerative responses. They closely interact with endogenous neural stems cells (NSC) residing in distinct niches of the adult brain. The current study aimed at elucidating the dynamics of microglia polarization and their differential effects on NSC function. Primary rat microglia *in vitro* were polarized towards an M1 phenotype by LPS, or to an M2 phenotype by IL4, while simultaneous exposure to LPS plus IL4 resulted in a hybrid phenotype expressing both M1- and M2-characteristic markers. M2 microglia migrated less but was more phagocytically active than M1 microglia. Defined mediators switched microglia from one polarization state to the other, a process more effective when transforming M2 microglia towards M1 than vice-versa. Polarized microglia had differential effects on the differentiation potential of NSC *in vitro* and *in vivo*, with M1 microglia promoting the generation of astrocytes, while M2 microglia supported neurogenesis. Regardless of their polarization, microglia inhibited NSC proliferation, increased NSC migration, and accelerated NSC differentiation upon mitogen withdrawal. Overall, this study unravels the complex conditions

governing microglia polarization, and the effects of differentially polarized microglia on key functions of NSC. Data will facilitate the prospective development of innovative therapeutic concepts supporting the regenerative capacity of the brain, e.g. after cerebral ischemia

Title: Investigations on improving the culturing conditions to retain the *in vivo*-like phenotype of primary microglia

Authors: *S. BARENDRECHT, R. EICHENTOPF, B. HIETEL, S. SCHILLING, H. CYNIS
Fraunhofer IZI-MWT, Halle (Saale), Germany

Abstract: Microglia are the phagocytic immune cells in the CNS, and make up 8-13% of the total cell population in the brain. Microglia cells derive from early yolk-sac macrophages and have many different functions, both in normal brain development and in pathological conditions. Besides their phagocytic function, microglia cells are known to secrete cytokines in response to certain stimuli. Overproduction of these cytokines in disease conditions, however, could lead to neuron loss and thereby aggravate pathology. The exact role of microglia in brain disorders remains elusive, because *in vitro* studies with isolated cells are hampered by a rapid loss of the *in vivo* microglial phenotype. We hypothesize that this loss of expression of microglia specific genes in culture is due to a lack of input from other CNS cells.
The aim of our study is to culture primary microglia *in vitro* in which the *in vivo* phenotype is retained or restored. We are comparing different isolation methods and culturing conditions for primary microglia. The culturing conditions are based on factors normally present in the CNS and known to be important for the activation state of microglia. To test the preservation of an *in vivo* phenotype, we analyze gene expression using qRT-PCR and gene arrays, as well as functional assays.
Compared to regular culturing, the culturing conditions for primary microglia from newborn mice tested in our lab significantly increased the expression of 5 out of 7 genes, previously found to be specific for microglia. Although an increase of microglia specific gene expression was accomplished, the gene expression was significantly lower in primary microglia from newborn mice than in freshly isolated microglia from adult mice. Functionally, we found no effect of the different culturing conditions using a phagocytosis assay.
Our culture conditions are able to at least partially mimic the environment in the CNS, and thereby improve the phenotype of primary microglia from newborn mice *in vitro*. Our next step is to isolate primary microglia from adult brains and use our established culturing conditions to prevent the loss of the *in vivo* microglial phenotype in these cells. We will compare these microglia cells to freshly isolated microglia in both gene expression and functionality.

Abstract: Dysregulated microglia-dependent synaptic pruning through the complement cascade and associated neuroinflammation processes have been linked with a wide range of neurodevelopment and neurodegenerative diseases such as schizophrenia, Alzheimer and Huntington disorders. Here we investigate the possibility of using cox-2, the rate-limiting enzyme in the biosynthesis of prostaglandins during the inflammation process, as a clinical marker of pathophysiological onset and progression of Huntington’s disease through the development of a brain-penetrant cox-2 specific PET radiotracer.

Title: Lysophosphatidic acid (LPA) promotes a pro inflammatory response in microglia cells via the JNK signaling pathway

Authors: *J. PLASTIRA, E. BERNHART, M. GOERITZER, C. KOYANI, W. SATTLER
Med. Univ. of Graz, Mol. Biol. and Biochem., Graz, Austria

Abstract: Microglia are the resident immune cells of the brain and are able to detect subtle alterations of the finely tuned micromilieu in the CNS. They regulate multiple aspects of inflammation, such as repair, regeneration, toxicity, and immunosuppression depending on their different activation states. Extrinsic signals, depending on disease context, determine whether microglia acquire a beneficial or detrimental phenotype. Their crucial role in brain homeostasis makes these cells potential therapeutic targets, which necessitate a thorough understanding of polarization cascades, transcriptome profiles, and pathways that modulate their function.
Lysophosphatidic acid (LPA) is produced via the autotaxin pathway or by phospholipase A-mediated pathways. LPA has numerous biological functions mediated by downstream signaling through different receptors. Aberrant LPA signaling has been implicated in several neurological disorders including neuropathic pain, traumatic brain injury, and schizophrenia. We have already unraveled a new role for LPAR5 via which LPA potently regulate microglia function and induce an inflammatory response. The distinct signaling cascades and transcriptional programs that drive this LPA-mediated M1-like signature in microglia are currently unknown.
Using an LPA ELISA we observed significally elevated LPA levels in CSF from AD patients and in both CSF and brain tissue of 5xFAD mice. In a mouse model of endotoxemia, increased LPA levels were detected in the cortices of LPS treated mice compared to controls.
Regarding the possible downstream pathways that controls the LPA induced microglial pro inflammatory response; immunoblotting results revealed that inhibition of JNK abrogates the activation of transcription factors (STAT1, p65 NFκB, and cJun) mainly responsible for the promotion of a pro inflammatory phenotype. Flow cytometry and immunofluorescence analysis showed that LPA induced expression of M1 markers is JNK dependent. In addition, we observed that the JNK pathway controls the LPA induced secretion of pro inflammatory cytokines and chemokines (IL-1β, TNFα, IL-6, CCL5, CXCL2, and CXCL10). These findings were accompanied by limited ROS and NO production, and decreased microglial cytotoxicity following inhibition of JNK pathway.
A better understanding of the role of bioactive lipids in microglia pathophysiology and the characterization of signaling cascades that control these responses can open new directions in modulating microglia function. Unraveling the LPA/LPAR-induced downstream kinase networks will support the development of targeted therapies to interfere with microglia polarization states.

Title: The voltage-gated potassium channel Kv1.3 is required for microglial pro-inflammatory activation *in vivo*

Authors: *J. DI LUCENTE[1], H. M. NGUYEN[2], H. WULFF[2], L.-W. JIN[1], I. MAEZAWA[1]
[1]Pathology and laboratory medicine, UC Davis, Sacramento, CA; [2]Pharmacol., UC Davis, Davis, CA

Abstract: Microglia show a rich repertoire of activation patterns regulated by a complex ensemble of surface ion channels, receptors, and transporters. We and others have investigated whether microglia vary their K^+ channel expression as a means to achieve functional diversity. However, most of the prior studies were conducted using *in vitro* models such as BV2 cells, primary microglia, or brain slices in culture, which may not accurately reflect microglia physiology in adult individuals. Here we employed an *in vivo* mouse model of selective innate immune activation by intracerebroventricular injection of lipopolysaccharides (ICV-LPS) to determine the role of the voltage-gated Kv1.3 channel in LPS-induced M1-like microglial activation. Using microglia acutely isolated from adult brains, we detected Kv1.3 and Kir2.1 currents, and found that ICV-LPS increased the current density and RNA expression of Kv1.3 but did not affect those of Kir2.1. Genetic knockout of Kv1.3 abolished LPS-induced microglial activation exemplified by CD11b immunoreactivity and expression of pro-inflammatory mediators such as IL-1β, TNF-α, IL-6 and iNOS. Moreover, Kv1.3 knockout mitigated the LPS-induced impairment of hippocampal long-term potentiation (hLTP), suggesting that Kv1.3 activity regulates pro-inflammatory microglial neurotoxicity. Pharmacological intervention using PAP-1, a small molecule that selectively blocks homotetrameric Kv1.3 channels, achieved anti-inflammatory and hLTP-recovery effects similar to Kv1.3 knockout. We conclude that Kv1.3 is required for microglial M1-like pro-inflammatory activation *in vivo*. A significant implication of our *in vivo* data is that selective Kv1.3 blockers could be therapeutic candidates for neurological diseases where microglia-mediated neurotoxicity is implicated in the pathogenesis.

Title: Microglia is not the resource but the modulator of the cytokines/chemokines in inflammatory neurovascular unit

Authors: *K. SATO[1], K. HOSHIKAWA[1], Y. KANDA[2], Y. SHIGEMOTO-MOGAMI[1]
[1]Lab. Neuropharmacol, Div. Pharmacol, [2]Div. Pharmacol, Natl. Inst. Hlth. Sci., Kanagawa, Japan

Abstract: Neuroinflammation is associated with blood brain barrier (BBB) disruption in the CNS diseases. Although microglial activation and subsequent concentration changes in various kinds of cytokines/chemokines (C/Cs) are suggested to be key steps to worsen the neuroinflammation and BBB disruption, little data are available concerning the significance of the interaction of microglia with BBB cells in this process. In this study, we mimicked neuroinflammation by adding LPS-activated microglia (LPS-MG) to the abluminal side of in vitro BBB model comprised of endotherial cells (EC), pericytes (Peri) and astrocytes (Ast). We then measured the abluminal concentrations of 27 kinds of C/Cs. We also investigated the contribution of interactions between LPS-MG and BBB cells to their concentration changes. LPS-MG induced BBB collapse as revealed by the decrease in the trans-endothelial electrical resistance (TEER) and in the expression levels of tight junction proteins (TJs). In this condition, 19 C/Cs were remarkably increased in the abluminal side. LPS-MG alone released 10/19 C/Cs, but unexpectedly, their concentrations were even lower than those detected in the in vitro BBB model supplemented with LPS-MG. On the contrary, co-culture of LPS-MG with Ast caused remarkable increases in 12/19 C/Cs, while co-culture with vascular cells (EC and Peri) caused significant increase in 1/19 C/C (fractalkine). These results suggest that C/C dynamics in neuroinflammation associated with BBB breakdown is mainly attributed to the interaction of activated microglia with Ast.

Title: Microglia gain functional IL-1R1 following chronic peripheral inflammation

Authors: *D. NEMETH[1], X. LIU[2], D. J. DISABATO[3], C. NEGRAY[4], N. QUAN[5]
[1]Inst. For Behavioral Med. Res., Columbus, OH; [3]Neurosci., [4]Col. of Dent., [2]The Ohio State Univ., Columbus, OH; [5]Dept Biosci., Ohio State Univ., Columbus, OH

Abstract: Peripheral inflammation is known to sensitize the central nervous system (CNS) and has been associated with the exacerbation of neurodegenerative disorders, such as prion diseases. The mechanism by which peripheral inflammation can sensitize and amplify CNS inflammation is unknown. To mimic chronic peripheral inflammation, intraperitoneal injections of lipopolysaccharide (LPS) were administered for four consecutive days (4d LPS). 4d LPS elicits microglial activation, as seen by an increase in percent Iba-1 area, whereas a single LPS injection does not. Microglia were observed to wrap around blood vessels in the cortex after 4d LPS, yet this action is attenuated in mice deficient in Interleukin-1 Receptor 1 (IL-1R1), suggesting IL1R1 is an important receptor in mediating microglial migration. Using a genetic mouse model, in which IL-1R1 is specifically restored in microglia (CX3CR1Cre IL-1R1$^{r/r}$); we were able to detect IL-1R1 mRNA expression after 4d LPS but not in PBS injected controls. Intracerebroventricular injection of IL-1β in LPS primed CX3CR1Cre IL-1R1$^{r/r}$ animals exhibited microglial morphological changes and an increase in IL-1R1 and IL-1β mRNA compared to PBS injected controls, indicating a gain of function on microglia. Overall, these data suggest a potential mechanism by which peripheral inflammation can sensitize the CNS microglia and contribute to augmenting neurodegenerative diseases.

[1]Neurología, Pontificia Univ. Católica De Chile, Santiago, Chile; [2]Univ. de Santiago, USACH, Santiago, Chile

Abstract: Microglia are the main innate immune effector cells of the brain and the main generator of inflammatory cytokines and oxidative products in the CNS. Beyond the immunological role, new and controversial functions have been described for microglia in normal and pathologic functions. To elucidate the role of microglia in those new functions, animal models that allow us to eliminate the microglia from CNS in vivo, without affecting the innate immune system of the whole animal, are especially important. A possibility is the use of the macrophage Fas-induced apoptosis (MaFIA) transgenic mice. In this model, a murine c-fms promoter induces the expression of a transgene containing a suicide fusion protein made of the FK506-binding protein and the cytoplasmic domain of Fas and enhanced green fluorescent protein (EGFP) only in macrophages and microglia. Because the dimerization of suicide protein and the induction of Fas-mediated apoptosis requires the administration of AP20187, a homodimerizer drug with limited ability to cross the blood-brain barrier, we injected AP20187 into the cerebral ventricles. Through stereotaxia and under deep isofluorane anesthesia, we implanted a 3.0 mm dummy cannula contained into a 2.5 mm guide cannula at lateral ventricle (-0.3 mm A.P., 1 mm M.L. axes) in 3-6 m old MaFiA mice. After 4 days (d) of recovery, the dummy cannula was replaced for a 3.0 mm internal cannula connected to a 5 µL Hamilton syringe for delivery of a) 0.2 µL of saline, or 100 ng Kg^{-1} AP20187 every 24 h per 5 d, b) 1 µg Kg^{-1} every 12 or 24 h per 5 or 8 d or c) simultaneous i.p. and i.v. injection of 5 µg Kg^{-1} every 24 h per 5 d. The number and morphology of microglia after treatment were evaluated by IBA1 immunostaining in 40 µm sections of hippocampus and brainstem. The inflammatory status was evaluated by ELISA. Whereas 100 ng Kg^{-1} or 1 µg Kg^{-1} AP20187 every 24 h per 5 or 8 d, did not modify microglia number in the hippocampus and brainstem, treatment with 1 µg Kg^{-1} AP20187 every 12 h per 5 d induced a 15% decrease on microglia number and conspicuous

morphological changes. Morphological changes consisted in an increased amoeboid activated state with reduction in both length and number of branches. The maximal effect on microglia was observed when mice received the simultaneous application of i.v. and i.p. AP20187, reaching a 28% reduction of microglia in brainstem areas. We suggest that, due to the fast proliferation of microglia that allows its rapid repopulation on the CNS, it is required chronic high levels of AP20187 for a most effective microglia ablation. MaFIA mice can be used as a complementary method for evaluating the role of microglia in conditions like neurodegenerative disorders.

Title: Dissociation of mRNA and protein molecular signatures in activated microglia

Authors: *J. KRIZ[1], H. BOUTEJ, G1J 2G3[2], L.-C. BÉLAND, G1J 2G3[2], R. RAHIMIAN, G1J 2G3[2]

Abstract: Microglia are the principal immune cells of the brain. Once activated, in injured and/or diseased brain, microglia can acquire a wide repertoire of the context-dependent immune profiles. However, at present, the molecular mechanisms involved in the control of microglia polarization profiles remain elusive. By using an in vivo model-system for analysis of the the dynamic translational state of microglial ribosomes with mRNAs as input and newly synthesized peptides as an output, recently created in our laboratory (Boutej et al. Cell Rep 2017),we found a marked dissociation of microglia mRNA and protein molecular signatures following an acute innate immune challenge. The results revealed that highly up-regulated and ribosome-associated mRNAs were not translated resulting in creation of two distinct microglia molecular signatures: i) a highly specialized pro-inflammatory mRNA and ii) immunomodulatory/homeostatic protein signature. The most striking divergence was observed in the key immune NF-κB network where we found that the cluster of highly up-regulated LPS-induced and polysome-associated mRNAs such as Saa3, Lcn2 ccl3, ccl5 (from 15-30 fold increase at mRNA level) were indeed not translated. As mechanism, we discovered a selective 3'UTR-mediated translational suppression of highly expressed mRNAs. Moreover, we identified a novel and previously unknown role for

RNA binding protein SRSF3 as a master suppressor/regulator of innate immune genes translation. The complex analysis of mRNA/protein networks in chronically activated microglia suggest existence of a similar ribosome-based mechanism/check point involved in the control of highly regulated mRNAs *in vivo*.

Title: Post-inspiratory complex (pico) rhythm irregularities after neuroinflammation

Authors: *I. M. AGOSTO[1], J. RAMIREZ[2]
[1]Seattle Children's Res. Inst., Seattle, WA; [2]Neurolog. Surgery, Univ. Washington, Seattle, WA

Abstract: Studies link neuroinflammation to devastating syndromes such as sudden infant death syndrome (SIDS), epilepsy, autism and many others. Infants are particularly susceptible to pathogens that can lead to neuroinflammation, for this reason this set of studies focuses on how neuroinflammation affects the neonatal medullary region. The medullary region contains neuronal populations necessary for respiration, cardiorespiratory coupling and swallowing. We tested how neuroinflammation affects two areas in the respiratory network, the pre-Bötzinger Complex (PreBötC) and the post-Inspiratory Complex (PiCo), in-vivo and in-vitro. We injected lipopolysaccharide (LPS, 3ug/g) to elicit a systemic inflammation, which leads to up-regulation of key pro-inflammatory cytokines (TNF-α (19-fold change), IL1β (10-fold change) at the medulla. In-vivo respiratory changes were characterized pre- and post-LPS injection using whole body plethysmograph. Three hours after the LPS insult, mice have significant changes in breaths per minute (BPM), interevents intervals (sec) and increase in apneic events ($P<0.05$). These mice are then characterized in population recordings from horizontal, medullary slices. This preparation keeps a large population of the respiratory column intact and includes the PreBötC and PiCo. Our in-vitro data showed a significant frequency increase in the PiCo area. Multiple bursts per respiratory cycle were generated in the absence of exogenously applied norepinephrine. By contrast, the PreBötC showed no significant changes after neuroinflammation. During hypoxic exposure PiCo activity is inhibited, which was associated with a temporary normalization of respiratory activity in vivo. Our findings suggest that

neuroinflammation specifically activates PiCo, which contributes to significant breathing disturbances manifested during the expiratory phase.

Title: A time course study of melatonin's effect on microglia responses to neural implants as revealed by two-photon imaging

Authors: *Q. YANG, X. PAN, A. GOLABCHI, J. ELES, T. D. Y. KOZAI, X. T. CUI
Univ. of Pittsburgh, Oakland, PA

Abstract: The inflammatory responses of brain tissue greatly hindered chronic applications of neural implants, causing loss of functional neurons and decreased recording quality over time. Melatonin (MT), a compound that is anti-inflammatory, antioxidant and anti-apoptotic, has been demonstrated to improve chronic neural recordings. When comparing chronic melatonin treatment, acute melatonin treatment and saline treatment, we have found that acute melatonin treatment benefits electrophysiological recording initially but the recording quality dropped down shortly after the treatment stopped, while chronic melatonin treatment (daily injection for 16 weeks) maintained high recording quality throughout the implantation period. Postmortem histology at 16 weeks post implant revealed reduced gliosis, decreased oxidative stress and increased neuronal viability in the chronic MT group. However, melatonin's specific effect on immune response during the acute phase is not clear. Here we used two-photon imaging to study the microglia response dynamics after neural probe implantation. 4 shank Michigan electrodes were implanted at 30 degrees in the CX3CR1-GFP transgenic mice cortex. All the animals were grouped for acute melatonin treatment, chronic melatonin treatment and control. We measured the velocity of microglia processes moving toward the implant immediately after neural electrodes insertion. Later on, microglia coverage of the probe surface and the region of activated microglia were traced over time. The imaging was conducted for 4 weeks. At the end time point of study, animals were sacrificed and perfused for further postmortem histology. We found that melatonin administration reduces immediate microglia coverage upon neural electrodes insertion, this data correlates with the higher recording performance (signal-to-noise ratio) in MT

treated compared to the control at the day of surgery. Further chronic imaging gave us the same trend of attenuated microglia infiltration at the implantation site. Characterizing microglia activity between different dosing will help uncover the mechanism of action for melatonin and guide future therapeutic strategies aimed at improving neural electrode-tissue interface.

Title: Neuroimmune activation and off-target toxicity testing of cell therapies using a novel brain-on-a-chip system

Authors: *J. T. SHOEMAKER[1], J. VUKASINOVIC[1], C. XU[2], Z. WEN[2], M. C. LAPLACA[3]
[1]Lena Biosciences, Inc., Atlanta, GA; [2]Dept. of Psychiatry and Behavioral Sci., Emory Univ. Sch. of Med., Atlanta, GA; [3]Georgia Inst. of Technol., Atlanta, GA

Abstract: Adoptive cellular therapies such as chimeric antigen receptor T (CAR-T) cell therapy have become a promising avenue for cancer treatment. However, unexpected off-target effects of treatment resulting in brain edema and neurotoxicity have raised concern as to how the safety of these therapies can be adequately assessed. Animal models have been ineffective for predicting such events as they require humanized immunodeficient mice for testing. In vitro models are insufficient in that they are often too short-lived and lack the complexity required to accurately recreate the human neural environment. Lena Biosciences has created a novel brain-on-a-chip system comprising human neurons, astrocytes, and microglia in a three-dimensional (3D) scaffold that models neuroinflammation. iPSC-derived neurons and astrocytes were co-cultured with cells from the human microglia cell line HMC3 in SeedEZ scaffolds. Cell viability was high after two weeks in culture. A pro-inflammatory response was confirmed by gene expression and protein release from cultures of microglia and co-cultures of astrocytes and microglia in response to treatment with lipopolysaccharide and interferon gamma. Complete cultures containing neurons were exposed to conditioned medium from activated Jurkat cells or from activated

primary human T cells. Both treatments resulted in a significant increase in the release of pro-inflammatory cytokines and chemokines, with the latter treatment proving to be more potent. Experimental conditions for individual experiments were in triplicate and the studies were repeated to confirm the results. These data validate this as a model of neuroinflammation that can be used to test new therapeutics. Preliminary data exploring the effects of adding perfusion to the 3D cultures has consistently shown improved cell viability and increased metabolic activity. Studies assessing the effects of perfusion on markers of neuroinflammation are ongoing. Additionally, the planned integration of iPSC-derived microglia is expected to enhance the induced neuroimmune response, further improving the relevance of the model. The immense promise of treatments such as CAR-T cell therapy necessitates the creation of preclinical models that can accurately predict off-target effects. Lena Biosciences' brain-on-a-chip system will serve as an invaluable tool for this application as well as any research focused on the mechanisms of neuroinflammation.

Title: Investigation of TSPO as a target for imaging neuroinflammation

Authors: *M. VICENTE-RODRIGUEZ[1,2], N. SINGH[1], C. SIMMONS[1,2], K. RANDALL[1,2], A. HAJI-DHEERE[3], W. NIMA CONSORTIUM[2], F. TURKHEIMER[1,2], C. A. PARKER[4,2], D. CASH[1,2]

(NIMA), London, United Kingdom; [3]PET Centre, St Thomas' Hosp., London, United Kingdom; [4]Exptl. Med. Imaging, GlaxoSmithKline R&D, Stevenage, United Kingdom

Abstract: Mitochondrial TSPO (18-kDa Translocator protein) is a widely used *in vivo* imaging biomarker of neuroinflammation in humans by Positron emission tomography (PET). TSPO has generally been labelled a 'biomarker of neuroinflammation' or 'microglia activation'. However, this is controversial as TSPO is expressed in various CNS and non-CNS cell types including

microglia, astrocytes, macrophages and endothelial cells in response to a variety of insults, as well as in neurodegenerative diseases, which complicates the interpretation of TSPO PET imaging. [^{11}C]PK11195 is a TSPO PET ligand that represents one of the most used imaging biomarkers for detecting inflammation in the CNS. This study aimed to characterise TSPO as an imaging biomarker of neuroinflammation using radiolabelled PK11195 in a rat model of neuroinflammation induced by intracranial LPS, which is known to induce a focal inflammatory reaction. All experiments were ethically reviewed and performed in accordance with the UK Animals (Scientific Procedures) Act 1986 and the GSK Policy on the Care, Welfare and Treatment of Animals. *In vivo* microPET data demonstrated a significantly higher uptake of [^{11}C]PK11195 in the LPS-injected side vs the non-injected side 24 hours following administration. TSPO mRNA and protein expression were also both found to have increased in the lesioned side of the brain 24 hours following the intracranial administration of LPS compared with the non-lesioned side. Additionally, after the intracranial administration of LPS, the increased expression of TSPO was demonstrated to co-localise with both Iba1 positive and negative cells, suggesting its presence in microglia/macrophages as well as other type of cells. Taken together, these findings suggest that TSPO PET signal could be labelling activated microglia alongside other immune-cell types in response to the inflammatory insult. Further analysis of the contribution of different cell types to the overall TSPO PET signal is ongoing to accurately characterise TSPO as an imaging marker in neuroinflammation.

Title: Luteolin inhibits fibrillary beta-amyloid$_{1-40}$-induced inflammation ina human blood-brain barrier model by suppressing the p38 MAPK-mediated NF-kappaB signaling pathways

Authors: *R. LIU[1], J. ZHANG[2], J. XING[3], L. WANG[2], H. JIANG[2], S. GUO[4]
[1]Inst. of Materia Medica, Beijing, China; [2]Inst. of Medicinal Biotechnology, Chinese Acad. of Med. Sci. and Peking Union Med. Col., Beijing, China; [3]Xinjiang Inst. of Materia Medica, Urumqi, China; [4]Beijing Friendship Hospital,Capital Med. Univ., Beijing, China

Abstract: Aims: Amyloid-β peptides (Aβ) exist in several forms and are known as key modulators of Alzheimer's disease (AD). Fibrillary Aβ (fAβ) has been found to disrupt the blood-brain barrier (BBB) by triggering and promoting inflammation.
Main methods: In this study, luteolin, a naturally occurring flavonoid that has shown beneficial properties in the central nervous system, was evaluated as a potential agent to preserve barrier function and inhibit inflammatory responses at the BBB that was injured by fAβ1-40. We established an in vitro BBB model by co-culturing human brain microvascular endothelial cells (hBMECs) and human astrocytes (hAs) under fAβ1-40-damaged conditions and investigated the effect of luteolin by analyzing cellular toxicity, barrier function, cytokine production and inflammation-related intracellular signaling pathways.
Key findings: Our results demonstrated that, in cells injured by fAβ1-40, luteolin increased cell viability of hBMECs and hAs. The cytoprotection of the co-culture against the damage induced by fAβ1-40 was also increased at both the apical and basolateral sides. Luteolin protected the barrier function by preserving transendothelial electrical resistance and relieving aggravated permeability in the human BBB model after being exposed to fAβ1-40. Moreover, in both the apical and basolateral sides of the co-culture, luteolin reduced fAβ1-40-induced inflammatory mediator and cytokine production, including cyclooxygenase-2 (COX-2), tumor necrosis factor α (TNF-α), inter leukin1 β (IL-1β), inter leukin6(IL-6), and inter leukin8(IL-8), however it did not show sufficient effects on scavenging intracellular reactive oxygen species (ROS) in hBMECs and hAs. The mechanism of BBB protection against fAβ1-40-induced injury may be related to the regulation of inflammatory signal transduction, which involves inhibition of p38 mitogen-activated protein kinase (MAPK) activation, downregulation of phosphorylated inhibitory κB kinase (phosphor-IKK) levels, relief of inhibitory κB α (IκBα) degradation, blockage of nuclear factor κB (NF-κB) p65 nuclear translocation, and reduction of the release of inflammatory cytokines. Moreover, the employment of p38 MAPK and NF-κB inhibitors reversed luteolin-mediated barrier function and cytokine release.
Significance: Taken together, luteolin may serve as a potential therapeutic agent for BBB protection by inhibiting inflammation following fAβ1-40-induced injury.

Title: Inflammation-associated release of MMP-9 increases neuronal vulnerability in an *in vitro* model of early Alzheimer pathogenesis

Authors: T. DEMARSE[1], T. J. COHEN[2], P. R. CARNEY[3], *R. B. MEEKER[3]
[1]Neurol., Univ. of North Carolina, Chapel Hill, NC; [2]Neurol., Univ. of North Carolina - Chapel Hill, Chapel Hill, NC; [3]Neurol., Univ. of North Carolina at Chapel Hill, Chapel Hill, NC

Abstract: Matrix metalloprotese-9 (MMP-9) is a zinc-dependent enzyme with widely diverse functions including contributions to normal synaptic plasticity. However, in degenerative diseases such as Alzheimer disease, chronic inflammatory conditions promote excessive secretion of MMP-9 by mononuclear phagocytes. The actions of this MMP-9 leads to neural dysfunction but the mechanisms are not well understood. To better understand the impact of factors secreted by microglia, we cultured primary mouse microglia and human monocyte-derived macrophages and challenged them with oligomeric Abeta. Medium from these cells was applied to 12-28 day old primary mouse cortical/hippocampal neurons grown on microelectrode arrays (MEAs) or coverslips. Factors released from the microglia induced a destabilization of neuronal calcium homeostasis 5-10-fold greater than that of Abeta oligomers alone. Exposure to Abeta conditioned media modified population bursting dynamics and increased firing rates for some neurons while decreasing rates in others. Results from antibody arrays and unbiased proteomic screens verified robust release of MMP-9 which was subsequently quantified at 40-65 ng/ml using a DQ gelatin based assay. The effects of the conditioned medium were partially inhibited by MMP-9 Inhibitor I and enhanced by a neutralizing antibody to tissue inhibitor of metalloprotease-1 (TIMP-1). Direct application of 20 ng/ml activated MMP-9 to the neurons resulted in an increase in NMDAR-dependent calcium signaling and a modest increase in firing rates with a transition to highly synchronous and more periodic burst dynamics. MMP-9 alone was minimally toxic but sensitized neurons such that a subsequent challenge with a low concentration of glutamate (1 μM) evoked pathological increases in calcium and associated structural damage. The p75 neurotrophin receptor ligand, LM11A-31, shifted the macrophage secretome toward increased relative expression of tissue inhibitor of metalloprotease-1 (TIMP-1) thereby reducing MMP-9 activity and associated neural damage. Thus, MMP-9 release in

response to inflammation at early stages of disease primes the nervous system for development of hyperactivity and aberrant network activity. Targeting therapies to these early effects may have the potential to slow disease progression.

Title: Glucose enhances endothelial cell-mediated activation of a pro-inflammatory phenotype in BV-2 microglia *in vitro*

Authors: *J. M. IANNUCCI[1,2], H. VITTAL RAO[1], P. GRAMMAS[1]
[1]George and Anne Ryan Inst. for Neurosci., [2]Interdisciplinary Neurosci. Program, Univ. of Rhode Island, Kingston, RI

Abstract: Diabetes has been identified as a strong risk factor for the development of Alzheimer's disease (AD). Neuroinflammation mediated by microglia has also been indicated in AD pathology. Microvascular complications in diabetes have been correlated with alterations in glucose control. Additionally, research has suggested a link between endothelial cell changes and neuroinflammation. We hypothesize that injury to endothelial cells by glucose and other noxious stimuli will induce a pro-inflammatory phenotype in microglia. Human brain microvessel endothelial cells (HBMVECs) and BV-2 microglia were grown *in vitro*. HBMVECs were divided into three treatment groups: control, glucose, and mannitol. Each of those three groups had four sub-treatment groups: normoxia, hypoxia, thrombin, thrombin+hypoxia. Following treatment, HBMVEC supernatant was collected and used to treat BV-2 microglia for 24 hours. At the end of 24 hours, MTT was used to determine cell viability, and Griess assay was used to measure nitric oxide (NO) production. MMP-9 and MMP-2 activity were measured using gel zymography, and Western Blot assessed TNFα and IL-6. Treatment with supernatant from glucose-treated HBMVECs induced a pro-inflammatory phenotype in BV-2 microglia characterized by increased NO production ($p<.0001$ vs. untreated control), increased MMP-9 activity, and increased TNFα and IL-6. The level of pro-inflammatory activation was correlated with the extent of endothelial cell injury, with the glucose-thrombin+hypoxia group showing the greatest increase in NO production ($p<.0001$ vs. glucose only) and MMP-9 activity. Overall, our results show that treatment with supernatant from injured endothelial cells induces a pro-inflammatory phenotype in microglia that is enhanced in the presence of glucose. This suggests a link between endothelial cell injury in diabetes-like conditions and the activation of a pro-

inflammatory phenotype in microglia in the brain. Further studies could help to determine the signaling mechanisms behind this phenotypic switch.

Title: Increased vascular density in an experimental rat model with neurodegeneration and inflammation

Authors: *M. S. THOMSEN, L. J. ROUTHE, S. S. HELGUDÓTTIR, T. MOOS
Aalborg Univ., Aalborg Ost, Denmark

Abstract: Introduction: The blood-brain barrier (BBB) represents the interface between the blood and brain parenchyma, and is important for ensuring sufficient nutrient transport and for maintaining brain homeostasis. Many conditions with neurodegeneration and inflammation are accompanied by changes of the BBB, including increased BBB permeability and changes of the vascular basement membrane. We have previously in an experimental model of neurodegeneration shown that excitotoxic-induced neurodegeneration in substantia nigra pars reticulata (SNpr) was accompanied by activation of microglial cells and infiltration of inflammatory cells. We therefore aimed to investigate if the neurodegeneration with inflammation is associated with changes of the BBB using the same model. Method: The model of neurodegeneration with inflammation was created by stereotactical injection of ibotenic acid into the left striatum, which subsequently results in excitoxicity in the left SNpr (lesioned side). We examined changes of the BBB by injection of 3 and 10 kDa Texas Red™-Lysine Fixable-Dextrans 4 minutes before termination and immunolabeling of endogenous albumin. Changes of the basement membrane proteins Fn1, Col4a1, Lama2, Lama4, Lama5 were investigated using RT-qPCR analysis. Results/conclusion: In response to the induced neurodegeneration with inflammation a significant increase in vascular density was observed in the lesioned side compared to the non-lesioned side. Furthermore, parenchymal labelling of albumin in the lesioned side indicates increased BBB permeability. There was no change in the gene expression of the basement membrane proteins Fn1, Lama2, Lama4, and Lama5, however the expression of Col4a1 was significantly decreased in both lesioned and non-lesion SNpr compared to SNpr

from aged matched control animals. Together, these results indicate that the BBB is greatly affected in conditions with chronic neurodegeneration and inflammation.

Title: The role of equilibrative nucleoside transporter-2 in the modulation of neuroinflammation

Authors: *C.-Y. LEE, K.-C. WU, Y.-H. KAO, C.-J. LIN
Sch. of Pharmacy, Col. of Med., Natl. Taiwan Univ., Taipei, Taiwan

Abstract: Neuroinflammation is a common characteristic of many neurodegenerative disorders. Adenosine is an endogenous anti-inflammatory agent and its extracellular level in the brain may play an important role in modulating the status of neuroinflammation. The equilibrative nucleoside transporters, ENT1 an ENT2, are the major membrane transporters responsible for cellular uptake of adenosine and the maintenance of extracellular adenosine level in the brain. Given that the expression of ENT2 is higher than that of ENT1 in the brain of mice, in the present study, ENT2 knockout (KO) mice were established and used to clarify the roles of ENT2 in modulating neuroinflammation induced by the treatment of lipopolysaccharide (LPS). The results showed that ENT2 KO significantly ameliorated the LPS-induced neuroinflammation, in terms of the increase of cytokine levels, astrogliosis and microglia activation. The results of in-vivo brain microdialysis study confirmed that LPS treatment increased extracellular levels of adenosine and the extent of increase in extracellular adenosine levels were significantly higher in ENT2 KO mice than in the littermate controls. Taken together, these findings suggest that ENT2 plays a crucial role in maintaining extracellular adenosine and adenosine-mediated neuroprotection in LPS-induced neuroinflammation.

Title: Protein expression profile of IL-1ß, phosphorylated p38 and VEGF-A in the hippocampus after 4-aminopyridine-induced seizures in adult mice

Authors: *M. E. URENA-GUERRERO[1], J. L. CASTAÑEDA-CABRAL[1], J. MURGUÍA-CASTILLO[1], B. GARCÍA-SANTIAGO[1,2], C. BEAS-ZÁRATE[1]
[1]Univ. de Guadalajara (CUCBA), Zapopan, Jalisco, Mexico; [2]Univ. de la Sierra de Juárez, Oaxaca, Mexico

Abstract: Recent evidence suggests that excessive neuronal activity in non-infectious pathological processes (as seizures) may induce an inflammatory response in the brain. In this sense, it is known that IL-1β mRNA expression level and its immunohystochemical reactivity are both increased by seizures; and that IL-1β-mediated signaling activation promotes the seizures and its blocking reduces them. The goal of this work was to establish a temporal course of the IL-1β protein expression in the hippocampus following the 4-aminopyridine (4AP)-induced *status epilepticus* (SE) onset in adult mice through ELISA quantitative assay (ELISAq) confirmed by western-blotting. Moreover in the same samples, phosphorylated p38 and VEGF-A protein expression levels were determined by western-blotting too. The study was performed in adult CD1 male mice of 25-30 g of body weight (b.w.). First, we established that 4AP 10.75 mg/kg of b.w. administered intraperitoneally was able to produce SE in 60% of the animals without dying. After that, 5 animals were sacrificed to obtain the hippocampus at 0, 0.5, 1.5, 3, 6, 12, and 24 h after SE onset by that 4AP dose. ELISAq assay showed that the IL-1β level at time 0.5 h was almost two-fold higher than the basal observed at time 0 h (without 4AP), and at time 1.5 h the IL-1β level reached a peak in four-fold higher than the basal. After that, the IL-1β level decreased to reach the basal at time 6 h, but increasing again at time 24 h almost at the same level of the peak. Western-blotting to IL-1β confirmed the temporal course described above, but the increases were more pronounced. Following the peak of IL-1β, phosphorylated p38 and VEGF-A protein expression levels increased to reach a peak at times 3 h and 6 h, respectively. Results indicates that IL-1β increase could trigger both cell death and angiogenesis process, and suggests that blocking IL-1β must be broadly studied as a putative strategy to avoid epileptogenesis process.

Title: Effects of short term sleep deprivation on the brain's immune compartment

Authors: *B. KORIN[1], S. AVRAHAM[2], H. AZULAY-DEBBY[1], F. HAKIM[3,4], A. ROLLS[1]

Abstract: A normal sleep cycle is vital for body and brain homeostasis, and many neurodegenerative diseases are accompanied by sleep disorders and immune dysfunction. The immune system in the brain compartment is comprised of multiple immune cell types that constantly interact with the neural tissue. We recently showed, using mass cytometry (CyTOF), the diversity of immune cells that are present even in the naïve mouse brain. Here, with mass cytometry, we characterize the immune cells of the brain compartment (i.e., the parenchyma, meninges and choroid plexus) following short term sleep deprivation (6 hours). We illustrate the alterations in immune cell composition and phenotype in the mouse brain, caused by sleep deprivation. We show that the abundance of the various immune populations remains largely un-affected. However, the expression pattern of functional, intracellular and extracellular markers is altered in several cell types, mainly, macrophages and natural killer (NK) cells. As sleep deprivation is a prevalent comportment of the modern world, our data may have relevant implications to the effects of sleep deprivation on normal and pathological brain function.

Title: The role of lysophosphatidic acid in post-hemorrhagic hydrocephalus

Authors: *P. SANCHEZ PAVON[1,2], V. A. BLAHO[1], N. LUMMIS[1,3], J. CHUN[1]
[1]SANFORD BURNHAM PREBYS MEDICAL DISCOVERY INSTITUTE, La Jolla, CA; [2]Sanford Burnham Prebys Med. Discovery Inst. Grad. Sch. of Biomed. Sci., La Jolla, CA; [3]Univ. of California San Diego Biomed. Sci. Grad. Program, La Jolla, CA

Abstract: Post-hemorrhagic hydrocephalus (PHH) is a neurological disease that primarily affects premature infants (~1 in 1000 births). It is characterized by an increase in intracranial pressure, enlargement of the brain ventricles (ventriculomegaly), accumulation of cerebrospinal fluid (CSF), and a representative dome-shaped head deformation. The current treatment involves the surgical introduction of a shunt into the brain ventricles to redistribute the excess of CSF into the patient's stomach, where it can be reabsorbed. Lysophosphatidic acid (LPA) is a bioactive lipid present in blood that signals through 6 known G-protein coupled receptors (GPCRs). Injection of LPA into the brain ventricles has previously been shown to initiate hydrocephalus. Previous studies in our laboratory using a neonatal PHH model have linked the development of PHH to the disruption of the ependymal cell barrier. These cells surround the ventricles and are responsible for the correct flow of the CSF. In addition to the loss of the ependymal layer, we have observed immune cell brain infiltration at different time points after LPA injection. To address the correlation between these two events we will test the hypothesis that immune cells are recruited by LPAR-mediated ependymal cell death, promoting a prolonged inflammatory environment that aggravates PHH. Temporal changes in immune cell number and population collected from whole mouse brain will be assayed by flow cytometry at different points in time post-LPA injection. We will also genetically and pharmacologically target LPA receptors (LPARs) to resolve their effect in ependymal cell integrity, immune cell infiltration and progression of PHH. This approach aims to reduce the need for CSF shunting and define a therapeutically tractable target cell type(s) at specific times post-PHH leading to improved quality of life for hydrocephalus patients.

Title: Peripheral macrophage infiltration post-stroke in the primate is attenuated by reactive astrocytes through NogoA-LILRB2 mediated signalling

Authors: *A. G. BOGHDADI[1], L. TEO[1], B. CAO[1,2], S. M. STRITTMATTER[3], S. K. NILSSON[1,2], J. A. BOURNE[1]
[1]Australian Regenerative Med. Inst., Monash Univ., Clayton, Australia; [2]CSIRO, Clayton, Australia; [3]CNNR Program, Yale Univ., New Haven, CT

Abstract: Blood brain barrier breakdown post-stroke results in peripheral immune cell infiltration, leading to an acute inflammatory response. Previous studies have demonstrated that reactive astrocytes can directly limit immune cell infiltration, thereby attenuating the inflammatory response post-stroke. A major immune modulator, leukocyte immunoglobulin like receptor 2 (LILRB2) is a MHC1 class receptor expressed on peripheral immune cells in primates, including humans. Upregulated neurite outgrowth inhibitor A (NogoA) post-stroke by glia is a major activator of LILRB2 signaling. This study explores the interaction between astrocytes and macrophages involving NogoA and LILRB2 at specific, acute time points post-stroke in the nonhuman primate neocortex.
Injections of 0.5uL endothelin-1 (1mg/mL) over 4 sites surrounding the posterior cerebral artery of operculum primary visual cortex (V1) in adult marmosets (>1 year; n=24) were used to induce stroke. Control, 1-day post injury (DPI), 7 DPI and 21 DPI brains were snap-frozen (n=12) or fixed (n=12) for downstream analysis. The human monocyte cell line (ATCC; TIB-202) was differentiated to represent infiltrating macrophages post-stroke. Western blot, immunohistochemistry, immunofluorescence and *in vitro* techniques were used to analyze the ligand-receptor interaction *ex vivo* and *in vitro*.
Elevated NogoA/LILRB2 expression was observed in marmoset V1 (peri-infarct) 7-21 DPI. LILRB2 labelled a distinct subpopulation of Iba1+/TMEM119- infiltrating macrophages at the lesion site at 7 DPI. Concurrently, NogoA labelled a distinct, complementary subpopulation of GFAP+ reactive astrocytes, juxtaposing LILRB2+ macrophages, proximal to the lesion site. NogoA expression on reactive astrocytes was downregulated by 21 DPI, corresponding to more discrete distribution of LILRB2+ macrophages in V1. Recombinant human NogoA (566-748aa) Fc-coated stripes significantly induced human macrophage cell repulsion *in vitro*. NogoA-induced repulsion was abrogated by pretreatment of macrophages with a LILRB2 blocking

antibody
These findings provide evidence of a novel NogoA/LILRB2 dependent, anti-inflammatory interaction between reactive astrocytes and infiltrating macrophages in the acute stages post-stroke in primates. Specifically, NogoA+ astrocytes limit the infiltration of LILRB2+ macrophages into underlying healthy brain tissue post-stroke. The implications of these findings are particularly significant in light of recent NogoA-based therapeutic strategies, especially in the context of treatment administration time, which can adversely affect endogenous repair mechanisms.

Title: Protective effects of the endogenous neurosteroid (3α,5α)3-hydroxypregnan-20-one (3α,5α-THP) on proinflammatory TLR4 signaling in immune cells and brain

Authors: *I. BALAN[1], M. C. BEATTIE[2], T. O'BUCKLEY[2], L. AURELIAN[1], A. L. MORROW[2]
[1]Pharmacol., Univ. of Maryland Baltimore, Baltimore, MD; [2]Dept. of Psychiatry and Pharmacology, Bowles Ctr. for Alcohol Studies, Univ. of North Carolina at Chapel Hill, Chapel Hill, NC

Abstract: Activation of toll-like receptor 4 (TLR4) signaling pathways plays a significant role in the pathogenesis of alcoholism, depression, traumatic brain injury, schizophrenia, multiple sclerosis, and Alzheimer's disease. The endogenous neurosteroid (3α,5α)3-hydroxypregnan-20-one (3α,5α-THP, allopregnanolone) has protective activity in these conditions, but its mechanism of action is still poorly understood. Until recently TLR4 signaling was believed to be limited to glial cells in the brain. It is now known that neurons also express TLR4, but the mechanism of TLR4 activation and signaling outcomes and the role of 3α,5α-THP in the TLR4 signal regulation in neurons are still poorly understood. To test the possibility that 3α,5α-THP inhibits proinflammatory neuroimmune signaling in the periphery and the brain, we examined the effects

of 3α,5α-THP on agonist (LPS)-induced TLR4 signal activation in immune cells (RAW264.7), as well as on the innately activated TLR4 signal in the ventral tegmental area (VTA) of selectively bred alcohol-preferring P rats. LPS activated the TLR4 signal in RAW264.7 cells as evidenced by increased levels of pTAK1, TRAF6, NFkB p50, phospho-NFkB-p65, pCREB, HMGB1, and inflammatory mediators, including MCP-1 and TNFα. 3α,5α-THP (0.5-1.0μM) substantially (~80%) inhibited these effects, indicating pronounced inhibition of TLR4 signaling. The mechanism of inhibition appears to involve blockade of TLR4/MD-2 protein interaction. In P rat VTA, 3α,5α-THP (15 mg/kg, IP) administration reduced TRAF6 (~20%), CRF (~30%), and MCP-1 (~20%) levels, as well as TLR4 binding to the $GABA_A$ receptor α2 subunit (~60%) and MyD88 (~40%). We found that LPS does not activate the TLR4 signal in the neuronal N2a cells, as evidenced by the failure to increase the levels of both phospho-NFkB-p65 and pCREB. By contrast, the pCREB levels and its nuclear translocation were significantly increased in the $GABA_A$ α2-transfected N2a cells, indicating that $GABA_A$ α2 activates the TLR4 signal in neurons. The $GABA_A$ α2-activated TLR4 signal was also inhibited by 3α,5α-THP in N2a cells through blocking of the interaction between the TLR4 and $GABA_A$ α2 proteins. The data identify the role of α2 and its ability to interact with TLR4 in neuronal TLR4 activation and document that inhibition of proinflammatory neuroimmune TLR4 signaling underlies protective effects of 3α,5α-THP in immune cells and brain, apparently involving blocking of protein-protein interaction.

Title: Conditional knockout strategies reveal opposing effects of prostaglandin receptor EP2 signaling in immune cells and neurons after status epilepticus

Authors: *N. H. VARVEL[1], D. CHEN[2], A. BIEGEL[2], R. J. DINGLEDINE[3]
[1]Pharmacol., Emory Univ., Atlanta, GA; [2]Dept. of Pharmacology, Emory Univ., Atlanta, GA; [3]Dept Pharmacol, Emory Univ. Sch. Med., Atlanta, GA

Abstract: Status epilepticus (SE) is a life-threatening medical emergency that triggers a succession of molecular and cellular events culminating in blood brain barrier (BBB) leakage,

activation of brain microglia, and infiltration of blood-borne monocytes into brain. Long-standing unresolved issues are how these adverse consequences of SE contribute to the debilitating neurobehavioral deficits that decrease quality of life in afflicted individuals. Previous studies in our group have identified neuron-derived prostaglandin E2 production and subsequent activation of prostaglandin receptor EP2 as a driver of SE-induced neuroinflammation and neuronal damage, contributing to mortality and neurobehavioral deficits. More recent work showed that EP2 activation in innate immune cells (monocytes and microglia) drives numerous deleterious consequences of SE including erosion of the BBB, neurobehavioral deficits, and suppression of weight gain. In the present study we sought to identify which effects of EP2 antagonism could be reproduced by conditional neuronal ablation of EP2 receptor via syntaxin promoter expression of Cre recombinase in male C57Bl/6CR mice bearing a floxed EP2 allele. Notably, pilocarpine-induced seizure activity and acute mortality were not different between EP2 conditional knockout animals and EP2-sufficient littermate controls. Surprisingly, elimination of EP2 receptor from forebrain neurons enhanced neuronal injury, selectively elevated induction of pro-inflammatory cytokines, TNFα and Ccl2, but not IL-1β and IL-6, in hippocampus, promoted leakiness of the blood-brain barrier, delayed weight recovery, and negatively affected animal posture and activity four days after pilocarpine-induced SE. Taken together these data highlight the complexities in neuroinflammatory signaling in the brain, wherein activation of EP2 receptor in brain innate immune cells is deleterious, whereas neuronal EP2 signaling is protective. Thus, effective treatments for patients targeting brain prostaglandin signaling pathways should be cell targeted in order to be optimally effective.

Title: Allostatic conditions of glioblastoma stem cells are maintained by mutual influence of chronic oxidative stress, basic intracellular ph and clic1 protein associated chloride current

Authors: I. VERDUCI, 20133[1], T. FLORIO[2], F. BARBIERI[2], V. CARLINI[1], M. PERETTI[1], F. M. RACITI[1], A. DAGA[3], *M. MAZZANTI[1]
[1]Univ. di Milano, Milano, Italy; [2]Dept. of Intrnl. Medicine, Sect. Pharmacol., Univ. di Genova, Genova, Italy; [3]Terapie Oncologiche Integrate, Ospedale Policlinico San Martino, Genova, Italy

Abstract: Glioblastoma (GB) is the most lethal, aggressive and diffuse among brain tumors. The main challenge for successful treatment is targeting the cancer stem cell (CSC) sub-population, considered the main responsible for tumor origin, progression and recurrence. CSCs lay in a chronic allostatic condition, characterized by upregulation of several molecular pathways and overexpression of membrane proteins. In this context, CSCs show abnormal ROS production and alkaline intracellular pH due to hyper activation of membrane NADPH oxidase and NHE1 proton pump, respectively. Previous experiments demonstrated that oxidative stress promotes the translocation of the chloride intracellular protein 1 (CLIC1) from the cytoplasm to the plasma membrane, where it is responsible for the increment of chloride membrane permeability. CLIC1 is constitutively present in the plasma membrane of CSCs. *In vitro,* CLIC1 inhibition leads to a significant arrest of GB CSCs in G1 phase of the cell cycle. Furthermore, CLIC1 knockdown impairs tumor growth *in vivo*. Here, we demonstrate that CLIC1 membrane localization and function are specific for GB CSCs. Mesenchymal stem cells (MSCs) do not show CLIC1-associated chloride permeability and inhibition of CLIC1 protein function has no influence on MSCs cell cycle progression.
The aim of our investigation is to downregulate the allostasis condition of CSCs to a steady state characteristic of glial cells by impairing CLIC1 membrane activity. Any action directed against the membrane oxidase and the proton pump results in cell death not only of CSCs but also of MSCs. On the contrary, CLIC1 membrane protein inhibition does not kill the cells but elongates cell cycle duration to a proliferative rate similar to control cells. Our results show that CLIC1 membrane protein is crucial and specific for GB CSC proliferation, and is a promising pharmacological target for successful brain tumor therapies.

Title: Different biguanide-related drugs eradicate human glioblastoma stem cell through the inhibition of chloride intracellular channel 1 activity

Authors: *T. FLORIO[1,2], F. BARBIERI[2], R. WURTH[2,3], I. VERDUCI[4], M. CATTANEO[5], A. SOLARI[2], A. DAGA[6], L. M. VICENTINI[4], M. MAZZANTI[5]

Cells and Cancer, Deutsches Krebsforschungszentrum, Heidelberg, Germany; [4]Univ. of Milano, Milano, Italy; [5]Univ. di Milano, Milano, Italy; [6]Ospedale Policlinico San Martino, Genova, Italy

Abstract: Drug repositioning is an appealing strategy for drug development. The biguanide metformin, an oral antihyperglycemic agent widely used for the treatment of type 2 diabetes, represents the paradigmatic non-cancer agent showing preclinical and clinical antitumor effects in numerous tumor types. Metformin antiproliferative activity is specifically directed against the cancer stem cell (CSC) subpopulation. CSCs are self-renewing and multipotent cells responsible for development and recurrence of most cancers, including glioblastoma (GBM), the most aggressive primary brain tumor. Metformin exerts antiproliferative effects in GBM CSCs by blocking the chloride intracellular channel 1 (CLIC1) activity inducing cell cycle arrest at the G1-S transition. However, high concentrations (mM range) of metformin are required to affect cancer cell proliferation, hardly transferable to the clinical setting. Therefore, more potent biguanide derivatives deserve further investigation. We tested the antiproliferative efficacy of several known biguanide drugs (phenformin, a withdrawn antidiabetic drug; moroxydine, a former antiviral agent; cycloguanil, used for the prevention of malaria) in GBM CSCs. All the compounds studied significantly impaired GBM CSC proliferation, reaching IC_{50} values lower than metformin (μM range). Cell survival inhibition was accompanied by decreased cell invasiveness in 3D models and correlates to the ability to inhibit CLIC1-mediated ion flux, showing the same higher potency than metformin. These effects were specific toward CSCs since no (or slight) cytotoxicity was observed in differentiated GBM cells and, more importantly, in human normal umbilical cord mesenchymal stem cells. Thus the inhibition of CLIC1 activity represents a biguanide class-effect mechanism of action to suppress CSC viability, proliferation and invasiveness. Despite differences among the dugs tested were observed as far as potency, efficacy and selectivity in inhibiting CLIC1 activity, CLIC1 is the common molecular determinants of all biguanides to specifically target CSCs while sparing normal cells. This high selectivity suggests the rational design of novel molecules containing biguanide moiety, characterized by high antitumor efficacy and safe toxicological profile.

Title: Inhibition of glioblastoma cell invasion and survival by targeting integrin beta 1 using anti-tumorigenic novel quinazoline derivatives

Authors: *T. K. KHAN
Rockefeller Neurosciences Inst., Morgantown, WV

Abstract: Glioblastoma multiforme (GBM) is the most common and most malignant (stage IV brain tumors) among all brain tumors (~50% of brain tumors). The median survival rate is ~14.5 months with no disease-modifying curative treatment. Radiation and adjuvant temozolomide (TMZ) chemotherapy after the surgical resection is the first line treatment of GBM. Common side effects of TMZ are bone marrow suppression, genotoxic, and teratogenic. The mechanism of action TMZ is damaging GBM cell by DNA methylation and triggering the death of GBM cells. DNA damage is not specific to GBM cells, as a result, it is genotoxic. Studies found that 60-75% cases have no benefit from TMZ chemotherapy[1]. FDA approved immunotherapeutic agent Bevacizumab (Avaztin, Genentech) produced some improvement including cognitive benefit[2], but 40% of patients developed therapeutic resistance in phase II clinical trial[3].
Here we report inhibition of glioblastoma cells by synthetic quinazoline derivatives as a new therapeutic approach. Novel quinazoline derivatives induced glioblastoma cell death and decreased glioblastoma cell invasion. This specific synthetic compounds induced GBM cell death, stopped the cellular invasion in three dimensional Matrigel matrix, and was highly specific to GBM cell death when tested with other cells. Some of the potent synthetic quinazoline derivatives are non-toxic to normal non-tumorigenic cells but toxic to cancerous cells. Newly discovered novel quinazoline derivatives can be synthesized very easily (less than 4 reaction steps) with very high yields. Most potent quinazoline derivative (6-Pyridin-2-yl-5, 6-dihydro-benzo [4,5]imidazo[1,2-c]quinazoline) was synthesized by one chemical step with 90% yield. Pharmacological intervention to GBM cells by the most potent quinazoline derivative caused increased GBM cell apoptosis and decreased GBM cell invasion by inhibiting β1 integrin. In cell adhesion dynamics integrins and extracellular matrix (ECM) mediate interactions that are required for tumor cells invasion and metastasis. Since the interaction of integrin β1 and ECM protects glioma cells drug-induced anoikis targeting integrin β1 has potential as an antiangiogenic therapy for glioblastoma. Novel quinazoline derivative decreases oncogenic PKC-epsilon activity in neuroblastoma cells. Most potent synthetic quinazoline derivatives can be used as an effective treatment of GBM alone, or in combination with other chemotherapeutic/immunotherapeutic agents.

Title: Microglial depletion compromises survival, brain growth and sensorimotor reflexes acquisition in mouse pups exposed to perinatal cerebellar insults

Authors: *S. TREMBLAY, A. PAI, W. MENG, D. GOLDOWITZ
CMMT, Vancouver, BC, Canada

Abstract: Background: Extreme preterm infants are exposed to multiple stressors including perinatal cerebellar haemorrhage (CBH) and postnatal infection, two major risk factors for neurodevelopmental impairments. Given microglia involvement in inflammatory functions across the central nervous system, they may play a central role in the pathogenesis of cerebellar injury in developing brains. By using a transgenic mouse model, the role of microglial cells on short-term outcomes in CBH and early inflammation (EIS) will be studied. **Methods:** Conditional transgenic mice dependent on diphtheria toxin (DT) intracerebellar injection to deplete *CX3CR1*-positive cells were made and CBH was induced by a local injection of bacterial collagenase at P2 combined with an intraperitoneal LPS injection to mimic EIS. **Results:** Survival is mainly affected by being exposed to DT (50%) or to CBH (48,6% to 54,6%) compared to control (71,4%) or vehicle-exposed mice (62,6%). *CX3CR1*-depleted mouse pups exposed to combined insults have smaller corrected brain weight compared to *CX3CR1*-depleted mice exposed to single insult (*$P<0.05$). Functional assessment reveals a significant delay of grasping acquisition in *CX3CR1*-depleted pups exposed to EIS compared to non-depleted mice (*$P=0.03$) or *CX3CR1*-depleted pups exposed to vehicle (**$P<0.0053$). **Conclusions:** Microglia-depleted mice exposed to early inflammation have worse neonatal outcomes including compromise survival and a delay in grasping acquisition compared to non-depleted mice, suggesting a potential protective role of microglial cells after EIS insult.

Title: Dehydration-induced anorexia increases microglia density in the rat prefrontal cortex

Authors: *P. REYES ORTEGA[1], A. MARTINEZ-TORRES[2], D. REYES-HARO[3]
[1]Inst. de Neurobiología UNAM, Queretaro, Mexico; [2]INB-UNAM, Queretaro, Mexico; [3]Inst. de Neurobiologia|910003400|0, Querétaro, Mexico

Abstract: Anorexia nervosa is an eating disorder characterized by restrictive caloric intake that induces profound weight loss. The neurobiology of this disorder is unknow, but magnetic resonance imaging studies reported functional and structural alterations in the prefrontal cortex of anorexic patients. Recent studies in murine models of anorexia suggest that glial cells deficits in this region may be linked to alterations observed in patients. Glial cells are the major group in the brain and cytokines such as interleukin 6 (IL-6) and tumor necrosis factor alpha (TNFα) are released by this cells during neuroinflammation. However, whether anorexia affects microglia is unknown. The aim of this study was to test if microglia of the prefrontal cortex is affected by dehydration induced anorexia (DIA). Methods: Three independent experimental series of seven female Wistar rats (180-200g) per group were used for this study: a) Control: received food and water *ad libitum*, b) DIA: received saline solution (2.5 % NaCl) and food *ad libitum*, c) Forced Food Restricted (FFR) group received water and the same amount of food as the DIA group. Body weight and food intake were monitored daily for 5 days. Subsequently, the rats were euthanized, brain tissue sections (30 μm) were obtained for immunofluorescence studies with the microglia marker Iba-1. Quantitative assessment of microglial density well as TNFα and IL-6 expression was estimated for the three experimental groups. Results: Microglia/nuclei ratio was significantly increased in medial prefrontal cortex of DIA and FFR groups (Control 0.10±0.01, DIA 0.18±0.02, FFR 0.22±0.03; $p = 0.003$; n=7). Likewise, reactive/resting microglia ratio was significantly increased for DIA and FFR (Control 0.70±0.06, DIA 2.14±0.42, 1.89±0.40; $p = 0.04$; n=7). Additionally, Western blots showed that anorexia increases the expression of the TNFα (DIA 1.98±0.1, FFR 1.81±0.08; $p = 0.02$; $n = 3$) and IL-6 (DIA 1.85±0.05, FFR 1.69±0.09; $p = 0.04$; $n = 3$). We conclude that in prefrontal cortex DIA and FFR increase microglia density and expression of TNFα and IL-6.

