Title: EphA4 signaling regulates tangential migration of neuronal precursors

Authors: M. B. EASTMAN, K. A. BAKER, N. B. GALLO, *J. C. CONOVER
Dept Physiol & Neurobiol, Univ. Connecticut, STORRS MANFLD, CT

Abstract: Tangential migration of neuronal precursors from the subventricular zone (SVZ) to the rostral migratory stream (RMS) leading to the olfactory bulb is tightly regulated. Molecular guidance factors and physical barriers in the form of glial tubes contribute to neuroblast confinement along the SVZ and within the RMS. Disruption of glial tubes can lead to neuroblasts escaping from their prescribed migratory pathway; however, little is known regarding cell contact-mediated molecular interactions within this cell-dense region, particularly what governs the unique cytoarchitectural organization of glial tube astrocytes. Eph receptor tyrosine kinases and their membrane-bound ephrin ligands are critical in brain development and have been shown to have persistent roles in adult stem cell niches. Expression of EphA4 and its associated ligands have been detected in the postnatal and adult SVZ. Here we provide evidence for EphA4 kinase-mediated restriction of neuroblasts within SVZ and RMS boundaries in the developing, postnatal and adult brain, and propose an updated model for the regulation of tangential neuroblast migration via glial tubes within the anterior forebrain.

Title: Synapsin III acts downstream Semaphorin 3A to regulate radial migration and orientation of pyramidal neurons *in vivo*

Authors: *L. CANCEDDA[1], L. PERLINI[1], J. SZCZURKOWSKA[1], B. A. BALLIF[2], A. PICCINI[3], S. GIOVEDÌ[3], F. BENFENATI[1,3]
[1]Inst. Italiano di Tecnologia, Genova, Italy; [2]Univ. of Vermont, Burlington, VT; [3]Univ. degli studi di Genova, Genova, Italy

Abstract: Synapsins (Syns) are phosphoproteins abundantly expressed in the brain, where they associate with synaptic vesicles and the actin cytoskeleton. In contrast to Syn I and II,Syn III localizes at the neuronal cell body and axonal growth cone, is highly expressed at early stages of neuronal development and downregulated afterwards.While *in vitro* evidence suggests a role for Syn III in neurite extension, parallel *in vivo* evidence is missing. Here, we acutely modulated the expression levels of Syn III *in vivo* via*in utero* electroporation. Downregulation of Syn III expression by RNA interference caused defects in migration and orientation of layer II/III pyramidal neurons. On the other hand, overexpression, also affected neuronal migration and morphology, but not orientation. The expression of a shRNA-insensitive Syn III cDNA (rSyn III) together with the shRNA downregulating Syn III completely rescued the observed silencing phenotype. Interestingly,chronic downregulation of Syn III in Syn III KO mice also resulted in neuronal migration, morphology and orientation defects. In this work, we also identified a novel Cdk5 phosphorylation site on Syn III (Ser^{404}) and proved it is essential for the Syn III developmental functions in rescue experiments with phosphorylation site mutants. The S404A non-phosphorylatable rSyn III mutant did not rescue the defect in radial migration caused by Syn III downregulation, while the S404D pseudophosphorylated rSyn III mutant rescuedthe knockdown phenotype similar to wild type Syn III. Finally, we showed that Syn III phosphorylation at the CDK5 site is induced by activation of Sema3A pathway, which is also involved in migration, and orientation of cortical neurons, and is known to activate CDK5. First, Syn III phosphorylation on Ser^{404} was induced in cultured cortical neurons by Sema3A treatment. Second, S404D-rSyn III partially rescued the defect in radial migration caused by the *in vivo* downregulation of Sema3A receptor NP1. Thus, a fine-tuning of Syn III expression and

phosphorylation by Sema3A-activated CDK5 is essential for a proper migration and orientation of pyramidal neurons.

Title: Neural Crest Micro array after Slit2 gain of function

Authors: D. MARTINEZ, M. Y. REYES, N. ZUHDI, H. RA, *M. E. DE BELLARD
biology, Cal State Univ. Northridge, Northridge, CA

Abstract: Neural crest cells are a multipotent cell lineage that delaminates from the dorsal neural tube of developing vertebrate embryos and subsequently undergo an epithelial to mesenchymal transition enabling stationary cells to actively migrate to distant areas. Neural crest EMT is valuable to study since the same process occurs in cancer metastasis. Mechanisms controlling migration of neural crest cells are not fully understood. Slit2 is a chemorepellant guidance molecule that stimulates the motility of trunk neural crest cells and repels them from the developing gut. Slit2 is known to be a tumor suppressor molecule. The individual connections of neural crest cell EMT and Slit2 in cancer metastasis led us to believe that there may be a link between Slit expression and proper neural crest cell migration. Recently we found that Slit molecules are capable of impairing neural crest cell migration and suggested that it played a role in pre-migratory neural crest. The present study looked further into whether Slit/Robo interactions have a role in the process of neural crest delamination via gain-of-function (GOF) by electroporating Slit2 and loss-of-function (LOF) experiments by electroporating dominant negative Robo. We found that forced Slit or Robo expression in neural crest cells significantly impaired proper migration while LOF knockdown favored earlier migration of neural crest cells. Slit2 crest microarray showed that in addition to a large set of molecules known to be important in maintaining cells in a non-motile, epithelial phenotype: Rabl2B, Ankyrin D1, DSCAM-L1. A good number of these molecules are also known to be downstream of Slit-Robo signaling, but we

also found new molecules previously not associated with Robo signaling: Claudins, Shh, HoxA, ezrin, merlin, Delta, GDF5, glial genes (S100, FABP, gcm2), Bcl2-A1, DSCAML1, Nkx2.6, Otx2, NCAM2, and olfactory receptors. Also among the genes regulated by Slit2 GOF in our microarray were a wide range of cell division ones: Ezh1, Nothch1, cdk5, NEDD1, GAS proteins, and STAT4. Our findings reveal for the first time a new role for Slit2 in neural crest cell emigration and provide evidence for the ability of Slits to affect timely migration of neural crest cells in a Robo-dependent manner. Funding was by NIH/NINDS AREA grant 1R15-NS060099-01 and NIH-SCORE-5SC3GM096904-02 to MEdB.

Title: Autism-related protein Negr1 is required for transition of migrating pyramidal neurons from layer V to layer II/III of the mouse cerebral cortex

Authors: *J. SZCZURKOWSKA[1], F. PISCHEDDA[2], F. MANAGO[1], C. HAAS[3], F. PAPALEO[1], M. SCHÄFER[4], G. PICCOLI*[2], L. CANCEDDA*[1]

Abstract: The mammalian cerebral cortex is a remarkably complex structure, and establishment of cortical neural circuitries requires its unique laminar organization. During perinatal development, newborn pyramidal neurons migrate along radial glia fibers, to create the six-layered structure of the neocortex. Disruption in neural migration can lead to brain malformations with functional consequences on proper wiring of the neuronal network, as already described in neurodevelopmental disorders such as Autism Spectrum Disorders (ASD). Common knowledge indicates cell-adhesion molecules (CAMs) as essential for proper neural migration. Neuronal growth regulator 1 (Negr1) is a CAM, and NEGR1 gene mutations have been recently associated to ASD. So far, nothing is known about Negr1 function in *in vivo*

neurodevelopment. By *in utero* electroporation coupled with RNA interference (siRNA), we downregulated Negr1 levels in late-born pyramidal neurons migrating to the superficial layers of the neocortex. We found that Negr1 siRNA caused ectopic positioning of neurons concentrated at the border between layer 5 and layer 4 of the somatosensory cortex. Downregulation of Negr1 did not cause migration defects in the motor or prefrontal cortices. We found that autism-related protein FGFR2 and its partner NCAM physically and functionally interact with Negr1 leading to activation of ERK signaling. Interestingly, downregulation of NCAM and FGFR2 *in utero* resulted in a strikingly similar phenotype on neuronal migration as found for Negr1, proving involvement of all three molecules in the same signaling pathway *in vivo*. Moreover, downregulation of Negr1 in the embryonic somatosensory cortex, but not in the prefrontal cortex resulted in decreased number of ultrasound vocalizations in pups. Finally, perinatal treatment of mouse pups with ERK signaling activator 7, 8-dihydroxyflavone (DHF) partially rescued both migration defect and vocalization impairment caused by Negr1 downregulation. These data suggest that Negr1/FGFR2/NCAM complex is necessary for proper neuronal migration of pyramidal neurons in the somatosensory cortex, indicating a possible role for this complex in autism. *: equal contribution

Title: Co-regulated gene expression downstream of Fezf2 selects axon guidance choices of corticospinal motor neurons

Authors: *S. LODATO[1], B. MOLYNEAUX[1], E. ZUCCARO[1], L. GOFF[1], H.-H. CHEN[1], W. YUAN[1], S. MAHONY[2], J. L. RINN[1], D. GIFFORD[3], P. ARLOTTA[1]

Abstract: The neocortex contains an unparalleled diversity of neuronal subtypes, each defined by distinct traits that are developmentally acquired under the control of subtype-specific and pan-neuronal genes. The regulatory logic that orchestrates the expression of these unique combinations of genes is unknown for any class of cortical projection neurons. Here, we report that Fezf2 is a selector gene able to regulate the expression of gene sets that collectively define CSMN. We find that Fezf2 directly induces the axon guidance molecule EphB1 *in vivo*, and demonstrate further that EphB1 is necessary to execute the ipsilateral extension of the corticospinal tract in the ventral forebrain. Our data indicate that co-regulated expression of neuron subtype-specific and pan-neuronal gene batteries by a single transcription factor is one component of the regulatory logic responsible for the establishment of CSMN identity.

Abstract: Neurogliaform (RELN+) and bipolar (VIP+) GABAergic interneurons provide local inhibition within the superficial layers of the mammalian cerebral cortex. In contrast to the medial ganglionic eminence (MGE)-derived basket/chandelier (Pvalb+) and Martinotti (SST+) interneurons, these subtypes originate from the caudal ganglionic eminence (CGE), and as such, little is known about the specific genetic programs that direct their migration, differentiation and network integration into neocortical circuits. Here, we report that the transcription factor Prox1 is selectively expressed in postmitotic CGE-derived cortical interneuron precursors, and that loss of Prox1 impairs the integration of cells into superficial layers. Postnatally, Prox1 regulates the maturation of each specific subtype (RELN, Calb2/VIP and VIP) through intrinsic differentiation programs that operate in tandem with extrinsically driven neuronal-activity dependent pathways. Thus, Prox1 represents the first identified transcription factor specifically required for the acquisition of CGE-derived cortical interneuron properties.

Title: The anti-epileptic drug valproic acid alters neuroprogenitor trajectories

Authors: *E. M. POWELL, R. F. MARTIN
Anat/Neurobio, Univ. Maryland, Baltimore, BALTIMORE, MD

Abstract: While it has been suspected for decades that prenatal exposure to antiepileptic drugs (AEDs) may cause birth defects, data gathered by pregnancy registries over the last decade show exposure to common AEDs increased the major malformations observed at birth by 2 - 10 fold

more than unexposed (control) children. In the case of valproic acid (VPA), nearly 10% of the children were born with major malformations. Verbal fluency and executive function, which are mediated by frontal cortical areas, were most affected. The primary mechanism of action of AEDs is to alter neurotransmitter systems. VPA increases inhibition by potentiating GABAergic transmission as a GABA transaminase inhibitor. VPA also acts as an inhibitor of histone deacetylase 1. Previous toxicity studies failed to show effects on neural stem cell viability or proliferation. Our *in vivo* data in embryonic mice exposed to a single dose of VPA during mid-gestation demonstrate increased exit from the forebrain proliferative zones and migration to final destinations. Adult mice that were prenatally exposed to VPA exhibit regional deficits in specific cortical GABAergic interneurons. The animal studies are supported by *in vitro* studies using human neural stem cells. Exposure to VPA alters the neuronal lineages and promotes the formation of glial populations. Our studies begin to reveal the molecular mechanisms and developmental perturbations that occur with AEDs. By understanding the critical pathways that lead to birth defects in the children of mothers who suffer from seizure and mood disorders, we can start to develop better therapies designed to effective treat women and protect their children.

Title: The miR379-410 cluster miRNA miR-543 regulates neurogenesis and neuronal migration *in vivo*

Authors: *J. WINTER[1], L. RAGO[2]
[1]Kemler, Univ. Med. Ctr. Mainz, Mainz, Germany; [2]Max Planck Inst. of Immunobiology and Epigenetics, Freiburg, Germany

Abstract: Several miRNAs of the miR379-410 cluster have important neuronal functions. Recently, we have shown that three miRNAs belonging to this cluster, namely miR-369-3p, -496 and -543, regulate the expression levels of N-cadherin in neural stem cells and neurons in the developing neocortex (Rago, Beattie et al. 2014). The overexpression of these three miRNAs in radial glial cells increased neural stem cell differentiation and neuronal migration - a phenotype which could be rescued when N-cadherin was expressed from a miRNA-insensitive construct. A

knockdown of the miRNAs reduced stem cell differentiation and increased cell proliferation. The overexpression of these miRNAs specifically in newborn neurons delayed migration into the cortical plate, whereas their simultaneous knockdown increased migration. Interestingly, migration already increased when only miR-543 was knocked down suggesting that this miRNA may have other targets in addition to N-cadherin that are involved in neuronal migration. We have now found that miR-543 directly regulates the expression of members of the semaphorin signaling pathway *in vitro* and *in vivo*. At the moment we are carrying out further studies to functionally evaluate this regulation. Rago, L., R. Beattie, et al. (2014). Title: Cortical interneurons require c-Jun N-terminal kinase (JNK) signaling to preserve migratory stream integrity during corticogenesis

Authors: A. K. MYERS[1], K. BAKER[2], J. P. SNOW[2], C. A. SMITH[2], *E. S. TUCKER[2]
[1]Neurosci. Grad. Program, [2]Neurobio. and Anat., West Virginia Univ., Morgantown, WV

Abstract: Cortical interneurons travel in well-defined migratory streams as they enter the cerebral cortex during embryonic development. The formation and maintenance of migratory streams is essential, since perturbations to migratory streams may misroute migrating cortical interneurons and lead to cortical circuit malformations present in severe brain disorders such as epilepsy, schizophrenia, and autism. Although molecular mechanisms mediating the formation and maintenance of migratory streams have been well studied, molecular events controlling departure from migratory streams remain obscure. We previously demonstrated that initial entry of cortical interneurons into the cerebral cortex depends on JNK signaling, largely mediated by the cell autonomous activity of *Jnk1*, and now find cortical interneurons require JNK to travel within migratory streams at later periods of cortical development. Pharmacological blockade of

JNK signaling in *ex vivo* slice cultures leads to rapid departure of cortical interneurons from migratory streams; specifically, live-cell imaging reveals a prompt shift from tangential to radial modes of migration, and quantification of interneuron distribution in JNK-inhibited slices reveals dose-dependent dispersion from migratory streams. Analyses of interneuron distribution in the developing cortex of JNK-deficient embryos parallels data obtained through pharmacologic inhibition, indicating JNK activity preserves tangential progression of cortical interneurons within migratory streams *in vivo*. These data suggest JNK signaling may be developmentally regulated in migrating cortical interneurons to control the timing of migratory stream exit and subsequent entry into the cortical plate. Current efforts explore the spatial and temporal extent of interneuron displacement from migratory streams in JNK-deficient embryos and JNK-inhibited slice cultures, cellular and molecular mechanisms underlying JNK-dependent preservation of migratory streams, and analyses of interneuron distribution within the mature cerebral cortex of JNK-deficient mice. Completion of this work is expected to illuminate fundamental mechanisms of corticogenesis and offer insight into pathogenic mechanisms underlying neurodevelopmental diseases of cortical circuitry.

Title: Effects of optogenetic stimulation on motility of differentiating neural stem cells

Authors: *K. MARKO[1], N. PAPP[3], T. KOHIDI[3], A. JADY[3], Z. KORNYEI[3], T. ANDRASI[3], D. MARIC[2], E. MADARASZ[3]
[2]Natl. Inst. of Neurolog. Disorders and Stroke, [1]NIH, Bethesda, MD; [3]Inst. of Exptl. Medicine, Hungarian Acad. of Sci., Budapest, Hungary

Abstract: Neural stem/progenitor cells (NSCs/NPCs) are exposed to bioelectric stimuli from their birth to tissue integration (Flavell, Greenberg 2008). Spontaneous Ca-oscillations are spreading in the early neural tube (Donovan 1999), and giant depolarizing potentials are

travelling in the developing brain (Ben-Ari 1989) before and during the formation of synaptically coupled neuronal networks. Ongoing potential changes influence the migration and integration of neuronal precursors in the adult hippocampus as well (Song et al, 2013). The responsiveness of various NSC/NPC populations to these stimuli or the necessity of such stimulation for survival, migration or adopting the right phenotype, however have not been explored in details. According to our previous data, NSCs/NPCs derived from the primary or secondary germinative zones display different electrophysiological properties (Jelitai et al., 2007; Marko et al., 2011). Novel optogenetic methods (Zhang et al., 2007) opened ways for controlled long-term, non-invasive stimulation of *in vitro*-maintained stem cell populations, and enabled us to follow the fate of stimulated cells in their later development. Preferential adhesion of neural stem cells to surfaces covered with a novel synthetic adhesive polypeptide (AK-cyclo[RGDfC]) provided a unique, rapid procedure for isolating a population of radial glia-like (RGl) cells from both fetal, perinatal or adult rodent brain (Marko et al., 2011). RGl cells displayed elongated cell shape, vivid nuclear translocation along the entire cell-axis, and migrated by sliding along neighbours, while in differentiating progenies, the motility decreased in parallel with the appearance of neuronal features. For non-invasive stimulation, channelrhodopsin- (ChR2)-expressing populations were established from existing RGl cell lines by transfecting with ChR2-coding constructs. RGl-type cell populations were isolated also from CAG^{loxp}Stop^{loxp}Chr2(H134)-EYFP transgenic mouse embryos and RG$^{loxp\text{Chr2}}$ cells were either transfected with Cre-recombinase coding constructs (RG$^{loxp\text{Chr2}+}$) or were used as ChR2-non-expressing (RG$^{loxp\text{Chr2}-}$) controls. Both, RG$^{loxp\text{Chr2}+}$ and RG$^{loxp\text{Chr2}-}$cells generated neurons in respone to EGF withdrawal and responded to illumination (488nm) with inward cation currents. Illumination modified the motility of differentiating RG$^{loxp\text{Chr2}+}$ cells by decreasing both nuclear translocations and migration. The findings indicate that optogenetic stimulation accelerates *in vitro* differentiation of radial glia-like neural stem cells.

Title: Characterizing the role of VEGFR1 in GnRH neuronal migration

Authors: *E. FLANNERY[1], D. DONOHUE[2], S. WRAY[1]
[1]NINDS, NIH, Bethesda, MD; [2]Integrative Systems Biol., US Army Med. Res. and Material Command, USACEHR, Fort Detrick, MD

Abstract: Neuronal migration is essential during development for appropriate circuitry to form. Disruption of neuronal migration causes neurological disease states, leading to a number of devastating cognitive and reproductive problems. As such, it is critical to understand the mechanisms underlying normal neuronal migration to begin to address/treat the event(s) associated with a disease. In vertebrates, appropriate migration of gonadotropin-releasing hormone-1 (GnRH) neurons to their final location within the brain is necessary for hypothalamic control of sexual maturation and reproductive function. Failure of this process leads to hypogonadotropic hypogonadism (HH), resulting in delayed puberty and infertility. To discover ligand/receptor signaling impacting this migration, we compared the transcriptomes of migratory vs. post-migratory GnRH neurons. Microarray analysis revealed that the receptor tyrosine kinase Fms-like tyrosine kinase 1 (also known as vascular endothelial growth factor receptor-1, VEGFR1) was upregulated in migrating neurons as compared to post-migratory neurons. VEGFR1 is most commonly associated with the developing vasculature and has been shown to function in vasculogenesis by sequestering VEGFA from another receptor, VEGFR2. Notably, both VEGFA and a related VEGFR1 ligand, VEGFB, were expressed along the GnRH migratory route and in GnRH cells, respectively, lending credence to their potential role in regulating GnRH neuronal migration. Single cell PCR and immunocytochemistry confirmed expression of VEGFR1 in migrating GnRH neurons. Functional assays revealed chronic treatment with a blocking antibody specific for VEGFR1 decreased the distance GnRH cells migrated compared to controls. In addition, acute *in situ* assays using the blocking antibody revealed an immediate decrease in cell migration rate. Unexpectedly, blocking the ligand VEGFA revealed a significant increase in migration rate, suggesting a dynamic balance between VEGFA and VEGFB in modulating VEGFR1-mediated GnRH migration. These data demonstrate a novel role for this receptor tyrosine kinase and its ligands in neuronal migration and may provide new candidates for genetic screening in HH patients. Furthermore, this work sheds light on the complex, yet well-known players in vasculogenesis and may provide an unexplored link between two critical developmental processes—vasculogenesis and neuronal migration.

Title: A growth factor-dependent Ca2+ signaling network during stem cell proliferation and neuronal migration in the developing neocortex

Authors: *B. G. RASH[1], J. B. ACKMAN[1], P. RAKIC[2]
[1]Dept. of Neurobiol., [2]Dept. of Neurobiol. and Kavli Inst. for Neurosci., Yale Univ., NEW HAVEN, CT

Abstract: Development of the cerebral cortex depends on the sequential genesis of neuronal subtypes in the ventricular zone (VZ) followed by their active migration to proper areal and laminar positions in the embryonic cerebral cortex. Calcium flux is a potential regulatory factor for these complex processes, but spatio-temporal dynamics of Ca2+ activity remain poorly understood. Here we show that cortical stem cells generate non-synaptic Ca2+ transient activity from the earliest stages of corticogenesis *in vivo*--even before the onset of synaptogenesis. We demonstrate strong Ca2+ activity in response to growth factors like fibroblast growth factor (FGF) 2, which has been shown to promote radial glial cell (RGC) proliferation and can also induce the formation of artificial convolutions in the mouse cerebral cortex. In addition we found that this Ca2+ activity is carried long distances within the elongated RGC fibers and propagated to multiple adjacent cells, including other RGCs, intermediate neuronal progenitors and migrating neurons. Correlation analysis reveals that some of these, seemingly random, events, are highly correlated and that target cells responded to the activity by initiating their own Ca2+ transients, indicating that much of this activity is not intrinsically spontaneous, but triggered by the patterned network activity. Our results indicate that growth factor-dependent Ca2+ activity mediates a widespread electrical network spanning the cortical wall and is involved in the development of radial units. This coordinated activity cannot be suppressed by the gap junction blocker, octanol, or by the glutamate receptor antagonist, CNQX, suggesting that at early stages cortical radial units communicate by a ligand-receptor based mechanism. Finally, exposure to the therapeutic drugs, fluoxetine and valproic acid, interfered with calcium activity and disrupted the radial glial scaffold, leading to cortical abnormalities.

Title: AGO61, a causative gene for dystroglycanopathy, is required for the maintenance of the basement membrane integrity and neuronal migration

Authors: *N. NAKAGAWA[1], H. YAGI[2], K. KATO[2], S. OKA[1]
[1]Kyoto Univ., Kyoto, Japan; [2]Nagoya City Univ., Nagoya, Japan

Abstract: Dystroglycan (DG) is a cell-surface glycoprotein, which requires *O*-mannosyl glycosylation to interact with basement membrane (BM) components such as laminin, agrin, and perlecan. Mutations in the genes encoding enzymes responsible for DG glycosylation, including *AGO61*, cause dystroglycanopathy, a subclass of congenital muscular dystrophy with brain malformation. Recently, we generated AGO61-knockout mice and revealed that their brain exhibited the disrupted BM, disorganized radial glial fibers, and neuronal overmigration due to the lack of ligand binding glycans on DG. However, early pathological changes resulting from the DG hypoglycosylation that lead to such severe consequences remain unclear. In this study, to further characterize the cortical dysplasia of AGO61-deficient mice, we immunohistochemically analyzed the expression of several marker proteins in the developing cerebral cortex. In the AGO61-deficient brain, the pial BM was properly formed at the embryonic day 10.5 (E10.5), but was obviously discontinuous at E12.5. At E14.5, breaches of the BM were more severe than those at E12.5 and neuronal ectopias were found. These results indicate that the BM has been once formed without functional DG and then progressively disrupted along with cortical development. Moreover, the failure of preplate splitting, a characteristic phenotype of reeler mice, was observed in the AGO61-deficient brain. This finding suggests that neuronal migration defects have already begun in the migration of early-born neurons, providing an important insight into the understanding of the aberrant neuronal layer formation in dystroglycanopathy.

Title: Regulation of neuronal cell migration by sphingomyelin synthase 1 is mediated through modulation of the key cell cycle protein p27 and matrix metalloproteinase

Authors: U. V. WESLEY, J. HATCHER, *R. J. DEMPSEY
Neurolog. Surgery, Univ. of Wisconsin SMPH, MADISON, WI

Abstract: Sphingomyelin synthase (SMS) is a key enzyme involved in the generation of the lipid sphingomyelin (SM) and regulation of cell growth and survival. However, little is known about the effects of SMS on neuronal cell migration. In this study, we examined the direct effects of SMS1 in regulating the migratory properties of Neuro-2a cells that are a widely used *in vitro* cell culture model for neuronal studies. Neuro-2a cells transfected with SMS specific shRNA expressed significantly lower levels of SMS1. RNA interference-mediated depletion of SMS1 also caused a significant decrease in SM levels. Silencing of SMS1 inhibited the migratory potential of Neuro-2a cells as indicated by the scratch induced migration assay, and Boyden chamber 3D matrigel invasion assay. At the molecular level, these changes were accompanied by the up-regulation of cyclin-dependent kinase inhibitor p27, and decreased levels of cyclin D1 and phospho-Akt in SMS1 depleted cells. Interestingly, nuclear accumulation of p27 was evident in SMS1 deficient cells, as shown by immunofluorescence staining. Furthermore, screening by PCR array containing motility related genes revealed significant down regulation of matrix metalloproteinase family members including MMP-2, -14, and -9 in SMS1 silenced cells. These results indicate that SMS1 plays an important role in mediating the key signaling pathways that are involved in the tight coordination of neuronal cell migration, and therefore may have significant implications in neurodegenerative diseases, as neuronal cell migration is central to proper establishment of neural network, disruption of which can lead to neurological disorders.

Title: Roles of MACF1 in pyramidal neuron migration during brain development

Authors: *M. KA, E.-M. JUNG, M. LATNER, W.-Y. KIM
Developmental Neuroscience, Munroe-Meyer Inst., Univ. of Nebraska Med. Ctr., Omaha, NE

Abstract: Neuronal migration is an essential process for the development of the cerebral cortex. However, little is known about the regulatory mechanisms of neuronal migration in the developing brain. Here, we show that regulation of MACF1 activity is critical in radial neuronal migration and differentiation in the developing dorsal telencephalon. Using genetic manipulation *in utero*, we find that MACF1 deletion defects migration of cortical and hippocampal pyramidal neurons. Also, MACF1 floxed allele mice show aberrant neuronal positioning in the developing brain. We observed that MACF1 elimination suppressed elongation of the leading processes. Importantly, microtubule stability is severely damaged in neurons lacking MACF1, resulting in abnormal microtubule dynamics. Our findings demonstrate that MACF1 is equired for correct positioning of telencephalic pyramidal neurons via the regulation of microtubule dynamics.

Abstract: The olfactory system constitutes a sensory system of major importance for mammals as well as a valuable tool for studying neuronal connections in the central nervous system. Much knowledge has been obtained in recent years on the organization of the odorant receptor map, formed by the connections of olfactory receptor neurons with the dendrites of projection neurons of the olfactory bulb, in specialized structures, the glomeruli. On the other hand, little is known about the corresponding mitral cell map, located in the mitral cell layer, consisting of the main projection neurons of the olfactory bulb. Our work aims to shed light on the organization and function of the mitral cell layer. Our experimental approaches include immunohistochemistry and *in situ* hybridization, explant cultures, transplants *in vitro*, neuronal activation experiments, behavioral analysis. We show that the absence of Transient Axonal Glycoprotein-1/Contactin-2 (TAG-1/CNTN2), a cell adhesion molecule of the immunoglobulin superfamily, results in a significant reduction in the number of mitral cells inside the main olfactory bulb in mice. This reduction occurs as a consequence of impaired migration of a subpopulation of projection neurons born at embryonic day 11.5. We report on the developmental series of events that occur before the final positioning of projection neurons into the mature mitral cell layer. Our study reveals that the detected alterations in the number of mitral cells are reflected in an aberrant neuronal activation profile as well as disturbed olfactory behavior. Our results propose that TAG-1/CNTN2 function is crucial for the proper organization of projection neurons in the main olfactory bulb, a prerequisite for proper OB function. Moreover they suggest that disturbing this station of the odorant information route disrupts its integration into the olfactory circuitry.

Title: Epigenetic modifications alter the expression pattern of KCC2 in a ferret model of cortical dysplasia

Authors: *F. T. DJANKPA[1], O. B. AKINOLA[2], S. POLUCH[3], D. BORST[3], C. DALGARD[3], S. L. JULIANO[3]

Abstract: The pathogenesis of neurodevelopmental disorders such schizophrenia, autism spectrum disorders, and epilepsy are associated with cortical dysplasia. This migration disorder can result from defects in the movement of GABAergic interneurons during corticogenesis, but the specific underlying mechanisms remain elusive. We know that KCC2, NKCC1, and GABA are strongly involved in mediating migration into the neocortex. Using a model of cortical dysplasia in ferrets, we found that small unique doses of the methylating agent methylazoxy methanol acetate (MAM) results in disrupted migration during corticogenesis, specifically of interneurons, when administered to pregnant jills at E33. We recently found that an underlying cause of impaired migration may be a consequence of the precocious and increased expression of the Cl^- exporter, KCC2, as indicated by western blot analysis and electrophysiological recordings. These findings suggest that increased KCC2 may play a critical role in impaired migration leading to cortical dysplasia. As KCC2 normally increases during development, NKCC1 (a Cl~ importer) reduces; levels of NKCC1, however, did not differ from normal in MAM treated animals. Here we confirm that KCC2 expression is elevated in this model by measuring increased mRNA transcript levels using qPCR in the cortex of P0 MAM treated ferret kits compared to untreated controls. We also found the methyl CpG binding protein 2 (MeCP2) to be elevated in organotypic tissue cultures treated with MAM, but not in control tissue. These increases were further confirmed by finding an overall increase in methylation in the neocortex of animals treated with MAM. We also found a slight increase in methylation of the KCC2 gene using bisulfite sequencing. With this method we observed a small increase in methylation of 5 CpG islands targeted by our primers. These findings point to possible epigenetic modifications contributing to increased KCC2 expression after MAM treatment in ferrets, which ultimately leads to impaired migration.

Title: Cdk5-mediated phosphorylation of RapGEF2 is required for neuronal migration during cerebral cortex development

Authors: ***T. YE**[1,2,3], J. P. IP[1,2,3], A. K. FU[1,2,3], N. Y. IP[1,2,3]

Abstract: The functional wiring of the cerebral cortex requires multiple coordinated steps of neuronal migration, including multipolar migration, locomotion and somal translocation. Although the small GTPase Rap1 regulates different steps of migration, how Rap1 is differentially activated during distinct migratory phases is not well understood. We found that activation of Rap1 by guanine nucleotide exchange factor RapGEF2 is specifically required for the initial phase of the migration process. RapGEF2 knockdown *in utero* arrests migrating neurons at the multipolar stage, leading to formation of subcortical band heterotopia in the postnatal mouse brain. The GEF activity of RapGEF2 towards Rap1 requires phosphorylation by the serine/threonine kinase Cdk5. In turn, Rap1 activation by RapGEF2 promotes the cell surface expression of N-cadherin, and subsequently enables the bipolar transition and radial neuronal migration. Our findings suggest that Cdk5-dependent phosphorylation of RapGEF2 plays an important role in multipolar-bipolar transition, and thus proper migration and wiring of the cerebral cortex.

Title: Galectin-3 decreases subventricular zone cell migration to the demyelinated corpus callosum

Authors: *J. M. HILLIS[1], J. SEVERS[1], R. E. JAMES[2], F. G. SZELE[1]
[1]Dept. of Physiology, Anat. and Genet., Univ. of Oxford, Oxford, United Kingdom; [2]Imperial Col. London, London, United Kingdom

Abstract: The glycoprotein binding protein Galectin-3 (Gal-3) has separately established roles in multiple sclerosis and subventricular zone (SVZ) cell migration. After demyelination SVZ cells migrate to the neighbouring corpus callosum, and we sought to determine if Gal-3 impacted this process. We treated Gal-3+/+ and Gal-3-/- mice with Theiler's murine encephalomyelitis virus (TMEV) or cuprizone demyelination models, and compared the SVZ responses using immunohistochemistry. Following TMEV Gal-3-/- mice contained more doublecortin-positive (Dcx+) neuroblasts in the corpus callosum. Following cuprizone treatment there were very few Dcx+ neuroblasts in the corpus callosum of either genotype. We had, however, administered bromodeoxyuridine (BrdU) at the beginning of cuprizone treatment to create label retaining SVZ cells, and after treatment there were more BrdU+ cells in the corpus callosum of Gal-3-/- mice. Preliminary results suggest these cells are Olig2+ oligodendrocytes. Interestingly Gal-3 co-labelled GFAP+ astrocytes and CD45+ immune cells, yet neither Dcx+ neuroblasts nor Olig2+ oligodendrocytes after cuprizone. Our working hypothesis is that Gal-3 secreted by resident astrocytes aids the migration of SVZ-originating neuroblasts and oligodendrocytes in a paracrine manner. When Gal-3 is absent the cells become 'uncoupled' from the rostral migratory stream and can more easily migrate to demyelinated regions such as the corpus callosum. Future short-term experiments will examine the molecular mechanisms behind these observations.

Title: Identification of a functional role of Laminin alpha 1 in the developing brain

Authors: *C. HENG-KISSENBERGER[1], C. GAMPE[1], A. KLEIN[2], D. BAGNARD[2], J. BOLZ[1]
[1]Allgemeine Zoologie Und Tierphysiologie, Jena, Germany; [2]Inserm 1109 - MN3t Lab., Strasbourg, France

Abstract: The extracellular environment of the developing brain plays a crucial role in its organization and functionality. Here, we focused on the extracellular matrix glycoproteins of the Laminin family because of their well established function in cell migration and differentiation in various organs. The Laminin α1 chain (Lama1) gene has been reported in the list of the 50 genes important for recessive cognitive disorders in human (Najmabadi et al., 2011). Consistent with their critical implication in embryonic development, Lama1 deficiency causes early death of embryos due to a defect in Reichert's membrane (a protective extra-embryonic basement membrane) at E7.5 avoiding further developmental studies. To circumvent this issue we developed a conditional knockout (Lama1cKO) mouse of the gene coding for Lama1, overcoming early lethality. We already observed a strong defect in the organization of the adult cerebellum (Heng et al., 2011), demonstrating the significance of Lama1 in cerebellar development. Strikingly, we discovered cortical dysplasia in Lama1cKO brains linked to lateral ventricles dilatation. Histological and functional assays revealed that Lama1 absence leads to radial glia defects and abnormal migration of deep layer neurons. Moreover we observed a mispositioning of the Cajal-Retzius cells in the marginal zone, which could explain the cortical dysplasia by modifying the release of Reelin. This may have an effect on the brain mapping as Lama1cKO mice exhibit alterations of the cortical barrels. Furthermore we performed behavioral tests and revealed a less anxious behavior compared to control mice. Additionally, *in vitro* experiments demonstrated decreased axonal outgrowth but increased neuronal migration on Lama1 deficient substrates. Hence, we suppose that Lama1 has a key role in cortical development as „stop“ migration and „go“ differentiation factor. These data provide a starting point to dissect the molecular mechanism of Lama1 to identify the therapeutic potential of this secreted protein in central nervous system diseases.

Title: Specific proteolytic cleavage of Reelin regulates duration and range of its signaling

Authors: *K. OKUMURA, A. HISANAGA, M. KOIE, T. KOHNO, M. HATTORI
Nagoya City Univ., Nagoya, Japan

Abstract: Reelin is a secreted protein that is essential for normal brain development and functions. Reelin is specifically cleaved around RR2 and RR3 (N-t site). We previously found that the N-t cleavage virtually abolishes Reelin signaling activity *in vitro*. As dysfunction of Reelin caused by N-t cleavage has been suggested to be involved in the pathogenesis of several neuronal diseases including Alzheimer's disease and schizophrenia, it is of great clinical importance to understand the N-t cleavage mechanism. In this study, We determined the exact N-t site catalyzed by a protease secreted by cerebral cortical neurons. N-t cleavage occurred between Pro1,244 and Ala1,245 within Reelin repeat 3. Reelin mutant in which Pro1,244 was replaced with aspartate (Reelin-PD) was resistant to a protease secreted by cerebral cortical neurons and its biological activity stayed longer than that of wild type Reelin. Interestingly, Reelin-PD remained in the intracellular region longer than wild type Reelin and persistently activated downstream signaling. We established a monoclonal antibody that recognizes uncleaved Reelin and found that it is localized in the vicinity of Reelin-producing cells while the N-terminal fragment diffuses, or is transported, to distant regions. These data demonstrate that N-t cleavage of Reelin plays critical roles in regulating the duration and range of Reelin functions. We also identified the protease in charge of N-t cleavage by purifying it from the culture supernatant of primary cortical neurons by a series of column chromatographies. Recombinant protein of this protease cleaved Reelin at N-t site and the cleavage of Reelin is markedly decreased in the embryonic cerebral cortex of its knockout mice. Importantly, the amount of Dab1 protein is decreased in the cerebral cortex of the knockout mice, indicating that Reelin signal is hyperactivated. Therefore, it is proven *in vivo* that N-t cleavage by a specific protease is the major inactivation pathway of Reelin in the developing cerebral cortex. The

understanding of its regulatory mechanism will help establish novel methods for prevention and treatment of neurological diseases.

Title: The novel function of Reelin in the dendrite development and layer formation in the postnatal brain

Authors: *T. KOHNO[1], T. HONDA[2], K.-I. KUBO[2], Y. NAKANO[1], A. TSUCHIYA[1], T. MURAKAMI[1], H. BANNO[1], K. NAKAJIMA[2], M. HATTORI[1]
[1]Biomed. science, Nagoya City Univ., Nagoya, Japan; [2]Dept. Anat., Keio Univ., Sch. of Med., Tokyo, Japan

Abstract: Reelin is a large secreted glycoprotein that regulates a variety of events in mammalian brain, including neuronal migration, neuronal dendritic formation, and synaptic plasticity. Reelin binds to apolipoprotein E receptor 2 (ApoER2) and very low-density lipoprotein receptor (VLDLR), and induces the tyrosine phosphorylation of an intracellular adaptor protein, Dab1. However, the primary role of Reelin in the developing brain and its underlying molecular

mechanisms remain largely unknown. Reelin protein is composed of the N-terminal domain, eight Reelin repeats, and the highly basic C-terminal region (CTR). The primary sequence of CTR is completely conserved in most vertebrates, suggesting its important function. Here we found that Reelin is proteolytically cleaved by furin-like proprotein convertases within CTR and a peptide of six amino acid residues is liberated. Reelin with an intact CTR, but not that without the last six residues, binds to a transmembrane protein that is different from the well-known Reelin receptors, ApoER2 and VLDLR. This interaction is blocked by the monoclonal antibody that specifically recognizes Reelin with an intact CTR. To clarify the significance of CTR *in vivo*, we generated a knock-in mouse lacking the CTR (ΔC-KI). We found that layer I of the cerebral cortex is narrower in postnatal ΔC-KI mice compared with wild-type mice. This phenotype is not observed in embryonic stage mice. Furthermore, we found that, in ΔC-KI mice, upper-layer neurons invade into layer I, and have misoriented and poorly branched apical dendrites. These results suggested that CTR is necessary for the correctly directed apical dendrites of migrated neurons in the cerebral cortex. Probably as a result of the failure in this process, the neuronal layers, especially layers II and III, become scattered and less packed. Thus, we propose that the interaction between Reelin and the transmembrane protein regulates the final stage of neuronal layer formation in the cerebral cortex and this event is regulated by specific proteolysis within the CTR.

Title: Involvement of nucleotides in glial growth following scratch injury in avian retinal cell monolayer cultures

Authors: *A. VENTURA, T. M. SILVA, G. R. FRANÇA, I. M. ORNELAS
Dept Neurobiol, Federal Fluminense Univ., Niteroi, Brazil

Abstract: Müller cells are the main glial cell type in the retina that is capable of re-entering cell cycle in response to retinal damage or disease. When retinal cell cultures cultivated for 7 days were scratched with a pipette tip, a significant cell growth at the empty area was detected between the 1st and 3rd days after scratch and the area devoid of cells decreased by ~70% (from 22.3 ± 1.0 mm^2/10^{-2} to 7.7 ± 0.9 mm^2/10^{-2}). Three days after scratch, only glial cells 2M6 positive, β-tubulin III negative were detected in the scratched area. Both diving and migrating glia could be observed in the scratched area. Incubation of the cultures with 2.5 U/ml of apyrase (APY), 100 μM suramin or 40 μM Reactive Blue II, but not 30 μM MRS 2179, significantly attenuated the growth of glial cells in the scratched region after 3 days (scratched area without cells: control, 31%; APY, 79.1%; suramin, 69.1%; RBII, 52.8%; MRS2179, 24%), suggesting that activation of nucleotide receptors distinct from the P2Y1 receptor are involved in the growth of glial cells. Treatment of the scratched cultures with APY in the presence of the enzymatically stable agonists UTPγS (10 μM) or ADPβS (50 μM) revealed that only the P2Y2/4 agonist was able to significantly increase the growth of cells over the scratched area (area without cells: control, 24.1%; APY, 73.3%; APY + UTPγS, 31.5%; APY + ADPβS, 60.2%), suggesting the participation of UTP-sensitive receptor subtypes in the growth of glial cells. No significant decrease in the number of PCNA positive cells was observed at the border of the scratched area in apyrase-treated cultures, suggesting that nucleotides did not affect glial cell proliferation in the cultures. In apyrase-treated cultures, a lower phalloidin labeling could be noticed in glial cells at the edge of the scratch that were without protrusions and with less organized actin filaments or with stress fibers parallel to the border of the scratch. Significant increases in the phosphorylation of Akt and ERK were observed by the incubation of the cultures with 100 μM UTP, effects that were completely inhibited by SRC inhibitor 1 and LY 294002, two compounds that inhibit SRC and PI3K, respectively, Cell growth in the scratched area was also significantly attenuated by these inhibitors, suggesting the participation of SRC and PI3K/Akt signaling pathway in UTP-induced growth of glial cells. These results suggest that mechanical scratch of retinal cell monolayer cultures induces the growth of glial cells over the empty area through a mechanism that is dependent on activation of UTP sensitive nucleotide receptors, SRC and PI3K/Akt pathway.

Title: Cellular dynamics underlying the generation of linear arrays of oligodendrocytes in CNS white matter

Authors: *T. D. MERSON[1,2], B. H. A. CHUANG[1], T. J. KILPATRICK[1,2], P. T. RÖTH[1]
[1]Multiple Sclerosis Div., Florey Inst. of Neurosci. and Mental Hlth., University of Melbourne, Australia; [2]Melbourne Neurosci. Inst., The Univ. of Melbourne, Parkville, Australia

Abstract: Linear arrays of glial cell somata, enriched with interfascicular oligodendrocytes, align the longitudinal axes of white matter tracts throughout the central nervous system (CNS). These structures consist of repeating units of cell bodies of glial cell bodies in tandem alignment with the principal axonal axis. The mechanisms responsible for linear array formation are poorly understood. We sought to investigate the cellular dynamics underlying the formation of linear arrays during early postnatal development and during the course of CNS remyelination. To address this question, sections of corpus callosi from C57BL/6 mice were labelled with cell-type specific markers to define the cellular composition and differentiation events during linear array formation. Here we demonstrate that linear arrays of cells in the corpus callosum first appear before the onset of postnatal myelination and their generation and complexity increases throughout ontogeny. Between 60-70% of cells within linear arrays belong to the oligogendroglial lineage, irrespective of postnatal age, with the proportion that adopt a mature myelinating phenotype progressively increasing with age. Analysis of hemizygous female H253 transgenic mice that carry an X-linked β-galactosidase gene on their X chromosome revealed evidence that both clonal expansion of sentinel cells and random reorganization of non-clonally related cells contribute to the formation of linear arrays. To assess the clonal relationship between cells within linear arrays during remyelination, H253 mice were submitted to the cuprizone model of de- and remyelination. Cuprizone challenge in adult mice abolished linear arrays but these were largely regenerated within 7 weeks after cuprizone withdrawal. Comparable patterns of cellular X-gal labelling within linear arrays were evident in control and cuprizone-challenged mice at recovery. These data demonstrate that the mechanisms underlying linear array formation and oligodendroglial differentiation during remyelination closely mirror the mechanisms that occur during postnatal myelination of the corpus callosum. Collectively our data suggest a model of linear array formation in which both *in situ* proliferation and random alignment of oligodendroglial cells contribute, a developmental mechanism that is reinstated during remyelination.

Abstract: The emergent self-organization of neuronal networks is a complex process, which involves a variety of cues, both internal and external. The spatial organization of a system of neurons, or a neural circuit, is known to be closely related to the functional activity of the system. Since the functional activities of the nervous system are based on the interactions among individual neurons within the neural circuit, the formation and behavior of neural networks deserves further study. Various models have been suggested in order to properly explain the neuronal network using modern microscopy imaging techniques, including phase contrast and fluorescence confocal microscopy. While these techniques provide the morphological structure and specificity at high resolution, they are limited by effects of phototoxicity. Further, adding fluorescence markers for live imaging perturbs the cells from their natural state. Here we report a new approach for label-free imaging of live neurons. Spatial light interference microscopy (SLIM) is a recently developed quantitative phase imaging technique based on a commercial

phase contrast microscope (Wang et al, Opt Express, 19, 2011). Therefore, SLIM provides a proper environment for label-free *in vitro* studies of live cells utilizing the atmospheric and temperature control peripherals. Due to its quantitative phase measurement, SLIM ultimately provides the dry mass density at each point in space and time. Also, SLIM provides a very high temporal and spatial sensitivity, which is capable of measuring the dry mass change at a femtogram level. Using this technique, a stem cell differentiated human neuron culture is imaged over 24 hours. Hundreds of neurons are captured under the field of view and are imaged every 10 minutes over 24 hours to provide the dry mass map of the entire field of view as they form a network. Increase in dry mass for the first 10 hours is detected, suggesting that the network stabilizes after the first 10 hours of growth. Further investigation of the spatial organization is done at scales corresponding to the cluster size, inter-cluster distance, inter-cellular distance and single-cell size. The result shows a gradual change in the signal corresponding to these scales, and shows the migration, aggregation and network formation among the cells over 24 hours. This result is compared with a different culture treated to suppress neurite growth, which does not show significant change in signals over time. Thus we show that SLIM is a label-free live imaging system that can be used to probe the dynamics of cell migration over long time intervals.

Title: Antrodia cinnamomea promotes neuritogenesis in mouse primary dorsal root ganglia neurons

Authors: *C. RAZA[1], K. S. Y. LEUNG[3], C. H. E. MA[1,2]
[1]Dept. of Biomed. Sci., [2]Ctr. for Biosystems, Neurosci. and Nanotechnology, City Univ. of Hong Kong, Tat Chee Avenue, Hong Kong; [3]Dept. of Chem., Hong Kong Baptist Univ., Kowloon, Hong Kong

Abstract: Axonal regeneration after peripheral nerve injury is crucial for functional recovery but the intrinsic axonal growth rate of peripheral neuron is extremely slow. Traditional Chinese

medicines (TCMs) have been used over the century for their diverse therapeutic potentials such as medicinal mushroom *Antrodia cinnamomea* (*Niu-chang-chih* in Chinese) has shown promising neuroprotective effects against amyloid β-protein-induced neurotoxicity in PC-12 cells and memory impairment in animal model of Alzheimer's disease. However, it's potential for repairing peripheral nerve after injury remains unclear. Current study aims to investigate promoting effects of *A. cinnamomea* extracts on axonal regeneration in mouse dorsal root ganglia (DRG) neurons. DRG neurons were treated with *A. cinnamomea* extracts (M8 or M13), incubated for 17 hours. Neurons were then fixed and immunostained with neuronal marker (anti-β-tubulin III) and visualized under fluorescent microscope. Neurons treated with the mushroom extract showed a significant increase (25-35%) in neurite outgrowth, as compared to control. Our results revealed that *A. cinnamomea* extract enhances the intrinsic growth capacity of peripheral neurons significantly. Further studies will be required to investigate the promoting effect of *A. cinnamomea* in animal model of peripheral nerve injury.

Title: Effects of extra-cellular matrix proteins on neurite extension in isolated neuronal cultures of dorsal root ganglia

Authors: *A. HIM[1], Y. UREN[2], G. OZTURK[3], E. K. OGUZ[2]
[1]Ondokuz Mayis Univ., Samsun, Turkey; [2]Yuzuncu Yil Univ., Van, Turkey; [3]Istanbul Medipol Univ., Istanbul, Turkey

Abstract: Extracellular matrix provides structural support to the cells and widely used in preparation of neuronal cultures to promote attachment of the neurons and neurite extension. To study their roles in mature peripheral nervous system regeneration, the effects of laminin, fibronectin, collagen type 1 and 4 on neurite extension were investigated in isolated dorsal root ganglia neuronal cultures. Dorsal root ganglia were removed from Balb/C mice sacrificed under ketamin anesthesia and isolated neuronal cultures were prepared using routine methods. Neuronal cultures were visualized at 24th and 48th hours using time lapse microscopy. The number of neurons that extend neurites and the number and length of neurites were measured in

ImageJ program. Laminin, fibronectin and collagen 4 significantly increased the number of neurons extending neurites at 24th hour (66%, 56% and 52%, respectively vs. 45% control) while the effects of only laminin and fibronectin were significant at 48th hour (85% and 76%, respectively vs. 70% control). Laminin and collagen 4 significantly increased the neurite number each neuron extended at 48th hour (6.5 and 6.0, respectively vs. 5.7 control). Laminin and fibronectin increased the total length of neuritis extended by each neuron both at 24th (136.0 μm and 88.6 μm, respectively vs. 61.2 μm control) and 48th hours (362.9 μm and 218.1 μm, respectively vs. 118.9 μm control) while collagen type 1 and 4 had significant effects only at 48th hour (147.1 μm and173.4 μm, respectively). The findings compares the effectiveness of the extracellular matrix proteins in promoting neurite growth in cultures and suggest that laminin and fibronectin promotes neurite extension more effectively than collagen type 1 and 2 in isolated neuronal culture of dorsal root ganglia. Laminin and fibronectin could be better candidates to encourage axonal elongation in the studies of neuroregeneration.

Title: Regenerating sensory and motor neurons preferentially reinnervate modality-specific trophic environments

Authors: N. RAHBIN[1], C. LI[1], A. VYAS[1], A. O'DALY[1], R. SKOLASKY[1], F. NEAF[1], R. WOLINSKY[1], A. HOKE[2], *T. M. BRUSHART[1]
[1]Dept Orthopaedic Surgery, Johns Hopkins, BALTIMORE, MD; [2]Neurology, Neurosci., Johns Hopkins, Baltimore, MD

Abstract: Hypothesis: Growth factors produced by grafts of ventral root and cutaneous nerve promote modality-specific regeneration of their native axon population (Hoke et al., 2006). These factors are upregulated by graft predegeneration (Brushart et al., 2013). We now ask

whether similar specificity can be generated within grafts of mixed nerve by selectively predegenerating the axons of one modality. **Methods**: Experiments were performed on 250gm Lewis rats and were approved by the Johns Hopkins Animal Care and Use Committee. Grafts of the femoral nerve and its sensory and motor branches were predegenerated by excising the L2, L3, and L4 DRGs and/or transecting the L2, L3, and L4 ventral roots, or by transecting the entire femoral nerve. Grafts are designated by the duration of motor (M) and sensory (S) predegeneration in weeks. Five groups of 12 grafts were prepared (I- M3,S3; II- M3,S12; III- M3,S0; IV-M12,S3; V-M12,S12) and transferred to fresh recipient animals. Regeneration was evaluated 8 weeks later by counting sensory and motor neurons retrogradely labeled from femoral sensory and muscle branches; DRG sections from groups II and IV were further processed with antibodies to heavy neurofilament (SMI-32) to identify large light neurons. **Results**: When motor pathways were predegenerated for 3 weeks, preferential reinnervation of the motor branch by motoneurons (PMR) was dramatic if sensory pathways were predegenerated for 3 weeks (I-M3,S3) or 12 weeks (II-M3,S12), but not when they were freshly axotomized (IV-M3,S0). Reinnervation of sensory and motor branches by motoneurons were equal when motor pathways were predegenerated for 12 weeks (IV-M12,S3 and V-M12,S12). Significantly more small DRG neurons reinnervated the sensory branch in group IV (M12,S3) than in group II (M3,S12). **Summary**: Motor axon regeneration is most effective through motor pathways predegenerated for 3 weeks except when acute Wallerian degeneration impedes pathfinding. The converse is true for sensory axons. This evidence confirms that sensory and motor pathways in adult animals differ in fundamental ways that can be sensed and responded to by both sensory and motor axons. Furthermore, acute nerve repair, the clinical standard, may degrade the potential for regeneration specificity.

Title: Injury-induced sensory axon regeneration is regulated by oxidative changes in the skin microenvironment

Authors: *S. RIEGER, T. LISSE
Regenerative Biol., Mount Desert Island Biol. Lab., Salsbury Cove, ME

Abstract: Acute injury stimulates cutaneous axon regeneration and sprouting of nerve fibers into the wound. The molecular mechanisms underlying this process are however not well understood. We previously demonstrated that hydrogen peroxide (H2O2) production upon skin injury in larval zebrafish is essential for cutaneous axon regeneration. Because H2O2 is diffusible and secreted into the skin microenvironment, we hypothesized that keratinocytes play a role in axon regeneration. H2O2 can act as a second messenger by oxidizing reactive cysteine residues in membrane-bound enzymes, leading to conformational changes due to disulfide bond formation and altered enzymatic activity. To test for the role of cysteine oxidation, we performed immunohistochemistry and assessed axon regeneration with time-lapse imaging in animals where oxidized thiol reactivity was inhibited with the chemical dimedone. We further expressed a transgene for glutathione peroxidase 1a (gpx1a) in keratinocytes to scavenge H2O2. Finally, we analyzed the role of the candidate Epidermal growth factor receptor (EGFR) in this process, as human EGFR was shown to be activated by H2O2-dependent oxidation. Our analyses revealed that cysteine oxidation occurs selectively at the wound margin. Accordingly, treatment of zebrafish larvae with dimedone significantly reduced axon regeneration. Mosaic expression of gpx1a in keratinocytes further revealed that axons are repelled from skin patches where H2O2 is scavenged. These results suggest that thiol oxidation in keratinocytes is essential for axon regeneration. To analyze the role of EGFR, we used a pharmacological approach to inhibit this receptor tyrosine kinase during injury. This showed a significant reduction in axon regeneration. In contrast, EGFR inhibition during development significantly enhanced cutaneous axon growth. Thus, EGFR is essential for injury-induced sensory axon regeneration but has an inhibitory function during development. The latter is similar to EGFR knockout mice, which show a higher axon density in the epidermis. To test for EGFR oxidation, we expressed a zebrafish EGFR variant with a mutated cysteine residue (C796A) in keratinocytes. Time-lapse imaging showed that keratinocytes expressing this mutant variant either repelled regenerating axons upon contact or induced axon branch degeneration. In conclusion, our results demonstrate that injury-induced sensory axon regeneration is dependent on H2O2-mediated oxidation of EGFR in keratinocytes.

Title: Macrophages may not be necessary for axonal and myelin degeneration after peripheral nerve injury in the CCR2-/- mouse

Authors: *J. LINDBORG, J. P. NIEMI, A. DEFRANCESCO-LISOWITZ, R. E. ZIGMOND
Neurosciences, Case Western Reserve Univ., Cleveland, OH

Abstract: Wallerian degeneration is the process by which transection or crushing of the axons of peripheral neurons leads to degeneration and clearance of the distal axonal segment. Studies on Wallerian degeneration widely report that monocyte entry into the degenerating distal nerve is necessary for phagocytosis and is required to promote regeneration by the proximal nerve segment. Macrophages, which differentiate from blood monocytes upon entering tissues, are purported to be the key player in this clearance process. Using a CCR2-/- mutant mouse model, in which the infiltration of monocytes is inhibited, we found that macrophages may not play as pivotal a role in axonal degeneration as previously believed. Specifically, the disappearances in the distal nerve of myelin and the axonal light neurofilament protein in CCR2 -/- mice were similar to that in wild type mice 7 days after a sciatic nerve transection, in spite of a lack of macrophage accumulation. We hypothesize that in the absence of infiltrating monocytes in the CCR2-/- mouse, a different phagocyte plays a compensatory role in the clearance of degenerating nerve debris. Flow cytometry, electron microscopy, immunohistochemistry, and a time course after injury are used to identify the fluctuating patterns of phagocytosis by leukocytes and Schwann cells during Wallerian degeneration of the sciatic nerve in wild type and CCR2-/- animals.

Title: Neuroinflammation near injured neuronal cell bodies is necessary for peripheral nerve regeneration

Authors: *J. P. NIEMI, J. LINDBORG, A. DEFRANCESCO-LISOWITZ, R. E. ZIGMOND
Neurosciences, Case Western Reserve Univ., Cleveland, OH

Abstract: Macrophages play a significant role in the regeneration of peripheral nerves following axotomy. After transection of a peripheral nerve, the axons distal to the lesion degenerate and the axons proximal regenerate. It is known that macrophages respond to nerve injury by accumulating in the distal nerve, as well as, around axotomized cell bodies which are located in ganglia (e.g., Schreiber et al., 1995). Utilizing various methods to block macrophage accumulation, previous studies have shown the necessary role macrophages play in the degenerative process of the distal nerve. In the nerve, macrophages clear debris, which is considered a necessary prerequisite for successful regeneration. The function of macrophage accumulation around axotomized cell bodies is less understood, but has recently been shown to be necessary for a maximal regenerative response following injury. Using the CCR2 -/- and slow Wallerian degeneration (Wld^S) mice as models, we showed that when macrophages did not accumulate in dorsal root ganglia, following sciatic nerve injury, and regeneration was significantly reduced. How macrophages, surrounding injured neuronal cell bodies, influence regeneration is not well understood. The present study further examines the role monocyte-derived macrophages play in stimulating regeneration by providing more direct evidence of this neuroimmune interaction, as well as examining the significance of neuron-derived CCL2. A bone marrow rescue of the CCR2 -/- macrophage accumulation deficiency was carried out by irradiating CCR2 -/- mice and transplanting WT bone marrow. The converse experiment was also done by irradiating WT mice and transplanting CCR2 -/- bone marrow to achieve a significant deficit in macrophage accumulation in dorsal root ganglia (DRGs) following injury. Both groups of animals were then given a conditioning lesion and regeneration was measured in

an *in vitro* assay. To probe the importance of CCL2 expression in neurons following injury, CCL2 was overexpressed specifically in DRG neurons. The effect of this overexpression was assessed alone and in the context of injury. Furthermore, chemokine and cytokine arrays were performed on WT DRGs and superior cervical ganglia (SCGs) to identify candidate molecules involved in macrophage-neuron signaling. Together, these experiments should provide direct evidence that inflammation around axotomized neuronal cell bodies, specifically macrophage accumulation, is necessary for a maximal regenerative response following peripheral nerve injury.

Title: The ErbB2 receptor pathway regulates regeneration following the repair of acute peripheral nerve transection injuries in a rat model

Authors: *M. HENDRY[1], E. PLACHETA[2], M. ALVAREZ-VERONESI[1], T. GORDON[1], G. H. BORSCHEL[1]
[1]Univ. of Toronto, Toronto, ON, Canada; [2]Med. Univ. of Vienna, Vienna, Austria, Austria

Abstract: Objective: Chronic denervation, the harmful consequence of long regeneration times and distance, profoundly inhibits functional recovery following nerve injuries. Surgical strategies that demonstrate the ability to protect against chronic denervation may do so by supplementing the growth supportive environment within the denervated nerve stump. Neuregulin, a potent Schwann cell mitogen that signals through its endogenous ErbB2 receptor is among the candidate regulators of these effects. Neuregulin regulates several aspects of peripheral nerve regeneration, however its exact role in regulating nerve regeneration and Schwann cell proliferation is unclear. In this study we selectively inhibit the receptor for neuregulin, ErbB2, with the high affinity monoclonal antibody Herceptin to examine its effect on nerve regeneration in a rat model. **Methods**: The common peroneal nerves of Sprague-Dawley rats were surgically transected and repaired with and without the systemic administration of Herceptin. Nerve repair was performed immediately or after 3 months of chronic denervation. The extent of nerve

regeneration was examined 1, 2 or 4 weeks after repair using retrograde labeling techniques where regenerated motoneurons were counted in the ventral spinal cord. Histomorphometry quantified myelinated fiber number and structural dimensions in the regenerated nerve. ErbB2 receptor activation and cellular proliferation were examined. **Results**: Significantly greater numbers of motoneurons regenerated in rats treated with Herceptin (169 ± 31) compared with rats receiving saline (62 ± 15) when assessed 1 week following immediate repair ($p < 0.05$). Total myelinated fiber counts were significantly increased in rats receiving Herceptin (2488 ± 154) compared to rats that received saline (1896 ± 251) ($p < 0.05$). When delayed repair was performed after a 3-month period of chronic denervation, Herceptin increased the number of acutely, but not chronically axotomized motoneurons after two weeks. Interestingly, Western blot analysis revealed no change in ErbB2 activation despite increased numbers of proliferating Schwann cells. **Conclusions**: Inhibition of the ErbB2 receptor with Herceptin paradoxically enhances nerve regeneration following acute and delayed nerve repair independent of neuregulin signaling. A novel inhibitory association between ErbB2 and EGFR may explain this effect. This raises the exciting possibility of using targeted molecular therapy to improve outcomes following surgical repair of nerve injuries.

Title: Neuromuscular electrical stimulation following nerve transection and immediate repair enhances reinnervation and functional recovery

Authors: *M. WILLAND, C. D. CHIANG, J. J. ZHANG, S. W. P. KEMP, T. GORDON, G. BORSCHEL
Div. of Plastic Reconstructive Surgery, The Hosp. For Sick Children, Toronto, ON, Canada

Abstract: Introduction: The use of chronic electrical muscle stimulation for treating partially or completely denervated muscle has been met with much controversy. Our previous work has shown that a moderate stimulation paradigm can significantly improve the numbers of motor units following long term muscle denervation and subsequent nerve repair. However, the use of

chronic electrical muscle stimulation using a clinically translatable stimulation paradigm immediately following nerve repair has not been thoroughly investigated. Research question: Does a moderate electrical muscle stimulation paradigm delivered chronically over 3 months improve reinnervation and functional outcome measures following nerve transection and immediate repair? Methods: Six groups of Thy1-GFP transgenic male rats were subjected to tibial nerve transection and immediate repair using two epineurial sutures. One group of rats underwent daily electrical muscle stimulation of the gastrocnemius with a paradigm comprising of 600 equally separated contractions throughout one hour, delivered 5 days per week. Rat gastrocnemius muscles were electrically stimulated for either 1, 2, or 3 months and then underwent terminal assessments which included evaluating muscle force, contractile properties, motor unit numbers, and wet weight. Rats in the 3 month group performed a tapered beam test weekly which assessed skilled location. Muscles were then harvested for immunohistological examination of motor end plate reinnervation. Results: Muscles that received daily electrical stimulation had a significantly greater number of motor units for all three time points (1, 2, and 3 months) as characterized using electromyographic methods. Mean motor unit sizes were significantly smaller in stimulated muscles suggesting that muscle stimulation may inhibit terminal sprouting as reported by others. This may allow for a more natural course of reinnervation resulting in improved functional recovery. Indeed, skilled loco-motor tests showed that stimulated muscles enhanced and maintained recovery at levels no different than normal functioning rats whereas non-stimulated controls became progressively worse and did not recover to baseline. Significance: Chronic treatment of denervated muscle using electrical stimulation can significantly enhance muscle reinnervation and functional recovery. As the muscle continues to become reinnervated, tailoring the stimulation paradigm to improve muscle force and fatigability may lead to shorter recovery times and reduce extensive physiotherapy and rehabilitation requirements.

Title: Enhancement of nerve regeneration with N-acetyl cysteine and acetyl-L-carnitine following neonatal nerve injury

Authors: *J. CATAPANO, C. CHIANG, M. C. ALVAREZ-VERONESI, T. GORDON, G. H. BORSCHEL
The Hosp. for Sick Children, Toronto, ON, Canada

Abstract: Objective: An overlooked component of disability following neonatal peripheral nerve injury is the death of central motor and sensory neurons crucial for repair and regeneration. Our lab has previously demonstrated that a novel aminopropyl carbazole, P7C3, protects neurons from retrograde death following neonatal peripheral nerve injury and improves functional outcomes. However, P7C3 is not yet approved for clinical use. N-acetyl cysteine (NAC) and acetyl-L-carnitine (ALC) are approved for use clinically and have demonstrated sensory neuron protection following adult peripheral nerve injury. This study investigates the efficacy of NAC and ALC in protecting motor and sensory neurons from cell death in a rat model of neonatal nerve injury. Method: Neonatal Lewis rats were used and a blinded observer completed all analysis. Animals were injured 3 days after birth with either a crush or transection injury of the sciatic nerve. Animals were then treated with i.p injections of NAC or ALC for 2 weeks at a dose of 750mg/kg/day and 300mg/kg/day respectively. One month after injury, surviving neurons were labeled proximal to the site of injury with a silicone well containing 4% Fluorogold solution for one hour. Animals were sacrificed 1 week after labeling. Samples distal to the site of injury were harvested for nerve histomorphometry and dorsal root ganglia and spinal cords were harvested for neuronal counts. Results: NAC significantly enhanced motor neuron survival following sciatic nerve crush injury (505.4 ± 39) compared to vehicle (403.7 ± 57) ($p<0.05$). Uninjured animals demonstrated significantly higher axon counts (7155 ± 198) than vehicle (5508 ± 908) and ALC treated animals (5915 ± 718) but were not significantly different from NAC treated (6224 ± 620). NAC and ALC did not protect motor or sensory neurons following a neonatal transection injury without nerve repair. Conclusions: NAC improved motor neuron survival and may improve axon regeneration following neonatal crush injury. NAC and ALC may not have demonstrated a similar benefit for motor and sensory neurons following transection injury because longer treatment periods may be required following more severe injuries where axon regrowth is delayed or inhibited.

Title: Improved peripheral motor and sensory nerve regeneration after delayed repair of transected common peroneal (CP) nerve is promoted by prior side-to-side bridging from a donor intact tibial nerve (TIBdonor) to the 3m chronically denervated common peroneal nerve stump (CPden) in an experimental Sprague Dawley rat model

Authors: *T. GORDON[1,2], J. J. ZHANG[1], A. LADAK[3], A. SNYDER WARWICK[2], J. HENDRY[4], G. H. BORSCHEL[5]
[1]Surgery, Univ. of Toronto, Toronto, ON, Canada; [2]Div. of Plastic and Reconstructive Surgery, The Hosp. for Sick Children, Toronto, ON, Canada; [3]Div. of Plastic Surgery, Univ. of Alberta, Edmonton, AB, Canada; [4]Dept. of Surgery, Inst. of Med. Sci., Toronto, ON, Canada; [5]Surgery, Div. of Plastic and Reconstructive Surgery, Toronto, ON, Canada

Abstract: Success of peripheral nerve regeneration declines with time and distance: injured neurons lose regenerative capacity with time and/or distance and denervated Schwann cells (SC) lose their ability to support regenerating axons, progressively reducing regenerative capacity to <5-10%. We asked "Can denervated SCs be 'protected' and, in turn, improve nerve regeneration through chronically denervated nerve stumps?" In Experiment#1 TIB motor and sensory neurons that grew axons into a recipient 3m CPden nerve stump were counted after aseptic surgeries to insert and secure 1) 1-3 autologous 3.2mm CP nerve grafts as side-to-side 'bridges' between corresponding numbers of ~0.5 mm epineurial windows opened in 10 mm parallel intact TIBdonor nerve and CPden distal nerve stump, and 2) 3-9 autologous 3.2mm long CP bridges between TIBdonor nerve and 3m CPden nerve stump, both of which had been stripped of epineurium over a 10mm length. TIB axons crossed 1 bridge in 10% of rats but crossed ≥3 bridges in all rats; very few TIB neurons sprouted axons into CPden stump. Motor and sensory neurons regenerated axons equally into the CPden stump either side of 3-9 bridges with very few neurons sending axons in both directions. A total of 25-35% neurons regenerated their axons through 3 bridges to occupy and become myelinated within endoneurial tubes in the CPden stump. Most axons regenerated through the first bridge with progressively fewer through the next bridges. Numbers of regenerating neurons and axons declined when >3 bridges were placed through the stripped epineurium, with many regenerated axons growing outside of the

endoneurial tubes. In Experiment #2, 5m after delayed CP nerve coaptation, a 3-bridge 'protection' of the 3m CPden nerve stump resulted in a significant 3-fold increase in the CP motor and sensory neurons that regenerated axons as compared to the numbers of CP neurons that regenerated axons without bridge 'protection'. Failure of >3 bridges to promote nerve regeneration concurred with regeneration of ~50% of the TIB axons outside of the endoneurial tubes of the CPden distal stumps. Measurement of evoked muscle and motor unit contractile forces in reinnervated extensor digitorum longus (EDL) muscles demonstrated a 2-fold increase in muscle twitch and tetanic contractile forces and increase in numbers of motor axons that reinnervated muscles when CP motoneurons regenerated their axons through a 3 bridge-protected 3m CPden nerve stump. Candidate molecules responsible for the "protection" of chronically denervated SCs may include neuregulin that is released from regenerating axons and would promote SC proliferation and expression of the growth permissive SC phenotype.

Title: Human umbilical cord perivascular cells (hUC-PVCs) rescue central nervous system and peripheral nervous system axonal degeneration *in vitro*

Authors: T. A. BARRETTO[1], K. PARK[1], J. FISH[1], *A. S. GAUTHIER[2], C. LIBRACH[1]
[2]Res., [1]Create Fertility Ctr., Toronto, ON, Canada

Abstract: Human umbilical cord tissue-derived perivascular cells (PVCs) and other MSCs are putative cell therapy candidates for regenerative medicine applications including neural injuries and degeneration. Here, we used *in vitro* models of neuronal injury to test our hypothesis that PVCs can prevent axonal degeneration following neuronal injury via paracrine or cell-cell contact mechanisms. Axonal degeneration induced by withdrawal of nerve growth factor (NGF) of cultured rat sympathetic cervical ganglia (SCG) was used as a PNS injury model1. Axon compartments were washed to remove NGF 7 days after neuronal cultures were established, and

treated with ultraculture media, or with established lines of fluorophore-labeled PVCs, BMSCs (Lonza) or neonatal fibroblasts (ATCC) for 3 days. Alternatively, compartments were treated with cell conditioned media (CM). Axons were immunostained for βIII tubulin, and the number of degenerating axons were counted. Similar treatments were used to test the ability of PVCs to protect rat cortical neurons from axonal degeneration following oxygen-glucose deprivation (OGD). When compared to control conditions (injury alone), treatment with PVCs reduced the number of degenerating SCG axons by 60± 13% ($n \geq 5$), BMSCs by 44± 6 % ($n=3$), and fibroblasts by 35± 18 % ($n=3$). PVCs dynamically extended processes and made localized contacts with axons after injury. PVC-CM treatment did not rescue axonal degeneration, and paradoxically, in most experiments exacerbated the injury level. PVCs, but not PVC-CM, were able to rescue axon degeneration in the OGD cortical neuron injury model. In summary, PVCs had the most profound effect on rescue of SCG axonal degeneration ($p<0.05$). Our data suggest that PVC-mediated protection against axonal degeneration is dependent on direct PVC-axon interactions and that, at least under the conditions tested, factors secreted by PVCs are not sufficient to rescue axonal degeneration. This suggests that local delivery of PVCs to injured nervous system would be a more effective approach for repairing certain types of neuronal injuries, for example in the PNS (peripheral neuropathy) or CNS (traumatic brain injury, spinal cord injury). Title: Neurotrophic effects of nicotine on perivascular adrenergic nerves in rat mesenteric arteries

Authors: *S. TAKATORI[1], H. HINO[2], F. TAKAYAMA[2], N. ONO[3], H. KAWASAKI[1]
[1]Matsuyama Univ., Matsuyama, Japan; [2]Okayama Univ., Okayama, Japan; [3]Fukuoka Univ., Fukuoka, Japan

Abstract: We reported that a topical phenol application on the rat superior mesenteric artery pronouncedly decreased a distribution of perivascular sympathetic adrenergic nerves and calcitonin gene-related peptide (CGRP)-containing nerves in small mesenteric arteries, and that nerve growth factor (NGF) reinnervated both nerves and nicotine regenerated only adrenergic nerves. To reveal possible mechanisms, the present study was investigated whether nicotine affects NGF contents of superior cervical ganglia (SCG), dorsal root ganglia (DRG) and mesenteric arteries and NGF receptor (TrkA) expression in SCG after topical phenol treatment *in vivo*, and neurite outgrowth of primary cultured SCG and PC12 cells *in vitro*. 10-week old Wistar rats underwent a topical application of 10% phenol to the superior mesenteric artery proximal to the bifurcation of the abdominal aorta. 7 days after the phenol treatment, animals were subjected to ELISA measurement of NGF contents in SCG, DRG and small mesenteric arteries, and Western blot analysis for TrkA expression in SCG. Nicotine at doses of 3 mg/kg/day (1.5 mg/kg/injection, twice a day) was subcutaneously (s.c.) administered for 7 days immediately after phenol treatment. The nicotinic acetylcholine receptor antagonist hexamethonium (5 mg/kg/day s.c.) was pretreated 15 min before nicotine administration. In *in vitro* studies, SCG cells isolated from rats and PC12 cells purchased were primarily cultured and neurite outgrowth from cell body was measured in the presence of nicotine, NGF or nicotine + NGF. Results: In *in vivo* study, nicotine markedly increased levels of NGF contents in SCG and mesenteric arteries, but not DRG. Nicotine also produced increased levels of TrkA expression in SCG. Nicotine-induced increases in NGF contents and TrkA expression were inhibited by hexamethonium pretreatment. In *in vitro* study using primary cultured SCG and PC12 cells, NGF (100 ng/ml) and nicotine (100 μM) induced a neurite outgrowth of tyrosine hydroxylase-immunopositive SCG cells and PC12 cells. Combination of NGF and nicotine further increased a neurite outgrowth of SCG and PC12 cells. These results suggest that nicotine has a neurotrophic effect on perivascular adrenergic nerves through activation of α7nAChR, which results in increase in NGF levels and TrkA expression.

Title: Synergistic effects of neurotrophins and pleiotrophins in stimulating nerve regeneration across long gap peripheral nerve defects

Authors: *M. I. ROMERO-ORTEGA[1,2], N. Z. ALSMADI[1,2], R. GRANJA[1,2], B. JOHNSTON[1,2], A. KANNEGANTI[1,2], G. BENDALE[1,2], E. HOR[1], H. SUMDANI[1], S. TRINH[1], M. LE[1]

Abstract: Peripheral nerve injuries resulting in the extensive loss of nerve continuity pose a challenge in reconstructive surgery. Current treatments, such as autograft, isografts and simple tubularization, are limited by the need for donor nerve harvest, minimal functional recovery, and gap restrictions(< 3cm). These limitations can be attributed to the lack of appropriate growth substrate and trophic support. Growth factors such as brain-derived growth factor (BDNF), glial-derived nerve factor (GDNF) and pleiotrophin (PTN) have been demonstrated to induce axonal growth of spinal cord motor neurons, as well as the proliferation and migration of Schwann cells, fibroblasts and endothelial cells. In this current study, a systematic approach to find a suitable combination of growth factors was tested *in vitro* to provide growth factor specific regenerative potency. Further, we tested whether multiluminal biosynthetic nerve implants (BNI) loaded with a combination of PTN and GDNF in the microchannels provide a synergistic effect to promote regenration across a critical long gap (4 cm) in a rabbit model. The toe spread index, measured at 19 weeks post implantation, increased by 25% with PTN and GDNF treatment compared to 15% for the BSA group when compared to those at 4 weeks post injury. As expected, the autograft group shows maximal functional recovery, with a 38% increase between the two time points. (Similarly, the ankle angle revealed that, from 4 weeks to 20 weeks post injury, the GDNF group (14° decrease) had the highest recovery when compared to BSA (2.5°), PTN (0°), and PTN+GDNF (3°), while the autograft treatment (24°) still remained the best . In addition, immunohistochemistry of the distal tissue sections showed that the total area containing regenerated axons was higher in the animals treated with PTN+GDNF than BSA, PTN, and GDNF. Our results demonstrated that PTN and GDNF act synergistically to bridge a long gap. The functional recovery assessed by toe spread index and ankle angle measurement indicate successful motor neuron regeneration. In addition, immunohistochemistry showed positive staining for β-tubulin and P0 indicating neural regeneration across the 4 cm gap. This approach

improves the current nerve repair constructs to bridge the transected neuron across critical peripheral gaps and improves the recovery of functions.

Title: A peripheral nerve regeneration strategy using a combination of bone marrow-derived stem cells transdifferentiated into Schwann-like cells and micropatterned biodegradable polymer conduits

Authors: ***S. ZBARSKA**[1], A. D. SHARMA[2], S. K. MALLAPRAGADA[2], D. S. SAKAGUCHI[3]
[1]Iowa State Univ., Iowa State Univ., AMES, IA; [2]Dept. of Chem. and Biol. Engin., Iowa State Univ., Ames, IA; [3]Genetics, Develop. and Cell Biol., Iowa State Univ., AMES, IA

Abstract: Peripheral nerve injuries (PNI) can lead to serious neurological deficits resulting in sensory/motor dysfunctions, including paralysis. Autologous nerve grafts including Schwann cells (SCs) are considered the “gold standard” for treatment of severe PNI. SCs are peripheral glia forming the myelin sheath around axons of motor and sensory neurons. SCs also secrete trophic and growth factors which promote neural regeneration. Previously we have demonstrated that SCs implanted inside of micropatterned nerve regeneration conduits (NRC) enhanced peripheral nerve regeneration (Rutkowski et. al, 2004). However, SC harvesting requires an additional surgery and sacrifice of a donor nerve that results in donor site morbidity. Due to these limitations, alternative cell sources and strategies are being investigated. Recently we have shown that rat bone marrow-derived mesenchymal stem cells (MSCs) can be transdifferentiated into SC-like phenotypes on micropatterned biodegradable poly-lactic acid (PLA) substrates. These results revealed that substrate topography strongly influenced the morphology and growth of the MSCs. Cells aligned in the direction of the grooves when grown on micropatterned PLA substrates, and micropatterning did not impact the level of transdifferentiation making

micropatterned PLA films an ideal base-component for fabricating NRCs. In our ongoing project we are using a synergistic approach combining micropatterned topographical cues in a NRC and biological cues in the form of transdifferentiated rat bone marrow-derived cells. Three groups of Brown Norway rats were implanted with micropatterned PLA NRCs to bridge a 10 mm sciatic nerve transection gap. Group 1 was implanted with control, empty conduits; Group 2 was implanted with conduits pre-seeded with tMSCs (Schwann-like cells); and Group 3 was implanted with conduits pre-seeded with undifferentiated MSCs (uMSCs). Both populations of MSCs express green fluorescent protein (GFP). After implantation animals are assessed for possible recovery of motor and sensory function. In the future, in addition to pre-seeded tMSC-NRCs, we plan to incorporate neurotrophic factor encapsulated nanoparticles to enhance peripheral nerve regeneration.

Title: Pacific ciguatoxin-1 reduces regenerative capacity of peripheral neuron *in vitro*

Authors: *N. P. B. AU[1], Y. L. MAK[2], L. L. CHAN[2], P. K. S. LAM[2], C. H. E. MA[1,2]

Abstract: Ciguatoxins (CTXs) are the most potent heat-stable neurotoxins acting on voltage-sensitive sodium channels (VSSCs). CTXs are commonly found in reef fish and consumption of these contaminated fish in human results in gastrointestinal and neurological disorders known as ciguatera fish poisoning (CFP). Due to the increase in international trading of tropical fish species, CFP has drawn significant attention as a global public health issue and increasing incidence of CFP has been reported around the world not limited to tropical regions. An estimated of 50000 victims all over the world are affected by CFP annually. CFP patients exhibit

a range of peripheral neurological and gastrointestinal symptoms such as muscle weakness, and sensory disturbance. Gastrointestinal symptoms usually last for about 2 weeks but severe neurological deficiencies involving the peripheral nervous system (PNS) can last for months to years in 20% of patients. However, little is known about the direct effect of CTXs on peripheral neurons and peripheral nerve regeneration. In the present study, we examined the effect of Pacific ciguatoxin-1 (P-CTX-1), which is described as the most abundant and potent form of CTXs, on the regenerative capacity in PNS using *in vitro* culture of dissociated dorsal root ganglion (DRG) neurons prepared from adult C57BL/6 mice. Dissociated DRG culture is widely used as an *in vitro* model to study PNS regeneration allowing assessment of neurite outgrowth in primary neurons individually. P-CTX-1 significantly attenuated the neurite outgrowth of DRG neurons at concentrations of 1 and 3ng/ml ($p<0.05$) without any adverse effect on the cell viability. These data suggest that P-CTX-1 reduces the regenerative capacity of DRG neurons by limiting neurite extension and thus, this may somewhat explain the phenomenon that damages of nerve were still observed several months after CFP due to the delayed or failure of axonal regeneration.

Title: Extracellular Matrix modifications guide pathway selection in peripheral nerve regeneration

Authors: *J. ISAACMAN-BECK, M. GRANATO
Univ. of Pennsylvania, PHILADELPHIA, PA

Abstract: Following injury, peripheral nerves maintain the remarkable ability to reestablish functional connections. Trophic factors such as BDNF and NGF provide critical and well-defined signals to spur regrowth, but the molecular cues that return these nerves to the correct pathway at choice points remain largely unknown. We use the larval zebrafish peripheral motor

nervous system to determine these regenerative guidance signals. In these larvae, all motor nerves exit the spinal cord together and initially fasciculate along a common ventral path. Just prior to the horizontal myoseptum, a subpopulation of axons turns acutely from this shared corridor and extends to innervate the dorsal myotome. After we transect both dorsally and ventrally projecting nerves, regenerating axons from both nerves navigate to their original synaptic targets, suggesting that cues exist to guide this binary pathway selection. Here, we provide real-time *in vivo* evidence that constituents of the extracellular matrix (ECM) govern pathway selection for peripheral motor nerve regrowth. In mutants lacking the ECM glycosyltransferase *lysyl hydroxylase 3 (lh3)*, ventral motor nerves regrow robustly to the ventral myotome, but dorsal nerves fail to stabilize growth to their dorsal targets. Interestingly, larvae deficient in the ECM collagen *collagen4a5* (*col4a5,* a known *lh3* substrate) and the canonical axon guidance receptor *robo2* show similar pathway selection defects in nerve regrowth. In mammalian models, *col4a5*, *robo2* and its ligand *slit* are upregulated after peripheral nerve transection, and *col4a5* is known to bind *slit* with high affinity to facilitate *slit-robo2* guidance of axons. We will link these findings with data that suggest that after injury, *lh3* acts in nerve associated glia, modifying the ECM to provide *robo2*-mediated guidance for dorsal pathway selection. To our knowledge, this is the first direct evidence defining a functional mechanism for ECM cues in establishing pathway selection in peripheral nerve regrowth *in vivo*.

Title: An implantable electrical interface for *in vivo*, chronic studies of electromyography in canine laryngeal muscles

Authors: *Y. LI[1], S. HUANG[2], D. ZEALEAR[2]
[1]Hearing and Speech Sci., Vanderbilt Univ. Med. Center/Oto, Nashville, TN; [2]Otolaryngology, Vanderbilt Univ., Nashville, TN

Abstract: It has been demonstrated that electrical stimulation of a denervated laryngeal muscle preferentially repressed reconnection by foreign motoneurons, thereby promoting correct reinnervation. However, its mechanism is unknown. Electromyography plays an important role in exploring the underlying mechanisms of selective reinnervation. Objective: The purpose of this study was to develop and test a simple, inexpensive, implantable system that could be used for repeated recordings of spontaneous and evoked EMG from the larynx over a long period of study. Methods: This system consisted of four bipolar nerve stimulus cuffs and four EMG recording electrodes, as well as an interface plug. During a sterile surgery, nerve stimulus cuffs were placed on the recurrent laryngeal nerves (RLNs) and the internal branches of superior laryngeal nerves (SLNs) bilaterally. The recording electrodes were put into the vocal fold adductor (thyroarytenoid, TA) and abductor (posterior cricoarytenoid, PCA) muscles bilaterally. EMG recordings from the PCA muscles during RLN stimulation gave an index of the overall magnitude of its reinnervation. EMG activity during SLN stimulation showed amount of incorrect reinnervation of the PCA muscle by foreign reflex glottic closure motoneurons. The spontaneous EMG activity during hypercapnic breathing provided a good estimate of the magnitude of appropriate PCA muscle reinnervation by inspiratory motoneurons. Small metal female pins were attached at the other end of coiled electrode leads and inserted into the holes of the skin plug. The plug was sutured to the anterior neck and served as an interface for connection between all implanted electrodes and the external equipment. This system was implanted and tested in 3 short-term and 2 long-term canines for as long as 6 months. Results: Device showed good compatibility in all animals. All the lead wires and recording electrodes remained intact and functional. Consistent EMG signals were recorded from the PCA and TA muscles in all animals. The shape and amplitude of the potentials were comparable to recordings from previous studies. Stimulus artifacts were minimal and did not impact the biological signals. The average rectified and integrated EMG potentials recorded from PCA muscle during RLN stimulation, SLN stimulation and spontaneous hypercapnic breathing were 12.2±4.1 μVs, 1.87±0.95 μVs and 0.73±0.33 mVs, respectively. Conclusion: We presented a chronic EMG implant method that was simple and capable of obtaining stable EMG recordings from both abductor and adductor muscles in canine's larynx for periods up to 6 months with minimal risk of device breakage, trauma or infection.

Title: Stimulation of a denervated laryngeal muscle promotes selective reinnervation, reduces synkinesis and restores function

Authors: *D. L. ZEALEAR, Y. LI, S. HUANG
Vanderbilt Univ. Med. Ctr., NASHVILLE, TN

Abstract: Previously, electrical stimulation of a denervated canine laryngeal muscle was shown to promote reinnervation by original over foreign motoneurons. An implantable nerve stimulation-EMG system was used to index the appropriateness of reinnervation of the vocal fold abductor (posterior cricoarytenoid, PCA) muscle by inspiratory versus foreign reflex glottis closure (RGC) motoneurons following recurrent laryngeal nerve section and repair. In the present study in nine canines, a clinical model was used, where both nerves were sectioned and ventilation compromised due to loss of abduction. The EMG system and a pulse generator were implanted, the latter for electrical conditioning of PCA muscles. After nerve section, animals were randomly assigned to four groups to assess the effect of different muscle stimulus paradigms on reinnervation quality and degree of functional recovery: 1)40 pps train, 2)20 pps train 3)10 pps train and 4)control-no stimulation. One msec pulses were applied with 4 sec on/4 sec off duty cycle during the post neurorrhaphy regeneration period. In bimonthly sessions, spontaneous vocal fold movement was measured endoscopically during induced hypercapnea in the anesthetized animal. Exercise tolerance was measured on a treadmill in the awake animal using pulse oximetry. Rectified integrated EMG potentials were recorded from abductor muscles and adductor (thyroarytenoid, TA) muscles in the anesthetized animal. Recordings were obtained during hypercapnic respiration to index reinnervation by inspiratory motoneurons, and during superior laryngeal nerve stimulation to index reinnervation by RGC motoneurons. Results demonstrated that nonstimulated controls, 40 pps stimulated and 20 pps stimulated animals had faulty reinnervation (EMG), severe paradoxical closure of the glottis during hypercapnea, and poor tolerance to exercise. In contrast, stimulated 10 pps animals showed a near normal pattern of low PCA and high TA reinnervation by RGC motoneurons, minimal paradoxical glottis closure, and normal exercise tolerance (12 minutes up to 8 mph). It would appear that low-frequency stimulation of a denervated PCA muscle simulating endogenous activity inhibits

reinnervation by foreign RGC motoneurons, leaving receptor sites available for native inspiratory motoneurons. As a consequence, reinnervation of adductor muscles by inspiratory neurons is depressed; paradoxical glottis closure is reduced and exercise tolerance restored to normal.

Title: Computational modeling of drug release from nerve guide conduit

Authors: *N. Z. ALSMADI[1,2], L. PATIL[1,2], C.-J. CHUONG[1,2], M. ROMERO-ORTEGA[1,2]
[1]Bioengineering, Univ. of Texas at Arlington, Arlington, TX; [2]Univ. of Texas Southwestern Med. Ctr., Dallas, TX

Abstract: In the injured adult nervous system, re-establishment of growth-promoting molecular gradients is known to entice and guide nerve repair. However, incorporation of three-dimensional chemotactic gradients in nerve repair scaffolds, particularly in those with multi-luminal (ML) architectures, remains extremely challenging. To address this limitation, we have developed a method that establishes highly tunable, three-dimensional molecular gradients in ML nerve guides (NG) by anchoring nerve growth-factor (NGF) releasing coiled microfibers onto the walls of collagen-filled hydrogel microchannels. The gradient is achieved by differential pitch in the coiling of neurotrophin-eluting fibers, and *in vitro* studies demonstated that axonal growth from dorsal root ganglia (DRG) is 60% longer and more linear as indicated by a reduced turning angle ratio, compared to those exposed to uniform growth factor concentration. Here, we developed a computer model to estimate the dynamics of growth factor release and the diffusion

into the luminal collagen, in six different designs of drug release conduits: a) collagen filled NG, b) NGF-Microparticle release in NG, c) NGF-coil release in NG, d) collagen filled ML-NG, e) NGF-Microparticle release in ML-NG, f) NGF-coil release in ML-NG. Finite element computational was used to calculate the spatiotemporal distributions of NGF in the six types of conduits over time, and to compare of growth factor diffusion over time in each of these devices. We further assessed the effect of geometrical parameters on the efficacy of drug release in NGs. Our models provides quantitative insights with time-varying NGF distribution in the microenvironment of the nerve guide conduits. The model could assist in enhancing the design of growth factor secreting nerve conduits, and improve the current nerve repair strategies to optimize the regeneration of injured neurons and the recovery of function.

Title: The role of the D1 receptor in the prefrontal cortex in the emergence and reduction of depressive-like behavior

Authors: *N. B. FREUND[1,2], R. A. NEVE[3], S. L. ANDERSEN[2]
[1]Dept. of Psychiatry, Universitaetsklinikum Tuebingen, Tuebingen, Germany; [2]Lab. for Developmental Neuropharm., McLean Hospital/Harvard Med. Sch., Belmont, MA; [3]Viral Gene Transfer Core, MIT, Cambridge, MA

Abstract: The adolescent prefrontal cortex undergoes major structural and neurochemical changes during maturation. For example, the density of dopamine D1 receptor (D1R) positive cells projecting from the prelimbic prefrontal cortex (plPFC) to the nucleus accumbens is transiently increased during this maturational stage. This peak in D1R elevates the motivational

salience of environmental cues, allowing the individual to process adverse situations. Disruptions in the maturation of this D1R population might decrease motivational salience sufficiently to induce depression. Here, we investigated the role of developmental plPFC D1R changes in learned helplessness in juvenile (21 days), adolescent (40 days), and adult (70 days) Sprague-Dawley rats of both sexes. Rats were conditioned on Day 1 with a tone and a light predicting the onset of a shock that they could not escape. On Day 2 subjects were placed in the same shuttle box where tone and light signaled shock, but subjects had the opportunity to escape. The latency to escape and escape failures decreased with age (main age effect: $F_{2,51}$=13.63; p<0.01 and $F_{2,51}$=17.84; p<0.01). While adolescents' escape latencies decreased relative to juveniles', significant differences were only observed between juveniles and adults (p<0.008, Bonferroni corrected). Sex differences were found for escape failures with more failures in males compared to females in adulthood (main sex effect: $F_{1,51}$=5.37; p=0.02). The role of high D1R density in learned helplessness was investigated by over-expressing D1R in glutamate neurons in the plPFC of juvenile animals with an adenovirus. In females, D1R over-expression decreased escape latencies and failures compared with females that expressed a control protein (latency: $F_{1,8}$=10.18; p=0.013; failures: $F_{1,8}$=12.35; p=0.008, Bonferroni corrected); no differences between virus groups were found in males. Immunohistochemical staining for *c-Fos* in animals sacrificed 90 minutes after behavioral testing revealed that the D1R over-expression increased neuronal activity in the nucleus accumbens shell of juvenile females ($F_{1,8}$=6.82; p=0.035). Furthermore the number of *c-Fos* positive cells in the nucleus accumbens shell positively correlates with escape behavior (latency: r=-0.671; p=0.048 and failures r=-0.763; p=0.017). Taken together, learned helplessness decreases with maturation, an effect that may be partially due to increased motivational salience mediated by plPFC D1R density. Failure or disruption in the maturation of prefrontal D1R expression may be responsible for the onset of depression during adolescence.

Abstract: Netrins are guidance cues involved in the proper organization of neuronal connectivity. We have shown that variations in the function of the netrin-1 receptor, DCC, result in *selective* changes to the development and organization of medial prefrontal cortex (mPFC) dopamine (DA) circuitry. In comparison to their wild-type littermates, adult *dcc*-haploinsufficient mice demonstrate increased DA innervation and exaggerated DA function in the mPFC in adulthood. These changes, in turn, lead to structural and functional alterations in mPFC Layer V pyramidal neurons and to changes in cognitive flexibility. Interestingly, none of the anatomical, neurochemical, and behavioural phenotypic traits of adult *dcc*-haploinsufficient mice are present prior to adolescence; a period during which mPFC DA circuitry undergoes substantial reorganization and functional refinement including overproduction and elimination of DA receptors. To begin to investigate whether *dcc* also plays a role in DA receptor regulation during adolescence we conducted quantitative receptor autoradiography experiments. We characterized the expression of D1 and D2 receptors in pregenual mPFC and striatal regions in male *dcc*-haploinsufficient and wild-type mice across three postnatal ages: postnatal (PND) 21±1, PND33±2, and adulthood (PND 85±15). Autoradiograms were generated by apposing serial brain sections incubated with either [^{3}H]SCH-23390 or [^{3}H]raclopride alongside tritium standards. Receptor binding was quantified using microdensitometric image analysis system (MCID System). We observed age- and region-specific differences in D1 and D2 receptor density between *dcc*-haploinsufficient and wild-type mice. Notably, dcc-haploinsufficent mice do not show the typical pattern of D2 receptor pruning observed in the mPFC of wild-type mice and, consequently, have an increased density of mPFC D2 receptor in adulthood. Conversely, we observed a trend toward decreased expression of D1 receptors in the mPFC of adult dcc-haploinsufficient mice relative to wild-type littermates. Furthermore, *dcc*-haploinsufficient animals show reduced receptor density in striatal regions at younger ages; this effect is transient. These findings suggest a role for DCC-mediated netrin-1 signaling in directing the dynamic refinement of DA receptor expression over the course of adolescence.

Title: A subset of pubertally born cells differentiate into astrocytes within the posterior-dorsal medial amygdala

Authors: *N. STAFFEND[1], F. GARCIA[2], M. M. MOHR[1], L. DONCARLOS[2], C. L. SISK[1,2]
[1]Neurosci., Michigan State Univ., East Lansing, MI; [2]Loyola Univ. Chicago Stritch Sch. of Med., Chicago, IL

Abstract: The posterior-dorsal medial amygdala (MePD) evaluates and assigns valence to social stimuli from conspecifics and is sexually dimorphic, such that it is larger in adult males than females. We have established that cell addition is a general mechanism for structural remodeling of the brain during puberty in rats, including sexually dimorphic structures like the MePD [Ahmed et al., 2008]. The present study aimed to identify the cellular phenotype of the pubertally born cells within the MePD, specifically whether they differentiate into mature neurons or astrocytes. Three injections of the thymidine analogue, bromo-deoxyuridine (BrdU; 200 mg/kg ip), were given at 8 hr intervals to 6 male and 6 female rats during early puberty, on P30; rats were sacrificed 21 days post-BrdU injection. Tissue was processed for BrdU, the mature neuronal marker, NeuN, and the mature astrocytic marker, GFAP. Using triple-label immunofluorescence and confocal microscopy, analyses conducted thus far of 3 males and 3 females revealed that the majority (86% in males, 85% in females) of BrdU labeled cells were not labeled with either NeuN or GFAP. However, a small proportion of BrdU-positive cells in both males (10%) and females (12%) did co-label with GFAP, indicating these pubertally-born cells mature into astrocytes. Even fewer BrdU-positive cells co-labeled with the mature neuronal maker, NeuN (4% males, 3% females). Although data exist demonstrating greater numbers of astrocytes in the adult male MePD compared to the adult female [Johnson et al., 2008], the current analysis of 3 animals per sex detected no significant sex difference in the number of pubertally born cells that differentiated into mature astrocytes ($p = 0.294$); analysis of remaining animals is ongoing. In addition, this experiment examined cells born on a single day during early puberty (P30), which may or may not be representative of the fate of all MePD cells born throughout puberty. Although we cannot yet determine whether there are sex differences in the phenotypes of pubertally born MePD cells, these data extend our previous findings by

demonstrating that a subset of pubertally born cells in both sexes differentiate into mature astrocytes, positioning these cells to contribute both structurally and functionally to pubertal maturation of the MePD and the behaviors it governs.

Title: The enduring effects of amphetamine on baseline dopamine function vary by age of drug administration

Authors: *C. FLORES[1,3], L. YETNIKOFF[4], M. POKINKO[2,3], M.-P. COSSETTE[5], A. ARVANITOGIANNIS[5]
[1]Dept of Psych, [2]Integrated Program in Neurosci., McGill Univ., Montreal, QC, Canada; [3]Douglas Mental Hlth. Univ. Inst., Montreal, QC, Canada; [4]Dept. of Pharmacol. and Physiological Sci., St. Louis Univ. Sch. of Med., Saint Louis, MO; [5]CSBN, Concordia Univ., Montreal, QC, Canada

Abstract: Adolescence is a vulnerable period in the lifespan, wherein individuals are prone towards perilous and impulsive behavior. The choices and decisions made during this vulnerable period can have long-term consequences on well being during adulthood. For example, in humans, experimentation with drug use during adolescence leads to a higher risk of developing drug abuse and addiction later in life than does initiation of drug use during adulthood. While the precise mechanisms underlying this enhanced risk are not clear, it is well-established that the behavioral vulnerabilities of adolescence are associated with numerous progressive and regressive changes in brain structure and function, particularly within the mesocorticolimbic dopamine system. Exposure to drugs of abuse during adolescence may therefore impinge on the

normal development of mesocorticolimbic circuitry, leading to long-lasting alterations in its function. Here we examined how repeated exposure to amphetamine at three distinct periods of the lifespan affects the functioning of the mesocorticolimbic dopamine system as assessed by baseline measures of dopamine and its metabolites. Specifically, early adolescent (P21-31), mid adolescent (P35-45) and adult (> P60) wild-type mice were administered 5 injections of amphetamine (4 mg/kg) or saline on alternating days. One month after drug pretreatment all animals were killed and bilateral punches of the nucleus accumbens, dorsal striatum and medial prefrontal cortex were obtained. Baseline levels of dopamine content and turnover were assessed by high performance liquid chromatography. Remarkably, repeated exposure to amphetamine during early and mid adolescence, but not during adulthood, induced long-lasting changes in baseline function of dopamine and/or its metabolites, with the direction of the observed effects varying by region examined. These findings suggest that enduring, age-specific changes in the function of dopamine circuitry by stimulant drugs of abuse underlie the increased vulnerabilities of early onset, as compared to adult onset, drug use.

Title: Pubertal expression of PSA-NCAM in the medial amygdala of the male Syrian hamster

Authors: *M. O. JOB
The Neurosci. Inst., GEORGIA STATE UNIVERSITY, ATLANTA, GA

Abstract: Male Syrian hamsters enter puberty around postnatal day 28 (P28), coinciding with an increase in serum androgen levels. In addition, male Syrian hamsters start displaying significant sexual motivation by P40 - a time when puberty is thought to have ended. Previous work has shown that pubertal androgens remodel the posterodorsal medial amygdala (MePD), a brain region that participates in socio-sexual behaviors, many of which emerge at puberty. The adult MePD contains high levels of polysialylated neural cell adhesion molecule (PSA-NCAM), which

plays a permissive role in synaptogenesis and plasticity throughout the brain during development, and in a few regions of the adult brain. In male hamsters ranging in age from P27 - P145 (n = 4 - 8 animals per age), we measured body, brain, and seminal vesicle weights, and serum testosterone and cortisol levels. In addition, we visualized NCAM and PSA-NCAM in the MePD of these same hamsters. As expected, there was a surge in testosterone from P27 to P40, and we observed strong positive correlations between age and body weights, age and seminal tissue weights, and age and brain weights. Interestingly, PSA-NCAM immunoreactivity also surged during pubertal development, reaching an apex around P32, and dropping to its nadir by P145. The increase in MePD PSA-NCAM occurred at the same time that there was a surge in serum testosterone levels, suggesting that androgens regulate MePD PSA-NCAM expression. Future studies will test this hypothesis, and will identify the necessity of PSA-NCAM for MePD neuronal remodeling and the emergence of MePD-dependent behavior.

Title: Exposure to prenatal, adolescent, or combined prenatal and adolescent stress increases contextual fear conditioning in male but not female Sprague-Dawley rats

Authors: *K. M. SCHULZ[1,2], M. B. BURKE[2], M. ZAJKOWSKI[2], I. RAMOS[2]
[1]Denver Veterans Admin. Med. Ctr., Denver, CO; [2]Psychiatry, Univ. of Colorado Anschutz Med., Aurora, CO

Abstract: Numerous rodent studies demonstrate that stress exposure during prenatal and adolescent development alters sexually-dimorphic cognitive and affective behaviors in adulthood. However, fewer studies have investigated the effects of prenatal and adolescent stress on fear-related learning, and most have focused only on males. Therefore, we investigated the effects of prenatal stress, adolescent stress, or combined prenatal and adolescent stress on adult contextual fear conditioning in both sexes. Male and female Sprague Dawley rats experienced

one week of chronic variable stressors prenatally (gestational days 14-21), during adolescence (postnatal days 23-30), a combination of these stressors during both prenatal and adolescent periods, or were nonstressed controls. In adulthood (~100 days old), animals were exposed to a series of foot shocks within a testing chamber, and contextual freezing behavior was assessed 24 hours later when subjects were returned to the same testing chamber for five minutes (no shocks administered). A significant sex by treatment interaction was observed in which stress increased contextual freezing durations in male but not in female rats [$F(3,124)=1.47$, $p=0.034$]. Specifically, males that had experienced prenatal ($p=0.03$), adolescent ($p=0.09$), or combined prenatal and adolescent stress ($p=0.01$) exhibited greater freezing durations than nonstressed males. In contrast, prenatal, adolescent, or combined stress exposures did not significantly impact contextual freezing in females. These data suggest that developmental stress exposure facilitates contextual fear learning in a sex-dependent manner, and highlight the importance of including both sexes in experimental designs.

Title: Mesocortical dopamine depletion reverses the protective phenotype of netrin-1 receptor deficient mice

Authors: *M. POKINKO[1,3], L. MOQUIN[3], A. GRATTON[2,3], C. FLORES[2,3]
[1]Integrated Program in Neurosci., [2]Psychiatry, McGill Univ., Montreal, QC, Canada; [3]Douglas Univ. Hlth. Inst., Montreal, QC, Canada

Abstract: The netrin-1 receptor, DCC, which is highly expressed by ventral tegmental area dopamine (DA) neurons, establishes the extent of their innervation to the medial prefrontal cortex (mPFC) during adolescence. In turn DCC signaling determines vulnerability to the

behavioral effects of stimulant drugs of abuse in adulthood. Interestingly, DCC-positive DA neurons in the ventral tegmental area co-express another netrin-1 receptor, UNC5C, from adolescence onwards. Furthermore, both adult dcc and unc5c haploinsufficient mice have increased DA innervation to the mPFC and exhibit blunted behavioral responses to amphetamine. This protective phenotype only emerges after adolescence. Because DA transmission in the mPFC can negatively regulate behavioral responses to drugs of abuse, we hypothesized that reduced sensitivity to the effects of amphetamine in dcc and unc5c haploinsufficient mice results from increased mPFC DA innervation. We therefore examined whether selective mPFC DA depletion in adulthood reverses the protective phenotype of these mice. To this end, adult wild-type, dcc, and unc5c haploinsufficient mice, bred in our animal facility, received bilateral injections of 6-hydroxydopamine (lesion) or vehicle (sham) into the mPFC. Ten days later, we challenged these mice with an i.p. injection of 2.5 mg/kg amphetamine and measured their locomotor activity for 90 min. As expected, dcc and unc5c haploinsufficient mice that received sham lesions showed significantly reduced amphetamine-induced locomotion compared to wild-type groups. Remarkably, dcc and unc5c haploinsufficient mice that underwent mPFC DA lesions no longer showed this blunted response to amphetamine challenge; their locomotor activity was similar to that observed in wild-type controls. There was no difference in amphetamine-induced locomotion between lesion and sham wild-type groups. These findings demonstrate that the protective phenotype of adult dcc and unc5c haploinsufficient mice results from the effects of DCC and UNC5C receptors on the development of the DA input to the mPFC. These finding raise the possibility that signaling mediated by DCC/UNC5C receptor complexes may be at play.

Title: Impact of dietary omega-3 fatty acid deficiency on DCC and other dopamine related measures

Authors: *S. LOTFI[1], C. MANITT[5], J. J. BALCITA-PEDICINO[2], C. O. BONDI[3], S. R. SESACK[4], C. FLORES[5], B. MOGHADDAM[4]

Abstract: Identifying mechanisms by which environmental factors affect the onset and course of psychiatric disorders is critical for their prevention and treatment. Nutritional factors, in particular dietary deficiency of omega-3 polyunsaturated fatty acids (n-3 PUFAs), have been implicated in the onset of schizophrenia and mood disorders in young individuals who are at high risk to develop these conditions. Animal models of this dietary deficiency in adolescents and adults are critical for understanding how n-3 PUFA deficiency influences overall behavioral health and symptoms of these illnesses. We recently developed such a model involving consecutive generations of n-3 PUFA deficiency based on the assumption that dietary trends toward decreased consumption of these fatty acids began four-five decades ago when the parents of current adolescents were born (Bondi et al., Biological Psychiatry, 2014). In addition to behavioral disruptions that were augmented in the second generation (G2) of n-3 PUFA deficient adolescent animals, we observed changes in the expression of dopamine-related proteins that were different in adolescents as compared to adults. To expand on these findings, we have focused on assessing DCC and TH expression, as well as dopamine cell number and structural characteristics in these diet groups. DCC is a receptor for the axonal guidance cue netrin-1, and is involved critically in the adolescent developmental organization of dopamine connectivity. Previous work shows that changes in DCC expression lead to altered DA connectivity and function in a manner that is dependent on age and region (Manitt et al., Translational Psychiatry, 2013). We find that DCC expression in G2 n-3 PUFA deficient adolescents is lower in the nucleus accumbens (NAc) and higher in the dorsal striatum (DS) compared to adequately fed counterparts. In G2 adult animals with n-3 PUFA deficiency, DCC expression in NAc and DS also is affected, but in an opposite direction from what is seen in adolescents: DCC expression is higher in NAc but lower in DS, as compared to adequately fed animals. Neuroanatomical analyses to determine potential alterations in dopamine cell number, somal size, and ultrastructural features are ongoing.

Title: Sex difference in pubertal cytogenesis in the posterodorsal medial amygdala of mice

Authors: *J. L. KIM[1], M. A. MOHR[2], N. A. STAFFEND[2], L. L. DONCARLOS[3], S. M. BREEDLOVE[2], C. L. SISK[1,2], C. L. JORDAN[2]
[1]Psychology, [2]Neurosci., Michigan State Univ., East Lansing, MI; [3]Cell and Mol. Physiol., Stritch Sch. of Medicine, Loyola Univ. Chicago, Maywood, IL

Abstract: The posterodorsal medial amygdala (MePD) is a sexually dimorphic brain region involved in social and sexual behaviors, many of which are sexually differentiated and emerge during puberty. Previous studies in rats and hamsters have demonstrated that new cells are added in sexually dimorphic regions of the brain including the MePD, that pubertal hormones promote their addition, and that some of these pubertally born cells differentiate into mature neurons or glia that are functionally incorporated into neural circuits [Nature Neuroscience (2008). 11(9):995-7; PNAS (2013). 110(12):4792-7]. Given the wide array of genetic tools available in mice to dissect and understand mechanisms of hormone action on pubertal cytogenesis in the brain, we now ask whether new cells are added during puberty in the mouse brain. Male and female juvenile mice were injected daily with bromodeoxyuridine (BrdU), a cell birth date marker, for 21 days (postnatal day 28-49). Animals were sacrificed as adults on postnatal day 60; BrdU-labeled cells could range from 11-32 days of age at the time of tissue collection. Using immunohistochemistry, we find evidence of BrdU+ cell labeling in many regions of the mouse brain including the dentate gyrus and MePD. Quantitative analysis using Neurolucida software revealed comparable numbers of BrdU labeled cells (# BrdU-labeled cells/mm2) in the dentate gyrus ($F=0.03$, $p=0.86$) of males and females but a significant sex difference in their number in the MePD ($F=12.19$, $p<0.02$), consistent with previous findings in rats, with males having nearly 1.5 times more BrdU-labeled cells than females. These results show for the first time that pubertal cytogenesis occurs in the mouse brain and that these newly born cells survive into adulthood with more in the MePD of males than females, suggesting they may contribute to the emergence of sexually differentiated social-sexual behaviors in adulthood. Critical questions to address include answering what the phenotype of these newly generated cells and determining

whether genesis or survival of BrdU labeled cells underlies the adult sex difference in their number.

Title: Adolescent Bisphenol A exposure leads to enduring alterations in cognition and dendritic spine density in adult rats

Authors: *S. C. DEWOLF[1], M. FRANKFURT[2], V. LUINE[3], H. KHANDAKER[3], R. BOWMAN[1]
[1]Sacred Heart Univ., Fairfield, CT; [2]Hofstra North Shore-LIJ Sch. of Med., Hempstead, NY; [3]Hunter Col., New York, NY

Abstract: Bisphenol-A (BPA) is an endocrine disrupter that exerts effects on a variety of neural, physiological, and behavioral measures. BPA effects during early developmental periods are well established and we have recently shown that adolescent exposure increases anxiety, impairs spatial memory, and decreases neuronal spine density. This study examined whether or not BPA exposure during adolescence (postnatal days [PND] 42-49) leads to behavioral and neural alterations in adulthood. Male and female, adolescent, 6 week old, rats received BPA, 40 µg/kg/bodyweight, or control treatments for one week. At 11 weeks of age, subjects were tested for anxiety (elevated plus maze), spatial memory (object placement), non-spatial visual memory (object recognition), and sucrose preference. In addition, we examined whether adolescent BPA exposure altered serum corticosterone levels in response to a restraint stress challenge immediately prior to sacrifice (13 weeks of age) and measured dendritic spine density in the medial prefrontal cortex (mPFC) and CA1 region of the hippocampus (CA1). BPA-treated males were more anxious as indicated by fewer total visits on elevated plus maze. While adolescent BPA exposure did not alter spatial memory, it did lead to long-term alterations in exploration and

BPA treated males had decreased exploration compared to other groups. On the object recognition task, the ability to discriminate between the old and new objects was decreased in BPA males, but not females. There were no significant group differences in sucrose preference or serum corticosterone levels in response to a stress challenge. However, BPA exposure, regardless of sex, significantly decreased CA1 spinal density on both apical (21% decrease) and basal dendrites (19% decrease) but led to a small, but significant, 5% increase in spine density of basal dendrites in the mPFC. The current data shows that adolescent BPA exposure, at a level below the current reference safe daily limit set by the U.S.E.P.A., leads to enduring alterations in behavior and neuronal morphology.

Title: Long-term effects of adolescent exposure to bisphenol A on neuron and glia number in the rat prefrontal cortex differs between the sexes

Authors: *L. M. WISE[1], R. N. SADOWSKI[2], T. KIM[1], S. L. SCHANTZ[3], J. M. JURASKA[1]
[1]Dept. of Psychology, [2]Neurosci. Program, [3]Comparative Biosci., Univ. of Illinois, Champaign, IL

Abstract: Bisphenol A (BPA), an endocrine disruptor used in a variety of consumer products, has been found to alter neuroanatomical structure in multiple brain areas. However, few studies

have examined long-term effects on the prefrontal cortex, an area where both the number of neurons and glia change during adolescence. In the current study, Long-Evans male and female rats were administered 0, 4, 40, or 400 µg/kg/day BPA during adolescent development (postnatal days 27-46). All other sources of BPA exposure were eliminated for the lifespan of the subjects. In adulthood (postnatal day 150), the number of neurons and glia in the prefrontal cortex were stereologically assessed. There were no changes in the number of neurons, but there was a significant dose x sex interaction in number of glia in the prefrontal cortex ($p=.05$). Pairwise comparisons between controls and each dose show a significant increase in the number of glia between 0 and 40 µg/kg/day in females ($p=.04$), and a trend towards a significant decrease in the number of glia between 0 and 4 µg/kg/day in males ($p=.06$). In order to determine the type of glia cells that are changing in these groups in response to adolescent BPA administration, immunohistochemistry was conducted to assess astrocyte number in the prefrontal cortex. There is a sex difference between male and female control animals with females having fewer astrocytes in layer 5/6 than the males ($p=.04$). There is also a trend towards an increase in astrocytes between 0 and 40 µg/kg/day in females ($p=.08$). There was no change in astrocyte number between 0 and 4 µg/kg/day in males. Ongoing research includes immunohistochemistry to assess the number of microglia to obtain a more complete picture of how BPA exposure during adolescence alters the prefrontal cortex.

Title: Isolation stress during adolescence in mice: Effects on adult behavior and hippocampal glutamate/GABA

Authors: *S. LANDER[1], I. GAISLER-SALOMON[2]
[1]33, Haifa Univ., Nesher, Israel; [2]Haifa Univ., Haifa, Israel

Abstract: The age of onset for many psychiatric disorders is adolescence, a time period characterized by enhanced sensitivity to environmental factors and by accelerated maturation of cortical and hippocampal circuitry. Human and animal studies show that the characteristics of the

social environment during adolescence are particularly crucial to adult brain function and behavior. In this study, we exposed adolescent and adult C57bl/6 male mice to a 3-week social isolation procedure and compared behavioral and gene expression patterns to those exhibited by control group-housed adult mice. Our behavioral battery included several assays of schizophrenia-like behavioral abnormalities: baseline and amphetamine (2 mg/kg)-induced locomotor activity, novel object recognition, and social preference. In addition, we tested reversal learning and extradimensional set-shifting in a modified wet T-maze with spatial and visual cues. In light of recent evidence supporting the involvement of hippocampal glutamate and GABA in susceptibility to schizophrenia, we also tested the effects of adolescent social isolation on gene expression of glutamatergic and GABAergic markers in hippocampal subregions. Results showed anxiety-like behavior and increased object exploration in all isolated mice. Interestingly, impairments in reversal learning and extradimensional set shifting were observed only in mice exposed to isolation stress during adolescence. Also, increased social preference was observed in this group alone. In the amphetamine challenge test, mice exposed to isolation stress during adulthood showed a greater response compared to mice isolated in adolescence. Taken together, these findings indicate that social isolation in adolescence impairs cognitive set-shifting in adulthood but does not disrupt behavior in all tests used to assess schizophrenia-like behavior. Further analysis of gene expression patterns may reveal loci of vulnerability to environmental insult. Combined with predisposing factors that affect hippocampal glutamate levels at early stages of development, adolescent social isolation may act as an environmental “trigger” that sets the stage for the onset of florid schizophrenia symptoms in early adulthood.

Title: The involvement of NMDA receptors in the consolidation and reconsolidation of cocaine place preferences across development

Authors: *A. R. URUENA[1], C. L. KIRSTEIN[2]
[2]Dept. of Neurosci. in Psychology, [1]Univ. of South Florida, Tampa, FL

Abstract: Drug-associated memories are created and stabilized following repeated drug use and have been shown to stimulate drug craving, motivate drug-seeking behavior and thereby increase the likelihood of drug relapse. Similarly, in animal models, repeated cocaine exposure in a specific environment results in a conditioned place preference (CPP) for the drug-paired environment. Glutamate-dependent neuroplasticity may mediate preference expression, as findings have shown pretreatment with the NMDA receptor antagonist, MK-801 disrupts the formation of cocaine CPP. Given that drug use before the age of 18 impacts maturation of neural systems implicated in neuroplasticity, it is critical to investigate the role of NMDA receptors in the acquisition and expression of cocaine-associated memories that underlie place preferences across developmental time periods. To determine if age differentially impacted the effects of routine MK-801 pretreatment on the acquisition of a cocaine conditioned place preference, adolescent (postnatal day (PND) 30) and young adult (PND 60) male Sprague-Dawley rats were pretreated with MK-801 (0.2 mg/kg, i.p.) 30 minutes before each cocaine CPP session (20.0 mg/kg, i.p.; 15 minutes). The effectiveness of acute and routine MK-801 treatment in blocking cocaine CPP expression was also assessed. Regardless of age, MK-801 pretreatment blocked the acquisition of a cocaine CPP, as well as the expression of place preferences following a cocaine challenge. Acute administration of MK-801 attenuated but did not completely block cocaine CPP in both ages examined. Findings suggest that similar mechanisms mediate the acquisition and expression of cocaine CPP across developmental time periods. Place preference attenuation following acute MK-801 exposure suggests that routine MK-801 treatment may be effective in blocking cocaine-associated memories. An alternative explanation may be that additional mechanisms are recruited following repeated cocaine treatment that may be resistant to NMDA antagonism. The observed findings further implicate and expand the role of NMDA receptors in mediating the consolidation and reconsolidation of cocaine-associated memories across development. The effectiveness of acute and repeated MK-801 on suppressing and blocking cocaine preferences, despite re-exposure to the drug itself provides further support for the potential therapeutic value for NMDA receptor antagonists in drug relapse and prevention.

Title: The effects of chronic unpredictable adolescent stress on fosb expression and anxiety-related behaviors during adulthood

Authors: *J. GARDNER GREGORY[1,2], M. WILKIN[3], E. DUMONT[2], J. MENARD[3]
[1]Queens Univ., Montreal, QC, Canada; [2]Ctr. for Neurosci., Queens Univ., Kingston, ON, Canada; [3]Psychology, Queens university, Kingston, ON, Canada

Abstract: It has been observed in rats that chronic unpredictable stress (CUS) during adolescence can cause a decrease in anxiety-like behaviours and an increase in risk-taking behaviours during adulthood. Currently it is unknown what neurological changes occur to rats exposed to CUS during adolescence that would cause these behavioural changes during adulthood. Therefore the aim of the study is to examine the changes in immediate early gene expression in adulthood after a test of anxiety between rats who underwent CUS during adolescents compared to those that did not in order to identify regions of interest. 18 rats were placed in the CUS group and were exposed randomly from post-natal day 35 to 46, to three different stressors twice that included the elevated platform, water immersion and forced swim. 14 control rats were handled in place of the stressors. At post-natal day 84, 12 CUS rats and 8 control rats were tested on the elevated plus maze (EPM) and perfused 2 hours after the test. The remaining 12 animals, 6 CUS and 6 control were perfused with no manipulation to act as a control for the effects of the EPM. Rats that were exposed to CUS during adolescence displayed a greater percent of open arm time and a lesser amount of closed arm time than controls tested on the EPM indicating a potential decrease in anxiety-like behaviours. This behavioural evidence suggests that CUS during adolescence may cause alterations to anxiety circuitry of the brain. Immunohistochemistry was used to examine FOSB immunoreactive (IR) cell count in anxiety related regions of the brain that include the lateral septum (LS) and the oval and anterior medial bed nucleus of the stria terminalis (BNST). We have observed a greater amount of FOSB-IR cell count in the LS of control rats that were tested on the EPM compared to CUS rats tested on the EPM. Moreover, no differences were observed in the LS between CUS rats that were tested on the EPM and CUS rats that were never exposed to the EPM, while controls exposed to the EPM displayed a statistically significant greater amount of FOSB-IR cell count than control rats never exposed to the EPM. CUS during adolescence appears to blunt neuronal activation of the LS when the rat is exposed to the EPM. CUS did not affect FOSB-IR cell expression in the oval and anterior medial BNST. However, exposure to the EPM increased FOSB-IR cell expression in the anterior medial BNST. Differences found in the LS but not in the BNST, may indicate that CUS during adolescence may selectively alter neuronal activation in specific regions in the anxiety circuitry.

Title: Altered sensitivity to cocaine enhancement of reward seeking in DCC haploinsufficient mice

Authors: *L. M. REYNOLDS[1,3], A. J. GIFUNI[3], P. SHIZGAL[4], C. FLORES[2,3]
[1]Integrated Program in Neurosci., [2]Psychiatry, McGill Univ., Montreal, QC, Canada; [3]Douglas Mental Hlth. Univ. Inst., Montreal, QC, Canada; [4]CSBN, Concordia Univ., Montreal, QC, Canada

Abstract: The receptor for the guidance cue netrin-1, DCC, is involved in the development and adult function of the mesocorticolimbic dopamine system. In adulthood, *dcc* haploinsufficient mice exhibit reduced behavioral response to stimulant drugs of abuse, including blunted response to their locomotor activating effects, reduced conditioned place preference, and lack of sensitization upon repeated drug exposure. To further investigate alterations in sensitivity to rewards in *dcc* haploinsufficient mice, we used the curve-shift method to measure cocaine-induced changes in intracranial self-stimulation (ICSS). We assessed (1) whether *dcc* haploinsufficient mice would acquire ICSS behavior at the same stimulation parameters as wild-type controls; and (2) whether cocaine would modulate performance for brain stimulation reward (BSR) similarly in *dcc* haploinsufficient and wild-type mice. To this end, mice were trained to self-administer electrical stimulation of the lateral hypothalamus, thus activating circuitry important for reward and motivated behavior. The vigor of responding was measured as a

function of pulse frequency, yielding curves analogous to pharmacological dose-response functions. These rate-frequency curves were then used to quantify the effect of cocaine on ICSS. The well-established facilitation of ICSS by stimulant drugs of abuse, such as cocaine, is expressed in a leftward curve shift that reflects a reduction in the strength of stimulation required to sustain performance at a given level. Here, we report that *dcc* haploinsufficient mice acquire ICSS behavior at comparable stimulation parameters to wild-type controls, suggesting that the underlying circuitry is functionally similar between the genotypes. However, due to the small sample size and variability in electrode placement, we cannot completely rule out differences in ICSS sensitivity at baseline. When challenged with 10 mg/kg of cocaine, *dcc* haploinsufficient mice exhibited smaller leftward shifts in rate-frequency curves than wild-type controls. However, a 20 mg/kg dose of cocaine produced leftward curve shifts of similar magnitudes in the two genotypes. The ICSS paradigm is often considered a primary screen for abuse liability. It is thus of interest that our results are consistent with decreased sensitivity to the rewarding effects of cocaine and/or decreased proclivity to invest effort in the pursuit of reward.

Title: Adolescent bisphenol-A exposure leads to enduring decreases in dendritic spine density

Authors: *R. E. BOWMAN[1], V. LUINE[2], H. KHANDAKER[2], J. VILLAFANE[1], M. FRANKFURT[3]
[1]Sacred Heart Univ., Fairfield, CT; [2]Hunter Col., New York, NY; [3]Hofstra North Shore-LIJ Sch. of Med., Hempstead, NY

Abstract: Bisphenol-A (BPA), one of the most common environmental endocrine disruptors, is known to modulate estrogenic, androgenic, and anti-androgenic effects throughout the lifespan. The effects of BPA exposure during early organizational periods of development have been well documented. In order to better understand the mechanisms responsible for BPA's effects on the

adolescent brain, male and female rats were exposed to BPA during adolescence (postnatal days [PND] 42-49) and spine density in the medial prefrontal cortex (mPFC) and CA1 region of the hippocampus (CA1) assessed immediately on day 49 (7 weeks of age), and later in adulthood, at 11 weeks of age. In addition, because perinatal exposure to low-dose BPA alters corticosterone levels under both basal and stress conditions in adolescence, we examined whether adolescent BPA exposure altered serum corticosterone levels in response to a restraint stress challenge at 7 and 11 weeks of age, immediately prior to sacrifice. Stress dependent corticosterone responses were not altered by adolescent BPA exposure at either 7 or 11 weeks of age; however, BPA caused a significant decrease in spine density on apical and basal dendrites of pyramidal cells in both the mPFC and CA1. There was also a sex difference in spine density: females had greater spine density than males on basal dendrites of the mPFC and CA1. This sex difference was further augmented by both age and treatment, with overall results indicating that BPA-dependent decreases in spine density were more pronounced in males than females. These results are the first demonstrating that BPA, at levels below the current U.S.E.P.A. recommended safe daily limit, given during adolescence leads to enduring effects on neural morphology in adulthood. Given that humans are routinely exposed to low levels of BPA through a variety of sources, the decreased spine density reported in both male and female rats after BPA exposure warrants further investigation.

Title: Toward a mechanism underlying the effects of neonatal sevoflurane on neuropsychiatric-like behavioral changes

Authors: D. LIN[1], J. LIU[2], J. E. COTTRELL[2], *I. S. KASS[3]
[1]Anesthesiol. and Physiol. and Pharmacol., [2]Anesthesiol., SUNY Downstate, Brooklyn, NY;
[3]Anesthesiol. and Physiol. and Pharmacol., SUNY Downstate, BROOKLYN, NY

Abstract: Converging evidence from human and animal studies show that neonatal exposure to volatile anesthetics increases the risk of learning and memory deficits during adolescence. Perturbation of neurons during a critical developmental time window is associated with numerous neuropsychological disorders in addition to learning and memory deficits. Whether exposure to anesthetics during early brain development impose similar risks and the mechanisms underlying the deleterious effects of volatile anesthetics on the developing brain remain unclear. Previous studies from our lab have shown that the signaling pathway kinase mTOR is involved in sevoflurane (sevo) mediated downstream effects. We hypothesized that exposure to volatile anesthetics such as sevo during the early postnatal period would result in changes in mTOR-related downstream signaling pathway, resulting in behavioral changes. Male C57BL6 mice were exposed to 2% sevo for 2 hours on postnatal day 7(P7). Starting at peri-adolescence P27 and continued until adult (2-3 months), untreated and sevo treated mice underwent a battery of behavioral tests. Hippocampal tissue samples were taken after the completion of behavior tests and examined for changes in gene expression using western blot hybridization. The hippocampus-dependent spatial learning and memory task, Active Place Avoidance, showed that sevo treated mice had significantly more entrances into the shock zone. Social-interaction tests showed that sevo treated mice had significantly decreased interest toward novel social targets compared to the non-sevo treated mice. We confirmed that changes in these behaviors were not due to impairment of olfaction. Additional behavioral tests showed no difference in repetitive behaviors. We then examined changes in the expression of two genes, phosphorylated-mTOR and PKMzeta, a gene that is critically associated with learning and memory and a downstream effector gene of mTOR. Although adult brains showed no change in the expression of these two genes, we are still in the process of analyzing postnatal brains immediately after treatment with sevo. Our lab has confirmed that early life anesthetic exposure impairs cognitive function during peri-adolescent age. We initiated a battery of neuropsychiatric behavioral experiments and demonstrated changes in social interaction. These behaviors have been shown to be impaired in mouse models of neuropsychological disorders, such as Autism Spectrum Disorder. In order to understand the mechanisms underlying the observed changes in behavior, we are investigating changes in genes and microRNA expression from postnatal brains immediate after sevo exposure.

Title: Developmental regulation of mouse midbrain dopamine neuron excitability by small-conductance calcium-activated potassium (SK) channels

Authors: C. FAIRCLOTH, C. BAYER, *A. PLACZEK
Mercer Univ. Sch. of Med., Macon, GA

Abstract: In both human and animal studies, adolescence has been shown to be a period of relative vulnerability to drug addiction. There is accumulating evidence for critical periods of altered excitability and synaptic plasticity during the development of reward-related brain systems. The release of dopamine (DA) from ventral tegmental area (VTA) neurons is an important component of behavioral reinforcement and drug addiction. This is particularly true in the shell of the nucleus accumbens (NAc), where addictive substances have been shown to increase DA release. Action potential firing is probabilistically coupled to neurotransmitter release, and both *in vivo* and *ex vivo* studies have shown an important relationship between action potential firing patterns in VTA DA neurons and the release of DA in the NAc. We have previously reported age-dependent variations in the action potential firing patterns of VTA DA neurons in C57BL/6J mice. In patch clamp studies using brain slices, the VTA DA neurons of adolescent (35-42 day-old) mice fire more action potentials than those of adult mice when depolarized with direct current injection. In contrast, adult (90-120 day-old) C57BL/6J mice fire fewer action potentials with sustained depolarization. The latter firing pattern has been associated with a tendency toward phasic activity, a firing mode that has been linked to both natural reward and the response to addictive drugs. While there are multiple factors that can potentially affect action potential waveforms and firing patterns in VTA DA neurons, previous studies have implicated small-conductance calcium-activated potassium (SK) channels as important regulators of both sustained activity and the shift from tonic to phasic firing. We therefore explored the relative contribution of SK channel-mediated conductances on the intrinsic excitability of VTA DA neurons during both adolescence and adulthood in C57BL/6J mice. Adolescent mice displayed a significant increase in both the apamin-sensitive component of the action potential afterhyperpolarization (AHP), and apamin-sensitive tail-current amplitude. This increased apamin-sensitive current was shown to be a key contributor to sustained action potential firing during adolescence, because bath application of 20 nM apamin resulted in reduced action potential firing, shifting the adolescent firing toward a more adult-like pattern. These findings suggest that adolescent action potential firing patterns lead to increased tonic-like activity and thus reduced dopamine release during excitation. This may therefore increase the probability of binge-like consumption of addictive substances during adolescence.

Title: The effects of social isolation in adolescent rats on cognitive function and prefrontal cortex circuitry in adulthood

Authors: ***D. LINDER**, I. GAISLER-SALOMON
Haifa Univ., Haifa, Israel

Abstract: The "two-hit" hypothesis of schizophrenia (SZ) states that genetic and/or early environmental factors lead to developmental disruption of the CNS, increasing vulnerability to future environmental stressors. Animal studies have shown that exposing adolescent rats to social isolation leads to the emergence of behavioral and neurochemical changes in adulthood that mimic pathophysiological features of SZ. Currently, few studies have addressed the contributions of individual differences in social and cognitive functions to this effect, although deficits in cognitive and social function are good predictors of patient outcome and exist in milder form in high-risk populations. Here, we screened rats for social preference in pre-adolescence (P25) and subjected them to two weeks of social isolation or social rearing during mid-adolescence. In adulthood, rats that exhibit high social preference in pre-adolescence exhibit deficits in reversal learning, regardless of housing conditions. However, as the cognitive demand increased, i.e. in an extra-dimensional set-shifting task, this effect was moderated by isolation stress, so that rats high in social preference reared in isolation performed set-shifting faster than isolated rats with low social preference. These results suggest that cognitive functions are influenced by individual differences in social preference as well as social stress in adolescence, but in a task-dependent manner. Guided by the hypothesis that predispositional and environmental factors converge to affect the balance between excitatory (E) and inhibitory (I) transmission in the prefrontal cortex (PFC), we studied the effect of early social factors combined with social or isolation rearing on the E/I balance in the PFC. This study could contribute to our understanding of the relative importance of predispositional and environmental influences on SZ risk and resilience.

Title: Antischizophrenic properties of dietary choline supplementation during adolescence: Comparing outcomes in the DISC1 knockout rat and chronic MK-801 models

Authors: A. A. BATALLAN, N. K. ZIV, W. YU, J. R. MITCHELL, A. S. MOORE, C. EVANGELISTA, *M. J. GLENN
Psychology, Colby Col., WATERVILLE, ME

Abstract: Schizophrenia is a debilitating psychological disorder characterized by a constellation of positive, negative, and cognitive symptoms. While a great deal is known about the underlying neural abnormalities that contribute to these symptoms, the etiological bases for the disorder remains elusive. It is clear, however, that development of the disorder rests significantly on genetic and experiential factors. Reproducing these factors, or the neurochemical abnormalities, in non-human animal models is a powerful research tool with the potential to greatly enhance our understanding of the disorder and enable the investigation of variables that may attenuate or prevent symptoms. Mounting evidence from our lab and others compelling points to the antischizophrenic properties of the essential nutrient choline. In the present work, we continued our investigation into the ways in which choline may be antischizophrenic and did so in two models: with a genetic DISC1 knockout or chronic MK-801 treatment. DISC1, or disrupted in schizophrenia1, is a significant risk gene that codes for proteins that contribute in various ways to neuron migration, function, and plasticity. DISC1-knockout rats lack both copies of the gene and we report here robust positive and negative symptoms in them. Interestingly, choline supplementation in adolescence resulted in mixed effects on adult symptoms: it modestly, though significantly, attenuated the negative symptom of anxiety, failed to combat the positive symptom of hyperactivity, and resulted in worse memory function than seen in standard-fed DISC1 rats. In the pharmacological model, rats were given daily injections of the NMDA antagonist, MK-801 (1 mg/kg) for 14 days. This significantly impaired pre-pulse inhibition (PPI), a hallmark symptom in schizophrenia, and adolescent choline supplementation completely prevented that

effect. Taken together, these results add to the growing literature that dietary choline may exert protective effects on neural systems that are dysfunctional in schizophrenia, yet there may be some specificity to the protection. Adding to this work, we also report that choline supplementation significantly enhanced cognitive flexibility in an attention set-shifting task, an analog of the Wisconsin card-sorting test that reveals the characteristic hypofrontality in humans with schizophrenia. This finding aligns well with our work in the rat schizophrenia models and future directions aim to investigate PPI and cognitive flexibility in DISC1 knockout rats to further characterize their phenotype and to systematically investigate the interaction of the genotype and choline availability.

Title: Adolescent cannabinoid treatment and persistent frontostriatal endocannabinoid signaling gene changes in mice and humans

Authors: *S. MUKHERJEE, K. GLEASON, A. SHUKLA, S. BIRNBAUM, S. GHOSE
Dept. of Psychiatry, UT Southwestern Med. Ctr., DALLAS, TX

Abstract: Cannabis is the most commonly abused drug in the United States. 2.1 million Americans used cannabis for the first time in 2007; of them 62.2% were less than 18 years old. This is of particular health concern given the association between adolescent cannabis use and adult onset of psychosis. Schizophrenia did not develop days or weeks after cannabis use, but years later, suggesting that cannabis use during a critical period of brain maturation may lead to long-term effects. We conducted a series of experiments to examine the long-term consequences of adolescent cannabinoid exposure on the endocannabinoid system. Mice were administered with a cannabinoid receptor 1 (CB1) agonist, (WIN 55,212-2) or vehicle for 10 days by I.P. injection at different developmental time points (5, and 9 weeks). At 16-18 weeks of age,

behavioral tests were carried out followed by molecular studies 2 week after the last behavioral test. Mice administered WIN 55,212-2 (WIN) at 5 weeks of age display significant deficits in PPI and fear conditioning learning and memory paradigm. These behavioral deficits were not observed in mice treated with the CB1 agonist at later developmental time points. Group I metabotropic glutamate receptor (mGluR) activation drives endocannabinoid synthesis and release and we previously reported changes in CB1 and mGluR5 expression patterns in the hippocampus. Here, we extend those studies, examining endocannabinoid genes in the frontal cortex and striatum in mice and a human post mortem tissue cohort of control and schizophrenia cases divided into individuals with and without a significant adolescent cannabis use history. Mice treated with WIN 55,212-2 at 5 weeks of age show a distinct profile in CB1 and mGluR5 the frontal cortex and striatum. There is a significant upregulation of CB1 in both the frontal cortex and striatum while mGluR5 protein levels demonstrated a bidirectional expression pattern with significantly increases in the frontal cortex and strong trend to reduction in the striatum. Our pilot human studies (n=5 per group) show a similar profile with higher levels of CB1 and mGLuR5 (effect size >0.6) in the prefrontal cortex (BA9) of schizophrenia cases with adolescent cannabis use history. These data suggest that adolescent cannabinoid administration leads to regionally specific persistent changes in the endocannabinoid pathway. These data may be relevant to understanding the long term sequelae of significant adolescent cannabis use and may be of particular importance in understanding mechanisms by which adolescent cannabinoid exposure leads to molecular changes predisposing to schizophrenia.

Title: The timing of neuroanatomical changes across adolescence in the male and female rat medial prefrontal cortex

Authors: *J. WILLING[1], T. KIM[2], J. M. BRODSKY[3], L. R. CORTES[3], J. JURASKA[1]
[1]Psychology, Univ. of Illinois, Champaign, IL; [2]Psychology, [3]Neurosci. Program, Univ. of Illinois at Urbana Champaign, Champaign, IL

Abstract: Adolescence is a critical period for brain maturation, characterized by the reorganization of many interacting neural networks. The medial prefrontal cortex (mPFC), a region highly involved in executive function, is particularly known to undergo synaptic pruning during this time. Disruptions of normal mPFC development have been associated with a variety of clinical disorders including schizohprenia, ADHD and depression. We have previously shown that rats lose neurons in the mPFC between adolescence and adulthood, with more prominent losses being observed in females. Additionally, previous data from our lab show that an increase in ovarian hormones at puberty play a significant role in neuronal loss in females, as OVX prevented this cellular loss. In the present study, we track neuronal and glial changes in the male and female mPFC at multiple time points from preadolescence to adulthood (P25, P35, P45, P60 and P90). Our preliminary analysis confirmed a greater neuronal loss in the female mPFC between adolescence and adulthood, and that the timing of neuronal loss in females coincides with the onset of puberty (between P35 and P45). The timing of loss was not as obviously discernible in males in this preliminary sample. In addition to adding animals to the analysis of cell number in the mPFC, we will also characterize levels of tyrosine hydroxylase immunoreactivity, representing dopaminergic axons innervating the region, at the time points mentioned previously. Elucidation of the precise timing of cellular pruning of the mPFC may have clinical implications with respect to mental illnesses characterized by mPFC dysfunction and the observed sex differences in prevalence of these disorders.

Title: Sleep deprivation at juvenile age causes alterations in cortical GAD67 levels in juvenile mice and induces prepulse inhibition deficit in adult female mice

Authors: *C. MONPAYS, A. TREMEY, J. DESLAURIERS, W. RACINE, K. ASLI, P. SARRET, S. GRIGNON
Physiol. and Biophysics, Univ. De Sherbrooke, Sherbrooke, QC, Canada

Abstract: Age at onset plays a significant role in the pathophysiology, clinical presentation and prognosis of bipolar affective disorder (BAD). In the present study, we assessed whether the sleep deprivation (SD) model of mania, which has been well-validated in adult rodents, could be successfully implemented in juvenile animals. We previously demonstrated that SD at juvenile age induced a PPI deficit in both males and females, compared to non-sleep-deprived animals. However, when SD was performed in adulthood (post natal day (PN) 70), we did not observe differences as compared to control. The fact that PPI deficits are only observed when SD is induced at juvenile age, but not during adulthood, supports the hypothetical interaction between age at onset and apparition of pathophysiological mechanisms. To verify this hypothesis, we compared a third group, submitted to juvenile SD and to behavioral tests at adult age, and we evaluated the involvement of relevant neurochemical parameters in the juvenile model. To induce SD, C57BL/6 mice were placed on a small 3-cm-diameter platform. When mice fell asleep, muscle tone relaxation made them fall into the water and provoked awakening. In the control condition, mice were placed on a larger 10-cm-diameter platform, compatible with uninterrupted sleep. Sleep deprivation was induced for 72 hours, from postnatal (PN) days 33 to 35. On PN70, sensorimotor gating deficits, mouse exploratory behaviors and social interaction were determined by investigating the prepulse inhibition of the acoustic startle response (PPI), open-field task and resident-intruder test, respectively. We also evaluated, by immunoblotting and qPCR, the protein and mRNA levels of dopamine D2 receptor and GAD67 in the prefrontal cortex (PFC). SD induced a PPI deficit in juvenile mice, which persisted in adult females (PN70) (-17.48%; $p<0.01$ compared to control group) but not in adult males. Preliminary results in juvenile mice showed a decrease, at trend levels, in dopamine D2 receptor protein levels in the PFC of female mice. Moreover, we observed an increase, at trend levels, in cortical GAD67 protein and mRNA expression in both sexes. We found here that juvenile SD induces a PPI deficit that is persistent only in adult females, in line with some epidemiological features of the condition. Interestingly, we also observed a trend for increased GAD67 protein and mRNA levels in the PFC, in contrast with the schizophrenia model developed in our laboratory (Deslauriers et al, 2013). This work may help to explore the pathophysiological differences between early stage schizophrenia and BAD.

Title: Altered female sexual receptive behavior after adolescent social isolation in mice

Authors: *G. MAJDIC[1], J. KERCMAR[2], S. A. TOBET[3]
[1]Univ. of Ljubljana, Vet. Fac., Ljubljana, Slovenia; [2]Ctr. for animal genomics, Univ. of Ljubljana, Ljubljana, Slovenia; [3]Colorado State Univ., Fort Collins, CO

Abstract: Exposure to stress during puberty can cause long lasting consequences in brain development and consequently changes in behavior in adult rodents. During this time the brain remodels and reorganizes as a function of sex steroid hormone actions. Stress hormones also could influence this development. Social isolation present a stress for social animals like mice, but little is known about effects of such stress during adolescence on reproductive behaviors. The present study examined the sexual behavior of ovariectomized, estradiol and progesterone primed female mice that were individually housed from 25 days of age until testing at approximately 95 days, or individually housed from day 25 until day 60 (during puberty), followed by housing in social groups. Mice in isolated groups were compared to females that were housed in social groups throughout the experiment. Receptive sexual behaviors of females and behaviors of stimulus males were recorded. Females housed in social groups displayed greater levels of receptive behaviors in comparison to both socially isolated groups. Namely, social females had higher lordosis quotients and more often displayed better lordosis postures in comparison to isolated females. No differences between female groups were observed in stimulus male behavior suggesting that female 'attractiveness' was not affected by their social isolation. Females housed in social groups had less area containing immunoreactive estrogen receptor α in the anteroventral periventricular nucleus (AVPV) and the ventromedial nucleus of the hypothalamus (VMH) than both socially isolated groups. These results suggest that isolation during adolescence affects female sexual behavior and re-socialization for one month in adulthood is insufficient to rescue lordosis behavior from the effects of social isolation during the pubertal period.

Abstract: The estimated prevalence of depression during pregnancy is 20%. Treatment of depression in this critical period raises the question about safeness of antidepressant therapy. The Most common treatment for maternal depression is selective serotonin reuptake inhibitor (SSRI) medications, e.g. Prozac (fluoxetine), which are prescribed to 5-10% of pregnant mothers. SSRIs cross the placental and blood-brain-barrier and are transferred, via breast milk, to the infant. This increased level of serotonin (5-HT) due to prenatal flouxetine treatment may interfere with functional maturation of the brain and can differentially affect neuronal plasticity of both, the mothers and their offspring. Previous work we have done shows that developmental exposure to fluoxetine affects hippocampal neurogenesis in both adolescent and adult offspring. Therefore the aim of this study was to evaluate the effect of flouxetine administration during sensitive functional brain development on hippocampal neurogenesis of the rat dams and their juvenile male and female offspring (P21). Pregnant Sprague-Dawley rats were subject to stress during gestation and were treated with fluoxetine (10 mg/kg/day) prior to parturition and throughout lactation. Animals from the following four groups were used were used: 1. Control+Vehicle (CV), 2. Control+Fluoxetine (CF), 3. Prenatal Stress+Vehicle (PSV), 4. Prenatal Stress+Fluoxetine (PSF). Preliminary results show that developmental fluoxetine exposure, but not maternal prenatal stress, significantly decreases the number of new immature neurons in the dorsal hippocampus of juvenile male and female offspring ($p=.024$). Furthermore, there were no signitifcant effects of prenatal stress or developmental fluoxetine exposure on the number of tryptophan-hydroxylase (TPH) positive cells in the dorsal raphe nucleus in juvenile offspring. Future work will assess the relationship between circulating levels of fluoxetine and norfluoxetine and measures of neural plasticity, as well as any effects on hippocampal plasticity in the dam. Understanding the impact of developmental exposure to SSRI medications will improve our understanding of the benefits and risks of this treatment for maternal mood disorders.

Title: Developmental SSRI exposure decreases serotonin and 5-HIAA levels in the PFC, but not the hippocampus, of prenatally stressed juvenile offspring

Authors: *M. GEMMEL[1], I. RAYEN[2], E. VAN DONKELAAR[2], H. W. STEINBUSCH[2], N. KOKRAS[3], C. DALLA[3], J. L. PAWLUSKI[1,2,4]

Abstract: Selective serotonin reuptake inhibitor (SSRI) medications are the most frequently used antidepressant treatment for maternal mood disorders during pregnancy and in the postpartum period. The ability of these antidepressant medications to cross the placental barrier suggests possible impact on fetal development. Likewise, serotonin has been shown to play a significant role in stress regulation and fetal development. Thus, investigation of SSRIs and their effects on the serotonergic system is crucial in understanding key aspects of development. The aim of this study was to determine the effect of the SSRI medication, fluoxetine, on both maternal and offspring serotonergic systems. Sprague-Dawley rat dams were subjected to stress during gestation and were treated with fluoxetine (5mg/kg/day) or vehicle via osmotic minipumps. Animals from the following four groups were used: 1.Control+Vehicle (CV), 2.Control+Fluoxetine (CF), 3.Prenatal Stress+Vehicle (PSV), 4.Prenatal Stress+Fluoxetine (PSF). At weaning, brains of male and female offspring and the dam were collected. Half the brain was used to assess serotonin (5-HT) and its metabolite, 5-hydroxyindoleacetic acid (5-HIAA), levels in the hippocampus and prefrontal cortex. Preliminary results show that at weaning, developmental fluoxetine exposure markedly decreases 5-HT ($p=.06$) and 5-HIAA levels ($p=.02$) in the prefrontal cortex of prenatally stressed offspring ($p=.02$), with no significant differences between groups in 5-HT or 5-HIAA levels in the hippocampus. In dams, the ratio of 5-HIAA/5-HT, an indication of serotonin (5-HT) metabolism, was significantly lower in the

prefrontal cortex of dams administered fluoxetine (p=.036). Furthermore, in the hippocampus there was a significant interaction effect of stress x fluoxetine (p=.006) with PSV dams having significantly higher 5-HT metabolism compared to CV and PSF dams. Further work will investigate the effect of developmental fluoxetine exposure on neuronal and synaptic plasticity in the hippocampus and prefrontal cortex. Understanding the impact of developmental exposure to SSRI medications on the serotoninergic system and neurodevelopmental processes will further enhance our understanding of the benefits and risks of these medications.

Title: Gene expression throughout human postnatal development in single cell populations in the prefrontal cortex

Authors: *E. KOHLBRENNER, *. WOO
McLean Hospital; Harvard Med. Sch., Belmont, MA

Abstract: Schizophrenia (SZ) is a neurodevelopmental disorder that has been associated with pre- and peri-natal insults such as maternal illness and poor nutrition during fetal development, as well as the season of birth and certain childhood infections. It is likely that hereditary factors also play a role. Together these genetic and environmental insults may explain, at least in part, cognitive deficits throughout childhood in things like attention, memory, and impulse control. For most individuals, however, the onset of the overt symptoms and deficits of schizophrenia do not occur until late adolescence or early adulthood, suggesting that additional events occurring during the peri-adolescent period contribute to the onset of illness. The prefrontal cortex (PFC), an area that has consistently shown severe disturbances in SZ, undergoes a very protracted course of maturation; it does not reaching full competence until the late teens- similar to the age

of onset of the overt symptoms and deficits of schizophrenia. Parvalbumin (PV) inhibitory neurons are found throughout the cerebral cortex and are known to coordinate the critical periods of development, as well as regulate maturation plasticity of the brain, placing them at the forefront of faulty plasticity research that includes neurodevelopmental disorders such as schizophrenia and autism. Malfunction of PV cells during adolescence can dismantle the synchronization of pyramidal neuronal circuits that is critical for the functional maturation of PFC connectional architecture, compounding on previous environmental insults and contributing to the onset of disease.We profiled gene expression (Affymetrix microarray)changes in laser-captured PV-immunolabeled neurons in layer 3 of Brodmann's area 9 of the PFC during normal human peri-adolescent development in order to understand genes and molecular pathways that underlie the maturation of these neurons. We examined a cohort of 18 normally developing individuals, 1-24 years old. Three groups were formed for comparison: 6 Pre-pubescent, 6 pubescent, and 6 post-pubescent. So far in pyramidal neurons, TGFβ signaling, EGFR signaling, folic acid network, cytoplasmic ribosomal proteins, mRNA processing, ubiquitin-mediated proteolysis and SNARE-mediated vesicular transport are among the pathways that are most significantly differentially regulated during peri-adolescent development. Interestingly, TGFβ signaling also appears to be dysregulated in layer 3 pyramidal neurons from the PFC in SZ. Comparison of these findings with gene expression changes in schizophrenia will shed light onto the developmental pathophysiology of schizophrenia onset.

Abstract: Background: Epigenetic regulation of gene expression is an important mechanism by which the brain coordinates its transcriptome, with modifications of histone proteins encoding the use or disuse of neuronal projections (Sharma, 2005; 2011; 2012). The best demarcated brain system, from input to encoding, is the visual system, making it ideal to investigate the kinetics of chromatin remodeling. In this system, light deprivation increases H3K27 methylation and decreases H3K9 acetylation binding to the trophic factor BDNF, decreasing gene transcription (Karpova, 2010). Pharmacologically induced increases in acetylated histone modifications can reverse the effects of monocular light deprivation (Silingardi, 2011). It is our hypothesis that chronic misuse or disuse will result in an accumulation of experience-dependent chromatin remodeling, allowing for kinetics of these changes in neuronal systems to be modelled. Methods: C57BL/6 strain male mice were weaned at PND 21 into either ocular deprivation (24h dark) or normal light conditions. Food and water was available ad libitum. Occipital cortices were removed upon euthanasia and snap frozen in 2-methylbutane. mRNA levels were measured through Real-Time RT PCR, and DNA-protein interactions through Chromatin Immunoprecipitation. Results: There were ocular deprivation-dependent changes of selected genes relating to relevant plasticity factors, known chromatin modifying enzymes and transcription factors. Coordinate changes in mRNA expression were associated with significant differences in promoter-specific H3K9me2 binding. Discussion: Through using the visual system as a model, termination of sensory input results in an accumulation of a transcriptionally restrictive landscape, allowing for a characterization of the kinetics of histone modification formation. This experience-dependent chromatin manipulation has important implications for both understanding and identifying potential treatment targets of neurocognitive disorders, stroke, rehabilitation for limb injury, loss and movement disorders.

Title: Ontogeny of circadian rhythms in the suprachiasmatic nucleus

Authors: A. T. C. SUN[1], C. L. SIMMS[1], *E. D. HERZOG[2]

Abstract: The mammalian suprachiasmatic nucleus (SCN), situated in the hypothalamus, is directly above the optic chiasm and a master circadian pacemaker. The SCN produces endogenous rhythms in gene expression to regulate daily rhythms in physiology and behavior. Although the function of the SCN is well studied in adult mammals, the ontogeny of SCN function is less well understood. We hypothesized, based on 2-deoxyglucose data, that SCN neurons initiate intrinsic circadian rhythmicity *in utero* and synchronize to each other when the neuropeptide, vasoactive intestinal polypeptide (VIP) is expressed. We monitored PER2::Luciferase, a bioluminescent reporter for PER2 levels, in fetal SCN explants. We found that SCN explants exhibited rhythms in PER2 expression as early as embryonic day 14.5 (E14.5) and the amplitude of the rhythms increased in later ages. However, PER2 expression was arrhythmic in E13.5 explants. From embryonic day 15.5 to postnatal day 3, most slices were circadian, and, from P5, all slices were circadian. Single cell imaging of fetal SCN explants revealed rhythmic and synchronized cells by E17.5. Consistent with these results, we found that VIP expression was present by E17.5 with more cells expressing VIP in later fetal stages. Our findings support the conclusion that the embryonic SCN is capable of producing daily rhythms in gene expression starting at E14.5 and, by E17.5, VIP expression supports synchrony among SCN cells.

Title: The effect of metformin on the developing central nervous system (cns), using *Drosophila* melanogaster

Authors: *N. DEWITTE[1], T. WILLIAMS[2], N. LEELANI[1]
[2]Biology/Neuroscience, [1]Trinity Univ., San Antonio, TX

Abstract: Type 2 Diabetes affects more than 26 million Americans, and the number of those diagnosed continues to rise. The Center for Disease Control estimates that 1 in 3 U.S. adults could have diabetes by 2050. A drug commonly prescribed to treat those with Type 2 Diabetes is Metformin. It is used in combination with exercise and diet in order to help control blood sugar levels in patients. While Metformin has shown significant success with treating Type 2 Diabetes, little is known about its long term effects on juveniles, especially as it relates to the developing brain. Therefore, the purpose of our research is to determine the effects of Metformin on the developing central nervous system (CNS), using *Drosophila melanogaster* as an animal model. Our results show flies exposed to high concentrations of metformin (39%), when compared to control (100%) or low-dose metformin (100%) exposed flies, leads to reduced viability in which flies do not develop beyond the third instar larval stage. Furthermore, we have shown the mRNA expression level of Neuroligin 4 is reduced by 50% for flies fed a high-dose of metformin as compared to controls or flies maintained on a low-dose metformin diet. Therefore, we predict daily exposure to metformin during early development can lead to altered CNS development.

Title: Serotonin suppresses and enhances temporoammonic path-CA1 responses *in vivo*

Authors: *J. GONZALEZ[1], B. E. DERRICK[1,2]
[1]Biol., U Texas San Antonio, San Antonio, TX; [2]The Neurosciences Res. Inst., San Antonio, TX

Abstract: Temporoammonic path (TAP) afferents arising from layer III of the entorhinal cortex convey cortical input directly to area CA1 of the hippocampus, and are thought to contribute to a variety of memory functions in the hippocampus, such as long-term memory and match-mismatch functions. Previous investigations reveal conflicting findings of serotonergic effects on TAP-CA1 synaptic responses, including suppression or enhancement of TAP-CA1 responses *in vitro* (Otmakhova & Lisman 2000; Otmakhova et al. 2005; Cai et al. 2013). Here we examine the neuromodulatory impact of serotonergic re-uptake inhibitors and releasers on medial TAP-CA1

responses *in vivo*. In urethane anesthetized animals, a consistent and reversible reduction in medial TAP-CA1 responses was observed following an acute, systemic injection of fluoxetine (10 mg/kg), a selective serotonin re-uptake inhibitor. Medial TAP-CA1 responses were maximally depressed at 1 hr and approached baseline levels 2 hr after fluoxetine injection. This effect appears to be limited to TAP-CA1 synapses as simultaneous recordings of commissural CA3-CA1 (cCA3-CA1) responses showed no change in amplitude following fluoxetine administration. As vehicle-treated animals did not exhibit decreased amplitudes of medial TAP-CA1 responses, these data suggest serotonin selectively suppresses medial TAP-CA1, not cCA3-CA1, neurotransmission following fluoxetine delivery *in vivo*. By contrast, intraperitoneal injection of d-fenfluramine (10 mg/kg), a selective serotonin releaser and re-uptake inhibitor, in anesthetized animals induced variable observations of either a robust increase in the amplitude of medial TAP-CA1 responses lasting more than 2 hr or a reversible reduction in medial TAP-CA1 responses. Although fluoxetine and d-fenfluramine both augment extracellular serotonin concentration, our data demonstrate serotonergic activity can suppress or enhance TAP-CA1 responses *in vivo*. As d-fenfluramine induces a more robust increase of synaptic serotonin levels when compared to fluoxetine, our data suggest variations in synaptic serotonin concentration may regulate bidirectional changes in TAP-CA1 responses via actions on distinct serotonin receptors.

Title: Nitrosylation of vesicular neurotransmitter transporters

Authors: *Y. WANG[1], H. TAN[1], Z. ZHOU[1], Y. SUN[1], S. ZHU[1], X.-M. LI[2], J.-F. WANG[1]

Abstract: Brain is the main site for oxygen consumption (80%), making the brain cells vulnerable to production of reactive oxygen/nitrogen species (ROS/RNS). Vesicular transporters

such as vesicular monoamine transporter 2 (VMAT2) vesicular glutamate transporter 1 (VGluT1) and vesicular glutamate transporter 2 (VGluT2) are key proteins for packaging and uploading neurotransmitters into vesicles. These transporters have high density of cysteine residues that are susceptible to ROS/RNS attack. Therefore we determined whether nitric oxide radical donor S-nitrosoglutathione (GSNO) induces nitrosylation of VMAT2, VGluT1 and VGluT2 and whether GSNO regulates vesicular uptake activity of glutamate in mouse brain. Cysteine nitrosylation of the transporters was measured by biotin-switch method followed by immunoblotting analysis, and tritium labeled glutamate was used to measure the uptake of glutamate by vesicles. We found that GSNO at 80 uM GSNO treatment significantly increased nitrosylation of VMAT2, VGluT1 and VGluT2 and inhibited the uptake of glutamate by vesicles. Our finding suggested that nitrosylation of vesicular transporters may play a role in the regulation of monoamine and glutamate neurotransmission.

Title: Stimulation of glutamate receptors on on- and off-cone bipolar cells leads to increased release of [3h]glycine in rat retina

Authors: *L. G. HARSING, Jr.[1], G. SZENASI[2], A. HANUSKA[1], A. SZABO[1], M. ALBERT[3]
[1]Dept. of Pharmacol. and Pharmacotherapy, [2]Dept. of Pathophysiology, Semmelweis Univ., Budapest, Hungary; [3]Ceva-Phylaxia, Budapest, Hungary

Abstract: Glutamate release establishes neuronal communication in the synapses of cone photoreceptors and bipolar cells as well as between bipolar and ganglion cells in the retina. This communication exhibits characteristic segregation of glutamate receptors. In the outer plexiform layer of the retina, AMPA ionotropic and mGluR6 metabotropic glutamate receptors are expressed in Off and On bipolar cells, respectively. Moreover, GABAergic and glycinergic

amacrine cells possess AMPA receptors, whereas Off- and On-type ganglion cells contain N-methyl-D-aspartate (NMDA) receptors in the inner plexiform layer. In this study, we have investigated the effects of various glutamate receptor agonists on [3H]glycine release from amacrine cells using posterior eyecup preparations lined by the retina. This preparation was made from rat eye, loaded with [3H]glycine and its release was determined by low-volume superfusion technique combined with scintillation spectrometry. The group III mGluR agonist L-(+)-2-amino-4-phosphonobutyric acid (L-AP4, APB), which blocks neurotransmission between cones and On bipolar cells, suppresses light-evoked activity in the On parallel pathway. Addition of L-AP4 in a concentration of 0.1 mM increased electrical stimulation (20 V, 10 Hz, 2 msec for 3 min)-induced [3H]glycine release. The AMPA glutamate receptor agonist (RS)-α-amino-3-hydroxy-5-methyl-4-isoxazoleproprionic acid (AMPA), which stimulates neurotransmission between cones and Off bipolar cells, increases dark-evoked activity in the Off parallel pathway. AMPA added in concentrations of 0.01 to 1 mM in combination with the positive allosteric modulator cyclothiazide (0.03 mM) also increased [3H]glycine release from isolated retina preparation. The AMPA receptor antagonist GYKI-53405 (0.05 mM) decreased electrically evoked [3H]glycine release and reversed the AMPA-stimulated [3H]glycine release. In the retinal circuitry, GABAergic amacrine cells negatively influence On pathway and glycinergic amacrine cells exert similar inhibitory effect on Off pathway. The two parallel pathways may communicate via amacrine-amacrine cell interactions. In the dark, when On pathway is inactivated, less GABA and more glycine may be released from the amacrine cells, whereas the activated Off pathway may directly enhance glycine release. An opposite shift in GABA and glycine release from retinal amacrine cells may occur in the light. This dual regulation of [3H]glycine release from amacrine cells may have a role in center-surround properties of the inner retinal neurons.