Abstract: Autism spectrum disorder (ASD), which is a severe neurodevelopmental disorder, is reported to show cerebral and cerebellar abnormalities. In particular, reduction in size and number of Purkinje cells in the cerebellum is observed in both postmortem human studies, and drug-administrated adult animals. Some antiepileptic drugs, organophosphorus agents, and other inflammatory agents are known as the candidates of the inducer of autism. Therefore, we have observed valproate (VPA) made recognizable structural and functional change in developing rat cerebellar cortex. The rats maternally administered 600 mg/kg VPA p.o. at embryonic day 16 (E16), showed irregular excess folding on lobule V - VII, and mossy Purkinje cell dendrites. Because neuronal differentiation and apoptosis would be controlled by neurotrophic factors and cytokines derived from astrocyte and microglia, microglial condition and releasing molecules could be focused on as a target to study the cause of ASD. Activated microglia is distinguished between two states, M1 or M2. M1-state microglia works to pro-inflammatory, whereas M2 works to neuronal protection. Understanding microglial condition and its factors should provide significant insights into neuronal development.To investigate the molecular mechanism of VPA-induced neuronal malformation, we examined the interaction of VPA-administered rat cerebellar glial cells with the differentiation of cerebral neurosphere and compared normal glia. Neurosphere derived from E16 rat cerebrum was differentiated on the confluent glial cells derived from native or VPA-administrated newborn rats. In some cases, we prepared the glia-conditioned differentiation medium (GCM) from the confluent glial sheet. Neurosphere cells mounted directly on normal glia migrated away through the glial fibrous scaffold and decelerated their differentiation, whereas it mounted on VPA-administered glia did not form fibrous morphology. Neuronal differentiation in GCM showed a decrease of synaptogenesis compared with it in normal differentiation medium, whereas, VPA-administered glia-conditioned differentiation medium (VPA-GCM) promoted a similar level of synaptogenesis with normal differentiation medium. Therefore, we suggest that some humoral factors in GCM would be related to neuronal differentiation and the candidate molecules might be secreted by microglia which is known as an immune cell in brain development. The sorts and quantity of those factors would be different between in GCM and VPA-GCM.

Title: Epimedium koreanum Nakai inhibits PMA-induced cancer cell migration and invasion in malignant human glioma cells

Authors: *J. KIM[1], W. LEE[1], J. NAM[1], J.-Y. LEE[1], Y.-M. WE[2], J. MA[3], H.-S. HOE[1]

Abstract: Previously, we showed that the herbal extract EYK (*Epimedium koreanum* Nakai) can regulate the immune response. Other studies showed that EYK has beneficial effects in human lung cancer, angiogenesis, and Alzheimer's disease (AD). However, it remains unknown whether EYK can affect cancer cell migration and invasion in human brain cancer cell lines. In this study, we found that pre- or post-treatment with EYK inhibited phorbol 12-myristate 13-acetate (PMA)-induced cancer cell migration and invasion in A172 cells, but not in U373MG or T98G cells. Additionally, pre- or post-treatment with PMA followed by EYK decreased MMP-9 activity in A172 cells. Moreover, treatment with a NF-κB inhibitor significantly decreased cell migration in A172 cells pre- or post-treated with EYK and PMA, suggesting that EYK requires NF-κB to alter cancer cell migration. Either pre-or post-treatment with EYK significantly decreased NF-κB nuclear translocation in comparison with PMA treatment. Taken together, our results suggest that EYK suppresses PMA-induced cancer cell migration in monomorphic malignant human glioma cells by downregulating the NF-κB pathway and decreasing MMP-9 activity.

Title: Evaluation of the cyclin dependent kinase inhibitor cr8 to mitigate neuroinflammatory responses following cessation of nerve agent-induced seizures

Authors: *D. D. PALMER, C. E. KAROLENKO, N. GARIBAY, K. LAITAPAYA, B. LAGER, J. CHANDLER, E. A. JOHNSON, J. W. SKOVIRA
US Army Med. Res. Inst. of Chem. Def., Gunpowder, MD

Abstract: Organophosphate (OP) nerve agents cause excessive excitatory signaling in the central nervous system through mechanisms involving inhibition of cholinesterase. Persistent seizures are a result of excessive signaling and can lead to progressive brain damage. Although great focus has been placed on interventions to control OP-induced seizures, few studies have examined the pathological processes that continue after seizures have been abated. The objective of this study is to determine (1) whether cellular neuroinflammatory responses continue following cessation of OP-induced seizures and (2) whether the cyclin-dependent kinase (CDK) inhibitor CR8 can mitigate the extent of the neuroinflammatory response. Mice were surgically prepared two weeks prior to the experiment with electrodes to record brain activity. The oxime HI-6 (50mg/kg) was given prior to nerve agent exposure to increase survival without affecting the onset of seizure activity. Mice were exposed to the nerve agent sarin to elicit seizure activity (256 µg/kg; control animals received an equivalent volume of saline). The CDK inhibitor CR8 (5mg/kg, ip) was administered 5 min following seizure onset. Seizures were terminated with midazolam (5 mg/kg) and the centrally active oxime monoisonitrosoacetone (50 mg/kg) at 15, 30, or 60 min following onset. Brain tissue was collected at 7 d or 30 d following exposure for analysis of gliosis and neuronal survival. The results suggest that nerve agent casualties may still be at risk for progressive neurodegeneration from the continuation of inflammatory processes, even if seizures are successfully terminated. CR8 treatment significantly reduced the extent of neuroinflammatory responses, thus aiding in neuroprotection following OP-induced seizures.

Title: The serine protease tPA modulates the phosphorylation of mTOR and autophagy during ischemic events

Authors: *A. THIEBAUT, D. VIVIEN, B. D. ROUSSEL
INSERM U1237, Caen Cedex 5, France

Abstract: The serine protease tissue type plasminogen activator (tPA) is a glycoprotein involved in thrombolysis and also found in the neurovascular unit where it has both deleterious and protective effects. tPA is known to be involved in excitotoxicity, apoptosis and inflammation. More recently, it has been reported that tPA protects neurons from oxygen and glucose deprivation (OGD)-induced endoplasmic reticulum (ER) stress (Louessard *et al.,* Cell Death Differ 2017) by binding to cell surface Grp78 (78 kD glucose-regulated protein). It leads to a decrease of the PERK pathway activation and results in neuroprotection. Plus, it has been shown that mTOR (mammalian target of rapamycin) activation mediates the neuroprotective effect of tPA following OGD-induced neuronal death (Wu *et al.,* J Neurosci 2011). mTOR complex 1 (mTORC1) is known to negatively regulate the initiation of autophagy. Moreover, it is well-known that ER stress and autophagy are closely linked. Here, we study autophagy during OGD-induced ER stress, and the effect of tPA on these events. In this study we used an *in vitro* ischemic model consisting in an OGD followed by reoxygenation, on twelve days old murine primary cortical neurons with or without tPA. First, we studied autophagy in OGD and reported that OGD induces a decrease of the Erk/Akt/mTORC1 pathway leading to an increase of the Light Chain 3-I (LC3-I) conversion to LC3 II, a microtubule-associated protein involved in autophagosome formation. Moreover, we observed a decrease of p62, also called sequestosome 1, a cargo-receptor itself degraded by autophagy, able to link ubiquitinated protein to enable their degradation by the lysosome. In a second time, we investigated the effect of tPA on autophagy during OGD. We show that tPA can decrease the LC3I conversion to LC3 II and increases p62. tPA is able to decrease autophagosome formation *via* an activation of the Erk/Akt/mTORC1 pathway. In conclusion, the present study demonstrates that tPA decreases OGD-induced autophagy, by reducing autophagosome formation via the activation of the Erk/Akt/mTORC1 pathway. The next step is to identify the cellular and molecular pathways involved in OGD-induced ER stress and autophagy to propose a new therapeutic target during stroke.

Title: MET activation modulates sctPA-mediated NMDA receptor signalling and neurotoxicity

Authors: E. HEDOU[1], A. THIEBAUT[1], A. CHEVILLEY[1], I. BARDOU[1], C. ALI[1], T. CREPALDI[2], P. COMOGLIO[2], D. VIVIEN[1,3], *B. D. ROUSSEL[1]

Abstract: Tissue type-plasminogen activator (tPA) is a serine protease used as a fibrinolytic agent to treat ischemic stroke. This protease is also expressed within the central nervous system where it is synthesized and released as a single-chain form (sc-tPA) and can be converted into a two-chain form (tc-tPA). Both of them have the same fibrinolytic activity but they display a differential effect on neuronal fate. Indeed, it has been described that sc-tPA is a positive neuromodulator of the glutamatergic transmission, inducing an overactivation of neuronal N-methyl-D-aspartate receptor (NMDAR) and a subsequent calcium influx . Under pathological conditions such as stroke, this phenomenon will enhance the excitotoxic neuronal death.. However, tc-tPA does not overactivate NMDAR, suggesting different mechanisms of action for the two forms of the same protease.
The aim of our study is to identify the mechanisms by which sc- and tc-tPA influence NMDAR signalling. tPA has been shown to be a pro-HGF convertase, capable to process the biologically inactive precursor into the mature form . As the main receptor for HGF is Met, we hypothesized that sc/tc-tPA could directly (though a binding to Met) or indirectly (by converting the pro-HGF into HGF) activate Met signalling and thus modulate NMDAR signalling.
Our data indicates that tPA is not able to convert pro-HGF into mature HGF. However the activation of MET receptor by HGF is able to decrease tPA-induced NMDAR signalling and the subsequent neurotoxicity, as demonstrated by Proximity Ligation Assay, live calcium imaging, toxicity experiments, and pharmacological approach.
Our results prove that MET receptor is able to modulate NMDAR signalling and decrease the associated toxicity, making of MET receptor a new therapeutic target to decrease excitotoxicity.

Title: Developing an animal model for studying cognitive impairment in chronic kidney disease

Authors: *J. Y.-S. HO[1], C. F. LAU[1], W. Y. TANG[3], J. Y. TIAN[2], R. YOU[2], C. C. C. PANG[2], D. S. K. CHEUNG[2], S. S. Y. YUNG[3], R. C. C. CHANG[3]

Abstract: Cognitive impairment are common among patients with chronic kidney disease (CKD). There is also increased risk of developing dementia among CKD patients. The affected cognitive domains include attention, executive functions and memory. Cognitive impairment is associated with poor decision making, reduced self-care ability and increased risk of disability. Apart from protecting the kidney, preserving cognitive functions have become one of the major concerns in recent CKD research. Currently, the mechanism that links the disease kidney and the brain is still unclear. Our group has established a mouse model for studying cognitive impairment in CKD. Eight weeks old male C57BL/6 mice were anesthetized to perform the Unilateral Ureteral Obstruction (UUO) surgery. The left ureter was ligated with silk thread. Sham operated mice received the same experimental procedure without ureteral obstruction. Three months after the surgery, the mice were subjected to behavioral tests and pathological changes were detected in their frontal cortex. We found that the UUO group made significant increased number of error in in the modified Y-maze test when comparing to the sham group. They also had poorer performance in the novel object recognition (NOR) test. These suggested impairment in the hippocampal-dependent memory. In the Puzzle Box test, mice in the UUO group spent significant longer time to reach the dark zone, suggesting a reduction in executive function. At the same time, we found that the protein expression of synaptophysin was reduced, and the levels of phosphorylated tau were increased, and the levels of drebrin were reduced in the frontal cortex of the UUO group. Oxidative stress and inflammation were also found in the brain of the UUO mice. In conclusion, we were able to detect cognitive impairment in mice that had received UUO surgery. Related pathological changes in their brain including inflammation, synaptic dysfunction and changes in tau protein may partly explained the observed phenomenon.

These will be useful for our future investigation on developing new intervention for preserving cognition.

Title: Autphagy induction in brain by severe hypoglycemia and its modulation by the ketone bodybeta-hydroxybutirate

Authors: *M. TORRES ESQUIVEL[1], M. FLORES-MÉNDEZ[2], T. MONTIEL[2], L. MASSIEU[2]
[1]Univ. Nacional Autonoma De México, CDMX, Mexico; [2]Inst. de Fisiología Celular, Univ. Nacional Autonoma de México, Cdmx, Mexico

Abstract: During hypoglycemia alternative substrates to glucose such as the ketone bodies (KB), acetoacetate (AcAc) and β-hydroxybutyrate (BHB) can be used as energy in brain. Furthermore diverse studies have shown that KB prevent neuronal death in different injury models. Nevertheless, the mechanisms by which KB prevent neuronal damage are still not well understood. Previous studies from our group have suggested that autophagy, a lisosomal-dependent degradation process activated during energy failure, participates in neuronal death induced by glucose deprivation in cultured cortical neurons. In these conditions, D-BHB, stimulates the autophagic flux and prevents neuronal death (J.Neurosci.Res. 41:600). In the present study we aimed to investigate whether autophagy is activated in vivo during insulin-induced hypoglycemia and glucose reperfusion and whether the neuroprotective effect of D-BHB, is related to autophagy. We analyzed the changes in the content of the autophagy proteins, LC3-II, used as index of autophagosome formation, and p62/SQSTM1, involved in autophagic degradation by western blot, in the cortex and hippocampus of hypoglycemic rats treated or not with BHB. Results show that autophagosome accumulation is promoted after 2 h of severe hypoglycemia in all studied cerebral regions as evidenced by the increased levels. 6 h after glucose reperfusion LC3-II content decreased to basal levels, suggesting less autophagosome formation or stimulated autophagosome degradation. However, after 24 h a second increase in LC3-II was observed in rats exposed to the hypoglycemic coma, while in those treated with D-BHB a significant decrease in LC3-II content was observed, suggesting that less autophagosomes are formed. No changes in p62/SQSTM1 were observed in the cortex, while in the hippocampus, a significant decrease in p62/SQSTM1 content was observed at 24 h in

animals treated with D-BHB, suggesting the stimulation of the autophagic flux. Altogether these results suggests that D-BHB prevent autophagosome formation and stimulates the autophagic flux during in vivo hypoglycemia.

Title: A novel neuroinvasive infection modality for francisella tularensis elicits neuroinflammation resulting in cellular damage

Authors: *M. G. RAMOS MUNIZ[1], R. CONTRERAS[2], A. TENA[2], C. T. SPENCER[2]
[2]Biol. Sci., [1]Univ. of Texas at El Paso, El Paso, TX

Abstract: *Francisella tularensis* (*Ft.*) is a gram-negative coccobacillus bacterium that causes the zoonotic disease tularemia in humans. *Ft.* causes the most severe, and fatal form of the disease through inhalation, however, *Ft.* is most commonly transmitted through direct contact with infected animal carcasses such as rodents and rabbits, consumption of contaminated food or water, and through arthropod bites, particularly ticks. Due to the extremely low infectious dose and high mortality rate, along with its potential use as a biological warfare agent, *Ft.* is classified by the CDC as a Tier 1 select agent. *Ft.* infection triggers an overactive inflammatory response, termed a cytokine storm, which often results in excessive tissue damage of vital organs causing multiple organ failure, therefore, leading to rapid death of the host before onset of adaptive immunity. In the periphery, macrophages, paradoxically the target cell for *Ft.*, provide innate immune defense against foreign material, including bacteria. Microglial cells, the resident macrophages of the brain and spinal cord, have been reported to rapidly respond to pathological changes in the central nervous system, serving a similar function as macrophages. Their rapid activation is an important factor in guarding the neural parenchyma against infectious diseases, inflammation, and neurodegeneration while maintaining and facilitating the return to tissue homeostasis. We made the novel observation that following peripheral infection the bacterium is trafficked to the brain. The purpose of this project is to identify the consequences of neuronal

infection after peripheral inoculation with *Ft.*. Since in the periphery, macrophages are the target cell for *Ft.*, it is likely that microglia cells may be the cell target in the brain. We hypothesize that after peripheral inoculation of *Ft.*, the bacteria then infiltrate the central nervous system using a Trojan horse-type mechanism allowing for infection of microglia cells, leading to overproduction of pro-inflammatory cytokines in the brain which then cause damage to surrounding neuronal cells ultimately leading to death. The proposed specific aims of this project are to 1) identify the cellular targets of *Ft.* in the central nervous system, 2) determine the resulting level of cytokine production from infected microglial cells, 3) identify the immune cell subsets in the brain that are activated after CNS infection, and 4) identify the mechanism being used by *Ft.* to infiltrate the central nervous system.

Title: Mammary tumor and mastectomy synergistically promote chronic neuroinflammation in a breast cancer survivor model

Authors: *K. EMMER[1], W. H. WALKER, II[1,2], N. ZHANG[2], A. C. DEVRIES[2]
[1]The Ohio State Univ., Columbus, OH; [2]West Virginia Univ., Morgantown, WV

Abstract: Even after treatment for breast cancer ends, many women experience mental sequelae including depression and anxiety that can last for years. Understanding the cause of these cognitive deficits is essential for developing targeted treatment plans and improving quality of life for breast cancer survivors. Microglial priming results in heightened responses to homeostatic disturbances thereby exacerbating neuroinflammation and neurodegeneration, and offers a potential mechanism for this cognitive dysfunction. This study examined whether mammary gland tumors prime microglia and augment the inflammatory profile and behavior of mice. To test this, we injected non-metastatic mammary tumor cells (67NR) orthotopically into BALB/c mice, allowed them to grow for 16 days, and then removed the tumors via mastectomy. Following 14 days of surgical recovery, we challenged the mice with lipopolysaccharide (LPS), then evaluated central and peripheral inflammation, anxiety, and depressive-like behavior. Here we show that after 16 days of tumor growth (the time of mastectomy surgery), there were no significant differences in inflammatory markers in the hippocampus or serum apart from

increased serum CXCL1 concentrations in tumor-bearing compared to non-tumor-bearing animals. Similarly, mastectomy surgery alone did not significantly affect major central or peripheral inflammatory markers. Interestingly, hippocampal mRNA expression of proinflammatory cytokines IL-1β and TNFα along with microglial scavenger receptor CD68 was increased following surgical recovery in mastectomy tumor removal animals relative to control animals. Nonetheless, after LPS administration there were no exaggerated immune responses or behavioral changes to substantiate microglial priming in the tumor removal group. In sum, these data demonstrate that tumor-bearing together with mastectomy surgery promotes neuroinflammation and microglial activation; however, immune challenge with LPS did not elucidate this inflammation as maladaptive for the host.

Title: Transcriptome of the mice hippocampus differently affected after subarachnoid hemorrhage (SAH)

Authors: *A. S. REGNIER-GOLANOV[1], L. PETERSON[3], E. I. BOVSHIK[2], E. V. GOLANOV[2], G. W. BRITZ[1]
[2]Neurosurg., [1]Houston Methodist Hosp., Houston, TX; [3]Ctr. for Outcome Res., Houston Methodist Res. Inst., Houston, TX

Abstract: SAH survivors present long-term neurological aberrations with signs of depression, anxiety and cognitive impairment. These disabilities are sufficiently significant that 44% of the SAH patients are unable to continue with their professional activities. SAH is often followed by general brain atrophy including the temporomesial area. The latter correlates with neurocognitive disorders. These observations are suggestive of hippocampal abnormalities following SAH. While hippocampal abnormalities have been demonstrated in acute period following the hemorrhage, the underlying molecular and cellular mechanisms of cognitive outcome after the initial ictus are still not completely understood. To identify leading processes in the hippocampus following SAH we used RNA next-generation sequencing to explore the changes in gene expression at the transcriptional level 4-days after SAH. SAH was induced in anesthetized male C56BL/6J mice (10 to 14-weeks old) by monofilament perforation of the circle of Willis. In sham-operated mice the filament was advanced to the perforation point and withdrawn without puncture. RNA of the whole hippocampus of SAH (n=4), sham (n=3) and naïve (n=3) group was extracted using Quiazol, and only RNA with RIN>9.0 were further sequenced. Reads alignment

(20-30.10^6/samples), fragments count and differential expression gene (DEG) analysis were done using Partek Genomic Suite 7.0. In total 20,067 genes were identified. Differential expression analysis showed 449 genes significantly differ between SAH and sham (-1.5<fold change>1.5; $p<0.05$) with 74% specific to SAH, and 142 genes were significantly changed between sham and naïve. About 6.9% of DEGs in SAH and sham overlapped suggesting that these genes relate to the surgery procedure. Gene ontology and pathway analysis (DAVID 6.8) showed that DEGs were prevalent in the categories of immune processes, angiogenesis, antigen processing and presentation, and extracellular matrix (false discovery rate [FDR]<10^{-4}). Gene set enrichment analysis with all genes sequenced (GSEA, FDR <0.15) revealed enrichment in complement, astroglial phenotype, interferon gamma and alpha, and depletion in oligodendrocytic phenotype. Prevalent transcriptome changes in the hippocampus in the subacute period (4 days) suggest that processes related to inflammatory and defense responses mostly localized to the extracellular domain are dominant in the hippocampus following the hemorrhage.

[1]Dept. of Anesthesiol. and Pain Med., Seoul, Korea, Republic of; [2]Dept. of Anesthesiol. and Pain Med., Yonsei Univ. Col. of Med., Seoul, Korea, Republic of

Abstract: Background Post-operative pain is common complication after surgery and closely associated with postoperative cognitive dysfunction. The previous studies suggested regulation of neuro-immune interactions is important during neuropathic pain and CX3C chemokine receptor 1 (CX3CR1) plays a key role in pain and inflammation. Therefore, in this study, we performed orthopedic surgery and confirmed CX3CR1 and inflammatory mediator levels in the spine and brain regions. **Materials and Methods** We used a model of tibial fracture with intramedullary pinning in ICR male mice. After surgery, we assessed pain behavioral test (von frey filaments), and cognitive/anxiety tests (passive avoidance test, open field test, novel

objective recognition test, elevated plus maze). At different time points, we confirmed the levels of pro-inflammatory cytokines such as interleukin (IL)-1β, IL-6 and Tumor necrosis factor alpha (TNF-α) in the lumbar spine, hippocampus, amygdala, and prefrontal cortex. The level of CX3CR1 was also measured in same regions after tibial fracture with pinning. **Results** In our data, mice showed mechanical allodynia at 1, 2, and 5 days after tibial fracture. Learning and memory were impaired after tibial fracture: in passive avoidance test, latency time to enter the dark compartment was significantly reduced at 5 days after tibial fracture, compared to the control. In novel objective recognition test, mice were showed reduced exploration time of new objects at 1, 2, and 5 days after tibial fracture, compared to the baseline, and in elevated plus maze, mice were exhibited lower learning index at 1, 2, and 5 days after tibial fracture, compared to the control. Anxiety-related behavior was increased after tibial fracture: in open field test, mice were showed reduced distance and time of central zone at 1, 2, and 5 days after tibial fracture, compared to the control and in elevated plus maze, time to enter closed arm was increased at 1 and 2 days in tibial fracture group, compared to the control group. By the enzyme-linked immunosorbent assay, IL-1β, IL-6 and TNF-α protein levels were upregulated at different time point after tibial fracture and *Cx3cr1* transcrips were upregulated at 2 days after tibial fracture. **Conclusions** We proved that tibial fracture surgery triggered proinflammatory cytokines and CX3CR1 expressoin in the lumbar spine and brain regions. Also, this surgery induced abnormal pain hypersensitivity and cognitive/emotional dysfunction. It is likely that inflammation and CX3CR1 is mainly involved in pathology of pain-mediated cognitive/emotional dysfunction after orthopedic surgery.

Title: Glycolysis drives leukocyte migration and subsequent neuropathology in an animal model of multiple sclerosis

Authors: *D. K. KAUSHIK[1], A. BHATTACHARYA[2], C. SILVA[2], V. WEE YONG[2]
[2]Clin. Neurosciences, [1]Univ. of Calgary, Calgary, AB, Canada

Abstract: The transmigration of leukocytes into the central nervous system (CNS) is a defining feature of multiple sclerosis (MS). Leukocytes penetrate into the CNS via several routes

including across the post-capillary venules where they accumulate initially in the perivascular space forming structures referred to as perivascular cuffs. The migration of leukocytes into the CNS across the blood brain barrier (BBB) likely utilizes significant energy resources that remain to be defined. Using the inflammatory mouse model of MS, experimental autoimmune encephalomyelitis (EAE), we found that leukocytes that remain within the perivascular space express the inducible glycolytic enzyme lactate dehydrogenase A (LDHA) that converts pyruvate to lactate. The lactate generated intracellularly is normally shuttled out via specialized transporters known as the monocarboxylate transporters (MCTs), and MCT-4 is known to efficiently accomplish this role in glycolytic cells. Accordingly, we found that leukocytes within inflammatory perivascular cuffs in cerebellum and spinal cords were strongly immuno-reactive for MCT-4 at peak clinical severity of EAE. The expression of MCT-4 on leukocyte membranes was regulated by extracellular matrix metalloproteinase inducer (EMMPRIN, CD147) as determined through co-expression studies, silencing, and by co-immunoprecipitation. Functional importance of glycolysis and MCT-4 in the infiltrating leukocytes was demonstrated by significant reduction of macrophage transmigration in culture following exposure to the selective LDHA inhibitor FX11, and to the MCT-4 inhibitor, the cinnamon derivative α-cyano 4-hydroxy-cinnamic acid (CHCA). Further, EAE mice treated with CHCA formed fewer cuffs in the spinal cords and exhibited significantly reduced clinical severity and histopathology as compared to the PBS-treated sham group. These results were mirrored by strong expression of MCT-4 and LDHA in inflammatory perivascular cuffs in brains from patients with MS. Our results suggest that glycolysis plays a crucial role in conferring the infiltrating leukocytes a pro-inflammatory phenotype and identify CHCA as a potential modulator of neuroinflammation in MS with therapeutic and dietary implications.

Title: Treatment with a CCR3 antagonist rescues neuroinflammation and cognitive dysfunction in acute and chronic LPS models

Authors: *S. REGE, H. HACKBART, E. CZIRR, S. P. BRAITHWAITE, S. S. MINAMI
Alkahest, Inc., San Carlos, CA

Abstract: Peripheral inflammation has been associated with cognitive dysfunction in both animal models and humans. Elevated levels of systemically circulating cytokines, a hallmark of inflammation, have been shown to correlate with lower cognitive performance. Further, the correlation between cognitive dysfunction and chronic peripheral inflammation in patients with type 2 diabetes or Alzheimer's disease has been well established. We, and others, have identified that eotaxin is a cytokine that is elevated peripherally in plasma in aging and disease and induces deficits in cognitive function.
Here we demonstrate that an antagonist of CCR3, the primary receptor of eotaxin, is efficacious in both acute and chronic models of LPS treatment in 2-month old C57BL/6 mice. A single dose of LPS (5mg/kg) was administered in the acute model, with cognitive dysfunction and neuroinflammation presenting one month later. These mice were treated with the CCR3 antagonist for 4 weeks following LPS injection and showed significantly reduced microglial activation in the hippocampus. Daily doses of LPS (0.5mg/kg) for 7 weeks were administered in the chronic model with treatment with the CCR3 antagonist for the last 4 weeks. In this chronic LPS model there was reduced neuroinflammation in the brain as well as reduced cognitive dysfunction after compound treatment. Our findings demonstrate that targeting the CCR3 receptor with an antagonist has therapeutic potential to alleviate CNS deficits associated with peripheral inflammation.

Title: Translational PET imaging of neuroinflammation in pre-clinical rodent models of neurogenerative diseases

Authors: *J. RYTKÖNEN[1], P. POUTIAINEN[2], D. MISZCZUK[1], A. J. NURMI[1], T. HUHTALA[1]
[1]Charles River Discovery, Kuopio, Finland; [2]Kuopio Univ. Hosp., Kuopio, Finland

Abstract: Pre-clinical nuclear imaging provides a translational approach to monitor progression of inflammation can be applied in several rodent models with neuroinflammation. Neuroinflammation is associated with several neurodegenerative diseases, including multiple

sclerosis, Parkinson's disease, Alzheimer's disease, Huntington's disease, and stroke. Mitochondrial translocator protein (TSPO) activation and changes in metabolic activity have been associated with neuroinflammation in central nervous system. Therefore TSPO ligands, glucose and acetate analogues, radiolabelled with positron emitting isotopes, can be applied to image the progression of neuroniflammation *in vivo*. TSPO expression in the brain is associated with activation of microglia, therefore TSPO is potential target to evaluate neuroinflammatory changes in a variety of CNS disorders. However, there is always a baseline expression present which prohibits the use of reference tissue models in dynamic PET imaging. To reach optimal readouts from the imaging and understand PET tracer kinetics metabolite corrected arterial input function has to be collected from the imaged animal. Optionally static PET imaging can be applied but static PET imaging data is more prone for variation due to technical aspects and data interpretation has to be made carefully.
Neuroinflammation was studied with TSPO PET and metabolic changes with FDG PET in several animal rodent models of neurodegenerative diseases. Furthermore, neuroinflammatory markers, including immunohistochemistry (IHC), were used as supportive readout. *In vivo* imaging TSPO PET imaging was used to effectively monitor neuroinflammation. Additionally, the metabolic alterations associated with neuroinflammation could be quantified with FDG PET imaging. IHC data provided supportive indications for the models.
As a summary, PET imaging gives multiple options to study neuroinflammation in pre-clinical for CNS disease animal models. It is a powerful research tool allowing comprehensive evaluation of disease progression and treatment interventions in vivo studies.

Title: Pathological hallmarks of a genetic and an induced Gaucher disease mouse model

Authors: *J. NEDDENS, E. SANTIAGO-MUGICA, S. FLUNKERT, V. NIEDERKOFLER, R. RABL, D. AMSCHL, M. POSCH, E. AUER, B. HUTTER-PAIER
Neuropharm., QPS Austria GmbH, Grambach, Austria

Abstract: Introduction: Gaucher disease is the most common lysosomal storage disease. The neuronal disease variant is characterized by aggregated protein accumulations in the brain and associated neurological manifestations. The disease is autosomal recessively inherited and

modeled by 4L/PS-NA mice that express low levels of prosaposin and saposins, as well as β-glucosidase (GCase) with a point mutation at V394L/V394L. Additionally, the disease can be modeled by treating mice with Conduritol-beta-Epoxide (CBE) a specific inhibitor of GCase activity.
To use these models for compound tests against the Gaucher disease a detailed characterization of these mice is needed. We thus analyzed 4L/PS-NA mice for their neurono- and non-neuronopathic features and treated wildtype mice for 15 days daily intraperitoneally with 100 mg/kg CBE.
Method: Both mouse models were analyzed for behavioral symptoms. Furthermore brain tissue of both models was analyzed for Gaucher disease relevant pathologies by histological methods. The 4L/PS-NA mouse model was further analyzed for visceral symptoms.
Results: Our results show that both mouse models present neuroinflammation by glial activation. Furthermore, 4L/PS-NA mice display a progressive muscle strength and motor coordination deficit, while CBE treated animals show no relevant motor deficits. Visceral organs like spleen, thymus, lung and liver of 4L/PS-NA mice are characterized by enlarged leukocytes and macrophages that are already visible at early age.
Conclusion/ Summary: In summary, 4L/PS-NA mice present with highly increased glial activation in the brain that is accompanied by strong motor deficits suggesting that 4L/PS-NA mice are a good model to study the chronic neuronopathic type 3 Gaucher disease in humans. Additionally, 4L/PS-NA mice present early alterations in visceral organs and thus further mimicking the non-neuronopathic phenotype of Gaucher disease. Treatment with CBE causes no motor deficits but strong neuroinflammation, suggesting that this induced model has in total a weaker phenotype compared to the 4L/PS-NA model.

Title: PEALut treatment: Role in preclinical and clinical delirium manifestations

Authors: *R. CRUPI, R. SIRACUSA[1], M. CORDARO[1], D. IMPELLIZZERI[1], A. PERITORE[1], R. DI PAOLA[1], S. CUZZOCREA[1,2]

Abstract: Delirium is a disturbance in attention, awareness and cognition. It is an aberrant response to stress that produces a syndrome of physiological and behavioral changes termed "sickness behaviour". Postoperative delirium (POD) is a common complication in elderly patients after hip fracture surgery and usually occurs within 5 days after surgery, especially during the first 24-48 h postoperatively. Neuroinflammation, is an important etiological factor associated with the development of POD. The lipopolysaccharide injection in mice has potency for performing mechanistic studies important to understanding how systemic inflammation and underlying neurodegeneration interact to induce delirium. Actually, there are no licensed treatments to manage delirium but it was recognized an interest in a role of the endocannabinoid system in neuropsychiatric disorders. N-Palmitoylethanolamine (PEA) acts as a lipid signaling molecule with antiinflammatory activity in preclinical models of acute and inflammatory pain and central nervous system injury and is efficacious for pain relief in man; Luteolin (Lut), a flavone of vegetable origin, is able to exert an antioxidant action. In our preclinical part of the study we focused on the hippocampus because it is sensitive to the insults of inflammation and is presumable involved in acute cognitive disorders that are relevant in patients with systemic infections.
Preclinical data demonstrate that co-ultraPEALut ameliorate cognitive function, emotional alteration and locomotor activity; moreover reduce the release of excitotoxic mediators, inflammation and apoptosis; stimulate anti-oxidant response and limite the loss of neurotrophins. In the second part of the research we studied the effects of co-ultraPEALut (Glialia®) administration in elderly hip fractured patient with an interventional, spontaneous, randomized, single-blind, monocentric study. The results obtained from the clinical study demonstrate that administration of co-ultraPEALut in elderly surgical patients with hip fracture is able to prevent the onset of POD and to attenuate the intensity of the symptoms and duration.

Title: Systemic interleukin-1 receptor antagonist reduces hippocampal injury and improves cognitive deficits in juvenile rats following neonatal exposure to lipopolysaccharide

Authors: *L.-W. FAN[1], L.-T. TIEN[3], J. W. LEE[1], S. LU[1], C. P. TALATI[1], N. B. OJEDA[1], X. DAI[2], M. A. TUCCI[2], A. J. BHATT[1], R. D. SAVICH[1], Y. PANG[1]
[1]Pediatrics/Newborn Med., [2]Dept. of Anesthesiol., Univ. of Mississippi Med. Ctr., Jackson, MS; [3]Sch. of Med., Fu Jen Catholic Univ., New Taipei City, Taiwan

Abstract: Perinatal infection/inflammation is associated with cognitive deficits later in life. Our previous studies have shown that systemic administration of interleukin-1 receptor antagonist (IL-1ra) can protect against lipopolysaccharide (LPS)-induced brain inflammation and neurobehavioral dysfunction in neonatal rats. The objective of this current study is to further determine whether systemic IL-1ra-mediated neuroprotection protects against systemic LPS-induced chronic brain inflammation, hippocampal injury, and cognitive dysfunction in juvenile rats. Intraperitoneal (i.p.) injections of LPS (2 mg/kg) or saline were performed in postnatal day 5 (P5) Sprague-Dawley rat pups of both sexes (equal numbers of males and females), and IL-1ra (100 mg/kg) or vehicle was administered (i.p.) at 5 min and 24 h after LPS injection. One animal from each sex from each litter was included in each experimental group. Four groups of 8 pups per group were include in the present study: Saline+Vehicle, Saline+IL-1ra, LPS+Vehicle, and LPS+IL-1ra. The control rats were injected with saline followed by vehicle (saline+0.1% BSA) in rats (Saline+Vehicle). Neurobehavioral tests were carried out from P20 to P21, and brain injury was examined at P21 in a double-blind manner. To ensure scientific rigor the molecular assays and histological assessment were evaluated by triplicate, and the sample size were calculated to reach a statistical power of at least 0.85 for a $P<0.05$. Control animals were from the same strain and same vendor. Data were analyzed by two-way ANOVA followed by the Student-Newman-Keuls test. Our results showed that neonatal systemic LPS exposure resulted in cognitive deficits, as demonstrated by poor performance in Y-maze, Novel object recognition, and Passive avoidance tests. LPS treatment also led to chronic neuroinflammation and hippocampal neuronal injury, as indicated by loss of NeuN (a marker for neurons) immunoreactivity in the hippocampus of the P21 rat brain. Systemic IL-1ra treatment significantly attenuated LPS-induced cognitive deficits and hippocampal injury, which was associated with a significant reduction in the numbers of Iba1+ cells (microglia) and IL-1β concentration in the hippocampus of the P21 rat brain. No significant difference was observed between the male and female rats within the same treatment group. These results suggest that systemic IL-1ra provides protection against neonatal inflammation exposure-induced long-term cognitive impairments in juvenile rats, which may be associated with the blockade of LPS-induced pro-inflammatory cytokine IL-1β.

Abstract: Multiple sclerosis (MS) is a severe and chronic autoimmune disorder of the central nervous system (CNS), that represents the main cause of neurological disability in young adults from the Western world. Although central aspects of the MS pathophysiology have been already characterized, the cause of the disease is still unknown. Pregabalin (Lyrica®) is used in the treatment of central neuropathic pain in MS. Chemically, pregabalin is an analogue of the inhibitory neurotransmitter γ-aminobutyric acid (GABA), that instead of binding to GABA receptors, binds to the α2δ subunit of voltage-gated calcium channels (VGCCs). Consequently, pregabalin decreases the calcium influx and reduces the presynaptic neurotransmitter release. Due to its direct effect on neuronal calcium levels, we here hypothesized that pregabalin exerts a neuroprotective effect in in an animal model of MS (experimental autoimmune encephalomyelitis, EAE). We observed that both prophylactic and therapeutic pregabalin treatments during the EAE course significantly ameliorated the clinical symptoms and reduced immune cell infiltration into the CNS. However, ex vivo analyses of immune cells from EAE mice revealed no functional differences in terms of cytokine production and proliferation. Additionally, pregabalin did not have any effect on the activation and integrity of a primary endothelial cell layer modelling the blood brain barrier (BBB). Importantly, pregabalin had a direct impact on neurons as its application to hippocampal brain slices was able to reduce long-term potentiation. Furthermore, it decreased the inflammation-induced elevation of neuronal intracellular calcium levels in EAE lesions. We conclude that pregabalin exerts a neuroprotective effect in mice. Future studies need to show whether pregabalin might be used as direct neuroprotective MS therapeutic at early disease stages.

Title: Sex-specific effects of central immune activation on memory consolidation

Authors: *C. K. POSILLICO[1], R. E. GARCIA-HERNANDEZ[2], N. C. TRONSON[1]
[1]Psychology, [2]Univ. of Michigan, Ann Arbor, MI

Abstract: The neuroimmune system is required for normal neural processes including learning and memory. Acute activation of the immune system has been shown to alter memory capabilities and memory-related signaling mechanisms, and persistent immune dysregulation may be both a cause and consequence of disorders of memory such as Alzheimer's disease and post-traumatic stress disorder (PTSD) which both correlate with altered immune function. Importantly, women are more likely than men to develop both Alzheimer's disease and PTSD, and underlying sex differences in immune function may be a contributing factor. We have previously demonstrated sex differences in hippocampal cytokine signaling following a peripheral immune challenge. Given these data, in this project we examined whether neuroimmune activation has differential effects on memory processes in both males and females. We used intracerebroventricular (ICV) administration of an immunostimulant and determined subsequent memory deficits and changes in memory-related signaling in male and female C57Bl/6 mice. Polyinosinic:polycytadylic acid (poly I:C) is a viral mimic consisting of synthetic, double-stranded RNA that stimulates toll-like receptor (TLR) 3 expressed on astrocytes, microglia, and neurons in the brain. We demonstrated that poly I:C 4 hours prior to contextual fear conditioning caused deficits in context fear memory at test three days later. Importantly, this disruption of memory was observed in female mice, but not in males, indicating that neuroimmune activation has sex-specific effects on memory. To further examine the effects of poly I:C on cellular activation during memory consolidation, we determined changes in hippocampal and amygdalar Arc and cFos activity after fear conditioning as a function of poly I:C treatment. To examine the effects of poly I:C on social memory, we used a social recognition memory task in which females interacted with a novel, same-sex conspecific. ICV infusions of

poly I:C immediately after this training session prevented females from recognizing a familiar mouse 24 hours later. Taken together, these data demonstrate that poly I:C administration differentially impacts memory mechanisms in females and in males, where females are more sensitive to the memory-impairing effects of neuroimmune activation. Uncovering the underlying mechanisms of immune disruption of memory processes in both sexes may help to explain the sex bias in memory-related disease prevalence and provide better directions for treatment development for both sexes.

Title: Sepsis-induced antinociception is associated with neuroinflammation and glial activation

Authors: *L. ANGENENDT DA COSTA, R. A. CAZUZA, N. N. SANTOS-JUNIOR, C. R. CATALÃO, J. M. G. TESSARI, M. J. A. ROCHA, C. R. A. LEITE-PANISSI
Univ. of São Paulo, Ribeirao Preto, Brazil

Abstract: Sepsis, a dysregulated host response to infection, can affect the central nervous system and lead to autonomic, cognitive and behavioral alterations. However, sensory evaluation during sepsis and the central mechanisms underlying this process are poorly investigated. Using male Wistar rats, we induced sepsis by cecal ligation and puncture (CLP) and after 24 hours the animals were submitted to different nociceptive tests (tail flick, acetone and von Frey). Periaqueductal gray (PAG) and rostral ventromedial medulla (RVM) were punched out for cytokines and western blot analyses. A last group was used for glial morphology investigation by immunofluorescence. Septic animals showed reduced thermal and mechanical allodynia as well as increased thermal analgesia. This reduction in nociception could not be attributed to lethargy or a decrease in animal mobility, since we did not observe any alteration in the crossing and rearing number. Quantification of inflammatory mediators in PAG and RVM indicated increased IL-1β, IL-6 and TNF-α levels, which was associated with microglial and astrocyte activation in both nuclei. A reduction in BCL-2, an anti-apoptotic protein, indicates that cells in these brain areas are more vulnerable to death. We conclude that experimental sepsis reduces nociception

and it is associated with glial activation and neuroinflammation in brain regions associated with nociceptive modulation.

Title: Systemic lipopolysaccharide induced spinal inflammation associated allodynia and hyperalgesia were reduced by minocycline in neonatal rats

Authors: *L.-T. TIEN[1], Y.-J. LEE[1], L.-W. FAN[2]
[1]Fu Jen Catholic Univ., Taipei, Taiwan; [2]Pediatrics/Newborn Med., Univ. of Mississippi Med. Ctr., Jackson, MS

Abstract: In this study, we investigated the effects of minocycline, a putative suppressor of microglial activation, on reducing systemic LPS-induced spinal cord inflammation, allodynia and hyperalgesia in neonatal rats. Intraperitoneal (i.p.) injection of LPS (2 mg/kg) or sterile saline was performed in P5 rat pups both sexes (equal numbers of males and females) and minocycline (45 mg/kg) or vehicle (PBS) was administered (i.p.) 5 min after LPS injection. The von Frey filament and tail-flick tests were performed to determine mechanical allodynia (decreased reaction thresholds to painful stimuli) and thermal hyperalgesia (decreased reaction latency to painful stimuli), respectively, and spinal cord inflammation was examined on P6. The results were analyzed by two-way ANOVA followed by the Student-Newman-Keuls test and results with a $p < 0.05$ were considered statistically significant. Systemic LPS administration resulted in reduction of tactile threshold in the von Frey filament tests and pain response latency in the tail flick test of P6 rats. LPS administration also significantly increased the levels of microglia and astrocyte activation, microglia-related pro-inflammatory cytokines including interleukin-1β (IL-1β), cyclooxygenase-2 (COX-2), and prostaglandin E2 (PGE2) in the P6 spinal cord. Treatment

with minocycline significantly attenuated the LPS-induced allodynia, hyperalgesia, and the increase of spinal cord microglia, astrocytes, and pro-inflammatory cytokine levels in P6 rats. No significant difference was observed between the male and female rats within the same treatment group. These results suggest that minocycline provides protection against neonatal systemic LPS exposure-induced enhanced pain sensitivity (allodynia and hyperalgesia), and that the protective effects may be associated with its ability to attenuate LPS-induced microglia activation, and microglia-related pro-inflammatory cytokines and pain mediators.

Abstract: Survivors of childhood acute lymphoblastic leukemia (ALL) are at an increased risk for long term cognitive deficits. These deficits include decreased working memory, a 6-8 drop in IQ, and attentional impairment. Commonly used chemotherapeutic agents used in treatment of ALL are known to have widespread adverse effects on cognition. Children are especially vulnerable because the prefrontal cortex (PFC), which is largely responsible for higher cognitive function, is still developing. While human studies link childhood ALL and chemotherapy to later cognitive dysfunction, the underlying mechanisms mediating these deficits remain unknown. Thus, it is necessary to develop an animal model that can be used to investigate these mechanisms and gain a better understanding of the resulting cognitive deficits.
Male and female adolescent mice were injected with L1210 leukemic cells at P19. Three tumor cell concentrations were tested to determine a dose that balances cancer severity with survival. Starting at P21, mice received four rounds of a standard ALL chemotherapeutic regimen consisting of methotrexate, vincristine, and leucovorin every four days. Survivors were then tested in adulthood for cognitive deficits using social recognition, novel object, and operant behavioral tests. Using RT-qPCR brain tissue was analyzed for changes in genes related to

immune function and synaptic plasticity, while intestinal tissue was analyzed for markers of inflammation and expression of tight junction molecules.
Male survivors showed deficits in the novel object and social recognition tests, suggesting alterations in working memory. In males, gene expression data indicate an acute neuroinflammatory response in the PFC that normalizes by adulthood. Additionally females demonstrated long lasting changes in plasticity in the PFC. In the small intestine, male survivors had long-term elevated expression of inflammatory factors. In summary, we have created an animal model to examine the relationships between childhood cancer, chemotherapy, and long lasting cognitive deficits. Future studies will be directed at further identifying underlying mechanisms responsible for cognitive deficits and testing of potential therapeutic approaches to protect brain function during chemotherapy.

Title: Regulation of pro-inflammatory cytokines using brassicaceae and asteraceae plants (kale, arugula, dandelion) in diet-induced obese pre-diabetic c57bl/6 mice

Authors: *A. A. OYETUNDE, T. SIMON, D. HICKS, B. TENG, L. BANNER

Abstract: Diabetes is a chronic disease that has an impact on many different organ systems in the body and can lead to serious long-term complications that are a major source of morbidity and mortality among diabetics. In addition to damage in organs such as the heart and kidney, prolonged elevation in blood sugar levels also adversely affects the central nervous system. Diet-induced obesity is an increasingly common occurrence that predisposes individuals to type-2 diabetes and contributes to complications including those of the nervous system and the immune system. Diabetes causes both structural and functional alterations often described as diabetic encephalopathy and changes in hippocampal plasticity and learning and memory have been demonstrated. Obesity increases the risk for dementia and Alzheimer's disease. These cognitive effects begin early as they are seen in children and adolescents with obesity and type 2 diabetes and include both structural and functional alterations. Obesity and type 2 diabetes leads to a

chronic state of inflammation that is thought to be important in initiating the chain of events that leads to dementia. Neuroinflammation is a complex response involving the activation of glia and the release of inflammatory mediators, such as cytokines. Cytokines involved in the inflammatory response are elevated in brains of animals fed a high fat diet (HFD) and a variety of anti-inflammatory/anti-oxidant treatments can reduce this expression and alleviate the cognitive changes. To investigate the role of dietary supplements, a high-fat diet model of prediabetes was utilized. Obese and control mice given a dietary supplement of kale, arugula, or dandelion greens for 22 weeks exhibit attenuated cognitive decline. To begin to determine the molecular mechanisms underlying this improvement, western blots were performed on hippocampal extracts. Animals on a HFD display increased levels of the astrocyte marker GFAP. Preliminary results show these elevated GFAP levels are reduced in animals on a HFD supplemented with the greens. Additional analysis will be performed with a variety of cellular markers.

Title: Effect of myrtillocactus geometrizans (garambullo) on the stress-oxidative and memory in the hippocampus of rats fed a hypercaloric diet

Authors: *C. SANDOVAL SALAZAR[1], D. RAMÍREZ-RAYA[2], S. JIMENEZ-GARCÍA[2], X. RAMÍREZ-GOMEZ[2], V. BELTRÁN-CAMPOS[2]

Abstract: The hypercaloric diets can develop overweight or obesity, as well as, oxidative stress. Some studies reported that chronic intake of a hypercaloric diet produce changes in the oxidative stress and it is accompanied by accelerate lipid peroxidation and can affect learning and memory. However, Fruits such as garambullo has a high content of phenolic compounds that show an antioxidant capability, and these could have a positive effect on the stress-oxidative produced by some diets. The aim of this study was to explore the effect phenolic compounds of garambullo (150mg of gallic acid in aqueous solution) on the lipid peroxidation and spatial memory in the hippocampus of rats fed a hypercaloric diet. A total of 40 healthy male rats were divided equally into four groups. 1) Standard diet + water; 2) Standard diet + garambullo; 3) Hypercaloric diet + water; 4) Hypercaloric diet + garambullo. All the groups were fed during six months, however in

the fifth month the second and fourth, groups received garambullo during a week. Subsequently, the water Morris maze test was performed. Lipid peroxidation levels were analyzed by measuring thiobarbituric acid reactive substances. Food intake was recordly daily. The SD-fed rat intake was approximately 50% higher than the hypercaloric groups and the garambullo have no effect to decrease lipid peroxidation and improve learning and memory. However our results demonstrated that the hypercaloric diet increases the lipid peroxidation and impairment the spatial memory. Therefore it is necessary to probe more doses of garambullo to determinate what is the optimal dose and understand how the treatment with phenolic compounds like Myrtillocactus geometrizans can improve the negative effects of hypercaloric diets, overweight or obesity.

Abstract: Neurocysticercosis is one of the most prevalent parasitic diseases in the world. It is caused because *Taenia solium* oncospheres invade human nervous tissue and become cysticerci, causing neurocysticercosis (NCC). Due to parasite is housed in the CNS, it is difficult to study the mechanisms that are modulated in man, hence the need to use animal models that help to understand the parasite-host interaction. The presence of the larvae in the CNS generates an

inflammatory response on the part of the host, which could generate neuronal damage. Neurofilament in the form of spheroids identified in axonal inflammations was used to observe neuronal damage. This study attempted to characterize the cystic damage, by means of the presence of spheroids around a viable cyst located in parenchymal, ventricular and meningeal tissue. For that, we used a rat model for neurocysticercosis, in which 70 rats of 12 days were infected with *T. solium* oncospheres. After 1, 2, 3, 4, 6, 10 and 12 months of infection, the rats were sacrificed and sections were ordered and analyzed beginning with the visible scolex as a point of reference an area of little variability in the pathologic lesion. We found spheroids extended beyond the inflammatory reaction and gliosis into otherwise appearing normal brain tissue. In addition, there is a greater presence of spheroids in cysts located in the parenchyma compared to those located in the ventricles and meninges. Axonal damage resulting in spheroids suggest this may be an important part of the mechanisms that could explain clinical symptoms of NCC.

Title: Resting state MEG signature of HIV and cannabis in young adults: Preliminary data

Authors: *S. L. NICHOLS[1], A. ROBB SWAN[2], A. ANGELES QUINTO[2], C. FENNEMA-NOTESTINE[3], R. LEE[2], M. HUANG[2]

Abstract: *Background:* In the current era of antiretroviral treatment (ART), sensitive paradigms are critical for detecting the central nervous system (CNS) effects of HIV prior to structural damage or impacts on daily functioning, and for disentangling effects of HIV from comorbidities such as substance use. Magnetoencephalography (MEG) measures brain functional activation across frequency bands with fine-grained spatial and temporal resolution. This preliminary study compared brain activity of youth with HIV (YWH) and uninfected controls and examined effects of cannabis use frequency using resting state MEG. *Methods:* Eleven male youth age 18-24 with behaviorally acquired HIV (YWH) on ART and 13 age- and education-matched uninfected male controls completed cognitive tests; questionnaires to quantify cannabis use frequency; resting state MEG; and structural MRI. MEG data were processed using Fast-VESTAL source imaging program. Activation for control subjects was subtracted from that of YWH across frequency

bands and cortical areas. Activation differences were compared using t-tests with $p < 0.01$ and an additional cluster analysis with size > 500 voxels. *Results:* YWH had significantly lower verbal learning and memory. Analysis of rsMEG showed low-frequency hyperactivity for YWH in frontal pole, anterior dlPFC; alpha band hyperactivity in bilateral anterior dlPFC and right FP, anterior insula, and temporal lobe (Fig.). Beta and gamma bands showed hypoactivity for YWH in bilateral hippocampi and OFC, but hyperactivity in vmPFC. Within YWH, weekly or daily cannabis use was associated with decreased rsMEG delta-theta activity in nucleus accumbens. *Conclusions:* YWH show altered rsMEG activity relative to controls, consistent with dysfunction in episodic and working memory and emotion systems, along with decreased motivation system activity for more frequent cannabis use. Findings support further study of MEG to determine whether it can serve as a sensitive marker of early HIV CNS impact prior to functional impairment.

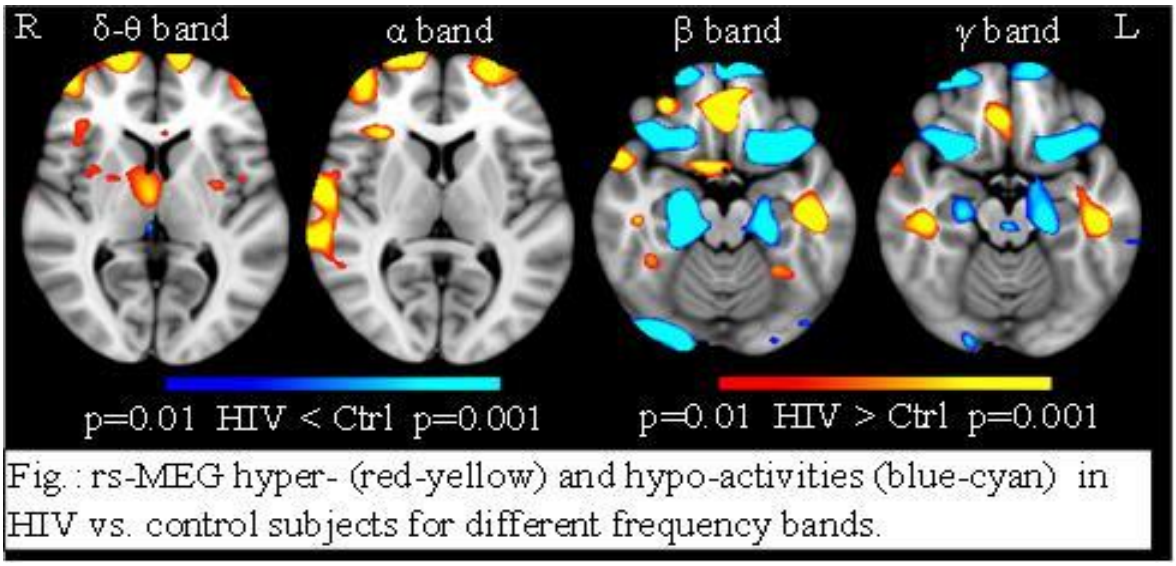

Fig. : rs-MEG hyper- (red-yellow) and hypo-activities (blue-cyan) in HIV vs. control subjects for different frequency bands.

Abstract: As of 2013, there are 3.2 million children under the age of 15 living with HIV, globally, with an estimated one new diagnosis every 2 minutes. The devastating neurological impact of HIV on children includes loss of brain growth, motor abnormalities and cognitive dysfunction. Despite early antiretroviral treatment (ART) intervention to suppress viral load, neurological consequences of perinatal HIV-1 infection persist. Utilizing the pediatric simian immunodeficiency virus (SIV) infection model, we tested the hypothesis that early life SIV infection induces inflammation leading to neuronal loss in the hippocampus. A total of 22 infant rhesus macaques (*Macaca mulatta*) were divided into three groups: Group 1 received intravenous inoculation of SIVmac251 on postnatal day 3 (n=3) with a survival time of 6-10 weeks; Group 2 was orally challenged with SIVmac251 at week 9 of age (n=15) with a survival period of 12 weeks post-infection; and Group 3 served as uninfected controls with a survival time of 15-22 weeks. Systematic sections through the hippocampus regions CA1 to CA3 were Nissl stained and Iba1, a putative marker for microglia cells. Cell populations was determined using design-based stereology, while cell body and ramifications were quantified by the nucleator probe. We have previously reported that intravenously SIV-infected neonatal infant macaques (Group 1) displayed a 42% neuronal reduction throughout the hippocampal CA fields. The orally infected infant macaques in Group 2 displayed a 75% neuronal reduction in the CA1 compared to controls and 54% fewer neurons than Group 1 infants. The CA2 region showed a similar pattern with a 67% reduction between Group 2 and controls and a 40% difference between Group 1 and 2. Here we show elevated microglia cell size and reduced ramifications in the SIV infected subjects indicating elevated neuroinflammatory reaction. The loss of hippocampal neurons, possibly related to neuroinflammation, may contribute to the rapid neurocognitive decline associated with pediatric HIV infection. These data underscore the need for early diagnosis and treatment including therapeutics targeting the CNS.

Title: Change in telomere length and cognitive function over 12 months in the context of HIV, major depressive disorder and childhood trauma

Authors: *J. S. WOMERSLEY, G. SPIES, S. M. J. HEMMINGS, S. SEEDAT
Univ. of Stellenbosch, Cape Town, South Africa

Abstract: Background: HIV-associated neurocognitive disorders continue to prevail in countries affected by HIV/AIDS despite improved access to antiretroviral therapies. Previous research from our group suggested that the interaction of childhood trauma (CT) and depression may increase the risk of neurocognitive decline, and that telomere length (TL) attrition, a marker of biological aging, may mediate this relationship. We expanded our investigation of whether change in TL is predictive of declining neurocognitive function as this has implications for timely intervention. **Methods:** HIV-positive (n=61) and negative (n=49) women underwent a battery of neuropsychological tests to measure seven domains of cognitive function: motor skill, verbal fluency, attention and working memory, processing speed, learning, recall, and executive function, from which a global cognitive score was calculated. Participants completed the Childhood Trauma Questionnaire and the Centre for Epidemiological Studies Depression Scale. Quantitative polymerase chain reaction using primers specific to telomeric repeats and the reference gene human β-globin was performed on DNA extracted from peripheral blood mononuclear cells. Neurocognitive tests and TL measurements were performed at baseline and at 12 months and change scores were calculated. Multiple linear regression models using the R statistical language were used to assess the relationships between HIV, CT, depression, change in TL and change in cognitive scores. **Results:** Depressive symptoms alone, and in interaction with CT, were associated with increased TL shortening across participants ($p = 0.037$ and $p=0.017$ respectively). HIV seropositivity was strongly associated with worsening global cognitive scores over one year ($p=2 \times 10^{-4}$). Finally, the interaction of CT experience, HIV status and change in TL was associated with a decline in cognitive performance ($p=0.025$). **Conclusions:** Our longitudinal data support the deleterious impact of HIV on cognitive function and suggest that TL attrition is predictive of worse cognitive performance in the context of CT and HIV.

Title: Divergent roles of osteopontin in the HIV-infected brain through its interaction with cell adhesion molecules & the extracellular matrix

Authors: *F. J. MAHMUD[1], A. M. BROWN[2], T. BOUCHER[1]
[1]Neurol., Johns Hopkins Hosp., Baltimore, MD; [2]Neurol., Johns Hopkins Univ. Sch. of Med., Baltimore, MD

Abstract: Human immunodeficiency virus type I (HIV-1) enters the brain early, but the virus is unable to infect neurons. Instead, HIV causes direct and indirect damage by shedding viral proteins that are toxic to neurons. Neurodegeneration and memory impairment in HIV infection remain a significant clinical problem. Our aim is to identify the molecular mechanisms by which HIV directly damages neurons. The HIV-1 envelope (Env_{IIIB}) gp120 protein is known to be toxic to neurons via disruption of Ca^{2+} signaling and the induction of apoptosis.
Moreover, HIV infection of glial cells and injury to neurons leads to widespread neuroinflammation and the production of cytokines like osteopontin (OPN). OPN is a secreted phosphoglycoprotein that signals via cell adhesion molecules (CAMs)- CD44, ß1 and/or ß3 integrin receptors, which are expressed by neurons and play a role in synaptic remodeling. Based on our prior work using SHSY5Y cells and primary rat cortical neurons exposed to increasing doses of OPN, we found neuroprotective and neurite growth promoting phenotypes, suggesting that OPN can rescue Env_{IIIB} mediated neuronal injury. Hippocampal neurons (HipN) play crucial roles in memory consolidation. Therefore, in this study we used an *in vitro* model of primary rat HipN free of glia to test the hypothesis that OPN blocks neuronal injury, and to explore molecular changes in synaptic structure.
HipN were treated with Env_{IIIB} and rat OPN and subsequently stained for cytoskeletal and synaptic proteins. A significant reduction in neurofilament intensity suggested that axonal development was impaired. In addition, synaptic contacts were greatly decreased as measured by the overlap of pre- and post-synaptic proteins. We also noted an absence of dendritic spines. Activation of CREB and total CAMKII were also significantly decreased. These phenotypes were reversed by RNAi silencing of specific CAMs. These results suggest that Env_{IIIB} and OPN mediate impairment of synaptic plasticity in HipN. Interestingly, OPN can also localize to the extracellular matrix (ECM), the latter plays an important role in proper synaptic function. Recent studies show that perineuronal nets (PNN), which are specialized ECM in neurons are important

for neuronal maturation. Interestingly, we noted a degradation of PNN on neurons treated with Env_{IIIB} that could be reversed by treatment with OPN. This protection was mediated by ß1 integrins.
In conclusion, our findings indicate a differential role for OPN in HIV-mediated interactions with neurons that depend on its localization at the synapse or ECM. OPN offers protection in the ECM, but is detrimental to axons and synapses in the presence of HIV Env_{IIIB}.

Title: A combination of free and exosomal cathepsin B released from HIV-infected macrophages trigger multiple mechanisms of neuronal dysfunction

Authors: *Y. M. CANTRES-ROSARIO[1], S. C. ORTIZ-RODRIGUEZ[1], A. SANTOS[2], L. M. MELENDEZ[1]
[1]Microbiology and Med. Zoology, Univ. of Puerto Rico, Med. Sci. Campus, San Juan, Puerto Rico; [2]Biol. Dept., Univ. of Puerto Rico, Bayamon Campus, San Juan, Puerto Rico

Abstract: Mild forms of HIV-associated neurocognitive disorders (HAND) prevail in 20-50% of the patients. HIV-infected macrophages infiltrate the brain contributing to the development of HAND. HIV-infected macrophages secrete the lysosomal protease cathepsin B (CATB) with serum amyloid p component (SAPC), as a neurotoxic protein complex. We hypothesized that CATB is released in exosomes and internalized by neurons, triggering dysfunction. We exposed neurons to histidine-tagged CATB and localized the histidine tag in neurons by flow cytometry and western blot. His-CATB was internalized by neurons (p=0.007), triggered activation of caspase 3, and decreased synaptophysin. However, pre-treating the media with anti-CATB and SAPC antibodies reduced CATB internalization by 20% and 40%, respectively, and rescued the neurons from apoptosis and synapse loss. Neurons exposed to His-CATB in HIV-infected macrophage-conditioned media (MCM) had significantly higher active caspase-3 than in uninfected media (p=0.0236). In addition, while HIV-infected MCM significantly increases amyloid beta peptides in neurons (p=0.0002), the same effect is not observed when the MCM is supplemented with His-CATB, suggesting that CATB might be degrading it. We then examined

the presence of CATB and SAPC in exosomes isolated from uninfected and HIV-infected MCM, by western blot and ELISA. Exosomes contained 34% of the total secreted CATB, as well as SAPC, CD63 and Hsp70. Exosomes from HIV-infected macrophages contained even more cathepsin B ($p=0.017$), increased the activity of caspase-3/7 in neurons (1.5 fold), and triggered neuronal death ($p=0.042$; TUNEL assay), compared to exosomes from uninfected macrophages. Pre-treating MCM with anti-CATB antibodies followed by exosome pull down, surprisingly shows that anti-CATB antibodies bind to a target in the exosome fraction. It is known that the pre-treatment of HIV-infected MCM with anti-CATB antibodies significantly decreases neuronal apoptosis, however they do not protect neurons against apoptosis triggered by exosomes derived from HIV-infected MDM. Our results suggest a novel neuronal damage process in which CATB: (1) is internalized by neurons triggering apoptosis and decreasing synapses, (2) alters the amyloid beta load, and (3) is partially secreted in exosomes inducing HIV-neurotoxicity. Since CATB and amyloid beta are elevated in the brain of HAND and Alzheimer's patients compared to normal cognition, we conclude that CATB/SAPC complex plays an important role in neurodegeneration. Further studies will allow us to determine if CATB/SAPC inhibitors could be considered as therapy candidates against HAND.

Abstract: The HIV-1 virus is known to affect microglial immune responses which likely play a paramount role in the development of chronic neuroinflammatory conditions and neuronal damage found in HIV-1 associated neurocognitive disorders (HAND). HIV-1 Tat protein is a neurotoxin known to provoke proinflammatory responses in glial cells which precipitate neuronal injury. Drugs targeting the degradative enzymes of endogenous cannabinoids have shown promise in reducing pain and inflammation with minimal side effects in rodent models. Our lab has demonstrated that Tat can produce neurotoxic effects through microglial proinflammatory action. Considering that markers of neuroinflammation can predict the extent of neuronal injury in HAND patients, we evaluated the neurotoxic effect of Tat-exposed microglia following blockade of fatty acid amid hydrolyze (FAAH), a catabolic enzyme responsible for degradation of endocannabinoid ligands, including anandamide. We have shown before that FAAH inhibition blunts the neurotoxic effects of Tat through cannabinoid receptor mechanisms. In the present study, cultured murine microglia were incubated with Tat and/or FAAH inhibitor (PF3845). After 24 hours, microglial conditioned media was collected for neuron exposure experiments. Neuron cultures (DIV 7-11) were then exposed to diluted (1:6) microglial conditioned media, and neurotoxicity was assessed using Ca^{2+} imaging. Interestingly, PF3845's strong attenuation of microglial responses to Tat was via $CB_{1/2}$ receptor independent mechanisms. Past reports have described neuroprotective effects of non-classical cannabinoid receptors GPR55/18 on glial cells therefore to determine the role of these receptors in our cell culture model, we pretreated microglia with either antagonist, O-1918, or agonist, Abn-CBD. Preliminary data suggest that attenuation of Tat-induced increases in neuronal $[Ca^{2+}]_i$ is mediated by GPR55/18 receptors. These findings not only further elucidate the neuroprotective mechanisms of endogenous cannabinoids but also highlight the potential therapeutic benefit of the non-classic cannabinoid receptors in treating HAND and other diseases with neuroinflammatory pathologies.

Title: HIV Tat impairs endocannabinoid signaling

Authors: *M. M. WU[1], S. A. THAYER[2]
[1]Grad. Program in Neurosci., [2]Dept. of Pharmacol., Univ. of Minnesota, Minneapolis, MN

Abstract: Despite the success of antiretroviral therapy in suppressing viral load, nearly half of the >37 million people infected with HIV experience neurocognitive impairments, collectively known as HIV-associated neurocognitive disorders (HAND). HIV-infected microglia release neurotoxic agents that induce excitotoxic synaptic injury, resulting in altered neuronal function. HIV Tat (transactivator of transcription) protein is one such neurotoxin that is thought to play a major role in the neuropathogenesis of HAND. Emerging evidence indicates a neuroprotective role of the endocannabinoid (eCB) system, which attenuates excitotoxicity. Indeed, activation of the eCB system prevents HIV-induced neurotoxicity. Whether this neuroprotective system is altered in the presence of HIV is unknown. Here, we examined modulation of the eCB system by HIV Tat in cultured hippocampal neurons. Using whole-cell patch-clamp electrophysiology, we measured adaptive changes in retrograde eCB signaling following exposure to Tat. We found that Tat exposure (50ng/mL, 24h) significantly reduced the magnitude of depolarization-induced (control: 53 ± 5%, Tat: 11 ± 6%; n=6 per group) and metabotropic suppression of excitatory postsynaptic currents (EPSCs) (control: 55 ± 4%, Tat (24h): 27 ± 3%; n=6-8 per group). These effects were not due to a loss of CB_1 receptor function, as indicated by no change in the concentration-response relationship for Win55,212-2 (a cannabinoid receptor agonist) inhibition of EPSCs in Tat-treated cultures. Thus, the mechanism of Tat-mediated reduction in eCB signaling may be postsynaptic. We hypothesize that exposure to Tat impairs synthesis of the eCB 2-arachidonoyl glycerol (2-AG). Consistent with this hypothesis, a recent study indicates that Tat sequesters phosphatidylinositol (4,5)-bisphosphate (PIP_2), a substrate required for 2-AG synthesis. The eCB system has garnered interest as a target for the treatment of neurodegenerative disorders due to its neuroprotective properties. Our data suggest that HIV Tat impairs eCB signaling. Alterations in eCB synthesis may contribute to loss of this neuroprotection, and may exacerbate the synaptodendritic injury seen in HAND. Thus, drugs that protect or enhance eCB signaling may attenuate the symptoms of HAND.

Title: Role of microglia specific p38 signaling in neuroAIDS

Authors: *D. BHULLAR[1], R. MAUNG[1], D. OJEDA-JUÁREZ[1,2], N. YUAN[1], R. SHAH[1], M. KAUL[1,2,3]

Abstract: Human immunodeficiency virus-1 (HIV-1) causes severe and progressive neurological impairment in humans called HIV-associated neurocognitive disorders (HAND). The HIV-1 envelope glycoprotein gp120 is an extracellular protein that is shed from infected cells and so has the potential to diffuse and interact with distant uninfected brain cells. Transgenic mice expressing HIV-1 coat glycoprotein gp120 in brain glial cells (HIVgp120tg) display neuropathological features similar to HIV dementia patients. During inflammation, p38α MAPK is known to regulate the biosynthesis of pro-inflammatory cytokines in endotoxin-stimulated monocytes. Inflammatory or stressful stimuli can also activate p38 MAPK in CNS resident cells, such as microglia, astrocytes and neurons. p38 MAPK plays crucial roles in various pathological processes associated with HIV infection, ranging from macrophage activation to neurotoxicity, impairment of neurogenesis and lymphocyte apoptosis. Thus, p38 MAPK may be an important mediator in the development of HAND and immunodeficiency during HIV-1 infection.
To determine the role of microglial p38 signaling in HIV mediated neuronal injury in vivo, we generated p38 floxed CX3CR1 Cre HIVgp120-expressing mice that have a p38 knockout specifically in microglia and macrophages. Immunofluorescence studies on brain sections of these mice were used to compare HIVgp120tg brains with and without microglia-specific p38 knockout. Non-tg brains served as controls. Brain sections were stained for neuronal MAP2 (Microtubule-associated protein 2) and astrocytic glial fibrillary acidic protein (GFAP), and nuclear DNA. Astrocytic GFAP levels remained unaffected by microglial p38 deficiency. However, we observed a significant loss of MAP2 levels compared to non-tg controls only in HIVgp120tg animals with p38-expressing microglia but not in HIVgp120-expressing brains with microglia-specific p38 knockout, indicating p38 deficiency in microglia protected neurons from HIVgp120 toxicity. Thus, our model confirmed a critical role of microglial p38 MAPK in the neurotoxicity caused by the envelope protein of HIV-1.

Title: Antiretroviral drugs increase excitability of pyramidal neurons in the medial prefrontal cortex of rats by enhancing Ca^{2+} channel function but reducing K^+ channel activity

Authors: L. CHEN[1], L. AL-HARTHI[1], *X.-T. HU[2]
[1]Microbial Pathogens and Immunity, [2]Immunology/Microbiology, Rush Univ. Med. Ctr., Chicago, IL

Abstract: Combined antiretroviral therapy (cART) suppresses HIV replication, improves immune function, and prolongs the life of HIV^+ patients. But despite cART, the prevalence of HIV-associated neurocognitive disorders (HAND) occurs in ~50% of HIV^+ patients; and that is associated with HIV-induced excitotoxicity/neurotoxicity. Recent studies reveal that many anti-retroviral medicines (ARVs) also induce neurotoxicity, including but are not limited to reduced dendritic processes, neuronal shrinkage, and mitochondrial dysfunction. Despite the well-known importance of cART in suppressing HIV, very little known is the impact of ARVs' side effects on neuronal activity in the brain regions that are susceptible and vulnerable to HIV; and whether that contribute to HAND. Lamivudine (a.k.a. 3TC) is a nucleoside reverse transcriptase inhibitor (NRTI), and one of the 3 ARVs (in combination with abacavir, ABC; and dolutegravir, DTG) that form Triumeq, a 1st-line cART regimen approved and recommended by FDA to treat HIV/AIDS. Here we assessed acute effects of 3TC and Triumeq *in vitro* on the excitability of pyramidal neurons in the medial prefrontal cortex (mPFC, a key regulator of neurocognition) using whole-cell patch-clamp recording in rat brain slices. We found that at the concentrations of 0.25-40μg/ml [1-175μM; that were comparable to those detected in the cerebral spinal fluid (CSF) of HIV^+ patients receiving Triumeq or 3TC], 3TC in bath induced a significant increase in firing of mPFC neurons (evoked by moderate stimuli that mimicked physiological excitatory inputs) in a concentration-dependent manner. This increase was associated with a significantly-enhanced Ca^{2+} influx through voltage-gated Ca^{2+} channels (by 0.25μg/ml, or 1.1μM), and a reduced activity of voltage-gated K^+ (K_v) channels and inwardly-rectifying K^+ (K_{ir}) channels. Both changes in Ca^{2+}/K^+ channel activity could depolarize the membrane potential; and therefore facilitate firing. Higher concentrations of 3TC (40μg/ml, or 175μM) began to diminish firing and Ca^{2+} channel activity in some mPFC neurons. Triumeq also significantly increased firing at a

concentration similar to that seen in CSF of HIV^+ patients (1:1, or 1x); and that was further increased by higher concentrations of the cART (10x and 100x). Collectively, these findings indicate that the NRTI 3TC increases mPFC neuronal excitability by abnormally enhancing Ca^{2+} channel activity and reducing K_v/K_{ir} channel activity; and that Triumeq also increases mPFC neuron firing, likely *via* similar mechanisms. Importantly, these novel findings suggest that chronic cART *in vivo* may exacerbate HIV-induced neuro/excitotoxicity in the mPFC.

Abstract: Over half of human immunodeficiency virus (HIV)-infected individuals suffer from HIV-associated neurocognitive disorders (HAND), yet the molecular mechanisms leading to neuronal dysfunction and death are poorly understood. Feline immunodeficiency virus (FIV) naturally infects cats and shares its structure, cell tropism, and pathology with HIV, including wide-ranging neurological deficits. We employ FIV as a model to elucidate the molecular pathways underlying HIV-induced neuronal dysfunction. Among HIV-induced neuron-damaging products, the HIV envelope glycoprotein gp120 triggers elevation of intracellular Ca^{2+} in neurons, resulting in apoptosis. By quantifying neuronal activity using intracellular Ca^{2+} imaging in mouse cultured hippocampal cells, we confirmed that the FIV envelope glycoprotein gp95 also elevates intracellular Ca^{2+} activity. In addition, we revealed that gp95 interacted with the chemokine receptor, CXCR4, and facilitated the release of intracellular Ca^{2+} by the activation of the endoplasmic reticulum (ER)-associated Ca^{2+} channels, inositol triphosphate receptors (IP3Rs). This suggests that gp120 and gp95 share a core pathological process in neurons.

Significantly, gp95's stimulation of glutamate NMDA receptors activates cGMP-regulated kinase II (cGKII) through the activation of the neuronal nitric oxide synthase (nNOS)-cyclic GMP (cGMP) pathway, which increases Ca^{2+} release from the ER and promotes surface elevation of AMPA receptors, an indication of synaptic excitotoxicity. Moreover, we cultured feline hippocampal neurons and confirmed that gp95-induced Ca^{2+} excitotoxicity was mediated by CXCR4 and cGKII. These results thus provide a novel cGKII-dependent molecular understanding of synaptic dysfunction in HAND.

Title: Wnt signaling regulates astrocyte activation during the pathogenesis of HIV-1 gp120-induced pain

Authors: *X. LIU, S. YUAN, J. ZHENG, C. BAE, S.-J. TANG
Neurosci. and Cellbiology, Univ. of Texas Med. Br. at Galveston, Galveston, TX

Abstract: HIV-related pathological pain is a debilitating complication that is associated with manifestations of neuroinflammation, including glial reaction and pro-inflammatory cytokine expression. However, the molecular mechanism regulating HIV-induced neuroinflammation remains obscure. Our studies indicate that the Wnt5a-ROR2 signaling pathway is crucial. We observed that HIV-envelope protein gp120 induced pain hypersensitivity via an MMP2-dependent IL-1β activation that is controlled by the Wnt5a in neurons and its co-receptor ROR2 in astrocytes. Although gp120 activated both microglia and astrocytes in the spinal cord, Wnt5a conditional knockout blocked the activation of astrocyte but not microglia. The Wnt5a-ROR2 signaling induced by gp120 appears to stimulate a MMP-2-dependent non-canonical pathway to control IL-1β activation. Our findings reveal a novel intercellular signaling mediated by neuronal Wnt5a and astrocytic ROR2 to regulate gp120-induced neuroinflammation and pain.

Title: IFNAR1 knockout affects neuronal MAP-2 expression in the presence and absence of neurotoxic HIV-1 envelope protein gp120

Authors: *H. SINGH[1], R. MAUNG[1], D. OJEDA-JUÁREZ[1,2], R. SHAH[1], M. KAUL[1,3]

Abstract: Infection with HIV-1 often causes brain injury, which presumably underlies HIV-associated neurocognitive disorders (HAND)/neuroAIDS. The pathogenesis of HAND is not completely understood but the most affected brain regions include frontal cortex, hippocampus, substantia nigra, putamen, basal ganglia and cerebellum. Our laboratory uses a transgenic mouse model of HIV-associated brain injury expressing the viral gp120 envelope protein in the central nervous system. These HIVgp120tg mice display key neuropathological features of human HIV brains, including loss of microtubule-associated protein (MAP)-2 positive neuronal dendrites and elevated expression of astrocytic glial fibrillary acidic protein (GFAP) compared to non-tg controls. The innate immune system responds to HIV-1 infection with the production of interferons (IFNs). Type I IFNs (IFNα and IFNβ) exert their biological functions through interaction with the type I interferon (α/β) receptors (IFNAR1 and −2). We recently showed that IFNβ prevented in vitro and in vivo neuronal injury induced by HIVgp120. Neuroprotection by IFNβ was dependent on IFNAR1. Our present study investigated the role of IFNAR1 in HIV induced brain injury by cross-breeding IFNAR1 knockout (IFNAR1KO) with HIVgp120tg mice. The brains of one-year-old IFNAR1-deficient and wild-type gp120tg mice and non-tg controls were analyzed using quantitative fluorescence microscopy. Our data shows that knocking down IFNAR1 partially ameliorates gp120-induced loss of neuronal MAP-2 in hippocampus but not cerebral cortex. Moreover, the lack of IFNAR1 itself in the absence of viral gp120 appears to diminish MAP-2 in cortex and hippocampus, suggestive of compromised neuronal dendrites. In contrast, astrocytic GFAP expression seems unaffected by the absence of IFNAR1. Altogether, our findings indicate a potentially general role for IFNAR1 in neuronal homeostasis, and a limited contribution to hippocampal injury in the presence of HIV gp120.

Title: Co-receptor tropism in HIV-1 gp120 induced synaptic dysfunction

Authors: L. K. SMITH[1], H. K. MCKEE[2], *T. B. KUHN[3]
[1]Dept Chem. & Biochem., [2]Biol. and Wildlife, Univ. of Alaska Fairbanks, Fairbanks, AK; [3]Dept Chem. & Biochem., Univ. Alaska Fairbanks, Fairbanks, AK

Abstract: While the implementation of combination antiretroviral therapy (cART) for the treatment of HIV-1 infection has achieved a dramatic decline in deaths attributable to HIV/AIDS, it remains that upwards of 50% of individuals with long-term HIV infection are affected by the onset of progressive neurological and cognitive complications referred to under the umbrella term HIV-associated neurocognitive disorders (HAND). The viral envelope protein gp120 has been identified as a potent neurotoxin affecting neurodegeneration via mechanisms involving interactions with chemokine co-receptors CCR5 and CXCR4. Early experiments have identified a role for gp120 signaling through CCR5 and CXCR4 in the activation of a pathway common to oligomeric, soluble amyloid β linking oxidative stress to the formation of cofilin-actin bundles (rods), which have been linked to synaptic dysfunction via sequestration of cofilin and the disruption of vesicular transport resulting from occlusion of neurites containing rods. Coalescence of lipid rafts paralleled by the activation of NADPH oxidase and a requirement for the cellular prion protein (PrP^C) are central to this pathway. Here we further characterize the role of co-receptor tropism in gp120 induced lipid raft coalescence, reactive oxygen species (ROS) generation, and formation of rods in SH-SY5Y human neuroblastoma cells expressing knocked-down (siRNA) or overexpressed (lipofectamine-based plasmid transfection) levels of co-receptors CCR5 and CXCR4. Transgenic SH-SY5Y cells were exposed to $gp120_{CM}$ (R5-tropic),

$gp120_{IIIB}$ (X4-tropic), and $gp120_{MN}$ (dual-tropic) in a dose and time dependent manner. Cellular lipid raft coalescence, ROS generation, and the formation of rods were quantified for each gp120 isoform and the contribution of each receptor to gp120-mediated signaling assessed. Here, we demonstrate that $gp120_{IIIB}$ signaling through CXCR4 induces more potent raft coalescence, ROS and rod formation ($p<0.05$, one-way ANOVA w/ post-hoc Dunnett's analysis, GraphPad Prism software). These results imply a potential link between HIV co-receptor tropism and the onset of early synaptic impairment mediated by the generation of cofilin-actin rods.

Title: Lipocalin-2 deficiency limits alterations of neurotransmission-related gene networks in a transgenic model of HIV-induced brain injury

Authors: *D. OJEDA-JUÁREZ[1,2], R. SHAH[1], A. B. SANCHEZ[3], R. MAUNG[1], M. KAUL[4]
[1]Univ. of California, Riverside, Riverside, CA; [2]Sanford Burnham Prebys Med. Discovery Inst., San Diego, CA; [3]UCSD, San Diego, CA; [4]Biomed. Sci., SOM, Univ. of California Riverside, Riverside, CA

Abstract: Infection with human immunodeficiency virus-1 (HIV)-1 remains a serious threat to global health. Up to 50% of HIV patients develop some form of neurological and neurocognitive complications categorized as HIV-associated neurocognitive disorders (HAND). The pathological mechanisms leading to HAND remain incompletely understood. Therefore, we studied the role of the acute phase protein lipocalin-2 (LCN2) in the context of HIV-induced brain injury. LCN2 has been shown to play a role in behaviour and cognitive function, neuronal excitability, microglial activation and as an autocrine mediator of reactive astrocytosis. In our study, we cross-bred transgenic (tg) mice expressing HIV envelope protein gp120 in their central nervous system (HIVgp120tg) with a genetic knockout of LCN2 (LCN2ko). The resulting four genotypes, wild-type, HIVgp120tg, LCN2ko, and LCN2ko x HIVgp120tg, were compared by analyzing neuropathology and changes in the expression of genes related to neurotransmission. Brains of HIVgp120tg mice display features observed in neuroHIV patients; including astrocytosis, microgliosis, and decreased synaptic connections and dendrites. Our results reveal

that expression of gp120 is associated with significant alterations in glutamatergic, GABAergic, dopaminergic and serotonergic neurotransmission systems. However, some of the changes associated with the expression of HIVgp120 are ameliorated or reversed in the absence of LCN2. Ingenuity Pathway Analysis (IPA) predicts significant alterations in biological and functional gene networks consistent with neuronal injury in HIVgp120tg and functional alterations in LCN2ko animals. However, the differential gene expression pattern in LCN2ko x gp120 animals indicates similar to normal activity or deactivation of biological pathways increased in HIVgp120tg and LCN2ko animals, suggesting that LCN2-deficiency ameliorates neuronal damage in HIVgp120tg brains. Histopathological analysis using immunofluorescence microscopy shows partial protection of neuronal dendrites in LCN2ko x gp120 animals when compared to HIVgp120tg and LCN2ko animals. Altogether, our findings suggest that LCN2 contributes to the pathological mechanisms underlying HIV-induced brain injury and thus may be a therapeutic target.

Inst., La Jolla, CA; [3]Dept. of Psychiatry, Univ. of California San Diego, San Diego, CA; [4]Animal Models Core, The Scripps Res. Inst., La Jolla, CA

Abstract: Methamphetamine (METH) use is common among individuals infected with human immunodeficiency virus type-1 (HIV-1) and appears to aggravate HIV-associated neurocognitive disorders (HAND). However, the pathological mechanisms underlying the combined effects of

HIV-1 and METH on the brain remain incompletely understood. Transgenic mice expressing a soluble viral envelope protein gp120 of HIV-1 in the brain (gp120tg) develop neuropathological features similar to those observed in brains of HIV patients, including decreased synaptic and dendritic density, as well as astrocytosis and increased numbers of activated microglia. For this study we treated gp120tg mice with an escalating METH binge regimen for 25 days and analyzed the animals after 7 months at about 12 months of age. We found that prior METH treatment aggravated behavioral impairment and induced a significant reduction of neuronal dendrites and presynaptic terminals in both gp120tg and WT brains. Moreover, METH-exposed gp120tg animals displayed reduced post-tetanic potentiation, while both gp120 expression and METH treatment diminished long-term potentiation. To understand the mechanistic basis of these alterations, we analyzed the expression of components of the dopaminergic, serotonergic, GABAergic and glutaminergic neurotransmitter systems at RNA level using quantitative RT-PCR arrays. Distinct areas of the brains were analyzed separately and in combination in female and male samples. The analysis revealed that METH treatment and HIV gp120 affected all neurotransmission systems, although with significant differences between cerebral cortex, hippocampus and striatum, and between females and males. Overall, METH and viral gp120 appeared to affect expression of neurotransmission related genes the most in hippocampus, and more in cerebral cortex than striatum. Sexual dimorphism was most pronounced for the dopaminergic and serotonergic systems in all brain structures. In summary, METH treatment and viral gp120 expression compromise learning and memory function and induce neuropathology in both sexes. However, our study shows significant sexual dimorphism and differences between distinct brain regions at the RNA level in the long-term effects of METH exposure and HIV gp120 expression.

Title: Effects of 7,8-dihydroxyflavone on glial metabolic response in the hippocampus of the HIV-1 transgenic mice

Authors: *D. PATEL
Neurol., Univ. of Maryland, Baltimore, MD

Abstract: Background: HIV-infected individuals are at a risk of developing neurological deficit. The long-term effects of HIV infection, in particular those originating in the CNS, such

as HIV associated depression, have gained attention. Animal models for HIV infection have helped to understand the pathology of the disease and developing treatment strategies. However, HIV associated depression remains poorly understood. BDNF and its receptor,TrkB, signaling represent potential therapeutic targets for major depression. The purpose of this study is to examine whether TrkB agonist 7,8-DHF shows antidepressant effects in Tg-26 mouse model. **Methods:** In this study, we examined the effects of TrkB agonist 7,8-dihydroxyflavone (7,8-DHF) (5 mg/kg) treatment for 30 days in Tg26 mice . Brains were isolated and immunohistochemical analysis was performed. **Results:** In the present study we examined the glial activity by determining GFAP and CD11b protein levels in the hippocampus of Tg26 mice before and after 7,8-DHF treatment to clarify changes in gliosis. The increased GFAP and CD11b expressions compared to control WT mice revealed the increase of glial activity and decreased after 7,8-DHF treatment, in the same condition we measured mitochondrial biogenesis and function by determining PGC-1α (mitochondrial biogenesis marker), Mfn2 (a mitochondrial fusion marker) and citrate synthase and SIRT3 (mitochondrial functional markers). Interestingly we found mitochondrial biogenesis and function are downregulated in the hippocampus of Tg26 mice compared to control group and after 7,8-DHF treatment mitochondrial biogenesis and function recovered. Furthermore, 7,8-DHF treatment also increase anti-inflammatory activities. **Conclusions:** These findings demonstrate that long lasting increased GFAP and CD11b expression in TG 26 mice indicate increased glial activity due to defect in mitochondria and 7,8-DHF treatment decreases gliosis by recovering mitochondrial homeostasis which may be involved in the impairment of the hippocampal-dependent learning of TG26 mice that plays a pivotal role in HIV associated depression and learning process.

Title: Identifying a role for E2F1 in synaptodendritic damage in mouse models of HIV

Authors: *C. MEURICE[1], T. J. CIRINO[3], B.-H. KIM[5], J. P. MCLAUGHLIN[4], D. VOLSKY[6], K. L. JORDAN-SCIUTTO[2]
[2]Dept Pathology, [1]Univ. of Pennsylvania, Philadelphia, PA; [3]Pharmacodynamics, [4]Univ. of Florida, Gainesville, FL; [5]Icahn Sch. of Med., Mt Sinai, New York City, NY; [6]Icahn Sch. of Med., Mt. Sinai, New York City, NY

Abstract: E2F1 is a transcription factor important for the transition from G1 to S phase of the cell cycle that has the potential to contribute to the development in HIV-associated neurocognitive disorders (HAND). In the CNS of HIV-infected patients with encephalitis E2F1 exhibits altered expression, and in rodent models loss of normal E2F1 function impairs synaptic health, learning and memory. To study the relationship between E2F1 and HIV-related neuropathogenesis in mice, we used two different HIV-related mouse models that exhibit neurocognitive impairment: brain-specific GFAP-driven TAT-inducible transgenic (GT-tg), in which brain-selective Tat expression is induced by activation of a doxycycline (Dox) promotor, and mouse-tropic HIV infection (EcoHIV) which utilizes a chimeric HIV that expresses ectopic murine leukemia viral envelope instead of HIV's normal envelope protein, gp120. Adult male GT-tg mice received saline or doxycycline (100mg/kg/day, i.p) for seven days to induce TAT expression or adult male wildtype mice were inoculated with EcoHIV (i.p). GT-Tg mice were euthanized 1 day after treatment and EcoHIV mice were euthanized 4-week post inoculation. Brain tissue was collected for quantification of E2F1, cleaved alpha-spectrin, pre- and post-synaptic proteins by western blot and immunofluorescence to identify potential mechanisms of synaptodendritic damage. In both models, E2F1 expression was increased which correlated with increased cleaved alpha-spectrin in GT-Tg mice and reduced PSD-95 expression in EcoHIV-infected mice. These results support our hypothesis that E2F1 plays a role in either the development or persistence of neurocognitive deficits in HIV-infected patients. Further research is required to identify a mechanistic relationship between increased E2F1 activity/expression and reduced synapse function.

Title: Epitranscriptomics: Correlation of N^6-methyladenosine RNA methylation and pathway dysregulation in the hippocampus of HIV transgenic rats

Authors: *V. R. CANONIGO[1], F. YU[3], B. ZORMAN[4], P. SUMAZIN[4], P. P. SANNA[2]
[1]The Scripps Res. Inst., San Diego, CA; [2]Departments of Immunol. and Neurosci., The Scripps Res. Inst., La Jolla, CA; [3]European Bioinformatics Inst. (EMBL-EBI), Hinxton, United Kingdom; [4]Dept. of Pediatrics, Baylor Col. of Med., Houston, TX

Abstract: The prevalence of severe HIV-associated dementia (HAD) has decreased since the introduction of combination antiretroviral therapy (cART), milder and chronic forms of neurocognitive impairment (NCI) remain high and the pathogenic mechanisms behind them are unclear. Internal RNA modifications have been known for decades, however their roles in mRNA regulation have only recently started to be elucidated. Here to provide new insight into the molecular events leading to neurocognitive impairments (NCI) in HIV, we analyzed the most abundant mRNA modification, N6-methyladenosine (m^6A) in transcripts from the hippocampus of HIV transgenic (Tg) rats. The pattern of m^6A methylation in HIV viral transcripts largely correspond to the ones observed in cell lines and T cells. Host transcripts were found to be differentially m^6A methylated in HIV Tg rats. The functional roles of the differentially m^6A methylated pathways in HIV Tg rats is consistent with a key role of RNA methylation in the regulation of the brain transcriptome in chronic HIV disease. In particular, host transcripts show significant differential m^6A methylation of genes involved in several pathways related to neural function, suggestive of synaptodendritic injury and neurodegeneration, inflammation and immune response, as well as RNA processing and metabolism, such as splicing. Changes in m^6A methylation of neuronal and inflammation-related transcripts were usually positively correlated with differential expression, while differential m^6A methylation of pathways involved in RNA processing were more likely to be negatively correlated with transcript changes. Thus, sets of differentially m^6A methylated, ontologically-related transcripts appear to be involved in coordinated transcriptional responses in the context of neuroHIV.
The results of the study indicate that specific mRNAs are differentially affected by RNA methylation. Differentially m^6A methylated transcripts are involved in the emergence of cognitive impairment in patients with HIV. Altogether, our results support that m^6A methylation represents an additional layer of regulation of HIV and host gene expression *in vivo* that contributes significantly to the transcriptional effects of chronic HIV.

Title: Immunomodulation of the type I interferon response protects against mortality in a murine model of neonatal HSV-1 encephalitis

Authors: *D. GIRALDO, D. R. WILCOX, R. LONGNECKER
Microbiology and Immunol., Northwestern Univ., Chicago, IL

Abstract: Newborn infection with herpes simplex virus (HSV) is a serious, life-threatening condition with an incidence of 1 in 3,200 deliveries in the U.S. Unlike adult infections, which are commonly asymptomatic, over 50% of neonatal HSV infections result in disseminated disease and encephalitis. Multiple studies suggest this stark contrast between the outcomes of newborn and adult infections is likely due to age-dependent differences in the host response to HSV infection in the CNS. However, the nature of these age-dependent differences remains largely understudied. Methods and Results: wild-type (WT) and IFN α/β receptor knock-out (IFNAR KO) 7-day-old (P7), and adult mice were intracranially inoculated with HSV-1. WT adult mice were highly resistant to infection but became susceptible in the absence of IFNAR. Newborn infections demonstrated IFNAR signaling prolongs survival in WT mice but fails to prevent mortality. Differences in susceptibility correlated with lower basal levels of IFNAR and protein kinase R (PKR) in the brain of P7 mice, which increased during the first weeks after birth to adult levels. Based on these findings, we hypothesized that increased susceptibility to HSV-1 infection of the CNS in the newborn was associated with decreased IFN signaling. Based on previous studies, we used intraperitoneal (i.p.) inoculation to model disseminated disease and hematogenous spread to the CNS, the normal route of infection in the newborn. WT and IFNAR KO P7 mice were i.p. inoculated with HSV. Functional IFNAR significantly delayed mortality suggesting it contributes to survival in response to i.p. HSV-1 infection. Because increased susceptibility to HSV-1 infection was associated with lower levels of IFNAR in the newborn brain, we hypothesized that priming the IFN response would provide protection against HSV infection. Daily doses of recombinant murine IFN-β or vehicle (PBS) were administered i.p. starting from the day before infection to newborn mice. Newborn mice were then inoculated i.p. with HSV-1 at P7. IFN-β treatment resulted in complete protection from HSV infection, and significantly higher levels of IFNAR and STAT1 compared to PBS treatment in naïve mice. We further analyzed the effect of IFN treatment on astrocyte and microglial innate responses using magnetic bead isolation. Conclusions: Our results show that increased susceptibility to HSV-1 infection in the newborn is associated with differential IFN signaling in the newborn brain. Administration of IFN-β peripherally resulted in complete protection of newborn mice from HSV-1 infection, which correlated with upregulation of IFN components in the newborn brain in response to the treatment.

Title: Induced human pluripotent stem cell immature astrocytes for neural repair after white matter stroke

Authors: *S. GALLEGOS[1], I. L. LLORENTE[2], W. LOWRY[2], S. CARMICHAEL[2]
[1]UCLA, Lake Balboa, CA; [2]UCLA, Los Angeles, CA

Abstract: Stroke is the leading cause of adult disability. Despite the progression of modern medicine stroke continues to afflict 800,000 individuals per year in the U.S. alone and ranks No. 5 among all causes of death. Globally, stroke is the second leading cause of death. As the population of people over the age of 45 increases, the prevalence of stroke is also expected to increase. White matter stroke accounts for approximately 30% of all stroke subtypes, yet they remain understudied due to the difficulty in reproducing these models in animals. Unlike cortical grey matter strokes, white matter strokes destroy axonal connection, astrocytes and glial cells; ultimately disrupting the connectivity of the brain. Damage to this area often results in irreversible permanent physical and mental disabilities. The brain has a very limited functional recovery in this stroke subtype. Stem/progenitor transplantation after stroke has shown promise in promoting recovery of function in other stroke subtypes. However, recent studies have failed to design a treatment model that allows for stem cells repair of brain structure or brain circuitry in white matter stroke. We have developed a model in the mouse that mimics the moderate to advance stages of white matter stroke and vascular dementia. We have designed a novel iPS-derived astrocytic therapy that is better suited to repair the damages after WMS, human iPS glial enriched progenitors (hiPSC-GEPs). hIPSC-GEPs were transplanted into the brain in the subacute period (7 days after stroke) after white matter stroke and induced endogenous oligodendrocyte differentiation and re-myelination. The hiPSC-GEPs enhanced motor recovery in comparison to other iPS-differentiated cell types. Here we test the efficacy of 5 additional hiPS-GEP lines in white matter stroke to identify the most efficacious line and to allow determination of mechanism of action, by comparing the differentiation and molecular expression profile among the 6 hiPS-GEP lines.

Title: Paracrine signals from reactive astrocytes that control microglial proliferation after brain injury

Authors: J. J. MCINNIS[1], *J. L. SPEES[2]
[1]Univ. of Vermont, Burlington, VT; [2]Med., Univ. of Vermont, Colchester, VT

Abstract: After brain injury, reactive astrocytes and microglial cells proliferate, undergo characteristic changes in morphology, and engage in autocrine, juxtacrine, and paracrine signaling. Defining the signaling network that controls cellular function(s) within jeopardized tissue after stroke has potential to provide new treatments for stroke patients. However, specific signals released by reactive astrocytes that regulate microglia (and vice versa) remain poorly understood. Using a distal Middle Cerebral Artery Occlusion (dMCAO) model of stroke, we previously demonstrated that Endothelin receptor type B (ETB_R) signaling regulates reactive astrocyte proliferation in the peri-infarct area. To further address the role(s) of ETB_R during reactive astrogliosis, we performed microarray and ELISA assays to determine effects of altered ETB_R signaling on the paracrine activity of reactive astrocytes. Through a series of complementary approaches, here we show that ETB_R signaling controls angiopoietin-2 mRNA expression and protein secretion by reactive astrocytes that impacts microglial cell proliferation.

Title: Human directly reprogrammed neural precursor cell transplants promote motor recovery in a mouse model of stroke irrespective of xenograft survival

Authors: *I. VONDERWALDE[1], A. AZIMI[2], G. ROLVINK[2], J.-E. AHLFORS[3], M. S. SHOICHET[1], C. M. MORSHEAD[2]
[1]Inst. of Biomaterials and Biomed. Engin., [2]Dept. of Surgery, Univ. of Toronto, Toronto, ON, Canada; [3]New World Labs., Laval, QC, Canada

Abstract: Stroke is one of the leading causes of acquired long-term disability worldwide. Cell transplantation is a promising therapeutic intervention; however, the identification of an optimal cell type remains a limitation to clinical translation. Here, we explored the efficacy of a novel population of clinically relevant directly reprogrammed human neural precursor cells (drNPCs) to treat the stroke-injured brain. Human drNPCs are generated from somatic cells through rapid reprogramming towards the neural lineage without the use of a viral vector or gene integration. The resulting drNPCs do not express pluripotency markers and have the ability to differentiate and give rise to cells within the neural lineage. We used a clinically relevant ET-1 model of stroke within the sensorimotor cortex of SCID/Beige mice which resulted in sustained motor deficits allowing us to determine the efficacy of drNPC transplants to promote functional recovery. We demonstrated that transplanting drNPCs 4 days after stroke leads to improved motor function within a month following transplant regardless of transplant vehicle (artificial cerebrospinal fluid or a hyaluronan methylcellulose hydrogel) and recipient sex (male or female). Importantly, when we analyzed xenograft survival, drNPCs were observed in 100% of mice at early timepoints post-transplantation (4 days) but only in ~70% of mice at 1 month following transplantation (28 days). Tissue analysis using immunostaining revealed that drNPCs that survive within the transplanted tissue primarily remain undifferentiated or give rise to astrocytes and immature neurons *in vivo*. Most interestingly, although transplanting human drNPCs was correlated with recovery, xenograft survival at 1 month was not correlated with improved functional outcomes. There was also no significant correlation between functional recovery and lesion volume or the extent of gliosis at 32 days post-stroke. These results suggest that drNPCs are a therapeutically relevant source of cells for clinical application and may be acting through a secretory mechanism to promote recovery.

Inst. of Physiological Sci., Okazaki, Japan

Abstract: Ischemic stroke is a main cause of chronic disability. However, there is currently no effective treatment to promote recovery from stroke-induced neurological symptoms. After stroke, newly-generated immature neurons called neuroblasts which occasionally form chain-like aggregates migrate from the neurogenic niche, ventricular-subventricular zone, toward the injured areas, where they differentiate into mature neurons. Interventions that increase the number of neuroblasts distributed at and around the lesion facilitate neurological repair in rodent models for ischemic stroke, suggesting that promoting neuroblast migration in the post-stroke brain could improve efficient neuronal regeneration. To move toward the lesion, neuroblasts form chain-like aggregates and we previously reported that they frequently migrate along blood vessels, which are thought to increase their migration efficiency. However, the molecular mechanisms regulating these migration processes are largely unknown. Here we studied the role of β1 integrin, a transmembrane receptor for extracellular matrix proteins, in these migrating neuroblasts. Using a transgenic mouse line in which β1 integrin is specifically deleted in neuroblasts after tamoxifen injection, we found that chain formation and blood vessel-guided migration of the neuroblasts were dependent on β1 integrin signaling. In vitro experiments revealed that β1 integrin was involved in adhesion of the neuroblasts to laminin coated dish surface, which is critical for their efficient somal translocation during migration. Moreover, injection of laminin-containing self-assembling gel into the post-stroke mouse brain promoted chain-formation and migration of neuroblasts toward the injured area. These data suggest that laminin signaling via β1 integrin supports vasculature-guided neuronal migration to efficiently supply neuroblasts to injured areas. This study also highlights the importance of vasculature-like scaffolds for cell migration in tissue regeneration.

Title: Health economical research for cell therapy against stroke

Authors: *H. SHICHINOHE[1], M. KAWABORI[2], K. HOUKIN[2]
[1]Hokkaido Univ. Hosp., Sapporo, Japan; [2]Hokkaido Univ., Sapporo, Japan

Abstract: Stroke is still a leading cause of death and disability, and despite intensive research, few treatment options exist. A recent breakthrough in cell therapy is expected to reverse the neurological sequelae of stroke. Since June 2017, we have also started the novel clinical trials, Research on advanced intervention using novel bone marrow stem cell(RAINBOW) study. It is a phase 1, open label, uncontrolled, dose response study. The primary purpose is to determine the safety of autologous BMSC product, HUNS001-01, when administered to acute ischemic stroke patients (Shichinohe H, et al. BMC Neurol. 2017;17:179). However, there are some problems to be solved before the clinical application, for examples, Ethical, Legal and Social Implications (ELSI) including Health Technology Assessment (HTA) for cell therapy. If the cost of cell therapy would be too expensive, should it be justified? National Institute for Health and Care Excellence (NICE) in UK proposed that less than £30,000 (about $40,000) per one quality-adjusted life year (QALY: Fig 1) would be appropriate. In our present study, we analyzed QALY using EQ-5D-5L and the medical cost in subjects of RAINBOW study. Because we obtained the preliminary data of QALY from 5 subjects, we will report them (Fig 2).

Title: A 3D scaffold and human cell neurovascular niche to test interactions between human neural and vascular cells *in vitro* and in stroke models

Authors: *L. A. FLANAGAN[1,2], J. ARULMOLI[2], D. T. T. PHAN[3], C. C. W. HUGHES[3]
[1]UCI Neurol., Irvine, CA; [2]Neurol. and Biomed. Engin., [3]MBB and Biomed. Engin., Univ. of California, Irvine, Irvine, CA

Abstract: Stroke is the leading cause of long term disability in the US. Current FDA-approved stroke treatments require immediate intervention, leaving 85% of patients untreated. Stem cell transplants may address this unmet need and significantly improve outcomes since cells can be transplanted days or months after stroke. Cell transplants for stroke focusing on neural or vascular brain components include neural stem/progenitor cells (NSPCs) that can generate neurons, astrocytes and oligodendrocytes or endothelial cells (ECs) that can form blood vessels. Co-transplantation of rodent NSPCs and ECs enhances the activity of both cell types, likely through synergistic communication between the cells.
We developed a human cell neurovascular niche comprised of a 3D biomaterial, human NSPCs (hNSPCs) and human ECs (hECs) to test interactions between human neural and vascular cells in vitro and in a stroke model. Our optimized 3D biomaterial scaffold of fibrin, hyaluronic acid, and laminin polymerizes effectively, ideally matches the mechanical characteristics of CNS tissue, resists rapid degradation, and supports the proliferation and differentiation of hNSPCs. Vessel formation from hECs was enhanced by hNSPCs in the scaffold, showing beneficial effects of human neural cells on human vessel formation in 3D. We found hNSPCs make a variety of factors previously identified from other cell types as positive regulators of vessel formation. We transplanted scaffolds and cells into the stroke injured rodent brain (middle cerebral artery occlusion model) and measured functional recovery and host tissue responses. HNSPCs survive

in brain tissue when transplanted with a scaffold. Rats treated with hNSPCs in a scaffold outperform control animals on rotarod tests of motor function. Host neuron survival in the penumbra region adjacent to the stroke is higher in animals treated with hNSPCs and scaffold, indicating that inclusion of an optimized scaffold improves beneficial effects of transplanted cells in stroke models. A human neurovascular niche comprised of an optimized 3D biomaterial scaffold, hNSPCs and hECs enables study of these cells' synergistic communication and can be used to assess impacts on functional recovery and host remodeling after transplant in rodent stroke models.

Title: Gpr56 intronic enhancer RNA is local regulator for gene expression and potential marker for ischemic stroke

Authors: *J.-Y. JOO[1], T.-S. PARK[2], Y.-J. JANG[2], B.-G. HA[2], J.-Y. HEO[2], S.-J. JEONG[2]
[1]Neurosci., [2]Korea Brain Res. Inst., Daegu, Korea, Republic of

Abstract: In mammalian cells, transcription and gene expression are dynamically regulated by a variety of factors, and transcriptional controls are paramount for most genes. The central dogma of gene expression includes two main steps, namely, RNA transcription from the DNA sequence, followed by protein translation from the RNA sequence. Enhancer RNAs (eRNAs) are a class of long noncoding RNAs (lncRNAs) that are transcribed from DNA sequences upstream or downstream of active enhancer regions. In cortical neurons, eRNAs are synthesized in response to membrane depolarization, prior to the end of mRNA transcription. A previous study showed that eRNAs interact with negative elongation factor (NELF) to specifically regulate target gene expression, and that transcription of eRNAs is strongly correlated with mRNA transcription and protein synthesis from proximal target genes. Several genome-wide studies show that eRNAs are transcribed bidirectionally from both the plus and minus strands of DNA in mouse cortical neurons and human cancer cells, and carry unique epigenetic markers, including monomethylation at histone H3 lysine 4 (H3K4me1) and acetylation at histone H3 lysine 27 (H3K27ac). Despite these exciting findings, the mechanisms of action and roles of eRNAs in

brain-related diseases such as stroke, Alzheimer's disease, and Fragile X syndrome have not been well characterized. Here, we identified intronic activity enhancer between the first exon and the second exon at 9.9 kb away from the *Gpr56* transcription start site (TSS) through genome-wide analysis, and this intronic enhancer transcribed enhancer RNAs (eRNAs). Total RNA-seq revealed that *Gpr56* eRNA and mRNA expression levels were downregulated by hypoxia in cultured mouse neurons. The results presented here suggest that *Gpr56* gene expression is specifically regulated by the eRNA, and this process involves direct binding of the CBP transcription factor to the *Gpr56* active intronic enhancer region. Knockdown of the *Gpr56* eRNA in cortical neurons increased the protein levels of synaptophysin and PSD-95. Analyses of various brain disease model mice revealed that *Gpr56* eRNA levels were reduced only in stroke model mice. These finding suggest that *Gpr56* eRNA play as local regulator for gene expression and differential display of *Gpr56* eRNAs transcription can be potential biomarker for human brain disease, and may therefore be useful therapeutic or diagnosis targets for various diseases.

Title: The role of mir-155 in the vascular barrier function after hypoxia

Authors: *T. ROITBAK[1], T. LORDKIPANIDZE[5], E. CABALLERO-GARRIDO[2], J. PENA-PHILIPPIDES[2], A. S. GARDINER[3], R. PAN[4]
[2]Neurosurg., [3]Neurosciences, [4]Pharmaceut. Sci., [1]Univ. of New Mexico, Albuquerque, NM; [5]Ilia State Univ., Tbilisi, Georgia

Abstract: miR-155 is a multifunctional microRNA implicated in regulating various physiological and pathological processes. Our studies demonstrate that *in vivo* inhibition of miR-155 supports cerebral vasculature after the experimental stroke (mouse distal middle cerebral artery occlusion, dMCAO) by improving microvascular integrity. Electron microscopy revealed that, in contrast with the control group, miR-155 inhibitor-injected dMCAO animals demonstrated well-preserved capillary tight junctions (TJ). Based on our experimental data, the improved TJ integrity was associated with stabilization of the major TJ protein ZO-1 and correlated with activation of miR-155 target protein Rheb. miR-155 inhibition after dMCAO

significantly altered the time course and the expression levels of the major cytokines (such as IL-10 and IL-4), and considerably modified the microglia/macrophage phenotype. miR-155 downregulation was accompanied by a decreased number of phagocytically active peri-vascular microglia/macrophages. Thus, miR-155 inhibition-induced support of microvascular integrity after stroke could be also influenced by altered post-stroke inflammation. This process is mediated via the activation of miR-155 target proteins SOCS-1, SHIP-1, and C/EBP-β. Based on our *in vivo* studies, we hypothesized that miR-155 inhibition could support the barrier functions of the cultured endothelial cells. We investigated the effects of changes in miR-155 expression on the endothelial monolayer integrity and expression of TJ proteins in primary human brain microvascular endothelial cells (HBMECs) subjected to oxygen-glucose deprivation (OGD). We demonstrated that, similar to our animal studies, miR-155 silencing in the endothelial cells strengthens their barrier functions. In addition, miR-155 inhibition significantly increased the levels of major TJ proteins claudin-1 and ZO-1, while its overexpression reduced these levels. Luciferase reporter assay verified that claudin-1 is directly targeted by miR-155. Based on the immunofluorescence microscopy and Western blot analyses, we concluded that in cultured HBMECs subjected to OGD, miR-155 inhibition-induced strengthening of endothelial TJs is mediated via its target protein claudin-1.
Both our *in vivo* and *in vitro* studies support our hypothesis that cerebral regeneration after stroke can be improved by the modulation of miR-155 activity.

Abstract: Cigarette smoking is a preventable risk factor for stroke, which is a leading cause of death and disability worldwide. Stroke disproportionately kills more women than men. Among women smokers, the risk of stroke remains high even at a young age. Smoking is a predictor of frailty, and pre-stroke smoking is associated with increased post-stroke frailty and even transient ischemic attacks that are characterized by mild ischemic episodes can result in a woman becoming frail. Frailty is characterized by an increased vulnerability to acute stressors and the reduced capacity of various bodily systems due to age-associated physiological deterioration. Although frailty is associated with increased in-hospital mortality, poorer outcome at discharge, and decreased likelihood of being discharged to the home, the prevention and treatment of smoking and stroke-associated frailty remains unaddressed. The ability to quantify frailty before and after stroke in an animal model will add to our understanding of frailty-related precursors to vascular disease. Studies performed in laboratory animals and humans support that whole body vibration (WBV) reduces or reverses pathological remodeling of bone and lessens frailty-related physiological deterioration. Adult female rats were exposed to nicotine (16 days) and to stroke by transient middle cerebral artery occlusion (tMCAO) and randomly assigned to either WBV(40 Hz; for twice a day, 5 days/week for 30 days) or control groups. We monitored the frailty index (FI) prior to and 1 month after tMCAO alone or in combination with WBV. The FI was composed of the following criteria: 1) activity levels, 2) hemodynamic measures, 3) basic metabolic status, and 4) cognitive performance of rats. Animals were sacrificed on the 30th day of WBV treatment, and brain tissue was harvested for histopathological analysis. The post-ischemic WBV intervention improves frailty parameters, reduces brain damage, and reduces frailty in control female rats, but not in the nicotine-exposed group. This suggests that WBV may be a potential therapy to reduce post-ischemic frailty and improve functional and cognitive outcomes after stroke in women. Results of this study define the frailty criterion that can be employed for future studies.

Title: Effect of rtms onset post-stroke: A systematic review and meta-analysis

Authors: *E. VAN LIESHOUT, V[1], B. VAN DER WORP[2], A. VISSER-MEILY[2], R. DIJKHUIZEN[2]
[1]Utrecht, Netherlands; [2]UMC Utrecht, Utrecht, Netherlands

Abstract: *Background.*Repetitive transcranial magnetic stimulation (rTMS) is a promising intervention to promote upper limb recovery in post-stroke rehabilitation. Several randomized controlled trials (RCTs) have assessed upper limb recovery after application of rTMS in different periods post-stroke, but it is unclear at which point in time rTMS is likely to be most beneficial. *Objective.*We aimed to identify the effects of different onset times of rTMS treatment on upper limb recovery after stroke. *Methods*. We searched PubMed, Embase, and the Cochrane Library to identify relevant RCTs. Meta-analyses were performed for separate and combined arm/hand motor scales, and timing of the follow-up measurement. Results.Thirty-eight studies with 1074 stroke subjects were included. Subgroup analysis of post-stroke treatment onset demonstrated benefit of rTMS applied in the early subacute phase, in comparison to the chronic phase post-stroke, on the score on the Fugl-Meyer Arm test (FMA) (<1 month; standardized mean difference (SMD), 0.77, $P < 0.001$). Tests at the level of function revealed improved upper limb outcome after rTMS (SMD 0.44, $P < 0.001$), which was not detected with tests at the level of activity (SMD 0.16, $P = 0.24$).
*Conclusions.*Based on the FMA,rTMS is more beneficial when applied in the early subacute than in the chronic phase post-stroke. Tests at the level of function are more sensitive to detect beneficial rTMS effects on upper limb outcome than tests at the level of activity. Future rTMS trials should include the FMA and work towards a core set of outcome measures.

Title: Action-observation treatment through an interactive home-based platform promoting child-to-child interaction improves hand function in children suffering from unilateral cerebral palsy

Authors: *A. NUARA[1], P. AVANZINI[2], G. RIZZOLATTI[2], M. FABBRI-DESTRO[2]
[1]Neurosci. Unit, Univ. di Parma, Parma, Italy; [2]CNR Inst. of Neurosci., Parma, Italy

Abstract: By engaging the Mirror Neuron System and brain networks shared with action execution, Action Observation Therapy (AOT) proved effective in improving hand motor

function in children with unilateral cerebral palsy (UCP). The aim of this study is to assess the effectiveness of an AOT-based platform combining video stories with interactive child-to-child remote sessions (*Mirrorable*) in improving hand function in children with UCP due to perinatal stroke.
Twenty UCP children (age 5-10) with mild-to-moderate hand impairment underwent 20 sessions structured as follows: first, they had to observe and imitate a wizard performing dexterity demanding magic tricks, a child-to-child live video session aimed at practicing the same exercises. During sessions, affected limb movement was accompanied by real-time positive feedbacks thanks to a Kinect 3D camera. The paretic hand motor function was evaluated through Besta Scale: a composite scale assessing global hand motor skills (Besta G), quality of grasp (Besta A), hand involvement in specific bilateral tasks (Besta B), hand recruitment in daily activities (Besta C). Moreover, Fugl Meyer Upper Extremity, Modified Ashworth Scale, segmental strength, mood VAS and Global Impression of change (GIC), were collected. Evaluations have been performed 1 month before (Tpre), at baseline (T0) and at the end of treatment (T1).
Subjects showed a T1-T0 improvement relative to T0-Tpre in paretic hand global motor function (Besta G, 53%$\pm$41 vs 57%$\pm$41, $p<0.01$), recruitment of paretic hand in bimanual activities (Besta B, 58%$\pm$25 vs 63%$\pm$24, $p<0.01$) and a trend to significant improvement in Grasping (Besta A, 57%$\pm$31 vs 60%$\pm$36, $p=0.056$). Moreover, a significant improvement was perceived (average GIC 0.50$\pm$0.65) by families, contrarily to the pre-treatment period. Noteworthy, a correlation between motor improvement and the difference in hand motor skills relative to the peer ($r=-0.519$, $p=0.019$) was found: in other words, the better is my peer, the better is the outcome of my treatment.
Our results evidenced that AOT associated with child-to-child interaction is effective in improving hand motor functioning in UCP. Peer-to-peer difference in hand motor ability is associated to the improvement, suggesting that it is preferable for a child to observe a leading fellow with higher motor skills than his own. In conclusion, Mirrorable showed a potential helpful role in hand rehabilitation programs for children with UCP, opening traditional AOT approaches to novel social-enriched scenarios, through which children could be at the same time beneficiary and provider of motor learning processes.

Title: Vagus nerve stimulation intensity and frequency modulate cortical plasticity and motor recovery after brain injury

Authors: *D. PRUITT, T. DANAPHONGSE, M. LUTCHMAN, N. PATEL, J. LE, P. REDDY, R. RENNAKER, M. KILGARD, S. HAYS
Univ. of Texas at Dallas, Richardson, TX

Abstract: Vagus nerve stimulation (VNS) has previously been demonstrated to enhance recovery of motor function after ischemic stroke, hemorrhagic stroke, traumatic brain injury, spinal cord injury, and peripheral nerve injury. Additionally, VNS has ameliorative effects in models of post-traumatic stress disorder (PTSD) and tinnitus. VNS shows promise as a useful clinical tool to treat multiple injuries and disorders. Currently it is unknown how different intensities and frequencies of VNS affect functional recovery. In this study, we assessed three different VNS intensities (0.4 mA, 0.8 mA, and 1.6 mA) in addition to three different VNS frequencies (15 Hz, 30 Hz, 60 Hz) and determined how these parameters affected either recovery of motor function after stroke or cortical plasticity. To assess motor recovery, rats were trained on the supination task. After training to proficiency, each rat received an ischemic stroke in motor cortex. Rats then continued training for six additional weeks, during which they received VNS at one of the pre-determined intensities. We observed that rats receiving 0.8 mA VNS had enhanced motor recovery compared to all other groups of animals. Rats receiving 0.4 mA and 1.6 mA VNS did not demonstrate motor recovery compared to rats receiving no VNS at all. Following behavioral assessment, each rat received injections of a retrograde neuronal tracer in the forelimb musculature. Six days later, animals were sacrificed and brain tissue was analyzed to assess the extent of cortical cells controlling forelimb muscle that were used in the supination task. We found that animals in the 0.8 mA VNS group had significantly greater number of labeled cells than animals in all other groups. This suggests that VNS-dependent functional recovery is related to cortical plasticity in both the injured and uninjured hemispheres. Finally, to investigate the importance of frequency on cortical plasticity, we paired eating behavior with VNS for 5 days. Rats were sorted into one of the pre-determined VNS frequency groups (15 Hz, 30 Hz, or 60 Hz). After 5 days, we performed intracortical microstimulation (ICMS) motor maps of the jaw region of motor cortex to investigate if VNS resulted in expansion of jaw representation. We found that 30 Hz VNS at the 0.8 mA intensity resulted in expansion of jaw motor maps when VNS was paired with eating behavior. This data suggests that VNS paired with training at the 30 Hz frequency and 0.8 mA intensity is optimal for enhancing functional recovery after neurological injury.

Title: Peri-lesional recordings and epidural stimulation in a non-human primate stroke model

Authors: *D. TOTTEN[1], J. M. CARMENA[2], R. J. MORECRAFT[3], K. GANGULY[1]
[1]Univ. of California, San Francisco, San Francisco, CA; [2]UC Berkeley, Berkeley, CA; [3]Univ. South Dakota Schl Med., Vermillion, SD

Abstract: Stroke is the leading cause of disability in the United States, with a substantial portion of the patients experiencing chronic motor deficits. The recovery of motor function after stroke is variable and the underlying physiological correlates of such recovery are unclear. A deeper understanding of the neural basis of motor recovery is critical to inform new avenues to improve post-stroke motor recovery. Our lab has recently conducted detailed investigations in a rodent model of stroke using rats trained to perform a reach-to-grasp task. This work establishes that low-frequency activity in peri-lesional motor cortex is correlated to the recovery of motor function after a primary motor cortex lesion. In our model, epidural stimulation delivered through skull screws boosted low-frequency activity and improved motor function. Here, we further this work by examining neural activity in the peri-lesional cortex and testing epidural stimulation as a means to boost motor recovery after stroke in non-human primates. We trained 4 male rhesus macaques between 5 and 7 years of age to perform a reach-to-grasp task and a center-out reaching task. Then, to model a stroke, aspiration was used to remove the forelimb region of primary motor cortex unilaterally. Microwire arrays or electrocorticography grids were implanted in the dorsal premotor and primary somatosensory cortex to monitor neural activity during recovery. Cranial-screws that transected the skull to contact the dura were used to deliver epidural alternating-current electrical stimulation. This exhibit includes preliminary analyses exploring the electrophysiological correlates of post-stroke recovery and the behavioral effects of epidural alternating-current electrical stimulation.

Title: Efficacy of multiple sessions of quadripulse stimulation in patients with stroke. A report of two cases

Authors: *K. SHINDO[1,2], F. KANEKO[2,1], M. OKAWADA[1,2], K. AKABOSHI[1,2], M. LIU[2]

Abstract: [Introduction]Quadripulse stimulation (QPS) is a new patterned repetitive transcranial magnetic stimulation (rTMS) protocol. It has been reported that the effects of QPS are less variable in healthy persons (Nakamura K, et al. 2016). Recently, rTMS has been used to improve motor function in patients with stroke (Hsu WY, et al. 2012). However, there is no evidence about the application of QPS to stroke patients. In this study, we investigated how multiple sessions of facilitative QPS over the primary motor cortex (M1) of the affected hemisphere changed motor function.[Methods]Two patients with chronic cerebral infarction gave their informed consent for participation and were included in the trial (see Table). The study was performed in accordance with the Declaration of Helsinki, was approved by the local Ethics Committee, and was registered to the UMIN Clinical Trial Registry (UMIN000032286).Because no MEPs were recorded from the affected M1, we determined the active motor threshold (AMT) of the unaffected first dorsal interosseus (FDI) muscle (MagStim 2002, The MagStim Co Ltd, UK). QPS protocol of successive four monophasic pulses delivered with an interstimulus interval (ISI) of 5 milliseconds (QPS-5) was applied to a symmetric position (mirror region) of the unaffected M1 hotspot. One therapeutic session consisted of 360 trains of four pulses (1440 pulses in total) at the intensity of 90% AMT and an intertrain interval of 5 seconds. After each QPS, the participants had kinesthetic illusion induced by visual stimulus (KiNvis) (Kaneko F, et al. 2016) 5 times a week for 2 weeks. Both conventional therapeutic exercise and Hybrid Assistive Neuromuscular Dynamic Stimulation (HANDS) therapy (Fujiwara T, et al. 2009) were also provided every day for 2 weeks.[Results]Just after one QPS session, reduced spasticity at wrist and finger flexors and improved voluntary finger movement were observed. After 10 sessions of QPS and the other interventions, both participants showed improved motor function of the paretic upper extremity (see Table). There were not definite MEPs from the affected M1.

There was no obvious adverse effect during the trial.[Conclusions]QPS may be a powerful adjunctive tool to induce motor recovery after stroke.

Title: Changes in the rat brain following transient ischemic stroke - An MRI study

Authors: *T. ROY[1], R. KUMAR[2], T. G. JACOB[2], U. SHARMA[3], N. JAGANNATHAN[3]
[2]Anat., [3]Dept. of Nuclear Magnetic Resonance, [1]All India Inst. Med. Sci., New Delhi, India

Abstract: Stroke remains a leading cause of morbidity and mortality worldwide. In ischemic stroke, blockage of cerebral blood flow causes an irreversibly damaged core region and a penumbra that may get permanently damaged in the absence of an effective intervention. Using MRI we explored the changes in the rat brain following transient ischemic stroke with the passage of time. Middle cerebral artery occlusion (MCAO) surgeries were performed on adult, male, Wistar rats. The right common carotid artery was exposed and MCAO suture (Doccol corporation, USA) was introduced into the internal carotid artery through the external carotid artery to block the origin of MCA. After one-hour, the suture was retracted to allow reperfusion. MRI evaluations (n=4) were made on 7T-BIOSPEC animal MRI-scanner (Bruker, BioSpin MRI GmbH, Germany) using a 72-mm resonator as transmitter/receiver coil. T2-weighted and Diffusion-Weighted-MRI images were acquired on days 4, 14 and 28 after reperfusion. Image analysis was done using Paravision 6.0 software. Regions of interest were traced and percentage of infarction volume was calculated. Apparent diffusion coefficient (ADC) ratio was calculated for each infarct slice as ratio between the ipsilateral and contralateral ADC values. These values (infarction volume and ADC ratios) were compared between days 4, 14 and 28 using repeated measures Analysis of Variance (ANOVA). There was a significant decrease in the infarction volume with time (overall $p<0.05$). This study provides baseline data and methods that can be used to investigate the efficacy of therapeutic interventions in transient ischemia of the brain.