Title: Spontaneous depolarization waves in medetomidine sedated Sprague-Dawley rats detected by fMRI

Authors: *A. SHATILLO[1], J. HUTTUNEN[1], A. AIRAKSINEN[1], J.-P. NISKANEN[2], O. GROHN[1]
[2]Dept. of Applied Physics, [1]Univ. of Eastern Finland, Kuopio, Finland

Abstract: Medetomidine is a highly specific a2-adrenoreceptor agonist that has recently been increasingly used as an anesthetic in experimental fMRI in rodents. Spreading depolarization (SD), a wave of neuronal depolarization moving across the cortex with a speed of 2-6 mm/min, is known to take place in number of neurological diseases. Here we report our findings of spontaneous SDs in medetomidine sedated Sprague-Dawley rats during prolonged (1h) BOLD fMRI imaging. Adult male Sprague-Dawley rats (n=9, 455 ± 65 g) were tracheotomized and cannulated prior to imaging for artificial ventilation, physiological monitoring and drugs administration. Bolus injection of medetomidine was given i.v. (Domitor, 0.05 mg/kg) followed by a continuous subcutaneous infusion (0.1 mg/kg/h) 5 min later. The fMRI data were acquired using 9.4T MRI scanner with a single-shot spin-echo echo planar imaging (SE-EPI) sequence (TR 4 s, TE 40 ms, 15x1.5 mm slices, in-plane resolution 0.4 mm) for 1 h 7 min (1000 images). We recorded total of 17 (2.1 ± 1.4 per animal, mean ± std) spontaneously occurring SDs. Site of the onset and propagation patterns were heterogeneous, varying even within one animal between repeated SDs. Most of the waves originated unilaterally from inferior cortical areas in medial and posterior parts of rat brain and subcortically. Mean duration of activation in a ROI was 193.3 ± 58.8 sec propagating in cortical regions with speed of 2.93 ± 0.6 mm/min. Observed features (spreading pattern and involvement of subcortical regions) were not typical for commonly reported spreading depression. There are reports of increased acoustic hyperexcitability in medetomidine sedated animals which can cause a SD upon strong auditory stimulation. Therefore acoustic stimulation during EPI fMRI imaging can be a triggering factor for spreading depression. Spontaneous depolarizations are clearly a potential confounding factor for fMRI studies in rats and origin of them should be studied in more detail. **Figure 1.** BOLD activation maps of one spreading depolarization in one representative case.

Title: Fast scan cyclic voltammetric recording of dopamine release in the mouse ventral pallidum

Authors: *K. STOUT[1], G. W. MILLER[2], T. S. GUILLOT, III[2]
[1]Envrn. Hlth., [2]Emory Univ., Atlanta, GA

Abstract: The ventral pallidum (VP) is a region of emerging importance in addiction research that is thought to mediate the translation of limbic motivation into motor output. The VP receives dopaminergic inputs from the ventral tegmental area, as well as GABAergic inputs from the nucleus accumbens. In turn, the VP projects to the pedunculopontine nucleus of the brainstem. Disruption of this pathway via VP lesioning ablates the increased locomotor response to stimulant administration in rodents. Further, rodents self-administer both drugs of abuse and direct electrical stimulation in the VP. Dopamine release in the VP likely plays an important role in these behaviors, though it has not been characterized in the literature. Using fast scan cyclic voltammetry (FSCV), we measured dopamine release in the VP of mouse brain slices. Optimal stimulation parameters (60 pulse, 60 hz, 700 μA, 4 ms, monophasic +) yielded 1.67 μM dopamine release, on average. Electrode placement in the VP was confirmed structurally and pharmacologically. D2 receptor antagonism with eticlopride resulted in a 50.7% increase in stimulated dopamine release, likely due to inhibition of presynaptic autoreceptors. Additionally, dopamine transporter inhibition with nomifensine increased stimulated release by 52.1%, which is substantially lower than nomifensine-induced release potentiation in the dorsal and ventral striatum. This effect is due to low expression of the dopamine transport within the VP. Finally, as dopamine and norepinephrine produce similar voltammagrams, we applied A2A receptor antagonist, idozoxan, which enhances norepinephrine signal in regions rich in noradrenergic innervation. The drug did not significantly increase stimulated release, further suggesting dopamine as the primary electroactive neurotransmitter in the VP. Following FSCV experiments, the slices were lesioned and electrode placement further confirmed using the hydrogel lipid-clearing method, CLARITY. Dopamine transporter immunofluorescence in clarified slices confirmed that the lesioned recording site does not co-localize with the dopamine transporter, verifying that we were not recording in striatal regions. As drugs of abuse affect VP signaling, modulation of VP dopamine signaling by methamphetamine was also investigated. Measurement of dopamine release in this region will provide the basis for further investigation of proteins that may contribute to dopamine neurotransmission, such as the synaptic vesicle glycoprotein 2C, which is highly enriched in the VP. Funded by 1F31DA037652-01.

Title: Neurotransmitter specificity in G-protein signaling cascades revealed by slowed activation of CaV2.2 channels

Authors: *D. E. GARCIA-DIAZ, L. DE LA CRUZ, I. ARENAS
Univ. Nacional Autonoma Mexico, Mexico DF 04510, Mexico

Abstract: Neurotransmitters and hormones such as noradrenaline, vasoactive intestinal polypeptide, somatostatin and gonadotropine releasing hormone have diverse modulating effects. One common means by which they affect cell function is via voltage-dependent inhibition of CaV2.2 channel. Neurotransmitter-induced calcium channel regulation is often by G-protein coupled receptors (GPCR) activation. However it is unknown which molecules in the GPCR signaling pathway determine a neurotransmitter's specificity in voltage-dependent regulation. As Gβ subunits directly mediate voltage-dependent inhibition of CaV2.2 channels, one possibility is that Gβ subunits mediate this specificity. Several neurotransmitters and hormones acting through GPCR elicit a voltage-dependent regulation of CaV2.2 channels, having profound effects on cell function and the organism. It has been hypothesized that protein-protein interactions define specificity in signal transduction. Yet it is unknown however how the molecular interactions in an intracellular signaling cascade determine the specificity of the voltage-dependent regulation induced by a specific neurotransmitter. Probably, specific effector regions on the Gβ subunits of the G-proteins may account to the voltage-dependent regulation. Therefore, the purpose of this study examines whether a neurotransmitter's specificity can be revealed by simple ion-current kinetic analysis. By using biochemical reagents and patch-clamp methods we analyzed kinetics of barium current activation in Gβ subunit-overexpressed superior cervical ganglion neurons. Therefore, we compared kinetic slowing and willing-reluctant population changes induced by agonist application in barium currents under prepulse facilitation. We found evidence that CaV2.2 channels are specifically modulated by every Gβ subunit isoform. Furthermore, changes in the speed of activation of the current and in the channel population interchange induced by neurotransmitters are mimicked by overexpression of specific Gβ isoforms. Also, that Gβ1-Gβ4

slows CaV2.2 activation kinetics while Gβ5 does not. These results contribute to understand the mechanism by which Gβ subunits specifically mediate neurotransmitter-induced CaV2.2 channel inhibition. In addition, they advance our understanding on the mechanisms by which signals conveying from a variety of membrane receptors are able to display precise homeostatic responses.

Title: Systemic 5-HT7 receptor activation by LP-211 increases LTM and cAMP production in the prefrontal cortex and attenuates scopolamine-induced impairments in rats

Authors: *A. MENESES
Cinvestav - IPN, Mexico, Mexico

Abstract: RATIONALE: The serotonin (5-hydroxytryptamine; 5-HT) 5-HT7 receptor is localized in brain areas mediating memory; however, the role of this receptor on memory remains little explored. OBJECTIVE: First, demonstrating the associative nature of P/I task, rats were exposed (3 sessions) to: CS-US (Pavlovian autoshaping), truly random control, free operant, presentations only of US only or CS and were compared to rats trained-tested 4 sessions to the P/I procedure. Systemic administration of 5-HT7 receptor agonist LP-211 on short- (STM; 1.5 h) and long-term memory (LTM; 24 and 48 h) or memory impairment (by scopolamine) as well as the production of cAMP were determined in other animals. METHODS: Autoshaping and its behavioral controls were studied. In other animals, an autoshaping training session and immediately afterwards, rats were given (IP) vehicle or LP-211 (0.1-10 mg/kg) and/or scopolamine (0.2 mg/kg) and were tested for STM and LTM; their brains were extracted for the cAMP ELISA immunoassay. RESULTS: P/I group produced the higher %CR. LP-211 did not affect STM; nonetheless, at 0.5 and 1.0 mg/kg it improved LTM. The 5-HT7 receptor antagonist SB-269970 (SB; 10.0 mg/kg) alone had not effect; nevertheless, the LP-211 (1.0 mg/kg) LTM facilitation was reversed by SB. The scopolamine (0.2 mg/kg) induced-decrement in CR was accompanied by significant increased cAMP production. Scopolamine-induced amnesia and increments in cAMP, were significantly but not completely reversed by LP-211.

CONCLUSIONS: autoshaping task is a reliable associative memory task and LP-211 is a useful tool in studying the effect of 5-HT7 receptor.

Title: Characterization of the expression of the synaptic vesicle glycoprotein 2C (SV2C) in the basal ganglia

Authors: M. OZAWA, A. R. DUNN, K. A. STOUT, T. S. GUILLOT, M. WANG, Y. LI, *G. W. MILLER
Ctr. for Neurodegenerative Dis., Emory Univ., ATLANTA, GA

Abstract: Vesicular packaging of dopamine has two important roles in the neuron: 1) compartmentalization of dopamine to facilitate rapid neurotransmission, and 2) sequestration of dopamine and other toxicants from the cytosol. Our lab and others have shown that impairment of vesicular function in dopamine neurons is detrimental to cell health, leading to increased cytosolic dopamine and subsequent cell degeneration, as well as increased sensitivity to dopaminergic toxicants. We have also recently shown that enhanced dopamine vesicle function_that is, increased vesicular capacity for dopamine by the overexpression of the vesicular monoamine transporter 2 (VMAT2)_is protective. Identifying additional modulators of dopamine vesicle function is of utmost importance, as they may represent novel pharmaceutical targets for the treatment of a wide range of dopamine-related neurological disorders such as Parkinson's disease (PD), addiction, and depression. The synaptic vesicle glycoprotein 2C (SV2C) is a vesicular protein preferentially expressed in dopaminergic brain regions, such as the basal ganglia and mesolimbic reward pathway. SV2C genotype modulates not only the protective effect of smoking against PD, but also response to some atypical antipsychotics, which suggests an important role of SV2C in dopaminergic neurons. Furthermore, SV2C's close family member SV2A is the specific target for the antiepileptic compound levetiracetam, suggesting that SV2C may be pharmaceutically relevant. A molecular function of SV2C has not yet been identified, and a more thorough characterization of SV2C's expression patterns in dopaminergic and other neurotransmitter systems is crucial to enhancing our understanding of

the protein's role in vesicular function and potential importance as a pharmacological target. Here, we present immunohistochemical data detailing SV2C's expression in mouse and human basal ganglia. We characterize a novel SV2C antibody designed by our lab. SV2C colocalizes with a majority of dopaminergic cells of the substantia nigra pars compacta (SNpc) and the ventral tegmental area (VTA), as well as some GABAergic areas including the fibers of the substantia nigra reticulata (SNr). Further, we performed coimmunoprecipitation experiments to characterize the association between SV2C and other vesicular proteins. Finally, we describe a novel line of SV2C-knockout mouse. The results from our experiments indicate that SV2C may play an important role in vesicular function in the basal ganglia and may represent a novel pharmaceutical target.

Title: Two major network domains within the dorsal raphe nucleus

Authors: *K. G. COMMONS
Anesthesia, Children's Hosp, Harvard Med., BOSTON, MA

Abstract: Serotonin neurons in the dorsal raphe nucleus (DR) are clustered into heterogeneous groups that give rise to topographically organized forebrain projections. However, a compelling definition of the key subgroups of serotonin neurons within these areas has remained elusive. In order to be functionally distinct, neurons must participate in distinct networks. Therefore we analyzed subregions of the DR and the median raphe (MR) by their afferent input. Clustering methods and principal component analysis were applied to anterograde tract-tracing experiments in mouse available on the Allen Brain Atlas. The results revealed a major break in the networks of the DR such that the caudal third of the DR was more similar in afferent innervation to the MR than it was to the rostral two thirds of the DR. The rostral part of the DR is associated with networks controlling motor and motivated behavior, while the caudal DR is closely aligned with

regions that regulate hippocampal theta rhythm. Thus a major source of heterogeneity within the DR is inclusion of the caudal component, which may be more accurately viewed as a dorsal extension of the MR.

Abstract: Vesicular storage of dopamine plays two important roles in neurons: to prepare the synapse for rapid neurotransmission, and to sequester dopamine and other toxicants from the cytosol. It is well-established that impaired vesicular function in dopamine neurons, such as that resulting from underexpression of vesicular monoamine transporter 2 (VMAT2), increases susceptibility to oxidative stress and toxicity. Our lab also recently demonstrated that enhanced vesicular function as the result of increased VMAT2 expression is neuroprotective. Identifying additional modulators of dopamine vesicle function is important, as they may represent novel pharmacological targets for the treatment of dopamine-related disorders such as Parkinson's disease (PD). The synaptic vesicle glycoprotein 2C (SV2C) is a vesicular protein enriched in dopaminergic areas, such as the basal ganglia. SV2C genotype modulates the protective effect of smoking against PD. SV2C's close family member SV2A is the specific target for the antiepileptic levetiracetam, suggesting that SV2C is pharmaceutically relevant. SV2C's function is unknown, although there is significant evidence that it plays a role in vesicular function. To characterize the role of SV2C in dopamine vesicles, we created SV2C-knockout mice (SV2C-KO) using the EUCOMM Knockout First construct. Here, we characterize the "SV2C-knockout first" (SV2C-KOF) line, which has disrupted transcription and expression of SV2C. Our results support previous findings that SV2C-KOF mice develop normally and have no gross behavioral

differences from wild type animals. Immunohistochemistry shows that markers of nigrostriatal dopamine pathways (tyrosine hydroxylase, dopamine transporter, and VMAT2) remain unchanged in the SV2C-KOF. SV2C-KO also does not result in upregulation of its family members, SV2A or 2B. However, preliminary data suggest that SV2C-KO alters vesicular dopamine handling. We observed a slight decrease (~20%; p=0.06) in vesicular capacity for dopamine, as well as altered dopamine release as measured by fast-scan cyclic voltammetry. Using the EUCOMM construct, we have developed a line of mice with a floxed SV2C gene; with this, we are currently generating conditional SV2C-KO animals with a CaMKII-driven cre-recombinase. Future experiments will more thoroughly explore the impact of this SV2C-KO on vesicular dopamine dynamics, as well as behavioral effects and susceptibility to dopaminergic toxicants. Given our preliminary results, we hypothesize that manipulation of SV2C modulates dopamine vesicle function. Supported by: 5T32ES012870-10

Title: Simultaneous assessment of cell type-specific activity through Ca2+ imaging in brain slices

Authors: *N. V. POVYSHEVA, J. W. JOHNSON
Neurosci., Univ. Pittsburgh, Pittsburgh, PA

Abstract: To assess excitation/inhibition balance in cortical brain slices, it is important to measure activity of excitatory and inhibitory neurons simultaneously in the same experimental conditions. Here we describe an approach that combines imaging of neurons bulk-loaded with cell-permeable Ca^{2+}-sensitive dye with imaging of specific types of inhibitory neurons, parvalbumin (PV)-positive and somatostatin (SST)-positive interneurons labeled with the green fluorescent protein (GFP). Experiments were performed on prefrontal cortical (PFC) slices from 3-7 month old transgenic mice that express GFP in PV-positive interneurons (CB6/Tg(Gad1-

EGFP)G42jh/J mice) and from the mice that express GFP in SST-positive interneurons (FVBTg(GadGFP) 45704Swn/J). Neurons in PFC slices were loaded with the cell-permeable Ca^{2+}-sensitive dye Fura-2 AM as previously described (MacLean & Yuste, 2009). Imaging was performed on a Leica TSC SP-5 multiphoton microscope. Fura-2 was visualized by laser excitation at a wavelength of 815 nm. GFP-labeled PV-positive or SST-positive interneurons were identified using an excitation wavelength of 900 nm. Pyramidal cells were identified by their triangular cell bodies and the initial regions of their apical dendrites. To increase activity of neurons in PFC slices, cells were depolarized by elevating the extracellular concentration of K^+ to 10 mM. The resulting increase in both synaptic excitation and action potential generation resulted in neuronal Ca^{2+} influx through Ca^{2+}-permeable ligand-gated channels (e.g., those associated with NMDA and Ca^{2+}-permeable AMPA receptors) and voltage-gated Ca^{2+} channels. We assessed neuronal activity by measuring the decrease in Fura-2 fluorescence intensity relative to resting fluorescence induced by Ca^{2+} influx. High K^+ produced a substantial decrease in fluorescence, indicating Ca^{2+} influx in pyramidal cells ($-\Delta F/F=31\pm8\%$, $n=10$, $p<0.001$) and in PV-positive interneurons ($21.6\pm10\%$, $n=11$, $p<0.001$) as well as in a SST-positive interneuron (20%). When the extracellular concentration of K^+ was returned to the control concentration (3.5 mM) we consistently observed that Fura-2 AM fluorescence intensity returned to near control values.

Abstract: Homocysteine (HCY), a sulfur-containing aminoacid, exhibits neurotoxic effects and is involved in the pathogenesis of several major neurodegenerative disorders. In contrast to well studied excitoxicity of glutamate (Glu), the mechanism of HCY neurotoxicity is not clearly understood. To study the neurotoxic action of HCY within the nociceptive system, we analyzed membrane currents, Ca2+ responses and changes in mitochondrial membrane potential induced by this aminoacid in cultured rat cortical and trigeminal ganglion (TG) neurons. We found that in large portion of cortical and trigeminal neurons HCY induced inward currents that could be completely blocked by the selective antagonist of NMDA receptors - AP5 and partially inhibited by MTEP, a selective blocker of mGluR5 receptors. In contrast to cortical neurons, in the minority TG neurons HCY induced currents could be completely blocked only by MTEP but not by AP5 co-application suggesting the predominant expression of mGluR5 receptors in this neurons. In addition, the fraction of TG neurons responding to HCY was relatively small. Comparison of Ca2+ responses to HCY, Glu or NMDA demonstrated that in all cortical neurons and the majority of TG neurons HCY induced short oscillatory type Ca2+ responses. In contrast, NMDA or Glu induced sustained increase of intracellular Ca2+. Interestingly, part of TG neurons had Ca2+ responses with the single peak to HCY and did not respond to Glu or NMDA. Such heterogeneity of Ca2+ responses to HCY might be determined by a distinct pattern of expression of NMDA and mGluR5 receptors in the plasma membrane of TG and cortical neurons. Analysis of changes in mitochondrial membrane potential demonstrated that in contrast to NMDA or Glu, HCY did not induced drop of mitochondrial membrane potential during first minutes of action. Our data suggest that in cortical and TG neurons, HCY induces the neurotoxic action through the activation of NMDA and mGluR5 receptors without significant changes in the mitochondrial membrane potential.

Title: Axonal segregation and role of the vesicular glutamate transporter type 3 in neuronal survival of serotonin neurons

Authors: *A. N. VOISIN[1], N. GIGUÈRE[1], G. M. FORTIN[1], S. EL MESTIKAWY[2], L.-É. TRUDEAU[1]
[1]Departments of Pharmacol. and Neurosciences, GRSNC, Fac. of Med., Univ. De Montréal, MONTREAL, QC, Canada; [2]Douglas Mental Hlth. Univ. Institute, Univ. McGill, Montréal, QC, Canada

Abstract: A subset of serotonin (5-HT) neurons, as well as of dopamine (DA) neurons, has been shown to release glutamate as a cotransmitter due to specific expression of the vesicular glutamate transporter type 3 (VGLUT3) or type 2 (VGLUT2), respectively. It is now well-established that VGLUT3 enhances 5-HT vesicular loading in a common pool of vesicles through functional synergy with the vesicular monoamine transporter (VMAT2).A recent study also revealed a functional role of glutamate release by mesencephalic DA neurons in promoting their growth and survival. However, whether glutamate co-release play a similar developmental role in Raphe 5-HT neurons and whether glutamate is released from distinct releases sites from 5-HT neurons has not been examined. Using postnatal mouse Raphe cultures, in which 5-HT neurons develop highly arborized axonal processes, we first tested the hypothesis of partial axon terminal segregation. Using immunostaining and confocal microscopy, we found that in contrast with 5-HT, the 5-HT reuptake transporter (SERT) was present in a subset of axon terminals. Furthermore, these 5-HT axonal branches displayed postnatal upregulation. Whereas 25 % of terminals were SERT-positive at day 1 *in vitro*, 48% expressed SERT at day 7. Interestingly, only a subset of SERT- and 5-HT-positive axonal varicosities expressed VGLUT3, with SERT and VGLUT3 being mostly segregated in different axonal domains. Finally, using a VGLUT3 knockout mouse, we found that VGLUT3 deletion did not impair the axonal and dendritic growth of cultured 5-HT neurons but reduced their survival by approximately 15%. In conclusion, our results demonstrate that Raphe 5-HT neurons express SERT and VGLUT3 mainly in segregated axon terminals and that VGLUT3 regulates the vulnerability of these neurons.

Title: miRNAs 29b and 181a down-regulate expression of the norepinephrine transporter in PC12 cells

Authors: M. DENG, *G. A. ORDWAY, M.-Y. ZHU
Biomed. Sci., ETSU Quillen Col. of Med., JOHNSON CITY, TN

Abstract: miRNAs 29b and 181a down-regulate expression of the norepinephrine transporter in PC12 cells. M.X. Deng, G. A. Ordway and M.-Y. Zhu. Dept. of Biomedical Sciences, Quillen College of Medicine, East Tennessee State University, Johnson City, TN, USA MicroRNAs are short non-coding RNAs that provide global regulation of gene expression at the post-transcriptional level. Such regulation has been found to play a role in stress-induced epigenetic responses in the brain. The noradrenaline transporter (NET) is a noradrenergic marker and regulates neurotransmitter signaling by rapidly clearing released norepinephrine from synapses. Our previous studies demonstrated that rat NET mRNA and protein levels are regulated by chronic stress and by administration of corticosterone. Whether miRNAs are intermediaries in the regulation of NET expression remains to be elucidated. The present study was undertaken to determine possible regulatory effects of miRNAs on NET expression in PC12 cells, a cell model for noradrenergic neurons. Using computational target prediction, we identified several miRNAs potentially related to regulation of NET expression. Mimics of these miRNAs were transfected into PC12 cells. NET protein expression was assayed by Western blotting 48 hours after transfection. miR29b- and miR181a-transfected cells showed significantly reduced NET protein levels. To identify the exact target loci, the 3'-UTR of NET mRNA was amplified by PCR from PC12 genomic DNA and cloned downstream of the red firefly gene of the pmirGlo vector. The NET 3'-UTR-bearing pmirGlo and miR29b or miR181a were co-transfected into PC12 cells and luciferase signals were measured 48 hours after transfection. Consistent with Western blots, co-transfection of these miRNAs with rat NET3'-UTR-containing plasmids resulted in reduced levels of luciferase activity in PC12 cells. We conclude that miR29b and miR181a can function as negative regulators of NET translation *in vitro*. Further studies to determine whether these miRNAs contribute to the regulation of NET expression induced by antidepressants are under way. (Supported by NIH grant NS052818)

Abstract: Posttraumatic Stress Disorder (PTSD) is a debilitating condition that is characterized by re-experiencing the traumatic event, avoidant behavior, hyper-arousal, and negative cognition and mood. Although extensive pre-clinically and clinically research has been done exploring PTSD, its neurobiology remains to be fully understood. The aim of this study was to examine the effects of single prolonged stress (SPS), an animal model of PTSD, on monoamine levels in the brain. Male Sprague-Dawley rats were exposed to SPS treatment, consisting of a consecutive series of stressors (2 h restraint, 20 min group forced swim, and ether exposure until unconsciousness) followed by a 7 d incubation period. Both SPS and control rats were decapitated after the incubation period and their brains dissected for analysis of monoamines (norepinephrine, NE; serotonin, 5-HT) using high pressure liquid chromatography (HPLC). Regions of interest involved in PTSD were examined: dorsal hippocampus (dHC), intermediate-ventral hippocampus (i-vHC), medial prefrontal cortex (mPFC), amygdala, and ventral tegmental area (VTA). Results showed significant increases in 5-HT within the dHC and i-vHC and NE within the i-vHC. A significant decrease in NE was seen within the VTA. There were no SPS-induced differences in the mPFC or amygdala. These data indicate that SPS alters NE and 5-HT levels in key brain regions involved in regulating emotional states in response to environmental stimuli.

Title: Kainate receptors mobilize endocannabinoids in striatal spiny projection neurons

Authors: *J. MARSHALL[1], J. XU[2], A. CONTRACTOR[2]
[1]Physiol., Northwestern Univ. - Dept. Of Physiol., Chicago, IL; [2]Dept. of Physiol., Northwestern Univ., Chicago, IL

Abstract: The striatum is the main input structure of the basal ganglia, integrating information from the thalamus and cortex to control planning and modulation of movement. The principal neurons of the striatum, spiny projection neurons (SPNs), express high levels of kainate receptors, members of the ionotropic glutamate receptor family, yet their functional roles within SPNs have not been fully characterized. Kainate receptors play diverse modulatory roles at synapses throughout the brain in regions where they are expressed. In addition to contributing to excitatory post-synaptic currents (EPSCs) they have been shown to presynaptically regulate neurotransmitter release and in some cases are metabotropically coupled to intracellular signaling pathways—activating downstream signaling independent of ionotropic currents. Here we show that kainate receptors are present at postsynaptic sites in SPNs where they are activated by endogenously released glutamate. We also show that activating kainate receptors with a low concentration of agonist, that produces little or no inward current, reduces glutamate release at excitatory synapses onto SNPs. In a subset of cells, this effect is blocked with a cannabinoid type 1 (CB1R) antagonist, indicating that activating kainate receptors leads to endocannabinoid (eCB) mobilization. Cannabinoid signaling itself has a well-established role in the striatum playing a crucial role in different forms of striatal plasticity. Furthermore, this effect of low-agonist activation of kainate receptors is sensitive to a number of downstream pharmacological manipulations that suggest kainate receptors mobilize eCBs through a metabotropic function—

signaling that is independent of ion flux through the channel pore. These experiments suggest a novel and significant role for kainate receptors in tuning striatal synapses and regulating striatal activity.

Title: Relationship between Rearing and Na,K-ATPase

Authors: *R. ALVES[1,2], A. VASCONCELOS[1], C. SCAVONE[1], M. A. C. VENDITTI[3]
[1]Pharmacol., Univ. of Sao Paulo, Sao Paulo, Brazil; [2]Marshall Inst. for Interdisciplinary Res., Marshall Univ., Huntington, WV; [3]Psicobiology, Federal Univ. of Sao Paulo, Sao Paulo, Brazil

Abstract: The Na^+/K^+-ATPase is of paramount importance for the proper functioning of the organism. The enzyme is involved in several aspects of brain function, such as the repolarization of the neuronal membranes and neurotransmitters uptake/release. Therefore, individual differences in the brain Na^+/K^+-ATPase activity may result in differences in the functioning of the brain, which, in consequence, could lead to behavioral divergences. We have showed a higher hippocampal activity of Na^+/K^+-ATPase in the subgroup of rats of higher rearings. The correlation between ouabain sensitivity and tissue specific expression of various isoforms of the Na^+/K^+-ATPase is impressive. The aim of this work was to verify if subgroups of rats selected according to the number of rearings differ in the isoforms of the Na^+/K^+-ATPase. Naive adult outbred male Wistar rats were used to select subgroups of rats showing low (LR) and high (HR) rearings number in the open field test. Twenty days after the open field session, the rats were sacrificed and the hippocampus was dissected. On the day of the assays, the pellets were

resuspended and the determination of the binding of the [^{3}H]Ouabain was assayed. The results obtained indicated statistically significant difference between LR and HR subgroups in the 1200 nM [^{3}H]Ouabain. This result suggests the involvement of α2 and α3 isoforms in the interindividual differences in rearing behavior. Our data suggest that the difference in the hippocampal Na^+/K^+-ATPase activity is innate and is involved in the expression of the rearing behavior.

Title: Glutathione: An antioxidant reservoir of synaptic glutamate

Authors: *T. W. SEDLAK[1], M. KOGA[1], A. KAMIYA[1], S. SNYDER[2], A. SAWA[1]
[2]Neurosci., [1]Johns Hopkins Sch. of Med., Baltimore, MD

Abstract: Glutamate is the most abundant excitatory neurotransmitter, utilized at 80-90% of cortical synapses and with 7-10 millimolar brain concentrations. It governs physiologic and pathologic processes ranging from learning and memory to stroke. The tripeptide, glutathione, is one third glutamate and present at 1-3 millimolar intracellular concentrations in brain, participating in antioxidant defense and drug detoxification. Multiple lines of evidence find abberant glutathione levels in neuropsychiatric disorders, including Alzheimer's Disease and Schizophrenia. Because of the substantial amounts of brain glutathione and its rapid turnover, we hypothesized that glutathione is a relevant reservoir of glutamate, and that this has not received systematic interrogation because the glutathione pathway was worked out over a decade prior to

the general acceptance that glutamate was a neurotransmitter. We find that drugs that inhibit liberation of glutamate from the glutathione cycle, acivicin and 2I4C, lead to decreases in cytosolic glutamate, decreased miniature excitatory post synaptic potential (mEPSC) frequency, and diminished depolarization-associated calcium fluxes in cortical neuron cultures. In contrast, pharmacologically decreasing the biosynthesis of glutathione with buthionine sulfoximine leads to increases in cytosolic glutamate, increased mEPSC frequency, and increased depolarization-associated calcium release. The glutathione pathway may complement the glutamate-glutamine shuttle for glutamate neurotransmitter, as restricting delivery of glutamine with MeAIB led to mEPSC decreases that could be rescued by increasing the liberation of glutamate from the glutathione cycle. We suggest that sulforaphane and pyroglutamate, which act on elements of the glutathione cycle, may have applications for human use to modulate oxidative stress and glutamatergic function.

Title: Striatin proteins within STRIPAK complex regulate the dephosphorylation of DARPP-32 as B subunits of PP2A

Authors: ***D. LI**, V. MUSANTE, A. C. NAIRN
Yale Univ., New Haven, CT

Abstract: Dopaminergic signaling is primarily mediated through phosphorylation and dephosphorylation events in downstream signaling targets. While previous studies have focused on the activity of protein kinases, emerging research has begun to investigate the increasing significance of protein phosphatases. In particular, the protein phosphatase PP2A is of interest due to its multiple substrates within dopaminergic pathways. One of these, DARPP-32, is a known mediator of psychostimulant action through regulation of multiple phosphorylation sites. Recent studies have identified a family of proteins, the striatins, as novel regulatory subunits of

PP2A; of particular interest is the fact that striatin is also known to assemble large signaling complexes termed STRIPAK, of which PP2A is a member. However, nothing is known of striatin or STRIPAK function within the striatum, despite known enrichment of these proteins within this brain region. Through the use of immunoprecipitation and affinity purification to interrogate the PP2A-striatin interactome, as well as through *in vitro* assays measuring the ability of striatin and STRIPAK proteins to dephosphorylate 32P-DARPP-32, we have accumulated evidence identifying DARPP-32 as a substrate of PP2A-striatin. More physiological studies within cell culture and primary cultures also indicate that this dephosphorylation activity functions in intact cells. Due to the role of DARPP-32 as a mediator of the action of drugs of abuse, this data implicates striatin and the STRIPAK complex as potential targets of these drugs. Future studies will expand into behavioral paradigms to examine the interactions of the psychostimulant, cocaine, with these proteins of interest.

Autónoma de Guerrero, Chilpancingo, Mexico; [6]Escuela Nacional de Ciencias Biológicas, Inst. Politécnico Nacional, Mexico D.F, Mexico

Abstract: Cerebral ischemia results from reduction of cerebral blood flow in the brain due to a blockage or thrombosis of a major cerebral artery. This event leads to an immediate activation of death or cell survival pathways, depending on the extent of injury after occlusion. Moderate levels of reactive oxygen species (ROS) of mitochondrial origin trigger survival pathways. On the other hand, antioxidants [e.g. resveratrol (RSV)] might support neuronal survival through

ROS level regulation during cerebral ischemia. Importantly, ROS regulates specific protein 1 (SP1) and respiratory factor nuclear 1 (NRF1) which are all together responsible for transcription of genes involved in neuronal function as the N-methyl-D-aspartate (NMDA) receptor subunits and the cytochrome c oxidase (COX) subunits. In this study, we investigated the possible effect of RSV on binding activity of SP1 and NRF1. Methods. Male Wistar rats (250 to 350 g) were subjected to middle cerebral artery occlusion (MCAO) for 2 h and different times of reperfusion (0, 15, 30, 60, and 120 min). RSV was administered (1 mg/kg; i.v; diluted in 50% ethanol) before reperfusion. Nuclear protein was extracted from parietal cerebral cortex and binding activity was analyzed by chemiluminescent electrophoretic mobility shift assay (EMSA). Results. We found that maximal binding activity for Sp1 factor was observed after 15 min of reperfusion (173.01%). RSV returns Sp1 binding activity to basal level (109.95%). Maximal NRF1 binding activity was observed 15 min after reperfusion (240.05%); it was kept elevated until 30 min (234.07%) and returned to basal level after 60 min (116.59%). RSV decreased NRF1 binding activity to 160.46% after 15 min of reperfusion. Our findings indicate that resveratrol decreased Sp1 and NRF1 binding activity. Therefore, it is possible that a RSV modulates mRNA transcription of genes involved in neuronal survival after injury.

Title: The role of presenilin1 in neurogenesis in zebrafish, Danio rerio

Authors: *J. M. SUNDVIK, P. PANULA
Inst. of Biomedicine/ Anatomy, Biomedicum Helsinki, University of Helsinki, Finland

Abstract: Abstract Histaminergic neurons play a major role in an array of different behaviors executed by the vertebrate brain. So far, the sole regulator of the development of the histaminergic neurons was recently shown to be the Alzheimer's disease associated *presenilin1* (*psen1*) gene. There are two presenilin genes, presenilin1 and presenilin 2, which both function

as the catalytic subunit of γ-secretase. The γ-secretase has tens of different substrates of which Notch and amyloid precursor protein are best known. We have previously shown that the number of histamine neurons in *psen1-/-* fish is lower than in wild-type control animals during development and that the number of histamine neurons in the old *psen1-/- fish* is increased compared with control animals. We hypothesized that this could be due to either neurotransmsitter respecification or neurogenesis. To answer this, we have done immunohistochemical analysis of markers associated with neurogenesis. We studied sox2, pax6a and NeuroD expression in *psen1-/-* and control zebrafish larvae at three days post fertilization which did not reveal any difference in expression. Neither did we find a difference in neurogenesis of seven days post fertilization old zebrafish larvae as incorporation of 5-bromo-2'-deoxyuridine was not altered between the two different genotypes. Histaminergic neurons are located in the caudal hypothalamus, surrounding the posterior recess of the diencephalic ventricle. Immunohistochemical studies of sox2, pax6a, NeuroD, PCNA and ki67 in the old *psen1-/-* animals revealed an increase in the number of sox2 and pax6a immunoreactive neurons in the inferior lobe of the posterior hypothalamus when compared with control animals. No difference in numbers of neuronal precursor cells was observed in the histaminergic caudal hypothalamus. These findings implicate that the increase in histaminergic neuron number observed in adult *psen1-/-* is likely due to neurotransmitter respecification rather than neurogenesis within the histaminergic caudal hypothalamus.

Title: Nuclear factor-Y and specificity protein factors act together to regulate the human beta1-adrenergic receptor gene transcription in human neuroblastoma SH-SY5Y cells

Authors: Y. NAWA[1], R. KUWABARA[1], T. HIROI[1], R. TAKAHASHI[2], *H. MATSUI[3]

Abstract: The beta1-adrenergic receptor (beta1-AR) mediates a variety of neural functions, including synaptic plasticity and memory formation. Regulation of the human beta1-AR gene is poorly understood. Here, we describe a detailed characterization of the human beta1-AR gene promoter in human neuroblastoma SH-SY5Y cells, which endogenously express the human beta1-AR. Site-directed mutagenesis analyses identified two cis-acting elements involved in the regulation of the gene: an inverted CCAAT box (ICB) (-369/ -365 relative to the ATG start codon) and a proximal non-canonical GC-box (-339/-330), which bind NF-Y and Sp factors (Sp1, Sp3 and Sp4), respectively. Electrophoretic mobility shift assays and chromatin immunoprecipitation assays indicated specific binding of NF-Y and Sp factors to the human beta1-AR promoter. Co-immunoprecipitation experiments revealed physical associations between NF-Y and Sp1, Sp3 or Sp4 in the intact cell. Treatment with a siRNA targeting NF-YA, a transactivation subunit of NF-Y, or mithramycin A, an inhibitor of Sp factors reduced the promoter activity. Whereas NF-Y was absolutely required for expression of human beta1-AR gene, overexpression of Sp1, Sp3 or Sp4 further enhanced NF-Y induced activation of the promoter. Taken together, these data demonstrate that ICB-bound NF-Y plays a pivotal role in regulating expression of the human beta1-AR gene via functional and possible physical interactions with Sp factors.

Title: Rapid antidepressant response to ketamine in treatment-resistant depression is not dependent on normalising kynurenine pathway metabolism

Authors: *G. CLARKE[1], M. NAUGHTON[1], R. O'SHEA[2], J. DOWLING[3], A. WALSH[3], F. ISMAIL[1], G. SHORTEN[3], L. V. SCOTT[1], J. F. CRYAN[4], T. G. DINAN[5]

Abstract: **Background:** Recently, the NMDA receptor antagonist ketamine has emerged as a fast acting antidepressant with therapeutic potential for treatment-resistant depression (TRD) cohorts but its clinical use is hampered by its psychotomimetic properties. Biological markers of the rapid antidepressant response associated with ketamine are urgently required to understand its mechanism of action. Increased peripheral kynurenine production from tryptophan has been considered as a potential biological marker of major depression and the kynurenine pathway has been suggested as a putative target for ketamine based on preclinical studies. However, the relationship between TRD, kynurenine concentrations and the response to ketamine treatment has not yet been evaluated in clinical populations. **Aim:** We hypothesised that ketamine treatment rapidly reverses abnormal kynurenine pathway metabolism and that this effect mediates the clinical improvement in TRD. **Methods:** 17 patients with treatment-resistant major depression were compared at baseline to 20 healthy control subjects. Subsequently, the TRD cohort received 3 ketamine infusions (0.5mg/Kg) spaced one week apart. Depressive symptoms were evaluated using the 17-item Hamilton Depression Rating Scale (HDRS). Tryptophan and kynurenine were measured in plasma using high-performance liquid chromatography (HPLC). **Results:** Ketamine significantly reduced HDRS scores with response rates ranging from 81% at 24h post infusion 1 to 67% 1 week post infusion 3. Kynurenine concentrations were significantly elevated in the TRD cohort pre-ketamine compared to HC (494 ± 26 vs 639 ± 61 ng/ml, $p < 0.05$). Ketamine treatment did not reduce the elevated kynurenine concentrations in the TRD cohort 2 hours, 24 hours or 1 week following the first ketamine infusion ($p > 0.05$). Moreover, there was no effect of repeated ketamine infusion on kynurenine concentrations at any time point evaluated. There was also no effect of ketamine infusion on plasma tryptophan concentrations ($p > 0.05$). **Conclusions:** To our knowledge, this is the first study to characterise the temporal relationship between the improvement in symptoms following ketamine treatment and tryptophan metabolism along the kynurenine pathway. Our results confirm the rapid efficacy of ketamine in TRD and suggest that this positive treatment outcome is not dependent on normalising kynurenine pathway abnormalities. Further studies are warranted to determine if these findings generalise to the other modalities used to treat TRD such as electroconvulsive therapy.

Title: Conditional knockout of gsk-3β in d1 versus d2 receptor-expressing neurons exhibits differential effects on pfc function

Authors: *Y. LI[1], B. XING[1], N. URS[2], M. CARON[2], W.-J. GAO[1]
[1]Drexel Univ. Col. of Med., PHILADELPHIA, PA; [2]Departments of Cell biology, Neurobiology, and Medicine, Duke Univ. Med. Ctr., Durham, NC

Abstract: Glycogen synthase kinase-3β (GSK-3β) is a key regulator of many cellular signaling pathways. In the dopamine (DA) system, GSK-3β is particularly involved in D2R-mediated signaling. Increasing evidence indicates that D1R and D2R are respectively restricted to a subpopulation of neurons in the striatum, hippocampus and PFC. However, how GSK-3β affects synaptic function in D1R- and D2R-expressing neurons in the PFC is unclear. A previous study reported that conditional knockout of GSK-3β in D1R- orD2R-expressing neurons (D1RGSK-3β -/- and D2RGSK-3β-/-) induced a differential antipsychotic response. Here we study whether genetic ablation of GSK-3β in D1R- or D2R-expressing neurons affects PFC cortical neuronal and synaptic activities. Using patch-clamp recording of layer V pyramidal neurons in the PFC, we found that neuronal excitability was increased in both D1RGSK-3β -/- and D2RGSK-3β-/- mice, with spike number increasing even more significantly in D1RGSK-3β -/- vs. D2RGSK-3β-/- mice. Furthermore, the amplitude but not frequency of both sEPSCs and mEPSCs was significantly increased in D1RGSK-3β -/- mice, suggesting a potential increased postsynaptic AMPAR function. Consistently, paired-pulse ratio (PPR) in AMPAR-EPSCs was unaffected; but the PPR in NMDAR-EPSCs appeared to be increased in D1RGSK-3β -/- mice. Interestingly, the frequency of sEPSC was increased whereas the amplitude of neither sEPSCs nor mEPSCs was changed in D2RGSK-3β -/- mice, indicating an increased presynaptic glutamate release. This change of sEPSCs was undetected in A2a (postsynaptic D2R) GSK-3β -/- mice. In addition, there were no changes in short-term plasticity mediated by either AMPAR-EPSCs or NMDAR-

EPSCs in D2RGSK-3β -/- mice. Together, these data suggest GSK-3β ablation exhibits a cell-type-specific action on neuronal and synaptic function in PFC.

Title: Prefrontal cholinergic overload and attentional capacities in aging

Authors: ***B. YEGLA**, A. KELBAUGH, A. MOOKHTIAR, V. PARIKH
Psychology and Neurosci. Program, Temple Univ., Philadelphia, PA

Abstract: The cognitive reserve hypothesis of aging posits that brain activity attempts to cope with functional age-related changes. Individuals with lower cognitive reserve are considered more susceptible to cognitive decline and age-related pathologies. However, what neuronal mechanisms underlie cognitive reserve, and how these mechanisms provide compensation for age-related decline in attentional capacities remains unknown. The basal forebrain cortical cholinergic input system is a critical component of the brain's attentional system. Healthy older adults show attentional load-dependent posterior-anterior shift in aging (PASA) characterized by higher activation of the prefrontal regions. However, it is not known whether prefrontal cortex (PFC)-driven cholinergic mechanisms compensate for age-related decline in attentional capacities. Here, we investigated the impact of partial cholinergic deafferentation of the PFC on attentional capacities in young and aged rats. The impact of cholinergic depletion on neuronal activation in the PFC and posterior parietal cortex (PPC) was also investigated using a semi-quantitiative c-fos immunohistochemistry procedure. Young and aged rats were trained in an operant sustained attention task (SAT) that required the animals to distinguish between signal and non-signal events to attain a reward. After attaining criterion (70% correct responses on both trial types), animals either received bilateral infusions of 192-IgG saporin or sterile saline into the PFC and the performance was monitored for 4 weeks. Aged rats required more training

sessions to acquire criterion than young rats. However, post-criterion performance prior to lesion surgeries remained similar between the two age groups. Saline-infused aged rats show a greater number of c-fos expressing cells in the PFC but not PPC as compared to the young animals. Restricted loss of prefrontal cholinergic inputs produced attentional impairments in aged rats (SAT scores: 0.43±0.08 vs. 0.63±0.05 in young lesioned rats). Moreover, lesioned aged rats show reduced c-fos positive counts in the PFC as compared to aged intact rats. Collectively, these data suggest that PASA shifts and prefrontal overload foster top-down processes to maintain attentional capacities in aging. Moreover, these compensatory processes are triggered by prefrontal cholinergic inputs.

Title: pH sensitive soluble adenylyl cyclase (sAC) regulates lysosomal pH

Authors: *N. RAHMAN[1], F. R. MAXFIELD[2], T. A. MILNER[3], J. BUCK[4], L. R. LEVIN[4]
[1]Dept. of Pharmacol., Weill Cornell Med. Col., NEW YORK, NY; [2]Biochem., [3]Brain and Mind, [4]Pharmacol., Weill Cornell Med. Col., New York, NY

Abstract: In age-related neurodegeneration, damaged proteins and organelles accumulate within neurons. Normally, these proteins and organelles would be degraded in the lysosomes by cathepsins, which are optimally active at acidic pH, but with aging, age-related diseases and lysosomal storage disorders, elevation of lysosomal pH hinders normal degradation and impairs autophagy leading to neuronal dysfunction. The molecular processes and signaling pathways that regulate lysosomal pH are not understood. While it has been shown that addition of exogenous cAMP can lower lysosomal pH, the relationship between cAMP and pH is unclear. Lysosomal pH is dependent upon the V-ATPase, and bicarbonate-regulated, soluble adenylyl cyclase (sAC) is essential for pH-dependent V-ATPase mobilization in both epididymis and kidney. We now

show sAC to be essential for lysosomal acidification. sAC null fibroblasts and primary neurons have several lysosomal alteration, including impaired lysosomal acidification, diminished cathepsin activity, reduced degradation of substrate and reduced lysosome-mediated autophagosome clearance during autophagy. The lysosomal acidification defect in sAC null cells is rescued by exogenous cAMP. Thus, sAC appears to be an essential source of cAMP which regulates lysosomal pH. These results suggest sAC serves as a previously unappreciated sensor of lysosomal pH, and define it as a possible target for designing novel treatment strategies for neurodegenerative disorders.

Title: Development of an assay for inhibitors of the deleterious interaction between wild type and Episodic ataxia-2 mutant CaV2.1 channels

Authors: *S. DAHIMENE, K. M. PAGE, J. S. CASSIDY, A. C. DOLPHIN
NPP, UCL, London, United Kingdom

Abstract: Episodic ataxia-2 is an autosomal dominant disorder caused by mutations of the *CACNA1A* gene that encodes for the pore forming calcium channel subunit $Ca_V2.1$. This channel is preferentially expressed in the presynaptic terminals where it plays a central role in neurotransmitter release. The majority of episodic ataxia-2 mutations reported so far are nonsense or deletion/insertion mutations predicted to form truncated proteins. Heterologous expression of wild-type $Ca_V2.1$ channel together with the truncated constructs that mimic episodic ataxia-2 mutants significantly suppressed the wild-type channel function, indicating that the truncated protein produces a dominant- negative effect (Jouvenceau et al.,2001; Page et al.,2004). A similar finding has been shown for $Ca_V2.2$ (Raghib et al.,2001). In addition, the

suppression effect required interaction between the full-length and the mutant construct. We aimed to develop a cellular assay in order to disrupt the destructive interaction between wild-type and episodic ataxia-2 mutant $Ca_V2.1$ channels and therefore restore partially or totally the trafficking and function of the wild-type $Ca_V2.1$. Using a cell imaging assay, we have confirmed that the truncated $Ca_V2.2$ protein (Dom I-II) prevents full-length $Ca_V2.2$ from reaching the plasma membrane. We have also confirmed that the N-terminus residues for both Cav2.1 and Cav2.2 channels which are highly conserved among Ca_V2 family are involved in this process. Additionally, it was possible to prevent the suppressive effect of the truncated protein by coexpressing constructs that mimic the key N-terminal residues. By doing so we were able to restore partially the function of the full-length channel. We postulate that the N-terminus is essential for the truncated proteins to interact with the full-length channel and as a result prevent the correct folding of the wild-type channel. Therefore, coexpressing the key N-terminal residues, would prevent the deleterious interaction. Title: Regulation of Cav2.2 channel functional expression by the light chain 1 (LC1) of the microtubule associated protein B (MAP1B)

Authors: M. A. GANDINI[1], *A. SANDOVAL[2], R. FELIX[1]
[1]Cell Biol., Ctr. for Res. and Advanced Studies of the Natl. Polytechnic Inst. (Cinvestav-IPN), Mexico City, Mexico; [2]Med., FES Iztacala UNAM, Tlalnepantla, Estado de Mexico, Mexico

Abstract: We reported recently a new mechanism by which the neuronal N-type Ca2+ (CaV2.2) channel expression may be regulated by ubiquitination. This regulation is mediated by the interaction between the channel and the light chain (LC1) of the microtubule associated protein B (MAP1B) and involves a binding sequence in the N-terminal of LC1 and binding domains within the C terminus of the pore-forming CaV2.2α1 subunit. We also showed that the LC1-mediated CaV2.2α1 down-regulation could be prevented by inhibiting the ubiquitin-proteasome proteolytic pathway and that LC1 could interact with the ubiquitin-conjugating E2 enzyme Ube2L3, playing a role as an ubiquitin-protein E3 ligase or as an adaptor protein for CaV2.2 channel ubiquitination. Here we report that i) LC1 can interact with the two main variants of the CaV2.2 channels (CaV2.2e37a and CaV2.2e37b), ii) the LC1-mediated regulation most likely involves an internalization of the CaV2.2 channels via a dynamin and clathrin-dependent pathway, and iii) the ubiquitination/degradation mechanism triggered by LC1 might be conserved among N-type and P/Q-type channels. Last, consistent with our previous functional analysis, siRNA-mediated LC1 and Ube2L3 silencing significantly increased the amplitude of whole-cell N-type Ca2+ currents expressed in dorsal root ganglion neurons. Therefore, the work reported here provides additional evidence that LC1 reduces N-type Ca2+ channel surface expression.

Title: Dynamics of CaV1.2 L-type voltage-gated calcium channels and β adrenergic receptors signaling complexes in cultured hippocampal neurons

Authors: *V. DI BIASE[1], A. STEINBERGER[1], M. HEINE[2], C. RAMPRECHT[1]
[1]Med. Univ. of Graz, Graz, Austria; [2]Leibniz Inst. of Neurobio., Magdeburg, Germany

Abstract: In neurons calcium influx via CaV1.2 L-type voltage gated calcium channels (L-VGCCs) controls excitation-transcription coupling, homeostatic plasticity, learning and memory. Therefore, the modulation of the L-VGCCs activity is instrumental to tuning of neuronal functions. Adrenergic stimulation increases the amplitude of CaV1.2 mediated calcium currents. A plausible underlying mechanism implies the release of the inhibitory interaction between the proximal and the distal CaV1.2 C-terminus induced by the adrenergic dependent phosphorylation of the channel. Here, we analyze the distribution of the signaling complexes including CaV1.2 and β adrenergic receptors (ARs) and the effect of adrenergic stimulation on their dynamics at the membrane of cultured hippocampal neurons. Anti-HA live surface staining in neurons transfected with an extracellularly HA-tagged CaV1.2 channel (CaV1.2-HA) shows the known distribution of CaV1.2s in discrete clusters along the dendrites. Similar experiments on FLAG tagged β1 and β2ARs transfected neurons reveal the grainy/homeogeneus pattern of β1ARs and the clustered localization of β2ARs throughout the membrane. Double anti-HA and -FLAG immunolabeling in neurons overexpressing CaV1.2-HA and FLAG-β1ARs or FLAG-β2ARs shows that CaV1.2 and β1ARs randomly overlap whereas CaV1.2 and β2ARs often specifically co-localize on the spines but not along the shaft. To analyze the lateral diffusion of CaV1.2s and β2ARs at the membrane we performed fluorescence recovery after photobleaching (FRAP) analysis on neurons expressing the fluorescently tagged CaV1.2 and β2ARs - eGFP/SEP-CaV1.2 and SEP-β2ARs, respectively. SEP-β2ARs display a FRAP curve significantly higher and faster than eGFP/SEP-CaV1.2 channels, indicating that the mobility is higher for β2ARs than for CaV1.2s. These results are corroborated by single particle tracking data in which the diffusion coefficients of CaV1.2 and βARs differ of at least one order of magnitude. Immunolabeling analysis on CaV1.2-HA transfected neurons suggest that the adrenergic agonist isoproterenol tends to increase the fluorescence intensity of membrane inserted CaV1.2-HA clusters. Finally, we introduced two point mutations at the CaV1.2-HA C-terminal rendering the channel constitutively unable to establish the C-terminal inhibitory interaction (CaV1.2-HA-RRQQ). The CaV1.2-HA-RRQQ mutant displayed significantly higher membrane expression levels than the control CaV1.2-HA. Our data suggest that the signaling complexes formed by CaV1.2 and βARs are restricted to specific subcellular compartments and that their dynamics at the membrane may be subject to activity.

Title: Modulation of CaV2.1 channels by neuronal calcium sensor-1 induces short-term synaptic facilitation

Authors: *J. YAN[1], K. LEAL[1], V. G. MAGUPALLI[2], E. NANOU[1], G. Q. MARTINEZ[1], T. SCHEUER[1], W. A. CATTERALL[1]
[1]Pharmacol., [2]Univ. of Washington, Seattle, WA

Abstract: Modulation of P/Q-type Ca2+ currents mediated by Ca2+/calmodulin binding to CaV2.1 channels contributes to short-term synaptic plasticity. Calcium sensor proteins displace calmodulin from its binding site and differentially modulate P/Q-type Ca2+ currents, resulting in diverse patterns of facilitation and depression of synaptic transmission. Neuronal calcium sensor-1 (NCS-1, frequenin) has been shown to modulate synaptic facilitation. However the underlying mechanism is not clear. In tsA201 cells transfected with NCS-1 and CaV2.1, NCS-1 reduces Ca2+-dependent inactivation of P/Q-type Ca2+ current through interaction with the IQ-like motif and calmodulin-binding domain in the C-terminal domain of CaV2.1 channels without affecting peak current or activation kinetics. This regulation by NCS-1 requires binding to the IQ-like domain and CBD domain of CaV2.1 channels. We also show that activity-dependent modulation of CaV2.1 current by NCS-1 significantly affects short-term plasticity in synapses between cultured superior cervical ganglion neurons. Co-expression of NCS-1 induces facilitation of synaptic transmission in response to paired pulses and trains of depolarizing stimuli, and this effect is lost in CaV2.1 channels with mutations in the IQ-like motif and calmodulin-binding domain. These results demonstrate that NCS-1 inhibits inactivation of CaV2.1 and enhances facilitation of synaptic transmission through direct interaction with CaV2.1 channels and further support the hypothesis that CaS proteins are crucial in fine-tuning short-term synaptic plasticity. Title: Substance P inhibits T-type Ca2+ channels in sensory neurons via redox-mediated mechanism

Authors: D. HUANG[1], J. SCRAGG[2], C. PEERS[2], H. ZHANG[1], *N. GAMPER[3,1]
[1]Pharmacol., Hebei Med. Univ., Shijiazhuang, China; [2]Fac. of Med. and Hlth., Univ. of leeds, Leeds, United Kingdom; [3]Univ. Leeds, Leeds, United Kingdom

Abstract: T-type voltage-gated calcium channels (T-type VGCCs; Cav3.1, Cav3.2, Cav3.3) are distinct from other VGCCs since they activate at voltages below -60 mV, have faster kinetics and smaller single channel conductances. The negative activation voltage of T-type VGCCs allows them to control neuronal firing threshold and pattern. T-type calcium channels are expressed in the somata, axons and nerve endings of peripheral somatosensory neurons (including pain-sensing neurons, the nociceptors), suggesting an important role in nociception. However, the mechanisms of T-type channel regulation are still poorly understood. We investigated the regulation of T-type VGCCs by the inflammatory mediator substance P (SP). Acute application of SP (1 μM) inhibited Cav3.2 currents in HEK293 cells co-transfected with NK1 receptor and native T-type Ca2+ currents in cultured small-diameter dorsal root ganglion (DRG) neurons by 30.2±6.8% (n=11, P<0.05) and by 25.9±5.3% (n=11, P<0.05) respectively. Inhibition was not reversible upon washout but was completely reversed by the application of reducing agent dithiothreitol (DTT; 1 mM) suggesting that the effect of SP on T-type channels involves oxidative process. Pre-application of DTT abolished the SP effect. Application of the mitochondrial inhibitor Antimycin A (1 μM), which was shown to induce superoxide anion release from mitochondria, mimicked SP-mediated inhibition of T-type calcium currents in DRG neurons, an effect that was reversed by DTT. Application of SP after Antimycin A did not produce significant further current inhibition. H2O2 (300 μM) also inhibited Cav3.2 currents in HEK293 cells and native T-type Ca2+ currents in cultured DRG neurons by 9.4%±1.7 (n=5, P<0.05) and by 9.3%±2.9 (n=7, P<0.05) respectively. Redox modulation of Cav3.2 is mediated by alteration of its interaction with inhibitory zinc ions; accordingly, mutation of zinc binding histidine (H191Q) in Cav3.2 significantly attenuated the SP-induced inhibition of this channel. Cav3.1 lacks histidine at a position homologous to H191 in Cav3.2 and was insensitive to SP in the expression system. Introduction of homologous histidine (Q172H) bestowed Cav3.1 with sensitivity to SP. Pretreatment of DRG with pertussis toxin completely abolished the effect of SP suggesting that the action of SP in DRG is mediated via Gi/o. Our results identify novel molecular mechanism of T-type Ca2+ channels inhibition by SP which is likely to contribute to

the autocrine/paracrine, anti-excitatory action of this neuropeptide in peripheral nociceptive fibers.

Title: A population density and moment-based approach to modeling domain calcium-mediated inactivation of L-type calcium channels

Authors: ***X. WANG**, K. HARDCASTLE, S. H. WEINBERG, G. D. SMITH
Applied Sci., The Col. of William and Mary, Williamsburg, VA

Abstract: We present a population density and moment-based description of stochastic domain calcium-mediated inactivation of L-type calcium channels. Our approach accounts for the effect of heterogeneity of local calcium signals on whole cell calcium currents; however, in contrast with prior work by Sherman et al. [Biophys J. 58(4):985, 1990], we do not assume that calcium domain formation and collapse are fast compared to channel gating. We demonstrate the population density and moment-based modeling approach using a12-state Markov chain model of an L-type calcium channel [Greenstein and Winslow, Biophys J. 83(6):2918, 2002]. Simulated whole cell voltage clamp responses yield an inactivation function for the whole cell calcium current that agrees or disagrees with the classic result of Sherman et al. when domains dynamics are fast or slow, respectively. We analyze the voltage-dependence of calcium inactivation that occurs via slow heterogeneous domains and find that when channel permeability is held constant, calcium inactivation increases as the domain time constant increases. However, when this parameter study is repeated for fixed maximum domain calcium concentration, inactivation decreases as the domain time constant increases. Comparison of simulation results using population densities and moment equations confirms the computational efficiency of the moment-based approach, and enables the validation of several distinct methods of truncating and closing the open system of moment equations. In general, a slow domain time constant requires

higher order moment truncation for agreement between moment-based and population density simulations.

Title: T-type calcium channels form a calcium-dependent complex with calmodulin

Authors: *H. ASMARA, N. C. HEATH, B. SIMMS, T. BARTOLETTI, R. REHAK, I. MICU, F. X. ZHANG, P. STYS, G. W. ZAMPONI, R. W. TURNER

Abstract: Calcium entry in neurons can activate a cascade of calcium-dependent second messenger systems that involve specific calcium sensors. We know that calmodulin (CaM) forms an association with high voltage-activated calcium channels that is modulated by calcium entry. CaM binds to L-type (Cav1.2) channels at multiple sites including pre-IQ and IQ motifs in the distal C-terminus, and this interaction is important for calcium-dependent facilitation (CDF) or inactivation (CDI) of Cav1.2 current. Although CaM interactions are thought to occur only with HVA channels, we noticed that the Cav3.1 channel isoform also contains a sequence in the C-terminal region that is homologous to the IQ motif of Cav1.2 channels. Indeed, Cav3.1 and Cav3.3 (but not Cav3.2) coimmunoprecipitate (co-IP) with CaM from lysates of either rat brain or tsA-201 cells expressing hCav3.1 and hCaM cDNA. Moreover, the co-IP from tsA-201 cell lysate was calcium-dependent in that the association was present in 0 calcium medium or in 100 nM resting [Ca] for both CaM or the calcium insensitive CaM1234 mutant, but exhibited a calcium-dependent loss of co-IP in 50 μM or greater [Ca]. Protein pull-down assays between CaM-beads revealed an association with Cav3.1 protein from lysates of tsA-201 cells that was eliminated upon deletion of the C-terminus of the channel. Imaging tsA-201 cells coexpressing cDNA for CaM-mKate and Cav3.1-GFP revealed FRET between the acceptor and donor pair upon excitation at 457 nm under resting conditions. FRET was reduced upon perfusing 0.05 mM

ionomycin to raise intracellular calcium, but not in 0.1 mM BAPTA-AM. FRET was strongly reduced upon depolarization mediated activation of Cav3.1 channels. The depolarization-induced loss of FRET was blocked in the presence of 1 μM mibefradil and 300 μM Ni2+, indicating that calcium influx via Cav3 calcium channels is sufficient to block the Cav3-CaM interaction. These data are important in revealing a constitutive association between the Cav3.1 channel isoform and CaM that is lost upon raising internal calcium, thus providing for an activity-dependent release of CaM from the channel complex.

Title: Differential effect of familial hemiplegic migraine mutations on excitatory and inhibitory synaptic transmission between cortical pyramidal cells and somatostatin-expressing interneurons

Authors: *N. PILATI[1], A. FORLI[1], M. SESSOLO[1], D. PIETROBON[1,2]
[1]Univ. of Padova, Padova, Italy; [2]CNR Inst. of Neurosci., Padova, Italy

Abstract: Familial hemiplegic migraine type 1 (FHM1) is a subtype of migraine with aura caused by gain-of-function mutations in CaV2.1 (P/Q-type) Ca channels. Knockin (KI) mice carrying FHM1 mutations show increased neuronal P/Q-type Ca current and facilitation of induction and propagation of cortical spreading depression (CSD), the phenomenon that underlies migraine aura and may activate the migraine headache mechanisms. We previously reported gain-of-function of excitatory synaptic transmission at cortical pyramidal cell (Pyr) synapses but unaltered inhibitory synaptic transmission at cortical fast-spiking interneuron synapses in FHM1 R192Q KI mice, suggesting that the balance between excitation (E) and

inhibition (I) could be altered in FHM1 (Tottene et al, 2009, Neuron 61:762). Another polysynaptic inhibitory subcircuit important for dynamic regulation of the cortical E-I balance involves somatostatin (SOM+) interneurons. To study the effect of the FHM1 mutation on synaptic transmission and short-term plasticity at the excitatory and reciprocal inhibitory synapses between layer 2/3 Pyrs and SOM+ interneurons we created a new transgenic mouse line by crossbreeding R192Q KI with GIN mice expressing GFP in specific SOM+ interneurons. Dual patch-clamp recordings in slices of somatosensory cortex revealed that i) P/Q-type Ca channels have a dominant role in controlling neurotransmitter release at both the Pyr-SOM+ interneuron excitatory synapse and the SOM+ interneuron-Pyr inhibitory synapse; ii) the FHM1 mutation enhances the strength of excitatory synaptic transmission and the probability of glutamate release at Pyr->SOM+ synapses, without affecting short-term facilitation during brief action potential trains at 25 Hz; iii) by contrast, the FHM1 mutation does not affect inhibitory synaptic transmission at SOM+ ->Pyr synapses. These findings further support the hypothesis that the dynamic regulation of the cortical E/I balance may be altered in FHM1.

Title: A non-canonical role for Cav1.4 Ca2+ channels in photoreceptor synaptogenesis

Authors: ***V. KEROV**[1], J. LAIRD[1], B. WILLIAMS[1], F. HAESELEER[2], S. BAKER[1], A. LEE[1]
[1]Univ. of Iowa, Iowa City, IA; [2]Univ. of Washington, Seattle, WA

Abstract: Voltage-gated $Ca_v1.4$ Ca^{2+} channels are localized in the synaptic terminals of retinal photoreceptors (PRs) and mediate Ca^{2+} influx that triggers synaptic vesicle release. Mutations in

the genes encoding $Ca_v1.4$ or the $Ca_v1.4$-regulatory protein, CaBP4, lead to visual disorders including congenital stationary night blindness type 2 (CSNB2), which has largely been attributed to loss- or gain- of function in $Ca_v1.4$ Ca^{2+} signaling. However, PR synapses do not form in mice lacking $Ca_v1.4$ ($Ca_v1.4$ KO), indicating an essential developmental role for $Ca_v1.4$ that may be affected in CSNB2. Here, we probed the requirement for $Ca_v1.4$ in PR synaptogenesis by examining the consequences of heterologous expression of recombinant $Ca_v1.4$ channels in $Ca_v1.4$ KO mouse retina. Remarkably, expression of either a wild-type or non-conducting mutant channel rescued mature PR synapses in $Ca_v1.4$ KO retina. This effect of Cav1.4 depended on its interaction with CaBP4: expression of a $Ca_v1.4$ mutant incapable of binding CaBP4 did not result in synapse rescue, whereas expression of a $Ca_v1.4$ channel tethered to CaBP4 restored PR terminals in $Ca_v1.4$ KO retina. Our results support a novel, non-conducting role for $Ca_v1.4$ channels in organizing PR synapse assembly that relies on association with CaBP4, and suggest that abnormal PR synapse development may contribute to vision impairment in some cases of CSNB2.

Title: The Ca2+ channel:mu opioid receptor signaling pathway in rat sensory neurons is altered following chronic femoral artery occlusion

Authors: M. FARRAG[1], J. KIM[2], B. HASSAN[1], M. P. KAUFMAN[2], K. SEDEEK[1], *V. RUIZ-VELASCO[1]
[1]Anesthesiol., [2]Heart and Vascular Inst., Penn State Col. of Med., Hershey, PA

Abstract: The exercise pressor reflex (EPR), a crucial component of the cardiovascular response under physiological and pathophysiological states, is activated via metabolic and mechanical mediators that originate from contracting muscles and stimulate group III and IV afferents. We previously reported that stimulation of mu opioid receptors (MOR), expressed in both afferents,

led to an attenuation of the pressor reflex in rats whose femoral arteries had been occluded for 72 hr. The present study examined the effect of arterial occlusion on the signaling components involved in the opioid-mediated modulation of Ca2+ channel currents in rat dorsal root ganglion (DRG) neurons (L4-L6) innervating the triceps surae muscle. Moreover, we focused on neurons that were transiently transfected with cDNA coding for EGFP whose expression is driven by the putative NaV 1.8 promoter region, a channel primarily expressed in nociceptive neurons. Employing the small interference RNA (siRNA) approach, our results show that the pertussis toxin (PTX)-sensitive Galphai3 subunit couples MOR and Ca2+ channels. On the other hand, this pathway does not employ Galphai2 and GalphaO while Galphai1 subunits do not appear to be expressed. We also observed a significant ($P<0.05$) leftward shift of the MOR agonist, DAMGO, concentration-response relationship in neurons isolated from rats with occluded arteries compared to those that were freely perfused. The mean IC50 (nM) values for the freely perfused and ligated groups were 283 and 146, respectively. Western blotting analysis indicated that the leftward shift resulted from a moderate increase in MOR expression but not in Galphai3 levels. Additionally, the Ca2+ channel density in DRG neurons was not altered as a result of arterial occlusion. We found that all neurons from both groups exhibited an inward current following exposure to the TRPV1 agonist, capsaicin. Our findings suggest that sensory neurons mediating the EPR express NaV 1.8 and TRPV1 channels and exhibit MOR upregulation following a 72 hr occlusion of the femoral artery.

Title: Voltage-dependent inhibition of Ca2+ currents mediated by substance P-stimulated neurokinin-1 receptors in rat celiac-superior mesenteric ganglion neurons

Authors: *S. SUGINO, M. FARRAG, V. RUIZ-VELASCO
Dept. of Anesthesiol., Penn State Univ., Hershey, PA

Abstract: The celiac-superior mesenteric ganglia (CSMG) contain postganglionic sympathetic neurons that regulate renal, gastrointestinal, hepatic, and pancreatic function. Previous reports have indicated that CSMG express neurokinin-1 receptors (NK-1R). NK-1R are G protein coupled receptors that are activated by the tachykinin known as substance P and signal via Gαq/11 protein subunits. In sympathetic neurons, such as superior cervical and stellate ganglion neurons, NK-1R activation modulates Ca2+ channel currents in a voltage-independent (VI) manner. However, the modulation by NK-1R of Ca2+ currents and the signal transduction elements are currently unknown. Therefore, the purpose of the present study was to examine coupling mechanisms between NK-1R and Ca2+ channels in acutely isolated male rat CSMG neurons employing the whole-cell variant of the patch-clamp technique. Ca2+ currents were evoked with a double-pulse voltage protocol. Surprisingly, the application of SP (1 μM) led to a voltage-dependent (VD) inhibition of Ca2+ currents as did exposure to NE (10 μM). The VD modulation of Ca2+ currents is generally associated with coupling of either pertussis toxin (PTX)-sensitive Gαi/o or cholera toxin (CTX)-sensitive GαS protein subunits. Thus, in one set of experiments, CSMG neurons were pretreated overnight with either PTX (500 ng/ml) or CTX (100 ng/ml). Under these conditions, exposure of the neurons to SP did not affect the coupling of NK-1R with Ca2+ channels (36±4, n=21 vs. 36±3, n=12), yet the modulation of the currents remained VD. On the other hand, PTX significantly ($P<0.05$) attenuated the NE-induced modulation of Ca2+ currents (56±4, n=14 vs. 5±1, n=13). Furthermore, CTX pretreatment significantly ($P<0.05$) eliminated the VIP-induced modulation of Ca2+ currents (26±4, n=11 vs. .2±1, n=10). In a separate set of experiments, we transfected CSMG neurons with the cDNA coding for phospholipase Cβ1 c-terminal construct. In neurons expressing the construct (n=3), the SP-mediated Ca2+ current inhibition was eliminated, while application of NE resulted in VD inhibition of Ca2+ channels. These preliminary findings suggest that in CSMG neurons, Gαq/11-coupled NK-1R modulate Ca2+ channels in a VD manner, indicative of a novel signaling pathway in sympathetic neurons.

Title: Human Cav1.3 (CACNA1D) calcium channel mutations associated with hyperaldosteronism or autism risk

Authors: *A. PINGGERA[1], A. LIEB[1], S. MONTELEONE[2], M. J. BROWN[3], K. R. LIEDL[2], P. TULUC[1], J. STRIESSNIG[1]
[1]Pharmacol. and Toxicology, [2]General, Inorganic and Theoretical Chemistry, Ctr. for Mol. Biosci., Univ. of Innsbruck, Innsbruck, Austria; [3]Clin. Pharmacol. Unit, Ctr. for Clin. Investigation, Addenbrooke's Hosp., Univ. of Cambridge, Cambridge, United Kingdom

Abstract: The L-type voltage gated calcium channel family comprises four isoforms (Cav1.1-1.4) and its members are crucial for a variety of physiological functions in electrically excitable cells. Cav1.2 and 1.3 are expressed in various tissues, including the brain, heart and endocrine cells. Gain of function mutations in Cav1.2 (CACNA1C) cause Timothy syndrome which includes autism and QT prolongation. Recently we identified four somatic mutations in aldosterone-producing adenomas (APA) which all showed a gain of function phenotype. A mutation in Cav1.3 has also been associated with increased risk of autism. Here we studied the functional consequences of three more APA mutations and a mutation associated with autism risk by expressing them together with β3 and α2δ1 subunits in tsA-201 cells. ICa (15 mM Ca2+) and ON-gating currents (QON) were recorded using the whole cell patch-clamp technique. Moreover we generated a 3D model of Cav1.3 α1 subunit using homology (MOE) and Rosetta ab initio modeling. Then we simulated the model in a membrane environment using Molecular Dynamics simulations to predict the consequence of human mutations on channel structure. APA mutation F747L, located in the activation gate of the channel (IIS6), activated at about 15 mV more negative potentials than the wild type (WT) and inactivated more slowly and less completely thus resulting in a gain of function. APA mutation R990H (IIIS4) showed neither a shift in the voltage dependence of activation nor altered inactivation kinetics. It significantly increased the ratio of peak tail current vs QON 1.6-fold suggesting a gain of function induced by higher open probability. Homology modeling of the voltage sensor revealed that R990H mutation could result in a gating-pore current during the resting state. This possibility is currently investigated. No phenotype was found for APA mutation M1354I. The autism risk mutation caused a strong gain of function phenotype evident from a shift of 10 mV towards more negative potentials and a 2-fold higher ratio of peak tail versus QON. Our data demonstrate that 6 out of 7 APA mutations are associated with a Cav1.3 channel gain of function phenotype. Cav1.3 gain of function may also contribute to autism risk in humans.

Title: Dual modulation of R-type CaV2.3 currents by M1 muscarinic receptor

Authors: J.-Y. JEONG, *B.-C. SUH
Dept. of Brain Sci., Daegu Gyeongbuk Inst. of Sci. and Technol., Daegu, Korea, Republic of

Abstract: Many of high voltage-gated Ca2+ channels (VGCCs) are modulated by Gq-coupled M1 muscarinic acetylcholine receptors through diverse signaling pathways. R-type CaV2.3 currents are known to be increased by M1 receptor activation. According to the previous studies, M1 receptor-induced increase in the amplitude of R-type current is mediated by phosphorylation of CaV2.3 channel via the activation of protein kinase C (PKC). Here we report that M1 muscarinic receptors are also able to inhibit CaV2.3 currents when the channels are fully activated by PKC. In the whole-cell configuration of tsA201 cells, phorbol 12-myristate 13-acetate (PMA, 1 μM), a PKC activator potentiated CaV2.3 currents by ~2-fold. We found that after the PMA-induced potentiation of CaV2.3 currents, application of the M1 receptor agonist oxotremorine-M (Oxo-M, 10 μM) decreased the currents by ~66%. We examined if the hydrolysis of membrane phosphoinositides (PIs) are involved in the muscarinic suppression of R-type currents. We used rapamycin-induced translocatable pseudojanin (PJ) system which can directly dephosphorylate 4- and 5-phosphates from membrane PI(4)P as well as PI(4,5)P2. After the addition of rapamycin, R-type currents dramatically and irreversibly decreased to ~34.2% of the initial level. Taken together, our results suggest that R-type CaV2.3 currents are modulated by M1 receptor in a dual mode, such as potentiation via PKC activation and suppression by poly-PI depletion. Activation of M1 receptor can solely decrease R-type currents in the PKC-activated but not in control cells and PJ-induced inhibition of CaV2.3 currents demonstrates that poly-PIs are important in the maintenance of R-type channel activity.

Title: Suppression of peripheral sympathetic outflow underlies agmatine-mediated hypotension

Authors: J.-H. JOENG, *S. CHUNG
Physiol., Dept. of Physiology, Yonsei Univ. Col. of Med., Seoul, Korea, Republic of

Abstract: Agmatine, an imidazoline deriviatives, suppress the vasopressor sympathetic outflow to produce hypotension. This effect has been known to be mediated in part by suppressing sympathetic outflow via acting imidazoline I_2 receptors (IR_2) at postganglionic sympathetic neurons. But, the cellular mechanism of IR_2-induced inhibition of noradrenaline (NA) release is still unknown. We investigated effect of agmatine activation on contraction evoked by electrical field stimulation (EFS) in superior mesenteric arterial. We also directly tested effect of agmatine activation on N-type Ca^{2+} current in isolated neurons of celiac ganglion (CG) which regulate vascular sympathetic tone of mesenteric artery. agmatine suppressed neurogenic contractions evoked by EFS in endothelium-denuded mesenteric arterial strips and did not affect contraction by external application of NA. In addition, ω-conotoxin GVIA (CgTx), a selective N-type Ca^{2+} channel blocker, significantly inhibited EFS-evoked contraction and this blockade nearly completely occluded suppression of EFS-evoked contraction by agmatine. Moreover, agmatine diminished I_{Ca} measured using patch-clamp method in an irreversible manner in rat CG neurons. In addition, blockage of N-type Ca^{2+} channel with w-CgTx nearly completely occluded I_{Ca} inhibition by agmatine. The present findings demonstrated that activation of agmatine suppresses peripheral sympathetic outflow by modulating N-type Ca^{2+} channel activity located in peripheral sympathetic nerve terminal, which appears to involve agmatine-induced hypotension. Title: Fragile x mental retardation protein regulates cav2.3 mrna

Authors: *E. E. GRAY, Y. LIU, I. TRANG, J. LEE, D. A. HOFFMAN
NICHD, NIH, Bethesda, MD

Abstract: Fragile X syndrome (FXS) is the most common form of inherited intellectual disability in humans, and is further characterized by autistic behavior, childhood seizures, and abnormal dendritic spine formation. FXS arises from the loss of function of the fragile X mental retardation protein (FMRP), an RNA binding protein that can regulate mRNA localization and translation in neurons. Loss of FMRP alters neuronal excitability and dendritic calcium signaling, and this may arise from the ability of FMRP to regulate the mRNA of voltage-gated ion channels. Recently it was shown that FMRP can bind the mRNA of the voltage-gated calcium channel Cav2.3 (Darnell et al, 2011), although the consequences of this interaction have not been investigated. Cav2.3 is highly expressed in the dendrites of hippocampal and cortical neurons, where it is capable of generating large calcium spikes in response to both back-propagating action potentials and synaptic activity. Thus, alterations in Cav2.3 mRNA localization and translation could have a dramatic impact on cellular excitability and calcium signaling. We seek to investigate the possibility that Cav2.3 mRNA can be regulated by FMRP, and to determine potential consequences of this interaction. Toward this goal, we performed real time PCR on mRNA isolated from the hippocampi or cortex of wild-type and FMR1-/- male mice, and examined the mRNA levels of several dendritic proteins. When comparing hippocampi from FMR1-/- and wild-type mice at 3- or 8-weeks of age, we found no significant difference in the mRNA levels of Cav2.3 (95 ± 5.3%; 103 ± 7.6%), Kv4.2 (100 ± 1.6%; 114 ± 11.1%), PSD-95 (96 ± 3.1%; 86.9 ± 5.7%), and HCN-1 (93 ± 2.2%, 3-weeks only) (n=6 and n=4; 3- and 8-weeks old, respectively). However, in cortical tissue isolated from 3-weeks old mice, we found a significant decrease ($p<0.05$, n=4) in the mRNA levels of Cav2.3 (79 ± 3.9%), Kv4.2 (77 ± 2.4%), PSD-95 (53 ± 18.6%), and HCN-1 (77 ± 1.2%) in FMR1-/- compared to wild-type mice. This data suggests that Cav2.3 mRNA is regulated by FMRP in cortex but not in

the hippocampus. We will further characterize this regulation by identifying FMRP binding sites on Cav2.3. Furthermore, we will determine how FMRP might affect Cav2.3 protein expression and ultimately cellular physiology.

Title: Altered synaptic plasticity and spatial learning in knock-in mice with a mutation that prevents regulation of $Ca_V2.1$ channels by calmodulin and neuronal calcium sensor proteins

Authors: *E. NANOU[1], J. M. SULLIVAN[2], T. SCHEUER[1], W. A. CATTERALL[1]
[1]Pharmacol., [2]Physiol. & Biophysics, Univ. of Washington, Seattle, WA

Abstract: A key component of short-term synaptic plasticity is regulation of P/Q-type Ca^{2+} currents through presynaptic $Ca_V2.1$ channels by Ca^{2+} binding to calmodulin (CaM) and CaM-like calcium sensor (CaS) proteins. Ca^{2+}-dependent facilitation and inactivation of the P/Q-type Ca^{2+} current translates into facilitation and rapid depression of synaptic transmission in cultured neurons that transiently express $Ca_V2.1$ channels. To understand the functional role of the regulation of $Ca_V2.1$ channels by CaS proteins *in vivo*, we introduced a mutation (IMAA) into the CaS protein binding site in the C-terminal domain of $Ca_V2.1$ channels. P/Q-type Ca^{2+} currents from hippocampal pyramidal cell bodies of WT and IMAA mice were indistinguishable, and basal neurotransmitter release in hippocampal autaptic synapses and in CA3-CA1 synapses in hippocampal slices was unchanged in amplitude and frequency. However, synaptic facilitation during paired-pulse stimulation of autaptic synapses in hippocampal cultures and CA3-CA1 synapses in hippocampal slices was significantly reduced. The ratio of amplitudes of AMPA- to NMDA-mediated EPSCs was not significantly different between WT and IMAA. Taken together, these results show that the $Ca_V2.1$-IMAA mutation alters short-term synaptic plasticity

in CA3-CA1 synapses without affecting basal excitatory transmission or postsynaptic function. Strikingly, CA3-CA1 synapses in hippocampal slices from IMAA mice show impaired long-term potentiation induced by a 100-Hz tetanus or by theta-burst stimulation. Because hippocampal plasticity is important for spatial learning, we tested the IMAA mice in context-dependent fear conditioning and found that they have impaired learning and memory for the spatial context of a mild foot shock. To assess spatial learning and memory without a component of fear, we utilized the Barnes Maze, in which mice learn to find a dark hole on the edge of a bright circular field. IMAA mice learned the location of the escape hole more slowly than WT, and they spent greater time to find the escape hole. Altogether, our results suggest that regulation of $Ca_V2.1$ channels by CaS proteins is essential for normal synaptic facilitation, long-term potentiation, and spatial learning and memory in mice.

Title: Densin-180 regulates cell-surface density of voltage gated Cav1.2 Ca2+ channels

Authors: *S. WANG[1], R. STANIKA[3], G. OBERMAIR[4], M. KENNEDY[5], R. COLBRAN[6], A. LEE[2]

[1]Mol. Physiol. and biophysics, Univ. of iowa, [2]Mol. Physiol. and biophysics, Otolaryngology Head-Neck Surgery, and Neurol., Univ. of Iowa, Iowa City, IA; [3]Div. of Physiol., [4]Med. Univ. Innsbruck, Innsbruck, Austria; [5]Div. of Biol., Caltech, Pasadena, CA; [6]Mol. Physiol. and Biophysics, Vanderbilt Univ., Nashville, TN

Abstract: $Ca_v1.2$ and $Ca_v1.3$ are the major voltage-gated L-type Ca^{2+} channels in the nervous system, and regulate Ca^{2+} -dependent gene transcription and synaptic plasticity. Polymorphisms in the *CACNA1C* gene encoding $Ca_v1.2$ are risk factors for multiple neuropsychiatric disorders. Thus, factors that regulate $Ca_v1.2$ are expected to play an important role in the neural control of cognitive/affective functions. Densin-180 is a protein enriched at excitatory synapses and functionally interacts with Ca^{2+}/calmodulin-dependent protein kinase II and $Ca_v1.3$ channels. Mice lacking densin-180 (densin KO) exhibit behavioral phenotypes of mental illness. Here, we report that densin-180 interacts with and regulates $Ca_v1.2$ channels, which contributes to their roles in modulating Ca^{2+} signaling in the brain. Densin-180 coimmunoprecipitates with $Ca_v1.2$ channels in both HEK293T cells and in mouse brain. In biochemical and electrophysiological experiments in HEK293T cells, densin-180 enhances the level of $Ca_v1.2$ at the plasma membrane. The density of cell-surface $Ca_v1.2$ channels is increased in dendrites of mouse hippocampal neurons overexpressing densin-180, and decreased in the brain of densin KO mice. Moreover, Ca_v1-dependent phosphorylation of the transcription factor CREB is decreased in neurons from densin KO mice. We conclude that densin-180 is an important determinant of $Ca_v1.2$ Ca^{2+} signaling in neurons and that further studies of densin KO mice may reveal insights into how dysregulation of $Ca_v1.2$ may lead to mental illness.

Title: Enhanced function of native T-type Calcium Channels in DBA2J mice undergoing alcohol withdrawal

Authors: *H. SHAN, M. RIEGLE, M. MASICAMPO, D. MOLINA, D. W. GODWIN
Wake Forest Univ. Sch. Med., WINSTON SALEM, NC

Abstract: Chronic ethanol exposure can profoundly alter brain rhythms. T-type calcium channels are an important contributor to these rhythms. Our lab has previously shown that one isoform of the channel, CaV3.2, is inhibited by acute ethanol administration (Shan et al, 2013). Upon withdrawal (WD), gene expression and gating properties of Cav3.2 channels in midline thalamus are upregulated in c57Bl/6 mice (Graef et al, 2011). Our lab previously demonstrated that alcohol withdrawal increased spike and wave discharge (SWD) events in DBA/2J mice. The number and duration of events increased with each successive withdrawal period. Ethosuximide, a T-type calcium channel antagonist, significantly reduced the seizure severity in DBA/2J mice undergoing withdrawal. It suggests that enhanced T-type calcium channel function contributes to hyperexcitability observed during withdrawal. Here, we examined T-type channel physiology in the thalamus of DBA/2J mice, a seizure prone strain, during a 4-week schedule of chronic intermittent ethanol exposures in a vapor chamber. Blood alcohol levels were maintained in the chamber at (180mg/dl) and verified through blood sampling. 24 hours after the 4th WD, slices containing midline thalamus were prepared. T-type currents were recorded at 32°C using visualized whole-cell patch clamp recordings. Native currents were isolated by voltage dependency, and sodium currents were blocked by tetrodotoxin. Inactivation currents were recorded by 1s voltage step commands from -135 mV to -60 mV followed by a 500 ms test pulse at -50 mV in a standard inactivation protocol. Currents were analyzed with the Boltzmann function fit to the channel inactivation curve, described by I/I_{max}. Recordings from mice undergoing 4 cycles of intermittent alcohol WD showed a depolarizing shift in voltage dependence of inactivation, measured by a shift in the V_{50} from -105.3+/-2.367 mV to -98.57+/-2.102 mV (n=13 per group; $p< 0.05$, unpaired t test). Current density was not significantly affected. Our study illustrates that hyperexcitability induced by multiple intermittent withdrawals from ethanol may be caused by enhanced channel function due to a depolarizing shift in inactivation kinetics. This shift is qualitatively similar to the observations made previously by Graef et al (Graef et al, 2011), and indicates that T-channel upregulation is a common feature of alcohol WD in seizure prone and seizure resistant animals.

Title: Control and plasticity of the presynaptic action potential waveform at small CNS nerve terminals

Authors: *M. B. HOPPA[1,2], G. GOUZER[2], M. ARMBRUSTER[3], T. A. RYAN[2]
[1]Biol., Dartmouth Col., Hanover, NH; [2]Biochem., Weill Cornell Med. Col., New York, NY; [3]Tufts Univ., Boston, MA

Abstract: The steep dependence of exocytosis on Ca^{2+} entry at nerve terminals implies that voltage control of both Ca^{2+} channel opening and the driving force for Ca^{2+} entry are powerful levers in sculpting synaptic efficacy. Using fast, calibrated, genetically-encoded optical voltage indicators we show that unlike at cell somas or certain giant nerve terminals, the peak of the presynaptic action potential (AP_{SYN}) at small nerve terminals typically reaches only ~ +7 mV, a value that optimizes the balance of voltage-dependent open-probability versus driving force for Ca^{2+} entry. Furthermore, we find that key AP_{SYN} parameters show adaptive plasticity: manipulations that increase presynaptic Ca^{2+} channel abundance and release probability result in a commensurate lowering of the AP_{SYN} peak and narrowing of the waveform while manipulations that decrease presynaptic Ca^{2+} channel abundance do the opposite. Our studies thus reveal that adaptive plasticity in the AP_{SYN} waveform serves as an important regulator of synaptic function.

Title: Role of voltage-gated calcium channels in spontaneous recurrent cortical activity

Authors: C. CAPUANI[1], A. TOTTENE[1], *D. PIETROBON[1,2]
[1]Univ. Padova, Padova 35100, Italy; [2]CNR Inst. of Neurosci., Padova, Italy

Abstract: Slow synchronous fluctuations between periods of persistent activity (up-state) and periods of relative quiescence (down-state) are observed *in vivo* in the cortex during slow-wave sleep and anesthesia. The up-states are driven by large bursts of spontaneous excitatory and inhibitory synaptic currents arising from correlated activity of a large population of presynaptic connected neurons, due to recurrent network activity. Given the prominent role of P/Q- and the N-type Ca2+ channels in controlling synaptic transmission in the cerebral cortex, we investigated the contribution of these two types of Ca2+ channels to the spontaneous cortical synaptic activity underlying the up-state-like oscillations that can be recorded in acute brain slices. We performed single and double patch-clamp experiments on slices of mouse somatosensory cortex to study the up-state-like activity in layer 2/3 pyramidal cells before and after application of the specific inhibitors of P/Q- and N-type Ca2+ channels ω-AgatoxinIVA (400 nM) and ω-conotoxinGVIA (1 μM). The block of N-type Ca2+ channels strongly reduced the up-states frequency to 39% of control, without affecting up-states duration. In contrast, inhibition of the P/Q-type Ca2+ channels transformed the up-states into simil-epileptiform events. We show that this transformation is due to a larger reduction of the inhibitory compared to the excitatory synaptic conductances underlying the up-states and to a consequent shift of the cortical excitatory-inhibitory balance towards excitation. This finding suggests that P/Q-type Ca2+ channels play a dominant role in controlling inhibitory synaptic transmission in the cerebral cortex.

Title: $Ca_V1.3$ C-terminal interaction with PDZ-domain scaffold proteins regulates channel membrane expression and dendritic spine morphology in hippocampal neurons

Authors: *R. I. STANIKA[1], M. CAMPIGLIO[1], A. LEE[2], J. STRIESSNIG[3], B. E. FLUCHER[1], G. J. OBERMAIR[1]
[1]Dept. of Physiol., Med. Univ. Innsbruck, Innsbruck, Austria; [2]Depts. of Mol. Physiol. and Biophysics, Otolaryngology Head-Neck Surgery, and Neurol., Univ. of Iowa, Iowa, IA; [3]Dept. of Pharmacol. and Toxicology, Ctr. for Mol. Biosciences, Univ. of Innsbruck, Innsbruck, Austria

Abstract: The L-type Ca^{2+} channel $Ca_V1.3$ critically contributes to neuronal excitability and pacemaking. Ca^{2+} entry through $Ca_V1.3$ may lead to the increased susceptibility of substantia nigra dopaminergic neurons in Parkinson's disease (PD). Alternative splicing gives rise to a long ($Ca_V1.3_L$) and two short ($Ca_V1.3_{42A}$, $Ca_V1.3_{43S}$) C-terminal variants, which differ with respect to voltage-dependence of activation and Ca^{2+}-dependent inactivation and may thus differentially contribute to the neuronal loss in PD. Only the long splice variant contains a cytoplasmic PDZ ligand (ITTL) that binds the synaptic scaffolding proteins densin-180, shank, erbin. Here we analyzed the role of the $Ca_V1.3$ C-terminus and its interaction with PDZ-domain scaffold proteins for membrane expression and the stability of dendritic spines in cultured hippocampal neurons. Immunofluorescence staining of HA-tagged full length $Ca_V1.3_L$ revealed a clustered distribution on the soma, dendrites, and spines. Surface expression levels of the short splice variants reached only 50% of $Ca_V1.3_L$, indicative of a role of the C-terminus in membrane expression. Consistent with a role in membrane trafficking or anchoring of the channel, deletion of the C-terminal ITTL sequence ($Ca_V1.3_{\Delta ITTL}$) reduced $Ca_V1.3_L$ membrane expression to the level of the short splice variants (45% of full length) by decreasing individual cluster size and cluster density. Coexpression of $Ca_V1.3_L$ with either densin-180 or shank1b significantly reduced overall surface expression of $Ca_V1.3_L$, whereas coexpression of erbin had no effect. At the same time, any of these proteins strongly affected dendritic spine morphology by increasing spine length and spine volume. Morphologically altered dendritic spines still contained functional synaptic sites as revealed by the correct apposition of pre- (synapsin) and postsynaptic (PSD-95) proteins. Importantly, expression of either the short splice variants or a $Ca_V1.3$ construct with a deleted ITTL sequence ($Ca_V1.3_{\Delta ITTL}$) in $Ca_V1.3$ prevented regulation of membrane expression and spine morphology by densin-180, shank1b, and erbin. Expression of dihydropyridine insensitive (T1033Y mutation) $Ca_V1.3$ channel constructs and pharmacological block of all endogenous Ca^{2+} currents in cultured hippocampal neurons allowed to exclusively isolate $Ca_V1.3$-mediated Ca^{2+} and Ba^{2+} currents. Preliminary data suggest differential effects of densin on $Ca_V1.3_L$ and $Ca_V1.3_{\Delta ITTL}$. Together our results indicate a critical role of C-terminus and particularly the ITTL sequence for $Ca_V1.3$ membrane trafficking and the regulation of dendritic spine morphology.

Title: Investigating the role of various types of Ca2+ channels on dopamine neuron firing patterns and their variability

Authors: V. A. J. DE VRIND[1,2], F. PHILIPPART[1], G. DRION[1], *J. J. MOREAU[1], D. ENGEL[1], V. SEUTIN[1]
[1]Univ. Liege, Liege, Belgium; [2]Masterprogram Neurosci. and Cognition, Brain Ctr. Rudolf Magnus, Univ. of Utrecht, Utrecht, Netherlands

Abstract: In rat brain slices, dopaminergic (DA) neurons of the medial substantia nigra pars compacta fire in a very homogenous pattern in control conditions. However, when their SK channels are blocked by a maximally active concentration of apamin (300 nM) (all synaptic inputs being blocked), their firing pattern becomes very heterogeneous, with a broad spectrum of "irregularity" (the coefficient of variation (CV) of the interspike interval (ISI), which is 0.056 $\pm$ 0.007 in control conditions becomes 0.528 $\pm$ 0.073 (upper range of CVs becomes ~1.8). This variability is very robust, since we confirmed it repeatedly throughout the last years (N total = 48). The increase in irregularity is due to a block of the apamin-sensitive medium duration afterhyperpolarization (mAHP). We asked what the role of various Ca^{2+} channel species is in either promoting irregularity (by generating an inward current opposing the SK current) or opposing it (by providing the source of Ca^{2+} for SK channels). We first investigated the mechanism of the irregularity by applying supramaximal (but still specific) concentrations of organic Ca^{2+} channel blockers. As already suggested by others (Shepard and Stump, 1999; Johnson and Wu, 2004), only a L-type Ca^{2+} channel blocker (5 µM nifedipine), but not a N-, T-, P/Q- or R-type blocker, was able to significantly decrease the CV in apamin and bring it back close to control values. We next asked whether any other single Ca^{2+} channel blocker could

induce irregularity, similarly to apamin. No single agent was able to do so, which is consistent with previous intracellular data from our lab, showing that no single Ca^{2+} channel blocker completely blocked the mAHP (Scuvée-Moreau et al., poster at 2005 SFN meeting), contrary to what had been found by others in young mice (Wolfart and Roeper, 2002). In our former experiments, the most active compound, omega-conotoxin (N-channel blocker) reduced the surface of the mAHP by only ~40 % (this is very different from the situation in serotonergic neurons: Alix et al., 2014). We are currently evaluating whether 1) combinations of Ca^{2+} channel blockers could mimick the apamin effect on firing pattern 2) in a computational semi-quantitative model, SK channels indeed need to be blocked almost completely to generate bursting-like irregularity. In conclusion, our data suggest opposite effects of various Ca^{2+} channels on regularity in these neurons, which is probably due to variable spatial relationships between different Ca^{2+} channel species and SK channels.

Title: Differential mechanisms in trafficking of N-type voltage-gated calcium ion channel (Cav2.2) alternative splice variants

Authors: *N. MACABUAG, J. S. CASSIDY, W. PRATT, A. C. DOLPHIN
Neuroscience, Pharmacol. and Physiol., Univ. Col. London, London, United Kingdom

Abstract: The N-type voltage-gated calcium ion channels (Cav2.2) play an important role in presynaptic neurotransmitter release, but how these channels are targeted to the presynaptic terminals is not well known. In this study, we compare intracellular trafficking of Cav2.2 isoforms, which are produced from alternative splicing of two mutually exclusive exons 37a (e37a) and 37b (e37b). The significance of the Cav2.2 e37a isoform is thought to be that it is

preferentially expressed in nociceptive dorsal root ganglion (DRG) neurons and gives rise to larger N-type calcium currents, with enhanced voltage-independent G-protein coupled receptor (GPCR) mediated inhibition (Raingo et al., 2007). Here we demonstrate that cell surface expression of the Cav2.2 e37a isoform is larger than for the e37b isoform by 35.4% (p=0.005, n=114 and n=104 respectively) without a significant increase in whole-cell protein expression, using exofacially tagged Cav2.2 channels with the auxiliary subunits (α2δ-1 and β1b) in a heterologous expression system (N2a cells). This increased expression at the cell membrane gives rise to a larger whole-cell current for Cav2.2 e37a. We compare the anterograde and retrograde trafficking of these Cav2.2 isoforms to examine the mechanism that accounts for the difference in the surface expression. We also investigate the mechanism of endocytosis of these Cav2.2 isoforms, including channel endocytosis due to GPCR activation, to examine whether there are differences in GPCR-mediated endocytosis of these Cav2.2 isoforms. Reference Raingo, J., Castiglioni, A.J., and Lipscombe, D. (2007). Alternative splicing controls G protein-dependent inhibition of N-type calcium channels in nociceptors. Nat. Neurosci. 10, 285-292.

Title: Suppression of N-type Ca2+ current by protease-activated receptor 2 activation in rat coeliac ganglia neurons

Authors: ***Y. KIM**, J.-H. JOENG, S. CHUNG
Physiol., Yonsei Univ. Col. of Med., Seoul, Korea, Republic of

Abstract: Protease-activated receptor (PAR)-2, highly expressed on endothelial cells and vascular smooth muscle, plays a crucial role in regulating blood pressure via modulating peripheral vascular tone. Although several mechanisms to explain the PAR-2-induced hypotension have been suggested, an exact mechanism for the hypotension has not been elucidated yet. We investigated effect of PAR-2 activation on contraction evoked by electrical field stimulation (EFS) in superior mesenteric arterial. We also directly tested effect of PAR-2

activation on N-type Ca2+ current in isolated neurons of celiac ganglion (CG) which regulate vascular sympathetic tone of mesenteric artery. PAR-2 agonists suppressed neurogenic contractions evoked by EFS in endothelium-denuded mesenteric arterial strips and did not affect contraction by external application of NA. On the contrary, thrombin, a potent PAR-1 agonist, had no effect on EFS-evoked contraction. In addition, ω-conotoxin GVIA (CgTx), a selective N-type Ca2+ channel blocker, significantly inhibited EFS-evoked contraction and this blockade nearly completely occluded suppression of EFS-evoked contraction by PAR-2 agonists. Moreover, PAR-2 agonists diminished ICa measured using patch-clamp method in an irreversible manner in rat CG neurons. Meanwhile, thrombin had little effect on ICa. In addition, blockage of N-type Ca2+ channel with w-CgTx nearly completely occluded ICa inhibition by PAR-2 agonists. The present findings demonstrated that activation of PAR-2 suppresses peripheral sympathetic outflow by modulating N-type Ca2+ channel activity located in peripheral sympathetic nerve terminal, which appears to involve PAR-2-induced hypotension.

Abstract: Low voltage-activated (LVA) T-type calcium channels play critical roles in neuronal excitability. Here we confirm the involvement of T-type channel activation in the excitability and generation of action potentials (APs) in cultured hypothalamic POMC neurons. The specific T-type channel blocker NCC 55-0396 reduced neuronal excitability and prevented post-inhibitory

rebound (PIR) responses. The Kelch-like 1 (KLHL1) KO mouse model displays homeostatic changes in the expression of LVA calcium channels, resulting in a down-regulation of the $Ca_V3.2$ α_{1H} isoform in whole brain and cerebellum, in line with this protein's function as a positive modulator of $Ca_V3.2$. In the hypothalamus, however, α_{1H} signal did not decrease significantly, and biophysical and western blot analysis show that the $Ca_V3.1$ α_{1G} isoform is up-regulated, with a 40 % increase in T-type current density in cultured hypothalamic KLHL1-KO neurons compared to WT. A leftward shift and slight increase in window currents was observed, but not a change in resting membrane potential. We found that the excitability and PIR probability of KLHL1-KO neurons was increased compared to WT, and that the spontaneously firing neurons displayed a decreased mean-intraburst interval. T-type channels are potential therapeutic targets for treatment of obesity, and interestingly, the KLHL1-KO mice were adult-onset overweight. Leptin treatment (100 nM) resulted in membrane depolarization and increased excitability in WT neurons; this effect was prevented by treatment with NCC 55-0396. In contrast, KLHL1-KO neurons exhibited a basal excitability similar to the leptin-treated WT group, and leptin treatment did not elicit further depolarization. Leptin action occurred *via* TRPC1 channels, as pre-treatment with 100 μM 2-APB decreased the number of APs induced by leptin by 20%, whereas its application after leptin treatment produced a 50% reduction. Our data suggest that leptin activation of TRPC1 channels induces neuronal depolarization, which recruits T-type channel activity. Hypothalamic neuronal excitability in KLHL1-KO POMC neurons is increased, rendering these neurons leptin-resistant. This mouse model provides insights into the modulation of the hypothalamic excitability by α_{1G} and the potential impact of α_{1G} in obesity.

Title: Single channel and whole cell analysis of an exonic mutation in human CACNA1B linked to Myoclonus Dystonia syndrome

Authors: *A. S. ANDRADE[1], J. GROEN[2], K. RITZ[2], M. HAAGMANS[2], T. BRADLEY[2], H. JALALZADEH[2], P. NUERNBERG[2], F. BAAS[2], D. VERBEEK[3], M. AJ TIJSSEN[3], S. DENOME[1], D. LIPSCOMBE[1]
[1]Neurosci. Dept., Brown Univ., PROVIDENCE, RI; [2]Dept. of Neurol., University of Amsterdam, Netherlands; [3]Univ. Med. Ctr. Groningen, Groningen, Netherlands

Abstract: The CACNA1B gene encodes CaV2.2 voltage-gated calcium channel α1 subunits that underlie N-type calcium currents in neurons. CaV2.2 channels are expressed at central and peripheral presynaptic nerve terminals where they regulate transmitter release. Here we describe the functional consequences of a single point exonic mutation in CACNA1B that is linked to a human disorder. R1389H was identified by exome sequencing and exclusion linkage in a 3-generation pedigree with a unique familial Myoclonus Dystonia syndrome. R1389H is located in the outer region of the CaV2.2 ion pore of domain III. We compared the biophysical properties of macroscopic and unitary currents of human wild-type (WT) and R1389H mutant CaV2.2 channels transiently expressed in the human cell line, tsA201. We used 2 mM calcium (whole cell) or 110 mM barium (single channel) as charge carrier. A comparison of whole cell CaV2.2 currents suggests that R1389H has little or no influence on ion selectivity or the voltage-dependence and kinetics of channel activation and inactivation. However, current densities in cells expressing R1389H were larger on average compared to wild-type (R1389H: 97.9 ± 15.0 pA/pF, n = 21 cells; WT: 55.1 ± 9.1 pA/pF, n = 26 cells; p = 0.014, Student's t-test). This could reflect differences in overall expression levels or in single channel properties between mutant and WT. Single channel current amplitudes of R1389H CaV2.2 were significantly smaller (0.77 ± 0.01 pA, n = 8 patches) compared to WT (1.03 ± 0.02 pA, n = 8 patches; p = 9.1 × 10-10 at +20 mV, 110 mM Ba). Further analysis showed that human CaV2.2 channels open to two different current amplitudes the larger of which, O2 (1.03 pA), dominates and represents about 85% of all openings, compared to O1 (0.82 ± 0.02 pA, 8 patches). We observed direct transitions between O1 and O2 within a single opening, suggesting that CaV2.2 channels can exist in two open states that conduct ions at different rates. By contrast, single R1389H channels open predominantly to a smaller amplitude level that is not significantly different from the O1 amplitude of WT channels (p = 0.35, Student's t- test). Our data suggest that R1389H stabilizes the smaller amplitude open state as compared to WT, however, this does not explain the larger whole cell CaV2.2 currents in cells expressing R1389H. Although more analyses are necessary, our preliminary data suggest that the activation duration of single R1389H mutant channels may be longer on average, at the single channel level, compared to WT channels. The different biophysical properties of R1389H channels compared to WT may be linked to the observed hyperexcitability phenotype of the Myoclonus Dystonia syndrome.

Title: Functional analyses of human CaV3.3 calcium channel variants corresponding to rare disruptive mutations in CACNA1I in schizophrenia

Authors: ***J. Q. PAN**[1], A. ANDRADE[2], A. ALLEN[1], J. HOPE[1], D. LIPSCOMBE[2]

Abstract: Voltage-gated calcium channels are key regulators of gene expression, neurotransmission, excitability and many other neuronal functions. Large-scale genome wide association studies have implicated common alleles in *CACNA1C* and other genes as contributing to the risk of schizophrenia and other psychiatric disorders (PMID: 23453885). More recently, a collaborative exome sequencing study identified rare disruptive exonic variations in calcium channel genes of schizophrenia cases (PMID: 24463508). Collectively, common alleles and rare disruptive variations in calcium channel genes appear to contribute to psychiatric disease susceptibility. Two *de novo* mutations in *CACNA1I* were reported in schizophrenia proband by exome sequencing of 105 schizophrenia trios (PMID:23911319). *CACNA1I* encodes low threshold $Ca_V3.3$ channels with relatively slow deactivation kinetics that are expressed in brain, and that regulate oscillatory bursting. Here we compare the biophysical features of $Ca_V3.3$ mutants T797M and R1346H to wild-type (WT) channels, transiently expressed in tsA201cells. T797 and R1346 are located in the pore region in domains II and III of

$Ca_V3.3$, respectively. Currents were recorded using 5 mM calcium as the charge carrier. Interestingly, 24hrs after transfection, tsA201 cells expressing $Ca_V3.3$ channels developed slow, spontaneous, repetitive oscillatory spiking as the membrane potential was hyperpolarized, consistent with the pacemaking role of Ca_V3 channels in excitable cells. Calcium channel current densities in cells expressing R1346H were smaller on average (22.5 ± 3.4 pA/pF, n = 13) compared to currents in cells expressing WT or T797M channels (65.0 ± 18.3 pA/pF, n = 12 and 86.5 ± 11.2 pA/pF, n = 17). Kinetics of deactivation and inactivation, and ionic reversal potentials were not different among $Ca_V3.3$ channels. Activation thresholds for WT and T797M channels were similar to each other (-36.9 ± 1.8 mV, n = 12 and -35.9 ± 0.9 mV, n = 16) but slightly more hyperpolarized relative to R1346H (-33.3 ± 0.9 mV, n = 12). The steepness of WT and T797M channel activation curves were also similar (5.3 ± 0.4, n = 12, and 5.0 ± 0.2, n = 16) but both differed from R1346H (6.2 ± 0.4 mV, n = 12). Our analyses suggest that R1346H mutants have biophysical properties different from WT $Ca_V3.3$ channels. Further analyses of T797M and R1346H $Ca_V3.3$ channels in neurons are necessary to assess their influence on neuronal function including oscillatory bursting, and their potential role in schizophrenia.

Abstract: Gangliosides are sialic acid-containing, complex glycosphingolipids naturally enriched in neuronal membranes. They are important in the regulation of signaling protein

function, cell morphology, cell cycle and neurotransmission; and they also function as membrane receptors for compounds such as cholera, tetanus and botulinum toxin. Alterations in ganglioside concentration are associated with gangliosiodoses. The monosialoganglioside G_{M1} is particularly abundant in the plasma membrane of neurons. The segregation of gangliosides within restricted lipid rafts provides the molecular basis for lateral interactions between them and membrane proteins. G_{M1} is a known modulator of L-type calcium channels in neuroblastoma cells (Carlson et al, 1994) and cerebellar granule neurons (Wu et al, 1996); and of $Ca_V2.3$ channels in sperm (Cohen et al, 2014). Here we report the modulation of $Ca_V3.2$ channels by $G_{M1.}$ We analyzed the effect of G_{M1} on $Ca_V3.2$ channels constitutively expressed in HEK293 cells. Treatment with 1 μM G_{M1} decreased current densities by 32%, an effect that could be completely reversed by addition of the B subunit of Cholera toxin (ChTxB), a specific binding ligand for G_{M1}. This effect was specific for $Ca_V3.2$, as G_{M1} had no effect on currents arising from $Ca_V3.1$. Moreover, G_{D1a}, a ganglioside with similar structure to G_{M1} induced no changes in $Ca_V3.2$ current densities. Treatment with G_{M1} also resulted in a hyperpolarizing shift in steady state inactivation, not reverted by ChTxB. Co-localization analysis exhibits a strong association between $Ca_V3.2$ and G_{M1} (Pearson's coefficient 84 ± 0.02 %), yielding a Manders' coefficient of 75 ± 0.03 % of the G_{M1} signal associated with $Ca_V3.2$. Overall, hyperglycemic conditions in culture (25 mM glucose) resulted in a reduction of G_{M1}-induced inhibition due to a decreased ganglioside presence compared to normoglycemic conditions (5 mM). Our studies show that G_{M1} is an endogenous, reversible, negative modulator of T-type $Ca_V3.2$ channels and that conditions leading to changes in G_{M1} levels at the membrane may affect neuronal excitability, and could contribute to the beneficial effects of G_{M1} therapies. Dis-inhibition of $Ca_V3.2$ channels by decreases in G_{M1} could contribute to increased excitability in diabetic neuropathy and other diseases.

Title: Differential contribution of S4 voltage sensors to the low-voltage activation of CaV3.3 channel

Authors: A. L. SANCHEZ-SANDOVAL[1], Z. HERRERA-CARRILLO[1], C. E. DIAZ-VELASQUEZ[1], J. F. HIGUELDO-GARCIA[1], H. M. RIVERA[2], *J. GOMORA[3]

Abstract: The family of voltage-activated ion channels (VGIC), i.e., Na_V, K_V and Ca_V channels exhibits four highly conserved transmembrane -helix known as S4 segments, which play the role of voltage sensing. In each of these S4 segments or voltage sensors, there is a positive charged residue (lysine or arginine) every third position of the -helix. However the voltage range of activation is quite different among the whole family of VGIC. In the case of high-voltage (HVA) and low-voltage (LVA) activated Ca_v channels, their activation is around 30-40 mV apart, despite they show S4 segments with similar sequences. To investigate the contribution of S4 segments to the gating of $Ca_v3.3$ (LVA) and $Ca_v1.2$ (HVA) channels we have constructed several chimeras by swapping the S4 segments between these channels. Wild-type channels and chimeras were transiently transfected in HEK-293 cells and the whole-cell patch clamp technique was used to characterize the biophysical properties of the constructs. Our results indicate that the substitution of S4 segment of domain II (IIS4) of $Ca_v3.3$ for that of $Ca_v1.2$ (named chimera ICIIS4) induced a 30 mV positive shift in the *I-V* peak with respect to the $Ca_v3.3$ wild type (WT). Also, the IVS4 segment shifted the *I-V* by 15 mV to depolarized potentials, while substitution of segments IS4 and IIIS4 moved the gating of $Ca_v3.3$ to more negative potentials (~ 5-10 mV). There were also significant changes in steady-state inactivation and current kinetics. An unexpected result was a drastic decrease (< 95%) in the current density of the ICIIS4 channel at physiological potentials, although current was very robust at more positive potentials (up to +150 mV). Western blot and immunofluorescence evidences demonstrate that there were no a substantial reduction in the amount of channel protein in HEK-293 cells expressing the chimera ICIIS4, as compared with the $Ca_V3.3$ WT channel. A likely explanation is that the IIS4 segment (the whole or some residues of it) of $Ca_v1.2$ is interacting with the rest of the channel protein in such way that makes more stable the closed state of the channel, requiring stronger depolarizations to get the channels open. The results suggest that IIS4 and IVS4 voltage sensors contributed significantly to the low-voltage activation of $Ca_V3.3$ channels.

Title: Differential distribution of Shank and GKAP at postsynaptic density

Authors: *J.-H. TAO-CHENG, Y. YANG, T. S. REESE, A. DOSEMECI
NINDS, NIH, Bethesda, MD

Abstract: Shank and GKAP are both scaffold proteins and binding partners at the postsynaptic density (PSD) of glutamatergic synapses. The distribution and dynamics of Shank and GKAP were studied in dissociated hippocampal cultures by pre-embedding immunogold electron microscopy. The PDZ domain of Shank is known to bind to the C-terminal of GKAP. Here, antibodies against epitopes containing their respective binding sites were used with the expectation that if all Shank molecules are bound to GKAP, distribution of label for the two proteins would coincide. However, labels for the mutual binding sites on Shank and GKAP showed significant differences in distribution, with label for GKAP located closer to the postsynaptic membrane, and label for Shank extending deeper into the cytoplasm. Under basal conditions, label for GKAP resided in a narrow band (~20-50 nm) with a median distance of ~30 nm from the postsynaptic membrane. In contrast, label for Shank occupied a wider band (~30-100 nm) with a median distance from the membrane of ~ 55 nm. Approximately 40% of label for Shank was located in the distal area of the PSD complex, 60-120 nm from the postsynaptic membrane, where less than 5% of GKAP resided. These observations indicate the existence of a population of Shank molecules at the PSD complex that are not bound to GKAP. Upon depolarization with high K+ (90 mM, 2 min), the intensity or distribution of label for GKAP did not change, but the intensity of label for Shank at PSD increased to ~150% of controls while the median distance of label increased from 54 to 61 nm. These results indicate a preferential recruitment of Shank to more distal parts of the PSD complex. Conversely, upon incubation in Ca2+-free medium containing EGTA (5 min), labeling intensity of Shank at the PSD decreased to ~75% of controls and the median distance of label from postsynaptic membrane decreased from 53 to 46 nm, indicating a preferential loss of Shank molecules in the distal area of the PSD complex. Additionally, a subpopulation of synapses emerged after EGTA treatment in which label for Shank appeared in a narrow band close to the postsynaptic membrane, a labeling pattern resembling that for GKAP. Thus, in these synapses under low calcium conditions, Shank

molecules are absent in the distal area of the PSD complex but persist in the proximal area near GKAP. Altogether these observations identify two pools of Shank at the PSD complex, one relatively stable and presumably bound to GKAP, and another more dynamic and situated at a more distal location that would preclude binding to GKAP.

Title: Palmitoylation-dependent CDKL5-PSD95 interaction regulates synaptic targeting and function of CDKL5

Authors: *Z.-Q. XIONG
Inst. Neurosci, Shanghai, China

Abstract: The X-linked gene cyclin-dependent kinase-like 5 (CDKL5) is mutated in severe neurodevelopmental disorders, including some forms of atypical Rett syndrome, but the function and regulation of CDKL5 protein in neurons remain to be elucidated. Here, we show that CDKL5 binds to the scaffolding protein postsynaptic density (PSD)-95, and that this binding promotes the targeting of CDKL5 to excitatory synapses. Interestingly, this binding is not constitutive, but governed by palmitate cycling on PSD-95. Furthermore, pathogenic mutations that truncate the C-terminal tail of CDKL5 diminish its binding to PSD-95 and synaptic accumulation. Importantly, down-regulation of CDKL5 by RNA interference (RNAi) or interference with the CDKL5-PSD-95 interaction inhibits dendritic spine formation and growth. These results demonstrate a critical role of the palmitoylation-dependent CDKL5-PSD-95 interaction in localizing CDKL5 to synapses for normal spine development and suggest that disruption of this interaction by pathogenic mutations may be implicated in the pathogenesis of CDKL5-related disorders.

Title: Neuronal pentraxins coordinate excitatory synapse maturation of parvalbumin expressing interneurons

Authors: *K. A. PELKEY[1], E. BARKSDALE[2], M. T. CRAIG[2], X. YUAN[2], M. SUKUMARAN[2], G. A. VARGISH[2], P. F. WORLEY[3], C. J. MCBAIN[2]
[1]NICHD/LCSN, NIH, BETHESDA, MD; [2]NIH, Bethesda, MD; [3]JHU, Baltimore, MD

Abstract: Afferent driven recruitment of widespread perisomatic inhibition through parvalbumin expressing basket cells (PVBCs) critically dictates the synaptic integration properties of downstream principal cells (PCs). At the network level such feedforward inhibition provides temporal constraints upon PC excitation-spike coupling to coordinate and bind firing rates within PC assemblies. Indeed deficient recruitment of PVBCs disrupts PC synchronization and promotes cognitive deficits associated with disorders like schizophrenia. To reliably coordinate network activity PVBCs exhibit specialized synaptic and membrane properties that promote efficient afferent recruitment such as the expression of high conductance, kinetically fast GluA4-containing AMPARs. Here, we demonstrate that at the neonatal stage interneurons fated to become PVBCs lack GluA4 only upregulating this subunit during the second and third postnatal weeks coincident with the developmental profiles of other PVBC hallmark proteins such as Kv3.1b, synaptotagmin 2 (Syt2), and PV itself. This developmental time course is also shared by the AMPAR interacting proteins neuronal pentraxin 2 (NPTX2/NARP) and neuronal pentraxin receptor (NPTXR/3). While previous work has implicated neuronal pentraxins in the synaptic localization of AMPARs we report a complete loss of PVBC GluA4 in NPTX2-/-/NPTXR-/- double knockout mice indicating a role beyond synaptic clustering. Quantitative PCR analyses revealed comparable levels of GluA4 mRNA between wild type and NPTX2-/-/NPTXR-/- brains suggesting normal GluA4 transcription with disrupted translation and/or protein stabilization. Moreover, development of parvalbumin, Syt2, and perineuronal nets proceeds normally in PVBCs of NPTX2-/-/NPTXR-/- mice indicating a selective deficit in AMPAR maturation during circuit integration. Functionally, adolescent NPTX2-/-/NPTXR-/- mice exhibit profound deficits

in basal PVBC AMPAR function with consequent disruption of hippocampal inhibition/excitation (I/E) balance and rhythmogenesis. In addition neonatal NPTX2-/-/NPTXR-/- display a protracted developmental window for hippocampal circuit maturation as revealed by prolonged expression of giant depolarizing potentials (GDPs) compared to wild type animals. These findings implicate neuronal pentraxins in controlling PVBC synaptic integration within cortical circuits providing a novel potential therapeutic target for disorders associated with altered I/E dynamics.

Title: Activity-dependent ubiquitination of GluA1 and GluA2 regulates AMPA receptor intracellular trafficking and degradation

Authors: *V. ANGGONO[1], J. WIDAGDO[2], Y. CHAI[1], M. RIDDER[2], P. SAH[2], R. L. HUGANIR[3]
[1]Clem Jones Ctr. for Ageing Dementia Res., [2]The Univ. of Queensland, Brisbane, Australia; [3]Dept. of Neurosci., The Johns Hopkins Univ. Sch. of Med., Baltimore, MD

Abstract: AMPA receptors (AMPARs) have recently been shown to undergo posttranslational ubiquitination in mammalian neurons. However, the underlying molecular mechanisms are poorly understood and remain controversial. Here we report that all four AMPAR subunits

(GluA1-4) are rapidly ubiquitinated upon brief applications of AMPA or bicuculline in cultured neurons. This process is Ca2+-dependent and requires the activity of L-type voltage-gated Ca2+-channel and Ca2+/calmodulin-dependent kinase II. The ubiquitination of all subunits occurs exclusively on AMPARs located on the plasma membrane post-endocytosis. We further mapped the sites of ubiquitination on lysine residues in GluA1 and GluA2 carboxy-terminal tails. Mutation of these lysines did not affect basal surface expression or AMPA-induced internalisation of GluA1 and GluA2 subunits. Instead, it reduced the intracellular trafficking of AMPARs to the late endosomes and thus, protein degradation. These data indicate that ubiquitination is important for endosomal sorting and stability of AMPARs, which may be crucial for synaptic plasticity.

Title: The de-ubiquitinating enzyme, USP8, is regulated distinctly by NMDA receptor signaling

Authors: *M. GOO, S. SCUDDER, A. MOLTENI, G. PATRICK
UCSD, La Jolla, CA

Abstract: Ubiquitination has emerged as a key post-translational modification to regulate trafficking and turnover of synaptic proteins. We have previously determined that the ubiquitination of AMPA receptors (AMPAR) by the HECT E3, ubiquitin ligase Nedd4-1 mediates a distinct internalization and endocytic sorting pathway to lysosomes for degradation. Specifically, we found that AMPAR ubiquitination occurs exclusively under AMPAR activation while NMDA receptor (NMDAR) activation, which also promotes AMPAR internalization, does not lead to AMPAR ubiquitination. Additionally, in recent studies we show that application of glutamate and glycine does not induce AMPAR ubiquitination. Since glutamate and glycine not

only activates AMPAR but also NMDAR, we hypothesized that NMDAR signaling negatively regulates AMPAR ubiquitination by activating a de-ubiquitinating enzyme (DUB) leading to the deubiquitation of AMPARs. To further support this hypothesis, we found that glutamate stimulation with subsequent blockage of NMDAR with APV induced robust AMPAR ubiquitination. We then identified that USP8/UBPY, a DUB which functions in the endosomal sorting complex required for transport (ESCRT) pathway, is specifically activated by NMDAR activation but not AMPAR activation. NMDAR activation leads to a rapid dephosphorylation of USP8, which increases its activity in a calcium dependent manner. Functionally, we found that overexpression of USP8 in hippocampal neurons significantly increases synaptic strength while knockdown of USP8 had significant decrease in synaptic strength. Taken together, we provide the first evidence for diametric and activity-dependent control of not only a ligase but a DUB at synapses in the regulation of surface AMPAR levels and synaptic strength.

Abstract: Regulated expression of synaptic nicotinic acetylcholine receptors (nAChRs) is vital for the development, maintenance and plasticity of cholinergic neurotransmission. Our lab has previously identified a Wnt-mediated signaling pathway that is responsible for the translocation of ACR-16, the *C. elegans* homolog of the vertebrate α7 nAChR, from subsynaptic stores to the surface of muscle cells. Mutations that disrupt this signaling pathway selectively decrease postsynaptic currents mediated by α7 nAChRs. In contrast, currents mediated by GABA receptors, or by non- α7 nAChRs (UNC-29) are unaffected. To further identify the molecules that participate in the trafficking of α7/ACR-16, we screened for genes that phenocopy acr-16 mutants when knocked down using RNAi. Similar to acr-16 mutants, RNAi against the Rho

GTPase gene cdc-42, produced a significant movement defect when in the unc-29 genetic background, but did not appreciably affect movement in wild type worms. Furthermore, we found that cdc-42 null mutants also produced a severe movement defect, but only in combination with the unc-29 mutation. This so-called synthetic defect suggested that the trafficking or function of α7/ACR-16, but not UNC-29 receptors, is dependent on CDC-42. We measured *in vivo* ACh-gated current in muscle cells and found that cdc-42 mutants had a specific decrease in ACR-16-mediated current, similar to that found in Wnt mutants. Interestingly, we found that cdc-42 mutants exhibited a decrease in ACR-16::GFP in muscle arms, contrary to what we observed in Wnt mutants. This result, in addition to data from informative cdc-42/Wnt double mutants, suggests that CDC-42 functions upstream of Wnt signaling by trafficking ACR-16 to subsynaptic stores, but does not mediate translocation of receptors to the cell surface. Together, these findings aid in understanding the pathway through which α7 nAChRs are targeted to synapses.

Title: CKAMP44 and TARP γ-8 modulate AMPA receptor-mediated currents in dentate gyrus granule cells

Authors: ***E. JACOBI**[1], P. FARROW[1], K. KHODOSEVICH[2], H. MONYER[2], J. V. ENGELHARDT[1]
[1]A300 Synaptic Signalling and Neurodegeneration, DZNE & DKFZ, Heidelberg, Germany; [2]Clin. Neurobio., Univ. Hosp. and DKFZ Heidelberg, Heidelberg, Germany

Abstract: Auxiliary subunits modulate gating properties, subcellular localization and surface trafficking of AMPA receptors (AMPARs). In dentate gyrus granule cells two prominently expressed AMPAR auxiliary subunits, CKAMP44 and TARP γ-8, show overlapping as well as opposing influences on AMPAR expression and function. TARP γ-8 and CKAMP44 both

increase the rate of deactivation, but have an opposite effect on receptor desensitization and recovery from desensitization. Interestingly, the slow recovery from desensitization affects synaptic short-term plasticity in dentate gyrus granule cells. This stands in contrast to the majority of synapses in the CNS, where changes in release probability of transmitter vesicles shape short-term plasticity. Furthermore, paired pulse ratio of synaptic AMPAR-mediated EPSCs, as a measurement of short-term plasticity, is increased and decreased in *CKAMP44*$^{-/-}$ and *TARP γ-8*$^{-/-}$ mice, respectively, when compared to wildtype mice. Paired pulse ratios did not differ between the genotypes when recordings were performed in the presence of cyclothiazide, a potent inhibitor of AMPAR desensitization. Thus, TARP γ-8 and CKAMP44 modulate short-term plasticity by their influence on the recovery from desensitization of AMPARs. Beside their effects on AMPAR gating, extrasynaptic and synaptic AMPAR-mediated currents are reduced in granule cells of *CKAMP44*$^{-/-}$ and *TARP γ-8*$^{-/-}$ mice, indicating that both auxiliary proteins promote the trafficking of AMPARs to the cell surface and their integration into synapses. Finally, extrasynaptic and synaptic AMPAR-mediated currents were strongly reduced in *TARP γ-8/CKAMP44* double-knockout mice, suggesting that these two co-expressed auxiliary proteins are the main auxiliary proteins, that traffic AMPAR to the cell surface of dentate gyrus granule cells. In conclusion, we demonstrate the importance of TARP γ-8 and CKAMP44 in influencing both AMPA receptor gating and trafficking and thereby fine-tuning the excitatory drive onto dentate gyrus granule cells.

Title: Arc regulates AMPA receptor-mediated synaptic transmission via direct interaction with the endocytic machinery

Authors: *S. A. CORREA[1], J. MULLER[1], M. J. WALL[1], S. C. WAUTERS[1], Y. JANUARIO[2], L. P. DE ALMEIDA[2], L. L. DASILVA[2]

Abstract: Activity-regulated cytoskeleton (Arc) is a neuron-specific immediate early gene required for learning and memory. As such, Arc protein expression is critical for group 1 metabotropic glutamate receptor-dependent long-term depression and homeostatic synaptic scaling by promoting endocytosis of AMPA receptors (AMPAR). To map the steps linking Arc expression to endocytosis of AMPAR, we immunoprecipitated endogenous Arc from C57BL/6 mouse hippocampal lysates and identified unknown components of the endocytic machinery as Arc-binding proteins using mass spectrometry. To characterize the Arc/endocytic proteins interaction we used several strategies: **a)** Arc co-IPs with components of the endocytic machinery in hippocampal lysates from adult C57BL/6 mice and **b)** recombinant Arc directly binds to the GST-containing the specific components of the endocytic machinery. To determine the Arc amino-acid (aa) sequence that mediates the Arc-endocytic proteins interaction, we generated Arc mutants with successive 50 aa up to 200 aa deletions from either the Nt or Ct and performed pull-down assays using GST-containing endocytic proteins. Next, we tested whether Arc regulates AMPAR endocytosis via the interaction with newly identified components of the endocytic machinery. To do this, we recorded AMPAR-dependent miniature excitatory postsynaptic currents (mEPSCs) from primary hippocampal cultures (PHCs) at 15-18 days *in vitro*. PHCs co-expressed microRNAs-eGFP-tagged to knockdown the endocytic proteins with either Arc-wild-type (Arc-WT) or Arc-mutants, which do not interact with the endocytic machinery. Scrambled miRNAs were used as a control. The significant decrease in mEPSC amplitude observed in PHC expressing Arc-WT is reduced in cells expressing Arc-mutants, suggesting that the Arc-dependent endocytosis of AMPAR requires interaction with the new identified components of the endocytic machinery. In conformation, the increase in AMPAR-endocytosis promoted by Arc was reduced in cells where the expression of these endocytic proteins was depleted. Together, the findings from this study identified the mechanistic link in which neuronal activity regulates constitutive trafficking to control synaptic strength.

Title: Cognitive flexibility and LTD are impaired following β-catenin stabilization *in vivo*

Authors: *F. MILLS[1], T. BARTLETT[2], L. DISSING-OLESSEN[3], M. WISNIEWSKA[4], J. KUZNICKI[4], B. MACVICAR[3], Y. WANG[2], S. BAMJI[1]

Abstract: The cadherin/β-catenin adhesion complex is a key mediator of the bidirectional changes in synapse strength which are believed to underlie complex learning and memory. In the present study, we demonstrate that stabilization of β-catenin in the hippocampus of adult mice results in significant impairments in cognitive flexibility and spatial reversal learning, including impaired extinction during the reversal phase of the Morris Water maze and deficits in a delayed non-match to place T-maze task. In accordance with this, β-catenin stabilization was found to abolish long-term depression (LTD) by stabilizing cadherin at the synaptic membrane and impairing AMPA receptor endocytosis, while leaving basal synaptic transmission and long-term potentiation (LTP) unaffected. These results demonstrate that the β-catenin/cadherin adhesion complex plays an important role in learning and memory, and that aberrant increases in synaptic adhesion can have deleterious effects on cognitive function.

Title: Aggressive experience increases PSD-95 in the nucleus accumbens of female hamsters via the Fragile X Mental Retardation Protein Signaling Pathway

Authors: *L. E. BEEN, K. M. MOORE, B. C. KENNEDY, R. L. MEISEL
Neurosci., Univ. of Minnesota, Minneapolis, MN

Abstract: Abstract: We recently discovered that aggressive experience increases dendritic spine density on medium spiny neurons in the nucleus accumbens (NAc) of female hamsters, suggesting that, like in males, the NAc may be a key brain region for modulating plasticity associated with aggressive experience in females. How aggressive experience produces changes in dendritic spine formation is, however, unknown. One possible mechanism underlying this synaptic plasticity is the Fragile X Mental Retardation Protein (FMRP) signaling pathway. Indeed, *in vitro* studies have demonstrated that binding at G-protein coupled receptors leads to activation of FMRP and dendritic protein synthesis consistent with spine formation. We therefore hypothesized that aggressive experience activates metabotropic glutamate receptor 5 (mGluR5), resulting in a decreased phosphorylation of FMRP and increased expression of spine scaffolding proteins, such as PSD-95, in the NAc. To test this hypothesis, adult female hamsters were randomly assigned to one of two behavioral conditions: experienced subjects received five consecutive days of aggressive experience, whereas naïve control subjects remained in their home cage. Thirty minutes prior to each aggressive or control experience, females received an i.p. injection of MPEP, an mGluR5 antagonist, or vehicle control. Following the last aggressive experience, subjects were sacrificed and bilateral tissue punches were taken from the NAc. PCR and Western blot analyses revealed significant increases in PSD95 mRNA and protein in the NAc of experienced subjects compared with naïve control subjects. This increase was blocked by systemic administration of MPEP. In addition, Western blot analysis revealed a significant decrease in the phosphorylation of FMRP protein in the NAc of experienced subjects compared with naïve controls. Together, these data suggest that the FMRP pathway is involved in regulating synaptic plasticity in the NAc following aggressive experience in female hamsters.

Abstract: Activity-dependent gene transcription and protein synthesis underlie many forms of learning-related synaptic plasticity. At excitatory glutamatergic synapses, the immediate early gene product Arc/Arg3.1 couples synaptic activity to postsynaptic endocytosis of AMPA-type glutamate receptors. Although the mechanisms for Arc induction have been described, little is known regarding the molecular machinery that terminates Arc function. Here we demonstrate that the RING domain ubiquitin ligase Triad3A/RNF216 ubiquitinates Arc, resulting in its rapid proteasomal degradation. Triad3A associates with Arc, localizes to clathrin-coated pits, and is associated with endocytic sites in dendrites and spines. In the absence of Triad3A, Arc accumulates, leading to the loss of surface AMPA receptors. Furthermore, loss of Triad3A mimics and occludes Arc-dependent forms of synaptic plasticity. Thus, degradation of Arc by clathrin-localized Triad3A regulates the availability of synaptic AMPA receptors and temporally tunes Arc-mediated plasticity at glutamatergic synapses.

Title: Systematic analysis of purification process of postsynaptic densities (PSDs) and postsynaptic membrane rafts (PSRs) by solubilization of synaptic plasma membrane with different types of detergents

Authors: *T. SUZUKI[1], L. ZHAO[1], G. WEIHENG[1], H. SAKAGAMI[2]
[1]Shinshu Univ. Grad. Sch. Med., Matsumoto, Japan; [2]Anat., Kitasato Univ. Sch. Med., Sagamihara, Japan

Abstract: Both postsynaptic density (PSD) and postsynaptic membrane rafts (PSR) are isolated separately. However, PSD and PSR are considered to make a complex *in vivo* (Suzuki et al., J. Neurochem. 2011, Liu et al., J. Neurogenetics, 2013). To elucidate the more detailed structural relationship between PSD and PSR, we investigated purification process of PSD and PSR from rat forebrain synaptic plasma membrane (SPM) using three different detergents, TX-100, n-octyl β-D-glucoside (OG) and CHAPSO at varied concentrations, and examined the distribution of subsynaptic structures and PSD proteins (both type I and type II) on sucrose density gradient by SDS-PAGE, electron microscopy and western blotting. This type of systematic examination has not been carried out before. Three types of detergents used showed distinct separation profiles of the synaptic subdomains. After TX-100 treatment, type I PSD was recovered in two fractions: pellet (fraction 12) and insoluble fraction 8, the latter of which contained membrane raft-PSD complex that was partially broken. Conventional PSD prepared after TX-100 treatment was suggested to be a mixture of these two types of type I PSD pools (pellet and fraction 8). It was found that the conventional PSD does not contain inhibitory type II PSDs. Association of type I PSD with PSR was identified in the TX-100-treatment but not in the OG-treatment. Association of type II PSD with membrane rafts was suggested in OG- and CHAPSO-treatments but not in the TX-100-treatment. Treatment with relatively high concentration of detergents, in particular OG, solubilized the type I PSD proteins. CHAPSO-treatment produced various novel fractions containing unique subsynaptic structures. Besides pellet/fraction 12, novel PSD-containing structures were isolated in an insoluble fraction 11. Tow pools of GluA were identified in the synaptic region in the OG- and CHAPSO-treatments; one was associated with type I PSD and the other possibly with membrane rafts. The knowledge obtained in this study is useful in understanding the studies using isolated PSDs and PSRs. Furthermore, novel subsynaptic structures obtained in this study may become useful materials for future analyses to understand the organization of synapses at the molecular level.

Title: Confined diffusion of AMPA receptors in the postsynaptic density

Authors: Y. SONG[1], T. LI[2], T. A. BLANPIED[3], *S. RAGHAVACHARI[4]
[1]Physics, Duke Univ., Durham, NC; [2]MSTP and Dept. of Physiol. and Program in Neurosci., [3]Dept. of Physiol. and Program in Neurosci., Univ. of Maryland Sch. of Med., Baltimore, MD; [4]Neurobiol, Duke Univ. Med. Ctr., DURHAM, NC

Abstract: Mechanisms that regulate the insertion, movement, positioning, and removal of AMPA-type glutamate receptors within the postsynaptic density (PSD) determine the strength of excitatory neurotransmission at excitatory synapses. Two key processes that control synaptic AMPAR number are receptor diffusion within the synaptic and extrasynaptic space and interactions between receptors and PSD scaffold proteins. Electron microscopy suggests that the PSD is highly crowded, potentially limiting the ability of receptors to diffuse and interact with scaffold proteins. However, the contribution of macromolecular crowding to receptor retention remains to be tested systematically. Here, we combine experimental and computational approaches to test the effect of synaptic steric hindrance on receptor mobility and enrichment. To examine the distinct contributions of crowding and receptor-scaffold binding, we developed a computational model for AMPAR diffusion in the synaptic and extrasynaptic space, which contains immobile obstacles, representing scaffolding, receptor and adhesion molecules in the PSD. The spatial distribution of scaffold proteins was determined directly from photo-activated localization microscopy measurements that mapped molecular positions with a resolution of ~30 nm. The AMPAR/scaffold association and dissociation rates were adjusted by computer simulations to fit single-particle tracking and fluorescence recovery after photobleaching measurements. The model predicts that variation of receptor size has the most influence on the recovery curves while variation of kinetic rates did not significantly alter receptor residence time or mobility. In order to directly address these questions experimentally and to verify model predictions, we used single-molecule tracking and bulk imaging techniques such as fluorescence recovery after photobleaching to quantify the diffusion dynamics of AMPARs and a set of uniquely designed transmembrane (TM) proteins that mimic receptors on living synapses. We find that diffusion of TM proteins is slowed in the synapse even in the absence of binding

interactions, while adding a single synaptic binding motif to a small TM protein also slows its diffusion within the synapse, consistent with modeling results. We also examined the effect of acutely increasing the protein bulk of the TM intracellular domain on its diffusion and exchange within dendritic spines. These results suggest that both protein size and binding play important roles in retaining surface-diffusing TM proteins within the excitatory synapse and shed light on the biophysical mechanisms that lead to high density of AMPARs at synapses.

Title: Tomosyn participates in synaptic plasticity and is subject to activity-dependent proteasomal regulation

Authors: ***J. J. SALDATE**, V. A. CAZARES, A. J. MANLY, E. L. STUENKEL
Univ. of Michigan, Ann Arbor, MI

Abstract: Transmission of information through neural circuits is dynamically modifiable and dependent upon neuronal activity, a process referred to as synaptic plasticity. Modulation of post-synaptic receptors is an extensively studied mechanism by which synaptic plasticity is implemented. However, presynaptic mechanisms have also been elucidated as integral to the modulation of synaptic strength through the regulation of vesicle release. The exocytosis of synaptic vesicles is largely mediated by the SNARE family proteins, which form trans-complexes between the vesicle and presynaptic plasma membrane. These proteins are essential to regulated molecular mechanisms underlying the efficacy of neurotransmission. Tomosyn is a unique SNARE protein in that it is cytosolic and serves as a negative regulator of presynaptic release. The level and activity-state of tomosyn in nerve terminals affects release probability by negatively regulating the availability of vesicles in the active zone. What remains unknown are the mechanisms and signaling pathways by which tomosyn activity is modulated. Our studies

support that the ubiquitin-proteasome system (UPS) is particularly influential in modulating synaptic strength. Preliminary data presented here, from cultured hippocampal neurons (21+ DIV), indicate that tomosyn proteostasis and activity are subject to regulation by the UPS. Tomosyn protein levels increase upon acute pharmacological proteasome blockade. This regulation may be mediated through a novel interaction with the E3 ubiquitin-ligase HRD1. Immunoprecipitation of tomosyn results in co-precipitation of HRD1, which has the ability to ubiquitinate tomosyn *in vitro*. This interaction is activity-dependent and subject to homeostatic plasticity and increases upon induction of homeostatic plasticity via AMPAR blockade using CNQX. Homeostatic activity subsequently decreases the overall endogenous tomosyn levels in our hippocampal culture system. As a whole, preliminary evidence presented here indicates that the UPS may induce presynaptically-mediated homeostatic plasticity in an activity-dependent fashion through the precise regulation of tomosyn.

Title: Synaptic protein distribution organized by a PSD nanocolumn

Authors: *A.-H. TANG[1], H. D. MACGILLAVRY[2], T. A. BLANPIED[1]
[1]Physiol., Univ. of Maryland Sch. of Med., Baltimore, MD; [2]Dept. of Cell Biol., Utrecht Univ., Utrecht, Netherlands

Abstract: Scaffold proteins are abundant and essential components of the postsynaptic density (PSD). They form the foundation of excitatory synaptic transmission by establishing the architecture of the PSD; deletion or mutations in their human genes cause severe neuropsychiatric disorders including autism, mental retardation, and schizophrenia. Though the

characteristics of individual constituents of the PSD has been extensively studied with genetic, biochemical, and molecular analysis, it is still unclear how these constituents are arranged within individual PSDs. Previously, by measuring the internal structure of single PSDs in live neurons using photoactivated localization microscopy (PALM), we have found that four major PSD scaffold proteins, PSD-95, GKAP, Shank and Homer1, were each organized in distinctive ~80 nm ensembles, and that PSD-95 ensembles were enriched for both GluA2-containing AMPARs and GluN2B-containing NMDARs. We now report that ensembles of PSD-95 undergo NMDAR-triggered reorganization: in particular, activation of NMDARs in an LTD induction protocol prompted the diminishment of PSD-95 nanoclusters. This effect is predicted to accentuate the decrease in synaptic strength during LTD by dispersing receptors within the synapse to regions of less efficacious glutamate exposure. To examine how the nanoclustered PSD-95 distribution may affect other synaptic constituents, we used multiple-color 3D stochastic optical reconstruction microscopy (STORM). We find that nano-ensembles of other PSD scaffold molecules are highly correlated to PSD-95, indicating that multiple proteins distributed along the axial extent of the PSD are co-enriched at specific points across the face of the synapse. This relatively compact, vertically oriented molecular organization within the bounds of the synapse suggests a “PSD nanocolumn” that may be important for establishing and modulating synapse function.

Title: Epigenetic editing of the PSD95 gene promoter impacts neuronal architecture

Authors: *F. J. BUSTOS[1,2,3], L. VARELA-NALLAR[3], R. AGUILAR[3,2], B. HENRIQUEZ[3], F. FALAHI[4], M. G. ROTS[4], M. MONTECINO[2,3], B. VAN ZUNDERT[3]
[1]MIT, Cambridge, MA; [2]FONDAP CGR, Santiago, Chile; [3]Ctr. de Investigaciones Biomedicas, Univ. Andres Bello, Santiago, Chile; [4]Epigenetic Editing, Dept. of Med. Biol. and Pathology, Univ. of Groningen, Groningen, Netherlands

Abstract: Epigenetic editing aims for long-term modulation of gene expression through changes in the epigenetic state of genes. To achieve specific and local epigenetic reprogramming, diverse epigenetic effector domains can be fused to zinc finger proteins (ZFPs). Artificial transcription factors (ATFs) containing such ZFPs have recently been successfully used to specifically and efficiently modulate various endogenous cancer genes. We first established a histone modification pattern of the neuronal plasticity gene PSD95, and then we designed ZFPs to induce targeted re-writing of the original histone signature of the PSD95 gene promoter and hence modulate bi-directionally its expression in primary hipocampal neurons. We focused on the PSD95 gene because it is the most abundant scaffolding protein in the post-synaptic density that regulates spine maturation, dendritic stabilization, and LTP induction. A ZFP was generated to target the PSD95 gene promoter (PSD95-ZFP) and directly cloned into lentiviral vectors alone (NoED; no effector domain), or fused to activation (VP64) or repression (SKD, G9a, Suv39H1del76) domains. Primary hippocampal neurons were infected with these lentiviral particles at 7 days *in vitro* (DIV) and processed at 12 DIV. ChiP-seq assays in hippocampal neurons demonstrate that PSD95-ATF-NOED binds specifically and efficiently to the PSD95 gene promoter (chromosome 10q24). Furthermore, we find that PSD95-VP64 increased histone H3 acetylation (H3Ac) at the promoter, concomitant with increased global and synaptic upregulation of PSD95 protein levels. Conversely, PSD95-SKD, -G9a or -Suv leads to decreased H3Ac and enhanced H3K9 methylation at the promoter, which parallels with a repression in the global and synaptic PSD95 protein levels. Additionally, morphological analyses showed that similar as for overexpression of PSD95, PSD95-VP64 decreases dendritic branching, whereas PSD95-SKD, -G9a or -Suv increase dendritic arborization relative to control neurons and those transfected with PSD95-NoED. Our data shows that we were able to generate a locus-specific ZFP that binds to the PSD95 promoter. This ZFP was able to direct epigenetic enzymes to edit histone tail modifications associated to the promoter thereby altering endogenous PSD95 gene expression. Additionally, modulation of PSD95 expression by epigenetic editing impacts dendritic arborization and spine morphology in hippocampal neurons.

Title: Developmental regulation of Kalrn promoter usage alters protein localization, lipid binding and intracellular trafficking at the PSD

Authors: *M. B. MILLER, K. S. VISHWANATHA, R. E. MAINS, B. A. EIPPER
Dept. of Neurosci., Univ. of Connecticut Hlth. Ctr., Farmington, CT

Abstract: Kalirin (Kal) is a dual Rho GDP/GTP exchange factor (GEF), highly expressed in the central nervous system (CNS). Alternative splicing generates 3 major Kalirin isoforms, which are developmentally regulated and serve essential roles in CNS development and function. While Kal9 and Kal12 are crucial for normal neurite outgrowth, Kal7 plays important roles in dendritic spine formation and synaptic plasticity. Full-length Kalirin expression is initiated at one of four alternate promoters, resulting in four unique initial exons (Ex1A, 1B, 1C, 1D). While roles of alternatively spliced Kalirin molecules have been studied extensively, little is known about the use and functional significance of the alternate promoters. We found that Kalrn promoter usage is developmentally regulated and varies across brain regions. Ex1B is used early in development, with Ex1C expression increasing postnatally. Promoters A and D are rarely used in brain, but Ex1D predominates in endocrine tissues. Interestingly, structural modeling and biophysical studies predict that Ex1C encodes an amphipathic helix, potentially influencing the adjacent Sec14 lipid-binding domain. We previously found that KalSec14 generated using Ex1A (aSec14) binds most strongly to PI(3,4,5)P3, with some binding to other phosphoinositides (PIPs), but not to more prevalent membrane lipids. Here, we show that alternative promoter usage confers differential lipid binding properties to KalSec14: bSec14 does not bind strongly to any of the lipids tested and cSec14 binds preferentially to PI(4)P. PI(4)P is enriched in the membranes of the trans-Golgi network (TGN) and when GFP-fusion proteins were expressed in neuroendocrine cells, cSec14, but not a- or b-Sec14, localized to the TGN. Since PIPs mediate localized protein interactions necessary for endocytic pathway functions, like AMPA receptor recycling, we used a transferrin uptake assay to evaluate KalSec14 interaction with endocytic pathway function. cSec14 expression interferes with receptor-mediated endocytosis in non-neuronal cells to a greater extent than bSec14. Lastly, we used an antibody specific to Ex1C to evaluate subcellular localization of Ex1C-containing proteins. In cultured neurons, most of the Ex1C signal was localized to dendritic spines and juxtaposed to Vglut1 puncta. In subcellular fractions of adult

mouse brain, the PSD is enriched in Ex1C-containing Kal7, while most extrasynaptic Kal7 is immune-negative for Ex1C. Thus, developmental regulation of Kalrn promoter usage modulates the lipid binding properties of the Sec14 domain, contributing to protein localization and interactions with membrane trafficking machinery.

Title: Immunoisolation and characterization of the PSD-95 interactome from postmortem human tissue with LC MS/MS

Authors: ***A. FUNK**[1], S. O'DONOVAN[1], J. MEADOR-WOODRUFF[2], R. MCCULLUMSMITH[1]
[1]Psychiatry and Behavioral Neurosci., Univ. of Cincinnati, Cincinnati, OH; [2]Psychiatry and Behavioral Neurobio., UAB, Birmingham, AL

Abstract: PSD-95 is the most abundant scaffolding protein in the postsynaptic density (PSD) and plays a major role in trafficking of ionotropic glutamate receptors. Through its PDZ domain, PSD-95 interacts with many synaptic proteins that regulate synaptic function. We developed a modified immunoisolation protocol using PSD-95 as the target to determine the PSD-95 interactome in four human brain regions (DLPFC, ACC, STG, and Hippocampus). We verified the specificity of this immunoisolation with Western blot analysis and mass spectrometry. Western blot analysis indicates a significant enrichment of PSD-95, capturing all available PSD-95 from 1500ug of total brain homogenate. Our PSD-95 immunoisolations were free of non-PSD proteins such as calreticulin, but included the GluA4 AMPAR subunit. Preliminary data from mass spectrometry show co-isolation of key postsynaptic components in order of abundance:

PSD-93, SAP97, SAP102, GluA2, Shank3, SynGAP, GluN1, GluA4, Homer1, GluA1, CaMKII, AKAP1, and Shank1. Previous studies indicate an immunoisolation of PSD-95 to be a de-facto postsynaptic fraction, containing putative PSD proteins. Our technique shows promise as a preparation of PSDs from human postmortem brain which would facilitate assessment of the PSD-95 interactome for postmortem studies of psychiatric, developmental, and neurodegenerative diseases with synaptic pathology.

Title: Activity-mediated synaptic trafficking of the palmitoyl-acyl transferase DHHC5

Authors: *S. BRIGIDI, B. SANTYR, J. SHIMELL, S. X. BAMJI
Cell. & Physiological Sciences, Brain Res. Ctr., Univ. of British Columbia, Vancouver, BC, Canada

Abstract: Neuronal activity can regulate the palmitoylation of synaptic proteins. However, the enzymatic activity of palmitoyl-acyl transferases (PATs) is not believed to be activity-regulated, suggesting that the precise control of palmitoylation may depend on the dynamic subcellular localization of PATs. The neuronal PAT, DHHC5, palmitoylates a number of synaptic proteins, including PSD-95, GRIP1b, and δ-catenin. We demonstrate that chemical LTP (cLTP) mediates the rapid and transient translocation of GFP-DHHC5 out of dendritic spine heads, followed by an increased interaction with δ-catenin and the co-transport of DHHC5/δ-catenin back into synapses. cLTP did not impact the localization of DHHC5 at inhibitory synapses. These results indicate that the activity-regulated dynamic trafficking of neuronal PATs allows for the rapid palmitoylation and delivery of substrate proteins to synaptic compartments.

Title: Dynamic developmental changes and gender differences in the abundance of postsynaptic NMDA signaling proteins in the mouse frontal cortex

Authors: *D. SINCLAIR[1], M. MCMULLEN[2], J. CESARE[1], G. C. CARLSON[2], C.-G. HAHN[1], K. BORGMANN-WINTER[1,3]
[1]Neuropsychiatric Signaling Program, Univ. of Pennsylvania, Philadelphia, PA; [2]Univ. of Pennsylvania, Philadelphia, PA; [3]Dept. of Child and Adolescent Psychiatry, Children's Hosp. of Philadelphia, Philadelphia, PA

Abstract: Background: Normal development of glutamatergic neural circuitry and underlying NMDA receptor (NR) signaling are critical for healthy brain function, while abnormal NR signaling has been implicated in neurodevelopmental psychiatric illnesses such as schizophrenia. The postsynaptic microenvironment plays host to, and modulates, critical NR signaling events, but it is not clear how the postsynaptic environment changes across the lifespan and how these changes may contribute to gender- and age-related vulnerabilities to psychiatric illness. We investigated the postsynaptic abundance of NR1/2A/2B (NR subunits), Src (a key modulator of NR activity), Psd95 (a PSD scaffolding protein) and PLCγ (an NR signaling target) in total membranes and the postsynaptic density (PSD) from the frontal cortex of neonatal, juvenile, adolescent and adult mice. Methods: PSD and membrane fractions were isolated biochemically from the frontal cortex of wildtype C57BL/6 and heterozygous DTNBP1 mutant mice aged 7, 14, 28 and 56 days (males; n=6 per age group, females; n=4 per age). Proteins were quantified by Western blotting, normalized to Psd95 (PSD) and actin (membranes) and analyzed by factorial ANOVA. Results: In the PSD, striking gender differences and developmental changes in the ratio of NR2A:NR2B and the abundance of Src in the PSD were observed. The ratio of NR2A:NR2B was greater in males than females ($p<0.0005$) and increased across development in both genders ($p<1x10-5$), consistent with an increasing role for NR2A-containing complexes later in life. In contrast, the abundance of Src in the PSD was lower in males than females

($p<0.0005$), and decreased across development in both genders ($p<0.001$). In membranes generally, there were no gender differences in NR2A:NR2B ratio or Src. PSD expression of NR1 ($p<0.0001$) and NR2B ($p<0.05$) decreased across development, despite increasing in membranes generally ($p<0.05$ and $p<0.00005$ respectively). PLCγ also decreased in the PSD across development ($p<0.01$). No differences between wildtype and DTNBP1 het mice were seen. Conclusions: Postsynaptic NR signaling machinery changes dynamically during development, and striking gender differences in key components of the NR signaling pathway exist throughout. Experiments are underway using SILAM mass spectrometry, immunoprecipitation, electrophysiology and behavioral assays to confirm and extend these findings. Observed gender differences in NR signaling in the PSD may be relevant to schizophrenia, a developmental disorder in which disrupted NR signaling and Src hypofunction have been implicated and sex differences in age-of-onset and symptom severity have been observed.

Title: AC5-PKA signaling pathways are required for a stress-induced AMPA receptor switch in cerebellar stellate cells

Authors: *Q. YANG[1], S.-Q. LIU[1], Y. ISHIKAWA[2]
[1]cell biology and anatomy, Louisiana State Univisity Hlth. Sicence Ctr., New Orleans, LA;
[2]Dept. of Cell Biol. & Mol. Med., New Jersey Med. Sch., Newark, NJ

Abstract: An acute natural stimulus, fox urine, can alter the synaptic AMPA receptor (AMPAR) phenotype from GluA2-lacking to GluA2-containing AMPARs in cerebellar stellate cells. This stress-induced AMPAR switch requires gene transcription and can be blocked by a beta-adrenergic receptor blocker (Liu, et al. 2010). However, the mechanism underlying this

transcription-dependent switch in AMPAR phenotype is not known. We hypothesize that adenylyl cyclase (AC)-PKA-CREB signaling pathways are involved. AC5 appears to be expressed in cerebellar stellate cells (Allen Brain Atlas). We found that the frequency of spontaneous action potentials in stellate cells increased during the application of noradrenaline or the AC activator forskolin (50 μM). This change was blocked by the AC5 antagonist NKY80 (20 μM), suggesting the presence of functional enzyme. Next, we determined the role of AC5 in the stress-induced AMPAR switch. Mice were exposed to fox urine for 5 min, and 3 hrs later we recorded spontaneous EPSCs in stellate cells at different potentials using a pipette solution that contained spermine. We found the I-V relationship of EPSCs changed from inwardly rectifying to linear in wild type mice, indicating that synaptic AMPARs had switched from GluR2-lacking to GluR2-containing receptors. In contrast the I-V relationship did not change in AC5 KO mice. To further investigate the underlying cellular mechanisms, we incubated cerebellar slices with noradrenaline (NA) at 37°C for 3 hrs to mimic the stress-induced AMPAR switch. We found that the NA treatment failed to change the I-V relationship of EPSCs to linear in AC5 KO mice. The presence of NKY80 during the incubation of WT cerebellar slices with NA also abolished the NA-induced switch. Thus activation of AC5 is required for the stress-induced switch in synaptic AMPAR phenotype. Activation of AC5 is known to elevate cAMP levels, thereby enhancing PKA activity. In the presence of a PKA inhibitor, PKI, NA failed to alter the synaptic AMPAR subtype in stellate cells. A second PKA inhibitor, H89, also abolished the NA-dependent switch in synaptic AMPA receptors. We also found that acute stress increased the pCREB level in cerebellar stellate cells from wild type animals. Together these results indicate that noradrenaline acting via adrenergic receptors activates AC5 and elevates cAMP levels, which increases PKA activity, thereby promoting GluA2 transcription.

Title: NMDA receptor-mediated signaling regulates NeuroD2 expression in developing cortex to control neuronal excitability and synaptic E/I balance

Authors: *F. CHEN[1], J. T. MORAN[2], K. ATES[2], Y. ZHANG[1], P. DAS[1], F. JONES[1], B. J. HALL[1]
[1]Dept. of Cell and Mol. Biol., Tulane Univ., New Orleans, LA; [2]Neurosci. program, Tulane Univ., New orleans, LA

Abstract: Activity-dependent regulation of gene transcription is critical for proper cortical development by promoting cell proliferation and differentiation as well as mediating regimes of synaptic plasticity involved in sculpting neural circuits. N-methyl-D-aspartate receptors (NMDARs) are critical regulators of gene expression. To determine how regulation of transcription by NMDARs is involved in cortical development, we first carried out genome-wide microarray analysis in cultured mouse cortical neurons treated with the competitive NMDAR antagonist APV. Neurogenic differentiation factor 2 (NeuroD2), a late-phase, calcium-activated, basic helix-loop-helix transcription factor, was identified as negatively regulated by NMDAR-mediated signaling both in this *in vitro* assay, and *in vivo*. Our data show that NeuroD2 mRNA expression is regulated by NMDARs via CaMKII, at the level of transcription but not mRNA stability. To examine its role in cortical development we over-expressed NeuroD2 in cultured cortical neurons. This resulted in an increase in spontaneous action potential firing rates, along with a decrease in mIPSC (mini inhibitory postsynaptic current) amplitudes. Furthermore, knocking-down NeuroD2 using siRNA increased mIPSC amplitudes. Genetic removal of NeuroD2 *in vivo* also resulted in an overall decrease in the excitatory/inhibitory synaptic ratio in cortical layer II/III pyramidal neurons. These results show that NMDAR signaling regulates NeuroD2 expression to control synaptic E/I balance and neuronal excitability.

Title: Role of ER calcium release in the mechanism of mGluR-LTD

Authors: *J. PICK, L. KHATRI, E. ZIFF
New York Univ. Med. Ctr., NEW YORK, NY

Abstract: Although insertion and removal of AMPARs at the synapse has been extensively studied, little is known about the signals required to initiate AMPAR trafficking from the endoplasmic reticulum (ER) towards the synapse. Recent studies from our lab have demonstrated that release of calcium from ER stores leads to GluA2 trafficking out of the ER and accumulation on the cell surface via a PICK1-CaMKII mechanism. In order to explore the physiological relevance of this mechanism we tested the hypothesis that induction of mGluR-LTD, a process that leads to the release of calcium from ER stores, causes the trafficking of GluA2 containing AMPARs from the ER towards the synapse. We used biochemical and immunoflorescent techniques to examine medium spiny neurons in a cultured neuron system, and we provide evidence that release of calcium from the ER upon DHPG induced activation of group 1 mGluRs leads to increased trafficking of GluA2 out of the ER and accumulation at the cell surface. Furthermore, activation of group 1 mGluRs in certain brain regions including the nucleus accumbens leads to removal of synaptic calcium-permeable AMPARs (CPARs) and replacement with GluA2-containing AMPARs that are not permeable to calcium. Using electrophysiological recordings we show that this calcium-induced GluA2 release is involved in the replacement of CPARs with GluA2-containing AMPARs. This mechanism may underlie recent behavioral findings that inducing mGluR-LTD in the nucleus accumbens can help alleviate incubation of cocaine craving by replacing CPARs with GluA2-containing AMPARs.

Title: Subunit-specific regulation of NMDA receptor trafficking by SAP102 splice variants

Authors: *B.-S. CHEN, Z. WEI
Georgia Regents Univ., Augusta, GA

Abstract: Synapse-associated protein 102 (SAP102) is a scaffolding protein abundantly expressed early in development and mediates glutamate receptor trafficking during synaptogenesis. Mutations in human SAP102 have been reported to cause intellectual disability, which is consistent with its important role during early development. SAP102 binds directly to N-methyl-D-aspartate receptors (NMDARs), anchors receptors at synapses and facilitates transduction of NMDAR signals. Proper localization of SAP102 at the postsynaptic density (PSD) is essential to these functions. However, how SAP102 is targeted to synapses is unclear. In the current study, we find that synaptic localization of SAP102 is regulated by alternative splicing. SAP102 splice variant that possesses a C-terminal insert is highly enriched at dendritic spines. Previously, we have shown that SAP102 expression promotes spine lengthening. We now find that the spine lengthening effect is independent of the C-terminal alternative splicing of SAP102. In addition, expression of SAP102 splice variants containing the C-terminal insert is regulated developmentally. Finally, knockdown of endogenous SAP102 splice variants containing the C-terminal insert differentially affect NMDAR surface expression in a subunit specific manner. These data reveal a novel role for SAP102 in the regulation of NMDAR trafficking.

Title: Postsynaptic mGluR5 promotes evoked glutamatergic synaptic transmission in neocortical Layer 2/3 Pyramidal Neurons

Authors: K. W. LOERWALD, A. B. PATEL, K. M. HUBER, *J. R. GIBSON
Ctr. for Basic Neurosci, UT Southwestern, DALLAS, TX

Abstract: The role of metabotropic glutamate receptor 5 (mGluR5) in regulating synaptic function has been demonstrated in various glutamatergic neocortical synaptic pathways. mGluR5's role has primarily been examined in acute paradigms in which either specific patterns of synaptic activity or chemical stimulation of the receptor are used to induce mGluR5-dependent forms of synaptic plasticity, and is generally thought to weaken synaptic transmission. However, the baseline role of mGluR5 in regulating the strength of evoked synaptic transmission in various pathways throughout early postnatal development has not been precisely examined. Previous studies seeking to address this question have employed large-scale deletions of mGluR5 in entire cell populations or throughout the entire brain. This approach is limited by secondary, indirect effects which complicate conclusions made about mGluR5-mediated synaptic regulation at the cell-autonomous level. To circumvent these issues inherent to manipulating an entire network of neurons, here we have deleted mGluR5 in a minority of individual layer 2/3 neocortical pyramidal neurons using *in utero* electroporation and examined the effects on excitatory synaptic transmission. Based on the well characterized role of mGluR5 as a negative regulator of synaptic function in the cortical pathways we examined, we hypothesized that deletion of mGluR5 throughout development would result in an increase in excitatory synaptic function. Electrophysiological measurements were made in acutely prepared slices to obtain an accurate snap shot of the *in vivo* effects due to loss of mGluR5. Loss of postsynaptic mGluR5 results in an increase in the frequency of action potential-independent synaptic events, but paradoxically, results in a decrease in evoked transmission in 2 separate synaptic pathways providing input to these pyramidal neurons. In the local L2/3 pathway, the decrease in evoked transmission appears to be largely due to a decrease in cell-to-cell connectivity and not in the strength of individual cell-to-cell connections. Our data suggest a new role for mGluR5, different from what has been observed in studies examining its acute function, where baseline mGluR5 function promotes synaptic pathway strength in multiple cortical glutamatergic pathways.