Title: Remote ischemic post-conditioning accelerates hematoma resolution after intracerebral hemorrhage by modulating innate immune activation

Authors: *M. BRAUN[1], K. VAIBHAV[1], M. B. KHAN[2], M. HODA[3], B. BABAN[4], D. C. HESS[2], K. M. DHANDAPANI[1]

Abstract: lntracerebral hemorrhage (ICH), a devastating neurological injury that accounts for 15% of all strokes, produces the highest acute mortality and worst long-term outcomes of all stroke subtypes. Hematoma volume is an independent determinant of ICH patient outcomes, making early clot resolution a primary goal of clinical management. Herein, remote ischemic post-conditioning (RIC), the repetitive inflation-deflation of a blood pressure cuff on a limb, accelerated hematoma resolution and improved neurological outcomes after experimental ICH. Parabiosis studies revealed RIC accelerated clot resolution via a humoral-mediated mechanism. Whereas RIC increased anti-inflammatory macrophage activation, myeloid cell depletion eliminated the beneficial effects of RIC after ICH. Myeloid-specific inactivation of the metabolic regulator, 5' adenosine monophosphate-activated protein kinase (AMPK), attenuated RIC-induced anti-inflammatory macrophage polarization, delayed hematoma resolution, and worsened outcomes, providing a molecular link between RIC and macrophage activation. Finally, bone marrow chimera studies functionally implicated myeloid CD36 expression in RIC-mediated recovery, including reduced white matter injury. Thus, RIC, a clinically well-tolerated therapy, non-invasively modulates immune responses to improve ICH outcomes.

Title: Mechanisms underlying epileptogenisis following blast induced traumatic brain injury in rat model

Authors: *M. MURUGAN[1], D. SUBRAMANIAN[2,3], V. SANTHAKUMAR[2,3], N. CHANDRA[1]
[1]Dept. of Biomed. Engin., New Jersey Inst. of Technol., Newark, NJ; [2]Dept. of Pharmacology, Physiol. and Neurosci., Rutgers New Jersey Med. Sch., Newark, NJ; [3]Dept. of Molecular, Cell and Systems Biol., Univ. of California, Riverside, CA

Abstract: Blast-related traumatic brain injury (bTBI) is the signature injury of combat troops in military conflicts and leads to long-term physical, mental and cognitive deficits. bTBI is defined as an injury due to "primary" blast wave exposure which is distinct from impact TBI which is caused due to blunt-force injury. Although brain injury is a known precursor for the development of post traumatic epilepsy (PTE), the singular contribution of the primary blast wave to PTE remains unknown. Hence, the primary aim of this study was to investigate the effect of bTBI on epileptogenesis in a military-relevant rat model of bTBI. Ten week old male Sprague Dawley rats were subjected to mild bTBI (130 kPa) in a shock tube. The changes in cortical oscillations were examined at 4 weeks after shock wave exposure using cortical screws implanted on the skull. Interestingly, rats subject to mild bTBI developed abnormal changes in cortical oscillations with a decrease in total power of theta (4-12 Hz) and increase in power of gamma (30-90 Hz) frequency oscillations. In response to a convulsive dose of kainic acid (5mg kg^{-1} body weight, i.p), the latency to electrographic and behavioral seizures in blast-exposed animals was significantly reduced and seizure severity increased compared to sham controls. Histological and electron micrograph imaging revealed neuronal damage including diffuse axonal injury at 4h after blast exposure which may underlie the subsequent seizure susceptibility of bTBI rats. Taken together, our data suggests that a primary shock wave is sufficient to cause EEG changes reminiscent of a pre-epileptic state. Moreover, bTBI induced axonal damage may contribute to changes in the neuronal excitability and lead to epileptogenesis. This study will determine the functional outcomes following primary bTBI and further our understanding of the mechanisms underlying bTBI-induced neuropathology and help identify targets for improved therapeutic solutions.

Title: Developing, validating, and phenotyping a novel mouse model of combined TBI and PTSD

Authors: *P. TEUTSCH[1], C. E. JONES[2], M. M. LIM[1,3]
[1]Veterans Affairs Portland Hlth. Care Syst., Portland, OR; [2]Behavioral Neurosci., [3]Oregon Hlth. & Sci. Univ., Portland, OR

Abstract: Traumatic brain injury (TBI) and Post traumatic stress disorder (PTSD) are highly debilitating conditions that occur in the Veteran population with dramatic prevalence. Despite their common co-occurrence and overlapping symptomology, conventional studies and treatment approaches to these diseases remain largely segregated. We hypothesize that comorbid TBI+PTSD interact to generate unique symptomology. We created a novel mouse model with which to begin exploring this condition. Using the single prolonged stress (SPS) protocol in combination with controlled cortical impact (CCI) method, four experimental groups were generated: Control, TBI, PTSD, and TBI+PTSD. Mice were tested for gait, locomotor activity, contextual fear conditioning, and acoustic prepulse inhibition. Gait and contextual fear recall were found to be significantly impaired in TBI+PTSD mice relative to controls without changes in overall locomotor activity in the home cage. Auditory sensory gating and acoustic startle were intact among the four groups. Future studies will explore pathological phenotypes, EEG/EMG recordings, and further behavioral testing in this novel combined murine model of TBI+PTSD.

Title: Mild blast induced traumatic brain injury disrupts the neuroendocrine stress response in male and female mice

Authors: *A. L. RUSSELL[1], I. M. HERNANDEZ[2], R. J. HANDA[4], T.-Y. J. WU[3]
[1]Program in Neurosci., [2]Obstetrics and Gynecology, [3]Uniformed Services Univ., Bethesda, MD; [4]Biomed. Sci., Colorado State Univ., Fort Collins, CO

Abstract: Traumatic brain injury (TBI) is a worldwide epidemic affecting 10 million people every year making it a leading cause of death and disability. Among military personnel, a significant portion of mild (m)TBI are induced by explosive blast devices. Mild blast TBI (mbTBI) has a unique signature, increasing susceptibility to anxiety disorders. Although the link between mbTBI and neuropsychiatric disorders is unknown, a likely candidate connecting these is the limbic-hypothalamus-pituitary-adrenal (HPA) axis. Dysregulation of the limbic-HPA axis is associated with anxiety. Therefore, we examined the effect of mbTBI (~15.5 psi) on resting and restraint-induced limbic-HPA axis reactivity in male and female mice 7-10 days post injury. mbTBI increased anxiety-like behaviors ($p<0.05$). We have previously shown that mbTBI dysregulates the HPA differently in males and females. In males, mbTBI increased ($p<0.05$) restraint-induced corticosterone (CORT) secretion, but decreased ($p<0.05$) corticotropin-releasing factor (CRF) activation, as measured by c-Fos-immunoreactivity (ir). In females, mbTBI decreased ($p<0.05$) restraint-induced CORT, but increased ($p<0.05$) CRF activation. mbTBI decreased ($p<0.05$) activation of non-neuroendocrine (pre-autonomic) CRF neurons in females, but not males, suggesting a potential link to autonomic dysregulation. mbTBI had no effect ($p>0.10$) on mineralocorticoid and glucocorticoid receptor gene expression. Surprisingly, mbTBI had no effect ($p>0.10$) on limbic expression of the well-studied CRF receptor subtype 1, a receptor involved in anxiety-like behaviors. However, mbTBI differentially altered CRFR2 gene expression. In males, mbTBI decreased ($p<0.05$) restraint-induced CRFR2 in the anterior BNST and amygdala. In females, mbTBI decreased ($p<0.05$) restraint-induced CRFR2 in the dorsal hippocampus. To further examine the impact of mbTBI on HPA axis-relevant limbic structures, we examined c-Fos-ir or EGR-1-ir, markers of neuron activation. In sham males and females, restraint increased c-Fos-ir in the infralimbic and prelimbic subdivisions of the PFC. mbTBI ablated ($p<0.05$) this restraint-induced increase. Preliminary data suggests no effect ($p>0.10$) on mbTBI on EGR-1-ir in the amygdala of males or females. Ongoing studies are examining the effect of mbTBI on c-Fos-ir in the BNST and hippocampus. Overall, our data suggests a sex-dependent dysregulation of the limbic-HPA axis stress circuitry. These data suggest that males and females utilize different strategies to cope with mbTBI, highlighting the importance of developing targeted sex dependent treatments.

Title: Cerebrolysin improves long-term histological outcomes and functional recovery in rats after moderate closed head injury

Authors: *Y. ZHANG[1], M. CHOPP[2,4], Y. ZHANG[2], Z. ZHANG[2], M. LU[3], T. ZHANG[3], H. WU[3], S. WINTER[5], E. DOPPLER[5], L. ZHANG[2], A. MAHMOOD[1], Y. XIONG[1]

Abstract: Background: Cerebrolysin is a neuropeptide preparation with the neurotrophic properties. The purpose of this study was to investigate the effects of Cerebrolysin on long-term functional and histological outcomes in rats after moderate closed head injury (mCHI). **Methods:** In this prospective, randomized, blinded, and placebo-controlled preclinical study, male adult Wistar rats subjected to mCHI were randomly treated with either placebo (saline, n=13) or Cerebrolysin at the optimal dose of 2.5 ml/kg (n=13) intraperitoneally administered daily for 10 days, starting at 4 h after mCHI. Animals were subjected to cognitive and sensorimotor functional tests at multiple time points, and they were sacrificed 90 days after mCHI. The brains were then processed for histological analyses of neuronal cell loss, amyloid precursor protein, axonal damage, astrogliosis, and neurogenesis. **Results:** Compared to the placebo, Cerebrolysin significantly increased the number of neuroblasts and neurogenesis in the dentate gyrus, and reduced amyloid precursor protein accumulation, astrogliosis and axonal damage in various brain regions as well as reduced neuronal cell loss in the dentate gyrus and CA3 region of the hippocampus ($p<0.05$). The global test using Generalize Estimating Equations was used to test the effect of Cerebrolysin on functional outcomes. There was a significant effect of Cerebrolysin on sensorimotor functional outcomes starting from 1 day to 3 months after injury compared to saline treatment ($p<0.05$). Cerebrolysin significantly and robustly improved long-term (up to 3 months) cognitive functional recovery measured by the Morris Water Maze, Odor Recognition, Social Interaction, and Novel Object Recognition tests. There were significant correlations between multiple histological and functional outcomes 90 days after mCHI, as detected by Pearson partial correlation analyses. **Conclusions:** Our data that Cerebrolysin significantly improves long-term histological and functional outcomes in rats after mCHI, with

functional outcomes significantly correlated with histological indices of plasticity support the efficacy of Cerebrolysin for the treatment of mCHI.

Title: Lysophosphatidyl choline induces post-hemorrhagic hydrocephalus through conversion to lysophosphatidic acid via autotaxin

Authors: ***A. FRANTZ**, N. LUMMIS, P. SANCHEZ-PAVON, Y. YUNG, J. CHUN
Sanford-Burnham Med. Res. Inst., LA Jolla, CA

Abstract: Hydrocephalus, or “water on the brain”, is a common neurological disorder that occurs in 1 in 1500 live births. Hemorrhage in the developing brain commonly results in hydrocephalus, indicating that one or more blood components contribute to the disorder. The pharmacological mechanism by which this occurs, however, is not well understood. Our lab has demonstrated that lysophosphatidic acid (LPA), a lipid that doubles as a signaling molecule, is one such component and can produce post-hemorrhagic hydrocephalus (PHH) in developing mice. Specifically, we have shown that a 10 mM LPA bolus delivered to the brain ventricles of E13.5 embryonic mice causes PHH by postnatal day 10 in a receptor-dependent manner. Genetic

deletion and pharmacological blockade of LPA receptor 1 (LPA1) both attenuate the severity of PHH. Similarly, our lab has found that a 5 mM LPA bolus delivered to the brains of postnatal day 8 mice is sufficient to produce PHH after 7 days. Preliminary data indicate that an LPA bolus delivered to the brains of adult mice may contribute to post-traumatic hydrocephalus (PTH). Ependymal integrity is compromised in 33% of LPA-injected adult mice. Additionally, lysophosphatidyl choline (LPC), another abundant blood component released during hemorrhage or trauma, is an LPA precursor that we hypothesize may also lead to hydrocephalus. LPC is converted directly into LPA by the enzyme autotaxin (ATX), which is highly expressed in the choroid plexus and neural cells of the developing brain. Intraventricular delivery of LPC produces hydrocephalus similar to that of LPA. Genetic deletion of LPA1 attenuates LPC-mediated PHH, indicating that LPA receptor-mediated signaling plays a role in the progression of the disease. We hypothesize that pharmacological inhibitors of ATX and LPA1 will similarly attenuate hydrocephalus. These experiments will determine the efficacy of pharmacological intervention following hemorrhage in preventing hydrocephalus, and introduce a novel treatment for the disease.

Title: Repeated mild closed head impacts to tau mice leads to selective neuroinflammation of the optic nerve and white matter tracts

Authors: *H. CHENG[1], J. FATHMAN[2], A. SCHUMACHER[2], J. WALKER[1]
[1]Sequencing/Expression Analysis, [2]Novartis (GNF), San Diego, CA

Abstract: Repeated mild traumatic brain injury (rmTBI) can lead to development of chronic traumatic encephalopathy (CTE). CTE is characterized by progressive neurodegeneration with presence of gliosis and hyper-phosphorylated tau. Literature reports of closed head rmTBI in rodents have yielded mixed results with regards to regions of injury and induction of phosphorylated tau. Here we report a 42 closed-head rmTBI impact paradigm on 3-4 month old male C57BL/6 mice that results in chronic inflammation of the optic nerve and associated white matter fiber tracts. We speculate these regions are most vulnerable because their anatomical location between brain and sphenoid/occipital bones facilitates biomechanical shear injury to the white matter tract during impacts. Because C57BL/6 mice do not spontaneously develop

phosphorylated tau even in the presence of rmTBI, homozygous Tau58.4 mice were subjected to injury as well. To identify the baseline pathogenesis of tauopathy and gliosis, a histological time course and peripheral immune cell profiling of these Tau58.4 mice was conducted. These mice develop minor tauopathy by 3 months of age, which begins to accelerate by 6 months of age. At 3 months post-impacts, rmTBI greatly induced inflammatory genes such as GFAP and IL-1a in the optic nerve tracts in the Tau58.4 mice, which was not nearly as robust in other brain regions. These models can reveal new information as to how rmTBI affects white matter and tau pathogenesis in the brain, and whether immune modulation can potentially alter the outcomes of the injury.

Title: The effect of repetitive mild traumatic brain injury on Alzheimer's mice containing mutations for amyloid precursor protein and tau

Authors: *N. COSCHIGANO, K. CRAVEN, S. LIPPI, J. FLINN
Psychology, George Mason, Fairfax, VA

Abstract: Traumatic brain injuries (TBI) are a known risk factor for Alzheimer’s disease (AD). Mild TBIs are the most common and often occur during adolescence. There is an increased risk of sustaining an additional TBI following the first one. This demonstrates a need to model repetitive mild TBI (rmTBI). rmTBIs lead to the development of tau tangles and amyloid plaques, similar to those in AD. Despite this, no study to date has assessed the impact of rmTBI during adolescence on a mouse model of AD containing both amyloid and tau. The proposed research aims to fill this gap in the literature by providing insight into the time-course of inflammatory markers as well as cognitive deficits in an AD mouse model following rmTBI. Offspring from the cross J20 (hAPP) and rTg4510 (TauP301L) mice (Lippi et al., 2017 SfN), were examined. This mouse demonstrates significant deficits that mimic symptoms of human AD. Furthermore, the rmTBI method utilized in our laboratory has been shown to cause spatial memory deficits 7 weeks following the last TBI and an increase in inflammatory markers in wildtype mice. We will examine the effects of rmTBI on the offspring of J20/rTg4510 mice using multiple behavioral measures, including: Morris Water Maze, Elevated Zero, Nesting,

Burrowing, and Circadian Rhythm. At eight weeks, mice will undergo rmTBI every other day for a total of 5 hits, followed by behavioral assessment at 3.5 and 8 months. This study will provide additional insight into the increased risk of the development of AD following TBI.

Title: Long-term effects of traumatic brain injury on fear

Authors: *J. POPOVITZ[1], K. HARKINS[1], S. P. MYSORE[2], H. M. ADWANIKAR[2]
[2]Psychological and Brain Sci., [1]Johns Hopkins Univ., Baltimore, MD

Abstract: In humans, it is well-known that traumatic brain injury (TBI) increases the risk of psychiatric disorders, and that those effects can last for many years post-injury. Some of the most commonly experienced disorders are related to dysregulation in the fear and anxiety circuits, such as generalized anxiety disorder and post-traumatic stress disorder. In animal models, short-term effects of injury in emotional behaviors have been well-studied, and fear conditioning has been paired with TBI to emulate the fearful events that may accompany the exposure to the injury. However, it is not clear how animals exposed to a TBI react to fearful experiences in the long term. To address this issue, in this project we use a controlled cortical impact injury to examine the long-term effect of TBI on fear acquisition and extinction, and on anxiety-like behaviors. Notably, animals were tested on the open field at eight weeks post-injury, and fear conditioning was performed at nine weeks to assess long-term effects of injury. For the fear conditioning, mice were exposed to three CS-US (tone + foot shock) presentations on conditioning day, followed by three days of context and cue extinction. Behavioral results suggest impairment in fear acquisition for TBI animals, accompanied by decreased anxiety and hyperactivity in the open field test. Immunohistochemistry results indicate upregulation of GABA in the ipsilateral basolateral nucleus of the amygdala. These results will start to address long-term affective consequences of TBI and shed light on underlying neural mechanisms.

Sch. of Med., Cleveland, OH; [6]LNS, Natl. Inst. on Aging, Baltimore, MD

Abstract: Traumatic brain injury (TBI) is a major worldwide health concern and is difficult to both diagnose and effectively treat. The overall incidence rate of TBI in the US is 577 in 100,000 (1.7 million cases per year) and the mortality rate is 17.6 in 100,000 (>51,000 deaths per year). Of these, mild (m)TBI accounts for the majority: 70%-90% of all cases. mTBI may result in loss of consciousness and/or changes in mental state that are benign but associated with neuropsychiatric symptoms. The time-dependence of the molecular mechanisms that underpin neuronal damage and recovery following a mTBI are not clearly understood, their elucidation may aid the development of effective treatments. To identify mechanisms involved in mTBI, we evaluated the protein cargo of plasma derived Extracellular Vesicles (EVs) enriched for neuronal origin. Recent studies suggest that protein profiles within bloodborne circulating EVs offer the potential to characterize initial injury and secondary pathological processes and provide potential biomarkers for clinical diagnosis. To evaluate this, 24 mice (6 weeks old) were subjected to weight drop (30 g)-induced concussive mTBI, and 10 mice to a sham procedure without injury. Blood derived plasma and cortical brain tissue samples were generated at 8, 24, 72 hr and 7, 14, 30 days post mTBI, all 4 mice per group, (sham: time 0 and 30 days, 6 and 4 mice per group). Neuronal origin enriched-EVs were extracted from plasma with a two-step process: first, total plasma EVs were isolated using Exoquick (Systems Biosciences), followed by enrichment by immuneabsorption with anti-L1CAM antibody, a transmembrane neuronal protein. EV samples were subjected to multiplexed proteomic technology (SOMAscan, SomaLogic, Inc) to profile

changes in sham vs. mTBI across time. SOMAscan technology allowed evaluation of >1000 proteins that we grouped under mechanism-based processes. Early (8 hr) changes in proteins associated with pathways related to inflammatory cytokines and acute phase responses, as well as apoptosis, cell adhesion and gluconeogenesis. These led to later (24 hr-30 days) changes in exosome markers of cytokine/chemokine activity as well as signaling cascades/proteins associated with neural development, differentiation, proliferation and migration, together with fatty acid biosynthesis and insulin resistance. Ongoing studies are cross-validating these changes by measuring key proteins in collected brain samples. Our focus is to map time-dependent proteins changes that occur in neuronal enriched, plasma derived EVs following mTBI as potential biomarkers of brain damage and response to treatment

Title: Functional suppression of premotor activity in a transient model of motor cortex injury

Authors: *K. C. ELLIOTT, J. A. BORRELL, S. BARBAY, R. J. NUDO
Univ. of Kansas Med. Ctr., Kansas City, KS

Abstract: When an injury occurs to a motor region, as from a stroke or traumatic brain injury, the entire motor network is disrupted, impairing movement. We previously demonstrated in the rat that motor deficits in skilled forelimb performance, caused by a traumatic brain injury to primary motor cortex (caudal forelimb area; CFA), can be rescued when the ipsilesional premotor (i.e., the rostral forelimb area; RFA) and somatosensory forelimb (FL-S1) cortices are co-activated (Guggenmos et al., 2013). The observed motor recovery from RFA/FL-S1 co-activation began eight days after injury suggesting an acute functional reorganization of motor control, seeming to precede significant reorganization of neuroanatomical circuitry. To determine if rapid functional reorganization of sensorimotor cortices is possible without neuroanatomical changes, we are establishing a model of transient inactivation that will leave the normal cortical motor connections intact. As a first step we characterized the functional relationship between CFA and RFA. In an anesthetized rat, CFA was temporarily inactivated with muscimol. This disrupts functionality within the motor network while leaving neural

connectivity anatomically intact. Using standard intracortical microstimulation techniques (ICMS), we found that CFA inactivation completely abolished stimulation-evoked forelimb movement from RFA; neural recordings confirmed that neural suppression due to muscimol did not spread into RFA. To determine the extent to which influence of RFA output to forelimb muscles was suppressed by inactivation of CFA, intramuscular electromyographical (EMG) recordings were obtained from forelimb muscles during ICMS in RFA. EMG recordings show that muscimol caused an overall loss of muscle activation. These results show that within the intact motor network of the rat, the influence of RFA on forelimb movement is mediated through CFA. This model will be used to determine if coactivation of RFA/S1, as in Guggenmos et al. 2013, can reinstate skilled motor performance after temporary suppression of neural activity in CFA, eliminating the need for compensatory anatomical reorganization.

Title: Action of the anti-epileptic drug phenytoin on mild traumatic brain injury in a mouse model

Authors: *J. SPIESS[1,2], C. WEISS[3], G. GARCIA[2], J. PINA-CRESPO[2], P. H. RIGBY[4], J. F. DISTERHOFT[3]
[1]Cortrop Inc., Encinitas, CA; [2]Sanford Burnham Med. Res. Inst., La Jolla, CA; [3]Dept Physiol., Northwestern Univ. Med. Sch., Chicago, IL; [4]L3 Applied Technologies, San Diego, CA

Abstract: Objective. Mild traumatic brain injury (mild TBI) is a closed-head axonal injury generated by impact from explosions, traffic accidents and sport events such as football, soccer, boxing. The axonal injury can be identified by diffusion tensor imaging (DTI). In addition to direct head trauma, peripheral pathological cellular impact-related changes may contribute to central disease. Generation of mild TBI probably induces neurodegenerative diseases such as Alzheimer's and Parkinson's disease, also depression diseases and epilepsy. In preliminary experiments, we observed the induction of absence seizures by high pressure (70 psi) exposure of a mouse model. Whether months after impact tonic-clonic seizures will appear, could not yet

be determined. To expand our experimental possibilities, we investigated the basic action of the sodium channel blocker 5,5-diphenylhydantoin (phenytoin), an antiepileptic drug, found to inhibit tonic-clonic, but not absence seizures, on mild TBI in the mouse model.
Experimental. We used male C57BL/6N mice (7-8 weeks old, single-housed) anesthetized with isoflurane. Their lungs and ears were protected with nylon ballistic coats and plastic plugs, respectively. High pressure exposure (blast) was provided by a supersonic helium wave generated in a 6 feet long and 2 inches wide aluminum tube. It hit the head of the anesthetized mouse with a reflective pressure of 69 psi for 1.4 msec. Four groups (n=10) were generated: blast/drug, blast/vehicle, no-blast/drug, no-blast/vehicle. On Day 1, 30 minutes before the blast, the mice were injected i.p. with 10 mg/kg phenytoin in vehicle (aqueous 1% Tween 80) or vehicle alone. On Day 3, the animals were trained by delay (to test non-declarative memory) or trace (to test declarative memory) fear conditioning. On Day 4, they were tested for conditioned contextual, pre-cue and cue freezing. Fecal boli were collected after each testing session. On Day 5, the mice were cardioperfused. The brains were fixed in 4% paraformaldehyde, coronally sectioned and stained for hyperphosporylated tau protein.
Results. The data were analyzed with one- or two-way anova. Fisher's PLSD tests were used for post-hoc analyses. Phenytoin enhanced differentially blast-induced contextual freezing and anxiety indicated by fecal boli increase in the absence of blast. No other specific drug effects were observed. Preliminary analysis of tau hyperphosphorylation did not show significant group or drug effects.
Conclusion. It is concluded that under blast conditions posttraumatic stress disorder (PTSD) and -based on earlier observations- absence seizures are enhanced by phenytoin, as is anxiety in the absence of blast.

Title: From trauma to neurodegeneration: A one year time course of functional and neuropathological outcomes following experimental traumatic brain injury

Authors: *A. ARULSAMY[1], F. CORRIGAN[2], L. E. COLLINS-PRAINO[1]
[1]The Univ. of Adelaide, Adelaide, Australia; [2]Univ. of South Australia, Adelaide, Australia

Abstract: Although traumatic brain injury (TBI) is a risk factor for the development of dementia and motor neuron disease, the time course of this relationship and whether it depends on the severity of the original injury is not yet known. The current study investigated the functional impairments and neuropathology following either mild (mTBI), repetitive mild (rmTBI) or moderate-severe TBI (msTBI) induced by the Marmarou model of impact-acceleration. A behavioural battery was conducted at 7 days, 1, 3, 6 or 12 months post-injury (n=10-14/group/timepoint) with molecular analysis performed for markers of inflammation and neurodegenerative pathology in the cortex, hippocampus and spinal cord. Assessment of general locomotion found no significant differences relative to sham animals in any of the TBI groups at any timepoints. Anxiety-like behaviour measured on the plus maze showed that at 1 month post injury, mTBI animals spent significantly more time in the open arm ($p<0.05$), which resolved by 3 months. However, the msTBI had a significantly higher number of crossings ($p<0.01$) and open arm entries ($p<0.05$) than the shams at 1 month post injury, which gradually decreased with time, showing a significant decrease at 12 months ($p<0.05$). While depression is common in individuals following TBI, only the rmTBI group at 6 months post injury exhibited a significantly higher number of immobility episodes on the forced swim test than shams ($p<0.05$). Cognitive dysfunction is also common post TBI, and may set the stage for the later emergence of dementia. Following msTBI, animals had significantly impaired memory at 1 month ($p<0.01$), learning deficit at 6 months ($p<0.01$) and an impaired cognitive flexibility at 12 months ($p<0.01$) in relation to shams, as measured by the Barnes maze. Using a test of executive function (5-Choice Continuous Performance Task), rmTBI animals showed a significantly poorer performance at 1 month post injury while msTBI animals was significantly more liberal in response to the task at 12 months. Molecular analysis also supports the neuropathological link between TBI and neurodegeneration; hallmark neurodegenerative proteins, including pTDP-43, and oxidative stress were significantly higher in the msTBI when compared to shams at long term post injury timepoints. Taken together, the results of the current study support the emergence of cognitive dysfunction, neuropsychiatric impairments and neurodegenerative pathology chronically following TBI. The specific type of functional impairments seen post injury appear to be dependent on the nature of the original insult, with the most detrimental outcomes evident following a single moderate-severe injury.

Title: Longitudinal structural changes in the brain following fluid percussion injury followed by diffusion MRI

Authors: *G. SMITH[1], C. SANTANA-GOMEZ[2], R. STABA[2], N. G. HARRIS[1]
[1]Neurosurg., [2]Neurol., UCLA David Geffen Sch. of Med., Los Angeles, CA

Abstract: White matter injury is a hallmark of traumatic brain injury (TBI) and diffusion-weighted (DW) magnetic resonance imaging (MRI) is most often the clinical research tool used to investigate this. In rodent experimental models of TBI, the analysis of such data is replete with difficulties and potential biases, especially given the lack of a standard parcellated brain atlas, on-going brain atrophy, and the difficulties in co-registering the injured brain. Problems also arise when attempting to reproducibly segment white and grey matter in order to produce a white/grey matter border seed region for tract-based analysis. We attempted to solve some of these issues by developing an analysis pipeline to first quantify microstructural abnormalities by fitting the data to a tensor model to calculate scalar indices of the tensor, and by using constrained spherical deconvolution and probabilistic tractography constrained by the underlying anatomy to obtain region-to-region tract counts using a parcellated, rat brain atlas. A fixel-based analysis was also conducted to obtain counts of fiber density and fiber cross-section in order to determine the effects of the processing pipeline on injury-related differences in brain structural connectivity.
TBI was induced in adult, male, Sprague Dawley rats using the lateral fluid percussion injury model and 250 mm^3 isotropic, 3-dimensional DW MRI data (b=0,2800 s/mm^2, 42 gradient vectors) were acquired longitudinally on a 7T Bruker spectrometer at 4 post-injury time-points: 2 days, 9 days, 1 month and 5 months (n=15) and compared to sham rats (n=9) imaged at the same time-points.
Data indicate that in agreement with prior published data in this model, fixel-based analysis for fiber density does provide useful measures that discriminate between regions of injury. On-going analysis will compare the effect of pipeline processing on microstructure and tract analysis data in order to obtain the optimal method for describing injury-related differences on white matter structure.

Abstract: Objectives: Rodent models may be able to provide important insights into some of the most pertinent issues surrounding concussion. Nonetheless, the relevance of existing models to clinical concussion is questionable, particularly regarding the use of surgery and anaesthesia, and the mechanism and severity of injury. Here, we aimed to characterize the neurobehavioural effects of an awake closed-head injury (ACHI) rat model that delivers an impact featuring clinically relevant head acceleration without use of surgery and anaesthesia.
Methods: 116, adolescent male Long-Evans rats were assigned to sham or single ACHI groups. All rats were restrained in a cone shaped bag with a 3D printed steel helmet positioned such that the impact target was centred on their left parietal cortex. Once positioned on a foam platform, a cortical impactor was used to strike the helmet target. Sham animals underwent the same procedure without impact. An array of behavioral testing was conducted post impact. Beam walk testing was used to assess sensorimotor function at baseline, 2 minutes and 24 hours post-impact. Locomotor activity was observed at 10 minutes and 24 hours using open field. Anxiety was assessed with elevated plus maze at 20 minutes and 24 hours, and finally y-maze was used to assess spatial memory at 5 minutes, 24 hours and 48 hours post-impact.
Results: Beam walk testing revealed that ACHI rats had increased hind limb slips at 2 minutes post-ACHI ($p<0.0001$), but not at 24 hours, indicating that a single injury induced transient sensorimotor deficits. Open-field showed that injured rats had transient hyperactivity, with increased distance travelled at 10 minutes ($p<0.05$) but not at 24 hours post-impact. Elevated plus maze revealed that a single ACHI increased anxiety at 20 minutes in rats, with more time spent in closed arms ($p<0.05$), less time in the centre ($p<0.05$), and trending towards less time in the open arms ($p=0.11$). A single ACHI decreased spatial memory of the Y-maze novel arm at both 5 minutes ($p<0.01$) and 24 hours ($p<0.05$) post-injury, however, by 48 hours there were no differences between sham and injured rats.
Conclusions: These findings indicate that our surgery and anaesthetic free model induces transient neurobehavioral impairments similar to that seen in clinical concussion, and as such, this model may be a valuable tool in pre-clinical concussion research.

Title: Evaluation of pathological high-frequency oscillations (pHFOs) during waking and sleep behavior in post-traumatic brain injury model

Authors: *C. E. SANTANA-GOMEZ[1], G. SMITH[2], N. G. HARRIS[2], R. STABA[1]
[1]Neurol., David Geffen Sch. of Med. at UCLA, Los Angeles, CA; [2]Neurosurg., Dept. Neurosurgery, UCLA, Los Angeles, CA

Abstract: Traumatic brain injury (TBI) is a serious health problem and after a severe TBI about 50% of injured individuals will develop post-traumatic epilepsy (PTE) within their lifetime. Currently there are no treatments that prevent PTE from occurring after severe TBI, and the discovery of treatments is hindered because there are no biomarkers that predict the development of PTE. Numerous studies involving patients with epilepsy and status epilepticus animal models of chronic epilepsy show pathological high frequency oscillations (pHFOs) are associated with brain areas capable of generating seizures, but only a few have studied pHFOs during the development of epilepsy. However, results from these studies suggest pHFOs could be a biomarker of epileptogenesis. Thus, the focus of our work is to develop surgical procedures and a protocol to record and analyze EEG from cortical and hippocampal sites immediately after injury in a rat model TBI, and determine whether pHFOs appear in TBI rats that develop acute (<=7 days post-injury) and/or late (>7 days post-injury) post-traumatic seizures. TBI was induced in adult, male Sprague Dawley rats (n=19) over the left hemisphere using a fluid-percussion device. During the same surgery session, electrodes were implanted within the cortex and hippocampus ipsilateral to the injury and in the cortex contralateral to the injury. A second cohort of rats ("sham"; n=6) underwent the same surgical procedures as the TBI rats, but TBI was not induced. The electrodes were mounted in 12-hole Plastic 1 pedestal and connected to the input. EEG activity was monitored 24/7 for the first week after TBI. EEG was sampled at 2 kHz/channel and bandpass settings of 0.1-500 Hz. Matlab-based RippleLab software was used to process EEG signals and detect HFOs during episodes of slow wave sleep and waking behavior. Results indicate in those rats that survive severe TBI (13 out of 19), there is a low percentage of rats (8%) that have complications from implanting electrodes immediately after TBI in the same surgical session. The initial review of the EEG recordings found acute seizures occurred in 100%

TBI rats. Review also found HFOs in all cortical and hippocampal electrodes of TBI and sham-injured rats. Ongoing analysis will assess the spatial and temporal profile of HFOs with respect to acute and late post-traumatic seizures in TBI and sham-injury rats. Epidural and/or intracerebral recording immediately after TBI could identify electrographic biomarkers of epileptogenesis that ultimately could help in the identification of patients at risk of developing PTE.

Abstract: Information from Magnetic Resonance Imaging (MRI) can be useful for managing infrequent neurological or neuroscientific cases, provided that there are no MRI contra-indications precluding scanning. Here we report on the utility of MRI-based monitoring in two cases with rhesus macaques. In both cases the monkeys presented with subtle to mild clinical signs, were well otherwise and without a significant increase in welfare impact, hence they were identified as suitable candidates for clinical investigation, MRI-based monitoring and treatment. The first case (M1) presented with left-handed weakness contralateral to a recording chamber

over sensory motor cortex above the central sulcus. T1 and T2 weighted MRI imaging (4.7 Tesla, Bruker) identified two suspected sub-dural abscess sites. These were targeted for antibiotic treatment and either aspiration or implant modification. Thereafter the animal's hand use returned to normal. The second case (M2) presented with left-handed weakness from a different basis. T1, T2 and proton density scans identified a suspected internal cerebral haemorrhage in the acute/subacute stage (hypo-intense signal on both T1 and T2), presenting as an area of MRI signal loss. Continued MRI monitoring coincided with a return to unremarkable behaviour and a substantial reduction in the size of the affected area combined with signal resolution under which normal tissue could once again be observed. Time of flight MRI angiography identified a subdural venous drainage network and recordings were planned to avoid it. In summary, MRI assists in a precise diagnosis of cerebral events and can be a valuable addition to clinical treatment to ensure resolution.

Title: Role of amyloid precursor protein in axonal pathology

Authors: *V. LACOVICH[1], K. TEXLOVÁ[1], B. P. HEAD[2], V. POZO DEVOTO[1], M. NOVAKOVÁ[1], M. FEOLE[1], G. STOKIN[1]
[1]TAP, Intl. Clin. Res. Ctr. FNUSA-ICRC, Brno, Czech Republic; [2]Anesthesiol., VA Med. Ctr., San Diego, CA

Abstract: Several studies demonstrated an association between Traumatic Brain Injury (TBI), memory impairments and the risk of developing neurodegenerative disorders including Chronic Traumatic Encephalopathy (CTE) and Alzheimer's Disease (AD). Post-mortem TBI brains exhibit extensive axonal pathology, often in the form of diffuse axonal injury (DAI), which can be best identified by aberrant axonal accumulation of the Amyloid Precursor Protein (APP), best known for its intimate link to the pathogenesis of AD. Despite likely non-coincidental

association between TBI, CTE and AD clinically and biochemically, the mechanisms leading to aberrant accumulation of APP in response to axonal injury remain largely unknown. To elucidate the role of APP in in response to axonal injury we decided to study first the response of the axons to TBI in wildtype (WT) and APP deficient (APP KO) mice in the C57Bl/6 genetic background. More specifically, in order to produce TBI we adopted the cortical controlled impact protocol, which is a well-established mouse model of TBI. In short, reaching adulthood 1/3 of littermates underwent TBI (TBI), 1/3 of littermates underwent sham surgery of the skull (Sham), while the remaining 1/3 did not undergo any manipulation (Control). Following manipulations mice were weighted and tested on inverted grid weekly for a total of 8 weeks. This was followed by an open field test and last by the 24h fear conditioning paradigm. Mice were then sacrificed and perfused and the brains collected for immunochemical and biochemical studies. Consistent with previous studies, APP KO mice exhibited reduced body weight compared to WT littermates. On inverted grid WT control mice performed best compared to all other mice with APP KO mice demonstrating the most severe phenotype. Intriguingly, behavioral assessment of WT and APP KO mice following TBI reveals APP KO specific as well as TBI specific phenotypes. Immunohistochemically, all mice demonstrated glial response to injury in addition to severe axonal pathology. Intriguingly, APP KO mice exhibited significant compensation of APP deficiency by other APP family proteins (APLP1, APLP2) in response to TBI. Axonal pathology findings observed in the mouse model of TBI are currently being replicated using human stem cell derived neurons in a unique cell culture TBI paradigm. In summary, we here used mouse and cell culture models of TBI in an APP deficient setting to uncover novel behavioral and immunohistochemical phenotypes, which further our understanding of APP in TBI, CTE and AD.

Title: Genetic analysis of anxiety behavior following mild traumatic brain injury in *Drosophila melanogaster*

Authors: G. FORT[1], M. CHAMPAGNE[1], R. K. KELLY[1], D. MORAN[1], J. MARRIOTT[2], *A. CROCKER[2]
[2]Neurosci. Program, [1]Middlebury Col., Middlebury, VT

Abstract: Traumatic brain injuries (TBIs) contribute to increased mortality and permanent disability in the United States each year. While the effects of a major TBI are well appreciated, the effects of repeated mild TBI are only now becoming apparent. The acute and long-term consequences of mild TBI can include impaired memory, impaired movement, sleep patterns, and emotional functioning, such as anxiety and stress responses. In humans we see variations in how mTBI manifests itself both acutely and over the long term. In the fruit fly, *Drosophila melanogaster,* we also see natural variation in lifespan and sleep following mTBI. In addition, flies possess an ancient anxiety pathway which is activated following heat stress and visualized through wall-following and aggregation. This allows us to explore how mTBI alters the anxiety response in a genetically tractable organism (the fruit fly). In this pilot project we hypothesize that natural variation in mTBI anxiety behavior is driven by genetic variation in fly populations. Specifically the idea that genetic variants of small effect contribute additively to the expression of anxiety behavior. To test this we used a subset of 37 inbred fly lines of the *Drosophila* Genetic Reference Panel (DGRP), to explore the anxiety responses following mTBI. The DGRP allow us to use whole genome association mapping of loci associated with the quantitative traits being studied. This pilot study looked at 3 biological replicates of 4 conditions (mTBI + heat stress, no mTBI + heat stress, mTBI + no heat stress, no mTBI+no heat stress) for each line. This pilot project sought to establish anxiety and mTBI as a quantitative trait and examine preliminary differences in populations in anxiety, motor (negative geotaxis) and mortality rate. To quantify anxiety the following data was collected: wall-following, speed of ambulation, distance traveled in arena, number of fly interactions, and distance between flies within arena. We recorded behavior from more than 1500 animals and scored them for behavior using Noldus Ethovision software. Preliminarily, we see differences in aggregation and wall-following, suggesting that these behaviors possess genetic components influencing their differential expression between lines. In parallel to this study, we also collected whole brain RNAseq data from CantonS flies following heat stress and mTBI. Preliminary data suggests that neuropeptide like protein 4 (Nplp4) may be playing a role in anxiety behavior. Further work in this study will focus on extending phenotypic classification to all the DGRP lines as well as genetic analysis of potential association loci and coupling this with the whole brain RNAseq dataset.

Title: The influence of a nematode parasite on host serotonergic system

Authors: *D. M. ZANCAN[1], C. V. MACHADO[2], F. J. V. FUENTEALBA[2], F. C. NICOLA[2]
[1]Physiol. Dept., [2]Neurosci. Grad. Program, Univ. Federal Do Rio Grande Do Sul (UFRGS), Porto Alegre, Brazil

Abstract: Mollusks are often involved in parasite life cycles as intermediate hosts. The parasites with such life cycle usually adopt strategies to facilitate its transmitting to the definitive host. To reach this target, the parasites can cause morphologic, metabolic, and immune alterations in different organs, including the nervous system of the intermediate hosts. This study aims at evaluating whether the parasite load (*Strongyluris* sp.) and the presence of the parasitic cysts in the nervous system of the *Megalobulimus abbreviatus* modifies the serotonin level in different lobes of cerebral ganglia (CG). Adult snails were collected from two areas of 90 m apart (Barra do Ribeiro, RS, Brazil), where the animals show distinct behaviors: in the first site the snails were in a shaded area and buried, while in the site 2 they were unearthed and in a high population density. The parasite load and the 5HT immunoreactivity (ir) were compared between these two sites. The optic densitometry (O.D.) were carried out. The 5HT-ir was also analyzed among three animal groups (G, n=24), constituted as follows: absence of cysts in the central nervous ganglia (G1), animals with cysts in the suboesophageal ganglia (SUBG, G2), and cysts in both CG and SUBG (G3). The values of O.D. of 5HT-ir from different lobes of CG were analyzed with one-way ANOVA (between G1, G2, G3). The correlation coefficient (Pearson's r) between the number of cysts in animals and the O.D. of 5HT-ir from different regions of CG was performed. Differences between the mean number of cysts and the O.D. from animals of each collection site were analyzed by Student's t test ($p<0,5$). The O.D. of 5HT-ir of all the animals showed significant negative correlation with the number of parasite cysts in snails ($r=-0,83$). Both the mesocerebrum, which regulates feeding behavior in all studied pulmonate gastropod mollusks, and the procerebrum, which is thought as an associative sensorial area, showed lower means of 5-HT-ir O.D. in G3 in comparison to G1 and G2 ($p=0,017$ and $p=0,06$). The medium region of CG, through which the pathways of those lobes project towards the SUBG, showed decrease of 5HT-ir, which has significant negative correlation with the number of cysts in all the animals ($r=-0,87$). The presence of *Strongyluris* cysts in the CG of the *M. abbreviatus* leads to a

5HT-ir decrease in the medium regions of CG. However, the relationship between the decrease of 5HT-ir and the unusual behavior observed in field snails was not clear. A systematic laboratory study of the behavior of snails infected with *Strongyluris* is required. Support: CAPES

Title: Chronic *in vivo* imaging of neurovascular changes in cortex following mild traumatic brain injury

Authors: *E. WITKOWSKI[1], E. ERDENER[2], K. KILIC[2], D. BOAS[2], I. DAVISON[1]
[1]Biol., [2]Biomed. Engin., Boston Univ., Boston, MA

Abstract: From war zones to athletics to everyday falls, traumatic brain injury (TBI) is increasingly recognized as a major health concern. However, there are still no effective treatments, largely due to lack of understanding about how TBI affects the brain during the minutes to hours after injury. To characterize the nature and time course of rapid TBI-induced damage *in vivo*, we used minimally invasive imaging methods to measure neural activity and cerebral blood flow (CBF) in mouse visual cortex in a closed-skull weight drop model of mild TBI. Chronic cranial windows allowed for repeated measurements at high temporal and spatial resolution. Multiphoton Ca^{2+} imaging revealed a dichotomy in effects on neural activity where most layer 2/3 excitatory cells had significantly reduced spontaneous activity compared to pre-injury levels, but a minority of the cells became hyperactivated and showed repetitive long-duration Ca^{2+} transients that appeared 30-60 minutes after mild TBI. These data indicate pronounced disruption of normal cortical function beginning immediately after injury, including prolonged rises in intracellular Ca^{2+} that may contribute to long-term pathology. Given the extremely high energetic demands of brain tissue and the tight coupling of neural and vascular function, we also examined corresponding changes in cerebral blood flow after mild TBI. We used laser speckle microscopy and optical coherence tomography to measure CBF *in vivo* throughout a large portion of the vascular tree at capillary-level resolution. Speckle data showed a ~40% drop in CBF in the superficial pial vessels, and tomography revealed a similar reduction in capillaries located ~250 um below the surface in layer 2/3 beginning within 20 minutes of

mild TBI. Capillary-level changes were due to a striking increase in extended 'flow stalls' on the day of injury. The majority of CBF recovered within 2-3 hours, though some animals showed reduced flow lasting at least 3 days. The pronounced, long-lasting decrease in CBF is likely to cause energetic stress that may further contribute to eventual neuropathology. Future experiments will examine the causal relationship between effects on neural activity and CBF after mild TBI, providing valuable insight into what changes are occurring and when, both of which are critical for developing new treatment strategies.

Abstract: In Traumatic Brain Injury (TBI) the initial injury phase is followed by a secondary phase as inflammatory events in the brain contribute to widespread cell death and neurodegeneration. To study the mechanisms that mediate TBI pathology, we developed a Drosophila head-specific model for TBI, where well-controlled, non-penetrating strikes are delivered to unanesthetized flies. This assay recapitulates many TBI phenotypes, including increased mortality, impaired motor control, impaired sleep, and increased neuronal cell death. We detect a strong sterile immune response as genes involved in innate immunity are transiently up-regulated 24 hours after TBI, including those involved in proteolysis and activation of antibacterial, antifungal and antiviral defense responses as well as activation of apoptotic, autophagic and phagocytotic pathways. TBI-dependent behavioral changes are dependent on the master immune regulator NF-KB. These studies validate a new model for TBI in Drosophila and

identify glial immune pathways as candidate mediators of TBI effects. This study is funded by a Discovery Award from the Peer Reviewed Medical Research Program (W81XWH-16-1-0166)

Title: Noise exposure at different developmental ages can induce different short and long term habituation memory alterations. Correlation with hippocampal oxidative state

Authors: S. J. MOLINA[1], M. RODRIGUEZ GONZÁLEZ[2], G. E. BUJÁN[2], F. CAPANI[3], *L. R. GUELMAN[2,4]
[1]Consejo Nacional de Inv. Científicas y Técnicas. Univ. de Buenos Aires, CEFYBO (UBA-CONICET), Buenos Aires, Argentina; [2]Univ. De Buenos Aires, Facultad De Medicina, Buenos Aires, Argentina; [3]Inst. Inv. Cardiológicas, ININCA (UBA-CONICET), Buenos Aires, Argentina; [4]CEFyBO (UBA-CONICET), Buenos Aires, Argentina

Abstract: We have previously shown that exposure of immature rats to moderate noise levels was able to induce hippocampus (HC)-related behavioral and molecular alterations during the peri-adolescence period. The housing of these animals in an enriched environment (EE) reversed most of these alterations. However, comparative data of behavioral performances between animals evaluated at different intervals post-training (short and long-term) was not obtained yet.Thus, the aim of the present work was to test behavioral parameters of rats exposed to noise at two early developmental ages and at different intervals post training in an open field device (OF), as well as to evaluate a potential correlation with differences in HC oxidative markers (thioredoxins Trx1 and Trx2). In addition, housing in an EE was also studied to evaluate the possible reversal of these changes.Male Wistar rats of 7 and 15 days of age (N7 and N15) were exposed to noise (95-97 dB) for 2 hours. After weaning, rats were transferred to an EE, consisting of toys, a wheel, plastic tunnels and ramps, whereas others were placed in standard cages. After one week, OF task was performed to evaluate short and long-term habituation memory and the levels of Trx1and Trx2 were tested through Western blot experiments. Results showed no differences in short-term memory of N7 rats and a decrease in long-term memory when compared to control group. On the contrary, N15 animals showed a decrease in short-term

memory without significant changes in long-term memory. Interestingly, short and long-term alterations were fully prevented when animals were housed in EE. Furthermore, western blot experiments showed that N7 and N15 rats had an increase in hippocampal Trx1 levels that was reversed when animals were housed in EE. Finally, no significant changes were observed in Trx2 levels in either group.In conclusion, these findings suggest that rats exposed to noise at different developmental ages might be differentially affected in their behavioral performance. On the other hand, Trx1 seemed to be more sensitive to the effects of noise exposure than Trx2. As differences between behavioral performances were observed but similar results in Trx1and Trx2 levels were found among groups, it could be suggested that these parameters do not seem to be correlated. Moreover, EE was an effective strategy to reverse all the behavioral and molecular alterations found in both groups, suggesting that visual, social and physical stimulation during the peri-adolescence period could be an effective strategy to reverse HC-related behavioral and molecular changes.

Abstract: Exposure to blast shockwave often leads to traumatic brain injury (TBI) in military and civilian populations. As air-filled structures and directly exposed to the surrounding air, the unprotected ears are among the most frequently damaged sites during blast exposure. Moreover, a previous study revealed a significant association between tympanic membrane perforation and

traumatic brain injury in victims of blast exposure (Xydakis et al., 2007). However, little is known about how and the extent to which blast energy impacts the central nervous system via the external ear canal. To fill this important knowledge gap, we developed a novel model showing that exposure to a single blast shockwave delivered into the external ear canal caused brain injuries in rats. Adult female Long-Evans rats were anesthetized and exposed to a single blast of 40PSI (275kPa, 80% of the lethal intensity determined in Sandlin et al., 2018) or 0PSI (sham condition) delivered to the left ear. Brain tissues were harvested for histology at 6 hours, 1, 3, 7, 14, 30 and 60 days after blast exposure. Preliminary immunohistochemistry data showed an extensive activation of microglia, demonstrated by a significant increase in IBa1+ cells with activated morphology, in the brain stem regions ipsilateral to the blasted ear. Caspase-3 and NeuN double-immunostained cells were also detected in these regions, indicating blast-induced neuron death. Open field tests further showed that the blasted rats exhibited signs of anxiety compared to rats in the sham condition. These results suggested that blast shockwave via the ear canal not only damages the inner ear hair cells as we showed previously, but also causes injuries in the brain. Ongoing studies will further characterize the biomarkers of the blast-induced TBI and investigate the underlying mechanisms for developing prevention and treatment countermeasures. (T.L., N.L and L.W. made equal contribution)

Abstract: Mild traumatic brain injury (mTBI) represents a major public health concern due to persistent behavioral and neurological effects. The mechanisms by which mTBI lead to such effects are largely attributable to an hyperacute indiscriminate glutamate release. Cerebral

microdialysis studies in rodents reported a peak of extracellular glutamate 5 minutes after injury. Microdialysis has the advantage of being one of the few techniques allowing the quantification of neurotransmitters *in vivo* and at different time points following injury without sacrificing the animal. In addition to such techniques, translational animal injury models are needed to better understand the effects of mTBI. The Wayne State weight drop model allows the induction of an impact on the skull of a subject unrestrained by the fall of a weight, which allows rapid acceleration and deceleration of the head and torso, an essential feature in human craniocerebral trauma and a factor that is missing from other existing animal mTBI models. The aim of our study was to develop a rat model of mTBI, based on the Wayne State model, which incorporates the microdialysis technique to study extracellular glutamate changes over time *in vivo* following a mTBI. Glutamate was harvested from the extracellular fluid (ECF) using microdialysis before and after a trauma inflicted by the Wayne State model or sham and analyzed by high-performance liquid chromatography. The measurements were performed in the hippocampus as this region contains a high density of glutamatergic receptors making it vulnerable to the excitotoxicity generated by the glutamate release. Brains were harvested following mTBI or sham and processed for histological verification of probe placement and injury. ECF glutamate concentrations in the rat hippocampus were increased immediately after mTBI as compared with the sham procedure. Our modified weight drop model thus induced changes in ECF glutamate concentrations that are representative of the peak previously reported. Given the simplistic nature of the Wayne State model, and the relevant ECF glutamate concentration changes measured using microdialysis, this combined rat model of mTBI and microdialysis could provide researchers with a reliable and translational model of mTBI that could be used in a wide variety of therapeutical studies.

Title: Microstructural and ultrastructural brain injury in a preclinical model of acquired symptomatic hydrocephalus: Exploring the spectrum of cilia injury

Authors: *T. R. YELLOWHAIR[1], J. NEWVILLE[1], C. SHROCK[2], J. MAXWELL[3], S. ROBINSON[4], L. JANTZIE[1]
[1]Dept. of Pediatrics and Neurosciences, Univ. of New Mexico Sch. of Med., Albuquerque, NM; [2]Johns Hopkins Sch. of Med., Baltimore, MD; [3]Univ. of New Mexico Hosp., Albuquerque, NM; [4]Neurosurg., Johns Hopkins Univ., Baltimore, MD

Abstract: Acquired symptomatic hydrocephalus (ASH), typically marked by ventriculomegaly and elevated intracranial pressure, is a serious problem worldwide. Currently, the only treatment available for ASH is surgical intervention to divert cerebrospinal fluid, and many people with ASH do not have access to safe and timely neurosurgery. Shunts, the most common intervention, are prone to malfunction and infection. Clinical studies suggest a strong correlation between systemic inflammation and the propensity for ASH in the setting of hemorrhagic brain injury. To facilitate improved understanding of the pathophysiology of ASH in the context of intraventricular hemorrhage (IVH) and systemic inflammation, we created a novel preclinical model. We tested the hypothesis that IVH plus systemic inflammation would induce ventriculomegaly, injury to ependymal motile cilia (EMC) and result in multiple diffusion tensor imaging (DTI) abnormalities. On postnatal days 21 (P21) and P23, Sprague Dawley rats received an intraperitoneal injection of 3mg/kg lipopolysaccharide (LPS) or saline. On P25, under anesthesia, rats received a bilateral intraventricular injection of either 50µl lysed littermate red blood cells (IVH) or phosphate buffered saline (PBS). On P45 rats were sedated and perfused for *ex vivo* magnetic resonance imaging (MRI) (n=3-6/group) on a Bruker 7T BioSpec 70/30 Ultra Shield Refrigerated nuclear system or for scanning electron microscopy (SEM) using a Zeiss Sigma 300 field scanning electron microscope. Ventricular volume was calculated on T2 structural imaging and fractional anisotropy (FA) analyzed in the corpus callosum on DTI. Group differences were compared with a Student's t-test with $p<0.05$ indicating statistical significance. Compared to saline-PBS treated rats, LPS-IVH rats have significantly reduced FA in the corpus callosum ($p=0.0003$) consistent with microstructural white matter injury and reduced anatomical connectivity. LPS-IVH rats also have significantly larger ventricular volumes than saline-PBS rats ($p=0.01$). SEM revealed LPS-IVH rats have denudated, matted, and patchy EMC compared to saline-PBS rats. Taken together, these data support the hypothesis of widespread structural abnormalities and ventriculomegaly in a novel rat model of ASH. Further stratification of the brain injury associated with ASH is necessary to facilitate the development of less invasive therapeutic strategies, and to improve long-term outcomes for people with ASH.

Title: Neonatal erythropoietin and melatonin as non-surgical combination therapy prevents posthemorrhagic hydrocephalus of prematurity in rats

Authors: *C. L. SHROCK[1], T. R. YELLOWHAIR[2], J. C. NEWVILLE[2], F. S. CONTEH[1], A. Y. OPPONG[1], J. R. MAXWELL[2], F. J. NORTHINGTON[3], L. L. JANTZIE[2], S. ROBINSON[1]

Abstract: Posthemorrhagic hydrocephalus of prematurity (PHHP) is a serious global problem. When available, surgery, the only treatment, has limited long-term success. A safe, effective nonsurgical therapy is needed. Very preterm infants are prone to intraventricular hemorrhage (IVH), particularly when exposed to chorioamnionitis (CAM). Erythropoietin (EPO) and melatonin (MLT) are safe, endogenous cytokines currently in separate neonatal clinical trials. Using our rat PHHP model we hypothesized that combined EPO and MLT can prevent progressive macrocephaly (PMC) and ventriculomegaly (VM), phenotypic hallmarks of PHHP. The transcription factor yes-associated protein (YAP) promotes specification of radial glial cells into ependymal cells. We hypothesized that systemic inflammation lowers YAP and hinders radial glial cell differentiation into ependymal cells, contributing to PHHP. Pregnant rats underwent laparotomy on embryonic day 18 with transient uterine artery occlusion for 60 min and intra-amniotic sac lipopolysaccharide injection. Shams underwent laparotomy for 60 min. On postnatal day 1 (P1), CAM and sham pups were randomized to IVH (bilateral injection of littermate lysed red blood cells) or sterile vehicle (veh, phosphate buffer saline) injection. On P2, CAM-IVH pups were randomized to EPO (2000U/kg ip P2-5, P7, and P9) plus MLT (20 mg/kg ip P2-P10) or vehicle. Rats were coded, and observers were blinded to group. Daily intra-aural distance (IAD) was measured as a surrogate for head circumference, and neurodevelopmental testing was performed. Ventricular volumes and microstructural abnormalities were analyzed with *ex vivo* MRI at P21. qPCR was used to quantify P15 YAP mRNA levels. Significance was calculated with two-way ANOVA with Bonferroni correction, and Wilcoxon rank sum, with $p<0.05$ significant. Neonatal EPO+MLT prevented macrocephaly and mitigated developmental delay in treated CAM-IVH rats, compared to vehicle-treated CAM-IVH rats (n=17-24, p=0.026). EPO+MLT treatment also significantly reduced P21 VM on MRI (Wilcoxon rank sum test, p=0.005). Reduction of YAP mRNA levels occurred in vehicle-treated CAM-IVH rats (n=4),

compared to shams (n=7, p=<0.001) and EPO+MLT treated CAM-IVH rats (n=5, p=0.036), suggesting that EPO+MLT prevents YAP loss. Diffusion tensor imaging (DTI) showed that vehicle-treated CAM-IVH rats had widespread loss of microstructural integrity which was prevented with EPO+MLT (all p<0.05). These results suggest that sustained, systemic, combined neonatal EPO and MLT treatment prevents multiple hallmarks of PHHP, consistent with a clinically-viable, non-surgical treatment strategy.

Title: Long term neuromodulation after experimental TBI results in rebound hyperexcitability indicated by enhanced fMRI activation and altered functional connectivity

Authors: *A. PAYDAR, J. S. SCHOENFIELD, E. YAN, A. KAMALI, T. KOCHAN, N. G. HARRIS
UCLA, Dept. of Neurosurgery, BIRC, Los Angeles, CA

Abstract: Functional disconnection and hyperconnectivity occur after traumatic brain injury, both clinically and in the rat model of CCI injury. We hypothesize that homotopic, cortical regions remote from the primary injury site develop hyperexcitability after injury, resulting in increased trans-hemispheric inhibition that prevents reorganization of the primary, injured hemisphere. This is supported by the finding that recovery of affected forelimb function can occur from early but not delayed temporary silencing of the contralesional cortex. To determine the effect of long term silencing of contralesional cortex on reorganization of brain circuits, we acquired forelimb-evoked-fMRI and resting state fMRI at 4 and 8wks post-injury after continuous intracortical infusion of muscimol into the contralesional, sensory-motor cortex homotopic to the primary injury site for 4 wks immediately following CCI injury and compared the data to vehicle-infused, injured (n=6 vs 5) and sham rats (n=2).Data were analyzed for forelimb-evoked brain activation and for network-based functional connectivity (fc). Despite recording a detrimental effect of muscimol on limb function opposite the muscimol-injected cortex at 7 days post-injury using a ladder behavioral task (indicating brain silencing), evoked

activation from the same forelimb 3wks later indicated the development of significant hyperexcitability (P&lt0.001, z&gt2.3 cluster-corrected), but not at 8wks post injury, 4wks following the removal of muscimol. There was no change in brain activation within the ipsilesional hemisphere evoked by the injury-affected limb at either time-point, indicating that the period of silencing was not long enough to enhance injured brain function, and/or the subsequent rebalancing of function toward hyperexcitation nulled any potentially positive effects. Hyperexcitability after TBI is likely to impact neural circuit and therefore we next determined the network topography that characterized the muscimol-induced hyperexcitability toward providing a network level understanding of TBI-induced hyperexcitability. We found a decrease in fc bilateral within and between the cortical hemispheres 4wks after chronic muscimol infusion, indicating cortical isolation (P&lt0.05, FDR-corrected q=0.05). This was accompanied by a significant, bilateral increase in cross-brain, cortico-subcortical fc, possibly indicating circuit-level refinement consistent with the enhanced evoked activation of the muscimol-affected limb. Data indicate that chronic neuromodulation after TBI may result in complex temporal effects, and that shorter periods may be more optimal.