Title: The putative cannabinoid receptor GPR55: Expression, modulation of hippocampal plasticity and behavior

Authors: *K. M. HURST, C. BADGLEY, S. BELL, B. PRINCE, J. G. EDWARDS
BYU, Provo, UT

Abstract: Learning and memory occur due to adaptive brain changes in response to our environment. These changes are mediated by synaptic plasticity, particularly within the hippocampus. Plasticity can either strengthen or weaken synapses, known as long-term potentiation (LTP) or long-term depression (LTD) respectively. While many forms of plasticity are NMDA-dependent, recently endocannabinoids were identified to mediate several new forms of hippocampal synaptic plasticity. Endocannabinoids bind to receptors such as cannabinoid receptor 1 (CB1) and transient receptor potential vanilloid 1 (TRPV1) in several brain areas including the hippocampus. However, research has demonstrated a non-CB1/TRPV1-dependent endocannabinoid synaptic plasticity in the hippocampus. While the receptor(s) involved is currently unknown, several potential candidate receptors that bind the endocannabinoid anandamide have been identified. These are among the orphan G-protein coupled receptors (GPRs) whose distribution in the brain and/or function is less well known. GPR55 is of particular interest as it activates second messenger systems, including IP3-mediated increases in intracellular calcium. Using quantitative RT-PCR, electrophysiological and memory behavioral tasks we examined hippocampal GPR55 expression and function. GPR55 is expressed in hippocampus of both rats and mice. Cellular expression is currently being examined and appears to be rare in interneurons and more likely expressed by pyramidal cells. Interestingly, application of the GPR55 agonist LPI (2 μM) to wild-type mice demonstrates a significant enhancement of LTP in brain slices. This LPI effect was not noted in GPR55 knock-out (KO) mice, which exhibit significantly ($p < 0.05$) smaller LTP (146%) than wild-type (WT) (181%). We are also examining CA1 LTD and preliminary data illustrates no significant difference to this point between KO and wild-type mice. GPR55 also appears to increase release probability (Sylantyev et al., PNAS, 2013), denoting a presynaptic role. Paired-pulse ratios are now being analyzed between GPR55 KO and WT mice to confirm this finding; however we did not note a change in EPSCs in CA1 in response to 2μM LPI. Behaviorally, KO and WT mice did not differ substantially in the novel object recognition test, but we are investigating spatial navigation to examine differences. These data suggest GPR55 is expressed and physiologically relevant in the hippocampus. Because enhanced LTP is usually associated with better memory performance in rodents, this provides a potential target to enhance the cellular mechanism associated with memory formation.

Title: Senescence-related impairment in short and long-term potentiation at the Mossy Fiber-CA3 synapse of the hippocampus

Authors: ***A. VILLANUEVA**, E. J. GALVAN
Pharmacobiology, CINVESTAV SUR, México, D. F., Mexico

Abstract: In the hippocampal formation senescence is accompanied by a progression of biochemical modifications that ultimately affects its ability to generate and consolidate long-term potentiation (LTP), the physiological process that underlies learning and memory. However, the aging effects on the CA3 feed-forward inhibitory circuit or the posttetanic potentiation (PTP) and LTP at the mossy fiber to CA3 synapse (MF-CA3) are poorly understood. To explore the age-dependent alterations of this synapse, extracellular recordings were performed in acute hippocampal slices from aged (34 ± 2 months old, Wistar rats) and young rats (1 month old). Paired pulse facilitation (PPF; 60 ms ISI) was dramatically reduced in aged rats (1.1 ± 0.1; n=9 vs. 2.2 ± 0.1 in young rats). To assess for changes in the CA3 feed-forward inhibitory circuit, a paired-pulse inhibition protocol (PPI, 8 ms ISI) was applied. Aged rats showed decreased PPI ratio (0.7 ± 0.3 and 1.1 ± 0.1; for young and aged animals, respectively; n=7). Next, we examined induction of MF-CA3 LTP. HFS (3 trains 100 Hz, at 10 sec interval), produced smaller posttetanic potentiation (PTP) in aged (157.6 ± 33%; n=6) vs. young animals (450.7 ± 57.8%; n=11). Furthermore, MF LTP induction in aged animals was smaller (85.0 ± 17.1) and was not induced in 8 out of 10 slices. In contrast, young animals consistently exhibit robust LTP (229.9 ± 44.2%; n=11). In all cases, DCG-IV suppressed the evoked responses (MF depression: 96.9 ± 10.3%). Because MF-LTP induction requires adenylyl cyclase/PKA activity, in another set of experiments, forskolin in combination with IBMX was bath-applied for 15 min. In aged animals, FSK+IBMX induced a fast but transient enhancement of MF fEPSPs, which gradually returned to baseline values in 5 out of 6 slices (MF fEPSP during FSK+IBMX wash in 248.4 ±

30.5%; at 30 min, 105.08 ± 5.9% and at 90 min, 81.1 ± 8.6). Taken together, these data show that hippocampal senescence is associated with significant weakening of the CA3 feed-forward inhibitory circuit, and biochemical changes that compromise the integrity of the signaling cascades responsible for MF PTP and LTP.

Title: Cellular and molecular correlates for neurotrophic and neurotoxic long-term potentiation in networked neurons derived from stem cell populations

Authors: *A. B. BRADFORD[1], P. H. BESKE[1], M. E. LYMAN[1], K. S. HUBBARD[1], I. M. GUT[2], P. M. MCNUTT[1]
[1]Cell. and Mol. Biol., MRICD, APG, MD; [2]BNBI, Frederick, MD

Abstract: Synaptic strengthening through long-term potentiation (LTP) underlies learning and memory. However, changes in synaptic weighting caused by trauma such as brain injury, epileptic seizure or chronic stress can increase susceptibility to activity-related pathophysiologies. An *in vitro* population of networked neurons that exhibits canonical responses to altered synaptic activity will provide a platform for controlled, focused studies of the roles of aberrant signaling mechanisms in neuropathologies. We have developed methods to reproducibly generate and characterize mouse embryonic stem cell-derived neurons (ESNs) for use as such a platform. ESNs develop active glutamatergic and GABAergic synapses and exhibit emergent network behavior with an excitatory:inhibitory balance and synaptically driven action potential propagation within 21 days after differentiation. Increasing excitatory synaptic signaling by addition of presynaptic (3,4-DAP) or post-synaptic (bicuculline) modulators rapidly activates the MAPK/ERK pathway, causing increased CREB phosphorylation within 1 min and upregulated transcription of a wide array of immediate early genes (IEG) within 30 min,

including *c-Fos, JunB, Homer-1a, Arc* and *Egr1-4*. Within 4 h, expression of brain-derived neurotrophic factor (BDNF) and phosphorylation of its canonical receptor TrkB is detected, suggestive of late-phase LTP. These data suggest that 3,4-DAP and bicuculline are acting as neurotrophic modulators in networked cultures of ESNs. In contrast, treatment with as little as 1 uM glutamate evokes excitogenic processes that lead to neurotoxicity within 6 h, mediated by extrasynaptic NMDAR Ca^{2+} uptake. These glutamate treatments evoke extrasynaptic signaling pathways that interrupt MAPK/ERK signaling, elicit acute energetic failure and prevent BDNF expression. These data confirm that ESNs exhibit canonical functional and molecular correlates of early and late phases of LTP as well as excitogenic responses to pathophysiologic conditions. Further temporal characterizations of LTP in ESNs include elucidation of electrophysiological markers, AMPA receptor trafficking and phosphorylation, involvement of the mTOR pathway and changes in synapse architecture. Determining the scope and types of treatments that distinguish between neuroprotection and excitotoxicity in a defined population of networked neurons will provide a reproducible, highly synchronized platform for more complex studies, such as characterizing susceptibilities to excitotoxicity based on development stressors, alteration of signaling pathways and other gene-environmental interactions.

[1]Biomed. Engin., The City Col. of New York, New York, NY; [2]Biol., Univ. of Pennsylvania, Phildelphia, PA

Abstract: Transcranial direct current stimulation (tDCS) is a promising neuromodulatory technique that has been shown to induce lasting changes in cognitive function. Generally, a weak direct current (<2mA) is applied via electrodes on the scalp for an extended period of time

(usually 20 minutes). tDCS has already been shown to elicit a number of desirable cognitive effects that are relevant to the treatment of many diseases, ranging from motor deficits to depression. Depending on the duration, intensity, location of scalp electrodes, and the cognitive or training task being performed, the effects of tDCS can outlast the duration of the stimulation for hours or even days. tDCS induces electric fields in the brain and the observed long-term effects suggest that electric fields influence training-induced plasticity. However, the exact mechanisms of action on plastic changes are not well understood. There are a number of human, animal and in-vitro studies showing lasting physiological effects that point to altered synaptic plasticity as the substrate for long term effects. However, there is not direct evidence that endogenous plastic mechanisms, such as Hebbian long term potentiation (LTP) are altered by electric fields. Here we studied frequency dependent LTP in the Schaffer collateral pathway of hippocampal slices in rat and mice. Tetanus consisted of 900 pulses at 20 Hz and occurred after 20 minutes. During the tetanus a DC electric field was applied across the hippocampal slice. We found a significant increase in the amount of LTP at 60 minutes after tetanus for anodal stimulation (in rat: 123.08 +/-14.4% control vs 151.86 +/-17.48% anodal, $p = 0.042$, N=5,3; in mouse: 127% +/- 12.4% control vs 167.9 +/- 6.6% anodal, $p = 0.037$ N=8,7). Thus, the electric fields induced during tDCS may lead to training-specific long-term changes in cognitive function by boosting Hebbian synaptic plasticity.

Title: Hippocampal overexpression of tau affects synaptic transmission, plasticity, and network function

Authors: *F. JOW, M. LI, S. BROWNE, T. BUSSIERE, M. WITTMANN
Biogen Idec, Cambridge, MA

Abstract: The microtubule associated protein tau is implicated in neurodegenerative diseases, such as Alzheimer's Disease (AD). During disease progression, hyperphosphorylation of tau leads to somatodendritic mislocalization, intracellular accumulation of fibrillar soluble tau species and eventually the formation of neurofibrillary tangles. Importantly, tau pathology

correlates well with the progression of cognitive decline in AD. It has been previously shown that in transgenic mice overexpressing mutant human tau, hyperphosphorylated soluble tau proteins are mislocalized to intact dendritic spines where they impact synaptic function and plasticity and thus might impair cognitive processes. In addition, tau has been implicated in seizure susceptibility and a recent publication demonstrated that mice overexpressing human mutant tau develop spontaneous seizures and have a higher sensitivity to seizures induced by the GABAA antagonist pentylenetetrazol (PTZ). Since it is not clear whether developmental processes are involved in synaptic and network disturbances in tau-overexpressing transgenic mice, we used an AAV vector expression system to increase tau expression in the hippocampus of adult wild-type mice. C57BL/6 mice were injected into the hippocampus with AAV expressing a Dual-2N4R-P301L/K18DK280 construct or empty vector and sacrificed 3 months and 6 months later. Acute hippocampal slices were prepared and extracellular field recordings conducted to measure synaptic function, long term potentiation, and seizure susceptibility. We found that long term potentiation was increased at 3 months and 6 months after injection. While synaptic transmission was comparable between groups at 3 months after injection, at 6 months it was significantly decreased in mice expressing mutant tau. In addition, overexpression of tau increased seizure susceptibility in a bicuculline-induced seizure-like activity assay. These data suggest that overexpression of tau is responsible for synaptic and network dysfunction and that some changes occur in the absence of loss of synapses. The decrease in synaptic transmission at 6 months suggests that overexpression and/or aggregation of tau protein over time could trigger a potential loss of functional synapses. Immunohistochemical analysis is ongoing to determine whether these changes correlate with synaptic loss or other synaptic changes.

Title: Evaluation of presynaptic actions using two different fluorescent probes for neurotransmitter release

Authors: *T. HIKIMA, G. ARBUTHNOT
Brain Mechanisms for Behaviour Unit, Okinawa Inst. of Sci. and Technol. Grad. Univ., Onna-Son, Okinawa, Japan

Abstract: Neurotransmitter release provides a powerful influence in neuronal network activity. It is a major resource and a source of reserve capacity for neuronal network processing. Typically an increase in synaptic efficacy is accompanied by an increase in presynaptic neurotransmitter release and imaging methods are an effective tool to investigate the kinetics for neurotransmission in cortical presynaptic terminals. We used two fluorescent probes for neurotransmitter release, synaptophysin-pHluorinx2 (SypHx2) and intensity-based glutamate-sensing fluorescent reporter (iGluSnFR) to optically visualize neurotransmitter release. SypHx2 is the fusion of synaptic vesicle protein synaptophysin with two molecules of the super ecliptic pHluorin, pH-sensitive green fluorescent protein (GFP), iGluSnFR is a sensor for synaptically released glutamate constructed using a bacterial periplasmic binding protein and circularly permulated GFP. We could detect the fluorescent change of SypHx2 (ΔSypHx2) with 5 pulses electrical stimulation and estimate the size of the readily releasable pool (RRP) with high stimulation rates. On the other hand, the fluorescent change of iGluSnFR (ΔiGluSnFR) was much higher. ΔiGluSnFR signals to single pulse field stimulation were reliably detected and reached a plateau after 5 pulses. Both signals were dependent on external calcium concentration. We found the cAMP/PKA activity uncovered a number of presynaptically silent synapses using both methods, and the increase depended on the size of the RRP. Based on our results, these two fluorescent probes are useful tools to follow the alteration of the presynaptic efficacy and examine the properties of presynaptic sites more precisely at tiny presynaptic terminals.

Title: Long-term potentiation of glycinergic synapses triggered by interleukin-1β

Authors: *A. M. CHIRILA[1], T. E. BROWN[3], R. J. STEVENSON[2], R. A. BISHOP[2], J. A. KAUER[1]
[1]Mol. Pharmacol. and Physiol., [2]Neurosci., Brown Univ., Providence, RI; [3]Sch. of Pharm., Univ. of Wyoming, Laramie, WY

Abstract: While glycine is a major inhibitory neurotransmitter in key areas of the CNS, little is known about the regulation of glycinergic synaptic strength in native tissue. Here we report that in the spinal cord dorsal horn, glycinergic synapses on GAD65-EGFP labeled lamina II inhibitory interneurons exhibit LTP, triggered rapidly after 10 minute exposure to the inflammatory cytokine interleukin-1 beta (IL-1β, 10ng/ml; IPSC amplitudes: 165.0 ± 11% of pre-IL-1β values, n=24, $p<0.0001$). Our data suggest that glycine receptor LTP (GlyR LTP) results from an increase in postsynaptic GlyR number or function. To probe this, we first disrupted membrane fusion reactions in GAD65-EGFP neurons. Blocking postsynaptic SNARE proteins by including N-ethylmaleimide (NEM; 5mM) in the recording pipette prevented GlyR LTP (IPSC amplitudes: 88.9 ± 9.3% of pre-IL-1β values, n=9, n.s.). We next recorded glycinergic IPSCs on GAD65-EGFP cells for a baseline period, followed by application of the high affinity GlyR antagonist strychnine (2μM) to block all surface GlyRs. Slices were then washed for 20 min and either IL-1β or BSA was bath-applied. Recovery from strychnine block was significantly greater in slices treated with IL-1β compared to BSA treated controls (% recovery at 40-46 minutes after washing strychnine: control 8.7 ± 3.7%; IL-1β: 28.8 ± 7.1%, n=5; $p<0.05$). Together our data are consistent with the possibility that IL-1β promotes exocytosis of intracellularly sequestered GlyRs. To test how GlyR LTP correlates with inflammatory hyperalgesia, we examined spinal cord slices from mice with *in vivo* formalin-induced inflammation vs. slices from saline treated controls. GABAergic neurons from saline-treated mice had robust IL-1β induced GlyR LTP, while those from formalin-treated hyperalgesic mice did not (IPSC amplitudes: saline-injected: 176.6 ± 16.7%, n=9; formalin-injected: 104.1 ± 10.5%, n=7; $p<0.005$). Furthermore, glycinergic mIPSCs in cells from formalin-treated mice were significantly larger compared to saline-treated controls (mIPSC amplitudes, formalin-treated, n=8: 148 ± 12% of saline-treated animals, n=5; $p<0.05$), suggesting that these synapses may be potentiated *in vivo* by inflammation-induced release of IL-1β. GlyR LTP is a novel form of plasticity that could disinhibit projection neurons carrying nociceptive information and may contribute to the development of inflammatory pain.

Title: Synaptic cooperativity and postsynaptic polarization jointly determine cortical plasticity during DC stimulation

Authors: *A. RAHMAN, M. BIKSON
Biomed. Engin., The City Col. of The City Univ. of New York, New York, NY

Abstract: Cortical neurons receive synchronous and convergent synaptic input from thousands of afferents that are susceptible to plastic changes. Effective long-term plasticity of the primary motor cortex is, however, contingent upon local disinhibition leading to rapid unmasking of latent intracortical connections. Alternatively, coincident input relieves the requirement for disinhibition to induce long-term potentiation. In rat primary motor cortex, we measured *in vitro* the population excitatory postsynaptic potentials evoked by a brief train of adapting afferent inputs and found that DC stimulation modulates synaptic efficacy through postsynaptic polarization and recruitment of ascending fibers. Acutely, we show that DC stimulation attenuates short-term depression during adaptation to afferent activity and post-adaptation, therefore sustaining higher levels of synaptic efficacy during stimulation. Modeling work based on experimental measurements indicates DC stimulation can enhance cortical potentiation through cooperative plasticity. Our results suggest a mechanism of inducing cortical synaptic plasticity during transcranial direct current stimulation (tDCS) driven by the number of coincident inputs. These results also point toward a prominent role of upstream brain regions from the primary motor cortex that drives motor output during tDCS and transcranial magnetic stimulation (TMS) through corticocortical and thalamocortical connections, particularly from somatosensory and premotor areas.

Title: Hippocampo-prefrontal synaptic plasticity and neuronal firing in the mediodorsal thalamus

Authors: *L. S. BUENO, JR, R. N. RUGGIERO, J. P. LEITE
Med. Sch. of Ribeirao Preto, Dept. of Neurosci., Univ. of Sao Paulo, Ribeirao Preto, Brazil

Abstract: Afferents from dorsal hippocampal CA1 and mediodorsal nucleus of thalamus (MD) share targets in the prefrontal cortex (PFC). MD and PFC are reciprocally connected, while projections from CA1 to the PFC are unidirectional. Noteworthy, there are no known projections from dorsal CA1 to the MD, suggesting that CA1 modulates the MD via PFC. Since MD and CA1 are thought to cooperate in PFC functions, we asked if CA1-induced long-term potentiation (LTP) in the PFC changes its communication with the MD. In urethane-anesthetized rats, we implanted a stimulating electrode into dorsal CA1, and recording microwire arrays into ipsilateral MD and PFC (prelimbic area). Electrical test pulses were applied into CA1 every 15 sec during a 30 min baseline, followed by LTP induction through high-frequency stimulation. Test pulses were then resumed for an additional two-hour recording. According to our initial results, test pulses changed firing in both PFC and MD, demonstrating the CA1-PFC-MD flow of information. High-frequency stimulation expectedly induced LTP of PFC field responses, and firing responses of both PFC and MD were altered by LTP induction. Our preliminary findings indicate that CA1-PFC synaptic plasticity can modulate MD activity. This could signify that MD-PFC excitatory reverberation assimilates information from CA1, especially during executive processes.

Abstract: Layer-specific developmental profile of visual cortex function in the awake mouse
J.L. Hoy and C.M. Niell Institute of Neuroscience and Department of Biology, University of Oregon The laminar structure and conserved cellular organization of mouse visual cortex provide a useful model to determine the mechanisms that support the development of basic visual system function. However, the normal development of many receptive field properties, as well as the emergence of synchronized network activity, have not yet been thoroughly quantified as a function of cortical layer. Here, we employ multisite electrophysiological recording in the awake mouse across an extended period of development, starting at eye opening, to measure these functional properties in V1. We find that receptive field structure and properties such as response linearity rapidly reach mature-like states over the first few days after eye-opening in nearly all cortical layers. This first phase of development coincides with the maximum change in the peak firing rate of visually evoked activity. In a second distinct phase of development, features such as the tuning width of orientation selective units and peak spatial frequency response remain poor up to 4 days after eye-opening, but then rapidly reach adult levels by 7 days after eye-opening. In contrast, we see a gradual increase in orientation selective units within layers 2-5 between eye-opening and 7 days later. Not all developmental trends are common between layers. Direction selectivity undergoes significant developmental change only in layer 4 and units in layer 6 display more complex developmental progression relative to the other layers. Finally, behavioral state modulation of LFP gamma power also changes significantly over development in a layer specific manner. Unlike many individual receptive field properties, LFP oscillations begin to gradually mature after eye-opening but do not fully reach maturity until approximately 1.5 months of age. On-going studies seek to determine the cell type-specific molecular mechanisms that drive these changes across layers.

Title: PSD-95 regulates experience-dependent maturation of excitatory synapses in the visual cortex

Authors: X. HUANG[1], *Y. DONG[2], S. LÖWEL[3], O. SCHLÜTER[1]
[1]European Neurosci. Inst., Göttingen, Germany; [2]Dept Neurosci., Univ. of Pittsburgh, Pittsburgh, PA; [3]Bernstein Fokus Neurotechnologie and Johann-Friedrich-Blumenbach Inst. für Zoologie und Anthropol, Univ. of Göttingen, Göttingen, Germany

Abstract: Postsynaptic density-95 (PSD-95) is a postsynaptic signaling scaffold protein. It regulates synaptic transmission in excitatory synapses, presumably via coordinating signaling events in long-term synaptic plasticity. In the visual cortex (VC), the expression level of PSD-95 increases after eye opening and reaches the plateau at adult. Here, we studied the role of PSD-95 in regulating synaptic maturation during the critical period. We performed electrophysiological analysis from acute VC slices of PSD-95 KO and WT mice at different developmental stages. Unlike in WT control animals, where the number of AMPA receptor silent synapses decreases during development, the percentage of silent synapse in PSD-95 KO mice prevailed at high levels. Furthermore, knocking down PSD-95 in adult WT mice restored high level of silent synapse. The development of GABAergic transmission was normal in PSD-95 KO animals, suggesting that PSD-95 does not regulate the maturation of the inhibitory system. Thus PSD-95 is essential for the experience-dependent maturation and maintenance of the matured state of VC excitatory pyramidal cell synapses.

Title: Keratan sulfate is involved in ocular dominace plasticity in visual cortex

Authors: *T. NATORI[1,2,3,4], K. NAGAI[2], K. KADOMATSU[3], Y. KOMATSU[4]
[1]Dept Healthy Nutr., Univ. Yamanashigakuin, Yamanashi, Japan; [2]Dept. of Epigenetic medicine, Univ. of Yamanashi., Yamanashi, Japan; [3]Dept. of Biochemistry, Nagoya Univ. Grad. Sch. of Medicine., Nagoya, Japan; [4]Dept. of Neuroscience, Res. Inst. of Envrn. Medicine, Nagoya University., Nagoya, Japan

Abstract: The major components of the extracellular matrix (ECM) in the central nervous system are proteoglycans (PG), hyarulonan, and tenascins. Especially, ECM around neurons is

called perineuronal nets (PNN). PNN begins to increase after critical period. In young animals, monocular deprivation leads to an ocular dominance shift, whereas in adults after the critical period, such shift can not be observed. However, it has been reported that the digestion of chondroitin sulfate with chondroitinaseABC (ChABC) recovers ocular dominance plasticity in adult rat primary visual cortex. Since there are many keratan sulfate proteoglycans (KSPG) in the central nervous system, KS may also function on the regulation of neuronal plasticity in primary visual cortex. We used slices of visual cortex prepared from adult rats. Before preparing slices, enzymes keratanase II (KSII) or ChABC was repeatedly injected at the same sites of visual cortex everyday for three days. After 4 or 5 days of treatment, we examined long-term potentiation (LTP). LTP was observed in slices from CP rats, but not from adult control rat. Interestingly, LTP was recovered in the slices from adults treated with KSII or ChABC. The magnitude of LTP in KSII or ChABC-treated adult slices was the same as that from CP. Next we examined whether KSII treatment of adult rats facilitates ocular dominance plasticity. Visual acuity was determined with visual evoked potentials. We found that KSII or ChABC treated rats recover ocular dominance plasticity like CP. Regarding the effects of enzyme treatment in brain cells, we surprisingly found that microglia was activated, and inhibition of microglial activation by minocycline prevented the recovery of ocular dominance plasticity. We found that KS digestion in primary visual cortex recovers ocular dominance shift in adult rats via microglial activation. Our data suggest that KS is involved in the regulation of neuronal plasticity and microglial activation contributes to the ocular dominance plasticity.

Inst. of Neurosci., University of Brescia, Brescia, Italy; [3]Dept. of Mol. and Human Genet., Baylor College of Medicine, Houston, TX; [4]Dept. of Psychiatry, Douglas Mental Hlth. Univ. Inst., Verdun, QC, Canada; [5]Dept. of Cell. and Mol. Med., Univ. of Ottawa, Ottawa, ON, Canada

Abstract: Fragile X Related Protein 1 (FXR1P) is one of two autosomal homologues of the Fragile X Mental Retardation Protein (FMRP), a protein whose expression is significantly reduced in Fragile-X Syndrome. Like FMRP, FXR1P is an mRNA binding protein that is implicated in regulating the translation of specific target proteins. However, in comparison to FMRP, little is known about the function of FXR1P in the brain. Our lab has recently discovered that FXR1P co-localizes with translational machinery near synapses suggesting that it could play a role in locally controlling the levels of proteins involved in synaptic plasticity and learning and memory. In order to test this, we have generated an FXR1 conditional knockout mouse model where the FXR1 gene is conditionally ablated from neurons in the forebrain, including the hippocampus. Interestingly, we have found that FXR1P is critical for regulating the expression of the AMPA-type glutamate receptor subunit GluA2; a protein known to have a profound role in synaptic plasticity and learning and memory. Moreover, we have also found that FXR1P conditional knock-out mice have significant changes in synaptic plasticity, synaptic morphology, and cognitive function. We are currently investigating the mechanism through which FXR1P regulates GluA2 expression, and in turn understand the implications of this mechanism in synaptic plasticity and learning and memory.

Title: Cortical synaptic plasticity requires the production of reactive oxygen species

Authors: *R. DE PASQUALE, T. F. BECKHAUSER, M. S HERNANDES, L. R. G BRITTO
Univ. of São Paulo, São Paulo, Brazil

Abstract: Reactive oxygen species (ROS) are signaling factors involved in many intracellular transduction pathways. In the nervous system, ROS are thought to modulate various mechanisms of synaptic plasticity. One important source of ROS production in the brain is the Nox2 isoform of the NADPH oxidase complex. Stimulation of NMDA receptors activates Nox2, which provides selective oxidative responses accompanying the induction of synaptic changes. Nox2 activity is known to be important for the induction of LTP in the hippocampus. However, the involvement of Nox2 in cortical plasticity is still unclear. To address this issue, we performed whole cell recordings in brain cortical slices obtained from wild type and knock out mice for the gp91phox subunit of Nox2. We evaluated synaptic plasticity by inducing LTP and LTD in layer 2/3 neurons of the primary visual cortex. We found that genetic ablation of Nox2 suppresses LTP and LTD. Our results also showed that this effect is age-dependent, suggesting that Nox2 is critical to maintain synaptic potentiation even after the maturation of visual cortical circuitry.

Title: Robust inhibition and gamma oscillations in a cortical area that lacks parvalbumin-expressing inhibitory interneurons

Authors: *A. U. SUGDEN[1], S. L. PATRICK[2], R. D. BURWELL[3], B. W. CONNORS[2]
[2]Neurosci., [3]Cognitive, Linguistic, and Psychological Sci., [1]Brown Univ., Providence, RI

Abstract: Three protein markers completely define exclusive classes of neocortical inhibitory interneurons in mice; parvalbumin (PV), somatostatin (Som), and a serotonin receptor subtype (5HT3aR). The relative proportions of these classes are consistent across the vast majority of the neocortex. As a group, inhibitory interneurons are vital for preventing seizures, regulating temporal and spatial coding, and generating oscillations and synchrony in pyramidal cells. Yet surprisingly, although PV cells are the most common class of inhibitory interneurons in most areas, PV cells are absent in the ventral region of postrhinal cortex (vPOR), a visuospatial association area. Furthermore, much work has implicated the fast-spiking (FS) PV cells in the generation of gamma oscillations; pulsed optogenetic activation of PV cells drives the network with strong resonance near 40 Hz. The naturally PV-sparse vPOR presents an opportunity for determining whether PV cells are critical for gamma oscillations. We have compared the sources of synaptic inhibition in vPOR to those of the neighboring dorsal POR (dPOR), where PV cells comprise 40% of the interneurons. Spontaneous miniature IPSCs onto excitatory cells were decreased in frequency by ~40% in vPOR, commensurate with the smaller number of inhibitory cells. Optogenetic stimulation of Som cells showed no difference in inhibitory currents between regions, while responses to stimulation of PV cells were lower by an order of magnitude in vPOR. Although the sum of the inhibitory currents from PV and Som cells would suggest a difference in global inhibition between vPOR and dPOR, optogenetic and electrical activation of all sources of inhibition onto excitatory cells yielded equally strong responses. Paired-pulse ratios of IPSCs were also similar in vPOR and dPOR. Furthermore, ramped optogenetic stimulation of excitatory cells induced gamma oscillations of similar power in both regions, even when the vPOR was isolated from neighboring PV-containing cortices. Optogenetic stimulation of inhibition onto inhibitory interneurons showed that inhibitory currents are smaller in vPOR. Reduced disinhibitory circuitry in vPOR enhances the total inhibitory input to its excitatory cells, which matches the dPOR control cortex. And, although Som cells demonstrate a low-threshold spiking phenotype in primary sensory cortex, roughly half of the Som cells of POR displayed a fast-spiking phenotype. Our results suggest that vPOR has adapted its local circuits and intrinsic physiological properties to maintain high levels of inhibitory function in the absence of PV interneurons.

Title: Functional mapping of developing neocortical networks

Authors: *J. B. ACKMAN[1], H. ZENG[2], M. C. CRAIR[1]
[1]Neurobiol, Yale Univ., NEW HAVEN, CT; [2]Allen Inst. for Brain Sci., Seattle, WA

Abstract: The cerebral cortex exhibits spontaneous and sensory evoked patterns of activity during fetal and postnatal development that are crucial for the activity-dependent formation and refinement of neural circuits. Knowing the source and flow of these activity patterns locally and globally is crucial to understanding self-organization in the developing brain. Here we describe a system for imaging patterns of activity throughout the developing isocortex *in vivo* at a 'mesoscopic' level of resolution in mice. Ongoing activity in the neonatal cerebral cortex was characterized by distinct and repetitively active domains measuring hundreds of microns in diameter that were coordinated within and between the hemispheres. These cortical activity patterns gave rise to characteristic network architectures with functional associations between brain areas and across hemispheres that were similar in mice of the same age but changed with development. Our imaging approach offers an unprecedented ability to study functional connectivity within and between the cerebral hemispheres at a scope and scale which bridges the microscopic and macroscopic resolutions offered by traditional neurophysiology and neuroimaging based recordings and will provide a practical non-invasive means to assess cortical connectivity with high spatial resolution across development and in pathophysiological models for autism, epilepsy, and schizophrenia.

Abstract: Changes in gamma power correlate with attentional deficits in psychiatric diseases, and can be induced by cholinergic modulation experimentally in the mammalian neocortex and hippocampus and in the avian optic tectum (superior colliculus). However, the mechanisms by which different acetylcholine receptors modulate the components of the gamma-generating circuitry are not well understood. The midbrain selection circuit includes a local gamma-generating circuit within the optic tectum (composed of both NMDAergic and GABAergic circuit elements) that is reciprocally connected to an evolutionarily conserved cholinergic nucleus (Ipc). Cholinergic feedback powerfully regulates the power of tectal gamma oscillations (Goddard et al 2012); the precise mechanisms underlying this modulation are not known. We investigated these mechanisms; we found that nicotinic acetylcholine receptors (nAChRs) are primarily responsible, acting to enhance the power of gamma oscillations by selectively increasing the inhibitory component of the midbrain gamma generator. We identified the precise site of this enhancement, a population of neurons that are driven via the action of non-a7 subunit-containing nAChRs (non-a7 nAChRs). These neurons are located within a region of the gamma generator that contains parvalbumin-positive interneurons, a type of neuron that is critical for the generation of gamma oscillations within the cortex and hippocampus. Activation of these non-a7 nAChRs is both necessary and sufficient for cholinergic modulation of tectal gamma oscillations. Together, our results suggest a mode of cholinergic modulation whereby acetylcholine is broadly released, but can exert precise effects on a complex circuit through the selective expression of specific postsynaptic receptors on a specific neuronal population.

Title: Optogenetic activation of glutamatergic medial septum neurons drive activity across the hippocampal network

Authors: J. ROBINSON[1], F. MANSEAU[1], *L. K. SRIVASTAVA[2], S. WILLIAMS[1]
[1]Dept. of Psychiatry, McGill Univ., Douglas Mental Hlth. Univ. Inst., Montreal, QC, Canada; [2]Douglas Hosp. Res. Ctr., Montreal, QC, Canada

Abstract: The medial septum diagonal bands of broca (Ms-DBB) area provides important connections to the hippocampus and plays a critical role in theta rhythms associated with learning and memory. Three main neuronal populations have been identified in this region: cholinergic, GABAergic and glutamatergic. While the role of GABAergic and cholinergic neurons connectivity have been explored for the several decades, the influence of glutamatergic neurons is not well understood. To further explore the role of MS-DBB glutamatergic cells we have used optogenetics to specifically target this population of neurons. The first aim of our study has been to determine at the cellular level how glutamate release from MS-DBB neurons can modulate post-synaptic targets in the subiculum, CA1 & CA3 on both principal cells as well as interneurons across the hippocampus. The second aim of the current study has been to determine whether increasing the firing rate of glutamate neurons is sufficient to modulate hippocampal theta oscillations *in vitro*. We have specifically targeted glutamatergic MS-DBB neurons through injection of a Cre- dependent AAV virus containing the light-sensitive protein ChETA construct in a VGLUT2-CRE mice line. Recording techniques include both patch-clamp and field recordings in the *in vitro* septo-hippocampal preparation. By selectively activating this neuronal population, we have observed postsynaptic responses in both neurons within the septum as well as interneurons in the hippocampus. With varying frequencies of light stimulation,

excitatory post-synaptic responses can be observed up to 2.5 mV on interneurons in the str oriens of area CA3. In addition, glutamatergic MS-DBB neurons can modulate hippocampal theta rhythm in the whole septo-hippocampal network *in vitro*, increasing both the power and oscillatory strengths of theta rhythm across subregions of the hippocampus. With periodic stimulation of the medial septum, theta oscillatory power was increased up to 30% from baseline. These experiments may provide insight into of how medial septum glutamate neurons contribute to hippocampal theta activity. Finally, these results will also provide the background necessary to investigate how medial septum glutamatergic input contribute to memory formation.

Title: Current versus voltage clamp measurements of resonance in neuronal systems: lessons from the response of biophysical models to oscillatory inputs

Authors: *F. NADIM[1], H. G. ROTSTEIN[2]
[1]Dept Biol. Sci., Rutgers Univ/Njit, NEWARK, NJ; [2]Mathematical Sci., New Jersey Inst. of Technol., Newark, NJ

Abstract: Many neuron types exhibit resonance properties in which the impedance amplitude of the neuron is maximal at a non-zero frequency (fres). Impedance (Z = V / I) can be measured using sinusoidal inputs in current clamp (Iclamp) or voltage clamp (Vclamp) conditions. Experimental studies have reported that similar fres values are measured in the two conditions; however, it is not clear whether these values correspond to identical impedance properties. We address this problem using mathematical analysis of conductance-based neuron models. Although the Iclamp and Vclamp techniques are complementary, there are fundamental differences between the two: in Vclamp, V and therefore dV/dt are controlled, whereas in Iclamp

these factors are free to vary. As a result, the description of the membrane properties in Iclamp requires an additional dynamic variable V and therefore one extra effective dimension. This has important consequences for the degrees of complexity in the two conditions and implies that time-varying signals should produce fundamentally different responses. We use 2D models to explore the impedance (amplitude and phase) properties in response to sinusoidal inputs in Iclamp and Vclamp. For the appropriate parameter values, these models exhibit amplitude and phase resonance (zero phase shift response at a nonzero input freq fphase). In Iclamp, the (sinusoidal) input signal is simple but the response dynamics are 2D. Conversely, in Vclamp, the response dynamics are 1D but there is higher complexity in the input signal which involves both the sinusoidal V and dV/dt. We first examine the resonant properties of linearized models. Despite the difference in effective dimensionality of the underlying systems, surprisingly, in the linear case, the impedance profiles (f-Z) are identical. In contrast, the effects of nonlinearities on the impedance profiles in the full biophysical models are properly captured only in Iclamp conditions. In particular, the amplification of resonance power by resonant and amplifying currents is lost in Vclamp and the two conditions produce different values of fres. Similarly, the two conditions produce different phase shifts and different fphase values. The advantage of Vclamp is that it provides complete instantaneous control over the voltage range and trajectory, thus resulting in a controlled measurement of ionic currents. However, although Vclamp and Iclamp conditions provide identical impedance profiles for linear systems, these methods are not equivalent when comparing the impedance profiles and resonance properties of neurons and that, in general, Iclamp conditions provide a more accurate estimate of the neuron's response.

Title: The role of a persistent inward current in shaping membrane resonance properties of different neuron types in an oscillatory network

Authors: *D. M. FOX[1], H.-A. TSENG[3], H. G. ROTSTEIN[4], F. NADIM[2]
[1]Biol. Sci., [2]Biol. Sci. and Mathematical Sci., NJIT & Rutgers Univ., Newark, NJ; [3]Biol. Sci., Rutgers Univ., Newark, NJ; [4]Mathematical Sci., NJIT, Newark, NJ

Abstract: Membrane resonance, a maximal voltage response to sinusoidal current input at a non-zero frequency (fres) is a property of many neurons types and is often correlated with the frequency of the networks in which they are embedded. Neuromodulators that act on voltage gated ionic currents that underlie membrane resonance can also change fres. However, resonance often involves the interaction of multiple voltage-gated currents and thus it is unclear how a neuromodulator that targets a single ionic current affects the resonance properties. It is also unknown whether the changes in fres influence network activity. We examine the modulatory effects of changing a persistent inward current in shaping the resonance properties of an oscillatory neuron. In the pyloric network of the crab stomatogastric nervous system, the pacemaker PD neurons show resonance with fres (~ 1Hz) correlated with the network frequency. In contrast, the follower LP neurons show a significantly higher fres (~1.5 Hz). Both cells have an h-current (Ih) and are targets of peptide neuromodulators that activate a voltage-gated non-specific inward current (IMI). We compare the sensitivity of fres, measured in voltage clamp, in the PD and LP neurons to the voltage ranges of oscillation (Vlo to Vhi). Our results show that fres in both cells increases if Vhi is increased. However, only in PD, and not in LP, fres is sensitive to Vlo. Using a multi-objective genetic algorithm approach, we compare single-compartment models that include Ih and IMI to show how the parameters of these two currents can give rise to the different sensitivities. In voltage clamp, fres results from the addition of currents having different amplitudes and phases. To understand why fres is sensitive to Vlo and Vhi we analytically track gating variables of individual ionic currents to see how the amplitudes and phases interact with input frequency. We show how fres, and the amplitude and phase of Ih and IMI change with changes in their dynamics. Moreover, we show how this is affected when Vlo and Vhi are varied. Finally, we explore the dynamics of IMI and Ih activation using realistic voltage waveforms of the PD and LP neurons at different amplitudes and frequencies to examine the role of this modulatory current during ongoing pyloric oscillations. Our results underline the different resonant properties generated by the same ionic currents in different neuron types in a network.

Abstract: Hippocampal sharp wave (SW)/ripple complexes are thought to contribute to memory consolidation. Previous studies suggest that behavioral rewards facilitate SW occurrence *in vivo*. However, little is known about the precise mechanism underlying this enhancement. Here, we examined the effect of dopaminergic neuromodulation on spontaneously occurring SWs in acute hippocampal slices. Local field potentials were recorded from the CA1 region. A brief (1 min) treatment with dopamine led to a persistent increase in the event frequency and the magnitude of SWs. This effect lasted at least for our recording period of 45 min and did not occur in the presence of a dopamine D1/D5 receptor antagonist. Functional multineuron calcium imaging revealed that dopamine-induced SW augmentation was associated with an enriched repertoire of the firing patterns in SW events, whereas the overall tendency of individual neurons to participate in SWs and the mean number of cells participating in a single SW were maintained. Therefore, dopaminergic activation is likely to reorganize cell assemblies during SWs.

Title: Somatostatin-positive inhibitory interneurons mediate inter-dentate gyrus inhibition

Authors: *T.-Y. YEN, C.-C. LIEN
Inst. of Neurosci., Natl. Yang-Ming Univ., Taipei, Taiwan

Abstract: Somatostatin-expressing (SOM+) GABAergic neurons of the dentate gyrus (DG) were thought to be local-circuit interneurons with their axons primarily restricted to the same side of the DG. Recent studies found a group of SOM+ GABAergic neurons with long-range axonal projections to the contralateral DG. However, the function of these long-range projections remain unknown. In this study, we combined optogenetics and electrophysiology to identify the targets of SOM+ GABAergic long-range projections in the contralateral DG. Our preliminary results showed that SOM+ neurons mediate inter-DG inhibition with target-cell-type-specific efficacy and connectivity. Intriguingly, interneurons receive stronger inhibition compared to granule cells. SOM+ neuron-mediated inhibition may provide an association signal for coordinated function of bilateral DGs and warrants further study.

Title: A synaptic homogeneity principle for parvalbumin-expressing interneuron synapses in the hippocampal dentate gyrus

Authors: *C.-J. CHEN, C.-C. LIEN
Inst. of Neurosci., Natl. Yang-Ming Univ., Taipei, Taiwan

Abstract: The hippocampus is a key brain structure for learning and memory. The dentate gyrus (DG) serves as a primary gate of the hippocampus. Local-circuit GABAergic inhibitory interneurons (INs) in the DG comprise a heterogeneous cell population with distinct molecular, morphological, and electrophysiological properties. Among them, parvalbumin expressing (PV(+)) INs are a striking type of inhibitory IN and play an important role in controlling neuronal activity and therefore mediate neuronal synchronization. PV+ INs are fast-spiking and exhibit extensive axonal arborization within the DG granule cell layer. They innervate granule cells, non-fast-spiking INs, and fast-spiking INs in the granule cell layer with high connection rates. Although anatomical evidence suggests that PV+ INs also innervate hilar neurons, including hilar mossy cells and hilar INs, the functional connections between PV(+) INs and hilar neurons remain unknown. Here, we combined optogenetics with electrophysiology to address this question. Our preliminary results found that granule cells receive strong synaptic input from PV(+) INs compared to hilar mossy cells and hilar INs. However, the temporal dynamics of inhibitory inputs to granule cells, hilar mossy cells, and hilar INs are not significantly different, indicating that synapses between PV+ INs and their target cells display target cell-independent short-term synaptic plasticity.

Title: Afferent-specific recruitment of interneurons in the dorsal hippocampal dentate gyrus

Authors: *T. HSU[1], M.-H. TAI[2], C.-C. LIEN[1]
[1]Inst. of Neuroscience, Natl. Yang-Ming Univ., Taipei, Taiwan; [2]Inst. of Biomed. Sciences, Natl. Sun Yat-Sen Univ., Kaohsiung, Taiwan

Abstract: Dentate gyrus (DG) is the primary gate of the hippocampus and receives several excitatory afferents projections from different brain areas. How the principal cells, that is,

granule cells (GCs) and various local-circuit GABAergic interneurons respond to different excitatory inputs remains unclear. Here, we used optogenetics to investigate the target-cell-specific neurotransmission at the hilar commissural pathway-DG and medial perforated pathway (MPP)-DG circuits. We found that monosynaptic excitatory transmission at both hilar commissural pathway-GC and MPP-GC synapses exhibited similar short-term synaptic depression. In striking contrast, hilar commissural pathway- and MPP-recruited GABAergic transmission onto GCs were markedly different. The ratio of inhibitory GABAergic conductance versus excitatory conductance (I/E ratio) in single GCs was monotonically increased during 10 Hz successive stimulation of the hilar commissural pathway, whereas the I/E ratio was decreased during the same stimulation of the MPP pathway. Differential recruitment of interneurons by these two pathways may account for the difference in GABAergic transmission. In agreement with this notion, ML-like and TML-like interneurons received stronger input from the hilar commissural pathway compared to the MPP pathway, and were more reliably recruited by the hilar commissural pathway during 10 Hz successive stimulation. By contrast, the MPP pathway preferentially recruited ML-like interneurons at the onset of stimulation train and did not recruit TML-like interneurons. Our results suggested that the use-dependent shift of the excitation-to-inhibition in the DG GCs is specific to the type of glutamatergic afferent.

Title: Inhibitory control of dynamic range of hippocampal dentate granule cell population

Authors: ***C.-T. LEE**, C.-C. LIEN
Inst. of Neuroscience, Natl. Yang-Ming Univ., Taipei, Taiwan

Abstract: The hippocampus plays an important role in learning and memory. The dentate gyrus (DG), which serves as a gateway to the hippocampus, filters the excitatory afferent inputs from

the cortex and sends the outputs to other hippocampal areas. Little is known, however, about the range of afferent input strengths that DG granule cell (GC) populations can represent. We found that the dynamic range that GCs can represent is much narrower compared to CA1 pyramidal cells. We examined the intrinsic properties, excitatory and inhibitory postsynaptic conductance evoked at threshold input strength of GCs recruited over the range of input strengths and founded that all these factors are not correlated to threshold input strength. However, application of gabazine, a $GABA_A$ receptor antagonist, revealed that feedforward inhibition participates in narrowing the dynamic range of GC populations, which is striking contrast to the CA1 region, the output station of the hippocampus. Examination of threshold input strength and spike delay suggested that this feedforward inhibition is primarily mediated by fast-spiking interneurons and molecular layer interneurons. By using optogenetics, we found that parvalbumin (PV)-expressing interneurons are primarily involved in regulating the dynamic range of GC populations during period of sparse activity. By contrast, GC dynamics during series of incoming activities are differentially regulated by PV- and somatostatin (SST)-expressing interneurons. PV-expressing interneurons control the onset of spike series, whereas SST-expressing selectively regulate the dynamics in the late spike series. Together, our results indicate that GABAergic interneurons constrain the dynamic range of dentate GC populations during different states of neuronal activities.

Title: Routing information in networks at the edge of synchrony

Authors: *A. PALMIGIANO[1,2], T. GEISEL[3,2], F. WOLF[3,2], D. BATTAGLIA[4,2]
[1]Max Planck Inst. For Dynamics and Self-Organiz, Goettingen, Germany; [2]Bernstein Ctr. for

Computat. Neurosci., Goettingen, Germany; [3]Max Planck Inst. For Dynamics and Self Organization, Goettingen, Germany; [4]Inst. de Neurosciences des Systèmes, Marseille, France

Abstract: Behavior and cognition require a dynamically reconfigurable communication scheme, flexible in scales much faster than the ones imposed by mechanisms modifying the architecture of the network's structural connectivity. Processes such as attention expose that the brain can actively select specific information-flow channels in very fast time scales. A well established hypothesis known as communication through coherence [Fries, 2005], proposes oscillatory coherence as a possible gating strategy to regulate inter-areal information transmission. Recent studies, however, have challenged this view arguing that synchronous episodes in brain signals are of short duration (100 ms) [Burns, Xing, Shapley,2011] and of a drifting frequency, [Ray, Maunsell, 2010] making oscillatory coordination an unreliable mechanism for information routing. In this work we aim to bring together these views in apparent contradiction. We show that in a model of a local neural circuit of randomly interconnected conductance-based neurons with heterogeneous properties, a robust regime characterized by transient synchrony emerges. When multiple local circuits are connected by long range excitation, short-lived events of coordinated synchronization between areas occur with a self-organized frequency tracking. We show furthermore that, during these events, phase locking also transiently occurs, not necessarily in phase, but favoring phase relations reminiscent of attractors that the connected circuits would develop for stronger synchrony ("ghost attractors"). These phase relations in turn determine preferential directions for the information transmission as measured by Transfer entropy. In particular, effectively unidirectional communication in presence of a bidirectional connectivity can arise at the edge of developing synchrony, and the direction of transmission can be flexibly inverted. In particular, we show that this direction can be actively controlled by applying a weak driving bias, and even by precisely-timed synchronous pulses stimulation. A newly developed time-resolved Transfer Entropy estimator further allows us to show that the resulting changes in the instantaneous phase difference distribution translate into changes of information flow within only a few oscillatory cycles, smaller than the average gamma-burst length.

Title: Contrasting the role of Ih and ICaT currents in post-inhibitory rebound mechanisms of reciprocal-inhibitory networks

Authors: J. DETHIER[1], G. DRION[1], *R. SEPULCHRE[2]
[1]Univ. of Liege, Liege, Belgium; [2]Univ. of Cambridge, Cambridge, United Kingdom

Abstract: Models with reciprocal inhibition are ubiquitous in the literature. For instance, common rhythmic motor behaviors produced by central pattern generators (CPGs) involve half-center oscillators. Those oscillators consist of two inhibitory neurons that do not oscillate in isolation, but oscillate when reciprocally connected (Marder & Calabrese 1996). The same mechanism is described in models of the thalamic reticular nucleus to account for thalamocortical spindle oscillations (Wang & Rinzel 1992). Reciprocal inhibition can generate oscillations only if the isolated neurons exhibit the property of post-inhibitory rebound (PIR), a transient depolarization evoked by a prior hyperpolarizing stimulus (Perkel & Mulloney 1974). Two distinct ionic currents have been clearly identified in PIR: a hyperpolarization-activated cation current, I_h (Ansgstad *et al.* 2005), and a low-threshold T-type calcium current, I_{CaT} (Steriade *et al.* 1990). While the two currents cooperate in PIR, we exhibit an important difference between them: I_h produces a transient increase in excitation in the neuron but is slow restorative, that is, it is a source of negative feedback in the slow time scale of the neuron repolarization, whereas I_{CaT} is slow regenerative, that is, is a source of positive feedback. As a consequence if PIR is caused by I_h only, the neuron remains memoryless/monostable at any time. The transient increase in excitation results in a rebound-burst mechanism with restorative firing. In sharp contrast, if I_{CaT} is involved in PIR, the neuron might acquire memory/bistability and produces regenerative firing activity during the rebound. The cellular regenerativity may be undetectable in the time trace of action potentials of the isolated neuron but has a major impact on robustness and modulation at the network level. We compare a network that is purely restorative with a model that includes a slow regenerative current: we investigate how the two networks respond to heterogeneity in the connections (maximal conductances and kinetics) and in the neuron intrinsic properties, as well as how modulation can affect the networks. We also explore the entrainability of the two networks by an external source. Our study shows that the network oscillations are endogenous/robust in the regenerative case and exogenous/entrainable in the restorative case. The properties of I_h and I_{CaT} suggest a drastically different role for the two currents, with I_h more prominent in networks with major sensory feedbacks, to deal with environmental perturbations for instance, and I_{CaT} more prominent in networks with a strong endogenous rhythm, much less responsive to external inputs.

Title: Distinct modulation of low-frequency and high-frequency γ-activity in the barrel cortex by GABAA receptors containing α1- and α2-subunits

Authors: *J. I. HOFMANN[1,2], C. SCHWARZ[1,2], U. RUDOLPH[3], B. ANTKOWIAK[4]

Section, Dept. of Anesthesiol. and Intensive Care, Eberhard-Karls-University, Tübingen, Germany

Abstract: High-frequency electrical activity in the cerebral cortex (>25 Hz) is associated with multiple aspects of cognitive information processing. It is shaped by GABAA receptor-mediated inhibition, but the individual contributions of GABAA receptors containing α1- and α2-subunits remain obscure. To further elucidate this topic, ongoing high-frequency activity in the mouse barrel cortex was modified by systemic administration of diazepam, a drug that binds to GABAA-receptors containing α1,2,3, 5 -subunits and a γ-subunit. Investigations were carried out on two different strains of mutant mice. In α2,3,5-knockin mice, diazepam only enhanced the function of receptors incorporating α1-subunits, whereas in α1,3,5-knockin mice only α2-containing receptors were sensitive to diazepam. In both strains diazepam decreased multi-unit action potential firing to a similar degree. Yet, local field potentials (LFPs) were differently affected by diazepam in the two genotypes. In α1,3,5-knockin mice, the drug significantly enhanced the power in the β- low γ-band (20-50 Hz) whereas high γ-power (60-100 Hz) was attenuated. But in α2,3,5-knockin mice, diazepam decreased the power density in both, the low and high γ-band. We further quantified the correlation between LFPs simultaneously monitored with four different electrodes in the barrel cortex. Correlated activity was enhanced by diazepam in α1,3,5-knockin mice but not in α2,3,5-knockin mice. Taken together, these findings suggest that diazepam-induced potentiation of GABAA receptors harboring α2- but not α1-subunits augments the power in the β- and low γ-band via strengthening cortical synchrony but probably not by increasing the discharge rates of cortical neurons. We hypothesize that α2- mediated

hyper-synchrony underlies the phenomenon of paradoxical EEG-excitation, which is a hallmark of sedative drugs acting via GABAA receptors. Furthermore, the opposing actions of diazepam on low- and high γ-activity are in line with the existence of at least two distinct generator networks.

Title: The role of Na+/K+ ATPase activity in neuronal oscillations and synchrony

Authors: *O. GONZALEZ, G. FILATOV, M. BAZHENOV
Univ. of California, Riverside, Riverside, CA

Abstract: Na+/K+ ATPase activity is a major mechanism for maintaining the balance of Na+ and K+ ion concentrations in the brain. This pump is electrogenic and therefore contributes to maintaining the resting state of a neuron. Previous computational and experimental studies suggested that the Na+/K+ ATPase may play an important role in epileptogenesis. It has been shown that applying cardiac glycoside Ouabain (ATPase antagonist) to mouse and rat hippocampal slices in concentration of tens to hundreds of uM leads to the development of epileptiform activity throughout the whole hippocampus. However, the exact mechanism of the effect of the Na+/K+ pump on neural excitability and network dynamics has yet to be established. Here, we studied the effects of sub-micromolar concentrations of the Ouabain analog Strophanthidin (STDN) in the mouse hippocampus *in vitro*. We observed two distinct synchronous firing patterns following bath application of STDN. Bath applications of 100 - 500 nM STDN generated low frequency, high amplitude continuous synchronous activity. However, bath applications of 500nM - 5μM STDN lead to the development of low amplitude, high frequency bursting firing of the hippocampal network. Spatio-temporal analysis revealed that all synchronous network activity was initiated, and had largest amplitudes in the CA3 region of the hippocampus before spreading to the other regions. Overall, we show the existence of distinct

patterns of network synchrony due to differences in pump activity, and that sub-micromolar concentrations of STDN are sufficient for generating synchronous network activity in the mouse hippocampus.

Title: Mechanisms of fast ripple generation in a computational model

Authors: ***C. G. FINK**[1], S. GLISKE[2], T. ASSAF[3], W. STACEY[2]
[1]Physics, Ohio Wesleyan Univ., Delaware, OH; [2]Neurol., Univ. of Michigan, Ann Arbor, MI; [3]Computer Sci., Univ. of Michigan, ANN ARBOR, MI

Abstract: High frequency oscillations (HFOs) have been associated with both normal and pathological brain activity [1], and show promise as biomarkers for identifying the epileptogenic zone in patients with epilepsy [2]. HFOs may be classified according to peak frequency content as either Ripples (100-250 Hz) or Fast Ripples (>250 Hz). Some studies indicate that Fast Ripples are better biomarkers of the epileptogenic zone than are Ripples [3], while other studies show that frequency content alone is insufficient to identify HFOs as normal or pathological [4]. Gaining a better understanding of the mechanisms which generate HFOs may help in making this clinical distinction. In this study we present a computational model to investigate mechanisms by which a wide range of network activity--from gamma rhythm to Fast Ripples--may be generated in hippocampal cortex, specifically focusing on the network properties necessary to produce Fast Ripples. In this model all activity is elicited from a network of pyramidal and basket cells simply by modulating the mean frequency of afferent synaptic noise. The LFP is obtained by summing the currents from all cellular compartments, thereby reflecting both action potentials (APs) and post-synaptic potentials (PSPs). Oscillations are generated in the network by varying the mean level of synaptic noise, and various network properties are modulated in order to determine their

effect upon Fast Ripple generation. We find that in general, PSP-dominated LFPs are incapable of generating Fast Ripples, while AP-dominated LFPs may generate both Ripples and Fast Ripples. Several factors may facilitate the emergence of Fast Ripples, including loss of inhibitory connections, recurrent connectivity between pyramidal cells, and loss of gap junction connectivity between basket cells. Counterintuitively, AP-dominated Ripples are characterized by asynchronous pyramidal cell spiking. Such Ripple activity is interrupted by brief (~50 ms) periods of Fast Ripple activity associated with transient organization of pyramidal cell spiking into two out-of-phase clusters (similar to the results in [5]). This model suggests that gamma, fast gamma, Ripples, and Fast Ripples, both normal or abnormal, exist on a continuum with specific features related to the underlying network activity and connectivity. Title: Circadian oscillations of [Ca2+]i and extracellular glutamate in the suprachiasmatic nucleus reveal a role for neuronal-glial interaction in circadian time-keeping

Authors: *M. BRANCACCIO, M. H. HASTINGS
Div. of Neurobiology, 1N439, Med. Res. Council- Lab. of Mol. Biol., Cambridge, United Kingdom

Abstract: The hypothalamic suprachiasmatic nucleus (SCN) is responsible for synchronising the circadian clocks present across cells and tissues and aligning them to day/night cycles, thereby establishing appropriate circadian rhythms of physiology and behaviour. SCN cells contain an intra-cellular transcriptional-translational feedback loop (TTFL), whereby Bmal1/Clock dimers activate transcription of *Per* and *Cry* genes, and the loop is completed by Per/Cry auto-repression of the Bmal/Clock activity. The entire process oscillates with a ~24h periodicity. The discovery that such an intra-cellular TTFL operates in virtually all cells has questioned its importance in, alone, conferring the unique properties of robustness and internal synchrony of the SCN. Clearly,

inter-cellular mechanisms within the SCN circuit may also be important. We therefore investigated the role of neuronal-glial interaction in SCN time-keeping. We first searched for potential extra-cellular mediators of such interaction and focused on glutamate, a principal glio-transmitter. We transduced SCN organotypic slices with AAV encoding the extracellular glutamate ($[Glu]_e$) reporter iGluSnFR and performed long-term imaging. A sustained ~24 hours $[Glu]_e$ oscillation was revealed, that persisted in the absence of exogenously provided glutamate. The GABAergic nature of SCN neurons (~95%) and the resistance of the glutamate oscillation to TTX, confirmed its extra-synaptic nature. We then investigated the relationship between $[Glu]_e$ and neuronal $[Ca^{2+}]_i$. We have previously shown that the peak $[Ca^{2+}]_i$ is an early event in the SCN circadian day and precedes TTFL genes activation. We performed long term calcium-glutamate imaging by using iGluSnFR and neuronal RCaMP1h. Surprisingly, we found that $[Glu]_e$ and $[Ca^{2+}]_I$ are perfectly anti-phasic. We hypothesised that the drop in $[Glu]_e$ may be due to increased glutamate uptake. Remarkably, inhibiting glial and neuronal glutamate uptake simultaneously de-synchronised neuronal $[Ca^{2+}]_i$ across the SCN, thus suggesting a role for $[Glu]_e$ in synchronising the circuit. Intersectional and pharmacogenetic approaches further demonstrated the presence of a glial-neuronal dichotomy, necessary to encode circadian time in the SCN.

Title: Contributions of electrical synapses and interneuron subtypes to correlated inhibition during cortical network activity

Authors: *G. NESKE, B. W. CONNORS
Brown Univ., Providence, RI

Abstract: Synchronous oscillatory activity in the gamma range (30-80 Hz) has been observed during sensation, attention, and working memory tasks. Synchronization of spikes in inhibitory interneurons and of inhibitory inputs to pyramidal cells is especially strong during these processing periods, suggesting that correlated inhibition is crucial for shaping the functional properties of the active neocortex. While interneurons are connected by both chemical and electrical synapses, the relative contribution of these connections to synchronized inhibition is still not well understood. Furthermore, while interneurons are physiologically diverse, the extent and functional roles of synchronized inhibition provided by different interneuron subtypes are not known. We studied the roles of electrical synapses among interneurons and correlated firing among interneuron subtypes during persistent network activation (i.e. Up states) in acute slices of mouse barrel cortex. We found, first, that while both excitatory cells and interneurons fire during Up states, spike synchrony is higher between interneuron pairs than between excitatory cell pairs. We then studied the roles of electrical synapses in correlated inhibition during Up states by comparing connexin36 knockout (Cx36 KO) and wild-type (WT) animals. Gamma-range power of the inhibitory inputs recorded in excitatory cells was slightly higher in WT compared to Cx36 KO. However, when we measured cross-correlations between inhibitory currents recorded in pairs of pyramidal cells, the half-width of the cross-correlogram was slightly, but significantly sharper in the WT, but peak cross-correlations in the WT and Cx36 KO were similar. Additionally, there were no significant differences between the WT and Cx36 KO in the phase relationships between excitatory cell spikes or inhibitory postsynaptic currents and gamma-range LFP activity. To study the roles of different interneuron subtypes, we directly controlled the level of interneuron-subtype-specific correlated inhibition by expressing ChR2 in either of two major interneuron subtypes, parvalbumin (PV) and somatostatin (SOM) cells, and pulsing light during Up states. We will consider the effects of enhancing correlated inhibition provided by these different subtypes on the following properties of excitatory cells during Up states: membrane potential dynamics, spike precision and reliability, and sensitivity or gain. Our data suggest that electrical synapses are not crucial for most aspects of correlated inhibition or regulation of spike timing during cortical network activity.

Title: Optogenetic investigation of septal GABAergic modulation of hippocampal theta rhythm

Authors: R. BOYCE[1], S. GLASGOW[1], *S. WILLIAMS[2], A. ADAMANTIDIS[3]
[1]McGill Univ., Montreal, QC, Canada; [2]Dept Psych, McGill Univ., Verdun, QC, Canada; [3]Neurol. Dept., Bern Univ. Hosp., Bern, Switzerland

Abstract: Hippocampal neurons oscillate in synchrony at theta (4-10 Hz) frequencies during periods of wakefulness and rapid-eye-movement (REM) sleep, and evidence suggests that these theta rhythms are required for cognitive processing. The hippocampus receives cholinergic, glutamatergic and inhibitory GABAergic inputs from the medial septum (MS), a brain region required for normal theta rhythm generation *in vivo*. Previous work using lesional, pharmacological or electrical modulation of MS cell activity suggested that septal GABAergic neurons may be important for theta rhythm generation. However, due to the difficulty in achieving both temporal precision in combination with cell-type specificity using these methods, the causality of this neural pathway on hippocampal theta rhythms remains to be clarified. Here, we genetically targeted archaerhodopsin (ArchT), a silencing opsin to GABAergic neurons of the MS. We found that yellow light pulses reliably hyperpolarized ArchT-expressing cells by ~ 40 mV, preventing spiking in transfected neurons completely, in the MS in brain slices *in vitro*. Using a combination of optogenetic and electrophysiological (MS unit recording and dorsal hippocampal CA1 field potential and unit recording) techniques in freely-moving mice, we further found that spiking of canonically GABAergic neurons in the MS was completely and reversibly blocked and hippocampal theta power was significantly (> 60%) and reversibly attenuated when septal GABAergic neurons were optically inhibited during periods of active wakefulness or REM sleep. These results demonstrate that septal GABAergic neurons are critical for normal hippocampal theta rhythm *in vivo*. Additionally, this data may implicate this neuronal population as an important component of cognitive processing mechanisms during wakefulness as well as REM sleep, a concept that is presently being tested experimentally.

Title: The mechanisms underlying pyramidal cell participation in hippocampal sharp waves

Authors: *L. A. ATHERTON[1], K. TSANEVA-ATANASOVA[2], J. R. MELLOR[1]
[1]Univ. of Bristol, Bristol, United Kingdom; [2]Univ. of Exeter, Exeter, United Kingdom

Abstract: The discovery of replayed sequences of hippocampal place cell activity during sharp wave ripples (SWRs) has led directly to the fundamental concept that this reactivation underlies the consolidation of memories formed during learning. However it is still unclear what cellular mechanisms govern which hippocampal pyramidal cells fire action potentials (or participate) within a given SWR. Here we addressed this question using a combined *in vitro* and computational modelling approach. We confirmed pharmacologically that both excitation and inhibition are critical for the emergence of spontaneous sharp waves in submerged mouse hippocampal slices. Analysis of the synaptic currents in hippocampal pyramidal cells, during the ongoing sharp waves, revealed that while inhibition dominated CA3 pyramidal cell responses, CA1 pyramidal cells were either dominated by excitation or inhibition. Using a recently developed hippocampal CA3-CA1 computational network model (Taxidis et al., 2012), we then predicted changes in pyramidal cell participation during SWRs resulting from modulation of excitatory or inhibitory synaptic transmission at different synapses within the hippocampal network. These predictions shed light on how network activity during learning may shape participation in subsequent SWR oscillations.

Title: Glutamatergic and GABAergic synaptic interplay underlies the theta-gamma network oscillations in the prefrontal cortex of neonatal rats

Authors: *S. H. BITZENHOFER, K. SIEBEN, K. SIEBERT, I. L. HANGANU-OPATZ
Developmental Neurophysiol., Univ. Med. Ctr. Hamburg-Eppendorf, Hamburg, Germany

Abstract: The emergence of mnemonic abilities critically depends on the oscillatory coupling within neonatal prefrontal-hippocampal networks. Hippocampal theta bursts drive via direct axonal projections the generation of discontinuous oscillatory activity in the prelimbic (PL) subdivision of the prefrontal cortex. While the features of prelimbic activity patterns have been characterized in detail and frequency analysis uncovered both theta- and gamma-band oscillations, the cellular elements contributing to their generation are still unknown. For their elucidation, we combined *in vivo* whole-cell patch-clamp recordings with extracellular multi-site local field potential (LFP) recordings from the PL of anaesthetized neonatal [postnatal day 6-8] rats. Biocytin-stained and morphologically characterized layer V neurons in the PL were classified in pyramidal and multipolar neurons. They had similar passive as well as active membrane properties and showed three classes of spontaneous postsynaptic currents (sPSCs): (i) glutamatergic fast sPSCs with monoexponential decay, (ii) glutamatergic slow sPSCs with biexponential decay, and (iii) GABAergic sPSCs. Both glutamatergic and GABAergic sPSCs occurred in bursts that synchronized in theta (4-12 Hz) and beta-low gamma (15-50 Hz) frequency with the extracellularly recorded discontinuous network oscillations. The coupling of synaptic inputs and outputs with the network activity was assessed by calculating the oscillation-triggered intracellular current average and event-triggered LFP average. Glutamatergic inputs to pyramidal and multipolar neurons were locked to theta or gamma oscillations, respectively, whereas GABAergic inputs to both cell types were locked to theta activity. The firing of multipolar neurons in the PL appeared phase locked to the network activity in theta and gamma frequency, but no locking was found for pyramidal neurons. Moreover, the bursts of glutamatergic inputs to pyramidal and multipolar neurons, as well as the action potential firing of pyramidal neurons were highly correlated to the start of local field activity in theta and gamma frequency. Thus, complex synaptic interactions between pyramidal and multipolar neurons may provide the framework for temporal coding in the neonatal PL.

Title: Structural irregularity in local neural circuit induces global modulations of neural synchronization

Authors: *P. SAILAMUL, J. JANG, S.-B. PAIK
Bio and Brain Eng. Dept., KAIST, Daejeon, Korea, Republic of

Abstract: Abnormality in neural synchronization is often accompanied with some brain disorders such as schizophrenia and epilepsy. Yet the link between these correlated neural activity patterns and structure of the underlying neural circuit is not completely understood. In this study, we use model simulations of large neural network to better understand the relation between the structural irregularity in local neural circuit and the global synchronization of neural activity. First, we examined how a neural circuit in the cortex can be structured by the interaction between nearby neurons. We developed the mosaics of Excitatory(E) and Inhibitory(I) neurons using our developmental model algorithm: the local repulsive interaction model. By setting different repulsive interaction range, we could generate mosaics of various spatial regularities. Next, to simulate neural activities in the network of various spatial regularity, we created model neural networks with a regular E mosaic and three different I mosaics; irregular, quasi-regular, and regular mosaics. The local cortico-cortical connections were generated by the statistical wiring model, where the probability and the strength of local synaptic connection only depend on the distance between two neurons. Then, using Hodgkin-Huxley model neurons in the NEURON simulator, we examined the correlated neural activities in above three cases. We observed that correlated neural activities -spontaneous oscillation in gamma band frequency- are generated in all three cases when a random Poisson spike train is given as a feedforword input to the network. However, from the statistical analysis of firing rates and inter-spike interval, we found that the irregular mosaic showed the most unevenly distributed local activity among the three cases. More importantly, we also observed that this spatial irregularity in neural activity can make the network unstable, which induces the modulation of global synchronization more readily. When we increase the feedforward input firing rate given to the network, the frequency of spontaneous gamma oscillation in the network also varied proportional to the input rate change, and this variation was most significant in the irregular mosaic network. In addition, irregular mosaic

network often showed a transition of global synchronization pattern from modest-synchronized oscillation to sharp-synchronized wave propagation. Our results show that the structural irregularity in the neural circuit can induce abnormal neural synchronizations, possibly leads to the modulation of global activity pattern that might be important to the normal operation of the brain system.

Title: Homeostatic conductance regulation in multicompartment conductance-based model neurons

Authors: ***A. H. WILLIAMS**, T. O'LEARY, E. MARDER
Brandeis Univ., Waltham, MA

Abstract: Neurons possess homeostatic mechanisms that maintain their electrophysiological properties over long time spans despite ion channel turnover and environmental perturbations. Such plasticity mechanisms have been observed at the level of circuits, single cells and within subcellular compartments including the soma [1], dendritic spines [2], the axon initial segment [3], and at pre-synaptic terminals [4]. It remains unclear how these spatially distributed regulatory mechanisms can be orchestrated to regulate the overall properties of a neuron. We extended an existing model of ion channel regulation [5] to a multicompartment model. We accounted for both global and local forms of homeostatic regulation by modeling the production of channel precursors (mRNA) and ion channels in two separate steps. The global regulation rules model the activity-dependent production and removal of ion channel mRNA transcripts; the local regulation rules within each compartment model the translation and insertion of ion channel proteins into the cell membrane. We find that a simple regulatory rule can compensate for

growth of neuronal processes as well as inter-neuronal variability in morphology. Furthermore, tuning the local regulation rules is sufficient to produce cell compartments with unique ion channel densities and electrical properties. For example, specific parameter combinations can establish active and passive dendritic compartments as well as a spiking axonal segment within the same multicompartment cell. The model predicts that channel densities will be spatially correlated, for example, a channel present in the soma and a distal dendritic branch may be expressed at a consistent ratio, even if the expression is variable from cell to cell at each of these locations. Finally, we explore the requirement for local vs global activity dependent regulation. If the global homeostatic mechanism (i.e. mRNA production) is activity-dependent, the model can compensate for perturbations that alter activity levels at the soma. However, perturbations that alter neural activity in distal cell compartments may not be sensed by the global mechanism. More fine-grained control can be implemented by making the local regulation rules (i.e. channel insertion rates) activity-dependent. [1] Swensen & Bean (2005). J Neurosci. 25(14):3509-20. Title: Modulation of frequency preference by changes in input resistance

Authors: *J. A. VERA[1], U. PEREIRA[2], B. REYNAERT[1], J. BACIGALUPO[1], M. SANHUEZA[1]
[1]Univ. De Chile, Santiago, Chile; [2]Dept. of Statistics, The Univ. of Chicago, Chicago, IL

Abstract: Neurons from different mammalian brain regions (including neocortex, hippocampus and amygdala) display subthreshold frequency preference in the theta range (4-12 Hz) when stimulated with oscillatory current injection, a phenomenon called neuronal resonance. It is speculated that this property may contribute to tune and to stabilize oscillatory activity in neuronal networks. Frequency preference results from the high-pass filter effect produced by the slow activation of a hyperpolarization-activated current in addition to the low-pass filtering of voltage fluctuations due to the passive membrane properties (resistance and capacitance). Together, these properties determine the impedance profile of neurons, characterized by the resonance frequency (frequency at impedance peak) and resonance strength (ratio between peak impedance and impedance at 0.5 Hz). In active neuronal networks membrane input resistance (Rin) varies in a wide range depending on synaptic bombardment (showing a 0-80% decrease from its value in a silent network). We investigated the relationship between Rin and frequency preference in CA1 pyramidal and cortical amygdala neurons in rat brain slices, using dynamic clamp and the ZAP protocol (injection of an oscillatory current of constant amplitude and linearly increasing frequency; 0-20 Hz). Our results show that a 50% decrease in Rin generated by the addition of a virtual leak conductance (16.6 ± 2.9 nS) shifted the resonance frequency from 6.3 ± 0.4 to 7.3 ± 0.4 Hz ($p<0.0005$, $n=10$), while decreasing resonance strength by 9% (from 1.23 ± 0.03 to 1.11 ± 0.02; $p<0.005$). On the other hand, a 50% increase in Rin by the addition of a negative virtual leak conductance of -6.1 ± 0.8 nS produced the opposite effect, increasing resonance strength from 1.23 ± 0.03 to 1.34 ± 0.05 ($p<0.005$, $n=10$) and decreasing resonance frequency from 6.5 ± 0.4 to 5.2 ± 0.3 Hz ($p<0.0005$, $n=10$). To test the modulation of frequency preference during spiking we used a similar stimulation protocol on cortical amygdala neurons. We showed that selective spiking at 2-4 Hz recorded in control conditions was shifted to 4-10 Hz after a 30% reduction in Rin, in agreement with our observations in hippocampal neurons. These results show that frequency preference of resonant neurons is modulated by changes in Rin and suggest that in the intact brain this property may constitute a tuning mechanism to adjust frequency preference of single neurons in interplay with network activity levels.

Title: Membrane potential-dependent synaptic integration in entorhinal stellate neurons

Authors: *J. J. MARTINEZ, M. ECONOMO, J. A. WHITE
Bioengineering, Univ. of Utah, Salt Lake City, UT

Abstract: Stellate cells (SCs) of the medial entorhinal cortex exhibit robust spontaneous membrane-potential oscillations (MPOs) in the theta (4-12 Hz) frequency band as well as theta-frequency resonance in their membrane impedance spectra. Past experimental and modeling work suggests that these features may contribute to the phase-locking of SCs to the entorhinal theta rhythm and may be important for forming the hexagonally tiled grid cell place fields exhibited by these neurons *in vivo*. Among the major biophysical mechanisms contributing to MPOs is a population of persistent (non-inactivating) sodium channels. Because the resulting persistent sodium conductance (GNaP) gives rise to an inward current with steep voltage dependence near spike threshold, these channels endow SCs with a prominent decrease in synaptic current as membrane potential approaches spike threshold, resulting in a negative slope conductance. In this study, we used dynamic clamp to test the hypothesis that this negative slope conductance gives rise to voltage-dependent, and thus MPO phase-dependent, changes in the amplitude of excitatory and inhibitory post-synaptic potential (PSP) amplitudes. We find that PSP amplitude depends on membrane potential, exhibiting a 4-6% increase in amplitude per mV depolarization. The effect is larger than_and sums quasi-linearly with_the effect of the synaptic driving force, V - Esyn. As SC MPOs 10 mV in amplitude are commonly observed *in vivo*, this voltage- and phase-dependent synaptic gain is large enough to modulate PSP amplitude by over 50% during theta-frequency MPOs. Phase-dependent synaptic gain may therefore impact the

phase locking of grid cells *in vivo* to ongoing network

Title: Intrinsic plasticity accompanies synaptic LTD in Purkinje cells

Authors: *Z. YANG, F. SANTAMARIA
UTSA, San Antonio, TX

Abstract: Cerebellar Purkinje cells show activity dependent changes of intrinsic excitability in both behavioral learning and *in vitro* slice recordings. It is still unknown whether long term depression (LTD) of parallel fiber-Purkinje cell (PF-PC) synapse is associated with modulation of intrinsic membrane properties. We performed whole-cell patch-clamp recordings in slice from mice 16-23 days old. PF-PC LTD was induced in voltage clamp mode by pairing parallel fiber stimulation and somatic depolarization. This protocol generated robust reduction of EPSC of about 40%. Intrinsic properties were recorded in current clamp mode before and after synaptic LTD induction. We found an increase of overall excitability in somatic recording and a leftward shift of the input-output curve after LTD induction. There was also a parallel decrease of sag ratio and an increase of input resistance at more hyperpolarized potential, indicating a reduction of h current. We did not observe significant changes in afterhyperpolarization amplitude following action potential trains. Since there are two components in our LTD induction protocol, we further tested the excitability change by somatic depolarization or parallel fiber stimulation only, in order to elucidate the stimulation pattern required for this intrinsic plasticity. We found that neither stimulation protocol alone can lead to overall excitability change, indicating the requirement of concomitant somatic depolarization and dendritic stimulation for intrinsic plasticity. This non-synaptic plasticity may serve as a homeostatic mechanism and could affect future information processing by Purkinje cells.

Title: Long lasting depression of intrinsic excitability in fast spiking interneurons decreases inhibition in putative granule cells of the dentate gyrus

Authors: *D. DASGUPTA, S. K. SIKDAR
Mol. Biophysics Unit, Indian Inst. of Sci., Bangalore, India

Abstract: The local fast spiking interneurons (FSINs) of the Dentate Gyrus (DG) are post-synaptically connected to the granule cells (GCs), which in turn make perisomatic inhibitory synapses onto the GCs, thus configuring a strong feedback circuit. Local FSINs and their feedback control are critical for neuronal network oscillations and have been associated with various behavioural paradigms. However, the prolonged effects of gamma frequency synaptic activity on the FSINs have not been explored previously. We used whole-cell current clamp patch recordings on acute hippocampal slices to address this question and observed a sustained decrease in intrinsic excitability in the FSINs following repetitive 30 Hz synaptic stimulations of the mossy fibers (gamma bursts). Interestingly, when the gamma bursts were paired with FSIN membrane hyperpolarization, the decrease in excitability was accentuated to ~ 35% from the baseline, while pairing with membrane depolarization significantly attenuated the plasticity of intrinsic excitability. Paired pulse ratio measurement of the synaptic responses did not show significant changes during the experiments. The induction protocols were observed to be associated with increase in post-synaptic calcium, with the maximum increase occurring during the pairing of gamma bursts with membrane hyperpolarization and a minimal increase during pairing with membrane depolarization. Bath perfusion of 1-Naphthylacetyl spermine (NASPM) significantly attenuated the calcium rise, suggesting the involvement of calcium-permeable AMPA receptors in the observed phenomenon. Chelation of post-synaptic calcium with intracellular BAPTA blocked the expression of plasticity. The calcium-permeable AMPA receptors and postsynaptic HCN channel conductance were found to be involved in this form of plasticity in the FSINs. Simultaneous dual patch recordings from synaptically connected FSIN and putative GC, confirmed that a decrease in intrinsic excitability of the FSINs was accompanied by decreased inhibitory post synaptic potentials in the GCs. Experimentally constrained network simulations using NEURON showed increased spiking in the post-synaptic GC owing to decreased input resistance in the FSIN. We hypothesize that the plasticity in the FSINs induced by local network activity may serve to increase information throughput into the downstream hippocampal subfields besides providing neuroprotection to the FSINs. This form of plasticity may have implications in epilepsy which is associated with high network activity and significant death of interneurons in neuronal microcircuits.

Title: Temperature robust neuronal function from activity-dependent ion channel regulation

Authors: *T. O'LEARY, E. MARDER
Volen Ctr. For Complex Systems, Brandeis Univ., Waltham, MA

Abstract: Animals that cannot regulate their body temperature (poikilotherms) far outnumber animals that do (homeotherms) in terms of biomass and number of species, yet the principles underlying temperature-robustness in poikilothermic nervous systems are not understood. Neuronal function depends on the kinetic properties of ion channels and other enzymes expressed in neurons, and this dependence can be very sensitive to small changes in parameters. The exponential temperature dependence of ion channel kinetics (the 'Q10') differs several-fold between ion channel types expressed in poikilotherms such as crustaceans. Nonetheless, important circuit properties - such as phase relations in central pattern generating circuits - are robust to temperature changes of more than 10 degrees Celsius [1, 2]. Modeling work has shown that such robust function does not come for free because membrane conductances with realistic Q10s generically become de-tuned and disrupt neuronal function as temperature changes by a few degrees [3]. How is temperature robust neural activity achieved in spite of this potential de-tuning? One possibility is that activity-dependent mechanisms [4] that maintain neuronal properties are constrained in cold-blooded animals by the requirement to produce temperature-robust output. We developed a model of activity-dependent ion channel regulation that can produce stable neuronal activity in spite of underlying differences in the temperature dependence and density of conductances in model neurons. We find that the constraints that temperature-robustness imposes on self-regulating models can be met due to the large number of parameter sets that map to specific activity patterns. As a consequence, neurons in poikilotherms are

predicted to co-regulate conductances in specific ways that make important neuronal properties temperature-robust. References 1. Title: Calcium-sensing receptor signaling mediates increases in neocortical neuron excitability following decreased external calcium

Authors: B. J. KNIGHT[1,2], C. L. WILLIAMS[1,2], N. P. VYLETA[3], *S. M. SMITH[1,2]
[1]PCCM, Portland VA Med. Ctr., PORTLAND, OR; [2]Oregon Hlth. & Sci. Univ., Portland, OR; [3]Inst. of Sci. and Technol., Klosterneuburg, Austria

Abstract: Reduction in extracellular [Ca2+] ([Ca2+]o) decreases action potential threshold in neurons, increasing excitability. Classically, this effect has been attributed to a loss of screening by Ca2+ of the negatively charged plasma membrane surface, reducing the electrical field within the membrane and thereby shifting the gating voltage-sensitive channels in a hyperpolarizing direction. Surprisingly, it was recently shown that [Ca 2+]o-dependent changes in excitability in hippocampal neurons are mediated by a pathway consisting of a cation channel (NALCN), and two intracellular proteins, UNC-79 and UNC-80. Furthermore, it was hypothesized that changes in [Ca2+]o were detected by the calcium-sensing receptor (CaSR), which is upstream of UNC-79, UNC-80, and NALCN. Using patch-clamp techniques we examined the role of CaSR in regulating excitability in mouse neocortical neurons. We found a large reversible increase in action potential firing (885 ± 161 mean ±SEM action potentials/150 sec; n=19) in pharmacologically isolated wild-type neurons (block of glutamatergic and GABAergic transmission) when external [Ca2+] and [Mg2+] were reduced from physiological values

(1.1/1.1 mM) to 0.2/0.2 mM. However, in recordings from CaSR-/- neurons, the response to the same decrease in [Ca2+]o/[Mg2+]o was substantially attenuated (246 ± 131, p=0.004; n=16). The CaSR-/- mice were kindly provided by Dr Wenhan Chang, UCSF and San Francisco VAMC. In wild-type neocortical neurons, voltage-clamped at -70 mV, the leak current was 11 ± 5 pA when [Ca2+]o/[Mg2+]o was 1.1/1.1 mM but shifted by -14 ± 4 pA (p=0.006, n=16 neurons) following reduction of [Ca2+]/[Mg2+] to 0.2/0.5 mM. This inward current was associated with a 26 ± 3% reduction in input resistance (p=0.0003), indicating channel activation. In contrast, in age-matched neurons (16.1 ± 0.4 vs 17.2 ± 0.5 days in culture) from CaSR-/- mice, leak current at -70 mV was 9 ± 6 pA when [Ca2+]o/[Mg2+]o was 1.1/1.1 mM and unaffected (9 ± 8 pA, p=0.9, n=15) by the same decrease in [Ca2+]o/[Mg2+]o. As well, null mutant neurons had lower basal input resistance (320 ± 32 MΩ, p=0.035) that decreased less with lowered [Ca2+]o/[Mg2+]o than wild-type (12 ± 4%, p=0.007). Taken together, our data are consistent with [Ca2+]o-dependent changes in intrinsic neocortical neuron excitability being mediated by CaSR and not entirely due to surface charge screening.

Title: Arx expression is necessary for normal maturation of intrinsic and synaptic properties of parvalbumin expressing inhibitory interneurons

Authors: ***D. J. JOSEPH**[1], A. J. MCCOY[1], E. D. MARSH[1,2]
[1]Pediatrics Neurol., Children's Hosp. of Philadelphia, Philadelphia, PA; [2]Perelman Sch. of Med. at the Univ. of Pennsylvania, Philadelphia, PA

Abstract: Transcription factors combinatorially specify the identity of interneurons during development. Some of these transcription factors remain expressed in the mature interneuron pool, suggesting a different, yet unknown, function. We found that postnatal conditional ablation of one transcription factor, the Aristeless Related homeobox gene (Arx), in parvalbumin positive

interneurons resulted in a loss of parvalbumin basket cell markers such as Kv3.1 and the Cat-315 component of the perineuronal net. These neurochemical changes were associated with hippocampal based learning deficits and electrographic seizures in some animals. Therefore, we studied the effect of Arx loss on both the intrinsic and synaptic properties of parvalbumin interneurons with postnatal loss of Arx. Arx was conditionally knocked out of Parvalbumin (Parv) interneurons by crossing a floxed Arx mouse (Arxfl/fl) with a Parv-Tomato Cre-recombinase (Parv-TomCre) mouse. Hippocampal slices were generated from postnatal day 35-40 mice. Whole-cell recordings were made from Arx+/+- or Arx-/- Parv-Tom positive neurons visually identified with fluorescence and patched using IR-DIC videomicroscopy in the hippocampal CA1 region. Membrane properties were characterized in response to rectangular current pulses. Excitatory and inhibitory synaptic events were recorded in each cell. Preliminary results revealed Parv+ interneurons with loss of Arx are marginally larger and displayed lower input resistance than control interneurons. Active membrane properties such as AP threshold, AP amplitude, and half-width duration are reduced in Arx-/- Parv-Tom positive interneurons compared controls. In addition, Arx-/- Parv-Tom cells require higher current intensity (Rheobase) to reach depolarization threshold. Current-frequency curves show that Arx-/- Parv-Tom cells fire fewer action potentials than controls with increasing current injection. Synaptic recordings of spontaneous and miniature excitatory show that synaptic events on Arx-/- Parv-Tom cells are generally of lower amplitudes and occur at lower frequency than controls. Interestingly, the amplitude and frequency of inhibitory synaptic events are reduced in Arx-/- Parv cells as well. Our preliminary study demonstrates that postnatal loss of Arx alters both passive and active intrinsic properties of Parv interneurons in the hippocampus. In addition, both inhibitory and excitatory synaptic transmissions onto PV+ cells were negatively modulated by loss of Arx. These findings suggest that active expression of Arx may be a key player in the maturation of electrophysiological properties of inhibitory interneurons.

Title: Cholinergic receptor induced long-lasting plasticity of hippocampal axonal KV7 channels

Authors: K. MARTINELLO, D. A. BROWN, *M. M. SHAH
Univ. Col. London, London, United Kingdom

Abstract: Kv7 channels underlie a slowly-activated and non-inactivating voltage-dependent K+ current that modulates action potential (AP) firing and synaptic integration. This current is fully blocked by muscarinic receptor activation, hence the name M-current (1). KV7 channels are expressed in both somata and axons. In hippocampal dentate gyrus granule cells, though, our findings suggested that the M-current is present preferentially in axons where it influences the action potential threshold (2). In support, immunohistochemistry showed that KV7 subunits are predominantly located in axons. Whether these axonal KV7 channels are modulated by muscarinic receptors remains to be elucidated. To investigate this, we performed electrophysiological recordings from granule cell somata in slices obtained from P22-28 rats and either stimulated cholinergic fibers or applied the muscarinic receptor agonist, Oxotremorine-M. Activation of muscarinic receptors by these methods led to a sustained reduction in the action potential threshold and persistently enhanced granule cell firing. This effect was due to long-term inhibition of axonal KV7 channels as pre-treatment with XE991 prevented it. This was confirmed using voltage-clamp recordings from granule cell neurons. Thus, our results show that muscarinic receptor activation causes a long-lasting inhibition of axonal KV7 channels, resulting in a decrease in action potential threshold and enhanced granule cell activity. 1. Title: Low-threshold calcium channel critical for activity oscillations of dopamine neurons in mouse arcuate nucleus

Authors: *X. ZHANG, A. N. VAN DEN POL
Dept. of Neurosurg., Yale Univ. Sch. of Med., New Haven, CT

Abstract: Bursting activity is important for neurons to increase efficacy of neuropeptide/neuromodulator release and neurotransmission. By inhibiting pituitary prolactin release, dopamine neurons in the arcuate nucleus play an important role in lactation. A previous study (Lyons et al., 2010) showed that dopamine neurons in the rat arcuate nucleus display rhythmic oscillations in action potentials with cells showing a burst of spikes, followed by a period of spike absence; the oscillations appeared to be dependent on gap junction coupling. Here we used transgenic mice expressing a fluorescent reporter gene driven by the tyrosine hydroxylase promoter in arcuate dopamine neurons to study electrophysiological characteristics with whole-cell patch-clamp recording. The resting membrane potential (RMP) for bursting dopamine cells was -74.1 ± 1.9 mV (n=30) which was negative to the RMP for POMC (-54.5±1.1mV, n=33, $p<0.01$) or NPY (55.4 ± 0.8 mV, n=25, $p<0.01$) neurons in the arcuate nucleus. The oscillation frequency was 0.068 ± 0.004 Hz (n=39) in whole-cell current-clamp. We did not observe any current oscillations in voltage-clamp configuration. When action potentials were blocked by TTX, the membrane potential oscillation was intact with a frequency of 0.072 ± 0.008 Hz (n=29). This is consistent with a report that other hypothalamic neurons also display oscillations in the presence of TTX (Chu et al., 2012). The oscillation was abolished by nonselective voltage-gated calcium channel and by selective T-type calcium channel blockers. These data together suggest that activation of T-type calcium channels is necessary for the regular bursting of mouse arcuate dopamine neurons. Short (2 ms) optogenetic stimulation of arcuate dopamine neurons expressing ChIEF-dtTomato induced a single action potential and after-depolarization potential of 15.1 ± 1.5 mV (n=6). Longer (5 ms) optogenetic stimulation induced a brief burst in dopamine neurons. Our results suggest that T-type calcium channel may play an important role in burst firing of arcuate dopamine neurons.

Abstract: The midbrain dopaminergic (DA) neurons in the substantia nigra (SN) and ventral tegmental area (VTA) are an essential part of the reward/hedonic system. Therefore, we are interested in the metabolic modulation of the intrinsic electrophysiological properties of these neurons (Cell Metab. 2011; 13:720-728 and Nat Neurosci. 2013; 16(8):1042-8). For this purpose we require a solid baseline from which the modulatory actions can be studied. *In vivo* studies, which combined electrophysiological recordings with behavioral test, revealed that DA neurons possess three firing patterns that are correlated with the prediction and detection of rewards: (1) a single spiking pattern, (2) a burst firing pattern and (3) a hyperpolarized state in which the cells remain silent. In contrast, *in vitro* DA neurons have frequently been described to produce a characteristic, highly regular pacemaker firing pattern (Brain Res Rev. 2008; 58(2), 314-21). Notably, this pacemaker firing persists even in complete synaptic isolation. However, in the SN of rodent brain slice preparations a subpopulation of DA neurons was identified that did not show pacemaker firing, but an irregular firing pattern (J Physiol. 2010; 588(Pt 10), 1719-35). This irregular, non-pacemaker firing pattern is within the same low frequency range as previously described for regularly firing, pacemaker DA neurons. To analyze the cellular mechanisms that lead to this irregular firing pattern, we performed perforated patch clamp recordings on acute brain slice preparations of adult mice. Here, we found that the small calcium-dependent (SK) potassium current was significantly decreased in non-pacemaking DA neurons. Additionally, the amplitude of the hyperpolarization activated (H) current is decreased compared to pacemaker DA neurons. However, single pharmacological blockage or reduction of either the SK potassium current or the H current in DA neurons with regular pacemaking did not lead to an irregular firing pattern. Currently, we are defining the exact role of the aforementioned currents in the generation of pacemaker patterns in DA neurons. Therefore we simultaneously

reduce the amplitude of the SK potassium current and the H current in DA neurons with regular pacemaking. The experimental data will be used to build computational models to verify whether the observed changes in intrinsic currents are sufficient to explain the different firing patterns recorded in DA neurons.

Title: Distinct roles of the soma and proximal dendrites in spontaneous firing activity of the midbrain dopamine neuron

Authors: ***J. JANG**, M. PARK
Sungkyunkwan Univ., Suwon, Korea, Republic of

Abstract: In spontaneously firing midbrain dopamine neurons, although action potentials are generated at the proximal dendrite from which an axon develops, we previously reported that pacemaker activity is determined by electrical balance between the soma and proximal dendrites. However, at the moment, it is not clear how the soma and proximal dendrites formulate pacemaker activities. A brief pulse of glutamate can generates two distinct excitatory and inhibitory responses on dopamine neuron firing; the initial high-frequency firing and the subsequent Ca2+-dependent pause. When we stimulated a series of small areas along a dendrite with caged-glutamate photolysis, excitatory and inhibitory firing responses were different distinctively according to the stimulation sites of a dendrite. The high-frequency firing was generated equally within the proximal dendritic region, but not in the distal dendritic regions. The postfiring pause was rapidly decayed with distance from the soma and no response from the distal dendritic regions. Local dendritic Ca2+-uncaging experiments revealed that Ca2+-induced suppression of spontaneous firing purely depended on the amplitude of the Ca2+ spikes or closeness to the soma. Firing induced Ca2+ dynamics was slow in the soma, whereas it was highly faster in the dendrite due to the different surface area/volume ratios. In addition, continuous suppression of local proximal dendritic regions with Ca2+ uncaging failed to

suppress spontaneous firing, permanently. All these data suggest the generator-counteract balancer model in which the proximal dendrites act as a leading zone for pacemaker potential generation and the soma plays as a counteract balancer.

Title: Caffeine effects on the intrinsic properties of lumbar ventral horn neurons

Authors: *M. S. RIVERA OLIVER[1], Y. ALVAREZ-BAGNAROL[2], M. DIAZ-RIOS[3,4]
[1]Univ. of Puerto Rico-Institute of Neurobio., San Juan, PR; [2]Biol., Univ. of Puerto Rico- Rio Piedras campus, San Juan, PR; [3]Anat. and Neurobio., Univ. of Puerto Rico-Medical Sci. campus, San Juan, PR; [4]Inst. of Neurobio., San Juan, PR

Abstract: Caffeine is the most consumed psychoactive drug in the world, with about 90% of the population (including children) in the United States regularly consuming caffeine-containing beverages or foods. It produces similar behavioral effects as other classical psychostimulants, such as cocaine and amphetamines, mainly motor activation, arousal, and reinforcing effects related to neural reward systems. Caffeine is known to be a non-selective adenosine receptor antagonist. Most of the studies assessing the effects of caffeine and/or adenosine receptor agonists and antagonists on locomotor behavior have been performed on freely behaving rodents using systemic administration of these drugs that can activate multiple neural pathways making extremely difficult to elucidate specific mechanisms of action. We propose to elucidate the cellular mechanisms by which caffeine modulates the intrinsic membrane properties of spinal neurons through bath perfusion onto spinal cord slices, which contain significant components of the spinal network for controlling locomotion. Preliminary data on extracellular recordings from spinal lumbar nerves in the presence of NMDA, dopamine (DA) and serotonin (5-HT) which is

known to elicit a fictive locomotor pattern, shows that caffeine modulates motor activity by enhancing the bursting properties of motorneurons producing the recorded motor output (Acevedo, et al. SfN abstract). We studied the effects of neuromodulation by caffeine and other adenosine receptor antagonists on the intrinsic properties of spinal neurons using pharmacological blockade and patch clamp recordings in current clamp mode. The application of caffeine in the presence of blockers for glutamatergic, glycinergic, GABAergic and cholinergic neurotransmission produce no significant effects on the membrane potential and action potential (AP) properties of most neurons recorded. The application of caffeine in the presence of locomotor inducing drugs (5-HT/NMDA/DA) had a dramatic excitatory effect by depolarizing the membrane potential, hyperpolarizing the threshold for AP elicitation and decreasing the AP afterhyperpolarization (AHP) of most neurons recorded. These results suggest that caffeine excites spinal neurons through the modulation of dopamine and possibly glutamate neurotransmission, as previously shown in the brain, in the spinal cord through its blockade of adenosine receptors.

Title: Energy constraints on neuronal activity

Authors: ***Z. GREGURIC FERENCEK**, M. L. GERTZ, Z. OBAIDA, J. R. CRESSMAN
George Mason Univ., Fairfax, VA

Abstract: Neuronal systems support a wide range of complex functions performed by networks of neuronal cells. Communication through these networks is mediated by the generation and transmission of action potentials, synaptic transduction, and dendritic summation. These processes dissipate energy stored in the electrochemical gradients of the cell, and reduction of these gradients can significantly alter neuronal signaling. These electrochemical gradients are continually reestablished through the conversion of ATP to ADP by the Sodium/Potassium pump. These dynamics are investigated using a conductance based model that incorporates ionic dynamics for the neuronal, glial, and vascular compartments. In addition, a simplified model of

aerobic and anaerobic glucose metabolism is used to determine ATP production. We report on the limits of sustained and transient neuronal computation as determined by the constraints of glucose metabolism, and ionic regulation.

Title: Stimulation-induced ionic effects on neuronal transmission

Authors: *M. L. GERTZ, Z. GREGURIC FERENCEK, J. R. CRESSMAN
George Mason Univ., Fairfax, VA

Abstract: Changes in ionic concentration gradients have profound effects on neuronal transmission and play an important role in neuronal activity. Under modest activity, ionic concentrations exist in a nearly steady state as the neuron re-establishes activity-induced fluctuations in its ionic gradients very rapidly. However, this system can be removed from its dynamic steady state by excessive activity, causing ionic concentrations to dissipate towards equilibrium leading to a number of effects that can dominate neuronal dynamics. Oxygen data show that the recovery from a short stimulating burst is on the order of minutes, and stimulating faster than this interval does not permit a recovery to baseline. These changes in oxygen can be linked to the sodium/potassium pump rate to help elucidate the ionic composition inside and outside the cells. Simultaneous potassium measurements show much faster recovery suggesting sodium accumulation is responsible for the prolonged metabolic stress reflected in the oxygen data. By taking simultaneous measurements of extracellular oxygen and potassium we have access to the flow of energy in and out of the tissue.

Title: Estimates of persistent inward current in human motor neurons during postural sway

Authors: R. C. A. FOLEY, *J. M. KALMAR
Dept. of Kinesiology, Wilfrid Laurier Univ., Waterloo, ON, Canada

Abstract: Persistent inward current (PIC) is a membrane property critical for increasing gain of motor neuron output. In humans, most estimates of PIC are made from plantarflexor or dorsiflexor motor units with the participant in a seated position with the knee flexed. This seated and static posture neglects the task-dependent nature of the monoaminergic drive that modulates PIC activation. It is well documented that there is an increase in descending serotonergic neuron activity during tasks requiring greater muscle activation or at increasing speeds of locomotion. Estimates of PIC made during isometric ramp contractions are technically less challenging; however these seated estimates may drastically underestimate the amount of PIC that occurs in human motor neurons during functional movement. The current study estimated PIC using the conventional paired motor unit technique which uses the difference between reference unit firing frequency at test unit recruitment and reference unit firing frequency at test unit de-recruitment (ΔF) during triangular-shaped, isometric increases in force as an estimate of PIC. Estimates of PIC and reciprocal inhibition were also collected during a standing anterior postural sway that elicited a ramped increase and decrease in soleus motor unit activation. For each paired motor unit, ΔF estimates of PIC made during conventional isometric ramps made during the seated posture were compared to those made during standing postural sway. Reciprocal inhibition was also measured in each posture using the post-stimulus time histogram (PSTH) technique. Inhibition was measured to ensure that any change in ΔF was due to neuromodulation and not the result of confounding factors associated with the change in joint angle during postural sway. It was hypothesized that an increase in ΔF would be seen during standing compared to sitting due to greater neuromodulatory input. We found that ΔF estimates during standing postural sway were an average of 1.06pps (SE±0.32pps) higher than PIC estimated in the isometric seated task for the same motor unit. Within participants, standing ΔF estimates averaged 214% (SE±25.9%) that of seated estimates. Instantaneous firing frequency at test unit onset was not significantly

different during postural sway (mean=9.41pps, SE±0.50pps) compared to seated isometric torque ramps (mean=10.41, SE±0.33pps). Standing ΔF measures met all validation criteria outlined for paired-motor unit estimates and are an effective functional estimate of PIC in humans. These results demonstrate that conventional seated PIC estimates should not be generalized to functional movement as a large component of PIC is task-dependent.

Title: The effect of focused ultrasonic stimulation on the activity of hippocampal neurons in multi-channel electrode

Authors: *J. B. CHOI, K. CHO, D. JANG
Dept. of Biomed. Engineering, Hanyang Univ., Hanyang Univ., Seoul, Korea, Republic of

Abstract: The neuromodulating methods for diagnostic and therapeutic tools in neurophysiology have been investigated in the last decade. Especially noninvasive methods, for example transcranial direct current stimulation and transcranial magnetic stimulation, have received attention for alternative tools to invasive ones with unavoidable risks. These noninvasive methods, however, showed a low spatial resolution and limited penetration depth. Recently some studies have shown that focused ultrasonic mechanical energy has modulatory effect on the nervous system. Mechanical waves generated from an ultrasonic transducer that can be focused in small spots provide high spatial resolution and depth of penetration than other noninvasive tools. Many experiments have investigated the neuromodulatory effects of ultrasonic stimulation, yet there are only a few researches investigating the effect of ultrasonic stimulation on associated neuronal cultures. The motivation for the present study was to investigate the modulatory effect of low intensity, low frequency ultrasonic stimulation on hippocampal neurons. In this study, the changes in neural network activities during ultrasonic stimulation were recorded using a multi-electrode array. Neuronal cells easily form monolayer on multi-electrode platform, providing neuronal network model *in vitro* that can be imaged, and stimulated. In this study, the ultrasonic stimulation changed the neuronal network activities, especially at specific parameters. In the

result, the relative change of neuronal activities shows great descent with pulse duration of 50 ms and pulse repetition frequency of 10 Hz. This change also had an effect on post exposure period. This result suggests that there is a possibility that mechanical stimulation can affect neuronal activities for a while. It is interesting that the timing of neuronal activity and stimulus seemed unsynchronized which suggests that the mechanical stimuli may not have a direct effect on neuronal activities but somehow help neuronal cells to be in a more excitable state, so the overall neuronal network activities were decreased. There is an assumption that ultrasonic stimulation promotes the secretion of substances from neuronal tissues, which effects the occurrence of neuronal network activities. Similar to previous study, sonication with specific parameters changed neuronal activities while other intensities had no modulatory effect on neuronal cultures. This observation might indicate that acoustic intensity is major key for stimulating neuronal activity. But further studies with various drugs such as channel blockers will be required.

Title: A computational model of collision detection in the optic tectum in Xenopus tadpoles

Authors: E. V. JANG[1], *A. S. KHAKHALIN[1,2], C. M. CIARLEGLIO[1], C. D. AIZENMAN[1]
[1]Neurosci., Brown Univ., Providence, RI; [2]Biol., Bard Col., Annandale-on-Hudson, NY

Abstract: Neural circuits in the optic tectum of Xenopus tadpoles are selectively responsive to visual stimuli that represent objects approaching the animal at a collision trajectory (looming stimuli). This stimulus selectivity is known to underlie an adaptive collision avoidance behavior in this species. While we recently showed that the balance of excitation and inhibition has a crucial role in enabling stimulus selectivity in the tectum, it is still unclear how the balance

between the recurrent network activity and the newly arriving sensory flow is achieved in this structure. More generally, it is still unknown how the looming stimuli are encoded and detected by the tectal circuits, and also, despite the clear indication for the presence of strong recurrent excitation in the tectum, the exact topology of these recurrent feedback circuits remains elusive. Recently we completed a comprehensive census of tectal cell electrophysiological properties, by measuring and analyzing 30+ synaptic and intrinsic excitability parameters in each of 200+ cells from 80+ experimental animals from different developmental stages and during homeostatic plasticity. When combined with over a decade's worth of electrophysiological analysis from our and other laboratories, we have an incredibly rich data set describing the development of tectal cell physiology during key developmental time periods. In this work we use this data set to build a high fidelity spiking network model of the tectum with the goal of generating predictions about the topology of recurrent connections within the tectum, as well as the dynamics of this system. After tuning and calibrating this model on experimental data, we compare different patterns of recurrent network connectivity, and different levels of balance between recurrent activity and sensory flow, to identify the range of parameters in which the network exhibits selectivity for looming stimuli. This allows us to make predictions about the topology of recurrent connections in the biological optic tectum that can then be tested experimentally. We also show how intrinsic excitability of individual tectal cells affects the selectivity of the network as a whole, and describe how homeostatic modulation of intrinsic properties can change selectivity thresholds in this model, thus affecting the behavior of the animal.

Title: Characterization of pattern recognition receptor expression in cerebellar granule cells and investigating their role in synapse development and maintenance

Authors: *N. W. DEKORVER[1], J. ARIKKATH[2], S. J. BONASERA[3]
[2]Developmental Neurosci. Department, Munroe-Meyer Inst., [3]Intrnl. Medicine, Geriatrics, [1]Univ. of Nebraska Med. Ctr., Omaha, NE

Abstract: Within the brain, aging can present with various phenotypes including loss of coordination, mobility, metabolic regulation, and as cognitive impairments. In order to find potential therapies to combat the effects of aging in the brain, it is crucial to investigate biological mechanisms underlying behavioral changes in regions of the brain corresponding to these deficits. We have demonstrated that the C57BL6 mouse strain present with a clear mobility phenotype and pronounced changes in excitatory synaptic organization within the cerebellar internal granule cell layer (iGCL) associated with aging. Our previous studies have also shown an increase in pattern recognition receptors (PRRs) and immune component expression that is not localizable to microglia in the aging brain. The roles of many PRRs have been well described within the immune system; however their role in nervous system, particularly in synapse formation and maintenance has yet to be fully described. To further investigate the role of PRRs and immune component proteins in synaptic formation, maintenance, and function, we have developed a purified cerebellar neuron culture from post natal day 3, 5, 7, and 9 C57Bl6 mice consisting of less than 2.0% astrocytes and 1.0% microglia, roughly 80% $NeuN^+$ cells and a 10-20% level of apoptosis measured by activated Caspase-3 staining at D6 *in vivo*. Primary granule cell cultures also stained positive for Tau and Map2, as well as for synaptic markers Vglut1 and PSD95 further confirming the neuronal phenotype. Neuronal activity was verified by calcium imaging of spontaneous action potentials and potassium chloride induced depolarization. Characterization of PRR transcript expression from purified cerebellar granule cell cultures at day 0, 3, 6 and 9 shows temporal increases in transcript expression of TLR2, TLR4, Trem2, Clec7a, Lilrb3, Fcer1g, and complement protein C3 closely following the *in vitro* time course of synaptic network development. These results further justify the validity of using primary cerebellar granule cell cultures to study granule cell physiology, including molecular mechanisms and cell signaling pathways underlying synapse development, maintenance, and cerebellar granule cell excitability.

Title: Elucidating the functions of gad1 in cranial development and neurotransmission within larval zebrafish

Authors: *L. JOHNSTON[1], A. VANLEUVEN[1], R. BALL[1], M. O'CONNOR[2], T. DORE[2], J. LAUDERDALE[1]

Abstract: γ-Aminobutyric Acid (GABA) is the primary inhibitory neurotransmitter in the central nervous system of all vertebrates. GABA is synthesized from glutamate by the enzymatic activity of glutamic acid decarboxylase (GAD). There are two GAD isoforms which are encoded by the gad1 and gad2 genes, and they produce a 67kD form called GAD67 and a 65kD form called GAD65, respectively. Our work is focused on characterizing the function of the gad1 gene in larval zebrafish. Previous work in mice has shown that gad2 mutants are phenotypically indistinguishable from their wild type littermates, yet they exhibit stress-induced seizures. Gad1 mutants, on the other hand, are not viable past birth due to a severe cleft palate. This defect has prevented further study of gad1's role in early development. Based upon this, the GAD-1 enzyme seems to be involved in both early cranial development and later in neurotransmission. In our study, translation blocking morpholinos against the gad1 and gad2 genes were used to alter GAD expression within the larval zebrafish. While the GAD-2 morphants look phenotypically normal at 24hpf, GAD-1 morphants exhibited altered cranial structures. These craniofacial deformities arise from abnormally developed cranial chondrocytes, leading to smaller and misshapen cranial cartilages. This phenotype can be rescued by injecting GAD-1 mRNA, which supports that this phenotype is specific to gad1 knockdown. Also, through the use of caged-morpholinos, these craniofacial deformities could be bypassed when uncaging was carried out at 1dpf. This has allowed us to focus on the neurological aspects of GAD-1 reduction. Electrophysiological recordings have shown increased and abnormal brain activity for the GAD-1 morphants, when compared to wild type animals. Together, these findings support the idea that the GAD-1 enzyme exhibits a novel function in craniofacial development, independent of its activity in GABA synthesis.

Title: Spines with multiple excitatory contacts are sites for axonal competition during synaptic development

Authors: *W. C. RISHER[1], S. PATEL[2], J. SINGH ALVARADO[3], O. Y. CALHAN[3], C. EROGLU[1]
[1]Cell Biol. / Neurobio., [3]Cell Biol., [2]Duke Univ., Durham, NC

Abstract: A dendritic spine is thought to receive a single excitatory synaptic input. This "one spine: one synapse" notion is a key assumption underlying many studies of brain connectivity. Using serial section electron microscopy (ssEM) in the mouse primary visual cortex (V1), we discovered that up to 25% of all excitatory synapses in this region are made onto spines with multiple excitatory contacts (SMECs) during early postnatal development (P14). This fraction decreases with age, revealing SMECs as an important transitory structure in synaptic maturation. Surprisingly, in the cortices of mice that lack the astrocyte-secreted synaptogenic protein hevin, SMECs persist into later ages (P25). Further immunohistochemical analyses revealed that, in the cortices of hevin KO mice, thalamocortical synapses are significantly reduced compared to WT. By contrast, intracortical synapses trended towards an increase. These findings show that astrocyte-secreted hevin is required for the establishment and maintenance of thalamocortical synapses in the developing cortex. In the absence of hevin, thalamocortical synaptic contacts are not stabilized, resulting in "takeover" of spines by the more numerous intracortical axons. Therefore, lack of hevin results in prolonged competition between axons for spines, thus the SMECs persist. Taken together, these findings reveal that spines can form excitatory synaptic connections with multiple presynaptic partners, challenging the "one spine: one synapse" assumption of connectivity. In addition, SMECs provide sites for competition between different axonal inputs during development, and astrocytes control this process via the release of hevin. Future studies may determine whether impaired resolution of axonal competition may underlie the structural deficiencies observed in many types of neurodevelopmental disorders.

Title: Profiling hippocampal neurons after early preconditioning with certain excitatory amino acids reveals distinct signaling pathways that promote neuronal survival

Authors: *L. K. FRIEDMAN, A. M. SLOMKO, S. HU, W. WAN
Cell Biol. & Anat., New York Med. Col., Valhalla, NY

Abstract: Immature neurons not only resist neurotoxicity produced by experimental epileptic seizures or early *in vitro* application of certain excitatory amino acids (EAAs), but also generate substantial neuroprotective/ preconditioning effects to subsequent seizures or certain EAAs. Our prior *in vivo* microarrays suggest that increases in anti-apoptotic genes, reduction in inflammation, and increased signal transduction pathways are induced by early excitatory events to promote cell survival. In order to gain better understanding of which genes and pathways are responsible for specific adaptive effects, we used our protocol to expose immature hippocampal neurons to high doses of glutamate (250μM), NMDA, (100μM), or kainate (KA) (300μM) for 48 hrs (5-7 DIV) followed by washout. Transcriptome profiling was performed 7 days later, just prior to a "second hit", a time when cultured neurons mature (14 DIV). Despite the delay, many genes were up- and down- regulated. Glutamate treatment resulted in the highest number of total upregulated (892) and uniquely upregulated genes (521). KA treatment had extensive gene overlap with glutamate and presented the lowest number of uniquely upregulated genes (17). NMDA treatment revealed large numbers of uniquely upregulated genes (328), and downregulated genes (234) compared to glutamate (10) or KA (18). Many commonly upregulated (211) and downregulated (228) genes were also observed. Similar to early life conditioning seizures, Ca2+-binding proteins, heat shock, oxidative stress, and certain anti-apoptotic Bcl-2 gene members significantly increased after glutamate or NMDA but not after KA. Presynaptic Ca2+ sensors, signal transduction, G-coupled proteins, certain growth factors, synaptic vesicle docking and neurotransmitter regulation predominated after NMDA exposure, whereas regulation of voltage gated Ca2+ and K+ channels, anti-apoptotic interleukins, presynaptic mGluR3 and mGluR7, KA and nicotinic cholinergic receptors, and phospholipase and phosphodiesterases predominated after glutamate treatment. Certain voltage gated Ca2+ channels were exclusively downregulated after NMDA treatment. Protective gene candidates expressed only after glutamate included neuropeptide Y, neurotensin R1, and neurotrophic

tyrosine kinase R2. KA was the only EAA that resulted in sustained opioid receptor (μ and δ) upregulation consistent with *in vivo* reports. However, except for overexpression of a Bcl-2 like gene, protective gene candidates were not observed after KA suggesting that sustained adaptation in early life is predominantly mediated via NMDA and other fast and slow glutamatergic related signaling pathways.

Title: Mechanism for astrocyte-mediated persistent activity

Authors: *M. DE PITTÀ[1,2], E. BEN-JACOB[3,4], H. BERRY[2]
[1]Dept. of Neurobiology, Univ. of Chicago, Chicago, IL; [2]INRIA Rhone-Alpes, INRIA, Villeurbanne cedex, France; [3]Sch. of Physics and Astronomy, Tel Aviv Univ., Ramat Aviv, Israel; [4]Ctr. for Theoretical Biol. Physics, Rice Univ., Houston, TX

Abstract: Persistent activity is marked by the increase of neuronal firing rates compared to baseline, in response to specific stimulatory cues. In primates performing delayed-response tasks, persistent activity emerges during the delay period and is regarded as the neural correlate of working memory - that is, the ability to transiently hold and manipulate goal-related information to forthcoming actions. Several different mechanisms have been suggested for persistent activity, yet it remains unknown whether it stems from inherent properties of neurons or the plasticity of their synaptic connections or both. Astrocytes, the main type of glial cells in the cortex, have recently emerged as potential active players in synaptic plasticity due to their proposed ability to regulate synaptic neurotransmitter release in response to neuronal activity. Because available models of persistent activity do not take into account astrocytes, we used a biophysical model to investigate the possible role of astrocyte regulation of synaptic plasticity in the emergence of persistent neuronal firing. Our study suggests that selective persistent activity could indeed

emerge from astrocyte-mediated short-term synaptic facilitation triggered by the brief presentation of a stimulatory cue. The remarkable time scale separation between synaptic dynamics and its modulation by astrocyte-released gliotransmitters indeed makes possible the coexistence of multiple states of synaptic release. In this fashion, astrocyte-mediated facilitation can outlast the cue and switch to a self-sustained mode where it is maintained by the ongoing synaptic activity. This form of astrocyte-mediated presynaptic long-term potentiation could be responsible for the emergence of persistent increased neuronal firing, thus providing the tripartite synapse with a persistent trace of the past presentation of the cue. Taken together, these results suggest a novel astrocyte-based mechanism for persistent activity, providing experimentally testable hypotheses for the possible involvement of astrocytes in cognitive tasks related to working memory.

Title: Schwann cell-mediated remodeling of the mouse neuromuscular synapse

Authors: ***Y. LEE**[1], I. W. SMITH[1], M. MIKESH[2], K.-A. NAVE[3], M. SCHWAB[3], W. J. THOMPSON[1]
[1]Dept. of Biol., Texas A&M Univ., College Station, TX; [2]The Univ. of Texas, Austin, TX; [3]Max-Planck-Institute of Exptl. Med., Goettingen, Germany

Abstract: The mouse neuromuscular junction (NMJ), the cholinergic synapse between a motor neuron and a skeletal muscle fiber, has contiguous “gutters” of high-density acetylcholine receptor (AChR) aggregates precisely apposed by terminal arbors of motor axons. This structure is normally highly stable. In contrast, mice whose motor axons overexpress a membrane-tethered form of neuregulin1 (NRG1-III) the AChR are found in non-contiguous “islands” innervated by nerve terminal varicosities. Such morphological change, commonly referred to as “fragmentation,” is observed frequently in muscles of aged or dystrophic muscles, likely from damage and regeneration of synaptic segment of muscle fibers. We found no evidence, however,

of increased necrosis/regeneration of muscle fibers in NRG1-III transgenic animals as these muscles had no change in centrally nucleated myofibers. While a diminished ability to induce and/or maintain NMJs could also result in fragmentation, agrin is concentrated at NRG1-III transgenic NMJs and its downstream signaling in muscle appear to be unaffected as indicated by AChR β subunit phosphorylation - a phenomenon closely associated with agrin-induced AChR aggregation. In addition, there was no evidence of denervation in muscles of transgenic mice. Although the components of the synaptic basal lamina - laminin β2 and acetylcholinesterase - are altered in their distribution to mirror the postsynaptic changes, evidence suggests their modification is subsequent to changes in postsynaptic AChR. Thus, none of the well known pre- or postsynaptic mechanisms causing fragmentation of NMJs appears responsible for the altered synaptic morphology of NRG1-III transgenic NMJs. However, the glial components of NMJs, terminal Schwann cells (tSCs), appear activated by the excess axonal NRG1: they increase in number at the synapse and extend fine processes. Ultrastructural examination of the transgenic NMJs revealed evidence of tSC activity normally seen only at neonatal NMJs and implicated in maturation and remodeling of developing NMJs: encroachment by tSC processes into synaptic cleft, despite the presence of a SC repulsive factor laminin β2 and increased phagocytic activity directed against presynaptic nerve terminals. These finding strongly suggest that the fragmentation of NMJs in NRG1-III mice is actively mediated by behaviors of SCs that normally aid in maturation of the peripheral synapse and are regulated by levels of axo-glial NRG1 signaling.

Title: Sonic hedgehog signaling in astrocytes regulates synaptic connectivity

Authors: *A. GARCIA[1,2], A. AHARON[2], Y. ZUO[2]
[1]Dept. of Biol., Drexel Univ., Philadelphia, PA; [2]Molecular, Cellular, Developmental Biol., Univ. of California, Santa Cruz, Santa Cruz, CA

Abstract: The secreted molecule, Sonic hedgehog (Shh), plays critical and well characterized roles during nervous system development, including patterning of the dorsal/ventral axis and regulation of cell proliferation and specification. In the postnatal cortex, Shh signaling between Layer 5 and Layer 2/3 neurons is required for the proper establishment of cortical microcircuits. Our previous study identified distinct populations of astrocytes in the adult forebrain that express the transcription factor, Gli1, indicating that Shh signaling persists well past development, and into adulthood. We identified neurons as the source of Shh, but the precise role of Shh signaling between neurons and astrocytes in the forebrain is unknown. In this study, we examine the hypothesis that Shh signaling in astrocytes is required for the proper establishment and long term maintenance of cortical synapses *in vivo*. We crossed GFAP-Cre;Smofl/fl with transgenic mice expressing green fluorescent protein (GFP) under control of the Thy1 promoter (Thy-GFPM). GFAP-Cre;Smofl/fl;Thy1-GFPM mice express GFP in a subset of Layer 5 cortical neurons in a Smo conditional knock out background (Smo CKO). We performed morphometric analysis of dendrites and spines in the somatosensory cortex. Smo CKO mice exhibit an increase in spine density in the apical dendrites of Layer 5 cortical neurons, and a concomitant increase in expression of the astrocytic glutamate transporter, GLT1. Interestingly, spine density in young animals (2- 4 weeks old) shows no difference between mutants and controls, suggesting that Shh signaling between neurons and astrocytes is required for developmental pruning of synapses. These results suggest that neuron-astrocyte communication through Shh signaling plays an important role in circuit formation. Ongoing studies are examining the dynamic turnover of dendritic spines by chronic, *in vivo* imaging.

Title: Study of the effect of the peptide Aβ25-35 in the neurogenesis and long-term memory

Authors: *E. RAMIREZ[1], A. SANCHEZ[2], A. PATRICIO[2], D. LIMON[2]
[1]Neurofarmacologia, Benemérita Univ. Autónoma De Puebla, Puebla, Mexico; [2]Benemerita Univ. Autonoma de Puebla, Puebla, Mexico

Abstract: The amiloid-β plays an important role in the neurodegeneration process of Alzheimer´s disease (AD), but its neurotoxic mechanisms is not entirely clear [5]. The Aβ (25-35) fraction mimics the toxic effects of the complete peptide Aβ (1-42) because this decapeptide is able to cause memory impairment and neurodegenerative events [1,4]. The Aβ (25-35) increase oxidative stress, cause neuronal damage and inflammation [6]. Recent evidences have shown that the injection of Aβ (25-35) into the temporal cortex (TCx) of rats increases the inflammatory response [3]; however, it is unclear how the inflammatory process could be involved in the progression of Aβ (25-35) toxicity and abnormal neurogenesis. This has led to a hypothesis which that impairment in memory in AD by inflammation can involve in generating an inappropriate environment for the new neurons to mature [2]. The objective of this study was determined if the administration of aggregated Aβ25-35 into the CA1 region of the rat hippocampus impairs the long-term memory and decrease the neurogenesis in the dentate gyrus (DG). The results showed that in the group Aβ 25-35 decreased the learning and memory in Morris water maze and decrease in the number of dendritic spines. Similarly a change was observed in the neurogenesis indicating that the effect of peptide Aβ 25-35 is chronic progressive. [1] Butterfield et al., TRENDS in molecular medicine. 2001; 7 (12): 548-554. Title: Dnmt1 is required for progenitor maintenance during spinal cord development of zebrafish

Authors: ***S. PANAHI**, R. I. DORSKY
Neurobio. and Anat., Univ. of Utah, Salt Lake City, UT

Abstract: Neural progenitor cells must be maintained during development to produce the full complement of neuronal and glial derivatives, and DNA methylation is an important epigenetic mechanism for regulating cell lineage differentiation. Previous studies have shown that genetic deletion of DNA methyltransferase I (Dnmt1) in neuronal progenitor cells results in DNA hypomethylation and premature glial differentiation, but the specific role of this gene in progenitor maintenance is poorly understood. Here we analyzed progenitor maintenance in the spinal cord of zebrafish dnmt1 mutants. We found that spinal cord progenitor markers are progressively lost in embryos lacking Dnmt1 and that the number of proliferative progenitors decreases accordingly. Our preliminary data suggest that Dnmt1 likely regulates methylation of specific developmental genes during spinal cord development. These results allow us to hypothesize that the targets of CpG methylation may be pluripotency genes, and in the absence of methylation progenitor cells may fail to differentiate as neurons. Therefore, loss of Dnmt1 should decrease neurogenesis by up-regulating pluripotency genes and misexpression of Dnmt1 should result in premature differentiation.

Title: Mechanisms underlying endogenous adult neural stem cell behavior during aging

Authors: *M. A. BONAGUIDI[1], R. STADEL[2], D. BERG[1], J. PARK[2], E. PU[2], M. OGAWA[2], S. PARK[2], M. BARADARAN-SHORAKA[2], G.-L. MING[1], H. SONG[1]
[1]Inst. for Cell Engineering-Neurology, [2]Inst. for Cell Engin., Johns Hopkins, Baltimore, MD

Abstract: Aging, simply the act of living longer, is a major risk factor for cognitive decline and the development of neurodegenerative disorders. Neurogenesis - the ongoing production of new cells - declines with age at a time that coincides with increasing incidence of brain vulnerability to injury and disease. Yet, the origins of this decline in structural plasticity remain unknown.

Here, we performed clonal lineage-tracing of radial glia-like neural stem cells (RGLs) marked by Nestin-CreERT2, Gli1-CreERT2 and Ascl1-CreERT2. Time course analysis with computational studies suggest that Gli1# marks the stochastic, multipotent nestin#-RGLs population at the pre-activation state, whereas Ascl1#-RGLs represent a discrete and more proliferative, primed neurogenic population. In young animals, depletion of individual stem cells within dual stem cell populations is compensated by expansion of others in a homeostatic process yielding population asymmetry. With age, overall stem cell number declines as the rate of expansion diminishes due to an increase in the quiescence of both multipotential and more active neurogenic RGLs. As the aged brain retains the capacity to dynamically regulate neurogenesis in response to macroenvironmental changes, remaining endogenous neural stem cells may preserve their capacity to repopulate brain regions - even in older individuals. Understanding the effect of age on neurogenesis and determining the extent of plasticity remaining within the aging neurogenic niche will be of considerable importance for defining age-related cognitive deficits and provide potential therapeutic candidates.

Title: Parasympathetic neurons originate from nerve-associated peripheral glial precursors cells

Authors: A. FURLAN[1], V. DYACHUK[1], M. KHATIBI SHAHIDI[1], M. GIOVINCO[1], N. KAUKUA[1], C. KONSTANTINIDOU[2], V. PACHNIS[2], F. MEMIC[1], U. MARKLUND[1], T. MÜLLER[3], C. BIRCHMEIER[3], K. FRIED[1], *P. ERNFORS[1], I. ADAMEYKO[1]
[1]Karolinska Institutet, Stockholm, Sweden; [2]MRC Natl. Inst. for Med. Res., London, United Kingdom; [3]The Max Delbrück Ctr. for Mol. Med., Berlin, Germany

Abstract: The peripheral autonomic nervous system reaches far throughout the body and includes neurons with diverse functions, such as sympathetic and parasympathetic. We show that the parasympathetic system in mice, including trunk ganglia and the cranial ciliary, pterygopalatine, lingual, submandibular and otic ganglia, do not arise from neural crest cells, as previously believed. Instead, the parasympathetic fate is induced in nerve-associated glial precursor cells at distal peripheral sites. These bi-potent progenitors generate both glia and neurons, and give rise to most of the neurons in these ganglia. The novel nerve origin places cellular elements for generating parasympathetic neurons in diverse tissues and organs which may enable wiring of the developing parasympathetic nervous system.

Title: Measuring synaptic and perisynaptic activity at the developing, neonatal and adult mouse neuromuscular junction using electrophysiological and optical methods

Authors: *D. HEREDIA, G. HENNIG, A. SCURRY, T. GOULD
Univ. of Nevada Reno, Sch. of Med., Reno, NV

Abstract: During embryogenesis, neuromuscular synapses form between presynaptic motor axons and postsynaptic skeletal muscle cells. Perisynaptic or terminal Schwann cells are a

subtype of Schwann cell found at this neuromuscular junction (NMJ). Embryonic NMJs form normally at embryonic day 14.25 (E14.25) but degenerate shortly thereafter in mutant mice lacking Schwann cells. Since genetic forms of activity blockade rescue this degeneration, we reasoned that embryonic Schwann cells regulate synaptic transmission, similar to the role of perisynaptic Schwann cells at the adult NMJ. However, analyzing synaptic activity in embryonic preparations has been difficult because the targets of drugs which block contractility and therefore allow recording are not expressed at these ages. In this study we measured neuromuscular activity using intracellular voltage recording of postsynaptic muscle cells in the E14.25 mouse diaphragm using a drug that selectively blocks skeletal muscle contractility. Similar to adult NMJs, embryonic NMJs exhibit pronounced synaptic depression in response to high-frequency stimulation of the phrenic nerve, although the duration and frequency of stimulation required to induce this form of synaptic plasticity were markedly different. At the embryonic NMJ, stimulation at 10Hz initiates a (50%) decrease of action potential (AP) amplitude within 10 seconds. Higher rates of stimulation, 20 and 40Hz, result in a reduction of AP amplitude (90%) within seconds. In contrast, newborn animals failed to exhibit depressed responses to 10Hz stimulation for 1 minute, but displayed progressively greater decreases in AP amplitude in response to 20 and 40Hz stimulation. Adult animals displayed no rundown in response to 1 minute of 10 and 20Hz stimulation, whereas 40Hz exhibited an AP reduction of ~10% after 1 minute. Measuring these changes both electrically and with fluorescence in mice expressing GCaMP3 in skeletal muscle, we obtained a correlation coefficient of 0.80. We also observed robust increases in intracellular calcium in GCaMP3-expressing Schwann cells in response to high-frequency stimulation at E14.25. Our observations suggest that similar to the adult, Schwann cells at the developing NMJ respond to synaptic activity, and thus may regulate synaptic maintenance by modulating neural activity.

Title: Neuroprotective mechanisms of the Parkinson’s disease-related protein DJ-1

Authors: *V. MISHRA, S. L. ROY, F. LIU, J.-C. ROCHET
Purdue Univ., West Lafayette, IN

Abstract: Parkinson's disease (PD) is a neurodegenerative disorder characterized by a loss of dopaminergic neurons in the *substantia nigra* region of the brain. Dysfunction of the neuroprotective protein DJ-1 is thought to play a role in familial and sporadic cases of PD. Previously we showed that human wild-type DJ-1 protects against different PD stresses (rotenone, proteasome inhibitor, aSyn) by inducing different pro-survival mechanisms, potentially because differences in the subcellular localization of DJ-1 could result in the activation of different neuroprotective responses. Here, we describe the results of studies aimed at testing neuroprotective effects of DJ-1 against another PD-related insult, methamphetamine (METH), which acts via a different mechanism. METH is a widely abused drug that triggers preferential toxicity to dopaminergic neurons by increasing cytosolic dopamine (DA) levels via inhibition of vesicular monoamine transporter-2 (VMAT-2) causing a buildup of cytosolic DA leads to the formation of DA quinone adducts that trigger oxidative stress. We found that METH exposure caused dopaminergic neurite retraction in primary midbrain cultures, and this METH-dependent neurite loss was less pronounced in cultures transduced with adenovirus encoding human WT DJ-1. In addition, we showed that DJ-1 levels are increased in SH-SY5Y and PC12 neuronal cell lines exposed to METH, suggesting that DJ-1 up-regulation is a cellular defense mechanism against METH neurotoxicity. To test the effect of subcellular localization of DJ-1 on neurite retraction, we overexpressed WT DJ-1and DJ-1 variants localized to mitochondria (MLS-DJ-1) or nucleus (NLS-DJ-1) in METH-treated cultures. We found that NLS-DJ-1 had a greater protective effect against METH-induced neurite retraction compared to MLS-DJ-1, suggesting a critical role for nuclear DJ-1 in neurite length regulation. Preliminary results also show a reduction in VMAT-2 mRNA levels in primary midbrain cultures depleted of DJ-1 via shRNA, suggesting that DJ-1 could protect against METH neurotoxicity by modulating VMAT-2 levels. Current efforts are focused on understanding (i) the interplay of DJ-1, VMAT-2 and Nurr-1, a transcription factor that controls the expression of the VMAT-2 gene, in METH treated primary cultures; and (ii) the role of DJ-1 expression in glia and/or neurons in protection against neurotoxicity elicited by METH and other PD-related insults. The results of these studies provide insight into mechanisms by which DJ-1 may alleviate neurodegeneration in the brains of PD patients, and they could stimulate the development of new strategies to treat PD or the neurotoxic effects of METH abuse.

Title: rAAV-mediated knockdown of GD3 synthase protects against MPTP-induced neurodegeneration and executive dysfunction

Authors: P. MAITI[1], T. S. REX[2], *M. P. MCDONALD[3]
[1]Neurol. and Anat. & Neurobio., Univ. of Tennessee Hlth. Sci. Ctr., Memphis, TN; [2]Ophthalmology & Visual Sci., Vanderbilt Univ., Nashville, TN; [3]Neurology, Anat. & Neurobio., Univ. of Tennessee, Memphis, TN

Abstract: Parkinson's disease is characterized by gradual degeneration of dopaminergic neurons in substantia nigra. More than half of the patients exhibit fronto-striatally-mediated executive dysfunctions such as deficits in attention, planning, judgment, and impulse control. We previously demonstrated that deletion of GD3 synthase (GD3S) is neuroprotective and improves cognitive function in a mouse model of Alzheimer's disease, and that GD3S knock-down protects against MPTP-induced neurodegeneration and motor deficits. The objective of the present study is to determine whether knockdown of GD3S can protect dopaminergic cells and prevent motor and cognitive dysfunction in mice lesioned with subchronic 1-methy-4-phenyl-1, 2,3,6-tetrahydropyridine (MPTP; 25 mg/kg x 5 days). Male C57BL/6N wild-type mice were trained on a 3-hole serial reaction-time (SRT) task, which included measures of sustained attention and impulsive behavior, and a battery of sensorimotor tasks. On baseline, each SRT trial included a variable pre-cue period ranging from 3-8 s, and a cue duration of 1 s. Correct responses to the cue resulted in delivery of a 14-mg sweet pellet to the food-restricted subjects. Sustained attention was measured by response accuracy and reaction time. Impulsive behavior was measured by premature responding in the response holes or the food well during the pre-cue period. After reaching stable performance mice were given bilateral striatal injections of a recombinant adeno-associated viral (rAAV) vector expressing a short-hairpin RNA (shRNA) construct targeting GD3S, or a scrambled-construct control. After 3 weeks, mice were received five daily injections of MPTP, followed by a 5-day quarantine period, and were re-trained on the SRT and sensorimotor tasks. GD3S knock-down protected dopaminergic neurons from MPTP-induced neurotoxicity, and prevented the executive and motor dysfunctions. Our data suggest that strategic modification of complex brain gangliosides warrants further investigation as a novel therapeutic strategy for Parkinson's disease.

Abstract: [91,4,5991,4,51,4,571,4,51,4,6781,2,3,4,51,2,4,51,4,9 123456_789]We previously observed that parkin regulates **PAR**kin **I**nteracting **S**ubstrate (PARIS,ZNF746) via ubiquitination and accumulated PARIS plays a role as transcriptional repressor on peroxisome proliferator-activated receptor-γ coactivator-1α (PGC-1α) in Parkinson's disease (PD). The significant reduction of PGC-1α associated with dopaminergic neuronal death and the restoration of PGC-1α is considered as a therapeutic target. Here, we identified CSU-1806 as a transcriptional inducer of PGC-1α by high-throughput screening. CUS-1806 restores the reduction of PGC-1α in the models of overexpression of PARIS or parkin deficit. Consistent with increase of PGC-1α by CSU-1806, it also significantly increases the level of nuclear respiratory factor (NRF-1) that is a pathogenic

target gene of PGC-1α on PD. Furthermore, increased protein level of PGC-1α in mouse olfactory bulb, hippocampus, and substantia nigra was observed in CSU-1806-fed mouse. CSU-1806 shows the protective efficacy against MPTP-mediated dopaminergic neuronal death in mice. Taken together, PARIS- PGC-1α pathway is a potential therapeutic target pathway and CSU-1806 may be beneficial to modulate patho-pathway in PD.

Title: Small proline-rich repeat 1a protein protects nigrostriatal axons from degeneration in the 6-hydroxydopamine lesion rat model of Parkinson’s disease

Authors: ***N. M. KANAAN**, T. GRABINSKI, B. COMBS, A. KNYENSBERG, A. COLE-STRAUSS, Z. MATTINGLY, F. P. MANFREDSSON, T. J. COLLIER, J. W. LIPTON

Abstract: Multiple lines of evidence suggest Parkinson’s disease (PD) is a dying-back axonopathy and axonal degeneration is quickly becoming recognized as a critical early event in PD pathogenesis. A recent study demonstrated that patients lose their striatal dopamine (DA) projections early in the disease, well before significant somatic loss occurs. This observation explains why DA somatic preservation strategies have not been successful in clinical trials: They do not prevent the dying-back of axonal DA projections in PD. To address the problem of early axonal degeneration in PD, we examined the progressive gene expression changes in the rat ventral midbrain from an intrastriatal 6-hydroxydopamine (OHDA) lesion over 16 weeks. We hypothesized that patterns of gene expression within the substantia nigra (SN) characterized by

early, highly upregulated expression would be indicative of potential protective responses to a striatal 6-OHDA insult. The largest group of genes fitting this expression pattern was the regeneration-associated gene (RAG) family. The most highly upregulated RAG was small proline-rich repeat 1a (Sprr1a), which has been shown to facilitate post-injury axonal regeneration in peripheral nerves likely through stabilizing the cytoskeleton at the growth cone. We then confirmed that Sprr1a is specifically upregulated (using RNAscope *in situ* hybridization) in degenerating SN DA (tyrosine hydroxylase, TH; immunohistochemistry) neurons. We then overexpressed Sprr1a or green fluorescent protein (GFP) with rAAV constructs in the SN followed 1 month later with a striatal 6-OHDA lesion. Animals receiving rAAV-Sprr1a exhibited significant protection of nigrostriatal axons in the striatum as compared to rAAV-GFP as measured by TH densitometry. The protective effect of Sprr1a was further confirmed by both stereological measurements of TH fiber density and volumetric assessments of striatal zones exhibiting severe, intermediate, or no lesion. Animals treated with rAAV-Sprr1a had significantly higher TH+ axon density in the striatum and significantly smaller zones of severe denervation as compared to GFP controls. These data show that Sprr1a is part of the DA neuron's natural armamentarium to resist axonal degeneration and that it can be manipulated to mitigate the loss of striatal DAergic fibers in a rat 6-OHDA model.

Austria; [3]Dept. of Drug Sci., Univ. of Torino, Torino, Italy; [4]CNS Res., Boehringer Ingelheim Pharma GmbH & Co KG, Biberach, Germany

Abstract: Parkinson's disease (PD) is one of the most common neurodegenerative disorders worldwide and until now no cure or treatment to stop its progression are known. The characteristic cell death of dopamine producing neurons in the substantia nigra pars compacta is thought to be caused by increased mitochondrial oxidative stress due to the activity of L-type Ca^{2+} channels (LTCCs) during autonomous pacemaking. Known LTCC blockers inhibit both main brain LTCC isoforms, Cav1.2 and Cav1.3, with similar potency. Therefore therapy-limiting cardiovascular side effects arise from Cav1.2 channel block in the cardiovascular system. Cav1.3-selective blockers without these effects appear as attractive neuroprotective agents in PD. Here we studied the pharmacological properties of a pyrimidine 2,4,6-trione derivative (Cp8; Kang *et al.*, Nat.Comm. 2012) recently reported as the first highly selective Cav1.3 blocker. Pharmacological modulation of I_{Ba} (10 or 15mM) or I_{Ca} (15mM) through Cav1.3 (rat or human long splice variant, $rCav1.3_L$, $hCav1.3_L$) and Cav1.2 (rabbit long or short C-terminus, $rbCav1.2_L$, rbCav1.2s) expressed together with β3 and α2δ1 subunits in tsA-201 cells or using mouse chromaffin cells (MCCs; 2mM Ca^{2+}) was measured using the patch-clamp technique. With Ca^{2+} as charge carrier and using different protocols and channel constructs, Cp8 reproducibly caused a change in current kinetics characterized by a slowing of activation and inactivation accompanied by a prolongation of tail currents. This modulation closely resembled the actions of the LTCC activator FPL64176 and was also observed in MCCs in which non-L-type currents were unaffected. Moreover, Cp8 significantly increased the spontaneous firing frequency of MCCs, accompanied by a reduced after-hyperpolarization of action potentials. Evidence for a weak and non-selective inhibition of Cav1.3 as well as Cav1.2 currents was only observed in a minority of cells using Ba^{2+} as charge carrier. In conclusion, neither potent nor Cav1.3-selective inhibition by Cp8 could be observed under our experimental conditions. Instead, Cp8-induced changes in channel kinetics resemble the activity of known LTCC activators such as FPL64176. Therefore, our data suggest that pyrimidine 2,4,6-triones can also act as Ca^{2+} channel activators.

Title: Optogenetic rescue of Parkinson's disease symptoms

Authors: *D. LEE, S. J. VARGA, C. QI
Ohio Univ., Athens, OH

Abstract: A key pathological feature of Parkinson's disease (PD) is the progressive loss of dopaminergic (DA) neurons in the substantia nigra which regulates motor function. Familial forms of PD are known to be directly associated with mutations of certain genes (e.g., α-Syn). In addition, neurotoxin-based models (e.g., rotenone) have been used to study DA neurodegeneration induced by non-genetic, environmental factors. All of these indicate that a combination of genetic and environmental factors contributes to the pathogenesis of PD. Currently, no cure exists. Although several treatments (e.g., L-dopa) are used to alleviate symptoms, none can slow or reverse the progression of the disease. This warrants the development of a new therapeutic method that can rescue both motor symptoms and molecular and cellular damage. An increasingly popular technique, optogenetics can be used in PD models to uncover the effects of stimulation on the DA neuronal circuits damaged by PD causing factors. The fruit fly *Drosophila* has long been used as a model organism for human diseases, primarily due to the genetic similarity with mammals and the sophisticate genetic tools available to study disease mechanisms as well as potential therapies. In this study, we developed a new model of PD using *Drosophila* larvae to study optogenetic rescue of PD symptoms. α-Syn and rotenone were chosen as a genetic factor and an environmental factor, respectively. *Drosophila* larvae (3^{rd} instar) expressing mutant human α-Syn showed age-dependent decline in locomotion and also a significant loss of DA neurons in the brain. Similarly, larvae chronically exposed to rotenone (10μM) showed significant reduction in locomotion accompanied by loss of DA neurons in the brain. Using these two PD models, we showed that application of blue light (470nm) to A53T mutant larvae expressing channelrhodopsin 2 in DA neurons is able to fully rescue their mutation-induced decrease in locomotor speed for both PD models. After one hour of blue light stimulation, the locomotion scores were indistinguishable from those of control larvae. The long-term exposure (24 hours) also rescued locomotor deficits in α-Syn larvae. Currently, we are examining to determine an optimal lighting duration and pattern, and also to test whether the optogenetic rescue of locomotor deficits is related to structural (e.g., number of DA neurons, mitochondria and synapses) and/or functional rescue (e.g. DA neuronal activity). Our study showed that optogenetic stimulation of the larval PD models can alleviate PD-like symptoms, and thus will help to develop better strategies for slowing or reversing the progression of the disease.

Title: The neuroprotective potential of intranasal dnsp-11 on nigral dopamine neurons against intrastriatal 6-hydroxydopamine neurotoxicity

Authors: *C. M. FOX[1], A. GHOWERI[2]
[1]Biol. Sciences/Neuroscience Program, [2]Neurosci., Moravian Col., Bethlehem, PA

Abstract: Using both *in vitro* and *in vivo* studies, glial cell line-derived neurotrophic factor (GDNF) became known as one of the more promising neurotrophic factors in its ability to protect dopamine neurons against neurotoxic insult in animal models of Parkinson's disease (PD). The proprotein version of GDNF has been post-translationally processed into a dopamine neuron stimulating peptide, known as DNSP-11. DNSP-11 has been shown to be neuroprotective against TaClo, MPP+ and an intranigral 6-hydroxydopamine (6-OHDA) lesion in rat models of PD. This research project used a different approach to introducing DNSP-11 into the animal model prior to the lesion. An intranasal DNSP-11 technique was used to assess the protection of nigral dopamine neurons against the more progressive intrastriatal lesion of 6-OHDA. Twenty Fisher 344 rats were divided into the following groups: citrate + 6-OHDA and DNSP-11 + 6-OHDA. Citrate or DNSP-11was delivered intranasally prior to the 6-OHDA lesion. The foot fault and cylinder tests were performed to assess behavior improvements following treatment. Brain tissue was processed for tyrosine hydroxylase immunocytochemistry and dopamine cell survival was quantified via stereology.

Title: Nrf2 signaling contributes to the neuroprotection of urate to dopaminergic cells

Authors: *L.-F. HU
Soochow Univ., Jiangsu, China

Abstract: Mounting evidence shows that urate may become a biomarker of Parkinson's disease (PD) diagnosis and prognosis and a neuroprotectant candidate for PD therapy. However, the cellular and molecular mechanisms underlying its neuroprotective actions remain poorly understood. In this study, we showed that urate pretreatment protected dopaminergic cell line (SH-SY5Y and MES23.5) against 6-hydroxydopamine (6-OHDA)- and hydrogen peroxide-induced cell damage. Urate was found to be accumulated into SH-SY5Y cells after 30 min treatment. Moreover, urate induced NF-E2-related factor 2 (Nrf2) accumulation by inhibiting its ubiquitinationa and degradation, and also promoted its nuclear translocation; however, it did not modulate Nrf2 mRNA level or Kelch-like ECH-associated protein 1 (Keap1) expression. In addition, urate markedly up-regulated the transcription and protein expression of γ-glutamate-cysteine ligase catalytic subunit (γ-GCLC) and heme oxygenase-1 (HO-1), both of which are controlled by Nrf2 activity. Furthermore, Nrf2 knockdown by siRNA abolished the intracellular glutathione augmentation and the protection exerted by urate pretreatment. In sum, our findings demonstrated that urate treatment may result in Nrf2-targeted anti-oxidant genes transcription and expression by reducing Nrf2 ubiquitination and degradation and promoting its nuclear translocation, and thus offer neuroprotection on dopaminergic cells against oxidative stresses.

Title: Sesamol has capacity to reverse the effect of rotenone-induced Parkinson's disease

Authors: *P. KUMAR[1], S. ANGELINE[3], R. K. AMBASTA[2]
[2]Biotech., [1]Delhi Technological Univ., Delhi, India; [3]VIT Univ., Vellore, India

Abstract: In the previous report (Sonia Angeline et al., 2012), we showed an altered expression of protective proteins in rotenone-induced Parkinson's disease (PD)-like rat model. This model exhibited a marked attenuation in the expression of parkin, C terminus Hsp70 interacting protein (CHIP) and PARK 7 protein (DJ1) while enhanced levels of caspases and ubiquitin were seen. Herein, we confirmed the neuroprotective role of sesamol on rotenone-induced rodent model of PD. Rotenone administration was given for 11 days to generate the PD model (Sonia Angeline et al., 2012). From 11th day onward individual doses of sesamol (15 mg/kg) and drugs were given orally to the rotenone PD rat model for 10 consecutive days. The impact of drugs markedly improved the motor skills, body weight, expression of parkin, DJ1, tyrosine hydroxylase and CHIP compared to the group treated with rotenone alone in the striatum and substantia nigra. These results were correlated with the reduction in caspase and ubiquitin levels by immunostaining and immunoblotting. Moreover, improved morphology and survivability of neurons were seen upon sesamol and naringenin treatment in the same rat PD model. Further we confirmed the efficacy of neuroprotective biomolecule administration on muscle from the above PD model and observed the restoration in muscle morphology, elevated level of parkin, DJ1, differential expression of heat shock proteins and reduced cell death. To conclude, for the first time we are demonstrating the comprehensive role of sesamol (rotenone-induced PD model) in neuro and myoprotection that would have great clinical significance.

Abstract: Interplay between the immune system and the brain is associated with the pathobiology of Parkinson's disease (PD). Our laboratory has shown that impaired innate and adaptive immunity herald rapid and progressive nigrostriatal degeneration in PD. Based on a large volume of previous work from our laboratory and others, we demonstrate that neurodestructive autoimmunity speeds neuronal injury while regulatory T cell (Treg) responses are protective against neural damage. Clinical investigations are currently ongoing to evaluate this therapeutic strategy in humans (NCT01882010). The study addresses the neuroprotective role of an established immune modulator, vasoactive intestinal peptide (VIP) in MPTP-induced nigrostriatal degeneration. VIP mediates a pleotropic range of biological activities via two related receptor subtypes, VIP receptor 1 and 2 ($VPAC_1$ and $VPAC_2$). One such biological activity has been shown to augment Treg-mediated control over neurodegenerative processes. As a therapeutic agent, the clinical utility of native VIP is limited by rapid metabolism and clearance from blood as well as the lack of receptor selectivity and significant untoward effects. Metabolically stable and selective VPAC agonists were developed with improved pharmacokinetic and pharmacodynamic properties compared to VIP. The selective $VPAC_1$ and $VPAC_2$ agonists were used to investigate their ability to prevent MPTP nigrostriatal injury and their role in lymphocyte transformation and adoptive transfer of lymphocytes to attenuate neuronal injuries. Stereological analysis of tyrosine hydroxylase (TH^+) neurons in the substantia nigra after treatment with MPTP and the novel $VPAC_1$ and $VPAC_2$ agonists showed 50% and 79% protection compared to MPTP controls. Densometric analysis indicated striatal termini in MPTP mice were, in part, spared after treatment with VPAC agonists. Immunohistochemical analysis of Mac-1^+ microglia showed a VPAC-mediated reduction in microglial reactivity following MPTP-intoxication. Furthermore, VPAC agonists led to significant downregulation of innate neuroinflammatory responses. Cytokines measured by cytometric bead analysis, demonstrated that either VPAC agonist decreased levels of Th1 and Th17 specific cytokines, including IL-17A, IL-6, and IFN-γ. These results suggest that stable VPAC agonists transform T cell phenotypes to neuroprotective Th2 or Treg phenotypes. The downregulation of pro-inflammatory cytokines implies a phenotypic shift of T cell subsets. Thus, the immune modulatory and neuroprotective properties of VPAC agonists provide evidence to support their development as potential therapeutic agents for PD.

Abstract: Parkinson's disease (PD) symptoms arise after a substantial loss of dopaminergic (DA) cells, mainly in the substancia nigra pars compacta (SNc) of the midbrain, with evidence of mitochondrial dysfunction. All treatments are symptomatic, none of them curative or preventive. Previous studies have shown that substances such as CoQ10 and melatonin help neuroprotecting DA cells in the SNc against neurotoxin induced degeneration in animal models of PD which induce mitochondrial dysfunction. Recent results have reported neuroprotective properties of low intensity light therapy (or photobiomodulation by Near Infra-Red (NIR) light) through activation of cytochrome C oxidase and ATP synthesis in the damaged cells. Preliminary experiments demonstrated *in vivo* protection of DA cells in the SNc of acute and chronic MPTP mice and 6-OHDA rats, associated to improvement of locomotor activity. Here is presented the continuation of the study in MPTP primates treated by NIR (wavelength 670nm) using a prototype of a fully implantable chronic illuminator delivering deep brain NIR treatment of DA cells in the SNc, using a fiber the tip of which is at mid distance between left and right SNc nuclei. The power out of the implant is 10 mW and the regimen of light administration is 5sec ON / 60sec OFF. Thermic effects of the device were previously shown to be limited to +1°C maximum. Acute and chronic control groups (5 monkeys each) received MPTP (0.3 mg/kg/day) during 5 days for the acute group, plus 1 injection per week during 2 additional weeks for the chronic group. NIR treated groups (5 monkeys each, implanted with NIR device) were also submitted to acute or chronic MPTP regimens. They received a NIR treatment, either NIR illumination restricted to

24h around each MPTP injection, or continuously for 3 weeks since the beginning of MPTP injections. Clinical score and motor activity were evaluated daily for 1 week before and 3 weeks after the onset of MPTP injections. Animals were sacrificed 3 weeks after the onset of injections, and the brains processed for histology (TH and Nissl staining, alphasynuclein), for quantification of the neuroprotective effect of NIR treatment. Further experiments are required to study better the dose-effect relationships before clinical application to early PD patients. This study is the first step towards a human clinical trial aimed at evaluating NIR neuroprotective potential for PD patients.

Title: Attenuation of alpha-synuclein-induced neuroinflammation and microgliosis via rho-kinase inhibition: A possible mechanism behind fasudil-mediated neuroprotection

Authors: *M. F. DUFFY[1], J. P. MACKEIGAN[2], F. P. MANFREDSSON[1], S. G. LAMPE[1], N. KUHN[1], C. J. KEMP[1], C. E. SORTWELL[1]
[1]Translational Sci. and Mol. Med., Michigan State Univ., Grand Rapids, MI; [2]Van Andel Inst., Grand Rapids, MI

Abstract: No treatments exist to halt or slow the progression of nigrostriatal degeneration in Parkinson's disease (PD), and many existing treatments exacerbate dyskinesias after prolonged use. The approach of repurposing drugs with known safety profiles in humans can accelerate new developments for PD treatment. Previous studies in our lab have shown that fasudil, a rho-kinase (ROCK) inhibitor, provides neuroprotection from recombinant adeno-associated virus (rAAV) α-synuclein-mediated toxicity. However, the mechanisms behind fasudil-mediated

neuroprotection remain unknown. Recent studies have shown α-synuclein to be a direct mediator of neuroinflammation via upregulation of phagocytic microglia. ROCK regulates microglial polarization and motility. In the present study we examined whether fasudil treatment to rats attenuated neuroinflammation associated with intranigral injection of rAAV α-synuclein. We hypothesized that neuroprotective fasudil treatment would be associated with attenuation of microglial polarization and motility via ROCK inhibition. Nigral tissue sections from rAAV α-syn injected animals treated orally with 1) neuroprotective high dose fasudil chow (25 mg/kg/day), 2) low dose fasudil chow (10 mg/kg/day, non-neuroprotective) or 3) control chow were utilized. Sections were double-labeled for tyrosine hydroxylase (TH, dopamine neurons) and Iba-1 (microglia) immunofluorescence and analyzed using near infrared imaging to quantify Iba-1 signal intensity. Stereological quantification of phagocytic marker CD68 was also performed. While there was a dramatic increase in CD68 immunoreactive cells ipsilateral to rAAV α-syn injection, there were no differences in CD68 immunoreactive cells between treatment groups. rAAV α-syn was associated with a marked increase Iba-1 immunoreactivity. High dose fasudil resulted in a significant decrease in Iba-1 immunoreactivity in the rAAV α-syn substantia nigra (SN), intact SN, and tectum (used as a control) suggesting that fasudil attenuates α-syn-mediated microgliosis. These findings, along with previous findings from our lab, demonstrate that fasudil may protect SN dopamine neurons against α-syn-mediated inflammation via inhibition of ROCK, ultimately attenuating microgliosis. Given that orally administered fasudil has an established safety profile in humans and is, to our knowledge, the first orally available drug to provide neuroprotection in the rAAV α-syn model of PD, it demonstrates potential for development as an effective therapeutic agent to slow progressive nigrostriatal degeneration in Parkinson's disease.

Title: Depletion of proinflammatory monocytes/macrophages is neuroprotective in the myenteric plexus but not in the basal ganglia in a mptp mouse model of parkinson's disease

Authors: *M. COTE[1], C. F. LAVALLÉE[1], A.-A. POIRIER[1], B. AUBÉ[1], S. LACROIX[2], D. SOULET[3]
[1]CHUQ Res. Ctr. (CHUL), Quebec, QC, Canada; [2]Médecine Moléculaire, [3]Psychiatrie et Neurosciences, Univ. Laval, Quebec, QC, Canada

Abstract: Patients suffering from Parkinson's disease (PD) frequently display non-motor symptoms like delayed gastric emptying, constipations and defecatory dysfunctions. These gastrointestinal impairments are associated with the degeneration of dopaminergic neurons in the myenteric nervous system. Furthermore, a growing body of evidence supports a critical role for inflammation in the dysfunction of neurons in the central nervous system (CNS) and the enteric nervous systems (ENS) during acute and chronic insults. Since studies suggest that peripheral inflammation originating from the gut may have a major impact in both the initiation and progression of PD, we investigated the role of the innate immune response in neurodegeneration occurring in the CNS and ENS secondary to 1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine (MPTP) lesioning. Proinflammatory monocytes/macrophages (also known as M1) were depleted by intraperitoneal injections of clodronate-encapsulated liposomes in MPTP and saline-treated animals. We examined the profile of immune cells in their blood and measured the immunoreactivity of several neuronal markers in their striatum and myenteric plexus. Our results show that mice depleted in proinflammatory M1 monocytes by clodronate-encapsulated liposomes treatments were protected against the MPTP-induced loss of tyrosine hydroxylase (TH) expression in the ENS. Furthermore, a strong immune response was observed in undepleted mice treated with MPTP, as demonstrated by the prominent presence of proinflammatory M1 monocytes and the production of IL-1β and IL-6 in all the segments of the gut. However, in the CNS mice were subjected to 25% of striatal TH signal loss following MPTP administration regardless of whether they were depleted or not in proinflammatory M1 monocytes. Moreover, the MPTP treatment elicited a strong microglial activation in the striatum in depleted and undepleted animals. Taken together, our results demonstrate a critical role for proinflammatory M1 monocytes/macrophages in the gastrointestinal dopaminergic dysfunction in the MPTP model of Parkinson's disease. In sharp contrast, the immune response in the CNS was not impaired by the clodronate liposome treatment as circulating monocytes did not cross the blood-brain barrier to reach the brain parenchyma, nor did they contribute to the MPTP-induced toxicity as observed by confocal microscopy.

Title: Targeting dephosphorylation of eukaryotic initiation factor-2a to treat parkinson's disease

Authors: *X. SUN[1], P. AIME[1], J. CRARY[1], L. GREENE[1], O. LEVY[2]
[1]pathology and cell biology, Columbia Universtiy, New York, NY; [2]Dept. of Neurol., Columbia Univ., New York, NY

Abstract: A critical unmet need in the treatment of Parkinson's disease (PD) is protecting vulnerable neurons from degenerating. The study of pathogenic mechanisms in PD-relevant cellular systems may provide targets for neuroprotective therapies. Multiple PD-relevant stressors lead to the phosphorylation of the eukaryotic translation initiation factor-2a (eIF2a), resulting in overall translational attenuation. However, certain transcripts, including the mRNA encoding the transcription factor ATF4, undergo a paradoxical increase in their translation. We have previously found that ATF4 promotes survival in multiple cellular PD models via up-regulation of parkin. These findings imply that phosphorylation of eIF2a would favor neuronal survival by increasing levels of ATF4 and its downstream effector parkin. Interestingly, eIF2a phosphorylation can either promote or reduce neuronal survival, depending on the paradigm studied. Phospho-eIF2a levels are increased in PD brain tissue, and indirect evidence suggests that eIF2a phosphorylation is protective in PD models. Taken together, these studies suggest that eIF2a phosphorylation may regulate neuronal survival in PD, and, further, that modulating eIF2a phosphorylation may be a therapeutic approach to slow neuronal loss. Phosphorylation of eIF2a is regulated by multiple kinase and phosphatase complexes. The regulatory subunit GADD34 binds to the phosphatase catalytic subunit PP1c and directs its dephosphorylation of eIF2a. The small molecule guanabenz acetate (GA) binds to GADD34, preventing its association with PP1c and increasing phospho-eIF2a levels. We have previously found that GA promotes survival of PC12 cells and primary ventral midbrain dopaminergic neurons treated with 6-OHDA through an ATF4-Parkin pathway. Here, we extend our previous findings by demonstrating that GA prolongs eIF2a phosphorylation after 6-OHDA treatment, validating the notion that GA blocks GADD34 and eIF2a dephosphorylation. In addition, GADD34 mRNA and protein are up-regulated in PC12 cells treated with 6-OHDA. We also assessed GADD34 expression in the midbrain of autopsy tissue from PD patients and controls using immunohistochemistry. GADD34 immunopositivity is detected in neuromelanin-containing, i.e. dopaminergic, neurons

of the substantia nigra pars compacta. PD patients display a coarse granular GADD34 label in neuronal perikarya and proximal dendrites compared to a fine granular label present in controls. Direct assessment of the role of GADD34 in PD cellular models is ongoing. In summary, our data suggest that eIF2a phosphorylation could be a therapeutic target for slowing disease progression in PD.

Title: Developing combination therapies of lithium/L-Dopa and novel AurimMed Compounds for Parkinson's Disease

Authors: C. A. LAZZARA[1], A. PESYAN[2], J. K. ANDERSEN[3], *Y.-H. KIM[1]
[1]Delaware State Univ., Dover, DE; [2]AurimMed Pharma, Inc., Park City, UT; [3]Buck Inst. for research on Aging, Novato, CA

Abstract: Something Old: Lithium has been suggested to have neuroprotective effects in several models of neurodegenerative disease including Parkinson's disease (PD). Levodopa (L-Dopa) replacement therapy remains the most common and effective treatment for PD, although it induces the complication of L-Dopa induced dyskinesia (LID) after years of use. Here we examined the potential use of lithium in combination with L-Dopa/Carbidopa for both reducing abnormal involuntary movements (AIMs) as well as protecting against cell death in MPTP-lesioned mice and MPP+ damaged N27 dopaminergic neurons. Chronic lithium administration (0.127% LiCl in the feed) in the presence of daily L-Dopa/Carbidopa injection for a period of 2 months was sufficient to effectively reduce AIMs in MPTP-lesioned mice. Mechanistically, lithium was found to suppress MPTP-induced calpain activities *in vitro* and *in vivo* coinciding with down-regulation of calpain-1 but not calpain-2 expression in both the striatum (ST) and the brain stem (BS). Calpain inhibition has previously been associated with increased levels of the rate-limiting enzyme in dopamine synthesis, tyrosine hydroxylase (TH), which is probably

mediated by the up-regulation of the transcription factors MEF-2A and 2D. Lithium was found to induce up-regulation of TH expression in the ST and the BS as well as increasing histone acetyltransferase (HAT) expression, likely resulting in the observed cytoprotection and reduced AIMs in MPTP-lesioned mice. These results suggest the potential use of lithium in combination with L-Dopa/Carbidopa not only as a neuroprotectant, but also for reducing LID and alleviating potential side-effects associated with current treatment for PD. Something New: Based on our *in vitro* cell viability studies, novel AurimMed compounds demonstrated their neuroprotective effects against H_2O_2 or MPP+ induced oxidative stress, in addition to their recovery effect from oxidative stress-induced insults. Currently we are optimizing the most effective combination therapy for preventing dopaminergic neurodegeneration as well as revitalizing damaged dopaminergic neurons in PD.