Abstract: Traumatic brain injury is one of the most prevalent risks of death and disability in young people, with about 1.6 million reported per year in the US. Some of the most devastating injuries from brain trauma are the rupturing of arteries between the dura and the skull in an epidural hematoma, as well as tears in emissary veins, resulting in hemorrhagic contusions seen in subdural hematomas. This accumulation of blood can squeeze and increase pressure on the brain. TBI can also cause structural and neurological damage, often seen in athletes who suffer

repeated injury. Here, we introduce a novel application of our previously developed imaging modality, quantitative ultra-short time-to-echo contrast-enhanced (QUTE-CE) MRI using FDA-approved superaramagnetic iron oxide nanoparticle (SPION) ferumoxytol to image blood accumulation and to detect cerebral blood volume (CBV) changes in mild TBI animals. Sprague Dawley rats were divided into two groups: control group and TBI group which received 3 mild hits for 3 continuous days. Rats in TBI group underwent QUTE-CE MRI before mild hit and immediately after each hit for 1.5 hours while control group underwent the same imaging sessions without traumatic brain injury. Quantitative global CBV map and regional CBV were calculated from QUTE-CE MRI and a 174-region rat brain atlas. This study demonstrates that QUTE-CE MRI is sensitive to detect CBV changes in mild TBI rats.
Conflict of interest QUTE-CE MRI is the subject of a patent application assigned toNortheastern University (inventors Codi A. Gharagouzloo and SrinivasSridhar).

Title: Traumatic brain injury: Characterization of a cryoinjury model using MRI and histopathology

Authors: *V. SHENOY[1], H. BATTAPADY[1], L. LOOSE[1], S. JOHNSON[1], D. LOSE[1], P. HARRIS[1], S. LUNN[1], B. D. TRAPP[2]
[1]Renovo Neural, Cleveland, OH; [2]Cleveland Clin. Fndtn, Cleveland, OH

Abstract: Traumatic brain injury (TBI) elicits an inflammatory response in the CNS that involves both resident and peripheral immune cells. In this pilot study, we characterize a cryoinjury animal model of TBI using MRI and histopathology, to study its pathogenesis and recovery.
10-week-old C57Bl/6J mice were used for cryoinjury. Cryoinjury was performed as described previously. Previous studies have shown inhibition of erythropoietin (EPO) activity worsens severity of neuronal injury, suggesting its involvement in an intrinsic neuronal repair pathway. Study groups: TBI only (n=3), TBI+EPO (n=3). A separate cohort of n=3 mice were used to study reproducibility of cryoinjury procedure. rhEPO at a dose of 5000 U/kg body weight was administered IP at 6 hours and at 3 and 7 days(d) after cryoinjury TBI. 2D MR images were acquired on a 7T Bruker-Biospec MRI at 1d, 2d, 3d, and 6d post injury. T2w MRI to quantify

total brain volume and abnormal volume (AV) (segmented into 2 categories: “hypo-intense”(HypoBV) and “hyper-intense”(HypreAV)) due to TBI; Brains from TBI animals perfused at day 3 post-TBI were embedded in paraffin. LFB staining was used to delineate lesion boundaries, adjacent Iba1-stained sections were used to quantify area covered by microglia, neuronal cell loss and degeration was quantified using NeuN stain and silver stain respectively. Cryoinjury model of TBI in mice shows high reproducibility in achieving consistent focal cortical lesions with a 100% survival rate. MRI can detect the timeline for recovery after cryoinjury, day 1 through day 6. By day 6 total abnormal MRI volume is reduced by 66% compared to day 1. EPO treatment reduces AV in mice after TBI compared to TBI only controls, with maximum reduction of 10% seen in EPO group at day 3 post TBI. HypoAV is consistently higher in EPO treated animals. HyperAV is reduced in the EPO group compared to TBI only control, with a maximum reduction of 25% seen at day3. HyperAV may be suggestive of inflammation and edema in this region. The area covered by IBA1 positive microglia in peri-lesion area ipsilateral to TBI in the cortex of EPO treated mice is significantly increased by 17% ($p<0.01$) compared to the contralateral control side and by 25% ($p<0.003$) compared to TBI only control group. Although we see a reduction in hyperAV in the EPO treated animals, there is an increase in IBA1 positive microglia cells in the peri-lesion region as shown by histology. This therapeutic significance of EPO may suggest neuroprotective functions of the microglia. These results suggest that this mouse cryoinjury model and the MRI and histopathology metrics can be a valuable tool for pre-clinical assessment of drugs to treat Traumatic Brain Injury.

Title: Increased rightward frontal alpha asymmetry after mild traumatic brain injury

Authors: *V. KUUSINEN[1,2], L. SUN[1,3], J. PERÄKYLÄ[1,2], K. H. OGAWA[4], K. M. HARTIKAINEN[1,2]
[1]Behavioral Neurol. Res. Unit, Tampere, Finland; [2]Fac. of Med. and Life Sci., Univ. of Tampere, Tampere, Finland; [3]Turku PET Ctr., Turku, Finland; [4]Dept. of Psychology, St. Mary's Col. of California, Moraga, CA

Abstract: Frontal rightward EEG alpha asymmetry (FAA) has been linked with depression or vulnerability to it (Thibodeau et al., 2006). Some patients with mild traumatic brain injury (mTBI) suffer from prolonged post-concussion symptoms, including depressive symptoms. In line with potential vulnerability to depression, we previously reported increased attention to threat-related emotional stimuli in subjects with history of mTBI (Mäki-Marttunen et al., 2015). In this exploratory study, we investigated whether patients with previous mTBI would show increased FAA.
We studied 26 patients (14 males, 12 females, mean age = 40.5 years) with previous mTBI who were on average 20 months post-injury and 17 control subjects (7 males, 10 females, mean age = 40.3 years) with no history of head injury. The mTBI group was further divided into symptomatic (n = 14, still reporting any post-concussion related symptoms) and non-symptomatic (n = 12) groups based on the Rivermead Post-Concussion Symptoms Questionnaire (King et al., 1995). Depressive symptoms were also assessed using the Beck Depression Inventory (Beck et al., 1996). Participants performed a computer-based executive function task containing emotional stimuli, i.e. Executive-reaction time test, while their EEG was recorded. Both task-related FAA and task-performance were assessed.
The mTBI group showed significantly increased frontal alpha asymmetry compared to the control group. Excluding participants with depressive symptoms did not change the result. When mTBI group was divided into symptomatic and non-symptomatic subgroups and compared to Controls, group difference in alpha asymmetry was close to significance ($p = 0.053$), but post-hoc tests yielded no further significance. There was also a Group x Emotion interaction, where post-hoc analysis showed increased FAA in context of emotional stimuli in symptomatic mTBI group and in context of neutral stimuli in non-symptomatic mTBI group. No effect of emotional stimuli on alpha asymmetry was seen in Controls. No differences in cognitive performance were observed between groups.
In conclusion, we detected increased rightward frontal alpha asymmetry in patients with previous mild traumatic brain injury. Pronounced alpha asymmetry in context of emotional stimuli in symptomatic mTBI patients may reflect increased tendency to process negative emotion, which may further predispose to emotional symptoms, like depression. FAA during a cognitive task

with threat-related stimuli has been suggested to reflect impact of neuromodulation on limbic circuitries (Sun et al., 2017) and may well have potential as a biomarker of altered emotional processing after mTBI.

Title: Investigation of the relationship of vocal-biomarker features and fMRI ROI time-series for the diagnosis of traumatic brain injury (TBI) in humans

Authors: *D. E. STURIM, J. WILLIAMSON, G. CICCARELLI, Y. GWON, 0242, T. QUATIERI
MIT Lincoln Lab., Lexington, MA

Abstract: In this work, we investigate the relationship between vocal eigen-features and the fMRI time-series of the BOLD response in regions of interest (ROI). We examine correlations between vocal features and the fMRI ROI time-series. Further investigation explores correlations between vocal features and the fMRI ROI to ROI connectivity measures. Initial results indicate relationships between vocal features and brain ROIs that may show which components of the neural speech networks effected by traumatic brain injury (TBI).
The data used for this study was collected by Purdue University on 32 high school athletes over the entirety of a sports season (Talavage, et al., 2014), and includes fMRI measurements made pre-season, in-season, and postseason. The athletes are 25 male football players and 7 female soccer players. The Immediate Post-Concussion Assessment and Cognitive Testing suite (ImPACT) was used as a means of assessing cognitive performance (Broglio, Ferrara, Macciocchi, Baumgartner, & Elliott, 2007). The test is made up of six sections, which measure verbal memory, visual memory, visual motor speed, reaction time, impulse control, and a total symptom composite. Using each test, a threshold is set for a change in cognitive performance. The threshold for each test is defined as a decline from baseline that exceeds one standard deviation, where the standard deviation is computed over the change from baseline across all subjects' test scores.
Time-series data are derived from resting state fMRI scans of the subjects. The pre-processing of the resting state fMRI and accompanying structural MRI data (for Atlas registration) was performed with the toolkit CONN (Whitfield-Gabrieli & Nieto-Castanon, 2012). Functional connectivity was generated using cortical and sub-cortical atlas registrations.

Our results are showing relatively high correlations between the vocal features and three regions of the brain, 1) Inferior Frontal Gyrus pars triangularis, 2) Superior Temporal Gyrus posterior division and, 3) Supramarginal Gyrus posterior division.

Hosp. of Liège, Liege, Belgium; [7]Univ. of Wisconsin, Madison, WI

Abstract: INTRODUCTION In Unresponsive Wakefulness Syndrome (UWS) patients Transcranial Magnetic Stimulation (TMS) evokes an EEG potential (TEP) characterized by a sleep-like, positive-negative slow wave, a phenomenon previously observed during physiological non-rapid eye movement (NREM) sleep, in which cortical neurons become bistable and tend to fall into a silent OFF period upon receiving an input. Here we firstly test whether TEPs in UWS patients are characterized by the hallmarks of bistability. Then, we assess the hypothesis that the presence of OFF-periods may disrupt causality and complexity in the cortex of UWS patients by

means of the phase-locking factor (PLF) and the perturbational complexity index (PCI), respectively. METHODS TEPs were recorded in 16 UWS patients, in 20 awake healthy subjects and 8 during NREM sleep targeting frontal and parietal areas. To assess the presence of cortical OFF-periods we measured the amplitude of TEPs filtered below 4 Hz and the high frequency (>20 Hz) suppression by means of time-frequency spectra decomposition. PLF was calculated after filtering trials above 8 Hz. Last significant time point was considered assuming a Rayleigh distribution of the baseline values and setting the statistical threshold at $\alpha<0.05$. PCI were calculated applying the automatic procedure described in (casali, casarotto). Specifically, given the temporal evolution of PCI, we measured the first time point in which PCI reached its maximum. RESULTS TEPs recorded in UWS patients differed from the waveforms obtained in healthy wakefulness but were similar to the responses obtained in healthy subjects during NREM sleep, which are characterized by a large positive-negative deflection associated with a significant suppression of high-frequency EEG power, reflecting a cortical OFF-period. Moreover, compared to healthy wakefulness, TEPs recorded in UWS patients were characterized by an early drop of PLF below significance level. Slow-wave amplitude, suppression of high frequency power and phase-locking duration were significantly correlated. Considering the first time point in which PCI reached its maximum, we found that the build-up of complexity in UWS patients was significantly shorter (Wilcoxon ranksum test, $p<0.01$) than healthy awake subjects and was significantly correlated with the timing of the high frequency suppression and the phase-locking duration. CONCLUSIONS Our results suggest that the slow waves evoked by TMS in UWS patients may be the EEG reflection of a cortical OFF-period that disrupts deterministic activity patterns in response to a stimulus and the overall brain complexity, a key theoretical requirement for consciousness.

Title: Elevated levels of BNDF, depression, anxiety, and stress following mild traumatic brain injury

Authors: *T. SUSA[1], R. BRANDT[2], K. J. KANGAS[2], C. BAMMERT[2], E. N. OTTEM[3], M. T. MOORE[4], J. M. CARLSON[5]

Abstract: Brain derived neurotrophic factor (BDNF) is an important protein involved in neuronal survival, synaptic plasticity, and stress reactivity. In particular, BDNF levels are heightened under conditions of stress and are altered following traumatic brain injury. BDNF levels can be reliably obtained in blood serum. Recently, it has been discovered that BDNF can also be measured in human (and non-human) saliva. However, the relationship between serum and salivary BDNF is poorly understood—especially in relation to alterations in BDNF levels following mild traumatic brain injury (mTBI). This study aimed to bridge this gap by collecting BDNF from both serum and saliva in a sample of 44 collegiate studente student athletes. Half of the participants (n = 22) were recently cleared to return to play after experiencing a sports-related concussion. The other half of participants (n = 22), had not experienced a concussion within the past year and were matched on age, sex, and sport. To assess participants' stress-related affective symptoms, the depression, anxiety, and stress survey (DASS) was administered. Saliva samples were collected using a passive drool method, 2-4 ml of saliva was collected per participant. Five ml blood samples were collected by a trained phlebotomist. All samples were aliquoted and centrifuged for their respective times and then stored at -80 degrees Celsius until further handling. BDNF levels were analyzed with a commercial ELISA kit in duplicate with standard curve R^2 values of .992, and .995 for the salivary and serum samples respectively. Levels of depression, anxiety, and stress were all elevated in the concussion, relative to the control, group. When controlling for these affective variables, serum BDNF was elevated in the concussion group. However, there was no difference in salivary BDNF when controlling for affective variables and time of sample. Furthermore, BDNF levels were not correlated across serum and saliva samples—suggesting that salivary BDNF is not a reliable substitute for serum BDNF. In sum, the results suggest that concussions are is associated with elevated levels of serum, but not salivary, BDNF as well as heightened levels of depression, anxiety, and stress.

(BASIC), UCSF, San Francisco, CA; [7]Professor of Radiology & Bioengineering, Univ. of California San Francisco, San Francisco, CA; [8]Univ. of Florida, Gainesville, FL; [9]Virginia Commonwealth Univ., Richmond, VA; [10]Univ. of Pittsburgh, Pittsburgh, PA; [11]UCSF, San francisco, CA

Abstract: Clinical research and management of traumatic brain injury (TBI) would greatly benefit from the development of diagnostic and prognostic blood biomarkers. The FDA recently approved protein biomarkers for TBI (GFAP, UCHL1) as diagnostic biomarkers to aid in the evaluation of mild TBI, however, there are currently no prognostic biomarkers available. This study aimed to assess the prognostic potential of candidate brain injury markers (GFAP, UCHL1, NFL, Tau) and inflammatory cytokines (IL-6, IL-10, TNF-alpha) for outcome after TBI. Plasma blood samples were collected from TBI subjects enrolled in the TRACK-TBI Pilot Study at three Level I academic medical centers, within 24 hours of injury. Biomarker assays were performed on the SIMOA HD-1 platform (Quanterix, Lexington, MA) using the Neurology 4-plex A and the Cytokine 3-plex A kits (n=53). Outcome was assessed at 6 months post-injury using the Glasgow Outcome Scale-Extended (GOSE) (n=21). Head computed tomography (CT) scans were classified based on the presence or absence of traumatic intracranial CT abnormalities (n=53). Logistic regression and area under the receiver operator curve (AUC) analyses revealed that the four brain-injury proteins combined (GFAP, UCHL1, NFL, Tau) had excellent discriminative ability for presence/absence of traumatic intracranial abnormality (AUC=0.87.) The brain injury proteins were poorly informative with regards to 6 month full recovery (GOSE=8, AUC=0.66). When all inflammatory biomarkers (IL-6, IL-10, TNF-alpha) were assessed together, they provided prognostic information for 6 month full recovery (GOSE=8, AUC=0.72). The combination of brain-injury proteins and inflammatory cytokines provided excellent prognostic information with regards to 6 month full recovery (GOSE=8, AUC=0.89). These results suggest that the brain injury protein biomarkers have diagnostic potential while the inflammatory biomarkers show potential to add prognostic information for TBI biomarkers. Further study of the longitudinal changes in multiple inflammatory cytokines and their relation to varying clinical outcomes in a larger cohort, may improve prognostic modeling after TBI and impact clinical practice and research.

Title: Sleep-wake disturbances following brain injury and relation to outcome

Authors: *S. N. HOWELL[1], G. S. GRIESBACH[2]
[1]Clin. Res., Ctr. for Neuro Skills, Irving, TX; [2]Clin. Res., Ctr. for Neuro Skills, Encino, CA

Abstract: Objective: To investigate the impact of sleep-wake disturbances (SWD) on cognitive function and quality of life measures following brain injury. Sex differences were investigated. **Methods:** Adult TBI (n=14) and stroke (n=28) patients were assessed for SWD via overnight polysomnography. The mean age was 49.3 ± 2 years and mean latency from injury was 115 ± 15 days. Sleep measures included total sleep time (TST), sleep and REM latency, percent time in sleep stages, apnea/hypopnea index (AHI), wake after sleep onset (WASO), and arousal index. Hormone levels were analyzed within 10 days of PSG. The primary outcome measures were: Montreal Cognitive Assessment (MoCA), Trails, Beck Depression Inventory (BDI-II), Neuro-QoL and Mayo Portland Adaptability Inventory (MPAI).
Results: Analysis of stroke data showed a negative correlation between REM latency and the MPAI ($p<.05$). For female stroke patients, there was a negative correlation between N2 sleep and the MPAI ($p<.01$), while males had significantly higher AHI ($F(1,19)=5.401$, $p<.05$). Percent time spent in REM sleep was positively correlated with IGF-1 levels ($p<.05$). For the TBI population, females spent a higher percentage of time in slow wave sleep (SWS) ($F(1,9)=5.688$, $p<.05$) and less time in REM ($F(1,9)=14.344$, $p<.01$). Females also had significantly higher latencies to REM sleep ($F(1,9)=6.753$, $p<.05$) and scored higher on subjective levels of anxiety, fatigue, and sleep disturbance ($p<.05$). Daytime sleepiness was associated with age ($p<.01$). Age was also positively correlated with the amount of time spent in N2 ($p<.001$) with a corresponding negative correlation with SWS ($p<.05$). Percent time spent in REM was positively correlated with scores on the MoCA ($p<.01$) and Trails ($p<.05$). WASO was also trending towards a negative correlation with MoCA scores ($p=.07$). Overall, 50% of stroke and 38% of TBI patients had sleep apnea. For TBI patients, apnea was not significantly correlated with BMI, which could be indicative of respiratory dysregulation driven by TBI-related autonomic disturbances.
Conclusion: Female patients were more likely to report subjective disturbances in sleep and females with TBI show significant impairments in REM sleep, which is critical for learning and memory. Sleep disturbances were associated with poorer cognitive performance and may ultimately affect outcome.

Title: Does motor memory usage change in concussed individuals performing a sensorimotor adaptation task?

Authors: *D. LANTAGNE[1], L. A. MROTEK[1], S. A. BEARDSLEY[1], D. G. THOMAS[4], D. LEIGH[2], S. I. AHAMED[3], R. A. SCHEIDT[1,5,6]
[1]Biomed. Engin., [2]Exercise Sci., [3]Mathematics Statistics and Computer Sci., Marquette Univ., Milwaukee, WI; [4]Pediatrics, [5]Med. Col. of Wisconsin, Milwaukee, WI; [6]Northwestern Univ., Chicago, IL

Abstract: We examined kinematic errors during practice of goal-directed reaching against unpredictable spring-like loads to quantify the impact of concussion on sensorimotor memories used in implicit learning. Subjects included 20 healthy and 11 concussed college students; each participated in four experimental sessions where they grasped the handle of a horizontal-planar robot while reaching out-and-back to a visual target in the sagittal plane. Sessions: < 100 hours post injury ("Time 0" T_0 for non-concussed individuals); return-to-play (RTP) date (T_0 + 10 days for healthy); +3 and +6 months post injury or T_0. In each session, subjects performed 20 practice reaches with concurrent visual feedback of hand motion. This allowed them to learn the general task requirements. They then performed 200 trials without visual feedback against a spring-like load that changed randomly between trials. This allowed evaluation of the sensorimotor memories used in implicit learning of environmental loads, as well as kinematic performance variables including reach accuracy and target capture time. We assessed concussion symptoms using self-reporting (SCAT-3). We also assessed cognition via CogState Research II computerized testing, which reports performance on executive function, psychomotor function, paired associative learning, attention, visual learning, and declarative working memory. On the first day of testing, we found considerable heterogeneity within the group of concussed individuals; some reported more symptoms than others. In the concussed group for the reaching task, the method by which subjects predicted the next trial's spring load based on the weighted sum of the previous load and reach error changed between the first and second session, but this measure did not change in the Healthy group . This trial-by-trial load prediction reflects a subject's memory integration process as derived from systems identification of memory-based sensorimotor adaptation (Judkins and Scheidt, 2014). We conclude that concussion does indeed

impact how motor memories contribute to the predictive compensation for uncertain environmental loads during sensorimotor adaptation.

Abstract: There is an unmet need for reliable and minimally invasive biomarkers of traumatic brain injury (TBI). A significant number of brain injury patients cannot be diagnosed with conventional imaging (i.e., CT or MRI). Recent studies suggest that circulating levels of small, non-coding microRNAs (miRNAs), that are post-transcriptional regulators of gene expression, may serve as non-invasive biomarkers of brain injury. Our *objective* in this study was to measure and compare miRNAs in archived serum and cerebrospinal fluid (CSF) samples of human TBI patients with uninjured controls. We *hypothesized* that a specific panel of circulating miRNAs would effectively discriminate TBI patients from uninjured controls. Archived serum (obtained 24, 48, and 96 hours after admission to the emergency department) and CSF samples (24 hours) were acquired from patients with a clinically diagnosed TBI. Serum samples were also obtained from chronic TBI patients (10-15 years after diagnosis). Control serum and CSF samples were prospectively obtained from BioreclamationIVT. RNA was isolated from all serum and CSF samples and enriched for small-RNA species. cDNA libraries were prepared for miRNA sequencing and sequenced on a NextSeq550 Illumina platform. MicroRNA-sequencing data was analyzed using EdgeR. Our *analysis* showed: 1) serum and CSF miRNA levels differentiated TBI from uninjured controls; 2) expression of some miRNAs overlapped in CSF and serum samples; 3) some of the discriminating miRNAs (from 24, 48, and 96 hours) were found persistently dysregulated in chronic TBI patients. Ingenuity Pathway Analysis (IPA) showed that

differentially expressed miRNAs are predicted to regulate genes involved in inflammation and neurodegenerative cell signaling pathways. Bioinformatic analysis suggested that some of these TBI dysregulated miRNAs are linked to deficits in the cognitive domain (i.e., executive function, emotional control, and memory). These miRNA signatures may be useful for prognosis of neuropsychological and psychiatric outcomes in future studies. We *concluded* that circulating miRNA signatures are representative of brain pathology and serum miRNAs may be useful as biomarkers of TBI. Future studies will assess the utility of miRNA signatures for confirmation of TBI subtypes from neuroimaging. MicroRNA profiling may also have therapeutic value for monitoring the recovery of chronic TBI patients.

Title: The impact of traumatic brain injury on physiological markers and sleep patterns

Authors: *C. K. SINGH, L. A. KREBER, M. SCHAFER, G. CASTILLO, G. S. GRIESBACH
Ctr. For Neuro Skills, Bakersfield, CA

Abstract: Introduction
Traumatic brain injury (TBI) sequelae may disrupt one's physiological state as well as psychological. Patients may be deconditioned meanwhile their injury negatively impacts their mood resulting in depression, which consequentially affects sleep patterns. Compromised aerobic fitness combined with disturbances in mood and sleep prove to be debilitating sequelae for survivors. The literature reports aerobic exercise positively impacts fitness and mood after TBI. This multipronged study aims to explore the effects of exercise on aerobic fitness while evaluating the impact of mood disturbances on sleep.
Methods
Cardiovascular fitness was assessed via cardio pulmonary exercise testing (CPET) in 12 adults with TBI (M age=32; 92% male; M injury chronicity= 300 days) every 2 weeks until discharge, and baseline comparative testing was performed in 6 healthy, uninjured controls (M age= 31; 83% male). CPET physiological measurements included maximum respiratory oxygen uptake (VO_2 max) and heart rate (HR) during a modification of the Bruce Treadmill Test. Actigraphy was also obtained on these patients. Patients were randomly assigned to a supervised aerobic exercise (E) (three times per week for 30 minutes) or a non-exercise group (NE). Cognitive,

depression, and fatigue measures were administered including Beck Depression Inventory-II (BDI), Epworth Sleepiness Scale, Trail Making Test A and B, and BORG at admission and discharge.
Results
The TBI group had a significantly higher resting HR at baseline than uninjured controls ($p < 0.05$). Furthermore, 33% of the E and 66% of the NE group were below normal VO_2 max norms at baseline. At four weeks, all of E group was above the normal range while 66% of NE group remained below. A significant correlation between BDI and Epworth scores ($r= .843$), as well as, between BDI and Trails A performance existed ($r=.686$; $p <0.05$). Additionally, Epworth scores were positively correlated with BORG scores ($r= .697$; $p <0.05$). Linear regression models revealed the following significant relationships ($p <0.05$): Admission BDI was predictive of time spent in bed and time spent asleep at baseline. Baseline BDI was predictive of wake after sleep onset (WASO) at weeks two, three, and four of the study. Baseline Epworth was predictive of the number of awakenings during week one.
Conclusion
TBI reduces VO_2 max but can be improved through participation in an exercise regimen. Depression after TBI may influence the perception of fatigue, and play a role in irregular sleep patterns. The role of aerobic exercise following TBI and its impact on depression, sleep, and consequently recovery necessitates further investigation.

Title: Towards a more ecologically valid and objective measurement of mTBI recovery in adolescents: fNIRs and miRNA reveal underlying physiological differences within an expected window of recovery

Authors: N. SIDEMAN[1], H. AYAZ[2], C. J. HAMMOND[3], A. SARGENT[2], D. M. APPELT[6], S. L. ALLEN[4], *B. J. BALIN[5]
[1]Neurol., Thomas Jefferson Univ. Hosp., Philadelphia, PA; [2]Sch. of Biomed. Engin., Drexel Univ., Philadelphia, PA; [3]Div. of Res., [4]Psychology, [5]Bio-Medical Sci., Philadelphia Col. of Osteo. Med., Philadelphia, PA; [6]Ctr. for Chronic Disorders of Aging, Philadelphia Col. Osteo. Med., Philadelphia, PA

Abstract: OBJECTIVES: The majority of individuals with mTBI return to baseline after injury at 2-4 weeks. Our previous work has shown resolution of neurocognitive deficits and emotional dysfunction associated with mTBI. Controversy exists about the subjectivity of self-report measures and the lack of sensitivity in neurocognitive measures raising the question if "full recovery" actually does occur within this time frame. Therefore, we used functional near infrared spectroscopy (fNIRS) and miRNA analyses on subjects with and without a recent mTBI to see recovery via objective measures of biological functioning. We also explored the potential modulating influence that emotions, symptom severity, days post injury, etc. have on these biological measures of functioning. METHODS: Adolescent athletes (n=13), nearly all within 4 weeks of injury, were compared to age matched non-injured athletes (n=12). Subjects (14 F, 11 M, ages 14-17) completed behavioral tasks (N-back and math fluency). miRNA, known to influence gene expression, was analyzed from subjects' saliva. Post-concussion symptom, smell identification, and emotional rating scales were also completed. RESULTS: Subjects did not differ in age, gender, education, handedness, or hours of sleep. Average age was 16 years (SD+/-1.26) and mean time since injury was 19.5 days (SD+/-7.7). Minimal differences in behavioral performance, smell identification, and emotional ratings were found between groups. Medial/lateral optode grouping were significantly greater for the mTBI group (p= .006) during the math fluency task. These findings remained stable even when anxiety, gender, previous concussion history, age, and grade were used as covariates. The difference between medial/lateral optode grouping activations was significantly greater in the high depressive symptom (p &lt.001) and high anxious symptom groups (p&lt.001). Female participants with mTBI displayed lower activation overall, but displayed higher left lateral optode activation during the math task (p = .031). miRNA analyses revealed significant differences between experimental groups and between specific mTBI subgroupings. CONCLUSIONS: Our findings captured through non-invasive measures revealed significant differences between groups and within mTBI subgroupings. This suggests that a more objective assessment of mTBI may provide a more comprehensive view of recovery. fNIRS and miRNA analyses should be considered when standard measures lack sensitivity. An interrelationship between emotional, behavioral and biological functioning was also found, suggesting the need for a more holistic evaluation of adolescents with mTBI.

Title: Functional rerouting along the structural connectome is associated with improved cognitive recovery after mild traumatic brain injury

Authors: *P. MUKHERJEE[1], K. W. JAMISON[2], J. P. OWEN[3], A. RAJ[4], A. KUCEYESKI[2]
[1]Professor of Radiology & Bioengineering, Univ. of California San Francisco, San Francisco, CA; [2]Weill Cornell Med. Col., New York, NY; [3]Radiology, Univ. of Washington, Seattle, WA; [4]Radiology and Biomed. Imaging, Univ. of California, San Francisco, San Francisco, CA

Abstract: Traumatic brain injury damages white matter pathways that connect brain regions, disrupting transmission of electrical signals and causing cognitive and emotional dysfunction. Recovery occurs over weeks or months in some, while others suffer chronic and debilitating impairment. The mechanism for how the brain compensates for injury has not been fully characterized. Here, we collect global structural and functional connectome metrics (derived from diffusion and resting-state functional MRI, respectively) and neuropsychological scores in 26 mild traumatic brain injury subjects (29.4±8.0 years, 20 male) at 1 month and 6 months post-injury. We quantified the relationship between functional and structural connectomes using network diffusion model propagation time, a measure of how much of the structural connectome is being used for the spread of functional activation. None of the structural or functional connectome metrics were significantly different between one and 6 months, or when either time point was compared to a group of 34 age- and gender-matched controls (28.6±8.8 years, 25 male). We predicted longitudinal changes in overall cognitive function from changes in connectome measures using a partial least squares regression model with leave-one-out cross validation ($R^2 = 0.21$, Fig 1A). Longitudinal increases in network diffusion model propagation time and structural connectome characteristic path length, along with decreased structural and functional connectome efficiency and functional connectome clustering coefficient were significant predictors of better improvements in overall cognitive function (Fig 1B). These findings align with our previous cross-sectional work showing increased network diffusion model propagation time was correlated with recovery after severe brain injury. We interpret our findings as support for the "functional rerouting" hypothesis, wherein irrevocably damaged structural connections are compensated for by rerouting of functional connections along alternate, possibly less efficient, structural connectivity pathways.

Title: Sex-related differences in the effect of concussion history on cognitive-motor integration performance in varsity athletes

Authors: ***A. PIERIAS**[1], D. J. GORBET[2], T. MELOCHE[3], L. M. HYNES[4], M. WOJTOWICZ[5], L. E. SERGIO[4]
[2]Ctr. for Vision Res., [1]York Univ., North York, ON, Canada; [3]Sport Med., [4]Sch. of Kinesiology and Hlth. Sci., [5]York Univ., Toronto, ON, Canada

Abstract: Cognitive-motor integration (CMI) is required when a rule is used to align the required motor output to spatially dissociated visual information, a situation prevalent in many sports. Previous cross-sectional research from our laboratory[1,2] has shown CMI deficits in

university-level, child, and adolescent athletes with a history of concussion (but were deemed recovered and symptom-free at the time of evaluation). Multiple concussion history may negatively impact executive function abilities[3], reaction time[4], and time to recovery[4]. As well, it has been shown that there are sex differences both in functional brain activity underlying CMI performance, and in the effects of concussion. Therefore, in the current study, we examine the interaction between sex, concussion history, and CMI performance. Participants included 14 male and 14 female varsity athletes with a history of one or more concussions. Participants were tested on two visuomotor transformation tasks. In both conditions, participants viewed targets for visually-guided reaching movements on a vertical touch screen and moved a cursor from a central target to one of four peripheral targets (up, down, left, right) by sliding their finger. Condition one was a "standard" visuomotor mapping task where participants hand movements were made on the vertical touch screen (i.e. gaze and hand responses were spatially congruent). In condition two, participants looked at targets on the vertical screen but made their hand movements on a horizontal touchpad, with the cursor feedback 180^{o} reversed so that the motion plane and cursor alignment were decoupled from guiding visual information (i.e. a non-standard visuomotor mapping requiring CMI). Overall, men and women did not significantly differ in performance on the tasks. In contrast, we observed significant differences between the effects of number of concussions on males versus females. In males, number of concussions had a strong negative correlation ($p<0.05$) with reaction time, a strong positive correlation with peak velocity ($P<0.05$), which was not seen in females. As well, we see a strong positive correlation with number of unsuccessful trials only in males with a history of more than one concussion. These results suggest that males and females respond differently to repeated injury and therefore may require different tools for clinical diagnoses, outcome projections, and recovery assessment. Title: Subtle motor signs and executive function in chronic pediatric traumatic brain injury

Authors: *J. CRASTA[1], B. S. SLOMINE[4], S. MOSTOFSKY[2], S. SUSKAUER[3]
[2]Dept. of Neurol., [3]Physical Med. and Rehabil., [1]Johns Hopkins Univ., Baltimore, MD; [4]Kennedy Krieger Inst., Baltimore, MD

Abstract: The chronic effects of pediatric traumatic brain injury (TBI) on cognition and behavior even in children with overall good recovery are well established. In other developmental disorders, subtle motor deficits have been shown to be related to executive functioning. Chronic subtle motor deficits have not been examined in pediatric TBI. This study examined the relationship between subtle motor deficits as measured by a "bedside exam", and executive functioning measured using a performance-based Go/No-Go task and a parent-report questionnaire and examined the neural correlates of subtle motor deficits in children with TBI. Sixteen children with moderate or severe TBI, ages 11-18 years, who had sustained their injury at least 1 year prior to study participation (Range 1-14 years since injury), and 16 age-matched typically developing controls were examined using the Physical and Neurological Examination of Subtle Signs (PANESS) and a simple (minimized cognitive demands) Go/No-Go task. Parents completed the Behavioral Rating Inventory of Executive Function (BRIEF). Measures of total cerebral volume (TCV) and motor/premotor volume were derived from MRI. The TBI group showed significantly more subtle motor deficits, including more proximal and mirror overflow movements on the PANESS, and significantly more executive functioning deficits on the BRIEF, compared to controls. On the Go/No-Go task, the TBI group showed significantly more commission errors and higher intrasubject variability (ISV) in response times than controls. Across all participants, greater proximal overflow correlated with greater deficits on the BRIEF (r = .4, p = .03) and increased ISV (r = .43, p = .01). Across all participants, MRI analyses revealed significant correlations between PANESS total score and motor/premotor volume (r = -.5, p = .005), and between proximal overflow and TCV (r = -.41, p = .027), such that lower volume correlated with greater subtle motor deficits. The study highlights the importance of examining subtle motor signs including overflow during clinical evaluation of chronic pediatric TBI and establishes the clinical utility of the PANESS as a measure sensitive to chronic subtle motor signs in this population. The correlation between persistence of overflow and real-world behavior suggests that overflow may be a marker of broader dysfunction in TBI. Further research is required to examine the neural basis of overflow and the relationship between overflow and cognitive performance in pediatric TBI.

Title: Low intensity focused ultrasound in disorders of consciousness: A preliminary report

Authors: *M. M. MONTI[1], C. SCHNAKERS[5], J. A. CAIN[1], J. P. COETZEE[2], N. M. SPIVAK[3], P. M. VESPA[4]
[2]Psychology, [3]Dept. of Psychiatry and Biobehavioral Sci., [4]Neurol., [1]UCLA, Los Angeles, CA; [5]Res. Inst., Casa Colina Rehabil. Hosp., Pomona, CA

Abstract: Despite a growing understanding of brain mechanisms underlying loss and recovery of consciousness in the clinical setting, there is still little that can be done for helping patients recover consciousness after severe brain injury (Schnakers & Monti, 2017). To date, the only intervention that has been shown to be effective relies on pharmacological modulation of the thalamo-cortical system (e.g., with amantadine). Other neuromodulatory approaches, based on neurostimulation, such as DBS and tDCS have also been attempted. Here we present a novel approach, based on Low Intensity Focused Ultrasound Pulsation (LIFUP), aimed at upregulating the thalamo-cortical system by directly stimulating thalamus with a non-invasive technique. Specifically, we recruited a convenience sample of acute (< 1 month; N=7) and chronic (> 1 year; N=2) patients with disorders of consciousness for an exploratory clinical trial. The protocol included 2 LIFUP sessions -- one week apart -- preceded and followed by behavioral assessment (with the Coma Recovery Scale - Revised; Giacino et al, 2004) and by neuroimaging testing. In our initial sample, LIFUP shows positive correlation with behavioral recovery, in both acute and chronic patients. From a safety standpoint, all of our patients either ameliorated after the procedure (whether serendipitously or because of our stimulation) or simply showed no change, confirming the excellent safety record of ultrasound and focused ultrasound. These preliminary results suggest that LIFUP might be a potential novel technique to help patients recover consciousness after severe brain injury which combines the non-invasiveness of TBS with the ability of DBS to directly modulate deep nuclei of the brain.

Title: Differential patterns of neural activation related to emotional face recognition in short-term and long-term recovery from concussion:Two fMRI case studies

Authors: J. RICKER[1], K. A. SMITH[1], A. SCHMIDT[2], A. E. CRIPPS[2], P. THALLA[3], *H. C. CROMWELL[2], X. WANG[4]
[1]Psychology, [2]Bowling Green State Univ., Bowling Green, OH; [4]Psychiatry, [3]Univ. of Toledo, Toledo, OH

Abstract: Concussions are heterogeneous injuries that occur at high rates in the United States. It is estimated that anywhere from 300,000 to 3.8 million concussions occur in any given year. Given this prevalence, there is a dire need to understand the neurological effects of this injury, as well as how the brain may recover. While there is a wide range of symptoms that can follow sustaining a concussion, the effects on all aspects of emotion have rarely been studied. One way in which concussions may affect cognition is through the ability to properly assess emotions being displayed by conspecifics. With each concussion being vastly different, group analyses may not detect differences in those with concussions due to large group variability. The current study sought out to understand the behavioral and neural effects that a history of concussion may have while taking the approach similar to that used in precision medicine. Five healthy control subjects performed an emotional face assessment task (EFAT) while in an fMRI scanner, and results were compared to two collegiate hockey players with a history of concussion. One player had sustained his most recent concussion approximately one year prior to testing (long-term recovery), while the other had sustained his most recent concussion 16 days prior to testing (short-term recovery). Control subjects showed neural activation profiles similar to that which was expected from previous research on emotional assessment. The long-term recovery case displayed a profile that differed from the control subjects with activation in areas outside of those expected. The short-term recovery case displayed no significant activation in any regions while performing the EFAT. These results demonstrate that the length of time since sustaining a concussion may determine how neural activation varies in cognitive tasks.

Title: Time-dependent prefrontal white matter differences and changes in attentional bias to threat following mild traumatic brain injury

Authors: *J. M. CARLSON[1], T. SUSA[2], M. T. MOORE[3]
[1]Psychology, [2]Psychology/Neuroscience, [3]Sch. of Hlth. and Human Performance, Northern Michigan Univ., Marquette, MI

Abstract: Magnetic resonance imaging (MRI) has been used to assess disturbances in brain function and structure following mild traumatic brain injury (mTBI). As of yet, however, there is no definitive MRI-based biomarker of mTBI or its associated symptoms. Recently, it has become clear that time since injury is critically related to changes in brain structure following mTBI. Although the prefrontal cortex (PFC) is typically affected by mTBI and plays an important role in affective processing, little is known about the time-dependent relationship between PFC disturbances and affective symptoms accompanying mTBI. This study aimed to better understand this relationship by collecting MRIs from a sample of 30 collegiate student athletes. Half of the participants (n = 15) were recently cleared to return to play after experiencing a sports-related concussion. The other half of participants (n = 15), had not experienced a concussion within the past year and were matched on age, sex, and sport. A dot-probe task with fearful and neutral faces was used to assess participants' attentional bias to threat by comparing reaction times to targets at locations previously occupied by fearful vs. neutral faces. To assess participants' more general affective symptoms, the depression, anxiety, and stress scale (DASS) was administered. Levels of depression, anxiety, and stress were all elevated in the mTBI group. Bilateral differences in PFC white matter were observed between groups. This affect was time-dependent such that white matter increased as time since injury increased. Time since injury also correlated with attentional bias such that attentional bias increased as the time since injury increased. PFC white matter and attentional bias to threat were positively correlated. The results add to a growing body of work indicating that time since injury is an important consideration when looking at structural changes following mTBI and that white matter increases post-mTBI are accompanied by an increase in attentional bias to threat.

Jackson Fndn. for the Advancement of Military Med., Bethesda, MD; [5]Univ. of Florida, Gainesville, FL; [7]Behavioral Biol. Br., [8]Psychiatry and Neurosci., [6]Walter Reed Army Inst. of Res., Silver Spring, MD; [9]Pennsylvania State Univ., University Park, PA; [10]Uniformed Services Univ. of the Hlth. Sci., Bethesda, MD

Abstract: There is question of whether chronic, low-level blast exposure impacts neurological/cognitive function. This study aimed to characterize symptoms and neuropsychological (NP) profiles of 20 experienced explosives specialists (career breachers) compared to 14 military/law enforcement personnel who were not breachers. Demographics, 46 self-report symptoms/responses, combat exposure checklist (CEC), 23 NP scores, and companion questionnaires were compared, with added analysis in subgroups of military only and those with lower combat experience. Due to the large volume and array of tests conducted, significance was set at $p<0.01$ to avoid Type I error, yet symptoms, NP tests, and companion test scores meeting $0.01<p<0.05$ were still carried forward alongside differing variables in hierarchical logistic or linear regressions with breaching experience. Breachers were exposed to more combat experiences than non-breachers, even in the low combat subgroup (CEC $p<0.01$, ANOVA). Military subgroup breachers reported more ringing in ears ($p<0.01$, Pearson Chi-square). Self-reported symptoms at $0.01<p<0.05$ in all breachers included memory and concentration problems, ringing in ears, and irritability, with light/noise sensitivity only in the low combat breachers (Pearson Chi-square). However, reported memory and concentration problems were also associated with CEC. Since CEC predicted outcomes more often than breaching experience, further tests controlled for CEC. Breachers performed better than non-breachers on subsets of the CVLT ($p<0.01$, ANOVA) and were slightly elevated on subtests of WASI and ImPACT ($0.01<p<0.05$, ANOVA). Slightly higher PTSD and lower vigor scales in

breachers ($0.01<p<0.05$ PCL-M and ANAM vigor; Mann Whitney U) disappeared after controlling for CEC, as did the ImPACT subtest. Low-combat breachers exhibited slower reaction times only after controlling for CEC (ANAM SRT: $p<0.01$, $0.01<p<0.05$ for ImPACT reaction time; ANCOVA). Breaching experience improved the model predicting NEOFFI conscientiousness in addition to CEC (F change $p<0.01$). In conclusion, breachers (specifically military) were associated with ringing in ears and better performance on a verbal learning task (CVLT). There may be baseline differences in learning and memory in those chosen for careers in explosives. When controlling for combat experience, a pattern of slower reaction time arose in breachers, and breaching experience predicted a better conscientiousness score. Combat exposure was a distinct contributor to outcomes, and should be explored further. Future analysis should focus on mediators of differential outcomes in blast-exposed personnel.

Title: A review of tools used to prevent or diagnosis concussions in sports

Authors: *A. ADAMI[1,2], J. VILLAPANDO[2]
[1]Res., San Diego Miramar Col., San Diego, CA; [2]Alpha Fiber, San Diego, CA

Abstract: Background: Mild traumatic brain injury (TBI) is a major public health concern as subsequent injuries in quick succession can intensify existing neuropathology making the brain vulnerable to acute and long-term neurological deficits. With over 2 million incidences of sports-related concussions (SRC) annually in the US, there is a critical need for objective assessment of forces sustained by the head. As technological advances continue to improve our understanding of SRC, little data has been available to the public correlating head impact and neurological deficits. The aim of this review was to investigate the validity of available tools to prevent or diagnosis concussions during athletic competitions. **Methods:** Primary research data were gathered using PubMed, Google Scholar, uspto.gov, clinicaltrials.gov, and a general google search. Published marketing materials were gathered using company websites, published interviews, and social media platforms. Our search yielded 16 commercially available tools and devices related to SRC. Devices were divided into 3 categories based on their primary use: (1) protective equipment used to reduce concussive injuries (2) recording devices to track head movement during impact, and (3) clinical evaluation used post-impact to confirm diagnosis.

Results: Biomechanical data were not available for 12 out of the 16 tools, and limit data were found for the other devices. No data were published from controlled trials in the US related to SRC devices. Without clinical data, marketing material for these devices suggested the ability to reduce the incidence of concussions. Angular and linear acceleration data published from wearable devices have primarily come from laboratory simulations. **Conclusion:** Little is known regarding the correlation of the type of impact sustained by the brain and acute/chronic neurological deficits. Recently, devices have been developed to diminish the impact to the brain or objectively monitor the force of the impact. Despite positive reviews for each device, there have only been a limited number of peer-reviewed publications and no independent laboratory evaluations of these devices. Increased transparency with collected data can exponentially improve our understanding of the cause of concussions.

Title: Advanced white matter mapping in the subconcussive brain

Authors: *B. A. CARON, F. PESTILLI, N. PORT
Indiana Univ., Bloomington, IN

Abstract: Background: The topic of behavioral and structural deficits caused by concussions is an increasingly important one in the related research fields. With an incidence rate of 2.9 competition concussions per 1,000athlete exposures (NCAA 2013)in collegiate football, the concussion risk to athletes is significant. However, even subconcussive blows, or blows that do not lead to a concussion diagnosis, appear to create health risks for athletes. These impacts appear to lead to significant neural changes, the severity of which may depend on the number of hits (McAllister et al, 2014).

ObjectivesandMethods: An anatomically informed, personalized-medicine tractography approach was used to determine which major white matter tracts showed the greatest degree of difference in white matter tensor measures between 17Division I upperclassmen football players, 15Division I upperclassman cross-country runners, and 9 socioeconomically-matched non-athlete controls. We determined the underlying microstructural white matter biomarkers, using a classic diffusion-tensor model (Pierpaoli and Basser, 1999)as well as Neurite Orientation Dispersion and Density Imaging (NODDI; Zhang et al, 2012), that predict differences across different white matter tracts in the groups of athletes.
Results: Results show widespread differences in white matter tissue properties in multiple tracts and among the three athletes groups, including decreased FA, increased ICVF, and OD in the football players versus the two control groups. These differences occurred more often in longer fiber tracts compared to shorter fiber tracts, suggesting a differential effect of head impacts based on the geometric properties of these tracts. As result of this work we also advanced methods for open neuroscience for the Big Ten and Concussion community. We developed a fully automated processing pipeline for this study. The pipeline is made available both as open source code as well as open service at www.brainlife.io . The open service will allow other investigators in the community to process new data using cloud computing and reuse the advanced mapping methods developed in this work.
Conclusions: These results support the hypothesis that multiple subconcussive blows can result in white matter structural changes, with differential effects based on the length of the fiber tract being investigated, that are detectable with diffusion MRI and tractography.

Title: The role of paravascular spaces for epileptogenesis after traumatic brain injury

Authors: *G. BARISANO[1,2], D. DUNCAN[1], F. SEPEHRBAND[1], R. CABEEN[1], H. KIM[1], P. VESPA[3], A. W. TOGA[1], M. LAW[1,2]
[1]USC Stevens Neuroimaging and Informatics Inst., USC, Los Angeles, CA; [2]Dept. of Radiology, Keck Med. Ctr. of USC, Los Angeles, CA; [3]Neurol., UCLA, Los Angeles, CA

Abstract: Objective: The occurrence of seizures after head trauma is a recognized cause of disability in traumatic brain injury (TBI) patients. Post-traumatic epilepsy (PTE) accounts for 10-

20% of symptomatic epilepsy in the general population. Despite the efforts made by the scientific community, the pathophysiologic mechanisms of PTE are not fully understood. Moreover, the identification of reliable biomarkers to predict and diagnose PTE may be particularly helpful for future clinical trials. Many studies have shown that Paravascular Spaces (PVSs) may play an important role in neuroinflammation: a strong post-traumatic inflammatory reaction was documented in PVSs of contused human brain tissue, suggesting that PVSs' impairment could explain the altered macrophage activity resulting in seizure onset. Also, structural changes in PVSs may affect their surrounding white matter networks. We investigate the role of PVSs in TBI as a potential biomarker for PTE.
Methods: We analyzed clinical and MRI data in 15 patients (age range: 7-68 years old) who suffered a moderate-severe TBI using data collected in the Epilepsy Bioinformatics Study for Antiepileptogenic Therapy (EpiBioS4Rx). MRI scans were performed 14 days after trauma using 3T MRI. 6 healthy subjects (age range: 12-62 years old) were used as controls. PVSs were analyzed on 3D T2-TSE sequences and were defined as tubular-linear or round-ovoid hyperintense structures with a diameter < 3 mm. Diffusion tensor imaging (DTI) technique was used to measure the diffusivity of water molecules in the specific regions where PVSs were identified.
Results: In TBI patients, we found a highly asymmetric PVSs distribution in the two cerebral hemispheres compared with controls. Patients who experienced at least 1 seizure within 6 months after the trauma presented the most asymmetric PVSs distribution. Lateralized Periodic Discharges were detected on EEG, and in all cases the affected hemisphere matched with the hemisphere where less PVSs were identified. Moreover, PVSs mean caliber in the affected hemisphere was smaller compared with the contralateral side. Changes in diffusion metrics were detected as well.
Conclusions: The occurrence of PTE is a clinically relevant complication of TBI. The evaluation of PVSs distribution and quantification may represent a potential noninvasive neuroimaging biomarker to predict the development of epilepsy after TBI. Moreover, PVSs structural analysis combined with DTI analysis can be helpful to define the suspected seizure onset area. Ultimately, these results may be of benefit for the design of future clinical trials and for the evaluation of new possible therapeutic targets.

Title: Highly sensitive single molecular array immunoassay measurement of t-Tau, NF-L, GFAP, and UCH-L1 biomarkers in concussion/mild traumatic brain injury serum samples

Authors: A. CHENNA[1], C. J. PETROPOULOS[2], *J. W. WINSLOW[3]
[1]Monogram Biosci. Inc, Lab. Corp. of America, Inc, South San Francisco, CA; [2]Monogram Biosciences, Lab. Corp. of America, Inc., South San Francisco, CA; [3]Oncology R&D, Monogram Bioscience/Labcorp Specialty Testing, South San Francisco, CA

Abstract: Central nervous system (CNS) proteins released into cerebral spinal fluid (CSF) and peripheral blood have been associated with brain injury, and are candidate prognostic biomarkers of concussion and mild to moderate traumatic brain injury (mTBI). The accurate and reproducible measurement of these markers in blood requires highly sensitive detection technologies. Recently, single molecular array immunoassays have enabled the accurate quantitation of candidate concussion/mTBI protein biomarkers in blood. In this study, to more fully assess assay analytical performance and characterize CNS protein markers of mTBI in human serum, single molecular array 2-site immunoassays utilizing microfluidic and paramagnetic bead digital technology (Quanterix Simoa) were performed in a multiplex format to generate quantitative measurements of total Tau (t-Tau), neurofilament light chain (NF-L), glial fibrillary acid protein (GFAP) and ubiquitin C-terminal hydrolase L1 (UCH-L1). Two sample groups consisting of 30 concussion/mTBI patients each, with blood collected within 1-4 hr (avg =1.8 hr) and 8-16 hr (avg = 12.5 hr) post-injury, respectively, were compared with healthy controls. A significant elevation of median GFAP levels was observed in both the 1-4 hr ($p = 0.013$) and 8-16 hr ($p = 0.029$) concussion/mTBI groups relative to controls. A similar increase in median UCH-L1 trended toward significance for both groups. These observations are consistent with previous reports describing both proteins as acute biomarkers of TBI (Papa et al., *JAMA Neurol*. 2016; 73 (5):551-560). With the exception of t-Tau, the median levels of the other three biomarkers trended toward higher levels in the 1-4 hr post-injury sample group relative the 8-16 hr group. Several individuals displayed elevated levels of biomarker combinations providing further support for the utility of ultra-sensitive multiplex CNS protein measurements in serum. Correlations between the serum protein levels overall were observed between t-Tau and UCH-L1, and NF-L and GFAP in the 1-4 hr post-injury sample group ($r = 0.56$-0.65; $p < 0.001$). These two correlations were also significant in the 8-16 hr sample group, including a correlation between NF-L and UCH-L1 ($r = 0.45$-0.65; $p < 0.01$). These correlations suggest that increases in serum t-Tau and NF-L may be observed in larger datasets or with extended post-injury time points. This study supports the multiplex immunoassay capability to detect increases in CNS proteins at high sensitivity in serum within 1-4 and 8-16 hr of concussion/mTBI.

Title: Conditioning electrical stimulation to enhance motor and sensory recovery following peripheral nerve injury

Authors: *J.-L. SENGER[1], M. CHAN[2], H. MACANDILI[1], V. M. K. VERGE[4], K. E. JONES[3], C. CHAN[1], C. A. WEBBER[1]
[1]Dept. of Surgery, [2]Dept. of Physical Med. & Rehabil., [3]Dept. of Biomed. Engin., Univ. of Alberta, Edmonton, AB, Canada; [4]Dept. of Anat. and Cell Biol., Univ. of Saskatchewan, Saskatoon, SK, Canada

Abstract: Background: Peripheral nerve regeneration is often incomplete with significant personal and socioeconomic costs. Although it is known that conditioning lesion (a nerve crush delivered prior to injury and repair) markedly accelerates nerve regrowth, clinical translation is impossible because it is unethical to intentionally injure a healthy nerve. In a proof of principle study, we showed that conditioning electrical stimulation (CES) of the fibular nerve enhances upregulation of regeneration-associated-genes (RAGs) and axonal growth. Whether similar beneficial effects can be generalized to other nerves and whether CES improves functional recovery remain unknown. This knowledge is critical before applying CES for clinical use. **Objectives:**To determine if CES upregulates RAGs, enhances nerve regeneration and improve sensorimotor function in a rat tibial nerve injury model.**Methods:** Sprague Dawley rats were divided based on the type of conditioning to the tibial nerve: i) CES, ii) conditioning crush lesion (CCL), iii) sham-CES controls, and iv) unconditioned controls. Expression of RAGs (GAP43, BDNF, pCREB, GFAP) were analyzed at 3-days post-conditioning (n=3). The length of regeneration was assessed at 7-days (n=6), and physiological and behavioral testing was performed at 7-weeks post-coaptation (n=10).**Results:**There was significantly increased axonal growth in animals conditioned with CES (6.35 ± 1.0 mm) and CCL (6.73 ± 1.0 mm) compared to controls (sham-CES, 2.67 ±0.5 mm; unconditioned, 2.78 ± 0.9 mm). There was a similar pattern of upregulation of RAG expression comparing CES and CCL to controls ($p<0.001$-$p<0.001$). Sensory testing (von Frey filaments, intraepidermal nerve fiber density counts), gait analysis (toe spread evaluation, horizontal ladder testing) and gastrocnemius muscle reinnervation (muscle weight, neuromuscular junction analysis) were significantly improved in the CES animals compared to not only the controls ($p<0.001$-$p<0.001$), but also the crush-conditioned cohort ($p<0.5$). Nerve conduction studies showed significantly larger compound muscle action potential

amplitude in CES compared to controls ($p<0.01$).**Conclusions:**Our data suggests preoperative electrical stimulation delivers a conditioning-like effect in the tibial nerve, with upregulation of RAGs and enhanced axonal outgrowth. Interestingly, CES induced improvements in sensorimotor outcomes beyond those obtained with traditional methods of conditioning. As electrical stimulation is safe and well-tolerated by patients, CES is a clinically feasible intervention that may improve the sensorimotor recovery of patients with peripheral nerve injury.

Abstract: Background: The use of brief postoperative electrical stimulation (ES) to enhance peripheral nerve regeneration is well described in the literature, and is the current standard of care at many centers. This treatment enhances staggered regeneration at the site of coaptation, with no effect on more distal regrowth. By contrast, a conditioning lesion, the intentional crush to a nerve prior to its cut and repair, accelerates regeneration along the entire length of the distal stump. We have recently shown that preoperative electrical stimulation delivers a conditioning-like effect (conditioning ES, CES). To establish the optimal treatment strategy, we compared the regeneration and reinnervation outcomes of postoperative-ES vs. CES. **Objective:** To compare axonal outgrowth and sensorimotor reinnervation outcomes follow CES, postoperative-ES, or both in a rat tibial nerve injury model. **Methods:** Sprague Dawley rats were equally divided into four cohorts: i) CES, ii) postoperative-ES, iii) CES + postoperative-ES, and iv) sham. CES was delivered one week prior to nerve cut/coaptation while postoperative-ES was delivered immediately following coaptation. Length of nerve regeneration was assessed at 7-days post-repair (n=6), and physiological and behavioural testing were performed at 7-weeks post-coaptation (n=4). **Results:** Animals treated with CES alone had significantly longer lengths of

regeneration and sensorimotor reinnervation compared to all other cohorts. One-week post-injury, CES-treated axons extended 8.5 ± 0.6 mm, significantly longer than in the postoperative-ES (3.6 ± 0.3 mm), CES + postoperative-ES (5.5 ± 0.5mm), or sham (2.7± 0.3 mm). Sensory reinnervation was significantly better in the CES group, with greater sensitivity to Von Frey filaments and a higher density of intraepidermal nerve fibers compared to all other cohorts ($p<0.001$). Similarly, motor reinnervation, evaluated using behaviour (width of toe spread, performance on the horizontal ladder test), electrophysiological (CMAP amplitude) and immunohistochemistry (reinnervated neuromuscular junctions) were all significantly better in the CES cohort ($p<0.001$). **Conclusion:** CES significantly improves regeneration and reinnervation beyond that attainable with current clinical standard using postoperative ES. It is a clinically feasible method of improving outcomes for patients with peripheral nerve injury. Further investigation is required to delineate molecular and cellular mechanisms associated with each treatment modality.

Title: Axon regeneration is enhanced in the absence of asparagine endopeptidase (AEP, δ secretase)

Authors: *A. W. ENGLISH[1], K. YE[2]
[1]Dept Cell Biol., [2]Dept Pathol & Lab. Med., Emory Univ. Sch. of Med., Atlanta, GA

Abstract: Injuries to peripheral nerves are common but functional recovery from them is poor. Enhancing axon regeneration after nerve injury has emerged as a target for the development of novel therapies to improve functional recovery. Elongation of regenerating axons is produced by the addition of cytoskeletal elements, mainly microtubules and actin filaments, to their distal ends. The axonal microtubule-associated protein, Tau, stabilizes microtubules in regenerating axons. Asparagine endopeptidase (AEP, δ secretase) is a lysosomal cysteine protease that cleaves Tau at N255 and N368 residues and degrades its microtubule-stabilizing function. We used an antibody specific to Tau N368 and enzyme activity assays to show that significant AEP activity and AEP-degraded Tau are found in the distal segments of cut and repaired mouse sciatic nerves. Using mice null for AEP bred on a background of the thy-1-YFP-H mouse, we found that, two

weeks after injury, regenerating axon profiles were more than three times longer in these AEP KO mice than in untreated wild-type (WT) controls and 40% longer than WT mice treated systemically with the small molecule trkB agonist, 7,8 dihydroxyflavone (7,8 DHF). The amplitudes of direct muscle EMG responses (M waves) evoked in gastrocnemius and tibialis anterior muscles by stimulating sciatic nerves proximal to a transection injury were restored more than twice as fast in AEP KO mice as untreated WT controls and comparable to that noted in WT mice treated with 7,8 DHF. The amplitude of M responses recorded 10 weeks after injury in AEP KO mice and WT mice treated with 7,8 DHF was comparable to the pre-transection responses. In untreated WT controls, this value was only 45% of pre-transection controls at that recovery time. Inhibiting AEP activity could be a potent strategy for enhancing axon regeneration and functional recovery after peripheral nerve injury.

Title: Pro-inflammatory macrophage phenotype and activation are regulated by CRYAB *in vitro* and after peripheral nerve damage

Authors: *S. S. OUSMAN[1], E.-M. F. LIM[2], V. HOGHOOGHI[2]
[1]Clin. Neurosciences and Cell Biol. & Anat., [2]Neurosci., Hotchkiss Brain Institute, Univ. of Calgary, Calgary, AB, Canada

Abstract: Macrophages play a critical role in creating a supportive environment for regrowing axons following injury to the peripheral nervous system (PNS). Post-PNS damage, de-differentiated Schwann cells (SCs) secrete cytokines and chemokines that promote the recruitment of monocytes to the injured site. These monocytes differentiate into macrophages that produce cytokines that contribute to further recruitment of hematogenous macrophages. Importantly, these blood-derived macrophages phagocytose axonal and myelin debris that are inhibitory to axon growth. The beneficial aspects of immune cells and their secretory products such as cytokines are evident. However, a prolonged inflammatory response after PNS injury has been implicated in the pathogenesis of negative symptoms such as neuropathic pain. Therefore,

the immune response after PNS damage must be carefully controlled to prevent secondary damage while allowing for beneficial regenerative processes to occur. CRYAB is a small heat shock protein that is expressed by PNS axons and SCs. We previously showed that the protein plays a beneficial role in peripheral nerve regeneration by promoting the re-differentiation of, and remyelinating ability of SCs after PNS injury. Due to the extensively reported immunomodulatory role of CRYAB, we investigated whether the small heat shock protein also influences macrophage responses during Wallerian degeneration. Using CRYAB null mice, we found that although the recruitment of macrophages into crushed sciatic nerves was not altered by CRYAB as shown by similar numbers of macrophages and, amount of cytokines and chemokines at 1-7d post-damage between wildtype (WT) and $CRYAB^{-/-}$ mice, there was a sustained presence of macrophages in the injured distal sciatic nerves of $CRYAB^{-/-}$ mice at 21 and 28d post-damage. To determine if CRYAB can affect the phenotype and activation of macrophages, we performed *in vitro* assays whereby macrophages from WT and $CRYAB^{-/-}$ mice that had been polarised to a pro-inflammatory or immunosuppressive phenotype were stimulated with lipopolysaccharide in the presence or absence of recombinant CRYAB and evaluated for the secretion of various cytokines. We found that CRYAB specifically impacts pro-inflammatory but not immunosuppressive macrophages by reducing their cytokine production. We are currently evaluating if the elevated number of macrophages in the injured sciatic nerves of $CRYAB^{-/-}$ mice is skewed towards a particular phenotype. Thus far then, we have found that the small heat shock protein CRYAB plays a role in preventing the prolonged presence of macrophages, possibly of the pro-inflammatory phenotype, after PNS damage.

Title: Nerve injury effects rapid mobilization of NGF receptors to the axonal membranes of sensory neurons and increased receptor activation, which can be enhanced by electrical stimulation

Authors: B. R. MCMILLAN, R. ZHAI, J. JOHNSTON, *V. M. VERGE
Anat. & Cell Biol., Univ. Saskatchewan-CMSNRC, Saskatoon, SK, Canada

Abstract: We and others have shown that therapies such as electrical nerve stimulation (ES) accelerate and increase the number of axons regenerating across the injury site, especially at early time points, thereby enhancing the probability that a patient will recover successfully from traumatic peripheral nerve injury (Geremia et al., 2007 Exp Neurol 205(2):347). We also found that small reductions in pH, consistent with that observed following injury, activate proton-sensitive ion channels, depolarize the neuron and effect rapid mobilization of` additional nerve growth factor (NGF) receptors (trkA) to sensory neuron membranes, making them more responsive to NGF (Bray et al., 2013 J Neurosci 33(19): 8202). Given the role of trkA in sensory axon guidance and response to NGF cues following injury (Webber et al., 2008 J Neuropath Exp Neurol 67(3) 212), we posited that the beneficial impacts of ES on regenerating nerves are associated with rapid changes in membrane properties of the axons with respect to the numbers of neurotrophin receptors on the axon surface. Thus, we examined whether brief 60 minute ES (20 Hz) of crush injured sciatic nerves or 20 mM KCl-mediated depolarization of cultured sensory neurons would result in rapid NGF receptor mobilization from intracellular stores to injured axon membranes and increase levels of receptor activation, providing a mechanism to rapidly alter the sensitivity of axons to local neurotrophin growth permissive cues. Using immunohistochemical approaches, preliminary findings reveal that sciatic nerve crush injury in adult male Wistar rats effects a rapid mobilization of the NGF receptor trkA to the axon membrane 60-minute post-injury, with a corresponding higher level of trk activation observed at the injured axon front. This response appeared to be enhanced in the ES-treated group and can be elicited by KCl-induced depolarization of cultured sensory neurons. The ability of increased neural activity to rapidly alter neurotrophin responsiveness in injured axons likely contributes to the improved regenerative events observed in response to ES.

Title: The addition of heat-releasable neurotrophin-3 and chondroitinase ABC to a nerve guidance conduit does not improve compound muscle action potential amplitudes in a rat model of sciatic never repair

Authors: *A. DONSANTE[1], K. E. MCDANIEL[1], N. S. HARDCASTLE[1], D. M. O'CONNOR[1], J. XUE[2], Y. XIA[2], N. BOULIS[1]

Abstract: Background: Peripheral nerve injuries are estimated to affect one million people worldwide each year, resulting in loss of motor function, loss of feeling, and/or the development of pain. In cases where the injury results in a substantial gap between the healthy portions of the nerve, an autograft is usually performed to bridge the gap. However, this requires sacrificing a functional sensory nerve, causing loss of feeling and potentially pain in another part of the body. In addition, long gaps are difficult to repair with this approach. Therefore, there is an urgent, unmet need for better tools to mend nerves. In a previous study, we tested the ability of nerve guidance conduits (NGCs) made from electrospun poly(ε-caprolactone) nanofibers to repair the sciatic nerve in a rat model of nerve transection. Animals receiving plain NGCs recovered ~40% of the muscle strength regained by autograft controls. Adding Schwann cells (SCs) differentiated from bone marrow mesenchymal stem cells to the NGCs boosted muscle strength to ~60% of animals receiving autografts.
Study Design: Seeking to further enhance the NGCs, we sought to augment them with two factors: neurotrophin-3 (NT-3) to enhance neurite extension and chondroitinase ABC to degrade inhibitory proteoglycans. These factors were incorporated together with a near infrared (NIR)-sensitive dye (indocyanine green) into microparticles made of phase change material (a eutectic mixture of lauric acid and stearic acid at a ratio of 8:2) which was sandwiched between two layers of electrospun nanofibers, allowing controlled release of the factors through the use of an NIR laser. In the current study, five treatments were compared: an autograft using the excised nerve segment, plain NGCs, NGCs+SCs, NGCs+factors, and NGCs+factors+cells. Each animal was challenged with an 8 mm gap in the sciatic nerve. For conduits containing factors, a NIR laser was externally applied weekly, moving stepwise from the proximal end to the distal end over three weeks.
Results: Twelve weeks after the injury and repair, compound muscle action potentials (CMAPs) were measured in the gastrocnemius muscle. Compared to an autograft, plain NGCs and NGCs+SCs produced CMAP amplitudes of 44% and 58%, respectively. Contrary to our expectations, NGCs+factors and NGCs+factors+cells produced lower CMAP amplitudes (28% and 30% of autografts, respectively). Axon counts, immunohistochemistry for regeneration markers, and analysis of neuromuscular junctions are on-going. The results suggest that the factors or the heat needed to release them have an adverse effect on axonal regeneration.

Title: Extending the maximum critical nerve gap in the rat sciatic nerve model using curved conduits

Authors: *G. S. BENDALE[1,2], Y. TONG[3], E. SHIMIZU[2], S. ANAND[2], B. N. JOHNSON[3], M. I. ROMERO-ORTEGA[4]

Abstract: Despite the ability of the adult peripheral nervous system to spontaneously regenerate, this process often fails in large nerve defects (i.e., >3 cm), resulting in permanent sensory and motor deficits. The study of regenerative strategies for large gaps, primarily relies on large animal models including rabbits, cats, dogs, and sheep. However, these models offer limited objective measurements of functional recovery. In contrast, the rat sciatic nerve (ScN) model is widely accepted, well characterized, and offers a number of metrics of functional regeneration. However, the maximum gap length in this model is 2 cm. We reasoned that a nonlinear silicone conduit fabricated with a microextrusion 3D printing process could be used to extend the critical nerve gap in the rat ScN. Thus, here, we tested the ability of the ScN to growth through an S-conduit. Ten adult rats were equally divided into two groups for repair of a gap injury: a) straight tubes, 10mm in length and b) S-shaped nerve guides with a path length of 13 mm . All conduits were filled with collagen to facilitate regeneration and implanted between the two ends of the transected nerve. Starting at one-week post-surgery, and weekly for two months, the animals were evaluated for gait analysis using Gait Scan. At the end of the study, electrophysiology was conducted across the gap to verify functional nerve conduction. Gross histology showed no apparent difference between the regenerated nerves in the straight tube compared to the S-shaped conduits. This was confirmed by measurements of average thickness of the regenerated nerves at multiple 2.5 mm segments across the gap, which showed no significant difference between the two groups. Toe-spread index indicated successful functional recovery at week 7 compared to week 1 post-surgery ($P<0.05$). However, no significant differences were noted between the straight guides and the S-shaped conduits at any time point. Histological evaluation of the regenerated tissue immunolabeled with β-III tubulin and protein-0 (P0), to visualize axons and myelin; respectively, showed comparable axonal regeneration in both types of conduits. These results confirmed that injured axons in the ScN grow effectively through curved conduits, opening the possibility of using S-guides to extend the nerve gaps in rats beyond the current 2 cm limit. This method may offer a viable alternative to the use of larger animal models for the test of long gaps repair strategies, while taking advantage of the broad behavioral sensory-motor tests, and biochemical and cell biology techniques, that are well established in the rat model.

Abstract: Although nerve injuries occur in the peripheral nervous system (PNS), dramatic reorganization occurs within the spinal cord, cortex, and subcortical structures following injury. In severe injuries such as transection, axonal sprouting is imprecise and numerous axons fail to reestablish prior connection. Due to the extensive amount of mismatch, natural reorganizational processes are incapable of complete functional recovery. Following injury and surgical repair no more than 50% of human patients regain useful function. Meyers et al. has shown that by enhancing reorganization throughout the CNS by the use of VNS paired with rehabilitation, we can selectively enhance the connectivity of the circuits mediating skilled forelimb use and enhance forelimb recovery. Patients have a limited time to do rehab so it is necessary to optimize VNS delivery during rehab. Patients with upper limb impairments after PNI train on many tasks with the physical therapist or clinician during their rehabilitation. Generalization is important because it determines whether more repeats of a single task should be paired with VNS, or fewer repeats with a variety of tasks. Previously Meyers et al. has shown that VNS benefits generalize after stroke, but it isn't clear if that happens after PNI. This aim will investigate if VNS paired with the isometric pull task can drive recovery on both the isometric pull task and the supination knob tasks simultaneously following peripheral injury. We hypothesize that by pairing VNS with the isometric pull task, VNS benefits will generalize to the supination task. If this hypothesis is incorrect and the VNS benefits do not generalize then it will be informative to understand that VNS may need to be paired with many tasks during rehabilitation or trying to rehabilitate many tasks with VNS therapy at one time may not be beneficial. Our previous results also demonstrate that VNS paired with rehabilitative training enhances functional recovery of forelimb strength. However, the effects of VNS did not last after the cessation of training for one month.

Additionally we will further investigate if VNS therapy effects are long lasting with continued rehabilitation.

Abstract: Direct cargo/gene delivery to peripheral nerves has the potential to enable a host of novel therapies to support nerve repair after traumatic injury and/or neuropathies. However, delivery of targeted therapies to nerves remains a challenge. Current delivery methods present significant translational hurdles, including heavy reliance on viral vectors, stochasticity, and tissue damage. This work describes a novel nanochannel-based platform for non-viral transfection of nerves *in vivo* in a fast (100 ms), highly efficient and benign manner. Nanochip platforms containing an array of nanopores were fabricated using cleanroom-based fabrication techniques and used to precisely nanoporate and deliver desired molecular cargo into nerve tissue via electrophoresis. We have successfully applied this technology for transfection of the sciatic nerve (SN) in a mouse model to deliver reprogramming angiogenic factors as a potential therapeutic strategy to aid axonal growth and nerve repair. Scalability of this intervention was assessed by transfecting the optic nerve (ON) of pigs with fenestrated and non-fenestrated dura mater. Transfection efficiency and retrograde transport to the PNS and CNS was assessed via immunofluorescence microscopy and qRT-PCR after transfection. Successful nerve transfection was observed in tissue sections collected 24 hours to 7 days after transfection. Cargo delivery extended beyond the initial transfection boundary (epineurium) into the endoneurium. One week after transfection with angiogenic reprogramming factors, we observed nerve stroma reprogramming into vascular tissue as evidenced by increased expression of CD31 in close proximity with axonal processes along the entire length of the nerve. Upstream tissue analysis after SN transfection revealed that tailoring the transfection conditions resulted in the delivered

gene cargo reaching the dorsal root ganglion (DRG) and ventral horn of the spinal cord (SC). Immunofluorescence analysis confirmed successful tissue transfection and strong pro-endothelial gene activity at the SN, DRG and SC levels with no appreciable behavioral changes (*e.g.*, paw clenching, gait perturbations). Pilot experiments in the optic nerve of pigs indicated successful cargo delivery as well as strong gene expression across the entire nerve cross-section. This study supports the feasibility of non-viral gene delivery to nerves as a tool to enhance nerve regeneration following a focal injury. Moreover, retrograde delivery to the CNS from peripheral nerves expands the potential applicability of our method to the treatment of focal CNS insults.

Title: Lithium attenuates diabetic neuropathic pain through augmentation of spinal glycinergic inhibitory control

Authors: *C.-R. LIN[1], W.-T. LIAO[2], C.-L. TSAI[3]
[1]Kaohsiung Chang Gung Mem. Hosp. and Chang Gung Univ. Col. of Medi, Niao-Sung District, Taiwan; [2]Chia-Yi Chang Gung Mem. Hosp., Chia-Yi, Taiwan; [3]Anesthesiol., Kaohsiung Chang Gung Mem. Hosp. and Chang Gung Univ. Col. of Medi,, Kaohsiung, Taiwan

Abstract: Lithium is an effective medication for the treatment of bipolar affective disorder. Accumulating evidence suggests that inflammation plays a role in the pathogenesis of neuropathic pain and that lithium has anti-inflammatory effects that may contribute to its therapeutic efficacy. However, the effects and mechanisms of lithium on diabetic lithium affect neuropathy remain unknown. The present study examined the effect of locally injected lithium on neuropathic pain induced by streptozotocin.Male Sprague-Dawley rats with or without streptozotocin intraperitoneal injections were used. Tactile sensitivities were assessed by measuring paw withdrawal thresholds to von Frey filaments for four weeks. The extent of GlyR-mediated inhibition controlling primary afferent-evoked excitation in dorsal horn neurons was examined by using the whole cell patch clamp recording technique in isolated adult rat spinal cord slices. The content of the spinal dorsal horn glycine levels was measured by microdialysis. We found that persistent hyperglycemia induced by the administration of STZ caused a decrease

in the paw withdrawal latency to mechanical stimuli. The miniature inhibitory post-synaptic current (mIPSC) rise, decay kinetics and mean GlyR-mediated mIPSC amplitude were not affected in DNP. The mean frequency of GlyR-mediated mIPSC of lamina I neurons from DNP rats was, however, significantly reduced when compared with neurons from control rats. Principal passive and active membrane properties and the firing patterns of spinal lamina I neurons were not changed in DNP rats. Spinal microdialysis rats had a significantly decreased glycine level following its initial elevation. Intraplantar administration of lithium diminished tactile pain hypersensitivity and attenuated decreased level of glycine in DNP rats. In conclusion, these results indicate that long-lasting hyperglycemia induced by STZ injections leads to a reduced glycinergic inhibitory control of spinal lamina I neurons. Intraplantar lithium administration partially reversed tactile hypersensitivity and reduced glycinergic inhibitory control.

Title: Involvement of vascular endothelial growth factor in regeneration of injured inferior alveolar nerve

Authors: *Y. NISHIDA[1,2], Y. YAMADA[3], H. KANEMARU[2], T. MAEDA[3], A. OHAZAMA[4], K. SEO[2]
[1]Niigata Univ. Grad. Sch. of Med. and, Niigata, Japan; [2]Dent. anesthesiology, [3]Ctr. for Advanced Oral Sci., [4]Oral Anat., Niigata Univ. Grad. Sch. of Med. and Dent. Sci., Niigata, Japan

Abstract: Introduction The activation of vascular endothelial growth factor (VEGF), a regulator of angiogenesis and vascular permeability, has been reported in damaged neuron. This molecule can induce neurotropic/neuroprotective functions in injured neuron by regaining of oxygen/nutrition supply from blood circulation. However, little information is available for the role of endogenous VEGF in the regeneration of peripheral nerves following injury. Aims The present study was undertaken to examine the function of endogenous VEGF on regeneration of damaged inferior alveolar nerve (IAN). In addition, we clarified the existence of VEGF receptor and the secretion mechanism during regeneration process. Material and methods This study used the IAN injured animal model of injured IAN which we have previously reported (Yamada et al.,

2018). Briefly, under deep anesthesia, the exposed IAN was resected and left apart with an interval of 0.5mm between the cut ends. The animals were sacrificed at post-operative day (PO) 1, 2, 3, 5 and 7. Some mice received a local administration of anti-VEGF antibody (1µg per day) at every 24 hours for 5days after operation. Observations focused on 1) the chronological changes in regeneration of axons and blood vessels, 2) the chronological changes in expression pattern of VEGF receptor 1 during damaged IAN regeneration, 3) the effects of local administration of anti-VEGF antibody on nerve regeneration process at PO day 7 by immunohistochemistry for PGP9.5, and 4) the invasive status of macrophages to the transection site at PO day 2. Results Current observations showed; 1) Blood vessels began to sprout into transection site at PO day 2 prior to the axonal regeneration. 2) The proximal stamp of the transected IAN expressed strong VEGFR1 at PO day 3. 3) A local administration of anti VEGF significantly suppressed the axonal growth. 4) Macrophages invaded in the proximal stump of the transected IAN at PO day 2. Expression of VEGF receptor and accumulation of macrophage appeared at the medial site of the damaged nerve immediately after the injury. Conclusions The present findings suggested the induction of local VEGF secretion by nerve damages. VEGF-VEGF receptor system may contribute to facilitate regeneration of axonal elongation from injured site as well as to re-establish micro-vascularization. Supported by JSPS KAKENHIs for H. Title: Effectiveness of portland cement on the repair of inferior dental nerve in mice C57bl/6

Authors: *M. VIVEROS SANCHEZ[1], A. L. GARCIA-HERNANDEZ[2], I. O. PEREZ-MARTINEZ[3]
[1]UNAM, Mexico, Mexico; [2]Lab. of Oral Inmunology and Osseous Regulation, Cuautitlán Mexico, Mexico; [3]Lab. of Neurobio. of Oral Sensations, Cuautitlán Mexico, Mexico

Abstract: Chronic neuropathic pain can be produced by injuries on peripheral nerves, superficial or deep damages under periapical areas of the teeth could hurt inferior dental nerve causing chronic pain and having negative repercussions at cognitive and emotional levels, decreasing people's life quality. Materials like Portland cement can be used for bone defects, because it has

osteogenic properties and anti-inflammatory effects reducing it; however, it is not known the consequences in the trigeminal damage in its intraosseous branch.
Objective: determinate the effectiveness of Portland cement on the repair of the exposed inferior dental nerve in a mandibular lesion.
Method: 12 mice C57bl/6 were used, divided in 3 groups: 1. Control, 2. Osseous lesion with exposed nerve and 3. Osseous lesion with exposed nerve treated with Portland cement. Presence of spontaneous pain was evaluated with the grooming behavior at -2,2,4,6 and 8 days. Affective component to induced pain was characterized using the place escape/avoidance paradigm at -1,1,3,5, and 9 days. Expression of pro-inflammatory cytokines IL-6 and TNF-α were determinate with ELISA assay at 3rd day. Three days after surgery the mice´s jaws were prepared for sectioning, serial sections (4µm thickness) was made and dyed with Hematoxylin and Eosin for histological observations.
Results: experimental group show a major hyperalgesia responds at days 5 and 7 (ANOVA $p<0.05$), there are significative differences in the presence of spontaneous pain in the groups with osseous lesion with exposed nerve against control group and experimental at 6 and 8 days (ANOVA < 0.05).
Conclusion: Portland cement decreases spontaneous pain however it can induce a peripherical sensitization when it is used like a therapeutic option in an osseous mandibular lesion with nerve exposure.

Title: Effective neuromodulation of pelvic floor nerves despite damage induced by multiparity and aging in incontinent rabbits

Authors: *A. G. HERNANDEZ-REYNOSO[1], K. LÓPEZ-GARCÍA[3], R. ZEMPOALTECA[4], D. L. CORONA QUINTANILLA[5], F. CASTELÁN[6], M. I. ROMERO-ORTEGA[2], M. MARTINEZ-GOMEZ[7]

Abstract: Pelvic floor muscles (PFM) provide organ support and participate in urinary and fecal continence as extrinsic closure mechanisms. Their dysfunction is involved in disorders including urinary incontinence (UI), a condition that affects 30-60% of the female population and 5-15% of males. Risk factors such as pregnancy cause stretch injury of the PFM, and aging weakens it. This damage can be either myogenic or neurological. Female rabbits have a well-developed pelvic floor and similar activity patterns to those observed in women. Additionally, vaginal birth and aging also result in UI symptoms in this animal model. We recently observed that the bulbospongiosus and the pubococcygeus nerves are partially compromised in multiparous rabbits, and that evoked compound action potentials in response to electrical stimulation were reduced in amplitude suggesting partial neurological dysfunction. Here we use electron microscopy to further define the neural damage in the pelvic floor nerves of young (1-2 years old) and old (3-4 years old) rabbits, either nulliparous or multiparous. Histomorphometric analysis showed that the number of large diameter axons in aged multiparous animals (4.46 ± 1.84 per 1000 μm^2) were comparable to those in nulliparous rabbits (5.21 ± 1.54 fibers per 1000 μm^2). We noted that the axons in the old multiparous animals were abnormally elliptical in shape. Quantitative analysis of axon roundness, estimated by the short over the long diameter ratio, show that axons in old animals were 35% more elliptical compared to young rabbits ($p<0.001$) suggestive of compression injury. We also observed injured axons undergoing Wallerian degeneration, some with abnormal myelin morphologies, including thick myelin, wide Schmidt-Lanterman incisures, and thin myelin on large axons, suggestive of re-myelination. Further analysis revealed that the g-ratios were not affected by parity, but were reduced approximately 25% in aging animals, with a characteristic degenerative invagination of the myelin sheath. We estimated the tortuosity of the myelin folding by dividing the myelin perimeter of the fiber over the calculated perimeter of a perfect ellipse of the same dimensions, and observed an estimated 20% increase in myelin tortuosity in old animals. Damage by multiparity involves Wallerian degeneration that re-myelinates spontaneously, which is exacerbated in old animals resulting in more prominent myelin defects. However, since most of the nerve fibers remain normal, we tested the effect of electrical stimulation of the PFM nerves as a strategy to modulate urodynamic parameters in this animal model. Evidence of effective neuromodulation of UI will be presented.

Title: Restoring central networks improves motor and sensory function after nerve damage

Authors: *E. MEYERS, N. KASLIWAL, E. LAI, M. ROMERO-ORTEGA, R. RENNAKER, M. KILGARD, S. HAYS
Univ. of Texas At Dallas, Richardson, TX

Abstract: Damage to the peripheral nervous system is common and results in debilitating, chronic loss of motor and sensory function. Directing plasticity within spared and reconnected circuits represents an avenue to restore function long after injury. Here, we describe a novel closed-loop neuromodulation strategy using precisely-timed vagus nerve stimulation (VNS) paired with rehabilitative exercises to facilitate neural plasticity. VNS paired with rehabilitation more than doubled recovery of forelimb motor function and somatosensation compared to equivalent rehabilitation alone after transection of the median and ulnar nerves in rats. In conjunction with functional recovery, VNS enhanced descending motor output and synaptic connectivity in motor networks selectively controlling the denervated muscles and reversed maladaptive non-selective muscle synergies. Recovery persisted after the cessation of VNS therapy because connectivity in central networks was restored. Manipulations that blocked plasticity in central networks prevented VNS-dependent recovery. Building on the clinical record of safety and ease of implementation, this VNS-based targeted plasticity strategy represents a readily translatable method to substantially improve motor and sensory function in patients suffering from nerve damage.

Title: Focal reduction of monocarboxylate transporter 1 (MCT1) in macrophages delays peripheral nerve regeneration

Authors: *M. K. JHA[1], F. YANG[1], C. XUE[1], Y. LEE[1,2], A. HOKE[1], J. D. ROTHSTEIN[1], B. M. MORRISON[1]

Abstract: The remarkable regenerative capacity of the peripheral nervous system (PNS) requires a high metabolic energy demand. Traumatic nerve injury triggers a cascade of events that culminate in a robust infiltrating macrophage-dependent inflammatory reaction, which is indispensable to normal progression of Wallerian degeneration and regeneration. However, the metabolism of macrophages in peripheral nerve regeneration has not yet been explored. We had previously published that reducing the primary lactate transporter in the peripheral nerve, monocarboxylate transporter (MCT1), by half in all cells dramatically delayed nerve regeneration. Through careful analysis of cell-specific deletion of MCT1, we have now determined that downregulation of MCT1 only in macrophages leads to a similar delay in nerve regeneration following injury, as measured by nerve electrophysiology and histology. Evaluating MCT1-deficient macrophages *in vitro* suggests that the delayed nerve regeneration in mice *in vivo* is due to impaired energy production in macrophages, since they have weakened capacity for both mitochondrial oxidative phosphorylation and glycolysis. Additionally, classic pro-inflammatory cytokines are increased, while pro-regenerative cytokines are reduced, in MCT1-deficient macrophage cultures, potentially disrupting their capacity to facilitate nerve regeneration. Detailed bioenergetic and functional evaluations of macrophages with and without MCT1 and potential implications to the process of nerve regenerations are ongoing. We have also begun to evaluate nerve regeneration in transgenic mice with focal upregulation of MCT1 in macrophages as a potential novel therapeutic pathway for accelerating peripheral nerve regeneration.

Title: Role of ASIC channels in mouse models of painful diabetic neuropathy

Authors: *J. NOEL, A. NEGM, K. STOBBE, E. DEVAL, E. LINGUEGLIA, C. ROVERE
IPMC, CNRS UMR7275, 06560 Valbonne, France

Abstract: Acid-Sensing Ion Channels (ASICs) are depolarizing cationic excitatory channels activated by tissue acidosis. ASIC channels are formed by the trimetric association of ASIC1 to ASIC3 subunits. They are largely expressed throughout the nervous system. In mice, ASIC3 is expressed in Dorsal Root Ganglion (DRG) neurons of small diameters responsible for pain perception. We have previously demonstrated the role of ASIC3 in inflammatory pain. We have shown that ASIC3 channel are activated by moderate tissue acidosis, as low as pH 7.0, and lipids, such as lysophosphatidylcholine (LPC) and arachidonic acid (AA), found at high concentrations in inflammatory exudates. Interestingly, LPC and AA are activators of ASIC3 at physiological pH 7.4, and subcutaneous injection of LPC and AA in mice hind paw induces pain that is dependent on ASIC3 channel. We are now using ASIC3 specific pharmacological tools and venom toxins, and ASIC3 transgenic mice to investigate the role of ASIC channels in diet induced painful diabetic neuropathy. We are using behavioral experiments to measure thermal, mechanical and chemical pain in diabetic mice using radian heat Hargreaves, dynamic von Frey, and nocifensive formalin tests. Electrophysiological approaches including patch-clamp techniques on DRG neurons and skin-saphenous nerve preparation allows us to study the consequences of diabetes on peripheral sensory neurons activity.
In diabetic mice, we found a deregulation of glucose homeostasis independent of the activity or expression of ASIC3 channel. Diabetic mice have a long lasting thermal hypersensitivity that is dependent on ASIC3 channel activity. We are now deciphering the role of ASIC3 channel in response to inflammatory mediators in the nociceptive neuraxis in the thermal hypersensitivity associated with diabetic conditions.

Abstract: Small fiber neuropathy (SFN) is characterized by injury to small-diameter peripheral nerve axons and loss of intraepidermal nerve fibers (IENF). Although available data suggest that SFN results from axonal degeneration and reduced regenerative capacity, the mechanism underlying those dysfunctions are poorly understood.
Gain-of-function variants in sodium channel NaV1.7 that increase firing frequency and spontaneous firing of dorsal root ganglion (DRG) neurons have recently been identified in 5-10% of patients with idiopathic SFN. In our previous in vitro study, DRG neurons transfected with those SFN-associated channel variants displayed reduced neurite length, suggesting that enhanced sodium channel activity can contribute to a decrease in length of peripheral sensory axons.
The activities of ion channels can disturb ionic gradients across the plasma membrane, and neurons consume ATP to maintain ionic homeostasis. Although a high mitochondrial density enables neurons to cope with that energetic challenge, the activities of normal (wild-type) voltage-gated sodium channels can contribute to growth impairment and degeneration of DRG neurites under metabolically challenging conditions.
Conversely, we have hypothesized that enhanced sodium channel activity due to gain-of-function mutations can trigger sustained sodium influx and then result in an energetic deficit in neurons. Therefore, we suggested that the energy deficiency contributes to the impairment of neurite integrity in DRG neurons and degeneration and loss of nerve fibers in SFN.
In the present study, to determine whether SFN-associated Nav1.7 variants can cause ATP deficit, we established a method to measure ATP level in live cells by using FRET technique and examined the effect of a SFN-associate variant NaV1.7 channel, I228M, on the ATP level in

sensory neurons. At 3 days after culturing, DRG neurons transfected with I228M channels exhibited a marked reduction in ATP level at the soma compared to cells expressing wild-type channels. When the culture was subjected to glucose starvation, the neurites expressing I228M showed more rapid ATP reduction, compared to wild-type channels. Our experiments suggest that expression of I228M mutant channels generates an energetic burden in cells as reflected by decreases in ATP level. This could contribute to impaired neurite integrity of DRG neurons transfected with SFN-associated Nav1.7 variants.
We are currently investigating ways to metabolically reverse the ATP deficit induced by the Nav1.7 variant and will determine whether these maneuvers protect against the impairment of neurite integrity in DRG culture and IENF loss in animal models.

Title: Mouse models of diabetic neuropathy: Decreased K_{ATP} channel expression and function in the peripheral and central nervous system

Authors: *A. H. KLEIN[1], C. FISHER[1], J. L. JANECEK[2], M. L. GRAHAM[2]
[1]Pharm. Practice and Pharmaceut. Sci., Univ. of Minnesota Duluth, Duluth, MN; [2]Dept. of Surgery, Univ. of Minnesota, St. Paul, MN

Abstract: Major complications from T2DM include diabetic neuropathy, which affect many adults with prediabetes and new-onset diabetes. It is clear that novel biomarkers and pharmaceutical targets are needed in order to confront the demand for new treatments that better manage diabetic neuropathy. There is a need for increased knowledge in how diabetes affects structural and molecular changes in the nervous system to lead to the progression of chronic pain. It is assumed that chronic hyperglycemia results loss of sensitivity to K_{ATP} channel blocking drugs (e.g. sulfonylureas) and decreased K_{ATP} channel expression in the central nervous system, which could indicate a widespread decrease in K_{ATP} channel function. K_{ATP} channel subtypes are located in the nervous system and already have implications in pain signaling, including mu opioid receptor signaling. Loss of K_{ATP} channel activity or function could cause nerve fiber hypersensitivity and consequently increased pain sensitivity due to neuron depolarization. In order to answer these questions, diabetic neuropathy was induced in male and

female C57Bl6 mice over a total of 16 weeks by feeding the animals a high-fat diet (HFD) or corresponding control diet (12330 and 12328, Research Diets Inc., New Brunswick, NJ) for over 16 weeks. Mice on the HFD for at longer than 8 weeks have significantly higher circulating C-peptide and insulin levels, higher thermal thresholds, and lower mechanical thresholds and compared to control diet mice. Mice fed a HFD also have decreased analgesia to systemic morphine (0-20 mg/kg, s.c.), which is exacerbated after systemic treatment with glyburide or nateglinide for four weeks, (KATP channel antagonist, glyburide or nateglinide, 50 mg/kg/day, IP or vehicle, 5% DMSO + 0.5% Tween). Decreased expression of KATP channel subunits Kncj8 (Kir6.1) and Abcc9 (SUR2) were found in the spinal cord, while Kcnj11 (Kir6.2) and Abcc8 (SUR1) were decreased in dorsal root ganglia. Sciatic nerves were harvested and electrical thresholds were measured using C-fiber compound action potentials (C-CAPs). C-CAPs from HFD mice had significantly higher electrical thresholds and significantly longer latencies than C-CAPs from control diet mice, which was also exacerbated after systemic treatment with glyburide or nateglinide for four weeks. We conclude that K_{ATP} channels are therefore a promising target to treat the progressive development of diabetes. Further investigation of KATP channel expression and function during chronic pain syndromes, including diabetic neuropathy, may help to find sufficient treatment options for patients.

Title: Participation of the trek1 potassium channel in neuropathy-induced mechanical hypersensitivity

Authors: *K. MENDEZ RESENDIZ[1], J. MURBARTIAN[2]
[1]CINVESTAV, Mexico, Mexico; [2]Cinvestav, Sede Sur, Mexico, DF, Mexico

Abstract: Dysregulated ion channel function in response to nerve injury results in enhanced neuronal excitability that underlies neuropathic pain. TWIK-related 1 potassium channel (TREK-1) is member of the two-pore domain potassium channel family that contribute to background conductances. TREK-1 channel is modulated by a variety of different physical and chemical stimuli (mechanical, temperature, intracellular acidification, poly-unsaturated fatty acids and phospholipids). TREK-1 activity is regulated in the C-terminal region of the channel by phosphorilation induced by G-protein coupled receptors activation. Nociceptors express TREK-1 channel, and this channel contributes to nociception in inflammatory pain models. However, the role of TREK-1 channel in neuropathic pain remains unclear. The aim of the present

investigation was to determine the participation of TREK-1 in the *mechanical* hypersensitivity induced by a neuropathic pain model in rats. All experiments were performed on adult female Wistar rats. Neuropathic pain was induced by L5/L6 spinal nerve ligation. Tactile allodynia was evaluated at 7 days after surgery. Drugs were administrated intrathecally. TREK-1 expression in the dorsal root ganglia (DRG) was determined by western blot. Spinal nerve ligation produced tactile allodynia from day 1 to 21 after the surgery. Moreover, TREK-1 protein expression increased in DRG (L4/L5) at 7 and 14 days after injury. Intrathecal injection of BL-1249 (TREK-1 activator, 1-100 μM), but not vehicle, reduced in a dose-dependent manner established tactile allodynia. Furthermore, intrathecal injection of Spadin (TREK-1 specific blocker, 1-10 μM) reduced BL-1249 (100 μM) antiallodynic effect in neuropathic rats. In addition, Spadin produced tactile allodynia in a dose-dependent manner in naïve rats. Results obtained suggest that TREK-1 has an antiallodynic effect in neuropathic rats. Furthermore, TREK-1 basal activity is responsible to keep background conductance that does not allow to development of pain in naïve rats.

Title: RE1 silencing transcription factor (REST) mediates nerve injury-induced downregulation of cholinergic receptor muscarinic 2 in primary sensory neurons

Authors: *J. ZHANG, S.-R. CHEN, H. CHEN, H.-L. PAN
Anesthesiol. & Perioperative Med., Univ. of Texas MD Anderson Cancer Ctr., Houston, TX

Abstract: Chronic neuropathic pain disrupts quality of life for many patients. Although persistent changes in gene transcription account for the long-lasting abnormal neuronal excitability, the transcriptional mechanisms involved remain unclear. The muscarinic cholinergic receptors (mAChRs) are tonically involved in the regulation of pain. Here we show that the expression level of cholinergic receptor muscarinic 2 (encode by *Chrm2*) is suppressed in the dorsal root ganglia (DRG) after peripheral nerve injury. Interestingly, the silenced gene expression of *Chrm2* is mediated by RE1 silencing transcription factor (REST; also known as neuron-restrictive silencing factor, NRSF), a transcription repressor. Nerve injury increases

REST gene expression in the rat DRG and promotes the occupancy of REST to the RE-binding site located in the *Chrm2* promoter region. *In vitro* promoter luciferase assay confirms the inhibitory function of RE-binding site for *Chrm2* expression. Knockdown of *Rest* in the rat DRG by siRNA or conditional genetic ablation of *Rest* in DRG neurons restores *Chrm2* gene expression reduced by nerve injury and augments the analgesic effect of muscarine on neuropathic pain. In addition, siRNA knockdown of *Rest* in the rat DRG or conditional knockout of *Rest* in DRG neurons enhances the inhibitory effect of muscarine on synaptic glutamate release from primary sensory nerve terminals to the spinal dorsal horn. Together, our findings support that REST is critically involved in the gene expression level of *Chrm2* in the DRG in neuropathic pain. REST may be targeted to enhance the analgesic effect of muscarinic drugs for in treating neuropathic pain. Of note, our finding may also be relevant to the mechanism of Alzheimer's disease because increased REST and decreased *Chrm2* expression occur in the brains of patients with Alzheimer's disease.

Title: HMGB1 redox isoforms selectively activate neurons and modulate pain-like behavior

Authors: *Q. ZENG[1], M. ADDORISIO[1], M. GUNASEKARAN[1], S. CHAVAN[1], U. ANDERSSON[2], K. TRACEY[1], H. YANG[1]
[1]Feinstein Inst. For Med. Res., Manhasset, NY; [2]Ctr. for Mol. Med., Karolinska Univ. Hosp. Solna, Stockholm, Sweden

Abstract: Pain involves nociception and pathophysiological reactions. Besides neuronal stimulation, nociception can be activated in a milieu of damage-associated molecular pattern (DAMPs) molecules. Among the DAMPs, HMGB1 released following nerve injury has been implicated in mediating the pathogenesis of neuropathic pain (Calvo M, Lancet Neurol 2012; Karatas H, Science 2013). HMGB1 directly acts on nociceptors to induce allodynia as well as to enhance pain-like response mediated by other factors. HMGB1 contains 3 cysteine residues and their redox states generate 3 isoforms of HMGB1 each with different biological functions. Fully reduced HMGB1 induces chemotactic responses; disulfide (mild oxidation) HMGB1 is cytokine-inducing and pro-inflammatory; and sulfonyl (all cysteine residues) HMGB1 has no known immune function (Andersson U, Seminars in Immunol, 2018). The role of isoforms of HMGB1 in neuropathic pain is unknown. Here we aimed to elucidate the effects of 3 isoforms of HMGB1 on neuronal activation and for inducing pain-like behavior. Using calcium mobilization as a

measurement of neuronal excitability, we observed the fluorescence changes / baseline fluorescence before stimulus ($\Delta F/F_0$) in sensory neuron-like F11 cells. Administration of disulfide HMGB1 elicited an intracellular calcium flux ($\Delta F/F_0 = 1.14 \pm 0.06$*), to a less extent by using fully reduced HMGB1 ($\Delta F/F_0 = 0.44 \pm 0.04$*), and further diminished with sulfonyl HMGB1 ($\Delta F/F_0 = 0.26 \pm 0.02$), (*: $p<0.05$ vs. sulfonyl HMGB1). Similar results were observed in sensory neurons isolated from dorsal root ganglia. To test whether the redox state of HMGB1 differentially modulates pain-like behavior *in vivo*, mechanical nociceptive threshold responses were analyzed in SD rats after administration of 3 isoforms of HMGB1 in a hindpaw. Compared to vehicle control, hindpaw injection of disulfide HMGB1 evoked mechanical hyperalgesia in a dose-dependent manner (threshold response (gm) of vehicle = 4.1 ± 0.4, 2 µg/paw = 3.8 ± 0.6; 12 µg/paw = 2.3 ± 0.2*; 20 µg/paw = 1.9 ± 0.2*. n=6 or 12 rats per group, *: $P<0.05$ *vs.* vehicle group). In contrast, neither fully reduced HMGB1 nor sulfonyl HMGB1 provoked any significant effect. Systemic administration of neutralizing anti-HMGB1 monoclonal antibodies (mAb) alleviated these hyperalgesic effects induced by disulfide HMGB1 (threshold response (gm) of vehicle-treated = 4.9 ± 1, HMGB1 + IgG = 1.9 ± 0.3, HMGB1 ± mAb = 3.3* ± 0.3. *: $P<0.05$ *vs.* HMGB1 + IgG), indicating that the hyperalgesia amelioration effects were HMGB1 specific. Taken together, these results suggest that disulfide HMGB1-targeted therapy has a potential as a novel strategy to control neuropathic pain.

Title: Peripheral macrophage recruitment to the dorsal root ganglia is critical to pain development after spinal cord injury

Authors: *S. J. CHHAYA[1], J. D. HOULE[1], M. R. DETLOFF[2]
[1]Neurobio. and Anat., [2]Neurobio. & Anat., Drexel Univ. Col. of Med., Philadelphia, PA

Abstract: Spinal cord injury (SCI) damages sensory systems and causes chronic, intractable neuropathic pain. Recruitment of macrophages and immune alterations in the dorsal root ganglia (DRG) can modulate nociceptor physiology and afferent sprouting, which are critical processes in SCI pain. This study examines whether macrophage recruitment to the DRG after SCI is

essential to pain development, and if the phenotype and cytokine release profile of macrophages in the DRG can dictate pain development. Adult female Sprague-Dawley rats received unilateral cervical (C5) contusive SCI that causes pain development in 40% of rats. We assessed the immune response to SCI in the C7 and C8 DRGs corresponding to the forepaw dermatome. At 12, 24, 48, 72 and 120 hours post-injury (hpi), CCL2 levels in the DRG were assessed using ELISA and qPCR. Macrophage phenotype markers mRNA and pro-inflammatory cytokine mRNA expression in the DRG were measured via qPCR. Macrophage recruitment into the DRG was assessed with ED1 immunohistochemistry. A cohort of rats received INCB3344, a CCL2 receptor antagonist intravenously for 72hpi after SCI to prevent myeloid cell recruitment. These rats were tested for pain development via von Frey and the mechanical conflict-avoidance paradigms. We observed a rapid, transient spike of CCL2 in the DRG, followed by recruitment of ED1+ cells to the DRG. 50% of rats showed elevated macrophages in the DRG at 120 hpi while the rest maintained near-normal levels. This echoes pain development seen in a subset of SCI rats at 28 dpi. Further, qPCR revealed two distinct clusters of rats—those with elevated pro-inflammatory cytokines in the DRG, or with normal expression. These early differences in cytokine profiles may predict pain development. SCI rats that received INCB3344 upto 72 hpi have fewer macrophages in the DRG at 120 hpi compared to vehicle-treated rats. We are currently assessing whether blockade of macrophage infiltration to the DRG alters SCI-induced pain behaviors. Our data supports the hypothesis that there is a dichotomy in the peripheral immune response to SCI that dictates neuropathic pain development. Future studies will examine the role of macrophage recruitment in causing nociceptor dysfunction as a mechanism contributing to SCI-induced pain.

Title: *In vivo* imaging reveals nociceptors acquire de novo cold sensitivity to drive cold allodynia in neuropathic pain

Authors: *D. I. MACDONALD, A. P. LUIZ, E. C. EMERY, J. N. WOOD
UCL, London, United Kingdom

Abstract: Innocuous cooling can elicit excruciating pain in patients suffering from peripheral neuropathy. This cold allodynia is recapitulated in mouse models of neuropathic pain which

show hypersensitivity to cooling. While cold sensing in the healthy state is relatively well understood, the cells and molecules that drive cold allodynia remain unclear. Here, we used *in vivo* calcium imaging of peripheral somatosensory neurons to ask which subsets of cells contribute to cold allodynia in neuropathic pain and by what mechanism. In healthy mice, cold-sensing neurons formed a rare population of small-diameter neurons that did not respond to any other stimulus modality. Cold hypersensitivity was elicited in male and female Pirt-GCaMP3 mice by intraplantar injection of the chemotherapeutic oxaliplatin (~3 mg/kg), which triggers cold allodynia within hours in human patients. Imaging of mice the same day as injection revealed oxaliplatin led to a population of large-diameter, mechanically-sensitive neurons acquiring a *de novo* sensitivity to cooling. There was no change in the response sizes or activation thresholds of the basally cold-sensing population. Combined functional and anatomical imaging *in vivo* revealed these neurons did not express *Ntrk2*, which labels low-threshold mechanosensors, but did overlap with *SCN10a*-expressing cells, a classic marker of mechanonociceptors. However, the voltage-gated sodium channel subtype $Na_v1.8$, reported to be critical for cold pain, was dispensable for *de novo* cold sensitivity. Intraplantar injection of 4-aminopyridine (10 mM), a non-selective inhibitor of voltage-gated potassium channels, induced cold responsiveness in previously cold-insensitive neurons within minutes. This points to functional downregulation of voltage-gated potassium channel subtypes expressed by nociceptors as a putative mechanism of *de novo* cold sensitivity in neuropathic pain. Taken together, these data implicate *de novo* cold sensitivity of mechanically-responsive nociceptors as driving cold allodynia induced by oxaliplatin. We are now investigating whether *de novo* cold sensitivity is a feature of cold allodynia resulting from nerve injury and ciguatera in order to determine whether different neuropathic pain conditions share common cellular and molecular mechanisms.

Title: Mitochondrial perturbations in sensory neurons exposed to fragments of myelin basic protein

Authors: *S. K. HULLUGUNDI[1,2], A. G. REMACLE[3], J. H. SIAMWALA[1], J. SCHILLING[1], A. V. CHERNOV[3], J. DOLKAS[1,2], A. Y. STRONGIN[3], H. PATEL[1,2], V. I. SHUBAYEV[1,2]
[1]Univ. of California San Diego, LA Jolla, CA; [2]VA San Diego Healthcare System,, La Jolla, CA; [3]Sanford Burnham Prebys Med. Discovery Inst., La Jolla, CA

Abstract: Myelin basic protein (MBP), a major myelin sheath protein, is an autoantigen. The immunodominant MBP84-104 epitope released from intact MBP is thought to contribute to painful peripheral neuropathy. RNA-seq-based pathways analyses of sciatic nerves injected with MBP84-104 identified mitochondrial dysfunction among the most activated pathways. Thus, we aimed to evaluate the effects of MBP84-104 peptide on the mitochondrial bioenergetics in sensory neurons. Our pull-down and mass spectroscopy studies performed in rat primary dorsal root ganglia (DRG) cultures revealed that the MBP84-104 peptide was capable of binding several ATP-dependent proteins associated with mitochondrial function, including voltage-dependent anion-selective channel 1 (VDAC-1), sodium potassium ATPase and ATP synthase. MBP84-104 did not affect cell viability of DRG cultures, as indicated by a minimal intracellular uptake of calcein dye. Extracellular flux analysis in adult rat DRG cultures at different time points of exposure to the peptide showed that neither ATP-linked respiration nor maximal respiration (both normalized to basal respiration) was significantly altered by the MBP84-104 peptide. However, MBP84-104 reduced the extracellular acidification rate (normalized to the basal levels) of female, compared to male, rat DRG cultures indicating specific alteration in glycolysis. This reduction possibly reflects a switch in neuronal substrate utilization. TEM analysis of DRG cultures treated with MBP84-104 for 24 hours revealed the presence of a high number of small mitochondria in neurons when compared to neurons from control cultures. Overall, it is likely that after their release into microenvironment, the myelin degradation products may affect mitochondrial structure and function in sensory neurons. Our preliminary data also suggests potential sexual dimorphism in this mechanism.

Title: Decreased protein expression of anoctamin-1 contributes to reduce neuropathic pain induced by spinal nerve ligation

Authors: *G. GARCÍA[1], V. A. MARTINEZ-ROJAS[2], E. J. GUTIÉRREZ-LARA[3], J. MURBARTIAN[4]
[1]Cinvestav Sede Sur, Mexico DF, Mexico; [2]Cinvestav Sede Sur, Mexico City, Mexico; [3]Pharmacol., CINVESTAV, Distrito Federal, Mexico; [4]Cinvestav, Sede Sur, Mexico, DF, Mexico

Abstract: Anoctamin-1 belongs to the family of calcium–activated chloride channels and is expressed in dorsal root ganglion (DRG) neurons. The activation of anoctamin-1 leads the development of the neuronal excitability observed in neuropathic pain. The aim of this study was to determine the participation of anoctamin-1 in two models of neuropathic pain in rats: L5/L6 spinal nerve ligation (SNL) and L5 spinal nerve transection (SNT).
We determined the protein expression of Anoctamin-1, as well as neuronal injury marker ATF-3 and apoptosis marker caspase-3 in injured L5 and in uninjured L4 DRG at 1, 3, 7, 14 and 21 days after SNL and SNT. SNL up-regulated anoctamin-1 protein expression in injured L5 and uninjured L4 DRG, but not after SNT. Whereas that ATF-3 and caspase-3 increased their expression only in injured L5 in SNL and SNT, but not in uninjured L4 DRG. In addition, repeated (3 times every 24 h) intrathecal (i.t.) injection of the anoctamin-1 blockers, $T16A_{inh\text{-}A01}$ (0.1-1 µg) or MONNA (1-10 µg), but not vehicle (15% DMSO) reverted tactile allodynia induced by SNL in a dose-dependent manner. In contrast, $T16A_{inh\text{-}A01}$ or MONNA modestly reverted tactile allodynia induced by SNT. Repeated intrathecal injection of $T16A_{inh\text{-}A01}$ or MONNA also reduced SNT-induced up-regulation of ATF-3 in injured L5 DRG but it did not have effect on SNT-induced up-regulation of caspase-3 expression in L5 DRG. Likewise, gabapentin (100 µg) diminished SNL-induced up-regulation of anoctamin-1, ATF-3 and caspase-3 expression in injured L5 DRG.
These data suggest that spinal anoctamin-1 in injured and uninjured DRG participates in the maintenance of neuropathic pain in rats. Our data also indicate that expression of anoctamin-1 in DRG is differentially regulated depending on the neuropathic pain model.

Title: Macrophage angiotensin II type-2 receptor triggers neuropathic pain

Authors: *A. J. SHEPHERD[1], A. D. MICKLE[1], J. P. GOLDEN[1], M. R. MACK[1], A. D. DE KLOET[2], V. K. SAMINENI[1], B. S. KIM[1], E. G. KRAUSE[3], R. W. GEREAU, IV[1], D. P. MOHAPATRA[1]

Abstract: Peripheral nerve damage initiates a complex series of structural and cellular processes that culminate in chronic neuropathic pain. The recent success of a type 2 angiotensin II (Ang II) receptor (AT2R) antagonist in a phase II clinical trial suggests angiotensin signaling is involved in neuropathic pain. However, transcriptome analysis indicates a lack of AT2R gene expression in human and rodent sensory ganglia, raising questions regarding the tissue/cell target underlying the analgesic effect of AT2R antagonism. We show that selective antagonism of AT2R attenuates neuropathic, but not inflammatory mechanical and cold pain hypersensitivity behaviors in mice. AT2R-expressing macrophages constitute the predominant immune cells that infiltrate the site of nerve injury. Interestingly, neuropathic mechanical and cold pain hypersensitivity can be attenuated by chemogenetic depletion of peripheral macrophages and AT2R-null hematopoietic cell transplantation. Our study identifies AT2R on peripheral macrophages as a critical trigger for pain sensitization at the site of nerve injury, and therefore proposes a novel, translatable peripheral mechanism underlying chronic neuropathic pain.

Title: Analgesic and preventive effects of free radical scavengers in chemotherapy-induced neuropathic pain in rats

Authors: *H. KIM, S. ABDI
Dept. of Pain Med., MD Anderson Cancer Ctr., Houston, TX

Abstract: Advances in the treatment of cancer using various types of chemotherapy agents have led to improvement in the survival rate of cancer patients. Unfortunately, pain associated with the chemotherapy including taxanes, vinca alkaloids, and platinum complexes is a dose-limiting adverse effect which affects the quality of life of the survivals. The purpose of study was to determine the analgesic and preventive effects of Tempol, a free radical scavenger, on paclitaxel (PAC)-induced neuropathic pain in rats. PAC-induced neuropathic pain was produced by interaperitoneal injections of PAC (2 mg/kg on days 0, 2, 4, 6) in adult male Sprague-Dawley rats. The pain behavioral tests as well as western blotting and live cell imaging of the L1-6 dorsal root ganglia (DRGs) were performed. Tempol was intraperitoneally injected or infused beginning on day 0, 6, or 20. For the analgesic effect, the single injection and infusion of Tempol reduced pain behaviors on day 20. PAC increased the levels of inflammatory cytokines and mitochondrial superoxide anion in the DRGs tissues and culture. However, Tempol decreased PAC-induced cytokines and superoxide anion. For the prevention, the infusion of Tempol beginning on day 0 for 1 week did not affect the development of pain behavior. In contrast, the infusion of Tempol beginning on day 6 for 1 week completely prevented further development of pain behavior. We conclude that Tempol alleviates and prevents chemotherapy-induced neuropathic pain in rats by reducing the levels of inflammatory cytokines and free radicals in the DRGs.

Title: Extended use of diagnostic skin punch biopsies of SFN patients to multiply limited material for new *in vitro* tools to investigate small fiber pathology

Authors: *F. KARL[1], T. MALZACHER[1], K. LUISA[1], S. NADINE[1], C. SOMMER[1], F. GROEBER-BECKER[2], N. ÜÇEYLER[1]

[1]Dept. of Neurol., Univ. of Wuerzburg, Wuerzburg, Germany; [2]Translational Ctr. Wuerzburg 'Regenerative Therapies in Oncology and Musculoskeletal Diseases', Wuerzburg Br. of the Fraunhofer-Institute Interfacial Engin. and Biotechnology, IGB, Wuerzburg, Germany

Abstract: Background and Objective: Small fiber neuropathy (SFN) is characterized by acral burning pain and dysesthesias. SFN primarily affects thinly myelinated A-delta and unmyelinated C fibers responsible for pain and thermal perception. The underlying mechanisms of SFN are unknown and research is hampered by the limited availability of biomaterial restricted to few mm² of diagnostic skin punch biopsies taken for intraepidermal nerve fiber density (IENFD) assessment. Our aim was to determine innervation patterns on skin biopsies of SFN patients, to establish primary fibroblast and keratinocyte cell cultures from 6-mm skin biopsies, and to generate patient-derived threedimensional (3D)-full thickness skin models (FTM) as an in vitro model to investigate small fiber pathology.
Methods: So far we recruited 56 SFN patients and healthy controls. Skin punch biopsies were taken from the lateral lower leg and the upper thigh. The IENFD was determined on one half of the biopsy by immunohistochemistry of protein gene product 9.5 and innervation patterns were determined compared to controls. The second part of the biopsy was used to isolate human dermal fibroblasts (HDF) and human epidermal keratinocytes (HEK) for primary cell culture. Additionally, HEK and HDF from adult healthy controls were used to establish a compressed FTM containing a collagen type I hydrogel. The histological structure of FTM was assessed using immunohistochemistry with hematoxylin-eosin.
Results: When applying the normative values of our laboratory obtained from n=180 healthy subjects, four patterns of skin innervation were found in SFN patients: distally reduced IENFD (women: 26%, men: 23%; control women 11%, control men 19%), proximally reduced IENFD (women: 3%, men: 9%; controls women: 3%, controls men:none), generally reduced IENFD (women: 21%, men: 45%; controls women: 3%, controls men: none), and normal IENFD (women: 50%, men 23%, control women 82%, control men 81%). Thus, 37% of SFN patients had normal skin innervation while reporting typical symptoms. We established primary cell cultures of HDF and HKF from 6-mm skin punch biopsies, and also succeeded in generating first FTM displaying regular human skin histology as an in vitro tool for pathophysiology research.
Conclusions: There is a relevant subpopulation of SFN patients that may be missed by current diagnostics due to normal skin innervation, which does not exclude the diagnosis. Thus, besides nociceptor quantity, potential local factors influencing nociceptor sensitivity need to be considered, which can be studied using primary cell cultures and FTM in future studies.

Title: Effect of neuronal globotriaosylceramide deposits on pain and sensory impairment in Fabry disease

Authors: *L. HOFMANN[1], D. HOSE[1], S. D. DIB-HAJJ[3], S. WAXMAN[3], C. SOMMER[1], E. WISCHMEYER[2], N. ÜÇEYLER[1]
[1]Dept. of Neurol., [2]Inst. of Physiol., Univ. of Wuerzburg, Wuerzburg, Germany; [3]Dept Neurol, Yale Sch. of Med. and VAMC, West Haven, CT

Abstract: Background and Objective: Fabry disease (FD) is an X-linked, progressive and life-threatening inherited lysosomal storage disorder with intracellular accumulation of globotriaosylcermaide (Gb3) due to α-galactosidase A (α-Gal A) deficiency. Starting in early childhood, Fabry patients characteristically suffer from episodic acral burning pain particularly triggered by heat and fever that substantially limits health related quality of life. We aimed to elucidate the mechanism linking neuronal Gb3 deposits with pain and sensory impairment, using the α-galactosidase A knockout (GLA KO) mouse as a model for FD. Additionally, we investigated the effect and potential reversibility of Gb3 depositions on pain associated ion channel function in an in vitro model of FD.
Methods: We investigated the localization of Gb3 in dorsal root ganglion (DRG) neurons of young (3 months) and old (12-24 months) GLA KO mice compared to wildtype (WT) littermates. Patch-clamp analysis was used for characterization of transient receptor potential vanilloid 1 (TRPV1), hyperpolarization-activated (I_h), and voltage-gated-sodium currents in cultured DRG neurons. We assessed pain associated behavior after intraplantar injection of capsaicin, chronic constriction nerve injury (CCI) of the sciatic nerve, and intraplantar injection of complete Freund`s adjuvant (CFA) as pain models. Finally, we investigated the effect of Gb3 accumulation on neuronal ion channel function in human embryonic kidney 293 (HEK) cells expressing voltage-gated sodium channel 1.7 ($Na_v1.7$), induced by α-Gal A silencing.
Results: Gb3 was increased in DRG neurons of old GLA KO mice compared to WT littermates and young mice. While electrophysiological characteristics of TRPV1 currents did not differ between genotypes, old GLA KO mice displayed increased and sustained heat hypersensitivity compared to old WT mice ($p<0.05$) after intraplantar capsaicin injection. In contrast, I_h- and

sodium-currents were notably reduced ($p<0.001$ each) in old GLA KO mice compared to old WT mice. Accordingly, old GLA KO mice did not develop heat or mechanical hypersensitivity after CCI and intraplantar injection of CFA ($p<0.001$ each). Finally, HEK cells in which α-Gal A was silenced by small hairpin RNA displayed an increase in Gb3 deposition and a subsequent reduction of $Na_v1.7$ currents ($p<0.01$) compared to control cells. Both effects were reversed by agalsidase-α incubation 24 hours prior patch-clamp analysis ($p<0.05$).
Conclusions: Our study provides first evidence for a direct effect of Gb3 on neuronal ion channel function as a potential contributor to pain and sensory disturbance in FD.

Title: Epigenetic modification by sigma-1 receptor at the dorsal root ganglion in neuropathic pain

Authors: *N. GOGUADZE, H.-E. WU, T.-P. SU
Cell. Pathobiology Section, NIDA, IRP, NIH, Baltimore, MD

Abstract: Chronic neuropathic pain alters nociceptive signal processing that causes suffering and reduces quality of life. The ER chaperone sigma-1 receptor (Sig-1R) was demonstrated to play a role in neuropathic pain and is known to exist in the dorsal root ganglia (DRG), notably, at the nuclear envelope. However, the molecular mechanisms whereby Sig-1Rs modulate neuropathic pain at the DRG are largely unknown. This study was undertaken to examine the role of Sig-1R on the DRG on the behavioral and molecular level.
In naïve rats, direct DRG injection (4^{th} and 5^{th} lumbar DRG) of the Sig-1R agonist (+)-pentazocine produced a hypersensitivity to threshold mechanical stimulation, as well as a trending hypersensitivity to noxious mechanical, brush, or cold stimulation. In “spared nerve injury” rats, the Sig-1R antagonist BD1047 caused a reduction in neuropathic hypersensitivity. At the molecular level, we noticed that the inhibition of histone methyltransferase at the DRG was recently shown to attenuate the neuropathic pain by correcting the dysfunctional potassium channels. Inasmuch as Sig-1Rs exist at the nuclear envelope, we hypothesized that Sig-1Rs may participate in the transcriptional regulation of epigenetic enzymes related to neuropathic pain. Therefore, we examined enzymes which affect the histone methylation/acetylation as well as

their respective products in DRGs from wild type and Sig-1R knockout mice. Immunoblottings from Sig-1R knockout DRGs, when compared to wild type DRG, showed a decrease in the level of the enhancer of zeste homolog 2 methyltransferase (EZH2) and euchromatic histone-lysine N-methyltransferase-2 (G9a). However, the level of the mixed-lineage leukemia 1 methyltransferase (MLL1) was increased in the Sig-1R knockout DRG. Correspondingly, the resultant level of the product for EZH2 and G9a, i.e., H3K27me3 and H3K9me2 respectively, was reduced whereas the H3K4me3 for MLL1 was increased. Our results suggest that the Sig-1R participates in the genesis of neuropathic pain through the epigenetic modification of histone in the DRG.

Boston, Boston, MA

Abstract: Objective/Specific Aims: Identify functional and transcriptional changes in primary somatosensory neurons after peripheral nerve injury and determine their contribution to neuropathic pain
Background: Neuropathic pain is a common disorder typically caused by disease of or damage to the peripheral nervous system. Spontaneous pain is a major feature of neuropathic pain disorders and is thought to be generated by the ectopic activity of peripheral somatosensory neurons. Unfortunately, it is not known which subtypes of peripheral sensory neurons become spontaneously active after nerve injury or what changes in gene expression cause their

hyperexcitability. Here, we present functional and transcriptional data exploring the changes that take place in injured somatosensory neurons and contribute to their hyperexcitability. Results and significance: Sciatic nerve injury, an animal model of neuropathic pain, produces thermal and mechanical hyperalgesia, and mechanical allodynia, which are also present in patients with neuropathic pain. At various time points after sciatic nerve injury, we dissected and cultured lumbar L3-L5 dorsal root ganglia (DRG) neurons in vitro and then performed functional and transcriptional analyses on these cultured neurons. We observed a higher incidence of spontaneous activity and higher excitability in ipsilateral injured DRG neurons as compared to naive control DRG neurons using both patch clamp electrophysiology and calcium imaging. We also observed a lower density of voltage gated potassium currents in ipsilateral DRG neurons, consistent with their hyperexcitability. Finally, we performed a single cell transcriptional analysis on injured vs naive DRG neurons and found a number of differences in gene expression associated with injury and consistent with injury-induced hyperexcitability. We believe that a combined functional and transcriptional analysis may help identify changes that take place in defined subpopulations of somatosensory neurons in neuropathic pain and potentially identify new drug targets for the treatment thereof.

Title: Histone demethylase LSD1 in peripheral sensory neurons regulates neuropathic pain in rats with chronic compression of dorsal root ganglion

Authors: *L. LIANG[1], S. WANG[1], X. ZHU[2], Y. CHEN[1], Y. WANG[3], F. HUO[3], S. JIA[2], S. LU[3]
[1]Xi'An Jiaotong Univ. Hlth. Sci. Ctr., Shaanxi, China; [2]Anesthesiol., Yantai Affiliated Hosp. of Binzhou Med. Univ., Yantai, China; [3]Key Lab. of Envrn. and Genes Related to Dis., Beijing, China

Abstract: Neuropathic pain is one of the most refractory and painful diseases in clinic and is lack of effective drug therapy due to unclear mechanisms. Histone methylation is one of major

epigenetic mechanism for gene expression and has been reported involved in the nerve injury induced neuropathic pain. Lysine-specific demethylase 1 (LSD1) is the first identified subfamily of histone Nε-methylated lysine residue demethylases. A previous RNA-seq data have analyzed the whole genome gene expression from sham and spinal nerve ligated DRGs and found the increased expression of LSD1 mRNA in injuried DRG. However, it is not clear if LSD1 contributes to neuropathic pain genesis. In this study, using two rat neuropathic pain models of spinal nerve ligation or chronic compression of dorsal root ganglion (CCD), we confirmed the increased LSD1 mRNA and protein levels in injured DRGs by qPCR or western blot methods. LSD1 inhibitor SP2509 or LSD1 siRNA relieved bilateral pain hypersensitivities to mechanical, thermal and cold stimuli. Moreover, LSD1 siRNA reversed the increased LSD1 and the decrease of its catalytic site histone 3 lysine 4 dimethylation (H3K4me2) expression induced by CCD. These data suggests that LSD1 may be a new potential target for neuropathic pain intervention.