Title: The beneficial effects of spargel in a *Drosophila* model of Parkinson’s disease

Authors: *K. WU[1], Z. QIAN[2], Y. KE[1]
[1]Sch. of Biomed. Sci., The Chinese Univ. of Hong Kong, Shatin, Hong Kong; [2]Lab. of Neuropharmacology, Fudan Univ. Sch. of Pharm., Shanghai, China

Abstract: Parkinson's disease (PD), which is caused by loss of dopaminergic neurons in the substantia nigra, is one of the most common neurodegenerative diseases affecting millions of people world-wide. Abnormal α-synuclein aggregation is the central hallmark of PD and many studies have already demonstrated the deleterious effects of oligomeric and aggregated forms of α-synuclein to dopaminergic neurons. Overexpression of peroxisome proliferator-activated receptor γ coactivator 1α (PGC-1α), the master regulator of mitochondrial biogenesis and cellular energy metabolism downregulated in PD, has resulted in contradictory outcomes in neurotoxin-induced PD models. In this study, we overexpressed spargel, the PGC-1α fly homolog, in the well-established A53T α-synuclein fly model to examine how spargel modulates α-synuclein toxicity and the underlying mechanisms. Our data indicated that spargel overexpression did not affect the reduced survival rate of A53T α-synuclein flies but significantly improved motor deficits 30 days post-eclosion, as revealed by negative geotaxis. Whole-mount immunohistochemistry results indicated that dopaminergic neurons in PPL1 and PPM3 cluster were rescued in 30 day-old A53T α-synuclein flies. To investigate the protective mechanism of spargel against α-synuclein, we first checked whether spargel overexpression could modify α-synuclein level and solubility. Our western blot results showed that spargel overexpression did not significantly affect SDS-soluble α-synuclein level when compared with age-matched A53T α-synuclein flies, but significantly reduced urea-soluble forms of α-synuclein, which may represent the toxic insoluble forms of α-synuclein aggregates. To conclude, our findings support that manipulation of endogenous PGC-1α in dopaminergic neurons, which is possible via a number of FDA-approved drugs, can be a promising and readily translatable treatment strategy against α-synuclein-induced toxicity in PD.

Abstract: Objectives: The involvement of inflammation in the pathogenesis of Parkinson's disease is well known in the field of basic research as well as in the clinical setting. Intranuclear high mobility group box 1 (HMGB1) moves towards extracellular space and acts as an inflammatory factor when the cells are damaged. In this study, we investigated the involvement of HMGB1 and the neuroprotective effects of anti-HMGB1 antibody for Parkinson's disease model of rats. Methods: Adult female Sprague-Dawley rats (200-250g) were used in this study. 6-OHDA (20 μg) was injected into the right striatum and then anti-HMGB1 antibody (1mg/kg), control IgG or saline was intravenously administered immediately, 6 and 24 hours after 6-OHDA injection. Cylinder test and amphetamine-induced rotation test were performed as behavioral assessment at 1 and 2 weeks after surgery. Tyrosine hydroxylase (TH) staining was performed at 2 weeks for evaluation of dopaminergic neurons. Iba1 which is a marker of microglia, HMGB1, MAP2 and GFAP staining were performed at 24 hours, 1 week and 2 weeks for histological evaluation. Results: Behavioral tests revealed that the number of amphetamine-induced rotations at 2 weeks decreased and contralateral bias of cylinder test at 1 and 2 weeks improved in anti-HMGB1 groups. Immunohistochemically, TH-positive fibers in the striatum and TH-positive neurons in the substantia nigra pars compacta were significantly preserved in anti-HMGB1 groups. Iba1-positive cells were decreased at 1 and 2 weeks in anti-HMGB1 groups. In control IgG group, cytoplasmic HMGB1 expressed in GFAP-positive cells at 1 week after surgery. Conclusions: These results suggested that HMGB1 released from GFAP-positive astrocytes was at least partly involved in the mechanism and pathway of degeneration of dopaminergic neurons induced by 6-OHDA exposure. Intravenous administration of anti-HMGB1 antibody suppressed microglial activity and preserved dopaminergic neurons. Anti-HMGB1 antibody exerts anti-inflammatory effects and with subsequent neuroprotective effects.

Title: 7-OH-DPAT induces neuroprotection and attenuate motor deficit in LRRK2 R1441G mice

Authors: *J. KIM, J. KIM, S. KANG, J. JANG, H. SEO
Dept. of Mol. and life sciences, Hanyang Univ., Ansan, Korea, Republic of

Abstract: Parkinson's disease (PD) is a neurodegenerative disorder that induces degeneration of dopaminergic neurons in substantia nigra pars compacta (SNpc). Several studies suggest that dopamine D3 receptor has relation to motor and cognitive function in PD. D3 receptor is a D2-like family that inhibits adenylyl cyclase through G-proteins. In this study, we determined the effects of D3R agonist, (±)-7-Hydroxy-2-(di-n-propylamino) tetralin hydrobromide (7-OH-DPAT), in *in vivo* model of PD. We found that LRRK2 R1441G mutant (MT) mice showed significantly decreased latency to fall compared to litermate mice (LM). 7-OH-DPAT treatment significantly increased the latency to fall in LRRK2 R1441G MT mice. In open field test, D3R agonist administered LRRK2 R1441G MT mice showed significant increase in the counts of rearing and grooming compared to vehicle control group. Also, the counts of wall rearing and cross were significantly decreased compared to vehicle control group. 7-OH-DPAT administration significantly increased the number of tyrosine hydroxylase (TH)-immunoreactive neurons in SNpc of MT mice. Our results suggest that D3R agonist could induce neuroprotection and attenuate motor deficit in PD model.

Abstract: mGluR3 is a novel target that could lead to neuroprotection through production of GDNF and TGF-beta in striatal neurons. This potential was previously demonstrated with a non-selective mGluR2/3 agonist and KO mice. At Domain Therapeutics, novel NCEs with selective mGluR3 positive allosteric modulator (PAM) property were recently discovered. These molecules were subject to chemical optimization and characterized *in vitro* in both neuroprotection and neurotrophic factor production models. Members of these mGluR3 PAMs showed protective activity on primary striatal and cortical neurons and neurotrophic factor production in an mGluR3-dependant manner. The present poster describes the full characterization of the best analogs of the series.

Abstract: Objective: This study investigated neuroprotection with ethanolamine plasmalogens (PlsEtn). Plasmalogens are a unique class of glycerophospholipids that contain a vinyl ether alcohol at the sn-1 position. They are promising because of the roles they play in membrane structure mediated functions such as vesicular release of neurotransmitters and membrane protein activity, free radical scavenging, and as a storage of depot of neuroprotective polyunsaturated fatty acids (docosahexaenoic acid (DHA)). Methods: Male mice were treated for 10 days with a daily oral administration of either the DHA-plasmalogen precursor PPI-1011 or the oleic acid-plasmalogen precursor PPI-1025 (10, 50 or 200 mg/kg). On day 5 the mice received 4 injections of 1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine (MPTP). The mice were killed on day 11 and striatal biogenic amine concentrations were measured by HPLC. Autoradiography of brain membrane (DAT) and vesicular (VMAT2) dopamine transporters were made and serum plasmalogens concentrations mesured. Results: PPI-1011 (10 and 50 mg/kg) and PPI-1025 (10 mg/kg) completely prevented the decrease of dopamine concentration induced by MPTP, the PPI-1025 prevention at 50 mg/kg was partial. PPI-1011 and PPI-1025 at 10 and 50 mg/kg prevented the MPTP induced decrease of DOPAC and HVA concentrations. We found significant correlations between the levels of DA and DAT or VMAT2 transporters, demonstrating that the precursors of plasmalogens help to protect the terminals of dopaminergic neurons. Results obtained with VMAT2 and DAT transporter demonstrate that a dose of 50 mg protect dopaminergic neurons in the striatum of MPTP toxicity. MPTP also induced a peripheral (serum) depletion in PlsEtn levels. Pre-treatment with plasmalogen precursors that bypass peroxisomal metabolism prevented all serum MPTP-induced effects. In conclusion, the neuroprotective effect of plasmalogen precursor analogs appears to have a bell-curve shape and was dose-dependent. The similar activity of oleic (PPI-1025) and DHA (PPI-1011) plasmalogen precursors suggests that the observed neuroprotection is due to the plasmalogen backbone rather than formation of DHA. The decrease of several plasmalogens observed in the striatum of MPTP mice is in agreement with the results obtained by Fabelo et al. (Mol Med. 2011;17 :1107) that observed a reduction of plasmalogens in cortex of parkinsonian patients. This research was

supported by a CHIR grant to TDP. EMG holds a studentship from FER of the Faculty of Pharmacy, Laval University.

Title: Prokineticin-2 gene therapy strategy shows anti-inflammatory and anti-apoptotic effects in preclinical cell culture and animal models of Parkinson’s disease

Authors: M. NEAL, D. LUO, D. HARISCHANDRA, R. GORDON, H. JIN, V. ANANTHARAM, *A. G. KANTHASAMY, A. KANTHASAMY
Biomed Sci, Iowa Ctr. for Advanced Neurotoxicology, Iowa State Univ., AMES, IA

Abstract: Prokineticin-2 (PK2) is a small secretory peptide with diverse biological functions. We recently identified that dopaminergic neurons upregulate PK2 in response to neurotoxic stress. To better understand the functional role of PK2 upregulation, we created stable PK2-overexpressing dopaminergic cells by transfecting the PK2 gene into mouse dopaminergic MN9D cells. Interestingly, PK2-overexpressing cells exposed to the Parkinsonian neurotoxicant MPP+ showed significant protection against neurotoxicity relative to vector control cells, suggesting a neuroprotective role for PK2 in dopaminergic neuronal cells. Furthermore, the PK2 receptor blocker PC7 attenuated the PK2-induced neuroprotective effects in PK2-overexpressing cells. The neuroprotection mediated by PK2 against MPP+-induced toxicity was associated with increased Bcl2 gene expression and reduced apoptotic cell death. To extend the results of cell culture studies to animal models, we adopted adeno-associated viral (AAV2) vector technology to develop a PK2-GFP gene construct delivery system, and we tested the efficacy of this new

viral vector in mouse models. Stereotaxic injections of the PK2 AAV and a control virus (GFP only) demonstrated that the virus could infect cells in the striatum and substantia nigra as determined by fluorescence microscopy and Western blotting. Neurobehavioral analyses revealed that the PK2 AAV injection does not alter basal motor behavior relative to control mice. PK2 AAV gene delivery in the striatum significantly reduced basal gene expression of inflammatory cytokines, including TNFα, IL-1β and IL-6, indicating an anti-inflammatory function for PK2 in the striatum. Also, iNOS gene expression was reduced following PK2 expression in the striatum. In contrast, PK2 AAV expression significantly upregulated Bcl2 and Pink1, suggesting that PK2 can upregulate cell survival signaling pathways. Initial results show that PK2 AAV expression attenuates MPTP-induced behavioral deficits and TH depletion in the C57 black mouse model. Taken together, these results demonstrate for the first time, that PK2 overexpression can protect dopaminergic neurons in both cell culture and animal models by attenuating the glial cell-mediated inflammatory response as well as by upregulating Bcl2 and Pink-1 protective signaling. Further characterization of the efficacy of PK2 gene therapy in preclinical models of Parkinson's disease may provide a viable neuroprotective strategy for the chronic neurodegenerative disease

Title: Neuroprotective and neurotrophic effects of Apigenin in MPTP induced Parkinson's disease in mice

Authors: *S. P. PATIL, SR, P. JAIN, S. SATHAYE
Pharmaceut. Sci. and Technol., Inst. of Chem. Technol., Matunga East, India

Abstract: Apigenin, a natural flavonoid, has potential biological effects, including antiproliferative, and anticancer activities. In the present study, our aim was to investigate the neuroprotective and neurotrophic effects of apigenin and also to explore the underlying

mechanisms with respect to Parkinson's disease (PD). MPTP (25mg/kg) along with Probenecid (250mg/kg) was administrated for five consecutive days to induce PD in mice. Apigenin (5, 10 and 20 mg/kg) was administrated orally for 26 days including 5 days of pretreatment. Bromocriptine (10mg/kg) was used as a standard drug. Motor co-ordination and locomotor activities were evaluated by rotarod and open field tests. Oxidative stress was evaluated specifically in the mid brain by assessing various antioxidant enzymes activities. Tyrosine hydroxylase (TH), glial fibrillary acidic protein (GFAP) and brain derived neurotrophic factor (BDNF) were evaluated in substantia nigra (SN) region of the brain by immunostaining. TNF-α was estimated using ELISA technique. Our results demonstrate that apigenin treatment improved the locomotor and muscular activities in MPTP treated mice. Apigenin treatment has significantly improved the antioxidant activity in comparison to MPTP treated mice. TH-positive cells decreased upto 7% in MPTP group as compared to normal mice ($p<0.001$) and were found to be protected from degeneration in apigenin (69%) treated mice ($p<0.001$). Levels of GFAP were also found to be decreased in the SN of the brain due to apigenin treatment as compared to MPTP mice ($p<0.001$). Additionally, BDNF levels were elevated significantly in apigenin treatment group when compared with MPTP treatment mice. In conclusion, apigenin protected the dopaminergic neurons probably through its antioxidant, anti-inflammatory and neurotrophic potential which could be the possible reason for amelioration of the disease process. The above results provide preclinical support for therapeutic potential of this compound in the treatment of PD.

Title: Neuroprotective effect of diphenyl diselenide on a rat model of Parkinson's disease induced by 6-hydroxydopamine

Authors: *A. DE SOUZA[1], S. PINTON[3], T. B. SAMPAIO[4], J. T. DA ROCHA[4], B. M. GAI[4], R. D. S. PREDIGER[2], C. W. NOGUEIRA[4]
[2]Dept. of Pharmacol., [1]Univ. Federal De Santa Catarina, Florianópolis, Brazil; [3]Dept. of Chem., Univ. Federal do Pampa, Uruguaiana, Brazil; [4]Dept. of Chem., Univ. Federal de Santa Maria, Santa Maria, Brazil

Abstract: Aim: Parkinson's disease (PD) is a progressive neurodegenerative disorder characterized by degeneration of dopaminergic neurons in the nigrostriatal pathway. The antioxidant and neuroprotective properties of diphenyl diselenide [(PhSe)2], together with its effectiveness in inhibiting MAO-B activity, suggest a potential effect of (PhSe)2 on motor dysfunction induced by dopaminergic depletion. Therefore, the purpose of the present study was to investigate whether (PhSe)2 reverses motor and neurochemical impairments in a model of PD induced by 6-hydroxydopamine (6-OHDA) in rats. Methods: Wistar rats (250-300 g) received 20 µg/3 µl of 6-OHDA or 3 µl of vehicle into the right striatum. Three weeks later, animals were subjected to rotational behavioral test induced by D-amphetamine and divided into four groups: Sham; (PhSe)2; 6-OHDA and 6-OHDA+(PhSe)2. Rats were treated with (PhSe)2 (1 mg/kg/day; orally) or vehicle (canola oil) during 30 days. At the end of treatment, cylinder, stepping, bridge, and open-field tests were performed and brain was collected for the measure of brain-derived neurotrophic factor (BDNF), proBDNF, and tyrosine hydroxylase (TH) in the nigrostriatal region by immunoblotting assay. Data were analyzed using a two-way ANOVA followed by the Duncan's test, when appropriate (significant when $p<0.05$). Results: 6-OHDA infusion triggered a considerable increase in D-amphetamine-induced rotational behavior demonstrating the effectiveness of 6-OHDA infusion before starting the (PhSe)2 treatment. Subsequently, 6-OHDA-injected rats decreased the number of wall contacts with contralateral forelimb in the cylinder test. 6-OHDA also decreased the number of responses with contralateral forelimb in rats evaluated in the stepping test. (PhSe)2 treatment restored the normal behavior in 6-OHDA-infused rats in both tests. In the bridge test, (PhSe)2 treatment reverted the altered equilibrium function induced by 6-OHDA infusion in rats. Besides, 6-OHDA infusion and/or (PhSe)2 treatment did not alter the number of crossing and rearing in the open-field test. In addition, the expression of BDNF, proBDNF, and TH in the nigrostriatal region of 6-OHDA-lesioned rats was reduced. Interestingly, (PhSe)2 treatment restored proBDNF and TH expression in the nigrostriatal region of 6-OHDA-infused rats. Conclusion: Results demonstrated that (PhSe)2 treatment reversed motor impairment in a model of PD in rats, which was mediated, at least in part, by restoring proBDNF and TH expression. Thus, the current study suggests a potential neuroprotective role for (PhSe)2 in PD.

Title: Nepalese and Native American traditional medicine: What can we learn to treat Parkinson's disease?

Authors: A. DE RUS JACQUET[1], R. SUBEDI[2], S. K. GHIMIRE[2], *J.-C. ROCHET[1]
[1]Medicinal Chem. &Molecular Pharmacol, Purdue Univ., W LAFAYETTE, IN; [2]Central department of botany, Tribhuvan Univ., Kathmandu, Nepal

Abstract: Parkinson's disease (PD) is an age-related neurodegenerative disorder characterized by the death of dopaminergic neurons from the substantia nigra. Five million people are affected by Parkinson's disease (PD) worldwide. Current therapies fail to slow the underlying neurodegenerative disease and can only temporarily relieve symptoms. On the other hand, Nepalese and Native American societies have a long tradition of herbal medicine. Although these societies evolved in different sociological and cultural contexts, herbal medicine is a central component of their identity. Our central hypothesis is that plant species used to treat PD-like symptoms in both Nepalese and Native American traditional medicines have a high potential to alleviate neurodegeneration. From May to July 2012, we conducted a total of 36 interviews in Nepal, and we identified 46 potentially active plant species. Subsequent interviews with Native Americans from the Lumbee and Blackfeet tribes led to the identification of additional plants with potential activity against PD-related symptoms. Plant extracts are being screened for protective activity in neuronal cultures exposed to environmental poisons that have been linked epidemiologically to elevated PD risk, including the pesticide rotenone and the herbicide paraquat. Our most promising plant candidates are being tested in fluorescence-based assays that monitor the ability to activate various pro-survival mechanisms, including induction of autophagy, rescue of mitochondrial function, and activation of cellular antioxidant responses. Tinospora sinensis, a climber used to treat paralysis in Nepal, shows exceptional neuroprotective activities in our cell culture models of PD. The ethanolic extract rescues neuronal death triggered by rotenone in a chronic exposure model and by paraquat and rotenone in primary midbrain cultures. In addition, the extract induces up-regulation of the Nrf-2 antioxidant pathway.

Tinospora sinensis is a promising medicinal plant for the design of therapies that not only are readily available to traditional communities but also have a high potential to be developed into a modern Western medicine. Our findings are relevant to the identification of therapeutic targets in PD and suggest public health strategies for indigenous and Western populations.

Abstract: Mutations in the *KCNQ2* gene, which encodes a subunit of the voltage-dependent potassium the Kv7.2 subunit of the voltage-dependent potassium channel responsible for the M current, have been identified in early onset epileptic encephalopathies (EOEE) and in benign familial neonatal seizures (BFNS). The prognosis for patients is very heterogeneous from benign forms (BFNS) with normal neurological development to severe forms (EOEE) with strong deterioration of motor and cognitive function. So far, the phenotypic variability has mostly been

explained by the functional impact of mutations on the M current measured in non-neuronal heterologous expressing system (decreased by ~25 % in BFNS and > 50% in EOEE, Miceli et al. 2013; Ohran et al. 2014). We have previously reported 16 de novo *KCNQ2* mutations in EOEE patients, without any cortical malformations or metabolic disease (Milh et al. 2013). Here, we investigated the functional consequence of the p.A294V hotspot mutation located in the pore domain and identified in 9 EOEE patients (7 in our cohort and 2 additional patients reported by Kato et al. 2013). For this purpose KCNQ current was recorded using the whole cell patch-clamp method in CHO cells transfected with a plasmid expressing $KCNQ2^{A294V}$ alone or together with plasmids expressing $KCNQ2^{WT}$ or KCNQ3. We report that the homomeric $KCNQ2^{A294V}$ is not functional. The association of $KCNQ2^{A294V}$ with KCNQ3 reduces the current by 83%, and by 30% when $KCNQ2^{WT}$ was added, an association that mimics the situation in cells of EOEE patients. Other parameters such as the kinetics and the conductance-voltage relationships for heteromeric mutant channels were not different from wild-type heteromeric channels. Surface biotinylation of CHO cell and western blot analysis of lysates show that the mutation decreased the total amount of KCNQ2 and reduced the surface expression of the subunit. We suggest that the p.A294V mutation accelerates KCNQ2 degradation and on the other hand, induces defects in the gating of KCNQ2 mutant channels that are successfully addressed to the membrane. In cultured hippocampal neurons, the presence $KCNQ2^{A294V}$ induces a strong redistribution of the heteromeric mutant channels from the axon initial segment to the somatodendritic compartment. This lack of KCNQ channels is susceptible to induce abnormal excitability by various mechanisms. From these data, we propose that (i) Ala-294 although located in the pore domain is essential for proper channel formation and expression to the plasma membrane; (ii) the degree of KCNQ current inhibition in non-neuronal heterologous system cannot predict the neurological outcome.

Title: Reorganization of the CA1 hippocampal network in the chronic kainate model of epilepsy

Authors: I. KHOURY[1], *Y. SCHILLER[1,2]
[1]Technion Med. Sch., Haifa, Israel; [2]Neurol., Rambam Med. Ctr., Haifa, Israel

Abstract: Epilepsy is a common neurological disorder characterized by recurrent unprovoked seizures caused by various pathologic processes in the brain. One of the best characterized chronic models of temporal lobe epilepsy is the kainate model. A potential mechanism that may underlie development of epilepsy (epileptogenesis) is reorganization of the network and change in the network topology, that in turn causes an increased tendency of the network to hyper-activate and hyper-synchronize.In this study we investigated this possibility by comparing the functional network characteristics and network topology in control and chronic epileptic rats. We simultaneously recorded action potential firing from multiple neurons from the CA1 region of the hippocampus using multi-tetrode single-unit recordings from control rats (Sprague Dawley) and rats with chronic kainate induced temporal lobe epilepsy, in which spontaneous seizures develop after a kainite induced status epilepticus (SE). Recordings were performed 5-10 weeks after the kainite induced SE. We used the multi-tetrode single-unit recordings, and especially the pair-wise cross correlations between recorded neurons to compare network synchronization, functional network properties and topology in normal and epileptic rats. Multi-unit single-unit recordings from the CA1 region of normal and epileptic rats revealed a significantly higher degree of synchronization in epileptic rats (as assessed by the pair-wise cross correlation function) compared to control. There were no significant differences in auto correlation between unit pairs which means that the difference in synchronization was not a result of increased bursting in the epileptic rats. With respect to network properties the network tended to show higher connectivity as shown by a significantly higher local cluster coefficient in the epileptic group compared to control. We found no significant difference in path length between the two groups. Our results show that the epileptic network undergoes reorganization with a higher functional connectivity and increased synchronization compared to control animals. These network changes may underlie the tendency to generate seizures in these rats.

Title: High-throughput assay of seizurogenic activity using multi-well microelectrode array technology

Authors: D. MILLARD[1], A. NICOLINI[1], S. CHVATAL[1], M. BROCK[1], K. COOK[1], *J. ROSS[2]
[1]Axion Biosystems, Atlanta, GA; [2]ATDC Biosci. Ctr., Axion Biosystems, Inc., Atlanta, GA

Abstract: The lack of advancement in anti-epileptic drugs (AEDs) over the last 30 years, along with the continued need for improved proconvulsant screening in drug safety, motivates the need for new assays of seizurogenic neural activity. An *in vitro* approach for detecting and quantifying seizurogenic activity could provide a predictive and high-throughput avenue for the evaluation of the efficacy of AEDs and the proconvulsant risk of other compounds. Towards this end, microelectrode arrays (MEA) have been used extensively for characterizing and quantifying neural activity *in vitro* and have recently been scaled to a multi-well format that facilitates high throughput electrophysiological analysis. Indeed, MEAs have shown promise in predicting the toxicity of neuro-active compounds by measuring changes in the population mean firing rate of a neuronal network. However, further consideration of how recorded spikes are grouped in space and time across neural populations may lead to improved sensitivity for *in vitro* seizurogenic assays. Here, we present an assay of seizurogenic activity based upon the Axion BioSystems Maestro multi-well MEA system. We used previously published metrics for the detection of burst spiking events and the quantification of synchronization across a neural population. Data are included from both rat cryopreserved cortical cultures and human induced pluripotent stem cell derived populations, in response to pharmacological manipulation with AEDs (i.e. Carbamazepine, Valproic Acid) and reference compounds with known proconvulsant risk (i.e. 4-Aminopyradine, Strychnine, Pentylenetetrazole). Our results support the use of multi-well MEA technology for the high throughput evaluation of complex neuronal networks *in vitro* to inform the development of AEDs, while also quantifying the proconvulsant risk of candidate pharmaceuticals in a pre-clinical setting.

Title: Circuit changes underlying network synchronization during post-traumatic epileptogenesis

Authors: *K. P. LILLIS[1], Z. WANG[1], G. Q. ZHAO[2], B. J. BACSKAI[1], K. J. STALEY[1]
[1]Neurol., Harvard Med. Sch., Charlestown, MA; [2]Stanford Univ., Palo Alto, CA

Abstract: In secondary epilepsy, a seizure-prone neural circuit forms following an injury to the brain (e.g. trauma). The nature of both the epileptogenic changes that take place during the latent period and the continuing evolution that occurs following the onset of seizures remain relatively unknown. We have used both whole-cell patch clamp electrophysiology and serial two-photon calcium imaging to characterize network changes occurring in the hippocampal organotypic slice culture model of post-traumatic epileptogenesis. The ratio of mIPSC to mEPSC charge transfer rate did not significantly change throughout early epileptogenesis, suggesting that the network alterations underlying the propensity for spontaneous seizures are more complicated than a simple dearth of inhibition. To characterize these network alterations during the first week *in vitro*, CA1 pyramidal neurons were imaged periodically using two-photon targeted path scan calcium imaging. Over the first 24 hours, as interictal population bursts emerged, there was a rapid increase in the proportion of neurons participating in the bursts and in the synchrony of each burst. Ictal activity typically began during the second or third DIV, and evolved more gradually than the interictal activity. Over the first 8 DIV, seizure onset became progressively more synchronous across the population of neurons imaged. Cross-correlation-based network analyses quantitatively confirmed that the earliest spontaneous seizures were characterized by a slow buildup of predominantly local, correlated activity preceding seizure onset. The onset of later seizures was comprised of an abrupt transition from unmeasurable to fully synchronous ictal calcium activity, corresponding to a sharp, spatially uniform increase in correlated activity. Concomitant with the decrease in pre-ictal buildup of activity, was also a significant decrease in

measurable, non-ictal calcium transients, suggesting that, in well-developed epilepsy, very moderate bursts of synchronous activity are sufficient to initiate seizures. Together, these data support the concept that epilepsy after brain injury is a consequence of changes in the synaptic circuitry of neural networks, rather than the proportion of excitatory to inhibitory synapses, and that this circuitry continues to evolve after the latent period and onset of seizure activity.

Title: Activation of parvalbumin interneurons at the epileptogenic focus facilitates focal seizures generation in a mouse model of temporal lobe epilepsy

Authors: I. MARCON[1], M. SESSOLO[1], S. BOVETTI[2], G. LOSI[1], L. MARIOTTI[1], T. FELLIN[2], *G. CARMIGNOTO[1]
[1]Neurosci. Institute, CNR and Univ. of Padova, 35121 Padova, Italy; [2]Dept. of neuroscience and brain technologies, Inst. Italiano di Tecnologia, 16163 Genova, Italy

Abstract: The potentiation of GABAergic inhibition is commonly used in clinical medicine to control seizures. Recent studies reported that optogenetic activation of a subset of GABAergic

interneurons, i.e., the Parvalbumin (Pv) fast-spiking interneuons, can interrupt ongoing seizures. Optogenetic targeting of this specific interneuron class has been thus proposed as a new, potentially effective strategy to control seizures. Such an approach might be particular relevant in focal temporal lobe epilepsy, where seizures initiate from a restricted brain region (i.e., the epileptogenic focus). At this region, Pv interneurons could be specifically targeted by current fiber optic-mediated strategies and their selective activation could, in principle, prevent seizure generation. However, a direct experimental proof of this hypothesis has not been provided yet. To clarify this issue, we used optogenetics in combination with intra- and extra-cellular electrophysiological recordings from layer V in a mouse cortical slice model of temporal lobe epilepsy in which evoked seizure events closely mimic those recorded *in vivo*. In this model focal seizure-like discharges could be evoked by local NMDA applications in the presence of 4-aminopyridine and low Mg2+. The fact that in the model we can predict in advance where and when a seizure will be generated, offers us the unique opportunity to investigate if and how Pv interneurons contribute to the early events that cause neural circuits to generate a focal seizure. We here provide evidence that a pulse light stimulation (473 nm) restricted to ChR2-expressing Pv interneurons at the epileptogenic focus before the application of the ictogenic stimulus (NMDA pulse): i) lowers the threshold of focal seizure generation (n=23) and ii) prolongs the overall duration of the epileptic event (duration of seizures in absence and presence of light stimulation were, respectively: 144 ± 17 s vs 194 ± 18 s n=16). In contrast, a similar light activation restricted to Pv interneurons of a region distant from the focus (i.e., the penumbra region) opposes seizure propagation (n=6). Our study call for a careful reconsideration of the optogenetic approach that aims to control seizures by targeting Pv interneurons.

Title: Neural field theory of generalized seizures

Authors: *X. ZHAO, P. A. ROBINSON
Univ. of Sydney, Sydney, Australia

Abstract: The mechanisms underlying generalized seizures are explored with neural field theory. A corticothalamic neural field model that has accounted for multiple physiological states observed in human EEG is extended with bursting dynamics and used to explore changes leading to pathological seizures. It is confirmed that generalized seizures arise from instabilities in the system and replicate experimental studies observed in numerous animal models and clinical studies. **Methods** We extend a well known neural field model by incorporating bursting dynamics in the reticular nucleus. Using previously published results, we show how bursting behavior can be expressed in terms of rate dynamics and incorporated into the firing activity of the reticular nucleus in our neural field model. The bursting dynamics in the reticular thalamus interacts with the thalamic relay nucleus to enhance network oscillations at frequencies near the bursting frequency. We first show that implementing the bursting dynamics preserves previous results in normal arousal states then proceed to examine the model's pathways to generalized seizures. **Results** (i) The neural field model extended with bursting dynamics is able to reproduce previously studied arousal states such as wake, spindles in light sleep, deep sleep, and seizure activity. (ii) We explore three new mechanisms through which generalized seizures arise in the extended neural field model. Firstly, increasing bursting dynamics in the reticular nucleus. Secondly, a shift in the differential activation of GABA receptors towards the slower GABA-B receptor also results in seizure activity. Thirdly, increasing corticothalamic coupling strength replicates seizure activity discovered in our original neural field model. Our dynamic spectra of the generalized seizures show that there is a strong $2-4$ Hz component during the generalized seizures, which is in agreement with clinical studies for generalized absence seizures. (iii) We provide a potential framework for explaining the pharmacological action of drugs used in the study absence seizures with a phase diagram describing the model's seizure activity. **Conclusion** We have used a neural field model with bursting dynamics in the reticular nucleus to study different types of instabilities which give rise to generalized absence seizure dynamics. We have shown that it can account for physiological arousal states and explain the onset of generalized seizures. Furthermore, we have provided a useful framework for understanding the pharmacology of seizure drugs in terms of the model's phase diagram.

Title: Thalamic circuit modulation by ATP-sensitive potassium channels

Authors: *K. A. SALVATI, D. R. WYSKIEL, R. P. GAYKEMA, M. P. BEENHAKKER
Pharmacol., Univ. of Virginia, Charlottesville, VA

Abstract: Absence epilepsy is a non-convulsive generalized seizure disorder characterized by a sudden arrest of consciousness and 3-5Hz spike-and-wave discharges (SWD) in electroencephalography (EEG) recordings (Crunelli and Leresche, 2002). Absence seizure generation involves the cortico-thalamo-cortical network comprised of the reticular thalamic nucleus (RT), thalamocortical neurons (TC) and cortical neurons. Hypoglycemia increases blood flow to the thalamus in humans (Arbelàez et al., 2012), suggestive of increased neuronal activity, and increases SWDs in rodents (Reid et al. 2011). Acute hypoglycemia can switch the body from a primarily glucose-dependent metabolic state to one dependent on the metabolism of the ketone bodies (KBs), β-hydroxybutyrate and acetoacetate, and may recruit ATP-sensitive potassium (K_{ATP}) channels. Indeed, K_{ATP} channels are highly sensitive to cellular metabolic states and can regulate neuronal excitability (Ma et al. 2007), and depress hippocampal circuit activity (Tanner et al., 2011). Here we investigate whether elevated KBs paradoxically promote SWDs driven by thalamic circuits. To begin testing this hypothesis, we first determined whether KBs are elevated during heightened SWD activity triggered by acute hypoglycemia. Specifically, we measured blood glucose and KB levels immediately prior to measuring SWD occurrence in non-fasted mice and after a 16 hour fast. Consistent with Reid et al. (2011), we found that a 16 hour fast increases the number of SWDs (mean % increase: 252.7 ± 2.45%; n=10, p=0.01). Furthermore, we found that fasted mice had significantly elevated levels of ketone bodies immediately prior to EEG recording (mean % increase: 227.3 ± 0.048%; n=10, p<0.0001). As K_{ATP} channels can link metabolism to neural activity, we next sought evidence for K_{ATP} channel expression in the thalamus. Both mRNA analysis and antibody staining revealed that K_{ATP} channels (Kir6.2) are expressed by RT and TC neurons. Moreover, *in vitro* electrophysiological methods revealed a significant K_{ATP} channel conductance in thalamic neurons. Specifically, application of the sulfonylurea receptor agonist, diazoxide, increased the holding current in voltage-clamped neurons in a dose-dependent manner, an effect that was blocked by the K_{ATP} channel antagonist, glibenclamide. Additionally, direct KB application to thalamic neurons also activated a glibenclamide-dependent conductance. In sum, we found that acute hypoglycemia elevates KBs, and that KBs recruit K_{ATP} channel activity in the thalamic brain slices. These findings provide initial support for the hypothesis that KBs elevate SWD activity observed during fasting.

Title: Exploration of functional connectivity among spiketrains of thalamic and cortical neurons in absence epilepsy

Authors: *M. V. JONES
Dept Neurosci., Univ. Wisconsin-Madison, Madison, WI

Abstract: The γ2(R43Q) mutation of the GABA-A receptor causes absence epilepsy and febrile seizures in humans and in knock-in mice (RQ). GABAergic tonic inhibition is abolished in these mice, whereas synaptic inhibition is only subtly altered. Furthermore, blocking tonic inhibition in wild type mice (RR), via i.p. injection of L-655,708, induces absence-like EEG spike-wave discharges. Therefore, reduction of tonic inhibition is sufficient to cause absence-like activity. In multielectrode single-unit recordings from thalamocortical slices of RR and RQ mice, spontaneous and repeating patterns of spiking occur that appear to reverberate between thalamus and cortex, and these patterns differ between RR and RQ mice. We therefore wish to determine whether these spike patterns might convey information about the functional connectivity between thalamus and cortex, and the role of tonic inhibition in thalamocortical communication, in health and epilepsy. We used Granger Causality as a measure of functional connectivity (J Neurosci Meth 223:50). Before analyzing experimental data, we tested whether Granger Causality is even suitable to detect known causal relationships in synthetic binary spiketrain data where the causal structure is known. We simulated 100 trials of Izhikevich Networks (IEEE Trans Neural Netw 14:1569) and compared the known causal connectivity with that estimated from Granger Causality analysis of the unfiltered binary spiketrains. For a small network of 10 randomly and sparsely (~7%) interconnected neurons (1/5 inhibitory), Granger Causality identified 100% of the existing connections, and predicted 0.08% false positives and 0% false negatives. For a larger network of 40 neurons (~4% connectivity), Granger Causality identified 90% of the existing connections, with 4% false positives and 0.9% false negatives. Overall, Granger Causality was relatively accurate, more likely to predict false connections than to miss true connections, and had a bias toward missing inhibitory connections. Using Granger Causality as a measure of functional connectivity on spike timing data is therefore tenable. Thus we are

proceeding with applying this method to comparing the functional connectivity of healthy and and epileptic tissue from γ2(R43Q) mice.

Title: How inhibition shapes interictal dynamics in awake epileptic mice

Authors: *R. A. COSSART[1], S. FELDT-MULDOON[2], V. VILLETTE[1], T. TRESSARD[1]
[1]INMED, INSERM U901, Marseilles, France; [2]Univ. of Pennsylvania, Philadelphia, PA

Abstract: In the normal brain, most cortical network dynamics are associated with sparse neuronal recruitment, shaped in space and time by the action of inhibition provided by GABA (γ-aminobutyric acid)-ergic microcircuit . A dysfunction of GABAergic microcircuits is generally linked to brain disorders, the most common of which is epilepsy. In fact, ictal and interictal discharges, the cardinal electrophysiological symptoms of epilepsy, are classically thought to reflect the breakdown of sparse activity into hypersynchronous population bursts resulting from collapsed inhibition. Although, this traditional view has recently been, the exact contribution of distinctive neurons to epileptiform dynamics *in vivo* remains unknown, largely due to the difficulty in monitoring spontaneous single-cell activity in the absence of anesthetics. Here, we use a chronic model of Temporal Lobe Epilepsy to show that GABAergic neurons are the main contributors to spontaneous interictal activity in the awake epileptic mouse hippocampus. For the first time, we apply two photon calcium imaging to map cellular recruitment within large populations of CA1 neurons in awake epileptic mice. We find that specific cellular dynamics of interictal spikes are highly variable, but always associated with the strong bursting of GABAergic neurons resulting in a perisomatic inhibitory restraint that reduces glutamatergic cell activity. This finding is in striking contrast with the canonical view that epilepsy results from an imbalance of inhibitory and excitatory action in favor of runaway excitation and instead supports earlier work indicating that the GABAergic microcircuits that are spared in the course of

epileptogenesis are hyperactive, hyperconnected, and could contribute in shaping epileptiform. Given the emergence of novel closed-loop therapeutic approaches that target abnormal brain patterns, our results provide valuable insight into microscale epileptiform dynamics which will be essential in developing efficient therapies.

Title: Optogenetic activation of parvalbumin interneurons synchronizes afterdischarges of seizures in a mouse model of temporal lobe epilepsy

Authors: M. SESSOLO[1], I. MARCON[1], G. LOSI[1], L. MARIOTTI[1], S. BOVETTI[2], *N. BERARDI[3], T. FELLIN[2], G. CARMIGNOTO[1]
[1]Neurosci. Institute, CNR and Univ. of Padua, Padova, Italy; [2]Dept. of Neurosci. and Brain Technologies, Inst. Italiano di Tecnologia, Genova, Italy; [3]Inst. Neurosci. del CNR, Pisa, Italy

Abstract: The epileptic seizure reflects an episode of abnormal activity that involves neuronal ensembles from large portions of the brain. In experimental models, seizure onset is characterized by an intense activity in GABAergic interneurons followed by a rapid recruitment

of principal neurons that fire intensively, but with a low synchrony, i.e., the tonic phase, and by the late phase, i.e., the clonic phase, composed of highly synchronous firing discharges in both principal neurons and interneurons. To gain insights into the role of a GABAergic interneuron subclass, i.e., the Pv interneurons, in epileptiform activities, we expressed the light-gated cation channel Channelrhodopsin-2 (ChR2) in Pv interneurons. We used optogenetic techniques in a model of focal seizures in temporal slice preparations that allows us to follow both the initiation and the progression of seizure-like discharges. We applied a light pulse stimulation (473 nm, 150 ms duration at 0.5 Hz) that induced a sustained firing in ChR2-expressing Pv interneurons from both the epileptogenic focus and the surrounding penumbra region while performing local field potential and patch-clamp recordings from layer V pyramidal neurons. We found that optogenetic activation of Pv interneurons during the clonic phase of evoked seizures, unexpectedly prolonged ictal duration (seizure duration in absence and presence of light stimulation respectively: 144 ± 17 s vs 194 ± 18 s; n = 16). We also found that afterdischarges (ADs) could initiate few milliseconds after the light pulse onset (362 out of 675 ADs from 9 ictals) suggesting a correlation between Pv interneuron activation and AD onset. Consistently, the synchronization of AD with light pulses progressively increased along with the ictal development and almost all events could become synchronized towards the end of the clonic phase (n = 9). The distribution analysis of the time intervals between two successive ADs revealed a large peak at 2 s corresponding to the 0.5 Hz light pulse stimulation frequency (number of peaks at 2 s in absence and presence of light stimulation respectively: 6.7 ± 1.3; n = 10 vs 28.5 ± 8.8; n = 9). Spectrograms from individual ictal events during light pulse stimulation also showed the emergence of a large signal power density at 0.5 Hz that could not be detected from ictal events in the absence of light stimulation (n = 7). In conclusion, our results indicate that the prolonged ictal duration that was observed upon optogenetic stimulation is possibly linked to a synchronization of the afterdischarges by activated Pv interneurons and suggest that synchronous activity in the Pv interneuron network may contribute to afterdischarge generation.

Title: Hyperexcitability of presubicular neurons in a rat model of Temporal Lobe Epilepsy

Authors: *S. ABBASI, S. KUMAR
Biomed. Sci., Florida State Univ., Tallahassee, FL

Abstract: Temporal Lobe Epilepsy (TLE) is the most common form of epilepsy in adults and is characterized by recurrent seizures originating in the temporal lobes. Evidence from patient and animal model studies suggests that several temporal lobe structures are affected by TLE, and contribute to seizure generation and propagation. This study looks at the impact TLE has on the presubiculum (PrS), a unique parahippocampal structure which both receives inputs from and sends projections to brain regions affected by TLE. We assessed the state of PrS in TLE using whole-cell electrophysiological recordings to determine which of the previously identified cell types become hyperexcitable in epileptic animals, and whether intrinsic and/or synaptic properties are altered in these neurons. We characterized cells based upon their action potential discharge profiles followed by unsupervised hierarchical clustering. PrS neurons from epileptic animals were divided into three groups consisting of Regular Spiking (RS), Irregular Spiking (IR) and Fast Adapting (FA). RS cells, the predominant cell-type encountered in PrS in both control and epileptic groups, and previously identified as sending long-range axonal projections to neighboring structures including medial entorhinal area, were the only group that was hyperexcitable. Alterations in intrinsic properties of RS cells supported an increased propensity for sustained firing of brief action potentials in rapid succession. Surprisingly, frequency of both spontaneous excitatory and inhibitory synaptic events in RS cells was reduced (49 and 38%, respectively), accompanied by amplitude reductions (23 and 40%, respectively). Further analysis of non-action potential dependent miniature currents (in TTX) led us to conclude that the reduced excitatory drive is likely due to a decrease in excitability of neurons which synapse directly onto RS cells and onto GABAergic interneurons that inhibit them under normal conditions. Alterations in physiology of individual PrS neurons from epileptic animals have not been examined in detail and our findings suggest that parahippocampal circuits, specifically in PrS, are altered, contributing to epileptogenesis of downstream structures including the medial entorhinal area.

Sci., Tehran, Iran, Islamic Republic of; [2]Egectrophysiology research center, Tehran, Iran, Islamic Republic of; [3]Physiol., Tehran, Iran, Islamic Republic of; [4]Iran university of medical sciences, Tehran, Iran, Islamic Republic of; [5]Shahed university, Tehran, Iran, Islamic Republic of

Abstract: Epilepsy is a chronic neurological condition that characterized by unpredictable and recurrent involuntary seizures. Temporal lobe epilepsy (TLE) is common and can be lead to hippocampal sclerosis and cell dead in different area of hippocampus. Between involved mechanisms, oxidative stress plays an essential role in the pathogenesis of epilepsy and it seems that antioxidants can prevent epilepsy-related disorders. Therefore, we evaluated the effect of Thymoquinone (TQ), as an antioxidant, on kainic acid-induced temporal lobe epilepsy in male rat. Male Wistar rats were randomly divided into four groups: sham, sham+TQ (10 mg/kg), kainic acid (4 μg intra-hippocampal), kainic acid+TQ (5 and 10 mg/kg). We evaluated the antiepileptic effect of TQ using behavioral and histological evidence and electrophysiological (iEEG) recording. Our results showed that induced and spontaneously seizures and the amplitude of iEEG were increased in kainic acid group ($p=0.0001$ and $p=0.03$, respectively). Also, kainic acid administration led to increase mossy fiber sprouting in dentate gyrus and decrease neurons in hilar, CA1 and CA3 regions of hippocampus ($p<0.0001$). Immunohistological results showed that kainic acid administration caused to increase GFAP positive cells in astrocytes and the number of hippocampal glutamate receptors compared to sham group ($p<0.01$ and $p<0.0001$, respectively), while it has no significant effect on number of iNOS positive cells. Oxidative stress assessment showed that kainic acid administration led to decrease SOD enzyme activity ($p<0.0002$) and increase lipid peroxidation ($p<0.0001$) and nitrite levels ($p<0.0001$) in hippocampus. TQ pretreatment in epileptic rats showed that TQ prevented spontaneously seizures incidence. Meanwhile, TQ pretreatment decreased neuron loss in hilar, CA1 and CA3 regions, mossy fiber sprouting in dentate gyrus, hippocampal glutamate receptors, and GFAP positive cells in stratum lucidum. On the other hand, thymoquinone administration caused to intensify SOD enzyme activity and decrease lipid peroxidation and nitrite levels in hippocampus ($P<0.01$-$P<0.0001$). Collectively, the results of this study revealed that TQ pretreatment could attenuate some of behavioral and histological disorders via prevention of astrogliosis, oxidative stress and glutamate toxicity related to TLE.

Title: Early capillary constriction impedes collateral blood flow to the acute stroke penumbra

Authors: *Z. J. TAYLOR, A. N. WATSON, A. Y. SHIH
Neurosciences, Med. Univ. of South Carolina, Charleston, SC

Abstract: All blood that flows through the cerebral arteries must pass through dense and narrow capillaries. Mechanisms that resist capillary flow will reduce blood supply to the brain and thus exacerbate stroke outcome (del Zoppo and Machubi, J Cereb. Blood Flow Metab. 2003, 23(8):879-94). Numerous mechanisms of capillary resistance have been described, including intravascular obstruction by leukocytes or thrombi, and extrinsic compression by contractile pericytes and swelling of astrocytic endfeet. However, the prevalence and impact of these events remain poorly understood *in vivo*. We used two-photon microscopy to study the degradation of capillary function during ischemia in the mouse cortex. We generated columnar strokes, spanning >1 mm in diameter, by photo-thrombotic occlusion of single, high flux penetrating arterioles (Shih et al. Nature Neuroscience, 2013, 16(1):55-63). These strokes grew radially outward over the course of 24 hours, providing an ideal means to visualize the evolving core-penumbra interface. Unexpectedly, rather than provide collateral blood flow to limit damage, penetrating arterioles that neighbored the occluded vessel slowly stagnated. To understand the source of this flow resistance, we tracked ~200 capillaries underlying these arterioles (7 mice) and measured their lumen diameter, the presence of intraluminal obstruction, and blood-brain barrier breakdown over 8 hours. Capillary constriction, defined as a decrease to less that 80% of pre-stroke diameter, was the earliest pathological event detected, affecting capillaries within 15 minutes of stroke onset, and progressively worsening until 4 hours post-occlusion. An increase in lumen obstruction lagged closely behind constriction. Indeed, individual capillaries that constricted at an early stage during stroke (0-4 hours post-occlusion) were twice as likely to lose

flow at a later stage (4-8 hours), suggesting that constriction was a key initiator of blood flow impedance in the penumbra. Blood-brain barrier leakage occurred only after capillary flow completely ceased, and was a relatively late event. Astrocyte endfoot swelling was not involved in this phenomenon, because constriction persisted in syntrophin knockout mice, which exhibit reduced edema due to mis-localization of the water channel aquaporin-4. In summary, early capillary constriction initiates a feed-forward spread of ischemia by impeding flow through the domains of neighboring penetrating arterioles during expansion of the acute stroke core.

Title: Cofilin: A new target for the treatment of ischemic stroke

Authors: *Q. M. ALHADIDI, Z. A. SHAH
Medicinal and Bioloogical Chem., Univ. of Toledo, Toledo, OH

Abstract: Cofilin is a cytoskeleton-associated protein that plays an important role in controlling actin dynamics and turnover. In the central nervous system, cofilin regulates neurite outgrowth and development and Schwann cell myelination. However, studies have shown that cofilin activation and cofilin-actin rod formation is involved in many neurodegenerative diseases such as Alzheimer Disease and Huntington Disease. In the present study, we conducted *in vitro* experiments to evaluate the role of cofilin in ischemia reperfusion using primary cortical neurons and the oxygen and glucose deprivation (OGD) model of ischemia. Primary cortical neurons were subjected to ischemia (1h OGD and 24 h reperfusion) and compared with sham treatment (no OGD). As compared to sham neurons, we observed elevated levels of cofilin in neurons subjected to OGD. Next, we used the siRNA technique to knock down cofilin and delineate the

role of elevated cofilin in ischemic paradigms. The outcomes were measured by neuronal viability (MTT assay) and caspase 3 activity, a component of the apoptotic pathway. Cofilin knockdown neurons subjected to OGD showed significantly increased neuronal viability compared to control neurons (treated with scrambled siRNA and subjected to OGD). To determine the plausible signaling mechanism and cofilin's interaction with the apoptotic pathway, we evaluated the expression levels of caspase 3 in neurons co-treated with cofilin siRNA and OGD. Compared to control neurons, expression levels of caspase 3 were significantly lower in cofilin knockdown neurons after OGD. Collectively, these data highlight a major role of cofilin in mediating apoptotic neuronal death in ischemia, and targeting this protein could open the doors toward a new group of neuroprotective agents that can aid in the cure of ischemic stroke. The study was partly funded by a grant from NIH (R00AT004197), Higher Committee for Education Development in Iraq (HCED) and start-up funds from The University of Toledo to ZAS.

Title: The effect of age on the immune cohort in the ischemic cortex of female Sprague-Dawley rats at 48 hours post-stroke

Authors: A. O'KOREEH[1], S. BAKE[3], R. C. ALANIZ[3], *F. SOHRABJI[2]
[1]Women's Hlth. in Neurosci Program, Texas A&M Syst. HSC, Bryan, TX; [2]Women's Hlth. in Neurosci Program, Texas A&M Syst. HSC, COLLEGE STA, TX; [3]Texas A&M Hlth. Sci. Ctr., Bryan, TX

Abstract: Our previous research has shown that adult female rats sustain smaller infarcts as compared to middle-aged female rats (Selvamani and Sohrabji, 2010). This is accompanied by increased permeability of the blood brain barrier in the middle-aged females as compared to adult females. Blood brain barrier permeability can result in infiltration of peripheral immune cells, such as T and B cells, and cytotoxic products, that can accelerate neuronal damage. In the

present study we tested the hypothesis that the proportion of T and B cells would be elevated in the ischemic cortex of middle-aged females as compared to adult females. Adult (6 month old) and middle aged (10-12 month old) Sprague Dawley rats were subject to ischemic stroke via stereotaxic injections of endothelin-1 (ET-1) to the middle cerebral artery. Forty-eight hours later, the ischemic tissue was homogenized in X-VIVO media and resuspended in 30% Percoll (Sigma-Aldrich). The suspension was layered on a 70% percoll solution with HBSS and centrifuged at 700g for 30 minutes. The supernatant containing myelin and other debris was removed via pipette. Cells in the interface layer were collected and washed in X-VIVO (Lonza, Basel, Switzerland). Spleens from each animal were pulverized and treated with red blood cell (RBC) lysis buffer, washed in X-VIVO, filtered with a pre-separation MACS 70 μm filter. (Miltenyi Biotec, San Diego, CA). Cells were stained for CD4 (general marker of T-cells), CD5+CD1d (general surface markers for B regulatory cells), CD3 and CD161 (general marker for NK cells). No age differences were seen in CD4+ and CD5+/CD1d+ cells in the spleen, however, middle aged females, as compared to adult females, had significantly higher percentage of CD4+ cells (18.6%+5.16 vs 8.63%+2.94)and CD5+ CD1d+ (11.21%+1.2 vs 3.00%+2.3) The older females thus had a 2-fold increase in CD4+ cells and a 3.5-fold increase in CD5+/CD1d+ double-positive cells, suggesting greater infiltration of immune cells in middle aged females, consistent with greater ischemic damage seen in this group. In addition, small cohorts of CD161+CD3- cells were also observed. Adult females had a 7-fold greater proportion of CD161+CD3- as compared to older females (0.54%+0.1) vs 0.077%+067). Although NK cells increase infarct volume (Gan, et. al. 2014), they also mediate infection and have anti-viral functions. Post stroke infections are well known, especially in the elderly and reduced expression of this cell type in the middle aged female population may contribute to the worse outcome seen in this group.

Abstract: Ischemic stroke remains one of the major causes of death and disability worldwide. Treatment modalities for improving the functional recovery remain limited in clinical practice despite extensive efforts in stroke research. Transgenic mouse stroke models add in better understanding the injury mechanisms in stroke and identifying potential therapeutic targets. Here, we generated a mouse transient ischemic stroke model using an intraluminal suture to block the middle cerebral artery and verified the blockage of blood flow using indocyanine green coupled with near infra-red radiation. The survival rate was as low as 10% in the groups of animals not treated with antibiotics while administration of prophylactic antibiotics significantly increased the survival rate upto 60%. Ischemic injury resulted in severe histological as well as functional impairments in animals but recovered spontaneously starting from the second week. Among various behavior tests, pole tests, neurological severity score tests, and body weight changes remained reliable up to 4 weeks, whereas rotarod and corner tests became less distinctive to assess the severity of ischemic injury. In conclusion, we have developed an improved approach which allows us to investigate the role of the cell death-related genes in the disease progression using genetically modified mice and to evaluate the modes of action of candidate drugs.

Title: Role of autophagy in cerebral ischemia-reperfusion injury in adult rats

Authors: *P. S. BHARTI, T. K. DAS
Anat., All India Inst. of Med. Sci., New Delhi, India

Abstract: Cerebral ischemia is a major causative factor of stroke, which is one of the leading causes of death and adult disability worldwide. Ischemic injury is initiated immediately after interruption of cerebral blood flow and neuronal death is the ultimate result of this condition. The ischemic insult has many pathophysiological consequences in which necrotic and apoptotic cell deaths are final outcomes. In the recent years, many studies have shown the importance of other types of cell deaths in ischemic-reperfusion (I/R) injuries, like autophagy and necroptosis. It has been reported that autophagy has great significance in pathological outcome, ischemic preconditioning and development of other therapeutics. In this study, we evaluated expression patterns of autophagic proteins LC3, Beclin-1 and Rubicon (KIAA0226) and ultrastructural morphology of cerebral I/R injury in rat middle cerebral artery (MCA) occlusion model. Adult Wistar male rats (200-250 gms) were used in two groups with sham-controls. Right MCA occlusion was performed and the occlusion period was 2 hours. Chloroquine (CQ) (25mg/Kg i.p.) was administered in one group 1 hour prior to surgery. Rats were sacrificed after 24 hours of surgery and brains were procured and processed for histological and western blotting experiments. Brain infarct was measured by 2,3,5-Triphenyltetrazolium chloride staining. For immunohistochemical and western blotting experiments LC3, Beclin-1 and Rubicon (KIAA0226) primary antibodies were used. We also have performed transmission electron microscopy to observe ultrastructural morphology of autophagy and cerebral I/R injury. In our results, LC3 and Beclin-1 expressions were increased significantly (LC3 is an autophagosomal marker protein and Beclin-1 is an autophagy initiator), whereas, expressions of Rubicon is decreased as it plays a role in inhibition of autophagy initiation in MCAo group. After CQ administration, it was observed that expression of LC3 was significantly more increased compared to MCAo group whereas expressions of Beclin-1 and Rubicon have not been changed significantly compared to LC3. The increase in expression of LC3 after CQ administration is due to accumulation of autophagosomes which could not fuse with lysosomes as in normal autophagic pathway. The accumulation and ultrastructural morphology of autophagosomes and autolysosomes in cytosol were further confirmed with transmission electron-microscopy. The present study concludes that there is an increase in autophagic proteins (LC3 and Beclin-1) and thus overall autophagy after cerebral I/R injury which can play an important role in developing therapeutics.

Title: The beneficial effect of cooling on male and female rats with experimentally induced hypoxia ischemia

Authors: *A. L. SMITH[1], H. GARBUS[2], T. S. ROSENKRANTZ[3], R. H. FITCH[2]
[1]Dept. of Psychology, [2]Univ. of Connecticut, Storrs, CT; [3]Univ. of Connecticut Heath Ctr., Farmington, CT

Abstract: Common events related to premature birth or term birth complications include reduced oxygen and/or blood flow to the brain (collectively termed hypoxia-ischemia; HI). HI can lead to varying degrees of tissue loss, as well as subsequent cognitive/behavioral deficits. For example, early HI insult can lead to later motor, learning/memory, or auditory processing impairments. Interestingly, clinical data suggest sex differences in outcomes following early HI, with males exhibiting more detrimental effects compared to females with similar damage (Smith et al., 2014). Clinically, hypothermia (i.e., head/whole body cooling) has been used as a neuroprotectant following an HI injury. Cooling may block aspects of apoptosis, thus impeding the downstream effects leading to brain injury. However, little is known about the relative ameliorative effects of cooling as a function of sex. To assess whether the neuroprotective effects of cooling are more beneficial to one sex, the current study used a postnatal day (P) 7 rodent model of HI injury (roughly equating to injury in a term infant). Based on previous data indicating better outcomes in female rats on a rapid auditory processing (RAP) task and a spatial learning task following early HI injury (suggesting an intrinsic female protection), we hypothesized that female P7 HI rats would benefit more from cooling compared to males. Alternatively, we hypothesized that rats kept at hyperthermic temperatures would show enhanced HI effects that might over-ride intrinsic female protection and mask sex differences. We sought to test these hypotheses using rota-rod, auditory discrimination, and spatial and non-spatial learning tasks. Preliminary results revealed a significant benefit of cooling in female HI rats on the rota-rod task, with male HI rats only marginally protected by cooling. However, other results from auditory and learning/memory tasks suggest that cooling was equally beneficial to both male and female rats with HI injury. Taken together, our data suggest that cooling in general appears to benefit both sexes from the deleterious effects of HI injury, but task and sex specific patterns will be presented in more detail. Current findings are consistent with previous studies in our lab, specifically indicating a female advantage following early injury on some but not all behavioral tasks (Smith et al., 2014).

Abstract: Stroke is one of the leading causes of death and disability worldwide. The initial triggers in stroke are deceptively simple: loss of blood flow and energy supply which leads to rapid neuronal cell death. However the subsequent pathophysiology is highly complex by multifactorial cascade of molecular mechanisms. Various mouse and human stroke studies have shown that expression of specific microRNAs (miRNAs) is either increased or decreased in post-stroke brain and serum. miRNAs are especially important candidates for stroke therapeutics because of their ability to simultaneously regulate many target genes. The goal of this study is to analyze expression of three miRNA (miR-34a, miR-132 and miR 146a) profiles in serum samples of ischemic stroke patients over the course of 90 days following recovery, as well as in serum and brain of transient Middle Cerebral Arterial Occlusion (tMCAO) mice by qRT-PCR. All three miRNAs were significantly increased 30 days after stroke in a patient's serum who survived, but no change of the miRNAs was observed in those who did not survive (after 30 days). Additionally, in mouse serum following tMCAO, miR-34a levels were increased by 6 hrs post-stroke, while miR-132 levels were increased by 24 hrs. Interestingly all of the miRNAs levels were increased in the brain of tMCAO mice by 24 hrs but the differences disappeared by 48 hrs. These results suggest that increased expression of these miRNAs may inhibit some of their target genes involved in post stroke neuronal death.

Title: Diet-induced obesity induces angiogenesis and worsens post-ischemic recovery following permanent ischemia

Authors: ***J. TULSULKAR**, S. NADA, B. SLOTTERBECK, M. MCINERNEY, Z. SHAH
Medicinal biochemistry, Univ. of Toledo, Toledo, OH

Abstract: Obesity-induced diabetes has substantially increased over the years and has become one of the risk factors for stroke. It is well-documented that obesity accelerates neuronal damage and induces post-ischemic seizures. An obesity-related increase in blood glucose levels leads to type-2 diabetes and hypertension, the number one risk factor for stroke. Diabetes also leads to excessive angiogenesis, causing diabetic retinopathy and impaired neovascularization which further result in coronary and peripheral complications. In this study, we investigated the influence of diet-induced obesity and diabetes on permanent ischemic stroke. Age-matched adult male C57/Bl6 mice were treated with a high fat, high carbohydrate diet (HFCD) or a normal diet (ND) for six months, and fasting blood glucose levels were monitored; these were observed to be higher in HFCD as compared to ND mice at the time of experimental stroke. ND and HFCD-treated mice were subjected to permanent distal middle cerebral artery occlusion (pMCAO) and sacrificed after 7 days. Infarct volume analysis showed no differences in HFCD compared to ND group, possibly due to higher neovascularization and collateral flow in HFCD mice. However, neurological deficits (NDS) were significantly higher in the HFCD group compared to the ND group. Cortical protein expression levels revealed that HFCD mice had significantly lower expression of GSK-3β, a key component in the Wnt signaling pathway. Blood vessel growth is

mainly due to the expression of a large amount of Sirt1 in the vasculature, which was observed to be significantly overexpressed in the HFCD group compared to the ND group. To investigate the cell death mechanisms in the HFCD group, we investigated axonal damage marker, amyloid precursor protein (APP) and apoptosis inducing factor (AIF) and observed a higher expression of APP in the HFCD group compared to the ND group. Translocation of AIF to the nucleus was observed in both the HFCD and ND groups, but HFCD mice showed a higher expression of AIF in the nucleus, suggesting that apoptotic processes are active even after 7 days of permanent ischemia. Together, our result suggests that overexpression of Sirt1 in the HFCD group results in neovascularization, and reduced post-stroke recovery is possibly due to impaired Wnt signaling and active apoptosis.

Title: Pin1-mediated Notch activation worsens brain damage and functional outcome in ischemic stroke

Authors: *S.-H. BAIK, Y. CHOI, U. YUN, Y. JANG, J. JEONG, D.-G. JO
Sch. of Pharm., Sungkyunkwan Univ., Suwon, Korea, Republic of

Abstract: Pin1, a peptidyl-prolyl cis/trans isomerase, is the enzyme known to catalyze a number of substrates containing phosphorylated Ser/Thr motif. Pin1 induces conformational change of target proteins and regulates cellular responses. Recently findings suggest that Pin1 has been related to certain disease. Here we found that role of Pin1 in ischemic stroke using mice affected by focal ischemia-reperfusion. Pin1 stimulates Notch1 activation and its pro-apoptotic function following ischemic stroke. Pin1 heterozygote (+/-) and knockout (-/-) mice, each showed reduced brain damage and improved functional outcomes in a model of focal ischemic stroke. These results suggest that Pin1 contributes to the pathogenesis of ischemic stroke and that inhibition of Pin1 is a novel approach for treating ischemic stroke.

Title: Effects of anoxia or post mortem changes?

Authors: ***K. SKOLD**[1,2], H. ALM[3], M. BORÉN[1], B. SCHOLZ[4]
[1]Denator AB, Uppsala, Sweden; [2]Dept. of Med. Sciences, Cancer Pharmacol. and Computat. Med., Uppsala, Sweden; [3]Leibniz Res. Inst. for Envrn. Med., Düsseldorf, Germany; [4]Dept. of Pharmaceut. Biosciences, Drug Safety and Toxicology, Uppsala, Sweden

Abstract: Aim A combined literature search and experimental approach has been performed to investigate the likeness of neural protein patterns between ischemia and those induced by the post mortem interval. Reverse phase protein arrays (RPPA) were used to confirm the consequences of different lengths of bioreaction termination intervals (BTI, also known as post-mortem intervals) on the phosphorylation levels of eleven known signal transduction proteins. Introduction There are similarities between the state of ischemia and the acute biological conditions introduced in animals and humans after death. The study of ischemia is often performed by cutting of the blood supply to the area that to be investigated that leads to subsequent hypoxia and anoxia. To ensure cell survival, a constant supply of oxygen and nutrients is needed. Without oxygen, oxidative phosphorylation and subsequently adenosine trisphosphate (ATP) production is halted, causing deficiencies in cell functions. This can in some extent be compared to regular sample handling. The study of tissues samples from patients or model organisms usually exposes samples to a certain time of oxygen and nutrient depletion before homogenization and enzyme inactivation occurs. The advancement of protein analysis techniques provides new ways of studying the protein content in various tissues and cell cultures. In the current study RPPA was used to study the influence from post-sampling BTI on the phosphotylation levels of several signal transduction proteins associated with ischemia in the brain. Results Eleven different well studied protein phosphorylations were analyzed in mouse striatum. The tissue were stored at the bench for 0, 10, 30 minutes before frozen to simulate different post-sampling BTIs. All phosphorylations rapidly decreased to the first time point

whereas there were almost no differences between 10 and 30 minutes. CamKII-Thr286p, ERK1/2-Thr202/185,Tyr204/187 and ATF2_Thr71p were found to be particular sensitive to the initial 10 min of post-sampling BTI. The findings indicate that the animal and sample handling in ischemia research is of great importance for mechanistic data interpretation. It further seems to imply that even small variation in experimental sample handling may lead to increased sample variation.

Title: Proteomics of hypothalamus and pituitary in brain ischemia

Authors: J. RICE[1,2], L. CAO[1], T. YANG[1], R. SIMON[1], *A. ZHOU[1]
[1]Morehouse Sch. of Med., Atlanta, GA; [2]Spelman Col., Atlanta, GA

Abstract: Molecular mechanisms that underlie systemic responses to focal brain ischemia are poorly understood. In parallel with the neuroanatomic pathways of the CNS and PNS, the hypothalamus-pituitary axis plays a pivotal role in neuroendocrine regulation of systemic responses to stroke. Accordingly, here, we characterized proteomic changes in the hypothalamus (HT) and pituitary (PI) of mice subjected to different degrees of focal brain ischemia. Transient focal cerebral ischemia was induced in adult, male mice by middle cerebral artery occlusion (MCAO) with the suture method followed by reperfusion. Three groups of animals were subjected to sham operation, 30 min MCAO (inducing limited cortical injury) and 60 min MCAO (resulting in hemispheric infarct), respectively. Proteins were extracted from HT and PI tissues and analyzed by a quantitative mass spectrometry-based proteomic approach. Proteins that showed a change in quantities after 30 min or 60 min MCAO, when compared with that in sham controls, were analyzed for their bioinformatics characteristics with the assistance of the

MetaCore program, and compared between the 30 min and 60 min MCAO groups. A total of 952 and 785 proteins were identified and quantified in the HT and PI, respectively. We found that, in both the HT and PI, both anatomically distant from the MCAO territory, the proteomic changes in response to 30 min or 60 min MCAO were largely different, as demonstrated by the association of regulated proteins with different biological processes. Among regulated biological processes, only about half were common between 30 min and 60 min MCAO groups. Similar results have been seen in proteomic changes in several peripheral organs (Zhou et al., unpublished results). Interestingly, following a 30 min but not 60 min MCAO, a significant decrease in neuropeptide biosynthesis-related biological processes was seen in the PI. These results suggest that, in the HT-PI axis, neuroendocrine changes in response to different degrees of focal brain ischemia may involve different cellular regulatory mechanisms, which in turn may determine different systemic changes after brain ischemia.

Title: Splenic monocytes contribute to cerebral ischemic tolerance induced by LPS

Authors: *C. BENAKIS, L. GARCIA-BONILLA, D. BREA, J. MOORE, C. IADECOLA, J. ANRATHER
The Feil Family Brain and Mind Res. Inst., Weill Cornell Med. Col., New York, NY

Abstract: Administration of a sub-lethal dose of the endotoxin lipopolysaccharide (LPS) renders the brain tolerant to a subsequent ischemic insult (preconditioning) [Nat Neurosci 14, 1363, 2011]. Although it is well established that reprogramming of the immune system plays a role, the immune cells involved in the induction of the tolerance remain to be defined. Given the prominent role of monocytes/macrophages as endotoxin sensors and the contribution of splenic

monocytes to post-ischemic inflammation [Science 325, 612, 2009], we tested the hypothesis that LPS preconditioning involves activation and mobilization of splenic monocytes. C57Bl/6 male mice (age 7 weeks) were treated with either LPS (dose ≤ 0.5mg/kg; i.p.) or saline (vehicle; Veh) and flow cytometry was performed on brain, spleen and blood cells after 24, 48 and 72 hrs (n=8/group). LPS increased the proportion of monocytes in the blood at all time points, e.g. at 24 hrs: LPS, 23±3%; Veh, 7±4% of total leukocytes ($p<0.05$; mean±SD), while in the spleen the proportion of monocytes was elevated only at 48 and 72 hrs (48 hrs: LPS, 11±6%; Veh, 3±1%; $p<0.05$). Consistent with a mobilization of splenic inflammatory monocytes, LPS increased $Ly6C^{high}$ monocytes in the blood at 24 hrs (LPS: 63±5%; Veh: 51±5% of total monocytes), and reduced $Ly6C^{high}$ monocytes in the spleen (48 hrs: LPS, 21±3%; Veh, 30±7%; $p<0.05$). In brain, LPS increased the total number of monocytes by 3.9±0.7 folds at 24 hrs, most of which were inflammatory (LPS: 66±18%; Veh: 40±4% of brain monocytes; $p<0.05$). To examine the contribution of splenic monocytes in LPS preconditioning, splenectomy or sham surgery was performed (n=5-10/group). Two weeks later, mice were treated with LPS or Veh and were subjected to transient middle cerebral artery occlusion 24 hrs later. Infarct volume was measured 72 hrs after ischemia. After Veh-treatment, infarct size was comparable in splenectomized (57±19 mm^3) or sham-operated mice (52±15 mm^3; $p>0.05$). However, after LPS, the neuroprotective effect was more marked in sham-operated (21±9 mm^3) than in splenectomized mice (39±23 mm^3; $p=0.066$). Splenectomy had no effect on LPS-induced brain monocyte recruitment (984±443 vs.1324±745 cells in controls, $p>0.05$) but reduced the percentage of $Ly6C^{high}$ cells (splenectomy: 45±6; control: 66±18%; $p<0.05$). The data suggest that splenic inflammatory monocytes are critical for the full expression of the preconditioning effects of LPS. Furthermore, the findings unveil a previously unrecognized role of splenic monocytes in the outcome of cerebral ischemia and suggest new therapeutic approaches based on modulation of peripheral monocyte populations.

Title: Diet and stroke: Expression of genes that modulate inflammation and neuronal remodeling in the adult and aged male rat cerebral cortex

Authors: *E. D. GRISLEY[1,2], T. REHNBERG[1,2], J. A. MACLEAN, II[1], W. J. BANZ[3], D. N. BUTTEIGER[4], J. L. CHEATWOOD[2]
[1]Physiol., [2]Anat., SIU Sch. of Med., Carbondale, IL; [3]Animal Science, Food, and Nutr., Southern Illinois Univ., Carbondale, IL; [4]Dupont Nutr. and Hlth., St. Louis, MO

Abstract: Nearly 800,000 Americans are stricken by ischemic stroke each year. Other than care with post stroke rehabilitation there are no specific treatments for improving functional recovery. To improve the recovery of stroke patients we are investigating anti-inflammatory, anti-apoptotic, and neuronal remodeling pathways. Estrogen receptor activators are known to be neuroprotective by initiating pathways through ERβ and ERα. The bioactive soy isoflavones, daidzein and genistein, do bind to these estrogen receptors. However, this binding alone is not sufficient to explain the ability of soy-based diets and purified isoflavones to reduce inflammation and improve neuroprotection and recovery after stroke. Herein, we focused on the PPARγ, ARG1, 14-3-3ε, SIRT1, GAP43, and Synaptophysin pathways to test the hypothesis that diets containing soy isoflavones and/or soy protein isolate will reduce inflammation and promote the expression of neuronal plasticity markers following stroke in adult and aged rats via these mechanisms. Adult and aged male Hooded Long Evans rats were fed a semi-purified diet of either 1) Sodium Caseinate (CAS), 2) Sodium Caseinate plus the isoflavones daidzein and genistein (CAS+ISO), or 3) Soy Protein Isolate (SPI) for two weeks prior to middle cerebral artery occlusion (MCAO). Permanent unilateral MCAO was performed and tissue was collected from both hemispheres at Day +3 (N=6/group) and Day +7 (N=6/group). Control (Day 0) animals (N=4/group) received no MCAO. Rats were maintained on their assigned diet throughout the experiment. RNA was extracted and cDNA synthesized for qPCR reaction. All data were normalized to GAPDH via the ΔΔCt method. qPCR analyses of the contralateral and ipsilateral brain tissue did not show a statistical change in relative mRNA level for any of the genes examined to this point between any of the diet groups at any post-stroke time point observed so far ($p<0.05$). Results are pending for analyses of additional genes of interest.

Title: Ethyl pyruvate ameliorates 3-nitropropionic acid-induced striatal toxicity through anti-neuronal cell death and anti-inflammatory mechanisms

Authors: ***M. JANG**[1,2], M. LEE[1], I.-H. CHO[2]
[1]Dept. of Anat., Kyung Hee Uni., Seoul, Korea, Republic of; [2]Kyung Hee Univ. BK21 plus Korean medicine science center, Seoul, Korea, Republic of

Abstract: The potential neuroprotective value of ethyl pyruvate (EP) for the treatment of the striatal toxicity is largely unknown. We investigated whether EP promotes the survival of striatal neurons in a 3-nitropropionic acid (3-NP)-induced mouse model of Huntington's disease (HD). EP (5, 10, 20, and 40mg/kg/day, i.p.) was daily injected from 30min before 3-NP intoxication (pretreatment) and from onset/progression/peak point of neurological impairment by 3-NP intoxication. EP produced a neuroprotective effect in dose- and time-dependant manners. EP pretreatment of 40mg/kg/day produced the best neuroprotective effect among other conditions. Pretreatment of EP significantly attenuated neurological impairment and lethality and prevented formation of lesion area and neuronal loss in the striatum after 3-NP intoxication. This neuroprotection afforded by EP was associated with the suppression of succinate dehydrogenase activity, apoptosis, and microglial activation. The suppressive effect of EP corresponded to the down-regulation of mitogen-activated protein kinases (MAPKs) and nuclear factor-kappa B (NF-κB) signal pathways, and mRNA expression of inflammatory mediators including tumor necrosis factor-alpha, interleukin (IL)-1β, IL-6, inducible nitric oxide synthase, and cyclooxygenase-2 in the striatum after 3-NP intoxication. Interestingly, the intrathecal introduction of inhibitors MAPKs and NF-κB into control mice decreased the lethality after 3-NP intoxication. Our findings indicate that EP may effectively alleviate 3-NP-induced striatal toxicity by inhibition of the MAPKs and NF-κB pathways in the striatum, and that EP has a wide therapeutic window, suggesting that EP may have therapeutic value in the treatment of aspects of HD's disease related to inflammation.

Title: Exosomes from IFNγ-stimulated dendritic cells mitigate hypomyelination from hypoxic-ischemic injury modeled in brain slice cultures

Authors: *R. P. KRAIG, A. D. PUSIC, K. M. PUSIC
Neurol., Univ. of Chicago, CHICAGO, IL

Abstract: Perinatal hypoxic-ischemic brain injury (HI) is a major cause of mortality and persistent morbidity (1) that includes cerebral palsy, cognitive dysfunction, and epilepsy (2). Though no effective pharmacological agents to reduce these birth-related injuries are in use, non-pharmacological stimuli from environmental enrichment (EE) after HI improves brain function (3). However, EE requires sufficient infant maturation for participation. Our goal is to identify/define the mechanisms by which EE improves brain function, to jump-start this effect. Work from our lab demonstrates that exposure to EE promotes the release of exosomes that promote myelination. These exosomes also improve remyelination following acute demyelination of slice cultures by promoting oligodendrocyte precursor differentiation into myelin producing cells (4). This work was extended to show that IFNγ-stimulated dendritic cells (IFNγ-DC-Exos) can be used to generate exosomes that are similarly therapeutic *ex vivo*. (5). Here, we extend use of these exosomes to HI, another disease involving loss of myelin (6). Hippocampal brain slices were cultured from P10 Wistar rats, and transferred to a serum-free media at P17 to eliminate protective effects of horse serum. Ischemic injury was modeled using a 90 minute epoch of oxygen-glucose deprivation (OGD). OGD-exposed slices were then treated with IFNγ-DC-Exos or left untreated and allowed to recover. Three days post-treatment, slices (n=6/group) exposed to OGD alone showed a significant (p=0.002) reduction in myelin basic protein (MBP; used here as a proxy for myelin). In contrast, levels of MBP in slices treated with 100 μg of IFNγ-DC-Exos did not significantly differ from that of pre-OGD controls. . Electron micrographs taken at 7 days after OGD exposure confirmed this protective effect. Exosomes have the additional benefit of low immunogenicity, and do not require an additional vehicle for delivery. There is evidence that nasal administration allows passage of agents across the blood brain barrier to the CNS (7). Indeed, our lab has already demonstrated that nasal administration of IFNγ-DC-Exos can significantly increase CNS myelination (5). Thus, this proof-of-principle study suggests that IFNγ-DC-Exos may be a promising therapeutic for treatment of perinatal HI.

Abstract: There is heightened interest in the field of stroke recovery as there is need for agents that would prevent the debilitating effects of the disorder, thereby tremendously reducing the societal and economic costs associated with it. We report the isolation of two flavonoids_RUA1 & RUA2_from *Rumex aquaticus* and their neuroprotective effects in the oxygen-glucose deprivation (OGD) model of *in vitro* cerebral ischemia in rat pheochromocytoma (PC12) cells. Bioassay-guided fractionation of the ethyl-acetate extract of *Rumex aquaticus* L. afforded the isolation of quercetin-3-*O*-galactoside and quercetin-3-*O*-arabinoside. The structures of compounds were established on the basis of spectroscopic analyses (UV, MS and NMR). Both compounds were isolated for the first time from this species. We found that both RUA1 and RUA2 (10 μM) significantly improved cell survival in OGD conditions. Moreover, these compounds also increased neurite outgrowth in differentiated PC12 cells subjected to ischemic insult. Investigations on the cellular mechanism for the observed effect revealed that RUA1(10 μM) enhances the expression of synaptophysin_a marker of synapses, and an indicator of synaptic plasticity. Rapid restoration of neurological function following injury is paramount to

the prevention of debilitating consequences of ischemic stroke. This combination of neuroprotection and neuritogenic potential could be particularly useful in the recovery phase of stroke. It would be interesting to study the molecular mechanisms for the observed effects, and also if they would be effective in animal models of stroke.

Title: Pro-apoptotic function of Pin1-mediated Notch1 activation in cell death

Authors: *Y. CHOI, U. YUN, J. JEONG, Y. JANG
Sch. of Pharm., Sungkyunkwan Univ., Suwon, Korea, Republic of

Abstract: The peptidyl-prolyl cis/trans isomerase (PPIase) Pin1 regulates factors involved in control of cell growth and apoptosis. Notch1 is a transmembrane receptor that plays a crucial role in neurogenesis and neuronal death. The proteolytic cleavage of Notch1 by γ-secretase results in the liberation of the intracellular domain of Notch (NICD), which translocates into the nucleus and regulates gene expression and neuronal death in ischemic stroke. However, the mechanisms underlying Notch activation in ischemic stroke remain unclear. Our findings indicate that Pin1 stimulates Notch1 activation and its pro-apoptotic function following ischemic stroke. Overexpression of Pin1 increased γ-secretase activity and NICD levels, and potentiated neuronal cell death in ischemia-like condition. By contrast, knockdown using siRNA or knockout of Pin1 reduced the NICD level and ischemic neuronal cell death. These results suggest that Pin1 contributes to the pathogenesis of ischemic stroke by promoting Notch signaling.

Title: Ischemia-induced cell-type specific alterations in brain mitochondrial homeostasis

Authors: K. OWENS[1], J. H. LEE[1], S. GOURLEY[1], *T. KRISTIAN[2,1]
[1]Veterans Affairs Maryland Hlth. Ctr. Syst., Baltimore, MD; [2]Dept Anesthesiol, Univ. Maryland Sch. Med., BALTIMORE, MD

Abstract: Mitochondrial homeostasis via mitochondrial dynamics and quality control is crucial to normal cellular functions. To study the cell-type specific changes in mitochondrial homeostasis following ischemic insult, we used our transgenic mouse model that expresses mitochondrially targeted yellow fluorescence protein (mito-eYFP) either in astrocytes or neurons. Both neuron-, and astrocyte-specific mito-eYFP expressing mice were subjected to transient 10 min global cerebral ischemia. Following 2, 4, 24 hours and 3 days of recovery, the mice were perfusion-fixed or hippocampal samples were collected for further analysis by western blots. By utilizing serial z-sectioning with a Zeiss confocal microscope, we examined the morphological alterations of the entire mitochondrial network within the whole cell. Images were taken from each sub-region of the hippocampus. At the designated recovery time points, we examined the localization and distribution of proteins that regulated fission, fusion and proteins that are involved in mitophagy mechanisms. Interestingly, we found that only neuronal mitochondria became heavily fragmented following ischemia. This intense fragmentation of neuronal mitochondria was observed at 2 hours of reperfusion and persisted during the whole 3 day recovery period in all hippocampal sub-regions. In both neurons and astrocytes, the total mitochondrial mass was decreased during reperfusion suggesting an activation of mitophagy. This notion was supported by dramatic increase in hippocampal PINK1 levels and co-localization of PARKIN, LC3 and lysosomal protein LAMP2 with mitochondria. At 2 hours of recovery, the PARKIN colocalization was observed only in the perinuclear region in both cell types. At 3 days of recovery, we also observed PARKIN co-localization with mitochondria located in astrocytic processes. Remarkably, in neurons, intracellular localization pattern of PARKIN did not change at later reperfusion times. Thus, only perinuclear mitochondria recruited PARKIN in hippocampal neurons. This data suggests that ischemic insult causes pathologic disturbances in mitochondrial homeostasis as reflected in massive fission preferentially of neuronal mitochondria. This is followed by activation of mitophagy in both neurons and astrocytes. In neurons, the mitophagy recruits mainly mitochondria localized in the perinuclear region. In astrocytes, the mitophagy also target peripheral mitochondria localized in processes at

3 days of recovery when the neuronal cell death is apparent in the CA1 sector of the hippocampus.

Title: The interaction between Notch-1 and HIF-1α enhances ischemic neuronal death

Authors: Y. CHOI, *D.-G. JO, U. YUN, Y. JANG, J. JEONG
Sch. of Pharm., Sungkyunkwan Univ., Suwon, Korea, Republic of

Abstract: Previous studies have shown that γ-secretase mediated Notch-1 signaling induces ischemic neuronal cell death, but the underlying mechanisms are poorly understood. Hypoxia inducible factor-1α (HIF-1α), a transcription factor of cellular adaption to hypoxia, can interact with Notch and modulate its signaling during hypoxic stress. We found that γ-secretase inhibitor and HIF-1α inhibitor protect primary cortical neurons under ischemia-like conditions, and combined inhibition of Notch-1 and HIF-1α further reduced neuronal cell death. HIF-1α and Notch-1 intracellular domain (NICD) are co-localized in the neuronal nucleus, and co-immunoprecipitated in cultured neurons and in brain tissue from mice subjected to focal ischemic stroke. Overexpression of NICD and HIF-1α in human neuroblastoma cells potentiated cell death under ischemic conditions, and a HIF-1α inhibitor rescued the cells. Knockdown of endogenous Notch-1 and HIF-1α using siRNA also decreased cell death under ischemia-like conditions. Finally, mice treated with the γ-secretase inhibitor and the HIF-1α inhibitor exhibited improved outcome and reduced brain injury after stroke. In conclusion, Our findings suggest that agents that target the Notch-1 and HIF-1α pathway may prove effective in reducing neuronal cell death and brain injury after ischemic stroke.

Title: Maged1 deficiency improves ischemic cell death

Authors: ***J. GAO**, L.-S. JU
Dept. of Neurobio., Nanjing Med. Univ., Jiangsu, China

Abstract: Maged1 is a member of the type II MAGE (melanoma antigen) family of proteins, which is well known to contribute to the p75NTR-dependent cell death. Recently, Maged1 has been reported to be involved in depression, impaired sexual behavior and memory in mice. However, the role of Maged1 in the ischemic cell death remains unknown. The aim of the present study was therefore to investigate whether Maged1 deficiency can protect neuron from ischemia-induced death. Focal cerebral ischemia was induced by middle cerebral artery occlusion (MACO) for 90 min. Infarct volumes and neurological scores were evaluated at 24 h after MACO. Neuronal apoptosis and the Bax/Bcl-2 ratio were also evaluated 24 h after reperfusion. Our results showed that MACO significantly enhanced neuronal expression of Maged1 in the ischemic penumbra 6 h after reperfusion. However, Maged1 deficiency increased infarct volume, decreased neurological outcome, and improved neuronal apoptosis following reperfusion. Moreover,in Maged1 knockout mic, we found the decreased levels of miR-200, which is showed to improve neural cell survival via prolyl-hydroxylase mRNA silencing and subsequent HIF-1α stabilization. In conclusion, Maged1 deficiency decreased miR-200 to improve cerebral ischemia.

Title: Neuroprotective effects of emodin against ischemia/reperfusion injury through inducing parkin expression *in vitro* and *in vivo*

Authors: *J.-H. LAI, ESQ
Taipei Med. Univ., Taipei, Taiwan

Abstract: **Introduction/Background** It is well recognized that ischemic stroke is a major cause of adult disability and death worldwide. Ischemia/reperfusion-induced injury can lead to irreversible cell damage and death. In recent studies, emodin has been reported to possess the antioxidative capability and protective effects in against myocardial ischemia/reperfusion injury. However, the underlying mechanism and neuroprotective function on rat middle cerebral artery occlusion model (MCAO) of ischemic stroke is still unknown. This study aimed to investigate the neuroprotective effects of emodin against oxygen-glucose deprivation/reperfusion (OGD/RP) damage on PC12 cells. **Materials and Methods** PC12 Cells were subjected to oxygen-glucose deprivation and treated with emodin. We further investigated neuroprotective effects of emodin in rat middle cerebral artery occlusion model. **Results** Results demonstrated that emodin reduced the infract volume and cells death in focal cerebral ischemia injury. The viability and ROS production of PC12 cells and glutamate release were restored by emodin treatment under an ischemiahypoxia environment. Emodin enhanced the Bcl-2, GLT-1 and Parkin expression, but suppressed Bax and Caspase 3 level through AKT/ERK-1/2 signaling pathway. **Discussion/Conclusions** The phosphorylation level of AKT and ERK-1/2 and the parkin expression were enhanced by emodin in a dose- and time- dependent manner. In summary, experimental findings indicated that emodin could induce the parkin for inhibiting neuronal apoptosis, ROS generation and depressing the release of glutamate toxicity via the AKT/ERK-1/2 signaling pathway. Furthermore, emodin could alleviate the injury of nerve cells to against ischemia/reperfusion-induced brain injury in rat models of middle cerebral artery (MCA) ligation. Parkin induced by Emodin has neuroprotective effects against ischemia/reperfusion injury both *in vitro* and *in vivo* through AKT and ERK-1/2 signaling pathway. Key words: Ischemia/reperfusion, MCAO, Emodin, Parkin, GLT-1

Title: Cerebral metabolic changes in chronic stroke, assessed by Magnetic Resonance Spectroscopy

Authors: *J. K. FERRIS[1,2], K. E. BROWN[3], C. S. MANG[3], K. P. WADDEN[3], M. R. BORICH[4], S. K. MEEHAN[5], L. A. BOYD[3]
[1]Brain Behaviour Lab., Vancouver, BC, Canada; [2]Univ. of British Columbia, Vancouver, BC, Canada; [3]Univ. of British columbia, Vancouver, BC, Canada; [4]Emory Univ., Atlanta, GA; [5]Univ. of Michigan, Ann Arbor, MI

Abstract: Background: Previous research has shown alterations in motor cortex excitability following chronic ischemic stroke, yet the neurochemical mechanisms underlying these changes remain poorly understood. MRS allows for *in vivo* examination of metabolite concentrations in target tissues. MRS may provide valuable information about metabolic changes occurring between the affected and unaffected hemisphere of the brain following an ischemic stroke. The primary objective of this study was to examine alterations to cerebral neurochemistry between cerebral hemispheres following chronic stroke, using magnetic resonance spectroscopy (MRS). **Methods**: 31 individuals with chronic ischemic stroke were recruited to participate (6 females 25 males, average age, average post-stroke duration: 62 months). All participants were experiencing some degree of hemiparesis. We assessed NAA, glutamate, myo-inositol and creatine concentrations with MRS in a 3T MR scanner, using LC model to extract metabolite concentrations. The voxel of interest was placed over the hand area of primary motor cortex. Upper extremity motor function was assessed with the Fugl-Meyer scale. **Results:** NAA, glutamate, and creatine concentrations were all significantly lower in ipsilesional primary motor cortex (NAA: $t = -3.549$, $p= 0.001$; Glu: $t= -4.416$, $p = 0.0001$; Cre: $t = -2.417$, $p = 0.022$). There was no difference in myo-inositol concentrations between hemipheres. There was a significant correlation of NAA in the affected hemisphere with Fugl-Meyer score ($r = 0.472$, $p = 0.007$), with no other correlations between metabolite concentrations and Fugl-Meyer score **Conclusions:** There appears to be several alterations to neurochemistry in the lesioned cerebral

hemisphere in chronic stroke. First, NAA, a marker of neuronal integrity, is reduced in M1 of the affected hemisphere, and this reduction in NAA is correlated with the degree of functional impairment of the upper extremity, as indexed by the Fugl-Meyer scale. Next, glutamate is reduced in the affected motor cortex, which may relate to previous reports of increased inhibition of the affected hemisphere in chronic stroke. Finally, creatine is reduced in the affected hemisphere, which is perhaps indicative of reduced energy availability in the affected hemisphere. Taken together these data indicate alterations in cerebral metabolites in the primary motor cortex in chronic ischemic stroke. Improved understanding of the neurochemical changes occurring in chronic stroke may provide valuable insights into future rehabilitative avenues for individuals suffering motor impairment following ischemic insult. Title: MEK1/2 inhibition diminishes ETB receptor-mediated vasoconstriction and improves neurological function after cerebral ischemia in female rats

Authors: *H. AHNSTEDT[1], M. MOSTAJERAN[1], F. W. BLIXT[1], K. WARFVINGE[1], S. ANSAR[1], D. N. KRAUSE[2], L. EDVINSSON[1]
[1]Lund University, Exptl. Vascular Res., Lund, Sweden; [2]Univ. of California, Dept. of Pharmacology, Sch. of Med., Irvine, CA

Abstract: Sex differences are well-known in cerebral ischemia as demonstrated by a higher incidence of stroke in men. Male-female differences may also impact the effects of stroke treatments. In male rats, the MEK1/2 inhibitor U0126 reduces brain infarct size and improves neurological function after experimental stroke; however, responses to this treatment in females

are not known. In males, U0126 also attenuates ET_B receptor upregulation that occurs in arterial smooth muscle of cerebral arteries subjected to experimental stroke *in vivo* or organ culture *in vitro*. This effect would thereby mitigate reduction in blood flow and increased tissue damage after ischemia in males, but these effects have also not been examined in females. Therefore, the present study investigated whether ET_B receptor upregulation occurs in cerebral arteries of female rats and, if so, whether the effect is mediated by activation of the MEK/ERK1/2 pathway. Furthermore U0126 was tested for potential benefit in female rats after cerebral ischemia. Transient middle cerebral artery occlusion (tMCAO, 120 min) was performed in female rats with and without U0126 treatment (30 mg/kg i.p.) administered at 0 and 24 h of reperfusion. Prior to the surgeries the estrous cycle of the animals were characterized by daily collection of vaginal smears. At the day of surgery only female rats that were under low influence of estrogen, i.e. not in proestrus, were selected. Additionally, *in vitro* organ culture of isolated cerebral arteries from female rats was studied as a model for ET_B receptor upregulation. Stroke infarct volumes were assessed with neuron-specific nuclear protein NeuN staining, and neurological examination was performed using a 6-point and 28-point neuroscore. ET_B receptor-mediated contraction was studied with wire myographs, and protein expression with immunofluorescence and western blot. Cerebral ischemia in female rats resulted in increased arterial ET_B receptor expression and vasoconstriction. U0126 treatment attenuated ET_B receptor-mediated vasoconstriction and inhibited ischemia-induced ET_B receptor expression and ERK1/2 activation in female cerebral arteries. Importantly, U0126 treatment of female rats after experimental stroke improved the neurological function. MEK1/2 inhibition is therefore a promising therapeutic strategy for stroke in both males and females.

Title: Lentiviral-mediated administration of interleukin-4 promotes alternative activation of microglia and reduces endothelin-1-induced cerebral ischemia

Authors: *S.-H. CHOI, A. C. SILVA
Lab. of Functional and Mol. Imaging, NINDS/NIH, BETHESDA, MD

Abstract: The precise role of microglia in cerebral ischemia has been contentious. Microglia are capable of synthesizing numerous soluble and membrane-bound molecules, some of which are known to be neurotoxic, whereas others have neuroprotective bioactivities. The molecular mechanisms through which microglia activate these molecules with apparently opposing physiological roles have thus become an important area of research in cerebral ischemia. To determine the impact of interleukin-4 (IL-4) in post-ischemic inflammation and to elucidate the mechanisms of IL-4-induced polarization of activated microglia, IL-4 was locally expressed into the mouse brain via recombinant lentivirus driven by the mouse phosphoglycerate kinase promoter. Focal cerebral ischemia was induced by intracortical injection of the vasoconstrictor peptide endothelin-1. We found that CD11b-positive cells in the ischemic core increased over time with a concurrent decrease in neurons. CD11b-positive cell population was initially formed of inducible nitric oxide synthase and CD16/32-positive M1 phenotype, which later shifted towards CD206 and Ym1-positive M2 phenotype. Lentiviral-mediated administration of IL-4 was able to modulate microglia towards an anti-inflammatory, neuroprotective M2 phenotype and ischemic brain injury was partly reduced compared to controls. This study may provide a promising strategy to investigate the potential role of protective microglia in neurological disorders.

Title: Neurovascular protection by post-ischemic injections of a lipoxin A4 receptor agonist, BML-111, in a rat model of ischemic stroke

Authors: *K. E. HAWKINS[1], K. M. DEMARS[1], J. SINGH[1], J. C. FRANKOWSKI[1], S. DORÉ[2], E. CANDELARIO-JALIL*[1]

[1]Neurosci., [2]Anesthesiology, Neurology, Psychiatry, and Neurosci., Univ. of Florida, Gainesville, FL

Abstract: Background: Resolution of inflammation is an emerging new strategy to reduce damage following ischemic stroke. Lipoxin A4 (LXA4) is an anti-inflammatory, pro-resolution lipid mediator with high affinity binding to its receptor ALX. Since LXA4 is rapidly inactivated, potent analogs have been created, including the ALX agonist BML-111. We hypothesized that post-ischemic intravenous administration of BML-111 would provide protection to the neurovascular unit and reduce neuroinflammation in a rat stroke model. Method: Wistar rats were subjected to 90 min of middle cerebral artery occlusion (MCAO) and BML-111 (1 mg/kg) was administered intravenously 100 min and 24 h after stroke onset and sacrificed 48 h after reperfusion. Infarct size and vasogenic edema were detected by TTC staining. Blood brain barrier (BBB) disruption and hemorrhagic transformation were calculated by measuring IgG and Hb extravasation, respectively. Matrix metalloproteinase (MMP)-9 was measured with gelatin substrate zymography and MMP-3 levels were determined with an immunocapture FRET peptide assay. Levels of CD68, myeloperoxidase (MPO), intracellular adhesion molecule (ICAM)-1, and zona occludens-1 (ZO-1) were detected by western blotting. Results: Post-ischemic treatment with BML-111 reduced infarct size, decreased vasogenic edema, protected against BBB disruption, and reduced hemorrhagic transformation. MMP-9 and MMP-3 were significantly reduced following BML-111 treatment. Administration of BML-111 dramatically decreased microglial activation, as seen with CD68, as well as neutrophil infiltration and recruitment, as assessed by levels of MPO and ICAM-1. The tight junction protein ZO-1 was protected from degradation by activation of ALX with BML-111. Conclusion: These results indicate that post-ischemic activation of ALX has resolution effects that limit the inflammatory damage in the penumbra and helps maintain BBB integrity after ischemic stroke.

Title: Lectin-like oxidized low-density lipoprotein receptor-1 (LOX-1) is a novel therapeutic target in neonatal hypoxic-ischemic encephalopathy (HIE)

Authors: *T. AKAMATSU[1,2], T. TANAKA[3], M. MIZUGUCHI[3], Y.-I. GOTO[2], M. ITOH[2]
[1]pediatrics, Teikyo Univ., Tokyo, Japan; [2]Dept. of Mental Retardation and Birth Defect Res., Natl. Ctr. of Neurol. and Psychiatry (NCNP), Tokyo, Japan; [3]Dept. of Developmental Med. Sci., the Univ. of Tokyo, Tokyo, Japan

Abstract: Background: Neonatal care has remarkably progressed for the last decades. However the incidence of nHIE has not been decreased, and severe neurological sequelas in nHIE. Major pathologies of nHIE are neuronal apoptosis and breakdown of neurovascular unit. Although hypothermia is the typical and efficient treatment against nHIE and improves neuronal apoptosis and neurovascular unit, more convenient and spreadable treatment is needed. We have reported that the suppression of the expression of oxidized low density lipoprotein receptor 1 (Olr1) was associated with the neuroprotection of hypothermia and Olr1 was expressed in neurons and endothelial cells in nHIE brains. Objectives: We assessed LOX-1 as a novel therapeutic target in nHIE, using rodent nHIE model. Materials & methods: We made nHIE rats, using postnatal-day 7 rats, and performed hypothermia at 28℃ for 3 hours. We tried the administration of anti-LOX-1 neutralizing antibody as a novel treatment against nHIE. We assessed infarct size by Nissl staining, apoptosis by TUNEL staining. We assessed the level of malondialdehyde (MDA) by ELISA and the level of cleaved caspase 3 (cCASP 3) by western blot, with proteins from infarct-side hemispheres. We assessed brain edema by water content and the levels of tight junction proteins (TJPs) by western blot. Results: The administration of anti-LOX-1 antibody significantly decreased infarct size and TUNEL-positive cells in nHIE rats. Moreover the antibody significantly decreased the levels of MDA and cCASP 3 which were increased in nHIE rats. The antibody suppressed brain edema and suppressed the degradation of TJPs in nHIE rats. These effects of antibody were equal to those of hypothermia. Conclusions: We revealed that anti-LOX-1 neutralizing antibody had the neuroprotective effects against nHIE to the same degree with hypothermia. The antibody improved the major pathologies of nHIE, neuronal apoptosis and breakdown of neurovascular unit. The antibody might directly suppress neuronal death induced by reactive oxygen species and improved neurovascular unit by acting on endothelial cells. Father research is necessary for clinical administration.

Title: Enhanced survival of melanopsin-expressing ganglion cells and the non-image-forming visual system after acute retinal ischemia

Authors: *D. DORFMAN, M. F. GONZALEZ FLEITAS, M. L. ARANDA, P. H. SANDE, R. E. ROSENSTEIN
Sch. of Medicine, UBA, CEFYBO/CONICET, Capital Federal, Argentina

Abstract: Retinal ischemia/reperfusion injury is an important cause of visual impairment. The loss of retinal ganglion cells (RGCs) is a key sign of retinal ischemia. A subset of RGCs expressing the photopigment melanopsin (mRGCs) regulates non-image-forming visual functions such as the pupillary light reflex (PLR) and circadian rhythms. We studied the effect of retinal ischemia on melanopsin expressing RGCs and the non-image-forming visual system. For this purpose, ischemia was induced in male *Wistar* rats by increasing intraocular pressure (120 mm Hg for 40 min). Retinal function (electroretinogram (ERG)), the number of Brn3a(+) and melanopsin(+) RGC (immunohistochemistry), Brn3a and melanopsin levels (Western Blot), and the consensual pupil light reflex (PRL) (after 10-s light flash) were examined. Anterograde transport was assessed after an intravitreal injection of cholera toxin β-subunit, and circadian rhythms of general locomotor activity were registered in cages equipped with infrared detectors of motion. After 4 weeks of ischemia, clear alterations in the visual function (ERG)and retinal histology were observed. Concomitantly with a significant decrease in the number of Brn3a(+) RGC and in Brn3a levels, no differences in the number of melanopsin(+) cells, and melanopsin levels were observed between non-ischemic and ischemic retinas.Ischemia decreased anterograde transport to the superior colliculus and lateral geniculate nucleus, whereas the anterograde transport to the suprachiasmatic nucleus and the olivary pretectal nucleus remained unaffected. At high light intensity, consensual PLR was conserved in ischemic eyes, whereas at low light intensity, a decrease in pupil constriction was observed in intact eyes contralateral to ischemic eyes. Animals with ischemia in both eyes showed a conserved locomotor activity pattern and a photoentrainment rate which did not differ from control animals. The present results indicate a marked preservation of a unique subtype of RGCs, mRGCs, which was functionally and structurally protected even after an extensive retinal damage such as that observed at 4 weeks after ischemia.

Title: Hippocampal pyramidal neurons lacking LC3A and LC3B are resistant to hypoxic-ischemic brain injury in neonatal mice

Authors: J. YAMAGUCHI[1], T. SUNABORI[2], M. KOIKE[2], T. NANAO[1], M. SHIBATA[3], *A. FURUTA[1], Y. UCHIYAMA[1]
[1]Dept of Cell Mol Neuropath, [2]Dept of Cell Biol Neurosci, Juntendo Univ. Grad Sch. of Med., Tokyo, Japan; [3]Niigata Univ. Sch. of Med., Niigata, Japan

Abstract: Although LC3, a mouse homologue of yeast Atg8, has mainly been used for a marker protein of autophagy, little is known about roles of subtypes of LC3, LC3A and LC3B, or whether these proteins compensate their roles for each other during autophagic processes. For this, we produced LC3A and LC3B (LC3A/B)-double deficient (KO) mice, which were born normally and were grown-up to be capable of reproduction. Using these KO mice, both mRNA and protein levels of LC3 homologous proteins, a GABARAP family of proteins, were examined in brain and other tissues, and found that they did not significantly alter between wild-type and LC3A/B-double deficient mice, except for that the expression level of GABARAP was significantly higher in liver tissue than in brain tissue. These results indicate that basic autophagy may work normally in neurons of LC3A/B-deficient brains. Since we have previously shown that Atg7-deficiency rescues mouse neonatal hippocampal pyramidal neurons from hypoxic-ischemic injury (H/I), LC3A/B-double deficient mice were applied to this H/I model. As previously reported, hippocampal pyramidal neurons in wild-type mice (wt) were vulnerable to H/I injury, while the protein amount of LC3-II was significantly more elevated in the ipsilateral hippocampus than in the contralateral hippocampus from 9 to 24 hours after H/I injury. In contrast, hippocampal pyramidal neurons deficient in LC3A/B were resistant to the H/I injury,

while the protein amount of LC3 II in the double KO mouse hippocampus was not increased after H/I injury, compared to that in the wt hippocampus. These results suggest that LC3A/B, but not GABARAP family of proteins, are involved in H/I injury-mediated pyramidal neuron death that occurs in the hippocampal pyramidal layers of neonatal mouse brains. As shown in our previous study, excess autophagic stress may induce neuron death. Our present data using LC3A/B-deficient mice strongly support the presence of H/I injury-mediated autophagic neuron death in neonatal brains. Of course, further study is required to elucidate the molecular mechanism of why H/I injury-mediated neuron death is suppressed by deficiency in Atg7 or LC3A/B.

Title: Changes in monocarboxylate transporter (MCT) expression following ischemia : an *in vitro* and *in vivo* study

Authors: K. ROSAFIO[1], X. CASTILLO[2], L. HIRT[3], *L. PELLERIN[4]
[1]Inst. de Physiologie, Univ. de Lausanne, CH-1005 Lausanne, Switzerland; [2]Dept. of Clin. Neurosciences, [3]Dept. of Clin. Neurosciences-Stroke Laboratory-Neurology Service, CHUV, Lausanne, Switzerland; [4]Inst. Physiologie, Univ. De Lausanne, CH-1005 Lausanne, Switzerland

Abstract: Accumulating evidence indicate that lactate represents an important neuronal energy substrate. Moreover, it has been suggested that lactate could be neuroprotective under various pathological conditions, including stroke. Indeed, 1Berthet et al. have demonstrated a beneficial effect of lactate injections following middle cerebral artery occlusion (MCAO) in both rat and mouse models. However, the precise mechanism by which lactate exerts this neuroprotective effect remains unknown. In parallel, we have recently demonstrated that a reduction in oxygen tension promotes glycolytic activity in cultured astrocytes and induces the expression of the monocarboxylate transporter MCT4. Thus, it is purported that alterations in lactate metabolism,

including changes in expression of the different MCTs found in the brain might participate to the recovery from an ischemic insult and could be necessary to explain the beneficial effects of lactate in this context. To obtain further insight about this question, we determined the level of expression of MCT1, MCT2 and MCT4 in the brain of mice following MCAO. The expression of all three MCTs was decreased at the protein level in the ischemic striatum compared to the contralateral hemisphere 1 hour after the ischemic event, while their expression was restored 24 hours after ischemia. When we looked at the expression of MCT4 by immunohistochemistry, the appearance of cells strongly labeled for MCT4 was observed in the striatum, hippocampus and cortex of the ischemic hemisphere, although these cells were not GFAP positive when examined by double labelling and confocal microscopy. In order to complement our *in vivo* data, we undertook a study of MCT expression on rat hippocampal organotypic culture submitted to oxygen-glucose deprivation (OGD). Preliminary data show that MCT2 expression is decreased following OGD, an observation that might be indicative of neuronal cell death. MCT4 expression also decreased while MCT1 expression was unaffected. Thus, our data indicate that MCT expression is modified under hypoxic/ischemic conditions. It remains to be determined how important are these changes for the functional recovery of the animal and whether they are necessary for the beneficial effects of lactate in these conditions 1Berthet et al (2009) J Cereb Blood Flow Metab 29 :1780-9 ; Berthet et al. Title: GPR30 mediates estrogen rapid signaling and neuroprotection

Authors: R. WANG[1,3,4], H. TANG[4], Q. ZHANG[1,3], L. YANG[4], Y. DONG[1], M. KHAN[1], F. YANG[4], *D. W. BRANN[1,3,2]

Abstract: G-protein-coupled estrogen receptor-30 (GPR30), also known as G-protein estrogen receptor-1 (GPER1), is a putative extranuclear estrogen receptor whose precise functions in the brain are poorly understood. Studies using exogenous administration of the GPR30 agonist, G1 suggests that GPR30 may have a neuroprotective role in cerebral ischemia. However, the physiological role of GPR30 in mediating estrogen (E2)-induced neuroprotection in cerebral ischemia remains unclear. Also unclear is whether GPR30 has a role in mediating rapid signaling by E2 after cerebral ischemia, which is thought to underlie its neuroprotective actions. To address these deficits in our knowledge, the current study examined the effect of antisense oligonucleotide (AS) knockdown of GPR30 in the hippocampal CA1 region upon E2-BSA-induced neuroprotection and rapid kinase signaling in a rat model of global cerebral ischemia (GCI). Immunohistochemistry demonstrated that GPR30 is strongly expressed in the hippocampal CA1 region and dentate gyrus, with less expression in the CA3 region. Furthermore EM and confocal analysis showed that GPR30 localized at extranuclear sites, including the plasma membrane, endoplasmic reticulum, and dendritic spines in the brain. E2-BSA exerted robust neuroprotection of hippocampal CA1 neurons against GCI, an effect abrogated by AS knockdown of GPR30. Missense control oligonucleotides had no effect upon E2-BSA-induced neuroprotection, indicating specificity of the effect. The GPR30 agonist, G1 also exerted significant neuroprotection against GCI. E2-BSA and G1 also rapidly enhanced activation of the prosurvival kinases, Akt and ERK, while decreasing proapototic JNK activation. Importantly, AS knockdown of GPR30 markedly attenuated these rapid kinase signaling effects of E2-BSA. As a whole, the studies provide evidence of an important role of GPR30 in mediating the rapid signaling and neuroprotective actions of E2 in the hippocampus.

Abstract: Cerebral ischemia causes an increase of the immune response by releasing mediators involved in leukocyte chemoattraction (chemokines) in cell damage. The subacute administration of ZnCl2 (2.5 mg/kg/day for 4 days) has shown to reduce the lipoperoxidation and cell death. The aim of this work is know if zinc subacute administration causes the expression of CXCL1 and CXCR2 during cerebral hypoxia-ischemia. Male Wistar rats (220 ± 190 g) with subacute administration of zinc was performed the common carotid artery occlusion (CCAO) for 10 min., other group was only administered with zinc and a positive control group with only CCAO. The cerebral cortex samples were obtained at different times (24h, 48h, 72h and 96h during the administration, and 4h, 8h, 12h, 36h, 96h and 168h post-reperfusion). Protein levels of CXCL1 and CXCR2 were measured by ELISA and mRNA by RT -PCR. The results show that CCAO caused upregulation of CXCL1 mRNA levels by 101.6% ± 18.7%, protein levels were increased by 70.0% ± 23% at 4 h, 28% ± 2.7% at 12 h, and 59 % ± 10.3% since 96h postreperfusion as compared with the sham group. The subacute administration of Zinc caused downregulation by 56.7% ± 4.1% in the CXCL1 mRNA levels since the first to fourth administration, the protein levels was increased by 56.7% ± 4.1% after of the first administration, by 79.5%± 4.7% at the 4 h after last administration. The subacute administration of zinc caused an upregulation in mRNA levels CXCR2 at 8 h post-reperfusion. These results suggest that zinc subacute administration causes a preconditioning effect through of CXCL1 and CXCR2 during brain hypoxia-ischemia process.

Title: Pharmacological inhibition of HDAC6 alleviates brain infarction and functional deficits after experimental stroke: Potential roles of α-tubulin acetylation, FGF-21 up-regulation and excitotoxicity mitigation

Authors: Z. WANG[1], J. WANG[1], Y. LENG[1], J. BERGMAN[2], P. LEEDS[1], A. KOZIKOWSKI[2], *D.-M. CHUANG[1]
[1]Mol. Neurobiol Section, Natl. Inst. Mental Health/NIH, BETHESDA, MD; [2]Dept. of Medicinal Chem. & Pharmacognosy, Univ. of Illinois at Chicago, Chicago, IL

Abstract: Histone deacetylase (HDAC) 6 exclusively exists in the cytoplasm and mainly uses cytoplasmic proteins such as α-tubulin as its substrate. Dysfunction of HDAC6 is known to be associated with CNS pathological conditions. Therefore, HDAC6 has recently emerged as a potential target for treatment of neurodegenerative diseases. The role of HDAC6 in the pathophysiology of ischemic stroke remains to be elucidated. The present study investigated the beneficial effects of tubastatin A (TubA), a novel specific HDAC6 inhibitor, in a rat model of ischemic stroke and an *in vitro* model of excitotoxicity. Male Sprague Dawley rats underwent middle cerebral artery occlusion (MCAO) for 60 minutes followed by reperfusion. TubA (i.p.) was administrated immediately after ischemic onset, and once daily for up to three days. Post-ischemic TubA treatment at both 25 and 40 mg/kg robustly reduced brain infarction on day three after MCAO. TubA treatment at both doses also facilitated functional recovery in MCAO rats at least three days after ischemia. Specifically, MCAO rats receiving TubA had much longer retention time on an accelerating rotarod compared with the untreated MCAO group. Concurrently, the increased neurological deficit score and body tilting percentage in MCAO rats were markedly attenuated by TubA treatment. Of interest, when given at 24 hours after MCAO, 25 mg/kg TubA still exhibited significant effects in reducing brain infarction and improving functional outcomes for at least three days after ischemia. Levels of acetylated α-tubulin were decreased in the ischemic cortex on days one and three after MCAO, and this was significantly restored by TubA (25 mg/kg). We recently reported that fibroblast growth factor-21 (FGF-21), a novel metabolic regulator, is inducible in brain neurons and has a robust neuroprotective role. Notably, FGF-21 was markedly down-regulated in the ischemic cortex after MCAO, and this down-regulation was significantly alleviated by TubA treatment. In addition, TubA conferred neuroprotection in primary cortical neuronal cultures against glutamate-induced excitotoxicity. Live cell imaging showed that TubA appeared to improve the impaired transport of mitochondria induced by glutamate. Together, our results suggest that TubA reduces brain infarction and promotes functional recovery in MCAO rats, and protects against glutamate-induced excitotoxicity. The neuroprotective effects of TubA likely involve HDAC6 inhibition and the

subsequent up-regulation of acetylated α-tubulin and FGF-21. These findings suggest HDAC6 as a promising target for the treatment of ischemic stroke and the clinical utility of TubA for this brain disorder.

Abstract: In previous studies have been demonstrated that subacute administration of zinc decreased the lipoperoxidation and caspase-3 during hypoxia-ischemia and Wilson's disease. The zinc treatment has caused an increase of presynaptic/extracellular zinc concentration in brain and distribution in liver and kidney. The aim of this work is investigate if chronic administration of zinc decreases the nitrosative stress in different tissues (cerebral cortex, liver, heart, kidney and serum). Male Wistar rats were treated with different concentrations of ZnCl2 (0, 0.1, 0.5, 1 and 2.5 mg/kg each 24 h during 14 days, i.p.) and sacrificed a later day. Lipoperoxidation was measured in the supernant by using Gerard-Monnier method; the pro-caspase-3 and nitrotyrosine levels of each organ were measured in the homogenized by ELISA. The results showed that chronic treatment of zinc decreased the lipoperoxidation by 35.1% ± 2.8% since the

administration of 0.5 mg/kg in the cerebral cortex, by 53.8% ± 2.5% with 0.1 mg/kg in the heart, and by 62.5% ± 3.2% only to 0.5 mg/kg in the serum. In addition there was an increase by 73.2% ± 22.6% of lipoperoxidation to the zinc administration of 2.5 mg/kg in kidney. The levels of procaspase-3 decreased by 35.1% ± 4.5% with zinc treatment since 0.5 mg/kg only in cerebral cortex. The optimal concentration of chronic administration of zinc below of 1.0 mg/kg decreased the lipoperoxidation and procaspase-3 levels. These findings provide crucial information about use a zinc optimal concentration to decrease nitrosative stress in these organs.

Title: The role of vagus nerve in the recovery of post-ischemic glucose intolerance and neuroprotective effect by hypothalamic orexin-A

Authors: *S. HARADA, S. TOKUYAMA
Dept. of Clin. Pharmacy, Sch. of Pharmaceut. Sci., Kobe Gakuin Univ., Kobe, Japan

Abstract: Orexin-A (a neuropeptide in the hypothalamus) plays an important role in many physiological functions, including the regulation of glucose metabolism. We have previously found that the development of post-ischemic glucose intolerance is one of the triggers of ischemic neuronal damage, which is suppressed by hypothalamic orexin-A (Harada et al., J. Pharmacol. Exp. Ther., 2013). Other reports have shown that the communication system between brain and peripheral tissues through the autonomic nervous system (sympathetic, parasympathetic and vagus nerve) is important for maintaining glucose and energy metabolism. The aim of this study was to determine the involvement of the hepatic vagus nerve on hypothalamic orexin-A-mediated suppression of post-ischemic glucose intolerance development and ischemic neuronal damage. Male ddY mice were subjected to middle cerebral artery

occlusion (MCAO) for 2 h. The hepatic vagotomy mice created to selectively transect at the hepatic branch vagus nerve. Neuronal damage was estimated by histological and behavioral analyses. Expression of each protein levels was analyzed by western blot and immunofluorescence staining. Intrahypothalamic orexin-A (5 pmol/mouse) administration significantly suppressed the development of post-ischemic glucose intolerance and neuronal damage on day 1 and 3, respectively after MCAO. MCAO-induced decrease of hepatic insulin receptors and increase of hepatic gluconeogenic enzymes on day 1 after was reversed to control levels by orexin-A. This effect was reversed by intramedullary administration of the orexin-1 receptor antagonist, SB334867, or hepatic vagotomy. In the medulla oblongata, orexin-A induced the co-localization of cholin acetyltransferase (cholinergic neuronal marker used for the vagus nerve) with orexin-1 receptor and c-Fos (activated neural cells marker). These results suggest that the hepatic branch vagus nerve projecting from the medulla oblongata plays an important role in the recovery of post-ischemic glucose intolerance and mediates a neuroprotective effect by hypothalamic orexin-A (Harada et al., PLos One, 2014).

Title: Activating transcription factor 3 by inhibiting carboxyl-terminal modulator protein transcription alleviates ischemia-reperfusion induced brain injury

Authors: H.-D. TSAI[1], C.-Y. HUANG[1], J.-S. WU[1], W.-M. CHEUNG[1], *T.-N. LIN[2]
[1]IBMS, [2]Academia Sinica, Taipei, Taiwan

Abstract: Activating transcription factor 3 (ATF3) is a stress-induced transcription factor with diverse functions in multiple cell types and disease states. ATF3 has been shown to have neuroprotective action against cerebral ischemia which may involve caspase 3. However, the molecular mechanisms underlying ATF3 regulation of apoptosis is largely unknown. Recently,

we identified an endogenous neuroprotective ATF3→CTMP (carboxyl-terminal modulator protein) signaling that binding of ATF3 to the ATF/CREB site blocked NF-κB binding to the CTMP promoter, which repressed CTMP expression, and the subsequent Akt inactivation and caspases activation in primary cortical neurons subjected to oxygen-glucose deprivation and reoxygenation. However, whether this signal cascade also plays an important role in the ischemic brain remains to be studied. In the present *in vivo* studies, with gain- and loss-of-function and rescue approached we showed that ATF3 overexpression or knockout led to respective down- and up-regulation of CTMP expression in the ischemic brain. Moreover, post-ischemic CTMP siRNA treatment not only reduced infarct volumes but also improved functional outcome. In summary, we report an endogenous neuroprotective signaling cascade under cerebral ischemic stress entailing ATF3 regulation of CTMP. The ATF3→CTMP signaling cascade is a promising therapeutic target for reducing ischemic brain injury.

Title: Effect of limb remote ischemic preconditioning on angiogenesis

Authors: L. YU, S.-S. DUAN, W.-S. DONG, J. CHEN, W. JIN, Z. JIN, *C. REN
Shanghai No.5 Hospital,Fudan Univ., Shanghai, China

Abstract: Abstract Objectives Remote ischemic preconditioning(RIPC) has emerged as a feasible and attractive procedure for cerebroprotection. However, its molecular mechaniams remain poorly understood. Angiogenesis, the growth of blood vessels from the existing vasculature, is an important natural process in the body used for healing and reproduction. This study's aim was to test whether RIPC has an effect on angiogenesis and the expression pattern of angiogenic molecules, through which RIPC exert its protective function. Methods Stroke was

generated by a permanent occlusion of the left distal middle cerebral artery (dMCAO) combined with a 30min occlusion of the bilateral common carotid arteries (CCA) in male rats. Limb preconditioning was generated by 15min occlusion followed with the same period of reperfusion of the left hind femoral artery, and repeated for hree cycles. Microvessel density (using anti-CD31) of both ischemic penumbra and ingarction core was counted, expression of VEGF/VEGFR2 system and Ang/Tie-2 system was measured semi-quantitatively by means of immunohistochemistry and western blotting. Results Microvessel density and the expression of VEGFR2 in ischemic penumbra was significantly increased in RIPC group than in ischemic control group from 3 hours to 2 weeks after dMCAO, both groups peaking at 7 days. Level of Tie-2 was upregulated more remarkably in RIPC group than in ischemic control group (compared with baseline level) from 2 days to 14 days after stioke, the former peaked at 7 days and the latter 14 days. For secretory factors, expression of VEGF and Ang-2 was more abundant in RIPC group than in control group at 2 days and 7 days after operation. Just the opposite, level of Ang-1 was lower in RIPC group. Conclusions RIPC enhanced process of angiogenesis and changed the expression pattern of angiogenic molecules after stroke in rats. This may be an important molecular mechanism of neuroprotection exerted by RIPC.<!--EndFragment-->

Title: Increased oligodendrogenesis by humanin promotes axonal remyelination and neurological recovery in hypoxic/ischemic brains

Authors: ***X. XU**[1], J. CHEN[2], H. ZHAO[2], C.-F. LIU[2]
[1]Insitute of Neurosci., Soochow Univ., Jiangsu, China; [2]The Second Affiliated Hosp. of Soochow Univ., Suzhou, China

Abstract: Oligodendrocytes are the predominant cell type in white matter and are highly vulnerable to ischemic injury. The role of oligodendrocyte dysfunction in ischemic brain injury is unknown. In this study, we used a 24-amino acid peptide S14G-Humanin (HNG) to examine oligodendrogenesis and neurological function recovery in a hypoxic/ischemic (H/I) neonatal model. Intraperitoneal HNG pre-treatment decreased infarct volume following H/I injury. Delayed HNG treatment 24 h after H/I injury did not reduce infarct volume but did decrease neurological deficits and brain atrophy. Delayed HNG treatment did not attenuate axonal demyelination at 48 h after H/I injury. However, at 14 d after H/I injury, delayed HNG treatment increased axonal remyelination, the thickness of corpus callosum at the midline, the number of Olig2+/BrdU+ cells, and levels of brain-derived neurotrophic factor (BDNF). Our results suggest that targeting oligodendrogenesis via delayed HNG treatment may represent a promising approach for the treatment of stroke.

Abstract: LP204A1 is a synthetic polyunsaturated fatty acid, with the properties of a non-steroidal anti-inflammatory drug (NSAID), that modifies the membrane lipid composition (lipid therapy). In this study we compare the effect of LP204A1 and celecoxib, an anti-inflammatory agent considered the most specific COX-2 inhibitor and a neuroprotective agent against cerebral ischemia. We used a transient focal cerebral ischemia model in rats where the middle cerebral artery was occluded for 60 minutes. One hour and 24 hours after the reperfusion onset (filament withdrawal), animals were treated with LP204A1 (1 g/kg), celecoxib (20 mg/kg) or vehicle. Forty eight hours after the ischemia the infarct volume and the unfolded protein response (UPR) were measured. The infarct volume with respect to the animals with vehicle was about 40% lower in celecoxib treated animals and 70% lower in LP204A1 treated animals. UPR markers were also strongly modified by these agents. We concluded that lipid therapy with LP204A1 constitutes a promising therapy to treat patients that suffered a stroke.

Title: Lactate neuroprotection in cerebral ischemia: What is the mechanism?

Authors: *X. CASTILLO[1], K. ROSAFIO[2], L. PELLERIN[2], L. HIRT[1]
[1]Clin. Neurosci. Dept., CHUV, Lausanne, Switzerland; [2]Physiol. Dept., Univ. de Lausanne, Lausanne, Switzerland

Abstract: Stroke is a highly disabling disease that accounts for one death every four minutes in the United States (Go AS et al., 2014). Despite enormous efforts worldwide for new treatments, rTPA given within 4.5 h of symptom onset remains the only approved treatment for ischemic stroke, the major stroke sub-type. We have previously shown that L-lactate administration during

reperfusion exerts long lasting protection in mice against ischemic damage after transient middle cerebral artery occlusion (tMCAO) (Berthet et al., 2009; 2012). New evidence suggests the possible involvement of the Hydroxy-Carboxylic Acid Receptor-1 (HCA1), a lactate receptor, in nervous system effects of lactate (Bergersen et al., 2013; Bozzo et al., 2013). The objective of the present work is to elucidate if the neuroprotective effects of lactate are exerted by lactate acting as a metabolic substrate or lactate acting on the HCA1 receptor. *In vitro* experiments subjecting organotypic hippocampal slice cultures (OHC) to 1h oxygen and glucose deprivation (OGD) were used to model ischemia. D-lactate, pyruvate, acetate, glucose or 3-5 DHBA, a specific agonist of the HCA1 receptor, were added to the culture medium after OGD. *In vivo* experiments used transient MCAO in adult CD1 mice with administration of Lactate (L or D isoform) or pyruvate at reperfusion. The endpoints were cell survival (*in vitro*), lesion size and neurological performance 48 hours after the insult *in vivo*. For protein expression analysis, mice were sacrificed either 1 or 24h after transient MCAO. Administration of D-lactate, pyruvate and the HCA-1 receptor agonist 3-5 DHBA after OGD improved cell survival, while the administration of acetate and glucose did not. *In vivo*, D- Lactate administration during reperfusion significantly reduced lesion size and improved the neurological performance. HCA1 expression is increased 24h after transient MCAO around the lesion site. As both lactate and it's metabolites, as well as the receptor agonist lead to neuroprotection, we suggest a dual mechanism of it's mode of action. Experiments using HCA1 -/- mice are underway to confirm the physiological relevance of these findings.

Title: Selective intra-arterial administration of neuroprotective agents directly to the site of ischemic injury after experimental stroke improves neuron survival and functional outcome

Authors: *M. E. MANISKAS[1], J. F. FRASER[2], G. J. BIX[3]
[1]Anat. & Neurobio., [2]Dept. of Neurosurg., [3]Sanders Brown Ctr. on Aging, Univ. of Kentucky, Lexington, KY

Abstract: There has long been a recognized disconnect between laboratory stroke therapy models and the clinical human condition. This has contributed to the translational failure of many promising preclinical neuroprotective stroke treatments. Thus, there is an urgent need to develop a reliable and reproducible animal stroke model that mirrors contemporary acute management for large vessel stroke which includes endovascular blood clot removal (thrombectomy) for larger clots that cannot be adequately dissolved with tissue plasminogen activator. We hypothesize that experimental neuroprotective stroke therapies may fail, in part, due to their failure to reach stroke-affected brain tissue if the blood clot has not been removed prior to treatment. To that end, we propose to use the transient ipsilateral common carotid artery (CCA)/middle cerebral artery (MCA) occlusion (MCAo) mouse model in combination with post-reperfusion selective (i.e. directly into the recanalized CCA) intra-arterial (IA) neuroprotectant administration to accurately mimic large vessel occlusion and the IA techniques used during surgical thrombectomy in patients, respectively. This stroke-targeted administration model also decreases potential systemic side effects. We have chosen to administer two distinct neuroprotective agents, a calcium channel blocker (CCB) that is currently FDA approved for IA cerebrovascular administration and is thus "shovel-ready" for stroke clinical trials, and an experimental N-methyl-D-aspartate receptor (NMDA) modulator. Selective administration of either of these agents significantly reduced mean brain infarct volumes and improved functional outcomes without any systemic side-effects. We conclude that the selective IA administration of potential neuroprotective agents can be successfully modeled in the laboratory to mimic contemporary human large vessel acute stroke management and may result in the successful translation of experimental stroke treatments.

Title: Ischemia postconditioning relieves cerebral ischemia injury

Authors: *Y. LUO[1], H. ZHAO[1], Z. TAO[1], R. WANG[1], F. YAN[2], X. JI[3]
[1]Xuanwu Hosp. of Capital Med. Univ., Beijing, China; [2]Xuanwu Hosp., Beijing, China; [3]Xuanwu hospital, Beijing, China

Abstract: Ischemic postconditioning (IPostC) protects against ischemic brain injury. To date, no study has examined the role of (T-LAK-cell-originated protein kinase) TOPK in IPostC-afforded neuroprotection. We explored the molecular mechanism related with TOPK in antioxidant effect of IPostC against ischemia-reperfusion. Focal ischemia was induced in male Sprague-Dawley rats by transient middle cerebral artery occlusion (tMCAO). Reactive oxygen species (ROS) production in the peri-infarct area was detected using dihydroethidium (DHE), MDA level, as a marker of lipid peroxidation, and 3-Nitrotyrosine (3-NT) level, as a marker of protein oxidation, were detected by ELISA. The expression or location of antioxidant proteins and signal molecules TOPK, Phosphatase and tensin homolog (PTEN) and Akt was analyzed by immunofluorescence and western blotting. Our results revealed that IPostC relieved tMCAO-induced oxidative damage by reducing ROS, MDA and 3-NT accumulation in the peri-infarct area, and raised levels of antioxidants peroxiredoxin 1 (Prx-1), Prx-2, and thioredoxin1 (Trx1). In addition, IPostC increased p-AKT and p-TOPK levels, which colocalized in neural cells. *In vitro*, TOPK knockdown, by siRNA, decreased the levels of antioxidants Prx-1, Trx, and MnSOD, and MnSOD activity in PC12 cells. *In vivo*, intracerebroventricular injection of TOPK siRNA reversed IPostC-induced neuroprotection by increasing infarct volume and nitric oxide content, and reducing MnSOD activity. Moreover, IPostC-evoked Akt activation was blocked by TOPK siRNA *in vivo*, but the decreased p-PTEN level in ischemia-reperfusion was not influenced by IPostC or by TOPK siRNA treatment. Our results suggest that the antioxidative effects of TOPK/Akt might contribute to the neuroprotection of IPostC treatment against tMCAO.

Title: Tilia americana reduces the infarct area in a model of middle cerebral artery occlusion (MCAO) in rats

Authors: *R. VENTURA-MARTINEZ[1], G. E. ANGELES-LOPEZ[1], M. E. GONZALEZ-TRUJANO[2]

Abstract: Tilia americana is a plant widely used in mexican traditional medicine for their effects on the central nervous system. The aim of this study was to determinate the infarct area in animals treated with hexane and aqueous extracts of T. americana in the middle cerebral artery occlusion (MCAO) model. Adult male Wistar rats were subjected to right carotid occlusion by intraluminal filament introduction. Two hours after the induction of ischemia, the filament was removed to allow reperfusion. Just before reperfusion, vehicle or extracts of T. americana (AQUOS 300 mg/kg or HEX 300 mg/kg) were administered intraperitoneally. After 2 h of reperfusion, animals were sacrificed and their brains were removed to determinate the infarct area using the TTC staining. Results showed that treatment with both extracts of T. americana, hexane or aqueous, significantly reduced the infarct area in the MCAO procedure, suggesting that this medicinal plant has neuroprotective property in brain ischemia.

Title: The role of neuronal expression of P2X7 receptors in the processes of brain injury in mice

Authors: *A. B. CAGLAYAN[1], M. C. BEKER[1], U. KILIC[2], B. CAGLAYAN[1], T. KELESTEMUR[1], G. OZTURK[1], E. KILIC[1]
[1]Physiol., Istanbul Medipol Univ., Istanbul, Turkey; [2]Bezmialem Vakif Univ., Istanbul, Turkey

Abstract: P2X7 receptors (P2X7R) are members of the family of cationic-selective ion channels gated by extracellular ATP. They are involved in regulation of receptor trafficking, inflammation and ATP-mediated cell death. There is an ongoing debate in the literature about the expression pattern of P2X7R in the brain. Studies submitted unclear data whether it is expressed in neurons or glial cells. To examine these conflicting results, we designed a series of experiments to

demonstrate the cellular expression pattern of these receptors and their roles and effect mechanisms in the development of neuronal injury after optic nerve transection and focal cerebral ischemia in mice. Here, we analyzed cellular expression profiles of P2X7R in retinal layers and brain cells using double immunohistochemistry. Furthermore, we investigated the role of these receptors in the processes of cellular injury by evaluating DNA fragmentation tests, neuronal survival, anti-apoptotic Bcl-XL, pro-apoptotic Bax, survival- and stress kinases by Western blot analysis. The cellular expression profiles of P2X7 receptors are only observed on neuronal cells in the brain and retinal ganglion cells and bipolar cells in the retina. In contrast to previous studies, double IHC studies with glial and microglial markers revealed that P2X7R expression was only observed in the neuronal cells. In addition, we observed that the activation of P2X7 receptor with varying concentrations of BzATP has no significant effect on neuronal survival. However, modulation of P2X7 receptors by Brilliant Blue G (BBG) significantly improved neuronal survival and infarct volume after ON transection and cerebral ischemia. Number of Fluoro-Gold positive RGCs was significantly higher in BBG treated animals than in vehicle treated animals. Moreover, inhibition of P2X7 receptors decreased infarct volume, brain swelling, blood-brain barrier permeability and neurological scores on animals following a 90 min focal cerebral ischemia and 24 hours reperfusion. In addition, inhibition of P2X7 receptors decreased DNA fragmentation and increased neuronal survival after 30 min of focal cerebral ischemia which was assocciated with increased phosphorylation of survival kinases AKT and ERK-1/2. With this study, we provide evidence that the cellular expression of P2X7 receptors is mainly observed on the neuronal cell and P2X7 receptor modulation can be important in neuronal cell survival. We predict that the clinical implementation of P2X7 receptor antagonists can be beneficial not only in patients with acute ischemic stroke, but also with more delayed degenerative neurological diseases.

Title: Thrombopoietin reduces injury and cognitive impairment in cerebrovascular disease models

Authors: D. M. ROSENBAUM, J. ZHOU, J. ZHUANG, C. POON, J. LI, *F. C. BARONE
Neurol., SUNY Downstate Med. Ctr., BROOKLYN, NY

Abstract: Objectives: Thrombopoietin (TPO) reduces brain injury and sensory-motor deficits following stroke in the rat. TPO brain protection is mediated by vascular protection. TPO reduces stroke-induced inflammatory cytokines, matrix metalloproteinase's and blood brain barrier injury. Here we demonstrate that TPO protects the brain and reduces vascular cognitive impairment in: [1] rat embolic stroke (+/- tissue plasminogen activator; tPA), [2] mouse suture-focal stroke, and [3] mouse chronic carotid stenosis-induced forebrain hypoperfusion. Methods: Rats (Wistar) underwent embolic middle cerebral artery occlusion (MCAO). Vehicle, tPA (10 mg/kg, iv), TPO (0.1 μg/kg, iv) or TPO plus tPA were administered 2 hours post-stroke. Mice (C57Bl/6) underwent suture-MCAO or carotid artery stenosis-induced forebrain hypoperfusion and then received Vehicle or TPO (0.3 or 0.1 μg/kg, iv) at 1 hr or 1 day after surgery. Neurological deficits, complex learning and hemispheric infarct size were measured for 1-21 days post-surgery. Results: In rat embolic stroke, tPA or TPO plus tPA improved stroke-induced neurological deficits significantly. Significant post-stroke-induced deficits in APA cognitive performance were improved 87.2±16.4% by TPO or 69.4±9.7% by TPO plus tPA, but not by tPA alone. In mouse suture-focal stroke, brain infarcts were reduced by 64.5±7.7% and neurological deficits were reduced by 90.3±6.4%. In mouse carotid artery stenosis-induced forebrain hypoperfusion a single administration of TPO 1 day after surgery improved APA performance 84.8+3.1% 3 weeks later (all $p<0.01$). Conclusions: We have demonstrated TPO long-term protection and safety with and without tPA. TPO exhibits protection in mouse suture-focal and in mouse forebrain hypoperfusion-induced complex learning deficits. These data present multiple model and species work that supports the potential "multiple use" of TPO in the future.

Title: The role of low density lipoprotein receptor-related protein 1 (lrp1) in cns myelin development, stability and repair

Authors: *J.-P. LIN[1,2], R. GIGER[3]
[1]Univ. of Michigan, Ann Arbor, ; [2]Cell and developmental biology, [3]Cell and developmental biology, Neurol., Univ. of Michigan, Ann Arbor, MI

Abstract: The Role of Low Density Lipoprotein Receptor-related Protein 1 (LRP1) in CNS Myelin Development, Stability and Repair. Jing-Ping Lin[1], Roman J Giger[1,2] University of Michigan, Department of Cell and Developmental Biology[1], Department of Neurolgy[2] Ann Arbor, MI Low density lipoprotein receptor-related protein 1 (LRP1) is a large cell surface receptor abundantly expressed in the developing and adult mammalian CNS, where it is thought to function as an endocytic receptor. LRP1 is required for proper myelination of the peripheral nervous system (PNS).Schwann cell conditional *LRP1* knockout mice present with thinner myelin sheaths during development, and faster axon degeneration after sciatic nerve crush injury. However, it is not clear whether LRP1 is important for proper myelination of the central nervous system (CNS) during development or during white matter repair. *In vitro* studies suggest that LRP1 is required for oligodendrocyte progenitor cell (OPC) differentiation, which is a critical step during myelin formation. LRP1 binds and internalizes myelin debris by direct binding to myelin components such as myelin basic protein (MBP) and myelin-associated glycoprotein (MAG). Moreover, LPR1 regulates inflammation and subsequent endocytosis of dead cells after injury, which is an important step for generating an environment permissive to myelin repair. These observations suggest that LRP1 functions in OPCs and/or oligodendrocytes (OLs) and potentially other cell types to regulate CNS myelination and/or remyelination. Germline deletion of *LRP1* in mice is embryonic lethal, therefore we generated *LRP1* OL lineage conditional knockout mice (*LRP1$^{flox/flox}$; Olig2-Cre*) to address its role in CNS myelination. Our preliminary data show that knocking out *LRP1* in oligodendrocyte linage cells results in reduced expression of proteolipid protein (PLP), a myelin-associated protein and a positive regulator of axonal integrity. To study the function of LRP1 in adulthood, we generated inducible *LRP1* knockout mice (*LRP1$^{flox/flox}$; CMV-ER Cre*). Currently, studies are investigating if *LRP1* is required for myelin repair. Injection of lysophosphatidylcholine (LPC) into the corpus callosum will be used to compare the extent of remyelination of the white matter lesions between control and *LRP1* mutant animals. A more detailed understanding of the role of LRP1 in the CNS may provide new insights into the molecular mechanisms of remyelination, and may further our understanding of the pathophysiology of demyelinating disorders.

Title: Leukemia-lymphoma related factor (LRF) is a transcriptional repressor of Hes5 and MBP that exhibits stage-specific expression during remyelination

Authors: *N. DAVIDSON[1], N. KIJPAISALRATANA[2], T. Q. LE[1], R. C. ARMSTRONG[1]
[1]USUHS, Bethesda, MD; [2]Chulalongkorn Univ., Bangkok, Thailand

Abstract: Leukemia/lymphoma-related factor (LRF) is a zinc-finger transcription factor that regulates differentiation, proliferation, and maintenance of multiple cell types. This study is the first to demonstrate the potential regulatory effect of LRF on oligodendrocyte progenitor (OP) cell differentiation in the adult mouse, and to provide evidence for the different mechanistic pathways affected by LRF in OP cells and the mature oligodendrocyte. Adult male C57BL/6 mice were treated with murine hepatitis virus strain A59 (MHV-A59) by intracranial injection to induce a demyelinating injury and then compared to vehicle-injected controls. We show that LRF is expressed in a small subset of OP cells and in nearly all mature oligodendrocytes. This expression pattern is tightly correlated with cell stage and remains consistent between MHV-A59 and vehicle treated mice despite significant changes in total OP and oligodendrocyte populations throughout the progression of demyelination and remyelination. LRF may therefore play a stage-dependent role with critical activity just prior to OP differentiation and with continuing activity in the mature oligodendrocyte. With this in mind, we examined the role of LRF in transcriptional regulation of the Notch effector gene hairy and enhancer of split 5 (Hes5), an OP differentiation inhibitor. In P2 rat brain cultures enriched in OP cells, LRF transfection significantly reduced luciferase activity driven by the Hes5 promoter. This supports our theory that LRF overcomes inhibition of OP differentiation by opposing Hes5 in a derepression model. When examining the effect of LRF expression on myelin-specific proteins, we find that LRF reduces the activity of promoters for both 2',3'-cyclic-nucleotide 3'-phosphodiesterase (CNP) and myelin basic protein (MBP). Using a truncated MBP-promoter, we show that LRF exerts its regulatory effect on MBP primarily over a 135 base pair region. We further demonstrate that LRF-specific inhibition of the MBP promoter is lost with a 3 base pair mutation of the truncated MBP promoter at a well-

defined site necessary for specificity protein 1 (Sp1) binding and activity. Consequently, LRF may be necessary to maintain homeostasis in the mature oligodendrocyte by regulating the production of myelin-specific proteins. Taken together, this data supports a clear mechanistic pathway whereby LRF enhances OP differentiation by opposing the Notch effector Hes5, and then modulates myelin protein transcription in the mature oligodendrocyte; in at least the case of MBP, this LRF effect requires the presence of a specific 3 base pair subset of an established Sp1 binding site.

Title: Cell-autonomous and non-cell-autonomous functions of lipid phosphatase FIG4/SAC3 in oligodendrocyte development, axon myelination, and white matter stability

Authors: *Y. MIRONOVA[1], G. M. LENK[2], J.-P. LIN[1], T. L. DICKENDESHER[3], M. H. MEISLER[2], P. SHRAGER[4], R. J. GIGER[1]
[1]Cell and Developmental biology, [2]Human Genet., Univ. of Michigan, Ann Arbor, MI; [3]Neurobio., Harvard Univ., Boston, MA; [4]Neurobio. and Anatomy, Univ. of Rochester Med. Sch., Univ. of Rochester, Rochester, NY

Abstract: Mutations of human *FIG4(SAC3)* are responsible for Charcot-Marie-Tooth 4J disease, a severe form of peripheral neuropathy (Chow et al, Nature 2007), Yunis-Varon Syndrome (Campeau et al, AJHG 2013), and polymicrogyria with epilepsy (Baulac et al, Neurology 2014). *FIG4* encodes an evolutionarily conserved lipid phosphatase that regulates intracellular vesicle trafficking in the endo-lysosomal compartment. Mice null for *Fig4* have severe myelination defects in the PNS and CNS. We are studying the cell-autonomy of FIG4 function in CNS myelination using mouse genetics. Remarkably, on a *Fig4* null background, neuron-specific

overexpression of transgenic *Fig4* is sufficient to rescue myelination defects in the optic nerve and corpus callosum, reduce tremor, and prevent premature lethality (Winters et al., J. Neurosci. 2011; Ferguson et al., HMG 2012). To examine *Fig4* loss-of-function in specific neural cell types, we generated *Fig4* conditional knockout ($Fig4^{flox/flox}$) mice (Ferguson et al., HMG 2012). Neuron-specific ablation of *Fig4* in $Fig4^{-/flox}$*,SynCre* mice results in severe hypomyelination of the optic nerve, demonstrating that neuronal *Fig4* is necessary for proper CNS myelination. Biochemical studies of $Fig4^{-/flox}$*,SynCre* brain tissue revealed reduced abundance of MBP (myelin basic protein) and MAG (myelin-associated glycoprotein). Recordings of compound action potentials on acutely isolated optic nerves revealed a delay in nerve conduction. Interestingly, selective loss of CNS *Fig4* in the oligodendrocyte (OL) lineage ($Fig4^{-/flox}$*, Olig2Cre*) also results in CNS hypomyelination. The data indicate that correct CNS myelination requires expression of *Fig4* in both neurons and OLs. To test whether FIG4 is required for myelin stability and repair, we generated mice that permit inducible gene ablation ($Fig4^{-/flox}$*,CMV-ER-Cre*). Preliminary data indicate that juvenile and adult inducible *Fig4* ablation does not result in reduced levels of myelin-associated markers, suggesting that Fig4 may be dispensable for CNS myelin maintenance and stability. Intriguingly, electron microscopy imaging of sciatic nerve in $Fig4^{-/flox}$*,CMV-ER-Cre* reveals axonal and myelin pathology, indicating that induction of *Fig4* deletion is deleterious in the adult PNS. Ongoing experiments include assessing whether inducible *Fig4* deletion thwarts axonal remyelination in the lysolecithin (LPC) white matter lesion model.

Title: Alterations in presynaptic release machinery and synaptic vesicle mobility in the frontal cortex of rats with experimental autoimmune encephalomyelitis

Authors: *N. L. CHANADAY[1], A. A. VILCAES[1], A. L. DE PAUL[2], A. I. TORRES[2], A. L. DEGANO[1], G. A. ROTH[1]
[1]Facultad de Ciencias Químicas, UNC., Dpto. De Química Biológica - CIQUIBIC (CONICET), Córdoba, Argentina; [2]Facultad de Ciencias Médicas, UNC, Ctr. de Microscopía Electrónica - INICSA (CONICET), Córdoba, Argentina

Abstract: Experimental autoimmune encephalomyelitis (EAE) is an animal model that mimics many of the clinical and pathological features of multiple sclerosis (MS). Both are inflammatory demyelinating and neurodegenerative pathologies of the central nervous system associated with motor, sensory, and cognitive deficits. In MS gray matter atrophy is related to the emergence of cognitive deficits and contributes to clinical progression. However the molecular bases of these changes are still unknown. Taking advantage of EAE similitudes, we herein analyze functional and morphological changes in isolated cortical presynaptic terminals (synaptosomes) from an acute rat model. We show that cortical functional changes during EAE are concentrated at the frontal region and appear concomitantly with the onset of EAE clinical manifestations, disappearing when animals begin to recover. In this region, nerve terminals exhibit reduced Ca2+-dependent glutamate release, with no changes in total synaptosomal glutamate content. We propose that this is due to a dysfunction in the presynaptic release machinery, mainly the synapsin I (SynI) pathway. In this regard, we found reduced basal levels of CaMKIIα associated to synaptic vesicles (SVs) and impaired SynI phosphorylation at site 3 (CaMKIIα substrate) after depolarization. In consequence, SynI fails to detach from SVs. Moreover, our study shows an increase in total and phosphorylated Erk1/2 accompanied by higher basal and stimulated levels of SynI phosphorylated at sites 4/5 (Erk1/2 substrates). This might imply that resting SVs-actin network is more disorganized. Overall, this changes lead to reduced SVs mobility as evidenced by electron microscopy, with no apparent morphological or SVs content differences. These are the first evidences unraveling the molecular pathways involved in neuronal dysfunction in the frontal cortex during EAE. The same mechanisms might be responsible for functional abnormalities in MS and could contribute to the development and progression of cognitive impairments and fatigue.

Title: Glatiramer acetate confers neuroprotection in experimental autoimmune encephalomyelitis through activation of SIRT1

Authors: *V. K. NIMMAGADDA[1], K. LAM[1], C. T. BEVER, Jr[1,2], D. TRISLER[1,2], S. I. V. JUDGE[1,2], T. K. MAKAR[1,2]
[1]Neurol., Univ. of Maryland Baltimore, Baltimore, MD; [2]MS Ctr. of Excellence-EAST, VA Maryland Hlth. Care Syst., Baltimore, MD

Abstract: Background: Recent evidence suggests a potential neuroprotective role for sirtuin1 (SIRT1), a NAD+-dependent deacetylase, in multiple sclerosis (MS) and its animal model, experimental autoimmune encephalomyelitis (EAE). Also, SIRT1 was reported to increase mitochondrial biogenesis and rescue mitochondrial density and fission-fusion balance in neurodegeneration models. Our recent studies indicate a relationship between the SIRT1 pathway and the brain derived neurotrophic factor (BDNF)-TrkB signaling pathway in EAE mice. Glatiramer acetate (GA) is one of the disease modifying therapies (DMTs) approved for MS. Previous studies showed that GA treatment increased BDNF secretion in both MS and EAE. Objective: Determine whether neuroprotective effect of GA is mediated via SIRT1 pathway in EAE. Methods: EAE was induced in C57Bl/6 female mice by immunization with myelin oligodendroglial glycoprotein peptide 35-55. GA (150 μg/mouse/day) was administered intraperitoneally starting at disease onset. Mice were euthanized on day 20 of GA treatment and lumbar spinal cords were examined histologically. Results: GA treated mice have less inflammation and demyelination as compared to untreated mice. Increased secretion of BDNF was observed in the spinal cords of GA treated mice. GA treatment increased the expression of SIRT1, SIRT3 and Nampt (a rate limiting enzyme of NAD synthesis) in the CNS of these mice. We also found an increased expression of Mito fusion-2 and OPA-1(regulators of fusion) and decreased expression of mitochondrial Fis1 and DNM1-L (regulators of mitochondrial fission) GA treated EAE mice. These mice also showed increased levels of peroxisome proliferator-activated receptor gamma co-activator 1 alpha (PGC-1α) and nuclear factor (erythroid-derived 2)-like 2 (NRF-2), indicators of mitochondrial biogenesis. Conclusions: Taken together, these findings indicate that GA confers neuroprotection in EAE by activating the SIRT1 pathway and thereby controlling mitochondrial biogenesis and dynamics. Studies are ongoing to further evaluate if GA acts directly on SIRT1 targets or indirectly through the BDNF-TrkB pathway. However, both the TrkB and SIRT1 pathways may contribute to novel neuroprotective targets in EAE and MS.

Abstract: Oligodendrogenesis is essential for successful remyelination and repair in demyelinating diseases such as multiple sclerosis (MS). Understanding the time course of the oligodendrocyte progenitor cell (OPC) response to demyelination in the cuprizone model may help determine the kinetics of the remyelinating response and could allow further modeling of why the process does not efficiently occur in MS patients. The aim of this study was to observe the accumulation and maturation of OPCs during cuprizone induced demyelination and subsequent remyelination after return to normal diet. Fate mapping of OPCs was performed using PDGFαR-CreER;Rosa26-eYFP mice that conditionally express YFP in OPCs after induction of recombination with 4-hydroxytamoxifen (4-HT). Mice were fed a diet of 0.2% cuprizone, a demyelinating neurotoxin, or regular chow for 6 weeks. Both groups then received regular chow for an additional 4 weeks. Recombination was induced with 4-HT at week 2. Mice were sacrificed weekly, beginning 2 weeks after recombination. The fate of the OPCs was determined imunohistochemically via colocalization of eYFP with multiple cellular makers including PDGFαR (OPCs), CC1 (oligodendrocytes), GFAP (astrocytes), and NeuN (neurons). At 4 weeks the density of YFP+ PDGFαR+ cells (OPCs) was 3 fold higher in the corpus

callosum of cuprizone treated animals as opposed to controls, while the density of YFP+CC1+ cells (mature oligodendrocytes) was low in both groups. This was followed by a 6 fold increase in the density of YFP+CC1+ cells at the 6 week time point and a return of YFP+ PDGFαR+ cell density to control levels. Interestingly, the kinetics of OPC differentiation and maturation in gray matter areas appeared to be quite different with much less expression of recombined cells at these time points. Additionally, we observed no deviation of OPCs into astrocytes (YFP+GFAP+) or neurons (YFP+NeuN+) in any brain regions. Analysis at other time points is ongoing. These results, in combination with knowledge of key demyelination/remyelination time points in white matter vs gray matter may provide unique insight into the capacity and mechanisms of remyelination in different parts of the brain. The weekly time course of these events allows insight into OPC proliferation, accumulation, maturation, and remyelination, and could provide insight into how this may occur in MS.

Title: Prostaglandin $F_{2\alpha}$ FP receptor inhibitor suppress demyelination and motor dysfunction in a cuprizone-induced multiple sclerosis mouse model

Authors: *K. YOSHIKAWA, K. IWASA, S. YAMAMOTO, K. MARUYAMA
Saitama Med. Univ., Iruma-Gun Saitama-Ken, Japan

Abstract: Previously, we have demonstrated that prostamide/PGF synthase, catalyzes the reduction of prostaglandin (PG) H_2 to $PGF_{2\alpha}$, is constitutively expressed in myelin sheaths and cultured oligodendrocytes, suggesting that $PGF_{2\alpha}$ has functional significance in myelin-forming oligodendrocytes. To investigate the effects of $PGF_{2\alpha}$/FP receptor signaling on demyelination, we administrated FP receptor agonist and antagonist to cuprizone-exposed mice, a model of multiple sclerosis. Mice were fed a diet containing 0.2% cuprizone for 5 weeks, which induces severe demyelination, glial activation, proinflammatory cytokine expression, and motor dysfunction. Administration of the FP receptor antagonist AL-8810 attenuated cuprizone-induced demyelination, glial activation, and TNFα expression in the corpus callosum, and also improved the motor function. These data suggest that during cuprizone-induced demyelination, $PGF_{2\alpha}$/FP receptor signaling contributes to glial activation, neuroinflammation, and demyelination, resulting in motor dysfunction. Thus, FP receptor inhibition is a potential therapy for reducing the extent of demyelination and the severity of motor dysfunction in multiple sclerosis.

Title: Lack of CerS2 suppresses the development of experimental autoimmune encephalomyelitis

Authors: J. MÄNNICH[1], K. SCHMITZ[1], Y. PEWEZNER-JUNG[2], A. FUTERMAN[2], *A. SCHMIDTKO[3], G. GEISSLINGER[1], S. GRÖSCH[1], S. SCHIFFMANN[1]

Abstract: Ceramide synthases (CerS) synthesize chain length specific ceramides (Cer) which are known to mediate cellular processes in a chain length dependent manner. In an animal model of multiple sclerosis (MS), the experimental autoimmune encephalomyelitis (EAE) model, we observed a significant elevation of CerS2 in neutrophils of EAE mice at disease onset. Mice with a total lack of CerS2 or a specific lack in blood cells develop clinical symptoms later than wild type mice. This is accompanied by a reduced amount of immune cells in the lumbar spinal cord of CerS2KO EAE mice as compared to CerS2WT EAE mice. Chemokine receptors (CCR) expressed on neutrophils promote the migration of neutrophils into the CNS which is a prerequisite for the recruitment of further immune cells and the inflammatory process leading to the development of MS. Interestingly, white blood cells isolated from CerS2KO EAE mice show lower CCR1, CXCR1 and CXCR2 mRNA expression levels as compared to CerS2WT EAE mice. Most importantly, the lack of CerS2 reduces the migratory potential of neutrophils isolated from EAE mice. In conclusion, our data indicate strongly that CerS2 is involved in the signaling process of the synthesis of chemokine receptors and promote thereby the migration of neutrophils and possibly contributes by these pro-inflammatory effects to the development of EAE and MS.

Title: Semaphorin4A causes an apoptotic response in oligodendrocytes

Authors: *D. F. LEITNER[1], B. TODORICH[3], X. ZHANG[2], J. R. CONNOR[1]
[1]Neurosurg., [2]Penn State Univ. Col. of Med., Hershey, PA; [3]Duke Univ. Eye Ctr., Durham, NC

Abstract: We have previously established that there is an H-ferritin (Hft) receptor on oligodendrocytes. This receptor was subsequently identified as Tim2 (T cell immunoglobulin and mucin domain containing 2). In addition to Hft, Tim2 is known to bind Semaphorin 4A (Sema4A), a class IV semaphorin expressed by macrophages and lymphocytes. We report herein that recombinant Sema4A binds to rat primary oligodendrocyte progenitor cells (OPCs) but not astrocytes and induces process collapse and apoptosis in OPCs. Sema4A also induces lactate

dehydrogenase (LDH) release in the human oligodendrocyte cell line MO3.13. Because oligodendrocytes are enriched for iron *in vivo*, we determined the influence of cellular iron status on the Sema4A effect. In rat primary oligodendrocytes and the MO3.13 cell line, the Sema4A effect on LDH release was increased following iron chelation in mature cells but iron loading did not alter the Sema4A effect. This finding indicates that both rat and human oligodendrocytes are vulnerable to Sema4A induced apoptosis and the vulnerability is influenced by iron status. Because peripheral macrophages express Sema4A, a potential source of Sema4A in the brain may come from microglia. In a cell culture model we found that rat primary microglia express Sema4A, and the level of expression was increased after activation with lipopolysaccharide (LPS). Because microglia accumulate iron when activated, we determined whether iron status influenced Sema4A expression by microglia. We observed that *in vitro* iron chelation decreased expression of Sema4A when microglia were activated with LPS. Iron loading in the presence of LPS increased Sema4A expression. These data suggest that Sema4A could be a link between the immune system and oligodendrocytes and that the response of these cells is iron sensitive. To determine the clinical relevance of our finding, we examined cerebrospinal fluid (CSF) and tissue samples from patients who had multiple sclerosis (MS). Sema4A depleted CSF from a primary-progressive MS patient improved the viability of OPCs, but Sema4A depleted CSF from a relapsing-remitting patient did not alter OPC viability when compared to control. We also found that 10% of MS patients had elevated Sema4A in chronic active lesions. This study provides a novel link between the immune system and oligodendrocytes and identifies the role of Sema4A in destruction of oligodendrocytes.

Title: Oligodendroglial TNFR2 mediates the protective effects of transmembrane tumor necrosis factor (tmTNF) by promoting remyelination in experimental autoimmune encephalomyelitis

Authors: *P. MADSEN[1,2], S. K. PATEL[1], H. GAO[1], D. E. SZYMKOWSKI[3], J. R. BETHEA[4], R. BRAMBILLA[1]

[1]Univ. of Miami Miller Sch. of Med., Miami, FL; [2]Dept. of Neurobio. Research, Inst. of Mol. Med., Univ. of Southern Denmark, Odense, Denmark; [3]Xencor, Monrovia, CA; [4]Drexel Univ., Philadelphia, PA

Abstract: Tumor necrosis factor (TNF) has been associated with the pathophysiology of multiple sclerosis (MS), as MS patients have elevated concentrations of TNF in cerebrospinal fluid and active lesions. TNF exists in two forms, transmembrane (tmTNF) and soluble (solTNF), whose functions are mediated by TNFR1 and TNFR2. Due to their different binding affinities, solTNF primarily signals through TNFR1 and tmTNF through TNFR2. The cellular processes activated by the two receptors are often opposite: TNFR1 mediates apoptosis and inflammation whereas TNFR2 is associated with cell survival, immunity and myelination. Numerous studies have linked MS to the detrimental effects of solTNF and TNFR1. In our own work we demonstrated not only that solTNF is detrimental, but that tmTNF is protective and important for repair and remyelination. We showed that mice treated with XPro1595, a selective solTNF inhibitor, have improved clinical outcome, preserved axon integrity and increased remyelination following MOG-induced EAE. Since TNFR2 is expressed throughout the oligodendrocyte lineage, we hypothesized that activation of TNFR2-dependent cascades in oligodendrocytes is associated with the protective functions of tmTNF in EAE. To test this hypothesis we used a genetic/pharmacological approach with oligodendrocyte-specific TNFR2 conditional knockout (CNPcreTNFR2fl/fl mice) in combination with XPro1595 treatment. Naïve CNPcreTNFR2fl/fl mice do not display any abnormal locomotor phenotype or differences in oligodendrocyte precursor and mature oligodendrocyte numbers compared to control mice. This suggests that TNFR2 does not play a major role in oligodendrocyte function during development. However, following EAE CNPcreTNFR2fl/fl mice show a significantly worse clinical outcome compared to TNFR2fl/fl littermates, and this behavior is not improved by XPro1595 treatment, which suppresses EAE in TNFR2fl/fl mice. Finally, we find that CNPcreTNFR2fl/fl mice have decreased axon and myelin preservation, as well as remyelination compared to TNFR2fl/fl mice. Collectively, our data demonstrate that TNFR2 activation in oligodendrocytes is key to the protective effect of tmTNF in EAE. A better understanding of how oligodendroglial TNFR2 signaling regulates remyelination may lead to new therapeutic strategies for MS, especially chronic progressive MS. Indeed, this form of MS is associated with failure of remyelination and irreversible axonal damage, and no therapies are currently available. Title: System xc- transporter modulates CNS infiltration of immune cells in autoimmune inflammatory disease

Authors: *K. S. EVONUK[1], B. J. BAKER[1], R. E. DOYLE[1], C. M. SESTERO[1], B. P. JOHNSTON[1], P. DE SARNO[1], A. TANG[1], I. GEMBITSKY[1], S. J. HEWETT[2], H. SONTHEIMER[1], C. RAMAN[1], T. M. DESILVA[1]

Abstract: T cell infiltration into the central nervous system (CNS) is a significant underlying pathogenesis in autoimmune inflammatory demyelinating diseases. Mechanisms that regulate immune cell infiltration into the CNS are not well understood. The neurotransmitter glutamate has been implicated in modulating blood-brain barrier permeability and may contribute to the vulnerability of the CNS to immune cell infiltration during pathological conditions. The system xc- transporter is a source of glutamate release during oxidative stress and is upregulated in leukocytes from human blood samples in patients with multiples sclerosis as compared to control samples. Therefore, we tested the role of system xc- in regulating immune cell infiltration in experimental autoimmune encephalomyelitis (EAE) using pharmacological and genetic approaches. Pharmacological blockade of system xc- in the C57Bl/6 animal model of EAE attenuated T cell, macrophage, and neutrophil infiltration into the CNS. These data were consistent with reduction in both clinical disease and myelin loss. Precursor frequency of peripheral MOGp-reactive T cells (CFSE assay) and their ability to enter into cell cycle was not affected by inhibitors of system xc-. These data suggest that low numbers of infiltrating

inflammatory cells in the CNS of mice treated with inhibitors of system xc- was not due to compromised activation of MOGp T cells in the periphery. Furthermore, mice harboring an Slc7a11 (xCT) mutation that inactivated system xc- were resistant to EAE corroborating a central role for system xc- in the pathogenesis of EAE. Taken together our data support a novel role for the system xc- transporter in mediating T cell infiltration into the CNS in autoimmune inflammatory diseases.

Title: *In vitro* models for the study of amiodarone-induced peripheral neuropathy

Authors: ***N. NIIMI**[1], M. TSUKAMOTO[2], H. YANAGISAWA[1], K. WATABE[1], K. SANGO[1]

Abstract: Amiodarone (AMD), a class III anti-arrhythmic agent prescribed for patients with atrial fibrillation and ventricular arrhythmias, has a number of adverse effects, including peripheral neuropathy. AMD and its metabolites (desethylamiodarone and bis-desethylamiodarone) are likely to inhibit lysosomal phospholipases and induce accumulation of phospholipids and other substances in the lysosomes of Schwann cells, thereby being a cause of Schwannopathy or myelinopathy. However, the molecular mechanisms of AMD toxicity in Schwann cells remain unknown. We have established a spontaneously immortalized adult rat Schwann cell line IFRS1, which displays distinct Schwann cell phenotypes and fundamental ability to myelinate neurites in coculture with dorsal root ganglion neurons (Sango et al., 2011) and PC12 cells (Sango et al., 2012). In this study, we investigated the effects of AMD on the viability and biochemical properties of IFRS1 cells and the myelination in PC12-IFRS1 coculture system. IFRS1 cells were maintained in Dulbecco's modified Eagle's medium

(DMEM) with 1% fetal calf serum and N2 supplement. Treatment of IFRS1 cells with AMD (1, 5, and 10 μM) for 24 h dose-dependently reduced the cell viability, increased the intracellular phospholipids, and upregulated the expression of a lysosomal marker LIMPII, an oxidative stress marker 4-hydroxy-2-nonenal, autophagy markers LC3-II and p62, and sterol regulatory element-binding protein (SREBP)-1. The upregulation of p62 suggests impaired autophagy, whereas SREBP-1 plays a role in lipid metabolism and its upregulation may be correlated with the AMD-induced phospholipid accumulation. PC12-IFRS1 cocultures were incubated in myelination medium (DMEM with B27 supplement, 50 μg/ml ascorbic acid, 10 ng/ml nerve growth factor and 25 ng/ml neuregulin-1 type III) for 21 days. Treatment of the cocultures with 20 μM of AMD for 48 h induced detachment of IFRS1 cells from the neurite networks as seen under a phase-contrast microscope and downregulated the expression of myelin protein P0 and neuregulin-1 receptor ErbB3 as revealed by western blot analysis.

Title: Role of N-Acylethanolamine Acid Amidase (NAAA) in the experimental autoimmune encephalomyelitis model of multiple sclerosis

Authors: *S. PONTIS, V. CAPURRO, A. GUIJARRO, M. SUMMA, D. PIOMELLI, A. REGGIANI
Drug Discovery and Develop., Inst. Italiano Di Tecnologia, Genova, Italy

Abstract: Multiple sclerosis (MS) is a chronic inflammatory disease of the central nervous system (CNS) characterized by autoimmune response and aberrant inflammatory response involving T cells, macrophages and microglia which leads to the gradual loss of myelin sheath that protects nerve fibers. Fatty acid ethanolamides (FAEs) are endogenous bioactive lipids involved in the modulation of inflammatory and immune response. Previous studies demonstrated that palmitoylethanolamide (PEA) exerts anti-inflammatory, analgesic and neuroprotective effects acting mainly through PPAR-α receptors in several models of inflammation. The administration of PPAR-α agonists gemfibrozil and fenofibrate inhibits

clinical signs of experimental autoimmune encephalomyelitis (EAE), an experimental model of MS. Moreover clinical studies showed that both plasma and cerebrospinal fluid levels of NAEs are altered in MS patients. N-Acylethanolamine Acid Amidase (NAAA) has been identified as the enzyme responsible for the degradation of palmitoylethanolamide (PEA). We have previously demonstrated that NAAA inhibition normalizes PEA levels in several inflammatory models. In order to investigate the role of NAAA in MS we produced EAE in mice and examined the expression of NAAA and inflammatory markers. EAE was induced in mice by immunization with myelin oligodendrocyte (MOG) 35-55 peptide, 200 μg/mouse and 200 ng pertussis toxin (PTX) in 200μL PBS after MOG injection and 48 h later. Control-immunized mice in addition to unimmunized mice served as negative controls. Mice were weighed and scored daily for clinical signs, killed at different time points and spinal cord tissue was processed for qPCR and immunohistochemistry. Gene expression of NAAA and markers of inflammation (iNOS , COX2, TNF-alpha) was evaluated. Immunofluorescence studies were conducted to determine the identity of NAAA-expressing cells. Analysis of qPCR data showed that, at day 7 and 10 post immunization, NAAA and iNOS mRNA levels were significantly up-regulated in mice showing symptoms at the moment of sacrifice compared to non-symptomatic mice ($p<0.0001$, Student's t test). Analysis of fluorescence in spinal cord sections showed significant increase of NAAA immunofluorescence in EAE mice vs control immunized mice (integrated density average in EAE mice 136 ±16 vs control immunized 0.29 ± 0.11; $p<0,001$ Student's t test). Overall, these preliminary results suggest that NAAA is altered during the development of MS. Further studies are needed to clarify whether their modulation could be beneficial for treatment.

Title: Human remyelination promoting IgM antibody rescues myelin-mediated inhibition of oligodendrocyte precursor cell process outgrowth

Authors: *Y. ZORINA, P. SARMIERE, A. O. CAGGIANO, D. BUTTON
Acorda Therapeut., Ardsley, NY

Abstract: rHIgM22 is an experimental recombinant antibody in clinical studies in patients with multiple sclerosis (MS). In MS, demyelinated central nervous system (CNS) lesions fail to sufficiently remyelinate despite the presence of oligodendrocyte precursor cells (OPCs) capable of differentiating into mature oligodendrocytes and producing new myelin. rHIgM22 is an IgM isotype antibody previously shown to promote remyelination in Theiler's murine encephalomyelitis virus-mediated model of demyelination. While rHIgM22 improves remyelination in animal models, its mechanism of action has not been fully defined. In mixed glial cultures, rHIgM22 improves OPC survival and increases OPC proliferation via PDGF-mediated paracrine signaling. While purified OPCs can bind rHIgM22, rHIgM22 does not show direct proliferative effects in isolated OPC cultures. MS lesions contain damaged myelin debris, which has been suggested to inhibit OPC process outgrowth. In this study, we examined if myelin inhibits OPC process outgrowth, and if this effect can be directly rescued by treatment with rHIgM22 by interfering with external inhibitory signals from the damaged myelin. OPCs were isolated by shaking postnatal (P1) rat mixed glial cultures, and expanded in proliferation media with growth factors. To determine if OPCs could directly bind rHIgM22, OPCs were differentiated using thyroid hormone (T3) and stained with rHIgM22 antibody along with markers of OPC differentiation. We found that rHIgM22 binds to OPCs over multiple stages of differentiation indicated by co-labeling of cells with rHIgM22 and phenotypic markers A2B5, O4 or MBP. For OPC process outgrowth assays, OPCs were plated on poly-d-lysine or adult rat myelin fraction coated slides, and treated with rHIgM22 in the presence of T3 for 48 hours. OPCs were imaged live using Calcein AM, and process outgrowth was analyzed using ImageJ software. We found that when plated on permissive poly-d-lysine substrate, OPCs adhere to the surface and put out multiple thin processes. However, when plated on myelin-coated substrate, OPCs form loosely adhering cell clusters with very few processes, suggesting that myelin inhibits OPC process outgrowth. Addition of rhIgM22 partially rescues this morphological effect, and allows OPCs to put out more processes on myelin substrate, resembling the more complex morphology observed on poly-d-lysine. Therefore, in addition to paracrine trophic support of OPC population, rhIgM22 may play a direct role in overcoming myelin-mediated inhibition of OPC process outgrowth, thereby providing an additional mechanism for promoting remyelination.

Title: Role of Tumor Necrosis Factor Receptor 2 signaling in microglia and macrophages in experimental autoimmune encephalomyelitis

Authors: *H. GAO[1], P. M. MADSEN[1,2], R. BRAMBILLA[1], R. BRAMBILLA[1]
[1]Univ. of Miami, Miami, FL; [2]Dept. of Neurobio. Research, Inst. of Mol. Med., Univ. of Southern Denmark, Odense, Denmark

Abstract: Tumor necrosis factor (TNF) is a pleiotropic cytokine involved in numerous physiological and pathological processes. It exists in two forms, transmembrane (tmTNF) and soluble (solTNF). The biological functions of TNF are mediated by TNFR1 and TNFR2. Due to their different binding affinities, solTNF signals preferentially via TNFR1, which is involved in activation of pro-inflammatory pathways and apoptosis, and tmTNF via TNFR2, which is associated with immunity, anti-inflammatory and pro-myelinating effects. To date, most studies have focused on TNFR1, and the role of TNFR2 in health and disease is poorly understood. TNF is involved in the pathophysiology of multiple sclerosis (MS). Interestingly, a clinical trial with a non-selective TNF inhibitor blocking both solTNF and tmTNF resulted in MS exacerbation, while selective blockade of solTNF resulted in ameliorated experimental autoimmune encephalomyelitis (EAE). Furthermore, TNFR2 knockout mice showed worse EAE outcomes than WT mice. These data suggest that tmTNF and TNFR2 are likely to mediate the beneficial functions of TNF in EAE/MS and modulation of TNFR2 could become a promising therapeutic

target in MS. Since TNFR2 is the only functional TNF receptor in microglia and is highly expressed in macrophages, we sought to elucidate the functions of TNFR2 in microglia and macrophages *in vivo* by conditionally ablating TNFR2 in both populations. To do so, we generated novel LysMcreTNFR2fl/fl mice. LysMcreTNFR2fl/fl mice do not display obvious phenotypical abnormalities. Under naïve conditions, immune cell profiles in the spleen, numbers of microglial cells, activity levels and locomotor behavior are comparable to TNFR2fl/fl littermates, suggesting that TNFR2 does not play a major role in microglia and macrophage function during development. However, following induction of EAE, LysMcreTNFR2fl/fl mice develop significantly delayed and suppressed EAE, contrary to expectations. This result may have multiple implications: 1) TNFR2, in either or both cell types, signals to the production of detrimental factors that sustain the EAE pathology; 2) TNFR2 is key to the immunological functions of macrophages, and in its absence the induction of EAE is prevented. Our data underscore that TNFR2 functions are cell type-dependent, likely not only associated with beneficial effects after EAE, and cell-specific conditional knockout models represent an invaluable tool to better understand TNFR2 signaling and function in health and disease. Title: Potential neuroprotective effect of PAC1 signaling in experimental autoimmune encephalomyelitis

Authors: *V. MAKHIJANI[1], M. C. CONDRO[1], Y. V. TAN[3], S. K. TIWARI-WOODRUFF[2], J. WASCHEK[1]
[1]Psychiatry, [2]Neurol., UCLA, Los Angeles, CA; [3]Univ. of Rouen, Rouen, France

Abstract: Pituitary adenylyl cyclase activating peptide (PACAP) is a neuropeptide that exerts strong anti-inflammatory actions *in vitro* and *in vivo*, through two receptor subtypes, VPAC1 and VPAC2, that also bind the related peptide vasoactive intestinal peptide (VIP), and one PACAP-specific receptor, PAC1, thought to mediate much of its neuroprotective actions. In the experimental autoimmune encephalomyelitis (EAE) model of multiple sclerosis, PACAP knockout mice exhibit more severe disease symptoms than wild type controls and VIP knockout mice, suggesting that PAC1 signaling might play a role in modulating this disease. PAC1 knockout mice were thus immunized with MOG35-55 and monitored for disease symptoms. PAC1 knockout mice exhibit more severe disease than wild type controls, similar to the PACAP knockout mice. Postmortem cortex and hippocampal samples were assayed for levels of total and non-phosphorylated neurofilament, as a measure of axonal degeneration. Protein lysates from the cortex and hippocampus in PAC1 knockout mice have an increased ratio of non-phosphorylated to total neurofilament relative to controls. These data support the hypothesis that PAC1 signaling exerts a neuroprotective effect in the EAE model.

Title: The role of the notch signaling pathway in the demyelination-remyelination process

Authors: *A. M. ADAMO, F. ALMEIRA GUBIANI, M. PEREIRA LUPPI, P. MATHIEU
Química Biológica, Facultad De Farmacia Y Bioquímica. Univ. of Buenos Aires. IQUIFIB-CONICET, CABA, Argentina

Abstract: In the CNS, the oligodendroglial cell (OL) is responsible for normal myelination, while demyelination is a pathological process characterized by myelin loss around axons. Demyelination is followed by remyelination, the process by which myelin sheaths are restored

around demyelinated axons resolving the functional deficit. In this work we examined the Notch signaling pathway involvement in the demyelination-remyelination process in a toxic model of demyelination induced by cuprizone (CPZ) ingestion. Twenty-one-day-old Wistar rats were fed a diet containing 0.6% (w/w) CPZ during 2 weeks. Demyelinated animals were sacrificed 7d before CPZ withdrawal (-7d), the day of CPZ withdrawal (0d), and 7, 14 and 21d after (+7d, +14d and +21d). Control animals were sacrificed at the same times. We characterized Notch signaling in the SVZ and CC through Notch intracellular domain (NICD) levels and the non-canonical Notch ligand F3/Contactin (F3) by WB and IHC, concomitantly with oligodendroglial progenitor cell (OPC) marker NG2 and OL marker Olig2. We also evaluated the expression of Notch downstream genes Hes1, Hes5 and MAG in SVZ and CC of control and demyelinated animals by Real Time-PCR. In addition, we characterized cell population in primary cell cultures of the SVZ from CPZ and control animals at the time points described above. Results show that Notch signaling pathway was activated in NG2+ OPCs in the CC and SVZ as a consequence of demyelination induced by CPZ. The level of F3 increased significantly in the SVZ of CPZ-treated animals at -7d, +7 and +21d, while this increase was observed at -7d, 0d and +7d in the CC of demyelinated rats. The number of Olig2+ cells expressing F3 was larger than that of NG2+ cells expressing F3, indicating that non-OPC further differentiated OLs express Notch's non-canonical ligand. There was a concomitant increase in the expression of Hes1 in the SVZ in CPZ demyelinated rats at 0d. This result suggests that Notch signaling activation through the non-canonical ligand F3 may be involved in OL maturation and, therefore, in remyelination.

Title: Expression of cxcl12 chemokine receptor cxcr7 in normal and demyelinated mouse brain

Authors: *G. BANISADR[1], J. R. PODOJIL[2], S. D. MILLER[2], R. J. MILLER[3]
[1]Pharmacol., Northwestern Univ., CHICAGO, IL; [2]Microbiology-Immunology, [3]Pharmacol., Northwestern Univ., Chicago, IL

Abstract: The chemokine stromal cell-derived factor-1 (SDF-1)/CXCL12 acting via its G-protein coupled receptor CXCR4 has been implicated in neurogenesis, neuromodulation, brain inflammation, HIV-1 encephalopathy and tumor growth in adult brain. Recently, CXCR7 was identified as a novel, alternate receptor for SDF-1/CXCL12. Like CXCR4, CXCR7 serves as a co-receptor for some HIV-1 strains and has also been shown to be involved in tumor growth. Characterization of CXCR7-deficient mice showed a role for CXCR7 in fetal endothelial biology, cardiac development, and B-cell localization. Despite its ligand binding properties, CXCR7 does not seem to signal like a conventional receptor. It has been suggested that CXCR7 may not function alone but may modulate the function of CXCR4. However, the *in vivo* role of CXCR7 within the CNS remains largely unexamined. Here, we investigated the regional localization of CXCR7 receptors in adult mouse brain using CXCR7-EGFP transgenic mice. We also studied the expression pattern of CXCR7 during Experimental Autoimmune Encephalomyelitis (EAE), an animal model for Multiple Sclerosis (MS). We found that the receptors were expressed in various brain regions including the olfactory bulb, cerebral cortex, hippocampus, subventricular zone, ventricular walls, hypothalamus, cerebellum and spinal cord. Extensive CXCR7 expression was also associated with cerebral blood vessels. In the cortex, CXCR7 expressing cells were predominant in layer IV-V and to a lesser extent in layers II and VI. In the hippocampus, CXCR7 expression was confined to the subgranular layer, molecular layer, pyramidal layer and hilus. Only a few cells expressed CXCR7 in the granular layer. Using cell type specific markers, CXCR7 expression was found in neurons, astrocytes and endothelial cells. GAD-expressing neurons showed CXCR7 expression in the hippocampus. We also compared the distribution of SDF-1/CXCL12 and CXCR7 using bitransgenic mice expressing both CXCR7-EGFP and SDF-1-mRFP. CXCR7 and SDF-1/CXCL12 expression overlapped particularly in blood vessels and neuronal cell populations in both normal conditions and after LPS treatment. In LPS-treated mice, SDF-1/CXCL12 expression was up-regulated in glial cells and blood vessels expressing CXCR7. High expression of SDF-1/CXCL12 was observed in the subventricular zone, white matter and cerebellum. In addition, we found that CXCR7 expression was increased during EAE and is co-localizes with oligodendrocyte progenitors (OPCs). Our findings suggest CXCR4-independent functions for CXCR7 in normal brain and during CNS inflammation.

Title: Astrocyte ETB-R activation delays OPC differentiation during remyelination

Authors: *T. R. HAMMOND, P. MORTON, M. RAYMOND, V. GALLO
Childrens Natl. Med. Ctr., Washington, DC

Abstract: Elevated levels of the signaling peptide Endothelin-1 (ET-1) are found in demyelinated subcortical white matter lesions in adults. ET-1 has been shown to promote reactive astrogliosis and inhibit OPC differentiation and remyelination in these lesions. ET-1 acts through two G-protein coupled receptors, ETA-R and ETB-R, but our understanding of their expression patterns and cell-specific function in demyelinated lesions is still poorly understood. We find that selective inhibition of the ETB-R - but not ETA-R - accelerates OPC differentiation in lysolecithin white matter lesions in mice. Conditional deletion of the ETB-R in astrocytes using ETB-R fl/fl hGFAPcreERT2 mice increased the rate of OPC differentiation, while ETB-R deletion in OPCs using ETB-R fl/fl PDGFrαcreERT2 had no effect on OPC proliferation, migration, or differentiation. Our findings demonstrate that ET-1 acts predominantly through the ETB-R on astrocytes - and not OPCs - to indirectly regulate the rate of OPC differentiation during remyelination. These results shed further light on the specific action of ET-1 in demyelinated lesions, and could lead to the development of cell- ET-R-specific therapeutic options to promote repair of demyelinated tissue.

Title: The inflammasome pyrin contributes to pertussis toxin-induced IL-1β synthesis, neutrophil intravascular crawling and autoimmune encephalomyelitis

Authors: *L. VALLIERES[1], A. DUMAS[2], N. AMIABLE[2], J. DE RIVERO VACCARI[3], J. CHAE[5], R. KEANE[4], S. LACROIX[1]
[1]Mol. Med., Laval Univ., Quebec, QC, Canada; [2]Neurosci., Univ. Hosp. Ctr. of Quebec, Quebec, QC, Canada; [3]Neurolog. Surgery, [4]Physiol. and Biophysics, Univ. of Miami, Miami, FL; [5]Med. Genet. Br., Natl. Human Genome Res. Inst., Bethesda, MD

Abstract: Microbial agents can aggravate inflammatory diseases, such as multiple sclerosis (MS) and its animal model, experimental autoimmune encephalomyelitis (EAE). An example is pertussis toxin (PTX), a bacterial virulence factor commonly used as an adjuvant to promote EAE, but whose mechanism of action is unclear. We have reported that PTX triggers an IL-6-mediated signaling cascade that increases the number of leukocytes that patrol the vasculature by crawling on its luminal surface. In the present study, we examined this response in mice lacking either TLR4 or inflammasome components and using enzymatically active and inactive forms of PTX. Our results indicate that PTX, through its ADP-ribosyltransferase activity, induces two series of events upstream of IL-6: 1) the activation of TLR4 signaling in myeloid cells, leading to pro-IL-1β synthesis; and 2) the formation of a pyrin-dependent inflammasome that cleaves pro-IL-1β into its active form. In turn, IL-1β stimulates nearby stromal cells to secrete IL-6, which is known to induce vascular changes required for leukocyte adhesion. Without pyrin, PTX does not induce neutrophil adhesion to cerebral capillaries and is less effective at inducing EAE in transgenic mice with encephalitogenic T lymphocytes. This study identifies the first microbial molecule that activates pyrin, a mechanism by which infections may influence MS and a potential therapeutic target for immune disorders.

Title: Protein glycation affects peripheral nerve myelination mechanism and is involved in the pathogenesis of demyelinating disorders

Authors: *H. HAGIWARA, F. SAITO, S. WAKATSUKI, T. ARAKI
Dept. of Peripheral Nervous Syst. Reserch, Natl. Ctr. of Neurol. and Psychiatry Dept. of PNS, Tokyo, Japan

Abstract: Advanced glycation endproducts (AGEs), which are cross-linked products that result from a reaction between glucose and protein, accumulate during aging or in diabetes. Several evidences suggest that AGEs accumulation is related to the age-related diseases (e.g. degeneration of intervertebral disk, Cataracta senilis) or the diabetes complications (e.g. diabetic pheripheral neuropathies, blood vessel impairments). Recently, it has been reported that AGEs accumulation is a risk factor of several neurodegenerative diseases, but little is known about the association between AGEs accumulation and development of the nerve disorders. To understand the involvement of AGEs accumulation in the pathogenesis of peripheral nerve disorders, we used *in vitro* myelination model to identify the specific target(s) in protein glycation. We found that pyridoxine, which is a subtype of vitamin B6 in culture media, increases the AGEs accumulation level and inhibits the nerve myelination. We also observed that CRMP2 is specifically glycated in *in vitro* myelination model in the presence of pyridoxine. CRMP2 is known to regulate microtubule formation and stabilization. Taken together, these observations suggest that the inhibition of the myelination in the presence of pyridoxine and the glycation of CRMP2 are involved in the pathogenesis of diabetic peripheral neuropahy. Now, we try to identify the specific glycation site(s) of CRMP2 and their effects on the CRMP2 function.

Title: Inhibition of system Xc- transporter protects the CNS in autoimmune inflammatory demyelination

Authors: *R. DOYLE, K. S. EVONUK, B. J. BAKER, C. M. SESTERO, B. JOHNSTON, P. DE SARNO, A. TANG, I. GEMBITZKY, C. RAMAN, T. M. DESILVA
Univ. of Alabama At Birmingham, Birmingham, AL

Abstract: Mechanisms underlying demyelination in autoimmune neuroinflammatory diseases are not well understood. Several lines of evidence suggest that glutamate dysregulation in the CNS is an important consequence of immune cell infiltration in neuroinflammatory demyelinating diseases. Excitotoxicity as a mechanism in autoimmune encephalomyelitis is supported by animal studies where blocking the AMPA-type glutamate receptor prevents myelin degradation. Evidence in this regard is further substantiated by studies in MS patients where elevated levels of glutamate are found in white matter lesions and cerebral spinal fluid. However, the causal link between inflammation and glutamate dysregulation is not well understood. Here, we examine the role of the system Xc- transporter as a glutamate release mechanism during inflammatory conditions. We report that myelin-specific CD4+ T cells stimulated nitric oxide production from microglia that was blocked by neutralizing antibodies to the cytokines IFN-gamma and TNF-alpha. Microglia stimulated with IFN-gamma and TNF-alpha showed increased expression of the system Xc- transporter, which enhanced glutamate release, causing excitotoxic death to mature oligodendrocytes, the cells that comprise the myelin sheath. We next examined the role of the system Xc- transporter in the CNS after immune cell infiltration. We observed increased expression of system Xc- in reactive glia in spinal cords of C57Bl/6 mice subjected to EAE compared to control. Pharmacological inhibitors of the system Xc- transporter administered after the first relapse in a SJL animal model of relapsing-remitting EAE abrogated clinical disease. This observation was consistent with a reduction in reactive gliosis and myelin loss. Taken together these studies support an important role for the system Xc- transporter in promoting myelin destruction after immune cell infiltration in autoimmune inflammatory demyelination.

Abstract: Experimental autoimmune encephalomyelitis (EAE) is an animal model of multiple sclerosis (MS). We characterized the impairments that represent EAE in female C57BL/6 mice. Mice were immunized subcutaneously with 100 μg of myelin oligodendrocyte glycoprotein emulsified in incomplete Freund's adjuvant supplemented with 500ug mycobacterium tuberculosis H37RA and 200 ng of intraperitoneal pertussis toxin on days 0 and 2. Tail paralysis was observed daily. In Experiment 1, we found that a battery of behavioral tasks delayed the onset and severity of EAE but did not affect nociception. In Experiment 2, we found that caloric restriction (CR) and chronic oral administration of riluzole, a glutamate antagonist, delayed the onset and severity of EAE. Additionally, CR and riluzole both reduced nociceptive behavior throughout disease progression. Glutamate neurotoxicity has been proposed as major determining factor that accompanies the demyelination and axonal degeneration observed during the course of MS. Further, CR plus riluzole decreased symptomology more so than CR alone. Lastly, we found altered levels in proteins important for normal immune reactions such as TNFα, Treg, IL-6, BDNF, pSTAT3, and leptin. Altered immunological function was also indicated by reduced demyelination in the spinal cords of mice treated with riluzole. These findings indicate a compelling need to delineate the roles of glutamate, the immune response, and CR in EAE.

Title: Acetylation changes regulate cytokine induced cell death and IRF-1 signalling in the HOG (Human Oligodendroglioma) cell line

Authors: *E. LODA, Y. WANG, J. PATEL, D. LIEBENSON, R. GOSWAMI, D. STEFOSKI, R. BALABANOV
Neurol., Rush Univ. Med. Ctr., Chicago, IL

Abstract: Objective: To investigate epigenetic mechanisms, specifically acetylation and its involvement in IRF-1 signaling, in cytokine induced cell death in the human oligodendroglioma (HOG) cell line. Background: Acetylation is key epigenetic modification that is involved in transcription, protein synthesis and posttranslational modification. Chromatin remodeling involves histone deacetylating enzymes (HDAC) which removes acetyl groups from lysine contributing to chromatin condensing and suppression of transcription. The opposing enzyme, histone acetylating enzyme (HAT) adds acetyl groups contributing to chromatin decondensing and activation of transcription. Our earlier studies with cell free plasma DNA have shown that epigenetic changes take place during the inflammatory stage of MS. We hypothesized that the interferon regulatory factor 1 (IRF-1) transcription factor, which is upregulated around MS lesions in oligodendrocytes and contributes to the inflammatory process, is modified by epigenetic mechanisms involving acetylation. Methods: HOG cells were treated with HDAC or HAT modifiers such as lysophosphatidic acid (LPA) and garcinal in the presence or absence of the cytokines interferon gamma, tumor necrosis factor alpha, and lipopolysaccaride. MTT and LDH assays were used to measure cell viability and cytotoxicity respectively. Immunopercipitation was used to analyze the acetylation status of IRF-1. Western blot was used for protein expression analysis. Results: Cells treated with the HDAC activator LPA, were rescued from cytokine induced cell death. The p300 inhibitor garcinal reduced expression of IRF-1 and acetylated IRF-1 expression. Conclusion: We demonstrate that acetylation epigenetic changes are involved in cytokine induced death in HOG cells. Limiting acetylation tends to rescue cells from cytokine induced death whereas increasing acetylation tends to increase cytokine induced cell death by mechanisms that involve IRF-1. Understanding the significance

of epigenetic modificatins in oligodrocyte cell death may provide a basis for development of novel therapies for cell protection in MS.

Title: Inducible deletion of myelin regulatory factor is a cell selective mechanism to impair oligodendrocyte remyelination

Authors: ***G. J. DUNCAN**[1], J. R. PLEMEL[2], J. LIU[3], R. E. HIRATA[3], Y. CHAEICHI[3], M. BERSON[3], W. TETZLAFF[3]
[1]ICORD-UBC, Vancouver, BC, Canada; [2]Univ. of Calgary, Calgary, AB, Canada; [3]Univ. of British Columbia, Vancouver, BC, Canada

Abstract: Evidence from multiple sclerosis lesions suggests chronic demyelination is associated with sustained degeneration of axons. Remyelination, is essential for the restoration of conductance following demyelination and is correlated to improved axon preservation. During remyelination, oligodendrocyte precursor cells (OPCs) are recruited to the lesion epicenter where they differentiate and mature into new myelinating oligodendrocytes, a process requiring intricate transcriptional regulation. Therapies that promote myelin repair hold enormous promise, but require a greater understanding of the key factors regulating transcription during oligodendrocyte maturation and subsequent remyelination. One factor, myelin regulatory factor (Myrf) is essential for the maturation of oligodendrocytes and the formation of central nervous system (CNS) myelin during development. However, its role in remyelination has not been elucidated. We crossed Myrffl/fl with PDGFRα Cre ERT2 mice to remove Myrf from OPCs (referred to as Myrf iKO OPC) while leaving mature oligodendrocytes intact. Mice were then

injected with lysolecithin to induce a focal demyelinating lesion in the corpus callosum, and examined at different time points post lesion. This allows for the direct assessment of the role of Myrf on different stages of OPC differentiation and remyelination. Myrf was not required for recruitment of OPCs following demyelination, but there was a marked reduction in the total number of CC1-Olig2+ mature oligodendrocytes at ten days post lesion (dpl). Additionally, by crossing Myrf iKO OPC mice with an inducible reporter mouse Rosa26-eYFP, reveals that recombined cells fail to robustly express GST-π, a marker of mature oligodendrocytes by 14 dpl. Thus, MYRF is required for the full maturation of OPCs into mature oligodendrocytes following demyelination. New nodes of Ranvier, suggestive of compact myelin formation, can be labelled by punctate caspr and ankG staining within the lesion. The number of nodes of Ranvier were reduced 14dpl in Myrf iKO OPC. Recombined cells visualized with a membrane tethered reporter reveal that when Myrf is deleted in recombined cells, they rarely contributed to forming new myelin internodes. Thus, the inducible deletion of Myrf from OPCs prior to demyelination mimics aspects of chronically demyelinated MS lesions: the inability of OPCs to mature and successfully remyelinate and can be used as new model to determine the long-term effects of impaired remyelination on demyelinated axons and its contribution to functional repair.

Title: A remyelinating antibody rHIgM22 induces proliferation in mixed glial cells

Authors: I. HAKIMI[1], *M. SRINIVAS[2], J. CAO[2], A. M. VECCHIONE[2], P. D. SARMIERE[2], M. RODRIGUEZ[3], A. O. CAGGIANO[2], D. C. BUTTON[2]
[1]Cell and Mol. Technologies, [2]Acorda Therapeut., Ardsley, NY; [3]Neurol., Mayo Clin., Rochester, MN

Abstract: The recombinant monoclonal IgM antibody known as rHIgM22 is in Phase 1 clinical trials for treatment of multiple sclerosis (MS). MS is characterized by inflammation, demyelination and axonal degeneration. rHIgM22 has been shown to induce remyelination in the Theiler's Murine Encephalomyelitis Virus and lysolecithin models of demyelination. While the

mechanism of action is not fully understood, there is evidence suggesting that rHIgM22 may influence the local environment and enable proliferation of oligodendrocyte precursors, thus supporting remyelination. To further elucidate the mechanisms of action of rHIgM22 we compared the effects of rHIgM22 with those of a human isotype control IgM (IC) on the proliferation of cells in mixed glial cultures (MGCs). While rHIgM22-induced OPC proliferation in MGCs has been shown previously (Watzlawik et al 2013), our results extend those observations by showing that microglia also proliferate in response to rHIgM22. MGCs were prepared from P2/P3 rat cortex and cultured in serum-containing medium for 5 days. Cultures were immunophenotyped using cell specific markers to ensure that a uniform complement of cells was generated from all dissections. Our MGCs are composed of GFAP-positive astrocytes (~60%), A2B5-positive OPCs (~20%), O4-positive oligodendrocytes (~10%) and IB4-positive microglia (~10%). Parallel cultures were switched to serum free medium in the presence of rHIgM22 or IC at concentrations ranging from 0.05 to 33µg/mL and incubated for 48 hours. Growth factors were included as positive control for proliferation. 5-ethynyl-2´-deoxyuridine (EdU) was added for the last 18 hours of stimulation to label proliferating cells. Fluorescent labeling of EdU was performed followed by DAPI labeling of nuclei. A Zeiss LSM 700 confocal microscope was used for image acquisition and the proliferation index was calculated as a ratio of EdU to DAPI staining. We observe a dose dependent increase in cell proliferation in rHIgM22-treated cultures that is at least two fold greater than IC with little to no proliferation in vehicle controls. To identify what cell types of the MGCs proliferate in response to rHIgM22, we co-labeled treated cultures with EdU and the cell specific markers listed above. Our results suggest that microglia and OPCs proliferate in response to rHIgM22. In addition to previously demonstrated effects on oligodendrocytes, it is also possible that rHIgM22 has an indirect activity through microglia which in turn influences OPC proliferation. Further studies are being pursued to examine actions of rHIgM22 on responsive cells in MGCs treated for either short (2 days or less) or long times (5-7 days).

Title: Is PGJ2 involved in the effect of indomethacin on bone marrow mononuclear cell migration to the sciatic nerve of the rat after a lesion?

Authors: V. USACH, C. I. CASALIS, K. WEBER, G. PIÑERO, M. FERNÁNDEZ-TOMÉ, *P. C. SETTON-AVRUJ
Sch. of Pharm. and Biochem, Buenos Aires, Argentina

Abstract: Demyelination is one of the hallmarks of the Wallerian degeneration (WD) process and cell therapy is among the strategies under study to induce remyelination. Results from our group obtained in a reversible model of WD induced by the crush of the rat sciatic nerve demonstrated the spontaneous migration of endogenous or transplanted bone marrow mononuclear cells (BMMC) exclusively to the injured nerve. Once in the ipsilateral nerve, some BMMC colocalized with Schwann cell markers and nerve fiber markers, which accelerated the degeneration process and, as a consequence, the regeneration process too. On the basis of these results, the aim of the present work was to evaluate whether prostaglandins (PGs), one of the molecules generated during the inflammatory process associated with the injury, is one of the signals involved in the migration and recruitment of BMMC to the demyelinated nerve. To that end, adult Wistar rats were submitted to sciatic nerve crush and one group of animals was transplanted with BMMC through the sacra artery immediately. The presence of BMMC in the injured nerve was evaluated through confocal microscopy 24 h, 3 and 5 days post injury; the expression of ciclooxigenases (Cox-1 and Cox-2) and the synthesis of PGs were evaluated between 0 and 24 h post crush, through Western blot and PGs radioconversion, respectively. Besides, the effect of a non-steroidal anti-inflammatory drug as indomethacin on the migration of BMMC and PGs biosynthesis was analyzed, treating the animals with a subcutaneous injection of indomethacin 50 mg/kg/day the day of the lesion and the previous day, and 5 mg/kg/day the subsequent days. The results obtained show that, as soon as 24 h post injury, BMMC arrived at the edges of the ipsilateral nerve, and after 3 days they became part of it. As regards PGs biosynthesis, the expression of the inducible form of ciclooxigenase, Cox-2, was observed in the ipsilateral nerve 2 hours after the nerve injury and continued at 24 h. Our results demonstrate the biosynthesis of PGE2, PGD2 and PGJ2 in sciatic nerve homogenates, and that their levels did not change significantly as a consequence of the lesion. Although indomethacin inhibited the migration of transplanted BMMC to the injured sciatic nerve, the biosynthesis of PGE2 and PGD2 was not affected. Surprisingly, indomethacin promoted a significant increase in PGJ2 both in the contralateral and the ipsilateral nerves. Further experiments are necessary to elucidate the specific participation of PGs in BMMC migration and to understand the effect of indomethacin on the degeneration-regeneration process.

Title: Zinc transporter 3 (ZnT3) gene deletion reduces spinal cord white matter damage and behavioral deficits in a murine MOG-induced multiple sclerosis model

Authors: ***B. CHOI**[1], J. KIM[1], H. KIM[1], B. LEE[1], I. KIM[1], M. SOHN[2], J.-Y. KOH[3], S. SUH[1]
[1]Dept. of Physiol., Hallym University, Col. of Med., Chuncheon, Korea, Republic of; [2]Dept. of Nursing, Inha Univ., Incheon, Korea, Republic of; [3]Dept. of Neurol., Ulasn University, Sch. of Med., Ulsan, Korea, Republic of

Abstract: The present study aimed to evaluate the role of zinc transporter 3 (ZnT3) on multiple sclerosis pathogenesis. Experimental autoimmune encephalomyelitis (EAE), a disease model of multiple sclerosis, was induced by immunization with myelin oligodendrocyte glycoprotein (MOG 35-55) in female mice. Three weeks after the initial immunization, demyelination, immune cell infiltration and blood brain barrier disruption in the spinal cord were analyzed with Luxol Fast Blue (LFB) staining, cresyl violet staining and immunohistochemistry. Clinical signs of EAE first appeared on day 11 and reached a peak level on day 18 after the initial immunization. ZnT3 gene deletion profoundly reduced the daily clinical score of EAE mice. The ZnT3 gene deletion-mediated inhibition of the clinical course of EAE was accompanied by suppression of inflammation and demyelination in the spinal cord. Cresyl violet staining of wild-type mice with EAE revealed intensive infiltration of mononuclear cells around microvessels in the spinal cord. LFB staining of the spinal cord also exhibited severe demyelination in wild-type mice with EAE. The behavioral deficits accompanying neuropathological changes associated with EAE were dramatically reduced in ZnT3 knockout mice with EAE. This reduction was accompanied by coincident reductions in demyelination and infiltration of encephalitogenic immune cells including CD4+ T cells, CD8+ T cells, CD20+ B cells and F4/80 cells in the spinal cord. These results demonstrate that ZnT3 gene deletion inhibits the clinical features and neuropathological changes associated with EAE. ZnT3 gene deletion also remarkably inhibited

EAE-associated BBB disruption and MMP-9 activation. The present study found that MOG-induced EAE increased ZnT3 expression in the spinal cord. Therefore, amelioration of EAE-induced clinical and neuropathological changes by ZnT3 gene deletion suggests that vesicular zinc may be involved in several steps of multiple sclerosis pathogenesis.

Title: Histological correlates of oct measures of retinal nerve fiber layer thickness in a large animal model of dysmyelination

Authors: ***I. D. DUNCAN**[1], J. VER HOEVE[3], B. GLATTING[3], L. TEIXEIRA[2], J. MAYER[1], R. DUBIELZIG[2], C. SMITH[1]

Abstract: Axon loss in multiple sclerosis (MS) is the likely reason that patients with relapsing-remitting disease decline and enter a secondary progressive phase. Determining axon loss in patients has relied primarily on MRI of the brain and spinal cord. Recently, non-invasive optical coherence tomography (OCT) imaging of the thickness of the retinal nerve fiber layer (RNFL).has been promoted as a means to study axon loss in MS patients. However, at present, there is no direct (histological) evidence of loss of retinal ganglion cell axons in MS. We studied the correlation between OCT measurement of RNFL thickness and histology in a large animal model of a genetic dysmyelinating disorder: dogs with a mutation in proteolipid protein gene *plp1*, allelic to the mutation causing Pelizaeus-Merzbacher disease in humans. We hypothesized that chronic dysmyelination may cause a chronic loss of axons in the optic nerve of *plp1* mutant dogs and result in atrophy of the RNFL. Here we present the results from four dogs (2 with *plp1*

mutation and 2 controls) over a period of 2 years, measuring spectral-domain OCTs (sdOCTs) and flash visual evoked potentials (VEPs) at quarterly intervals. Axon numbers in the optic nerve and in the retina were then quantitated histologically. We found sdOCT estimates of RNFL thickness were significantly thinner in the affected dog retina and correlated with histologically-determined measures. Microcystic changes in outer retina, reported in MS, were not observed in these dogs. Functional measures, including behavioral assessments and VEPs from affected dogs were markedly reduced. PLP1 mutant dogs show evidence of RNFL thinning on OCT and corresponding histology and therefore may be a valuable model for validating the use of non-invasive imaging in demyelinating disorders.

Title: Brain-derived neurotrophic factor and tau as molecular markers of multiple sclerosis

Authors: *A. ISLAS[1], C. F. CUEVAS[2], L. M. ESPAILLAT[2], B. BERTADO-CORTES[2], P. GARCIA-DE LA TORRE[1]

Abstract: Multiple Sclerosis (MS) is an inflammatory, progressive, and degenerative disorder of the central nervous system (CNS). It affects mainly white matter, causing axonal demyelination and deterioration. Whith a relapsing-remitting course, followed by a secondary progressive disability, which leads inevitably to deficiencies in life's quotidian activities and functional capacity. Severity of cognitive deterioration in this disease is directly related to the location of the demielinizated tissue. MS development can be measured by MIR, taking into account the presence and number of lesions in the brain. Activation of immune system in response to MS can also be a predictor of the disease´s course. Besides, several proteins have been studied as potential predictors of disease´s development, which could provide quantitative, sensitive, and

reliable information about MS. Among these biomarkers, BDNF has been associated to neuroprotection, and Tau has been studied as a marker for neural damage. Both markers are potential predictors of MS progression, however there are contradictory data about them. Here, we measured BDNF and Tau in peripheral blood of 50 MS patients and 50 control subjects. We found that BDNF levels in peripheral blood of MS patients was lower than in controls, which could be related to a diminished neuroprotection for patients with MS. It could also mean that the consumption of BDNF is higher in MS patients as a consequence of the damage the disease itself produces to the tissue. On the other hand, we found no differences between patients and controls when Tau was measured. In conclusion, our results show that BDNF can be used as a biomarker of MS, as it diminishes in peripheral blood in patients with the disease; on the other hand, Tau cannot be used as a marker.

Title: Electroacupuncture promotes the differentiation of transplanted trkc gene modified bone marrow mesenchymal stem cells into oligodendrocyte-like cells and remyelination in the demyelinated spinal cord of rat

Authors: *Y. DING[1,2]
[1]Div. of Neuroscience, Dept. of Histology and Embryology, Zhongshan Sch. of Medicine, Sun

Yat-Sen Universi, Guangdong, China; [2]Div. of Neuroscience, Dept. of Histology and Embryology, Zhongshan Sch. of Medicine, Sun Yat-sen Univ., Guangzhou, China

Abstract: Our previous study indicated that electroacupuncture (EA) treatment could promote NT-3 expression, increase the cell number and differentiation of endogenous oligodendrocyte precursor cells (OPCs), and remyelination in the demyelinated spinal cord. However, the number of oligodendrocytes differentiated from the endogenous OPCs is limited. It is known that NT-3 promotes the survival and differentiation of cells by preferentially binding to its receptor TrkC. In this study, we attempted to transplant TrkC gene modified MSCs (TrkC-MSCs) into the demyelinated spinal cord to investigate whether EA treatment could promote NT-3 secretion in the demyelinated spinal cord, and to determine whether increased NT-3 could further enhance transplanted TrkC-MSCs to differentiate into oligodendrocytes, remyelination and functional recovery in the demyelinated spinal cord. The spinal cord of adult Sprague-Dawley rats was microinjected with ethidium bromide (EB) at T10, to establish a demyelinated model. Six groups of animals were performed for the experiment: Sham, EB+PBS, MSCs, MSCs+EA, TrkC-MSCs and TrkC-MSCs+EA group. Our results showed that TrkC-MSCs transplantation combined with EA (the TrkC-MSCs+EA group) treatment significantly increased the number of NG2-positive OPCs and APC-positive oligodendrocyte-like cells differentiated from transplanted MSCs compared with the other transplantation groups. By toluidine blue-stained semithin and electron microscopy analysis, we found that concomitantly the number of newly formed myelins was increased and oligodendrocyte-like cells differentiated from TrkC-MSCs formed myelin sheaths. Immunofluorescence histochemistry and Western blot analysis showed that TrkC-MSCs transplantation and EA treatment could promote the MBP expression and Kv1.2 arrangement trending to normal level. Furthermore, behavioural test and cortical motor evoked potentials detection demonstrated a significant functional recovery in the TrkC-MSCs+EA group. In conclusion, our results suggested that EA treatment increased NT-3 expression and promoted oligodendrocyte-phenotype differentiation from TrkC-MSCs and remyelination in the demyelinated spinal cord as well as the functional improvement of demyelinated spinal cord.

Title: Intermittent blockade of the OGF-OGFr axis by low dose naltrexone upregulates OGF and inhibits the progression of established relapse-remitting experimental autoimmune encephalomyelitis

Authors: L. A. HAMMER, P. J. MCLAUGHLIN, *I. S. ZAGON
Dept Neural & Behav Sci, H109, Penn State Univ. Coll Med., HERSHEY, PA

Abstract: Relapse-remitting multiple sclerosis (RR-MS) is a chronic immune system related disorder. RR-MS affects approximately 350,000 people in the U.S., with progressive physical and emotional deterioration. The Opioid Growth Factor (OGF)-OGF receptor (OGFr) pathway has been reported to inhibit progression of established chronic progressive EAE as well as reduce astrogliosis and neuronal damage in the spinal cord. RR-EAE was established in SJL/J mice with PLP139-151 immunizations, and previous studies have shown that OGF therapy initiated with induction of disease markedly reduce behavior and neuropathology. OGFr blockade was invoked by daily injections (ip) of 0.1 mg/kg naltrexone (low dose naltrexone, LDN) or saline beginning 2 days after initial signs of disease. Within 9 days of LDN treatment, mice responding to LDN treatment had markedly reduced mean behavioral scores compared to controls, with the sum of behavioral scores being 142.9±11.5 for the RR-EAE+Saline group in comparison to 78.8±9.1 for the RR-EAE+LDN group. In the LDN group, 80% of the mice had complete remission (behavioral scores of 0.5 or less) during the 40 day observation period. Exogenous administration of OGF (10 mg/kg) to mice with established RR-EAE also resulted in changes in behavior within 9 days. OGF-responder mice had markedly reduced mean behavior scores relative to controls; the sum of the behavior scores was 140.1±14.4 for the saline-treated group in comparison to 72.2±11.5 for the group of mice responding to OGF. Disease severity scores were 3.6±1.7 for OGF treated mice in comparison to 16.3± 5 for mice receiving saline. No saline-treated RR-EAE mouse had a complete remission, whereas 83% of OGF mice had complete remissions (behavioral score $\leq$ 0.5); the total length of time in complete remission was 9.1±3.4 days for the RR-EAE+OGF animals over the course of the 40-day experimental period. Approximately 40-50% of mice receiving either LDN or OGF did not respond to treatment when initiated 2 days after established disease. In summary, OGF given exogenously or induced by intermittent receptor blockade , inhibited the severity of initial flair and limited the progression of clinical disease in mice with RR-EAE. These observations support LDN or OGF as non-toxic and safe biotherapies for the treatment of RR-MS.

Title: Physical exercise alters the composition of the lesion extracellular matrix and promotes white matter regeneration

Authors: *S. K. JENSEN, M. B. KEOUGH, L. CRAIG, J. PLEMEL, C. BRIDEAU, V. YONG
Univ. of Calgary, Calgary, AB, Canada

Abstract: Physical exercise is considered a critical component of a healthy lifestyle and is known to have efficacy in treating/controlling many systemic disorders. In the central nervous system, regular exercise has been associated with a decrease in the risk of developing neurodegenerative disorders. Indeed, a possible role for exercise in the treatment of Parkinson's disease, age-related cognitive decline and neuroinflammation, and mood/anxiety disorders has been described. Studies conducted within these model systems have identified pleiotropic mechanisms activated by exercise with the capability of promoting neuroregeneration. Specifically, described mechanisms include: increased neurogenesis and oligodendrogliogenesis, enhanced neural plasticity, induction of growth factor expression, and modulation of the immune system and the pathological microenvironment. Our previous data has implicated lesion-accumulated chondroitin sulfate proteoglycan (CSPGs) as inhibitors of oligodendrocyte migration, maturation and remyelination (Lau et al., Ann Neurol 72:419, 2012; Nature Rev Neurosci 14:722, 2013). In the current study, we hypothesized that physical exercise is an efficacious intervention for promoting white matter regeneration following a demyelinating insult, and that its mechanisms of benefits involve affecting the microenvironment/extracellular matrix, particularly CSPG deposition. To examine this, we induced a focal demyelinating lesion via injection of lysolecithin into the dorsal funiculus of the mouse spinal cord. Mice were singly housed and given free access to an electronically monitored running wheel, which were locked in control animals, at the day of injury until sacrifice at either 7, 14, or 21 days post lesion (representing peak demyelination, early remyelination, and late remyelination, respectively). We observed reduced lesion volumes in exercising animal, which was associated with an increased presence of lesion-associated myelin as assessed by eriochrome cyanine staining and myelin basic protein immunohistochemistry. Further, phosphorylated neurofilament immunoreactivity revealed a greater number of axons present in the lesion of exercising animals. The frequency of $GFAP^+$ reactive astrocytes, $Iba1^+$ macrophages/microglia, and $Olig2^+$ oligodendrocyte precursor cells appears to be unaltered by exercise. Impressively, a significant reduction in the accumulation of versican, a member of the CSPG family, was observed. These results indicate that physical exercise can improve white matter regeneration and may be an important tool for the treatment of demyelinating disorders, such as multiple sclerosis.

Title: Fingolimod increases hippocampal histone H3 Lys14 acetylation and ameliorates behavioural and cognitive functions in a mouse model of reactive depression

Authors: L. DI NUZZO[1], R. ORLANDO[2], C. TOGNOLI[3], P. DI PIETRO[4], M. MOTOLESE[4], E. MOSCARDO[3], M. PELLITTERI[3], G. BERTINI[3], P. F. FABENE[3], G. BATTAGLIA[4], *V. BRUNO[1,4,5], F. NICOLETTI[1,4,5]
[1]Univ. Sapienza, Rome, Italy; [2]I.R.C.C.S. Associazione Oasi Maria S.S., Trona, Italy; [3]Neurolog. and Movement Sci., Univ. of Verona, Verona, Italy; [4]Neurosci., I.R.C.C.S. Neuromed, Pozzilli, Italy; [5]I.R.C.C.S. Neuromed, Sapienza University, Italy, and Univ. of Lille, France, LIA (International Associalted Laboratories), Roma, Italy

Abstract: Since epigenetic regulation of gene expression has been implicated in the hippocampal dysfunction that characterizes the pathophysiology of depressive disorders, drugs able to influence chromatin remodeling in this brain area can have antidepressant properties. Fingolimod, a CNS-permeant sphingosine-1-phosphate (S1P) analogue, is the first oral drug to have received the regulatory approval for the treatment of multiple sclerosis. Independently of its immunological mechanism of action, fingolimod can increase hippocampal BDNF expression when injected intraperitoneally in mice. Considering that S1P can inhibit *in vitro* the activity of type-2 hystone deacetylase (HDAC2), fingolimod could influence gene expression by affecting chromatin regulation in the hippocampus. BDNF levels are reduced in the hippocampus of depressed individuals and this reduction can be due to an alteration in the epigenetic regulation of the bdnf gene promoter. Moreover, it is hypothesized that the clinical efficacy of antidepressant drugs is based, at least partially, on their ability to restore normal concentrations of the neurotrophin. We examined the antidepressant-like activity of fingolimod in mice exposed to four weeks of chronic unpredictable stress (CUS). Different groups of mice were treated daily with vehicle or fingolimod (3 mg/kg). Treatments started from the 3rd week of CUS and continued for 4 weeks (i.e. up to 3 weeks after the end of CUS). We examined depressive-like

behavior (forced swim test), anxiety-like behavior (elevated plus maze), spatial memory (Morris water maze), and social memory (social recognition test). In addition, we measured acetylated and non-acetylated H3 (Lys14) levels in the hippocampus, HDAC2 and BDNF mRNA and protein levels in the hippocampus and prefrontal cortex. Moreover, we evaluated hippocampal neurogenesis (BrdU and Dcx immunostaining). We found a significant antidepressant-like activity of fingolimod in the forced swim test, which was associated with an improvement of cognitive functions measured by the Morris water maze test and with an antidepressant-like neurochemical phenotype. Accordingly, CUS-exposed mice treated with fingolimod showed an increased acetylation of H3 at Lys14, a reduced expression of HDAC2 and an increased expression of BDNF in the hippocampus. In addition, fingolimod-treated mice showed an increased neurogenesis in the hippocampal dentate gyrus. These findings are consistent with the recent clinical evidence that multiple sclerosis patients who switched from first-line disease modifying drugs into fingolimod showed a significant reduction of depressive symptoms.

Title: A small molecule ligand for TrkB/TrkC neurotrophin receptors improves motor dysfunction and pathology in trembler mice

Authors: ***F. M. LONGO**[1], T. YANG[1], K. C. TRAN[1], S. M. MASSA[2,3]
[1]Dept. of Neurol. and Neurolog. Sci., Stanford Univ. Med. Ctr., Stanford, CA; [2]San Francisco Veterans Affairs Med. Ctr., San Francisco, CA; [3]Dept. of Neurol., Univ. of California, San Francisco, CA

Abstract: Charcot-Marie-Tooth disease (CMT) disease is the most common hereditary peripheral neuropathy and CMT1A is a dominantly inherited form, affecting an estimated 50% of CMT patients. It is most frequently caused by duplication of peripheral myelin protein 22

(PMP22), but is also caused by point mutations in the PMP22 gene. Currently, there is no effective drug therapy for CMT1A. Previous studies showed that neurotrophin-3 (NT-3) administered via gene therapy promoted nerve regeneration and increased myelin thickness in the Trembler-J (TrJ) CMT1A mouse model (Sahenk et al., Molecular Therapy, 2014) and in sural nerves from CMT1A patients (Sahenk et al., Neurology, 2005). However, long-term treatment with NT-3 and other neurotrophins such as brain-derived neurotropic factor (BDNF) is limited by short half-lives and poor bioavailability. Treatment of TrJ mice with TrkB and TrkC agonist antibodies individually or in combination over 20 weeks via subcutaneous injection were found to improve myelin and axonal morphological measures, with the combination TrkB/C therapy most effective for some endpoints. Our laboratories have developed a small molecule, non-peptide ligand, BC-2, that binds to and activates both TrkB and TrkC, but not TrkA or p75 neurotrophin receptors. We hypothesized that BC-2 might have effects similar to TrkB/C agonist antibodies and consequently evaluated its effects on morphological and behavioral deficits in TrJ mice. BC-2 was administered via intraperitoneal injection (50 mg/kg) three times per week for 20-21 weeks starting at 10-12 weeks of age in male TrJ mice, which begin to manifest tremor and demyelination at 4-6 weeks of age. BC-2 significantly increased myelin thickness in the sciatic nerve of TrJ but not wild type mice, and resulted in diminished clasping behavior and improved performance on gait and catwalk testing relative to vehicle treatment. Further, BC-2 treatment increased the number and size of myelinated axons and partially reversed the deficit in levels of phosphorylated neurofilament (NF)-H. Overall, these results support the idea that concomitant targeting of TrkB and TrkC might offer a novel, pharmacologically feasible small molecule strategy for treatment of patients with CMT1A and other neuropathies.

Title: Acute desipramine restores presynaptic cortical defects in murine experimental autoimmune encephalomyelitis by suppressing central CCL5 overproduction

Authors: *A. PITTALUGA, S. DI PRISCO, E. MEREGA, A. UCCELLI, S. CASAZZA
Univ. of Genoa, Dept. Pharm., Genoa, Italy

Abstract: Altered glutamate exocytosis and cyclic adenosine monophosphate (cAMP) production in cortical terminals of Experimental Autoimmune Encephalomyelitis (EAE) mice occur at the early stage of disease (13 days post immunization, d.p.i.). Neuronal defects were paralleled by central chemokine Regulated upon Activation Normal T cell Expressed and Secreted (RANTES or CCL5) overexpression, suggesting its role in presynaptic impairments. We propose that drugs able to restore CCL5 content to physiological levels could also rescue presynaptic defects. Because of its efficacy in controlling CCL5 overexpression, desipramine (DMI) appeared to be a suitable candidate to test our hypothesis. Control and EAE mice at 13 d.p.i. were acutely or chronically DMI administered and monitored for behaviour and clinical score. Noradrenaline and glutamate release, cAMP, CCL5 and TNF-α productions were quantified in cortical synaptosomes and homogenates. Peripheral cytokine production was also detected. Noradrenaline exocytosis and α2-autoreceptor-mediated activity were unmodified in EAE mice at 13 d.p.i. when compared to control. Acute, but not chronic, DMI reduced CCL5 level in cortical homogenates of EAE mice at 13 d.p.i., leaving unaltered peripheral IL-17 and TNF-α contents as well as CCL5 plasma levels. Acute DMI caused a long-lasting restoration of glutamate exocytosis, rescued endogenous cAMP production, and impeded the shift from inhibition to facilitation of the CCL5-mediated control of glutamate exocytosis. Finally, DMI ameliorated anxiety-related behaviour but not motor activity and clinical scores. We propose DMI as an add-on therapy to normalize neuropsychiatric symptoms in MS patients at the early stage of disease.

Title: Pro-myelinating serum-derived exosomes from environmentally enriched rats are secreted by peripheral blood mononuclear cells

Authors: *A. D. PUSIC, K. M. PUSIC, R. P. KRAIG
Univ. of Chicago, Chicago, IL

Abstract: Grey matter demyelination is an important component of multiple sclerosis (MS) pathogenesis, particularly in the secondary progressive disease phase. Extent of damage is strongly correlated to decline in memory and cognitive dysfunction. Aging likewise occurs with cognitive decline from myelin loss, and age-associated failure to remyelinate significantly contributes to MS progression.Evidence shows that parabiotic exposure of aged animals to a youthful systemic milieu improves remyelination. We discovered that this effect involves serum exosomes that increase oligodendrocyte precursor cells and their differentiation into mature myelin-producing cells - both under normal conditions and after acute demyelination (1). Environmental enrichment (EE) of aging animals produced exosomes that mimicked this pro-myelinating effect. We found that both young and EE serum-derived exosomes were enriched in miR-219, which is necessary and sufficient for production of myelinating oligodendrocytes (2). Thus, peripherally produced exosomes found in the serum of young or environmentally enriched animals may be a useful therapy for remyelination. Here, we aimed to better characterize these exosomes. Exosomes found in the blood can originate from a multitude of sources, and it is precisely this attribute that makes them ideal candidates as biomarkers of disease. For example, in a variety of solid organ cancers, tumor-derived exosomes can be isolated from blood (3). However, based on work demonstrating that the properties of serum-derived EE exosomes could be reproduced *ex-vivo* using cultured primary dendritic cells (Pusic et al., 2014, J Neuroimmunol), we focused on immune cells. As a first step in determining the cellular source of pro-myelinating exosomes, we briefly cultured peripheral blood mononuclear cells (PBMCs) isolated from whole blood of EE and control animals and harvested exosomes from the conditioned media. Like EE serum exosomes, PBMC exosomes increased baseline myelin content when applied to slice cultures. This begins to confirm our hypothesis that these exosomes are produced by immune cells and allows us to further focus on specific cell populations within the broad category of 'PBMCs'. Accordingly, we sorted PBMCs into constituent cell populations (T cells, B cells, dendritic cells and macrophages) for collection of exosomes. Functional assays are in progress, and miRNA screens of exosome content for each group will be performed and expression profiles compared to that of exosomes harvested from EE serum. Title: Nasal administration of IFNγ-stimulated dendritic cell exosomes inhibits spreading depression

Authors: *K. M. PUSIC, A. D. PUSIC, R. P. KRAIG
Dept. of Neurol., Univ. of Chicago, Chicago, IL

Abstract: Migraine with aura (MwA) and multiple sclerosis (MS) are clinically correlated, and both display brain imaging white matter abnormalities suggestive of myelin disruption (1). Likewise, MS modeled in rats reduces the threshold to spreading depression (SD), the likely cause of aura and pain in MwA (2). Using brain slice cultures, we discovered that SD transiently disrupts grey matter myelin. Like MS, this SD-induced demyelination involves T cells, their release of IFNγ and increased oxidative stress, which may serve to increase neutral sphingomyelinase-2 (nMase-2) activity by depleting glutathione. (3). These changes are consistent with a shift in microglia to a predominantly M1 (pro-inflammatory) phenotype (3). Importantly, we have shown that exosomes derived from IFNγ-stimulated dendritic cells (IFNγ-DC-Exos) increase brain myelination and microglial glutathione (4), and may do so through modulation of microglial polarization states. Since microglia are essential for SD and their M2a polarization by environmental enrichment prevents SD (5), we probed the impact IFNγ-DC-Exos on SD. We showed that an hour of recurrent (6) neocortical SDs *in vivo* (n=5) also significantly ($p<0.001$) reduced grey and adjacent white matter myelin (as measured via myelin basic protein levels) a day later compared to the contralateral areas. When applied to slice cultures, IFNγ-DC-Exos evoked a 13-fold significant ($p<0.001$) increase in SD threshold compared to controls (n=8/group) three days later. Similarly, nasal administration of IFNγ-DC-Exos (n=6/group) caused a significant ($p<0.001$) 57-fold increase in SD threshold compared to unstimulated exosome treated shams and untreated control animals (n=5,3,4/group). Furthermore, IFNγ-DC-

Exo treatment reduced the M1 polarization shift normally observed with SD. Treatment with unstimulated exosomes did not have this effect. Examination of the contralateral hemisphere, which was not exposed to SD, showed reduced expression of M1 microglia products with IFNγ-DC-Exo relative to unstimulated exosome treatment. (n=5,3/group). Taken together, these results support a pathophysiological link between myelin dysfunction in MwA and MS. Additionally, they suggest that IFNγ-DC-Exos, which have been suggested as a novel treatment to reduce inflammation and promote remyelination in MS (6) may also be beneficial for MwA and perhaps migraine in general. Title: Multiple sclerosis therapeutic glatiramer acetate enhances oligodendrocyte precursor cell differentiation and remyelination

Authors: *S. COTTRELL-CUMBER, A. ROSEN, A. FERNANDEZ-CASTANEDA, A. GAULTIER
Univ. of Virginia, Charlottesville, VA

Abstract: Multiple Sclerosis (MS) is a progressive neurological illness characterized by destruction of the myelin sheath surrounding neurons in the central nervous system. The destruction of the myelin sheath is mediated by autoreactive T cells. Current pharmacological therapies seek to decrease the severity of the inflammatory response on the damaged axons by suppressing various aspects of the immune system. One such current MS treatment, Glatiramer Acetate (GA), is believed to act as an immunomodulatory peptide that shifts the immune response by simulating myelin basic protein. However, evidence suggests that GA also has the ability to directly modulate oligodendrocyte progenitor cells function (OPCs) to enhance differentiation and remyelination in MS lesions. Chronic demyelination is a major cause of neurodegeneration in MS patients. The CNS contains OPCs that have the potential to differentiate into mature oligodendrocytes and remyelinate denuded axons. However, myelin

debris lingering in the MS plaques inhibits the process of axon remyelination. Here we **demonstrate an immune independent action of GA and OPCs, through the enhancement of OPC differentiation and remyelination.** Our data shows that GA increases markers of myelination in CG4 cells, an OPC cell line. We have observed increased myelin basic protein (MBP) RNA and protein expression in CG4 cells treated with GA. Since myelin is known to inhibit the differentiation of OPCs, we will challenge OPCs with myelin, and then measure production of MBP in the presence or absence of GA. We expect to see increased MBP expression when GA is applied; this would indicate the ability of GA to overcome myelin inhibition and augment remyelination. We believe GA promotes OPC differentiation in MS, which could explain its beneficial effects as a therapeutic; further identification of a downstream signaling pathway could lead to the development of a novel remyelination therapeutic.

Title: CB2 receptor mediated cannabinoid signaling contributes to the therapeutic effect of 2-AG hydrolytic enzyme ABHD6 inhibition on EAE

Authors: J. WEN, M. TANAKA, R. RIBEIRO, *Y. ZHANG
Anatomy, Physiology, Genet., Uniformed Services Univ., BETHESDA, MD

Abstract: Agents targeting both inflammation and neurodegeneration at the early stage might be desirable for the treatment of multiple sclerosis (MS). The endocannabinoid system, consisting of cannabinoid receptors, their endogenous ligands including anandamide (AEA) and 2-arachidonoylglycerol (2-AG), and enzymes for their synthesis and degradation, is known to play a crucial role in controlling neuroinflammation and neurodegeneration. Studies have shown that increasing endogenous levels of 2-AG by inhibition of its principal hydrolytic enzyme

monoacylglycerol lipase (MAGL) can cause 2-AG overload, desensitization and behavioral tolerance despite of its demonstrated therapeutic effect. ABHD6 is a recently identified serine hydrolase and can compete with MAGL for 2-AG degradation. In this study, we investigated the role of ABHD6 inhibitor WWL70 in experimental autoimmune encephalomyelitis (EAE), an animal model of MS. At 28 days after EAE induction, the expression of ABHD6 significantly increased and treatment with WWL70 (10 mg/kg, i.p.) starting from the disease onset and then once daily remarkably reduced mouse symptoms, inflammatory response and neuronal damage, demonstrated by significantly lower clinical scores, less expression of iNOS, IL-1β and TNF-α, decreased infiltration of T cells, increased number of mature oligodendrocytes and preserved myelination in EAE spinal cord. Interestingly, When EAE mice were treated with WWL70 together with CB2 antagonist AM630, mice displayed the similar symptoms and pathological changes to that seen in the EAE control mice. Co-treatment with the CB1 antagonist AM281 did not affect the efficacy of WWL70 in EAE mice. WWL70 also attenuated blood-brain barrier damage through inhibiting activated leukocyte cell adhesion molecule (ALCAM) expression. Furthermore, the findings that the increased expression of CB2 receptors in EAE mouse spinal cord and the lack of effects of WWL70 in CB2 knock out EAE mice provide strong evidence that CB2 mediated endocannabinoid signaling contributes to the therapeutic efficacy of ABHD6 inhibition. In addition, we found that treatment with WWL70 reduced the induction of COX-2 and the production of prostaglandin E2 (PGE2) in microglia activated by lipopolysaccharide, consistent with the recent notion that inhibition of 2-AG hydrolysis can enhance cannabinoid signaling and reduce eicosanoid signaling. These results suggest that selectively targeting the 2-AG hydrolytic enzyme ABHD6 might be used as a novel therapeutic strategy for MS.

Title: Fingolimod promotes primary sensory afferent growth through S1P1 receptor inhibition of cAMP

Authors: *M. MCNAMARA, A. GALVIN, T. CLASON, C. J. FOREHAND
Neurosci. Grad Program, Univ. of Vermont, Burlington, VT

Abstract: Fingolimod, a Sphingosine-1 phosphate (S1P1) agonist is an approved oral treatment for relapsing forms of multiple sclerosis. The primary therapeutic mechanism of Fingolimod is to bind to S1P1 receptors on the surface of lymphocytes, internalize the receptor and prevent S1P1 dependent egress from the primary lymphoid tissue where it would infiltrate the central nervous system and cause neurodegeneration (Gasperinin et al., 2012). In addition to its effects on immune cells, Fingolimod is known to increase brain derived neurotrophic factor (BDNF) secretion from neurons *in vitro* (Deogracias et al., 2012). During neural development, dorsal root ganglion (DRG) cells produce a peripheral and central process. The central process of DRG neurons extend into the spinal cord at the dorsal root entry zone. These processes branch and extend longitudinally along the rostral-caudal axis in the white matter prior to growth into the grey matter of the cord. Longitudinal growth is increased by BDNF and inhibited by blocking TrkB. We show here that Fingolimod increases the rate of extension of the DRG central process along the rostral-caudal axis ($p<0.0001$). Further, we have shown that application of Fingolimod significantly increases the release of BDNF into the media ($p<0.05$) suggesting that Fingolimod promotes BDNF release to accelerates axon outgrowth. The current experiments are designed to test the hypothesis that Fingolimod increases axon outgrowth through the S1P1 receptor to promote BDNF release. Application of an S1P1 antagonist W123 significantly decreased longitudinal growth while application of S1P1 agonist SEW2817 increased longitudinal growth. As activation of the S1P1 receptor is known to decrease cAMP we tested whether manipulation of cAMP affected axon outgrowth. We show here that application of Forskolin, a drug known to increase cAMP decreased axon outgrowth. In contrast, H89, a drug known to decrease PKA activation by cAMP increased axon outgrowth. Fingolimod and H89 together showed no greater increase in axonal extension than either alone. However, Fingolimod was able to decrease the inhibitory effect of Forskolin on axonal extension. These results suggest that Fingolimod acts by decreasing cAMP to stimulate axonal outgrowth. These results further suggest that a decrease in cAMP will lead to an increase in BDNF secretion in this system.

Title: Optical coherence tomography (OCT) as a predictive and longitudinal *in vivo* biomarker of disease and estrogen receptor β agonist-induced repair in a mouse model of multiple sclerosis

Authors: *A. J. KHALAJ[1,2], P. KIM[3], M. SYED[2], S. HABIB[3], S. NUSINOWITZ[3], J. A. KATZENELLENBOGEN[4], S. K. TIWARI-WOODRUFF[1,2]
[1]Div. of Biomed. Sci., Univ. of California, Riverside, Riverside, CA; [2]Neurol., [3]Jules Stein Eye Inst., UCLA, Los Angeles, CA; [4]Chem., Univ. of Illinois, Urbana, IL

Abstract: Identifying predictive and longitudinal *in vivo* biomarkers to assay therapeutic efficacy is integral to developing treatments for neurodegenerative diseases such as multiple sclerosis (MS). Optic neuritis (ON) is a common acute manifestation of MS onset; similarly, experimental autoimmune encephalomyelitis (EAE) mice, a rodent model of MS, exhibit ON. Optical coherence tomography (OCT) allows for direct visualization of retinal structure, including optic nerve head topography. Quantification of the retinal nerve fiber layer (RNFL) and ganglion cell layer (GCL) by OCT provides an indirect measure of axonal and neuronal loss in anterior visual pathways. Optic neuropathies and numerous neurological disorders, including MS, show abnormal RNFL thickness. Here, we investigated the effects of late myelin oligodendrocyte glycoprotein (MOG_{35-55})-induced chronic EAE and therapeutic treatment of chronic EAE mice with the highly selective estrogen receptor β agonist Indazole-Cl (Ind-Cl) on retinal and optic nerve health. Fundus imaging and serial high-resolution spectral domain optical coherence tomography (sdOCT), followed by immunohistochemistry and electron microscopy analysis, were performed on normal and chronic EAE mice therapeutically treated with Ind-Cl or vehicle (i.e., treatment was initiated after peak clinical disease). Image analysis using template-based marking of retinal layers, including RNFL, GCL, nuclear layers, and retinal pigment epithelium (RPE), was performed using Bioptigen software (Durham, NC). Significant differences in RNFL, GCL, and RPE between normal, vehicle-, and Ind-Cl-treated EAE groups were observed. Preliminary immunohistochemical and electron microscopy data indicate increased inflammation in the retina and optic nerve, and decreased axon myelination in the optic nerve, of EAE mice. As compared to vehicle treatment, therapeutic treatment with Ind-Cl decreased retinal and optic nerve inflammation and improved optic nerve axon myelination. These data support OCT and optic nerve analysis as strongly translational *in vivo* biomarkers with which to assess the efficacies of potential neuroprotective agents for the treatment of inflammatory neurodegenerative diseases. Further, these data support therapeutic Ind-Cl as a treatment capable of improving widespread, quality-of-life-diminishing MS-related retinal and optic nerve pathology.

Abstract: Promoting generation of new myelin is an important therapeutic objective of treating demyelinating diseases such as multiple sclerosis (MS). Remyelination involves both lateral extension of oligodendrocyte processes along the axon to increase internodal length and radial growth to extend the myelin spiral. Experimental studies of remyelination most frequently utilized myelin thickness and g-ratio (axon:fiber diameter) measurements, while internodal lengths have been technically difficult to obtain. Serial blockface scanning electron microscopy (SBF-SEM) provides serial images of tissue with ultrastructural resolution and comparatively wide fields of view (0.5mm or more), which allows axonal reconstruction in 3 dimensions. To investigate rates of change in myelin thickness, internodal length, and g-ratio during remyelination, we used SBF-SEM datasets to evaluate remyelinating internodes in mouse corpus callosum at different time points after demyelination. Mice were subjected to a 12-week course of cuprizone chow and daily rapamycin injections in order to induce and maintain demyelination. They were subsequently allowed to recover for a period of either 0, 3, or 6 weeks. Myelin thickness increased to WT values by 6 wk recovery. Internodal length measurements were a more sensitive indicator of remyelination, increasing with 3 and 6 weeks recovery but not reaching WT values. Reduced internodal length also identified the few myelin internodes that had resisted demyelination in the demyelination-only treatment. In contrast, g-ratio values did not differ significantly between groups. In studies of remyelination *in vivo*, SBF-SEM-based measurements offer a sensitive metric of internodal regeneration.

Title: A comparison of therapeutic candidates for promoting oligodendrocyte differentiation and remyelination

Authors: *B. SHULTZ, Y. ZHONG
Biomed. Engin., Drexel Univ., Philadelphia, PA

Abstract: Demyelination occurs when oligodendrocytes are killed, often in response to injury or disease. Once neurons lose this myelin sheath, they lose the ability to readily transmit action potentials, resulting in a loss of patient function. To replace lost oligodendrocytes, neural stem/progenitor cells (NSPCs) can be transplanted to the injury or disease site, where they could differentiate into mature oligodendrocytes and promote new myelin formation. Alternatively, endogenous NSPCs may also be manipulated to differentiate into new oligodendrocytes. In practice, however, oligodendrocyte differentiation and maturation are often limited *in vivo* due to the abundance of inhibitory and pro-inflammatory signals that can be found in injured or diseased tissue. To overcome this hurdle, therapeutic molecules can be delivered to promote either endogenous or transplanted NSPCs to preferentially differentiate into mature, myelin-forming oligodendrocytes. A number of growth factors/molecules have been shown to promote NSPCs to differentiate into mature oligodendrocytes. However, few studies have been conducted to directly compare their potency. The objective of this study is to identify the molecule that is most effective in promoting oligodendrocyte differentiation and maturation. NSPCs were isolated from E17 rat brains, expanded in neurosphere suspension, plated down onto multiwell plates, and then differentiated in the presence of BDNF, NT-3, Sonic Hedgehog (SHH), or 3,3',5-triiodothyronine (T3), a thyroid hormone. After 10 days, the cells were fixed and stained with antibodies against O4, an early oligodendrocyte marker; myelin basic protein (MBP), a mature oligodendrocyte marker and myelin component; Tuj1, a neuronal marker; and glial

fibrillary acidic protein (GFAP), an astrocyte marker. Cells differentiated in media supplemented with 30 ng/mL T3 exhibited a significantly higher percentage of MBP+ cells than any other group, indicating that T3 is the most effective at promoting oligodendrocyte differentiation and maturation. Systemic T3 administration, however, is likely to cause patients to experience hyperthyroidism, resulting in a wide range of possible side effects including muscle weakness, nervousness, anxiety, and weight loss, among others. Thus, controlled local delivery is a much more suitable approach. Currently, our lab is developing an injectable hydrogel capable of providing sustained local release of T3, which is a promising therapeutic approach to promoting new myelin formation.

Title: Young plasma treatment delays the onset and decreases the severity of chronic eae

Authors: A. C. MARCU[1], M. C. JOSYLN[1], P. J. YANNIE[1], R. CUTLER[1], J. L. DUPREE[2], *G. H. DE VRIES[1]
[1]Res., McGuire VA Med. Ctr., Richmond, VA; [2]Dept. of Anat. and Neurobio., VCU Hlth. Sci., Richmond, VA

Abstract: The severity and onset of multiple sclerosis (MS) is closely related to age: patients usually develop the disease after the age of 20 and when diagnosed in older patients (>40 years), the disease takes an unrelenting progressive course for which there is no therapy. Therefore, a therapeutic strategy would be to reverse aging and decrease susceptibility to disease. Previous studies reportedthat the decline in neurogenesis and cognitive impairments observed duringaging can be reversed when an older CNS is exposed to a young systemic milieucreated by injection of young plasma. Using the chronic experimental autoimmune encephalomyelitis (EAE) model for demyelinating disease, we investigated the possibility that young plasma treatment can render the CNS less susceptible to EAE by reversing the aging process. Cohorts of 12 week old mice were pre-treated with young plasma (4 weeks old) or homologous plasma (12 weeks old) every

other day for 10 days, followed by initiation of EAE. Plasma injections were continued every other day for another 20 days. Mice were monitored daily and scored for the onset, severity and incidence of disease. In the mice injected with young plasma, the onset of EAE symptoms was delayed by 3 days compared to the control group, reaching a maximum average EAE score of 1, while the homologous plasma injected group had a maximum average EAE score of 3. The incidence of disease was decreased in the young plasma injected group with only 5 out of 12 mice becoming sick (42%), while in the homologous plasma injected control group, 11 out of 12 mice (92%) exhibited clinical signs of EAE. Microglial infiltration and activation was dramatically decreased in the young plasma injected group. This group also showed dramatic axonal preservation as revealed by the ratio of phosphorylated to non-phosphorylated filaments. Further experiments are underway to evaluate the molecular basis for these results. In summary, young plasma treatment is a novel therapeutic strategy which delays the onset, decreases the severity and greatly decreases the incidence of demyelinating disease in mice.

Title: 7, 8 dihydroxyflavone suppresses optic neuritis in experimental autoimmune encephalomyelitis

Authors: *D. TRISLER[1,2], V. K. C. NIMMAGADDA[1], B. TANDUKAR[1], S. I. V. JUDGE[1,2], C. T. BEVER[1,2], T. K. MAKAR[1,2]
[1]Dept Neurol., Univ. Maryland Sch. Med., BALTIMORE, MD; [2]MS Ctr. of Excellence-EAST, VA Maryland Hlth. Care Sysytem, Baltimore, MD

Abstract: Background: Optic neuritis (ON) is characterized by inflammation of the optic nerve, and is one of the first clinical signs of multiple sclerosis (MS). ON often manifests as an acute, self-limited episode with visual impairment that recovers over several weeks in the majority of patients. However, permanent visual symptoms can persist in a significant number of patients and repeat episodes of ON can lead to significant optic nerve atrophy. TrkB signaling pathways have been demonstrated to be a promising strategy to suppress inflammation and impart

neuroprotection in many neurodegenerative diseases including MS. 7, 8 dihydroxyflavone (DHF) is a small molecule has been reported to mimic the physiological actions of brain derived neurotrophic factor and to activate TrkB receptors in the brain when administered systematically. Objective: Determine the effect of DHF treatment on optic neuritis in experimental allergic encephalomyelitis (EAE), an animal model for MS. Methods: EAE was induced in C57Bl/6 female mice by immunization with myelin oligodendroglial glycoprotein peptide 35-55. DHF (5 mg/kg/day) was administered intraperitoneally from the day of disease induction. Mice were euthanized on day 28. Optic nerves were fixed in 10% formalin and embedded in paraffin. 5µm sections were used for histological analysis. Results: DHF significantly suppressed the clinical severity of EAE paralysis. Histological examination revealed decreased inflammation (H&E) and demyelination (Luxol Fast Blue) in optic nerves of DHF treated mice compared to untreated. There is a significant increase in TrkB activation in optic nerves of treated mice. Immunohistochemical analysis of optic nerves showed a significant decrease in CD45 (Common Leucocyte antigen), CD3 (T-Cell marker) and CD 20 (B-cell marker) expression in DHF treated mice compared to untreated. Conclusion: We showed that DHF treatment significantly reduced the clinical severity of EAE paralysis and also suppressed optic neuritis in these mice. DHF may prove to be a potential therapeutic approach in MS patients presenting with ON.

Title: Chondroitin sulfate proteoglycan scar formation after chronic nerve compression injury is attenuated by chondroitinase ABC administration

Authors: M. D. TAPADIA[1], M. LUU[1], J. JUNG[1], W. WANG[1], J. SU[1], T. MOZAFFAR[2], *R. GUPTA[1]
[1]Orthopaedic Surgery, [2]Neurology/Orthopaedic Surgery, Univ. of California, Irvine, Irvine, CA

Abstract: Spinal cord injury (SCI) stimulates glial scar formation rich in chondroitin sulfate proteoglycans (CSPGs). Previous work has shown that this scar can be digested with chondroitinase ABC (ChABC) to improve functional outcomes (1-2). Improvements in axonal

regeneration have also been noted with ChABC administration after peripheral nerve transection (3). Recent data from our lab confirms scar formation after CNC injury consisting of upregulation of ECM proteins such as laminin α2, collagen IV, and fibronectin. With this in mind, we sought to determine whether CSPG's are implicated in neural scar formation following chronic nerve compression (CNC) injury, and whether glycosaminoglycan digestion with ChABC might improve the dysfunction that persists in later stages of CNC despite surgery (4). Mouse sciatic nerves were harvested at 2- and 6-weeks after CNC injury for western blot (WB) and immunohistochemistry (IHC) of CSPGs including decorin, brevican, and NG2. A subset of mice then underwent intraneural injection of ChABC (0.2U/mL) at 6 weeks. Myelin degeneration and ultrastructural changes were examined with toluidine blue staining and electron microscopy. Electrophysiology studies were performed prior to each harvest. Of all CSPG's analyzed, decorin showed remarkable upregulation on both WB and IHC with 1.5 times greater expression in epi- and perineurium of compressed nerves at 6 weeks that was attenuated by ChABC injection. These data suggest that CNC injuries, similar to peripheral nerve transection and spinal cord injuries, result in proteoglycan scar that is reduced with ChABC. Further investigation is warranted into the relationship between proteoglycan scar and Schwann cell dysfunction following CNC injury, and the optimal dosing and treatment duration of ChABC. Title: A chondroitin sulfate proteoglycan synthesis inhibitor promotes myelin regeneration and immunomodulation in experimental models of demyelination

Authors: *M. B. KEOUGH, J. A. ROGERS, P. ZHANG, S. K. JENSEN, E. L. STEPHENSON, M. G. HURLBERT, J. R. PLEMEL, C.-C. LING, V. W. YONG
Univ. of Calgary, Calgary, AB, Canada

Abstract: Following demyelination, reactive astrocytes accumulate and generate a barrier of molecules known as the glial scar. One component of the scar, the chondroitin sulfate proteoglycans (CSPGs), are well established inhibitors of axonal regrowth. Our group and others have shown that CSPGs are also capable of inhibiting oligodendrocyte precursor cell (OPC) responses to injury, by reducing morphological differentiation *in vitro* and remyelination *in vivo*. Direct CNS injection of the enzyme chondroitinase ABC has been effective at reducing the CSPG burden following traumatic injuries, however practical limitations arise when considering this treatment approach for widespread demyelinating diseases such as multiple sclerosis. Here we tested the utility of a novel CSPG synthesis inhibitor, acetylated 4-fluoro-N-acetylglucosamine (fluorosamine), which prevents elongation of CSPG side-chains, to promote remyelination after injury. We show that CSPGs inhibit primary cultured murine OPCs in a side-chain dependent manner, confirming existing reports. Cultured murine astrocytes produce CSPGs in their media following cytokine stimulation; treatment with fluorosamine reduces both the amount of side-chains as well as total protein cores secreted into the media, while not affecting cell viability. Experimental demyelination via injection of the toxin lysolecithin into the mouse spinal cord white matter induces a glial scar with pronounced CSPG accumulation. Systemic treatment with fluorosamine reduces this CSPG burden, resulting in a greater extent of remyelination. We observe an additional benefit of fluorosamine in that it reduces the proliferation of stimulated T cells *in vitro*. Indeed, fluorosamine treatment following induction of experimental autoimmune encephalomyelitis in mice reduces disease severity when treatment is initiated at onset of clinical signs or peak disease. All available medicines for multiple sclerosis target only the aberrant immune component of the disease; we believe the next generation of therapeutics will require direct enhancement of myelin regeneration in addition to immunomodulation, and this may be achieved by altering the inhibitory microenvironment.

Title: Fingolimod therapy in multiple sclerosis is associated with an increase in inner nuclear layer thickness

Authors: O. A. S. AL-LOUZI[1], A. LANG[2], P. BHARGAVA[3], A. CARASS[2], J. PRINCE[2], S. SAIDHA[3], P. CALABRESI*[3]
[2]Dept. of Electrical and Computer Engin., [3]Dept. of Neuroimmunology and Neuroinfectious disorders, [1]Johns Hopkins Univ., Baltimore, MD

Abstract: **Background:** Fingolimod, a sphingosine-1-phosphate (S1P) receptor modulator, was the first oral medication approved for the treatment of relapsing-remitting multiple sclerosis (RRMS), and is a known cause of macular edema. Recently, an increase in macular volume, as measured by optical coherence tomography (OCT), has been described in MS patients following fingolimod initiation. However, it remains unclear within which retinal layers alterations occur, contributing to this increase in macular thickness. **Goal:** To determine whether initiation of fingolimod is associated with an increase in thickness of specific retinal layers. **Methods:** Spectral-domain OCT, with automated intra-retinal layer segmentation, was performed on 20 RRMS patients before and after initiation of fingolimod. OCT was also performed on a control group of 20 RRMS patients, not commenced on fingolimod. The control group was matched based on age, gender, and time interval between OCT exams. Macular segmentation measures were obtained by averaging the thickness values within 3 regions centered at the fovea: a circle of diameter 1mm (central macula), an annulus with an inner radius of 1mm and outer radius of 2.5mm (inner macula) and an annulus with an inner radius of 2.5mm and an outer radius of 5mm (outer macula). Retinal layer thickness changes within and between groups were analyzed using mixed-effects linear regression accounting for within-subject inter-eye correlation. **Results:** The average inner nuclear layer (INL) thickness increased by +0.19μm ($p<0.001$) in the group of patients who initiated fingolimod, over a mean follow-up duration of 7 months (SD 3) after starting the medication, versus a mean change of -0.06μm ($p=0.51$) in the control group. In the fingolimod-treated group, no statistically significant change was found in the average change of

the ganglion cell+inner plexiform layer thickness (GCIP; mean -0.12µm, p=0.33), the outer nuclear layer (ONL; mean +0.07µm, p=0.64), or the average macular thickness (AMT; mean +0.24µm, p=0.49). The increase in INL thickness was greatest in the central macula (mean change of +0.6µm, p<0.001), followed by the inner macula (mean change of +0.27µm, p=0.005), and was least in the outer macula (mean change of +0.14µm, p=0.025). **Conclusions:** Fingolimod therapy in patients with MS is associated with an early increase in INL thickness. This finding helps localize the retinal biological changes that occur in MS eyes as a result of S1P receptor modulation.

Title: Targeted growth arrest-specific protein 6 (Gas6) delivery to the CNS protects axons from damage during chronic experimental autoimmune encephalomyelitis (EAE)

Authors: *R. C. GRUBER, A. RAY, B. SHAFIT-ZAGARDO
Albert Einstein Col. of Med., Bronx, NY

Abstract: Growth arrest-specific protein 6 (Gas6) is a soluble agonist of the Tyro, Axl, Mer, (TAM) family of receptor tyrosine kinases identified to have anti-inflammatory and promyelinating properties. During experimental autoimmune encephalomyelitis (EAE) wildtype (WT) mice demonstrate a significant induction of Gas6, Axl, and Mer but not Protein S or Tyro3 mRNA. We tested the hypothesis that intracerebroventricular (ICV) delivery of Gas6 directly into the CNS of WT mice during myelin oligodendrocyte glycoprotein (MOG)-induced EAE would improve the clinical course of disease relative to artificial cerebrospinal fluid (ACSF)-treated mice. Gas6 did not delay disease onset, but significantly reduced the clinical scores

during peak and chronic EAE. Alternate-day subcutaneous interferon-beta (INFβ) injection delayed the onset of EAE by ~3-days, but did not reduce clinical scores during acute or chronic EAE. ICV Gas6+INFβ injections marginally reduced clinical scores relative to ACSF+INFβ treatment; however, the dual treatment resulted in higher clinical scores relative to Ivc-Gas6. Mice receiving Gas6 for ≥30 days had preserved SMI31+ neurofilament immunoreactivity, significantly fewer SMI32+ axonal swellings in the ventral spinal cord and less demyelination, relative to ACSF-treated mice. $Gas6^{-/-}$ mice sensitized with MOG_{35-55} peptide exhibit higher clinical scores, with significantly increased Iba1+ glia, and enhanced expression of TNF-α, IL-17, and IL-6 mRNA relative to WT mouse spinal cords with scores for 8 consecutive days. Our data is consistent with a role for Gas6 in dampening the inflammatory response as well as preserving axonal integrity and myelination during EAE.

Title: Exendin-4 promotes neurite outgrowth, neuronal survival and myelination *in vitro*

Authors: *K. SANGO[1], M. TSUKAMOTO[1,2], N. NIIMI[1], Y. KANAZAWA[1,2], K. WATABE[1], K. UTSUNOMIYA[2]
[1]Dept Sensory Motor Syst, Tokyo Met Inst. Med. Sci., Tokyo, Japan; [2]Div. Diabetes, Metab & Endocrinol, Dept Intrnl. Med., Jikei Univ. Sch. Med., Tokyo, Japan

Abstract: Glucagon-like peptide (GLP)-1 is an endogenous incretin hormone secreted from enteroendocrine L cells in response to oral nutrient ingestion. Besides its insulinotropic actions on pancreatic β-cells, the widespread distribution of GLP-1 receptors (GLP-1R) suggests pleiotrophic actions of GLP-1 on extrapancreatic tissues, including the nervous system. In the present study, we investigated the neurotrophic and neuroprotective properties of exendin (Ex)-4, a GLP-1R agonist, on adult rat dorsal root ganglion (DRG) neurons. Predominant localization of GLP-1R to small peptidergic and large DRG neurons *in vivo* and *in vitro*, as revealed by immunohistochemistry, suggests the involvement of GLP-1 in both small and large fiber

functions. Treatment of DRG neurons with Ex-4 at 100 nM significantly increased the average neurite length from 114.3 μm to 164.5 μm after 2 days in culture, and the average survival ratio from 55.7% to 67.4% after 7 days in culture. The enhancement of neurite outgrowth and neuronal viability induced by Ex-4 may be partially attributed to the inhibition of Rho kinase activity, as we observed in PC12 cells exposed to Ex-4 at 100 nM for 30 min. Moreover, Ex-4 promoted myelination in coculture of DRG neurons and immortalized adult rat Schwann cells IFRS1; treatment with Ex-4 at 10 and 100 nM accelerated the migration of IFRS1 cells toward the neurites extending from DRG neurons after 14 days of coculture, as seen under a phase-contrast microscope, and upregulated the expression of myelin proteins PMP22 and P0 after 21 days of coculture, as revealed by western blotting. These findings imply the efficacy of Ex-4 for the promotion of functional repair after axonal injury and the restoration of diabetic and other peripheral neuropathies.

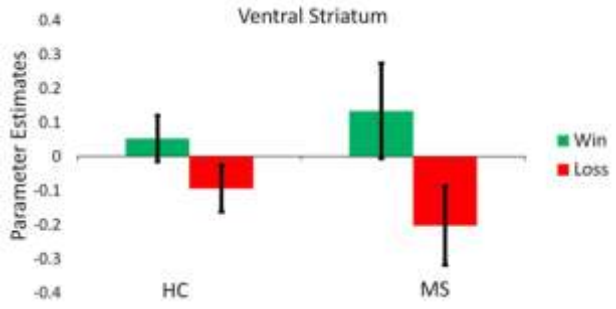
Title: Reward-related decreases of mental fatigue in individuals with multiple sclerosis: an fMRI study

Authors: *E. DOBRYAKOVA[1], H. GENOVA[2], J. DELUCA[3], G. WYLIE[3]
[1]Neurosci. and Neuropsychology Lab., Kessler Res. Foundati8on, West Orange, NJ;
[2]Neuropsychology/Neuroscience Lab., [3]Kessler Fndn., West Orange, NJ

Abstract: Up to 95% of people with multiple sclerosis (MS) experience mental fatigue (Walker et al., 2012). Mental fatigue has been proposed to be associated with impairment of the striatum (Chaudhuri & Behan, 2000), a primary input nuclei of the basal ganglia that receives dopamine-projection neurons from the substantia nigra. The striatum has been shown to be involved in affective and cognitive processes, such as effort calculation and reward valuation. Thus, there might be a link between mental fatigue and reward processes. Hence, stimulating the striatum during a affective/cognitive task may lead to a modulation of the expression of mental fatigue in individuals with MS. To test this theory we recruited 16 individuals with MS who experience

mental fatigue and 16 healthy control subjects (HC). Participants in the MS group had higher levels of fatigue compared to the HC group, as per Fatigue Severity Scale and Modified Fatigue Impact Scale. During the fMRI scan, participants performed the card-guessing task (Delgado et al., 2000) previously shown to engage the striatum via presentation of positive and negative monetary feedback. The task consisted from a reward and a no reward conditions. During the reward condition, participants had an opportunity to win a monetary bonus, while during the no reward condition this opportunity was not presented to them. Self-reported fatigue ratings were also acquired during the scan. fMRI data showed that, compared to HCs, differential striatal activity to positive and negative feedback was greater in the MS group and was associated with lower levels of self-reported fatigue. This suggests that MS subjects who experience fatigue may judge a given amount of reward differently from HCs and that increased dopamine in the striatum may lead to a decrease of fatigue in



MS.

Title: White matter degeneration in pericyte-deficient mice

Authors: *G. L. SI, A. MONTAGNE, Z. ZHAO, A. P. SAGARE, A. M. NIKOLAKOPOULOU, B. ZLOKOVIC*
Dept of Physiol. and Biophysics, Keck SOM, Zilkha Neurogenetic Institute, U of Southern Cal, Los Angeles, CA

Abstract: White matter degeneration is observed in a variety of neurological disorders, including Alzheimer's disease (AD). Previous studies have shown that patients with AD often exhibit demyelinated white matter, in some cases even prior to the formation of amyloid-β plaques and neurofibrillary tangles. Hypoxic and ischemic brain injuries are also strongly associated with white matter damage. Pericytes are critical for the maintenance of vascular integrity; however, whether pericyte loss contributes to white matter abnormalities is unknown. Here, we report that white matter brain regions in pericyte deficient-mice undergo accelerated degeneration with age. First, we observed reduced axonal projections in highly-myelinated brain regions, such as the corpus callosum and internal capsule, using AAV-GFP labeling of the axonal projections. Our subsequent DTI-MRI experiments showed that both young and aged pericyte-deficient animals have overall reduced white matter integrity, as well as axonal disorganization within myelinated regions. Histological data confirmed presence of disorganized fibers as well as reductions in myelin sheath thickness, relative abundance and volume in pericyte-deficient animals. Observed phenotypes may be attributed to vascular leakage and cerebral blood flow reductions, which are caused by pericyte loss. White matter and axonal changes correlate with behavioral deficits in pericyte-deficient animals. As neurovascular dysfunction and pericyte loss have been reported as a prominent feature of AD, these findings suggest that white matter injuries found in AD patients may, at least in part, stem from pericyte degeneration and vascular abnormalities.

Title: Correlation between iron deposition and increased microglia activation in MS: Subcortical grey matter and cortical white matter differences

Authors: *E. B. JOHNSON
Psychiatry, Univ. of Alberta, Edmonton, AB, Canada

Abstract: Multiple Sclerosis (MS) is an autoimmune demyelinating disease of the central nervous system and microglia are implicated in its pathogenesis. The development of the disease is accompanied by the activation of microglia. Previous studies have shown Magnetic Resonance Imaging (MRI) scans displaying transverse relaxivity R_2* and frequency shifts that characterize gradient echo signal decay which are closely correlated with iron and myelin occurrences within brain tissue. A trend of iron accumulation in the core and perilesional areas of MS has been reported while increased density of activated microglia is observed in areas showing iron accumulation. However, to our knowledge, neither a direct link between regions of MRI signal change and lesional iron accumulation, nor the causal relationship between iron accumulation and microglia activation within MS lesions have been fully determined. To investigate the link between MRI signal intensity and increased microglia activation as a result of iron accumulation tissue was analyzed from MS patients whose brain were previously scanned *in situ* with high field quantitative MRI (R_2* mapping, phase susceptibility imaging). *In situ* MRI was correlated with Perl's staining for ferric iron, Weil's staining for myelin, and immunohistochemistry to detect iron deposition and microglial morphology, within patient tissues including lesions in white matter and regions of iron-rich deep grey matter. Additional analyses were used to quantify microgliosis and regions of iron accumulation. Findings indicate two discrete patterns of iron deposition, which may suggest distinct pathological mechanisms of iron accumulation based on the location of the lesions within cortical white matter as well as within non-lesional deep grey matter. The existence of intra- and inter-patient variations of iron accumulation within lesions and within non-lesional deep grey matter may be found to act as an important marker for disease progression and pathology.

Title: The effect of social disruption stress on pain behaviors and cognitive deficits in chronic phase TMEV infection

Authors: *H. R. LINSENBARDT[1,2], J. L. COOK[2], E. E. YOUNG[2], E. G. VICHAYA[2], C. R. YOUNG[2], N. REUSSER[2], R. STORTS[2], C. J. WELSH[2,1], M. W. MEAGHER[2,1]
[1]Inst. for Neurosci., [2]Texas A&M Univ., College Station, TX

Abstract: Multiple sclerosis (MS) is an inflammatory demyelinating disease of the CNS, with symptoms including motor impairments, sensory deficits, pain, and cognitive impairments. Pain and cognitive deficits affect over half of MS patient, but little is know about the underlying mechanisms. The present study used the Theiler's murine encephalomyelitis virus (TMEV) model to characterize changes in pain and memory during late disease and to determine whether social disruption stress (SDR) exacerbates these impairments. Although previous TMEV studies have relied on withdrawal reflex measures (Lynch et al., 2008), these measures do not reflect the affective and motivational experience of pain. Alternative measures of pain, such as fear conditioning, that reflect the aversive motivational significance of pain, have started to be used in pain research but have not been applied to models of MS. Likewise, previous EAE studies of MS-like memory impairments have relied on the Morris water maze task (D'Intino et al., 2005), however performance may be confounded by motor impairments. Thus, alternative measures of memory, such as the novel object recognition task, that minimize motor performance demands should be explored. To this end, we examined the effects chronic TMEV infection and SDR have on behavioral measures of pain, cognition, and motor impairments. Male SJL mice were assigned to 3 groups: stress + TMEV, unstressed + TMEV, unstressed + vehicle. Following the SDR stressor, mice were injected with TMEV or vehicle after which assessments were taken until day 177 post-injection. Behavioral measures included fear conditioning to assess the affective dimension of pain and the novel object recognition to assess recognition memory impairments. Consistent with prior studies, TMEV infection led to impaired motor function during the acute and chronic phases. However, the effects of stress on motor function were mixed during the acute phase. Importantly, stress exacerbated the effect of infection on sensitivity to mechanical stimuli, and fear conditioning to footshock was enhanced in the stressed infected mice, suggesting that the affective dimension of pain was enhanced. Furthermore, stress impaired memory in the novel object recognition test in infected mice. Histological analyses revealed that the unstressed uninfected controls had significantly fewer lesions than infected mice. Infected mice also had increased hippocampal CA1 lesions which was negatively correlated with decreased memory consolidation. Our results support the use of fear conditioning and novel object recognition in the study of MS-induced impairments.

Title: Do Glyoxalase 1 enzyme levels differ with people peripheral neuropathy?

Authors: *S. ALOTHMAN[1], N. WILSON[2], J. RYALS[2], L. D'SILVA[1], L. HERBELIN[3], M. PASNOOR[3], P. KLUDING[1], D. WRIGHT[2]
[1]Physical Therapy and Rehabil. Sci., [2]Anat. & Cell Biol., [3]Neurol., The Univ. of Kansas Med. Ctr., Kansas City, KS

Abstract: Introduction: Glyoxalase 1 (Glo1) is a key enzyme that breaks down reactive dicarbonyls and helps prevent the buildup of advanced glycation end-products (AGE). AGE accumulation, combined with reduced neurotropic and insulin support, glucose toxicity, and oxidative stress, contributes to the development of diabetic peripheral neuropathy (DPN). The purpose of this study is to determine the levels of Glo1 in blood and skin in people with DPN or cryptogenic (idiopathic) neuropathy. We hypothesize that Glo1 levels are lower in people with DPN compared to people without neuropathy. Methods: Participants in this pilot study were assigned to one of four groups based on their diabetic and neuropathy status: 1) no diabetes and no DPN, 2) diabetes without DPN, 3) diabetes with DPN, and 4) cryptogenic neuropathy and no diabetes. Nerve conduction studies, quantitative sensory testing, and clinical examinations were used to calculate a Total Neuropathy Score, a measure of DPN severity. The primary outcome measure is fasting blood Glo1 levels. Glo1 levels will be correlated with the severity of DPN. Results: Preliminary results demonstrate a trend of lower blood Glo1 activity in people with DPN and in people with cryptogenic neuropathy compared to normal controls. Complete results on Glo1 levels in blood and skin are pending. Between groups statistical comparison will be completed with an ANOVA. Discussion: If our hypothesis is supported, targeting AGEs through increased Glo1 enzyme activity might be a new treatment option to lessen the symptoms of DPN. Understanding the relationship between Glo1 and neuropathy severity is the first step in establishing clinical trials investigating the therapeutic effects of agents regulating Glo1 level in patients with DPN.

Title: Immunohistochemical characterization of multiple sclerosis plaques in human brain

Authors: *J. BAUN[1], B. TIPTON[1], C. ZURHELLEN[1], C. SEGOVIA[1], R. C. SWITZER III[1], S. O. AHMAD[2]
[1]Neurosci. Associates, Knoxville, TN; [2]St. Louis Univ., St. Louis, MO

Abstract: Multiple Sclerosis (MS) is a demyelinating disease with a complex pathological profile that includes myelin degeneration, neuronal damage, and immune cell infiltration in the areas containing plaques. We evaluated the pathology associated with MS in the brain of a 39 year old female whose cause of death was unrelated to the disease. In acute plaques the amino cupric silver method (de Olmos) revealed a dense core of degenerating nerve cells and fibers. Chronic lesions had little staining of cells or fibers and were devoid of staining by the Nissl counterstain, Neutral Red. Another silver stain, the silver nucleolar stain (AgNOR) was developed to reveal the nucleolar organizing regions in cancerous cells. We utilized the stain here to reveal the differences in interior cellularity between acute and chronic plaques. This is useful in getting accurate counts of the cell populations present in brain regions undergoing demyelination, and has proven to be a useful tool for stereological purposes. Weil-Myelin staining revealed roughly spherical plaques devoid of myelin staining. Nissl staining with Thionine distinguished acute and chronic lesions. Acute lesions appeared to be surrounded by a dense band of cells while the interior of the plaque had a normal distribution of cells. In chronic lesions the core was much lighter suggesting a loss of cells. The Perl's iron stain revealed a paucity of staining in acute lesions. Chronic lesions were surrounded by iron positive cells, some of which appeared to be phagocytic and filled with debris. Iba-1 immunoreactivity in acute plaques was observed both in the center of the plaque and in a dense ring of immunoreactive microglia surrounding the plaque. In chronic lesions the central immunoreactivity was diminished, but the ring of cells surrounding the plaque appeared thicker and more dense. Staining of near adjacent sets of serial sections reveals the chemoarchitechtural differences between acute and chronic states in MS lesions.

Title: The role of chronic meningeal pro-inflammatory cytokine expression in grey matter pathology in multiple sclerosis

Authors: ***R. JAMES**, E. J. BROWNE, R. M. SCHALKS, N. D. MAZARAKIS, R. REYNOLDS
Med., Imperial Col. London, London, United Kingdom

Abstract: The secondary progressive phase of multiple sclerosis (SPMS) is characterized by accumulating axonal loss and grey matter pathology that at present cannot be adequately treated. Subpial demyelinated lesions in cerebral cortical grey matter are suggested to result from the diffusion of pro-inflammatory cytokines from areas of meningeal inflammation into the brain parenchyma. The presence of tertiary lymphoid organ-like (TLO) structures within the meninges has been reported in a large proportion of SPMS cases and is associated with immune cell recruitment, greater cortical demyelination, substantial neuronal loss and shorter disease duration. We have shown a 2-fold increase in lymphotoxin-α (LTα) gene expression by RT-qPCR in human postmortem MS meningeal tissue compared to controls. To test the hypothesis LTα might drive TLO formation in MS we have developed an animal model of cortical demyelination driven by meningeal inflammation involving acute or chronic delivery of cytokines into the subarachnoid space (SA) of the rat brain. In acute studies, recombinant LTα and IFNγ were stereotaxically injected into cortical SA of DA rats immunised 21 days previously with low dose MOG sufficient to induce an anti-myelin humoral response without CNS infiltration and clinical symptoms of EAE. 7 days following cytokine delivery there was a substantial increase in CD4+/CD8+ T-cells and microglial inflammation along with focal B cell-rich areas within dense SA cellular aggregates in IFA- and MOG-immunised animals compared to PBS injected controls. In MOG-immunised animals, extensive subpial demyelination was

observed underlying these cellular aggregates in a pattern highly reminiscent of subpial lesions observed in MS cortex. No demyelination was observed in IFA-immunised animals injected with LTα + IFNγ, suggesting demyelination is not a direct cytotoxic effect of the cytokines but required the development of a specific anti-myelin autoimmune response. To study the effects of chronic cytokine expression we injected a high titre VSV-G pseudotyped lentiviral vector (LV) expressing either GFP or human LTα under the control of a CMV promoter into the SA. The LV vector is able to induce long-term GFP expression up to 12 weeks after injection that is localised in epithelioid cells of the meninges, subpial astrocyte end-feet and a few pyramidal neurons. Aggregates of cells including CD8+ T-cells were observed in the sagittal sulcus and SA together with cells expressing human LTα at 28 days post injection. Our results suggest that LTα is a potent inducer of meningeal inflammation and thus may contribute to subpial demyelination lesion formation and clinical progression in MS.

Title: Mouse models of intracerebral hemorrhage in ventricle, cortex, and hippocampus

Authors: *Y. GAO[1,2], W. ZHU[2], C.-F. CHANG[2], J.-R. WAN[4], S.-S. ZHU[3], J. WANG[2]
[1]The First Clin. Col., Wuhan Univ. Renmin Hosp., Hubei, China; [2]Anethesiology & Critical Care Med., [3]Psychiatry and Behavioral Sci., Johns Hopkins University, Sch. of Med., Baltimore, MD; [4]Biol. Sci., Illinois Inst. of Technology, Col. of Sci., Chicago, IL

Abstract: Intracerebral hemorrhage (ICH) is a devastating condition. Existing preclinical ICH models focus largely on striatum but neglect other brain areas such as ventricle, cortex, and hippocampus. Clinically, however, hemorrhagic strokes do occur in these other brain regions. In this study, we established mouse hemorrhagic models that utilize stereotactic injections of autologous whole blood or collagenase to produce ventricular, cortical, and hippocampal injury. We validated and characterized these models by histology, immunohistochemistry, and

neurobehavioral tests. In the intraventricular hemorrhage (IVH) model, C57BL/6 mice that received unilateral ventricular injections of whole blood (25 microliters) demonstrated bilateral ventricular hematomas, ventricular enlargement, and brain edema in the ipsilateral cortex and basal ganglia at 72 h. Unilateral injections of collagenase (150 U/ml, 0.4 or 0.2 microliter, respectively) caused reproducible hematomas and brain edema in the frontal cortex in the cortical ICH (c-ICH) model and in the hippocampus in the hippocampal ICH (h-ICH) model. Immunostaining revealed cellular inflammation and neuronal death in the periventricular regions in the IVH brain and in the perihematomal regions in the c-ICH and h-ICH brains. Locomotor abnormalities measured with a 24-point scoring system were present in all three models, especially on days 1, 3, and 7 post-ICH. Locomotor deficits measured by the wire-hanging test were present in models of IVH and c-ICH, but not h-ICH. Interestingly, mice in the c-ICH model demonstrated emotional abnormality, as measured by the tail suspension test and forced swim test, whereas h-ICH mice exhibited memory abnormality, as measured by the novel object recognition test. All three ICH models generated reproducible brain damage, brain edema, inflammation, and consistent locomotor deficits. Additionally, the c-ICH model produced emotional deficits and the h-ICH model produced cognitive deficits. These three models closely mimic human ICH and should be useful for investigating the pathophysiology of ICH in ventricle, cortex, and hippocampus and for evaluating potential therapeutic strategies. Key words: cognition; emotion; forced swim test; intracerebral hemorrhage; motor; tail suspension test; wire-hanging test Support Contributed By: Grants from AHA and NIH

Title: The effects of mild traumatic brain injury and psychosocial stress on limbic anxiety-like behaviors are mediated by glucocorticoid receptors

Authors: L. FOX, D. DAVIES, J. SCHOLL, D. MEYER, *M. J. WATT, G. FORSTER
Basic Biomed. Sciences, Sanford Sch. Med., Univ. of South Dakota, VERMILLION, SD

Abstract: Mild traumatic brain injury (mTBI) occurs in settings ranging from sports to warfare, often associated with heightened arousal or stress. Consequences of mTBI include generalized anxiety and symptoms of posttraumatic stress disorder. We developed an animal model of mTBI with psychosocial stress to better simulate realistic conditions for mTBI acquisition, and sought to determine the consequences of this perturbation on anxiety-like and fear behaviors. Adult male Sprague-Dawley rats were subjected to social defeat or control conditions immediately prior to mTBI (induced by weight-drop) or sham surgery. Peripheral corticosterone levels were measured at the time of surgery using ELISA, and behavioral testing was conducted 7 days following surgery. The experience of social defeat immediately prior to surgery significantly increased plasma corticosterone levels. Either mTBI or social defeat alone increased anxiety-like behaviors in the elevated plus maze (EPM), but the combination of mTBI and psychosocial stress further increased anxiety states. Furthermore, mTBI, social defeat or the combination of mTBI with social defeat increased fear conditioning as compared to controls, but only mTBI with social defeat impaired extinction of the fear response. Next, we determined whether corticosterone receptors (glucocorticoid or mineralocorticoid) underlie the effects of mTBI with psychosocial stress on anxiety-like behaviors. Adult male Sprague-Dawley were injected (sc.) with spironolactone (50 mg/kg), mifepristone (20 mg/kg), or a propylene-glycol vehicle, 40 minutes prior to the social defeat or control conditions, which were immediately followed by mTBI or sham surgery. Rats were tested in the EPM 8-9 days post-surgery. Mifepristone, but not spironolactone, was able to prevent heightened anxiety-like behaviors induced by mTBI combined with social defeat, suggesting that glucocorticoid receptors play a role in modulating anxiety-like behavior following mTBI with psychosocial stress. Therefore, early targeting of glucocorticoid receptors may provide a novel direction in preventing mTBI-associated affective symptoms.

Title: The effect of levetiracetam treatment on gene expression and functional behavior using a controlled cortical impact model of traumatic brain injury

Authors: *B. E. ELMORE[1], G. D. ANDERSON[2], E. D. KANTOR[2], F. M. FARIN[3], T. K. BAMMLER[3], J. W. MACDONALD[3], M. R. HOANE[1]
[1]Psychology, Southern Illinois Univ. - Carbondale, Carbondale, IL; [2]Pharm., [3]Envrn. and Occup. Hlth. Sci., Univ. of Washington, Seattle, WA

Abstract: Traumatic brain injury (TBI) is one of the leading causes of death and disability in the United States, affecting more than 1.7 million Americans each year. Phenytoin has been the standard of care for prevention of acute seizures for 7 days after TBI. However, phenytoin, a broad-spectrum enzyme inducer, can decrease the concentrations and effect of other drugs and has been shown not to decrease the incidence of post-traumatic epilepsy (PTE). Unlike phenytoin, levetiracetam (LEV), has antiepileptogenic effects in animals models and has been identified as a potential candidate for treating not only PTE, but also in enhancing recovery function following TBI. It is currently approved for use as an adjunct therapy for seizure disorders, and contains a unique pharmacological profile belonging to the pyrrolidine class of drugs. Unlike phenytoin, LEV has been well tolerated in clinical populations without significant side effects, and the need for serum monitoring. The current understanding of its mechanisms is incomplete, but past research has found that it reduces high voltage activated calcium currents, up-regulates the expression of glutamate transporters, and decreases regional IL-1β expression. The purpose of the current study was to evaluate the effect of LEV on gene expression and functional recovery in a CCI model of TBI using a clinically relevant dose and regimen. The total sample consisted of 65 male Sprague-Dawley rats in two experiments. Animals were randomly assigned to one of three treatment conditions: TBI + vehicle (0.9% sterile saline), TBI + Levetiracetam (14 mg/hr/Kg), and Sham TBI + vehicle. A moderate to severe unilateral parietal injury was induced (AP: -2.4, ML: 2.4, ID: 2.5) at a velocity of 3 mm/s using a 4 mm tip. Treatment with LEV was administered for 7 days using osmotic infusion pumps, with an i.p. loading dose of 50 mg/Kg. This dosing regimen was determined to provided serum concentrations associated with clinically relevant doses. Microarray-based transcriptional profiling was done to access gene expression. Recovery of function was assessed using the locomotor placing task, rotor-rod task, and the Morris water maze. The results showed no evidence of any functional detrimental effects from LEV treatment, but changes in gene expression were observed. With the need to provide AED prophylaxis in TBI, it will be important to determine the effect of LEV in combination with other potential neuroprotective agents (i.e. nicotinamide, progesterone).

Title: Exosomes derived from multipluripotent mesenchymal stromal cells improve functional recovery and promote brain remodeling in rats after traumatic brain injury

Authors: Y. ZHANG[1], M. CHOPP[2,3], Y. MENG[1], M. KATAKOWSKI[2], H. XIN[2], A. MAHMOOD[1], *Y. XIONG[1]

Abstract: Object. Transplanted multipotent mesenchymal stromal cells (MSCs) improve functional recovery in rats after traumatic brain injury (TBI). Here, we test a novel hypothesis that systemic administration of cell-free exosomes generated from MSCs promotes functional recovery and neurovascular remodeling in rats after TBI. Methods. Wistar rats were subjected to TBI followed by tail vein injection of 100 μg protein of exosomes derived from MSCs or an equal volume of vehicle phosphate-buffered saline (n = 8/group) 24 hours later. To evaluate cognitive and sensorimotor functional recovery, the modified Morris water maze, neurological severity score and footfault tests were performed. Animals were sacrificed at 35 days after TBI. Histopathological and immunohistochemical analyses were performed for measurements of lesion volume and neurovascular remodeling (angiogenesis and neurogenesis). Results. Compared with saline-treated controls, exosome-treated TBI rats showed significant improvement in spatial learning at 34-35 days measured by the Morris water maze test ($p < 0.05$), and sensorimotor functional recovery, i.e., reduced neurological deficits and footfault frequency, observed at 14-35 days post injury ($p < 0.05$). Exosome treatment significantly increased the number of newborn endothelial cells in the lesion boundary zone and dentate gyrus, and significantly increased the number of newborn immature and mature neurons in the dentate gyrus. Conclusions. We, for the first time, demonstrate that MSC-generated exosomes significantly improve functional recovery, at least in part, by promoting endogenous

angiogenesis and neurogenesis in rats after TBI. Thus, MSC-generated exosomes may provide a novel cell-free therapy for TBI and possibly other neurological diseases.

Title: Are there strain differences to anatomical and behavioral sequelae of repetitive mild traumatic brain injury in mice?

Authors: *G. D. ROSEN[1], G. C. JOHNSON[1], T. KEHINDE[1], K. O'CONNELL[2], A. RENDALL[2], R. H. FITCH[2]
[1]Neurol., Beth Israel Deaconess Med. Ctr., BOSTON, MA; [2]Psychology, Univ. of Connecticut, Storrs, CT

Abstract: Scientific interest on the effects of repetitive mild TBI (RmTBI) has grown in the past decade, undoubtedly propelled by the increased incidence and awareness of concussions sustained by participants in ongoing military conflicts as well as those who play contact sports. RmTBI can produce a constellation of acute and chronic symptomology (post-concussive syndrome, PCS), and the serious consequences of RmTBI_chronic traumatic encephalopathy (CTE)_are associated with cognitive and psychiatric disturbances, increased co-morbidity of neurodegenerative disorders, as well as an increase in tau deposition in selected regions of the brain. Despite the dramatic increase in attention to this serious problem, our understanding of the risk factors that can predict outcome_CTE, PCS, etc._is severely limited. The research presented here will use a mouse model to address the following question: Why is it that some individuals can sustain multiple concussions with no lingering effects, whereas others with fewer injuries are devastated? We aim to determine the biological and/or genetic markers than can help us predict outcome following RmTBI, specifically examining two important risk factors_age of injury and

genetics. We used a weight drop injury model that effectively mimics the physiological and cognitive effects of RmTBI, but without the severe brain damage that is typically associated with rodent models (Kane et al., J Neurosci Methods. 2012;203(1):41-9). In this experiment, we exposed adolescent (5 weeks of age) and adult (11 weeks of age) male mice from two strains (C57BL6/J and DBA/2J) to 5 successive days of mild TBI or a sham procedure. One cohort of mice were sacrificed 30 days after the last injury and their brains removed, and the remaining mice were given a battery of behavioral tests. Brains were assayed for phospho-tau by Western Blot. In addition, we used highly efficient and accurate stereological procedures to estimate the number of GABAergic neurons in the cerebral cortex, in order to assess changes in GABAergic tone associated with RmTBI. Behavioral outcome measures included assessments of anxiety and social behaviors, as well as measures of sensory processing and memory. Understanding the effects of age and genetics (and, importantly, their interaction) on RmTBI susceptibility could lead to ameliorative or even preventative treatments.

Title: Central and systemic levels of pigment epithelium-derived factor are altered in the rat following traumatic brain injury

Authors: *V. L. REEVES[1], S. W. CARLSON[2], E. E. KERSHAW[1], C. E. DIXON[2]
[1]Medicine, Div. Endocrinol. and Metabolism, [2]Neurosurg., Univ. of Pittsburgh, Pittsburgh, PA

Abstract: Background: Pigment epithelium-derived factor (PEDF), a multifunctional protein found in multiple tissues, is associated with metabolic effects as well as anti-angiogenic and neurotrophic properties. These effects may be protective in the setting of brain injury and offer a

potential biological therapeutic target for the treatment of traumatic brain injury (TBI). Changes in the systemic and brain abundance of PEDF in the context of TBI are unknown. Methods: To examine the effect of TBI on serum and brain PEDF concentrations, anesthetized male Sprague-Dawley rats were subjected to controlled cortical impact (CCI) brain injury (4m/sec, 2.7mm deformation) or sham injury and euthanized 1 week post-injury. The abundance of PEDF in the serum, white and brown adipose tissue, muscle, pancreas, liver, and multiple brain regions were assessed by ELISA. To determine the localization of PEDF in cell types in the brain, the incidence of colocalization between PEDF and markers of neurons, astrocytes, endothelial cells, microglial, and oligodendrocytes were evaluated by immunohistochemistry. Results: Brain-injured rats exhibited a significant increase in the concentration of PEDF in brown adipose tissue one week post-injury, compared to sham-injured rats. In the brain, CCI-injured rats exhibited a significant increase in PEDF in the contused cortex, hippocampus, and striatum, compared to sham-injured rats. PEDF immunoreactivity appeared to colocalize with markers of astrocytes, vasculature, endothelial cells, neurons, and oligodendrocytes in contused brain regions following brain injury. Conclusions: Following CCI-injury, an elevation in PEDF abundance was observed in multiple systemic and central tissues. Our findings highlight that not only does CCI-injury result in regional specific elevations in PEDF concentrations in glial, endothelial, and neuronal cells following TBI, but also CCI-injury results in peripheral changes in PEDF concentrations in metabolically active tissues. These results suggest that PEDF is modulated by TBI both in the peripheral tissue and in brain tissue.

Title: Knockout of androgen receptor decreases the expression of aquaporin-4 following traumatic brain injury

Authors: Y.-H. CHEN[1], C.-C. TSENG[2], *L.-Y. YANG[3]
[1]Grad. Inst. of Med. Sci., [2]Sch. of Med., [3]Col. of Med., Taipei Med. Univ., Taipei, Taiwan

Abstract: Traumatic brain injury (TBI) is one leading global health issue and has been estimated to affect more than 10 million people each year. The pathophysiology of TBI is quite complex and is still poorly understood. Androgens have been shown to exert a beneficial effect on injured neurons and to reduce the expression of microglia and reactive astrocytes following brain injury. It is generally accepted that androgen receptor mediates the neuroprotective effect of androgens. Our recent data show that deletion of androgen receptor enhances the TBI-induced expression of glial fibrillary acidic protein (GFAP). Evidence has shown that the water-channel protein aquaporin-4 (AQP4) has been involved in the regulation of water balance in the brain. However, it remains undetermined if deletion of androgen receptor affects the expression of AQP4 following TBI. In this study, we investigated the impact of deletion of androgen receptor on the expression of AQP4 following TBI using male androgen receptor knockout (ARKO) mice and male control littermates. We induced brain injury using the cortical impact device and evaluated the expression of AQP4 4 and 24 h after the injury. Our preliminary results showed that knockout of androgen receptor decreased the expression of AQP4 4 and 24 h following TBI. Moreover, the AQP4 expression in the injured brain was significantly lower in male ARKO mice than in male controls. Because deletion of AQP4 has been shown to decrease the water efflux in vasogenic edema and to aggravate the edema in the obstructive hydrocephalus, our findings strongly suggest that deletion of androgen receptor worsens brain edema following TBI.

Title: Evaluation of behavioral paradigms to assess functional deficits following single and multiple mild traumatic brain injuries in a murine model

Authors: *J. N. NICHOLS, T. L. NIEDZIELKO, S. A. EPPS, C. L. FLOYD
Physical Med. and Rehabil., Univ. of Alabama at Birmingham, Birmingham, AL

Abstract: Mild and repeated mild traumatic brain injury (mTBI) is a major health concern, particularly for military personnel and individuals participating in contact sports. In the United

States, it is estimated that 1.7 million persons sustain a TBI each year, of which approximately 75% are mTBI. Individuals that acquire an mTBI typically experience cognitive and neuropsychiatric deficits with individuals sustaining multiple mTBIs having a worse prognosis. Cognitive deficits include impairments of attention and learning/memory, while neuropsychiatric changes can consist of sleep disturbances, obsessive compulsive behaviors, depression, anxiety, and aggression. The use of animals to elucidate the underlying mechanisms of mTBI-associated deficits is critical for understanding of the pathophysiology and development of novel therapeutics. Although there have been behavioral assessments established to evaluate moderate-severe TBI, elucidation of robust behavioral tests that are sensitive to mTBI has been challenging and inconclusive. Consequently, the goal of this study was to evaluate the behavioral changes incurred after single and multiple instances of mTBI utilizing a panel of behavioral tests. We utilized an impact-acceleration model to induce single or multiple (3) mTBI(s) in adult male C57BL/6 mice with an inter-injury interval of 24 hours. Acutely following injury or sham surgery, mice were subjected to an array of tasks to assess the extent of functional deficits. Attention and learning/memory was assessed using Bussey chambers and the reversal Morris water maze (rMWM). An automated vibration platform (LABORAS chamber) was used to track ethological behaviors such as immobility and grooming. Neuropsychiatric symptoms were evaluated using the Porsolt swim test (depression), elevated plus maze (anxiety), and resident intruder task (aggression). No significant differences in cognitive performance tests were observed between sham, mTBI, and multiple mTBI groups. Data from the LABORAS chambers revealed decreased immobility duration and increased grooming duration in the multiple mTBI mice suggesting insomnia and obsessive behavior. When gauging despair behavior, we found that multiple mTBI mice spent less time immobile which could represent disinhibition. We also found that mTBI mice exhibited a reduction in aggressive behavior indicating a social impairment. Classically, the field has focused on tests of cognitive function to assess functional impairments after mTBI, but our results suggest that deficits might be better evaluated using tasks that target neuropsychiatric symptoms. Title: Acute inflammatory response in rodent brain and blood following a blast-induced traumatic brain injury

Authors: *C. C. TENN, N. CADDY, M. GARRETT, L. MCLAWS, C. VAIR
DRDC Suffield, Medicine Hat, AB, Canada

Abstract: Introduction: The predominant cause of neurotrauma among the military population is exposure to a blast wave. The shockwave produced by an explosive device can travel through the brain causing mild brain damage without visible signs of injury. Traumatic brain injuries (TBI) are known to trigger a neurinflammatory cascade which contributes to the brain injury as well as long term neuronal damage and cognitive impairment. A number of inflammatory cytokines are released in response to TBI and their temporal profile could provide information about the injury severity. This study examined the central and systemic inflammatory response to TBI by comparing cytokine levels in rat brain and blood at various time points after a shockwave exposure. Methods: To create a blast-induced TBI, a custom designed shocktube capable of simulating a blast insult was used. Anaesthetized rats received a side-on, head only exposure to the shockwave at a pressure of 138 kPa. Controls underwent the same treatment except for the shockwave exposure. Following exposure, serum and brain tissues (hippocampus and cerebellum) were collected either at 6, 24 or 48 hours. The samples were assayed for several inflammatory cytokines (IL- 1α, IL-1β, IL-6, IL-10 and TNF-α) and chemokine levles (MCP-1 and MIP-1α) using a multiplex cytokine array system. Results: An acute cytokine response was observed in brain tissues and serum of animals exposed to the shockwave. Levels of IL-1α, IL-1β and IL-6 significantly increased in the brain at 6h post exposure as compared to controls. Serum levels of IL-1α and IL-6 significantly increased at the 6h time point only while IL-1β levels were elevated at the 24h and 48h time period. No differences were observed in TNF-α levels between the groups at any of the time points measured. The anti-inflammatory cytokine, IL-10 levels in brain samples showed an increase at 24h post-exposure and remained elevated up to 48h while serum levels for this cytokine did not show any difference from the controls until the 48h time point. The chemokines, MCP-1 and MIP-1α levels showed an early increase in both serum and brain tissues and persisted for hours following exposure. Conclusion: The results are consistent with TBI triggering an acute response of pro- and anti-inflammatory cytokines and chemokines. The early increase in several of these inflammatory cytokines observed in the brain before blood would suggest there is no clear relationship between the central and systemic inflammatory response to the brain injury induced by shockwave exposrue. Determining a cytokine profile inducedby TBI could provide insights into neuroprotective approaches to treating this type of injury.

Title: CRMP2 modulation for treatment of TBI-induced cognitive dysfunction and pathology

Authors: *M. E. HARRIS-WHITE[1], A. POTESHKINA[1], M. F. JOHNSON[1], P. ESLAMI[1], K. M. VENKOVA-HRISTOVA[2], A. M. HRISTOV[2], K. HENSLEY[2]
[1]UCLA & Veterans Administration-Greater Los Angeles, Los Angeles, CA; [2]Univ. of Toledo, Toledo, OH

Abstract: Widespread traumatic damage to axons, termed diffuse axonal injury (DAI), may be a central contributor to functional/behavioral deficits following traumatic brain injury (TBI). Studies suggest axonal injury is not limited to time of injury and that progressive axonal injury continues many days post injury. What may not be readily apparent are the longer-term consequences of TBI that may manifest in this population. Risk for chronic neurodegenerative disease, including Alzheimer's disease (AD), is increased by TBI. Although a complex problem, science must identify safe and effective treatments that can be used both acutely and chronically to assist short-term recovery and prevent long-term neurodegenerative disease risk. Dysregulation of tau appears to be common across the different types of TBI. Chronic traumatic encephalopathy (CTE) is a progressive tau protein-linked disease associated with repetitive concussive injury in athletes and in military blast TBI. The frequent association of CTE with other disorders suggests that repetitive brain trauma and hyper phosphorylated tau protein deposition promote accumulation of other abnormally aggregated proteins including amyloid beta protein (Aβ). Although currently unclear how Aβ deposition and tau dysregulation following TBI are related, a destabilized proteostasis network (i.e., imbalanced axonal transport and autophagy) is a likely culprit. Similar to tau, CRMP2 is a microtubule associated protein though CRMP2 is functionally distinct from tau. CRMP2 stabilizes microtubules and facilitates protein trafficking important to maintenance of synapse stability. Manipulating CRMP2-dependent processes may affect development of AD pathology, specifically, APP processing and microtubule stability and may also be a useful TBI target. In the present study we show that lanthionine ketimine ester (LKE), a bioavailable derivative of a natural brain sulfur amino acid

metabolite, lanthionine ketimine, which we have previously shown to alleviate pathology and slow cognitive decline in the 3xTgAD mouse model, can spare cognition and pathology following DAI through mechanisms involving CRMP2. Methods: C57Bl6 mice underwent craniotomy plus moderate central fluid percussion injury (cFPI). Sham surgery (craniotomy) was performed on controls. Barnes maze was performed five weeks post surgery followed by histological analyses (APP, phospho c-Jun, Iba-1) and biochemical analysis (CRMP2, autophagy markers). cFPI mice fed 100 mg/kg/d LKE had significantly better Barnes maze performance and reduced phospho c-Jun staining in the corpus callosum and hippocampus compared to cFPI mice on control diet.

Title: Energy-related biochemical changes in the peri-lesion area of striatum of conscious rats following penetrating ballistic-like brain injury

Authors: *L. LEUNG, M. WINTER, Y. DENG-BRYANT, D. SHEAR, F. TORTELLA
Walter Reed Army Inst. of Res., Silver Spring, MD

Abstract: This study utilized microdialysis in awake, freely moving rats to evaluate cerebral interstitial levels of glucose, lactate and pyruvate following unilateral frontal penetrating ballistic-like brain injury (PBBI). Pre-injury baseline measures were taken 2h prior to PBBI, from 1 to 4h post-injury and at 1, 2, 3, 7 and 14 days post-injury (DPI). The results were compared to those obtained from sham control group (received craniotomy only; n=9/group). Prior to injury, glucose concentrations in both groups were similar (PBBI = 2.82±0.4 mg/dL and Sham = 2.09±0.28 mg/dL). The glucose level following PBBI dropped to 1.32±0.48 mg/dL at 3h post-injury. It remained low for the first 72h, followed by an increase from 7 to 14 DPI. The

glucose concentration of control group remained near baseline levels with a graduate increase evident at 14 DPI. Interstitial lactate levels were significantly increased in the PBBI group during the first 24h following injury (baseline = 0.37±0.09 mmol/L; 24h post-PBBI = 0.88±0.19 mmol/L) and remained elevated out to 7 DPI (0.65±0.13 mmol/L). No significant changes in lactate concentration were detected over time in control group (baseline = 0.35±0.07 mmol/L; 24h post-PBBI = 0.48±0.07 mmol/L; 7 DPI = 0.29±0.08 mmol/L). Pyruvate levels did not differ between the sham (17.51±5.06 μmol/L) and PBBI animals (20.91±5.44 μmol/L) during the first 48h following injury but were significantly decreased at 3 DPI (13.64±6.29 in PBBI group vs. 24.18±6.87 μmol/L in sham control group; $p < .05$) and resolved by 7 DPI. Following PBBI, the lactate/pyruvate ratio increased significantly within the first 3h (2h post-PBBI = 132.04±29.39 vs. 2h-Sham = 53.90±22.74) and then dropped to levels comparable to sham control by 24h. The acute reduction in interstitial glucose levels following PBBI may be due to the increase in glucose utilization immediately after injury. Reduced metabolic activity near the lesion at later time points might account for the increased interstitial glucose concentration. Increased lactate levels within brain tissue are suggestive of dysfunctional oxidative metabolism and may be attributed to reduced cerebral blood flow and increased glycolysis following PBBI. The lactate/pyruvate ratio reflects the cellular redox state. Accordingly, increased lactate/pyruvate ratio suggests an impaired cellular respiration which may be related to mitochondrial dysfunction following PBBI. Overall, this study identified the temporal profile of energy dysregulation induced by PBBI in the peri-lesion area. These time-dependent alterations in brain metabolism may serve as therapeutic targets for treating brain trauma.

Abstract: D-serine, a co-agonist at the NMDA receptor (NMDAR), is synthesized from L-serine by the enzyme serine racemase (SR), which is heavily expressed in the forebrain. SR and D-serine were originally thought to be expressed in astrocytes. However, data from our laboratory and others has shown that SR and D-serine are primarily expressed in neurons *in vivo*. The original work describing SR and D-serine localization utilized primary astrocyte cultures derived from neonatal brains, which were recently shown not to be representative of mature astrocytes *in vivo* and display a gene expression profile more akin to reactive astrocytes. Therefore, to reconcile this discrepancy we examined the expression of SR and D-serine after controlled cortical impact (CCI), a model of traumatic brain injury known to induce reactive astrocytes. We found that CCI increased the amount of glial fibrillary acidic protein (GFAP)-positive astrocytes in the hippocampus, particularly in the ipsilateral hemisphere, in a time-dependent manner with peak expression occurring between 3 and 7 days post injury. Remarkably, CCI also induced the expression of SR in GFAP+ astrocytes and reduced neuronal SR expression in the ipsilateral hippocampus. However, SR expression remained primarily neuronal in the contralateral hemisphere, particularly at early time-points following CCI. D-serine localization also switched to GFAP+ astrocytes following CCI, although its transition occurred later than SR (7-14 days post-CCI). Our findings demonstrate that SR and D-serine can be found in astrocytes *in vivo*, but only under reactive conditions.

Title: Modification of somatosensory evoked potentials following focal traumatic brain injury in the mouse

Authors: *J. A. FISHER[1,2], S. HUANG[2], M. YE[2], M. NABILI[2], E. F. CIVILLICO[2], V. KRAUTHAMER[2], M. MYERS[2], C. G. WELLE[2]

Abstract: Traumatic brain injury (TBI) presents a significant challenge to civilian and military medicine. In the U.S., each year there are over 1.5 million TBIs, resulting in 50,000 deaths. Non-fatal brain injuries can also cause impairment that lead to long-term disability. Even mild TBI can have severe long-term consequences, such as cognitive deficits, psychiatric morbidities, epilepsy and increased risk for Alzheimer's and Parkinson's disease. Whereas clinical neuroimaging, namely CT and MRI, is an important tool for diagnosing TBI, such imaging is typically performed at a much later time relative to the initial injury, precluding the ability to monitor the progression of the injury and ensuing sequelae. Identifying easily obtainable, quantitative electrophysiological biomarkers could therefore represent a breakthrough for the diagnosis of TBI. Both early- and late-onset components of the somatosensory-evoked potential (SEP) elicited by mild electrical stimulation of the median nerve have been shown to reflect brain injury and are sensitive to even mild neural perturbations such as low-intensity ultrasound. We utilized high-intensity focused ultrasound (HIFU) to induce focal, calibrated brain injuries in anesthetized mice. Using micro-electrocorticography (μECoG) arrays, we recorded SEPs triggered by median nerve stimulation and mapped the triggered average responses across primary somatosensory and motor cortices. In preliminary experiments, focal HIFU insult reduced the amplitude and altered the temporal profile of late-onset (>50 ms post stimulus) SEPs. Adjusting the intensity and position of the injury also affected the signals recorded at the primary somatosensory cortex. These results represent a significant step toward establishing a quantitative electrophysiological biomarker for diagnosing TBI. From a regulatory standpoint, additionally, quantitative physiological metrics, such as electrophysiological signals, could improve the consistency and rapidity of the scientific evaluation of neurological devices used for the diagnosis of brain injury.

Title: Electrophysiological signatures of brain injury in the mouse primary motor cortex

Authors: ***M. YE**[1], M. NABILI[1], J. FISHER[1,2], S. HUANG[1], Y. KIM[3], E. CIVILLICO[1], V. KRAUTHAMER[1], M. R. MYERS[1], C. WELLE[1]

Abstract: Diagnosis of mild brain injury is a clinical challenge due to the lack of objective biomarkers. Electrophysiological indices, such as quantitative EEG (qEEG), have the potential to serve as biomarkers for neural damage. Recent advances in EEG detection technology may soon allow for rapid, non-invasive signal detection on inexpensive and portable platforms. However, the signature changes in neural activity that accompany mild brain injury have not been well established. In our study, we identify electrophysiological signatures of mild brain injury in a novel mouse model. Brain activities are recorded with a 16-channel epidural micro-electrocorticography (μECoG, Neuronexus) array implanted on the primary motor cortex. Controllable high-intensity focused ultrasound (HIFU) pulses that mimic blast overpressure waves are used to produce brain injury in mouse (McCabe JT, et al. 2014). HIFU-induced brain injury is evaluated by immunohistochemical markers for microglial activation (Iba-1), astrocyte reactivity (GFAP), blood-brain barrier disruption (IgG), overexpression of phosphorylated-tau (p-tau), and assessed by the open field and rotarod behavioral tests. μECoG recordings and behavioral tests from freely moving animals are performed once per week for 4 consecutive weeks prior to the HIFU exposure for baseline characterization. The acute electrophysiological and behavioral responses following injury are collected immediately and 24 hours after the HIFU exposure. Chronic changes are monitored weekly, up to 8 weeks or until the electrophysiological signal patterns stabilize. The frequency content of all electrophysiological correlates is quantified

by multitaper fast fourier transform (FFT) following artifact rejection (Chronux toolkit and custom MATLAB code). At the completion of the chronic electrophysiological recording period, animals are sacrificed for histological evaluation of brain injuries. A long-term reduction in the lower frequency band of μECoG signals following HIFU exposure was observed in the pilot experiments. Also, preliminary data demonstrate an elevated expression of Iba-1 and GFAP in the corpus callosum and hippocampus 24 hours after HIFU exposure, in agreement with a previous report (McCabe JT, et al. 2014). These preliminary results indicate the potential of quantitative EEG as a brain injury biomarker, as well as the possibility for rapid brain injury detection using portable technologies.

Title: Cellular mechanisms underlying the baroreflex dysfunction in a rat model of traumatic brain injury

Authors: ***J. OH**[1], C.-K. LEE[2], K. WHANG[1], S.-W. JEONG[2]
[1]Neurosurg., [2]Physiol., Wonju Col. of Medicine, Yonsei Univ., Wonju, Korea, Republic of

Abstract: The arterial baroreflex is one of the homeostatic mechanisms for maintaining blood pressure. In human patients, traumatic brain injury (TBI) is known to lower baroreflex sensitivity (BRS) which is associated with a high mortality rate. To date, cellular mechanisms underlying the TBI-blunted BRS remain unknown. With a hypothesis that the baroreflex dysfunction arises from autonomic imbalance, we tested whether TBI differentially modulates excitability of cardiac sympathetic and parasympathetic neurons. In this regard, TBI was induced in 8-week-old male Sprague-Dawley rats using a head impactor (TBI-0310, PSI, USA). Four week after TBI, the baroreflex was assessed by the phenylephrine pressor test. Compared with control rats (1.1 ± 0.09, n=4), BRS was significantly reduced in TBI group (0.57 ± 0.08, n=4). Under the gramicidin-perforated configuration of the current clamp, action potentials (AP) were recorded in sympathetic stellate ganglion (STG) and parasympathetic intracardiac ganglion (ICG) neurons. In response to current injection (1X, 2X, and 3X), the frequency of action potentials (AP) was

significantly increased in the STG neurons, while decreased in the ICG neurons of TBI group. TBI altered rheobase and AP duration in the opposite direction in the STG and the ICG without affecting other passive and active properties. Real-time PCR analysis revealed that expression of the K_A 3.3, K_A 3.4, K_A 4.1, K_A 4.2, and K_A 4.3 was down-regulated in the STG of TBI group. Consistent with this finding, A-type K^+ currents was significantly attenuated, which may increase excitability of the STG neurons. Interestingly, N-type Ca^{2+} channels were significantly down-regulated in the ICG neurons, which may possibly cause hypoexcitability. Taken together, these data suggest that TBI-blunted BRS arises from the imbalanced cardiac autonomic motor activities which is caused by the ionic mechanisms including down-regulation of either A-type K^+ or N-type Ca^{2+} channels.

Title: Increased expression of uPAR after traumatic brain injury in uPA deficient mice

Authors: ***T. BOLKVADZE**[1], A. PITKÄNEN[1,2]
[1]Dept. of Neurobio., A.I.Virtanen Inst. For Mol. Sciences, Univ. of Eastern Finland, Kuopio, Finland; [2]Dept. of Neurol., Kuopio Univ. Hosp., Kuopio, Finland

Abstract: Rational: The urokinase-type plasminogen activator (uPA) together with its reseptor, urokinase-type plasminogen activator receptor (uPAR) constitutes a proteolytic system associated with tissue remodelling after various epileptogenic insults, such as traumatic brain injury (TBI). The regulation of post-injury expression of different components of uPAR-interactome (ligands and receptors) is, however, poorly understood. In the present study we assessed the effect of uPA deficiency on the expression of its receptor, uPAR, after TBI. Methods: TBI was induced by controlled cortical impact (CCI, velocity 5m/s, depth 0.5 mm) on 12 wk old male Wt (n=8) and uPA (n=10) mice. After 4 days post-CCI mice were decapitated for qRT-PCR. Expression of uPAR and uPA genes were assessed in Ipsilateral and contralateral perilesional cortex, hippocampus and thalamus. Results: The expression of uPA mRNA in the

perilesional cortex was elevated 4-fold in the Wt-CCI group as compared to that in controls ($p<0.05$). The expression of uPAR mRNA was similarly upregulated in the perilesional cortex both in the Wt CCI (4-fold, $p<0.05$) and uPA -/- CCI groups (4-fold, $p=0.01$). There was no difference between the injured groups. In the uPA -/- CCI group uPAR mRNA was elevated also in ipsilaterally in the hippocampus (6-fold, $p=0.01$) and thalamus (4-fold, $p<0.05$). Conclusion: The present study shows that expression of uPAR mRNA after TBI is not compromised by genetic deficiency of its ligand uPA. Therefore, uPAR may stay functional for mediating the signaling initiated by other components of uPAR-interactome.

Title: A neuroprotective effect of Salubrinal in traumatic brain injury

Authors: *C. G. PICK[1], V. RUBOVITCH[3], S. BARAK[2]
[2]Anat., [1]Tel Aviv Univ., Tel Aviv, Israel; [3]Anat., Tel-Aviv Univ., Tel Aviv, Israel

Abstract: We have previously reported that mild traumatic brain injury (mTBI) induced various short and long term cognitive deficits as well as apoptosis in the mice brains. Apoptosis may be caused by prolonged and severe accumulation of misfolded proteins and protein aggregation in the endoplasmic reticulum (ER stress). In addition, we reported that mTBI activated the pro-apoptotic arm of the unfolded protein response (UPR). The main goals of the present study were to test the involvement of the eIF2α/ATF4 pathway (the translational/adaptive arm of the ISR (integrated stress response) in mTBI brains and to suggest this pathway as a potential therapeutic target. In order to do so we directly activated the translational/adaptive arm of the ER stress by salubrinal, which is a selective phosphatase inhibitor of p-eIF2α. We induced head injury with a non-invasive closed-head weight drop (30 gr). Salubrinal was injected to mTBI mice immediately and 24h after injury (1mg/kg, ip). The Y-maze and the Novel Object recognition tests (to assess spatial and visual memories, respectively) were conducted either 7 or 30 days post trauma. Salubrinal administration significantly reversed memory deficits following mTBI either 7 or 30 days after injury. In order to understand the mechanism that underlies salubrinal's neuroprotection, Western blot analysis was conducted: mTBI induced a significant reduction in

eIF2α phosphorylation, which was prevented by Salubrinal. While ATF4 (activating transcription factor 4), the immediate target molecule of eIF2α, was not altered in Salubrinal mTBI brains (with or without salubrinal), the phosphorylated ATF4 was significantly reduced in mTBI brains. This reduction was prevented by salubrinal administration. Our results show that targeting the adaptive arm of ER stress with Salubrinal may serve as a potential therapeutic strategy for brain damage.

Title: Development of a ferret model of traumatic brain injury; preliminary imaging, behavioral and immunohistochemical findings

Authors: *S. C. SCHWERIN[1], E. HUTCHINSON[3], K. NGALULA[1], C. PIERPAOLI[3], S. L. JULIANO[1,2]
[1]Anatomy, Physiol. and Genet., [2]Neurosci., Uniformed Services Univ., Bethesda, MD; [3]Natl. Inst. of Child Hlth. and Develop., NIH, Bethesda, MD

Abstract: In recent years, multiple preclinical models of traumatic brain injury (TBI) have emerged to investigate mechanisms of damage and plasticity following injury as well as to test novel therapeutic approaches. Mouse and rat models of TBI provide important insights into the brain's response to injury. However, the low relative volume of white matter and their lissencephalic cortex reduce their relevance to study hallmark human pathologies such as diffuse white matter injury. In contrast, the ferret's brain surface is highly folded and has a ratio of white to gray matter that is comparable to humans. These similarities may facilitate the translation of basic science discoveries to clinical research. In this study we developed a ferret model of TBI using controlled cortical impact (CCI). Methods. 9 adult male ferrets were included in the development of the surgical protocol. We then studies the effects of CCI in 4 additional ferrets (control, sham, mild, severe) using MRI, behavioral and histological outcomes with a 7 day survival. The mild CCI parameters were: bit diameter = 3 mm, penetration depth = 1 mm, impact

velocity = 3 m/s, and dwell time = 100 ms. For the severe CCI the depth was increased to 4 mm and the velocity was increased to 5 m/s. We acquired MRI in-vivo before and 1 day after surgery and ex-vivo. We tested behavioral abilities before and after CCI (6 hours; 1, 3, 7 days) including beam walk, gait analysis, open field, novel object recognition, righting reflex, and adhesive removal tests. Results. Surgical protocol improvements: 1. Retraction, not incision, of the large temporalis muscle covering the skull. 2. Closing of the cranial window is necessary to avoid direct pressure by the muscle on the brain. 3. Pre-surgical MRI for placement of the cranial window is advantageous due to considerable heterogeneity in cranio-cerebral geometry across ferrets. In-vivo MRI findings: At 1 day post injury we found T2W hyperintense regions in both injured ferrets, but greater in extent for the severe case. Ex-vivo MRI findings: At 1 week, we found increased T2 values in the perilesional cortex and white matter. DTI abnormalities included disrupted orientation near the lesion, reduced FA and abnormal MD diffusely in the body of the white matter. Behavioral findings: Motor, but not sensory deficit that was recovered by the seventh day. Histopathology revealed increased GFAP, microglia and extracellular matrix protein immunoreactivity in the injured brain. In conclusion, we have developed a CCI protocol for use in the ferret and our initial observations suggest the utility of this model as a sensitive and translationally relevant approach to the study of TBI.

Title: Lorazepam does not negatively impact neurobehavioral outcome after experimental brain trauma

Authors: K. E. FREE[1], J. B. LEARY[1], A. M. VOZAR[1], B. S. KIM[1], S. D. STEVENS[1], C. M. EDWARDS[1], J. P. CHENG[1], C. O. BONDI[1], *A. E. KLINE[2]
[1]Phys Med. & Rehab, Safar Ctr. Resuscitation Res., [2]Phys Med. & Rehab, Psych, Safar Ctr. Resuscitation Res., Univ. Pittsburgh, PITTSBURGH, PA

Abstract: **Introduction:** Traumatic brain injury (TBI) affects 10,000,000 people worldwide, making it a significant health concern. In addition to motor and cognitive dysfunction, TBI also induces aggression and agitation, which hampers acute care and rehabilitation. To manage these behavioral dysfunctions, antipsychotic drugs (APDs) are administered. Studies from our laboratory have shown that chronic administration of APDs impedes the acquisition of spatial learning. Despite the negative effects, some form of sedation is necessary so that physicians can assess and treat disruptive patients. **Hypothesis:** Lorazepam, a benzodiazepine, will not produce deleterious effects on motor and cognitive outcome after experimental TBI. **Methods:** Twenty-eight anesthetized adult male rats received either a controlled cortical impact (2.8 mm tissue deformation at 4 m/sec) or sham injury and then were randomly assigned to 4 groups where a TBI and corresponding sham group received either lorazepam (1.0 mg/kg; i.p.) or saline vehicle (1.0 mL/kg; i.p.) once daily for 19 days. Motor function and cognition were assessed using established tests on days 1-5 (beam-walk) and 14-19 (water maze), respectively. **Results:** No significant motor and cognitive differences were revealed between the TBI + lorazepam and TBI + vehicle groups ($p = 0.60$ and $p = 0.09$, respectively). **Conclusions:** These results suggest that daily administration of lorazepam (1.0 mg/kg) does not impair motor and cognitive outcome after experimental TBI, which is unlike that reported for APDs. **Significance:** Lorazepam should be considered as an alternative treatment to control clinical TBI-induced agitation and aggression as it will allow for patient assessment and treatment without impairing subsequent recovery. Ongoing studies are determining the range of doses that can be safely administered.

Title: Attentional set-shifting after brain trauma is restored by a preclinical model of neurorehabilitation

Authors: *C. O. BONDI[1], J. P. CHENG[1], H. M. TENNANT[1], N. LAJUD[3], K. E. FREE[1], C. M. MONACO[1], J. B. LEARY[1], A. E. KLINE[2]
[1]Phys Med. & Rehab, Safar Ctr. for Resuscitation Res., [2]Phys Med. & Rehab, Psych, Safar Ctr. for Resuscitation Res., Univ. of Pittsburgh, Pittsburgh, PA; [3]Lab. de Neuroendocrinologia,

Introduction: Cognitive impairment associated with prefrontal cortical dysfunction is a major component of disability in traumatic brain injury (TBI) survivors. Specifically, deficits in executive function and behavioral flexibility are present across all injury severities. While impairments in spatial learning have been extensively reported, experimental models of TBI investigating more complex cognitive disabilities are relatively scarce. We have begun to employ the attentional set-shifting test (AST), a complex cognitive paradigm analogous to the Wisconsin Card Sorting Test, which is used to measure strategy-switching deficits in patients with frontal lobe damage, TBI, and psychiatric disorders. Previously, we demonstrated that a controlled cortical impact (CCI) injury produced significant impairments in executive function and cognitive flexibility in the AST. **Hypothesis:** Environmental enrichment (EE), a preclinical model of neurorehabilitation, will restore cognitive performance post-injury in the AST. **Methods:** Thirty-one isoflurane-anesthetized male rats received a CCI (2.8 mm cortical deformation at 4 m/s) or sham injury and then were randomly assigned to TBI and sham groups that were further divided into EE and standard (STD) housing (n=6-10/group). At four weeks post-surgery, rats were tested on the AST, which involves a series of increasingly difficult discriminative tasks to obtain food reward, including simple and compound discriminations, stimulus reversals, and intra-and-extradimensional (ED) shifts. **Results:** TBI impaired ED set-shifting and stimulus reversal learning and increased total response errors and set loss errors (i.e., after 50% or more of the contingency rule has been achieved) ($p < 0.05$). Moreover, EE significantly attenuated the detrimental effects of TBI on cognitive performance in the AST ($p < 0.05$). **Conclusions:** EE exposure as a model of preclinical neurorehabilitation significantly attenuated CCI injury-induced impairments in executive function and behavioral flexibility, which supported the hypothesis. **Significance:** These novel findings demonstrate that executive function and behavioral flexibility deficits in our CCI model are sensitive to the beneficial effects of EE, which may be viewed as a viable preclinical model of cognitive rehabilitation. **Future directions:** Evaluation of pharmacological and cognitive rehabilitation therapies as a clinically relevant combinational paradigm, as well as elucidating mechanisms underlying the neuropsychological deficits.

Title: Manipulating initiation time and duration of environmental enrichment exposure after traumatic brain injury to more accurately mimic clinical rehabilitation

Authors: *A. M. GREENE[1], V. V. MATTIOLA[1], J. B. LEARY[1], L. J. CARLSON[1], J. P. CHENG[1], C. M. MONACO[1], C. O. BONDI[1], A. E. KLINE[2]
[1]Phys Med. & Rehab, Safar Ctr. Resuscitation Res., Univ. Pittsburgh, Pittsburgh, PA; [2]Phys Med. & Rehab, Crit Care Med, Psych, Ctr. Neurosci, Safar Ctr. Resuscitation Res. Univ. Pittsburgh, Pittsburgh, PA

Abstract: Environmental enrichment (EE) consists of increased living space, complex stimuli, and social interaction that promotes exploration and confers improvements in behavioral outcome and histopathology after experimental traumatic brain injury (TBI) vs. standard (STD) housing. However, as a model of rehabilitation, continuous EE is not clinically relevant due to the timing parameters of the typical EE and thus translatability could be limited. Specifically, TBI patients typically receive rehabilitation only after critical care has been provided and then only for 3-6 hours per day. Thus, to mimic the clinic, the goal of this study was to determine whether delaying EE by three days and providing only six hours per day would provide benefits similar to continuous EE. To address this rehabilitation relevant issue, isoflurane-anesthetized male rats were subjected to a controlled cortical impact (2.8 mm depth at 4 m/s) or sham injury and randomly assigned to TBI+EE (continuous), TBI+EE (3 day delayed, 6 hr day), and respective sham controls. Motor function (beam-balance/beam-walk) was assessed on post-operative days 1-5. Spatial learning/memory (Morris water maze) was evaluated on days 14-19. The data showed that EE, regardless of timing, improved motor and cognitive function compared to STD housing ($p < 0.0001$). Moreover, there were no differences between the TBI+EE (continuous) and TBI+EE (3 day delayed, 6 hr day), $p > 0.05$. These data demonstrate that delayed and abbreviated EE produces motor and cognitive benefits similar to continuous EE after TBI and thus further supports EE as a preclinical model of neurorehabilitation. Ongoing studies are evaluating the effects of longer delays in implementing EE after TBI.

Title: Examines of depressive responses for posttraumatic stress disorder-like rats in forced swimming task

Authors: *L. H. YEH, F.-Y. WU, A. HUANG
Psychology, Dept. of Psychology, Fo Guang Univ., Jiaosi, Yilan County, Taiwan

Abstract: Patients with posttraumatic stress disorder (PTSD) are often associated with the depressive behavior. With regard to pharmacological interventions, the opiate system and the hippocampus-pituitary-adrenal gland (HPA) stress system has been shown to respectively involve in the symptoms of PTSD. However, whether opiate and HPA systems govern the depressive comorbidity of PTSD in animal model remains unknown. The purpose of the present study addresses this issue. At the beginning of the experiment, all of rats encountered footshock (3 mA, 10 second) to form PTSD effects and were intraperitoneally administrated with 10 mg/kg of morphine, 1 mg/kg of naloxone, and its vehicle normal saline on Day 1. Later, rats were subjected to the situational reminder procedure where rats were placed 2 minutes each trial in the footshock compartment on Days 2, 7, and 13. On Day 14, all rats received a forced swimming test for 5 minutes to assess the depressive behavior, including floating, swimming, and struggling responses. The results indicated that non-significant differences occurred at the factors of opiate drugs, dexamethasone, and the interaction of opiate drugs and dexamethasone for floating behavior. For swimming, non-significant differences occurred at opiate drugs and the interaction of opiate drugs and dexamethasone. However, there was a significant difference in dexamethasone treatments. For struggling behavior, a significant difference occurred at dexamethasone treatments but non-significant differences occurred at opiate drugs and the interaction of opiate drugs and dexamethasone. Taken together, the opiate system does not govern the depressive responses of PTSD; however, a high-dose of dexamethasone probably increases the swimming responses; indicating the high dose reduces depressive responses. The high-dose of dexamethasone decreases the struggling responses when compared to the low-dose

of dexamethasone; indicating the high dose of dexamethasone facilitates depressive responses. Thus, the low- and high-doses of dexamethasone show an inconsistent result between swimming and struggling responses. The paradoxical findings need to be scrutinized in the further studies.

Title: A single head impact in adult mice produces two patterns of neurological and behavioral deficits

Authors: *N. M. GRINKINA, Y. LI, A. M. EL SEHAMY, M. HABER, P. J. BERGOLD
Pharmacol. and Physiol., SUNY Downstate Med. Ctr., BROOKLYN, NY

Abstract: In clinical traumatic brain injury, a single closed head impact (CHI) produces a heterogeneous pattern of behavioral and neurological deficits. We have developed a CHI animal model that reliably produces two injury syndromes (CHI-1 and CHI-2) after a single impact to a closed head of an adult C57/Bl6 mouse. Within minutes after impact, mice could be separated into CHI-1 and CHI-2 groups based upon the recovery from apnea and righting reflex. CHI-1 mice spontaneously reinitiated breathing and regained a righting reflex in 312 ± 42 seconds. CHI-2 mice had apnea lasting more than 30 seconds and required cardiopulmonary resuscitation with 100% O_2. CHI-2 mice regained righting reflex in 528 ± 72 seconds. At seven days, the sham, CHI-1 and CHI-2 groups were trained on an active place avoidance task in which mice avoid a stationary shock zone on a rotating arena by attending to relevant distal spatial cues while ignoring proximal olfactory cues. CHI-1 and CHI-2 mice had different behavioral deficits. Sham and CHI-1 animals acquired the task while CHI-2 animals did not. Also, sham-CHI mice lowered time to 1st entrance, a parameter of task retention, while CHI-1 mice did not. The inability of CHI-1 mice to lower time to 1st entrance was also seen on the next day on the same task with the shock zone location rotated 180^{o}. These data suggest that CHI-1 mice are deficient

in task retention and CHI-2 mice are deficient in task acquisition. These behavioral deficits of CHI-1 and CHI-2 mice did not differ one month after injury. CHI-1 and CHI-2 mice also had different patterns of grey and white matter injury (Sangobowale, et al., accompanying poster). Minocycline (MINO) and N-acetycysteine (NAC) limited behavioral deficits in rats injured in the controlled cortical impact model (Abdel-Baki, et al., 2010; Haber, et al., 2014). We therefore tested whether the drugs also limited deficts in the CHI-injured mice. Treatment with MINO plus NAC greatly diminished the acquisition deficit of CHI-2 mice. These data suggest that MINO plus NAC has an effect in two models of traumatic brain injury (controlled cortical impact and CHI) and in two species (mouse and rat). We are now testing whether the drug combination has an effect on the retention deficit of CHI-1 mice.

Title: A single head impact to adult mice produces two patterns of white matter injury

Authors: *M. A. SANGOBOWALE, N. GRINKINA, Y. LI, M. HABER, P. BERGOLD
Pharmacol. and Physiol., SUNY Downstate Med. Ctr., Brooklyn, NY

Abstract: The inherent heterogeneity of TBI (traumatic brain injury) has been a barrier to finding effective therapies. To better understand the heterogeneity of TBI, we report a closed head injury (CHI) animal model that reliably produces two injury syndromes (CHI-1 and CHI-2) after a single closed head impact to adult mice. CHI-1 and CHI-2 mice differ in righting reflex, and cognitive and memory deficits (Grin'kina, et al., accompanying poster). The two injuries also differ in structural damage to the brain. At 14 days, NeuN staining shows little difference between the hippocamppi of CHI-1 and CHI-2 mice. In contrast, at one month, there was significantly less NeuN immunoreactivity in the hilus, CA3 and CA1 regions. No change was observed in the granule cell layer of the dentate gyrus at either 14 days or one month. At one month, CHI-1 and CHI-2 mice show a significant loss of MAP2 immunoreactivity in the hilus,

CA3 and CA1 regions. White matter injury was assessed in cerebellum, cingulum, corpus callosum, fimbria and splenium. Myelin was assayed using luxol fast blue and axon density measured using a pan neurofilament antibody. CHI-2 mice had widespread myelin and neurofilament loss in cerebellum, cingulum, corpus callosum, and fimbria while white matter injury in CHI-1 mice was limited to cingulum and corpus callosum. CHI-2 mice have a more severe injury than CHI-1 mice, thus, CHI provides a model for the clinical heterogeneity of human TBI. In a rat controlled cortical impact model, the combination of the FDA-approved drugs minocycline (MINO) and N-acetylcysteine (NAC) repair white matter through remyelination. One month after injury, MINO plus NAC treatment increased luxol staining in CHI-2 mice. We are testing whether remyelination is responsible for the increase in luxol staining.

Title: Minocycline and N-acetylcysteine protects oligodendrocytes and promotes remyelination after mild controlled cortical impact

Authors: M. HABER[1], J. Y. KIM[2], J. JAMES[3], M. SANGOBAWALE[1], N. M. GRIN'KINA[1], A. RAMADANI[3], *P. J. BERGOLD[4]

Abstract: Mild controlled cortical impact (mCCI) demyelinates white matter. This white matter damage can potentially be repaired through remyelination. The combination of minocycline (MINO) plus n-acetylcysteine (NAC) limits white matter damage after mCCI. White matter was examined using antibodies against antigenic markers on oligodendrocyte precursor cells (PDGFR-α, platelet derived growth factor receptor α), oligodendrocyte soma (APC, adenomatous polyposis coli protein) or myelinating processes (PLP, phospholipid protein;

CNPase, 2',3'-Cyclic-nucleotide 3'-phosphodiesterase). Myelin lipid was assessed with luxol fast blue and axons were assessed with a pan-neurofilament antibody. After mCCI, the corpus callosum of saline-treated rats lowered luxol binding and APC, CNPase, and PLP immunoreactivity. Neurofilament immunoreactivity was unchanged. Thus, mCCI induced oligodendrocyte, but not axonal, loss. Two days after injury, PDGFR-α immunoreactivity was high and decreased over subsequent days. Over the next 14 days, APC immunoreactivity increased in saline-treated injured rats, but CNPase and PLP expression and luxol fast blue staining remained significantly below sham-CCI values. Semithin sections of corpus callosum showed an absence of myelin sheaths. These data suggest that, despite production of new oligodendrocytes, remyelination fails following mCCI. MINO plus NAC treatment resulted in similar demyelination as saline treatment. There was no drug effect on axons. MINO plus NAC treated rats showed PDGFR-α and APC expression levels similar to sham-mCCI rats. MINO plus NAC also increased expression of CNPase and PLP. Luxol fast blue staining also increased and myelin sheaths were seen in semi-thin sections of corpus callosum. These data suggest that MINO plus NAC repairs white matter by protecting oligodendrocytes acutely after injury and promotes remyelination. We are studying later time points to test if there is a long-lasting failure to remyelinate after mCCI. MINO and NAC are also being applied as individual drugs to understand the contribution of each drug to remyelination. The repair of white matter by MINO plus NAC is a novel mechanism to treat traumatic brain injury.