Title: Neuropathic pain susceptibility in prenatal alcohol exposed (PAE) females is mediated by the proinflammatory actions of lymphocyte function-associated antigen (LFA)-1 on immune and glial cells

Authors: *S. NOOR[1], J. SANCHEZ[1], Z. PERVIN[1,2], J. SANCHEZ[1], M. S. SUN[1], L. EPLER[1], S. DAVIES[1], D. SAVAGE[1], N. MELLIOS[1], L. JANTZIE[1,3], E. MILLIGAN[1]

Abstract: Previous work demonstrates that PAE male rat offspring with peripheral nerve injury augments spinal and peripheral immune cell responses and elevates pro-inflammatory cytokine levels that underlie heightened allodynia (non-painful stimuli perceived as painful) in PAE rats. Furthermore, upregulation of adhesion molecules such as LFA-1, occur concurrently with PAE and allodynia. In the current study, female PAE rats were examined to determine whether a

similar pattern of allodynia is observed following sciatic neuropathy induced by either standard (4 suture) chronic constriction injury (CCI) or minor nerve injury (a *single* suture CCI) as seen in males. In addition, the LFA-1 antagonist, BIRT377 was used to explore the critical actions of peripheral immune cells/factors underlying peripheral neuropathy in these rats. Data demonstrate that females display neuropathic susceptibility following standard or minor nerve injury, which could be reversed by *intravenous* but not *intrathecal* (spinal) injection of BIRT377. In contrast, BIRT377 suppressed neuropathy in males via both routes of administration. These data suggest blocking the actions of immune cells factors by suppressing LFA-1 actions in the spinal cord is not sufficient to reverse allodynia in females, suggesting sex-related differences exist between spinal immune phenotypes that contribute to neuropathic pain. The sciatic nerve, dorsal root ganglia and spinal cord were collected from these females to investigate the underlying PAE-related immune mechanisms and the effects of BIRT377. Real time PCR and protein (via multiplex) cytokine analysis demonstrate that the pro-inflammatory cytokines, tumor necrosis factor (TNF) and interleukin (IL)-1β are greater in PAE rats with allodynia than the control rats. A CCI injury-induced compensatory increase of the anti-inflammatory cytokine, IL-10 occurs at the sciatic nerve in non-PAE rats, while PAE females display blunted IL-10 responses. BIRT377 treatment reduces TNF and IL-1β and rescues normal IL-10 expression in neuropathic PAE rats. Moreover, augmented glial activation (GFAP mRNA levels) occurs in PAE females with neuropathy compared to the control animals, suggesting astrocyte activation may contribute to neuropathic susceptibility in PAE females. BIRT377 treatment reduced astrocyte activation in neuropathic PAE rats. These data suggest that exaggerated peripheral immune cell and glial actions lead to the development of neuropathic pain susceptibility in PAE females that is reduced by BIRT377 by promoting an anti-inflammatory environment.

Title: The analgesic efficacy of low frequency stimulation in docetaxel-induced neuropathic pain decreases ultrasound vocalizations in mice

Authors: *S.-Y. KANG[1], Y. RYU[1], S.-Y. SEO[1], O. KWON[1], K.-H. CHOI[1], S. CHO[1], H. YOO[2], J. LEE[3]

Abstract: Objective. Docetaxel, a chemotherapeutic agent used to treat breast cancer, produces a robust painful neuropathy that is aggravated by mechanical and thermal stimuli. This study was undertaken to investigate the analgesic effects of low frequency stimulation on docetaxel-induced neuropathic pain in mice and to identify associated changes in ultrasound vocalizations. **Methods.** Peripheral neuropathy was induced with intraperitoneally injected docetaxel (5mg/kg) on 3 times every 2 days in male ICR mice. Low frequency wrist stimulation (Care band, 16 Hz) was administered and pain behavior signs were evaluated by von Frey filaments and thermal stimulation on the hind paw. Ultrasound vocalizations were measured using ultrasound microphones (frequency range: 10-200 kHz, Avisoft Bioacoustics), after low frequency stimulation. **Results.** After mice developed docetaxel-induced neuropathic pain behavior, a single low frequency stimulation temporarily attenuated mechanical allodynia and thermal hyperalgesia. In formalin and NMDA test, pain-induced mice showed increases in 10-30 kHz ultrasound vocalizations, but not in 30-50 and 50-80 kHz vocalizations. Treatment with docetaxel for 3 times every 2 days selectively increased 10-30 kHz ultrasound vocalizations, whereas low frequency stimulation caused a meaningful decrease. **Conclusions.** These results suggest that low frequency stimulation can be a potential strategy for the management of chemotherapy-induced neuropathy. We showed the ability of low frequency stimulation to attenuate pain in a mouse model of chemotherapy-induced neuropathy. This approach could potentially provide a new method to treat peripheral neuropathic pain in cancer patients.

Title: A conditioning lesion induces an arachidonic acid-containing phosphatidylcholine level increase and lysophosphatidic acid precursors level decrease in the dorsal root ganglion of mice

Authors: *Y. MIHARA[1], T. OMURA[2]
[1]Orthopaedic Surgey, Hamamatsu Univ. Sch. of Med., Hamamatsu/Shizuoka, Japan; [2]Hamamatsu Univ. Sch. of Med., Hamamatsu, Shizuoka, Japan

Abstract: [Introduction] Pre-conditioning peripheral nervous system neurons by a peripheral axonal injury primes them through massive transcriptional changes to regenerate more vigorously. Conditioning lesion also triggers cellular and molecular changes in the dorsal root ganglion (DRG) and promotes intrinsic growth capacity for nerve regeneration in the DRG neurons. However, little is known about how lipids are regulated in the DRG after conditioning lesion. Previously we reported lipid investigations of several nervous systems using matrix-assisted laser desorption/ionization imaging mass spectrometry (MALDI-IMS). In this study, lipids changes of DRG after conditioning lesion were analyzed using MALDI-IMS. [Experimental procedure] 8-week-old C57BL/6JJmsSlc male mice were used for this study. Sciatic nerve transection (SNT) was performed by transection of the left sciatic nerve at mid-thigh level under anesthesia. Five days after SNT, 3 mice were sacrificed and L4-6 DRG were extracted for analysis. The same number of naive mice was used as controls. These DRGs were flesh frozen and were cut at -20℃ using a cryostat, then placed alternately onto glass slides coated with indium-tin-oxide. IMS analyses were performed using a MALDI time-of-flight (TOF)/TOF-type instrument (Solarix XR). Regions of interests (ROIs) in DRG were determined by selecting 20 points randomly. [Results] We found that arachidonic acid-containing phosphatidylcholine (AA-PC), [PC(16:0/20:4)+K]+ , increased significantly in the DRG after sciatic nerve transection (SNT). Moreover, [PC(16:0/18:1)+K]+, [PC(18:0/18:1)+ K]+ and [phosphatidic acid (PA)(36:2)+K]+ decreased significantly in the DRG after SNT. [Discussion] According to our previous research, the increase of [PC(16:0/20:4)+K]+ is associated with neuropathic pain. The decrease of [PC(16:0/18:1)+K]+, [PC(18:0/18:1)+ K]+ and [PA(36:2)+K]+ might be induced by production of lysophosphatidic acid (LPA), a initiator of neuropathic pain. There are 2 major pathways for synthesis of LPA. One is from lysophosphatidylcholine (LPC) by autaxin (ATX) enzymes. Another is from PA by phospholipase A2 (PLA2) enzymes. Reduction of [PC(16:0/18:1)+K]+ and [PC(18:0/18:1)+ K]+ might be as a consumption by the former pathway to produce LPA. [PA(36:2)+K]+ was also consumed by the latter pathway. [Conclusion] These results suggest that mechanisms of conditioning lesion might be associated with neuropathic pain. Suitable nerve stimulation must be benefit for nerve regeneration, though neuropathic pain is the excessive stimulation of nerve.

Title: The immunoreactive expression pattern of neun as a neuronal-nuclei qualifier for high-throughput data analysis in rat dorsal root ganglion: 2-day adjuvant-induced arthritis

Authors: *M. B. ANDERSON, K. E. MILLER
Oklahoma State Univ., Tulsa, OK

Abstract: Automated high-throughput data analysis in neuronal tissue is currently an uncommon practice. This is typically due to strict software parameters required to identify neurons within tissue sections that have morphological differences and immunohistochemical labeling variability. Also, available fluorescent markers to identify cellular landmarks must be relatively consistent in their intensity between control and experimental conditions to identify consistent populations of neurons. In dorsal root ganglion (DRG), the requirement of a proofing-system is critical in the automatic and successful selection of neurons due to the presence of satellite/glial cells. To overcome these obstacles, we utilized the nuclear marker DAPI (4' 6-Diamidino-2-Phenylindole, Dihydrochloride) and NeuN immunoreactivity (ir) to automatically identify and select neuronal nuclei from a heterogeneous cell population in frozen tissue sections. NeuN has been shown to be expressed in nuclear ($NeuN_N$), cytoplasmic ($NeuN_C$), nuclear/cytoplasmic ($NeuN_{NC}$), or NeuN negative neural cell populations. In addition, peripheral nerve resectioning has shown a near-complete loss of NeuN-ir in facial motoneurons. Due to the reported differences of NeuN-ir, it is important to carefully evaluate its expression as a neural selective marker in specific control and experimental conditions. The focus of this study was to evaluate the immunoreactive expression and use of NeuN in DRG neurons as a neuronal-nuclei qualifier, in conjunction with DAPI, for the automatic identification of neurons in the high-throughput data analysis of frozen tissue sections from rat DRG during adjuvant-induced arthritis (AIA). To further understand any potential subcellular changes of NeuN, we examined whole cell, cytoplasmic, and nuclear expression of NeuN between experimental conditions with immunohistochemistry and western blots. Glutaminase (GLS), the enzyme for neurotransmitter glutamate synthesis, also was evaluated during AIA. AIA was induced by injection of complete Freund's adjuvant into the right hindpaw of anesthetized rats. A reliable and robust script for ImageJ was written that produces neuronal-nuclei seed images based on the presence of DAPI within the boundary of NeuN-ir. This script was designed to be flexible enough to overcome observed variability of NeuN-ir and was successful in its ability to equally measure both control and AIA neuronal cell populations. High-throughput data analysis was achieved using these seed images and establishes a novel method of high-throughput evaluation of frozen tissue sections from rat DRG neurons during AIA.

Title: BIRT377, an inhibitor of lymphocyte function-associated antigen 1, suppresses allodynia in males and females through different immune signaling cytokines

Authors: *M. S. SUN[1], S. NOOR[1], A. G. VANDERWALL[1,2], M. A. HAVARD[2], J. E. SANCHEZ[1], N. W. HARRIS[1], M. V. NYSUS[3], J. P. NORENBERG[3], E. D. MILLIGAN[1]
[1]Neurosciences, [2]Anesthesiol. and Critical Care, [3]Radiopharmaceutical Sci., Univ. of New Mexico, Albuquerque, NM

Abstract: Recent evidence suggests that peripheral neuropathic pain relies on immune cell phenotype and function that may be sexually dimorphic. BIRT377 is a small molecule inhibitor of lymphocyte function-associated antigen 1 (LFA-1), a β_2 integrin adhesion molecule expressed on leukocytes such as T cells and monocytes, and is important for migration of these cells into areas of tissue damage. Allodynia (pathological sensitivity to light touch) is observed in rodent models of peripheral neuropathy such as the Chronic Constriction Injury (CCI) of the sciatic nerve. During neuropathic pain, T cell actions are observed to play a greater role in female rodents than in males. Recently, we reported that blocking LFA-1 actions robustly reverses allodynia in male and female mice with CCI, with its actions occurring specifically on female-derived but not male-derived T cells (SfN Poster, 2017, Sun et al.). Therefore, we hypothesized that the sexually dimorphic pain-suppressive actions of BIRT377 occurs by altering discrete proinflammatory signaling molecules (cytokines and chemokines) in anatomical regions of the pain pathway (lumbar spinal cord (LSC), dorsal root ganglia (DRG), sciatic nerve (SCN)). Behavioral hindpaw assessment (von Frey fiber test for light touch threshold responses) of male and female C57BL/6 mice (10-12 wks; N=6/gp) prior to and after sham or CCI (sciatic loose ligation using three 5-0 chromic gut sutures) surgery was performed. On Day 10 after surgery, mice were injected with BIRT377 (intravenous; i.v., tail vein; 2.5 µg in 50µL) or vehicle and assessed daily to Day 3 after injection. mRNA levels were assessed for pro- and anti-inflammatory cytokines (C-C Chemokine Ligand 2 (CCL2), Interleukin-1β (IL-1β), Tumor Necrosis Factor (TNF), IL-10, IL-17A), T_{Reg} cell transcription factor (Forkhead Box P3

(FoxP3)), and the glial activation markers (Glial Fibrillary Acidic Protein (GFAP): astrocytes; Transmembrane Protein 119 (TMEM119): microglia). Differences in various cytokines between male and female mRNA levels following CCI, and separately as a result of BIRT377, were observed in SCN, DRG, and LSC. Specifically, in female SCN, i.v. BIRT377 increased IL-10 mRNA. Sexually distinct decreases of pro-inflammatory CCL2, IL-1β, and TNF mRNA cytokines were seen following BIRT377 treatment. Additionally, decreases in pro-inflammatory cytokine, IL-17A, and increases in anti-inflammatory FoxP3 were seen in female tissues only. GFAP mRNA levels were decreased while TMEM119 remained unaffected by BIRT377. Thus, BIRT377 controls neuropathic pain in both males and females but by affecting different immune and glial cell actions.

Title: Over-expression of secreted amyloid precursor protein alpha ameliorates pathological hallmarks of type 1 diabetes

Authors: *G. L. ODERO[1], B. D. AULSTON[2,3], D. R. SMITH[2], G. W. GLAZNER[2,3]
[1]Pharmacol. & Therapeut., [2]Div. of Neurodegenerative Disorders, Albrechtsen Res. Ctr., Winnipeg, MB, Canada; [3]Pharmacol. & Therapeut., Univ. of Manitoba, Winnipeg, MB, Canada

Abstract: Secreted amyloid precursor protein alpha (sAPPa) has been shown to confer beneficial properties in central nervous system neurons such as increasing neurite outgrowth, enhancing long-term potentiation and acting in a neuroprotective capacity. However, relatively little is known about the function of sAPPa in the peripheral nervous system, specifically, in the context of diabetes. To study its function, we used transgenic mice that over-expressed sAPPa. Expression of the transgene was detected in whole DRG and sciatic nerve as determined by reverse transcript-polymerase chain reaction (RT-PCR). Immunohistochemistry (IHC) in whole dorsal root ganglia (DRG) detected increased expression of APP protein most dramatically in the satellite glial cells. IHC also indicated increased expression of APP protein in sciatic nerve, presumably in Schwann cells. In this study, wild type and transgenic sAPPa over-expressing mice were rendered type 1 diabetic by injection of streptozotocin. After 4 months of uncontrolled

diabetes, thermal testing revealed retention of thermal sensation in the transgenic sAPPa mice relative to their wild type controls. Furthermore, histological quantitation of intra-epidermal nerve fibers showed a greater density of nerve fibers in the transgenic sAPPa mice relative to their controls. We also report that demyelination of nerve fibers associated with type 1 diabetes was decreased in the diabetic transgenic sAPPa mice relative to their diabetic controls. Hematoxylin and eosin staining indicated no differences in neuronal morphology or distribution of neuronal cell sizes between the wild type and transgnic mice, nor did it indicate increased number of satellite glial cells/DRG neuron. Collectively, our data suggests that sAPPa may mediate pathways in the development of key neuropathological hallmarks of type 1 diabetes and may represent a novel target for future therapeutic interventions. This data also suggest that the effects observed may be glial-derived.

Title: Loss of heat pain sensitivity in patients with diabetic and chemotherapy-induced neuropathic pain is nociceptor fiber specific and spontaneous pain may not assess by contact or radiant heat

Authors: *M. I. NEMENOV[1,2], M. KLUKINOV[2], D. C. YEOMANS[3], M. SCHMELZ[4]
[1]Lasmed LLC, Mountain View, CA; [2]Anesthesia, Stanford Univ., Palo Alto, CA; [3]Stanford Univ., Stanford, CA; [4]Heidelberg Univ., Mannheim, Germany

Abstract: Denervation of epidermal nociceptors leads to pain sensitivity loss to contact or radiant heat in the area where patients experience spontaneous neuropathic pain (NP). Likely because of this paradox, no correlation between NP and heat pain thresholds are found, in contrast with inflammatory pain states. We found that a group of C fibers is sensitized to heat similarly as in inflammatory pain [1] and the loss of pain sensitivity in the NP patients is nociceptors type specific [2]. These novel findings may explain why spontaneous NP may be observed in the area of pain sensory loss in diabetic and chemotherapy-induced NP patients. Thus, sensitized and spontaneously active C mechano-insensitive (CMi) nociceptors are likely responsible for spontaneous NP but not accessible by contact or radiant heat. In contrast, the loss

of readily accessible C and Aδ polymodal nociceptors is responsible for loss of heat pain sensitivity. Heat sensitive CMi as well as C polymodal and Aδ nociceptors are trpv1 positive and thus have same thresholds to heat. The inaccessibility of CMi compared to polymodal nociceptors may be explained by their deeper location. **We hypothesize that the CMi are located mainly in subepidermal and dermal tissue unlike C and A δ polymodal nociceptors which are mainly epidermal.** To test this we recruited 12 healthy volunteers without a history of peripheral neuropathy. Activation of CMi fibers was assessed by measuring the flare response to heat, as CMi fibers are solely responsible for this. Activation of the CMi and pain thresholds were defined in normal skin of 33 °C and in skin cooled to 22 °C. The skin cooling numbs epidermal fibers and mimics heat sensory loss in the patients. Diode Laser pulses (LasMed, CA) that produces deep skin heating and selective activation of C fibers were used. Neurogenic flare was documented by perfusion recording (Perimed, Sweden). Temperature was monitored by thermal camera (Flir, USA). Skin cooling was performed by controllable CO_2 gas spray. ***Activation of CMi nociceptors as assessed by induction of neurogenic flare response required less energy when compared to induction of pain, in particular after superficial cooling, suggesting a matching of stimulation depth of DL and CMi nociceptors location.*** Such matching may explain abnormally low C fibers pain thresholds in the patients as they have few epidermal polymodal fibers but deeper CMi fibers may be relatively intact and sensitized [1,2]. 1. Title: A novel role of oxidized omega-6 polyunsaturated fatty acids in diabetic pain

Authors: *P. M. LOCOCO, A. R. FURR, D. A. ARRIS, K. M. HARGREAVES
Univ. of Texas Hlth. Sci. Ctr. at San Antonio, San Antonio, TX

Abstract: Diabetic neuropathy (DN), one of the most common, taxing complications of type 2 diabetes (T2D), arises from persistent metabolic abnormalities that damage the peripheral nerves, especially sensory afferent fibers that innervate the feet and hands, leading to debilitating numbness, neuropathic pain and other sensorimotor symptoms. There is an urgent need to delineate mechanisms underlying DN and identify novel treatments, as an effective therapy does not exist. We demonstrated previously that oxidized metabolites of linoleic acid (LA), a prominent omega-6 polyunsaturated fatty acid (PUFA), regulate TRPV1 and TRPA1 activity in nociceptors and trigger pain behaviors. The purpose of this study is to investigate the contribution of omega-6 PUFAs to diabetic pain. Using db/db mice as a model of T2D and dyslipidemia, we first characterized the development of DN by monitoring changes in nociceptive thresholds to various stimuli. By 16 weeks of age, db/db mice developed mechanical and cold allodynia, but sensitivities to heat, pinprick, and brush were unchanged. To determine whether acute oxidation of omega-6 PUFAs affected neuronal responsiveness, we administered a single intraplantar injection of LA (1 mg) to the mice. 30 min post-injection, LA exacerbated the mechanical hypersensitivity in db/db mice, suggesting a likely interaction between omega-6 PUFAs and/or their metabolites with afferent neurons in the hindpaw. We next asked whether pharmacological inhibition of omega-6 PUFA-oxidizing enzymes affected mechanical thresholds. Ketoconazole (10 mg/kg, i.p.), voriconazole (10 mg/kg, i.p.), or vehicle were injected daily for 4 days. Mechanical thresholds were measured the day before the first injection and the day after the last injection. Interestingly, both ketoconazole and voriconazole treatment attenuated the mechanical allodynia in db/db mice, suggesting that enzymatic oxidation of omega-6 PUFAs contributes to DN. We also performed single-fiber electrophysiology using isolated glabrous skin-tibial nerve preparations to measure spontaneous activity and changes in stimulus-evoked functional responsiveness of primary afferent fibers innervating the glabrous paw skin. Nociceptive fibers from db/db mice exhibited an increase in spontaneous firing as well as a leftward shift in mechanical sensitivity. Collectively, these data indicate a novel role for omega-6 PUFAs in T2D-associated pain.

Title: Spatial organization of oral tongue cancer invasion into peripheral nerves in a murine oral carcinogenesis model

Authors: *A. BHATTACHARYA[1,2], R. VEERAMACHANENI[3], B. L. SCHMIDT[2], D. G. ALBERTSON[2]
[2]Bluestone Ctr. for Clin. Research, Oral and Maxillofacial Surgery, [3]Bluestone Ctr. for Clin. Res., [1]NYU Col. of Dent., New York, NY

Abstract: Perineural invasion (PNI) is associated with increased risk for tumor recurrence, increased risk for cervical node metastasis and decreased overall patient survival in oral cavity squamous cell carcinoma (SCC). Oral SCC patients with PNI also report function related pain which is not relieved by opioids (the current standard of care). PNI is classically defined as cancer cell "invasion in, around, and through peripheral nerves." Although the College of American Pathologists Oral Cavity Cancer Protocol (2017) recommends reporting the presence and extent of perineural invasion in a pathology report, pathologists differ in their interpretation of this prognostic histologic feature. Furthermore, PNI is evaluated only in surgical resection specimens and not in preoperative biopsy tissue, and therefore evaluation of this critical parameter is not available for surgical treatment planning. The 4-nitroquinoline-1-oxide (4NQO) oral carcinogenesis model recapitulates histopathological features of human oral SCC, including invasion, tumor heterogeneity, PNI and lymphovascular invasion. A subset of tongue SCC shows extensive PNI that can be defined by specific histological patterns of nerve-cancer cell associations (e.g., complete vs incomplete encirclement of nerve, tangential contact). The 4NQO model offers an opportunity to develop a three dimensional map of oral SCC-nerve associations from serial sections. These maps can guide pathological analysis of human tongue SCC.

Title: Sex differences in cell-specific toll-like receptor 4 signaling on neuropathic pain development

Authors: *T. A. SZABO-PARDI, N. M. AGALAVE, K. A. LINDQUIST, M. D. BURTON
Brain and Behavioral Sci., Univ. of Texas At Dallas, Richardson, TX

Abstract: Chronic pain is a widespread burden that affects millions of people worldwide. It is incumbent to identify and understand the cellular mechanisms involved so that we may develop effective therapeutics to combat the growing opioid epidemic. Danger-associated molecular patterns (DAMPs) released from cells following traumatic peripheral nerve injury promote pain plasticity underlying chronic pain. High-mobility group-box-1 is a DAMP produced after injury and activates toll-like receptor-4 (TLR4). TLR4 is a pattern-recognition receptor expressed on peripheral sensory neurons and immune cells whose activation promotes pain states. Understanding how different cell types respond to TLR4 activation could lead to a better grasp on the mechanisms of pain plasticity and lead to novel therapeutic insights. We hypothesize that TLR4 acting on macrophages contributes to the development of neuropathic pain in male mice as opposed to sensory neurons in female mice. Here we have employed a transgenic model that allows for Cre-mediated deletion of a floxed TLR4 allele, utilizing the $Na_V1.8$ and Lysozyme M promoters to drive *cre* expression in peripheral nociceptors or macrophages, respectively. We implemented a spared-nerve injury model and subjected adult male and female transgenic mice to von Frey mechanical tests and cold allodynia measures. In addition, we assayed changes in HMGB1 expression within the dorsal horn of the spinal cord 3 days following nerve injury in wild-type mice. We find that TLR4 removed from $Na_V1.8^+$ sensory neurons confers a reduction in mechanical hypersensitivity at day 3 and 5 post-surgery in female, but not male mice. In contrast, we find that TLR4 removed from $LysM^+$ macrophages reduces mechanical hypersensitivity at day 3 and 5 post-surgery in male, but not female mice. There were no differences in cold allodynia. We see elevated expression of HMGB1 in deeper laminae in females after injury, versus superficial laminae in males. We have observed a robust, sexually dimorphic behavioral effect when TLR4 is removed from macrophages in males versus nociceptors in females. Our data shows that TLR4 acting on sensory neurons mediates development of neuropathic pain in females and TLR4 acting on macrophages mediates development of neuropathic pain in male mice.

Title: Development of pain hypersensitivity in a model of non-compressive disc herniation

Authors: M. M. MULEY, Y. TU, *M. W. SALTER
Neurosciences & Mental Hlth. Program, Hosp. for Sick Children, Toronto, ON, Canada

Abstract: OBJECTIVE: Disc-herniation can be caused by biochemical inflammation and mechanical deformation. Here, we have developed a mouse model of non-compressive disc herniation to assess the contribution of inflammatory cells in the development of changes in pain behavior. **METHODS:** Nucleus pulposus (NP) material collected from littermate tail was placed on the sciatic nerve of C57BL/6 mice (22-36g). In sham animals, only the sciatic nerve was exposed. von Frey algesiometry and dynamic weight-bearing were measured at every other day over the subsequent two weeks. In a separate cohort, immunohistochemistry on day 7 and 21 was used to study infiltration of inflammatory cells in nerve and ATF3 expression in the dorsal root ganglion (DRG). **RESULTS:** Heterotopic placement of NP onto the sciatic nerve induced mechanical sensitivity at day 1 ($P < 0.0001$) compared to sham, and the mechanical sensitivity persisted for up to 11 days ($P < 0.05$). We observed weight-bearing deficits in the ipsilateral hind paw at day 5 ($P < 0.05$) as compared to sham. Immunohistochemical analysis revealed intraneural macrophage (F4/80) infiltration compared with sham controls, with localized and most infiltration at nerve observed at 1 week ($P < 0.05$), and resolved by day 21. Animals exposed to NP did not show ATF3 expression within DRG. **CONCLUSIONS:** These results demonstrate that surgical placement of heterotopic NP onto the sciatic nerve triggers a behavioral pain phenotype and transient inflammatory response characterized by infiltration of inflammatory cells. Therefore, blocking inflammation may be a viable strategy in treating radiculopathy associated with disc herniation.

Title: Reduced skin innervation in Charcot-Marie-Tooth disease type 1A patients

Authors: *B. HARTMANNSBERGER[1], K. DOPPLER[1], J. STAUBER[2], B. SCHLOTTER-WEIGEL[2], P. YOUNG[3], C. L. SOMMER[1]
[1]Dept. of Neurol., Univ. of Wuerzburg, Wuerzburg, Germany; [2]Ludwig Maximilian Univ. of Munich, Munich, Germany; [3]Univ. of Muenster, Muenster, Germany

Abstract: Background and Objective:
The most common hereditary neuropathy is Charcot-Marie-Tooth disease. The subtype with the highest prevalence of estimated 1:5,000 is CMT1A which is caused by a duplication of the PMP22 gene on chromosome 17p11. There is currently no treatment approved for CMT1A. However, there is a triplet medication called PXT3003 which is tested in clinical trials. Our aim is to provide objective and reproducible outcome criteria for future clinical trials. Therefore, we analyzed the cutaneous innervation and density of mechanoreceptors of skin punch biopsies of patients with CMT1A.

Methods:
Glabrous skin samples were taken from the index finger of 39 CMT1A patients, 16 small fiber neuropathy (SFN) patients, 7 chronic inflammatory demyelinating polyneuropathy (CIDP) patients and 43 healthy controls. CMTNSv2 scores of the CMT1A patients ranged from 3 (mild disease) to 27 (severe disease). Immunohistochemical double labeling was performed with anti-MBP (myelin marker), anti-S100 (to detect Meissner corpuscles (MCs)) and anti-cytokeratin20 (CK20, Merkel cells (MrkC) marker) combined with anti-PGP9.5 (axonal marker) on 40 µm thick cryosections. So far, we analyzed the density of MCs, MrkCs, free nerve endings in the epidermis and myelinated fiber bundles throughout the dermis by IHC staining.

Results:
Analyses of skin samples stained with anti-CK20 and anti-PGP9.5 showed a reduction of MrkC density in CMT patients compared to controls ($p=0.042$). Staining with anti-S100 and anti-PGP9.5 showed no reduction in MC density in CMT patients compared to controls. However, the ratio of samples without MCs was clearly higher in the CMT group (46%) than in the three other groups together (21%, $p=0.0003$). Dermal nerve bundle densities were not different between the groups for both bundles with and without myelinated fibers. Assessment of the intraepidermal nerve fiber densities (IENFD) revealed a reduction in CMT patients compared to all control groups (SFN: $p=0.056$, CIDP: $p=0.042$, Control: $p=0.005$). Moreover, the CMT-IENFD and the CMTNSv2 score were negatively correlated, meaning that more severely affected patients have fewer intraepidermal nerve fibers ($r=-0.400$, $p=0.013$).

Conclusions:
Our results show reduced skin innervation in CMT1A patients. In addition, our data suggest that skin innervation (IENFD) is reduced in CMT1A patients with high CMTNSv2 scores compared to patients with lower CMTNSv2 scores. This might provide a possible outcome marker for clinical trials. Further IHC labeling of proteins of the node of Ranvier will reveal more insight into the effect of CMT on nerve structures.

Title: Development of inhibitory wiring specificity in mouse cerebral cortex

Authors: *A. G. GOUR, K. M. BOERGENS, P. LASERSTEIN, Y. HUA, M. HELMSTAEDTER
Dept. of Connectomics, Max Planck Inst. For Brain Res., Frankfurt, Germany

Abstract: The development of interneurons in the cerebral cortex has been studied for their migrational origin, time of integration into the cortical plate and electrophysiological properties. The connectomic development and the development of wiring specificity of interneurons is however still largely unknown. Here, we studied 3D EM datasets from the primary somatosensory cortex in mice at postnatal ages 7, 9, 14 and 28 days to map inhibitory connectomes over ontogenetic development. We find that the specificity of inhibitory axons for subcellular components of the postsynaptic neuron is already mutually exclusive at the earliest circuit stages, but the quantitative specificity of inhibitory wiring further increases over age. This development is dependent on the type of inhibitory target preference: the synapse specificity to apical dendrites develops first, followed by wiring specificity to somata, and finally to axon initial segments (AIS). These data provide a first quantification of connectomic specificity over development in the cerebral cortex, pointing towards differential mechanisms of synaptic specificity created by enhancement of target selection over age, and selective pruning of unspecific synapses.

Title: Connectomic study of mice barrel cortex after sensory deprivation in adult

Authors: *K. SONG, M. HELMSTAEDTER
Max-Planck Inst. For Brain Res., Frankfurt Am Main, Germany

Abstract: Whisker trimming can lead to substantial structural plasticity changes in the adult barrel cortex. In order to examine the structural plasticity at a finer scale, we sought to compare the connectomes between mice that were whisker trimmed vs. normal control. Starting at P28, the experimental mice underwent 4 weeks trimming that remove the A,B,C rows of whiskers on both side every second day. By correlative imaging of light microscope and electron microscope, we are able to sample the targeted barrels with high precision; as the mice barrels are about 250 μm in size, we are able to have 2~3 targeted barrels in one sample (1 mm in diameter). This is a first step towards understanding the connectomic changes induced by sensory deprivation in barrel cortex.

Title: The inhibitory input connectome of apical tuft dendrites in mouse cerebral cortex

Authors: *A. KARIMI, J. ODENTHAL, F. DRAWITSCH, K. BOERGENS, M. HELMSTAEDTER
Connectomics, MPI Brain Res., Frankfurt, Germany

Abstract: All pyramidal cells, the principal neurons of the cerebral cortex, send large apical dendrites into cortical layer 1, where long-range inputs from higher-order brain areas are thought to converge onto the pyramidal cells' tuft dendrites. The synaptic input from these sources has been shown to permit regenerative electrical activity, which can yield action potential output of the pyramidal cell that is dependent on the coincidence of basal and distal inputs - interpretable as a cellular binding mechanism. Importantly, these distal dendritic input zones are thought to be controlled by powerful inhibitory inputs, in place to prevent such regenerative activity. Here, we used 3-D electron microscopy to acquire datasets from mouse somatosensory, secondary visual, anterior cingulate and posterior parietal cortices to study the inhibitory connectome of distal apical tufts. To our surprise, we find that only supragranular pyramidal cell dendrites, but not the main bifurcations of deep-layer pyramidal cells are substantially innervated by inhibitory inputs. Rather, deep-layer pyramidal cells receive substantial inhibitory input at the most distal tips of their apical tufts. These results imply that the apical tuft of the main cortical output neurons is largely unhinged, allowing powerful excitation. Furthermore the inhibitory control of apical

dendrites is highly selective between supragranular and deeper-layer principal neurons, with axons selectively innervating supra- but not infragranular apical dendrites and vice versa. These differential inhibitory connectomic structures are preserved between cortices of early sensory and higher-order type, indicating a general wiring mechanism in the upper layers of the cerebral cortex.

Title: FluoEM: virtual labeling of axons in 3D EM data for long-range connectomics

Authors: *F. P. DRAWITSCH, A. KARIMI, K. M. BOERGENS, M. HELMSTAEDTER
Max Planck Inst. for Brain Res., Frankfurt Am Main, Germany

Abstract: Current volume electron microscopy methods allowing for dense neuronal circuit reconstruction are so far limited to dataset volumes a few hundred micrometers in extent. However, since most neuronal circuits receive substantial non-local input, the projection sources for a large fraction of local synapses remain unknown in such data. Most correlative labeling strategies applied so far to alleviate this limitation rely on label conversion which is technically challenging and augments label space only slightly because of the limited EM color space. Here, we present FluoEM, a set of experimental and computational methods allowing for the direct identification of fluorescently labeled axons in EM without label conversion. Instead, we computationally match reconstructed neurites resulting in a virtual labeling of EM axons and allowing us to utilize the rich color palette of available fluorophores. We then apply FluoEM to explore the specificity of long-range projections from primary motor- (M1) and secondary somatosensory (S2) cortex impinging in L1 on the apical dendrites of primary somatosensory (S1) barrel cortex pyramidal neurons.

Title: High-throughput connectomics in mouse barrel cortex

Authors: *M. SCHURR, J. STRAEHLE, L. DADASHEV, A. MOTTA, H. KEBIRI, N. SHETTAR, M. HELMSTAEDTER
MPI For Brain Res., Frankfurt, Germany

Abstract: Dense mapping of neuronal circuits at single-cell resolution in a sufficiently large volume requires 3D imaging techniques which are able to bridge five to six orders of magnitude. Currently, comprehensive EM-based connectomic analysis is still hampered by the size and number of available datasets. The effective acquisition rate of conventional single-beam SEMs is ultimately limited by the scan speed. Data rates up to 6 $MVxs^{-1}$ have been reported (Schmidt et al, 2017). However, even at 6 $MVxs^{-1}$ imaging of a cubic millimeter of neuronal tissue at nanometer resolution would take several years. Here we report the application of a 61 beam MultiSEM setup in combination with the ATUMtome approach (Hayworth et al, 2006) for high-throughput connectomics in mouse barrel cortex. Taking into account overheads caused by stage settling time, automated focusing routines and wafer calibration, data rates were pushed by two orders of magnitude up to 237 $MVxs^{-1}$ at a voxel size of 4 nm x 4 nm x 35 nm. Together with an appropriate data infrastructure to process petabytes of data this enables connectomic screening of a cubic millimeter within only three to four months expected time.

Title: Deep learning for axon tracing in high-resolution connectomics

Authors: *M. SCHMIDT, A. MOTTA, B. STAFFLER, M. BERNING, M. HELMSTAEDTER
MPI Brain Res., Frankfurt Am Main, Germany

Abstract: Mapping neuronal wires for a mechanistic understanding of computation in the brain is a major goal of high-resolution connectomics. While acquisition of mm^3-sized 3D electron microscopy datasets is becoming feasible, axon reconstruction remains the main bottleneck. Here, we present a new framework to automatically trace axons in 3D-EM data, where a convolutional neural network is trained end to end in a supervised fashion to predict neurite continuation from EM images. Integration of the prediction and application of the network in a recurrent manner yields a sparse skeleton representation of axonal branches. Application of this framework on linear branches of axons in a 3D-EM dataset from mouse primary somatosensory cortex layer 4 results in error rates that make it plausible to deploy the framework in conjunction with existing automated reconstruction approaches in order to further reduce the human annotation needs in connectomics.

Title: Comparative connectomics in the mammalian cerebral cortex

Authors: *S. LOOMBA, J. STRAEHLE, K. BOERGENS, M. HELMSTAEDTER
Max Planck Inst. For Brain Res., Frankfurt Am Main, Germany

Abstract: The advancements in subcellular-resolution connectomics and the reconstruction of neurons and their synaptic connectivity are opening the possibilities to find general principles of wiring across a wide range of brain systems. Here we report a comparative connectomics analysis of serial block-face electron microscopy (EM) data from mouse and rat. For this SegEM (Berning et al 2015 Neuron) for automated dense reconstruction and analysis of the 3D EM data had to be extended. We ask whether a 3-fold increase in neuron number between mouse and rat is accompanied by connectomic alterations along the species axis. We are currently extending this analysis to non-human primate and human tissue.

Title: Dense connectomic reconstruction in layer 4 of the somatosensory cortex

Authors: *A. MOTTA, M. BERNING, K. M. BOERGENS, B. STAFFLER, M. BEINING, S. LOOMBA, C. SCHRAMM, H. WISSLER, M. HELMSTAEDTER
Connectomics, Max Planck Inst. For Brain Res., Frankfurt, Germany

Abstract: The dense circuit structure in the mammalian cerebral cortex is still unknown. With developments in 3-dimensional (3D) electron microscopy, the imaging of sizeable volumes of neuropil has become possible. The dense reconstruction of connectomes from such image data, however, is still the limiting step in connectomics. Here, we report the dense reconsruction of a volume of about 500,000 cubic micron from layer 4 of mouse barrel cortex, about 250 times larger than previous dense reconstructions from the mammalian cerebral cortex. Using a novel reconstruction technique, FocusEM, we were able to obtain a total of 600 millimeters of dendrites and about 2 meters of axons investing only about 3,000 human work hours, thus about 30 times more efficient than previous dense reconstructions from the mammalian brain. We used this dense connectomic data for the quantitative analysis of subcellular synaptic target specificity; we determine the maximum fraction of geometrically explainable connectivity and extract a connectomic snapshot of the plasticity history of the circuit.
AM, MB, KMB, and BS contributed equally to this work.

Title: A parametric texture discrimination task reveals an essential role of primary somatosensory cortex in mice

Authors: *J. PARK[1], C. RODGERS[3], Y. HONG[2], R. M. BRUNO[1]
[1]Neurosci., [2]Dept. of Neurosci., Columbia Univ., New York, NY; [3]Columbia Univ. Med. Ctr., New York, NY

Abstract: Touch is a fundamental part of our sensory perception, yet our understanding of the neural circuitry that underlies it is limited. For example, the primary somatosensory cortex (S1) has long been assumed to play a crucial role in tactile processing. Yet recent and surprising results from our lab show S1 to be completely unnecessary for simple whisker-based tactile tasks, such as detecting the presence of an object. This corroborates previous findings in other primary sensory areas. It is possible, however, that more complex tasks with greater computational demands require the cortex. To better understand S1 function and circuitry, we have developed a two-alternative forced choice paradigm for head-fixed mice in which the animals discriminate textures using their whiskers. Unlike many previous studies that use sandpaper stimuli, we have machined plastic grooved textures to precisely manipulate and quantify various parameters that determine the perception of roughness. The mice readily learn to distinguish textures at various distances and orientations using all or even just one whisker. We have confirmed by trimming or physically blocking their whiskers that this task is completely whisker-dependent. We find that lesioning S1 reduces their performance to chance, demonstrating that within the tactile domain, texture discrimination is a cortex-dependent task. This result highlights the need to reexamine cortical function in tactile and other sensory modalities. Using this S1-dependent texture discrimination task, future work is aimed at examining the underlying neural mechanisms that encode tactile discrimination.

Title: Differential roles of cortex and striatum in tactile detection

Authors: *Y. HONG, B. C. PIL, R. BRUNO
Dept. of Neurosci., Columbia Univ., New York, NY

Abstract: Numerous studies have sought to establish whether the primary sensory cortex (S1) is required for sensory detection behaviors, but with conflicting results. In mice trained to perform a whisker-mediated detection task, we demonstrate that transient S1 inactivation initially alters both whisking motor output and sensory threshold, resulting in impaired sensory detection. However, in S1-lesioned animals, these effects are only momentary, as the subject recovers after a single session of re-exposure to the task, bypassing any requirement for S1 in sensory detection. What is the mechanism by which transient, but not chronic, inactivation disrupts detection behavior? One hypothesis is that sudden loss of activity in S1 temporarily disrupts connected downstream areas that may themselves be essential for task performance, but that over a short period, recovery of the downstream area enables resumption of detection abilities. An essential first step in understanding tactile detection is to delineate the key pathways that can mediate detection behaviors in in the absence of S1. We narrow down the essential S1 targets by taking advantage of available mouse transgenic Cre recombinase subset lines that label cells in distinct cortical laminae. We inactivated different subsets of cortical neurons in S1 during the detection task to determine which conditions recapitulate the transient behavioral deficit observed during inactivation of all cortical layers. We find that only a few subset lines yielded a deficit in detection behavior. These had one major subcortical target in common: the dorsal striatum. Indeed, while S1-lesioned animals recovery rapidly recover behavioral performance, additional damage to the striatum permanently impaired detection behavior. Together, our results implicate the dorsal striatum, rather than S1, as a key player in mediating sensory detection for sensory perception.

Title: Stabilization of cortical neuron ensembles by sensory association learning

Authors: *J. LEE, S. M. BERNHARD, N. J. AUDETTE, A. L. BARTH
Dept. of Biol. Sci., Carnegie Mellon Univ., Pittsburgh, PA

Abstract: Sensory features are thought to be encoded by specific ensembles of neurons, such as orientation cells in visual cortex. To determine whether experience could alter neuronal ensembles in somatosensory cortex, we monitored the distribution and percentage of activated

neurons in fosGFP transgenic mice during multi-whisker sensory association training. We trained the mice to associate gentle air puff stimulation to the whiskers with water reward. Since fosGFP-positive neurons are known to show large responses to multi-whisker stimulation, we hypothesized that the number of fosGFP-positive neurons would increase by this training. We imaged fosGFP-positive neurons in layer 2/3 of barrel cortex through cranial window with 2-photon in vivo microscopy, once before and once after training. When we compared before and after, we found that training does not change the overall number of fosGFP-positive neurons. But when we looked at individual cell's fosGFP expression level, there were more cells with stable fosGFP expression over two days. Therefore, we found that multi-whisker sensory association training stabilizes multi-whisker representing ensembles, which may play a role in learning.

Abstract: Thalamocortical inputs to neocortical circuits can be altered during sensory learning. To determine the temporal and laminar sequence of changes in neuronal response properties during learning, we designed an automated homecage system for sensory association training in mice, using a gentle airpuff coupled to a water reward. Electrophysiological recordings from pyramidal (Pyr) neurons in somatosensory (barrel) cortex revealed that optogenetic stimulation of Pom thalamic inputs initiated increased activity across the neocortical column after 24 hr of training. Electrophysiological responses to Pom stimulation were enhanced in L5 neurons, due to an increase in postsynaptic quantal EPSC amplitude. To examine training-dependent changes in the anatomical distribution and morphological properties of Pom synapses, we expressed a synapse-labeling fluorophore (FAPpost) in L5 Pyr neurons for quantitative analysis. Alignment of GFP-labeled Pom inputs with postsynaptic sites on L5 Pyr neurons revealed training-

dependent differences in the density and location of Pom inputs across the L5 dendritic arbor. The fluorescent properties of postsynaptic sites assigned to Pom inputs were also evaluated for changes in synaptic labeling intensity, shape, and organization. The convergence of electrophysiological and anatomical data indicate that Pom inputs undergo significant plasticity during sensory learning that may be localized to specific cell types and subcellular compartments in neocortex. High-throughput synapse labeling and quantitative analysis provide a means to study structural correlates of synaptic plasticity, driving new and testable hypotheses about synaptic reorganization during learning.

Title: Refinement of spatiotemporal cortical dynamics in mice learning to discriminate between two textures

Authors: *A. GILAD, F. HELMCHEN
Brain Res. Inst., Univ. of Zurich, Zuerich, Switzerland

Abstract: The neocortex is crucial in learning a new behavioral task. However, how different parts of the neocortex contribute to the learning process remains largely unknown. Here, we trained head-restrained transgenic mice expressing GCaMP6f in layer 2/3 excitatory neurons in a ‘go/no-go’ texture discrimination task. A trial started with an auditory cue after which either a ‘go’ or a ‘no-go’ sandpaper texture approached the mouse’s whisker pad. Mice gradually learn to lick to the go texture (‘hit’) and withhold licking to the no-go texture (‘CR’). Throughout learning we imaged calcium signals across large parts of the cortex. During learning a consistent flow of activation that started in auditory cortex (A1) in response to the auditory cue, shifting to rostrolateral association area (RL) as the texture approaches the mouse, and then spreading to the barrel cortex (S1BC) when the texture touches the whiskers. The strength of this flow was

positively correlated with the mouse's learning curve, i.e. responses in A1, RL and S1BC are enhanced while the mouse gains expertise. In addition, discrimination between hit and CR trials gradually built up in S1BC during learning and appeared only during the whisker touch period. We also observe a spatial refinement of the activation in association areas. Naïve mice displayed responses to the approaching texture in many association areas, including RL, posterior medial are (PM), and primary visual cortex. In expert mice cortical responses were spatially confined to RL whereas PM decreased its activity with learning. These results imply that during learning the cortex refines spatiotemporal processing to highlight behavior-related integration paths while deemphasizing irrelevant ones.

Title: Discrimination learning with tactile stimuli in rodents

Authors: *N. PACCHIARINI[1], R. C. HONEY[1], K. D. FOX[2]
[1]Sch. of Psychology, [2]Biosci., Cardiff Univ., Cardiff, United Kingdom

Abstract: The barrel cortex lies within the somatosensory cortex and processes information from the vibrissae. While a great deal is known about the anatomy, physiology and plasticity of the barrel cortex, less is known about its role in tactile discrimination and learning. The experiments reported here are aimed at investigating whether the barrel cortex is involved in discrimination learning with textured surfaces using a range of novel testing procedures, including a modified two-choice digging task (Chuang, Huang, and Hsueh, 2014). The chemogenetic DREADD system was used to test whether the barrel cortex is required for discrimination learning. In the two-choice digging task, a food reward was consistently buried in one sawdust filled bowl that was differentiated from the second bowl by whether its outer surface texture was smooth or ridged. Ten-week old mice were trained to locate the reward by touch in a room lit only with red light in which odours had been masked. Our results show that mice learn the task rapidly within one day and retain the memory of which texture was rewarded the following day. Whisker trimming reduced the animal's ability to perform the texture task to chance levels; however, the same mice were able to successfully perform the task two weeks later, when their whiskers had regrown. Additionally, whisker trimming did not affect task performance when the relevant stimulus was odour based. Further experiments show that if the barrel cortex neurones express

virally introduced DREADDs, mice are unable to learn the task following systemic injection with CNO (4mg/kg). CNO administered at the same dose in mice lacking DREADD expression were able to learn the task. Future experiments will allow us to observe structural plasticity during this period of rapid learning.

Abstract: Movement is the result of complex interplay of activity in a large number of sensory and motor circuits. The whisker system is a model sensory and motor system, where individual whiskers are associated with intrinsic muscles, and furthermore, depending on the behavioral context, the motion of whiskers can be bilaterally synchronized or asymmetric. Here we trained head-fixed Nex-cre chanelrhodopsin mice (n=3) to perform a simple auditory-go-cue triggered movement that brought the C2 whisker into contact with a sensor. The C1 and C2 whisker on the right side, the contact side, and C2 whisker on the left side were painted and tracked offline using Image J macros. Bilateral tracking of whisker motion revealed: 1) the correlation between side to side motion of the whiskers was behavioral state -- i.e. cue onset, movement onset or licking -- dependent; the frequency bands in the correlation and the extent of motion, varied with state; 2) the main whisker used to touch the sensor began movement earlier than the other whiskers, and whiskers on the non-contact side, moved to a greater extent; 3) the effect of M1 and S1 stimulation on the side to side correlation varied from trial to trial but stimulation altered the side to side phase lag-lead relationship, and could even completely abolish correlations. Taken together our results show that cortical control of whisker motion is complex and the side to side motion of whiskers change dynamically.

Title: Rapid learning in a whisker-dependent sensory association task using homecage automated training

Authors: *S. BERNHARD, N. J. AUDETTE, A. T. HODGE, A. BARTH
Carnegie Mellon Univ., Pittsburgh, PA

Abstract: Automated, homecage behavioral training for rodents has many advantages: it is low stress, requires little interaction with the experimenter, and can be easily manipulated to adapt any experimental condition. We have developed an inexpensive, Arduino-based, homecage training apparatus for sensory association training in freely-moving mice using bulk whisker stimulation coupled to a water reward. Animals learn this task readily, within 1 day of training, and performance continues to improve over multiple training days. We examined the parameters that regulate task acquisition using different airpuff intensities, directions, and reward valence. Learning was assessed by comparing anticipatory licking for the stimulus compared to the no-stimulus (blank) trials. At high airpuff intensities, animals showed markedly less task participation and no difference in lick frequency between the rewarded and blank trials. Very weak airpuff intensities were not sufficient to generate learning behavior. At intermediate airpuff intensities, a majority of mice learned that the airpuff predicted the water reward, showing increased licking after the airpuff stimulus and suppressing licking for blank trials. Mice learned to discriminate between multiple directions of airpuff rapidly and accurately. Systematic reductions in the angular distance between rewarded and non-rewarded airpuff direction was examined and compared to learning trajectories for airpuff versus blank training regimens. Our results show that a tactile association task in an automated homecage environment can be monitored by anticipatory licking to reveal rapid and progressive behavioral change. These Arduino-based, automated mouse cages enable high-throughput training that facilitate analysis of large numbers of genetically modified mice with targeted manipulations of neural activity.

Title: Sensory responsiveness of cortical neurons predicts their behavioral salience in an operant conditioning task

Authors: *H. W. DALGLEISH, A. M. PACKER, L. E. RUSSELL, M. HAUSSER
Wolfson Inst. for Biomed. Res., Univ. Col. London, London, United Kingdom

Abstract: Identifying which neurons are most important for driving behavior is central to our understanding of how the brain represents and evaluates information during decision-making. In sensory cortex, stimulation of small numbers of neurons can produce a behavioral report. However, it is unclear which neurons are endowed with the greatest power to drive such behavior. It has been difficult to address this question with traditional electrophysiological and optogenetic techniques since the populations of neurons most relevant for decision-making are hard to target. To overcome this, we have used an all-optical approach, combining two-photon calcium imaging and optogenetics, to enable targeted interrogation of functionally defined neurons in vivo during behavior. We first trained head-fixed mice to report the optogenetic activation of specific, functionally defined groups of hundreds of neurons in L2/3 barrel cortex. Within this initially trained population, targeted activation of subgroups of strongly sensory responsive neurons was better able to drive the learned behavior than activation of subgroups of weakly sensory responsive neurons. Furthermore, preliminary results suggest that the sensory response strength of non-photostimulated neurons in the local network recruited during photostimulation epochs correlates with the sensory response strength of neurons that were photostimulated. These results demonstrate that the sensory response strength of neurons in mouse barrel cortex predicts their power to drive subsequent learned behaviour, and suggest that sensory neurons that are more informative about the outside world may also be privileged in their ability to broadcast that information and influence behavior.

Title: Effect of sensory associative learning on parvalbumin neuron plasticity in the barrel cortex

Authors: *E. PARK[1,2], D. A. KULJIS[1,2,3], M. P. BRUCHEZ[1,2,4], A. L. BARTH[1,2,3]

Abstract: GABAergic parvalbumin (PV) neurons are a dominant source of inhibition to neocortical pyramidal (Pyr) neurons, and prior studies suggest that these inputs can be altered during learning. Here we examined evidence for anatomical changes in PV input to Pyr neurons in mouse somatosensory cortex during learning. We employed a novel postsynaptic fluorescent marker for synapses on PYR neurons that employs a neuroligin-1 trafficking motif (FAPpost) in mice where presynaptic PV neurons expressed YFP (PV-Cre x Ai3). PV inputs were aligned to postsynaptic fluorescent puncta for automated detection and quantitative analysis of PV inputs to Pyr neurons. Mice were trained to associate a gentle airpuff (sensory stimulus) with the reward (water). Labeled synapses on different compartments of the postsynaptic Pyr neuron were quantified using 3-dimensional detection and reconstruction (Imaris). While there was no change in PV inputs to layer 5 (L5) Pyr neurons, PV inputs to L2 Pyr neurons decreased after sensory association learning, particularly on the dendrites. Characterizing learning-dependent changes in PV inputs across the cortical column will enable a comprehensive understanding of how plasticity of inhibitory synapses in the brain is modified by experience.

Title: Sensorimotor specificity of decision-related activity in somatosensory cortex

Authors: *E. FINKEL, E. E. LUBIN, A. J. CHANG, J. Y. COHEN, D. H. O'CONNOR
Neurosci., Johns Hopkins Sch. of Med., Baltimore, MD

Abstract: Detection of a tactile stimulus is accompanied by increased firing rates of neurons in primary somatosensory (S1) cortex (e.g. Sachidhanandam et al., 2013; Yang et al., 2016). This enhanced activity begins hundreds of milliseconds before the report of the stimulus, and its optogenetic inhibition interferes with detection (Sachidhanandam et al., 2013). How such choice-related late activity relates to motor planning and attention is not currently understood. Here, we trained head-fixed mice (>15) on a novel cross-modal attention task, in which stimuli of different sensory modalities were associated with different movements. The task consisted of interleaved trials in which either a weak tactile stimulus (brief single-whisker deflection) or a weak visual stimulus (faint LED flash) was presented. In a "tactile block" of trials, mice were rewarded for reporting detection of the tactile stimulus by licking at a lickport while responses to the visual stimulus were unrewarded. Conversely, in a "visual block" of trials, mice were rewarded for detecting the visual stimulus by licking at a different lickport while responses to the tactile stimulus were unrewarded. Tactile blocks and visual blocks were alternated several times across each experimental session. After 3-4 weeks of training, mice learned to respond to the tactile stimulus and ignore the visual stimulus during tactile blocks, while ignoring the tactile stimulus and responding to the visual stimulus during visual blocks (~75% correct for each block type). We performed extracellular tetrode recordings from >2000 neurons in S1 barrel cortex of well-trained mice. 773 recorded S1 neurons showed significant choice-related activity. A large fraction of these neurons (~34%) showed higher evoked firing rates only in trials where the mouse detected the tactile stimulus and executed the associated licking response (tactile-hits). Other neurons (~21%) showed increased firing rates only when mice detected the visual stimulus and made the (different) associated licking response (visual-hits). The remaining ~45% of neurons showed increased firing rates in trials where the mouse detected either stimulus. Neurons showed similarly low levels of activation in trials where the mice failed to detect stimuli (misses) as in trials where they correctly ignored the stimuli (correct rejections). These data suggest that choice-related activity is associated with the upcoming movements required of the mouse to report its perceptual detection. Thus, S1 neurons encode a conjunction of motor and sensory variables.

Title: The mechanically activated Piezo channels are sufficient for conferring specific modalities of mechanosensation

Authors: *M. ZHANG, B. XIAO
Sch. of Pharmaceut. Sci., Tsinghua Univ., Beijing City, China

Abstract: The mechanosensation of light-touch and proprioception, but not mechanical pain, requires a single mechanically activated cation channel, Piezo2, which mediates the rapidly but not intermediately or slowly adapting currents of sensory neurons. However, it remains unknown whether distinct mechanotransduction channels are sufficient for conferring specific modalities of mechanosensation. Piezo1, a homologue of Piezo2 without expression in sensory neurons, displays intermediately adapting current properties. Here we generate transgenic mice ectopically expressing Piezo1 and the associated current in sensory neurons. Remarkably, Piezo1 expression not only sensitizes light-touch in normal mice but also rescues the defective light-touch and proprioception of Piezo2 knockout mice. Intriguingly, the mechanical pain is suppressed by Piezo1 expression, but enhanced by Piezo2 deletion, suggesting its inhibition by Piezo-mediated touch sensation. Together, Piezo channels confer specific sensation of light-touch and proprioception and analgesic effect on mechanical pain. Thus, activation of Piezo2 might serve as a strategy for treating mechanical pain.

Title: Limb sensory mapping: Toward a full map of the sensory innervation in larval zebrafish pectoral fins

Authors: *K. HENDERSON, M. E. HALE
Univ. of Chicago, Chicago, IL

Abstract: Larval zebrafish provide unique access to a whole, intact vertebrate nervous system in a living organism. Whole brain and spinal circuit exploration has been made possible by the optical clarity and extensive genetic toolkit available in the zebrafish. These methodological advantages can also be harnessed to explore the brain and spinal cord function in neuromechanical systems. Here we use larval zebrafish to examine the neural architecture of the pectoral fins, forelimb homologs. Previous work has described motor innervation of intrinsic pectoral fin muscles and the associated kinematics. At the larval stage, the fins beat rhythmically and have been shown to mix fluids for cutaneous respiration. Here, we investigate sensory architecture of the pectoral fin in 5 day post fertilization (dpf) larvae. We look at both Rohon-Beard neurons (RBs) and dorsal root ganglia neurons (DRGs). The RBs are an early population of mechanosensory cells considered transient and lost during the juvenile stage. We stochastically labeled RBs by injecting UAS:ptagRFP into isl2b:Gal4 embryos, imaged these at 5dpf with confocal microscopy, and reconstructed neurons and their peripheral arborizations. We found that a subpopulation of islet2B+ RBs located at the level of the fourth and fifth myomeres innervate the pectoral fin. These cells display classic RB morphology with dense primary afferent arborization. Once in the fin, the processes branch and spread through the skin. The degree of innervation of the fin varied between RBs, with some cells branching to cover a large area of the fin while others projected into smaller regions only at the base of the fin. In all cases, RBs consistently had enlargements at the ends of primary afferents within the fin. We found that the later developing DRGs also extend processes into the pectoral fins. To isolate clusters of DRGs, we photoconverted groups of cells in isl2b:Kaede fish with a 405nm laser line. At this stage, DRGs follow the path of pectoral fin motor neurons to reach the base of the fin. Within the fin, they have simpler arborizations, narrower distributions, and less elaborate endings than RBs, possibly due to the fact that these cells have not yet reached their mature morphology. Taken together, these data provide a morphological description of the sensory innervation of the 5dpf fin by two distinct cell types, one associated with early larval behaviors and one developing later and continuing to mature throughout the late larval stages. The sensory map presented here provides a basis for future functional studies of sensorimotor integration in the pectoral fin.

Title: Zebrafish mechanosensory afferents exhibit morphological and physiological regionalization along the body axis

Authors: *H. R. KATZ, E. MENELAOU, M. E. HALE
Univ. of Chicago, Chicago, IL

Abstract: Mechanosensory neurons play an important role in converting mechanical forces into the sense of touch. In zebrafish it is well established that Rohon-Beard (RB) neurons serve this role at the larval stage. Recent physiological studies have shown that in response to a tactile stimulus, zebrafish can produce different patterns of motor output in rostral and caudal regions of the body. There is no evidence of rostrocaudal variation in interneuron or motor neuron populations in the spinal cord that could account for these region-specific motor patterns. This led us to hypothesize that differences in the RB population between rostral and caudal regions of the body may play a role in differential axial motor output. To address this hypothesis, we examined the morphology and physiology of rostral and caudal RB populations. We used *in vivo* single cell labeling approaches in the isl2b:gal4 zebrafish to examine the architecture of their peripheral processes (n=21). We found that RB neurons exhibit morphological differences related to their somatic location. RB neurons located in rostral segments (≤15) have peripheral afferents that exit the spinal cord within one body segment of the soma (18.54um ±10.37) and their area of arborization is narrow. In contrast, RB cells located in caudal segments (>15) exit the spinal cord much further away from the soma (248.1um ±267.6) and, on average, have broader areas of arborization. We also measured the trajectory of the peripheral processes at 200um from the soma at the level of the skin across the RB neuron population (102 cells) in islt2b:GFP zebrafish. We found that more caudal RB cells tended to have more longitudinal processes that extend further caudally. To directly examine the mechanosensory response properties and receptive range of individual RB neurons, we developed a preparation for whole cell recordings while a piezo electric actuator simultaneously delivered graded mechanical stimulation at different body locations. All RB neurons examined (6 rostral; 6 caudal) exhibited fast adapting properties in response to mechanical force applied on the skin. RB neurons encoded stimulation intensity by increasing spike counts and decreasing response latency. The receptive fields established electrophysiologically matched the morphological arborization ranges: rostral cells responded to stimuli close to the soma, while caudal cells responded to more distant stimuli over a broader area. This regionalization of the zebrafish mechanosensory system can provide insights into how sensory information is encoded in the periphery and how spinal circuits transform touch information into behavioral outputs.

Title: Describing sensory innervation and texture encoding in forelimbs using a fish fin model

Authors: *A. R. HARDY, M. E. HALE
Univ. of Chicago, Chicago, IL

Abstract: Tactile sensation is critical to limb-based behaviors. Understanding limbs as touch sensors provides insight into the integration of mechanosensory information in behavior and the engineering of limb-like devices. Given the thin, optically transparent structure of fins, fish have the potential to be a complementary vertebrate model for somatosensory research to the mammalian systems currently studied. The pectoral fins, paired forelimbs of fish, function as sensors that touch and deform in response to contact with their physical surroundings. We chose the Round Goby (*Neogobius melanostomus*), a substrate associated species, to investigate 1) the ability of the fin mechanosensory system to encode the texture of contacted surfaces and 2) how mechanoreceptors are distributed throughout the fin to facilitate touch sensation. Using linear brush stimulations, we found that a subset of the afferent population has small receptive fields (~2 – 4 mm) suggestive of the ability to discriminate texture. To examine this possibility, we recorded fin ray nerve fiber activity in response to rotating 3D printed grating patterns of varying spatial period (0.5 – 7 mm) presented at a range of speeds (20 – 80 mm/sec). We found that afferents accurately encode millimeter-sized features at stimulus temporal frequencies of 3 - 50Hz, indicating similar levels of resolution to the mammalian somatosensory system and the ability to discriminate textures in their environment. We hypothesized that, similar to limb structures in other systems such as the human hand, mechanoreceptors within fins are not uniformly distributed, but instead reflect the functional demands for touch sensation. Merkel cells are an important component of touch sensation in mammals and immunolabeling has indicated their presence in fins. We sought to map the density and distribution of these putative Merkel cells across a fin. Immunolabeling with an antibody to cytokeratin 20, revealed that these cells are present and their distribution varies significantly across the fin's area. We found the highest density of putative Merkel cells in locations of fin ray branching. These regions of the fin touch, spread, and deform as fins make contact with a surface. The similar physiological responses to features of textures and apparent consistency in key sensory structures between fish

and mammals support the utility of investigating touch sensation in fins. In the applied realm, fin mechanoreceptor distribution and physiology informs optimal sensor placement for engineered sensory surfaces.

Title: Characterization of mechanoreceptors involving the sense of touch using a modified single fiber recording technique

Authors: *M. SONEKATSU, J. G. GU
Dept. of Anesthesiol. and perioperative medicine, Univ. of Alabama At Birmingham, Birmingham, AL

Abstract: The sense of touch is transduced by highly specialized tactile-sensing organs and is important in life. A gentle touch may also produce an exaggerated painful sensation under pathological conditions. Whisker hair follicles are important tactile-sensing organs for performing tactile tasks. Although Merkel discs are one of the most prominent types of mechanoreceptors using Piezo2 channels as transducers in whisker hair follicles (Ikeda et al., Cell 2014), anatomical evidence has indicated the presence of other mechanoreceptors whose electrophysiological and functional properties are not well defined. We have previously used conventional suction recording electrode to study impulses conveyed on whisker afferent bundles following mechanical stimulation, and the responses might represent the signals from multiple mechanoreceptors. In the present study, we modified the conventional suction recording method. This allowed us to perform single fiber recordings from whisker afferent nerves to characterize electrophysiological properties of mechanoreceptors in whisker hair follicles. Using the modified single fiber recording method, we identified three types of mechanical responses following mechanical stimulation of whisker hair follicles. These three types of mechanical responses are rapidly adapting (RA) response, slowly adapting type1 (SA1) response, and slowly adapting type2 (SA2) response. RA responses had impulse firing only during rapid step of displacement stimulation. The two types of SA responses were analyzed for coefficient of variation (CoV) in their inter-spike intervals. The CoV was 0.89 ± 0.06 (n=12) in SA1 responses, consistent with the high irregularity in their inter-spike intervals. The CoV was 0.31 ± 0.02 in

SA2 responses (n=21), consistent with the high regularity in their inter-spike intervals. We investigated pharmacological properties of each type of mechanoreceptors. High concentration of serotonin (2 mM) largely inhibited SA1 responses but did not significantly affect RA responses. Similarly, Cd^{2+} a voltage-gated calcium channel blocker, also inhibited SA1 response but did not affect RA responses. Our electrophysiological and pharmacological characterization of different mechanoreceptors should help us understand physiological aspects of the sense of touch such as tactile discrimination. It may also provide insights into pathological aspects of the sense
of touch such as static and dynamic mechanical allodynia seen in pathological pain states.

Title: Alterations in tactile sensation following lidocaine iontophoresis: A case of turning slow into fast?

Authors: *A. MARSHALL[1], F. P. MCGLONE[2], A. MAKDANI[2], F. O'NEILL[2]
[1]Salford Royal Hosp. Fndn. Trust, Salford, United Kingdom; [2]Liverpool John Moores Univ., Liverpool, United Kingdom

Abstract: Research objective and rationale: The role unmyelinated low-threshold mechanosensitive afferent (LTMA) fibers, C-tactile afferents (CTs), play in the expression of dynamic mechanical allodynia (DMA) is unclear. CTs fire optimally to slow gentle dynamic touch but this preferred stimulus unavoidably co-activates A-beta LTMA fibres. A method differentially blocking CTs would facilitate future human pain models assessing the role of LTMA sub-types in DMA. To address this a model utilizing non-invasive administration of lidocaine was developed. Methods: Lidocaine ($0.2mg/cm^2$) and adrenaline ($2.5\mu/cm^2$), were co-iontophoresed on a $16cm^2$ area of the volar forearm of 17 healthy participants (9 female).

Adrenaline was given to increase the depth and duration of local anesthesia. Adrenaline-only was administered contralaterally. Thermal and tactile detection thresholds as well as pleasantness and intensity ratings to slow (3cm/s) and fast (30cm/s) dynamic touch were performed bilaterally. In separate investigations the underlying neural mechanisms were explored using single unit recordings of LTMA fibres in forearm hairy skin. Assessment of mechanical threshold and firing pattern to mechanical skin stimulation were performed before and after lidocaine and adrenaline co-iontophoresis over the receptive field. Results: Compared to control, lidocaine iontophoresis resulted in significant impairment in warm ($p<0.008$), cold ($p<0.007$) and, most evidently, tactile detection thresholds ($p<0.001$). Touch pleasantness was unaffected but there was a significant reduction in intensity ratings for dynamic touch ($p<0.01$). All but one slowly adapting type 1 (SA1) fiber (6/7) showed preferential block of firing during the sustained indentation phase of mechanical skin stimulation post-lidocaine. This partial blockade temporally matched an elevation of tactile detection threshold. One slowly adapting type 2 LTMA (1/9) showed a similar pattern but other sub-types (hair follicle afferent (n=10), field unit (n=2) and CT (n=1)) showed no appreciable change in firing. Conclusions: No evidence of differential blockade of CTs following lidocaine iontophoresis was seen and the model is unlikely to be of use in deciphering their role in DMA. The lack of blockade could reflect the ion channel population, yet to be clarified, present on these fibers. Instead, the impairments to dynamic and punctate mechanical stimuli following lidocaine are associated with a phenotypic switch of SA1 fibers to fast adapting. The mechanisms underlying SA1 firing during the sustained phase of skin indentation appear more sensitive to sodium channel blockade than at onset or offset.

Abstract: As a sensory-neural organ, skin provides both a protective epithelial barrier and an environmental interface that allows organisms to react to changing conditions. Signaling between skin's epithelial cells and somatosensory neurons has recently been shown to shape touch, itch and nociception. Little is known, however, about the mechanisms through which skin cells release neuroactive molecules to govern neuronal excitability. Since their first description as "*touch cells*" in 1875, Merkel cells have served as the archetypical skin cell that mediates somatosensation. These epithelial derived cells complex with Aβ low-threshold mechanoreceptors (LTMRs) to produce slowly adapting type I (SAI) responses. Touch-sensitive Merkel cells are proposed to activate Aβ LTMRs through chemical synaptic transmission. To test this hypothesis, we employed a set of classical criteria for chemical neurotransmission as a framework. Using transcriptomic analysis, high performance liquid chromatography, and *ex vivo* electrophysiology, we show that Merkel cells are molecularly equipped for chemical synaptic transmission, and that SNARE-mediated synaptic vesicle release is required for SAI responses. Moreover, Merkel cells display robust, activity dependent release of fluorescent neurotransmitter analogues. Lastly, complementary pharmacological and genetic approaches demonstrate that Merkel-cell afferents are excited by chemical neurotransmitters, and that neuronal neurotransmitter receptors are necessary for SAI responses in Aβ LTMRs. These experiments reveal that Merkel cells form *bone fide* chemical synapses with Aβ LTMRs to encode gentle touch.

Title: What can mechanosensory neurons tell the mouse brain about whisking?

Authors: *K. S. SEVERSON[1], D. XU[1], H. YANG[2], D. H. O'CONNOR[1]
[1]Dept. of Neurosci., Johns Hopkins Univ. Sch. of Med., Baltimore, MD; [2]Molecular, Cell, and Systems Biol., Univ. of California, Riverside, Riverside, CA

Abstract: Perception during active touch involves integrating information about surface features and sensor motion. We commonly interact with the tactile world using our hands, feet and orofacial regions. Despite this, our understanding of facial sensation and proprioception is limited. Classical proprioceptors are not found in most facial muscles. Instead, it is hypothesized

that low-threshold mechanoreceptors (LTMRs) could serve as “cutaneous” proprioceptors. Here, we used the mouse whisker system as a model for facial movement to investigate this hypothesis. Specifically, we surveyed cutaneous afferents at locations across the face and quantified how well they encode aspects of whisker motion.
During whisking in air, whisker afferents encode whisk phase, the relative position of the whisker within a whisk cycle. How well is whisk phase encoded by whisker afferents? And, are there other types of facial afferents that encode whisking kinematics? We compared whisking-related responses from primary afferents categorized by receptive field type: whiskers (n=67), non-mystacial vibrissae (n=35), facial fur (n=85), and jaw muscles (n=28). We used mutual information calculations to quantify how well whisk phase was encoded by each type of afferent. Jaw muscle afferents encoded the least information about whisk phase (median I = 0.42 bits/s). Facial fur afferents encoded phase (6.3 bits/s) better than jaw afferents but less well than whisker afferents (20 bits/s). Afferents with non-mystacial vibrissae receptive fields encoded phase to an intermediate degree (10 bits/s).
We next quantified how strongly movements of various parts of the face correlated with whisker motion. We found that skin motion near the whisker pad and the supraorbital and genal non-mystacial vibrissae was phase-locked with whisking. Correlated motion between these parts of the face and the whiskers explains how non-whisker afferents encode whisk phase.
In summary, whisker afferents encode whisk phase much better than other afferents. However, non-mystacial vibrissa and facial fur afferents may provide additional and complimentary proprioceptive inputs to the brain.

Title: Effect of surface texture on the encoding of touch, pressure, and shear in the glabrous skin of a Rhesus macaque

Authors: *M. F. LIU[1], J. E. WINBERRY[4], C. VERSTEEG[6], T. W. SIMPSON[1], E. R. OBY[1], A. D. DEGENHART[2], A. P. BATISTA[1], R. A. GAUNT[3], S. J. BENSMAIA[5], L. E. MILLER[7], D. J. WEBER[1]

Abstract: Cutaneous mechanoreceptors in the fingers encode information about the mechanics of touch, enabling the perception of grip force and object properties, such as shape, weight, and texture. Understanding the interaction between parameters such as force of contact and surface properties such as roughness, will yield insight into how the nervous system can extract object-specific information such as texture. Tactile signals originate from mechanoreceptors in the skin, innervated by nerve fibers whose cell bodies are located in the dorsal root ganglia (DRG). To elucidate how aspects of texture and touch mechanics are encoded in DRG neurons, we implanted penetrating multielectrode arrays in the C6, C7, and C8 DRG of two anesthetized rhesus macaques. We identified cutaneous and proprioceptive units via manual palpation of the arm and hand. Cutaneous units were further classified as rapidly adapting or slowly adapting based on their responses to a touch-and-hold stimulus. Tactile stimuli were delivered via two different paradigms. In the first, 10 different textured materials were scanned across the monkey's finger at fixed speeds using a rotating drum. In the second, a handheld probe was used to apply normal and shearing forces to the palm and fingers, at locations containing receptive fields for identified neurons. The probe contained a force transducer to measure the normal and shear forces. Any of several interchangeable tips was attached to the end of the probe, each containing a different material, spanning a range of roughnesses. This allowed us to examine how populations of neurons in the DRG encode contact parameters such as force and scanning speed, as well as object properties such as texture. We used the firing rates of a small population of neurons with receptive fields in the palmar surface of the hand to predict texture and speed of the stimulus with 70% accuracy. Predictions based on rapidly-adapting units were more accurate than those based on slowly-adapting units. We could also predict normal force (mean R^2 = 0.8) and shear force (mean R^2 = 0.6) from the responses of a small population of neurons with higher accuracy than from the responses of individual neurons.

Title: Effect of noradrenaline on synaptic response facilitated by peripheral mechanical stimulation by an *in vivo* patch-clamp recording

Authors: *M. SONOHATA[1], A. DOI[2], T. YASAKA[3], M. MAWATARI[1], M. YOSHIMURA[4]

Abstract: Introductioin: Although The substantia gelatinosa (SG) of the spinal cord is known to process not only noxious (pain) but also innocuous (touch) information, our knowledge about how these sensory inputs are moderated by exogenous noradrenaline (NA) at the synaptic level is still largely limited. In the present study, therefore, the modality selective synaptic effects of NA were investigated in SG neurons by using both in vivo anesthetized condition of rat and patch-clamp technique. **Methods:** We applied *in vivo* patch-clamp technique to anaesthetised rats to investigate the actions of NA on synaptic responses in SG neurons to mechanical stimuli before and after NA application to the surface of the L4 - L5 spinal cord. Innocuous or noxious mechanical stimuli were applied to the receptive field of the ipsilateral hindlimb with an air puff or toothed forceps, respectively. **Results:** NA reversibly suppressed the amplitude of the pinch-evoked excitatory postsynaptic currents (EPSCs) in 16 of 21 neurons (76% of control) and enhanced the amplitude in a small number of neurons. Moreover, NA inhibited the amplitude of puff-evoked EPSCs in 9 of 21 neurons (43% of control). Statistical analysis revealed that the inhibitory rate of pinch-evoked EPSCs was significantly higher than that of puff-evoked EPSCs. **Discussion:** These data indicate that NA acts on both noxious and innocuous mechanical transmission in the SG with modality specific manner. Action of NA studied *in vitro* slice preparations were only suppression of EPSCs and enhancement of IPSCs, but not enhancement of EPSCs. It is obvious that neuronal circuitry in the spinal dorsal horn in the *in vivo* preparation is completely preserved, while that in the slice preparation is very limited. Thus, the discrepancy of NA action may result from these differences.

Title: Speed invariant coding of texture in somatosensory cortex

Authors: *J. D. LIEBER[1], K. H. LONG[2], S. J. BENSMAIA[3]
[2]ISTP/CNS, [3]Dept. of Organismal Biol. and Anat., [1]Univ. of Chicago, Chicago, IL

Abstract: We are endowed with a remarkable ability to identify objects across a wide range of contexts and perspectives. For example, we can visually identify objects over broad changes in lighting, distance, or viewing angle; we can also auditorily identify the timbre of voices and musical instruments across a wide range of loudness and pitches. In both vision and audition, perceptual invariance is achieved despite sensory representations at the periphery (the retina, the cochlea) that are highly dependent on perspective and context.
In touch, the best known instance of perceptual invariance is for texture: the tactile perception of a textured surface has been shown to be nearly independent of the speed at which it is scanned across the skin (Boundy-Singer et al., 2017). This perceptual invariance is achieved despite that fact that scanning speed strongly modulates both the firing rate and temporal patterning of responses in the somatosensory nerves (Weber et al., 2013). To achieve an invariant percept of texture, texture-specific information must be extracted from peripheral signals that are highly dependent on exploratory parameters, a process about which nothing is known.
To study these interactions, we recorded the spiking responses of neurons in somatosensory cortex - including Brodmann's areas 3b, 1, and 2 - to natural textures scanned over the skin at various speeds, spanning the range used in natural texture exploration. We then compare the effect of speed in cortical responses to their peripheral counterparts. We find that, while the strength of the response evoked by textures in tactile fibers is highly speed-dependent, the strength of the response of many neurons in somatosensory cortex is speed-independent. This speed independence gives rise to a rate-based texture representation in cortex which, unlike its counterpart in the nerve, is robust to changes in scanning speed. We also find that a subset of neurons in cortex exhibit responses to texture that are temporally patterned, much like those in the periphery, and that these patterns scale with speed. As the rate-based code is sufficient to account for our ability to perceive textures across changes in scanning speed, however, the role of these temporal signals in cortex remain to be elucidated.

Title: Fingertip skin deformation during the pre-loading phase of lifting

Authors: *F. SCHILTZ[1], A. BARREA[2], J.-L. THONNARD[3], P. LEFEVRE[4]
[1]Catholic Univ. of Louvain, Louvain la Neuve, Belgium; [2]Univ. Catholique de Louvain, Louvain-la-Neuve, Belgium; [3]Univ. Catholique de Louvain, Brussels, Belgium; [4]ICTEAM and Inst. of Neuroscience, Univ. Catholique de Louvain, Louvain-la-Neuve, Belgium

Abstract: The specific friction between fingertip and object has been shown to affect the coordination of finger forces during the early phases of object lifting. We hypothesize that the effect of friction on finger forces is mediated by fingertip deformation. Here, we investigated the relationship between object friction and fingertip deformation and how the latter affects the control of finger forces. To this end, we designed a compact instrumented object equipped with a camera allowing recording the fingertip skin deformation during manipulation. The object was designed to be held in precision grip, i.e. between the thumb and index finger. In addition, it is equipped with sensors measuring forces and torques applied by the thumb and index finger on the object. In the experiment, a human subject was asked to grasp the manipulandum in precision grip, lift it approximately 10cm above its support, hold it for a few seconds, and then place it back on the support. This procedure was repeated twenty times in consecutive trials. The proportion of the contact area between fingertip and object that experienced slipping was determined using image processing techniques. First, feature points were sampled automatically within the contact area. Then, the position of these points was tracked across consecutive frames using an optical flow algorithm. A point was considered slipping if it moved more than a fixed threshold between two consecutive frames. Two frictional conditions were tested. In the first one, the subject manipulated the object with bare fingers, while in the second condition fingertips were coated with oil. Analysis of the sticking and slipping parts of the contact area showed that the sticking part propagated from the center to the periphery of the contact during the preloading phase. Further analysis showed that fingertip skin underwent large mechanical deformation under the oil condition during the pre-loading phase, i.e. during the built-up of grip force before the object is lifted off the table. This suggests that skin deformation during the pre-loading phase may constitute valuable information about friction between fingertip and object that could be transmitted by the mechanoreceptors of the fingertips to the central nervous system in the very first stages of lifting.

Title: A quantitative perceptual model for tactile roughness

Authors: *C. TYMMS[1], E. P. GARDNER[2], D. ZORIN[1]
[1]Computer Sci., New York Univ., New York, NY; [2]Dept Physiology/Neuroscience, New York Univ. Sch. of Med., New York, NY

Abstract: Everyone uses the sense of touch to explore the world, and roughness is one of the most important qualities in tactile perception. Roughness is a major identifier for judgments of material composition, comfort and friction, and it is tied closely to manual dexterity. The advent of high-resolution 3D printing technology provides the ability to fabricate arbitrary 3D textures with surface geometry that confers haptic properties. In this work, we address the problem of mapping object geometry to tactile roughness. We fabricate a set of carefully designed stimuli and use them in experiments with human subjects to build a perceptual space for roughness. We then match this space to a quantitative model obtained from strain fields derived from elasticity simulations of the human skin contacting the texture geometry, drawing from past research in neuroscience and psychophysics. We demonstrate how this model can be applied to predict and alter surface roughness, and we show several applications in the context of fabrication.

Abstract: Grasping an object requires intricate coordination of tactile perception with fine motor skills. In particular, humans adapt fingertip grip forces to the object's surface friction and adapt

their load forces to the object's weight. If the adjustment in grip-load force is too small, the object may be dropped, while applying too much force, risks damaging it. Some attention has been given to perception of surface friction in the past, but it has typically focused on non-controllable natural materials or on a narrow range of artificial materials. The advent of high-resolution 3D printing technology provides the ability to fabricate arbitrary 3D shapes with textures of precise surface geometry to be used in tactile studies. Using high resolution stereolithography 3D printing and parametric modeling, we created eight different textures, whose texture elements were small bumps with diameters of 0.1, 0.3, or 0.5 mm, and had a mean spacing of 0.75 mm, 1.0mm, or 1.25mm. Previous studies demonstrated that surfaces with small wavelengths and large textons were judged most smooth, and textures with large wavelengths and small textons were judged least smooth. We used these same surfaces to measure the interaction between surface texture and object mass on efficient grasp-and-lift actions. Ten healthy adult subjects grasped and lifted an instrumented grip device with 3D printed surfaces and weights of 250, 450 and 650 g. The adaptation of fingertip forces was quantified using the peak grip force rate (PGFR) and grip force at lift (GF). We quantified the coefficient of friction (COF) as the inverse of the slip ratio (grip force/ load force at the moment of slip). We found that the load lifted had clear effects on grip force, but the texture effects were weaker due to a small range tested. Rough surfaces with large spacing and small diameter textons result in a significantly higher COF and produced lower PGFR. Friction was negatively correlated with subjective smoothness estimates. Textures generated with different texton size and spacing using stereolithography 3D printing can be used to generate a variety of quantified frictional surfaces that then can be used in studies for tactile roughness perception and in related neurological applications.

Title: Localizing sensorimotor cortex using vibro-tactile stimulation

Authors: *T. XIE[1,2], Z. WU[3], P. BRUNNER[1,4], X. SHENG[2], X. ZHU[2], G. SCHALK[1,4,5], L. CHEN[3]
[1]Nat. Ctr. for Adapt. Neurotechnologies, Wadsworth Ctr., New York State Dept. of Hlth., Albany, NY; [2]State Key Lab. of Mechanical Syst. and Vibration, Shanghai Jiao Tong Univ., Shanghai, China; [3]Dept. of Neurosurg., Huashan Hospital, Fudan Univ., Shanghai, China; [4]Dept. of Neurol., Albany Med. Col., Albany, NY; [5]Dept. of Biomed. Sci., State Univ. of New York, Albany, NY

Abstract: Localization of sensorimotor cortex is often performed during presurgical planning prior to resective brain surgery to minimize post-surgical deficits. Electrical stimulation of the median nerve (MNS) has been used for decades to identify the central sulcus, i.e., the boundary between motor and sensory areas. MNS is typically performed by qualitatively assessing the polarity and shape of the responses to electrical stimulation, which has to be done by experts and can lead to ambiguous results. We aim to overcome these limitations by developing an alternative technique that is quantitative (and hence can be automated) and accurate. In our ongoing study, we localized sensorimotor cortex by assessing population-level cortical responses to vibro-tactile stimulation and compared the results to those obtained by median nerve stimulation and self-paced movement.
To date, we collected data from two human subjects who underwent an awake craniotomy and median nerve stimulation for the purpose of localizing sensorimotor cortex prior to tumor resection. Both subjects had electrocorticographic (ECoG) grids placed over sensorimotor cortex (8x8 configuration, 5mm inter-electrode spacing, 2mm exposed diameter). While the subjects were awake during the surgery, we performed three experiments on the hand contralateral to the implant while acquiring ECoG signals at 2048 Hz: (1) Median nerve stimulation of the wrist for a duration of 1-6 minutes (2.3 Hz, bi-phasic, 5.5-7.5mA current); (2) Vibro-tactile stimulation of the index finger for a duration of 10 minutes (175 Hz vibration frequency, pulsed at 23-29 Hz); (3) Self-paced flexion of the index finger (40-60 trials of 2s flexion and 3-4s rest). In offline analyses, we determined the spatial concordance between the functional maps of sensorimotor cortex determined by analysis of ECoG broadband gamma (60-140 Hz) activity during vibro-tactile stimulation and finger movement, and their relationship to the location of the central sulcus as determined from median nerve stimulation.
Our results show that vibro-tactile stimulation and self-paced finger flexion produce broadband gamma responses anteriorly and posteriorly to the central sulcus and that these responses have distinct time courses that may be informative for attributing them to motor or sensory cortex. Furthermore, vibro-tactile stimulation activates a subset of the cortical areas that are activated by self-paced finger movement. With additional data, our study may lead to a new clinical procedure for automatic localization of sensorimotor cortex.

Title: The effects of remote subthreshold electrical stimulation on skin sensitivity in the lower extremity

Authors: *E. PLATER[1], R. PETERS[2], L. BENT[1]
[1]Univ. of Guelph, Guelph, ON, Canada; [2]Univ. of Calgary, Calgary, ON, Canada

Abstract: Introduction: Skin at the foot sole acts as an interface with the support surface and can therefore affect balance. Lower extremity amputation (LEA) leads to changes in the skin interface. The skin at the foot sole is glabrous; in LEA, the interface between the residual limb and the prosthetic socket is comprised of hairy skin, which has different sensory properties, the specifics of which are not as well known. A sensory augmentation technique, stochastic resonance (SR), has been shown to improve sensitivity in glabrous skin through application of a remote subthreshold stimulus. The objective of the current study was to determine if remote subthreshold electrical stimulation at the foot sole and hairy skin on the posterior leg can improve sensation to a vibration stimulus in a similar way, in healthy individuals with no sensory impairments.
Methods: 10 young, healthy subjects (5 females, age 22-27 years) had a vibrotactile stimulus applied to the second metatarsal, heel and calf at the same time that an electrotactile noisy stimulus was applied remotely to the posterior calf (for second metatarsal and heel locations) or thigh (for calf location). Thresholds were determined for both stimuli (vibro or electrotactile) prior to testing. A two forced-choice protocol was then used to determine detection ability of the vibration at 90% of determined threshold, with varying electrotactile levels superimposed. A greater percent-correct value indicated better detection. Any value above 67.5% correct was considered significantly above a guessing rate and was determined to be an “SR effect”.
Results: 30 observations were compared (10 subjects x 3 skin sites). Of these, approximately half (13/30) showed an SR effect. When present, the SR effect did not have a clear distribution across noise intensities. On average, the SR effect was larger at the calf (0.53) than the other sites (0.15, 0.38) There is some evidence of a relationship between performance on two different sites in a single individual.
Discussion: The SR effect was seen here in both glabrous and hairy skin in a subset of the observations. Previous studies suggest that there is an optimal noise intensity that most effectively improves sensitivity; this was seen here but it appears to vary between individuals

and sites. Our results suggest that subthreshold electrotactile stimulation may be effective at improving skin sensitivity to vibration on both glabrous and hairy skin, but the intensity required varies between individuals and locations and is not effective in everyone. Testing in an LEA population is the next step with future work targeting new technology in prosthetics to improve balance and prevent falls.

Title: Study on brain imaging when using micro-cone to reduce pain using fmri

Authors: *S. FUKASAWA[1,3], H. EDA[2], S. IDE[3]
[1]Grad. Sch. for GPI, Nishi-Ku Hamamatsu, Japan; [2]Grad. Sch. for GPI, NIshi-ku Hamamatsu, Japan; [3]ToyoResin, Shizuoka, Japan

Abstract: Introduction Due to its response with diverse factors, pain mechanism has not been elucidated. Instead, importance of pain management has been pointed out. We made a report on SfN in 2013. Pain is relieved by attaching a micro-cone. Objective of the study is to examine fMRI images during pain relief. Methods Applying pain stimulus in the experiment, a comparison was performed between those with and without pain relief effect. We designed a factor-based experiment using two factors (2×2 levels). A stick (ToyoResin corporation, Japan) was used to relieve pain. Somacept•Somareson (ToyoResin corporation, Japan) was used as micro-cone disk for pain relief. A flat disc was used as placebo with no pain relief by removing micro-cone projections. MAGNETOM Verio (3T) made by Siemens was used for fMRI. Pressure stimulus was given on the side of little finger nail. Prior to stimulation, a disc was attached between PM and CM joints on the back of the hand. The experiment was performed by replacing attached micro-cone and placebo twice separately by new one. The subject was a healthy woman aged 45. All procedures were approved by Ethics and Study Committees of ATR-Promotions, Inc (ATR Ethics Committee, Ethical number 13-020). Result The subject was asked in advance about degree of pain when stimulus was given. Evaluation was based on VAS value. It was 7 against 10 as the maximum unbearable pain. The figure shows images when the same pain stimulus was given under conditions with (Fig. 2) and without (Fig.1) micro-cone. condition. A pain stimulus image without micro-cone showed activities on multiple sites in the brain. ($p < 0.01$) Such activity was not observed in a pain stimulus image with micro-cone. Conclusion Reported VAS value indicates that the subject felt pain by the stimulus. The image without micro-cone showed a state of the brain feeling a pain. The result was coincident with

previous knowledge on PainMatrix. Activities were observed on multiple sites in the brain. Regarding PainMatrix, we referred to Plant 73 (1997) 431-445 published by Derbyshire et al. in 1997. Activities were observed at S1, S2, insula, ACC, and thalamus in placebo. An image has suggested that activities were not recognized at such sites (e.g. S1, S2, insula, ACC, thalamus) even feeling the same pain stimulus by attaching a micro-cone.Micro-cone has suggested its mechanism to suppress activities at sites feeling a pain. The current experiment has provided just a preliminary result of one subject.In order to clarify brain activity when a pain is relieved by a micro-cone, we intend to examine the mechanism by further increasing subjects in the future.

Title: Characterizing breast sensation and its relationship with sexual arousal

Authors: K. H. LONG[1], A. K. SURESH[1], *S. J. BENSMAIA[2]
[1]Committee on Computat. Neurosci., [2]Dept. of Organismal Biol. and Anat., Univ. of Chicago, Chicago, IL

Abstract: Each year, 100,000 women undergo mastectomy, including a growing number who elect bilateral prophylactic mastectomy to reduce their risk of breast cancer. Most (40-80%) of the women who have this procedure experience loss of sexual function, even among the majority who are satisfied with the appearance of their reconstructed breast(s). Surgical innovations have led to marked advances in restoring the breast's physical *form*, but very little has been done to restore or preserve breast *function*, including touch (discriminative, affective, and erogenous), thermoreception, and thermoregulation. As is well-understood for the role of penile function in male sexual physiology, these sensorimotor and neurovascular components of breast function are essential to normal female sexual physiology. Simple (or total) mastectomy, the most common mastectomy procedure for women with breast cancer, amputates all of the breast tissue, including the lateral cutaneous branches of the third through sixth intercostal nerves and the entire nipple areolar complex (NAC), preserving the underlying pectoral muscles and axillary lymph nodes. This loss of innervation causes partial or complete loss of sensation in the breast. To develop strategies for preserving and restoring breast function, we aim to identify (1) the contribution of specific mechanoreceptive afferents in both the breast and the NAC, (2) the role

of individual intercostal nerves in breast sensation and arousal, and (3) the relationship between arousal and breast sensation. To this end, we designed and constructed an experimental apparatus to passively deliver diverse, well-controlled tactile stimuli to the breast and NAC. With this apparatus, we present a variety of tactile stimuli - including vibrations and textures - and have subjects perform perceptual judgments adapted from well-established psychophysical paradigms. We then use virtual reality audiovisual stimuli to elicit a state of sexual arousal and investigate the effects of arousal on breast sensation. Finally, we pharmacologically block individual intercostal nerve fibers and assess the impact on sensation and arousal.

Title: Sensitivity of foot cutaneous mechanoreceptors is altered by ankle-joint posture

Authors: *S. G. SMIITH[1], S. BEAUDETTE[1], S. BROWN[1], L. BENT[2]
[1]Univ. of Guelph, Guelph, ON, Canada; [2]Univ. Guelph, Guelph, ON, Canada

Abstract: Background:
Locomotor patterns are adapted to account for changes in our environment. Modification of such patterns are achieved through sensory inputs, for which cutaneous feedback from the foot is known to have a crucial role. The foot moves through various postures with locomotion, which results in structural deformations to the skin of this region. It is important to assess if skin sensitivity, and therefore contribution, is modified in different foot postures along with structural deformations.
Aim: To assess the effect of ankle posture on skin sensitivity measures across the foot.
Methods: 20 subjects (9 male, age = 22 ± 1) were positioned with their right foot in dorsiflexion, plantarflexion, and a neutral posture. Measures of perceptual skin sensitivity were assessed across the foot sole or dorsum; proximal, middle, or distal regions of the dorsum or the heel, medial arch, lateral arch, and the first metatarsal of the sole. Tactile sensitivity tests were used to target subclasses of cutaneous mechanoreceptors and included measures of touch contact sensitivity (Semmes Weinstein monofilaments for FAI), stretch sensitivity (fastened tabs, SAII), and spatial acuity (JVP Domes, SAI.)
Results:
Sensitivity differed significantly across locations; increased sensitivity to touch contact at the

distal site and medial arch as well as decreased sensitivity at the heel and proximal site. Skin stretch and spatial acuity measures were most sensitive at the heel. For posture, skin sensitivity was altered at regions that undergo large structural deformations, such as the foot dorsum and metatarsals, across ankle postures. Specifically, skin stretch resulted in decreased monofilament sensitivity on the foot dorsum as well as increased sensitivity to longitudinal stretch. Sensitivity to transverse stretch also increased across the foot dorsum. The opposite response occurred with skin retraction. Spatial acuity was not altered by postures.
Conclusions: Skin sensitivity was found to be location dependent on the foot sole and dorsum for almost all measures, with the heel being most sensitive for skin stretch and spatial acuity and the medial arch being the most sensitive for touch contact. Overall, touch contact sensitivity was decreased with skin stretch and increased with retraction. The opposite occurred with stretch; with greater sensitivity in a stretched position. As a result we suggest the structural alterations to the skin on the foot across postures affects skin sensitivity.
Significance: The ability of skin input to alter gait outcomes may be variable across ankle postures, which changes the effectiveness of interventions across phases of movement.

Title: Direct effects of simulated knee movements on firing behavior of muscle spindles located within a one-joint ankle extensor

Authors: *H. MAAS, W. NOORT
Dept. of Human Movement Sci., Vrije Univ. Amsterdam, Amsterdam, Netherlands

Abstract: We recently showed in rat that muscle spindles not only signal length changes of the muscle in which they are located, but also local length changes that occur as a result of changing the length of synergistic muscles (Smilde et al. J. Neurophys. 2016). The mechanism for this is force transmission via connective tissue linkages between adjacent muscles. However, in our previous study, the imposed relative muscle positions were non-physiological, i.e. only one of the triceps surae muscles (e.g. soleus, SO) was lengthened distally. The aim of the present study was to investigate the effects of intermuscular connections on feedback from muscle receptors during physiological conditions. We hypothesized that proximal length changes of the two-joint ankle plantar flexors (mimicking knee extension) will affect the output from muscle spindles located with the one-joint SO. In fully anesthetized Wistar rats (n=20), the distal tendons of SO, lateral gastrocnemius (LG) and plantaris (PL) were dissected, cut and together tied to a servo

motor, which controlled MTU length and measured tendon force. Also the shared proximal tendon of LG and PL was attached to a servo motor. Connective tissues at the muscle belly level were left intact. Action potentials from single afferents were recorded intra-axonally by penetrating dorsal roots. Axons from muscle spindles were identified using their characteristic response properties. To assess in which muscle the spindle was located, the muscle surface was probed. To further confirm location within SO, ramp stretches were applied both distally (including SO) and proximally (only including LG and PL). Afferent firing was measured during distally applied 3 mm ramp stretches (20 mm/s), corresponding to ankle plantar flexion from 90° to 45°. During the hold phase, three successive proximally applied symmetric triangular stretch-release trials (1 mm, 2mm/s; corresponding to knee extension from 90° to 110°) were performed. Instantaneous firing rate (IFR) was instantly affected by LG+PL triangular stretch-releases in 20 out of 27 SO muscle spindles. Not lengthening, but shortening of LG+PL proximally resulted in an increase of the IFR, by on average 26 pulses per second). These results extend previous findings that output of muscle spindles can be affected by length changes of neighboring muscles, also if conditions stay within physiological limits. This indicates that spindles do not encode angles of individual joints unambiguously, but may also provide information about adjacent joints that the muscle does not span and, hence, limb endpoint position.

Title: Neural substrates of a proprioceptive discrimination task

Authors: *N. ELANGOVAN[1], A. MAHNAN[2], J. KONCZAK[3]
[1]Sch. of Kinesiology, [3]Human Sensorimotor Control Lab., [2]Univ. of Minnesota, Minneapolis, MN

Abstract: Proprioceptive inputs from the limbs are crucial for producing accurate movements. Impairment in proprioception leads to movement deficits in neurological conditions. Proprioceptive evaluation typically involve a position sense discrimination task. However, the cortical areas involved in the processing proprioceptive discrimination task has never been systematically evaluated. Here, we evaluate a neural substrates of a wrist position sense discrimination task using electroencephalography (EEG). Healthy adults with no known neurological deficits were recruited for study participation. Testing involved 2 steps - threshold estimation and EEG evaluation. Proprioceptive discrimination thresholds were determined using a 2-alternate forced choice paradigm. Each participant discriminated wrist position stimuli for 30

trials, verbally identifying the farthest position among stimulus pairs in each trial. A wrist robotic apparatus was used to deliver the position sense stimuli. Size differences between the position sense stimulus pairs were obtained by psi-marginal method, an adaptive psychophysical algorithm. Thresholds were estimated based on subject responses and stimulus size differences using a logistic-weibull function. After threshold estimation, each participant completed 300 discrimination trials with a supramaximal stimulus (150% of threshold) under EEG. Instruction on whether to identify the nearest or the farthest position was randomized during the discrimination trials. Participants were cued on the decision after the stimulus pairs were presented. This delayed cue was introduced during EEG evaluation to dissociate the processes related to proprioceptive discrimination from verbal judgment. We present the results of event-related activity during the proprioceptive discrimination task in the frontal and parietal cortical areas. These results provide insights on the influence of proprioceptive processing in the perceptual and the motor areas and thereby cortical motor processing.

Title: An integrative neuromorphic approach to modeling of voluntary motor function

Authors: *S. CHAKRAVARTHI RAJA[1], F. J. VALERO-CUEVAS[1,2,3]
[1]Dept. of Electrical Engin., [2]Dept. of Biomed. Engin., [3]Div. of Biokinesiology and Physical Therapy, USC, Los Angeles, CA

Abstract: In Niu, et al. (2017) we implemented a realtime Field-Programmable Gate Array (FPGA)-based simulation of neuromorphic models of monosynaptic stretch reflex circuitry of an agonist-antagonist muscle-pair. We then characterized the system in Jalaleddini, et al. (2017) by coupling the simulation to the flexor digitorum profundus and the extensor carpi radialis longus tendons of the MCP joint of a cadaveric hand preparation to show that such systems can indeed evoke human-like stretch reflexes as in the work of Edin and Vallbo (1990).
We now present improvements to that system such as including Golgi tendon organs, Renshaw cells, and polysynaptic interneuronal pathways to form a system akin to a simplified spinal-like regulator as in Raphael et al. (2010). Nonlinear adaptive controls and simple neural networks

allow us tune the descending commands (pulse trains) to both fusimotor and alpha motoneuron pools. We use such time-based running of descending commands to demonstrate the ability to produce “voluntary” movement. We find that realistic models of muscle mechanics, force-velocity properties in particular, are critical to produce stable movements. By selectively adding/removing components and interconnections, we are also able to show the sufficiency of the same for enabling voluntary movement. Future extensions will include homonymous and heteronymous sensorimotor pathways to control more muscles and produce motor function in cadaveric human fingers.

The authors acknowledge Dr. Gerald E. Loeb, Dr. Terence D. Sanger and Dr. Kian Jalaleddini for their guidance with the setup of the system.

Title: Pulvinar modulates contrast responses in visual cortex as a function of cortical hierarchy

Authors: *N. CORTES[1], B. O. SOUZA[2], C. F. CASANOVA[3]
[1]Ecole d'optometrie, Univ. De Montreal, Montreal, QC, Canada; [2]École d'Optométrie, École D'Optométrie, Univ. De Montréal, Montreal, QC, Canada; [3]Univ. Montreal, Montreal, QC, Canada

Abstract: The pulvinar is the main extrageniculate visual nucleus in all mammals including humans. Given its extensive reciprocal connectivity with the visual cortex, it allows the transthalamic cortico-cortical transfer of visual information. Little is known about the driver or modulatory nature of these connections across the visual hierarchy. To address this question, we studied the impact of pulvinar inactivation on the contrast response function (CRF) of neurons localized in two distant hierarchical levels of the cat visual cortex: areas 17 and 21a. Single-unit responses to gratings presented at different contrasts were recorded in both areas using linear probes before, during and after the GABA inactivation of the lateral (LPl) or medial (LPm) parts

of the lateral posterior nucleus. Here, the distinction between driver (D) and modulator (M) inputs was based on its effects on the CRF. Linear effects (e.g., changes of CRF position; C50) were associated with D inputs, while nonlinear effects (e.g., changes of CRF dynamic range; Rmax) with M inputs (Abbot and Chance, 2005). In area 17, LPl inactivation impacted mostly the Rmax with 63% of cells showing an increased and 37% a decrease of activity. Only 3 cells showed an increase of C50. Moreover, putative excitatory neurons (i.e., regular spiking cells) showed most of the Rmax changes, with supra- and infragranular layers presenting increased and decreased activity, respectively. In area 21a, LPl inactivation yielded an increase in Rmax for most cells (30/35) irrespective of the excitatory/inhibitory nature, with only 2 neurons exhibiting changes in C50. The inactivation of the LPm yielded an increase in C50 and Rmax for 1/3 of 21a cells (11/31), while for the rest, only the Rmax increased. These effects were not layer- nor cell-type dependent. Overall, the impact of the pulvinar inactivation was stronger in area 21a than in area 17. In addition, while the pulvinar inactivation caused changes in Rmax in area 17, it led to changes to both Rmax and C50 in area 21a. Thus, these findings indicate that the pulvino-cortical signals are mostly modulatory in area 17 and modulatory and driver in area 21a. The distinctive influence of pulvinar across the cortical hierarchy may play a central role in visual attention mechanisms.

Title: Corticogeniculate feedback enhances suppression of extraclassical surround in select LGN neuron subtypes

Authors: *A. J. MURPHY[1,2,3,4,5], J. M. HASSE[5,3,4,7], F. BRIGGS[5,3,4,6]
[1]Rochester, NY; [2]Neurosci. Grad. Program, [3]Ernest J. Del Monte Inst. for Neurosci., [4]Ctr. for Visual Sci., [5]Neurosci., [6]Brain and Cognitive Sci., Univ. of Rochester, Rochester, NY; [7]Ctr. for Neural Sci., New York Univ., New York, NY

Abstract: An important function of the visual system is to filter relevant visual information from the noisy visual environment. The corticogeniculate (CG) pathway, which connects primary visual cortex (V1) with the visual thalamus (lateral geniculate nucleus or LGN) in the feedback

direction, may play a role in this filtering process. Previous work has shown CG feedback results in LGN gain modulation, changes in LGN spiking mode, timing, and precision, and sharpening of LGN receptive fields. How CG feedback modulates the extraclassical surround of LGN neurons remains unresolved. We address the contribution of CG feedback to extraclassical surround suppression of LGN neurons by optogenetically manipulating CG feedback neurons in areas 17 and 18 of anesthetized ferrets. First, we inject a modified Rabies virus expressing m-Cherry and channelrhodopsin2 (ChR2) into the LGN such that CG neurons are selectively infected. Following surgical virus injection, we perform an in vivo experiment in which we place electrode arrays into retinotopically-aligned regions of the LGN and V1. We use a fiber-optic cable to deliver 465nm LED light that activates ChR2-expressing CG neurons in the visual cortex. We record the activity of V1 and LGN neurons in response to drifting sinusoidal gratings and m-sequence stimuli under conditions in which CG neurons expressing ChR2 are light-activated. Preliminary results of m-sequence stimulation suggest that the total extent of extraclassical surrounds among LGN neurons are slightly reduced with optogenetic activation of CG feedback. Additionally, optogenetic activation of CG feedback differentially modulates surround suppression among LGN neurons dependent upon size tuning. Together these results suggest CG feedback influences LGN extraclassical surrounds in a cell type specific manner.

Title: Retinotopic mapping of the optic radiation tract

Authors: *O. ABDULLAH[1], K. DESIMONE[2], A. TEMUDO[3], K. SREENIVASAN[3]
[1]Abu Dhabi, United Arab Emirates; [2]Psychology, New York Univ., New York City, NY; [3]Psychology, New York Univ. Abu Dhabi, Abu Dhabi, United Arab Emirates

Abstract: A central aim of cognitive and clinical neuroscience is to map structure to function, which will enable the prediction of functional deficits from structural damage. In clinical practice, evidence from post neurosurgical evaluations has underscored the importance of minimizing damage to white matter structures in the brain during tumor resections. For example, damage to the optic radiation (OR) tract can result in serious visual field defects. The OR carries visual field information from the lateral geniculate nucleus (LGN) to primary visual cortex (V1). An important gap in our knowledge is understanding the relationship between individual fiber bundles within the OR and information about specific parts of the visual field.
Diffusion-MRI (dMRI) has emerged as a noninvasive modality for tracing and virtually

dissecting major white matter bundles in the living brain. Several studies highlighted the utility of dMRI for predicting post-surgical damage of the OR in individual patients. However, due to variability of the location and trajectory of the OR between subjects, this technology has not been widely adopted. In this study, we combined retinotopic mapping of the visual cortex obtained from functional magnetic resonance imaging (fMRI) to guide dMRI fiber tracking algorithms of the OR in young healthy male and female adults. We analyzed data from the publicly available Human Connectome Project dataset (10 subjects; 7T fMRI co-registered to 3T and 7T dMRI), as well as data that we acquired at New York University Abu Dhabi (4 subjects; 3T fMRI co-registered to 3T dMRI). The fMRI data was collected during visual stimulation with high contrast sweeping bar and expanding ring stimuli. We employed a population receptive field (pRF) approach, which assigned each voxel a receptive field center and size. The aggregate maps were used to draw visual regions of interest and determine polar angle and eccentricity maps, consistent with standard retinopic mapping procedures. The fMRI-generated maps in V1 were used in turn to classify specific white matter bundles in the OR (LGN to V1) according to their terminating points in V1, which provided white matter retinotopic dissection of the visual field. Eccentricity color-coded OR resembled a ribbon-like structure entering V1 with the foveal fibers occupying the middle part. When color-coded with the Polar Angle, the OR where mainly split into superior and inferior parts resembling the lower and upper visual fields. The combination of fMRI and dMRI to assign specific functional roles to white matter tracts represents a potentially valuable tool both for basic science and as a guide for neurosurgeries conducted under general anesthesia.

Title: Visual response properties of mouse TRN are consistent with its potential role for feedback-mediated surround suppression

Authors: *G. BORN[1,2], M. A. SPACEK[1], C. LAO[3], L. BUSSE[1,4]
[1]Div. of Neurobiology, Dept. Biol. II, LMU Munich, Planegg-Martinsried, Germany; [2]Grad. Sch. for Systemic Neurosciences, LMU Munich, Planegg-Martinsried, Germany; [3]Inst. of

Physiological Genomics, Viral Vector Facility, LMU Munich, Planegg-Martinsried, Germany; [4]Bernstein Ctr. for Computat. Neurosci. Munich, Planegg-Martinsried, Germany

Abstract: Neurons in the dorsolateral geniculate nucleus (dLGN) of the thalamus are suppressed by stimuli extending beyond the classical receptive field into the surround. Surround suppression increases between the retinal ganglion cells and dLGN, where it has been hypothesized that corticothalamic (CT) feedback from layer 6 (L6) contributes to this enhancement (Andolina et al., 2012). Because L6 CT neurons are excitatory they can inhibit thalamic relay cells only indirectly via local geniculate interneurons or inhibitory neurons in the thalamic reticular nucleus (TRN). We hypothesized that if neurons in TRN were responsible for mediating feedback-induced surround suppression in dLGN, they should have large receptive fields (RF) and be suppressed if CT feedback is disrupted.

We tested this hypothesis by head-fixing C57BL/6 mice on a floating Styrofoam ball and recording extracellular single-unit activity using high-density silicon probes in the visual part of TRN (perigeniculate nucleus, PGN). For post-mortem confirmation of our recording site, we injected a retrograde AAV into dLGN leading in connected PGN neurons to the expression of green fluorescent protein. We presented full-field drifting gratings to identify visually responsive neurons and mapped their RFs with sparse noise stimuli. We measured surround suppression by showing drifting gratings of varying sizes.

We observed that activity in PGN was strongly modulated by behavioral state; thus, we restricted our analysis to trials, in which the animal was sitting. Numerous PGN neurons showed visually evoked responses at the temporal frequency of the drifting grating. Overall, PGN neurons had large RFs (mean = 19.6 deg^2), substantially exceeding the size of those in dLGN (mean = 3.3 deg^2, $p < 10^{-4}$). PGN RFs exhibited a rough topographic mapping, where units that resided more ventrally in the PGN tended to have lower RF centers. Examining responses to varying stimulus sizes revealed that PGN neurons exhibited a broad range of suppression strengths, including some weak ones.

Next, we tested how PGN responses are affected by CT feedback. In visual cortex (V1) of PV-Cre mice we used a viral approach to conditionally express Channelrhodopsin-2 in parvalbumin positive interneurons. Activating these neurons allowed us to suppress V1 activity and hence disrupt CT feedback to PGN. Suppression of CT feedback led to a substantial reduction of PGN responses (31.7 Hz vs. 10.9 Hz, $p = 0.02$).

We conclude that PGN, given its large RFs and its suppression during disruptions of CT feedback, might play an important role for feedback-mediated surround suppression in dLGN.

Title: Laminar origins of the cortical projections to the lateral posterior thalamic nucleus in the mouse

Authors: E.-M. FRIGON, R. TREMBLAY-LALIBERTÉ, S. STROMEI-CLÉROUX, *D. BOIRE
Anatomie, UQTR, Trois-Rivieres, QC, Canada

Abstract: Cortical feedback to thalamic nuclei is an important source of contextual modulation of sensory perception. The lateral posterior thalamus (LP) of rodents is a high-order thalamic nucleus that receive projections from primary visual cortex (V1) as well as from all extrastriate visual cortices. Recent studies suggest that high-order thalamic nuclei are implicated in predictive coding circuits that detect differences between bottom-up inputs and top-down predictions. Top-down corticofugal projections originate from subsets of layer 5 and 6 neurons and thought to act as drivers and modulators respectively. In addition, layer 6 neurons are believed to generate alpha oscillation of core thalamic neurons and layer 5 would convey prediction errors. Iontophoretic injections of cholera toxin B fragment (CTB) were performed in LP of adult C57BL6J mice. Retrogradely labelled neurons in cortical layers 5 and 6 were charted throughout the ipsilateral cerebral cortex (Neurolucida MBF Bioscience) and quantified. Labelled neurons were found in V1 and in all extrastriate areas in all cases. In V1, labeled neurons were more abundant in layer 6 than in layer 5. In the extrastriate visual areas, labeled neurons in layer 5 and 6 were found in a range of proportions and abundant in both layers 5 and 6. This contrasts with knowledge of visual cortex projections to the LP-Pulvinar in cats and primates in which cortical projections from V1 to the LP-Pul originate almost only from layer 5 and from both layers in extrastriate areas. This suggest that the functional impact of V1 on this high-order thalamic nucleus would be different in the mouse compared to cats and primates. This suggests that V1 of the mouse would exert mainly a modulatory role on LP neurons whereas V1 in the cat and primate would have a strong driving influence on LP. This could be a general pattern for cortical projections to high-order thalamic nuclei in rodents. Previous studies reported abundant retrogradely labeled layer 6 neurons in the primary somatosensory cortex following tracer injection in the high-order somatosensory thalamic nucleus Po. Areal differences in the ratio of layer 5 and layer 6 corticothalamic projection neurons further suggest that the cortical feedback input to the LP from extrastriate areas is functionally heterogeneous.

Title: Modulatory signals from the visual cortex to the pulvinar increase along the hierarchical order of cortical areas

Authors: *R. ABBAS FARISHTA[1], D. BOIRE[2], C. CASANOVA[1]
[1]Sch. of Optometry, Univ. de Montréal, Montreal, QC, Canada; [2]Anatomie, UQTR, Trois-Rivieres, QC, Canada

Abstract: The Lateral Posterior (LP), a homologue of primate pulvinar, is a higher order (HO) thalamic nucleus with reciprocal connections with most visual areas of the cortex, providing alternative transthalamic pathways for the transmission of cortical information. Two types of axon terminals have been identified in cortico-thalamic (CT) pathways: the type I (modulators) and type II (drivers) characterized by thin axons with small terminals and by thick axons and large terminals respectively. Studies in our lab have shown that the projections from the cat primary visual cortex (V1) to the LP comprise mainly type II terminals whereas those from the PosteroMedial lateral Suprasylvian cortex (PMLS) comprise mainly type I. It is hypothesized that in HO thalamic nuclei, the proportion of type I/type II CT terminals would increase with the hierarchical level of visual areas. To test this hypothesis, we charted the distribution of CT terminals from area 21a, considered to be at a higher hierarchical level than the PMLS. The vast majority of terminals labelled in the LP were type I (77%) and formed small boutons located on short stalks of thin axons. Some terminals were larger than type I and located on thicker axons and were classified as type II (23%). None of the projections exhibited large terminals with complex rosette-like structures. Projections from V1 exhibited a higher number of type II terminals (75%) with single large boutons located on a long axonal side branch classified as singleton, and more complex rosette-like structures composed of three or more distinct swellings. In conclusion, the majority of the projections from the high order cortical area 21a in the LP exhibited a type I like morphology, suggesting that area 21a exerts mainly a modulatory influence on pulvinar. Our results further suggest that the number of modulatory cortical inputs to the pulvinar increases with the hierarchical order of cortical visual areas.

Title: Visually evoked gamma oscillations organize into standing, traveling and rotational waves that are detected in visual and association cortices in the anesthetized mouse brain

Authors: *A. AGGARWAL[1], C. BRENNAN[2], B. SHORTAL[2], A. MCKINSTRY-WU[3], D. CONTRERAS[2], M. B. KELZ[3], A. PROEKT[3]

Abstract: Visual stimuli induce a wave of neural excitation initially in a small region within the visual sensory cortex, that subsequently spreads across large areas of cortex and long outlasts stimulus presentation. Currently, the means by which this population evoked activity integrates with ongoing neural activity within the brain without distorting afferent information remains unknown. Here, we utilized isoflurane anesthesia to parametrically alter the spectral state of the brain of mice while recording visual evoked responses over an entire hemisphere with high-density electrocorticography (ECoG). We find that the shape of visual evoked potentials changes on a trial by trial basis, between anesthetic concentrations, and across individuals. However, there is a consistent visually evoked gamma band oscillation (30-50Hz) that is present in all mice, under all isoflurane concentrations, and in all trials. This gamma oscillation is coherent between trials in the early phase (<250 msec) of the visual evoked potential. There is also later (<300 msec) induced oscillation that peaks in power at 25Hz, which is not consistently in phase between trials. The early evoked 35 Hz gamma oscillations organize into standing, traveling and rotational wave patterns, which are present in primary and secondary visual cortices, the posterior partial association cortex, and the somatosensory cortices. These widespread evoked gamma oscillations that are prominent in multiple cortical regions may be important for global brain processing of multisensory stimuli, even in the unconscious brain.

Abstract: Patterns of unique functional neural activations correlated with a motion detection paradigm can illustrate the implication of alternative pathways allowing residual vision following visual impairment. Individuals with a clinical blind hemifield, caused by a unilateral post-chiasmatic lesion involving the striate cortex, report not seeing objects presented in their blind field, yet demonstrate the ability to detect, point towards and distinguish visual stimuli. This blindsight phenomenon represents a rare dissociation between consciousness and performance and is observed in homonymous hemianopia (HH) subjects with a contralateral visual loss. This study demonstrates cortical and subcortical structures involved in blindsight after a visual cortex lesion with blood oxygen level-dependant signal of functional magnetic resonance imaging (fMRI) using an event-related motion detection task. Whole brain and sliced thalamic fMRI scan sequences showed a reorganization in the structure and function of the visual pathways in HH individuals compared to neurotypical controls. Acquiring and associating neural correlates, specific structures and functional networks of the midbrain during blindsight performances represents a significant original contribution. Behaviourally, the presence of residual visual abilities was demonstrated through accurate performance rates, although with slower reaction times in the blind field. With respect to activations, when the normal hemifield was stimulated, significant contralateral activations were observed in primary and secondary visual areas as well as in motion specific areas, such as the supramarginal gyrus and middle temporal area, as well as sub-thalamic activations of the superior colliculi (SC) and pulvinar. These results attest the involvement of subcortical structures in spontaneous motion detection. When the blind hemifield was stimulated, contralateral activity in extrastriate areas was observed, with no activation of the primary visual cortex but robust activations of the SC.

However, unexpected ipsilateral cortical activations were observed within the same motion specific areas, as well as bilateral frontal activations. These results highlight the importance of secondary pathways bypassing the primary visual area (V1) in residual vision. The results elucidate the blindsight paradox and may potentially impact the development of restoration therapies targeting these alternative, in particular subcortical, pathways.

Title: The synaptic impact of directionally selective LGN neurons on primary visual cortex

Authors: *Y. I. BERESHPOLOVA[1], C. R. STOELZEL[1], J. ALONSO[2], H. A. SWADLOW[1]

Abstract: Directional selective (DS) neurons are found in the retina and lateral geniculate nucleus (LGN) of rabbits and rodents. In the rabbit, LGN DS neurons are relatively rare (< 7%[1, 2, 3]), and most LGN neurons have concentric receptive fields. Notably, whereas most neurons in rabbit visual cortex (V1) are sharply tuned for orientation and direction[4, 5], the role of LGN DS neurons in V1 processing, and the laminar distribution of their axon termination sites, is unknown. Here, we investigated LGN DS neurons in awake rabbits, examined the laminar profile of presynaptic (axonal) and monosynaptic LFPs/currents generated in the retinotopically aligned region of V1 by these neurons, and compared these results for DS neurons with those of LGN concentric neurons. To do this, we first obtained extracellular recordings from LGN DS neurons using methods that yield stable, multi-day recordings. After characterizing their visual response properties, we identified the retinotopically aligned region of V1, and placed a 16-channel linear probe (Neuronexus) within this precisely aligned cortical region. We then studied the laminar profile of axonal and monosynaptic currents generated by spontaneous spikes of the LGN neurons. This method, single-axon spike triggered LFP/current source-density analysis, yields a view of the laminar profile of axonal and synaptic currents generated in the cortex by single thalamocortical neurons[2, 6-9].
We studied 14 LGN DS neurons in this manner, and our results are very similar to our previous results for LGN concentric neurons[2]. Thus, (1) the major synaptic impact of each LGN DS

neuron was in layer 4 and/or 6, with none showing a significant impact in superficial cortex. (2) Axonal conduction times of all DS neurons were short (range 0.65 - 1.8 ms), and (3) the monosynaptic thalamocortical responses exhibited prominent activity-dependent synaptic depression. We conclude that the presynaptic (axonal) and monosynaptic currents generated in V1 by the spikes of LGN DS neurons and concentric neurons are similar in their laminar profile, synaptic dynamics, and axonal conduction times, suggesting similar synaptic connectivity in layers 4 and 6, and similar roles in cortical functioning. Title: Monosynaptic rabies tracing reveals input-output connections between visual cortex and the lateral posterior nucleus of the thalamus

Authors: *R. M. CASSIDY, E. M. CALLAWAY
The Salk Inst. for Biol. Studies, La Jolla, CA

Abstract: Higher-order visual thalamus is extensively connected to the visual cortex. Its outputs target both primary visual cortex (V1) and higher visual areas (HVAs), and its inputs come from those same regions. The pulvinar, the higher-order visual thalamus of primates, coordinates cortical activity according to behavioral demands (Saalmann et al., 2012; Zhou et al., 2016) and could hypothetically relay sensory information between visual areas (Sherman and Guillery, 2002). In the mouse, the lateral posterior nucleus (LP) is the analog to the pulvinar and shares its extensive cortical connectivity. To understand the specific circuits involved in these thalamocortical interactions, a precise map of the input/output connections of LP is needed. Cortical inputs to an LP projection population might originate from the target area, creating a reciprocal loop. Alternatively, they might originate from upstream or downstream areas, mirroring the direct corticocortical pathways. Corticothalamic projections can be “drivers”

originating in layer 5b or “modulators” from layer 6. This study characterizes the inputs to specific LP projection populations using intrinsic signal imaging (ISI) and monosynaptic rabies tracing. Our lab previously demonstrated that most LP neurons project to only one visual area. Therefore, we can access projection populations in LP using retrograde (AAVretro, Tervo et al., 2016) viral infection. Using male and female Ai14/Tlx3Cre mice, we generate a map of V1 and HVAs with ISI and target individual areas with an AAVretro virus expressing Flp recombinase. By injecting AAVs expressing Flp-dependent optimized rabies glycoprotein and a Flp-dependent TVA receptor fused to mCherry in LP, we are able to target specific projection populations for transynaptic tracing. After 21 days, we inject a pseudotyped EnvA, G-deleted rabies virus expressing GFP, which infects only those LP neurons projecting to a given HVA (starter cells). Mice are euthanized after another 7 days to allow for monosynaptic spread of the rabies virus from starter cells to input cells. Because the Ai14/Tlx3Cre mice express tdTomato in layer 5, we can assign a laminar location to the GFP+ input cells. Tangential cortical sections facilitate alignment with ISI maps. Our results show that many different visual areas provide input to a specific LP projection population, and this input originates from layer 5 and layer 6. We also find that the presence of tectal input to LP neurons is dependent on their cortical target. By fully characterizing the input/output connections of LP, these experiments add to our understanding of thalamocortical circuits and can inform future physiological studies.

Title: Hypersensitivity of the parvocellular visual pathway in trait-anxious individuals

Authors: *Y. YOU[1], W. LI[2]
[1]Psychology, [2]Dept. of Psychology, Florida State Univ., Tallahassee, FL

Abstract: Growing evidence from recent studies has revealed biases in basic visual processing among patients with psychiatric disorders such as autism, depression and schizophrenia (Butler & Javitt, 2005; Dakin & Frith, 2005; Fitzgerald, 2013). These patients exhibit unbalanced recruitment of parvocellular (P) and magnocellular (M) visual pathways, which are known to be segregated and tuned to distinct physical properties of the stimuli (Livingstone & Hubel, 1988). However, it is unclear whether such biases are tied to broad personality traits, such as trait anxiety. Across four independent studies, we assessed early visual evoked potentials (VEPs) to