Title: Assessment of the Time Dependent changes in the amygdala of rats exposed to Blast-Induced Neurotrauma

Authors: *F. GHODDOUSSI[1], S. V. SAJJA[2], M. P. GALLOWAY[1], P. VANDEVORD[2]
[1]Anesthesiol. & Psychiatry and Behavioral Neurosciences, Wayne State University, Sch. of Med., DETROIT, MI; [2]Sch. of Biomed. Engin. and Sci., Virginia Polytechnic and State Univ., Blacksburg, VA

Abstract: Introduction: Traumatic brain injury (TBI) induced by blast waves (blast TBI, bTBI) is a significant clinical problem in soldiers returning from combat. Psychiatric illnesses such as depression, anxiety, sleep disturbances, memory impairment, and PTSD have a delayed expression after the bTBI event. Reliable biomarkers are non-existent for bTBI which is under diagnosed partly due to the absence of criteria in morphology based neuroimaging modalities (e.g. CT and MRI). Therefore using other neuroimaging modalities such as MRS and DTI may provide an avenue for diagnostic biomarkers of the pathology. Central processing of fear-related memories and emotions occurs in the amygdala. Multiple clinical studies support a critical role for amygdalar nuclei in the disordered emotional reactions of patients with PTSD. Methods: We used proton magnetic resonance spectroscopy (1H-MRS) *ex vivo* to assess the neurochemical profiles in the amygdala (AMYG) of male rats 3 hours, 1, 2, 3 and 7 days, 1 and 3months after exposure to a calibrated blast overpressure (117kPa). Immunohistochemistry assessed the progression of cell death and astrogliosis. Short-term and working memory impairment as well as anxiety-like behaviors was assessed by novel object recognition and light/dark box respectively. Results: In the bTBI group, anxiety-like behavior was evident from 2 d thru 3 mo and impaired memory tasks evident at 7 d thru 3 mo post insult. MRS analysis showed that GABA, GLU [and their ratio to creatine (CRE)] and the NAA/CRE ratio was decreased in the AMYG 2 d after blast. The ratio of myo-inositol (INS)/CRE and N-acetyl-aspartate-glutamate (NAAG) was significantly increased after 3m. Caspase-3 was elevated in the acute (3h-7d) but not at the chronic stages (1-3m) after bTBI. Microglial activity (Iba1 staining) was elevated at 1 & 3mo. Fluorojade B (neurodegeneration) and GFAP (astrogliosis marker) were increased over the entire experimental period. Increased microglial activity in amygdalae was positively correlated with anxiety-like behaviors. Discussion: Decreased NAA/CRE, GLU, and GABA observed 2 d after blast is consistent with compromised mitochondrial (oxidative) stress and energy metabolism and may herald the activation of cellular death pathways. Since INS is primarily present in astrocytes, the increased level of INS/CRE ratio after 3m may reflect the increased astrogliosis, a pathology that was positively correlated to the anxiety-like behavior. Increased levels of INS were also correlated with impaired memory in the novel object recognition task. These results highlight the utility of 1H-MRS for assessment of the status of the brain after bTBI and during treatment

Title: The kinetics of intracranial pressure changes following exposure to blast and the effect of n-acetylcysteine amide on recovery after blast in a rat model

Authors: U. KAWOOS, M. GU, J. LANKASKY, *J. N. NORRIS, R. M. MCCARRON, M. CHAVKO
Neurotrauma, Naval Med. Res. Ctr., Silver Spring, MD

Abstract: Background - Blast-induced traumatic brain injury (bTBI) has been a leading cause of neurocognitive impairment in the military population. Blood brain barrier (BBB) integrity has been shown to be compromised in traumatic brain injury including bTBI. However, the long term kinetics of BBB changes and its consequences remain unclear. In this study, the effects of blast overpressure (BOP) on intracranial pressure (ICP), its correlation with BBB breakdown, and the effect of N-acetylcysteine amide (NACA) on the BOP induced changes were explored in a rat model. Methods - Animals were exposed to either one or three BOPs (110 kPa) in frontal orientation with animal's head facing the blast. ICP was monitored by a telemetric device over a period of 7 days. BBB permeability and integrity were determined by Evans Blue staining and occludin immunoreactivity, respectively. NACA was administered either pre- or post-blast by single i.p injection (500 mg/kg). Results - A significant elevation in ICP was observed after single or repetitive exposures to BOP. The amplitude of ICP increase was higher in the repetitive exposure group. The degree of ICP elevation in the groups treated with NACA pre- or post-blast was reduced. A two-way repeated measures ANOVA followed by Bonferroni post-hoc analysis was performed to compare the groups. In the repetitive group, the effect of pre-blast injection was significant ($p<0.001$) when compared to a placebo treated group. All injured, NACA treated groups were significantly different ($p<0.001$) than naïve control group. In a single blast group, ICP immediately declined after post-blast NACA administration and returned to near pre-blast levels. The BBB permeability after blast, examined by Evans Blue (EB) dye, was increased in the brain two hours after single or multiple exposures of blast, indicating a compromise in the integrity and function of the BBB. The increase in BBB permeability could result from a

decreased immunoreactivity of occludin, which is one component of tight junctions in BBB after blast. Conclusions - These results demonstrate that BBB breakdown may play an important role in the mechanism of mild TBI. The subsequent ICP increase can be used as one of the markers of brain damage and the antioxidant NACA may be useful as a new therapeutic modality for ameliorating BOP-induced brain damage.

Abstract: In pre-clinical traumatic brain injury (TBI) research, a critical element is to validate instrument performance in relation to biomechanical, physiological, histological, and behavioral effects of the injury. The purpose of this study was to characterize instrument performance of one of the most widely used pre-clinical models of TBI, by using high speed videography. Two electromagnetically-driven CCI impact actuators of the same model (Impact One™ Stereotaxic Impactor for CCI, Leica Biosystems) were used with a 3mm short impactor tip, a dwell time of 100ms, and impact penetration depth controlled by changing the position of the stereotaxic frame. Poron cushioning material and a mouse brain with craniotomy were used to record CCI impactor tip with a high speed digital camera (Y3-S1, IDT Inc.). Motion analysis indicated that in the initial ~15ms after activation, the impactor tip makes two or three distinctive advances before it reaches the desired depth setting for full extension. The velocity of the impactor tip on the 1st extension was normally faster than the preset values. The velocity of the tip on the subsequent extension was significantly slower. The amount of over-speed was greater during the

1st extension when the velocity was set at slower values. In the 1st and 2nd advances, the tip extended less than the targeted distance. The terminal location of the tip when it was stationary during final extension was near the desired depth for most of the impact time. Excluding movement of the tip for the first 15ms, the velocity and location of the tip were essentially identical regardless of settings. A similar phenomenon was observed when impact testing was performed on the mouse brain with craniotomy. The analysis suggests that device velocity setting plays little, if any, role as a variable in CCI injury. Depth performance was reproducible and closely matched stereotaxic setting, suggesting this variable (as well as tip diameter and shape; not studied here) may be the most significant factor in the application of CCI in pre-clinical TBI research.

Title: Caloric intake affects behavioural outcomes following pediatric concussion in rats

Authors: *R. M. MYCHASIUK[1], H. HEHAR[2], A. FARRAN[3], I. MA[2], M. J. ESSER[2]
[1]Neurosci., Univ. Lethbridge, Lethbridge, AB, Canada; [2]Med., [3]Univ. of Calgary, Calgary, AB, Canada

Abstract: Recent statistics released by the World Health Organization indicate that in industrialized countries like the United States and Canada, over 60% of the population is at risk for being overweight (as determined with a BMI $\geq$ 25). These findings are alarming as compelling evidence suggests that excessive caloric intake negatively affects brain plasticity. This research also indicates that there is a link between obesity and adverse neurological outcomes such as reduced cognitive functioning, stroke, and Alzheimer ’s disease. Conversely, dietary restriction and lowered caloric intake have been associated with increased synaptic plasticity, reduced neurodegeneration, improved brain health, and increased life span. Although pediatric concussion and mild traumatic brain injury (mTBI) are very common and the initial

symptoms can be very distressing, the majority of children have a complete acute recovery. However a significant proportion may suffer permanent impairment and the long-term implications of these early life injuries is not fully known. Currently, most research has focused on treatment strategies after the injury, rather than the factors that may predict differential susceptibility or resilience to outcomes. The current study was designed to determine if exposure to a high fat diet (HFD) or caloric restriction (CR) throughout life (including the prenatal period) would differentially alter behavioural outcomes following a mTBI/concussion in early childhood. Eight dams were fed a HFD, CR, or the standard rat chow (STD) (total dams; n = 24) for the duration of pregnancy and weaning at which point rat pups were maintained on the same diet as their mothers. At postnatal day 30 (P30) half of the rat pups received an mTBI/concussion (n =44) and the other half received a sham injury (n =44). Rats underwent a behavioural test battery including: beam-walking, the elevated plus maze (EPM), and the Morris water task (MWT). Results from this study indicate that caloric intake prior to a mTBI/concussion does alter behavioural outcomes on the three tasks discussed above. mTBI animals on the HFD tended to have poorer motor outcomes on the beam walking task, increased anxiety on the EPM, and altered executive functioning in the MWT probe trial. On the contrary, mTBI rats maintained on the calorically restricted diet exhibited heightened recovery on these tasks and were often indistinguishable from their sham counterparts. This study therefore indicates that daily routines, such as dietary intake, may influence mTBI/concussion related outcomes in early childhood.

Title: Hippocampal excitability after diffuse brain injury in swine

Authors: *A. ULYANOVA, M. R. GROVOLA, P. F. KOCH, J. P. HARRIS, V. E. JOHNSON, D. K. CULLEN, J. A. WOLF
Neurosurg., Univ. of Pennsylvania, Philadelphia, PA

Abstract: Hippocampal excitability and the development of epileptogenesis after diffuse brain injury were studied using a model of closed-head rotational acceleration in swine. We utilized *in vivo* electrophysiological recordings to investigate changes in hippocampal circuitry after mild traumatic brain injury in sham versus injured animals. Male Yucatan swine (age 6 months) were injured by rotational acceleration of the head (180-260 radians per second) in the coronal plane. There was no prolonged loss of consciousness (< 15 min) or subdural bleeds, however axonal pathology was present. In order to appropriately place the 32-channel probe, cell layers of the swine hippocampi were mapped via single unit activity in each animal prior to probe insertion. Field potential activity and neuronal firing rates in the dorsal hippocampus were recorded using high-density electrode arrays with simultaneous afferent stimulation in sham (n=5) or injured animals (n=10) one or two weeks post injury. Single and paired pulse stimulations in the Schaffer collateral and a theta burst paradigm in the entorhinal cortex were utilized. Hippocampal responses were analyzed for changes in baseline activity, firing rates and response to stimulation. Changes in hippocampal excitability were also analyzed in repetitively injured animals (180 rad/sec, 7 days apart) and in minocycline-treated animals. There were significant changes in baseline activity and in responses to stimulation at all levels of injury. Return to baseline after paired pulse stimulation took at least 100 msec after single-injury and was further increased after repetitive injury. At the same time, responses to stimulation recorded at 15 days post injury were similar to that in sham. At higher injury levels (260 rad/sec), recurrent paired pulse stimuli rendered hippocampal circuitry unresponsive and induced epileptiform activity such as paroxysmal depolarizing shifts and high-frequency oscillations. Theta burst stimulation induced epileptiform activity at higher injury levels but not in sham or lower injury levels, however firing rates were reduced at all injury levels tested. These alterations suggest an increased excitability, or a shift in the excitation-inhibition balance of the local hippocampal circuitry. These data suggest that single diffuse brain injury induces hippocampal axonal dysfunction and hippocampal excitability changes such as baseline oscillatory activity and neuronal firing rates. Throughout the post injury period, these alterations lead to circuit-level changes in the hippocampus that will elicit sub-clinical epileptiform activity.

Title: Neuronal death induced by endoplasmic reticulum stress is blocked by overexpression of co-chaperone E3 ubiquitin ligase CHIP in hippocampus

Authors: *F. CABRAL MIRANDA, J. ADAO NOVAES, H. PETRS SILVA, L. CHIARINI
UFRJ, RIO DE JANEIRO, Brazil

Abstract: INTRODUCTION: The unfolded protein response (UPR) is triggered after endoplasmic reticulum (ER) stress and is involved with mechanisms regarding cellular stress adaptation and death. Here we show for the first time that E3 ubiquitin ligase and co-chaperone carboxyl terminus HSP70/90 interacting protein (CHIP) prevents neuronal death in hippocampus after severe ER stress. **MATERIAL AND METHODS**: We use organotypic hippocampal slice cultures of male Lister Hooded rats (post natal day 7) cultured for 13 days. After that tissue slices are exposed to tunicamycin, an inhibitor of N-glicosylation, to induce ER stress. Overexpression of CHIP was performed by adeno-associated virus (AAV8-CHIP) infection. Quantification of cellular death was performed by propidium iodide (PI) uptake, chromatin condensed nuclei counting. Slices were processed for western blot or immunofluorescence in order to analyze activation of UPR. **RESULTS:** Overexpression of CHIP decrease the PI uptake, indicating that CHIP blocks necrosis induced by tunicamycin in hippocampus. In addition we found that overexpression of CHIP blocked both chromatin condensation and DNA fragmentation, indicating that CHIP blocks apoptosis induced by tunicamycin in hippocampus. Tunicamycin induces upregulation of CHOP expression. We found that overexpression of CHIP prevent the upregulation of CHOP induced by tunicamycin. In addition, phosphorylation of eIF2alfa induced by tunicamycin was prevented by overexpression of CHIP. Thus, we found that CHIP prevents activation of death pathways associated with the Unfolded Protein Response. **CONCLUSIONS**: Our results points to a connection between CHIP and ER stress death triggering. Our data suggest a neuroprotective role for CHIP in harmful cellular stimuli and even to neurodegenerative diseases related to UPR and endoplasmic reticulum stress. **Financial Support: CNPQ / FAPERJ**

Title: Cyclin-dependent kinase 5 promotes truncated apoptosis inducing factor-mediated neuronal cell death via phosphorylation of stub1/chip

Authors: *C. KIM, W. H. SHIN, K. C. CHUNG, Y. J. OH
Dept. of Systems Biol., Yonsei Univ., Seoul, Korea, Republic of

Abstract: Cyclin-dependent kinase 5 (CDK5) is a proline-directed Ser/Thr kinase and plays critical roles in many cellular pathways associated with neurodegenerative diseases. Likewise, it has been established that C-terminus of Hsp70-interacting protein (*STUB1*/CHIP), a co-chaperone as well as one of the E3 ubiquitin ligases, also exerts a pathophysiological role on autophagy and neurodegeneration. However, the possibility and/or mechanisms underlying regulation of CHIP function via CDK5 are not examined. Here, we report that CHIP is a novel CDK5 substrate in various models of neurodegeneration established by using neuronal cell lines and mouse cortical neurons. More specifically, CDK5 phosphorylates CHIP via direct binding with highly charged domain of CHIP as determined by *in vitro* and *in vivo* assays. Moreover, the phosphorylation of CHIP by elevated CDK5 activation significantly attenuates CHIP-mediated ubiquitination of endogenous substrates, but not its ligase activity. The degradation of truncated AIF (tAIF), alpha-synuclein, and p53 among CHIP substrates is negatively regulated by CDK5-mediated phosphorylation of CHIP. For example, CHIP-mediated tAIF degradation via ubiquitin-proteasomal system (UPS) is significantly inhibited through disruption of binding between CHIP and tAIF as a consequence of CDK5-mediated phosphorylation of CHIP. Consistently, the phosphorylation of CHIP by elevated CDK5 activation following neurotoxic stimuli generates and stabilizes tAIF, leading to caspase-independent neuronal cell death. Thus, we propose a novel regulatory loop by which phosphorylation of CHIP via CDK5 eventually leads to tAIF-mediated neuronal cell death.

Title: Activation of β-catenin/TCF signaling in p25-overexpressing cells induces trans-neuronal loss of β-catenin and activated apoptosis in p25-free neurons by secreted factor Notum

Authors: *H. CHOW[1], K. HERRUP[1,2]
[1]Div. of Life Sci., The Hong Kong Univ. of Sci. and Technol., Hong Kong, Hong Kong;
[2]Rugters Univ., Piscataway, NJ

Abstract: The cyclin-dependent kinase 5 (CDK5) activators, p35 and p25, have a proposed role in the pathogenesis of neurodegenerative disorders. We have recently shown that glycogen synthase kinase 3β (GSK3β) also binds to p25 (but not p35). When it does so, GSK3β hyperphosphorylates tau; yet the phosphorylation of β-catenin is reduced, increasing its stability. This stabilized β-catenin increases in the cell nucleus and should protect neurons from apoptosis. Intrigued by observations that tangle-free neurons close to tangle-bearing neurons display degenerative morphologies and markers, we hypothesized that the tangle-bearing neurons, though themselves protected from cell death, might produce a factor that damaged otherwise healthy cells nearby. To test this idea we analyzed the bi-transgenic CK-p25 Tg mouse in which the expression of p25 is under the control of CamKII promoter and can be switched on or off with doxycycline. After inducing p25 expression for 8 weeks, we found that neurons in frontal cortex showed robust p25 expression and these cells had enhanced nuclear β-catenin. We found a one-third increase in the number of cleaved caspase-3 positive neurons, yet only half of these cells were also GFP-p25 positive. Intriguingly, nearby neurons with limited induction of GFP-p25 (and low levels of nuclear β-catenin), showed substantially elevated cell death markers. We observed the same phenomenon *in vitro*; cleaved caspase-3+ N2a cells or primary cortical neurons were significantly more frequent in close proximity to cells ectopically expressing p25; nuclear β-catenin was not present in the majority of these cells. A possible mechanism for this result is that Notum - a secreted Wnt antagonist and a β-catenin downstream target - was significantly elevated in conditioned medium from p25-overexpressing cells. Notum immunostaining was also elevated in brain sections of CK-p25 Tg mice. Our findings suggest that persistent aberrant activation of β-catenin by p25-expressing neurons triggers a trans-neuronal inhibition of Wnt signaling by Notum that leads in turn to the degeneration of

p25/tangle-free neurons. The existence of this neuron-killing-neuron scenario has significant implications for our understanding of neurodegenerative disease.

Title: Study on ATP concentration changes in cytosol and mitochondria of individual cultured neurons during glutamate-induced deregulation of calcium homeostasis

Authors: *V. G. PINELIS[1], A. M. SURIN[2,3], L. R. GORBACHEVA[5], I. G. SAVINKOVA[1,6], R. R. SHARIPOV[4], B. I. KHODOROV[4]

Pathology and Pathophysiology, RAMS, Moscow, Russian Federation; [5]Dept. of Human and Animal Physiol., [6]Lomonosov Moscow State Univ., Moscow, Russian Federation

Abstract: For the first time, simultaneous monitoring of changes in the concentration of cytosolic and mitochondrial ATP ([ATP]c and [ATP]mit accordingly), pH (pHc), and intracellular free Ca2+ concentration ([Ca2+]i) of the individual neurons challenged with toxic glutamate (Glu) concentrations was performed. To this end, the ATP-sensor AT1.03 for cytosol and mitochondria, which binds to ATP and therefore enhances the efficiency of resonance energy transfer between blue fluorescent protein (energy donor) and yellow-green fluorescent protein (energy acceptor), was expressed in cultured hippocampal neurons isolated from 1-2-day-old rat pups. Excitation of fluorescence in the acceptor protein allowed monitoring changes in pHc. Cells were loaded with fluorescent low-affinity Ca2+ indicators Fura-FF or X-rhod-FF to register [Ca2+]i. It was shown that Glu (20 μM, glycine 10 μM, Mg2+-free) produced a rapid acidification of the cytosol and decrease in [ATP]c and [ATP]mit. An approximately linear relationship (r2 = 0.56) between the rate of [ATP]c decline and latency of glutamate-induced delayed calcium deregulation (DCD) was observed: higher rate of [ATP]c decrease corresponded to shorter DCD latency period. DCD began with a decrease in [ATP]c of as much as 15.9%. In

the phase of high [Ca2+]i, the plateau of [ATP]c dropped to 10.4% compared to [ATP]c in resting neurons (100%). In the presence of the Na+/K+-ATPase inhibitor ouabain (0.5 mM), glutamate-induced reduction in [ATP]c in the phase of the high [Ca2+]i plateau was only 36.6%. Changes in [ATP]c, [Ca2+]i, mitochondrial potential, and pHc in calcium-free or sodium-free buffers, as well as in the presence of the inhibitor of Na+/K+_ATPase ouabain (0.5 mM), led us to suggest that in addition to increase in proton conductivity and decline in [ATP]c, one of the triggering factors of DCD might be a reversion of the neuronal plasma membrane Na+/Ca2+ exchange. We thank Dr. H. Imamura for kindly providing the plasmid of the ATP-sensors. This work was supported by Russian Foundation for Basic Research grants 10-04-01770 and 11-04-01961

Title: Early activation of autophagy during glucose deprivation contributes to cortical neuronal death

Authors: *C. GERÓNIMO, L. MASSIEU
Inst. De Fisiología Celular, UNAM, México Distrito Federal, Mexico

Abstract: A decrease of blood glucose levels or insufficient supply to the brain results in impairment of neuronal function. Whenever blood glucose decreases below 20 mg/dl, the hypoglycemic coma and brain injury take place. Hypoglycemia can occur as a complication of insulin treatment in diabetic patients, leading to brain glucose deprivation (GD). Neuronal damage induced by hypoglycemia is initiated by an excitotoxic mechanism triggered by the release of glutamate and aspartate. However, several molecular and cellular mechanisms are activated that ultimately lead to cellular death. A variety of stress stimuli are able to induce autophagy including nutrient and energy deprivation. Autophagy is a lysosome-mediated intracellular catabolic mechanism characterized by the appearance of double- or multiple-membrane cytoplasmic vesicles and the lipidation and redistribution of the cytoplasmic protein LC3-I, towards vesicles. The main role of autophagy is to maintain the cellular homeostasis and supply of building blocks for protein synthesis and energy in response to starvation. However, excessive autophagic degradation can lead to cell death, known as autophagic cell death. The aim of the present study is to analyze the role of autophagy in GD-induced neuronal death. Cortical cultures of 7-8 DIV were exposed for different times to GD followed by glucose reintroduction (GR) to evaluate morphological (the presence of double membrane vesicles) and biochemical (LC3-I/LC3-II, beclin1 and p62 protein levels) features of the autophagic pathway. To evaluate the role of autophagy in neuronal death by the MTT reduction and LDH release assays, cultures were exposed for 2 h to GD and 22 h to GR. We found a rapid activation of autophagy and accumulation of autophagosomes during the GD period. However, the autophagic flux was completed until the first stages of GR. Autophagy inhibition by 3-MA incubation during or after GD prevented neuronal death. Conversely, inhibition of autophagic degradation with chloroquine (CQ) during the GD period resulted in aggravation of neuronal death. Nonetheless, CQ treatment during GR improved cell viability, suggesting that regulated activation of autophagy during GD is beneficial for cortical cell survival. This study was supported by IN204213 PAPPIT grant to LM.

Title: Astrocytes provide a neuroprotective effect that counteracts rapid glutamate-receptor mediated neurotoxicity

Authors: D. MCEWEN, T. GARAY, J. BROWN, O. MCMANUS, D. ROCK, *V. GROPPI
Essen Biosci., Ann Arbor, MI

Abstract: Glutamate is the primary excitatory neurotransmitter in the central nervous system. Signaling through glutamatergic receptors, such as NMDA, AMPA, and kainate, is important in synaptic plasticity and cognitive function, such as learning and memory. While glutamate signaling is critical to neuronal function, excess glutamate can cause an influx of calcium through NMDA receptors, resulting in excitotoxicity, mitochondrial damage, and upregulation of pro-apoptotic genes. In injury or disease, such as ALS, Alzheimer's disease, and stroke, accumulation of extracellular glutamate results in neural damage and even cell death. *In vitro*, stimulators of glutamate receptors, such as glutamate and kainate, show a potent and rapid toxic effect on cortical and forebrain neurite outgrowth when neurons are cultured alone. However, *in vivo*, it has been suggested that glial cells, such as astrocytes, contribute significantly to overall neuronal health and survival. Here, we developed a quantitative, kinetic *in vitro* model of forebrain neurons with astrocytes to investigate neurotoxicity in a co-culture setting. The forebrain neurons are lentivirally infected to express a fluorescent protein and enable real-time neurite quantitation, using IncuCyte Zoom live-content imaging system. When placed in culture, the forebrain neurons extend neurites and form complex neural networks over the first seven days, after which the networks continue to develop and mature. In a monoculture setting, kainite produces a concentration- and time-dependent decrease in neurite length. However, in the presence of astrocytes, kainate treatment shows low toxicity compared to untreated cultures and can modestly stimulate neurite outgrowth at low kainite concentrations at early times *in vitro*. These *in vitro* findings agree with *in vivo* evidence suggesting that kainate-stimulated astrocytes secrete trophic factors such as BDNF and NGF. Interestingly, however, in the co-culture setting continued kainate treatment eventually results in a concentration-dependent toxicity causing neurite retraction. This neurotoxic effect may be due to maturation of the cultures, leading to the development of synaptic connections and the upregulation of glutamate receptors. Together, these data demonstrate the importance of the glial contribution to neuronal cell health and neuropharmacology in an *in vitro* co-culture setting.

Title: Glutamate toxicity changes expression profile of gangliosides in neurodegenerating rat primary cortical neurons

Authors: *D. PARK[1], G. A. LAJOIE[2], S. N. WHITEHEAD[1]
[1]Anat. and Cell Biol., [2]Biochem., Western Univ., London, ON, Canada

Abstract: Neurons within different brain regions have varying levels of vulnerability to external stress and therefore respond differently to injury. A potential reason to explain this may lie within a key lipid class of the cell's plasma membrane called gangliosides. These glycosphingolipid species have shown to play various roles in the maintenance of neuronal viability. The purpose of this study is to use electrospray ionization mass spectrometry (ESI-MS) technique and immunohistochemistry to evaluate the temporal and structural changes in the expression profiles of various ganglioside species during the course of neurodegeneration in rat primary cortical neurons exposed to glutamate toxicity. Primary embryonic (E18) rat cortical neurons were cultured to DIV14. Glutamate toxicity was induced for 1, 3, 6 and 24 hours and immunohistochemistry was used to stain for GM1 and GM3 species. ESI-MS was used to quantify the ganglioside species expressed within these injured neurons, which were compared to expression profiles of healthy neurons. Immunohistochemistry revealed that at early stages of glutamate toxicity, level of GM1 was highly expressed along the neuronal projection. At later time points, these levels decreased but still showed high expression relative to significant reduction in these projections. GM3 were undetectable in uninjured control neurons, but the

expression was initiated by 1 h and remained elevated throughout neurodegeneration. ESI-MS data shows abundant detection of GD1a and GT1a in healthy neurons. Other species such as GM1, GM2, and GM3 still remains to be quantified. These data suggests that different gangliosides play diverse roles in the process of neurodegeneration.

Title: Calpain 5 carries dual nuclear localization signals

Authors: *J. W. GEDDES[1], R. SINGH[2], M. K. BREWER[2], C. B. MASHBURN[2], D. LOU[2], V. BONDADA[2], B. GRAHAM[2]

Abstract: The calpain family of Ca^{2+}-dependent cysteine proteases has 15 members in mammals. Most investigations have focused on the classical calpains 1 and 2 which bind to a common small subunit through penta EF hand domains. Other ubiquitous calpains are also expressed in the CNS, although little is known regarding their localization and function. Calpain 5 (CAPN5) is a non-classical member of the calpain family. It lacks the EF hand motif characteristic of classical calpains but retains catalytic and Ca^{2+} binding domains, and contains a unique C-terminus domain. Tra-3, an ortholog of CAPN5, has been shown to be involved in necrotic cell death in *C. elegans*. CAPN5 is expressed throughout the CNS, but its expression relative to other calpains and subcellular distribution has not been investigated previously. Based on relative mRNA levels, Capn5 is the second most highly expressed calpain in the CNS, with Capn2 mRNA being most abundant. Unlike classical calpains which are cytosolic, CAPN5 is predominantly localized to the nucleus and was not detected in the cytosol. CAPN5 possesses

two nuclear localization signals (NLSs): an N-terminal monopartite NLS and a unique bipartite NLS closer to the C-terminus. The C-terminal NLS contains a SUMO-interacting motif that contributes to nuclear localization, and mutation or deletion of both NLSs renders CAPN5 exclusively cytosolic. Dual NLS motifs are common among transcription factors. Interestingly, CAPN5 is found in punctate domains associated with promyelocytic leukemia (PML) protein within the nucleus. PML nuclear bodies are implicated in transcriptional regulation, cell differentiation, cellular response to stress, viral defense, apoptosis, cell senescence, as well as protein sequestration, modification, and degradation. The roles of nuclear CAPN5 remain to be determined.

Title: Upregulation of the energy sensor AMPK inhibits mTOR function and promotes neuronal death in glaucoma

Authors: ***N. A. BELFORTE**, J. CUEVA VARGAS, A. DI POLO
Dept. of Neurosci., Univ. of Montreal Hosp. Res. Ctr., Montreal, QC, Canada

Abstract: Background: The AMP-activated protein kinase (AMPK) is an intracellular energy sensor within cells. AMPK is activated under conditions of energy stress when intracellular ATP levels decline and intracellular AMP increases, as occurs during nutrient deprivation and hypoxia. Activation of AMPK leads to the inhibition of mammalian target of rapamycin (mTOR), a key regulator of cell growth and protein synthesis. Our preliminary data show that mTOR activity in retinal ganglion cells (RGCs) is markedly reduced soon after acute optic nerve lesion. Mitochondrial dysfunction leading to ATP deficiency has been proposed to play a role in RGC death in glaucoma. Here, we investigated the role of the AMPK-mTOR axis in experimental glaucoma. Methods: Ocular hypertension was induced in C57BL/6 mice by injection of polystyrene magnetic microbeads (8×10^8 beads/ml) in the anterior chamber. AMPK

or mTOR activity in RGCs was assessed by retinal immunostaining using phospho-AMPK antibodies$^{(Thr172)}$ or phospho-S6 antibodies, respectively, in combination with RGC-specific markers. Inhibition of AMPK was achieved by intraperitoneal injection of the compound C, a cell-permeable and selective AMPK blocker, while mTOR was inhibited with rapamycin. RGC soma or axons were quantified by Brn3a immunostaining on flat-mounted retinas or using toluidine blue-stained optic nerve cross sections, respectively. Results: Our data show marked upregulation of AMPK activity that occurred concomitant with a decrease in mTOR function at one and two weeks after induction of ocular hypertension and prior to RGC death. Blockade of AMPK activity with compound C restored mTOR function and promoted robust RGC soma and axon survival. Administration of rapamycin inhibited the compound C-mediated neuroprotection suggesting that this response is mTORC1-dependent. Conclusion: Our study provides evidence that activation of the energy sensor AMPK contributes to RGC death in experimental glaucoma, suggesting that the AMPK-mTOR pathway plays a role in neuronal loss during metabolic stress.

Title: L-lactate as a neuroprotective agent against excitotoxicity: implication of an energy-dependent process

Authors: ***J. PASCAL**[1], I. ALLAMAN[1], P. MARQUET[2], P. J. MAGISTRETTI[3]
[1]EPFL, Lausanne, Switzerland; [2]Dept. of Psychiatry, Univ. Hosp. of Lausanne, Lausanne, Switzerland; [3]KAUST, Thuwal, Saudi Arabia

Abstract: The development of neuroprotective strategies is a key issue in translational neuroscience. In this context, several reports have described a neuroprotective action of L-lactate (Izumi *et al.*, 1994; Ros *et al.,* 2001; Berthet *et al.*, 2009, 2012). We have recently undertaken an in-depth investigation of the neuroprotective properties of L-lactate taking advantage of Digital Holographic Microscopy (DHM), a new imaging technique able to detect early signs (within minutes) of cell death in culture (Jourdain *et al.*, 2011; Pavillon *et al.*, 2012). In this study,

excitotoxicity-induced neuronal death in primary cultures of mouse cortical neurons was used as a model. In these experimental conditions early signs of neuronal death were observed in 65% of cells following application of glutamate (100 μM; 2min). This process is mediated by the activation of NMDA receptors since APV (50 μM) and L689.560 (10 μM), respectively an antagonist of NMDA receptor and a blocker of glycine site of NMDA receptors, significantly decreased the extent of cell death induced by glutamate (only 15% cell death under these conditions). When neurons were exposed to glutamate in the presence of 10 mM L-Lactate the percentage of neuronal death was significantly decreased to 28 % instead of 65%. The neuroprotective action of L-Lactate was mimicked by L-pyruvate (10 mM) but not by D-Lactate (10 mM), a non-metabolized enantiomer of L-lactate, suggesting that neuroprotection induced by L-lactate and L-pyruvate relies on increases in energy substrates availability. Consistently, in the presence of UK5099 (1 μM), a specific blocker of L-Lactate transport, L-lactate-mediated neuroprotection was fully prevented (63% cell death). Finally, we observed that in the presence of Xanthine Amine Congener (10 μM), a nonselective adenosine receptor antagonist, the neuroprotective effect of L-Lactate was abolished (58% cell death), strongly suggesting that the effect of L-Lactate involves activation of adenosine receptors, through mechanisms to be elucidated, stimulation of adenosine release being one possibility. As a whole these results demonstrate that L-lactate confers neuroprotection to excitotoxic insults through a mechanism relying on an increase neuronal energy substrates availability and activation of adenosine receptors.

Title: Effect of ATP7B knockdown on cellular morphology and viability in human neuroblastoma (SH-SY5Y) cells

Authors: *R. KUNJUNNI[1], M. K. SRIWASTVA[1], S. SATHIANATHAN[1], P. CHATTOPADHYAY[2], M. BEHARI[3], V. SUBBIAH[1]
[1]Neurobiochemistry, [2]Biochem., [3]Neurol., All India Inst. of Med. Sci., New Delhi, India

Abstract: BACKGROUND In human beings copper export is mediated by two copper transporting ATPases - ATP7A and ATP7B. The protein ATP7B is expressed in liver, brain, placenta and kidneys where it is localized at the trans-Golgi network and vesicles. Mutations in ATP7B causes hepato-lenticular degeneration or Wilson Disease (WD) which is characterized by copper accumulation mainly in liver and brain. Incidence of WD is reported between 1 in 5000 to 1 in 30,000 live births worldwide. The present study aims to reveal the changes in morphology and viability brought about by ATP7B silencing in SH-SY5Y cells. METHOD Cells were transfected with specific siRNA to silence the human ATP7B gene and its downregulation was confirmed by quantitative real-time PCR. These cells were studied by phase contrast microscopy for various morphological parameters and the results were statistically evaluated by Mann Whitney test. Cell viability was studied by MTT assay and the mitochondrial membrane potential ($\Delta\Psi m$) was assessed by fluorescence microscopy with JC-1 staining. RESULTS Knockdown of ATP7B resulted in significant decrease in mean area, length and perimeter ($P<0.05$), indicating a gross decrease in cell size. The increase in shape factor and circularity ($P<0.01$) indicates variation in cell morphology. When cells were silenced for ATP7B and then treated with copper; and in reverse order, the resultant cellular morphology was same. When cells were treated only with copper, there was no significant change in morphological parameters. The cell viability was decreased to 62.5% in ATP7B silenced cells ($P<0.05$). The mitochondrial membrane potential, $\Delta\Psi m$ also showed significant decrease on ATP7B silencing. CONCLUSION We observed significant changes in cellular morphology on silencing of copper transporter gene ATP7B and not on mere copper treatment. The mitochondrial membrane potential, $\Delta\Psi m$ and cell viability was decreased in ATP7B silenced cells indicating a destructive stress response. This might possibly be due to intracellular copper accumulation which may also be found in WD pathology.

Title: Expression and distribution of the scavenger receptor CD36 after Spinal Cord injury and its potential modulation by an O3PUFA and Vitamin E enriched diet

Authors: *K. CORDERO, J. D. FIGUEROA, M. DE LEÓN
Loma Linda Univ. Sch. of Med., Loma Linda, CA

Abstract: Spinal cord injury (SCI) remains a devastating cause of lifetime medical comorbidities in modern society. Spasticity and hyperreflexia are prevalent comorbidities observed in spinal cord injury and multiple sclerosis patients. Because the neuronal membrane lipid composition and metabolism are markedly altered during the first few days after injury, increasing attention is now being paid to understand lipid transport and metabolism under these conditions. Evidence supports that aberrant neural metabolism occur within the spinal monosynaptic H-reflex in animal models of spasticity. Although lipid trafficking and metabolism changes after SCI, the functional role for these perturbations has not been studied. Previous findings from our lab have shown that dietary omega-3 polyunsaturated fatty acids (O3PUFAs) confer strong prophylaxis against SCI morbidities.There is inadequate understanding on the molecular mechanisms involved in their transport and metabolism after SCI. The fatty acid translocase membrane cluster of differentiation 36 (FAT/CD36) is a B class scavenger receptor, which has been implicated in the uptake and signaling of hydrophobic molecules. FAT/CD36 in humans has multiple polymorphisms associated with the risk of metabolic dysfunction and stroke. The purpose of this study was to 1) investigate the expression and roles of CD36 in the context of SCI and dietary O3PUFAs and Vitamin E; 2) Determine protective roles of hydrophobic molecules (O3PUFAs and Vitamin E) after SCI. We hypothesized that trauma to the spinal cord will result in a reduction in the protein levels of this protein. Further, we proposed that dietary O3PUFAs and Vitamin E may regulate the expression of CD36 after SCI. Here we determined the protein expression of CD36 after SCI and expanded the knowledge of a potential protective diet enriched with Vitamin E in addition to O3PUFAs. In particular, we analyzed locomotion recovery, H-reflex depression, bladder recovery, and the temporo-spatial expression of CD36 after SCI using behavioral and electrophysiogical studies, Credé's maneuver, immunoblotting and double-labeling immunofluorescent experiments respectively. Our data demonstrates that Vitamin E and O3PUFAs accelerate locomotor and bladder recovery, improves H-reflex depression, and that acute SCI results in a marked downregulation of CD36. This protein was predominantly observed in both neuronal and glial cells. Our next step is to determine if dietary lipids may be implicated in the regulation of this important protein. This protein may represent an important therapeutic target to reduce the burden of SCI in humans.

Title: The Cdk5 modulator TFP5 displays anti-inflammatory and anti-oxidative actions in neurons

Authors: *J. P. STEINER[1], M. BACHANI[1], K. MATHER[1], E. FENNELL[1], N. CHESTER[1], A. POPESCU[2], V. SHUKLA[3], N. AMIN[3], B. BALACHANDRANKRISHNAMMA[3], H. C. PANT[3]
[1]NINDS Translational Neurosci. Ctr., [2]Section of Infections of the Nervous Syst., [3]Lab. of Neuronal cytoskeletal Protein Regulation, Natl. Inst. of Health/NINDS, Bethesda, MD

Abstract: Alzheimers Disease brains have increased activity of cyclin-dependent kinase 5 (Cdk5) and higher levels of p25, an abnormal activator derived as a truncated form of the normal p35 activator. Recently, we have found that the Cdk5 modulator TFP5 is able to selectively reduce the p25-induced hyperphosporylation of tau and neurofilament (NF H/M) and avert the biochemical, neuropathological and behavioral deficits *in vivo* in 5XFAD mice (Shukla et al *FASEB J. 27:* 174-186, 2013). In order to address the molecular mechanisms of the TFP5, we explored the effects of neuroinflammation and oxidative stress in addition to beta amyloid on rat and human neurons in culture. We found that TFP5 not only protected neurons and promoted survival from Ab_{1-40} neurotoxicity, but also prevented decreases in neurite length, cross sectional area and neuritic caliber to their media control levels. TFP5 was also effective against LPS-mediated inflammatory lesions to the neurons, blocking decreases in neurite length and increased axonal fragmentation. Effects of TFP5 on inflammatory cytokine levels in these cultures are being evaluated. TPF5 also prevented neuronal damage from oxidative stress injury in a concentration dependent manner, with an EC_{50} of 10 nM. Thus, TFP5 not only provides neuroprotective actions to these neurons, but also an anti-inflammatory action as well. Targeting multiple facets of the neurodegenerative process may help underlay the robust effects of TFP5 observed in multiple neurodegenerative disease models.

Title: Tumor Necrosis Factor Related Apoptosis Inducing Ligand reduces the expression of the neuroprotective Na+/Ca2+ exchanger isoform 3 in human neuronal cells *in vitro*

Authors: O. VALERIO[1,2], G. DI BENEDETTO[2,3], G. CANTARELLA[2], V. LARICCIA[1], S. AMOROSO[1], *R. BERNARDINI[2]
[1]Biomed Sci. & Publ. Hlth., Univ. Politecnica Marche, Ancona, Italy; [2]Clin. and Mol. Biomedicine, Univ. Catania Sch. of Med., Catania, Italy; [3]Li-Sa Lab, dept Exp Med, Med. Physiopathol Endocrinol Nutr, Univ. of Roma "La Sapienza", Roma, Italy

Abstract: Tumor Necrosis Factor Related Apoptosis Inducing Ligand (TRAIL) is a pro-apoptotic cytokine belonging to the tumour necrosis factor/nerve growth factor (TNF/NGF) superfamily. The protein Na+/Ca2+ exchanger isoform 3 (NCX3) protects neurons from damage and death following ischemic injury and plays important roles in regulating intracellular calcium. Following aberrant proteolytic cleavage of NCX3, such as for example, by calpain, neuroprotective function of the former is significantly reduced. NCX3 expression may be induced by nerve growth factor (NGF), a neurotrophin which binds the tyrosine kinase receptor TrkA and activates downstream kinases, such as Erk1/2, and the survival-related kinase Akt. Here, we verified the hypothesis that TRAIL can influence the expression of NCX3 via modulation of the NGF/TrkA system. Retinoic acid-differentiated human neuroblastoma SH-SY5Y cells were incubated 48 h with appropriate concentrations of TRAIL. NCX3 protein expression was then studied in SH-SY5Y cell lysates by means of Western blot analysis after 6, 16, 24 and 48 h of incubation. NCX3 expression decreased in a time-dependent fashion in the presence of TRAIL. Moreover, protein analysis of the phosphorylated forms of TrkA, Erk1/2 and Akt, performed at the same time intervals, revealed that p-TrkA expression was initially increased in SH-SY5Y cells treated with TRAIL after 6 and 16h, whilst it declined thereafter, until it almost disappeared after 48h. A similar pattern was observed for both p-Erk1/2 and p-Akt. Results indicate that the documented increase of TRAIL expression occurring during neuronal damage parallels with down-regulation of NGF-related kinases and substantial attenuation of NCX3 expression. As a result, neuroprotective properties of NCX3 are

significantly reduced. The TRAIL system could thus represent a potential target for treatment of neural damage related to down regulation of NCX3.

Title: Ligand binding to the GluN2B subunit is required for NMDA-induced superoxide production independent of ion flux

Authors: ***A. M. BRENNAN**[1], J. A. GRAY[2], X. JIANG[3], R. A. SWANSON[1]
[1]UCSF, VA Med. Ctr., SAN FRANCISCO, CA; [2]Neurol., UC Davis, Ctr. for Neurosci., Davis, CA; [3]Pediatrics, UCSF, San Francisco, CA

Abstract: Emerging evidence suggests that NMDA receptor dependent signaling may not simply be a product of ion flux, but involves conformational changes in receptor subunits following ligand binding. Sustained activation of NMDA receptors leads to excitotoxic cell death in stroke, trauma, and neurodegenerative disorders. These effects are, in part, attributable to superoxide produced by the enzyme NADPH oxidase (NOX2). We report here that NMDA receptor dependent activation of NOX2 requires two independent events; (1) ligand binding to the NR2B subunits of NMDA receptors and (2) increased intracellular calcium. We find that increasing intracellular calcium with ionomycin to similar levels as following NMDA application is not sufficient to induce superoxide production in neurons. However, significant increases in superoxide were detectable following ionomycin application when neurons were co-treated with NMDA in the presence of the NMDA receptor glycine site antagonist 7-Chlorokynurenic acid to prevent channel opening. Treatment with NMDA, ionomycin, and the NMDA receptor glutamate site antagonist AP5 showed no increase in superoxide or cell death. Additional studies using genomic and mutational approaches demonstrated that the c-terminus of NR2B, but not NR2A, is required for NMDA induced NOX2 superoxide production. Taken together our work suggests that NMDA receptor activation of NOX2 superoxide production is

not simply an effect of NMDA-induced changes in intracellular calcium, but also requires agonist binding to the NR2B-subunit.

Title: Investigation on the role of the BH3-only protein Bid in promoting excitotoxic neuronal injury

Authors: ***B. D'ORSI**, H. P. BONNER, H.-G. KÖNIG, J. H. M. PREHN
Physiol. and Med. Physics, Royal Col. of Surgeons In Ireland, Dublin, Ireland

Abstract: Excessive Ca^{2+} entry though NMDA receptors (excitotoxicity) has been implicated in several neurological disorders, including Ischemic Stroke, Epilepsy, Alzheimer's disease and amyotrophic lateral sclerosis. Bid is a pro-apoptotic BH3-only member of the Bcl-2 family of proteins which has been implicated in promoting the mitochondrial apoptosis pathway. Studies in excitotoxic-injury models have shown that following increased Ca^{2+} levels in the cytosol, Bid translocates to the mitochondrial membrane triggering mitochondrial outer membrane permeabilization (MOMP) and the release of apoptogenic intermembrane space proteins. In this study, we investigated the role of Bid in mediating neuronal death using combined models of excitotoxic/Ischemic injury, in mouse neocortical neurons *in vitro* and cerebral ischemic injury *in vivo*. *Bid*-deficient and WT cortical neurons were similarly sensitive to NMDA-induced excitotoxic tolerance and apoptosis, however, our data also suggested that Bid may actually play a critical role in contributing to excitotoxic injury under conditions that are associated with immediated calcium deregulation (ICD) and excitotoxic necrosis. Furthermore, detailed analysis of intracellular neuronal Ca^{2+} dynamics, using time-lapse confocal microscopy, revealed that neurons deficient in *bid* showed markedly reduced Ca^{2+} levels during the NMDA excitation period. Surprisingly, we also observed similar infarct size after middle cerebral artery occlusion in *bid*-deficient and WT mice *in vivo*. However, we here show that deficiency in *bid* exerted neuroprotection in cultured neurons when exposed to oxygen/glucose deprivation (OGD). In

conclusion, our data suggest that Bid may rather play a role in excitotoxicity in pathways associated with necrotic cell death and that the proposed role of Bid as a crucial mediator of cell death after focal cerebral ischemia may be need to be reconsidered.

Title: The inactivation of M current is the link between acetylcholinesterase inhibition by diisopropylfluorophosphate and excitotoxicity

Authors: *P. FERCHMIN, D. PEREZ, V. A. ETEROVIC
Biochem., Univ. Central Del Caribe, Bayamon, PR

Abstract: Poisoning with organophosphorous inhibitors of acetylcholine esterase (AChE) causes an accumulation of acetylcholine and overstimulation of the muscarinic receptors. The supraphysiological muscarinic activity causes glutamatergic seizures and excitotoxicity responsible of the majority of the brain injury caused by organophosphates. Current literature suggests that the activation of muscarinic M1 receptors coupled to Gq protein activates phospholipase C (PLC), which depletes the pool of membrane phosphatidylinositol 4,5-bisphosphate required for the activity of the Kv7.2-7.5 channels. Kv7.2-7.5 (KCNQ2-5) voltage gated potassium channels mediate the hyperpolarizing M-current. Decreased activity of these channels leads to neuronal membrane depolarization that result in glutamate release and excitotoxicity. Here we test the hypothesis that preserving or reactivating the activity of M currents prevents the excitotoxic neuronal injury. We used *ex vivo* acute hippocampal slices to measure excitotoxic damage and neuroprotection. The excitotoxic effect of diisopropylfluorophosphate was measured as the decrease of population spikes, and neuroprotection was assessed as preservation or recovery of population spikes. This parameter is appropriate for measuring early neurotoxicity and neuroprotection because it is proportional to the number of functionally active pyramidal neurons. This method was validated by us and other investigators. Using pharmacological tools, we explored the pathway between DFP inhibition of

AChE and neural damage. Atropine and the more selective M1 antagonists, pirenzepine, prevented the neurotoxic effect of DFP. Two inhibitors of PLC, which prevent the depletion of membrane phosphatidylinositol 4,5-bisphosphate abolished the effect of DFP. Retigabine and flupirtine, positive modulators of Kv7.2-7.5 (KCNQ2-5) channels, were also effective in preventing the noxious effect of DFP. The evidence that excitotoxicity was the final neurotoxic effect of DFP was shown by the neuroprotective efficacy of APV a reversible antagonist of the NMDA receptor. In conclusion, we hypothesize that DFP and most likely, other irreversible inhibitors of AChE cause neural damage by an overstimulation of muscarinic receptors, which activate PLC. PLC depletes membrane phosphatidylinositols leading to inhibition of the M current. The resulting depolarization is followed by glutamate release and excitotoxicity. Therefore, most of the neurotoxic effect of irreversible inhibitors of AChE can be prevented by preservation of the M currents.

Title: Developing a model of spreading neurotoxicity

Authors: *A. J. SAMSON, C. N. CONNOLLY
Univ. of Dundee, Dundee, United Kingdom

Abstract: The spreading progressive deterioration of the penumbra that surrounds a brain lesion is a major therapeutic target for the treatment of stroke and head injury. However, the mechanism(s) by which this spreading toxicity occurs is unknown. A major contributor to spreading toxicity is thought to be glutamate excitotoxicity. This is based on the fact that increased levels of local glutamate are released from dying cells (Rossi, et al 2000). Unfortunately, neuronal cell death is enhanced by use of NMDA receptor antagonists. This is thought to reflect a requirement for basal NMDA receptor synaptic activity in pro-survival signalling (Hardingham et al 2002, Hardingham & Bading 2003, Soriano et al 2006). Our lab has developed and characterised a novel primary rat neuronal culture model of spreading toxicity, and investigating morphological (synapse loss, dendritic beading and mitochondrial collapse) and functional (mitochondrial depolarisation, Na+/K+ -ATPase dysfunction and a block in

neurotransmitter release) events following a neuronal insult, the role these early neuronal events play in neuronal survival, both locally within the site of insult, and their consequences to neurons at a distance. Understanding the mechanisms of spreading penumbral toxicity will provide novel approaches to limit the effects of brain injury.

Abstract: Inhibition of proteasome activity and the resulting protein accumulation are known to be important events in the development of many neurological disorders, including Alzheimer's and Parkinson's diseases. In the present study, we demonstrate that pretreatment with all-trans-retinoic acid (RA) and basic fibroblast growth factor (bFGF) protects human neuroblastoma SH-SY5Y cells from programmed cell death caused by the proteasome inhibitor MG132, which initiates apoptotic pathways through the accumulation of ubiquitinated proteins. Since ubiquitinated protein aggregates appear in both unprotected and protected cells after MG132 insult, we sought to determine how RA and bFGF are able to slow or prevent the toxic effects of protein accumulation. In unprotected cells, MG132 treatment activates stress pathways, identified as increased levels of P53, phosphorylation of JNK, and a reduction in β-catenin expression. This results in cell death, which is preceded by cytoskeletal damage and by the appearance of apoptotic markers, including an increase in PARP cleavage, cytochrome c release from mitochondria, and a decrease in caspase-3 activity. Co-Treatment with RA and bFGF

markedly reduces PARP and caspase 3 cleavages, the expression of P53, and JNK phosphorylation, and the protected cells have normal β-catenin levels. We conclude that growth factors and other neuroprotectants, used in combination, could enhance neuron protections from toxic insults encountered in the microenvironment of the aging brain. In turn, this approach could replace or augment the efficacy of current therapies under study for the treatment of Parkinson's and Alzheimer's disease.

Abstract: Glutamate excitotoxicity is a common cause of neuronal injury and apoptosis. At present, there are no pharmacological treatments to ameliorate glutamate excitotoxicity and provide neuroprotection for the related neuronal injury. Sartans (Angiotensin II AT1 Receptor Blockers, ARBs), which is a class of compounds commonly used for the treatment of cardiovascular and metabolic disorders, is one of such emerging therapeutic targets. They are

powerful neuroprotective agents *in vivo* and protect against IL-1β neurotoxicity *in vitro*. The purpose of our research was to determine the extent of sartans neuroprotection against glutamate excitotoxicity. LDH release assay, TUNEL staining and DNA fragmentation assay results show that sartans significantly reduces glutamate-induced neuronal injury and apoptosis in cultured rat primary cerebellar granule cells (CGCs). Telmisartan was the most potent sartan studied, with an order of potency telmisartan > candesartan > losartan > valsartan. Mechanisms were further studied. Reduction of pro-apoptotic caspase-3 activation, protection of the survival PI3K/Akt/GSK-3β pathway, and prevention of glutamate-induced ERK1/2 activation were involved. Participation of AT1A receptor was supported by glutamate-induced upregulation of AT1A gene expression and AT1 receptor binding. However, glutamate-induced neuronal injury and the neuroprotective effect of telmisartan were not abolished in CGCs obtained from AT1A knock-out mice. This indicates that part of the neuroprotective effect of telmisartan is independent of AT1 receptor blockade. Since PPARγ activation was reported as a pharmacological profile of telmisartan, we also determined if it was involved in the neuroprotective effects of telmisartan. PPARγ nuclear translocation was enhanced by telmisartan and the PPARγ antagonist GW9662 partially reversed the neuroprotective effects of telmisartan. The present results substantiate the therapeutic use of sartans, in particular telmisartan, in neurodegenerative diseases and traumatic brain disorders where glutamate neurotoxicity plays a significant role.

Title: Chemokine CXCL12 increases CaMKII synaptic localization and glutamate-induced cell death

Authors: R. M. BRAGG, III, *J. K. ROSE
Psychology, Western Washington Univ., BELLINGHAM, WA

Abstract: Cerebral ischemia is known to induce cell death through hypoxia and oxidative stress following reperfusion. However, cell death can spread beyond the ischemic core when toxic

glutamate levels act on NMDA receptors of surrounding regions. Levels of CXCL12, a chemokine primarily released from glia, reportedly elevate following ischemia. Acute activation of its receptor, CXCR4, appears to serve a neuroprotective function while prolonged activation results in cell death and this cell death was reported to be dependent on the combined release of calcium from intracellular stores as well as calcium influx through NMDARs (Shepherd et al. 2012). Calcium influx through NMDA receptor channels leads to activation of CaMKII, and it has also been shown that intracellular calcium can be sufficient to activate CaMKII (McCord et al., 2013). Thus, it is of interest to determine if cell death following CXCL12 application is mediated by CaMKII; and further, if exposure to CXCL12 primes neurons for glutamate-induced toxicity thus increasing cell death. In the present study, it was confirmed that acute (30 min) delivery of CXCL12 is not detrimental, as uptake of a cell death indictor dye was not different from controls ($p > 0.01$), while sustained activation (3 hr) resulted in a significant increase in cell death compared to controls ($p < 0.01$). In addition, both acute and sustained CXCL12 induced translocation of CaMKII to synapses, measured as an increase in colocalization with PSD-95 ($p < 0.001$ and $p < 0.01$). Exposure to a strong excitatory stimulus (500 μM glutamate + 10 μM glycine) following either acute or sustained CXCL12 application appeared to elevate susceptibility to glutamate-induced cell death ($p < 0.001$). Interestingly, pre-exposure to CXCL12 also induced cell death following delivery of a more physiologically relevant concentration of glutamate (100 μM glu + 10 μM gly) ($p < 0.001$). Peptide inhibitors that act to block CaM or ATP binding to CaMKII both appeared to reduce CXCL12-induced increases in cell death. These results suggest that both acute and sustained CXCR4 activation increase neuron susceptibility to excitotoxicity and this priming is at least partially mediated by CaMKII.

Title: Evaluation of neurobehavioral and genotoxic parameters in rats treated with vigabatrin

Authors: *J. N. PICADA, SR[1], K. SOUSA[1], T. PIRES[1], M. AMBROZIO[1], C. VIEIRA[2], L. SOUZA[2], R. ANTUNES[2], V. COELHO[2], M. LEAL[2], P. PEREIRA[2]
[1]Lab. of Toxicological Genet., Lutheran Univ. of Brazil, Canoas, Brazil; [2]Federal Univ. of Rio Grande do Sul, Porto Alegre, Brazil

Abstract: Vigabatrin (VGB) is an Antiepileptic Drug used to treat Infantile Spasms and Refractory Epilepsy. This drug is able to increase brain GABA levels through irreversible inhibition of GABA-transaminase, the GABA catabolic enzyme. Vigabatrin also may produce an increase in GABA concentration, by inhibiting the glial uptake or stimulating its release. Currently, the benefits of VGB use may outweigh the risks in some conditions; however, previous studies have shown that VGB may be neurotoxic and should be used with caution. The aim of this study was to evaluate neurotoxicological effects of VGB measuring motor activity and genotoxic and mutagenic effects. Methods: Male Wistar rats were divided into 4 groups and given saline, VGB 50 mg/kg, 100 mg/kg or 250 mg/kg by gavage in both acute and sub-chronic treatments and evaluated in rotarod. For acute treatments, the administrations were conduced 24 h after the initial training and the latency to fall from the rotarod (one of maximum 60 sec) was determined 30, 60, 90, 120 min after administrations. For the sub-chronic treatments, animals received one administration a day during 14 days. Twenty four hours after the last administration, the animals were tested in the rotarod and the latency to fall from the apparatus (one of maximum 60 sec) was determined. The genotoxicity was evaluated using the alkaline version of comet assay in samples of blood, liver, hippocampus, and brain cortex. The mutagenicity was evaluated by micronucleus test in bone marrow of the same animals used in the sub-chronic treatment. Results: The groups treated with VGB showed similar performance in rotarod in comparison to saline group. Regarding the acute treatment, it was observed that VGB was able to induce DNA damage in blood and hippocampus only in higher doses. However, in the sub-chronic treatment, VGB did not show genotoxic or mutagenic effects. Conclusions: VGB did not impair motor activities in rats after acute and sub-chronic treatments. It showed a repairable genotoxic potential on central nervous system, since the genotoxicity was observed in the acute treatment.

Title: Functional alterations of motor cortical circuits in Arginase I knockout mice

Authors: *G. CANTERO[1], C. HU[1], M. T. LAZARO[2], P. GOLSHANI[3], G. S. LIPSHUTZ[4]
[1]Dept. of Surgery, [2]Neurol., David Geffen Sch. of Medicine, UCLA, Los Angeles, CA; [3]Neurol., David Geffen Sch. of Medicine, UCLA. West Los Angeles VA Med. Ctr., Los Angeles, CA; [4]Dept. of Surgery, Medicine, Psychiatry, David Geffen Sch. of Medicine, Semel Inst. for Neurosci. and IDDRC at UCLA, Los Angeles, CA

Abstract: Complete arginase I deficiency is the least severe urea cycle disorder, characterized by hyperargininemia and episodic hyperammonemia. Patients suffer from neurological impairment with cortical (Oldham, MS. et al., 2010) and pyramidal tract deterioration, spasticity, loss of ambulation, seizures, and intellectual disability (Prasad AN. et al., 1997). These neurologic abnormalities may arise from the accumulation of arginine and its metabolites or may result from hyperargininemia, and the resultant increase of several neurotoxic guanidino compounds. In a mouse model of the disorder, onset is heralded by weight loss beginning around postnatal day 15; gait instability soon follows, progressing to inability to stand and development of tail tremor with seizure-like activity and death. Previous results from our lab demonstrated that AAV-based therapy for hyperargininemia is effective and prevents development of neurological abnormalities and cognitive dysfunction in a mouse model of hyperargininemia (Lee EK. et al., 2013). Yet the mechanisms underlying neurological dysfunction caused by arginase deficiency is not understood. This level of understanding will be essential for development of other therapeutic strategies. To determine whether arginase deficiency alters the intrinsic excitability of cortical circuits, we performed whole-cell recordings from L5 excitatory neurons in slices of primary motor cortex of arginase I knock-out mice at postnatal day 13-16. We found strikingly decreased intrinsic excitability of regular spiking neurons, with fewer action potentials elicited at each current step injected. Moreover, we found that both rising and repolarization phases of action potentials are slower in knockout mice. The other measured parameters as resting membrane potential, threshold, input resistance, membrane time constant and capacitance were not altered. These results suggest that arginase I knockout mice display functional property deficits. Future studies will address whether synaptic function is also altered and whether these deficits can be rescued by gene therapeutic strategies.

Title: Sensitivity, specificity and limitation of *in vitro* rodent hippocampal brain slice assay for assessment of drug-induced seizure liability

Authors: *J. ZHAI[1], Y.-Y. ZHOU[2], H. ZENG[2], A. LAGRUTTA[2], F. SANNAJUST[2]
[1]Dept. of Safety & Exploratory Pharmacology, SALAR Division, Merck Res. Lab., [2]Dept. of Safety & Exploratory Pharmacology, SALAR Division, Merck Res. Labs, Merck & Co., West Point, PA

Abstract: Drug-induced seizures are common adverse drug reactions that can result in the failure of drugs to be licensed for clinical use. An effective screen to detect seizure liability in preclinical development can contribute to better lead molecule optimization prior to candidate selection. Compared to conventional *in vivo* experimental animal models the *in vitro* rat brain slice assay can provide a higher throughput, and overcome *in vivo* exposure margin limitations. However, it remains uncertain how well an *in vitro* brain slice can recapitulate the complex process of seizure generation *in vivo*. We examined the effects of 27 reference pharmacological agents (including GABA, glutamate, M_3, D_2 and adenosine receptor ligands, K-channel blockers, β-lactam antibiotic and acetylcholinesterase inhibitor) acting through different mechanisms on a conventional electrophysiological rat hippocampal brain slice assay, to define its sensitivity, specificity, and potential limitations. Population spikes (PS) were evoked at 30 s intervals by electrical stimulation of the Schaffer collateral synaptic pathway and recorded using extracellular electrodes positioned in the cell body layer of CA1 pyramidal neurons from adult Wistar and Sprague-Dawley rats. Most positive reference agents elicited concentration-dependent increase in PS area and/or PS number, indicating a sensitivity of 88% (15 out of 17 agents). The responses to 4 ionotropic glutamate receptor agonists differed markedly: AMPA, CX546 (Ampakine), and kainic acid (KA) enhanced PS area and/or PS number, but KA (at higher concentration) and NMDA induced a reversible reduction or abolishment of PS area and/or PS number. Interestingly, NMDA increased PS area and/or PS number only under modification of ACSF composition (i.e. Mg^{2+}, Ca^{2+}, and glycine level). Among 3 groups of metabotropic glutamate receptor (mGluR) ligands, only DHPG (group I mGluR agonist) and MSOP (group III mGluR antagonist), but not LY341495 (group II mGluR antagonist), induced seizure-like activities consistent with *in vivo* EEG data. All 10 negative reference agents tested had little

effect on PS area and PS number, showing a 100% specificity of the assay to date. Overall, our study demonstrated that the rat brain slice assay can provide a good (93%) predictivity. The main limitation (false negative) could be related to the potential low expression of specific receptors or co-factors within the neuronal pathway(s). This *in vitro* hippocampal rat brain slice model is therefore of potential value to detect seizure liability at preclinical development stage(s) with a higher throughput, lower compound and animal usage than existing *in vivo* models.

Title: Nmda receptor- and mitochondria-dependent neurotoxicity of berberine

Authors: *K. KYSENIUS, C. A. BRUNELLO, H. J. HUTTUNEN
Univ. of Helsinki - Neurosci. Ctr., Helsinki, Finland

Abstract: The global incidence of metabolic and age-related diseases, including type 2 diabetes and Alzheimer's disease, is on the rise. In addition to traditional pharmacotherapy, drug candidates from complementary and alternative medicine are actively pursued for further drug development. Berberine, a nutraceutical traditionally used in Chinese and Ayurvedic medicine as an antibiotic, has recently been proposed to act as a multi-target protective agent against type 2 diabetes, dyslipidemias, ischemic brain injury and neurodegenerative diseases, such as Parkinson's and Alzheimer's disease. However, the safety profile of berberine remains

controversial, as isolated reports suggest risks with acute toxicity, bradycardia and exacerbation of neurodegeneration. We report that low micromolar concentrations of berberine cause rapid mitochondria-dependent toxicity in primary cultures of murine cerebellar granule neurons and rat hippocampal neurons, characterized by mitochondrial swelling and depletion of ATP content. Berberine induced cell death remained insensitive to pan-caspase inhibitor z-VAD-FMK treatment. However, inhibition of NMDA receptors by memantine and MK-801 were able to completely block berberine-induced neurotoxicity, indicating an excitotoxic cell death mechanism. The mitochondrial permeability transition pore inhibitor cyclosporine A could also partially protect neurons from berberine toxicity. Additionally, subtoxic nanomolar concentrations of berberine were sufficient to sensitize neurons to secondary insults by glutamate and rotenone. Our results indicate mitochondrial function and NMDA receptors as the central adverse targets of berberine in neurons. Our study highlights the need for thorough safety assessment, especially with the chronic use of berberine, due to its tendency to accumulate in the CNS and the potential risk of neurotoxicity as a consequence of increased bioavailability of berberine pro-drugs.

Title: Heterogeneous nuclear ribonucleoprotein a1 as a target disease-associated protein in progressive multiple sclerosis

Authors: ***S. LEE**[1,2], Y. SHIN[1,2], M. C. LEVIN[1,2]
[1]Univ. of Tennessee, Memphis, TN; [2]Veterans Affairs Med. Ctr., Memphis, TN

Abstract: Deficiency in repair of nuclear and mitochondrial DNA damage has been linked to several neurodegenerative disorders. Many recent experimental results indicate that the post-mitotic neurons are particularly prone to accumulation of unrepaired DNA lesions potentially leading to progressive neurodegeneration. Recently our observations in progressive multiple sclerosis (MS) patient's peripheral blood mononuclear cell (PBMC) and brain suggest that the

accumulation of point mutations (N265D, F273L, P275S, K277N, F281L, R284G and S285G) in the nuclear localization sequence (NLS) region (transportin 1 binding site) of heterogeneous nuclear ribonucleoprotein A1 (hnRNP A1) may be important in progressive MS pathology. Mutations in genetic coding for stress granule-associated hnRNP A1 lead to enhanced stress granule formation, which accelerates the pathophysiology of protein aggregation in neurodegenerative diseases. Thus, dysregulated aggregation caused by a potent mutant in RNA binding proteins might initiate progressive MS. We propose that two pathological hits, namely nuclear import defects and cellular stress, are involved in the pathogenesis of hnRNP A1 mutations in neurodegenerative disease like progressive MS. Furthermore, increased proteolytic activity is a hallmark of several pathological processes, including neurodegeneration. Increased expression and activity of cathepsins and caspases, during degeneration of the central nervous system is frequently reported. We found that the addition of apoptosis-inducing agent (camptothecin) or transcription inhibition agent (actinomycin D) to cells results in the cleavage of hnRNP A1 isoforms by cathepsin S and caspase-3. In addition, proteolytic degradation of hnRNP A1 in the experimental allergic encephalomyelitis (EAE) MS model was confirmed. This cleavage of hnRNP A1 separated the N-terminal region, containing RRM1-RRM2-RGG box, from the C-terminal region, containing the NLS. Our data indicate that there are two cathepsin S target sites and one caspase-3 target site in hnRNP A1 isoforms, namely LFIG19↓GLSF, SNFG255↓GGGS and SYND261↓FGNY. The N-terminal hnRNP A1 fragments localized to the cytoplasm, as opposed to the nucleus where most C-terminal hnRNP A1 fragments were found. Moreover, these C-terminal hnRNP A1 fragments showed toxicity effects on neuronal cell lines. Taken together, these data suggest an important role of hnRNP A1 in the damage and degeneration of neurons in progressive MS.

Title: Caramiphen as adjunct to standard treatment suppresses GD-induced status epilepticus, attenuates neuropathology, and prevents cognitive deficits in rats

Authors: *M. K. SCHULTZ[1], L. K. M. WRIGHT[1], M. DE ARAUJO FURTADO[2], S. H. ROBERTSON[1], M. F. STONE[1], M. C. MOFFETT[1], A. R. BOURNE[1], C. R. SCHULTZ[1], J. E. SCHWARTZ[1], L. A. LUMLEY[1]

Abstract: The progression of epileptiform activity following soman (GD) exposure is characterized by a period of excessive cholinergic activity followed by excessive glutamatergic activity resulting in status epilepticus (SE), which may lead to neuropathological damage and behavioral deficits. Caramiphen edisylate is an anticholinergic drug with antiglutamatergic properties, which conceptually may be a beneficial therapeutic approach to the treatment of nerve agent exposure. In the present study, rats were exposed to 1.2 LD50 GD or saline, treated with atropine sulfate (2 mg/kg, im) and HI-6 (93.6 mg/kg, im) 1 min after GD exposure, and monitored for seizure activity. Rats were treated with diazepam (10 mg/kg, sc) and caramiphen (0, 20 or 100 mg/kg, im) 30 min after seizure onset. Following GD exposure, rats received a series of behavioral tests to assess cognitive and motor capabilities. Caramiphen treatment reduced GD-induced deficits in locomotor and rearing activity in the open field, spatial memory in the Morris water maze, associative learning in the fear conditioning test, and efficiency in the differential reinforcement of low rate operant conditioning schedule, but did not prevent GD-induced increase in acoustic startle response and decrease in prepulse inhibition. In addition, caramiphen in combination with diazepam reduced seizure activity and dose-dependently reduced GD-induced neuronal fiber degeneration and neuronal loss. These findings show that physiological, behavioral, and neuropathological effects of GD exposure can be attenuated by treatment with caramiphen as an adjunct therapy, even if administration is delayed to 30 min after seizure onset. This research was supported by the Defense Threat Reduction Agency-Joint Science and Technology Office, Medical S&T Division & Physical Science Division.

Title: Validating protein-protein interactions and disruptions using AlphaScreen methodology

Authors: *W.-H. LEE[1], Y. LAI[2], A. HOHMANN[2,1,3]
[1]Interdisciplinary Biochem. Grad. Program, [2]Psychological and Brain Sci., [3]Gill Ctr. for Biomolecular Sci., Indiana Univ., Bloomington, IN

Abstract: **Background:** Activation of NMDA receptors and the neuronal nitric oxide (nNOS) signaling cascade requires the binding between nNOS and the scaffold protein postsynaptic density 95 kDA (PSD95), which tethers nNOS to the NMDAR signaling complex. This cascade plays a critical role in neuronal excitotoxicity and pathological disorders of the nervous system. The PDZ2 domain of PSD95 interacts with the β-finger of nNOS, coupling NO production and p38 activation to NMDAR activity. Due to the physiological importance of this interaction, *in vitro* approaches to quantify protein-protein interactions and measure their disruption need to be developed and validated. **Objective:** We developed a protein-protein interaction bead-based assay using AlphaScreen (Perkin Elmer) methodology to validate known protein-protein interactions between nNOS and PSD95. We also used this assay to characterize putative nNOS-PSD95 protein-protein interaction disruptors such as the natural product honokiol. **Methods:** AlphaScreen involves phthalocyanine-containing donor beads and thioxene derivatives-containing acceptor beads. When excited by 680nm light, the donor bead will convert ambient oxygen into singlet oxygen. The singlet oxygen will be accepted by the acceptor beads when the beads are within 200 nm range. The singlet oxygen activated beads emit light at 520-620nm that can be detected by the Enspire instrument. We used glutathione-coated donor beads and Ni-chelate coated acceptor beads to recognize GST-tagged and His-tagged protein, respectively. The derived 50% binding was used to determine the concentrations of the protein to be used in the latter disruption assay. Here, we used the PSD95 constructs containing PDZ1-3 and nNOS constructs containing PDZ and β-finger in the interaction and disruption assay. Titrations of GST-PSD95 and His-nNOS were performed to determine 50% binding. Next, we used a non-tagged protein construct in a competition assay and compared it with honokiol, a natural product recently postulated to serve as a PSD95-nNOS inhibitor based upon co-immunoprecipitation studies. **Results:** The 50% binding between GST-PSD95 and His-nNOS determined by AlphaScreen was in the10-30 nM range. Moreover, PSD95/nNOS was disrupted by a known plant derivative, honokiol. **Conclusion:** AlphaScreen is a reliable technology for assaying disruption of protein-protein interactions. **Support:** DA037673.

Title: Neurodevelopment, mitochondrial dynamics, autophagy and huntingtin aggregation differ in cortical vs. striatal neurons: Effects of HDAC6 inhibition

Authors: P. GUEDES-DIAS[1,2,3], M. R. DUCHEN[2], *J. M. OLIVEIRA[1,3]
[1]Univ. of Porto - Fac. of Pharm., Porto, Portugal; [2]Cell and Developmental Biol., Univ. Col. London, London, United Kingdom; [3]REQUIMTE, U.Porto, Porto, Portugal

Abstract: Differential mitochondrial-dependent calcium handling may contribute for enhanced striatal vs. cortical vulnerability in Huntington's disease (HD). We previously showed that histone deacetylase (HDAC) inhibitors accelerate mitochondrial-dependent calcium recovery following NMDA receptor activation in neurons from HD mice. Here we test whether neurite outgrowth, mitochondrial and autophagy dynamics differ in primary rat cortical and striatal neurons, together with the consequences for mutant huntingtin (mHtt) clearance, in the presence or absence of a selective HDAC6 inhibitor (tubastatin A). In live imaging experiments, striatal neurons displayed decreased neurite outgrowth and a smaller motile mitochondria fraction than cortical neurons. Also, striatal mitochondria moved slower and stopped more frequently than that in cortical neurons. Furthermore, striatal neurons presented a lower autophagic flux than cortical neurons, as suggested by LC3-II and p62 immunoblots. Live imaging of neuronal EGFP-Htt(exon1)Q74 expression revealed that the proportion of neurons exhibiting mutant huntingtin inclusion bodies is smaller in striatal vs. cortical neurons. HDAC6 deacetylase activity was previously reported as a key step in autophagosome-lysosome fusion, and affecting mutant huntingtin clearance in cell lines. In live imaging experiments with neurons expressing mCherry-EGFP-LC3B, tubastatin did not inhibit autophagosome-lysosome fusion, but increased the retrograde flux of LC3-positive vesicles. Consistently, tubastatin also increased the number of autolysosomes in neuronal somata. Nevertheless, tubastatin treatment did not alter mutant huntingtin inclusion body formation in either cortical or striatal neurons. Together, these results suggest that selective HDAC6 pharmacological inhibition does not interfere with mutant huntingtin proteostasis in neurons. Also, we report the differential neurite outgrowth, mitochondrial dynamics and autophagy in cultured cortical and striatal neurons that may assist our understanding of differential neuronal vulnerability in HD. Title: Crude venom of the South American rattlesnake (Crotalus durissus terrificus) induces CA1 neuronal death in rats' organotypic hippocampal slices

Authors: ***D. CARVALHO**[1], E. GERACE[2], D. PELLEGRINI-GIAMPIETRO[2], I. S. SANO-MARTINS[3], G. F. XAVIER[1]

Abstract: Intrahippocampal administration of the South American rattlesnake (Crotalus durissus terrificus, Cdt) venom in rats permanently disrupts performance in spatial memory tasks, thus indicating the occurrence of damage to this brain area. The present study investigated the time course of neurotoxic effects of 0.05-1 μg/mL of crude Cdt venom on organotypic hippocampal slice cultures. The intensity of propidium iodide (PI) fluorescence levels in different hippocampal subfields either 2, 4, 6 or 24 h after incubation of the slices with venom were compared to corresponding scores of both (1) slices treated only with vehicle (negative control) and (2) slices incubated with 1 mM glutamate (positive control for maximal neuronal death). While negative control slices did not exhibit any neuronal damage, positive control slices exhibited strong neuronal damage in the CA1, CA3 and dentage gyrus. The ANOVA revealed dose- ($F(5,312)=7.1229$, $p=0.00001$) and time- ($F(3, 312)=4.8483$, $p=0.00260$) dependent significant increases in neuronal damage in slices exposed to Cdt venom. This effect was particularly prominent in the CA1 sub-field as compared to the CA3 and dentate gyrus ($F(2, 624)=20.763$, $p=0.00001$); in these latter brain areas damage occurred only after exposure to 0.5 and 1 μg/mL venom concentrations. In conclusion, these data show that crude Cdt venom induces selective CA1 damage (at lower concentrations) in organotypic hippocampal slice

cultures. These findings may be helpful in the elucidation and management of rattlesnake envenomation.

Title: Long-term effects of single or multiple neonatal sevoflurane exposures on hippocampal ultrastructure

Authors: L. G. AMROCK[1], M. STARNER[2], K. L. MURPHY[3], *M. G. BAXTER[2]
[1]Dept Anesthesiol., [2]Dept Neurosci., Mount Sinai Sch. Med., New York, NY; [3]Dept Biomed. Serv, Univ. Oxford, Oxford, United Kingdom

Abstract: Neonatal exposure to general anesthetics (GA) may pose significant neurocognitive risk. Human epidemiological studies demonstrate higher rates of learning disability among children with multiple, but not single, exposures to anesthesia. Here we employ a rat model to provide a histological correlate for these population-based observations. Twenty male Long-Evans rat pups (n=5/condition) were exposed to 2.5% sevoflurane under one of four conditions: a single two-hour exposure on postnatal day 7 (P7); a single six-hour exposure on P7; repeated two-hour exposures on P7, P10, and P13 for a cumulative six hours of GA; or a control exposure to 30% oxygen on P7, P10, and P13. At P91, rats underwent behavioral testing at using a spatial memory task, followed by euthanasia on P105-112. Long-term differences in hippocampal CA1 synaptic density, mitochondrial density, and dendritic spine head morphology were examined using unbiased electron microscopy. Repeated two-hour exposures to GA resulted in greater synaptic loss relative to a single two-hour exposure ($p<0.001$) and a single six-hour exposure ($p=0.022$). Repeated exposures did not alter the distribution of postsynaptic density length, indicating a uniform pattern of neurodegeneration across spine types. In contrast, mitochondrial toxicity was best predicted by the cumulative duration of exposure. Both repeated two-hour exposures and a single six-hour exposure were associated with equivalent reductions in the

fraction of presynaptic terminals containing mitochondria ($p<0.001$). These findings suggest a "threshold effect" for GA-induced neurotoxicity, whereby early mitochondrial damage sensitizes surviving synapses to subsequent exposure.

Title: Leptin attenuates the methamphetamine-induced apoptosis and inflammatory response in the murine striatum

Authors: *N. H. KUTUB[1,3], J. LIANG[2], V. PAHALYANTS[2], J. MAMTORA[2], J. A. ANGULO[1]
[1]Biol., [2]Psychology, Hunter Col., New York, NY; [3]Psychology, The Grad. Center, CUNY, New York, NY

Abstract: Methamphetamine (METH) is an addictive psychostimulant that is neurotoxic and causes cognitive and motor deficits. METH-induced neurological damage colocalizes with deficits among neurodegenerative injuries such as Parkinson's and Huntington's disease. We seek to identify neuroprotective agents that can attenuate degeneration. Leptin is a peripheral hormone produced mainly by adipocytes, circulates in the plasma and the central nervous system (CNS). Leptin mainly acts via its long form receptor, ObRb, identified in many brain areas including the hypothalamus, hippocampus, cerebellum, brain steam and striatum. The precise molecular pathway underlying the direct effects of leptin in these regions is mostly unknown. *In vitro* and *In vivo* studies reported antiapoptotic properties of leptin upon neural injury in these areas. Little is known about the neuroprotective abilities of leptin in the striatum. To measure the role of leptin on the METH-induced apoptosis, a single toxic dose of METH (30 mg/kg) and several doses of leptin (0.25, .5, 1, 2, 3 mg/kg) were administered to 10-week old mice. METH-induced apoptosis was measured 24hr post injections by terminal deoxynucleotidyl transferase mediated dUTP nick end labeling (TUNEL) immunofluorescence. A reliable baseline of the total

number of neurons in the striatum was established following published laboratory procedures. Percentage of TUNEL-positive cells relative to baseline was analyzed. Our results show that different doses of leptin alone do not cause any pro-toxic effects in the striatum. Furthermore, we found attenuation of apoptosis in the leptin + METH group across all five doses compared to METH alone group. METH alone caused 20-25% of the striatal neurons to undergo apoptosis and leptin treatment significantly attenuated the apoptosis. The minimum optimal leptin dose that elicited peak attenuation is 1mg/kg leptin, this dose was used in all future experiments. Furthermore, we found leptin does not protect dopamine (DA) terminals from METH toxicity by western blot analysis measuring tyrosine hydroxylase which is the rate-limiting enzyme of DA production. We also found both short and long isoforms of the leptin receptor to be expressed in mice striatal neurons. Finally, leptin can also attenuate METH-induced inflammatory response by reducing the over activation of astrocytes and microglia by 50-60% in expression levels for both signals within 72 hour post treatment when compared to METH alone groups. We demonstrate here that leptin signaling can be neuroprotective against METH-induced toxicity in striatal neurons of mice.

novel protection by quinolinic acid. Katelyn E. Holmes*, David Smith, Guenter W. Gross
Abstract Mefloquine Hydrochloride (MEF) has been used as an antimalarial agent for the past 40 years. The US Army to discontinue its use in 2013. However, MEF is still widely used because of its ability to interfere with all five species of plasmodium that cause malaria [1]. Despite serious side effects, such as depression, general anxiety disorder, psychoses, convulsions, seizures, tinnitus, and movement disorders, there are no quantitative data on MEF toxicity in the literature [1]. We have used primary cultures of mouse cortical tissue, growing on MEAs, to investigate MEF toxicity and potential blockers of such toxicity. At low concentrations, MEF is functionally toxic by suppressing spontaneous network activity with an IC_{50} of 420.7 +/- 14.3 nM (n=6). At 1 microM, MEF becomes cytotoxic within 10 min after compound application. Spontaneous activity cannot be retrieved by 2 medium changes and neurons and glia show clear signs of cell stress, apoptosis, and extensive membrane blebbing. This is followed by cell death of all neurons and glia in the network (n=3). We have found that the ubiquitous metabolite, quinolinic acid (QA), is protective by shifting the IC_{50} to higher concentrations. In the presence of 100 uM QA, the MEF IC_{50} is 1.06 +/- 0.07 uM, a 2.5-fold increase (n=5). Within the brain, QA is synthesized from L-tryptophan in the kynurenine pathway and is produced by microglia and resident macrophages [3]. However, such responses have not been seen in cultured networks until QA concentrations reach 500 microM (n=6) Furthermore, for 10 min MEF exposures, blebbing of neurons is shifted from 1 micoM to 3 microM in the presence of QA. QA and MEF do not interact directly (UNT mass spectrometry data), implying that QA may interfere with apoptosis receptors or pathways [5]. We hypothesize that the highly variable responses of mefloquine users are at least partially caused by different endogenous concentrations of quinolinic acid.

Title: Cranial irradiation regulates multiple brain-derived neurotrophic factor transcript variants in the mouse hippocampus

Authors: *S. KANG[1], Y. SON[1], M. YANG[1], J. KIM[1], S. LEE[1], J. KIM[1], S.-H. KIM[1], J.-S. KIM[2], U. JUNG[3], C. MOON[1]
[1]Vet. Anat., Chonnam Natl. Univ., Gwangju, Korea, Republic of; [2]Res. center, Dongnam institute of Radiological & Med. Sci. (DIRAMS), Busan, Korea, Republic of; [3]Radiation Res. Div. for Bio-Technology Inst., Atomic Energy Res. Inst., Jeongeup, Jeonbuk, Korea, Republic of

Abstract: The brain can be exposed to ionizing radiation in many fields, but it can develop adverse effects on brain functions, such as memory ability. However, little is known of the molecular and cellular mechanism of cognitive impairments induced by cranial irradiation. In the hippocampus, brain-derived neurotrophic factor (BDNF) plays a role in neurogenesis, neuronal survival, differentiation and synaptic plasticity, and the importance of BDNF transcript variants is emerging in numerous neurologic disorders. In this study, the object recognition memory and contextual fear conditioning task performance in adult C57BL/6 mice at 1 month after single exposure to γ-rays (10 Gy) was assessed to evaluate hippocampus-related behavioral dysfunction following cranial irradiation. The changes in common BDNF expression, phosphorylation of cAMP response element binding protein (CREB), and mRNA expression of individual BDNF transcript variants were analyzed in the hippocampus 1 month after cranial irradiation. In the object recognition memory test and contextual fear conditioning, mice at 1 month after irradiation displayed significant memory deficits compared to the sham-irradiated controls, while no apparent change was detected in locomotor activity. The levels of BDNF expression and CREB phosphorylation were significantly down-regulated in the mouse hippocampus after irradiation. Cranial irradiation significantly declined mRNA levels of BDNF exon IV, VI, VII, VIII, and IXA transcripts in the hippocampus. Therefore, the decrease of CREB-BDNF signaling and the differential regulation of BDNF exon transcripts may be associated with memory deficits after cranial irradiation.

Title: The modulation of GABA-ergic system in postnatal development and trimethyltin-induced neurodegeneration in the mouse hippocampus

Authors: *J. KIM[1], J. KIM[1], M. YANG[2], S. LEE[1], S. KANG[1], S.-H. KIM[1], T. SHIN[3], H. WANG[2], C. MOON[1]
[1]Vet. Anat., Chonnam Natl. Univ., Gwangju, Korea, Republic of; [2]Physiol. and Neurosci. Program, Michigan State Univ., East Lancing, MI; [3]Vet. Anat., Jeju Natl. Univ., Jeju, Korea, Republic of

Abstract: The organotin compound trimethyltin (TMT) induces excitotoxicity in hippocampal neurons accompanied by transient seizure/tremor behavior in mice. γ-aminobutyric acid (GABA) is a major inhibitory neurotransmitter, and GABA-mediated signaling has been considered to be implicated in brain development and neurotoxicity. Here, we examined the mRNA expressions of GABA receptors subunits and GABA-related pre- and postsynaptic signals in the hippocampus of mice using real-time RT-PCR to understand the regulation of GABA-ergic system during postnatal development and TMT neurotoxicity in the mouse hippocampus. During postnatal development, the mRNA levels of GABAA receptor subunits (α1, α2, α4, α5, β1, β2, β3, γ1, γ2 and γ3), GABAB receptors subunits (GBR1 and GBR2), and pre- (VGAT, GAD-65 and GAD-67) and post-synaptic signals (KCC2 and gephyrin) were significantly increased in the mouse hippocampus. In adult hippocampus after TMT treatment, the mRNA levels of GABAA receptor α1, α2, α4, α5, β2, β3, and γ2 subunits and GABAB receptors GBR1 and GBR2 subunits were significantly decreased in the hippocampus 1-4 days post-treatment, and then the levels were recovered. Further, the mRNA levels of VGAT and KCC2 were also significantly decreased 1-2 days post-treatment, while the levels of GAD-65, GAD-67 and gephyrin remained relatively stable in the hippocampus after TMT treatment. Therefore, we suggest that the differential regulation of GABA receptor subunits and related pre-/post-synaptic signals may be associated with maturation of excitatory/inhibitory neurotransmission during postnatal development, and dysregulation of synaptic plasticity and seizure/tremor behavior in TMT-induced neurotoxicity.

Abstract: Trimethyltin (TMT) intoxication induces both histopathological damage to the hippocampus and clinical symptoms, including seizure, in mice. The lesions and symptoms spontaneously recover over time. However, little is known about the precise mechanisms of recovery from TMT-induced neurodegeneration. In the present study, we investigated the change of ERK1/2 activation and Wnt/PI3K signaling pathways in the mouse hippocampus following TMT intoxication. Mice (7 weeks old C57BL/6) administered with TMT (2.6 mg/kg, i.p.) showed severe acute neurodegeneration with markedly increased TUNEL-positive cells in the dentate gyrus (DG) of the hippocampus. Western blot analysis revealed that phosphorylation of ERK1/2 in the mouse hippocampus was significantly increased 1-4 days after TMT treatment. Immunohistochemical analysis revealed that TMT treatment markedly increased phosphorylated ERK1/2 expression in the DG, whereas the expression was decreased in mossy fibers of CA3. As well, the upstream signaling Wnt/PI3K, including Wnt5a/b, AXIN, PI3K and Akt, were dynamically regulated 1-8 days after TMT treatment. Therefore, the dynamic changes of ERK and Wnt/PI3K signaling pathways may be involved in spontaneous recovery from TMT-induced hippocampal degeneration.

Title: Postnatal glucocorticoids suppress glutamatergic neurogenesis

Authors: M. T. K. ZIA[1], A. Z. KIDWAI[3], G. VINUKONDA[3], L. CARSON[3], *P. BALLABH[2]
[1]Pediatrics, Cell Bio & Anat., New York Med. Coll, Valhalla, NY; [2]Pediatrics, Cell Bio & Anat., New York Med. Coll, VALHALLA, NY; [3]Cell Biol., NewYork Med. Col., Valhalla, NY

Abstract: Background: Postnatal glucocorticoids (GCs) are widely used in the prevention of chronic lung disease in premature infants. Their use is associated with reduced cortical growth and neurodevelopmental delay. However, the underlying mechanism of GC-induced impairment of cortical growth remains elusive. Cerebral cortex consists of glutamatergic (80%) and GABAergic neurons (20%). Glutamatergic neurogenesis is orchestrated in the dorsal ventricular (VZ) and subventricular zones (SVZ) of the cerebral cortex. Radial glia cells in the VZ generate intermediate progenitor cells (IPCs) that migrate to the SVZ to further divide, migrate, and form projection neurons in the cortical layers. Pax6 is a key transcription factor regulating production of glutamatergic neurons. Since glutamatergic neurogenesis continues in preterm infants until 28 gestational weeks, it is important to determine whether GCs influence generation of projection neurons. **Objective:** Evaluate the effect of postnatal dexamethasone and betamethasone on glutamatergic neurogenesis in preterm rabbit pups. **Design/Methods:** Preterm rabbit pups were delivered at E29 (term=32d) by C-section. The pups were randomized at 24 h age into three groups: IM betamethasone (0.5mg/kg/dose once daily for 5d), dexamethasone (0.25mg/kg/dose twice daily for 5d), or saline. The pups were euthanized at postnatal d3 and 7. The coronal sections at mid-septal nucleus level were immunostained with Sox2 (radial glia) or Tbr2 (IPC) antibodies along with Ki67(cell proliferation) and DAPI. The cells were counted in the dorsal SVZ using stereological protocol. Pax6 was assayed by Western blot analysis. **Results:** Stereological analysis of immunostained sections revealed that both total and cycling $Tbr2^+$ IPCs were significantly less abundant in betamethasone and dexamethasone treated pups compared with saline controls ($P<0.05$, n=5 each group) at d3 and 7. However, $Sox2^+$ radial glia were comparable between GC treated groups and controls at d3. Western blot analysis showed that Pax6 levels were reduced in betamethasone treated pups compared with controls at d3 ($P<0.05$), but not at d7. **Conclusions:** Postnatal GCs suppress glutamatergic neurogenesis by downregulating the Pax6 transcription factor. We speculate that postnatal GCs reduce cortical growth by suppressing glutamatergic neurogenesis and subsequent corticogenesis.

Title: Striatal dopaminergic neurotoxicity and neuroinflammation caused by methamphetamine are differentially affected by *in vivo* stressors versus corticosterone treatment

Authors: *D. B. MILLER, K. A. KELLY, J. P. O'CALLAGHAN
Ctr. Dis. Control & Prevention, CDC-NIOSH, MORGANTOWN, WV

Abstract: In the mouse methamphetamine (METH) causes striatal dopaminergic nerve terminal damage accompanied by neuroinflammation as evidenced by a loss of dopamine (DA), tyrosine hydroxylase protein (TH), an increase in the astrogliosis marker GFAP and an increase in the mRNA of a number of proinflammatory cytokines and chemokines (e.g., IL-1B, LIF, CCL-2). Previously, we found exposure to corticosterone (CORT), a known anti-inflammatory agent, for 7 days in the drinking water prior to METH dosing unexpectedly enhanced the striatal damage and neuroinflammation. As CORT is released with *in vivo* stressor exposure, here we determined how METH neurotoxicity and neuroinflammation were affected by exposure to a different daily stressor for 4 days. Male C57Bl6J mice were exposed to a single s.c. injection of SAL or METH (20 mg/kg) ~ 22 hrs after the final stressor exposure and their rectal temperatures monitored at 0, 1, 3, 5, 7, 9, and 24 hrs post dosing. Striatum and cortex samples were collected 6 & 12 hrs after METH for cytokine gene expression and at 72 hrs for neurotoxicity evaluation. On the 4 days prior to dosing, mice were weighed daily and the control group (No Stress: NS) remained in their home cage while the stressed groups (S) were exposed to the following stressors: (Day 1) damp bedding 6PM to 6AM; (Day 2) a strobe light 6PM to 6AM; (Day 3) restraint from 6AM to 6 PM in home cage; (Day 4) restraint and 1.0 mA inescapable 5 sec electric shock every 30 sec for 100 shocks. Surprisingly, stressor exposure reduced the mortality associated with METH. Stressor exposure reduced thymus weight by 39 & 82% in the S-SAL & S-METH indicating the stressor exposures caused CORT release. *In vivo* stressor exposure did not modify METH hyperthermia. In contrast to our previous work, *in vivo* stressor exposure did not exacerbate striatal neuroinflammation but rather reduced cytokine expression. Striatal astrogliosis was not exacerbated but greater striatal DA and TH reductions were observed. The differences in these neurotoxicity biomarkers may reflect an ability of the *in vivo* stressor protocol to down-regulate DA and TH rather than an increased neurotoxicity. (Supported by CDC-NIOSH intramural funds)

Title: Cellular zinc levels are modulated by TRPML1-TMEM163 interactions

Authors: *J. SILVA, L. BASILIO, T. HART, M. P. CUAJUNGCO
Biol. Sci., California State University, Fullerton, Fullerton, CA

Abstract: Loss of function mutation in the Mucolipin-1 (TRPML1) ion channel protein causes the human lysosomal storage disorder Mucolipidosis type IV (MLIV). We previously reported that the brain tissues of mice knocked out of TRPML1 protein have significantly higher zinc levels compared to wild-type mice. Tissue culture models using MLIV patient fibroblasts and RNA interference (RNAi) of TRPML1 in human embryonic kidney cells confirmed that the loss or knock down of TRPML1 protein results in intracellular zinc accumulation. However, the mechanism of zinc elevation in these paradigms remains unknown. Using a membrane-based yeast two-hybrid technique, we identified a putative zinc-binding protein called transmembrane (TMEM)-163 protein as an interacting partner for TRPML1. We confirmed the interaction by co-immunoprecipitation and mass spectrometry. Confocal microscopy of TMEM163 and TRPML1 each tagged with a unique fluorescent protein showed partial co-localization and a punctate distribution pattern in human embryonic kidney (HEK)-293 cells. We hypothesized that the interaction between TMEM163 and TRPML1 plays a role in regulating TMEM163, and thus intracellular zinc. Interestingly, we found that TMEM163 mRNA and protein levels were markedly reduced in MLIV fibroblast cells when compared to wild-type control. This result correlated with our observation of intracellular zinc accumulation in lysosomes of MLIV patient fibroblast cells. RNA interference targeting TMEM163 alone, or TMEM163 and TRPML1 in HEK-293 cells resulted in significant increase of intracellular zinc. Meanwhile, deletion of the N-terminus of TMEM163 protein disrupts its binding to TRPML1, and resulted in relatively higher intracellular zinc levels when exposed to exogenous zinc. Evidence from cell surface biotinylation showed that co-expression of TRPML1 reduced TMEM163 levels localized within the plasma membrane of HEK-293 cells. This result explains why a reduction of cellular zinc flux is evident when TRPML1 is co-expressed with TMEM163, while the loss of interaction by

TMEM163 deletion mutants with TRPML1 results in intracellular zinc elevation. Overall, our data suggest that both TRPML1 and TMEM163 proteins play a role in regulating intracellular zinc. Thus, the loss of TRPML1 protein interaction with TMEM163 and/or the reduction of TMEM163 protein could result in zinc dyshomeostasis in MLIV.

Title: The levels of E3 ligase Parkin are decreased in rat colon after self-administration of neurotoxic doses of methamphetamine

Authors: *A. FLACK[1], A. L. PERSONS[2], S. M. KOUSIK[2], T. NAPIER[2], A. MOSZCZYNSKA[1]
[1]Wayne State Univ., Detroit, MI; [2]Rush Univ. Med. Ctr., Chicago, IL

Abstract: Methamphetamine (METH) is a highly abused psychostimulant that is associated with an increased risk for developing Parkinson's disease (PD; Callaghan et al. Drug Alcohol Depend 120:35,2012). This enhanced vulnerability may relate to the known neurotoxic effects of METH via oxidative stress, mitochondrial dysfunction and inflammation (Yamamoto et al. Ann NY Acad Sci. 1187,2010), factors also implicated in PD pathology. Both PD and high-dose METH decrease the function of E3 ligase Parkin, a neuroprotective protein, in the striatum. Self-administration of lower doses of METH decreases levels of tyrosine hydroxylase in the straitum (Kousik et al. Eur J Neurosci. In press). Evidence from the PD field suggests that peripheral factors may contribute to central degenerative processes; for example, α-synuclein aggregates have been identified in the enteric nervous system of the colon of PD patients prior to the onset of motor symptoms (Shannon et al. Mov Disord. 27:709,2012). The aim of our study was to measure the levels of Parkin in the colon at different times following withdrawal from self-administered METH in the rat. We hypothesized that self-administered METH will cause a deficit in colon Parkin at 14 days or earlier. Male Sprague-Dawley rats were implanted with an indwelling jugular catheter allowing self-administration of METH at the concentration of 0.1 mg/kg per infusion. The animals were allowed to self-administer the drug for 3 h per day for 7 days on an FR-1 schedule. At day 8, the administration schedule was increased to FR-5 for 14

days. Control rats received saline. Colon tissue was analyzed at 24 h and 56 d after cessation of METH self-administration. Coronal colon sections were examined for Parkin and Neu-N immunoreactivity, using immunofluorescence and confocal microscopy. Total levels of parkin and its levels in Neu-N positive cells were markedly decreased at 24 h post METH as compared to their saline-treated counterparts. At 56 d post METH, Parkin levels returned to the levels similar to those demonstrated in the saline treated controls. Since we observed a deficit in colon Parkin earlier than deficits in striatal tyrosine hydroxylase, colon Parkin might serve as an early sign of METH neurotoxicity in the brain of human chronic METH users.

Title: Methamphetamine induces activation of eNOS in cultured mouse brain endothelial cells

Authors: *J. SEO[1], S. M. JONES[1], J. P. ELLIOTT[2], G. A. WEST[3]
[1]Swedish Med. Ctr., Englewood, CO; [2]Colorado Brain and Spine Inst., Englewood, CO; [3]Neurosurg., Houston Methodist Hosp., Houston, TX

Abstract: Methamphetamine is a potent psychostimulant producing neurotoxicity and blood-brain barrier dysfunction in the brain. Also it is known to cause vessel dysfunction in human and animals. In our previous study, we reported that methamphetamine caused ET-1 mediated vasoconstriction of isolated intracerebral arterioles from mice. Prior to vasoconstriction, vessels exhibit slight vasodilation that lasts for approximately 5 min. Some studies report that methamphetamine induces nitric oxide, which may cause neurotoxicity by inducing BBB dysfunction. To understand the mechanism underlying this bi-phasic response of vessels, we investigated the involvement of NO in methamphetamine-induced responses. Western blot of total eNOS and phosphorylated eNOS on cultured bEND3 mouse brain endothelial cells showed

that activated eNOS proteins were increased significantly in cells treated with 10 μM and 100μM methamphetamine for 24hrs. However, qRT-PCR of eNOS shows that synthesis of eNOS was not induced by methamphetamine treatment. These findings demonstrate that short-term vasodilation which precedes long-lasting vasoconstriction induced by methamphetamine might be caused by NO produced from post-translational modification and activation of eNOS.

Title: Effect of the synthetic neurosteroidal derivatives BNN 20 and 27 in an *ex vivo* model of chemical ischemia and the *in vivo* STZ-model of diabetic retinopathy: Neuroprotection via TrkA signaling

Authors: *K. A. THERMOS, N. MASTRODIMOU, S. LISA, R. IBÁN-ARIAS, S. POULAKI, P. IORDANIDOU, P. GIANNOGONAS, D. KOKONA, M. KAMARATOU, E. VOLITAKI, I. CHARALAMPOPOULOS, A. GRAVANIS
Med., Univ. of Crete, Heraklion, Crete, Greece

Abstract: The main objective of this study was to investigate the neuroprotective actions of the novel spiro-epoxy derivatives of the neurosteroid Dehydroepiandrosterone (DHEA), BNN27 and BNN20, that were shown to have antiapoptotic and neuroprotective activities and no peripheral side effects. Earlier studies in our laboratory showed that DHEA protected the retina from AMPA excitotoxicity *in vivo* via NGF TrkA receptor activation. In a preliminary study, we showed that the BNN27 analogue (10mg/kg, i.p) afforded neuroprotection to amacrine cells but not to ganglion axons, in the streptozotocin (STZ)-model of diabetic retinopathy (DR). The focus of the present study was to investigate further the neuroprotective properties of the novel synthetic neurosteroid BNN27, but also BNN20, in an *ex vivo* model of chemical ischemia (C.I) and in the *in vivo* STZ-model of DR, and examine the involvement of the NGF TrkA receptor in the neuroprotection. Adult Sprague-Dawley rats were used. Retinal C.I was induced by the use of NaCN (25mM) and iodoacetic acid (5mM), whereas diabetes was induced by a single

injection of STZ (70mg/kg, i.p). Antibodies against retinal markers, known to be affected in the two models, ganglion cell axons (NFL), amacrine cells [nitric oxide synthase (bNOS)] and rod bipolar cells (PKC), were employed to assess retinal cell loss and neuroprotection. BNN 27 protected the bNOS and PKC expressing cells, mimicking the DHEA effect in the C.I model, reaching control levels at 100nM concentration. The neuroprotection of both neurosteroids was attenuated in the presence of an inhibitor of TrkA receptor (Calbiochem 648450). BNN20 was less efficacious than BNN27 in affording neuroprotection. In the STZ-model, BNN27 protected both the nitric oxide synthetase expressing cells and ganglion axons in a dose-dependent manner. Full protection of the amacrine cells was reached at the dose of 10mg/kg (i.p), whereas the ganglion axons at 50mg/kg (i.p). To determine if TrkA receptor and its downstream pathways were activated in retinas of control and diabetic rats, as well diabetic rats treated for one week with BNN27 (2,10,50mg/kg), western blot analysis was performed using specific antibodies against the phosphorylated and total isoforms of TrkA, as well as phosphorylated and total ERK1/2 proteins. At the higher dose of 50mg/kg, the levels of pTrkA and pERK in retinal tissue were significantly increased. The results from both the *ex vivo* and *in vivo* models suggest that the neurosteroid BNN 27 provides neuroprotection to rat retina via TrkA signaling. Ongoing studies are investigating further the mechanisms involved in the neuroprotection of BNN27 and BNN20 and the biology of DR.

Title: Ethanol induces chemokine MCP-1 increasing neuroinflammation and neurodegeneration in mouse brain

Authors: *L. QIN, F. T. CREWS
Bowles Ctr. Alcohol Studies, Univ. North Carolina, Sch. Med., Chapel Hill, NC

Abstract: Alcohol abuse is associated with proinflammatory gene induction, neuroinflammation and neurodegeneration. We have found the chemokine MCP-1 is elevated with both acute and chronic ethanol treatments in the brain. Binge drinking levels of ethanol treatments of C57BL/6 mice increased brain mRNA and protein levels of MCP-1, as well as many other innate immune genes as determined by real-time PCR and ELISA. To investigate the effect of ethanol on innate immune gene induction, mice were treated with acute ethanol (6 g/kg, i.g., 25% ethanol w/v, 1 dose), and brain chemokines, cytokines (mRNA and ELISA) and other innate immune genes were determined at various times and compared to blood alcohol levels. Innate immune gene induction by ethanol was greatest after ethanol clearance. Acute ethanol treated mice increased the number of activated caspase-3 (a cell death marker) +IR cells by 110% ($p<0.05$) in the prefrontal cortex (PFC) 24 hours after ethanol treatment. Confocal microscopy shows that MCP-1+IR cells are co-localized with Neu-N (a neuronal marker) and with activated caspase-3, suggesting that MCP-1 contributes to acute ethanol neurodegeneration. To investigate the effects of prolonged alcohol abuse, mice were treated with ethanol for 10 days (5 g/kg, i.g., 25% ethanol w/v, daily for 10 days). At 24 hours after ethanol treatment, the chemokine MCP-1 and other innate immune genes were measured; neurotoxicity was measured using activated caspase-3 immunohistochemistry and Fluoro-Jade B (FJB) staining and compared to the orbito-frontal cortex (OFC) of human post-mortem alcoholics. Ethanol treated mice showed increased markers of neuronal cell death: Fluoro-Jade B positive staining and activated caspase-3 immunohistochemistry in several brain regions including cortex and hippocampus. These markers of cell death were co-localized with Neu-N, consistent with ethanol-induced neurodegeneration. In the PFC mice showed a 605% increase in FJB and in the OFC human post-mortem alcoholic brain showed an 85% increase in FJB cell death. Together, these results suggest that both acute and chronic ethanol induce MCP-1 increasing neuroinflammation and neurodegeneration mimicking human alcoholic pathology. (Supported by NIAAA.)

Title: Assessment of reflex sympathetic activity after guanethidine-induced depletion of postganglionic neurons in rat

Authors: *C.-N. LIU, M. ZAHNER, C. OKERBERG, I. PARDO, C. NORTHCOTT, D. PELLETIER, J. AUBRECHT, C. SOMPS
Drug Safety R&D, Pfizer Worldwide R&D, Groton, CT

Abstract: Guanethidine is a peripherally restricted adrenergic-neuron-blocking agent, that when administered in toxic doses, destroys sympathetic postganglionic neurons in rat. By virtue of its ability to selectively deplete postganglionic neurons while sparing the preganglionic neurons guanethidine is a very useful tool that can be used to better understand sympathetic activity. While many aspects of neuronal depletion using guanethidine have been well characterized, the degree of neuronal loss required to produce functional deficits in sympathetic outflow is not well known. Thus, the goal of these experiments was to determine the degree of sympathetic postganglionic neuronal loss that correlates to a reduced excitability of the sympathetic nervous system. To do this we treated rats with guanethidine (100 mg/kg/day, i.p.) or vehicle (saline, n=4) for either 5 days (n=4) or 11 days (n=4). We assessed sympathetic activity by measuring the renal sympathetic nerve activity (RSNA) during basal conditions and during baroreflex and chemoreflex testing. Neurophysiological testing was performed 24-28 days after the final guanethidine dose, in order to minimize confounding effects of decreased body weight and guanethidine pharmacology during the dosing phase of the experiment. Although modest decreases in baseline blood pressure were observed in both groups of guanethidine-treated rats there was no effect on basal heart rate. Both vehicle-treated and 5-day guanethidine-treated rats displayed strong pulse-synchronous RSNA during baseline and robust baroreflex and chemoreflex responsiveness during sympathetic testing. However, rats treated with guanethidine for 11 days displayed decreased basal sympathetic tone and attenuated baroreflex and chemoreflex responsiveness. When comparing basal sympathetic activity to baseline blood pressure and heart rate, we found that guanethidine-treatment resulted in greater decreases in sympathetic activity than blood pressure. In 5-day guanethidine-treated rats a 19% decrease in ongoing basal sympathetic activity correlated to only a 7% decrease in ongoing basal blood pressure and in the 11-day guanethidine-treated rats a 61% decrease in ongoing basal sympathetic activity correlated to only a 13% decrease in ongoing basal blood pressure. Whereas the disproportionate decrease in basal blood pressure to sympathetic neuronal depletion may be attributed to long-term blood pressure compensatory mechanisms these data suggest that treatment reported in the literature to cause loss of sympathetic postganglionic neurons, and confirmed by us using stereologic techniques, may be tolerable under basal conditions.

Title: MDMA-induced reductions in hippocampal parvalbumin interneurons is associated with NMDA receptor activation

Authors: *S. A. COLLINS[1], G. A. GUDELSKY[2], B. K. YAMAMOTO[1]
[1]Neurosciences, Univ. of Toledo, Toledo, OH; [2]James Winkle Col. of Pharm., Univ. of Cincinnati, Cincinnati, OH

Abstract: MDMA is a widely abused synthetic psychostimulant which causes rapid and extensive release of the monoaminergic neurotransmitters dopamine and serotonin. Several studies have shown that MDMA is selectively neurotoxic to serotonergic (5HT) terminals in the brains of exposed rats. This neurotoxicity is prevalent throughout limbic and cortical regions and parallels the learning deficits in rats exposed to MDMA. Previous findings by our lab and colleagues revealed a significant increase in glutamate within the hippocampus during binge MDMA exposure suggesting that excitotoxicity is involved. This effect was dependent on increases in extracellular serotonin and the activation of 5HT2a receptors. In addition to the long term depletions of 5HT, the acute increases in extracellular glutamate coincided with a loss of parvalbumin-immunoreactive (PV-IR) interneurons of the dentate gyrus region. Given the known susceptibility of PV interneurons to excitotoxicity, we examined whether MDMA-induced increases in extracellular glutamate in the dentate gyrus are necessary for the loss of PV cells. The results indicate that extracellular glutamate is increased (52% increase, p=.003) in the dentate gyrus of the hippocampus and that the NMDA receptor antagonist, MK-801, when administered during MDMA (7.5 mg/kg x 4, ip) exposure, prevented the loss of PV-IR interneurons seen 10 days after MDMA exposure. Additionally, the administration of the 5HT2a antagonist MDL100907 during MDMA exposure, blocked the reduction of PV-IR. MDMA-induced hyperthermia was maintained during MK801 and MDL100907 treatments by elevating ambient temperature. Moreover, the increases in extracellular glutamate and the subsequent decrease in PV-IR (30% decrease; p<.001) were prevented when rats were treated with the prostaglandin EP1 receptor antagonist, SC-51089, during MDMA exposure. These findings are consistent with previous studies by others showing that 5HT2a receptor activation promotes prostaglandin production that in turn, can be excitotoxic. Therefore, increases in extracellular serotonin during MDMA exposure may promote excitotoxicity to PV interneurons through 5HT2a activation and increased production of prostaglandins. Given the known role of the

hippocampus in learning and memory, it remains to be determined if this loss of GABAergic interneurons could lead to a loss of cognitive function.

Title: An early exposure to general anesthesia modulates gene expression in the developing rat subiculum

Authors: H. OSURU, L. DALLA MASARA, A. OKLOPCIC, *V. JEVTOVIC-TODOROVIC
Anesthesiol., Univ. Virginia, CHARLOTTESVILLE, VA

Abstract: Background: Clinically- used general anesthetics, alone or in combination, cause damage to the developing mammalian brain. Many cellular mechanisms have been investigated and several were found to play potentially important role in anesthesia-induced killing of young neurons. While many studies have focused on morphological outcomes, little is known about anesthesia-induced alteration in transcription and DNA methylation of genes important for neuronal development. **Aims:** To decipher the potential for anesthesia-induced modulation of gene expression during early brain development. **Experimental Design**: At PND7 (peak of synaptogenesis) experimental rats were administered midazolam (9 mg/kg, intraperitoneally), followed by 6 hours of nitrous oxide (70%), isoflurane (0.75%) anesthesia (in 30% oxygen). Sham-controls received 6 hours of mock anesthesia (vehicle+air). Rats were sacrificed at PND8; fresh subicular tissue was collected for microarry profiling and DNMT/DNdeMt enzyme activity. Differentially and significantly modulated brain development- and disease-associated genes were further confirmed by qRT-PCR. In addition, locus Specific 5-mC and 5-hmC levels were also estimated by methylation-insensitive (MspI) and sensitive (HpaII) restriction

digestion-qPCR. **Results:** Using microarray approach we found that in anesthesia-treated group compared to the control group total of 266 genes were significantly up-regulated and 158 genes were significantly down regulated ($p<0.05$) in developing subiculum. The qRT-PCR analysis of genes found to be most profoundly modulated by anesthesia; i.e. target genes (e.g. *Oxtr, Mecp2, Avpr2, Mrgprb2, Cdk5,Grik1,Wnt1and Drd2*) confirmed good correlation with microarray findings and significant modulation when compared to controls. When 5-mC and 5-hmC levels and the activity of DNMT/DNdeMt enzymes were assessed we found a strong correlation between anesthesia-induced effects on DNA methylation and target gene expression. **Conclusions:** An early exposure to general anesthesia disrupts target gene expression via altered DNA methylation. Since these genes are important for functional and morphological synapse development and behavioral defense responses we conclude that anesthesia-induced developmental neurotoxicity could be at least in part caused by early genetic modulations.

Title: Egb761 attenuates zinc-induced tau phosphorylation at Ser262 via GSK3β regulation in rat primary cortical neurons

Authors: *K. KWON[1], E. LEE[2], K. CHO[2], S. YANG[2], M. KO[2], C. SHIN[3], S.-H. HAN[4]
[1]Dept. of Neurology, Sch. of medicine, Konkuk Univ., Seoul, Korea, Republic of; [2]Dept. of Neurosci., [3]Dept. of Pharmacol., [4]Dept. of Neurol., CGNR, IBST, Konkuk Univ. Sch. of Med., Seoul, Korea, Republic of

Abstract: In brain, excess zinc promotes the deposition of amyloid β protein and intraneuronal accumulation of neurofibrillary tangles (NFTs), composed of hyperphosphorylated tau protein. Egb761, a standardized Ginkgo biloba extract, is known to be a powerful antioxidant and exhibits neuroprotective effects. In this study, we investigated the effects of Egb761 on zinc-induced tau phosphorylation in rat primary cortical neurons. We investigated whether administration of Egb761 can modify tau phosphorylation in primary cortical neurons employing Western blotting analyses: 1) the site of zinc-induced tau phosphorylation; 2) the effects of Egb761 on zinc-induced tau hyperphosphorylation; 3) the signal pathway regulated by Egb761, 4) we also test the effects of Egb761 on cell viability and ROS generation by MTT reduction assay and ROS measurement. Zinc induced tau phosphorylation at Ser262 in time and dose-dependent manner in rat primary cortical neurons. However, other sites of tau were not phosphorylated. Tau phosphorylation at Ser262 was elevated at 30 min, peaked at 3 h after the zinc treatment (control: 100±1.2%, 30 min: 253±2.24%, 3h: 373±1.3%). Egb761 was attenuated zinc-induced tau hyperphosphorylation at Ser262 in concentration-dependent manner. NAC, an antioxidant, also inhibited zinc-induced tau phosphorylation at Ser262. Egb761 was prevented the zinc-induced MAPKs and GSK3β activation. Lithium inhibited zinc-induced tau phosphorylation. Zinc treatment increased ROS generation and neuronal cell death which was effectively prevented by Egb761. These results suggest that Egb761 inhibited zinc-induced tau phosphorylation dependently of an antioxidative action through GSK3β regulation, and support the efficacy of Egb761 for treatment of tauopathy in neurological disorder such as Alzheimer's disease. Title: Early exposure to general anesthesia alters developmental synaptic transmission and excitability

Authors: *N. LUNARDI[1], M. R. DIGRUCCIO[2], S. M. TODOROVIC[1], V. JEVTOVIC-TODOROVIC[1]
[1]Anesthesiol., Univ. of Virginia Hlth. Syst., Charlottesville, VA; [2]Neurosci. Grad. Program, Univ. of Virginia, Charlottesville, VA

Abstract: Objectives: Exposure of young rats to general anesthesia (GA) during critical stages of their brain development leaves many surviving synapses with ultrastructural changes indicative of degeneration and is followed by cognitive deficits that persist in their adult life. In view of the possibility that early GA exposure may affect neurons ability to connect and establish proper synaptic circuitries, *we asked whether and how GA alters the synaptic*

transmission of neurons surviving an initial early exposure to GA. **Methods:** At post natal day (PND) 7 (peak of synaptogenesis) experimental rats were administered midazolam (9 mg/kg, intraperitoneal), followed by 6 hours of nitrous oxide (70%), isoflurane (0.75%) and oxygen (30%). Sham-controls received 6 hours of mock anesthesia. Rats were sacrificed from PND 8 to 15 for extensive electrophysiology studies of excitatory synaptic transmission (i.e., miniature post synaptic currents (mEPSCs), evoked post synaptic currents (eEPSCs) and action potential firing patterns) from freshly prepared CA1-subiculum brain slices. We focused on the subiculum since it is very sensitive to the toxic effects of GA and crucial for learning and memory. **Results:** I. Early GA alters spontaneous excitatory synaptic currents. While mEPSCs recordings from sham-controls showed evenly distributed, very low frequency, single-spike currents, traces from GA-treated rats showed irregularly distributed, high frequency, multiple-spike currents. Upon quantification, we found about a 20-fold increase in the frequency of mEPSCs (****, $p<0.0001$) and a significant decrease in the decay time constant (**, $p<0.01$) in GA-treated rats compared to sham-controls, with no changes in amplitude and net charge transfer. II. Early GA alters evoked excitatory synaptic currents. Upon analysis of eEPSCs recordings, GA-treated rats showed a significantly decreased decay time (**, $p<0.01$) and responded to increasing stimulus strengths with significantly higher amplitude depolarizations compared to sham controls ($p< 0.05$), with no changes in paired pulse ratio. III. GA causes hyperexcitability of subicular electrical networks. Our cell-attached patch clamp recordings of spontaneous action potential (AP) firing showed about a 4-fold increase in the frequency of AP firing in GA-exposed rats compared to sham-controls (**, $p<0.01$). **Conclusions:** Early exposure to GA disrupts the function of surviving synapses by altering both pre- and post- synaptic aspects of excitatory synaptic transmission in rat subiculum. Early exposure to GA also disturbs excitatory synaptic transmission by forcing surviving synapses into a state of heightened excitability.

Title: Selective sigma receptor ligands attenuate methamphetamine-induced neurotoxicity and genetic alterations in the striatum: Microarray study and validation of select targets

Authors: *R. R. MATSUMOTO[1], M. J. ROBSON[1], N. KAUSHAL[1], A. COOP[2]
[1]Basic Pharmaceut. Sci., West Virginia Univ., Morgantown, WV; [2]Univ. of Maryland, Baltimore, MD

Abstract: Methamphetamine (METH) is a widely abused substance worldwide with neurotoxic potential after high and/or repeated dosing. AC927 is a selective sigma receptor ligand shown in preclinical studies to attenuate depletions of dopamine and 5-HT levels and transporter expression in the striatum resulting from neurotoxic exposure to METH. To identify potential mechanisms that contribute to the neuroprotective potential of AC927 and other sigma ligands, a microarray and validation study was conducted. Male, Swiss Webster mice were treated four times at 2 h intervals using effective doses from earlier studies with: Saline (Sal)/Sal, AC927/Sal, Sal/METH, or AC927/METH. Six hours after the last treatment, the striatum was dissected and later processed for microarray analysis using Mouse Exon 1.0 ST arrays. Neurotoxic METH significantly ($P<0.05$) changed the expression of 2131 genes compared to saline. Of these genes, AC927 pretreatment significantly attenuated the METH-induced changes in 22 genes (greater than 2-fold change) to 119 genes (false discovery rate correction). The changes observed in the microarray studies were independently confirmed for three genes (OSMR, GFAP, Lilrb4) using qRT-PCR, and also a time course series involving a second sigma ligand SN79. The METH-induced changes and protection by sigma ligands were also confirmed at the protein level for OSMR and GFAP using Western blots and immunohistochemistry and shown to specifically involve astrocytes. Together, the data suggest that sigma ligands can target multiple mechanisms, including glial processes, to mitigate the neurotoxic effects of METH.

Title: Cerebromicrovascular human endothelium: Characterization of functional responses induced by arachidonoyl serine

Authors: T. KINO[1], T. TOMORI[2], P. CASTRI[3], Y. CHEN[2], F. LENZ[4], *R. ABUTARBOUSH[2], R. MCCARRON[2], M. SPATZ[1]

Abstract: INTRODUCTION Arachidonoyl serine (ARA-S) is one of many endogenous lipids found in the brain. This agent is chemically related to the endocannabinoid N-arachidonoylethanolamine also known as anadamide and was shown to have similar physiologic and pathophysiologic functions. Overall the reports indicate that ARA-S possesses vasoactive and neuroprotective properties resembling those of cannabinoids. In contrast to other cannabinoids, ARA-S is considered a 'cannabinoid-like' substance since it binds weakly to its known classical receptors - CB1 and CB2. The originally described ARA-S endothelial-dependent vasorelaxation induced in rat abdominal and mesenteric vessels was not abrogated by CB1, CB2 or TRPV1 receptor antagonists. Other reports suggested that G protein-coupled receptor 55 (a putative cannabinoid receptor may be involved in mediating the ARA-S effects. In addition, the reports indicate that ARA-S stimulated phosphorylation of the kinases MAPK and AKT. This report will demonstrate that ARA-S stimulated these kinases as well JNK and cJUN via CB1, CB2 and TRPV1 receptors. In particular the findings will focus on the involvement of Rho/PI3/Akt pathway in the ARA-S-induced phosphorylation of kinase and actin reorganization in human brain endothelial cells (HBEC). METHODS Cultured HBEC which were >95% Factor VIII+ were exposed to ARA-S for 15 min alone or pre-treated with selective antagonists for CB-1, CB-2 and TRPV1 receptors (SR141716A, SR141728A and capsazepine, respectively). The levels of phosphorylation of p44/42 MAPK, Akt, JNK and c-Jun were determined by Western blot analysis. RESULTS 1. ARA-S activated both CB1 and CB2 receptors in HBEC as demonstrated by increased fluorescence (3-4 fold). 2. ARA-S stimulated phosphorylation of the above mentioned stress kinases (up to 3 fold) was inhibited by CB1, CB2 and TRPV1 receptor antagonists. 3. (a) ARA-S also increased the activity of Akt as demonstrated by the phosphorylation of Glycogen synthase kinase 3. (b) The ARA-S induced phosphorylation was enhanced (2-fold) by inhibition of Rho kinase. 4. ARA-S reduced (30%) activity of Rho kinase in control and ET-1-stimulated cells. 5. ARA-S induced reorganization of cellular actin in control and ET-1-stimulated HBEC. CONCLUSION The HBEC responses induced by ARA-S are mediated by CB1, CB2 and TRPV1 receptors and involve Rho /PI3/Akt signal transduction pathway. The findings suggest that ARA-S is an inhibitor of rho kinase and may play a critical role in the regulation of rho kinase activity and its subsequent effects of cell properties including the cytoskeleton.

Title: Choroid plexus-directed gene therapy as a source of alpha-N-acetyl-glucosaminidase-IGF2 fusion protein in Sanfilippo B mice

Authors: *S.-H. KAN[1], S. Q. LE[1], M. HADDAD[2], E.-Y. CHOI[2], A. DONSANTE[2], S. G. KALER[2], P. I. DICKSON[1]
[1]LA Biomed At Harbour UCLA, Torrance, CA; [2]Eunice Kennedy Shriver Natl. Inst. of Child Hlth. and Develop. at the Natl. Inst. of Hlth., Bethesda, MD

Abstract: Mucopolysaccharidosis type IIIB (MPS IIIB; Sanfilippo B) is an inherited neurodegenerative disorder for which no effective treatment is currently available. The cause of MPS IIIB is deficiency of the lysosomal enzyme, α-N-acetyl-glucosaminidase (NAGLU) and resultant storage of heparan sulfate. Impediments to enzyme replacement therapy include the short half-lives, absence of mannose 6-phosphate (M6P), and poor blood-brain barrier penetration associated with recombinant human NAGLU.. A modified human NAGLU fused to the receptor binding motif of insulin-like growth factor 2 (hNAGLU-IGF2) has been shown to enhance entry to MPS IIIB fibroblasts via M6P/IGF2 receptor-mediated endocytosis. In this study, we administered a recombinant adeno-associated virus, serotype 5 (AAV5) vector expressing rhNAGLU-IGF2 that targets the choroid plexus epithelia via lateral ventricle injection to deliver the missing enzyme to the cerebrospinal fluid (CSF) of MPS IIIB mice. We cloned the hNAGLU-IGF2 cDNA into an AAV vector plasmid and generated recombinant AAV5 vector by the triple transfection method. NAGLU activity assay and western blots confirmed robust expression of the recombinant protein in (what cell type) . An *in vivo* pilot study was then performed in MPS IIIB mice by injecting 5x10E10 vector genomes (v.g.) of rAAV5-rhNAGLU-IGF2 to the lateral ventricles of adult mice, or 5x10E9 v.g. in neonatal mice. The brains were taken 2 weeks after viral injection and compared with brains of untreated MPS IIIB or control (heterozygous) mice. NAGLU activity reached twice normal levels in the AAV5-treated brains. β-hexosaminidase activity, which is abnormally elevated in MPS IIIB, was significantly reduced in the AAV5-treated brains. Histochemical evaluations confirmed

NAGLU-IGF2 expression in the choroid plexus epithelium. NAGLU-IGF2 was also detected in brain parenchyma, even contralateral to the administered site, indicating delivery from the CSF. Evaluation of the efficacy of AAV5 gene therapy to correct brain lysosomal storage is in progress. Our results suggest that the combination of M6P/IGF2 receptor-mediated endocytosis and choroid plexus-targeted viral gene therapy may overcome the major obstacles for enzyme replacement therapy for MPS IIIB and enable feasible, sustained, and efficient distribution of NAGLU throughout the brain.

Title: P11 gene therapy for Parkinson's disease L-Dopa induced dyskinesias

Authors: *R. MARONGIU[1], M. ARANGO-LIEVANO[1], A. FELIZ[1], A. CENCI NILSSON[2], P. GREENGARD[3], M. G. KAPLITT[1]
[1]Neurolog. Surgery, Weill Med. Col. of Cornell Univ., New York, NY; [2]Basal Ganglia Pathophysiology Lab., Lund Univ., Lund, Sweden; [3]Lab. of Mol. and Cell. Neurosci., The Rockefeller Univ., New York, NY

Abstract: P11 (S100A10) is a scaffold protein involved in the membrane localization and activity of its interactors, including ion channels and serotonin receptors. P11 KO mice have altered dopamine responsiveness in the 6OHDA mouse model of Parkinson's disease (PD). Here we investigated the relationship between dopamine signaling and striatal p11 in 6OHDA mice. We generated an AAV vector which blocks production of murine p11 (AAV-sh.p11) and stereotactically injected it into the dorsal striatum, which is the area that receives dopamine produced in the substantia nigra and is lost in PD. We first found that inhibition of striatal p11 significantly decreased rotational behavior in response to acute treatment with D1 and D2

receptor agonists, apomorphine, and L-Dopa. This suggested a reduction in hypersensitivity to dopamine due to decreased striatal p11. We therefore explored the effects of p11 on chronic complications of L-Dopa therapy in mice. We observed that inhibition of p11 in the dorsal striatum significantly decreases all abnormal involuntary movements due to L-Dopa chronic treatment by roughly 50% when compared to control mice. This indicates that normal striatal p11 levels are necessary for full expression of L-Dopa-induced therapy dyskinesias, consistent with our rotational data. Finally, we sought to study if p11 influence on striatal motor function is mediated by either D1 or D2 receptors by using the Cre-LoxP system. We developed a novel CRE inducible AAV vector, lox.sh.p11, to selectively express the sh.p11 only in the presence of CRE recombinase. To specifically silence p11 in D1R or D2R expressing neurons, we injected either lox.sh.p11 or lox.sh.luc (control) AAV vectors into the ipsilateral dorsal striatum of previously 6OHDA lesioned D1R-Cre and D2R-Cre transgenic mice. As controls, the respective wild-type (wt) mouse littermates were lesioned and received a striatal injection of either sh.Luc or sh.p11. Inhibition of p11 in only D1R-Cre mouse line recapitulated motor behaviors previously obtained by knocking down p11 in every cell of the dorsal striatum. A comparable significant decrease was observed in the wt littermates when p11 was knocked down in all cell types, as observed earleir. D2R-Cre mice injected with AAV.sh.p11 did not show any changes compared to their Taken together our results demonstrate that normal p11 levels are necessary for striatal dopamine responsiveness and also suggest that blocking striatal p11 may be a potential therapeutic target to treat PD and dyskinesias following chronic dopaminergic drug therapy.

Univ., Daegu, Korea, Republic of

Abstract: Adeno-associated virus 1 (AAV1) transduction with an active human ras homolog enriched in brain [hRheb(S16H)] induces trophic and protective effects on the nigrostriatal dopaminergic projection in neurotoxin models of Parkinson's disease. Moreover, hRheb(S16H) transduction stimulates the production of neurotrophic factors such as glial cell line-derived neurotrophic factor and brain-derived neurotrophic factor, contributing to the survival of dopaminergic neurons, suggesting that its expression can impart to mature dopaminergic neurons the important ability to produce multi-neurotrophic agents for anti-neurodegeneration in the adult brain. Cilliary neurotrophic factor (CNTF) is another representative agent for the survival of dopaminergic neurons, showing the remarkable reduction in dopaminergic neurons in Parkinson's disease. In the present study, we have investigated the cellular alteration on the levels of CNTF and CNTF receptor α (CNTFRα) by transduction with hRheb(S16H) in the substantia nigra of rats. AAV1 packaging hRheb(S16H) was unilaterally injected into the rat substantia nigra, and 1-methyl-4-phenylpyridinium (MPP^+) was injected into the medial forebrain bundle for a neurotoxin model of Parkinson's disease at 3 weeks after injection of hRheb(S16H). Our results show that transduction with hRheb(S16H) significantly up-regulates the expression of CNTF and CNTFRα in the nigral dopaminergic neurons at 4 weeks after injection of AAV-hRheb(S16H). In addition, the expression of CNTFRα increased by hRheb(S16H) is significantly preserved against the MPP^+-induced neurotoxicity. These results suggest that transduction of dopaminergic neurons with hRheb(S16H) may contribute to the activation of CNTF signaling pathway as a potential therapeutic mechanism against Parkinson's disease. This research was supported by the National Research Foundation of Korea (NRF) grant funded by the Korea government (No. 2008-0061888 and 2012R1A1A1039140).

Title: Recombinant adeno-associated and lentiviral vector transduction efficiency in the young adult and aged rat midbrain

Authors: *N. POLINSKI, F. P. MANFREDSSON, M. BENSKEY, C. J. KEMP, N. C. KUHN, A. COLE-STRAUSS, K. STEECE-COLLIER, K. L. PAUMIER, J. W. LIPTON, C. E. SORTWELL
Translational Sci. and Mol. Med., Michigan State Univ., Grand Rapids, MI

Abstract: Clinical trials currently examine the efficacy of viral vector-mediated gene delivery for treating age-related neurodegenerative diseases such as Parkinson's disease. While viral vector strategies have been successful in preclinical studies, to date, human clinical trials have disappointed. This may be partially due to the fact that preclinical studies fail to account for aging as an important covariate. In fact, aging is the greatest risk factor for developing PD, and cellular processes used by viral vectors for gene transduction can also be altered with age. Previously, we found that gene transfer utilizing recombinant adeno-associated virus serotype 2/5 (rAAV2/5) results in decreased transduction efficiency in the aged rat midbrain as compared to the young adult rat. Injection of rAAV2/5 expressing green fluorescent protein (rAAV2/5 GFP) to the substantia nigra (SN) of aged rats resulted in: 1) ~60% fewer transduced cells, 2) ~50% less striatal protein, and 3) 4-fold lower mRNA expression than identical injections into the young adult rat SN. These results were generalizable over rat strain, duration of expression, and location sampled in the nigrostriatal system. In the present series of experiments, we investigate if the phenomenon of deficient transduction in the aged brain is generalizable to other vector constructs. We chose to analyze the transduction efficiency of rAAV constructs 2/2 and 2/9, which utilize different receptors for capsid endocytosis, to examine whether deficiencies in rAAV transduction in aging are receptor-dependent. Additionally, we chose to analyze the transduction efficiency of vesicular stomatitis virus envelope glycoprotein-G pseudotyped lentivirus (LV) due to its transduction processes that are distinct from rAAV. Aged (20 month) and young adult (3 month) male Fischer 344 rats were stereotaxically injected into the SN with either rAAV2/2, rAAV2/9, or LV expressing GFP. Outcome measures four weeks after surgery will include striatal GFP protein expression, nigral GFP qPCR, stereological quantification of THir SN neurons, and total number of GFPir cells as well as GFP mRNA visualization using RNAscope *in situ* hybridization. Aging-related deficits in transduction have the potential to

impact current and future gene therapy clinical trials. The identification of vector constructs that can more efficiently transduce the aged brain will provide insight into approaches to optimize future gene therapy clinical trials for age-related neurodegenerative diseases.

Title: Cell surface receptor targeting expanded: From oncolytic viruses to lentiviral and AAV vector

Authors: ***T. ABEL**, R. C. MÜNCH, C. J. BUCHHOLZ
Mol. Biotech. and Gene Therapy, Paul-Ehrlich-Institut, Langen, Germany

Abstract: Viral vectors are important tools for the delivery of genes in basic research and molecular medicine. Examples include but are not limited to gene marking and gene function studies or the destruction of unwanted (tumor) cells. While gene transfer with viral vectors is usually very efficient, it does not discriminate between target and non-target cells. Attachment of vector particles to a cell surface receptor is the primary step of gene transfer. Altering the receptor usage of a viral vector was first accomplished for oncolytic measles viruses (MVs) by fusing a tumor antigen specific single chain antibody fragment (scFv) to the virus attachment protein and abolishing natural receptor usage through point mutations. We have transferred this strategy to lentiviral vectors (LVs) by pseudotyping LV particles with the engineered MV glycoproteins (Anliker et al., 2010). More recently, the approach has been extended to the non-enveloped AAV vectors by mutating the native heparan-sulfate proteoglycan binding site and

simultaneously fusing a designed ankyrin repeat protein (DARPin) providing receptor specificity to the capsid protein (Münch et al., 2013). Cell surface targeted viral vectors have been described for a variety of target receptors. We have shown that oncolytic MVs targeted to CD133, a putative marker of tumor stem cells in glioblastoma, selectively eliminate CD133-positive tumor cells and substantially prolong survival in an orthotopic glioma tumor model (Bach et al., 2013). LVs have for example been targeted to subtypes of mouse neurons by addressing particular glutamate receptor subunits or to mouse endothelial cells (ECs) including brain ECs. Surface targeted AAV vectors allow the specific and exclusive genetic modification of rare target cells, both *in vivo* upon systemic injections or *ex vivo* in cell cultures. Thus three different vector types can now be manipulated in a flexible and rationally based approach to enter cells via a free-chosen surface molecule

Title: Gene therapy for spinal cord injury using hypoxia-inducible neuron-specific VEGF expression system

Authors: *Y. YUN[1], D. YOON[2], M. LEE[3], Y. HA[2]
[1]Brain Korea 21 PLUS Project for Med. Science, Yonsei Universit, [2]Dept. of Neurosurgery, Spine and Spinal Cord Institute,, Yonsei Univ., Seoul, Korea, Republic of; [3]Dept. of Bioengineering, Col. of Engineering, Hanyang University,, Hanyang Univ., Seoul, Korea, Republic of

Abstract: Objective : To increase vascular endothelial growth factor(VEGF) gene expression in spinal cord injury lesion but avoid unwanted overexpression in normal site, we developed hypoxia-inducible tissue-specific gene expression system consisting of the erythropoietin(Epo) enhancer and neuron-specific enolase(NSE) promoter. We assessed whether NSE promoter is specific to neuron and gene expression is more inducible under the hypoxia condition. Methods : The tissue-specific luciferase or VEGF plasmid was constructed using NSE promoter with Epo enhancer. The constructed plasmid was transfected mNSC cells by Polyethylenimine(PEI), followed by 48-hr incubation in hypoxia or normoxia. Spinal cord injury was made using clip

compression. Plasmids were injected directly into the injured spinal cord immediately following injury. The gene expression was assessed by luciferase assay. Results : The gene expression system containing NSE promoter showed the higher amount of luciferase under normoxia condition than the gene expression system containing SV promoter. Also, Epo enhancer/NSE promoter combined hypoxia-inducible tissue-specific gene expression system increased the expression of the reporter luciferase under the hypoxia condition. Conclusion : These results strongly suggest the Epo enhancer and NSE promoter systems are specifically effective in neurons under the hypoxic condition. This Epo-NSE-VEGF gene expression system has therapeutic effect in the spinal cord injury.

Title: Mito-mouse model of Leber hereditary optic neuropathy and the rescue

Authors: *H. YU, J. GUY
Bascom Plamer Eye Inst., Miami, FL

Abstract: Purpose: To describe the vertical gene transfer of the mutant human *ND4* (*hmutND4*) bred from founder mice generated by mitochondrial targeting AAV infection of mouse embryonic stem cells, and the rescue of mito-mice. **Methods:** *hmutND4* with a *FLAG* epitope and mitochondrial encoded m*Cherry (mtCherry)* were put under the control of a mitochondrial promoter and packaged into mito-targeted AAV2. The resulting rAAV was microinjected into the mouse blastocyst to generate mitochondrial transgenic founder mice. Gene expression was assessed using confocal laser scanning ophthalmoscopy (CLSO), PCR, 2D blue native polyacrylamide gel electrophoresis, complex I activity assay, histopathology and ultrastructural analysis. Visual function and retinal structure was monitored using serial pattern electroretinography (PERG) and SD-OCT. *In vitro* DNA replication and next generation

sequencing were performed using transgenic mouse mtDNA. **Results:** 60 founder mice were generated that contained varying expression of *mCherry* in the eye. Three females with the highest *mtCherry* expression were backcrossed with C57BL/6 males for over 8 generations, resulting in a total of 233 viable, fertile mutND4 mito-mice, Among them, 77% showed red fluorescent particles in retina and optic nerve head under the CLSO, and cells with fluorescence increased as mice aged. The expressed mutND4 assembled into mouse complex I and induced complex I dysfunction in various tissues. Pathological features of mito-mice could be observed in the eye as visual loss, swelling of the optic nerve head with a progressive demise of ganglion cells in the retina and their axons comprising the optic nerve, mild demyelination and mitochondrial abnormalities in the brain and fiber degeneration in the skeletal muscle but not evidence of abnormality in the heart. Mito-mice regained PERG amplitudes back to the normal level at younger age when rescued with the injection of mitochondrial targeting AAV carrying wild type human *ND4*, otherwise, they exhibited a progressive decline in PERG amplitudes from 3 months after birth to noise levels by 11 months of age. No integration of the delivered DNA was detected in the mouse mitochondrial genome and a 2kb band was generated in *in-vitro* DNA replication using transgenic mouse mitochondria after hybridized to human *ND4* probe, suggesting that the construct might replicate independently of mitochondrial genome. **Conclusions:** Vertical transmission of mutant human ND4 into subsequent generations of transgenic mito-mice results in the characteristic hallmarks of human LHON affecting predominantly the optic nerve and retina. They could be rescued in earlier stage.

Title: A comparison of effects of (i) AAV-mediated delivery of NG2 function-neutralizing antibody (AAV-NG2Ab), (ii) delivery of NG2-Ab via intrathecal mini-pumps and (iii)

intraspinal injections of Chondroitinase-ABC on synaptic transmission and functional recovery after SCI in adult rats. Translational potential of treatments for clinical application

Authors: *V. L. ARVANIAN[1,2], H. PETROSYAN[1,2], V. ALESSI[1], S. SANDLER[2], J. LEVINE[2]
[1]VA Med. Ctr., Northport, NY; [2]Stony Brook Univ., Stony Brook, NY

Abstract: An increased level of proteoglycan NG2 and insufficient neurotrophin (NT-3) support are among the major factors restricting synaptic transmission and plasticity in the damaged spinal cord. We have successfully created a new construct, i.e. cDNA for NG2 function-neutralizing antibody (Mab 69, Levine lab; packaged into AAV10 vector by PENN vector core) and examined its effects on neuro-muscular transmission and recovery of motor function following T10 contusion (150 kdyn) SCI (Arvanian lab). We found that intraspinal injections of AAV-NG2Ab induced sustained improvements of BBB scores. These improvements of function associated with strengthened transmission. AAV10-based extended treatment with NG2-Ab induced a significantly greater degree of recovery compared with effects of NG2-Ab delivered for 2 weeks via minipump (*Petrosyan et al., 2013*). Best improvements of both transmission and motor function were seen in animals that received treatment with AAV-NG2 combined with AAV-NT3. We have recently reported improvements of transmission and motor function following the same T10 contusion (150 kdyn) injury but using AAV10-NT3 combined with intraspinal injections of Chondroitinase-ABC (ChABC) (*Hunanyan et al., 2013*) as a treatment. Thus, it was important to establish whether treatment with AAV-NG2Ab/AAV-NT3 may have advantages over treatment with ChABC/AAV-NT3 following contusion SCI. Comparisons revealed that intraspinal injections of AAV-NG2Ab/AAV-NT3 after contusion SCI induced significantly better improvement of synaptic transmission ($P < 0.05$) and locomotor function ($P < 0.05$) than intraspinal injections of ChABC/AAV-NT3. In an attempt to improve the delivery method for these treatments, we examined less invasive intrathecal injections since this method is used in clinics for drug administration. We found an excellent transduction of spinal cord tissue by AAV10-gfp that was injected intrathecally 2 weeks following initial moderate (150 kdyn) and severe (250 kdyn) T10 contusions. Transduction of different cell types in the vicinity of contusion injury generated by delayed intrathecal administration of AAV-gfp was comparable with intraspinal injections of AAV-gfp immediately after contusion. These results confirm that the AAV10-based approach for transgene delivery of NG2-Ab and NT-3 can be used for extensive treatment delivery via intrathecal administration at delayed time points after moderate and severe contusion injuries and thus carries a translational potential for clinical application.

Title: Non-invasive widespread gene delivery to rat striatum using MRI-guided focused ultrasound

Authors: *M. A. STAVARACHE[1], J. MARKUS[2], J. T. SCHWARZ[2], Z. ROSENFELD[2], S. A. MUSATOV[2], M. G. KAPLITT[2]
[2]Neurolog. Surgery, [1]Weill Cornell Med. Coll, NEW YORK, NY

Abstract: The past few years have seen significant progress in vector-mediated gene therapy of neurologic disorders. To date, however, this has required invasive surgery to infuse vectors into the brain, and delivery to large brain regions has been a challenge. Recently, focused ultrasound (FUS) coupled with intravenously circulating lipid-coated microbubbles, under MRI-guidance, has been successfully employed in animals to deliver therapeutic or diagnostic agents to brain regions of interest by transient disruption of blood -brain barrier (BBB) permeability. FUS has also been reported to safely generate highly focal lesions in human brain to treat tremors and pain, thus raising the potential for therapeutic BBB disruption in humans. Here we report widespread and uniform gene delivery throughout the rat striatum using non-invasive intravenous infusion combined with FUS. Sprague-Dawley rats (300-350gr) were anesthetized and the tail vein catheterized for administration of microbubbles, viral vector and Gd-DTPA contrast during sonication. An adeno-associated virus (AAV) vector encoding the marker gene green fluorescent protein (GFP) was used as the gene delivery agent. BBB disruption was performed with a 3-axis positioning system and a 1.145 MHz single-element focused ultrasound transducer in combination with Optison microbubbles. FUS (10ms pulses, 1Hz pulse-repetition frequency, 120sec total duration) was applied to four points located at the level of striatum. Contrast -enhanced T2 weighed MRI scans were performed before sonication to determine the target and T1 weighed MRI scans after the sonication to assess the spread of the Gd-DTPA contrast as an indicator of the adequacy of BBB opening. All animals recovered well and showed no clinical signs of brain injury or deficit following treatment. Four weeks post sonication, animals were sacrificed for histological analysis. GFP staining covered up to 80% of the sonicated striatum while the striatum on the opposite side was unaffected. With this method, the BBB remained open for up to 4 hrs post sonication. There appeared to be a good correlation between the extent of Gd-DTPA contrast extravasation during FUS sonication and the spread of AAV-mediated gene delivery as measured by GFP staining 4 weeks later. There was no gross histological evidence of necrosis, edema or brain injury in the area of sonication 4 weeks following treatment. These findings indicate that a high viral transduction at the level of rat

striatum can be achieved safely using FUS, suggesting that clinical applications of human CNS gene therapy may be possible using non-invasive intravenous gene delivery.

Title: Development of tissue-specific gm-csf gene expressing system and combined cell therapy in spinal cord injury model

Authors: ***Y. YOU**[1], J. OH[1], D. YOON[2], Y. HA[2]
[1]Brain Korea 21 PLUS Project for Med. Sci., [2]Neurosurg., Yonsei Univ., Seoul, Korea, Republic of

Abstract: Spinal cord injury (SCI) induces a great deal of cell loss, then followed secondary degenerative response. Granulocyte-macrophage colony-stimulating factor (GM-CSF) is a cytokine that associates with neuronal survival and anti-apoptosis. We hypothesized that combined stem cells with tissue specific gene expression system would be enhanced cell therapeutic effects in SCI models. The aim of this study is to make modified neural stem cells(mNSCs) which are over-expressing neuron specific GM-CSF and to assess the effects of transplanted cells combined with gene in SCI model. Before we constructed the GM-CSF plasmid, we produced mNSCs expressing luciferase with SV or NSE promotor and showed that NSE-LUCI-NSCs were over-expressing luciferase *in vitro* and *in vivo*. Like a preliminary study, we manufactured mNSCs expressing GM-CSF and those were compared with SV-GM-CSF-NSCs measured by western blot. As a result, expression of NSE-GM-CSF was higher than SV-GM-CSF. Moreover, *In vivo* model, each group of mNSCs expressing GM-CSF was transplanted into mice after SCI, NSE-GM-CSF-NSCs show that significantly higher amount of surviving NSCs in SCI model compared with those of SV-CM-CSF.In this experiment, we represented that

combining NSE promotor with NSCs can increase expression of GM-CSF and enhance the cell therapeutic effects in SCI model. Furthermore, this system may be clinically useful to treat SCI.

Abstract: Recent evidence has shown that Ras homolog enriched in brain (Rheb) is dysregulated in Alzheimer's disease (AD) brains. However, it is still unclear whether the activation of Rheb contributes to survival and protection of hippocampal neurons in the adult brain. To assess the effects of active Rheb in hippocampal neurons *in vivo*, we transfected neurons of the cornu ammonis 1 region in normal adult rats with adeno-associated virus 1 to induce expression of a constitutively active human Rheb [hRheb(S16H)], and evaluated effects on thrombin-induced neurotoxicity. Here we report that transduction with hRheb(S16H) significantly induces neurotrophic effects in hippocampal neurons through the activation of mammalian target of rapamycin complex 1, and the expression of hRheb(S16H) prevents thrombin-induced neurodegeneration *in vivo*, an effect that is diminished by treatment with specific neutralizing

antibodies against brain-derived neurotrophic factor. These results suggest that viral vector transduction with hRheb(S16H) may have therapeutic value in the treatment of neurodegenerative diseases such as AD. This research was supported by the National Research Foundation of Korea (NRF) grant funded by the Korea government (No. 2008-0061888 and 2012R1A1A1039140).

Abstract: Rett syndrome (RTT) is a neurological disorder affecting girls and is characterized by impairment of motor and cognitive functions. Typical RTT is caused in > 95% of cases by de novo mutation of the X-linked gene MECP2. The protein product of this gene, MeCP2, is expressed globally, but at especially high levels in the nuclei of postnatal neurons. Studies in mice suggest that reactivation of a silenced Mecp2 allele can reverse and prevent RTT-like neurological deficits. More recently, we and others have demonstrated the effectiveness of viral-based gene therapy approaches in ameliorating aspects the RTT-like phenotype in knockout mice. There are many variables to consider for translational application including vector design,

route and age of delivery. The aim of this study was to compare perinatal versus juvenile administration of transgenic MeCP2 using a self-complementary AAV9 vector. Human MECP2 minigene was cloned as a fusion with a Myc epitope tag under the control of a Mecp2 endogenous core promoter fragment (MeP). This construct was flanked by AAV2 ITR elements and used to generate self-complementary (SC) AAV9 virus particles. After testing in primary neuronal culture, viral particles were injected intravenously into wild-type and knockout (Mecp2 -/y) mice at P0-3 days (perinatal) and 28-35 days (juvenile). Perinatal injection of scAAV9-MeP/MECP2 was able to deliver exogenous MECP2 into the brain of neonatal mice (brain transduction efficiency ~ 8 - 12 %; MeCP2 levels ~1.4-1.8x endogenous). At the organismal level, the injected mice displayed an impairment of hindlimb function in both wild-type and Mecp2-/y mice, which developed at around 3 weeks post-injection. Histological examination of the lumbar spine of affected mice revealed axonal degeneration within the posterior column. In contrast, juvenile Mecp2-/y mice treated with identical vector did not display this hindlimb dysfunction. Importantly, while the transduction efficiency was less in juvenile mice (2-4% neurons), these mice showed increased survival. The current study therefore suggests that the timing of MeCP2 delivery may be another important factor in maximizing therapeutic benefits and minimizing adverse effects

Title: Clinical grade-MSCs for the treatment of brain tumor after retroviral transduction of a cytosine deaminase gene

Authors: *S. LEE[1,2], J. PARK[1], D.-Y. CHANG[1], J. JUNG[1,2], J. PARK[3], Y.-D. LEE[1,2], H. SUH-KIM[1,2], S.-S. KIM*[1]
[1]Dept. of Anat., [2]Neurosci. Grad. Program, [3]Dept. of Hematology-Oncology, Ajou Univ. Sch. of Med., Suwon, Korea, Republic of

Abstract: Human mesenchymal stem cells (MSCs) have emerged as attractive cellular vehicles to deliver therapeutic genes for ex-vivo therapy of diverse diseases; this is in part because they

have the capability to migrate into tumor or lesion sites. However, concerns about the clinical application of gene modified MSCs still exist because of the risks associated with the viral vector-based methods. Previously, we showed that MSC could be utilized to deliver a bacterial cytosine deaminase suicide (CD) gene to brain tumors. Here, we report that MSCs were isolated in a GMP facility as colony forming-unit fibroblasts from bone marrows of 10 healthy donors. Colony formation ability and proliferation rates differed among divers bone marrow donors. The cells were transduced with a retroviral vector encoding CD gene and further expanded. We found that proliferation and differentiation potentials, chromosomal intergrity, and surface antigenicity of GMP-compliant MSC were not altered by retroviral transduction. The results indicate that retroviral vectors can be safely utilized for delivery of suicide genes to MSC for ex-vivo therapy. We also found that a single retroviral transduction was sufficient for sustained expression of CD up to passage 10. The results indicate that retroviral vector-transduced MSCs provide a practical approach for potential use in allogeneic therapy. This study was supported by a grant (HI10C1411/A101446) of the Korea Health technology R&D Project, Ministry of Health & Welfare and a grant (NRF-2012M3A9C6049725) of National Research Foundation of Korea.

Title: Immunoaffinity isolation of COPII vesicles from human brain

Authors: *S. D. YATES[1], J. H. MEADOR-WOODRUFF[1,2]
[1]Psychiatry & Behavioral Neurobio., Univ. of Alabama at Birmingham, Birmingham, AL;
[2]Evelyn F. McKnight Brain Inst., Birmingham, AL

Abstract: Schizophrenia (SZ) has a complex pathophysiology which is not well understood. Currently, data from our lab suggests that patients with SZ are more vulnerable to endoplasmic reticulum (ER) stress and activation of the Unfolded Protein Response (UPR). Part of the stress

response is the impairment of properly folded proteins being trafficked by COPII vesicles from the ER to the ER-Golgi Intermediate Compartment (ERGIC) and on to the Golgi for further processing. Recent studies have shown that the components of these vesicles are degraded under ER stress. COPII vesicles are formed when a cargo protein is targeted for transport out of the ER and into the Golgi. Although the exact mechanism for the recognition of which cargo proteins are ready for transport is still not known, it is established that certain components are activated sequentially to form a budding reaction, scission, and formation of the vesicle before reaching the ERGIC. In this study, we have successfully isolated intact COPII vesicles from postmortem human brain tissue using an immunoaffinity isolation technique targeting one of the outer coat components of the vesicle, Sec31. This technique utilizes a magnetic bead-antibody complex to isolate Sec31 which is then prepared for Western Blot analysis for confirmation or embedded and fixed for Electron Microscopy (EM). We have previously used this approach to successfully isolate other subcellular compartments from human brain. Using this novel approach, we plan to assay COPII vesicle content in SZ and comparison subjects with a hypothesis that alterations in COPII vesicle content lead to a decrease in trafficking of cargo in the face of ER stress in SZ.

Title: Circadian rhythm abnormalities of somatostatin expression in the amygdala of subjects with bipolar disorder

Authors: *H. PANTAZOPOULOS[1], J. WISEMAN[2], M. MARKOTA[4,3], L. EHRENFELD[3], S. BERRETTA[4,2]
[1]Psychiatry, Harvard Med. School, McLean Hosp., Belmont, MA; [2]Translational Neurosci. Lab., [3]Lab. for Translational Neurosci., Mclean Hosp., Belmont, MA; [4]Psychiatry, Harvard Med. Sch., Boston, MA

Abstract: Growing evidence supports a role for circadian rhythm abnormalities in the pathophysiology of bipolar disorder (BD). Subjects with BD exhibit shorter circadian periods, and the most effective treatments, lithium and valproic acid, modulate expression of core clock proteins and lengthen circadian period. In addition, multiple genetic polymorphisms for core

clock molecules have been associated with BD. Despite this evidence, little is known regarding how circadian rhythm abnormalities contribute to mood dysregulation in BD. Recent rodent work has reported that somatostatin (SOM), a neuropeptide with strong anxiolytic effects in the amygdala, is rhythmically expressed in the amygdala of mice and regulates anxiety-like behavior in a circadian manner. In human subjects, reports of altered levels of SOM in the cerebrospinal fluid of depressed subjects only in the early morning suggest that altered rhythm of SOM expression may be present in subjects with mood disorders. We tested the hypothesis that SOM may be rhythmically expressed in the human amygdala, and that this rhythm may be altered in subjects with BD. Serial sections including the entire rostro-caudal extent of the amygdala from 15 BD and 15 control subjects were processed for immunocytochemical detection of SOM. Total numbers (TN) and numerical densities (ND) of immunoreactive (IR) neurons were measured in the lateral (LN), basal (BN), accessory basal (AB), and cortical (CO) nuclei using computer-assisted light microscopy. Time of death for each subject was used to analyze circadian expression of SOM-IR neurons. Stepwise linear regression models were used to test for the main effect of diagnosis together with a broad range of confounding factors. In control subjects, numbers of SOM-IR neurons plotted by time of death displayed a circadian rhythm, with a peak at 9 AM, antiphase to the rhythm reported in the mouse amygdala. In subjects with BD, this rhythm was reversed in comparison to control subjects, with a low point at 9 AM. SOM-IR neurons were found to be decreased selectively in the LN of BD (TN, $p= 0.003$; ND, $p = 0.007$), with a significant effect of time of death as a co-variate ($p=0.02$). This effect was driven by marked decreases of SOM-IR neurons in BD subjects who died in the morning. Our results show, for the first time, that the expression of SOM in the human amygdala changes according to a circadian rhythm, and that this rhythm is abnormal in subjects with BD. Together, these abnormalities may contribute to a disruption of circadian rhythms in BD, accompanied by marked anxiety and vulnerability to stress.

Abstract: Schizophrenia is a severe mental illness affecting approximately 1% of the population. The disorder is highly debilitating, with symptoms including cognitive impairments, psychosis, and flat affect, with limited treatment options. A better understanding of the pathology of the disease could improve drug therapies for patients. While pathology of the dopamine system in the striatum is well documented in schizophrenia, it lacks solid support from postmortem tissue, which allows for detailed subregional brain analysis. Further, a region of the ventral striatum, the nucleus accumbens, is traditionally assumed to play an important role in these abnormalities; however, this has never been validated. In the present study, postmortem tissue from schizophrenia subjects and demographically matched controls was used to study the dopamine system in the nucleus accumbens and dorsal striatum. All schizophrenia subjects had been chronically medicated; thus, to verify these results were not due to medication, rats were chronically treated with antipsychotics for 6 months. Levels of tyrosine hydroxylase (TH), a synthesizing enzyme of dopamine, were analyzed using immunohistochemistry and optical densitometry. When compared to controls, schizophrenia subjects did not significantly differ in levels of TH in the nucleus accumbens core and shell, but had reduced levels in the dorsal striatum. Antipsychotic drug treatment did not significantly affect TH levels in rats, suggesting the findings in postmortem tissue are not due to chronic medication. These findings suggest that abnormalities in the dopamine system in schizophrenia may be localized within the dorsal striatum, not in the ventral striatum, offering new insight into the dopamine hypothesis of schizophrenia.

Title: Abnormal expression of adaptor protein complex subunits in the superior temporal gyrus in schizophrenia

Authors: *S. L. MOORE, JR[1], V. HAROUTUNIAN[2], J. H. MEADOR-WOODRUFF[1]
[1]Dept. of Psychiatry and Behavioral Neurobio., Univ. of Alabama At Birmingham, Birmingham, AL; [2]Dept. of Psychiatry, Mt. Sinai Sch. of Med., New York, NY

Abstract: Schizophrenia is a devastating psychiatric illness thought to involve the dysfunction of several neurotransmitter systems, including glutamatergic and GABAergic transmission, which have been hypothesized to contribute to the pathophysiology of schizophrenia. Recent work from our lab has shown that glycosylation provides a common mechanism thought to contribute to the observed synaptic dysfunction in these various neurotransmitter systems. In schizophrenia, glutamatergic and GABAergic neurons may exhibit altered cellular trafficking that we hypothesize is vital to the underlying mechanisms of the illness. Adaptor protein (AP) complexes are involved in the transport of vesicular glutamate transporters (VGLUTs) and the GluA2 subunit of the AMPA receptor, components previously shown to be altered in schizophrenia. AP complexes are heterotetramers composed of two large chains (alpha/gamma and beta), a medium chain (mu), and a small chain (sigma). Considering that the AP complexes may have a regulatory role in AMPA receptor and VGLUT cellular localization, we measured transcript expression of AP1/2 complex subunits, VGLUTs, and AMPA receptor subunits in the superior temporal gyrus (STG) of patients with schizophrenia (N=16) and matched comparison subjects (N=16). We found significant increases in the transcript expression of select AP complex subunits, including AP1B1 and AP2A1, and GluA2. In addition, AP subunits and VGLUT1/2 or GluA2 transcript levels were analyzed for correlation in comparison (N=22) and schizophrenia (N=16) samples. AP complex genes AP1M1, AP1S1, AP2B1, and AP2S1 had significantly altered associations with specific glutamatergic components in schizophrenia. Given the significant alterations in gene expression and correlation of these AP subunits with GluA2 and VGLUTs, the APs may be an underlying mechanism contributing to the altered trafficking and subsequent synaptic dysfunction observed in schizophrenia.

Title: A redox dysregulation affects the integrity and function of the fornix / fimbria and anterior commissure: Relevance to schizophrenia

Authors: *P. STEULLET[1], A. CORCOBA[1,2], P. S. BAUMANN[1,4], A. GRIFFA[3], J. DUARTE[2,5], Y. VAN DE LOOIJ[2], C. FERRARI[1], J.-P. THIRAN[3,5], M. CUENOD[1], P. HAGMANN[3,5], P. CONUS[4], R. GRUETTER[2,5], K. Q. DO[1]

Abstract: Compelling evidence indicate oxidative stress and dysregulation of antioxidant systems in schizophrenia. In this study, we investigated the impact of impaired synthesis of the antioxidant and redox regulator, glutathione, on white matter (WM) using knockout mice for the modulatory subunit of the key enzyme of glutathione synthesis (Gclm KO mice). We first analyzed in a longitudinal study WM integrity throughout the brain of Gclm KO and wild-type

(WT) mice using diffusion tensor magnetic resonance imaging (DTI). After correction for multiple testing, we found significant reduced fractional anisotropy (FA) in Gclm KO compared to WT mice only in the fornix-fimbria (FF) (-4.5%, p=0.03) and the anterior commissure (AC) (-7.5%, p=0.005). Reduced FA in these two fiber tracts was present from adolescence to adulthood. We also detected a significant reduction in myelin basic protein immunoreactivity in AC (-18.8%, p=0.046), but not in FF. Using electrophysiological methods, we found a small but significant decrease in conduction velocity along the fast-conducting fibers in the posterior limb of the AC (-14%, p=0.024) and the slow-conducting fibers of the FF (-9%, p=0.027). Non-significant decrease in conduction velocity was also observed along the fast-conducting fibers of the FF and of the anterior limb of the AC. Together, these data suggest that FA alterations in FF and AC may reflect different structural aberrations at the cellular level. In the AC, reduced myelin basic protein and conduction of the fast-conducting fibers point to anomaly at the level of myelination. In the FF, other processes than myelination may be also implicated in the WM anomalies observed in Gclm KO mice. Collectively, this study reveals that two fiber tracts affected in schizophrenia patients are particularly vulnerable to a deficit in glutathione. Interestingly, we also found that patients in early phase of psychosis (EP) have significantly reduced hippocampal volume (p=0.004) and generalized FA (p=0.005) in the FF compared to age-matched controls. Association between hippocampal volume, FF metrics and redox dysregulation in patients are under investigation.

Title: Double labeled quantitative immunohistochemistry of midbrain dopamine neurons in human brain

Authors: ***M. S. SIMMONS**, J. MEADOR-WOODRUFF
PSYCH-BEHAVIORAL NEUROBIOGY, UAB, Birmingham, AL

Abstract: Schizophrenia (SZ) is a severe psychiatric illness with a complex pathophysiology. To gain insight into the complexity of this illness we developed a new tool for quantitative double immunohistochemical labeling to study proteins associated with dopaminergic neurotransmission in postmortem human brain. A constant finding in patients with SZ is dysregulation of dopamine neurotransmission. Tyrosine hydroxylase (TH) and the dopamine transporter (DAT) were chosen in the development of this tool based on the key roles each has in regulating synaptic dopamine levels. Assay validation began with sections of human midbrain containing the substantia nigra individually labeled with TH and DAT antibodies. Using the Odyssey® imaging system by LI-COR, slides were scanned at 21μm after infrared conjugated secondary antibodies were incubated for 1 hr at room temperature. After confirmation of specific labeling, dual labeling was tested on dot blots with serial dilutions of human striatal homogenates spotted on nitrocellulose membrane. The mean optical densities (OD) from each blot were plotted; no signal change or cross reactivity from individual or dual labeling was observed. Next, midbrain sections were dual labeled with TH and DAT antisera, along with a dot blot. The slide and dot blot were scanned simultaneously, then the mean OD was measured from TH and DAT expression and plotted on the standard curve from each dot blot to insure linearity of both signals. We next determined the coefficient of variation for each antibody which was % for TH and % for DAT labeling. This new approach to generate quantitative dual channel immunohistochemical data will be used to investigate the status of the midbrain dopamine neurons in SZ and comparison subjects.

Title: RCAN1/CaN signaling modulates behavioral expression in schizophrenia

Authors: *P. CAIN[1], J. LEVENGA[2], H. WONG[3], A. FALKNER[3], M. ROCHE[2], B. ROTHERMEL[4], C. HOEFFER[2]

Abstract: Schizophrenia is estimated to afflict approximately 1% of the world's population, typically appearing in early adulthood and continuing throughout life. There is strong evidence that heritable genetic contributions combine with environmental factors to trigger the disorder. Recent studies have shown that genes highly correlated with the appearance of schizophrenia control the production of calmodulin-dependent phosphatase calcineurin (CaN) isoforms. Regulator of calcineurin 1 (RCAN1) and Ca2+/CaM are major modulators of CaN and perturbation of RCAN1 and CaN function have been implicated in the pathophysiology of schizophrenia. Previously we showed that innate anxiety and anxiogenic responses, along with memory, are modulated by RCAN1. Each of these has been implicated in the constellation of behaviors displayed in schizophrenia. Our new preliminary data indicate that RCAN1 may control the expression of behaviors associated with schizophrenia. We examined the role of RCAN1/CaN signaling in the expression of schizophrenia-related behaviors in Rcan1 knockout (KO) mice and transgenic Rcan1 overexpression (Rcan1tg) mice as compared to wild-type (WT) mice. We found differences among the groups in response to contextual fear conditioning extinction, social interaction and novelty response. To test the idea that these behavioral abnormalities are related to hippocampal-prefrontal function, we recorded differences in local field potentials (LFP) from the subiculum of each of these three groups. The critical finding was associating the differences in LFPs with schizophrenia-related behaviors. These studies may link RCAN1 and its modulation of CaN with the neuronal substrates underlying schizophrenia-related behavior.

Title: Abnormal protein levels of cytosolic chaperone subunits in the superior temporal gyrus in patients with schizophrenia

Authors: *C. E. REMEDIES[1], S. D. YATES[2], V. HAROUTUNIAN[3], J. H. MEADOR-WOODRUFF[2]

Abstract: Schizophrenia is a devastating psychiatric illness that has a complex pathophysiology that is not well understood. Recent data suggest that a component of this illness includes endoplasmic reticulum (ER) stress and activation of the Unfolded Protein Response. An aspect of this stress response is impairment of properly folded proteins. We have recently found that cytosolic chaperones, including the Chaperonin containing TCP1 complex (CCT) and heat shock proteins (40kDa and 70kDa), involved in proper protein folding are impaired at the transcript level. CCT is a major cytosolic chaperone involved in folding dozens of substrates including actin and tubulin. These heat shock proteins are involved in protein folding and regulation of endoplasmic reticulum associated degradation (ERAD). In this study, the protein levels of these chaperones and co-chaperones, specifically three subunits of CCT: TCP-1, CCT-4, and CCT-7, and three heat shock proteins: HSPA4L, DNAJC4, and DNAJB9, were measured by Western Blot analysis in the superior temporal gyrus of patients with schizophrenia (N=13) and matched comparison subjects (N=13). Data shows a 21% decrease in TCP-1 in schizophrenia. We hypothesize protein expression of these subunits are abnormal in schizophrenia leading to an increase in misfolded proteins and ER stress in this illness.

Title: Detailed characterization of olfactory cells via nasal biopsy: Surrogate biospecimens to define brain-relevant molecular and functional changes

Authors: *Y. CHUNG, S. NARAYAN, H. YUKITAKE, T. TSUJIMURA, N. J. GAMO, T. MASEDA, Y. HORIUCHI, S.-I. KANO, K. ISHIZUKA, A. SAWA

Abstract: Comparison of gene expression and epigenetic profiles of biospecimens from patients and controls is one of the methods to identify biomarkers and to elucidate disease mechanisms. However, difficulty of accessing cells and tissues relevant to the disease pathophysiology has been a major barrier in promoting this strategy in brain disorder research. To overcome this question, we have developed olfactory cells via nasal biopsy (Kano et al, Mol Psychiatry, 2013). Through unbiased expression analysis, we have defined that the expression profile of the olfactory cells is similar to that of mesenchymal stem cells that can be differentiated into neurons and glia, suggesting that olfactory cells might be a good surrogate system to investigate disease-associated molecular changes in the brain (Horiuchi et al, Neurosci Res, 2013). In order to further characterize and validate the utility and validity of olfactory cells, further analyses are being taken place at molecular, protein, and functional levels. Title: The differential effects of Activin and TGFbeta on signaling pathway transduction in mouse primary neurons

Authors: *Q. CHEN[1], K. TAJINDA[1], C.-J. HAN[2], S. MIYAKE[1], N. M. WALTON[1], M. MATSUMOTO[1]

[1]Neuroscience, Astellas Res. Inst. of Ameri, Skokie, IL; [2]Master of Biotech. program, Northwestern Univ., Evanston, IL

Abstract: Activins are members of the Transforming growth factor beta (TGF-beta) superfamily that participate in regulation of many biological processes, including cell differentiation and proliferation, apoptosis , hormone homeostasis and brain functions. Activin/TGFbeta and their receptors are highly expressed in embryonic and adult brain. Accumulating evidence suggests that Activin / TGFbeta signaling pathways are involved in the neurological diseases, such as depression and Alzheimer's disease. Our in-house data also showed hippocampal Activin infusion could reverse the molecular and behavioral abnormalities in CaMKIIa heterozygous knockout mouse, an animal model of psychiatric disorders (data will be presented in a separate abstract). To further elucidate Activin / TGFbeta function in adult neurons, we investigated the Activin and TGFbeta signaling pathways in primary neurons. E19 mouse hippocampal neurons were cultured in serum-free neuronal culture medium. Quantitative RT-PCR results demonstrated that both Activin and TGFbeta receptors (type 1 and type 2) were expressed in day8 cultured neurons. In order to investigate the downstream Smad2/3 signaling pathways, 100ng/ml Activin A and 10ng/ml TGFbeta1 were administrated to primary neuron. There were dynamic and significant increases in phosphor-Smad2 and phosphor-Smad3 expression after Activin A stimulation. In the meantime, immunocytochemistry experiment also showed the nuclear translocation of Smad2 and Smad3 after Activin stimulation. Very surprisingly, we only detected the increase in phosphor-Smad3 after TGFbeta 1 treatment, TGFbeta 1did not alter phosphor-Smad2 expression. In addition, we performed lentivirus Smad binging element (SBE) - Luc reporter assay in primary neurons with Activin A and TGF beta1 stimulation. Consistent with our previous data, Activin A stimulation significantly enhanced SBE - Luc reporter signal. No increase in reporter signal was detected with different doses of TGFbeta stimulation. These data indicated the selective activation of Smad2/3 signaling by Activin A in primary neuron. Furthermore, gene expression profiling by microarray analysis also showed the differential expression of downstream target genes after Activin A and TGFbeta1 treatment. Together, these results suggest the plausible differential effects of Activin and TGFbeta in adult neurons.

Title: ER stress and unfolded protein response in schizophrenia

Authors: *P. KIM[1], V. HAROUTUNIAN[2], J. MEADOR-WOODRUFF[3]
[1]Dept. of Psychiatry & Behavioral Neurobio., Univ. of Alabama At Birmingham, Sch. of Med., Birmingham, AL; [2]Psychiatry, Mt. Sinai Sch. of Med., New York, NY; [3]Psychiatry and Behavioral Neurobio., Univ. of Alabama at Birmingham, Birmingham, AL

Abstract: The pathogenesis of schizophrenia (SZ) is poorly understood but recent reports have found gene and protein expression changes in SZ. The endoplasmic reticulum (ER) is an essential cellular compartment for protein synthesis and maturation. The exposure to diverse cellular stress factors can lead to dysfunction of the ER and to imbalance between protein-folding capacity and protein-folding load. Protein-misfolding events have been observed in a variety of disorders and may contribute to both the initiation and the progression of disease through endoplasmic reticulum (ER) stress. To cope with ER stress, a signaling network called the unfolded protein response (UPR) is activated. The UPR is signaled through three ER transmembrane protein sensors: inositol-requiring enzyme1 (IRE1), protein kinase RNA like ER kinase (PERK) and activating transcription factor 6 (ATF6). The UPR consists of four mechanisms:1) attenuation of protein synthesis, 2) restoration of protein folding, 3) degradation of misfolded protein (ER- associated degradation: ERAD) and 4) apoptosis. We hypothesized that there may be abnormalities of the UPR pathway by ER stress and protein misfolding in SZ. Accordingly, this study focused on measuring the expression of genes and proteins involved in multiple UPR pathways in gray matter and pyramidal neurons derived from prefrontal cortex of subjects with schizophrenia and a comparison group. A human UPR pathway PCR array was used to measure expression of 84 genes associated with ER chaperones which are responsible for the folding and response pathways following ER stress. We identified 41 genes significantly changed in prefrontal cortex in SZ and 36 genes changed specifically in pyramidal neurons. The genes clustered into 11 different functional categories associated with the UPR. These results support that there are abnormalities of UPR pathway function in SZ and suggest possible therapeutic approaches to ameliorate ER stress in this illness.

Title: Altered cortical expression of immediate early gene NARP in schizophrenia: Impact on parvalbumin neurons

Authors: ***S. KIMOTO**[1,2], M. ZAKI[1], H. H. BAZMI[1], D. A. LEWIS[1]
[1]Dept. of Psychiatry, Univ. of Pittsburgh, Pittsburgh, PA; [2]Dept. of Psychiatry, Nara Med. Univ., Nara, Japan

Abstract: Working memory impairments in schizophrenia appear to reflect abnormalities in the generation of gamma oscillations in dorsolateral prefrontal cortex (DLPFC) neural networks. Gamma oscillations are generated by the synchronized inhibition of neighboring populations of pyramidal neurons by fast-spiking, parvalbumin (PV)-containing interneurons. Specifically, because the phasic excitation of PV interneurons plays a crucial role in gamma oscillation generation, gamma oscillations depend, in part, on the composition of synaptic glutamate receptors on PV interneurons. However, little is known about the molecular regulation underlying the alterations in glutamate receptor-mediated excitation of PV interneurons in schizophrenia. The immediate early gene (IEG) NARP, an AMPA-receptor (AMPAR) binding protein, is secreted by presynaptic pyramidal neurons in response to neuronal activation and localizes prominently to excitatory synapses on PV interneurons. NARP plays crucial roles in the formation of excitatory inputs onto, and the excitability of, PV interneurons by clustering AMPARs at the postsynaptic membrane. Since previous work has shown that fast AMPAR-mediated excitation of PV interneurons is sufficient to support gamma oscillations, altered NARP mRNA expression may lead to changes in AMPAR-mediated excitation of PV interneurons in schizophrenia. Furthermore, given that GAD67 expression is regulated by neuronal activity, alterations in NARP mRNA expression may contribute to lower GAD67 expression and GABA synthesis in PV interneurons in schizophrenia. Consequently, we first

used qPCR to evaluate the status of the representative IEGs known to regulate glutamate synaptic neurotransmission in the DLPFC from 62 matched pairs of schizophrenia and comparison subjects. *In situ* hybridization was then performed to explore the change of NARP mRNA levels at different levels of resolution. NARP mRNA levels were significantly lower in schizophrenia subjects both by qPCR and *in situ* hybridization (-26% and -40%, respectively). Of the variables frequently comorbid with schizophrenia that could be assessed, none accounted for the lower levels of NARP mRNA in schizophrenia subjects. Finally, NARP mRNA levels were positively correlated with GAD67 mRNA levels in schizophrenia subjects and in the total sample. These findings suggest that lower NARP mRNA expression in the DLPFC may contribute to lower excitatory drive onto PV interneurons, resulting in an activity-dependent down regulation of GAD67 expression and GABA synthesis, providing a potential molecular basis for altered gamma oscillations and impaired cognition in schizophrenia.

Title: Altered ErbB4 splicing is associated with lower cortical parvalbumin expression in schizophrenia

Authors: *D. W. CHUNG, D. ARION, D. A. LEWIS
Psychiatry, Univ. of Pittsburgh, Pittsburgh, PA

Abstract: Dysfunction of the dorsolateral prefrontal cortex (DLPFC) in schizophrenia is associated with markers of lower activity in parvalbumin (PV) interneurons which might reflect impaired excitatory synapse formation in these cells. ErbB4, a receptor tyrosine kinase, plays an essential role in excitatory synapse formation in PV cells. Total ErbB4 mRNA levels are

unaltered, but levels of two minor splice variants of ErbB4, JM-a and CYT-1, are higher in DLPFC gray matter in schizophrenia, suggesting dysregulated splicing, but not altered transcription, of ErbB4 mRNA in the illness. In human DLPFC, ErbB4 is expressed predominantly in PV cells in layer 4, but predominantly in calretinin (CR) cells in layer 2. Since PV, but not CR, mRNA expression is altered in schizophrenia, these findings suggest that abnormal ErbB4 splicing is associated selectively with PV cells in layer 4. To test this hypothesis, DLPFC layers 2 or 4 were selectively laser microdissected from 39 matched pairs of schizophrenia and control subjects, RNA was isolated and qPCR was performed using primers for three house-keeping genes (beta-actin, GAPDH, cyclophilin A), two layer enriched markers (CR and PV), four ErbB4 splicing variants (JM-a, JM-b, CYT-1,CYT-2) and Pan-ErbB4. In layer 2, CR expression was ~10X fold higher than PV, whereas in layer 4 PV expression was ~10X fold greater than CR, indicating that the samples of layers 2 and 4 were enriched for CR and PV cells, respectively. In schizophrenia, CR levels were not altered in either layer, whereas PV levels were 20% lower only in layer 4. In layer 4 of schizophrenia subjects, JM-a levels were 22% higher and JM-b levels were 17% lower, suggesting that ErbB4 splicing at JM locus is dysregulated in PV cells. Finally, the JM-a:JM-b ratio was inversely correlated with PV levels in layer 4 of SZ . As PV expression depends on excitatory inputs onto PV cells, these findings support the interpretation that a higher ratio of JM-a to JM-b ErbB4 splice variants is associated with fewer excitatory synapses and lower excitatory drive onto PV cells in schizophrenia.

Title: Lower GAD65 mRNA and protein levels in the prefrontal cortex of schizoaffective but not schizophrenia subjects

Authors: *J. R. GLAUSIER, S. KIMOTO, K. N. FISH, D. A. LEWIS
Psychiatry, Translational Neurosci Prgm, Univ. Pittsburgh, PITTSBURGH, PA

Abstract: Altered GABA signaling in the prefrontal cortex (PFC) has been associated with cognitive dysfunction in schizophrenia and schizoaffective disorder. GABAergic neurotransmission is in part regulated by activity of the GABA-synthesizing enzymes, glutamic acid decarboxylase 65kD and 67kD (GAD65 and GAD67). Lower levels of cortical GAD67 mRNA and protein have been consistently reported in postmortem studies of schizophrenia. However, fewer studies have examined GAD65 and the findings are mixed. Here, we quantified GAD65 mRNA and protein in the PFC from a large cohort of subjects. GAD65 mRNA levels were assessed by quantitative PCR in right PFC area 9 gray matter from 62 matched pairs of schizophrenia or schizoaffective disorder subjects and healthy comparison subjects. Based on these results, GAD65 protein levels were quantified in a subset of subject pairs using confocal immunofluorescence microscopy. Fluorescence intensity, which reflects relative protein levels, was measured across all cortical layers of left PFC area 9. Mean GAD65 mRNA levels were 6.2% lower in the affected subjects relative to comparison subjects ($p=0.016$, paired ANCOVA; $p=0.051$, unpaired ANCOVA). Further examination showed that GAD65 mRNA was unchanged in subjects with schizophrenia ($p=0.4$ paired; $p=0.8$, unpaired), but was 13.6% lower in subjects with schizoaffective disorder ($p=0.006$, paired; $p=0.004$, unpaired). In these subjects with schizoaffective disorder, GAD65 relative protein levels were 19.4% lower ($p=0.012$, paired; $p=0.033$, unpaired), and GAD65 mRNA and protein levels were positively correlated ($r=0.56$, $p=0.019$). Lower GAD65 mRNA and protein measures within schizoaffective disorder subjects was not attributable to factors commonly comorbid with the diagnosis. In concert with previous studies, these findings suggest that schizoaffective disorder is associated with lower levels of both GAD65 and GAD67 mRNA and protein in the PFC, whereas subjects with schizophrenia have lower mean levels of only GAD67 mRNA and protein. Because cognitive function is generally better preserved in subjects with schizoaffective disorder relative to subjects with schizophrenia, these findings may support an interpretation that GAD65 down-regulation provides a homeostatic response complementary to GAD67 down-regulation expression that serves to reduce inhibition in the face of lower PFC network activity.

Title: Differential alterations of perineuronal net components in the dorsolateral prefrontal cortex of subjects with schizophrenia

Authors: *J. F. ENWRIGHT, III[1], A. FOGLIO[2], R. BERRY[2], S. SANAPALA[2], D. ARION[1], K. FISH[1], D. LEWIS[1]
[1]Psychiatry, Univ. of Pittsburgh Med. Ctr., Pittsburgh, PA; [2]Neurosci., Univ. of Pittsburgh, Pittsburgh, PA

Abstract: Alterations in GABA interneurons that express the calcium protein PARVALBUMIN (PV) have been widely reported and may underlie some of the cognitive deficits seen in subjects with schizophrenia. Interestingly, PV neurons as well as a subset of pyramidal cells are surrounded by perineuronal nets (PNNs), extracellular structures that can be histochemically identified with the plant lectin *Wisteria floribunda* agglutinin (WFA). PNNs are thought to form in an activity-dependent manner, and may be partially responsible for the fast-spiking properties of certain cell types. Furthermore, recent postmortem studies have reported PNN deficits (as determined by WFA labeling) in subjects with schizophrenia. Using spinning disc confocal microscopy, stereological approaches, and quantitative immunofluorescence, we analyzed PNNs using two different markers, WFA and an antibody raised against AGGRECAN, a major protein component of the mature PNN, in layer 3 of area 9 in 28 matched pairs of subjects (healthy comparison/schizophrenia). Along with decreased PV immunofluorescence intensity per cell in schizophrenia subjects, at low magnification we found a decrease in the percentage of PV cells with detectable PNNs. However, this deficit was significantly more robust when WFA was used as the PNN marker. Furthermore, in both healthy comparison and schizophrenia subjects the percentage of PV cells with AGGRECAN- labeled PNNs was significantly higher than the percentage of PV cells with WFA-labeled PNNs. While high magnification analyses of individual PNNs showed a decrease in the average fluorescence intensity for both WFA and AGGRECAN in schizophrenia subjects, WFA-labeling was more consistently and robustly decreased. Additionally, when observed at high magnification, the percentage of PV cells with

detectable PNNs (as determined by AGGRECAN labeling) was not altered in schizophrenia subjects. Furthermore in schizophrenia subjects, PNNs around pyramidal cells had deficits in WFA, but not AGGRECAN, labeling. These effects do not seem to result from exposure to antipsychotics as neither PV nor PNN labeling was altered in a cohort of monkeys chronically exposed to haloperidol. These data suggest that in the dorsolateral prefrontal cortex of subjects with schizophrenia various components of the PNN are differentially affected, PNNs around both PV and pyramidal cells are altered, and the detectability of PNNs is dependent both on the marker and magnification used.

Title: Altered Cdc42 signaling pathway in cortical layer 3 pyramidal cells in schizophrenia

Authors: *D. DATTA[1], D. ARION[2], D. A. LEWIS[2]
[1]Neurosci., [2]Psychiatry, Univ. of Pittsburgh, Pittsburgh, PA

Abstract: Disturbances in the circuitry of the dorsolateral prefrontal cortex (DLPFC) appear to contribute to the pathophysiology of the cognitive deficits in schizophrenia. In particular, pyramidal cells, the principal source of cortical glutamate neurotransmission, exhibit morphological alterations in schizophrenia. These alterations include a smaller somal size, a less complex dendritic arbor and a lower density of dendritic spines. This pattern of pathology is particularly marked in pyramidal neurons located in layer 3, and may reflect an intrinsic deficit in the expression of genes that regulate the actin cytoskeleton in these neurons. This notion is supported by limited data demonstrating that subjects with schizophrenia exhibited altered DLPFC gray matter levels of transcripts in the Rho family of GTPases (e.g., Cdc42) which regulate the organization of the actin cytoskeleton. The goal of the present study was to examine in more detail the molecular mechanisms that may contribute to the morphological alterations, especially the lower density of dendritic spines, present in layer 3 pyramidal neurons in the

DLPFC of subjects with schizophrenia. Individual pyramidal cells (400 cells/subject) in DLPFC deep layer 3 were captured using laser microdissection from 19 matched pairs of schizophrenia and healthy comparison subjects. Total RNA was isolated and levels of transcripts for the intracellular interacting partners of the Cdc42 pathway (Cdc42, Cdc42EP4, PAK1, PAK2, LIMK1, LIMK2, ACTR2, WASL and ARHGDIA) were quantified using RT-PCR. The mRNA expression of upstream regulators of the Cdc42 pathway were modestly lower (e.g., Cdc42, -11%; PAK1, -16%; WASL, -15%), whereas expression levels of downstream regulators/effectors were significantly higher (e.g., LIMK2, 59%; Cdc42EP4, 54%) in layer 3 pyramidal cells in schizophrenia. Using a cell-type specific approach, our results identify several intracellular interacting partners of Cdc42 with altered expression in DLPFC layer 3 pyramidal cells in schizophrenia. The decrease in mRNA expression of upstream regulators may directly compromise the structural stability of spines while the increase in mRNA expression of downstream regulators/effectors may serve as a compensatory mechanism to enhance the stability of remaining spines and restore spine plasticity. Our findings support the notion that altered signaling in the Cdc42 pathway represents a molecular mechanism that might contribute to the lower density of dendritic spines in layer 3 pyramidal cells in the DLPFC of subjects with schizophrenia.

Title: Whole-transcriptome analysis of hippocampal ca3 and gene verification in schizophrenia

Authors: *J. M. PEREZ, K. GLEASON, S. GHOSE, H.-C. HUANG, T. HWANG, T.-K. KIM, C. A. TAMMINGA
UT Southwestern, Dallas, TX

Abstract: Schizophrenia (SZ) is one of the thirty most incapacitating conditions and affects over 67 million people worldwide; suicide occurs in 10% of those diagnosed with schizophrenia. Symptoms are persistent and often severe. They include hallucinations, delusions, thought

disorder, and deficits in executive function and memory. Treatments available are not always efficacious. 20-40% of people with schizophrenia are resistant to treatment and less than 20% completely recover after one episode of psychosis. Due to a lack of understanding of the molecular pathophysiology of schizophrenia, its diagnosis is based on behavioral symptomatology. Unfortunately, due to only phenomenological diagnoses, these categories are inadequate. Therefore, we are examining human tissue for molecular causes and correlates of the illness. Our lab has proposed a model of psychosis as a disorder of learning and memory that critically involves dentate gyrus (DG) and CA3. We suggest that reduced glutamatergic neurotransmission from DG to hippocampal CA3 serves to generate an increase in CA3 basal activity and function through homeostatic plasticity changes within CA3. This increase in function may lead to the generation of inappropriate or illogical memories with psychotic content. Our lab has shown an increase in perfusion in CA3 in schizophrenia, a correlate of neuronal activity level, as well as an increase in spine density and dendritic complexity and increased protein levels of synaptic plasticity markers like GluN2B and PSD-95 in CA3 of schizophrenia postmortem tissue. Using a hypothesis generating approach, we have analyzed the CA3 transcriptome from control and off-drug schizophrenia cases, in a global and unbiased manner, using whole transcriptome (WT) sequencing to identify additional molecular changes, which have not been hypothesized. These analyses have focused our interest on genes like GRPIN1, AGAP1, and BCR among others. We have conducted differential expression analysis, gene coexpression network analysis, and variant mining analysis for this data set and are currently verifying the RNA-seq results through qRT-PCR and Sanger sequencing. We expect to show a network of abnormalities in CA3, which support the increases in activity we have shown with our *in vivo* imaging analyses.

Title: Molecular characteristics of cerebral networks for psychosis

Authors: W. LI[1], N. SAMUDRA[1], C. MEYER[1], K. GLEASON[1], E. I. IVLEVA[1], S. GHOSE[1], *C. A. TAMMINGA[2]
[1]Psychiatry, [2]Univ. Texas Southwestern Med. Ctr., Dallas, TX

Abstract: The molecular, cellular and network underpinnings of psychosis in diseases like schizophrenia are unknown but remain essential knowledge for rational treatment development. Hippocampal hyperactivity has been repeatedly demonstrated in schizophrenia, potentially generating mistakes of memory and false memories with psychotic content within relevant brain networks, a pathological alteration in learning and memory. To identify the cerebral networks associated with this hippocampal pathology, we performed regional seed connectivity analyses on N=87 resting state fMRI acquisitions from psychosis probands and found alterations in connectivity between anterior hippocampus and medial, dorsolateral and cingulate prefrontal cortex as well as with superior temporal gyrus and cerebellum. Guided by these outcomes, we are carrying out a molecular analysis of hypothesized protein alterations in the regions of these circuits. We have started by analyzing molecular markers of synaptic strength in ACC and cerebellum in a single postmortem tissue cohort (N=20 SZ; N=20 HC) and analyzing the association between these changes and changes in hippocampus. In layers 1-3 of ACC, we found trend increases of Glu2B in all schizophrenia cases (p=0.099) and the same in off medication schizophrenia cases (p=0.10). We did not observe any change in GluN1 (p=0.82), in Glun2A (P=0.49), in GAD67 (p=0.39), in ERK1 (P=0.67) or in ERK2 (p=0.93) in schizophrenia cases. In layers 5a-6 of ACC, we found a significant increase in GluN2B (p= 0.034) and in GluN2B/GluN1 (p=0.016) in off medication cases, though the increases were not significant when tested within the whole sample of schizophrenia cases (p= 0.15 for GluN2B, and p= 0.32 for GluN2B/GluN1), suggesting that these proteins may be modified by antipsychotic treatment. There was a trend increase in GluN2A (p=0.10) and a significant increase in GluN2A/GluN1 (p= 0.0089) in off medication schizophrenia cases though the increases were not observed in the on medication schizophrenia cases (p= 0.76 for GluN2A, and p=0.68 for GluN2A/GluN1). There was no significant change observed in GluN1 (p=0.19), in GAD67 (p=0.57), in PSD95 (p=0.48), in GluA1 (p=0.79), in ERK1 (p= 0.73), or in ERK2 (p=0.78) in schizophrenia cases. Data from cerebellum and other regions in this circuit will be reported and correlations between regional molecular markers and hippocampus will be developed. Ultimately, regional transcriptome analyses might be the strongest way to identify the molecular signaling systems which mediate this functional connectivity.

Title: Haloperidol-exposure does not affect schizophrenia-linked reductions in microtubule associated protein 2 immunoreactivity

Authors: *M. A. SHELTON[1], J. T. NEWMAN[1], H. GU[2], A. R. SAMPSON[2], K. N. FISH[1], P. P. PENZES[4], D. A. LEWIS[1], R. A. SWEET[1,3,5]

Abstract: Background: Microtubule-associated protein 2 (MAP2) is crucial for establishing and maintaining experience-dependent plasticity of dendrite and spine structure. The neuropathology of schizophrenia (Sz) includes a drastic reduction in MAP2 immunoreactivity (IR) in a number of cortical regions; however, the contribution of anti-psychotics to this finding is unknown. Despite the loss of immunoreactivity, MAP2 mRNA expression levels are unaffected in tissue from schizophrenia subjects. Thus, we hypothesized MAP2-IR would be unaffected by anti-psychotic exposure. Methods: Using quantitative fluorescence confocal microscopy, we examined MAP2-IR intensity as well as spine density and number in human post-mortem tissue taken from BA41 of 20 individuals with Sz and matched controls. We utilized a cohort of four macaques chronically administered the anti-psychotic haloperidol and four matched sham-treated control animals in order to determine the effect of anti-psychotics on MAP2-IR. Results: MAP2-IR was reduced by 70.0% (p=0.001) in Sz subjects, with a sub-group comprising 60% of our Sz cohort that exhibited fluorescence values near background, below the lowest intensity values

observed in control subjects. In addition, spine density and number were significantly reduced exclusively within this sub-group (spine density, p=0.0018; spine number, p=0.0042). Finally, there was no effect of chronic haloperidol exposure on MAP2-IR in BA41 deep layer 3 in drug exposed macaques. Conclusions and Future Directions: MAP2-IR, spine density, and spine number are significantly reduced in BA41 deep layer 3, and our results show that these changes are not a consequence of anti-psychotic exposure. These results suggest that alterations to MAP2 represent disease pathophysiology as opposed to an effect of treatment. We previously reported no significant effect of drug treatment on spine density in these animals. Future experiments will combine quantitative microscopy, antibody-based epitope mapping, and targeted proteomics, to perform total and domain specific measures of MAP2 in order to determine how changes in MAP2's regulatory state and epitope availability contribute to the loss of MAP2-IR in Sz.

Title: Loss of pattern separation performance and fMRI BOLD activation in schizophrenia

Authors: T. DAS[1], *E. I. IVLEVA[2], C. E. L. STARK[3], A. WAGNER[4], C. A. TAMMINGA[1]
[1]Psychiatry, Univ. Texas Southwestern Med. Ctr., Dallas, TX; [2]UT Southwestern Med. Center, Dept. of Psychiatry, Dallas, TX; [3]Psychology, UC Irvine, Irvine, CA; [4]Psychology and Neurorsciences, Stanford Univ., Standford, CA

Abstract: In healthy individuals, the hippocampus has long been implicated in forming new memories, storing them independently, retrieving memories from partial cues and flexibly

applying stored memories to partial cues. Hippocampal-mediated memory allows the discrimination of similar events as distinct and orthogonal, called *pattern separation (PS)*. Motivated by evidence that the dentate gyrus differentially mediates the *PS* component of declarative memory function and that it harbors molecular and cellular pathology in schizophrenia, we examined *PS* performance in schizophrenia (SZV) vs healthy volunteers (HV) using the Behavioral Pattern Separation (BPS) task (Stark et al., Neuropsychologia, 2013). In well-characterized SZV and HV, we contrasted behavioral performance and fMRI BOLD activation during the BPS task. Behaviorally, we have calculated two outcome measures, *PS* and Recognition Memory (RM). The BPS task includes an incidental 'encoding' phase (runs 1-2) (with 128 pictures of everyday objects) where volunteers identified each object as "indoor" or "outdoor". A subsequent 'test' phase (runs 3-4) exposes volunteers to 192 pictures/run, with 64 repetitions (old), 64 new objects (foils) and 64 similar objects (lures) to pictures shown in runs 1-2, and volunteers were instructed to identify objects as repeated, new, or similar. The SZVs showed a significant decrement in *PS* performance relative to HV (mean±SEM, SZV: 3.1±2.7%; HV: 17.1±5.8%; *p=0.039); whereas SZV and HV did not significantly differ in RM performance (SZV: 50.1±8.1%; HV: 59.3±5.5%; p=0.350) (Fig). We have acquired high resolution fMRI BOLD task-associated scans on 3T Philips Achieva. These data are being analyzed using SPM5. We hypothesize that SZV will activate the DG/CA3 hippocampal subfield to a significantly lower degree than HV for correct lure identification and that the magnitude of activation will correlate with *PS* performance. fMRI BOLD data will be presented by group and by subfield. Hence our behavioral finding of lack of pattern separation in schizophrenia leads us to expect a dysfunctional dentate gyrus in the illness, a feature that could contribute to declarative memory impairment in the disorder and possibly, schizophrenia psychosis.

Title: Prefrontal cortical interneuron transplants reverse deficits in reversal learning in a rodent model of schizophrenia

Authors: *A. M. BOLEY, S. M. PEREZ, D. J. LODGE
Dept. of Pharmacol., UTHSCSA, SAN ANTONIO, TX

Abstract: Schizophrenia is a debilitating disease that affects up to 1% of the population. Current therapies are associated with various adverse side effects or are ineffective, making identifying novel targets and treatments a necessity. A consistent pathology, observed in schizophrenia patients and rodent models of the disease, is a loss of interneuron function, specifically interneurons containing the calcium binding protein parvalbumin (PV). We have previously demonstrated a decrease in PV expression (induced by lentiviral delivered shRNA) in the ventral hippocampus was sufficient to cause hippocampal hyperactivity and downstream dysfunction of the dopamine system. Additionally, we have shown that by replacing deficient interneurons (via cell transplantation) into the hippocampus, we were able to reverse hippocampal hyperactivity, normalize aberrant dopamine neuron activity, and reverse the hyper-responsive locomotor response to amphetamine in the methylazoxymethanol acetate (MAM) model of schizophrenia. Furthermore, the loss of PV observed postmortem in schizophrenia patients is not specific to the hippocampus and involves cortical regions such as the prefrontal cortex, which may underlie symptoms that are not related to psychosis. Given the association between prefrontal cortical function and cognitive flexibility, we examined whether interneuron transplants in the medial prefrontal cortex (mPFC) could reverse cognitive deficits in the MAM rodent model of schizophrenia. Here we demonstrate that mPFC interneuron transplants are able to reverse deficits in reversal learning in an attentional set-shifting task designed to assess cognitive flexibility. These findings support the basis of targeting cortical interneuron function, in addition to the hippocampal region, to treat features of schizophrenia that encompass both psychosis and non-psychosis related symptoms.

Title: Cell adhesion molecules in psychiatric diseases and aging

Authors: T. BUTT[1], A. SANTIAGO[2], A. DWORK[2], G. ROSOKLIJA[1], V. ARANGO[1], R. HEN[1], J. MANN[1], *M. BOLDRINI[3]
[1]Columbia Univ., New York, NY; [2]NYSPI, New York, NY; [3]Psychiatry - Mol. Imaging and Neuropathology, Columbia Univ. - NYSPI, New York, NY

Abstract: Adult neurogenesis in the dentate gyrus (DG) of the hippocampus is found in rodents (Santarelli 2003), nonhuman primates (Kornack and Rakic, 1999), and humans (Eriksson 1998). Impaired neurogenesis is reported in psychiatric and neurodegenerative disorders, such as major depression (MDD, Boldrini 2009, 2012, 2013), and Alzheimer's (Winner 2011). One third of DG neurons turn over postnatally in human (Spalding 2013), three times as fast than in rodents (Imayoshi 2008). Neural progenitor cells (NPCs) decrease with age in MDD even when treated with antidepressants (Boldrini 2009), as in rodents (Couillard-Despres 2009). Adult mammalian neurogenesis involves the birth of NPCs expressing nestin (Kalman and Ajtai, 2001); later, polysialylated-neural cell adhesion molecule (PSA-NCAM) is expressed by transiently amplifying progenitors, (Kempermann 2004, Kempermann, 2011) and neuroblasts (Kempermann, 2011). PSA-NCAM mediates structural remodeling, synapses growth (Seki and Rutishauser, 1998), cell migration and axonal growth (Keynes and Cook, 1995), learning and memory (Venero 2006). Expression of PSA-NCAM molecule in relationship with aging, MDD and antidepressant treatment by quantifying immunoreactive (IR) was assessed in autopsy DG from non-psychiatric sudden deaths (controls, n=12), untreated MDD (n=12) and antidepressant-treated MDD (n=12). We performed psychological autopsy, neuropathology and toxicology. Frozen hippocampi were fixed and processed for immunohistochemistry and stereology. PSA-NCAM-IR cells with multipolar (r= -.797, *p*= .010) and immature morphology (r= -.717, *p*=

.030) in anterior DG decreased with age in controls. PSA-NCAM-IR cell number did not correlate with age in MDD, which did not differ from controls in any DG region. MDD treated with tricyclic antidepressants (TCA) have more PSA-NCAM-IR immature cells *vs*. untreated MDD (p=.027) and controls (p=.007). PSA-NCAM-IR multipolar cells are more in MDD treated with TCA *vs*. controls (p=.030), untreated MDD (p=.018) and MDD treated with selective serotonin reuptake inhibitors (SSRI, p=.030). Fewer PSA-NCAM-IR cells and NPCs in anterior DG with aging in non-psychiatric controls may contribute to age-related memory and pattern recognition decline. Cellular changes with age in anterior DG were not present in MDD, perhaps because MDD neuropathology may obscure or over-ride the age effect. The relationship between TCA and PSA-NCAM-IR cells could be explained by TCA noradrenergic effect because it is not seen with SSRIs, which have a serotonergic effect.

Title: Alterations in the structure, plasticity and connectivity of inhibitory networks in a double hit model of schizophrenia

Authors: *C. GARCÍA MOMPÓ, E. CASTILLO-GÓMEZ, B. RIPOLL-MARTÍNEZ, Y. CURTO-SASTRE, J. GILABERT-JUAN, J. NÁCHER
CELL BIOLOGY, UNIVERSITAT DE VALÈNCIA, BURJASSOT, Spain

Abstract: Schizophrenia is a complex psychiatric disorder, which results in dramatic changes in behavior, perception and cognition, as well as alterations in the structure and function of cortico-limbic regions, including the prefrontal cortex and the amygdala. Current pathophysiological theories of schizophrenia point to abnormalities in the development, organization and physiology of inhibitory circuits as responsible for some of these alterations. However, the cellular and molecular bases of these alterations are still unclear. In this line, the generation of animal models reproducing some of the core features of schizophrenia, constitute valuable tools to investigate these alterations. By generating a double developmental/environmental mice model of schizophrenia in a transgenic strain displaying fluorescent interneurons, we sought to mimic a wide range of features of this disorder and find alterations in the structural plasticity of inhibitory circuits. Mice were subjected to a perinatal injection of a N-methyl-D-aspartate receptor (NMDA-R) antagonist, MK-801, and were socially isolated from postweaning to adulthood. We found that these mice reproduce some of the behavioral and structural alterations previously seen in other models. Consequently, abnormalities in the structural plasticity of cortico-limbic interneurons may have a key role in the pathophysiology of schizophrenia.

Title: Ventral pallidum is key to the endocannabinoid regulation of dopamine system function in a rodent model of schizophrenia

Authors: *D. D. AGUILAR[1], L. CHEN[2], D. J. LODGE[1]
[1]Pharmacol., UTHSCSA, San Antonio, TX; [2]Physiol. and Pathophysiology, Med. Sch. of Xi'an Jiaotong Univ., Xi'an, China

Abstract: Schizophrenia is a debilitating disorder that affects over 3 million Americans. Existing pharmacological therapies have pronounced side effects which lead many patients to discontinue their medication. Therefore, alternative therapies such as endocannabinoid upregulation are being studied. Clinical observations reveal an inverse relationship between levels of the endocannabinoid anandamide and psychotic symptoms in patients with schizophrenia. Furthermore anandamide upregulation alleviates social withdrawal, a negative symptom of schizophrenia, in a rodent model of schizophrenia. The psychotic symptoms of schizophrenia are correlated with augmented dopamine system activity. Here we show anandamide upregulation alleviates augmented dopamine neuron population activity in the phencyclidine model of schizophrenia. Although hippocampal activity drives this phenotype, we have demonstrated that the site of action of anandamide is the ventral pallidum. Specifically, URB597 administered directly to the ventral pallidum is sufficient to restore aberrant dopamine neuron population activity. The endocannabinoid system and/or ventral pallidum may prove to be attractive targets for reducing psychotic episodes in schizophrenia patients.

Title: Impact of age and chronic ketamine treatment on parvalbumin expression in rats: Evidence for variation in protein expression

Authors: *J. A. CORRIVEAU, C. MCMAHON, J. J. CHROBAK
Psychology, Univ. of Connecticut, Storrs, CT

Abstract: A selective decrease in parvalbumin (PV) immunoreactivity is a stable finding in post-mortem schizophrenic hippocampus and prefrontal cortex. Animal models of schizophreniform dysfunction following acute and/or chronic ketamine treatment show comparable decreases in PV expression in rodents, and it is often considered a marker of pathology. However, there are some groups reporting conflicting findings indicating no change in PV following sub-chronic treatment, which calls into question the efficacy of using PV as a pathological marker. Upon close examination of methodology across studies, it is clear that there exist differences in

protocols, especially with regard to the age of the rodents during treatment and/or sacrifice. Furthermore, the literature lacks a sufficient understanding of baseline/normative PV expression in drug- and behaviorally-naïve tissue. In order to understand the putative role of PV in pathology, systematic characterization of normative distribution across ages is imperative. The present study examined PV expression across the septotemporal axis of the rat hippocampus and surrounding somatosensory cortex (barrel fields) in 1-, 6-, and 12-month old rats. Our findings suggest variation in expression of PV in untreated naïve rats as a function of age, with decreased PV in older rats compared to younger rats, along with changes across the septotemporal (long) axis dependant on age. Based on our data, we propose that PV expression is a more dynamic marker than previously thought, and that changes in expression based on age should be considered when modeling pathology. Ongoing research in our lab is investigating the impact of chronic ketamine administration on PV expression and behavior to better characterize the nuances and translatability of this model of schizophreniform dysfunction.

Title: NMDA receptor antagonist-induced changes in rat EEG power spectra as a model of schizophrenia

Authors: *N. UPTON, G. WADSWORTH, K. WATERS, D. VIRLEY
TRANSPHARMATION LTD, LONDON, United Kingdom

Abstract: Schizophrenia is a debilitating neuropsychiatric disorder characterised by an array of symptoms, with negative symptoms (e.g. lack of emotion) and cognitive dysfunction proving resistant to current therapies. Recent EEG studies have provided evidence that changes in synchronicity in the Gamma range (30-80Hz) are associated with this treatment resistance in schizophrenic patients. A large body of evidence now points to the disruption of N-methyl-D-aspartate (NMDA) mediated signalling as a core pathophysiological deficit in schizophrenia, including the observation that pre-clinical species administered NMDA antagonists display a phenotype consistent with schizophrenia. In this study we investigated the effects of two NMDA antagonists, ketamine (Ket) and phencyclidine (PCP) on EEG spectral power and sleep-wake

stages in freely moving rats. EEG signals were recorded from electrodes over the frontal-parietal cortex using intracranial electrodes; nuchal EMG was recorded to enable sleep stage scoring. Signals were recorded from the onset of the dark period for 24hrs. The animals were dosed with either vehicle (saline s.c.), Ket (3, 10, 30mg/kg, s.c.) or PCP (0.3, 1, 3mg/kg, s.c.) 30min following the onset of the dark period. Data were analysed over the period of peak effect for each agent.

Significant effects on activity and sleep-wake (% change from vehicle)

		Wake		Sleep Stage		
Agent	Activity	Active	Quiet	1	2	PS
Ket 3mg/kg	NS	NS	NS	NS	NS	-65.0
Ket 10mg/kg	438.8	364.4	232.8	-52.78	-60.4	-97.1
Ket 30mg/kg	704.0	587.0	272.8	-66.29	-91.3	-96.1
PCP 0.3mg/kg	NS	NS	NS	NS	NS	-28.8
PCP 1mg/kg	NS	192.1	27.8	-49.3	-21.4	-73.0
PCP 3mg/kg	789.2	600.4	27.1	-92.7	-87.7	-100.0

Effect on EEG Power (% change from vehicle)

Treatment	Delta	Theta	Alpha	Beta	Gamma
Ket 3mg/kg	NS	NS	NS	NS	NS
Ket 10mg/kg	NS	NS	NS	NS	182.3
Ket 30mg/kg	NS	NS	NS	NS	349.7
PCP 0.3mg/kg	NS	NS	NS	NS	NS
PCP 1mg/kg	NS	NS	NS	-18.2	80.0
PCP 3mg/kg	-60.3	-49.2	-48.3	-36.2	265.6

Both PCP and Ket caused profound changes in the behavioural and EEG profiles of the animals. Activity was increased and sleep-wake was shifted to an arousal profile with an increase in wake phases and decrease in all sleep phases. In terms of EEG power, PCP and Ket dramatically increased gamma frequencies. These data add further weight to the use of NMDA receptor antagonists to provide a valid translational model of schizophrenia and suggest that EEG biomarkers may have utility in identifying novel treatment strategies for restoring more normal gamma synchronicity.

Title: Characterization of a mouse model of the human 22q11.2 microdeletion syndrome

Authors: ***J. B. LAURIDSEN**[1], K. FEJGIN[1], F. GASTAMBIDE[2], S. NILSSON[3], V. NIELSEN[1], D. CLAUSEN[1], P. H. LARSEN[1], M. TRICKLEBANK[2], T. BUSSEY[3], L. M. SAKSIDA[3], M. DIDRIKSEN[1], J. NIELSEN[1]
[1]H. Lundbeck A/S, Valby, Denmark; [2]Eli Lilly & Co. Ltd., Windlesham, United Kingdom; [3]Univ. of Cambridge, Cambridge, United Kingdom

Abstract: Certain recurrent human copy number variants have been associated with a highly increased risk of schizophrenia. A hemizygous deletion of the 22q11.2 region constitutes the strongest discovered genetic risk factor for this disease (odds ratio≈30). The region is well conserved between human and mouse which allows modelling the human 22q11.2 deletion syndrome in mice. We have generated a new mouse model of the 22q11.2 microdeletion syndrome (Df(h22q11)/+). Transcriptional analysis showed an expected 50% reduction in the expression levels of genes within the deleted region of the Df(h22q11)/+ compared to wildtype and confirmed an earlier reported increase in ER membrane protein complex subunit 10 (Emc10) as well as other genes. Df(h22q11)/+ mice were born at a non-Mendelian ratio with about 40%

hemizygous mice. Histological analysis identified no gross abnormalities in brain morphology. Likewise, Df(h22q11)/+ mice had normal basic behavior such as reflexes, thermal pain sensitivity and motor performance. Baseline exploratory behavior, motility and anxiety parameters were also unaltered. However, Df(h22q11)/+ mice displayed increased hyperactivity in response to both ketamine and phencyclidine challenge and, importantly, this hypersensitivity first occurred post puberty. Furthermore, Df(h22q11)/+ mice showed a significantly increased acoustic startle response with shorter response latencies, indicating putative changes in auditory processing. Prepulse inhibition (PPI), a measure of sensorimotor gating commonly disrupted in patients with schizophrenia, was robustly decreased across all ages tested. Finally, Df(h22q11)/+ mice showed a complex cognition phenotype including both trends towards impairments in watermaze and t-maze tests, paralleled with improvements in multiple touch screen based tests. In summary, we have successfully created a mouse model of the human 22q11.2 microdeletion syndrome that recapitulates some of the findings in patients with schizophrenia such as an increased sensitivity to NMDA antagonists and a strong PPI deficit. Further studies on the impact of the deletion on social interaction are currently ongoing.

Title: Brain oscillatory patterns in 22q11.2 transgenic mice model of schizophrenia. Interaction with non-competitive NMDA-R antagonists

Authors: L. LLADÓ-PELFORT, *P. CELADA, F. ARTIGAS
IIBB (CSIC-IDIBAPS), CIBERSAM, Barcelona, Spain

Abstract: Brain oscillations are one of the pillars of neural processing allowing for the coordinated activity of brain regions and the emergence of higher brain functions. Abnormal functional connectivity between brain areas has been hypothesized to explain schizophrenia pathophysiology, which would result in alterations of brain oscillatory patterns [1]. Copy number variants (CNV) provide valuable information about the relationship between genes, brain and behavior. Individuals carrying the 22q11.2 microdeletion display a high incidence of psychiatric symptoms, including schizophrenia [2]. 22q11.2 mice models of the human microdeletion may help to understand the etiology and pathophysiology of schizophrenia, also providing a valuable tool to study new treatment strategies. Non-competitive NMDA receptor (NMDAR) antagonists like phencyclidine (PCP) and ketamine are able to induce psychotic symptoms in healthy individuals and aggravate them in schizophrenic patients. Indeed, NMDAR hypofunction has been proposed as a schizophrenia hypothesis and is routinely used as a pharmacological model of the disease [3]. Here we examined the effects of a 22q11.2 model microdeletion in basal and NMDAR antagonist-induced patterns of oscillatory activity in cortical and subcortical brain networks. We performed local field potential multi-recordings of cortical (prefrontal cortex, PFC) and subcortical brain regions (hippocampal areas and thalamic nuclei) in freely moving wild type (WT) and Df(h22q11)/+ mice (provided by H. Lundbeck A/S) receiving acute saline, PCP or ketamine. Compared to WT mice, Df(h22q11)/+ mice showed an abnormal pattern of brain oscillations, including differences at low and high frequencies in PFC and subcortical areas. PCP and ketamine differentially altered brain oscillations, with PCP showing more marked and persistent effects than ketamine in WT and Df(h22q11)/+ mice. Moreover, the effects of both drugs were significantly different in WT and Df(h22q11)/+ mice, especially in the fast oscillation bands (beta, gamma and high frequency oscillations). The present results indicate the presence of altered baseline and NMDAR antagonist-induced oscillatory patterns in cortical and subcortical areas of Df(h22q11)/+ mice. These abnormalities may underlie the cognitive and behavioral alterations of 22q11.2 deletion carriers and illustrate the usefulness of CNV as intermediate phenotypes to gain insight into the pathophysiology and treatment of schizophrenia.

Title: Gamma rhythms link interneuron dysfunction with cognitive inflexibility in Dlx5/6+/- mice

Authors: *K. K. CHO, R. HOCH, A. T. LEE, T. PATEL, J. L. R. RUBENSTEIN, V. S. SOHAL
Dept. of Psychiatry, UCSF, San Francisco, CA

Abstract: Dysfunction of the prefrontal cortex (PFC) contributes to cognitive deficits that represent the core of schizophrenia. Abnormalities in prefrontal GABAergic interneurons are found in post-mortem brain tissue from individuals with schizophrenia (Lewis et al., 2005), and are particularly prominent within fast-spiking interneurons (FSINs), which can be identified by either their electrophysiological properties or their expression of the calcium-binding protein parvalbumin (PV). FSINs generate synchronized gamma frequency (~30-120 Hz) oscillations that are hypothesized to enhance cortical information processing (Cardin et al,. 2009; Sohal et al., 2009), and deficient gamma oscillations may link interneuron dysfunction to cognitive deficits in schizophrenia (Uhlhaas and Singer 2010). Indeed, task-evoked cortical gamma oscillations are deficient in patients with schizophrenia (Cho et al., 2006). However, studies that disrupt FSIN function in mice have only found increases in baseline gamma oscillations, not deficient cognitive task-evoked gamma oscillations. Thus, the hypothesized link between deficits in interneurons, gamma oscillations, and cognition remains unclear. Specific developmental abnormalities that may contribute to the post-adolescent onset of schizophrenia are also unknown. Here we show that in Dlx5/6+/- mice, which are deficient in transcription factors necessary for FSIN development (Wang et al., 2010), the post-adolescent maturation of FSINs is

impaired. This coincides with the post-adolescent appearance of behavioral, cognitive, and electrophysiological endophenotypes of schizophrenia. Notably, adult Dlx5/6+/- mice exhibit both deficient gamma oscillations during PFC-dependent cognitive tasks and elevated gamma oscillations at baseline, matching the complex pattern of changes observed in schizophrenia, whereas the behavioral, cognitive and electrophysiological properties in adolescent Dlx5/6+/- mice were normal compared to age-matched wild-type controls. These results illustrate how the post-adolescent arrest of FSIN maturation could drive key cognitive and electrophysiologic endophenotypes of schizophrenia.

Title: Dopaminergic responses in shell part of the nucleus accumbens to MK801 administration are disrupted in adult rats after neonatal prefrontal cortex transient inactivation

Authors: T. POUVREAU[1], E. TAGLIABUE[1], S. EYBRARD[1], F. MEYER[2], *A. E. LOUILOT[1]
[1]INSERM U1114- Fac. of Medicine- Uds, Strasbourg, France; [2]Radboud Univ. Nijmegen, Donders Inst. for Brain, Cognition and Behaviour NCMLS, Nijmegen, Netherlands

Abstract: Schizophrenia would result from a defective connectivity, between several integrative regions, stemming from developmental anomalies (Weinberger and Lipska, 1995; Bullmore et al., 1997; Lewis and Levitt, 2002). Various abnormalities reminiscent of early brain development disturbances have been observed, in particular in patients' left prefrontal cortex (PFC) (Akbarian et al., 1993; Kalus et al., 2000). A striatal dopaminergic (DA) disturbance in schizophrenia is generally well accepted (e.g. Harrison, 1999; Carlsson et al., 2001). Non-competitive NMDA/glutamate receptors antagonists, can induce psychotic symptoms in healthy humans and exacerbate these symptoms in patients with schizophrenia (Malhotra et al., 1997; Lahti et al., 1995; 2001). The striatal DAergic dysregulation in schizophrenia may be dependent of prefronto-striatal disconnection involving glutamatergic NMDA receptors (Jentsch et Roth, 1999

; Carlsson et al., 2000 ; Laruelle et al., 2005).Thus, the present study was designed to investigate the effects of the non-competitive NMDA receptor antagonist, MK801, in adult rats on ventral striatal DA responses in the dorsomedial shell, following a postnatal inactivation of the left PFC (infralimbic/prelimbic region).During the neurodevelopmental period, impulse electrical activity appears to be crucial for shaping connections once developing axons reach the target structure (Katz and Shatz, 1996 ; Frostscher et al., 2000). Tetrodotoxin (TTX), is a potent and specific Na+ channel blocker (Mosher, 1986). Therefore, transient functional inactivation of the left PFC was carried out by local TTX microinjection in 8-day-old rats, i.e a critical time of the neurodevelopmental period (Clancy et al., 2001). DA variations were recorded in the dorsomedial shell using *in vivo* voltammetry in freely moving adult rats (11 weeks). Control animals received a s.c. injection of NaCl (0.9%); MK801 was administred s.c. at 0.1 mg/kg or 0.2 mg/kg. The obtained results were the following : 1) A clear dose-dependent decrease in dorsomedial shell DA levels was observed in PBS-microinjected animals whereas dose-dependent DA increase was observed with the two MK801 doses in TTX-microinjected animals; 2) DA changes were significantly different in PBS and TTX groups in adult animals after the administration of the highest MK801 dose. These data suggest that NMDA regulation of DA release in the dorsomedial shell is disrupted in animals microinjected with TTX in the left PFC at PND8. In conclusion, these findings may provide new insights in the involvement of NMDA glutamatergic receptors in the pathophysiology of schizophrenia.

Abstract: The human brain is a complex, dynamic system with computations occurring at several levels of organization, from individual synapses to networks that span multiple brain regions. These large-scale neural systems underlie behavior and cognition. Psychotropic drug administration or neuropsychiatric diseases such as schizophrenia affect behavior by acting on such large-scale neuronal networks. Abnormal synchronization of neural activity between distal brain regions has been proposed as the underlying core symptomatology of schizophrenia. The hippocampal-prefrontal cortex (HPC-PFC) network has been studied extensively in recent years to better understand disconnectivity in a wide range of neurodevelopmental as well as neurodegenerative diseases. Multi-electrode electroencephalographic recordings (EEG) allow monitoring of electrical oscillations generated in distal brain structures involved in the same functional networks. These oscillations and their relationships (i.e. synchrony) are associated with physiological and pathological states of consciousness. The present study analyzes differences in EEG recordings of the PFC and HPC, and synchrony changes in control versus Df(h22q11)/+ mice, carrying a microdeletion on chromosome 16 synteny of del (22q11.2) in humans. To restore this functional connectivity in these mice, we measured the synchronization of neuronal activity between the HPC and the PFC in the presence and absence of clozapine, an atypical antipsychotic with known efficacy in treating symptoms of schizophrenia. We have also administered ketamine non-competitive NMDA receptor antagonist, known to mimic schizophrenia-like symptoms in human studies including memory deficit, to examine the differential response between wild type and Df(h22q11)/+ mice.

Title: Synaptic plasticity dysfunction in a model of psychosis-like behavior

Authors: *M. G. HERNANDEZ, I. RUÍZ-PÉREZ, C. LÓPEZ-RUBALCAVA, E. J. GALVAN
Pharmacobiology, CINVESTAV SUR, Mexico City, Mexico

Abstract: The sub-chronic, neonatal administration of MK-801 is a model that mimics the psychosis-like behavior symptoms of schizophrenia. However, the relationship between synaptic plasticity and the emergence of the behavioral alterations associated to schizophrenia remains unclear. Rats administered with saline or MK-801 (0.2 mg/kg) were behaviorally examined at 30 and 90 postnatal days (PNDs) using the novel object recognition (NOR) test and pre-pulse inhibition (PPI) of the acoustic startle response test. Consistently, MK-801 reduce the NOR and PPI indexes at 90 but not at 30 PNDs (see table). Next, hippocampal slices were prepared from these animals and extracellular recordings were performed on CA1 area to assess for possible changes in paired-pulse facilitation (PPF), long-term depression (LTD) and long-term potentiation (LTP). Pretreated animals had a reduced PPF (ISI 60 ms; PPF control, 1.54 ± 0.08; MK-801 animals, 1.01 ± 0.08; at 90 PND control, 1.71 ± 0.11; MK-801 1.28 ± 0.06). High frequency stimulation (2 trains 100 Hz, 10 sec interval), failed to induce LTP in the pretreated animals (control LTP at 60 min post HFS, 150 ± 4 n=8. In MK-801 animals, 76 ± 21 n=9; at 90 PND control LTP, 169±4, n=9; for MK-801 animals, 71±1 n=9). Conversely, induction of LTD (900 pulses at 1 Hz) was not affected by the MK-801 pretreatment (synaptic depression compared to control at 60 min post LFS, 20.98 ± 5.4 % n= 8. MK-801 animals, 30.6 ± 12.2 n= 9; at 90 PND Control LTD, 36.46 ± 3.48% n=3; MK-801, 32.3 ± 1.9% n=3). These behavioral impairments shows that neonatal administration of MK-801 leads to the onset of memory and sensorimotor deficits at 90 PNDs (young adulthood) but not at 30 PNDs. However, the extracellular recordings revealed alterations in the mechanisms that underlie neurotransmitter release and induction of LTP as early as 30 PNDs. Nevertheless, our data indicate that the cellular mechanisms necessary for induction of LTD are not affected by the neonatal pretreatment with MK-801.

Effects of the sub-chronic administration of MK-801

	30 PNDs	90 PNDs
Behavioral tests(values compared to control):	MK-801	MK-801
NOR	Normal	Decreased

PPI	Normal	Decreased
Electrophysiology(values compared to control)		
PPF ratio	Decreased	Decreased
Long-term Potentiation	Impaired	Impaired
Long-term Depression	OK	OK

Title: Comparing the response of ventral tegmental area and substantia nigra neurons during acquisition and maintenance of a reward-mediated instrumental task

Authors: ***M. A. WEGENER**, B. MOGHADDAM
Ctr. For Neurosci. Univ. of Pittsburgh, Pittsburgh, PA

Abstract: Dopamine neurons have been the focus of many influential theories and proposed mechanisms related to motivated behavior. These mechanisms and theories focus primarily, if not exclusively, on limbic circuitry involving dopamine neurons in the ventral tegmental area (VTA) that project to the nucleus accumbens. However, much of the electrophysiological research into motivated behavior has been performed in the substantia nigra pars compacta (SNc) of primates. While both VTA and SNc contain dopamine neurons, each region has distinct afferent and efferent projections and is implicated in different aspects of motivated behavior and cognition. Here we aimed to directly compare the response pattern of VTA and SNc neurons

during reward-related behavior. Adult rats were bilaterally implanted with microelectrode arrays to conduct single-unit recordings in the VTA and SNc of adult rats during acquisition and maintenance of a reward-mediated instrumental learning task. Rats learned to execute a naturalistic nose poke during presentation of a cue to receive a single sugar pellet. During task learning, we observed phasic responses to unexpected reward in both the VTA and SNc, and cue-evoked activity developed gradually over multiple sessions. Reward-related activity persisted strongly in the SNc throughout task performance, and still was prominent in the final session. In ongoing analyses, we will further examine the comparison of VTA and SNc single-unit responses to task-related events, isolate and compare putative dopamine and non-dopamine neurons and investigate how these regions respond to the extinction of this reward-mediated behavior.

Title: Rescue of the trafficking deficient schizophrenia associated KCNH2 splice variant hERG 3.1 for the purpose of drug discovery

Authors: N. E. CALCATERRA[1], *J. C. BARROW[2]
[1]Pharmacol., Johns Hopkins Sch. of Med., Baltimore, MD; [2]Lieber Inst. for Brain Develop., Johns Hopkins Univ., Baltimore, MD

Abstract: Cultivated from advances in GWAS studies, numerous exciting schizophrenia drug targets have recently been discovered, including a novel KCNH2 splice variant, KCNH2 3.1. This gene translates to an N-truncated hERG channel with fast deactivation kinetics, Kv11.1-3.1. However, preliminary efforts to develop a cell line amenable to automated patch clamp platform for drug discovery have been difficult due to low assay signal and expression inconsistency. A robust system is needed for comparison to the full-length cardiac IKr channel, Kv11.1-1A, which will be an important counterscreen to avoid off target effects on the heart. It has been suggested that the truncation of 102 amino acids seen in Kv11.1-3.1 leaves the resulting protein product

without an intact Per-Ant-Sim (PAS) domain, found to be critical in Kv11.1-1A stability, trafficking, and regulation of deactivation rate. Mutations and deletions in this domain have been well characterized; similar characterizations of poor trafficking, stability, and fast deactivation rates have been suggested of KCNH2-3.1. Here we examine the trafficking characteristics by biochemical, electrophysiological, and imaging methods compared to the full transcript. Kv11.1-3.1 shows increased colocalization to the endoplasmic reticulum (ER), decreased colocalization to the plasma membrane, and diminished current. Trafficking of the protein responds differentially to a variety of literature rescue methods. Optimization of these rescue methods has resulted in transfection/expression protocol amenable to testing inhibitors for potency and selectivity. Kv11.1-3.1 is a promising drug target, now with tools in place for drug screening.

Title: Correlating ventral hippocampal lesion volume with working memory performance in an animal model of schizophrenia

Authors: *T. BADIUDEEN, J. M. HYMAN, J. K. SEAMANS
Psychiatry, Univ. of British Columbia, Vancouver, BC, Canada

Abstract: The neonatal ventral hippocampal lesion (NVHL) model is the most well-characterized neurodevelopmental animal model of the cognitive deficits in schizophrenia. Reminiscent of the cognitive deficits seen in human patients, NVHL animals display marked impairments in cognitive flexibility and working memory. However, inherent to any lesion model, there is notable variability in the size and extent of lesions across individual animals. To the best of our knowledge, no study has analyzed the impact of variability in NVHL lesion size on adult performance of cognitive paradigms assessing working memory. One possibility is that cognitive deficits are produced by lesions of a given size and larger lesions have little additional impact. Alternatively, the cognitive deficit could be a linear or non-linear function of lesion size. To test these possibilities, NVHL and sham operated rats were trained on a delayed non-match to

sample (DNMS) task in a T-maze as adults. Following training, magnetic resonance imaging (MRI), was performed on all animals. Consistent with the current literature, NVHL animals showed a significant deficit in task performance when compared to sham operated animals, at a 10 second delay. We also found an impressive inverse linear correlation between the size (measured in cubic mm) of the lesion and working memory performance (percentage of correct trials), as performance on the DNMS task decreased linearly with increased lesion size. Lesion size was able to account for 49% of the total variability in working memory performance across animals.

Title: Impaired generation of high frequency oscillations in a rat model of schizophrenia

Authors: L. R. HARMS[1,5], D. M. HODGSON[1], W. R. FULHAM[2], A. S. W. WONG[3], M. PENTTONEN[6], U. SCHALL[2,5], J. TODD[4,5], *P. T. MICHIE[3,5]

Abstract: Persons with schizophrenia exhibit an impaired capacity to generate high-frequency gamma (>30Hz) oscillations. Gamma oscillations play an integral role in cognition and their reduction in schizophrenia is a candidate neurophysiological mechanism underlying cognitive impairments. The aim of this study was to establish an animal model with which to explore the neurobiological and behavioural implications of disrupted gamma oscillations. Here we used a well-accepted developmental animal model of schizophrenia, the maternal immune activation

(MIA) model. MIA was induced in Wistar rats by administering pregnant rats with Poly (I:C), a viral mimic, at gestational day 19. The offspring grew to adulthood, when they underwent surgery to implant EEG electrodes. A wireless telemetric headstage was fixed to the rat's head and the EEG recorded from multiple sites while rats were exposed to auditory steady-state white noise clicks, presented at a range of frequencies (10-50Hz). Recordings were made from three separate drug-free sessions, then rats were administered MK-801, an NMDAR antagonist, over three separate sessions at escalating doses (0.1, 0.3, 0.5mg/kg). Oscillatory power and inter-trial coherence were extracted for each stimulus frequency. Auditory steady-state responses (aSSRs) were elicited to all frequencies of auditory stimulation, but the strongest responses were observed to 50Hz stimulation over frontal sites. MK-801 dose-dependently reduced aSSR oscillatory power of high-frequency (>30Hz) aSSRs. Rats exposed to MIA exhibited a reduction in frontal 50Hz aSSRs, similar to that seen in control rats exposed to a low dose (0.1mg/kg) of MK-801. MIA in rats altered the trajectory of brain development, affecting systems responsible for the generation of high-frequency gamma oscillations. MK-801, a NMDAR antagonist that also indirectly impairs inhibitory neurotransmission also was found to reduce 50Hz oscillatory activity, perhaps indicating that both MK-801 and MIA are affecting similar neurobiological pathways. Further experiments will focus on the cognitive and neurobiological correlates of MIA-associated reductions in gamma oscillations, with the ultimate goal of furthering our understanding of the neurobiology of cognitive impairments in schizophrenia.

Title: Investigation of schizophrenia-related behavioural phenotypes following early versus late gestation maternal immune activation in a rat model

Authors: *C. L. MEEHAN[1], J. FROST[1], L. R. HARMS[1], D. M. HODGSON[1], U. SCHALL[2], J. TODD[1], K. ZAVITSANOU[3], C. SHANNON-WEICKERT[3], P. MICHIE[1]

[1]Univ. of Newcastle, Sch. of Psychology, [2]Sch. of Med. and Publ. Hlth., Univ. of Newcastle, Callaghan, Australia; [3]Sch. of Psychiatry, Univ. of New South Wales, Sydney, Australia

Abstract: Maternal immune activation (MIA) during gestation has been identified as a risk factor for schizophrenia. Evidence from a mouse model suggested that MIA in late gestation promoted schizophrenia-related cognitive dysfunction and altered NMDA receptor expression, whereas activation during early gestation was associated with changes in behaviours related to dopamine neurotransmission. The current study aimed to determine whether MIA in rats results in a reliable model of schizophrenia, and if MIA during different stages of gestation preferentially alters either dopaminergic or NMDA-related neurotransmission as observed in the mouse model. Wistar rats were administered with either 4.0mg/kg of PolyI:C or saline on either gestational day 10 (early) or 19 (late). Prepulse inhibition (PPI) of the acoustic startle response, working memory on an operant delayed non-match to position task and locomotion in response to MK-801 and amphetamine were examined in male and female adult offspring. Female rats exposed to MIA during late gestation had impaired working memory, exhibiting a reduction in the proportion of correct responses in comparison to controls in a one second delayed non-match to position task ($p = .01$). A similar trend was also seen in late gestation males, however this difference was not significant. No differences were seen at longer delays indicating that deficits in working memory are not delay-dependent. MIA during early or late gestation did not produce observable effects on MK-801- and amphetamine-induced locomotion, nor did it affect PPI of the acoustic startle response. The lack of any significant changes in the dopamine related behaviours of PPI and amphetamine-induced locomotion indicate that this rat model of MIA does not replicate the perturbed dopaminergic phenotype previously seen in the mouse model, and other rat models in which MIA was induced at different developmental time-points. Therefore, a later gestational time-point may be needed to induce changes in dopamine-related behaviours. The presence of non-delay dependent working memory deficits suggests that MIA in late gestation, in females more so than males, produces a model of schizophrenia-related cognitive impairments.

Title: Altered cortical neuronal avalanches in a rat model of schizophrenia

Authors: *S. SESHADRI, D. PLENZ
NIMH, Bethesda, MD

Abstract: Schizophrenia (SZ) is a psychiatric disorder whose pathophysiology is thought to involve impaired cortical balance of excitation and inhibition (E/I), as well as altered dopaminergic signaling, which may underlie cognitive symptoms such as working memory deficits. The resting state activity of cortex in humans, non-human primates, and rodents has been shown to be composed of neuronal avalanches, i.e. spontaneous spatiotemporal cascades of synchronized activity that exhibit a precise organization, described by power laws. This suggests that resting state dynamics of cortex are critical, which theory and experiment indicate is beneficial for information processing. Avalanche dynamics are highly sensitive to the E/I balance and exhibit an inverted U-shaped profile of dopaminergic dependency similar to that identified for working memory function. We therefore hypothesized that network-level disturbances in SZ may correlate with deviations from neuronal avalanche dynamics. To address this, we used the neonatal phencyclidine (PCP) model of SZ. Rat pups were injected with PCP (s.c., 10 mg/kg) at postnatal day 7, 9, and 11, and subjected to behavioral testing at 4-6 weeks. In confirmatory behavioral tests, PCP-treated rats showed hyperlocomotion in response to a PCP challenge and impairment in novel object recognition. Avalanches were first studied at the population level by recording the local field potential in layer 2/3 (L2/3) of frontal cortex of adult rats under anesthesia (1.5% isoflurane) using microelectrode arrays (MEAs, 8x4 electrodes, NeuroNexus). Ongoing LFP activity deviated from criticality, exhibiting dynamics consistent with a supercritical regime of propagation in neonatal PCP treated rats (kappa, PCP: 1.150, control: 0.934, $p=0.030$; sigma, PCP: 1.769, control: 0.825, $p=0.038$; N=7 rats). We plan to extend these results in awake, behaving rats by chronically implanting MEAs into L2/3 of cortex, and recording LFP at rest and during visual and spatial working memory tasks. Deviations in avalanche dynamics will be assessed in different phases of the task (e.g. habituation, delay, test) and correlated with performance. We found that neonatal PCP-treated rats display behavioral deficits and abnormal neuronal avalanche dynamics. These results suggest that studying disruption of neuronal avalanches in disease states may be a translatable tool for psychiatric disorders.

Title: The effects of the maternal immune activation and MK-801 models of schizophrenia on mismatch negativity-like responses in awake, freely-moving rats

Authors: *L. R. HARMS[1], D. M. HODGSON[1], W. R. FULHAM[1], M. PENTTONEN[2], U. SCHALL[1], J. TODD[1], P. T. MICHIE[1]
[1]The Univ. of Newcastle, Callaghan, Australia; [2]Univ. of Jyväskylä, Jyväskylä, Finland

Abstract: Reductions in the amplitude of mismatch negativity (MMN) to rare, unexpected (deviant) auditory stimuli are one of the most robust neurophysiological changes observed in patients with schizophrenia and are thought to be critically dependent on glutamate n-methyl-d-aspartate receptor (NMDAR) function. In this study, we aim to establish a rat model of schizophrenia-related MMN impairments by using a novel rodent EEG recording system to assess MMN in rats exposed to pharmacological (MK-801, an NMDAR antagonist) and developmental (Maternal Immune Activation, MIA) interventions known to model schizophrenia. Pregnant rats were administered the viral mimic Poly (I:C) (4mg/kg) or saline at gestational day (GD) 19. In adulthood, stainless steel screw electrodes were surgically implanted over five cortical locations in MIA and control offspring (n=7-10). After recovery, a wireless transmitter was attached to the recording electrodes and EEG was recorded while the rats were exposed to two oddball sequences (either a high- or low-frequency deviant), and a control sequence of randomly-intermixed frequencies that controlled for adaptation. Rats were tested on each sequence during three 'baseline' (drug-free) sessions, then tested on three successive sessions after progressively escalating doses of the NMDAR antagonist MK-801 (0.1, 0.3 and 0.5mg/kg), each dose separated by at least 4 days. Five components of the auditory event-related potential (ERP) were identified: two early positive components, (P13, P30), an early negative component (N18), and two later broad negative peaks (N-shift1, N-shift2). Adaptation-independent deviance-detection was observed in control rats for high frequency, but not low frequency deviants on both early and late ERP components. MK-801 dose-dependently increased adaptation-independent deviance detection on early components, but reduced deviance detection for N-shift1. MIA increased deviance detection on early components as well, but did not reduce deviance detection on N-shift1. These findings indicate we have established a reliable rat model

of MMN, evident in the late negative peak, N-shift1, which exhibits sensitivity to reduction by NMDAR antagonists as human MMN does. However, we have also identified an unexpected increase in deviance detection in early ERP components in response to both MIA and the NMDAR antagonist. These findings suggest that the neurobiological underpinnings of deviance detection may not be conserved from early to late stages of auditory processing.

Title: Contribution of a novel neuronal inhibitor to the cellular and behavioral deficits observed in a mouse model of 22q11.2 microdeletion-related schizophrenia

Authors: *A. DIAMANTOPOULOU[1], B. XU[1], Z. SUN[1], K. FÉNELON[2], M. KARAYIORGOU[1], J. A. GOGOS[1]
[1]Columbia Univ., New York, NY; [2]Univ. of Texas at El Paso, El Paso, TX

Abstract: Adult Df(16)A+/− mice, a model of 22q11.2 microdeletion associated SCZ, show significant behavioral and cognitive deficits, especially in prepulse inhibition (PPI), working memory (WM) and fear conditioning tasks, accompanied with abnormalities in dendritic morphogenesis and formation of dendritic spines of hippocampal and cortical pyramidal neurons. Such abnormalities can be linked to aberrant processing of brain microRNAs (miRNAs), a result of the 22q11.2 microdeletion. Recently, Mirta22, a previously uncharacterized gene, was identified as a major miRNA target mediating the effects of the 22q11.2 microdeletion on neuronal maturation and connectivity. Elevated Mirta22 levels found in brains of Df(16)A+/− mice have been shown to inhibit dendritic and spine development in Df(16)A+/− neurons, both *in vitro* and *in vivo*, whereas reduction of abnormally increased Mirta22 levels restores structural abnormalities in the HPC of Df(16)A+/− mice. We hypothesized that such restoration would

impact behavior, leading, at least, to partial rescue of behavioral abnormalities. For that reason, we generated a Df(16)A+/-; Mirta22 +/- compound heterozygote (HET) strain. Reduction of the dosage of the Mirta22 gene by half, to almost WT levels, in the compound HET strain will be used to evaluate the contribution of this miRNA target to the behavioral phenotypes induced by the 22q11.2 deletion. Indeed, Df(16)A+/-;Mirta22+/- mice show significantly increased PPI levels, when compared to their Df(16)A+/- littermates, which reach the level of WTs, while the Df(16)A+/- PPI deficit was consistently reproduced. Normalizing Mirta22 levels in Df(16)A+/-;Mirta22+/- was sufficient to significantly increase working memory performance in a T-maze task, in which Df(16)A+/- mice have a prominent impairment. This result suggests that at least some of behavioral deficits observed in Df(16)A+/- mice can be attributed to the inhibitory influence of Mirta22 upregulation and that Mirta22 gene is a key regulator of the brain circuitry that controls PPI and WM. Also it points out that restoring normal Mirta22 levels in the brains of Df(16)A+/- mice can prevent structural changes governed by Mirta22 overexpression which would result in local and long-distance disruptions of neuronal communication. In fact, behavioral phenotyping of Mirta22-/- mice, revealed significant deficits in various domains, ranging from abnormal novelty exploration, startle reactivity and diminished anxiety to substantial increase in fear memory, compared to WT, advocating for a significant biological role of the Mirta22 protein in regulating appropriate behavioral responses.

Title: Striatonigral contribution to individual variability in susceptibility to chronic haloperidol-induced vacuous chewing movements

Authors: *S. E. BACHUS[1], C. BLANCHARD[2]
[1]Psychology, [2]George Mason Univ., Fairfax, VA

Abstract: We have previously found that the elevation of striatal enkephalin mRNA by chronic haloperidol, in rats, is not significantly correlated, across individuals, with variability in emergence of vacuous chewing movements (VCM) (Blanchard & Bachus, SfN Abstr. 2011), a

model for tardive dyskinesia. Here, the possibility that the "direct" striatonigral pathway might be involved in the induction of vacuous chewing movements was evaluated by exploration of striatal D1 receptor and dynorphin (DYN) mRNA levels in this same cohort. Group housed male Long-Evans rats, with starting body weights of 90-165g, were treated for 24 weeks with HAL (28.5mg/kg/ml, i.m.: n=43) or vehicle (sesame oil: n=21) injections every 3 weeks. VCM were counted for each rat for 2 minutes weekly, for 7 weeks prior to HAL treatment and then throughout HAL treatment, by observers blinded to treatment group. Over the final 2 weeks, 4 samples were rated under both quiet (only ambient air-conditioning) and noisy (constant loud music and key-rattling) conditions. Cryostat-cut sections from fresh-frozen brains, containing neostriatum and nucleus accumbens, were then assayed by *in situ* hybridization histochemistry with oligonucleotide probes complementary to D1 or preprodynorphin mRNA, or a mis-sense control probe. Neither D1 nor DYN mRNA in any striatal region was significantly altered by chronic haloperidol. Nor were D1 and DYN mRNA levels significantly correlated with each other, in either the controls or the haloperidol-treated rats. D1 mRNA was not significantly correlated with VCM under either quiet or noisy conditions. In contrast, DYN mRNA was significantly positively correlated with VCM under noisy conditions, though not under quiet conditions, in all neostriatal regions and nucleus accumbens, in the haloperidol-treated rats. DYN mRNA was also significantly positively correlated with previously measured nigral GAD67 mRNA in this cohort, in the haloperidol-treated rats, but not in vehicle controls. Conversely, significant positive correlations between striatal DYN mRNA and previously measured paraventricular hypothalamic CRF mRNA and nigral D2 dopamine receptor mRNA, in controls, were abolished in haloperidol-treated rats. These results add to evidence suggesting that differential effects on striatonigral neurons, secondary to striatal D2 receptor upregulation by chronic haloperidol, may play a role in the determination of individual vulnerability to the development of vacuous chewing movements, and, by analogy, tardive dyskinesia.

Title: 15q13 microdeletion syndrome - characterization of homozygous knockout mice

Authors: *A. FORSINGDAL[1,2], J. NIELSEN[1]
[1]H. Lundbeck A/S, Valby, Denmark; [2]Neurosci. and Pharmacol., Univ. of Copenhagen, Copenhagen, Denmark

Abstract: Genome wide association studies have revealed that certain copy number variants (CNVs) strongly increase the risk of schizophrenia and other psychiatric diseases. One such CNV is a 1.5 MB long hemizygous deletion located in the 15q13.3 region. Hemizygous 15q13 microdeletion increases the risk of schizophrenia, epilepsy and autism by several fold (Ben-Shachar et al., 2009). A mouse model of the human 15q13 hemizygous microdeletion has recently been generated by deleting the homologous genes on the mouse chromosome 7. Characterization of the model identified disease-related phenotypes (Fejgin et al., 2013). However, the phenotypes observed in the hemizygous mouse model are relatively subtle. Subtle alterations are not unexpected in the hemizygous model as the penetrance is also variable in human hemizygous deletion carriers (Ben-Shachar et al., 2009). Human cases of homozygous microdeletion carriers have also been reported, all with severe impairments (Hoppman-Chaney et al., 2013). These patients suffer from seizures, severe mental retardation, major motor symptoms, hypotonia, developmental delay and other deficits. The present study is a basic characterization of 15q13 homozygous knockout mice. The first tests show that these mice recapitulate some of the phenotypes seen in the human homozygous deletion carriers, namely hypotonia and decreased size, but they do not appear to be as strongly impaired as the human cases. Further characterization of the 15q13 homozygous knockout mice is ongoing. **References** Ben-Shachar S et al. Title: Human iPSC glial mouse chimeras reveal glial contributions to schizophrenia

Authors: J. MUNIR[1], J. BATES[1], S. SCHANZ[1], S. WANG[1], *M. S. WINDREM[1], R. FINDLING[2], P. TESAR[3], S. A. GOLDMAN[1]
[1]Ctr. for Translational Neuromedicine and Dept. of Neurol., Univ. of Rochester Med. Ctr., ROCHESTER, NY; [2]Div. of Child & Adolescent Psychiatry, Johns Hopkins, Baltimore, MD; [3]Genet., Case Western Reserve Univ., Cleveland, OH

Abstract: Recent genetic and neuroradiological studies have suggested a role for glia, and oligodendrocytes in particular, in the pathogenesis of schizophrenia. To assess the potential role of glia in the ontogeny of schizophrenia, we established human glial chimeric mice using glial progenitor cells produced from iPSC cells derived from patients with juvenile onset schizophrenia, or from their age- and gender-matched controls. We did so by neonatally implanting donor iPSC GPCs, derived from schizophrenic patients or their normal controls, into either normally-myelinated immunodeficient rag1-/- hosts, in which implanted GPCs remain as progenitors or become astrocytes, or into hypomyelinated and immune deficient shiverer mutant MBPshi/shi x rag1-/- mice, in which the donor GPCs also develop as myelinating oligodendrocytes. We found that by 18 weeks of age, the schizophrenic patient-derived iPSC GPCs exhibited less white matter engraftment than their matched controls, migrating prematurely and aberrantly into the overlying cortical gray matter. These schizophrenia-derived iPSC GPCs were also more proliferative, as measured by both Ki67 and BrdU. Although individual schizophrenia-derived hiPSC GPCs differentiated as normal myelinogenic oligodendroglia within the callosum and capsules, the excessive cortical influx and hence lower density of GPCs in the white matter of schizophrenic hiPSC GPC-engrafted mice, resulted in the latter's overt hypomyelination, relative to mice engrafted with control-derived hiPSC GPCs. Remarkably, we also noted that when schizophrenia-derived hiPSC GPCs were neonatally transplanted into normally-myelinated mice, yielding GPC and astrocytic chimerization of the recipient brains, that the resultant glial chimeric mice manifested overtly abnormal behavioral phenotypes relative to control-engrafted mice. The mice engrafted with schizophrenic-derived hiPSC GPCs exhibited diminished prepulse inhibition, and when evaluated at 8 months, higher anxiety in the elevated plus maze, less interest in stranger mice in the 3-chamber social test, and

socially avoidant behavior in free interaction with a stranger mouse, all as analyzed by ICY software. These data suggest a significant contribution of cell-autonomous glial pathology to the genesis and development of juvenile-onset schizophrenia.

Title: Regulation of BDNF exocytosis and GABAergic interneuron synapse by the schizophrenia susceptibility gene, dysbindin-1

Authors: *H. S. JE[1], Y. QIANG[2], N. HUSAIN[2], Y. XIAO[2], W. HAN[3]
[1]Program In Neurosci. and Behavioral Disorders, Singapore, Singapore; [2]Duke-NUS GMS, Singapore, Singapore; [3]SBIC, Singapore, Singapore

Abstract: Genetic variations in the dystrobrevin binding protein 1 (DTNBP1, dysbindin-1) have been implicated as risk factors in the pathogenesis of schizophrenia. The encoded protein, dysbindin-1, functions in the regulation of synaptic activity and synapse development. Intriguingly, a loss of functional mutation in dysbindin-1 in mice disrupted both glutamatergic and GABAergic transmission in cerebral cortex- cortical pyramidal neurons showed enhanced excitability due to reduction of inhibitory synaptic inputs and inhibitory neurons. However, the underlying mechanism of inhibitory synaptic deficits due to reduced dysbindin-1 remains unknown. In this study, we identified the unexpected role of dysbindin-1 in the exocytosis of brain-derived neurotrophic factor (BDNF) from excitatory pyramidal neurons. And this reduction of BDNF exocytosis in excitatory neurons trans-synaptically reduced the number of inhibitory synapses formed on excitatory neurons. Furthermore, exogenous BDNF rescued inhibitory synaptic deficits due to reduced dysbindin-1 in cultured neurons and *ex vivo* cortical slices. Taken together, our result demonstrates that the two, well-known schizophrenia

susceptibility gene products (BDNF and dysbindin-1) function together at the protein level to regulate interneuron development and cortical network activity. Furthermore, our results provide considerable insight into the cellular and molecular mechanisms that regulate the development of the neural circuitry in the brain, and to link abnormalities in BDNF secretion to cognitive disease.

Abstract: We find increased cellular autofluorescence (AF) in lymphoblasts from patients with schizophrenia (SZ), compared to those from matched controls. In addition, two animal models relevant for mental disease, EAAC1 knockout and dominant-negative DISC1 transgenic mice, reveal elevated AF (see the abstract by Tsuyoshi Tsujimura et al, SFN 2014). In the present study, we explore a possible mechanism that underlies this cellular phenotype. To address this question, we tested compounds that may correct AF in SZ cells. Among several tested, a novel compound that selectively interfered with the GAPDH-Siah1 binding was effective in attenuating increased AF in SZ. Based on the emission wavelength of AF elevated in SZ cells, we hypothesized that lipofuscin mediates the AF. To address this question, we examined lymphoblasts from SZ patients and those from normal controls in a comparative manner with

electron microscopy (EM), and observed lipofuscin-like accumulation in lysosomes of SZ cells but not control cells. Given that GAPDH is reportedly a protein component of lipofuscin, we are currently testing immuno-EM with an anti-GAPDH antibody to validate a specific accumulation of GAPDH in lysosomes of SZ cells. The final question we are now addressing is the biological function of lysosomal GAPDH in the pathophysiology of SZ.

Title: Age-dependent decrease in Parvalbumin interneuron density and in inhibitory transmission in hippocampal area CA2 in the 22q11.2 mouse model of schizophrenia

Authors: *V. CHEVALEYRE[1], R. A. PISKOROWSKI[1], J. MUKAI[2], S. A. SIEGELBAUM[2], J. A. GOGOS[2]
[1]Univ. Paris Descartes, CNRS8118, Paris, France; [2]Neurosci., Columbia Univ., New York, NY

Abstract: An imbalance between excitation and inhibition is observed in several pathologies. More specifically, a reduction in interneuron number has been observed in area CA2 in the hippocampi of schizophrenic patients in post-mortem studies. Our previous work has demonstrated that inhibition in area CA2 of the hippocampus can act as a gate to control the ability of CA3 to excite CA2 neurons, and thus alter information flow. Motivated by findings in human tissue, we asked whether inhibition in area CA2 might also be affected in a mouse model of schizophrenia. The highest known factor for developing schizophrenia is the 22q11 deletion syndrome. The mouse model of the 22q11 deletion syndrome, the Df(16)A+/- mice, recapitulate many of the behavioral deficits and neuroanatomical changes observed in 22q11 deletion carriers. We found that the Df(16)A+/- mice have fewer Parvalbumin (PV) expressing interneurons in CA2, with no differences found in areas CA1 and CA3. In addition, inhibitory transmission in CA2 recruited by CA3 inputs was decreased while excitatory transmission from

cortical inputs and from CA3 was not altered. Interestingly, similar to disease onset in humans, these differences did not manifest until the mice were between 8 and 12 weeks old. Furthermore, CA2 pyramidal cells of Df(16)A+/- were more hyperpolarized and had a lower membrane resistance. As a consequence, CA2 pyramidal cells in Df(16)A+/- mice displayed fewer action potentials in response to CA3 or cortical input stimulation. Finally, the decrease in inhibition in Df(16)A+/- mice impaired the activity-dependent increase in the excitatory drive between CA3 and CA2 resulting from a long-term depression of PV inhibitory synapses in CA2. These results indicate that both information transfer and synaptic plasticity are altered in Df(16)A+/- mice. Thus, this mouse line is a promising model for examining the cellular mechanisms underlying the changes occurring in the hippocampus during the onset of schizophrenia in humans.

Sch. of Med., New Haven, CT; [4]Cardiovasc. Res. Ctr. and Mandel Ctr. for Hypertension and Atherosclerosis Res., Duke Univ. Med. Ctr., Duham, NC

Abstract: Major depressive disorder (MDD), bipolar disorder (BD), and schizophrenia together affect over twenty million American adults in a given year. Matrix metalloproteinases (MMP's) are a family of zinc-dependent protease enzymes that degrade extracellular matrix proteins and process bioactive molecules into mature forms. Of these MMP's, MMP-9 is one of the most abundant in the brain and is involved in synaptic plasticity and long term potentiation, modulation of network connectivity, neurogenesis, and neurite growth. Furthermore MMP-9

transcription is induced by growth factors and cytokines during events that require plasticity and remodeling. The aim of the present study was to determine the effects of a highly selective and potent inhibitor of MMP-9, Compound A, in rodent models of various psychiatric illnesses. Compound A attenuated urine sniffing and escape deficits in the learned helplessness model in rats, decreased immobility time in the tail suspension test in a lipopolysaccharide (LPS)-induced model of depression, partially reversed amphetamine-disruption of prepulse inhibition, attenuated morphine-induced hyperactivity, and attenuated naloxone-induced dysphoria as measured by conditioned place aversion and escape jumping. Furthermore, preliminary data from an angiogenesis protein array and microarray showed that Compound A blunted the increases in Il-10, GM-CSF, PDGF-AA, Fractalkine, MIP-1a, and Il-1a in plasma caused by LPS as well as attenuated several transcriptional responses to LPS in frontal cortex. Hence, the data suggest that Compound A exerts its antidepressant-like, antipsychotic-like, and mood-stabilizing effects in animal models through its anti-inflammatory actions or effects on plasticity in the CNS. These data highlight MMP-9 inhibitors as a class of possible therapeutic targets.

Title: Prefrontal cortex and dopamine single neuron spike rates and LFP phase represent time over distinct scales

Authors: *B. MOGHADDAM[1], N. K. B. TOTAH[2]
[1]Univ. Pittsburgh, Pittsburgh, PA; [2]Physiol. of Cognitive Processes, Max Planck Inst. for Biol. Cybernetics, Tübingen, Germany

Abstract: Expectations are generated on multiple timescales. During behavioral planning and working memory utilization, expectations are constructed on the multi-second level (sec), whereas expectations can be externally guided at the sub-second level by rhythmic stimuli (msec). Estimation of multi-second intervals has been associated with monotonic, "climbing" changes in neuron spike rate. On the other hand, sub-second expectations have been associated with rhythmic fluctuations of neuronal excitability in relation to phase of mesoscopic signals. It is not known if changes in gradual spike rate and phase-modulation of neuronal excitability co-occur during multi-second expectations. We studied this question by measuring spike rate, across-trial phase consistency, and phase locked modulations of excitation during a multi-second stimulus expectation task. We recorded single unit spiking and local field potentials from 3 rodent brain regions that have been implicated in time interval estimation, as well as in expectancy and behavioral planning: the prefrontal cortex (PFC), the anterior cingulate cortex (ACC), and the dopamine-producing ventral tegmental area (VTA). A stimulus-evoked phase reset in the PFC, ACC and VTA was observed, which may allow adaptive coding by these neurons and underlie their necessity for behavioral flexibility. In contrast, intrinsic across-trial phase consistency was not observed and phase modulations of excitation did not change in a climbing pattern. These data suggest that expectation over multi-second time intervals is better represented by climbing activity of single dopamine and PFC neurons as compared to mesoscopic signal phase.

Title: Nicotine, even at low doses, suppresses body weight gain independent of food intake

Authors: *L. RUPPRECHT, T. T. SMITH, R. L. SCHASSBURGER, D. M. BUFFALARI, E. C. DONNY, A. F. SVED
Univ. of Pittsburgh, Pittsburgh, PA

Abstract: The ability of nicotine (NIC) to suppress food intake and body weight (BW) is cited as a factor impacting smoking initiation and the failure to quit. Smokers have reduced food intake, but it is unknown whether NIC reduces BW when food intake is constant and restricted. Furthermore, the FDA is considering a policy of markedly reducing the allowable NIC levels in cigarettes; such a reduction could have a detrimental effect on BW. To model new smokers of reduced NIC content cigarettes, we assessed the effects of a range of self-administered (SA) doses of NIC on BW gain in food-restricted rats. Adult rats restricted to 20 g chow/day SA intravenous infusions of NIC (0, 3.75, 7.5, 15, or 60 μg/kg) in daily 1-h sessions. After 20 days, NIC dose-dependently suppressed BW. A low dose of NIC (3.75 μg/kg/infusion) that results in relatively little daily intake of nicotine suppressed BW compared to saline. We modeled NIC reduction in current smokers in a separate group of food-restricted rats that SA 60 μg/kg/infusion NIC before immediate reduction (1.875 or 3.75 μg/kg/infusion) or a gradual stepped dose reduction (dose halved every 10 days to 1.875 μg/kg/infusion). Both immediate and gradual reductions resulted in BW significantly greater than constant 60 μg/kg NIC. Reduction of NIC in cigarettes to a dose that will not maintain smoking will likely cause significant weight gain in current smokers. However, in new smokers low NIC levels may still restrict BW, possibly motivating continued use and maintaining exposure to other harmful chemicals in cigarettes.

Title: Self-administration of cigarette smoke extract vs. nicotine alone in adolescent and adult male rats

Authors: *C. GELLNER, H. R. SMITH, S. L. DO, P. KAUR, S. SALSABILIAN, J. M. L. DEGUZMAN, J. D. BELLUZZI, F. M. LESLIE
Pharmacol., Univ. of California, Irvine, Irvine, CA

Abstract: To challenge the current animal model of using nicotine alone to study tobacco dependence, we have established a model of intravenous self-administration of cigarette smoke extract (CSE). Previous research in our lab has shown that adult male rats will not only self-administer CSE but that they find it more reinforcing than nicotine alone at the 7.5µg/kg per infusion dose. We now test the hypothesis that CSE will be even more reinforcing in adolescence, the age at which most humans initiate tobacco use. Adolescent male rats (aged postnatal day 25, P25) and adults (P85) were trained to work for food pellets on an FR1TO20 schedule (1 pellet/ lever press, time out 20 seconds). After rats reached the reinforced lever press threshold (R=35 and 50 for adolescents and adults, respectively), they underwent surgery in which a catheter was implanted into the right jugular vein. After three days recovery, rats (P37 and P97) underwent three progressively harder schedules of lever pressing: FR1TO20, FR2TO20, and FR5TO20 for one of 5 doses of CSE or nicotine (Nic) (0, 3.75, 7.5, 15, or 30 µg/kg per infusion). The results show that both adolescent and adult male rats will self-administer CSE and Nic at all test doses. Preliminary results also suggest that there are no differences in responding for CSE and Nic at either age, but that adolescents show a dose-related increase in drug intake as well as a dose-related increase in non-reinforced responding. . These findings suggest that age and dose are important factors in tobacco dependence models.

Title: Rats that self-administer cigarette smoke extract are more sensitive to drug-induced relapse

Authors: *D. REYNAGA, J. BELLUZZI, F. LESLIE
Univ. of California Irvine, Irvine, CA

Abstract: Tobacco dependence is extremely difficult to treat and the vast majority of those who try to quit will relapse within the first year. The most effective pharmacological treatment for smoking cessation is varenicline, an α4β2 nicotinic receptor antagonist. However, only 23% of subjects treated with varenicline maintain abstinence for over a year. Although improvements in experimental models may result in better smoking cessation treatments, current preclinical tests largely use nicotine alone, ignoring the other ~8000 constituents also found in tobacco smoke. We have recently shown that rats which self-administer aqueous cigarette smoke extract (CSE), a solution of saline containing nicotine and other non-nicotine constituents, are more sensitive to stress-induced relapse to drug-seeking behavior than those that worked for nicotine alone (Costello et al., 2014). We have now examined whether rats that self-administered CSE are also more sensitive to drug-induced relapse. Adult male Sprague-Dawley rats were allowed to self-administer nicotine (15 µg/kg/inf) or CSE (15µg/kg/inf of nicotine content) under a fixed FR5 ratio for a minimum of 10 days or until self-administration was stabilized (reinforced responses (R) within 20% of the mean over 3 days; $R \geq 2 \times$ non-reinforced (NR) responses; $R \geq 6$). Animals then began extinction training, where drug and cues were removed, for a minimum of 5 days or until reinforced responding was reduced to 20% or less of that of the last day of drug self-administration. Animals were then tested for reinstatement of responding using the following conditions in a counterbalanced design: cues alone, a priming dose of nicotine or CSE alone (0.15mg/kg; i.p), or a priming dose of drug and cues combined. We found that animals that self-administered CSE reinstated more robustly than animals that self-administered nicotine alone ($F_{1,12}= 6.03$; $p = 0.03$), when given a priming dose of CSE alone ($p = 0.046$) and paired with the introduction of drug cues ($p = 0.028$). The results suggest that the non-nicotine constituents in cigarette smoke contribute to smoking craving and relapse. Keywords: cigarette smoke extract (CSE), drug-primed reinstatement, nicotine

Title: Differential effects of tobacco smoke containing either high or low levels of nicotine during adolescence on novelty seeking and anxiety-like behaviors

Authors: *D. P. BRANCO, M. CORREA-SANTOS, C. C. FILGUEIRAS, C. C. CAVINA, V. F. NAIFF, A. C. MANHÃES, A. RIBEIRO-CARVALHO, Y. ABREU-VILLAÇA
Dept. de Ciências Fisiológicas, Univ. do Estado do Rio de Janeiro, Rio de Janeiro, Brazil

Abstract: There is a lack of experimental studies that investigate the effects of tobacco smoke exposure during adolescence. Here, we investigated the short- and long-term effects of tobacco smoke generated from cigarettes containing either high or low levels of nicotine on novelty seeking and anxiety-like behavior of adolescent mice. From postnatal day 30 to 45 (PN30-45), male and female Swiss mice were exposed to tobacco smoke (whole body exposure for 8 h/day, 7 days/week) generated from one of two reference research cigarettes: type 2R1F (HighNIC group - 1.74mg nicotine/cigt) or type 4A1 (LowNIC group - 0.14mg nicotine/cigt). Control mice were exposed to ambient air. By the end of the exposure period (PN45) we assessed the levels of cotinine (nicotine metabolite) in serum. During exposure (PN44-45), short- (PN49-50) and long-term deprivation (PN74-75), the elevated plus maze was used to assess anxiety-like behavior and the hole board to assess novelty-seeking. Only HighNIC mice presented detectable cotinine serum levels (109.1±24.0ng/ml). There were no differences in anxiety-like behavior among groups. Effects on novelty-seeking were largely dependent on the type of cigarette. HighNic mice presented increased novelty-seeking during exposure and a late-emergent females-only decrease in exploration during deprivation. Distinctively, LowNic mice presented reduced novelty-seeking both during exposure and short-term deprivation. Differential behavioral effects of tobacco smoke containing high or low nicotine levels are associated with differences in the compounds inhaled during exposure: In addition to relevant behavioral effects of nicotine, we suggest that smoke components other than nicotine play a role.

Title: Phosphorylation of mGluR1/5 by protein kinases after nicotine challenge

Authors: *I. RYU, J. KIM, E. CHOE
Dept. of Biol. Sci., Pusan Natioanl Univ., Pusan / Keumjeong-Gu, Korea, Republic of

Abstract: Exposure to nicotine, a psychoactive component in tobacco, alters mesolimbic dopaminergic and glutamatergic pathways innervated to the nucleus accumbens (NAc). Our preliminary study shows that nicotine challenge (0.2, 0.4, or 1.0 mg/kg/day) after six days of withdrawal, followed by fourteen daily systemic injections of nicotine (0.2, 0.4, or 1.0 mg/kg/day), significantly increased both locomotor activity and stereotypy in a dose-dependent manner. In this study, therefore, we will unravel mechanisms involving nicotine challenge-induced relapse by investigating the hypothesis that nicotine challenge phosphorylates metabotropic glutamate receptor subtype 1 and 5 (mGluR1/5) through the activation of protein kinases, which we believe it contributes to behavioral changes.

Title: Acute nicotine delays extinction of contextual fear in mice

Authors: M. G. KUTLU, *T. J. GOULD
Dept Psychol, Temple Univ., PHILADELPHIA, PA

Abstract: Smoking is linked to Post-Traumatic Stress Disorder (PTSD) which suggests smoking is either a risk factor or an attempt at self-medication. The ability to reduce or extinguish fear-related memories may be altered in patients with PTSD and it is possible that nicotine modulates this. Although there are numerous studies examining the effects of nicotine on acquisition of fear learning, the effects of nicotine on extinction of contextual fear are not well understood. In the present study, we examined the effects of acute nicotine (0.18 mg/kg) on extinction of contextual fear in C57BL/6J mice. Animals were first trained in a background contextual fear conditioning paradigm using a white noise as a conditioned stimulus (CS), which co-terminated with a 2 s

0.57 mA unconditioned foot-shock stimulus (US). Animals were then administered either nicotine or saline and exposed to either the training context or a novel context in order to measure freezing to the context during extinction. Our results demonstrate that nicotine administration during extinction delays extinction of contextual freezing while nicotine did not affect cued freezing or freezing to the novel context. These results suggest that initiation of smoking after a traumatic event may interfere with the extinction of fear response to a trauma-associated context by enhancing the recall of the contextual fear memory.

Title: The effect of appetitive interoceptive conditioning on nicotine reinforcement: A novel nicotine self-administration model

Authors: *S. CHARNTIKOV, S. PITTENGER, N. SWALVE, R. BEVINS
Dept of Psychology, Univ. of Nebraska-Lincoln, Lincoln, NE

Abstract: Nicotine is the primary addictive component of tobacco and is one of the active ingredients included in e-cigarettes. Notably, nicotine's reinforcing effects appear weak at best in animal models. Although understanding nicotine's reinforcing effects is of great importance, learning processes involving nicotine are likely to be more complex. There is a need to study this complexity in order to design more relevant and efficacious treatment strategies. The goal of this study was to test whether appetitive interoceptive conditioning with the nicotine stimulus in the initial self-administration stage would enhance nicotine's rewarding properties as revealed through later responding on a progressive ratio schedule of reinforcement. To this end, rats were first trained to self-administer nicotine using a variable ratio 3 (VR3) schedule of reinforcement. There were 24 nicotine self-administration sessions using right and left levers as a manipulanda. Thirty seconds after each earned nicotine infusion, one group of rats (n=13) received 4-sec access to liquid sucrose. The comparison group (n=15) was reinforced with nicotine on a VR3, but had no access to sucrose in the initial self-administration phase. The number of infusions was limited to 10 for all rats; this provided some control over nicotine intake between the two groups. In the second phase, the response manipulanda were switched to nose-pokes and relocated on the

opposite side of the self-administration chamber. The levers were removed, but the sucrose receptacle now inactive, remained on that opposite side wall from the nose-poke holes. Also, the schedule of reinforcement for each nicotine infusion was changed to a progressive ratio (PR). A PR schedule, with its increasing response requirement after each nicotine infusion, provides a good index of reinforcer value. Rats in both groups rapidly acquired nicotine self-administration, had comparable self-administration pattern of responding on the VR3, and comparable drug intake throughout the initial phase using levers as manipulanda. In the second phase, rats with a history of nicotine-sucrose pairings had significantly higher PR responding on the active nose-poke than rats in comparison condition that only received nicotine in the initial phase. Thus, for the first time, we show that appetitive interoceptive conditioning with the nicotine stimulus can enhance later nicotine self-administration suggesting that the early establishment of an appetitive nicotine - sucrose association enhances the reinforcing value of nicotine; an understudied factor that may play a role in the progression to nicotine dependence.

Title: Individual differences in forced and free-choice novelty differentially predict nicotine sensitization behaviors

Authors: *A. M. FALCO, R. A. BEVINS
Psychology, Univ. of Nebraska-Lincoln, Lincoln, NE

Abstract: Work with traditional psychostimulants has reported a relation between response to novel environments and drug-induced behaviors. This relation is less clear when reactivity to a novel environment is correlated to nicotine-induced behaviors. The current research asked whether a set of tasks that included novelty in different forms predicted later locomotor sensitization to nicotine. Male Sprague-Dawley rats were first assessed in the individual differences screens. The screens were reactivity to an inescapable novel environment, consumption of a novel tastant (sucrose), consumption of a novel food in an unfamiliar

environment (L-maze), and approach and interaction with a novel object. Following screening, rats underwent a 10-day sensitization regimen. Rats were injected SC with either 0.4 mg base/kg nicotine or saline and placed in the locomotor chamber (dia. 30.5 cm) for 30 min (n=16/group). After sensitization, a drug-free test was conducted to determine whether the chamber evoked enhanced locomotion (conditioned hyperactivity). Subsequently, two nicotine (0.4 mg/kg) challenge tests were conducted to assess the lasting effects of nicotine sensitization. Locomotor sensitization developed in nicotine-treated rats. Context-evoked conditioned hyperactivity was seen in the drug-free test. Later challenge tests found that sensitization lasted up to 7 days without nicotine. For each individual difference screen, a median split was performed. Rats with performance above the median were defined as high responders (HR); rats below the median were low responders (LR). There were no locomotor differences between saline HR and LR rats. This was not so for nicotine-sensitized rats. HRs on in the inescapable novel environment significantly higher than LR nicotine-sensitized rats on day 10, conditioned locomotor test, and nicotine challenge I and II. Interestingly, the only other novelty-related behavior that consistently predicted the effects of nicotine was average duration of sniffing the novel object. For this screen, HRs were significantly lower than LRs for day 10, conditioned locomotor test, and nicotine challenges I and II. This experiment suggests that two types of novelty, forced and free-choice, predict nicotine sensitization differentially. This likely occurs via different mechanisms that have yet to be elucidated.

Title: Neuroanatomic mapping of dopamine D1 receptor involvement in nicotine self-administration in rats

Authors: *B. J. HALL, S. SLADE, C. ALLENBY, E. D. LEVIN
Dept. of Psychiatry and Behavioral Sci., Duke Univ. Med. Ctr., Durham, NC

Abstract: The dopamine system is known to be critically involved in addiction to nicotine, as well other drugs of abuse. The dopaminergic projections from the VTA to the nucleus accumbens and prefrontal cortex have been well established to be critical to the reinforcing effects of these drugs. However, other projections of dopamine neurons are likely have significant roles in this process. In addition, the relative contributions of dopamine D1 and D2 receptors in drug addiction and its treatment remains to be fully understood. In a series of studies we have investigated a variety of different dopaminergic projections with regard to their involvement in nicotine self-administration in rats. The relative involvement of dopamine D1 receptors were studied in specific cortical and subcortical neuroanatomic brain regions including: nucleus accumbens shell (AcS), anterior cingulate cortex (ACC), and parietal association cortex (PAC). Young adult female Sprague-Dawley rats were fitted with jugular catheters and given access to self-administer nicotine (0.03 mg/kg) on an FR1 schedule of reinforcement. A bilateral infusion cannula was implanted in each respective brain region in separate cohorts of rats to allow local infusion of the DA D1 receptor antagonist SCH23390. Infusions of SCH23390 occurred 5 min prior to the start of self-administration sessions, and each session lasted 45 min. Doses of SCH23390 (1.0, 2.0, and 4.0 μg/side) were infused in a repeated measures, counterbalanced design two times. Bilateral infusions of SCH23390 into the AcS caused significant reductions in nicotine self-administration (measured as number of nicotine infusions per session) at all doses, compared to infusions of ACSF vehicle, while infusions into the PAC resulted in significant reductions at the 2.0 and 4.0 μg doses. Infusions of 4.0 μg/side SCH23390 into the ACC resulted in a slight reduction in nicotine self-administration but did not reach the level of significance. The results of this series of experiments demonstrates the importance of D1 dopamine receptors in the aquisition and maintenance of nicotine addiction, and also may show significant contributions to this process from previously overlooked neuroanatomical brain regions. This research was supported by P50 grant DA027840 from NIDA.

Title: Serotonin receptor type1 function in nicotine-induced locomotor behavior

Authors: *H. SCHNEIDER, B. F. KOPECKY, N. J. SNYDER, S. OWIREDU, E. E. CLOR, S. INDIA-ALDANA, K. Y. CHEN
Dept. of Biol., Depauw Univ., GREENCASTLE, IN

Abstract: The serotonin system has been linked to the modulation of psychostimulant-induced behavior and could be targeted for the treatment of nicotine dependence, the number one cause of preventable diseases in the U.S. Neurobehavioral responses of zebrafish larvae to nicotine following treatment with agonists for various serotonin receptors could lead to the identification of new chemicals for smoking cessation therapy in patients. The goal of this study was to determine the action of the htr1a agonist (R)-(+)-8-hydroxy-DAPT, the partial htr1a agonist busprione and the htr1b agonist eletriptan on nicotine-induced motor behavior in zebrafish (Danio rerio) larvae at 5-7 days post fertilization (pdf) and in comparison to the acteylcholine receptor agonist varenicline, which is used successfully in smoking cessation therapy. Treatment with (R)-(+)-8-hydroxy-DAPT, busprione or eletriptan reduces spontaneous swimming activity and the acute nicotine-induced motor response. In control experiments, a reduced locomotor response to an irritant chemical is also observed in treated zebrafish larvae. In contrast, varenicline treatment reduces the nicotine-induced motor behavior but not the response to the irritant chemical. Together, these results suggest that treatment with (R)-(+)-8-hydroxy-DAPT, busprione or ETT reduces motor behavior of 5-7dpf larval zebrafish more broadly unlike the more specific action of varenicline. Genes of htr1a and htr1b are expressed by 5dpf in zebrafish larvae. The action of additional serotonin receptor agonists and antagonists will be explored in future studies.

Title: Dextromethorphan interactions with the histaminergic H1 antagonist pyrilamine and the serotonergic 5HT2c agonist lorcaserin to reduce nicotine self-administration in rats

Authors: S. A. BRIGGS, C. WELLS, S. SLADE, M. MORRISON, P. JASKOWSKI, *J. E. ROSE, E. D. LEVIN
Duke Univ., DURHAM, NC

Abstract: Tobacco addiction is a complex syndrome involving multiple interacting neural systems. A variety of drug treatments affecting different neurotransmitter receptors have been found to reduce nicotine self-administration. Combining effective treatments for smoking cessation may provide more effective treatments by affecting multiple points of control in the neural circuits underlying addiction. Previous studies in our laboratory have shown that the H1 histamine antagonist pyrilamine and the serotonin 5HT2c agonist lorcaserin significantly reduce nicotine self-administration in the rat model. In addition, dextromethorphan a drug with alpha3beta4 nicotinic and NMDA glutamate antagonist actions has been shown to decrease nicotine self-administration in the rat model. To explore ways to enhance success for reducing nicotine self-administration and provide new, more effective treatments to help smoking cessation, the current studies were conducted to determine the combined effects of dextromethorphan with pyrilamine or lorcaserin. Young-adult female rats were fitted with jugular IV catheters and trained to self-administer with a nicotine infusion dose of 0.03 mg/kg/infusion. In an initial dose-effect function study of dextromethorphan we found a monotonic decrease in nicotine self-administration over a dose range of 1 to 30 mg/kg with lowest effective doses seen at 3 mg/kg. In the combination studies rats were given varying doses of both dextromethorphan (3.3, and 10 mg/kg) and pyrilamine (4.43, and 13.3 mg/kg) or lorcaserin (0.3125 and 0.625 mg/kg) to test an acute dose-effect function and drug interactions. The saline vehicle was used as control. As seen before, pyrilamine significantly reduced nicotine self-administration. Dextromethorphan significantly augmented this effect. Also as seen previously, lorcaserin significantly reduced nicotine self-administration. This effect was also significantly augmented by dextromethorphan. Combined treatments affecting multiple components of the neural circuits underlying nicotine dependence may be useful to enhance success at smoking cessation.

Title: Nicotine-suppressive properties of the high affinity α3β4 nAChR ligand AT-1001 are different than those of varenicline

Authors: *A. CIPPITELLI[1], J. WU[1], K. GAIOLINI[1], J. SCHOCH[1], G. BRUNORI[1], R. CICCOCIOPPO[2], N. ZAVERI[3], L. TOLL[1]

Abstract: The α3β4 subtype of nicotinic acetylcholine receptors (nAChR) has been shown to play an important role in mediating nicotine reinforcement processes. A recently reported series of compounds was found to possess high affinity and selectivity for α3β4 nAChR when measuring binding affinity *in vitro*. One such compound, AT-1001, was also found to decrease nicotine self-administration in rats. Here we present *in vitro* studies that demonstrate that AT-1001 and AT-1012 are functionally selective as antagonists for α3β4 over α4β2 nAChR, but not to the same extent as the binding selectivity. Furthermore, these compounds have partial agonist activity at α3β4 nAChR. Additional experiments demonstrate that AT-1001 and varenicline, a partial agonist at α4β2 nAChR with binding but not functional selectivity *in vitro*, have very different *in vivo* properties, indicating distinct mechanisms of action. First, AT-1001 made available intravenously, did not exhibit reinforcing properties per se in fixed and progressive ratio reinforcement schedules, while varenicline (20 μg/kg) was self-administered. Secondly, systemic treatment with AT-1001 did not induce reinstatement of extinguished nicotine seeking but in fact attenuated activation of nicotine seeking induced by varenicline (0.15 mg/kg), as well as nicotine (0.15 mg/kg). Finally, AT-1001 selectively blocked nicotine self-administration without altering alcohol lever pressing as assessed in an operant co-administration paradigm. These findings describe a more complex AT-1001 *in vitro* profile than previously appreciated and provide further support for the potential of AT-1001 and congeners as clinically useful compounds for smoking cessation, with a mechanism of action distinct from currently available medications.

Title: Hippocampus goes depression: Structural and functional correlates of negative mood states after smoking cessation

Authors: *F. WUTTIG, N. B. KROEMER, C. BURRASCH, M. N. SMOLKA
Section of Systems Neurosci., Technische Univ. Dresden, Dresden, Germany

Abstract: Individuals with a history of major depressive disorder require more attempts to successfully quit smoking, and after quitting the risk for recurrence of depressive symptoms is increased. So far little is known about the neurobiological substrates of affective symptoms which often emerge within the first days after smoking cessation and last for several weeks. Using MRI, we examined structural and functional changes in emotional circuits subsequent to smoking cessation. We hypothesized that smoking cessation should preferentially affect structure and function of the hippocampus. Thus, we investigated 68 nicotine-dependent smokers and 70 non-dependent controls that completed two MRI sessions within approximately one month. Abstinent smokers took part both before and after quitting successfully; relapsing smokers were not invited for a second scan. Images were processed with cross-sectional and, if both sessions were completed, longitudinal FreeSurfer streams. Hierarchical linear modeling was used to investigate the effects of smoking cessation and baseline depression scores (measured with BDI) on volumetric changes in subcortical areas. In addition, we measured fMRI BOLD signaling during passive viewing of emotional (pleasant, unpleasant, neutral) pictures in a subsample (23 smokers, 37 controls). Relating to structural changes, we observed greater volume loss in the right hippocampus, left amygdala and bilateral nucleus caudatus in smokers compared to controls. Moreover, volume loss in the left hippocampus occurred in more dependent and more

depressed smokers. Functional ROI analysis revealed increased bilateral hippocampal response to unpleasant, but not to pleasant stimuli in smokers after smoking cessation. Increases of BDI scores covaried with elevated BOLD signaling to unpleasant stimuli in the left hippocampus. Critically, increases in brain responses to unpleasant stimuli in bilateral hippocampus predicted relapse within the first 6 month after smoking cessation. Taken together, we were able to identify structural and functional neuroadaptations induced by smoking cessation in regions which are involved in emotion and motivational processing. Our results suggest that the hippocampal formation in a particular has a substantial association with the occurrence of negative mood states after quitting. Changes in neural reactivity might be caused by cessation-induced elevated cholinergic levels and result in increased susceptibility to unpleasant events which increases the risk for relapse.

Title: Attenuating combined cue and prime-induced reinstatement of nicotine-seeking following chronic dosing of the novel D3-receptor antagonist PF-04363467

Authors: *E. R. DUNN-SIMS[1], A. ROSADO[1], A. FOOTE[1], C. TYSZKIEWICZ[1], N. C. STRATMAN[2], C. J. SCHMIDT[2], A. SAWANT-BASAK[2], A. N. MEAD[1], T. T. WAGER[2], T. A. CHAPPIE[2]

Abstract: Learned associations between the rewarding properties of drugs of abuse and environmental cues contribute to craving and relapse in humans. Dopamine D3-receptors are preferentially expressed in mesocorticolimbic DA projection areas: areas of the brain highly associated with reward-related learning induced by drugs of abuse. Nicotine dependence is a chronic relapsing disorder and increasing evidence supports a model where D3-receptor activity is implicated in the relapse-related cellular and behavioral effects underlying nicotine-seeking behavior. We have previously reported that the novel D3-receptor antagonist PF-04363467 attenuates reinstatement of nicotine-seeking in rats under different test conditions when

administered acutely. The purpose of the present studies was to understand whether these same effects of PF-04363467 were observed when dosed chronically for 28 days. Male Sprague-Dawley rats were initially trained to self-administer nicotine, I.V., under a fixed ratio schedule of reinforcement using a standard 2-lever choice design, with infusion-paired cues. Training sessions were conducted during either short-access (90-minute) or long-access (15-hour) conditions. Following acquisition, an extinction period commenced to dissociate the act of lever pressing from delivery of nicotine. Reinstatement tests were then conducted, with reinstatement induced by a combination of nicotine prime and cues. PF-04363467 was administered once daily for a total of 28 days, and reinstatement tests were conducted once per week. Congruent with prior findings, PF-04363467 attenuated reinstatement of nicotine seeking when given acutely to rats trained under short and long-access conditions (30 mins prior to session start). However, chronic treatment of PF-04363467 resulted in tolerance to this effect after 3 weeks in rats trained under both short and long access conditions. The results are discussed in relation to potential reasons for the loss of efficacy with repeated administration of PF-04363467, as well as published examples relating to the lack of translation of chronic dosing regimens from rodents to humans. These data raise important questions regarding gaps in knowledge when pharmacological agents are chronically dosed to rats.

Title: Maternal care deprivation and chronic alcohol consumption prevents conditioned place preference to nicotine in rats

Authors: *R. GARCÍA
UNAM, DF, Mexico

Abstract: Perinatal maternal care is a condition that may influence many aspects of de brain development and behavior including the response to drugs of abuse. The deprivation of maternal care (MCD) in rats for few hours a day may predispose litters for alcohol consumption in the

adulthood. In this study we use the maternal deprivation model for three hours for 16 days in male Wistar rats to determine whether the maternal deprivation affect the quantity of chronic voluntary consumption of Ethanol solution (at 10%) across two months (during puberty). At the end of this period we applied a conditioned place paradigm in order to analyze the possible interaction with the preference to 0.8 mg /kg of nicotine. Our results show a marked influence of maternal separation on the development of aversive nicotine in CPP (66% in rats not separated vs 44% of separated rats, both groups without exposure to ethanol). By contrast, non-deprived rats exposed to voluntary ethanol consumption showed strong preference for the CPP nicotine compared to non-deprived without exposure to ethanol (54% vs 33% respectively). We found a negative correlation aversion (r=-0.77) in nicotine CPP associated with increased ethanol consumption (as much as 5.22mg/kg of ethanol) during the period of conditioning in maternal deprived rats exposed to ethanol. This study suggests that MCD plus alcohol consumption enhances nicotine intake Supported by Grants 129103 and IN224314 from CONACyT and DGAPA-UNAM respectively and Fundación Miguel Aleman to OPG, and CONACyT 240173 to Ricardo García-Ruiz

Title: Choice between nicotine and sucrose in rats as a model of the development, maintenance, and treatment of tobacco use

Authors: *L. V. PANLILIO[1], L. HOGARTH[2], M. SHOAIB[3]
[1]Behav Pharmacol Sec, NIDA-IRP, BALTIMORE, MD; [2]Univ. of Exeter, Exeter, United Kingdom; [3]Newcastle Univ., Newcastle, United Kingdom

Abstract: Animal models of drug abuse that allow subjects to choose between drug and nondrug reinforcers might provide unique insights into how drug use is developed and sustained, and how it might be decreased through therapeutic treatments. Choice procedures have been used extensively in rats with cocaine, but not with nicotine. Here, male hooded Lister rats were trained with a concurrent-choice schedule in which pressing one lever delivered intravenous nicotine (0.03 mg/kg) and pressing another lever delivered sucrose pellets. When rats were initially

trained with only the sucrose lever available on some days and only the nicotine lever available on other days, they immediately showed a preference for sucrose when they were given a choice. In contrast, when rats were initially trained with nicotine for three days but given no sucrose training prior to being allowed to choose, about half developed a preference for nicotine. Subcutaneous treatment with varenicline (1.5 mg/kg), a partial agonist of nicotinic receptors, selectively decreased nicotine self-administration in the choice procedure. When food-related manipulations were performed, nicotine responding increased when the sucrose lever was removed, but decreased gradually when food restriction was discontinued. The finding that rats can prefer nicotine over sucrose is surprising in light of studies showing that rats tend to prefer sweet tastes over intravenous cocaine, even when trained exclusively with cocaine prior to being given a choice. Testing with varenicline, which is known to be effective in promoting smoking cessation, indicates that the choice procedure could be useful for testing therapeutic treatments. The results obtained with food-related manipulations are consistent with previous studies showing that food restriction enhances drug self-administration, and that availability of alternative reinforcers can decrease drug use. Overall, these findings demonstrate the choice procedure's ability to reveal and account for individual differences that were not apparent with a simple schedule of nicotine self-administration.

Title: The rewarding and reinforcing effects of nicotine in drug-naïve, nicotine pretreated, or tobacco smoke pre-exposed adolescent and adult rats

Authors: *A. H. MUHAMMAD, J. DE LA PENA, C. BOTANAS, R. TAMPUS, N. JEONG, J. KIM, H. KIM, J. CHEONG
Pharm., Uimyung Res. Inst. for Neurosci., Seoul, Korea, Republic of

Abstract: Cigarette (tobacco) smoking is one of the most prevalent addictions worldwide. Millions are affected by this addiction, and thousands more light their first cigarette every day.

More alarming is that most of these first time smokers are adolescents. Similar to other abused substances, cigarettes are primarily taken because it makes the user “feel good”. The main substance implicated in the addictive effect of cigarettes/tobacco is nicotine. However, when tested in animal models of addiction, the rewarding and reinforcing effects of nicotine is hard to establish. Furthermore, studies delving into the effects of chronic or repeated nicotine pre-exposure have reported conflicting results. Thus, in the present study we sought to characterize the rewarding and reinforcing effects of nicotine in adolescent (4-6 weeks) and adult rats (8-10 weeks) under three conditions: (1) drug-naïve, (2) nicotine-pretreated, or (3) cigarette smoke pre-exposed. The rewarding and reinforcing effects of nicotine were evaluated in two of the most widely used and accepted animal models of addiction, the conditioned place preference (CPP) and the self-administration (SA) tests. In drug-naïve rats, adolescents demonstrated enhanced nicotine CPP (0.2 mg/kg) and SA (0.03 mg/kg/infusion) as compared to the adult group. 7 days pre-exposed rats exhibited greater CPP for the initially unrewarding high dose (0.06 mg/kg) of nicotine, especially appreciable in cigarette smoke pre-exposed adolescent rats. On the other hand, in the SA test, pre-exposed adolescent and adult rats demonstrated reduced/diminished nicotine (0.03 mg/kg) SA. These results suggest that adolescents are more vulnerable to the addictive effects of nicotine, and repeated nicotine or cigarette smoke exposure changes subsequent response towards this drug.

Title: Paternal nicotine self-administration is associated with increased acquisition and maintenance of nicotine taking in offspring

Authors: *A. C. ARREOLA, B. A. KIMMEY, H. D. SCHMIDT
Univ. of Pennsylvania, Philadelphia, PA

Abstract: Recent evidence indicates that paternal smoking is associated with nicotine dependence and increased incidence of childhood cancer in offspring. These findings indicate that tobacco smoke is capable of influencing behavioral phenotypes in future generations. Epigenetics is a key mechanism by which the environment can influence and interact with genetics to influence behavior. Epigenetic mechanisms have been shown to underlie drug-induced behavioral plasticity by coordinating expression of gene networks in the brain. Thus, one direct mechanism by which nicotine may influence genetic events involved in the development of nicotine addiction as well as its heritability in future generations is epigenetics. However, the epigenetic mechanisms by which paternal nicotine exposure influences smoking behavior in subsequent generations are not clear. The goal of this study was to establish a preclinical rodent model of inter-generational susceptibility to nicotine dependence. Male rats were allowed to self-administer nicotine (0.03 mg/kg/infusion) on a fixed-ratio 1 schedule of reinforcement for 60 consecutive days. Nicotine-experienced rats and yoked saline controls were then allowed to mate with drug-naïve dams. When the offspring reached 60 days of age, male and female progeny were implanted with jugular catheters and the acquisition of nicotine self-administration was assessed. Offspring of nicotine-experienced sires self-administered more nicotine when compared to the offspring of yoked saline controls. These data are consistent with human epidemiological studies and indicate that paternal nicotine exposure increases susceptibility to nicotine taking in offspring. Identifying novel epigenetic mechanisms underlying the transmission of enhanced vulnerability to nicotine dependence will aid in the development of novel smoking cessation medication in generations at high risk for chronic smoking behavior. Abstract: Endogenous cannabinoid signaling is known to be involved in nicotine addiction, but the functions of specific endocannabinoid transmitters in the abuse-associated effects of nicotine have long remained unclear. Inhibition of fatty acid amide hydrolase (FAAH) counteracts certain aspects of nicotine reward in rats (Scherma et al., 2008), but its effects have not been studied with addiction-related procedures in non-human primates. Here we studied the effects of first and second generation FAAH inhibitors, URB597 and URB694, on reinforcing effects of nicotine in squirrel monkeys using a fixed-ratio intravenous nicotine self-administration procedure. Systemic treatment with either FAAH inhibitor: 1) almost completely blocked FAAH activity in monkey brain and liver, increasing levels of endogenous ligands (anandamide, PEA and OEA) for cannabinoid and alpha-type peroxisome proliferator-activated receptors (PPAR-α); 2) shifted nicotine self-administration dose-response functions to the right in a manner consistent with reduced nicotine reward; and 3) blocked reinstatement of nicotine seeking induced by re-exposure to either nicotine or cues that had been associated with nicotine. The behavioral effects of FAAH inhibition on nicotine self-administration and nicotine-induced reinstatement were reversed by treatment with a PPAR-α antagonist MK886. Moreover, FAAH inhibition had no effect on cocaine or food self-administration under the same schedule of reinforcement. In these non-human primate models, both URB597 and URB694 show promise for the initialization and maintenance of smoking cessation, due to their ability to block the rewarding effects of nicotine and to block nicotine-induced and cue-induced reinstatement.

Title: Monoamine oxidase (MAO) inhibition decreases the threshold for nicotine self-administration in rats

Authors: T. T. SMITH[1], R. L. SCHASSBURGER[1], L. E. RUPPRECHT[1], S. N. CWALINA[1], D. M. BUFFALARI[1], S. ALI[2], E. C. DONNY[1], *A. F. SVED[1]
[1]Univ. Pittsburgh, Pittsburgh, PA; [2]Natl. Ctr. for Toxicological Res., Jefferson, AR

Abstract: In chronic cigarette smokers brain monoamine oxidase (MAO) activity is partially inhibited. Previous studies have suggested that drugs that inhibit MAO increase nicotine self-administration in rats. The present studies sought to address three issues. First, does the MAO inhibitor tranylcypromine (TCP) lower the threshold dose of nicotine required to support self-administration in rats? Second, do other drugs that inhibit MAO have a similar effect? Third, does partial inhibition of MAO, to the extent observed in chronic smokers, similarly impact nicotine self-administration? To assess the effect of a large dose of TCP on the dose-response curve for nicotine self-administration, adult male rats responded (nose poke, fixed ratio 2 schedule) for an i.v. infusion of a nicotine solution paired with a 15-s stimulus light and received a pre-session injection of TCP (1 mg/kg i.p.) or saline (n=12-14). Self-administration sessions were one hour each day during the dark portion of the light-dark cycle. After every 7 sessions the nicotine dose was increased (0→1.875→3.75→7.5→15→30→60→90 µg/kg/infusion). TCP, at this dose of 1 mg/kg that produced near complete inhibition of MAO-A and MAO-B, shifted the dose-response curve to the left, with the threshold dose supporting nicotine self-administration being 7.5 ug/kg/inf in the TCP group versus 15 ug/kg/inf in the group of rats not receiving TCP. Similarly, in a separate group of rats (n=8) a combination of clorgyline (1 mg/kg i.p.; MAO-A inhibitor) plus pargyline (10 mg/kg i.p.; MAO-B inhibitor), which produced near complete inhibition of MAO-A and MAO-B, increased responding for a low dose of nicotine. A dose of TCP (0.1 mg/kg) that inhibited MAO activity by ~35%, comparable to what is observed in chronic smokers, also increased responding for a low dose of nicotine. Together, these studies show that MAO inhibition increases self-administration of low doses of nicotine. Furthermore the studies suggest that MAO inhibition produced by cigarette smoke may contribute to the reinforcing properties of cigarettes and may be even more important if nicotine levels in tobacco products is reduced as part of a tobacco regulatory policy.

Title: Nicotine and alcohol induce inhibition of medial vta dopaminergic neurons

Authors: S. VALVERDE[1], R. EDDINE[1], F. MARTI[1], S. TOLU[1], A. HAY[1], C. MOREL[1], Y. CUI[2], D. DAUTAN[1], *R. HEPP[1], L. VENANCE[2], B. LAMBOLEZ[1], P. FAURE[1]

Abstract: Midbrain dopamine (DA) neurons are key players in motivation and reward processing. Increased DA release is thought to be central in the initiation of drug addiction. Whereas dopamine neurons are generally considered to be activated by drugs such as nicotine and alcohol, we report here that nicotine not only induces excitation of Ventral Tegmental Area (VTA) DA cells but also induces inhibition of a subset of VTA DA neurons that are anatomically segregated in the medial part of the VTA. These opposite responses are also elicited by ethanol, but do not correlate with the inhibition and excitation induced by noxious stimuli. We show that this inhibition requires D2 receptor (D2-R) activation, suggesting that an intra-VTA dopaminergic release is involved in the mechanism.. Our findings provide a novel organizing principle of concurrent excitation and inhibition of VTA DA cells in response to reinforcing stimuli. It promotes unexplored roles for DA release in addiction contrasting with the classical views of reinforcement and motivation, and give rise to a new comprehension of the mode of operation of the reward system.

Title: Repeated nicotine exposure in rats: Alteration of medial habenula and blockade effect of oxytocin

Authors: *H. LEE[1], J. NOH[2]
[1]Dept. of Sci. Education, Col. of Sci. Educ., [2]Dankook Univ., Suji-Gu, Yongin-Si, Gyeonggi-Do, Korea, Republic of

Abstract: Nicotine can not only stimulate the reward circuitries, but also can produce aversive reaction. Although the neurobiological mechanism of nicotine reward has been heavily studied, relatively little is known about the mechanism of nicotine aversion. Because growing evidences suggest that medial habenula to interpeduncular nucleus circuitry plays a pivotal role in nicotine aversion, we investigated the neural activity of medial habenula between the repeated saline and nicotine injected rats using an extracellular recording. We found that the basal spontaneous spike frequency in medial habenula was minimized and nicotine-evoked response was also reduced in repeated nicotine injected rats compared to saline injected rats. Moreover, in repeated nicotine injected rats, increased nicotine preference was observed. Because oxytocin is implicated in drug addiction to reduce the tolerance, self-administration and even withdrawal symptoms, we determined the effect of oxytocin on nicotine-induced behavior alteration. Oxytocin completely blocked an augmentation of nicotine intake preference and an increase of nicotine-mediated anxiety-like behavior by repeated nicotine exposure. These results demonstrate a medial habenular activity is one of candidates for determining an inhibitory motivation to avoid nicotine consumption. Additionally oxytocin has fascinating potential to reverse nicotine-mediated addictive behavior and to inoculate against vulnerability to nicotine-mediated addictive disorders.

Title: The effects of varenicline, bupropion, lorcaserin, and naltrexone on nicotine-enhanced responding for a conditioned reinforcer

Authors: *E. G. GUY[1], D. C. FISHER[5], G. A. HIGGINS[2,6], P. J. FLETCHER[5,3,4]
[1]Univ. of Toronto, Redmond, WA; [2]Pharmacol., [3]Psychology, [4]Psychiatry, Univ. of Toronto, Toronto, ON, Canada; [5]Biopsychology, Ctr. for Addiction and Mental Hlth., Toronto, ON, Canada; [6]InterVivo Solutions, Toronto, ON, Canada

Abstract: Stimuli that have been repeatedly associated with natural or drug reinforcement can become motivationally significant and elicit reward-seeking behaviors, making them conditioned reinforcers. Nicotine, the primary psychoactive ingredient in tobacco, enhances responding for conditioned reinforcement. This type of interaction between nicotine and cues associated with rewards, or conditioned stimuli (CSs), may contribute to nicotine addiction. This work examined how pharmacological interventions that are used for smoking cessation alter the ability of nicotine to enhance responding for conditioned reinforcement. Thus we looked at interactions between nicotine and the nicotinic receptor partial agonist varenicline, and between nicotine and the DAT inhibitor bupropion. Preclinical studies have shown interactions between nicotine and lorcaserin (a 5-HT_{2C} receptor agonist), and between nicotine and naltrexone (μ-opioid receptor antagonist) on several behavioral measures. Since both drugs are FDA-approved, albeit for other indications, we also examined their effects on nicotine-induced responding for conditioned reinforcement. Thirsty rats were exposed to 13 Pavlovian conditioning sessions where a CS was paired with water delivery. Nicotine (0.4 mg/kg) injections were administered prior to each of these sessions. Then, in separate groups of animals (n=10 each), a repeated-measures design was used to test the effects of varenicline (1 mg/kg), bupropion (10 and 30 mg/kg), lorcaserin (0.6 mg/kg), and naltrexone (2 mg/kg) and their interaction with nicotine (0.4 mg/kg) on responding for conditioned reinforcement. Varenicline alone modestly increased responding for conditioned reinforcement compared to saline, but fully antagonized the response-potentiating effects of nicotine. Lorcaserin and naltrexone both reduced the effect of nicotine to enhance responding for conditioned reinforcement. In contrast, the 30 mg/kg dose of bupropion enhanced responding for conditioned reinforcement, and further increased the response-potentiating effects of nicotine. These studies inform one possible mechanism by which these four, FDA approved medications affect smoking behavior in humans; by interacting with the effect of nicotine to enhance the motivating properties of nicotine-associated CSs.

Title: Smoking moderates association of 5-HTTLPR and *in vivo* availability of serotonin transporters

Authors: *M. N. SMOLKA[1], M. REIMOLD[2], A. KOBIELLA[1], G. REISCHL[2], M. RIETSCHEL[3], A. HEINZ[4]
[1]Technische Univ. Dresden, Dresden, Germany; [2]Univ. Tübingen, Tübingen, Germany; [3]Central Inst. of Mental Hlth., Mannheim, Germany; [4]Charité, Berlin, Germany

Abstract: Although preclinical studies clearly indicate an effect of 5-HTTLPR genotype on 5-HT transporter (5-HTT) expression, studies in humans provided inconclusive results, hypothetically due to environmental factors and differences in individual behavior. For example, nicotine and other constituents of tobacco smoke elevate serotonin (5-HT) levels in the brain and may cause homeostatic adaptations in 5-HTT availability that moderate effects of 5-HTTLPR genotype. To test whether 5-HTT availability in the midbrain is affected by smoking status and 5-HTTLPR genotype, we pooled data from prior studies on *in vivo* 5-HTT availability (BPND) measured with positron emission tomography (PET) and [11C]DASB. In total, we reanalyzed 5-HTT availability in 116 subjects using ANCOVA statistics. ROI analysis revealed that midbrain BPND is higher in former smokers than in smokers and non-smokers. Interestingly, smoking

status significantly interacted with 5-HTTLPR genotype, i.e. the association of active smoking with reduced 5-HTT availability was only seen in LL subjects but not in carriers of the S-allele. Or from the perspective of genotype effects, former smokers and non-smokers showed the expected association with 5-HTTLPR, i.e. higher 5-HTT availability in LL subjects compared to carriers of the S-allele, whereas this pattern was actually reversed for active smokers. Our study indicates that smoking status moderates the association of 5-HTTLPR genotype and 5-HTT expression. This may help to explain inconsistent findings in previous studies. Regarding the mechanism, we suggest that smoking induces epigenetic processes such as methylation of SLC6A4 which might differ depending on its genetic constitution.

Title: Neuroanatomical location of orexin projecting nerve fibers in mesocorticolimbic pathways of GAD67-GFP knock-in mice

Authors: *O. DEHKORDI[1], J. E. ROSE[2], S. ASADI[1], R. M. MILLIS[1], A. J. TROUTH[1]
[1]Dept. of Neurol., Howard Univ., WASHINGTON, DC; [2]Dept. of Psychiatry, Duke Univ. Med. Ctr., Durham, NC, NC

Abstract: Orexin-and GABA-containing neurons are implicated in the neurobiology of nicotine addiction. However, the neuroanatomical and neurochemical relationships between such neurons in the neurocircutry of addiction is not known. Therefore, In the present study in glutamic acid decarboxylase-green fluorescence (GAD67-GFP) knock-in mice, we used immunohistochemistry to identify the neuroanatomical location of orexin-containing neurons and nerve fibers with respect to GABAergic neurons in hypothalamic regions and in areas overlapping the mesocorticolimbic pathways.Consistent with previous studies, orexin inmmunoreactive (IR) cells were present exclusively in the lateral hypothalamus. Orexin IR nerve fibers were observed at multiple sites throughout the CNS. In the hypothalamic region,orexin IR nerve fibers were found to be intermingled with GAD67-GFP positive cells. The GAD67-GFP positive cells at these sites were seen medial and ventral to the orexin IR cells and at sites which correspond to the dorsomedial hypothalamic nucleus and the arcuate hypothalamic nucleus. In the ventral tegmental area (VTA), orexin IR nerve fibers were seen at areas rostral to the GAD67-GFP positive cells of interpeduncular nucleus (IPN) and at sites overlapping paranigral nucleus, parainterfascicular nucleus and parabrachial pigmented nucleus. More rostrally, orexin IR nerve fibers were seen in areas overlapping retromamillary nucleus, interfascicular nucleus and rostral VTA, at sites which were lateral to the GAD67-GFP positive cells of medial terminal nucleus and substantia nigra compact part. In nucleus accumbens (Acb) and prefrontal cortex (PFC), orexin IR nerve fibers were found to be intermingled with GAD67-GFP positive cells. In addition, orexin IR nerve fibers were detected in many other brain regions subserving the reward pathways. The present anatomical data demonstrate that orexin-containing neurons of the lateral hypothalamus have direct projections to structures of the mesocorticolimbic reward centers. The close proximity of orexin IR nerve fibers to GAD67-GFP positive cells of the prefrontal cortex and nucleus accumbens suggests that orexin-containing nerve fibers may modulate activity of GABAergic neurons at these sites.

Title: Menthol speeds the desensitization of human α3β4 nicotinic acetylcholine Receptors

Authors: *H. TON, A. SMART, T. XIE, K. J. KELLAR, G. P. AHERN
Georgetown Univ., Washington, DC

Abstract: The α3β4 receptor is the most prevalent nicotinic acetylcholine receptor expressed in the peripheral nervous system. Notably, α3β4 receptors in airway sensory nerves may transduce the irritant effects of nicotine in tobacco smoke. In our study, we sought to examine potential effects of menthol, a counterirritant, at these ion channels by performing Ca^{2+} imaging, whole-cell voltage-clamp recording and [^{3}H]-epibatidine binding in HEK cells stably expressing human α3β4 nAChRs. Co-application, but not pre-treatment, of menthol with acetylcholine and nicotine inhibits the function of α3β4 nAChRs by increasing desensitization. This is demonstrated by a reduction of the current integral as well as an increase in the rate and magnitude of the current decay. Menthol does not act at the orthosteric nAChR binding site as it does not compete for [^{3}H]-epibatidine binding. Menthol-induced inhibition of α3β4 nAChRs may contribute to the counterirritant action of menthol in nicotine-induced irritation.

Title: Menthol induces anesthetic effects mediated by GABAA-receptors in fishes

Authors: *M. KASAI
Grad. Sch. of Sci. & Engineering,, Kagoshima Univ., Kagoshima, Japan

Abstract: Menthol is well known to be able to induced cold and pain sensations in subjects. To determine whether fishes respond to menthol, Japanese medaka, goldfish and zebrafish were exposed to various types of menthol receptors agonists and the behavioral responses to these drugs were observed. Waterbone application of dl-menthol (0.5 mM) induced surgical anesthesia in 100% of medaka, 90% of goldfish, and 100% of zebrafish. The percentage of response increased dose-dependently from 0.2 mM to 0.5 mM. Sedation (motion loss) was observed more than 0.2 mM in goldfish by both d-, and l- types of menthol in goldfish. There were no differences in either percentage or the response in the anesthesia among dl-, d-, and l- types of menthol. A high (3.0 mM) concentration of any of the three types of menthol induced rapid movement followed by the surgical anesthetic response. Rapid movement was observed with allyl isothiocyanate, a cold nociceptor agonist, but not with icilin, a cold receptor agonist, in medaka and goldfish. Both allyl isothiocyanate and icilin failed to induce surgical anesthesia. To determine the involvement of γ-aminobutyric acid (GABA) system in menthol-induced anesthesia, the effect of the receptors antagonist was tested. Pretreatment with a specific GABAA receptor antagonist prolonged the latency of the surgical anesthetic responses and completely attenuated the sedation to menthol in goldfish. These results demonstrate that menthol may play a role in the induction of anesthesia in fishes, related at least in part to the activation of GABAA receptors, and of rapid movement possibly via cold nociceptors.

Title: A menthol conditioned reinforcer promotes acquisition of nicotine self-administration in rats

Authors: M. R. KELLICUT[1], A. M. BROWN[1], A. B. SHEPPARD[1], E. M. ODINEAL[1], *M. I. PALMATIER[2]
[1]Psychology, [2]East Tennessee State Univ., Johnson City, TN

Abstract: Nicotine (NIC) by itself is a weak to moderate reinforcer but it potently increases responding for non-drug conditioned reinforcers (CRs). Twenty-five percent of all cigarettes sold in the United States are menthol flavored and menthol is a common flavor additive in candy, ice-cream, and other foods. Thus, menthol may serve as a CR and interact with nicotine to promote tobacco use. These experiments investigated the effects of a menthol CR on NIC self-administration in rats. To do so, menthol was established as a CR (Menthol-CR groups) or neutral stimulus (Menthol-Neutral groups). Each group received access to two gustatory stimuli (0.0005% menthol or 0.05% grape Kool-Aid). For the Menthol-CR groups, sucrose (20% w/v) was added to the menthol solution. For the Menthol-Neutral groups, sucrose was added to the grape solution. Rats were then instrumented for intravenous (IV) NIC self-administration. In Experiment 1 responses on a nose-key resulted in presentation of 0.0005% menthol solution (unsweetened) in a liquid dipper and IV NIC (1.5-60 ug/kg/infusion, dose calculated as base). The Menthol-CR robustly increased responding at low NIC doses, peak responding was observed at 3.25 ug/kg/infusion. For the Menthol-Neutral group peak responding was observed at a dose almost 5 times higher, 15 ug/kg/infusion. In Experiment 2, the experimental group (Menthol-CR+NIC) was compared to two controls - a group that provided a baseline for the primary reinforcing effects of NIC (Menthol-Neutral+NIC) and a group that provided a baseline for the conditioned reinforcing effect of menthol (Menthol-CR+SAL infusions). The peak unit dose from Menthol-CR groups in Experiment 1, 3.25 ug/kg/infusion, was available during acquisition. For all groups the reinforcers (0.1 ml menthol and IV NIC or SAL infusion) were contingent upon lick responses at a sipper tube. The Menthol-CR+NIC group made more lick responses than both control groups. The Menthol-Neutral+NIC group did not acquire reliable NIC self-administration at this dose. Subsequent tests under a progressive ratio schedule indicated that the motivation to obtain the reinforcers in the Menthol-CR+NIC group was inversely related to unit NIC-dose, with the lowest doses (3.25-6.5 ug/kg/infusion) supporting the highest responding. These experiments indicate that a menthol CR increases the reinforcing effects of low unit NIC doses, promotes acquisition of NIC self-administration, and may alter the relationship between NIC dose and reinforcer efficacy.

Title: A chilling connection; menthol's effect on nicotinic acetylcholine receptor expression and synaptic structure in the rodent brain

Authors: *S. P. BRIDGES[1], J. R. KING[1], J. C. NORDMAN[1], P. MULDOON[2], M. LIZARRAGA[1], I. DAMAJ[2], N. KABBANI[1]
[1]Dept. of Mol. Neurosci., George Mason Univ., Fairfax, VA; [2]Dept. of Pharmacol., Virginia Commonwealth Univ., Richmond, VA

Abstract: Although menthol, a common flavoring additive to cigarettes, has been found to impact the addictive properties of nicotine cigarettes in smokers, little is known about its molecular actions in the brain. To test the involvement of nicotinic acetylcholine receptors (nAChR) in menthol associated nicotine addiction, we examined proteomic and structural changes in the brain of rodents exposed to nicotine with and without menthol. Western blot analysis of α7, α4, and β2 nAChR subunit expression suggests that menthol impacts the levels and distribution of several nAChRs in various brain regions. In particular, co-administration of menthol and nicotine appears to promote significant alterations in β2 and α7 nAChR subunit expression in the hippocampus, amygdala, and striatum of mice. Immunohistochemical analysis of α7 nAChR and synaptic marker protein expression reveals dynamic alterations in post-synaptic structures within hippocampal neurons in response to menthol administration. Because the addition of menthol to tobacco products has been suggested to augment their addictive potential, the current findings reveal several new molecular adaptations that may contribute to its unique addictive profile.

Title: Menthol alone alters the number and assembly of α4β2 and α6β2* nAChRs

Authors: *B. J. HENDERSON[1], T. WALL[1], W. A. NICHOLS[2], R. SRINIVASAN[2], H. A. LESTER[1]
[1]Div. of Biol., [2]Div. of Biol. and Biol. Engin., Caltech, Pasadena, CA

Abstract: We report the first observation that chronic exposure to presumed smoking-relevant levels of menthol affects the properties and numbers of neuronal nicotinic acetylcholine receptors (nAChRs) *in vivo* and *in vitro*, even in the absence of nicotine. Using mice expressing fluorescent α4 and α6 nAChR subunits we show that menthol increases the numbers of α4* and α6* nAChRs in midbrain neurons. The α6* nAChRs on dopaminergic neurons of the ventral tegmental area (VTA) and substantia nigra pars compacta (SNc) become more abundant during chronic treatment with menthol. We also found that chronic menthol increased numbers of α4* nAChRs in both VTA and SNc dopaminergic neurons; but α4* nAChRs in GABAergic neurons of the substantia nigra pars reticulata (SNr) did not change. To investigate effects of chronic menthol treatment in more detail, we studied cultured cells transiently expressing α4β2 or α6β2β3 nAChRs. In cells expressing α4β2 nAChRs, chronic treatment with menthol increases α4β2 nAChRs, but does not affect peak current amplitudes or desensitization kinetics of ACh-induced currents. We also found that chronic menthol treatment shifts the α4β2 nAChR stoichiometry from the usual mixed population (higher and lower sensitivity) toward the lower sensitivity using two metrics: 1) analysis of concentration-response curves and 2) the use of Förster resonance energy transfer (FRET). In cells expressing α6β2β3 nAChRs, chronic menthol treatment increased the population of α6β2β3 nAChRs, but decreased peak ACh-induced currents. This decrease in peak current amplitude resulted presumably from menthol-induced stabilization of α6β2(non-β3) nAChRs. Chronic menthol treatment reduced the FRET efficiency between fluorescent protein-labeled α6 and β3 nAChR subunits. This suggests that chronic menthol treatment does not favor (or destabilizes) assembled nAChRs pentamers containing the β3 subunit. Together, these data suggest that menthol, even in the absence of nicotine, increases nAChR numbers and preferentially stabilizes lower sensitivity assemblies of α4* and α6* nAChRs. These effects of chronic menthol on two populations of high-sensitivity nAChRs differ in detail from the effects of chronic nicotine. **Support:** DA017279; DA019375; DA033721.

Title: Metabotropic glutamate receptor 5 modulation within NAc shell during environmental elicited cocaine conditioning

Authors: *K. TORRES, A. MARTÍNEZ-RIVERA, D. SANTIAGO-TRISTANI, I. CARRO-CRUZ, A. ROSADO, C. S. MALDONADO-VLAAR
Biol., Univ. De Puerto Rico, Rio Piedras, San Juan, PR

Abstract: The metabotropic glutamate receptor 5 (mGluR5) within the Nucleus Accumbens (NAc) have been implicated in modulating psychostimulant reward. Data from our laboratory demonstrate that mGluR5 blockade decreased environmental-elicited cocaine conditioning response. Our results imply that mGluR5 could be modulating the memory processes regulated within the NAc shell, essential for the association of environmental cues with cocaine effects. Different mechanisms can be driving this conditioning response. ERK1/2 have been related with cocaine addiction, both acute and repeated cocaine injections increase ERK phosphorylation (a measure of ERK activity) in projection areas of the mesocorticolimbic dopamine system. Moreover, studies have shown that mGluR5 activation leads to ERK1/2 phosphorylation and the up-regulation of CREB and Elk-1. We focused in elucidating which proteins have been affected during the expression of environmental elicited locomotion conditioning when we block mGluR5 with MPEP. Rats were implanted with cannula within NAc shell, and separate groups were exposed to a multimodal environment within activity chambers that signaled cocaine (paired) or saline (controls, unpaired). Prior to placing the animals in the chambers, rats received systemic injections of saline or cocaine for 10 consecutive sessions. On the test session (Day 12) separate groups of animals were infused within NAc shell with 25nmol/.5µl/side of MPEP. Preliminary data showed that the ratio of pERK/ERK 41-42 within NAc shell is not affected during the expression session after mGluR5 blockade. These results suggest that other proteins associated with mGluR5 cascade are modulating the expression of the conditioning. Furthermore, previous results report that mGluR5 positive allosteric modulators (PAMs) enhance synaptic plasticity, improve spatial learning and it's have a beneficial effects in the treatment of

cognitive impairment associated with schizophrenia. However, no study to date has investigated the therapeutic potential of other mGluR5 PAM novel compounds on specific aspects of cocaine addiction such as conditioned locomotor response. Our hypothesis is that the mGluR5 selective agonist CHPG will promote and enhance the expression of the cocaine conditioned response. Different groups of rats were microinjected with vehicle or the CHPG into the NAc shell and then they were placed in the activity chambers during Day 12. Interestingly, no change in the expression of the conditioned response were found in cocaine paired experimentally treated animals. Future studies are needed to further characterize these effects.

Title: Sex differences in hippocampal activation during initial abstinence from cocaine: Effects of the beta-adrenergic antagonist, propranolol

Authors: *A. S. KOHTZ, J. I. OSBORNE, M. E. SMITH, A. M. CASON, G. ASTON-JONES
Neurosci., Med. Univ. of South Carolina, Charleston, SC

Abstract: Prior studies indicate that female rats exhibit greater drug-seeking behavior during initial abstinence following a period of cocaine self-administration when compared to male rats. The first day of extinction is important as it represents the initiation of abstinence, which is stressful due to absence from chronic drug. Locus coeruleus norepinephrine NE (LC-NE) neurons are involved in stress responses, including the ability of stress to drive relapse of drug-seeking. As well, LC-NE neurons are more sensitive to stress in females than males. One prominent target of LC-NE neurons is the dorsal hippocampus (DH), which has a number of structural and biochemical sex differences that modulate stress responsivity including axonal growth, granule cell density, cholinergic enzyme activity, as well as adrenergic-, corticosterone-, and GABA- receptor expression. Notably, the DH is required for context-dependent reinstatement of drug seeking, and drug relapse often occurs when addicts are re-exposed to

drug-associated contexts. Therefore, we hypothesize that the stress of initial abstinence may influence hippocampal neuron activity via beta-adrenergic receptors in a sex-dependent manner. Male and female Sprague-Dawley rats were implanted with indwelling jugular catheters and trained to lever-press for cocaine (iv, daily 2 hr sessions, 0.2mg/kg/ infusion) for 10 days of stable FR1 responding (>10 infusions/session). Rats were then administered 10mg/kg propanolol, a beta-adrenergic antagonist, or saline vehicle (IP), 20 minutes prior to being placed in the self-administration chamber during an initial abstinence/extinction session (ED1, 90 minutes, no cocaine infusions given), or remained in their home cages (HC) as controls. Rats were then deeply anesthetized, transcardially perfused with saline and 4% paraformaldehyde, and brains were removed and processed for immunohistochemical localization of Fos as a marker of neuronal activation. Results indicate that drug-seeking behavior on ED1 among both male and female rats is significantly decreased by administration of propranolol. Expression of Fos in hippocampal CA1 neurons is increased in female rats subjected to ED1 training compared to male rats, or compared to female HC controls. Administration of propranolol decreased CA1 Fos in both ED1 males and female rats. These findings indicate that hippocampus CA1 neurons may contribute to context driven drug-seeking behavior during initial abstinence.

Title: The interaction between cocaine and ethanol within the nucleus accumbens shell

Authors: ***C. P. KNIGHT**[1], G. A. DEEHAN JR.[1], S. R. HAUSER[1], J. A. WILDEN[2], W. J. MCBRIDE[1], Z. A. RODD[1]

[1]Psychiatry, Indiana Univ. Sch. of Med., Indianapolis, IN; [2]Neurosurg., Louisiana State Univ. Hlth. Sci. Ctr., Shreveport, LA

Abstract: The co-abuse/use of cocaine and ethanol (EtOH) is common and occurs in 96% of cocaine users. Co-administration of alcohol and cocaine prolongs the euphoric effects of the drugs while diminishing the anxiogenic effects of cocaine. Cocaine and EtOH are directly self-infused into the nucleus accumbens shell (AcbSh). The current experiment was conducted to determine the interaction between ethanol and cocaine within the AcbSh to produce reward. In alcohol-preferring (P) rats, the threshold to establish self-infusion directly into the AcbSh is 100 mg% EtOH and 200 pmol/100nl cocaine. The current experiments examined co-infusion of combinations of sub-threshold doses of both drugs. Following one week of recovery for implanting guide cannulas aimed at the AcbSh, subjects were placed in standard two-lever (active and inactive) operant chambers. Test sessions were 60 min in duration and occurred every other day for a total of 7 sessions. Rats were randomly assigned to one of 17 groups (n=6-9/group) that self-infused (FR1 schedule) combinations of EtOH (0, 12.5, 25, 50, or 75 mg%) and combinations of cocaine (0, 6.25, 12.5, 25, 50, and 100 pmol/100nl) for the first 4 sessions. All rats received only aCSF in the infusate for sessions 5 and 6 (extinction), but received the original infusate again for session 7 (reinstatement). The results indicated that numerous sub-threshold doses of cocaine and EtOH are self-infused directly into the AcbSh. For example, 6.25 pmol/100nl cocaine + 50 mg% EtOH was self-infused directly into the AcbSh, but 6.25 pmol +25 mg% EtOH was not. In addition, 25 pmol/100 nl cocaine + 25 mg% EtOH was also self-infused into the AcbSh. The data indicate that cocaine would be self-infused at 32-fold lower concentrations if co-infused with EtOH than if given alone. Similarly, a 4-fold lower concentration of EtOH was co-infused with cocaine than if given alone. Overall, the data indicated that the combination of EtOH and cocaine acted synergistically within the AcbSh to produce reinforcement. The data provide a possible biological basis for the high rate of EtOH and cocaine co-abuse, and detail how the drugs interact to enhance their euphoric effects.

Title: Retrospective carbon-14 birth dating demonstrates effects of cocaine and alcohol abuse on adult hippocampal cell turnover

Authors: H. DRUID[1], T. WARDI[1], K. ALKASS[1], S. BERNARD[2], *S. P. GARAMSZEGI[3], L. DUQUE[3], B. A. BUCHHOLZ[4], G. DHANABALAN[1], M. SALEHPOUR[1], K. SPALDING[1], D. C. MASH[3]

Abstract: The global increase in atmospheric carbon-14 resulting from nuclear weapons testing affords a method for birth dating new neurons in the human brain. We used the retrospective carbon-14 birth dating technique developed at the Karolinska Institute in Stockholm to estimate when hippocampal cells were born to determine the effects of chronic cocaine and alcohol abuse on neuronal and nonneuronal cell turnover. Information about alcohol and drug use history, and medical conditions were obtained from structured interviews with relatives and informants and by review of forensic pathology investigations, police reports, and medical records. Archived brain specimens were sampled for FACS sorting and accelerator mass spectrometry of DNA extracted from the human hippocampus to compare levels of atmospheric carbon-14 during the birth year and across the lifetime of the alcoholic and cocaine dependent subjects. Mathematical modeling of carbon-14 concentrations was based on birth and death processes and renewal equations representing different scenarios for turnover of NeuN-positive cells (neurons) and NeuN-negative populations (oligodendrocytes, astrocytes, microglia, and endothelial cells) to quantify the overall extent of cell renewal. Analysis of the carbon-14 concentrations in hippocampal genomic DNA revealed that the majority of analyzed subjects had levels corresponding to time points after their birth, establishing postnatal cell generation in the human hippocampus. Weighted regression estimates of hippocampal cells were significantly lower in alcoholics as compared to controls ($p=0.015$, Wilcoxon rank-sum test, alcoholics vs. non-alcoholics). However, when comparing groups with or without cocaine dependence, the difference was not significant ($p=0.073$). The results show that although nonneuronal cells are exchanged in chronic cocaine abusers, the hippocampal neurons and nonneuronal fractions are as old or older in alcoholics, supporting the view that postnatal hippocampal cell turnover is damaged by chronic alcohol abuse.

Abstract: Stress promotes relapse of drugs of abuse. In animal studies, stress reinstates drug-seeking behavior through the effects of CRF. The VTA is involved in the stress-induced and CRF-mediated reinstatement of drug self-administration. The orexigenic/hypocretin system drives cocaine reinstatement through activation of stress pathways and involves orexin receptors (OXR) localized in the VTA. In the present study we demonstrate the existence of allosteric interactions between ligands of CRF receptors (CRFR) and OXR in transfected cells and in the VTA that depend on CRFR-OXR heteromerization, and which modulate local dopamine somato-dendritic release. In transfected HEK-293T cells, CRF1R-OX1R and CRF2R-OX1R heteromerization was demonstrated with bioluminescent resonance energy transfer (BRET) and bi-molecular fluorescent complementation (BMFC) techniques. Negative crosstalk and cross-antagonism of CRFR and OXR ligands was observed with cell-signaling experiments. Synthetic peptides with the amino acid sequence of transmembrane 1 and 5 domains of OX1R (OX1R-TM1 and OX1R-TM5) disrupted BMFC and the negative crosstalk and cross-antagonism observed with MAPK signaling both in transfected cells and in rat VTA slices, demonstrating the presence of functional CRF1R-OX1R heteromers in the VTA. Also cocaine and the selective σ1

receptor agonist PRE-084 disrupted crosstalk and cross-antagonism of CRF1R and OX1R ligands in the VTA and modified the quaternary structure of CRF1R-OX1R heteromers, as demonstrated with BRET experiments in transfected cells. Sequential RET (SRET) experiments in transfected cells demonstrated the ability of σ1 receptor to complex with CRF1R-OX1R heteromers. *In vivo* microdialysis experiments in rats showed that local infusion of orexin A, but not CRF, induces dopamine release, which was antagonized by CRF. This negative crosstalk depended on CRF1R-OX1R heteromers, since it was counteracted by OX1R-TM1 and OX1R-TM5 peptides and by local perfusion with PRE-084. In the presence of the σ1 receptor agonist, CRF also induced VTA dopamine release. These results demonstrate that the CRF1R-OX1R heteromer is a target for cocaine and can explain the previously reported apparently independent effects of CRF and orexin A on stress-induced cocaine reinstatement.

Title: CB1 receptor involvement in reconsolidation of context-cocaine memories that drive instrumental drug-seeking behavior

Authors: M. A. PRESKER[1], S. J. STRINGFIELD[1], *K. M. HARMON[2], J. A. HIGGINBOTHAM[2], A. A. ARGUELLO[2], R. A. FUCHS[2]
[1]Psychology, Univ. of North Carolina, Chapel Hill, NC; [2]Integrative Physiol. & Neurosci., Washington State Univ., PULLMAN, WA

Abstract: Exposure to drug-associated contextual stimuli precipitates relapse in cocaine users and cocaine-seeking behavior in rats. This phenomenon requires the maintenance of context-cocaine associative memories in long-term memory stores through the process of memory reconsolidation. Studies utilizing aversive or appetitive Pavlovian learning paradigms have

indicated a role for cannabinoid CB1 receptor-mediated signaling in memory reconsolidation. Here, we investigated the role of CB1 receptors in the reconsolidation of associative memories that promote drug context-induced cocaine-seeking behavior with focus on two brain regions implicated in this phenomenon: the basolateral amygdala and dorsal hippocampus. Male Sprague-Dawley ratswere trained to press a lever for intravenous cocaine infusions in a distinct context, followed by extinction training in a different context. On day 8 post cocaine, rats were re-exposed to the previously cocaine-paired context for 15 min in order to reactivate cocaine-related memories or remained in their home cages (no reactivation control). Immediately after this session, rats received systemic, intra-basolateral amygdala, or intra-dorsal hippocampal administration of the CB1 receptor antagonist, AM251. The rats were tested for reinstatement of extinguished cocaine-seeking behavior in the cocaine-paired context after at least two daily extinction sessions in the extinction context. Systemic administration of AM251 at the time of memory reconsolidation dose-dependently attenuated subsequent cocaine-seeking behavior in a memory reactivation-dependent fashion. Our preliminary findings indicate that post-memory reactivation AM251 administration into the basolateral amygdala disrupted, while AM251 administration into the dorsal hippocampus failed to alter, subsequent cocaine-seeking behavior. These findings suggest a requisite role for CB1 receptor stimulation in the reconsolidation of contextual cocaine memories that inform instrumental drug-seeking behavior.

Title: The dopamine-prefrontal-accumbens circuit and cocaine reinstatement behavior

Authors: *M. H. JAMES, G. ASTON-JONES
Neurosciences, Med. Univ. of South Carolina, Charleston, SC

Abstract: Background: Dopamine (DA) in medial prefrontal cortex (mPFC) is both necessary and sufficient for reinstatement of cocaine seeking (McFarland & Kalivas, 2001). Further evidence indicates that glutamatergic projections from mPFC to nucleus accumbens core (NAc) are involved in such reinstatement behavior. For example, reinstatement is blocked by optogenetic inhibition of mPFC terminals in NAc (Stefanik et al., 2013), as well as by intra-NAc microinfusions of an AMPA receptor antagonist (LaLumiere & Kalivas, 2008). The present study sought to provide evidence that dopamine input onto NAc-projecting mPFC cells is involved upstream of this circuit for reinstatement behavior, using a contralateral disconnection design. **Methods:** Sprague Dawley rats (n=27) were prepared with guide cannulae in the prelimbic area (PL) and NAc (contralateral hemispheres) and underwent cocaine self-administration training, followed by 7+ days of extinction. Prior to cue-induced reinstatement testing, animals received intra-PL microinfusions of either the D1/D2 antagonist fluphenazine (33.3mM/0.3µl) or vehicle, as well as either a cocktail of the NMDA/AMPA receptor antagonists AP-5 (33.8mM/0.3µl) and CNQX (3.3mM/0.3µl) or vehicle in NAc. One week following reinstatement testing, animals received similar treatments and were tested for locomotor activity. **Results:** Animals that received PL-directed fluphenazine and NAc-directed AP-5/CNQX in a contralateral fashion exhibited significantly attenuated reinstatement compared to vehicle-treated controls ($p<0.05$). Infusions of either fluphenazine or AP-5/CNQX alone in combination with vehicle in the contralateral hemisphere had no effect on reinstatement behavior. No differences were observed between treatment groups in terms of locomotor activity. **Conclusions:** These data provide evidence that dopamine acts on mPFC glutamate neurons that project to ipsilateral NAc to drive cue-induced reinstatement of cocaine seeking. These results extend those in the companion poster by McGlinchey et al that show that cue-induced reinstatement is associated with activation of PL neurons that project to NAc but not those that project to NA shell or ventral tegmental area. Studies are currently underway to characterize the electrophysiological properties of NAc-projecting mPFC cells that are responsive to dopaminergic input.

Title: Activated glutamatergic projections to the nucleus accumbens core vs. shell during cue-induced cocaine and sucrose seeking

Authors: *E. M. MCGLINCHEY, S. V. MAHLER, G. ASTON-JONES
Neurosciences, Med. Univ. of South Carolina, Charleston, SC

Abstract: The nucleus accumbens (NAc) is well established as an integral region in brain reward pathways. Glutamatergic inputs to the NAc are thought to promote motivated behaviors, including conditioned drug seeking. The three main brain regions that provide drug cue-related glutamatergic input to the NAc include the medial prefrontal cortex (mPFC), basolateral amygdala (BLA), and ventral subiculum of the hippocampus (VSub). We aimed to determine if mPFC (separated into prelimbic, PL, and infralimbic, IL, regions), BLA, or VSub neurons that project to the NAc core (NAcc) vs. NAc shell (NAcSh) are activated by cue-induced reinstatement of extinguished cocaine- or sucrose- seeking. We paired injections of the retrograde tracer cholera toxin B subunit (CTb) with Fos immunohistochemistry to investigate Fos activation of mPFC, BLA, and VSub neurons that project to NAcc and NAcSh. Rats trained to self-administer cocaine or sucrose by pressing a lever, then extinguished of this behavior. On test day, some rats received an additional extinction day, and other rats received a cue-induced reinstatement test in which cocaine- or sucrose-associated light/tone cues were presented on lever press without reward. We found that PL, BLA, and VSub neurons that project to the NAcc are activated during cued reinstatement of cocaine seeking compared to extinction of self-administration. No such differences were seen in PL neurons that project to the ventral tegmental area (VTA; Mahler 2012), in IL neurons that project to the NAcc, or in any of these regions that project to the NAcSh. We also found that the PL-NAcc circuit was uniquely activated during cocaine seeking, but not with sucrose seeking, whereas both cocaine and sucrose seeking activated NAcc-projecting BLA and VSub neurons. Moreover, the percentage of PL neurons projecting to NAcc that were also Fos+ correlated with active lever pressing during cocaine seeking, but not during sucrose seeking; such a correlation was not found for other projections studied. These results demonstrate differential activation of projections to NAcc vs. NAcSh with reinstatement of cocaine seeking. They also show marked selectivity for the PL-NAcc projection during cue-induced cocaine seeking, not seen in PL-VTA projection (Mahler, 2012). These results reveal important specificity in circuits underlying cue-induced relapse to cocaine seeking.

Title: Orexin/hypocretin knockdown decreases cocaine seeking but does not alter cocaine taking

Authors: *B. A. ZIMMER, B. S. BENTZLEY, G. ASTON-JONES
Neurosciences, Med. Univ. of South Carolina, Charleston, SC

Abstract: Studies indicate that hypothalamic orexin/hypocretin neurons play an important role in the psychostimulant addiction process, and that these cells are specifically involved in motivated responding for drugs of abuse. For example, orexin 1 receptor (OxR1) blockade significantly decreases behavior that requires high-effort responding such as progressive ratio performance, but not low-effort schedules such as fixed ratio-1 responding. It is thought that behavior under low-effort conditions is regulated primarily by consumptive (drug-taking) mechanisms, whereas high-effort responding is driven more by drug-seeking mechanisms. However, distinguishing between drug-taking and drug-seeking has historically been very difficult as both mechanisms are active at the same time under normal iv self-administration procedures. We used a novel within-session behavioral economics (BE) threshold procedure to quantitatively dissect and analyze both drug-taking and drug-seeking within a single self-administration session. In this study, we trained animals to self-administer cocaine and established baseline cocaine demand via behavioral economic analysis. We then microinjected vivo-morpholinos targeted to orexin into the lateral hypothalamus. This treatment has been shown to selectively knock down orexin production for several days. Rats continued to self-administer cocaine on a within-session threshold procedure during this treatment phase. BE analysis revealed that orexin knockdown attenuated cocaine demand at high effort but had no effect on hedonic setpoint (cocaine consumption under low-effort conditions). These results suggest that in a single session, the orexin system plays a crucial role in the motivational aspects of drug seeking under high-effort conditions, but is not necessary for mechanisms regulating low-effort drug consumption. These results combined with previous research indicate that the orexin system could be a productive target for clinical interventions.

Title: Incubation of cue-elicited cocaine-craving relates to sensitized glutamate release in the vmPFC

Authors: *C. B. SHIN, J. R. SHAHIN, M. M. SERCHIA, A. E. AGARONOVA, K. K. SZUMLINSKI
Univ. of California, Santa Barbara, Santa Barbara, CA

Abstract: Relapse to drug-taking is a reoccurring phenomenon impairing addiction recovery that can be triggered by the elicitation of intense drug craving upon re-exposure to drug-paired cues. Cue-elicited drug craving increases in a time-dependent manner during drug abstinence - a phenomenon termed “incubation of craving”. The neural substrates of this phenomenon are not fully understood but may involve a sensitization of cue-elicited neurotransmitter release within the ventromedial prefrontal cortex (vmPFC). To test this hypothesis, male Sprague-Dawley rats were trained to lever-press for cocaine (0.25 mg/infusion; 6 h/day) or sucrose pellets (45 mg) and in both cases, reinforcer delivery was signaled by a light-tone compound stimulus. A control group was allowed the opportunity to lever-press for the compound stimulus only. After 10 consecutive days of self-administration training, animals were left undisturbed for either 3 or 30 days. Rats then underwent a 3-h *in vivo* microdialysis session in the operant chamber, during which animals were allowed to respond for presentation of the cues, in the absence of reinforcer delivery. As expected, cocaine-trained animals exhibited a time-dependent intensification of cue-reinforced responding that was selective for the lever that previously delivered cocaine. On the other hand, sucrose and control animals did not exhibit a difference in responding across withdrawal. The opportunity to lever-press for cocaine-paired cues elicited a time-dependent sensitization of vmPFC glutamate release during withdrawal, while the capacity of cocaine-cues to elevate extracellular dopamine dissipated with withdrawal. In contrast, the changes in vmPFC glutamate and dopamine elicited by sucrose-paired or neutral cues did not vary with the passage of time during withdrawal. These data provide novel evidence that the glutamate responsiveness of the vmPFC incubates during protracted withdrawal in parallel with the behavioral responsiveness to cocaine-paired cues. This heightened cortifugal glutamate drive likely contributes to the desensitization of vmPFC mGluR1/5 receptors underpinning extinction

learning deficits reported in “incubated” animals and pose pharmacotherapeutic strategies that curb corticofugal glutamate responsiveness to cocaine-paired cues as a viable strategy for facilitating addiction recovery.

Title: A novel combination treatment of levo-tetrahydropalmatine (l-THP) and low dose naltrexone (LDN) for the prevention of cocaine relapse

Authors: *S. A. SUSHCHYK[1], J. WANG[1], Z.-X. XI[2]
[1]Univ. of Maryland, Baltimore, Baltimore, MD; [2]Natl. Inst. on Drug Abuse, Baltimore, MD

Abstract: l-THP is a promising agent for the treatment of substance abuse related disorders. It functions primarily as a modest dopamine antagonist and has been previously reported to be effective in attenuating cocaine-taking and cocaine-seeking behavior in rats. However l-THP’s dopamine antagonism produces some sedative side-effects. Interestingly when LDN is co-administered with l-THP, the sedative side-effects appear to be diminished. LDN (<0.5mg/kg) is proposed to regulate endogenous opioid release. Recent research suggests that long-term use of cocaine induces alterations in the mesolimbic dopamine pathway and the endogenous opioid system, which may play an important role in the pathophysiology of cocaine addiction. Based on these, we propose that the L-THP and LDN combination medication, which targets both the dopamine and endogenous opioid systems, may be more promising at preventing relapse. In the present study, we examined the combination treatment l-THP-LDN as a therapeutic agent for the prevention of cocaine relapse. Male Wistar rats were trained to self-administer cocaine under fixed ratio 2 (FR2) reinforcement to assess the effect of l-THP-LDN (5 mg/kg l-THP + 0.1 mg/kg LDN and 3 mg/kg l-THP + 0.1 mg/kg LDN) on cocaine self-administration. Additional

groups of rats were first trained to self-administer cocaine and then went to extinction to assess the effect of chronically administered l-THP-LDN on cocaine-induced reinstatement of drug-seeking behavior. We found that the combination of 5 mg/kg l-THP and 0.1 mg/kg LDN is more efficacious in attenuating intravenous cocaine self-administration and cocaine-induced reinstatement of drug-seeking behavior than l-THP or LDN alone. The combination of l-THP-LDN also attenuates l-THP-induced sedative effect as assessed by open field locomotor measurement. We conclude that the combination of l-THP and LDN could be a more effective pharmacotherapy with less unwanted sedative effect for the prevention of cocaine relapse in humans.

Title: Neuropeptide Y attenuates cocaine-induced vocalizations and reinstatement behavior in the rat

Authors: *L. M. STRAND[1], C. P. KING[1], M. SUAREZ[1], E. NEILANS[1], D. HOLFOTH[1], J. M. DIPIRRO[2], M. L. DENT[1], A. C. THOMPSON[1]
[1]Psychology, Univ. at Buffalo, Buffalo, NY; [2]Psychology, Buffalo State Col., Buffalo, NY

Abstract: Neuropeptide Y (NPY) is a neurotransmitter found within neural substrates associated with drug use and dependence (e.g., mesolimbicortical pathway) and known to modulate dopaminergic and glutamatergic neurotransmission. Our research has investigated the role of NPY in cocaine relapse. Here we tested the hypothesis that increasing central NPY attenuates (a) cocaine-prime induced reinstatement of cocaine self-administration (SA) and (b) cocaine-evoked 50 kHz vocalizations (USV) in rats with a history of cocaine use. Male Long-Evans rats were allowed to self-administer cocaine (0.5 mg/kg, IV) for 21 3-h sessions by snout-poking into the active hole which was a randomly-assigned hole in the wall. Each snout-poke into the active

(cocaine-paired) hole initiated a cocaine infusion and a cued 25-sec timeout period in which no cocaine infusions were allowed. After 3 weeks, snout poking in the active hole was extinguished by exposure to the SA procedure, without cocaine infusions, for 21 sessions. After extinction, rats were tested twice for reinstatement of the snout-poking response: once after a cocaine prime (10 mg/kg, IP) and once after a saline prime (1 ml/k, IP). NPY was administered (0 or 0.30 nmol, ICV) 30 min before each reinstatement test. Active and inactive snout-poking responses were measured to assess reinstatement of SA behavior. The number of 50 kHz USVs was measured during the first 30 min of the reinstatement session to quantify the USV intensity. As expected, the cocaine prime significantly increased the frequency of snout-poking into the active "cocaine-paired" hole relative to that observed during the last extinction session, that observed in saline-primed rats, and that observed for the inactive (non-cocaine paired) holes. Similarly, the cocaine-prime, but not the saline-prime, significantly increased the frequency of USVs during the reinstatement session (508 ± 67 vs 31 ± 11.4 50 kHz USVs respectively). ICV NPY significantly reduced both the number of active hole snout-pokes and the frequency of 50 kHz USVs during the cocaine primed reinstatement session but had no effect on these measures in the control saline-primed reinstatement session (50.3± 30.2 vs 6.7±1.2 50 kHz USVs respectively). These findings support the idea that central administration of NPY decreases the strength of cocaine and cocaine-associated cues to induce drug seeking behavior and decreases the intensity of 50 kHz USV induced by cocaine. As previous literature has suggested that 50 kHz USV are emitted in response to rewarding stimuli, these results suggest that NPY administered before cocaine, reduces its rewarding value.

Title: Effects of caffeine and its primary metabolite, paraxanthine, administered alone or in combination with cocaine on intracranial self-stimulation in rats

Authors: *M. F. LAZENKA[1], F. G. MOELLER[2], S. S. NEGUS[1]
[1]Pharmacol. and Toxicology, [2]Div. of Addiction Psychiatry and Pharmacol. and Toxicology, Virginia Commonwealth Univ., Richmond, VA

Abstract: Intracranial self-stimulation (ICSS) is one behavioral procedure for preclinical evaluation of abuse liability of drugs. Caffeine is the most widely used psychostimulant in the world, yet little research has been done to determine its effects on intracranial self-stimulation (ICSS). Further, the primary metabolite of caffeine, paraxanthine, has not been tested in ICSS, even though its efficacy to increase locomotor activity and cause dopamine release in the striatum is greater than that of caffeine. This study compared the potency and time course of effects produced by caffeine (3.2-32 mg/kg) and paraxanthine (3.2-32 mg/kg) in a frequency-rate ICSS procedure in rats. Effects of caffeine (32 mg/kg) or paraxanthine (32 mg/kg) in combination with cocaine (10 mg/kg) were also examined, because caffeine and paraxanthine are under consideration as candidate agonist medications that might attenuate abuse-related cocaine effects. Male Sprague-Dawley rats were equipped with electrodes targeting the medial forebrain bundle and trained to respond under a fixed-ratio 1 schedule for electrical stimulation that varied by frequency (56-158 Hz, 0.05 log increments) within each session. Each stimulation consisted of a 0.5 sec train of square-wave 100 μsec pulses at the designated frequency, and stimulation was accompanied by onset of stimulus lights located over the lever. These 0.5 sec periods of stimulation delivery served as time out periods, such that responding during a stimulation produced no scheduled consequences. Rates of reinforced responding (i.e. responses that produced stimulation) and time out responding (i.e. responses during a stimulation) were evaluated as a function of stimulation frequency. In the absence of drug, rats maintained a frequency-dependent increase in both reinforced and time out responding, with time out responding ~5-10% of reinforced response rates. Caffeine significantly facilitated both reinforced and time out responding at 10 mg/kg, as defined by a leftward shift of the ICSS curve, while 3.2 mg/kg and 32 mg/kg produced no effect. Paraxanthine did not alter reinforced responding, but 32 mg/kg paraxanthine significantly increased time out responding. Cocaine facilitated both reinforced and time out responding and pretreatment with either caffeine or paraxanthine failed to alter cocaine-induced facilitation of ICSS. These studies are consistent with the weak abuse liability of caffeine and paraxanthine. In addition, these studies did not yield evidence for a decrease in abuse-related cocaine effects following acute pretreatment with caffeine or paraxanthine.

Title: Role of Oxytocin on the anxiety environment-elicited cocaine seeking behavior and cocaine conditioning

Authors: *A. MORALES-RIVERA[1], J. PEREZ[2], C. M. COLON[3], C. PEREZ[2], C. S. MALDONADO[2]
[1]Univ. Puerto Rico RCM, Comerio, PR; [2]Univ. of Puerto Rico at Rio Piedras, Rio Piedras, Puerto Rico; [3]Univ. of Puerto Rico at Bayamon, Bayamon, Puerto Rico

Abstract: Several clinical studies have revealed that the maintenance of cocaine addiction requires three key contributors: (a) the reinforcing effects evoked by cocaine intake, (b) the environmental stimuli associated with the drug, and (c) the stress (Sinha, 2003). Moreover, a stress stimulus triggers the reinstatement of cocaine seeking behavior, following long periods of abstinence in dependent subjects. The neuronal and anatomical basis of this behavioral phenomenon deserves further investigation. Oxytocin (OT), a neuropeptide produced within the hypothalamus-pituitary axis (HPA) axis, has been related to reward, learning, memory and stress, events that previously have been associated with cocaine addiction. Previously published data from our laboratory demonstrated an increase in mRNA OT levels within the NAc by acute and chronic cocaine exposure (Borrero 2009). Furthermore, it was demonstrated that OT treatments prior to cocaine conditioned stimuli resulted in a significant decrease in anxiety levels of the animals. These results support the notion that OT is involved in the anxiogenic effects of cocaine actions and might play a modulatory role in the rewarding properties of cocaine. The present set of experiments aims to examine the role of OT on environmentally elicited cocaine-seeking behavior and whether OT could reduce anxiety associated with this behavior. OT bind to its receptors distributed widely within several brain regions and upon binding OT triggers a cascade of intracellular events that mediate OT effects. OT receptor activation via PKC phosphorylate extracellular signal-regulated kinase 1 /2 (ERK1/2) within Hypothalamus pituitary axis (HPA). Thus we hypothesized that OT is modulating the stress/anxiety response triggered by environmentally elicited cocaine seeking behavior via MAPK/ERK1/2 within the amygdala and the NAc regions. Results showed that OT pre-treatment significantly reduced reinstatement of cocaine-seeking behavior. Most significantly, OT treatment reduced the anxiety triggered by cue-induced reinstatement conditions and cocaine-paired conditioned locomotion. The present studies demonstrate for the first time that OT actions within the brain mediate the anxiety response triggered by cues previously paired with cocaine intake.

Title: Potentiation of behavioral sensitization by the co-administration of methylenedioxypyrovalerone (MDPV) and cocaine in rodents

Authors: ***M. M. PEET**[1,2], E. L. HARVEY[2], J. L. WALTERS[2], L. E. BAKER[2]
[1]MPI Res., Mattawan, MI; [2]Psychology, Western Michigan Univ., Kalamazoo, MI

Abstract: Reports of abuse and fatal intoxication associated with synthetic cathinones known as "bath salts" are on the rise nationwide. Methylenedioxypyrovalerone (MDPV), one of the primary constituents of bath salts, is commonly used in combination with other drugs such as cocaine (COC) to enhance or prolong stimulant effects. Recent studies have indicated MDPV is a catecholamine transport inhibitor similar to but more potent than COC. Co-administration of these substances may therefore result in additive or synergistic effects. The combined behavioral effects of MDPV and COC have not yet been thoroughly examined. Behavioral sensitization following repeated psychostimulant exposure is considered an index of neuroadaptive changes in brain dopamine reward pathways. The present study sought to investigate the effects of repeated, concomitant administration of MDPV and COC on the development of sensitization and on cross-sensitization to COC. Four groups of male Sprague-Dawley rats were treated with subcutaneous injections of 0.5 mg/kg MDPV, 5 mg/kg COC, 0.5 mg/kg MDPV + 5 mg/kg COC, or saline. Treatments were conducted once daily for 7 consecutive days with locomotor assessments on the first and last day of treatment. Following a 10-day washout period, all groups were administered a challenge dose of 5 mg/kg COC. Behavioral indices evaluated were horizontal activity, vertical activity, and stereotypy counts. Horizontal activity and stereotypy counts in both the MDPV alone and MDPV+COC groups were significantly higher on Day 7 compared to Day 1 with a more pronounced effect in the MDPV+COC group, and vertical activity was significantly higher in the MDPV+COC group only. Furthermore, COC administration following the 10-day washout period significantly increased horizontal activity and stereotypy counts in animals previously treated with MDPV+COC compared to animals

previously treated with saline. These results indicate the development of sensitization and cross-sensitization to COC is enhanced by concurrent administration of MDPV+COC. Moreover, these findings warrant further assessment of the enhanced risk of developing addiction with concurrent MDPV and COC use.

Title: Substance-specific influences of setting on drug reward: An ultrasonic vocalization study in rats self-administering heroin and cocaine

Authors: *R. AVVISATI[1], L. CONTU[1], E. STENDARDO[1], C. MONTANARI[1], M. L. SCATTONI[2], A. BADIANI[1]
[1]Physiol. and Pharmacol. Vittorio Erspamer, Sapienza Univ. of Rome, Rome, Italy; [2]Inst. Superiore di Sanità, Rome, Italy

Abstract: Clinical and preclinical evidence indicate that the setting of drug use affects drug reward in a substance-specific manner. When heroin and cocaine co-abusers, for example, report on the circumstances of drug use, they indicate distinct settings for the two drugs: heroin being used preferentially at home and cocaine preferentially outside the home (Caprioli et al. 2009; Badiani and Spagnolo 2013). Similar results were obtained in rats that were given the opportunity to self-administer intravenously both heroin and cocaine. Rats living in the self-administration (SA) chambers (Resident rats) exhibited in fact a preference for heroin vs. cocaine, whereas rats that were transferred to the SA chambers only for the test sessions (Non-Resident rats) tended to prefer cocaine to heroin (Caprioli et al. 2007, 2008, 2009). It has been hypothesized that the emotional appraisal of drug effects varies as a function of the setting (Badiani 2013). The sympathomimetic and arousing effects of cocaine, for example, would be appraised as unsuitable to a familiar home environment whereas the sedative effects of heroin would be appraised as unsuitable to novel, potentially dangerous environments. Hence, cocaine would be less rewarding at home than outside the home whereas heroin would be less rewarding outside the home. The hypothesis that cocaine produces a more positive affective state when rats self-administer it outside the home relative to the home environment (and vice versa for heroin)

was investigated here by recording ultrasonic vocalizations (USVs) during drug SA. It has been reported that rats emit USVs in the range of 50-kHz when exposed to rewarding stimuli, suggesting that 50-kHz USVs reflect positive affective states (Burgdorf et al. 2000, 2001, 2008). We found that, overall, Non Resident rats emitted more 50-kHz USVs than Resident rats, indicating a state of heightened arousal during exposure to a novel environment. Most important, we found that Non-Resident rats emitted more 50-kHz USVs when they self-administered cocaine than when self-administered heroin whereas Resident rats emitted more 50-kHz USVs when self-administering heroin than when self-administering cocaine. Differences in USVs in Non Resident rats were more pronounced during the first SA session (78±22,3 for cocaine vs. 43±23,5 for heroin), that is when the SA chambers were completely novel to them. In contrast, the differences in USVs in Resident rats were more pronounced during the last SA sessions (38±16,9 for cocaine vs. 100±45,7 for heroin). These findings indicate that the setting of drug taking exerts a substance-specific influence on the ability of drugs to induce positive affective states.

Title: The sensitivity of preclinical abuse potential models to detect reinforcing signals of the local anesthetic procaine

Authors: *D. B. HORTON, E. DUNN-SIMS, A. FOOTE, A. N. MEAD
Drug Safety Res. and Develop., Pfizer, Inc, Groton, CT

Abstract: Local anesthetics, such as procaine, have an extensive history of medical use and act primarily through sodium channel inhibition. While procaine is not scheduled and widespread misuse of procaine does not exist, data from preclinical and clinical studies reveal weak reinforcing signals. Furthermore, the novel sodium channel blocker lacosamide was recently designated a schedule V drug, consistent with a drug thought to possess low potential for abuse. The purpose of the current study was to further characterize the discriminative stimulus and reinforcing properties of procaine in two “classic” preclinical models of abuse potential

assessment, drug discrimination and self-administration. Specifically, the discriminative stimulus properties of procaine (0-60 mg/kg, IP) and cocaine (0-10 mg/kg, IP) were examined in rats which had previously been trained to perform an operant discrimination task based on the interoceptive cue induced by cocaine (9 mg/kg, IP). Additionally, the ability of procaine (0-10 mg/kg/infusion) to support IV self-administration in rats previously trained to self-administer cocaine (0.75 mg/kg/infusion) was determined. As expected, cocaine engendered partial generalization at 2.5 and 5 mg/kg and full generalization at 10 mg/kg. Procaine (30 and 60 mg/kg) produced partial generalization to the cocaine discriminative cues and examination of individual animal data revealed two populations, with some animals displaying full generalization to cocaine and the remaining animals showing little to no generalization. Furthermore, results showed that procaine (1 and 3 mg/kg/infusion) robustly supported self-administration with increases in both infusion rates and active lever responses compared to vehicle. The dose response followed an "inverted U-shape" pattern, similar to that induced by many drugs of abuse in this model. Furthermore, an increase in active lever selectivity was observed at all procaine doses. Analysis of response patterns revealed that procaine maintained inter-infusion intervals with a regularity similar to those maintained by cocaine, suggesting clear control of drug intake. In conclusion, the current study expands on existing data showing that drugs which are not widely abused can display clear reinforcing or discriminative signals in models in which experimental parameters are optimized to detect such signals. These findings are consistent with the perception that preclinical models of abuse potential can be exquisitely sensitive to the reinforcing or discriminative effects of drugs with minimal abuse potential, and that data from such experiments should be interpreted with this information in mind.

Title: Cocaine addiction pharmacogenetics of buprenorphine therapy

Authors: *D. A. NIELSEN[1,2], R. WALKER[3], S. C. HAMON[4], M. H. HARDING[1,2], W. LING[5], T. R. KOSTEN[1,2]
[1]Psychiatry and Behavioral Sci., Baylor Col. of Med., Houston, TX; [2]Michael E. DeBakey V.A. Med. Ctr., Houston, TX; [3]UT Southwestern, Dallas, TX; [4]Statistical & Genet. Consulting LLC, Darien, CT; [5]UCLA, Los Angeles, CA

Abstract: The aim of this study was to identify genetic markers that modulate therapeutic response to buprenorphine/naloxone (Suboxone) treatment of cocaine addiction. Since buprenorphine is a μ-opioid, δ-opioid, and nociceptin receptor full agonist, as well as a κ-opioid receptor partial agonist, we have focused our analysis to several genes of the opioidergic system. A clinical trial, the CTN-0048 Cocaine Use Reduction with Buprenorphine, was conducted with 302 cocaine-dependent subjects who had past-year opioid dependence/abuse, or past-year opioid use and a history of lifetime opioid dependence. Subjects were randomly assigned for 8 weeks to one of three daily medication arms on a platform of naltrexone: 4 mg buprenorphine, 16 mg buprenorphine, or placebo. Subjects also received once-weekly cognitive behavioral therapy. DNA was obtained from 234 subjects. Six genes were genotyped for a total of 13 variants. Treatment efficacy was evaluated by the percent cocaine positive urines per two week period. Modest reductions in cocaine positive urines were observed in both the 4mg and 16 mg buprenorphine groups. Since these reductions were similar, the two buprenorphine groups were combined and compared with the placebo group. Using repeated measures ANOVA, significant interactions of variant x treatment were observed for two variants in the *proopiomelanocortin* (*POMC*) gene (both experiment-wise p=0.003). Buprenorphine decreased positive urines from 43% to 39% and placebo increased positive urines from 57% to 60% in the *POMC* rs1009388 C allele-carrier group. No difference was observed in the GG genotype group between those receiving placebo and buprenorphine. These results suggest that POMC peptides may be targets for subsequent studies on cocaine addiction pharmacotherapy.

Title: Cocaine self-administration results in a distinct epigenetic state in the dorsal medial prefrontal cortex

Authors: *K. PLOENSE[1], A. CARR[2], D. BAKER-ANDRESEN[3], N. WOODWARD[2], X. LI[3], Y. SUN[4], T. BREDY[3], T. KIPPIN[2]
[1]Univ. of California Santa Barbara, Goleta, CA; [2]Univ. of California Santa Barbara, Santa Barbara, CA; [3]Queensland Brain Inst., St. Lucia, Australia; [4]Univ. of California Los Angeles, Los Angeles, CA

Abstract: DNA methylation is a key determinant of gene expression and is implicated in neuroplasticity relevant to addiction. Here, we examine DNA methylation and mRNA expression for two genes, Homer2 and NPAS4, within the dorsal medial prefrontal cortex (dmPFC) following saline, short-access (1h), or prolonged-access (6h), to cocaine during self-administration. As reported previously, only 6h rats exhibited escalated cocaine intake across sessions. Initial MeDIP-CHIP analyses of dmPFC tissue by ChIPMonk software revealed dramatic and extremely gene-specific changes in DNA methylation/demethylation within promoter regions and flanking the transcription start site (TSS). The Homer2 and NPAS4 promoters showed active changes in DNA methylation following 6h and 1h cocaine self-administration compared to saline. A follow-up analysis, via sodium bisulphite conversion followed by mass spectrophotometry interrogating a 1000bp sequence of the Homer2 promoter, confirmed increased methylation of CpG7 in the 6h rats, which contains putative consensus sequences for GATA-1 and p300. Additionally, MeDIP followed by qPCR revealed an increase in DNA methylation for both 1h and 6h rats within the 457-645bp upstream of the NPAS4 transcription start site (TSS).qPCR revealed an increase in Homer2 mRNA levels in the 6h versus 1h and saline conditions, and a decrease in NPAS4 mRNA in 1h and 6h versus saline conditions. These results demonstrate that prolonged cocaine self-administration alters DNA methylation of the Homer2 and NPAS4 gene promoters within the dmPFC in a distinct manner. Additionally, the altered DNA methylation leads to decreases in NPAS4 mRNA and increases in

Homer2 mRNA expression within the dmPFC. Given the known roles of Homer2 as a scaffolding protein for the metabotropic glutamate 1 and 5 (mGluR1/5) receptors and NPAS4 as a transcription factor promoting inhibitory synapse formation, these data indicate that excessive cocaine intake induces changes in gene regulation for inhibitory and excitatory synapses. Thus, excessive cocaine intake induces a distinct change in DNA methylation which may contribute the long-term alterations in brain function associated with addiction.

Title: Predisposing genetic differences in opioid peptides and receptors mRNA levels contribute to the escalation of cocaine intake in rats

Authors: *M. VALENZA, R. PICETTI, V. YUFEROV, M. KREEK
Rockefeller Univ., New York, NY

Abstract: Vulnerability to drug addiction is influenced not only by environmental factors but also by genetic heritability. Since endogenous opioids play a central role in mediating the reinforcing properties of drugs of abuse, including cocaine, the expression of genes involved in those pathways may contribute to the vulnerability to abuse. Therefore aim of the present study was to investigate on the expression of genes coding opioid peptides and receptors in reward-related brain regions to determine their contribution to the vulnerability to escalate in cocaine consumption. We compared two inbred strains known to behave differently when exposed to drugs of abuse, such as Fischer and Lewis rats. Rats were daily exposed to cocaine for 18 h per day, and were allowed to choose the dose to self-administer, closely modelling the human condition of cocaine exposure. Fischer rats had a stable intake while Lewis escalated

progressively their consumption over 14 days. Rats were sacrificed after 24 h withdrawal. Saline-yoked rats were used as control. By quantitative PCR, we found interesting differences between strains in the basal mRNA levels of some genes, e.g. in saline-yoked Lewis rats, never exposed to cocaine, the basal hypothalamic prodynorphin, proenkephalin and delta opioid receptor gene expression were higher than in Fischer rats. The basal delta opioid receptor mRNA levels were found significantly higher in the core of the nucleus accumbens of Lewis compared to Fischer rats. Lewis control rats showed also a lower level of mu opioid receptor gene expression than Fischer saline rats in the nucleus accumbens shell. Prodynorphin mRNA levels were found increased in both the nucleus accumbens shell and in the hypothalamus of Fischer rats exposed to cocaine compared to yoked-saline rats. Such changes were not found in Lewis rats which escalate their cocaine intake. The present results corroborate the hypothesis that predisposing genetic factors are crucially important in the escalation of intake in rodent models of cocaine addiction.

Title: Neuron-subtype specific transcriptional changes following cocaine self-administration in mice

Authors: ***E. C. ANDRADE**[1], E. F. SCHMIDT[1], J. L. WARNER-SCHMIDT[2], J. ALVAREZ[1], S. B. PICKETT[1], P. GREENGARD[2], N. HEINTZ[1]

Abstract: Studies aimed at understanding the molecular basis of drug addiction have focused largely on the mesolimbic dopamine system and related structures. From these studies, long-lasting alterations in transcription are a clear consequence of repeated exposure to drugs of

abuse. What remain elusive are the specific contributions of neuronal subtypes within these regions to addiction. To better understand the contributions of different cell-types, bacterial artificial chromosome (BAC) transgenic mice which drive the expression of EGFP-tagged ribosomal protein L10a in defined cell populations (known as bacTRAP transgenic lines) were trained to self-administer cocaine. Cell-types of interest include those found in the mesolimbic dopamine system, such as striatal and cortical neurons. Following 3 weeks of cocaine self-administration, polysomal mRNA's were isolated by affinity purification and analyzed by RNA-seq to identify translational profiles of each cell type. Results from these studies provide insight into the neurocircuitry most affected by cocaine use as well as classes of genes most affected.

Title: Nicotine and Cocaine induce temporally-regulated, drug-specific and genome-wide changes in nucleosome occupancy

Authors: *A. N. BROWN[1], J. H. DENNIS[2], P. G. BHIDE[3]
[1]Florida State Univ. Col. of Med., Ctr. for Brain Repair, Biomed. Sci., Tallahassee, FL; [2]Dept. of Biol. Sci., Florida State Univ., Tallahassee, FL; [3]Ctr. for Brain Repair, Florida State Univ. Col. of Med., Tallahassee, FL

Abstract: Drugs of abuse alter the expression of numerous genes throughout the brain that ultimately manifest as behavioral alterations. DNA methylation and histone modifications resulting from drug use have been shown to repress or permit transcription of specific genes by altering local chromatin structure and DNA accessibility. These epigenetic changes may be transient or persist long after drug-use has ceased. In the last several years, changes in DNA methylation and histone modifications following exposure to drugs such as nicotine or cocaine, in correlation with corresponding transcriptional and behavioral alterations, have been well characterized for a variety of genes, *in vitro* and *in vivo* models. However, the underlying molecular mechanisms facilitating these drug-induced epigenetic changes, specifically the masking or unmasking of the DNA to the action of transcription factors and regulatory

machinery, have remained elusive. We exposed human neuroblastoma cells (SH-SY5Y) to nicotine or cocaine, two of the most highly abused drugs in our society today, to examine changes in nucleosome occupancy. Nucleosome occupancy also restricts accessibility of DNA; nucleosome-bound DNA is unavailable for binding by other trans-acting factors, and sets the stage for alterations in transcriptional capability. Using Comparative Genome Hybridization (CGH) to examine the genomic distribution of nucleosomes following exposure to either nicotine or cocaine has revealed widespread, drug- and time-dependent changes in nucleosome occupancy. These drug-induced changes can be predicted based on DNA sequence and often coincide with transcription factor binding sites. However, presence/absence of nucleosomes does not regulate transcription *de facto*. Based on our data, we propose that the effects of drugs of abuse on nucleosome positioning represent an initial genome-wide alteration of the intracellular transcriptional capability, followed by cell-type specific responses in the cascade of downstream signaling or gene expression events. Detailed characterization of the mechanisms and effects of these drug-specific alterations in chromatin structure will further our understanding of drug-induced behavioral responses, pathologies, mechanisms of transgenerational inheritance and potential therapeutic targets for future studies.

Title: Alterations in behavioral regulation and Pavlovian conditioning in cadherin-13 (Cdh13) knock-out rats

Authors: C. P. KING[1], C. VERSAGGI[1], L. MILITELLO[2], J. CATLIN[1], A. A. PALMER[3], J. B. RICHARDS[2], *P. MEYER[1]
[1]Psychology, Univ. at Buffalo, Buffalo, NY; [2]Res. Inst. on Addictions, Univ. at Buffalo, Buffalo, NY, NY; [3]Dept. of Human Genet., Univ. of Chicago, Chicago, IL

Abstract: Variants of the cadherin-13 (*CDH13*) gene have been associated with the subjective response to amphetamine, drug addiction, and attention deficit hyperactivity disorder (ADHD). To examine the role of CDH13 in rodent behaviors related to these disorders, *Cdh13* knockout rats were tested in five paradigms: sensory reinforcement, responding for saccharin, choice

reaction time task, Pavlovian conditioned approach, and cocaine-induced conditioned place preference. Knockout rats responded significantly more for a saccharin reinforcer. Knockout rats also acquired the choice reaction time task more slowly than wild types, but had similar reaction times and number of premature responses once the task was learned. There was also a significant effect of genotype on conditioned place preference, where knockout rats failed to develop a preference for a cocaine-paired cue. There were no differences between knockout and wild-type rats in sensory reinforcement, responding for water, or Pavlovian conditioned approach. Taken together, these data suggest that *Cdh13* is involved in the sensitivity to palatable rewards as well as the conditioned effects of cocaine. Future studies will examine whether these differences depend on sex and extend to drug self-administration phenotypes.

Abstract: Investigations of the precise role of monoaminergic signaling, norepinephric (NE), serotoninergic (5HT) and, dopaminergic (DA) has led to the creation of VMAT2 (Vesicular Monoaminergic Transporter) knockout (KO) mice. While it results in death within few days after birth, VMAT2 heterozygous (Het) mice are viable and display 50% reduction in VMAT2 expression associated with a specific behavioural phenotype. To unravel the specific implication of NE, 5HT and DA in the behavioral effects observed in the constitutive VMAT2-HET mice in which the 3 systems are compromised, we created conditional VMAT2 models. The floxed gene

VMAT2 is specifically spliced in the NE, 5HT or DA neurons by the cre-recombinase expressed under the control of the DBH, SERT or DAT genes respectively. In KO mice, an absence of VMAT2 is revealed respectively and specifically in the LC, in the raphe and in the VTA and SN. A whole brain HPLC study indicates a drastic decrease of NE, 5HT or DA respectively. While complete depletion of DA results in death after 3 weeks, mice with 5HT or NA depletion are viable. Behavioral study of the conditional VMAT2-HET mice specific to NE, 5HT or DA neurons allow us to shed light on the individual and collective contributions of DA and NA in locomotion and the one of DA and 5HT in drugs response. However, independent alteration of only one system is not sufficient to induce depression-like behaviour. This study allows determining the exact contributions of NE, 5HT and DA in specific behaviour associated with psychiatric disorders.

Title: Norepinephrine (NE) function in basal and acute stress conditions with a new NE depletion model: the conditional VMAT2 knockout mice

Authors: *L. C. PERRET, E. ISINGRINI, L. MOQUIN, M.-E. DESAULNIERS, A. GRATTON, B. GIROS

Abstract: The noradrenergic (NE) neurons, mainly located in the locus coeruleus (LC), have been linked to psychiatric disorders involving anxiety and depression. Previous studies have shown that changes in NE transmission from the LC influence anxio/depressive-related behaviors. The purpose of this study was to develop a viable model with NE depletion in the central nervous system without affecting the periphery to investigate NE functions. The NE depletion model was developed using the cre recombinase expressed by the dopamine β-hydroxylase (DBH) genes, which splices out the floxed VMAT2 gene (Vesicular

Monoaminergic Transporter). The VMAT2DBHcre KO mice were validated by a lack of VMAT2 mRNA expression specifically in the LC and NE depletion in the entire brain. The assessment of development and motor abilities confirmed VMAT2DBHcre KO as viable subjects for further testing. VMAT2DBHcre KO mice demonstrated less anxiety- and depression-related behaviors. Moreover, tissue level of DA and 5HT were altered in different brain structures associated with mood and motivational behavior. While basal corticosterone levels were not affected in the VMAT2DBHcre KO mice, acute stress through physical restraint revealed a faster return to basal corticosterone levels in VMAT2DBHcre KO mice. However, prior to the restraint, dexamethasone injections did not yield further differences between wildtype and KO mice. All together, these observations showed a predisposition for VMAT2DBHcre KO mice to exhibit an altered susceptibility to developing anxiety and depression related psychiatric disorders.

Title: Unravelling norepinephrine function in cognition with the new conditional VMAT2 knock-out mice with brain-specific norepinephrine depletion

Authors: *E. ISINGRINI, L. PERRET, N. EILSTEIN, V. GORGIEVSKI, E. GUMA, M.-E. DESAULNIERS, L. MOQUIN, A. GRATTON, B. GIROS
Psychiatry, McGill University, Douglas Inst., Montreal, QC, Canada

Abstract: The norepinephrine (NE) system extensively modulates cognitive functions, in particular via its ascending projections to the prefrontal cortex, the hippocampus and the limbic circuitry. In order to unravel the specific role of NE in learning, memory and executive functions, we took advantage of a new conditional knock-out (KO) mouse model for the

Vesicular Monoamine Transporter type-2 (VMAT2) gene. To generate VMAT2DBHcre mice, a floxed VMAT2 gene is specifically spliced in NE neurons by the cre recombinase that have been introduced in a BAC-DBH (dopamine β-hydroxylase) cassette. Because the VMAT2 is almost not expressed at the periphery (where VMAT1 is present), this conditional KO is brain-specific. Contrarily to the DBH-KO mice that died shortly after birth, VMAT2DBHcre mice are viable and show no obvious developmental deficits. In the VMAT2DBHcre-KO mice, autoradiographic *in situ* hybridization confirmed the absence of VMAT2 expression specifically in the locus coeruleus (LC) and whole brain HPLC showed a drastic decrease of NE. An exhaustive characterization of learning and memory processes was performed. Our results indicate that NE depletion does not alter 1) spatial memory in the Morris water maze paradigm, including both long term and working memory, and 2) recognition memory both in the object and place recognition test. In the fear conditioning test, while no alteration was found in the cued test, VMAT2DBHcre-KO mice exhibited a significant increase in freezing behavior during the contextual recall test, indicating a specific impairment in emotional memory. Finally, executive functions were studied in the attentional set shifting task including a reversal, an intra-dimensional and an extra-dimensional shifting stage. While VMAT2DBHcre-KO and WT mice had similar performances in the reversal and intra-dimensional shift stages, VMAT2DBHcre-KO mice exhibited an increased tendency in the number of trials needed to rich criteria in the extra-dimensional shift stage. With this new model of NE depletion in the whole brain, we demonstrated the specific implication of NE in contextual emotional memory recall and in executive functions such as shifting behavior. Increased fear reactivity and maladaptive shifting behaviors are symptoms frequently associated with affective disorders, especially anxiety, panic disorders and post-traumatic stress disorders. Based on these observations, this model of complete NE depletion constitutes a valuable tool in order to shed light on the neurocircuitry and mechanisms implicated in such disorders.

Title: Binge-eating behaviour produces alterations in dopaminergic neurochemistry in the brains of rats

Authors: *S. C. CHEETHAM[1], J. GOSDEN[1], M. R. PROW[1], P. H. HUTSON[2], D. J. HEAL[1]
[1]RenaSci Ltd, Nottingham, United Kingdom; [2]Shire Develop. Inc, Wayne, PA

Abstract: Binge-eating disorder (BED) is a common psychiatric condition, affecting ~2% of adults. It presents as compulsive, excessive consumption of highly palatable foods. BED is associated with obesity, but a significant proportion of BED sufferers are normal weight. We developed a rodent model where freely-fed rats are given irregular, limited access to chocolate. Rats develop robust, intermittent, hyperphagia of palatable food with concomitant reductions in consumption of normal chow and as a result maintain normal bodyweight. This rodent model mirrors human BED without obesity [Vickers et al, 2013 SfN, Abstract 236/03.]. Recent evidence linked eating disorders with CNS dopaminergic dysregulation [Geiger et al, 2009 Neuroscience 159, 1193; Johnson & Kenny, 2010 Nat Neurosci 13, 635]. We have, therefore, determined the effects of binge-eating in rats on dopamine neurochemistry and D1 and D2 receptors in various brain regions. Forty-five adult, lean, female Wistar rats were housed individually on reversed-phase lighting with free access to standard diet and water. Ground milk chocolate was offered to rats for 2 hr periods at irregular intervals to establish binge eating. Control rats were treated identically except empty glass jars were placed in their cages during the binge sessions. Rats were killed 1 hr after the final binge. Dopamine (DA) and its metabolites (DOPAC, HVA and 3 MT) were measured in striatum (STR), prefrontal cortex (PFC) and hypothalamus (HPT) by HPLC ECD. D1 and D2 receptors were quantified by saturation binding analysis in STR membranes using [3H]SCH23390 and [3H]raclopride. Acquired binge-eating did not alter the concentration of DA or its metabolites in STR, PFC or HPT. Compared with controls, DA turnover (DA/DOPAC ratio) was increased by 18% ($p<0.05$) in HPT, but it was not altered in STR or PFC. STR D1 receptors were reduced by 39% in BED rats (Bmax [fmol/mg protein]: BED = 176 ± 26 [n=10]; Control = 287 ± 25 [n=10]; $p<0.01$), but D2 receptors were unaltered (Bmax [fmol/mg protein]: BED = 303 ± 8 [n=6]; Control = 289 ± 21 [n=8]). The affinity (Kd) values of D1 and D2 receptors for [3H]SCH23390 and [3H]raclopride were unchanged. Binge-eating decreased STR D1 receptors without altering the size of the DA neuronal pool or rate of DA turnover. Together, they indicate binge eating is associated with decreased dopaminergic signalling via D1 receptors in STR. There were no neurochemical changes in PFC suggesting that dopaminergic neurotransmission was unaltered. The HPT is an important regulator of food intake and increased DA turnover suggests dopaminergic signalling is also dysregulated in this region. This study was funded by Shire Pharmaceuticals, UK.

Title: Selective dopamine and noradrenergic antagonist oppositely modulate the PFC neuronal activity following chronic MPD exposure

Authors: *N. DAFNY, C. CLAUSSEN
Univ. Texas Med. Sch., Houston, TX

Abstract: The illicit use of methylphenidate (MPD), a psychostimulant, among students and adults has steadily increased. The prefrontal cortex (PFC) has been shown to play a role in the response to MPD exposure. Specifically, a subset of D1 and D2 DA receptors and noradrenergic alpha 2 receptors are essential in the mechanism of MPD action. The objective of this study was to determine the role of different dopamine and noradrenergic alpha 2 receptors in the mechanism of MPD action. Therefore the neuronal activity in the PFC units were recorded on awake freely behaving animals previously implanted with 4 permanent semi microelectrodes. Neuronal recordings were obtained following acute and chronic MPD and following selective (SCH 23390) D1 DA antagonist, (Raclopride) D2 DA antagonist and Yohimbine the selective alpha 2 antagonist. On experimental day 1 (ED1) animals were exposed to an acute 0.6 or 2.5 or 10.0 mg/kg MPD single injection and continued with daily MPD maintenance injections given for ED2-ED7, followed by a 3 day washout (ED7-9) and then a rechallenge of 0.6 or 2.5 or 10.0

mg/kg MPD at ED10. On ED11 animals after the chronic effect of MPD was established animals were exposed to their respective selective antagonist and activity was recorded for 30 minutes proceeded by a rechallenge of either a 0.6, 2.5 or 10.0 mg/kg MPD. The findings showed that the D1 DA antagonist given prior to MPD rechallenge elicited a significant decrease in neuronal firing rates in 67%, 72%, 84% of PFC neurons in the groups exposed to chronic 0.6, 2.5, and 10.0 mg/kg chronic MPD, respectively. The D2 DA antagonist given prior to MPD rechallenge was able to slightly modulate the PFC neuronal response; however those results were not significant. The 1.0 mg/kg Yohimbine elicited a significant increase of the MPD effect in 45%, 60% and 69% of neuronal firing activity in PFC neurons. These results demonstrate the involvement of dopamine D1 and noradrenergic alpha 2 receptors in the electrophysiological effects of MPD on PFC neurons.

Title: Differential expression of dopamine signaling proteins in Wfs1-deficient mice

Authors: *T. VISNAPUU, K.-L. ESKLA, R. REIMETS, H. LUUK, A. TERASMAA, C. A. HUNDAHL, E. VASAR
Univ. of Tartu, Tartu, Estonia

Abstract: Behavioral and biochemical studies have shown that homozygous Wfs1-deficient mice have blunted dopamine release. At the same time, dopamine receptors seem to be functional in these animals. Therefore, we here studied the expression of pre- and postsynaptic proteins which mediate dopaminergic signaling. We dissected the dorsal striatum (caudate-putamen) after amphetamine (5 mg/kg) or saline administration (20, 45 and 120 min following the injection). By using western blot, we determined the relative expression levels of dopamine

transporter (Dat), tyrosine hydroxylase (TH), p-Akt (Thr308), p-Akt (Ser473) and p-DARPP-32 (Thr34). Wild-type mice exhibited a rise in Dat expression at 120 min after amphetamine injection, whereas this effect of amphetamine did not appear at any of the time points in Wfs1-deficient mice. In addition, TH levels were significantly higher in amphetamine-treated wild-type and Wfs1-deficient mice at 120 min when compared with the respective saline-treated group of mice of the same genotype. The basal levels of relative p-Akt (Thr308) expression were higher in Wfs1-deficient mice than in their corresponding wild-type littermates and amphetamine failed to inhibit p-Akt (Thr308) in Wfs1-deficient animals at 20 min and 45 min. In wild-type animals, amphetamine significantly inhibited p-Akt (Thr308) at every time point. We did not observe an effect of amphetamine on the expression level of p-Akt (Ser473) in either of the genotypes and the relative baseline values were similar for this protein. The basal levels of relative p-DARPP-32 (Thr34) expression were similar when comparing the genotypes and amphetamine significantly increased the phosphorylation of this protein in wild-type animals at 20 min. Homozygous animals did not exhibit an elevation of this phosphoprotein in response to amphetamine. These data show that major proteins mediating dopaminergic signaling are differentially expressed in Wfs1-deficient mice and these findings shed light to the nature of dopaminergic impairment caused by lack of functional Wfs1 protein.

Title: Phenotypical, behavioral and pharmacological characterization of a novel Knockout Rat model lacking the Dopamine Transporter

Authors: P. ILLIANO[1], D. LEO[1], I. SUKHANOV[1], L. MUS[1], S. ESPINOZA[1], T. D. SOTNIKOVA[1], M. C. HOENER[2], *R. R. GAINETDINOV[1]
[1]Inst. Italiano Di Tecnologia, Genova, Italy; [2]Neurosci. Research, Pharmaceuticals Division, F. Hoffmann-La Roche Ltd., Basel, Switzerland

Abstract: The major function of Dopamine Transporter (DAT) is the reuptake of dopamine (DA) from the synaptic cleft into presynaptic nerve terminals. Wistar Han rats in which the gene

encoding the DAT (SLC6A3, belonging to the family of Solute Carrier Transporter genes) has been disrupted, were produced by means of Zinc Fingers Nucleases technology. DAT homozygous knockout rats (DAT-/-) do not show any pre- and postnatal impairment, since they feed, develop and reach adult stage as their wildtype (DAT+/+) and heterozygotes littermates (DAT+/-). Nevertheless, (DAT-/-) show an impaired weight gain during developmental stage; naïve homozygotes have a pronounced Spontaneous Locomotor Activity (LMA), as detected throughout development up to adulthood, at different ages and over different periods of observation. Preliminary tissue content and fast scan cyclic voltammetry analysis suggest that the increase in the LMA is a direct consequence of the extended length of time that DA spends in the extracellular space following release. Preliminary pharmacological characterization of (DAT-/-) with amphetamine and a Tyrosine Hydroxylase reversible inhibitor show further support for the hyperdopaminergic functional state induced by the knockout of DAT, key protein for the homeostasis of dopaminergic terminals. The DAT knockout rats should be an excellent and improved tool for the study and development of drugs used in the management of dopaminergic dysfunctions. Our goal is to provide a complex and translational model for several human diseases involving aberrant DA function or mutations affecting DAT or altered DAT regulatory mechanisms *in vivo* such as schizophrenia, ADHD and newly discovered Dopamine Transporter Deficiency Syndrome (DTDS).

Title: Dopamine D1 antagonist prevents and D2 antagonist attenuates methylphenidate eliciting behavioral sensitization

Authors: C. CLAUSSEN, *J. ARONOWSKI, N. DAFNY
Neurol., Univ. Texas HSC - Houston, Houston, TX

Abstract: Methylphenidate (MPD) is a readily prescribed drug for the treatment of attention deficit hyperactivity disorder (ADHD) and moreover is used illicitly by youths for its cognitive enhancing effects and recreation. Repetitive MPD exposure leads to an augmented behavioral response referred to as behavioral sensitization, an experimental marker for a drugs ability to elicit dependence. There is evidence that dopamine (DA) is a key player in the acute and chronic MPD effect, however the exact role of DA in the effects elicited by MPD is still debated. The objective of this study was to investigate the role of D1 and/ or D2 DA receptors in the acute and chronic effect of MPD. Seven groups of adult male SD rats were used with control group, three groups treated with SCH 23390 the 0.3 mg/kg D1 DA antagonist and three groups treated with 0.3 mg/kg D2 DA antagonist given before and after acute and chronic 2.5 mg/kg MPD administration during a twelve day protocol as follows: Group I saline only, group II and III received a D1 and D2 antagonist injection at ED2 prior to the initial MPD exposure, group IV and V received either a D1 and D2 antagonist at ED3 prior to the second MPD exposure and group VI and VII received either a D1 or D2 injection prior to MPD exposure at ED12 following six daily MPD exposures (ED2 to 7) three washout days (ED8-10) and MPD rechallenge at ED11. The D1 antagonist was able to significantly ($P<0.05$) attenuate the locomotor activity when given at experimental day 2 (ED2) prior to the initial MPD exposure (group II), at ED3 following a single MPD injection (group IV) and at ED12 before the MPD rechallenge administration group (VI). The D2 antagonist did significantly attenuate the locomotor activity only when given at ED3 before the second MPD exposure. The results show the role, at least in part, of the D1 DA receptor in the mechanism of behavioral sensitization whereas the D2 DA receptor only partially modulates the response of the MPD effects.

Title: DREADD'ed addiction: Investigating the effect of DREADD-mediated modulation of G-protein coupled signaling in lateral habenula neurons projecting to the ventral tegmental area on cocaine self-administration and reinstatement in rats

Authors: *S. G. NAIR[1], D. SMIRNOV[2], J. F. NEUMAIER[2]
[1]Psychiatry and Behavioral Sci., [2]Univ. of Washington, Seattle, WA

Abstract: The lateral habenula (LHb), part of the habenular complex in the dorsal diencephalon, is an important regulator of midbrain dopaminergic systems that are known to be involved in the reinforcing properties of cocaine. The LHb projects to the ventral tegmental area (VTA) and the rostromedial tegmental nucleus (RMTg) among other brain regions. Here, we examined the role of the LHb neurons projecting to the VTA in cocaine reinforced operant responding, and cocaine-priming induced reinstatement. A Cre-recombinase dependent viral vector based flip-excision method was employed that involved injecting a combination of floxed, inverted Gi/o coupled DREADD (hM4Di) into LHb neurons and a canine adenovirus 2 (CAV-2) engineered to express Cre recombinase into the VTA. CAV-2 efficiently infected VTA axon terminals and was retrogradely transported to the neuronal cell bodies in the LHb, resulting in the expression of hM4Di receptors exclusively in LHb neurons that project to the VTA. Approximately 10-14 days after viral infusions, male, Long-Evans rats were trained to self-administer cocaine (0.75 mg/kg/infusion) on a fixed ratio 1, 20 second timeout reinforcement schedule. Activation of hM4Di by the otherwise inert synthetic ligand clozapine-N-oxide CNO (1 and 3 mg/kg, i.p) had no effect on cocaine reinforced operant responding. Secondly, a distinct cohort of rats was infused with viral vectors as described above and trained to self-administer cocaine (0.75 mg/kg/infusion) on a progressive ratio reinforcement schedule. Interestingly, preliminary data indicate that increased Gi/o-coupled signaling in LHb neurons projecting to the VTA increases operant responding on a progressive ratio schedule. Finally, rats were trained to self-administer cocaine and the operant responding was extinguished over 10-14 days. Exposure to a single injection of cocaine (10 mg/kg, ip) reinstated operant responding. Preliminary data indicate that increasing Gi/o-coupled signaling in LHb neurons projecting to the VTA decreases cocaine-priming induced reinstatement. Taken together, these results suggest a differential role of activation of Gi/o-coupled signaling in LHb neurons projecting to the VTA in the motivation to self-administer cocaine versus reinstatement of cocaine seeking in rats.

Title: Selective D1 agonists induce head twitch response in mice: Implications for modeling comorbid Tourette's syndrome and obsessive-compulsive disorder

Authors: *L. M. KLEIN[1], M. A. GEYER[2], A. L. HALBERSTADT[2]
[2]Dept. of Psychiatry, [1]Univ. of California At San Diego, San Diego, CA

Abstract: Tourette's syndrome (TS) and obsessive-compulsive disorder (OCD) demonstrate remarkable comorbidity, with up to 60% of TS patients exhibiting OCD-like behaviors. Several independent rodent models for OCD and TS have been proposed. For instance, the perseverative grooming induced by the D1 receptor partial agonist SKF 38393 has been used to model aberrant behaviors found in OCD patients, and the head twitch response (HTR) induced by 5HT2A receptor agonists represents a possible model for the tics associated with TS. However, few reliable animal models exist for comorbid TS and OCD. Interestingly, we found that the D1 agonist SKF 38393 induces perseverative grooming and HTR in C57BL/6J mice (Halberstadt & Geyer, Psychopharmacology 227:737 (2013)), providing a potential model for comorbid OCD and TS. Since the HTR is typically associated with activation of 5HT2A rather than D1, we investigated the pharmacology of the HTR induced by D1 agonists in C57BL/6J mice. Using a head-mounted magnet and a magnetometer coil to detect head movements, we tested whether SKF 38393 and the highly selective D1 full agonist (+)-doxanthrine induce the HTR. We also assessed the involvement of D1 and 5HT2A receptors in mediating the response to SKF 38393 and (+)-doxanthrine. Administration of SKF 38393 (5-40 mg/kg, IP) produced a dose-dependent increase in HTR. Treatment with (+)-doxanthrine (1 and 5 mg/kg, IP) similarly induced a significant increase in the frequency of HTR. The D1 antagonist SCH 23390 (0.025 and 0.1 mg/kg, SC) dose-dependently blocked the HTR induced by SKF 38393 (40 mg/kg) and (+)-doxanthrine (5 mg/kg). Pretreatment with the selective 5-HT2A antagonist M100907 (0.01 and 0.1 mg/kg, SC) completely blocked the HTR induced by SKF 38393 and (+)-doxanthrine. The ability of SCH 23390 to block the HTR induced by SKF 38393 and (+)-doxanthrine suggests that these effects are mediated by D1 receptor activation. This conclusion is supported by the fact that (+)-doxanthrine is highly selective for D1 over 5-HT2A. However, our results also suggest that the HTR induced by D1 agonists is dependent on 5-HT2A receptor activation. Future studies will investigate whether D1 agonists induce the HTR by stimulating the release of 5-HT, which consequently activates 5-HT2A receptors. The combination of perseverative grooming and HTR behaviors induced by D1 agonists in mice represents a potential model of comorbid TS and OCD. Further investigation of the mechanisms for these behavioral effects may reveal new insights into the neural underpinnings of these disorders.

Title: Behavioral economics in dopamine D2-like receptor mutant mice

Authors: *P. L. SOTO[1], T. HIRANITA[2], M. XU[3], D. K. GRANDY[4], J. L. KATZ[5]
[1]Educational Psychology, Texas Tech. Univ., Lubbock, TX; [2]U.S. Food and Drug Admin., Jefferson, AR; [3]Univ. of Chicago, Chicago, IL; [4]Oregon Hlth. & Sci. Univ., Portland, OR; [5]Natl. Inst. on Drug Abuse, Baltimore, MD

Abstract: Dopamine receptors play an important role in reinforcement processes however the precise roles played by different dopamine receptor subtypes are not known. Previous research demonstrated that demand curves for food were steeper (i.e., more elastic) for mice lacking dopamine (DA) D2 receptors (D2R knockout [KO] mice) compared to wild-type (WT) littermates, suggesting a role of D2Rs in the reinforcing effectiveness of food. The current studies investigated whether the economic conditions (i.e., whether the mice received food outside of the experimental sessions) affected the differences in food's reinforcing effectiveness between DA D2R KO and WT. Additionally, the current studies extended the study of food's reinforcing effectiveness to DA D3R and D4R KO and WT mice. Mice of all genotypes responded for food under fixed-ratio (FR) schedules of food reinforcement. FR values were varied over a wide range under short 30-min open economy conditions, wherein mice were fed outside of the experimental sessions, and long 11-hr closed economy conditions, wherein mice were not fed outside of the experimental sessions. Demand curves for D2R KO mice were more elastic than demand curves for D2 WT mice under both open and closed economies. Demand

curves for D3R KO mice did not differ from demand curves obtained in their WT littermate counterparts, whereas demand curves for D4R KO mice decreased more steeply under open, but not closed economy conditions, compared to demand curves obtained in D4R WT mice. Demand curves decreased more steeply under open versus closed economy conditions in all genotypes, consistent with food having a higher reinforcing effectiveness under closed versus open economy conditions. The present findings replicate previous results and indicate that the role of D2Rs in the reinforcing effectiveness operates in both open and closed economies. Further, these results suggest that of the D2-like receptor subtypes, the D2R subtype is the primary receptor subtype involved in mediating food's reinforcing effectiveness.

Title: Increased mesocorticolimbic dopamine before, during, and after social defeat stress: Role of corticotropin releasing factor receptors in the ventral tegmental area

Authors: *E. N. HOLLY, J. F. DEBOLD, K. A. MICZEK
Dept. of Psychology, Tufts Univ., Medford, MA

Abstract: Stress potently excites dopamine (DA) neurons in the ventral tegmental area (VTA), promoting phasic DA increases in the medial prefrontal cortex (mPFC) and nucleus accumbens (NAc). In rats, many stressors acutely cause a phasic DA increase in both the NAc and mPFC, while repeated aversive experience can produce long term changes in DAergic tone in these regions. The neural mechanisms which activate VTA DA during stress may provide clues as to how stress can interact within the reward system to result in stronger behavioral and neural responses to drugs of abuse. Due to their key function in the physiological stress response and localization within the mesolimbic DA system, corticotropin releasing factor (CRF) and its receptors (CRFR1 and CRFR2) are proposed to be critical in the behavioral and neural interactions of stress and reward. This study examines the influence of VTA CRF receptors on

monoamine concentrations in response to acute and repeated social defeat as well as neural cross-sensitization to cocaine. Long Evans rats were implanted with bilateral microinjection cannulae in the VTA as well as unilateral microdialysis cannulae aimed at both the mPFC and NAc. After 1 week recovery, rats were microinjected with a CRFR1 antagonist (CP376395), CRFR2 antagonist (Astressin2B), or vehicle (aCSF) 20 min prior to social defeat on days 1, 4, 7, and 10. Extracellular monoamine (norepinephrine (NE), serotonin (5HT), and DA) concentrations in the mPFC and NAc were assessed via *in vivo* microdialysis on days 1 and 10. On day 20, rats again underwent microdialysis and were assessed for neural cross-sensitization to cocaine (10 mg/kg, ip). Consistent with prior findings using other stressors, acute social defeat (day 1) significantly elevated extracellular DA levels in both the NAc and mPFC, and the increased DA was sustained for the duration of exposure to social stress, with no effects on NE or 5HT. Repeated social defeat altered the DAergic response, such that tonic DA concentrations were reduced on day 10, although there was no difference in percent change from baseline. These aCSF pretreated animals also exhibited neural cross-sensitization to cocaine, in the form of augmented extracellular DA in the NAc. Intra-VTA CRFR1 and CRFR2 antagonism had no immediate effects on NAc or mPFC monoamine concentrations and were both able to prevent the induction of neural cross-sensitization. These data indicate VTA CRFR activation is necessary for promoting stress-induced increased phasic downstream DA (presumably through increased neuronal firing) and neural cross-sensitization to cocaine. As such, CRFRs continue to be important targets for therapeutic intervention in addiction.

Title: Pharmacology in sexually sluggish male Wistar rats: A new animal model to examine serotonin 5-HT_{1A} and dopamine disorders?

Authors: *J. S. CHAN[1], E. Y. BIJLSMA[1], M. F. H. VAN SCHAIK[1], E. KOOIJMAN[1], F. N. VAN HASSELT[1], J. TITULAER[1], R. E. VERDONSCHOT[1], M. D. WALDINGER[1], A. NEWMAN-TANCREDI[2], M. VARNEY[2], R. S. OOSTING[1], B. OLIVIER[1]
[1]Pharmacol., Univ. Utrecht, Utrecht, Netherlands; [2]Neurolixis, Inc., Dana Point, CA

Abstract: Male Wistar rats with consistently low or no sexual behaviors are unusual in an otherwise healthy population of rats and can constitute a model of sexual dysfunction. Drugs that activate serotonin 5-HT_{1A} and/or dopamine systems typically facilitate male rat sexual behaviors. Therefore, various compounds were examined in normal (N), delayed ejaculating (DE), and non-copulating (NC) rats in a 30 minute test session with an estrus female rat. 8-OH-DPAT, a prototypical 5-HT_{1A} receptor agonist, increased ejaculation frequencies in N and DE animals to normal to fast levels and drastically reduced mounts and intromissions before the 1st ejaculation, while NC rats remained sexually inactive. Buspirone, a non-specific partial 5-HT_{1A} agonist, increased ejaculation frequency and lowered mounts for DE rats. NC rats remained inactive. F13714 and F15599, a pre- and post- synaptic 5-HT_{1A} receptor 'biased' agonist, respectively, facilitated sexual behaviors in DE, with F13714 acting more potently; suggesting that the facilitating effects are mediated through presynaptic receptors. The facilitating effects of F13714 are blocked by WAY100,635, a selective 5-HT_{1A} antagonist. Quinpirole, a selective D_2 and D_3 receptor agonist, reduced mounts in DE rats and increased ejaculation frequencies in DE and NC. GBR12909, a selective dopamine reuptake inhibitor, did not significantly affect any sexual behaviors in either type of rats, however NC rats again showed some sexual behaviors. Bupropion, a noradrenalin and dopamine reuptake inhibitor, and Apomorphine, a dopamine agonist, did not significantly affect the sexual behaviors of DE rats. Tadalafil, a PDE5 inhibitor, reduced the number of mounts before the 1st ejaculation in DE rats while NC rats remained inactive. Overall, DE rats appear to have a blunted response to all dopamine-challenging treatments (only high doses of quinpirole induced a facilitating effect). NC rats may have a perturbed serotonin/dopamine system since 8-OH-DPAT normally elicits a strong ejaculatory response in other rats. DE and NC rats are also heavier than N, with NC rats heaviest; an interesting find since serotonin and dopamine plays an important role in food intake. No differences in the open field test and in serum testosterone levels were found. Together, DE and NC rats mimic the human symptoms of sexual dysfunctions with low libido, delayed ejaculation, and anorgasm. The number of mounts before the first ejaculation were reduced in some compounds which may indicate an improvement in genital sensitivity. This, in conjunction with the lowering of the ejaculation threshold in some compounds, may be the cure for human sexual dysfunctions.

Title: Effect of activation of Gi/o-coupled signaling in the lateral habenula on food reinforced operant responding and cue-induced reinstatement of food seeking

Authors: *J. F. NEUMAIER, D. SMIRNOV, S. NAIR
Dept Psych, Box 359911, Univ. Washington, SEATTLE, WA

Abstract: The lateral habenula (LHb) is part of the habenular complex in the dorsal diencephalon. Uniquely positioned anatomically to participate in reward-related brain circuits, this nucleus is an important regulator of the midbrain dopaminergic system that is known to be involved in the neuronal circuitry underlying various feeding behaviors. However, very little is known about the precise role of this nucleus in operant food self-administration and relapse to food seeking. Here, we utilized the DREADD (Designer Receptors Exclusively Activated by Designer Drugs) technology that we have successfully used to bidirectionally manipulate LHb neuronal activity associated with motivated behaviors. Male, Long Evans rats were infused with adeno-associated virus expressing Gi/o coupled human M4 (hM4Di) receptors into the LHb bilaterally. Approximately 10-12 days following viral infusion, rats were trained to self-administer food pellets for 10 days on a fixed ratio 1, 20 second timeout reinforcement schedule; food pellet delivery was paired with a compound tone and light cue. Activation of hM4Di by the pharmacologically inert synthetic ligand clozapine-N-oxide (CNO) activates GIRK currents and results in hyperpolarization of neuronal activity. Our initial data indicate that activation of hM4Di in the LHb with CNO (1 and 3 mg/kg, i.p) had no influence on food reinforced operant responding. Studies are currently underway to determine the effect of activation of Gi/o-coupled signaling in the LHb on the motivation to self-administer food pellets on a progressive ratio schedule of responding as well as cue-induced reinstatement of food seeking.

Title: Point mutations in the dopamine transporter reveal an obligatory role in learning and memory

Authors: *S. A. CARMACK[1], S. L. SCUDDER[1], K. K. HOWELL[1], G. N. PATRICK[1], H. H. GU[2], S. G. ANAGNOSTARAS[1]

Abstract: Monoaminergic neurotransmission, such as dopamine and norepinephrine neurotransmission, is traditionally thought to play a modulatory, rather than essential, role in learning and memory. Previous research investigating the role of the dopamine transporter in learning and memory using knockout mice or pharmacological methods has largely been uninterpretable due to profound confounding effects on locomotion. Here we show that novel knock-in mice with highly selective point mutations in the dopamine transporter show dramatic memory deficits on several memory tasks, independent of any effects on locomotion and without any apparent effect on hippocampal synaptic plasticity. Our results suggest an obligatory role for the dopamine transporter in learning and memory.

Title: The effects of early-life risperidone administration on behavior in the social interaction test during adulthood

Authors: *C. BROWN[1], M. A. GANNON[2], M. E. BARDGETT[2]
[2]Psychological Sci., [1]Northern Kentucky Univ., Highland Heights, KY

Abstract: Antipsychotic drugs, such as the atypical antipsychotic drug, risperidone (Risperdal®), have been approved for use in young children with autism, a disorder marked by deficits in social interaction. Recent work in our laboratory has found that risperidone administration to young rats decreases social play immediately after injection due to drug-induced sedation. In addition, qualitatively different decrements in social play can be observed at 23 hours post-risperidone administration when the drug is absent from the blood. The purpose of this study was to determine if early-life administration of risperidone led to changes in social interaction during adulthood, long after cessation of drug administration.Thirty-six Long-Evans rats received subcutaneous daily injections of one of four doses of risperidone (vehicle, 0.3, 1.0, or 3.0 mg/kg) from postnatal day 14 through 42. Beginning on postnatal day 60, each rat was tested over four phases of a standard, three-chamber social interaction test. During the last two phases, rats were allowed to make contact with a novel male rat (phase 3), or with a novel rat or the same rat from phase 3 (phase 4). In each phase, the target rats were confined to a small cage placed in one of the apparatus chambers. All rats spent more time and travelled a greater distance in the chamber that contained the novel rat during phase 3 but more evenly split their time and distance travelled between the two occupied chambers in phase 4. Early-life risperidone administration did not modify any of these behaviors during either phase. Early-life risperidone administration may alter social play in rats during the course of treatment but does not appear to have dramatic, long-term effects on social contact during adulthood. Future studies in this area should consider more nuanced assessments of social behavior that allow for direct interaction between rats. Such research, along with the present results, could provide a more fully informed picture of the short- and long-term impact of early-life antipsychotic treatment on social behavior.

Title: Modulation of *C. elegans* electrotactic swimming behavior by dopamine signaling

Authors: *S. SALAM[1], R. K. MISHRA[2], P. SELVAGANAPATHY[3], B. P. GUPTA[1]
[1]Dept. of Biol., [2]Dept. of Psychiatry and Behavioural Neurosciences, [3]Dept. of Mechanical Engin., McMaster Univ., Hamilton, ON, Canada

Abstract: Dopamine (DA) is an important neuromodulator which is involved in controlling movement and psychological functions such as cognition and reward processing. Alteration in DA levels is associated with various neurological disorders and behavioral changes. The nematode Caenorhanbditis elegans is an established model organism for study of neuronal regulation of behaviors. The *C. elegans* nervous system consists of only 302 neurons including eight dopamine neurons which has conserved dopamine pathways. DA modulates a range of behaviors such as egg laying, feeding and locomotion. In an electrotaxis behavior assay the worms show movement toward cathode in low external DC electric field. However, the mechanism of how DA signaling modulates electrotactic swimming behavior is elusive. To investigate the role of DA signaling in electrotactic swimming behavior, we employed a novel microfluidic platform that facilitates on-demand control of worm movement using electric fields. In this study, we demonstrate how DA modulates the electrotactic swimming speed in a microfluidics channel. The DA deficient mutant cat-2 which encodes a tyrosine hydroxylase has a wild type like electrotactic swimming speed. DA transporter mutant dat-1 has a slow electrotactic swimming. DA deficient mutant bas-1 and cat-1 encode for aromatic amino acid decarboxylase and vesicular monoamine transporter respectively and these mutants showed a faster electrotactic speed which is partially rescued by the exogenous DA treatment. Similar to mammalian system, *C. elegans* DA mediates extrasynaptic signaling through the DA receptors that are expressed in different cells including cholinergic motor neurons and muscle cells. The D2 like receptor DOP-3 is expressed in the cholinergic motor neurons. dop-3 showed a faster speed suggesting that DOP-3 is the primary receptor through which DA acts on to slow movement. The D1 like receptors dop-1 and dop-4 and D2 like dop-2 mutant showed a wild type like electrotactic swimming speed. To demonstrate the antagonistic signaling of D1 and D2 type receptors we examined the dop-2;dop-1dop-3. We also reveal that longer exposure of *C. elegans* in the electric field induces slow electrotactic swimming speed which is regulated by DA. The induce slow speed is mediated by the D2 type DA signaling. We also examined the role of DA neurons for their function in electrosensory behavior. DA neuron ablated worms demonstrated a slow speed without any impaired electrosensory behavior.

Title: The effect of acutely inhaled toluene on locomotor activity and extracellular dopamine is moderated by gaba in the mouse caudate putamen

Authors: *S. CALLAN, A. A. APAWU, T. A. MATTHEWS, S. E. BOWEN
Wayne State Univ., Detroit, MI

Abstract: Toluene is a ubiquitous solvent commonly abused for intoxication. Despite its frequency of misuse, there is little understanding of how toluene acts within the brain. Previous in-vivo examinations of dopamine (DA) levels during toluene inhalation have been mixed with some investigations showing increases in extracellular DA during toluene exposure with other studies showing little to no effect of toluene on DA levels. Additionally, the majority of in-vivo microdialysis studies have focused on the rat, specifically the nucleus accumbens. Previous neurochemical work has also suggested that toluene is active at GABA sites, and that DA levels in the caudate are mediated by increases in GABA, suggesting that toluene's action on DA levels may be related to GABA levels. In the present study, we employed an acute solvent inhalation model to observe the impact of toluene exposure on DA release in the mouse caudate in-vivo using microdialysis techniques in Swiss Webster mice. This project represents the first *in vivo* examination of toluene-DA dynamics using a mouse model. This project employed a novel dynamic vapor exposure chamber to allow for freely moving animals during dialysate collection. Toluene doses of 4000ppm and 8000ppm increased locomotor activity, while neurochemically toluene exposure increased DA levels at only the highest dose (8000ppm) examined. In a second experiment, animals pretreated with 10μM bicuculline, a GABAA antagonist, 30 min before toluene exposure via reverse-dialysis displayed elevated DA release as compared to controls. In addition, animals in the bicuculline/toluene group showed potentiated locomotor activity compared to all other groups. These preliminary neurochemical findings suggest that acute toluene exposure potentiates the release of DA in the caudate and that this effect is enhanced

with bicuculline pretreatment. Taken together, these effects provide evidence that the action of toluene on DA levels in the caudate may be mediated by the action of GABA.

Title: The neurobehavioral consequences of gestational and chronic atrazine exposure in male and female Sprague-Dawley rats

Authors: ***J. L. WALTERS**[1], T. A. LANSDELL[3], K. LOOKINGLAND[3], L. E. BAKER[2]
[2]Psychology, [1]Western Michigan Univ., Kalamazoo, MI; [3]Pharmacol. and Toxicology, Michigan State Univ., Lansing, MI

Abstract: Atrazine is an herbicide used extensively around the world to control weeds on crops such as corn, sorghum, and sugarcane. The adverse risks of exposure to this herbicide in humans are not fully understood. Although numerous studies have demonstrated atrazine to be an endocrine disrupter, the neurobehavioral consequences of developmental atrazine exposure have not been thoroughly examined. The aim of this study was to investigate the effects of environmentally-relevant levels of gestational followed by continued chronic atrazine exposure on rodent locomotor activity, motor coordination, and striatal dopamine function. Male and female Sprague-Dawley rats were mated and upon detection of the vaginal plug, 12 dams were randomly assigned to one of three treatment groups. Dams received daily oral feedings of corn oil or atrazine (100 µg/kg or 10 mg/kg) dissolved in corn oil throughout pregnancy and lactation. Within 1 to 2 days of birth, pups were culled to 5 males and 5 females per litter. Upon weaning, the offspring continued daily corn oil or atrazine feedings for an additional six and a half months. During this time, rats were subjected to a series of behavioral assays, including locomotor activity assessments and a walking-beam task to assess motor coordination. Twenty-four hours after the last treatment, animals were euthanized by rapid decapitation and brains were immediately frozen for tissue analysis. Tissue punches were performed in the striatum, nucleus accumbens, and median eminence and samples were analyzed for dopamine (DA) and

3,4dihydroxyphenylacetic acid (DOPAC) by high performance liquid chromatography with electrochemical detection (HPLC-EC). Results revealed increased locomotor activity at 1 month of age in males exposed to 100 μg/kg atrazine compared to controls as well as impaired walking beam performance on PND 37-46 in both males and females exposed to 100 μg/kg and 10 mg/kg atrazine. At 6 months of age, males exposed to 10 mg/kg atrazine displayed decreased locomotor activity compared to controls. Neurochemical assays revealed decreased striatal DA and DOPAC in males and females exposed to 10 mg/kg atrazine and in males exposed to 100 μg/kg atrazine. However, females exposed to100 μg/kg had decreased striatal DA with no changes in DOPAC compared to controls. These findings provide evidence that developmental exposure to environmentally relevant levels of atrazine significantly impairs motor coordination with associated reductions in striatal DA in rodents. Further investigation of the potential impact of atrazine exposure on neurological development in humans and increased risks for Parkinson disease may be warranted.

Title: Antinociceptive effect of tizanidine and tramadol combinations in rats: Isobolographic analysis

Authors: *K. BELTRÁN-VILLALOBOS[1], M. DÉCIGA-CAMPOS[2]
[1]IPN, Mexico City, Mexico; [2]Sección de Estudios de Posgrado e Investigación ESM, Inst. Politécnico Nacional, Mexico City, Mexico

Abstract: The use of more than one drug to achieve a desired effect has been a common practice in pharmacologic testing and in clinical practice. For example, combinations of analgesics are frequently prescribed with a view to enhancing pain relief and reducing adverse effects. It is also well established that administration of more than one drug may give effects that are greater than, or less than, the additive effect of each drug given individually. This study sought to evaluate the

nature of the antinociceptive interaction of systemic administration of a combination of the tramadol with tizanidine, by isobolographic analysis in the formalin pain test of rat. Concentration-response curves were generated in rats for tramadol, tizanidine alone or their combination at the fixed ratios of 1:1 and 3:1 respectively. The study was carried out in female rats weighing 180-200 g, and the protocol was to test each drug (at dosages of 0.1-100 mg/paw of tramadol and 0.01-10 mg/paw of tizanidine) alone and in combination. Tizanidine (CE50= 0.125 ± 0.026 μg) was more potent than tramadol (CE50=16.45 ± 6.4 μg). Combination of tramadol-tizanidine at the fixed ratios 1:1 (CE50exp = 67.43 ± 11 μg.12; CE50teo = 8.28 ± 3.2 μg) and 3:1 (CE50exp = 31.25 ± 9.49 μg; CE50teo =12.36 ± 4.8 μg) generated a subadditivity effect (antagonism). Bassed on the current preclinical data, the pharmacological profile of combinations of tramadol-tizanidine evaluated with isobolograms produce antagonism. In this sense, it's important to utmost caution is requires during the use of this combination in clinical practice, because their present antagonism interaction.

Title: Early-life risperidone administration enhances locomotor responses to amphetamine during adulthood

Authors: B. L. STUBBEMAN, C. J. BROWN, *M. E. BARDGETT
Psychological Sci., Northern Kentucky Univ., Highland Heights, KY

Abstract: Antipsychotic drug prescriptions for pediatric populations have increased tremendously over the past 20 years, particularly the use of atypical antipsychotic drugs such as risperidone. In rats, forebrain dopamine receptor densities are elevated upon cessation of early-life risperidone administration. This finding suggests that adult rats administered risperidone early in life should display enhanced behavioral sensitivity to drugs that elevate dopamine

neurotransmission. This hypothesis was tested by measuring locomotor responses to amphetamine - a drug that releases forebrain dopamine - in adult rats administered risperidone early in life. Thirty-five Long-Evans rats received one of four doses of risperidone (vehicle, 0.3, 1.0, or 3.0 mg/kg) daily from postnatal day 14 through 42. Beginning on postnatal day 75, locomotor activity was recorded for 30 minutes once a week for four weeks. After 30 minutes, each rat received a subcutaneous injection of one of four doses of amphetamine (saline, 0.3, 1.0, or 3.0 mg/kg) in a counter-balanced order across the four weeks. Locomotor activity was measured for 27 hours after amphetamine administration. Activity levels did not differ between the vehicle and risperidone groups for six hours after saline injection. Rats administered risperidone early in life displayed significantly greater locomotor activity for six hours after amphetamine injection. This effect was most prominent in the first two hours after injection of the 0.3 and 1.0 mg/kg amphetamine doses, and was seen in all groups administered risperidone early in life, but was most marked in the risperidone 3.0 mg/kg group. The results suggest that the development of forebrain dopamine systems is permanently altered by early-life antipsychotic drug administration. The data raise concerns about possible increases in sensitivity to recreational and therapeutic drugs that target dopamine in adults treated with antipsychotic drugs during childhood.

Title: Functional selectivity at the dopamine D1 receptor and its role in mediating antiparkinson effects

Authors: *Y. YANG, S.-M. LEE, X. HUANG, C. A. LIEU, T. SUBRAMANIAN, V. MURTHY, R. B. MAILMAN
Penn State Univ., Hershey, PA

Abstract: Dopamine D1 receptors are expressed highly in basal ganglia and cerebral cortex, and modulate movement and cognition, both of which are impaired in neurodegenerative disorders like Parkinson's disease. Dopamine D1 agonists directly activate D1 receptors in these brain areas to reduce symptoms dramatically. The activation of D1 receptors is known or hypothesized to be associated with the changes in several intracellular signaling pathways, including cAMP, β-arrestin, and ion channels. There is, however, minimal knowledge of the role of each signaling pathway. Using a combination of pharmacological and behavioral techniques, we investigated how biased D1 agonists may activate these signaling pathways to modulate movement and cognition. We used dihydrexidine (DHX), EFF0311 (EFF) and CY208243 (CY) as test compounds, and dopamine and the partial agonist SKF38393 (SKF) as reference drugs. The intrinsic activity (IA) of these compounds was evaluated for *in vitro* functional selectivity using activity at cAMP and β-arrestin signaling. Phospholipase C signaling was not examined as we have recently shown this is likely an off-target effect of D1 agonists. Compared to dopamine, both DHX and EFF showed almost 100% IA at adenylate cyclase vs. 88% for CY. SKF had the expected partial agonist activity (IA =ca. 50%). At β-arrestin signaling, both DHX and EFF had somewhat higher activity than dopamine (138% and 122%, respectively), whereas CY and SKF had ca. 50% activity. Thus, DHX and EFF appear to be true full agonists, whereas CY has high IA, but is biased towards cAMP signaling. Several mechanisms may explain why DHX, and to a lesser extent EFF, showed slightly higher intrinsic β-arrestin activity than dopamine. Previous studies in the MPTP primate model of Parkinson's disease have shown that DHX caused profound antiparkinson effects that are greater than levodopa. We now report that EFF also causes dramatic antiparkinson effects in non-human primates without inducing dyskinesias. Conversely, CY has been reported to be somewhat less effective. These data suggest that full activation of both cAMP and β-arrestin signaling pathways is necessary for maximal antiparkinsonian effects. The discovery of highly biased D1 agonists will be very important in elucidating the relative roles of these pathways. It will be important to determine if the D1 signaling responsible for antiparkinson effects is the same as that which improves various aspects of learning and memory.

Title: Attenuation of synaptic dysfunction by a novel experimental therapeutic that targets a single kinase present in both neurons and glia

Authors: O. ARANCIO[1], L. J. VAN ELDIK[2], F. SAEED[1], A. BACHSTETTER[2], J. P. SCHAVOCKY[3], J. C. PELLETIER[3], S. M. ROY[3], *D. WATTERSON[4]

Abstract: The p38α MAPK is a stress-activated, serine/threonine protein kinase (S/T PK) that mediates increased production of neurotoxic substances by glia as well as being directly involved in stress related neuronal dysfunctions. For example, the pathophysiological upregulation of proinflammatory cytokine production and other neuroinflammatory responses through p38α MAPK in activated glia can be injurious to neurons, which is compounded by neuronal p38α MAPK involvement in the dysfunction of fast axonal transport and synaptic homeostasis. The parallel process provides a novel pharmacological opportunity to modulate a biological systems wide response by targeting a single molecular entity. Prior art from preclinical animal model studies has shown that dosing with CNS drugs of appropriate design can attenuate the excessive proinflammatory cytokine production back towards homeostasis in the absence of immunosuppression, indicating the promise of this novel therapeutic approach. Our recent development of specific p38α MAPK inhibitor probes for *in vivo* investigations has allowed extension to the attenuation of synaptic and cognitive dysfunction (PLOS ONE, 2013). We report here further preclinical drug development advances, with the successful medicinal chemistry optimization of the *in vivo* molecular probes driven by ADMET (adsorption, distribution, metabolism, excretion, toxicology) considerations. MW 150 is a new chemical entity that has survived initial de-risking that renders it appropriate for investigational new drug (IND) enabling development.

Title: Characterization of pharmacological effects of a novel LRRK2 inhibitor

Authors: *J. M. THOMAS, X. HE, F. XUE, T. LI, S. ZHONG, D. YANG, J. LIU, L. KONG, P. VOULALAS, H. E. HASSAN, J.-S. PARK, A. D. MACKERELL JR., W. W. SMITH

Abstract: Mutations in the leucine-rich repeat kinase 2 (LRRK2) gene cause autosomal-dominant Parkinson's disease (PD) and contribute to sporadic PD. LRRK2 contains GTPase and kinase activities that have been implicated in the neuronal degeneration in PD pathogenesis and therefore LRRK2 becomes a potential drug target. To date, there is no disease-modifying drug to slow the neuronal degeneration of PD. Here, we characterized a novel LRRK2 inhibitor, FX2149, which was synthesized by chemical approaches. It altered LRRK2 GTP domain activity and reduced LRRK2 kinase activity *in vitro* in cell culture. It penetrated into the blood brain barrier and altered the LRRK2 GTP domain and kinase activities in brains of LRRK2 transgenic mice. Moreover, FX2149 significantly reduced the mutant LRRK2-induced neuronal toxicity in human neuroblastoma SH-SY5Y cells. These studies not only provide a pharmacological tool to further study LRRK2 biological functions but also provide a lead compound for further development of novel therapeutics for PD.

Title: Blood-brain barrier permeable Hsp90 inhibitor reduces soluble tau burden in mouse models of Alzheimer's disease

Authors: *J. KOREN, III, C. INDA, M. UDDIN, P. PANCHAL, G. CHIOSIS
RM 2019, Mem. Sloan-Kettering, New York, NY

Abstract: Current Alzheimer's disease (AD) medications attempt to address the symptoms associated with this disorder. However, there are no FDA approved AD medications which can act on the biochemical mechanisms which drive toxic pathology including tau (MAPT, tau) accumulation. Toxic tau aggregates are a hallmark AD pathology and are also the primary pathogenic species in a collection of neurodegenerative disorders, similar to AD, described as "tauopathies." In these disorders, tau accumulation is driven, in part, by abnormal phosphorylation progressing to a state of hyperphosphorylation. One avenue for treatment is the inhibition of the 90kDa heat shock protein (Hsp90); a molecular chaperone found to be capable of inducing the formation of neurotoxic species of the microtubule associated protein tau. Normally, aberrant protein accumulation is regulated by the molecular chaperones. However, AD presents a disease-specific population of Hsp90; a population which preserves disease driving tau accumulation. Here, we present data obtained through *in vivo* studies utilizing two different transgenic mouse strains treated with a blood-brain barrier permeable Hsp90 inhibitor, PU-HZ151, designed by our lab. PU-HZ151 capably reduces tau species associated with neurotoxicity, ameliorates strain-specific tau-related phenotypes, and significantly improves memory as assessed through behavioral analysis. Mice treated display no signs of toxicity; confirmed through chronic administration. Additionally, PU-HZ151 induced the expression of the pro-survival chaperone Hsp70, a chaperone also associated with tau degradation. Together, these findings demonstrate the potential for Hsp90 inhibition in the treatment of neurodegenerative diseases involving tau accumulation; namely, Alzheimer's disease.

Title: R-flurbiprofen attenuates experimental autoimmune encephalomyelitis in mice

Authors: K. SCHMITZ[1], *N. DE BRUIN[2], J. MÄNNICH[1], J. LÖTSCH[1], M. J. PARNHAM[2], G. GEISSLINGER[1], I. TEGEDER[1]
[1]Inst. of Clin. Pharmacol., Pharmazentrum Frankfurt, Frankfurt, Germany; [2]Transl Med. & Pharmacol (TMP), Fraunhofer Inst. Mol Biol and Appl Ecol (IME), Frankfurt Am Main, Germany

Abstract: R-flurbiprofen is the non-cyclooxygenase inhibiting R-enantiomer of the non-steroidal anti-inflammatory drug flurbiprofen, which was assessed as a remedy for Alzheimer's disease. Because of its anti-inflammatory, endocannabinoid-modulating and antioxidative properties, combined with low toxicity, we assessed R-flurbiprofen in experimental autoimmune encephalomyelitis (EAE) models of multiple sclerosis in mice. Oral R-flurbiprofen prevented and attenuated primary progressive EAE in C57BL6/J mice and relapsing-remitting EAE in SJL mice, even if the treatment was initiated after the first flare of the disease. R-flurbiprofen reduced immune cell infiltration and microglia activation and inflammation in the spinal cord, brain and optic nerve and attenuated myelin destruction, which was investigated via immunofluorescence studies and *in vivo* imaging. Also the EAE-evoked hyperalgesia was attenuated in the R-flurbiprofen treated mice compared with the vehicle group. FACS analyses revealed that R-flurbiprofen treatment increased CD4+CD25+FoxP3+ regulatory T-cells, CTLA4+ inhibitory T-cells and interleukin-10, whereas the EAE-evoked upregulation of pro-inflammatory genes in the spinal cord was strongly reduced. The effects were associated with an increase of plasma and cortical endocannabinoids but decreased spinal prostaglandins, the latter likely due to R- to S inversion. The promising results suggest potential efficacy of R-flurbiprofen in human MS and its low toxicity may justify a clinical trial.

Abstract: Parkinson's disease (PD) is usually diagnosed clinically based on classical motor symptoms, while definitive diagnosis is made post-mortem, based on the presence of Lewy bodies and nigral neuron cell loss. Alpha-synuclein (ASYN), the main protein component of Lewy bodies, appears to play an important role in the onset of neurodegeneration that characterizes PD. Additionally, mutations in the ASYN gene or copy number variations are associated with some forms of familial PD. Olesoxime is a promising neuroprotective drug demonstrating in a pivotal phase II/III study, a protective effect on motor function loss and an improvement in overall health status in spinal muscular atrophy patients. Here, the objective was to evaluate whether olesoxime can prevent ASYN-mediated neurotoxicity by using a novel and attractive cellular model based on the inducible over-expression of human wild-type ASYN in neuronally differentiated neuroblastoma cells. This model demonstrates gradual cellular degeneration coinciding temporally with the appearance of soluble and membrane-bound ASYN oligomers and eventually cell death combining both apoptotic non-apoptotic pathways. We find that olesoxime fully protects differentiated SHSY-5Y cells from neurite retraction, cytoplasmic shrinkage and cell death induced by moderate ASYN overexpression. This protection was associated with a reduction in cytochrome c release from mitochondria and caspase-9 activation suggesting that olesoxime prevents ASYN toxicity by preserving mitochondrial integrity and function. In addition, we show that olesoxime displays neurotrophic effects on neuronally differentiated SHSY-5Y cells regardless of ASYN expression, by promoting their differentiation. Since ASYN-triggered neurodegeneration may be a common underlying factor in PD, olesoxime could be a promising therapy to treat PD, but also for other related disorders, termed synucleinopathies.

Title: Correlation between HSP90 target engagement and HSP70 level in mice brain

Authors: K. THIRSTRUP[1], *L. C. RONN[2], S. M. NIELSEN[3]
[1]Neurodegeneration 1, [3]Mol. Pharmacol., [2]Lundbeck, Valby, Denmark

Abstract: HSP90 (Heat shock protein 90) is a molecular chaperone protein ubiquitously expressed throughout all tissues in the body. As many of the HSP90 client proteins are oncogenic, HSP90 has been considered a promising chemotherapeutic target. In addition, HSP90 has also been proposed as a target to clear pathological proteins leading to neurodegeneration in Huntington's disease, Parkinson's disease and Alzheimer's disease. The mechanism of how HSP90 inhibition leads to clearance of misfolded proteins is not fully understood. It may involve direct effect of inhibiting ATPase function, indirect effects by inducing the Heat-shock-response resulting in upregulation of other chaperone proteins like HSP70 or a combination of both. Although HSP70 induction is routinely used as readout for HSP90 inhibition, the relationship between target engagement and HSP70 induction has only been studied to a limited extent *in vitro* and *in vivo*. In the current study we use pharmacological tools to establish the link between binding affinities, target occupancies and heat-shock upregulation effects of different HSP90 inhibitor tool compounds. In particular we describe how a simple and general method using ^{3}H-17AAG as tracer can be used to measure target engagement *in vitro* and *ex vivo* in brain tissue to correlate HSP90 target engagement with the down-stream upregulation of HSP70 using an ELISA assay. The current developed assay methodologies may first of all be of significant importance in the further elucidation of the mechanism involved in the *in vivo* effect of HSP90 inhibition in models for neurodegeneration, but may also be highly useful tools in any *in vivo* disease model, where HSP90 inhibition display positive effect.

Abstract: Impairments in protein clearance are a hallmark of multiple neurodegenerative diseases including Alzheimer's, Parkinson's, Huntington's and Amyotrophic Lateral Sclerosis (ALS). It is thought that intracellular accumulation of proteins such as tau in Alzheimer's and α-synuclein in Parkinson's may cause neuronal dysfunction and death. Enhancing protein clearance and reducing levels of potentially toxic proteins could have therapeutic benefits. One novel approach to increase endogenous protein clearance is to identify activators of the 20S proteasome, which is a core molecular complex involved in protein degradation. Here we describe a strategy to identify small molecule activators of 20S function. This includes a set of biochemical and cell-based assays to support target validation, screening, and post-screen evaluation of compounds. Biochemical assays that we describe, and validate using established proteasome inhibitors such as epoximicin, involve 20S-mediated proteolysis of various peptide substrates as well as native protein substrates such as α-synuclein. Cell based assays measure the turnover of proteins thought to be 20S substrates, including α-synuclein. In addition to assay platforms, we also describe refinement of methods to generate purified human 20S and detect small molecule binding using microscale thermophoresis. Using the array of tools at our disposal, we implemented a high throughput screening campaign for small molecule activators of 20S function, and identified compounds that increased the proteolysis of peptides, and in some cases, full length α-synuclein, by 20S.

Title: Acidic dual γ-secretase modulators/PPARγ agonists improve the mitochondrial dysfunction in a cellular model of Alzheimer's disease

Authors: *M. POHLAND[1], S. HAGL[1], M. WURGLICS[2], M. SCHUBERT-ZSILAVECZ[2], G. P. ECKERT[1]
[1]Dept. of Pharmacol., [2]Inst. of Pharmaceut. Chem., Goethe-University Frankfurt am Main, Frankfurt am Main, Germany

Abstract: Alzheimer's disease (AD) is a progressive, neurodegenerative disorder leading to dementia. Deposits of beta amyloid protein (Aβ) and intracellular neurofibrillary tangles are pathological hallmarks of AD. Increasing evidences indicate mitochondrial dysfunction as an early event in AD pathogenesis. Mitochondria are essential for the supply of energy but are also involved in oxidative stress and apoptosis. Current drugs act merely symptomatic and new disease modifying drugs against AD have almost failed in human clinical trials recently. We investigated the efficacy of a novel class of acidic γ-secretase modulators/PPARγ agonists with a dual mechanism of action against mitochondrial dysfunction in HEK293-APP_{695} cells expressing neuronal APP. Dimebon, DAPT, and Pioglitazone were used as controls. The basic structure of the new compounds, derivated of pirinixic acid, is thiobarbituric acid. Optimization of pharmacological activities leaded to new molecules with a significantly increased activity at both pharmacological targets. All examined compounds were active and influenced the cell biology of the studied HEK293-APP_{695} cells. First, the cell viability was measured by MTT assay in the range of 0,03 - 30 μM. For the non-toxic concentrations we measured changes in mitochondrial membrane potential (MMP) and levels of adenosine triphosphate (ATP) to determine alterations of mitochondrial efficiency and function. The compounds MH49, MH73, MH84 and MH163 were able to exhibit significant protective effects against NO-releasing drugs like sodium nitro prusside (SNP). Aβ-induced changes in mitochondrial enzyme activities are leading to oxidative stress and enhanced apoptosis. The rate of mitochondrial respiration was investigated and especially in the complex-IV respiration, which is decreased by Aβ, we were able to show a significant improvement after treatment with compound MH84 compared to control group. To get a closer look insight, we measured the citrate synthase (CS) activity, used as a marker enzyme for the mitochondrial mass. CS activity in HEK293-APP_{695} cells was increased by the GSM MH84, indicating an increased mitogenesis. In summarizing review substances MH84 and MH73 in our in-vitro experiments were the most convincing compounds in the nM range. Further experiments will reveal the molecular consequences of γ-secretase/PPARγ modulation and to test the compounds in mouse models of Alzheimer`s disease.

Title: Role of oxidative redox shift on STEP activity

Authors: *D. GHOSH[1], J. ELLMAN[2], A. C. NAIRN[3], P. J. LOMBROSO[3,4,1]
[1]Yale Child Study Ctr., Yale Sch. of Medicne, New Haven, CT; [2]Dept. of Chem., [3]Dept. of Psychiatry, [4]Dept. of Neurobio., Yale Univ., New Haven, CT

Abstract: Protein tyrosine phosphatases (PTPs) are enzymes that dephosphorylate phospho-tyrosine in target proteins. STEP (Striatal-enriched protein tyrosine phosphatase; or Ptpn5) is a brain-specific phosphatase associated with cognition and which is upregulated in several neuropsychiatric disorders including Alzheimer's disease (AD), Parkinson's disease (PD), fragile X syndrome (FXS) and schizophrenia. We previously reported that genetically decreasing STEP activity restores cognitive deficits in an AD mouse model (3xTg-AD). Recently, our lab reported the identification and characterization of a STEP inhibitor that improved cognitive function in these mice. The mechanism of action of the inhibitor was to form a covalent bond with the catalytic cysteine (Cys). Addition of glutathione (GSH) decreased the inhibitory capacity of this compound, suggesting an oxidative mechanism for STEP inhibition. PTPs, including STEP, have a conserved redox-active Cys residue in the catalytic center and the active thiol (SH) moiety in this Cys makes it prone to oxidation. Since the effect of reactive oxygen species (ROS) on STEP remains largely unexplored, here we investigated the role of oxidative stress on STEP protein level and activity, as well as the Tyr phosphorylation of downstream targets: pNR2B, pERK, and pPyk2. We hypothesized that free radicals would initiate redox changes in the active cysteine that would reversibly decrease STEP expression and activity. We exposed neuronal cultures to either 1) a more oxidative environment by increasing levels of ROS with H2O2 in a dose and time dependent manner or 2) a more reducing environment by decreasing ROS with catalase and superoxide dismutase, and observed the effects on STEP levels and substrate phosphorylation. Using several biochemical and molecular approaches, we show direct effects of oxidative stress on STEP activity. Moreover, our findings will give us a better understanding of whether increased ROS in neurodegenerative disorders function, at least in part, through modulation of STEP activity.

Title: Characterization of TC-2153 as a potent inhibitor of STriatal Enriched protein tyrosine Phosphatase

Authors: *M. CHATTERJEE[1], J. XU[1], T. BAGULEY[2], J. BROUILLETTE[1], P. KURUP[1], D. GHOSH[1], J. KANYO[3], J. GRESACK[5], P. GREENGARD[5], T. LAM[3], L. TAUTZ[6], J. ELLMANN[2], A. C. NAIRN[4], P. LOMBROSO[1,3,4]
[1]Child Study Ctr., [2]Chem., [3]Psychiatry, [4]Neurobio., Yale, New Haven, CT; [5]Lab. of Mol. and Cell. Neurosci., The Rockefeller Univ., New York, NY; [6]Infectious and Inflammatory Dis. Ctr., Sanford-Burnham Med. Res. Inst., La Jolla, CA

Abstract: STEP (STriatal-Enriched protein tyrosine Phosphatase), a neuron-specific phosphatase is overactive in several neuropsychiatric conditions including Alzheimer's disease, fragile X syndrome, schizophrenia, Parkinson's disease as well as in age-related memory deficits. Genetic reduction of STEP in models of several of these diseases improved their cognitive function. Based on these results, STEP represents a novel target for cognitive disorders. Here we characterize a small molecule inhibitor, benzopentathiepin 8-(trifluoromethyl)-1,2,3,4,5-benzopentathiepin-6 amine hydrochloride (known as TC-2153), as an inhibitor of STEP. We tested TC-2153 in *in vitro* para-nitrophenyl phosphate assay and in cell-based secondary assays along with *in vivo* wild-type (WT) mice experiments by measuring the increased tyrosine phosphorylation of STEP substrates ERK1/2, Pyk2, and GluN2B that occur with inhibition of STEP activity. We tested TC-2153 for its specificity in WT and STEP KO mice and cognitive improvement in in 6- month old triple transgenic AD (3xTg-AD) mice. We present data indicating that the mechanism for STEP inhibition involves oxidative attack of the catalytic cysteine residue in the phosphatase domain. Our results indicate that TC-2153 is a potent inhibitor of STEP *in vitro* with an IC50 of 24.6 nM, and that TC-2153 was able to inhibit STEP at 0.1 μM in neuronal cell and at 10 mg/kg, i.p in WT mice. Moreover, TC-2153 does not target homologous PTPs known to dephosphorylate ERK1/2 and Pyk2 when tested *in vivo* and showed no cytotoxicity response at doses 10 times higher than the effective dose in neuronal cultures. Administration of TC-2153 improves cognitive performance of AD mice in Y-maze alternation, the Morris water maze, and the novel object recognition task. These findings demonstrate that TC-2153 is capable of reversing cognitive deficits in a mouse model of AD.

Title: STEP61 is a novel substrate for the E3 ligase parkin, and is implicated in Parkinson's disease

Authors: *E. FOSCUE[1], P. KURUP[1], R. ALEXANDRA VIDEIRA[3], J. XU[1], C. ONONENYI[1], G. BALTAZAR[3], A. C. NAIRN[2], P. LOMBROSO[1]

Abstract: Parkinson's disease (PD) is characterized by degeneration of substantia nigra pars compacta (SNc) dopamine neurons that leads to severe motor and cognitive dysfunction. The E3 ubiquitin ligase parkin is involved in both genetic and sporadic forms of PD and inactivation of parkin by genetic mutations or by toxins leads to accumulation of parkin substrates in the brain. $STEP_{61}$ (STriatal-Enriched protein tyrosine Phosphatase) is a protein tyrosine phosphatase highly enriched in striatum. Previous studies showed that $STEP_{61}$ is regulated by ubiquitin-mediated proteasomal degradation and it is up-regulated in several neuropsychiatric illnesses. Here we demonstrate that $STEP_{61}$ is a novel substrate of parkin, and that $STEP_{61}$ levels are regulated by ubiquitin-mediated proteasomal degradation. $STEP_{61}$ is increased in human PD brain and MPTP-induced PD toxin models. The increases in $STEP_{61}$ levels are associated with a decrease in the phosphorylation of ERK1/2 and the downstream target of ERK1/2, CREB. These results indicate that parkin inactivation leads to accumulation of $STEP_{61}$ and altered ERK1/2 and CREB signaling in striatum, which may have potential implications in striatal synaptic plasticity and

symptoms associated with PD. Funding: The Michael J. Fox Foundation, the National Institute of Health, and the Department of Defense.

Title: The tyrosine phosphatase STEP is implicated in age-related memory decline across different species

Authors: *J. BROUILLETTE[1], C. MÉNARD[2], R. QUIRION[3], B. BONTEMPI[4], J. S. SCHNEIDER[5], C. M. NORRIS[6], G. FERLAND[2], E. BÉZARD[4], P. GAUDREAU[2], P. J. LOMBROSO[1]

Abstract: Age-associated memory deficits are observed across many species, but the underlying molecular mechanisms remains to be determined. Here we report elevations in the levels and activity of striatal-enriched protein tyrosine phosphatase (STEP) in aged memory-impaired mice

and rats. We also observed increased STEP expression in aged rhesus monkeys and humans with mild cognitive impairments (MCI) compared to age-matched controls. These increases are linked to enhanced dephosphorylation of the STEP substrates GluN2B and ERK1/2, as well as increased internalization of GluN2B-containing NMDARs. STEP accumulation with aging appears to involve dysfunction of the ubiquitin-proteasome system (UPS). Genetic reduction of STEP levels alleviates age-related memory decline and restores active phospho-CREB and BDNF levels, both implicated in memory consolidation. Elevated STEP levels that occur with advancing age constitute a molecular mechanism common to several species that contributes to age-related cognitive deficits, and may represent a target for pharmacological therapy to enhance cognition in the elderly and MCI patients.

Title: Effects of inhibiting STEP activity on synaptic connections in Alzheimer's Disease

Authors: *C. SULERZYSKI[1], M. CHATTERJEE[1], P. J. LOMBROSO[1,2,3]
[1]Child Study Ctr., [2]Psychiatry, [3]Neurobio., Yale Univ., New Haven, CT

Abstract: Dendritic complexity is reduced in Alzheimer's disease (AD). The altered morphology of AD neurons causes changes in neuronal firing and contributes to the cognitive deficits observed in the disease. Previous studies have shown that STEP (striatal-enriched protein tyrosine phosphatase) is upregulated in AD. The increase in STEP expression is due to a beta amyloid (Aβ)-mediated inhibition of the proteasome, resulting in a decrease in STEP degradation. We demonstrated that genetic reduction of STEP in 3xTG-AD mice restores memory deficits associated with the pathology. These studies validated STEP as a target for drug

discovery and we recently identified a pharmacological inhibitor of STEP, TC-2153 Here we test the hypothesis that administration of the STEP inhibitor TC-2153 to neuronal cultures will improve dendritic and synaptic connections in cortical cultures derived from a mouse model of AD. We have tested this hypothesis by quantification of dendritic length, arborization, and number and location of nodes. Neuronal cultures were grown from wild type and triple transgenic (3xTG-AD) mice. The wild type cultures were treated with Aβ peptide as well as vehicle or TC-2153. In addition, a control group was treated with vehicle alone, as well as drug vehicle or TC-2153. Treatment with TC-2153 rescued some of the Aβ-induced deficits in neurons. This research demonstrates a physiological mechanism that may explain, at least in part, how TC-2153 treatment alleviates cognitive deficits in 3xTG-AD mice. Moreover, these results suggest a role for STEP in the development of synaptic connections, a new hypothesis that will be tested in future studies.

Title: Effects of orally administered TC-2153, an inhibitor of the tyrosine phosphatase STEP, on cognitive deficits in an Alzheimer's mouse model

Authors: *S. BAKSHI[1], M. CHATTERJEE[2], J. ELLMAN[3], A. NAIRN[4], P. J. LOMBROSO[4,2,5]
[2]Child Study Ctr., [3]Chem., [4]Psychiatry, [5]Neurobio., [1]Yale Univ., New Haven, CT

Abstract: STriatal-Enriched protein tyrosine Phosphatase (STEP) has been implicated in Alzheimer's disease (AD). Increased levels of STEP61 were noted in the prefrontal cortex of patients with AD, as well as in four different mouse models of the disease. In addition, earlier studies demonstrated that beta amyloid (Aβ) mediates the increased expression of STEP61 through inhibition of the ubiquitin proteasome pathway. The increased level of STEP61 results in greater NMDA and AMPA receptor internalization. Thus a current model of STEP function is that it normally opposes the development of synaptic strengthening, and that increased expression of STEP disrupts synaptic function and contributes to cognitive deficits. Consistent

with this model, we previously reported that genetic reduction of STEP in 3xTg-AD mice increased the Tyr phosphorylation of STEP substrates, improved hippocampal synaptic plasticity, and rescued cognitive deficits. These results validated STEP as a promising target for AD drug development. We recently characterized TC-2153 as a potent STEP inhibitor with therapeutic potential (see nearby poster). Results were obtained in a mouse model via intraperitoneal injection of TC-2153. It is not known, however, whether TC-2153 is similarly efficacious when administered orally, which may be preferable as a non-invasive long-term treatment. In this study, we tested this by administration of TC-2153 to 3xTg-AD and wild-type (WT) mice via oral gavage. The Tyr phosphorylation of ERK1/2, Pyk2, and GluN2B was examined in the cortices of WT mice 3 hours after oral administration. In addition, behavioral tests including the Y-maze alternation task for spatial working memory and the novel object recognition test were performed for the WT and 3xTg-AD mice. Findings from this study will elucidate the potential of TC-2153 as an orally administered therapeutic agent in AD, in animal models of the disorder.

Title: SUVN-D4010: Novel 5-HT4 receptor partial agonist for the treatment of Alzheimer's disease

Authors: *N. MUDDANA, R. SUBRAMANIAN, R. MEDAPATI, R. ABRAHAM, R. GADI, V. BENADE, R. PALACHARLA, A. MANOHARAN, V. GOYAL, S. PANDEY, A. MOHAMMED, S. RAVELLA, R. NIROGI
Discovery Res., Suven Life Sci., Hyderabad, India

Abstract: Alzheimer's disease (AD) is a progressive neurodegenerative disorder and AD patients have impaired cognitive skills. 5-HT4 receptors are densely present in the hippocampus and frontal cortex suggesting the role of this receptor in memory and cognition. 5-HT4 ligands have the ability to induce neurogenesis in various brain regions such as hippocampus. These compounds replace the degenerated cells by inducing production of neurons. 5-HT4 partial

agonists offer both symptomatic and disease-modifying effects hence may be beneficial in treatment of AD. 5-HT4 ligands may offer improved clinical efficacy and/or tolerability relative to acetylcholinesterase inhibitors which are being currently used in the treatment of AD. SUVN-D4010 a potent, selective and orally bioavailable and brain penetrant 5-HT4 partial agonist, was evaluated for its procognitive property. Modulation of acetylcholine levels by SUVN-D4010 was evaluated using brain microdialysis technique. Striatal 5-HT4 receptor occupancy was measured using non-radiolabeled tracer in rats. Cortical sAPPα levels and CSF amyloid-β protein levels were also evaluated in the preclinical species using ELISA kits. Safety, toxicity and mutagenic potential of SUVN-D4010 were evaluated in rodents/non rodents and *in vitro* models. SUVN-D4010 reversed time induced memory deficits using object recognition task. Alleviation in working and emotional memory deficits induced by scopolamine in radial arm maze task and fear conditioning assay were also observed. Oral administration of SUVN-D4010 significantly increased the brain acetylcholine levels. The above observed improvement in cognition was blocked by selective 5-HT4 antagonist. SUVN-D4010 showed a dose dependent increase in receptor occupancy in rat brain. A significant increase in cortical sAPPα and decrease in CSF amyloid-β protein levels were noted in non-transgenic animal models. SUVN-D4010 was well tolerated in preclinical toxicity studies and did not show any mutagenic potential *in vitro*. SUVN-D4010 is a novel, potent, selective, orally bioavailable, brain penetrant, efficacious and safe 5-HT4 receptor partial agonist. IND enabling studies have been completed and US IND filing is in progress.

Title: Effect of gender and food on the single dose pharmacokinetics of SUVN-502, a potent and selective 5-HT6 receptor antagonist

Authors: *R. V. NIROGI, K. MUDIGONDA, K. PENTA, G. BHYRAPUNENI, D. AJJALA, N. MUDDANA, V. BENADE, V. CHOWDARY PALACHARLA, V. GOYAL, S. PANDEY, R. ABRAHAM, P. JAYARAJAN, R. BADANGE, R. KAMBHAMPATI
Suven Life Sci., Hyderabad, India

Abstract: Efficacy studies conducted in animal models of cognition and early clinical studies suggest that 5-hydroxytryptamine receptor [5-HT6] antagonists improve cognition by releasing neurotransmitters acetylcholine and glutamate. SUVN-502 is a potent and selective 5-HT6 receptor antagonist exhibiting cognitive enhancement in rodent models. SUVN-502 is being developed for the treatment of Alzheimer's disease (AD). SUVN-502 was investigated in a single-center, multiple-faceted, phase 1 clinical study (US IND) to evaluate its safety and effects of gender and food on the pharmacokinetics following a single dose of 100 mg oral tablet in healthy subjects. To evaluate the gender effect 12 healthy male and female subjects between 18 to 45 years of age were given a single dose under fasted conditions. Similarly food effect was evaluated in 12 healthy male subjects between 18 to 45 years of age. Subjects were given a single dose of 100 mg tablet on Day 1 and 8 with and without food in a crossover manner. SUVN-502 and its active metabolite M1 of SUVN-502 were quantified using a validated LC-MS/MS method. There were no clinically relevant or serious adverse events reported by any subject during the Phase I study. No subject was withdrawn from the study for safety reasons. Pharmacokinetic parameters were comparable between the male and female groups. Mean AUC(0-inf) and Cmax in the fed group were approximately 20% higher and 15% lower than that in the fasted group, respectively. Median tmax was slightly delayed in the fed group (3.5 h in fed vs 2.5 h in fasted) while mean t1/2 was similar between the fasted and fed groups at approximately 10 hours. Mean AUC(0-inf) and Cmax of M1 of SUVN-502 in the fed group were approximately 13% higher and 27% lower than that in the fasted group respectively. SUVN-502 has favorable safety and pharmacokinetic profile after single dose administration. Gender and food did not have any affect on pharmacokinetic parameters of SUVN-502.

Title: *In vitro* inhibition of glutamate/cystine transporter in microglial cells reduces excitotoxic conditions

Authors: M. FIGUERA-LOSADA[1], M. STATHIS[2], *K. M. WOZNIAK[1], B. STOCKWELL[4], C. ROJAS[1], B. S. SLUSHER[3]
[1]NeuroTranslational Program, Johns Hopkins Med. Brain Sci. Inst., Baltimore, MD; [3]Depts of Neurology, Psychiatry and Neurosci., [2]Brain Sci. Inst, Johns Hopkins Sch. of Med., Baltimore, MD; [4]Columbia Univ., New York, NY

Abstract: Virtually every pathological condition that disrupts brain homeostasis, including neurodegenerative disorders such as Parkinson's, Alzheimer's and HIV-associated neurocognitive disorders, can trigger microglial cell activation. This event is characterized by the release of glutamate, nitric oxide, and cytokines, and changes in cell morphology and behavior. System xC- is an antiporter that imports extracellular cystine and exports intracellular glutamate leading to an increase in the extracellular levels of this neurotransmitter and neuronal cell death

via excitotoxicity. We show that system xC- activity increases upon lipopolysaccharides (LPS) activation of rat primary microglia, leading to a ≥3-fold change in extracellular glutamate. Inhibition of system xC- with prototype inhibitors significantly reduced glutamate release from LPS- and HIV Tat protein-treated microglia. Erastin, also known to be an anti-cancer agent, was the most effective compound tested (IC50 = 14 ± 3 nM) and its effects were selective for glutamate, since a different marker of microglia activation, tumor necrosis factor alpha release, was not affected. An inactive analog, erastin A8, showed no effects modulating glutamate levels, while more potent analogs showed enhanced inhibitory activity. No cell toxicity was observed with erastin at the effective concentration and it did not induce pro-apoptotic or endoplasmic reticulum stress-associated gene expression profile changes. However, inhibition of system xC- by erastin decreased the redox capability of microglial cells as a direct consequence of lower cystine uptake. Excess extracellular glutamate could be decreased by inhibiting system xC- in microglial cells with specific and potent small molecule inhibitors such as erastin, consequently protecting neurons from excitotoxic insults.

Title: Characterization of MARP1, a novel positive allosteric modulator of the AMPA receptor that amerliorates age-related cognitive deficits in rats

Authors: ***J. A. MORROW**[1], L. H. SMITH[2], F. MARTIN[2], S. NEALE[2], N. ABROUS[3], P. V. PIAZZA[3], H. M. MARSTON[2]
[1]Merck Res. Labs., West Point, PA; [2]Merck Res. Labs., Newhouse, United Kingdom; [3]Neurocentre Magendiem, INSERM, Bordeaux, France

Abstract: AMPA receptors are ligand-gated ion channels that mediate the majority of fast excitatory amino acid transmission in the CNS and also participate in forms of synaptic plasticity

underlying learning and memory. Drugs that positively modulate AMPA receptor function hold promise for the treatment of cognition related dysfunction in disorders such as Alzheimer's disease and schizophrenia. Here, we describe the characterization of MARP1, a novel small molecule positive allosteric modulator of the AMPA receptor. The effect of MARP1 at native AMPA receptors was determined by whole-cell patch-clamp recordings in rat cultured cortical neurons. Glutamate (0.5 mM) was applied for 1s either alone or with the test compound using a semi-rapid drug application system. Co-application of MARP1 (1-100μM) with glutamate decreased desensitisation leading to increases in steady-state current in a reversible and concentration dependent manner: maximum increases were 680±115% (n=9) and the EC_{50} value was 2.5μM. The *in vitro* effects of MARP1 on synaptic transmission and plasticity were studied in submerged hippocampal slices from rats. Field excitatory postsynaptic potentials (fEPSPs) were recorded from stratum radiatum of CA1 area in response to Schaffer-commissural pathway stimulation. To induce LTP, presynaptic fibres were stimulated with a theta burst stimulation in which 10 bursts of stimulation pulses were delivered at a frequency of 5Hz; each burst contained three pulses at 100Hz. Bath application of MARP1 (10μM) increased the slope of fEPSPs by 34±4% (mean±S.E.M) ($p<0.01$, n=8). The effect on fEPSPs was rapid and peaked within 10 minutes of drug applications. 100nM MARP1 was effective in inducing LTP with three pulse theta burst stimulation. While synaptic potentials were unchanged in all 8 control experiments, 6 out of 6 experiments performed in the presence of MARP1 (100nM) showed stable LTP with an average potentiation of 224±119% in fEPSP slope, ($p<0.05$, n=6). 10 μM MARP1 was also demonstrated to ameliorate LTP deficits following four pulse theta stimulation in hippocampal slices from aged rats. In a series of tests designed to determine the impact of MARP1 on behavioral functioning in rats, MARP1 was demonstrated to ameliorate age-related cognitive deficits in spatial learning and memory in a water maze task and cognitive flexibility in a serial reversal learning task. These results indicate that MARP1 is a positive allosteric modulator of recombinant and native rat AMPA receptors. Thus, it represents an interesting and informative tool for investigating the therapeutic potential of glutamatergic enhancement in psychiatric and neurological disorders.

Title: Targeting nicotinic acetylcholine receptors with the designed multiple ligand (DML) approach

Authors: I. TOMASSOLI[1], A. J. REINHART[1], M. R. PICCIOTTO[2], T. T. TALLEY[3], R. L. PAPKE[4], *D. GUNDISCH[5]
[1]Pharmaceut. Sci., Univ. of Hawaii at Hilo, Col. of Pharm., Hilo, HI; [2]Dept. of Psychiatry, Yale Univ., New Haven, CT; [3]Biomed. and Pharm. Sci., Idaho State University, Col. of Pharm., Meridan, ID; [4]Dept. of Pharmacol. and Therapeut., Univ. of Florida, Col. of Med., Gainesville, FL; [5]Col. of Pharm. UHH, HILO, HI

Abstract: The designed multiple ligand (DML) approach allows the development of compounds with desired poly-pharmacological profiles for the treatment of many disorders, including complex central nervous system (CNS) diseases. Recently, we designed and synthesized DMLs targeting the nicotinic acetylcholine receptor (nAChR) family (JPET, 2013, 347:424-437) and we have now expanded this approach. Diaza(bi)cyclic moieties, which are known to be important scaffolds for nAChR ligands (nAChRL) and for a variety of other CNS drugs, are attached or merged with other CNS active compounds or derived scaffolds. Example compound libraries including nAChRL/nAChRL, and nAChRL/riluzole hybrids will be presented. Riluzole has been approved by the US FDA for the treatment of amyotrophic lateral sclerosis (ALS) and interacts with diverse ion channels. It displays a privileged scaffold - benzothiazole - which provides a hydrogen bond acceptor motif. nAChRL based scaffolds were attached to, or merged with, riluzole in two different ways to alter its poly-pharmacological properties while attempting to retain a favorable CNS druggability profile and create a designed multiple ligand (DML) lead

with combined or amplified activities. These compound libraries were tested against diverse nAChRs to obtain insight into their structure activity relationships. Radioligand binding assays were performed with [3H]epibatidine, [3H]methyllycaconitine, [3H or 125I]alpha-bungarotoxin, [3H]NS14492 and [3H]NS10743 using membrane fractions of rat brains, pig brains, pig adrenals, and Torpedo californica electroplax to evaluate the affinity of these compounds for nAChR subtypes. A broad spectrum of affinities (Ki values: < 10 nM to > 10,000 nM) and subtype selectivity provided important hints for further "designing in", "balancing", and "designing out" strategies to obtain DML lead candidates.

Title: Investigation of selective monoacylglycerol lipase (MAGL) inhibition and selective fatty acid amide hydrolase (FAAH) inhibition in comparison to simultaneous FAAH/MAGL inhibition on catalepsy and brain endocannabinoid, arachidonic and prostaglandin levels in mice

Authors: *B. FERGER[1], C. PORAZIK[1,2], N. PASQUARELLI[1,2], A. WITTING[2]
[1]CNS Dis. Res., Boehringer Ingelheim Pharma GmbH & Co. KG, Biberach, Germany; [2]Dept. of Neurol., Ulm Univ., Ulm, Germany

Abstract: Monoacylglycerol lipase (MAGL) and fatty acid amide hydrolase (FAAH) are the principal enzymes for endocannabinoid metabolism and are of particular interest to study behavioral and neurochemical alterations mediated by the endogenous cannabinoid receptor ligands 2-arachidonoylglycerol (2-AG) and anandamide (AEA). Here, we investigate the effects of the commercially available selective MAGL inhibitor KML29 and the commercially available selective FAAH inhibitor PF3845 in comparison to the simultaneous MAGL/FAAH inhibition by JZL195 or a combination of KML29 + PF3845 on the potential induction of cataleptic behavior and endocannabinoid pathway biomarker correlates. Male adult C57BL/6JRj mice were orally treated with KML29 (10,20mg/kg), PF3845 (10mg/kg), JZL195 (10mg/kg) or vehicle.

Haloperidol treatment (1mg/kg) served as positive control for catalepsy which was determined in the bar test 0, 30, 60, 90 and 120 min after compound administration. After the catalepsy test brains were removed and the tissue was processed for liquid chromatography coupled with tandem mass spectrometry (LC-MS/MS) analysis (for details of LC-MS/MS please see poster of Porazik et al., this SFN meeting). Neither the selective MAGL inhibitor nor the selective FAAH inhibitor produced any cataleptic behavior at any time. In contrast, a simultaneous MAGL and FAAH inhibition either by the dual MAGL/FAAH inhibitor or by a combination of the MAGL and FAAH inhibitors showed a significant and time dependent increase of catalepsy. 2-AG levels were highest in the brains of mice which received the KML29 + PF3845 combination followed by KML29 and by JZL195 and were unchanged after PF3845 and haloperidol treatment. The ranking order of AEA increase was led by PF3845 followed by the combination of KML29 + PF3845 and JZL195 and no change was observed after KML29 and haloperidol treatment. Interestingly, the 2-AG and AEA metabolite arachidonic acid and PGE_2 were only decreased by KML29, JZL195 and the combination of KML29 + PF3845 but not by the selective FAAH inhibitor PF3845 alone. In conclusion, a simultaneous inhibition of FAAH and MAGL was not well-tolerated in mice and did not produce any synergistic effects on 2-AG or AEA brain levels. Thus, selective MAGL or FAAH inhibition is less prone to a cataleptic motor phenotype and probably less prone to cannabimetic effects in comparison to simultaneous FAAH/MAGL inhibition.

Title: Pharmacological characterization of TASP0428980, a dual orexin receptor antagonist

Authors: J.-I. KARASAWA[1], *T. AOKI[1], D. KAMBE[1], T. SHIMAZAKI[1], H. HIKICHI[1], D. NOZAWA[2], H. KAWAMOTO[2]
[1]Pharmacology-1, [2]Medicinal Chemistry-1, Taisho Pharmaceut. Co., Ltd., Saitama, Japan

Abstract: The orexin system plays an important role in the regulation of sleep and wakefulness by activating two G-protein coupled receptors, orexin 1 (OX1) and orexin 2 (OX2) receptors. Many clinical and pre-clinical studies have shown that the dual orexin receptor antagonists at OX1 and OX2 might be a promising drug candidate for the treatment of insomnia. Here we show pharmacological profiles of TASP0428980, a newly synthesized and potent dual orexin receptor antagonist. TASP0428980 showed potent antagonist activity at both human and rat OX1/OX2 receptors, and shifted the dose-response curve of an orexin A analog-induced Ca2+ mobilization rightward without altering the maximal response. In contrast, TASP0428980 at 10 μM had no apparent affinity for 72 other receptors, transporters, and ion channels. In the electroencephalogram studies using freely moving rats, administration of TASP0428980 (3, 10, 30 mg/kg, ip) significantly shortened the non-REM sleep latency, and increased the time spent in both non-REM sleep and REM sleep. In contrast, TASP0428980 did not exhibit impairment of the motor performance at 30 mg/kg (ip), which was commonly observed by treatment of pharmacological effective dose of GABA-A receptor positive modulators, assessed by rotarod test in rats. These results show that TASP0428980 is the potent and selective dual orexin receptor antagonist with sleep-promoting effects, and that this compound can be used as a tool to explore pharmacological significance of blockade of orexin receptors.

Title: Induced expression of Nor1 is not important for neurite outgrowth in PC12 cells

Authors: *K. SHIMOKE[1], T. TOMIOKA[1], H. AOYAMA[1], Y. NISHIHATA[1], H. MARUOKA[2], T. IKEUCHI[1]
[1]Dept Life Sci, Fac Chem Mat Bio, Kanasai Univ., Suita, Osaka, Japan; [2]Technol. Res. Laboratory, Kurabo Co. Ltd, Neyagawa, Osaka, Japan

Abstract: Histone deacetylase (HDAC) inhibitors can induce neuronal differentiation in the central nervous system (CNS) or peripheral nervous system (PNS). The effect of HDAC inhibitor is not limited to neuronal differentiation but to the cell survival. We have reported that HDAC inhibitor promotes neurite outgrowth and cell survival via expression of Nur77, one of the immediate early gene (IEG), in PC12 cells. While Nur77 has a family protein, for instance, Nor1, the function of Nor1 by HDAC inhibitor is still unclear. Thus, we analyzed whether Nor1 is essential gene product for neurite out growth by HDAC inhibitor, comparing with expression of Nur77 by forskolin (FSK) because FSK is well-known to induce neurite outgrowth. We used tricostatin A (TSA) as a HDAC inhibitor and FSK as a positive control for neurite outgrowth. We also added siRNA to deplete the expression of Nur77. Then, the neurite was photographed using phase-contrast microscopy and the length was measured using analysis software (BZ-9000). As a result, we found that TSA, a potent HDAC inhibitor, or FSK induced neurite outgrowth accompanied with expression of Nur77 when TSA or FSK was treated to the cells for 24 hours. We also observed that only FSK induced the expression of Nor1. In addition, the experiment using siRNA against mRNA for nur77 gene demonstrated that TSA did not induce neurite outgrowth. These results suggested that the expression of Nor1 is not essential but the expression of Nur77 is necessary for neurite outgrowth by TSA.

Title: Cathepsin s: a novel therapeutic target for alzheimer's disease

Authors: ***B. YI**[1], A. K. EVANS[1], L. J. HOLSINGER[2], R. BOOTH[2], M. SHAMLOO[1]
[1]Behavioral and Functional Neurosci. Lab., Stanford Univ., Palo Alto, CA; [2]Virobay Inc, Menlo Park, CA

Abstract: Cathepsin S is a cysteine protease exhibiting both extra- and intracellular activities important for regulation of MHC Class II antigen presentation and neuroinflammation. During neuronal injury, cathepsin S is secreted from microglia and cleaves membrane bound fractalkine (FKN), releasing soluble FKN. The released FKN activates the fractalkine receptor (CX3CR1), which modulates microglial activation, release of inflammatory mediators, and lymphocyte recruitment. Chronic neuroinflammation and elevation of microglial-derived cytokines are a key hallmark of Alzheimer's Disease (AD). In mouse models of AD, deletion of the FKN receptor prevents neuronal loss, microglial activation, beta-amyloid deposition, and loss of cognitive function. Moreover, an overexpression of cathepsin S and FKN is detected in postmortem human AD brains. In line with this, we have also shown an over-expression and activation of cathepsin S in a mouse model of AD along with a concomitant activation of microglia. In a preclinical study using the Thy1-APP$^{Lond/Swe+}$ (T41B) transgenic mouse model of AD, we have shown that once-daily administration for 6 weeks of VBY-50365, a selective cathepsin S inhibitor, which possesses good central nervous system penetration, leads to a significant improvement in working memory in a Y-maze test. Moreover, a trend for improvement was also seen in passive avoidance and fear conditioning tests. A reduced level of amyloid-beta was also detected in the treated animals. These results suggest that modulation of cathepsin S may have tremendous therapeutic value and VBY-50365 may be an efficacious therapeutic for the treatment of AD with a novel mechanism of action. Further preclinical and biochemical studies are ongoing to confirm these findings.

Title: The use of stereological analysis in non-clinical models of neurological disease and neurodegeneration

Authors: M. CERRADA-GIMENEZ, P. SWEENEY, A. NURMI, O. KONTKANEN, *T.-K. STENIUS, T. AHTONIEMI, N. VARTIAINEN

Abstract: Stereology is a technique used for the morphological analysis of tissue samples in biological research, it is gaining increased importance in the study of preclinical neurological disease models as it is currently the only methodology capable of providing unbiased and accurate results for a wide variety of morphological analysis. The employment of stereology is particularly important for analysis of a variety of unique morphological biomarkers biomarkers in rodent models of neurodegeneration such as Huntington's disease (HD), Amyotropic Lateral Sclerosis (ALS) and for various models of Parkinson's disease (PD). We have performed basic characterization of the R6/2 and zQ175KI mouse models for Huntington's disease by analyzing the levels of inflammatory microglia (Iba-1 or Ferritin-positive) and GFAP-positive astroglia in the striatum. In the case of the Amyotropic Lateral Sclerosis, the stereological analysis focused on the determination of Acetylcholine Esterase-positive fibers in the sciatic nerve. For the Parkinsons's disease models we have performed accurate counts on the Tyrosine Hydroxylase-positive cells in the *Substantia nigra pars compacta* of rats that had been injected with an AAV harboring the human α-synuclein gene with the A53T mutation. Stereology may be considered a rather more labour intensive component of preclinical studies relative to standard immunohistochemistry but due to the fact that it readily provides unbiased and accurate results for the biomarkers being analyzed like, such as Iba-1 positive microglia, tyrosine hydroxylase-positive neurons, or Acetylcholine Esterase-positive fibers among others, preclinical neurobiologists, cell biologists and pathologists are beginning to employ this methodology as an adjunctive end-point along with behaviour, immunohistochemisty and imaging end-points in preclinical proof-of-concept studies in neurodegeneration.

Title: Further development of PADK for Alzheimer's disease: CNS lysosomal modulation by oral dosing and initial safety evaluation

Authors: S. RUIZ[1], M. C. PAIT[1], L. H. ELLIOTT[1], C. T. LONG[1], C. TIRLA[2], H. ROMINE[1], *B. A. BAHR[3], U. S. IKONNE[4]

Abstract: Alzheimer's disease (AD) is characterized by pathological assembly states of Aβ42, tau pathology, and associated synaptotoxicity. Inefficient clearance contributes to AD accumulation events, thus drug discovery efforts have targeted the lysosomal pathway of autophagy to enhance protein clearance. Positive modulation of the lysosomal enzyme cathepsin B (CatB) was previously found to be linked to PHF-tau clearance in the hippocampal slice model of protein accumulation (Bendiske & Bahr 2003: JNEN 62:451). Recently, CatB was discovered to degrade Aβ42 via C-terminal truncation, and its modulation effectively reduced higher orders of Aβ assemblies (Mueller-Steiner et al. 2006: Neuron 51:703; Butler et al. 2011: PLoS One 6:e20501; Wang et al. 2012: JBC 287:39834). In addition to clearing intracellular Aβ in transgenic AD models, CatB modulator Z-Phe-Ala-CHN2 (PADK, also called ZPADK or Z-FA-DMK; MW = 394.4) and its derivatives were found to reduce Aβ deposits, ameliorate behavioral deficits, and, as in the brain slice model, restore synaptic markers (Bahr et al. 2012: Rejuvenation Res 15:189; Viswanathan et al. 2012: ACS Med Chem Lett 3:920). Here, multiple dosing by stressful oral gavage was avoided by using an alternative formulation of compound mixed to a homogenous suspension in peanut butter that was fed to rats twice daily for 11 days. The lowest PADK dose tested, 3 mg/kg/0.5d, produced significant 1.5- to 2-fold increases in the active CatB isoform and CatB activity in hippocampus, frontal cortex, midbrain, and cerebellum as compared to rats fed peanut butter with Z-FA-OH (non-modulator control compound). The same regions as well as neocortex and brainstem exhibited 2- to 4.5-fold increases in CatB at higher PADK doses, a selective effect since cathepsin D activity was unchanged as were GluR1 and actin levels. Behavior assessment also found no difference between PADK and Z-FA-OH groups in open field exploration and passive avoidance learning. A higher MW derivative with similar

CatB modulation as PADK in the slice model was less effective by oral dosing. For safety tests in mice, 15-40 mg/kg/d PADK i.p. produced a dose-dependent increase in active CatB in brain samples, while pre- and postsynaptic markers were unchanged. BUN and ALT blood markers were also unchanged, tissue from major organs scored normal by a pathologist, and no adverse effects on motor coordination or spatial memory learning were found. *In vitro*, 5-100 μM PADK did not cause bacterial cytotoxicity, at 3800 times the IC50 of mitomycin C, nor did PADK cause mutagenicity in the Ames test. PADK's safe toxicity profile and lysosomal modulatory efficacy after oral dosing support its potential to treat AD.

Title: The novel M1/M4-selective muscarinic agonist NSX-0527 for the treatment of Alzheimer's disease

Authors: J. C. OCKULY, S. A. HANSON, J. D. BECK, *M. L. HENDRICKSON
Neurosci., NeuroSolis, Inc., Madison, WI

Abstract: Selective M1 muscarinic agonists have long held promise as potential treatments for Alzheimer's disease (AD). However, compounds investigated in early clinical trials suffered from a lack of efficacy, likely due to low potency. The M1/M4-preferring agonist xanomeline, a more recent compound that has undergone significant clinical assessment, did show efficacy in AD patients in a Phase II trial, but was abandoned due to poor tolerability. NSX-0527 is an M1/M4-selective orthosteric muscarinic agonist showing good bioavailability (~75%) and brain penetration (~60%). A terminal half-life of one hour has been observed in rats following oral and IV dosing, with excellent metabolic stability as determined by incubation in human liver microsomes. NSX-0527 displayed potent activation of central M1 receptors as demonstrated by

an increase in hippocampal inositol-1-phosphate (IP1) concentration following oral dosing in rats with significantly greater intrinsic efficacy and potency compared to xanomeline. In the novel object recognition behavioral test, mice receiving subcutaneous doses of NSX-0527 as low as 0.1 mg/kg showed improved cognitive performance compared to controls. Finally, NSX-0527 produced an acute reduction of hippocampal A-Beta1-42 in Tg2576 transgenic mice as measured by microdialysis, indicating the potential of NSX-0527 for disease-modifying activity in Alzheimer's disease.

Title: Selective PPARγ activation improves memory deficits and increases BDNF expression

Authors: *J. BLOEMER[1], G. NANAYAKKARA[1], K. PARAMESHWARAN[2], M. DHANASEKARAN[1], V. SUPPIRAMANIAM[1], R. AMIN[1]
[1]Dept. of Drug Discovery and Develop., [2]Col. of Vet. Med., Auburn Univ., Auburn, AL

Abstract: Alzheimer's disease (AD) is the sixth leading cause of death in United States, suggesting the limitations of the current therapies to prevent the advancement of the disease. Continual increases in mortality rates due to AD indicate the urgent need for establishing novel molecular targets for therapeutic potential. Many reports verify direct pathological links between AD and diabetes, which highlights the contribution of diabetes to the development of AD. Insulin sensitizing agents that activate the nuclear receptor peroxisomal proliferator activating

receptor gamma (PPARγ) such as rosiglitazone (rosi) and pioglitazone (pio), have been recognized as promising agents for improving cognition in diabetic and AD rodent models by reducing amyloid beta (Aβ) levels. However, these agonist display poor blood brain barrier (BBB) permeability and produce a number of adverse effects in humans such as ectopic lipid accumulation and increased plasma volume leading to increased incidence of heart failure and weight gain. Further, there is even less information on the effects of PPARγ agonists in the hippocampus in relation to synaptic plasticity and memory formation. We have developed a library of selective PPARγ modulators (SPPARγMs) based specifically upon computational evaluation of the crystal structure of PPARγ. These compounds have enhanced BBB permeability, and our lead compound, SPPARγM 9, was found to improve cognitive deficits in diabetic type 2 leptin deficient (db/db) mice. This compound also displays positive effects upon cellular metabolic regulation while displaying no harmful effects upon the heart or increased ectopic lipid accumulation. Compared to rosi, SPPARγM 9 lacks interaction with Tyr473 of the PPARγ ligand binding domain thus signifying the importance of interaction with Tyr473 for the off target effects of full PPARγ agonism. Our findings support that selective PPARγ modulators ameliorate cognitive deficits and lack off-target toxicity in peripheral tissue. Recently, we determined that SPPARγM 9 acted similarly to intracerebroventricular (ICV) rosi by inducing the expression of brain derived neurotrophic factor (BDNF) in the hippocampus of diabetic mice. Further, both rosi and SPPARγM 9 transcriptionally regulate BDNF expression as demonstrated by promoter activity assays (luciferase) in hippocampal neuronal cells as well as increased the expression of post synaptic receptor (GluA1 and GluN2A). These studies are novel as they will provide greater insights into activity of selective PPARγ agonism and delineate roles of partial vs. full agonism in diabetes and AD models for improving cognitive deficits.

Title: Drug discovery for Alzheimer's disease targeting tau oligomers

Authors: *P. K. KRISHNAMURTHY, G. PAPIANI, P. LOPEZ, D. ROMERO, E. DAVIDOWITZ, J. MOE
Oligomerix, Inc., New York, NY

Abstract: Small molecule drugs are being developed targeting tau oligomers for the treatment of Alzheimer's disease (AD) and related tauopathies. We and other laboratories have studied the role of tau oligomers in memory formation and disease progression. Oligomeric forms of tau are highly correlated with neuronal loss and memory impairment. Moreover, extracellular tau oligomers cause impairment of memory formation in mice and induce synaptic dysfunction. Tau oligomers are specifically taken up by neurons and are vectors for transmission of pathology to healthy neurons. The tau oligomer target has been validated for drug discovery in mouse models of tauopathy using an immunotherapeutic approach. Here, we present the progress of our small molecule program in validating our drug discovery approach *in vivo* and in lead optimization for drug development. Validation studies are being performed using tool compounds discovered from screening a highly diverse library of 100,000 drug-like small molecules. The primary assay measured tau self-association using a proximity-based method of detection. There are no mutations in tau associated with AD, therefore, full-length tau without mutations was used in the assay optimized for tau oligomer formation. Hits were validated and dose response and neurocytotoxicity assays were performed. Medicinal chemistry analysis was used to organize the hits into chemical series and to select hits for secondary assays. Although drug development will utilize a mouse model expressing tau without mutations, the *in vivo* validation study is being performed with the JNPL3 tauopathy mouse model provided by Taconic to complete the validation within a shorter timeframe. Similarly, cell models for tau oligomer formation were developed with tau constructs with and without tauopathy mutations facilitating aggregation. Pilot validation studies are currently being performed in mice to select a tool compound for assessing in a full validation study. Fifty-seven drug-like molecules predicted to have good CNS penetration were selected from 11 chemical series and 19 singletons. The most active hits of 8 series were chosen as tool compounds and for lead development. Some of these compounds showed good dose response in the cell assay. Acute toxicity evaluation *in vivo* showed no adverse effect in wild type mice at high, medium and low doses. Brain homogenates from our first pilot validation study are currently being evaluated. Analysis of lysates from mice cortex tissue indicates a dose-dependent reduction in tau aggregates, supporting the validation of this approach for drug discovery.

Title: An in silico simulator to study oscillopathies and drug effects in various neurological disorders

Authors: A. LEGENDRE[1], M. BEDEZ[1], M. SARMIS[1], A. F. KELLER[1], N. AMBERT[1], R. GREGET[1], F. LALOUE[1], J.-M. C. BOUTEILLER[1,2], M. BAUDRY[1,3], *S. BISCHOFF[1], S. MOUSSAOUI[1]
[1]Rhenovia Pharma, Mulhouse Cedex, France; [2]Biomed. Engin., USC, Los Angeles, CA; [3]Western Univ. of Hlth. Sci., Pomona, CA

Abstract: Several neurological disorders, including Alzheimer's disease and epilepsy, are characterized by early changes in cerebral electrical activities in various brain areas. These changes in electrical activity may represent biomarkers of high value for early diagnosis, based on their correlation with clinical symptoms, and for monitoring the clinical efficacy of new therapeutic strategies. Using anatomical data as well as a variety of experimental data, we developed computational models of intracellular pathways, synapses, neurons and neuronal networks in order to simulate the effects of drugs at multiple levels of analysis. At the molecular level, our library includes kinetic models of glutamatergic, GABAergic, cholinergic,

dopaminergic, ionotropic and metabotropic receptors, as well as diverse ion channels, transporters and enzymes. At the cellular level, we have built and validated morphologically and biophysically realistic neuronal models (e.g. hippocampal CA1 pyramidal cell), incorporating key molecular players involved in action potential generation, dendritic integration, and neurotransmission. At the network level, we implemented models of neuronal circuits capable of reproducing oscillatory activities observed experimentally and clinically. One of the key implemented neuronal circuits includes CA1 and CA3 neurons, septal cholinergic and GABAergic neurons as well as fast-spiking basket cells, and stratum oriens interneurons. In addition to simulating intracellular neuronal firing activity, the simulator also generates extracellular field potential, which can be compared to experimental data obtained with microelectrode arrays, or linear probes. Results of the simulations were validated by reproducing changes in electrical activity observed under physiological and pathological conditions as well as following treatment with a variety of drugs acting on various molecular targets. In particular, the effects of a variety of procognitive and antiepileptic compounds were investigated. The simulator represents a powerful tool for the identification of new drug-able targets and for screening and profiling new drug candidates, and to identify potential new therapeutic strategies for devastating neurological disorders.

Title: Using nonstationary contrast and intensity statistics for sound category identification

Authors: *M. A. ESCABI, R. NARAYAN
Univ. Connecticut, STORRS MANFLD, CT

Abstract: Environmental sounds, both man-made and natural, vary on multiple time and frequency scales generating a large range of temporal, spectral and amplitude modulations that are evident in the high-order statistics of the sound spectrogram. Healthy hearing humans perceive high-order statistical regularities and use this information to categorize and discriminate

sounds. Furthermore, neural responses in the central auditory system, including inferior colliculus and auditory cortex, can be modulated by high-order sound statistics. Here we test the hypothesis that nonstationary high-order statistics derived from computational auditory model enable discrimination and identification of sound categories from a computational standpoint. A large catalogue of animal vocalizations (speech, birds, primates, frogs etc.), environmental sounds (water, wind, thunder etc.), and man-made sounds (music, machine sounds etc.) and their associated high-order statistics was developed, and the information carrying content of each statistic for sound recognition and discrimination was measured. Time-varying statistics related to the sound contrast and time-varying intensity where measured for each sound at time-scales comparable to perceptual integration of intensity and comparable to adaptation times for such features in auditory cortex. Using statistical priors as model distributions for each sound category, Bayesian classification and signal detection theory were applied to the sound database to test discrimination limits amongst sounds or categories. Using these nonstationary contrast and intensity statistics alone, we show sound categories can be recognized with near 100% accuracy given observations times in the order of ~10 sec.

Title: Auditory evoked potentials reveal harmonic structure as a signal attribute

Authors: ***J. W. LEWIS**[1], W. J. TALKINGTON[2], B. SMITH[2], S. KHOO[1], C. FRUM[3], D. W. GRAHAM[4], M. SCHADE[5]
[1]Dept Neurobio. & Anat., [3]Dept Physiol. & Pharmacol., [4]Dept Computer Sci. & Electrical Engin., [5]Dept Psychology, [2]West Virginia Univ., Morgantown, WV

Abstract: Introduction Speech and mammalian vocalizations may be differentially processed relative to other natural sounds based in part on quantifiable acoustic signal attributes, including their harmonic content (harmonics-to-noise ratio; HNR value). Our group previously used natural and artificial sound stimuli with well-defined harmonic content to reveal cortical foci that

are parametrically sensitive to HNR. Here we sought to evaluate the temporal characteristics of harmonic signal processing in cortex. We evaluated whether classical auditory evoked potential (AEP) waveforms (P1-N1-P2 complex) demonstrate parametric sensitivity to harmonic signal content. Methods We recorded cortical AEPs evoked by artificially constructed white noise stimuli (iterated ripple noise; IRNs) that differed systematically in their HNR values. Fifteen healthy right-handed participants completed two experiments, each involving the randomized presentation of six IRN harmonic profiles (-7.6, -3, +3, +9, +15, and +24 dB-HNR). During EEG recording, IRNs were delivered to the right ears of participants as they watched silent, subtitled films. For the second experiment, the six IRNs were reverse-biased in perceived loudness as a critical control. We used ERPLAB software and independent component analyses (ICA) to analyze N1/P2 AEPs and independent components with respect to different HNR conditions. Results We observed a biphasic response profile of the N1-P2 AEP complex that persisted even with reverse intensity-biased IRNs, such that the peak-to-peak N1-P2 amplitude decreased with increasing harmonicity from -7.6 to -3dB, but increased from -3 to +24dB. ICA further revealed dipole activities contributing to the differences initially seen in AEP features. Conclusions Our findings suggest that the HNR signal attribute is robustly represented in the N1 component and N1-P2 complex when an ethologically-relevant range of HNR is presented (normal speech: +6 to +15 dB-HNR). Further, our chosen IRN HNR range was broader than ranges employed in earlier studies and revealed a unique, biphasic HNR processing profile. It appears that harmonic signal processing is instantiated as a distinct intermediate cortical processing stage in the human auditory system - perhaps including two filtering functions that work in concert to simultaneously optimize harmonic signal enhancement and noise suppression. This putative signal processing principle could be tested in future models of the human auditory system, included in biomimetic prosthetic device algorithms, and used to augment hearing prosthetics that are designed specifically for the enhancement of vocalizations and speech.

Title: Limitations in fine-grained within-category semantic auditory discrimination: Insights from spatio-temporal analyses

Authors: *R. DE MEO[1], M. M. MURRAY[1,2,3,4], R. W. THOMPSON[5], S. CLARKE[1]
[1]Dept. des Neurosciences Cliniques, Service De Neuropsychologie Et Neuroréhabilitation, Lausanne, Switzerland; [2]Dept. of Radiology, Univ. Hosp. Ctr. and Univ. of Lausanne, Lausanne, Switzerland; [3]Electroencephalography Brain Mapping Core, Ctr. for Biomed. Imaging (CIBM), Lausanne, Switzerland; [4]Dept. of Hearing and Speech Sci., Vanderbilt Univ. Med. Ctr., Nashville, TN; [5]Div. of Pediatric Cardiol., Johns Hopkins Univ. Sch. of Med., Baltimore, MD

Abstract: Correct recognition of individual sound objects within a semantic category (e.g., bird songs) involves cortical regions along a left lateralized temporo-fronto-parietal network. Here, we investigated how representations of other environmental sounds, i.e. heartbeats, differ when sounds have been correctly versus incorrectly categorized. Thirteen medical students, of which 2 were excluded due to poor performance during the training session, participated in this study. EEG and behavioural data were recorded from eleven participants who completed: 1) an audio-visual training session requiring recognition of 4 categories of real patients' heartbeat sounds (the training session ended when participants reached 70% accuracy); and 2) a testing session requiring discrimination of the 4 previously learned categories on recordings of new heartbeat sounds. Accuracy data were analyzed with a one-way ANOVA with Category (A: Normal vs. B: Variable split of S2 vs. C: Both S2 are widely split vs. D: Early systolic click) as factor. There was a main effect of category ($p = 0.033$) that was due to early systolic clicks being the most difficult to recognize. EEG analyses compared correctly vs. incorrectly recognized items with a paired t-test of source estimations calculated for each participant. The results identified a distributed spatio-temporal sequence that included: i) the left fusiform and parahippocampal gyri, left cuneus and lingual gyrus and right STG at 126-155 ms; ii) the cuneus and lingual gyrus bilaterally at 182-212 ms; iii) bilateral cingulate cortex, left superior frontal gyrus and right middle frontal gyrus at 252-295 ms; and iv) the left superior frontal gyrus at 384-419 ms. Thus, correct and incorrect recognition of heartbeat sounds relied on distinct brain networks, and these networks involved areas located predominantly outside the auditory brain regions. This pattern of activation differences between correct and incorrect categorization demonstrates that errors in fine-grained discrimination of objects within a semantic category, such as heartbeat sounds, can be driven more by incorrect labeling, rather than by limitations at a lower, i.e. perceptual, processing level.

Title: Auditory network optimized for sound discrimination predicts hierarchical trends of the auditory system

Authors: *F. KHATAMI[1], M. A. ESCABI[2]
[1]The Univ. of Connecticut, Willimantic, CT; [2]The Univ. of Connecticut, Storrs, CT

Abstract: Sound recognition, including speech recognition, is accomplished by multiple hierarchical levels of sound processing. Starting with the cochlea, sounds are decomposed into frequency components and subsequent auditory levels such as the inferior colliculus and cortex further decompose sound into spectro-temporal components. This multi-level processing combined with highly nonlinear neural mechanisms produces a robust neural representation enabling sound recognition in acoustically challenging environments (e.g., high noise levels). Here we develop a biologically inspired computational auditory model consisting of multiple hierarchical levels of spiking neurons and test its performance in a speech recognition task. The proposed biologically inspired model contains three components. The first stage consists of a cochlear model that transforms speech into spike trains for multiple frequency channels as observed in the auditory nerve. Stage two consists of a hierarchical biologically motivated neural network of spiking neurons designed simulate the central auditory pathway. The hierarchical network consists of 6 network layers containing 100 biologically realistic spiking neurons per layer and biologically realistic architecture that contains excitatory and inhibitory connections between layers. The final stage consists of a statistical classifier that reads the output spike trains from the network to categorize and identify speech words. Upon optimizing the network to discriminate speech sounds from multiple speakers, the model achieves high performance even under conditions of low signal-to-noise ratio. Furthermore, the model predicts several features present in the mammalian auditory system hierarchy. The optimal integration time constants increase systematically across the network layers such that the most central layers are substantially slower. Furthermore, selectivity increases and spike rates decrease systematically across the network layers analogous to trends observed in the auditory system.

Title: Mapping intracranial ECoG responses onto the surface of the human superior temporal plane

Authors: *H. OYA[1], H. KAWASAKI[1], K. V. NOURSKI[1], J. D. GREENLEE[1], T. D. GRIFFITHS[2], M. A. HOWARD[1]

Abstract: Accurate mapping of electrocorticographic (ECoG) responses recorded within the human superior temporal plane using depth electlodes (Howard et al., J Neurosurg. 84:129-32, 1996) requires careful consideration of anatomical detail. The human superior temporal plane is veiled with the overlaying frontal, parietal and temporal lobe structures, and is highly convoluted with large inter-individual variability. Traditionally used “top-down” depiction of the superior temporal plane with lines representing deep sulci (first transverse temporal sulcus and the Heschl's sulcus) is not necessarily the best way to present obtained responses. In addition to mapping the responses on individual subject basis, with data from multiple subjects, spatial patterns of responses, if stable, could be mapped onto a representative brain to facilitate the interpretation. Image processing pipeline developed in our laboratory for response mapping onto the reconstructed surface of the human superior temporal plane includes the following steps: 1) Surface reconstruction of whole hemispheres with FreeSurfer; 2) Superior temporal plane patch creation; 3) Warping of individual subjects' brains onto a template brain using spherical diffeomorphic deformation (Yeo et al., IEEE Trans Med Imaging, 29:650-68, 2010); 4) Projection of responses recorded at each recording site contact to the surface vertices is done with inverse-distance weighting; 5) Smoothing of values assigned to the surface vertices using recursive heat-kernel weighting. The Gaussian process prediction and interpolation is also evaluated. We find that manual delineation of the two major sulci and superior temporal gyrus in addition to the curvature values confined within the superior temporal plane increases reliability of the matching between the two brains. Mapped data can be visualized on both inflated and original surface models from various angles. Effects of smoothing, interpolation and parameter settings are discussed.

Title: Human auditory cortical coding of speech in background noise as a function of age and noise type

Authors: N. MAAMOR[1,2], *C. BILLINGS[1,3]
[1]Portland Veterans Affairs Med. Ctr., Portland, OR; [2]Sch. of Rehabil. Sci., Natl. Univ. of Malaysia, Kuala Lumpur, Malaysia; [3]Otolaryngology/Head & Neck Surgery, Oregon Hlth. & Sci. Univ., Portland, OR

Abstract: Speech perception in background noise is modulated by both patient factors (e.g. age and hearing loss) and stimulus characteristics (e.g. signal-to-noise ratio (SNR) and background noise type). The purpose of this study was to improve our understanding of how signals in noise are neurally coded as a means to better diagnose and rehabilitate speech perception in noise in people with peripheral and central auditory problems. Cortical auditory evoked potentials (CAEPs) were used to determine the effects of SNR, background noise type, and age on the neural representation of speech in noise. Ten younger and ten older normal-hearing individuals participated in this study. Using a passive oddball paradigm, the syllables /ba/ and /da/ were presented in four noise conditions: quiet, continuous speech-spectrum noise (SSC), one-talker modulated noise (1TM), and four-talker babble (4TB). In addition, noise levels were varied to create three different SNRs: -3, +3 and +9 dB. Evoked response latency and amplitude, as well as rectified area measures were determined for each of the 10 conditions. A significant effect of SNR and noise type on CAEPs was found for all CAEP measures. The largest effect of SNR was seen when stimuli were presented in SSC noise followed by the 1TM and 4TB noise. Poor CAEP morphology was seen for all 4TB conditions and may be due to the spectral and temporal similarities between the signal and noise. The 1TM noise was predicted to show a stronger SNR

effect than observed. We attributed this lack of effect on the long gaps present in the 1TM noise used in this study. A significant interaction between SNR and noise type was also found: at high SNRs, the response for SSC noise was larger than for 1TM noise; however, the reverse was found at low SNRs, suggesting that speech sounds are encoded differently depending on the SNR level and noise type. There was no significant main effect of group (i.e., age) and only limited age interactions associated with SNR and noise type. These results demonstrate an important first step in understanding the link between the underlying electrophysiology associated with speech perception in noise.

Title: Vocal signal processing and social categorization during natural communication in marmoset frontal cortex neurons

Authors: ***V. JOVANOVIC**, S. H. COOP, C. T. MILLER
UC San Diego, La Jolla, CA

Abstract: Communication is an inherently interactive process. While the exchange of information is central to this process, the nature of these interactions is heavily affected by the social setting. During vocal communication, callers must distinguish between individuals before deciding how to respond. Here we examined the responses of single neurons in marmoset frontal cortex during naturally occurring vocal interactions known as antiphonal calling. In the first experiment, we recorded ~300 neurons while subjects performed this natural vocal behavior. We found that a relatively small percent of units exhibited responses to vocalizations in this context (~25%). This occurred even in populations with direct anatomical connections with auditory cortex, such as ventral prefrontal cortex. In the second experiment, we implemented a novel interactive playback design to test social category perception during marmoset antiphonal calling. In these experiments, subjects were broadcast vocalizations from one caller during bouts of antiphonal calling. During some of these bouts, the calls of a different animal were broadcast

after 2 consecutive antiphonal calls. Previously, we reported that the change in caller identity elicited significant changes in subjects' vocal behavior. Their overall response rate decreased and the latency to respond increased. To test the role of frontal cortex for social categorization in natural communication, we are currently recording the responses of single neurons in marmoset ventral prefrontal cortex while animals engage in this behavioral task. We will compare neural responses to vocalization stimuli during tonic states of antiphonal calling to unexpected changes in social categories to determine the role of frontal cortex for recognition in natural primate communication.

Title: Neuronal mechanisms of vocalization sound processing in the primary auditory area of common marmosets

Authors: *T. BANNO, W. SUZUKI, N. MIYAKAWA, H. ABE, N. ICHINOHE
Natl. Ctr. of Neurol. and Psychiatry, Kodaira, Tokyo, Japan

Abstract: Social animals including humans communicate with each other by using various types of vocalization sounds. The animal vocalization sounds contain complex acoustical features, and how the auditory nervous system processes complex sounds with various combinations of multiple acoustical features is therefore an important question to understand the neuronal mechanisms underlying our vocal communications. We carried out electrophysiological recordings from common marmosets (Callithrix jacchus), a promising model animal for vocal communications due to their highly complex vocalizing behavior, to examine neuronal activities while they are hearing conspecific vocal sounds. In this study, we acoustically analyzed three major marmoset calls (phee, trill, and twitter) and extracted sinusoidal amplitude and frequency modulations as essential spectro-temporal features of these calls. We then resynthesized sounds by simply manipulating pure tones with various combinations of these acoustical features and created a set of stimulus sounds that covered a wide range of a parametric space composed of these component feature combinations. Our recordings from the primary auditory area revealed that all of the three types of real marmoset calls activated a large proportion of cells in this region

even though these calls had distinct spectro-temporal features. We observed weaker but significant responses to the synthesized sounds whose acoustical features were matched with the real marmoset calls (simplified calls) in 55% of the real call responsive sites. Further analyses revealed that the responses to the simplified calls could be predicted by a simple multiplication of the responses to their corresponding component features in 64 % of the simplified call responsive sites. We also found that the spike timing was more precisely locked to the modulation frequency of the combination sounds with the same modulation rhythms in both of the components, compared with the rhythmic responses to their component sounds whose amplitude or frequency alone were separately modulated. In this study, we demonstrated the usefulness of our simplified calls to examine computational principles underlying the vocal communication signal processing. Our results indicate that the simplified calls contain partial but sufficient information of the real marmoset vocalizations enough to evoke a large proportion of the neurons responsive to the real calls and suggest that these neurons in the primary auditory area perform various types of neural computations to process complex acoustical features in the communication sounds.

Title: Development of an awake-behaving fMRI preparation for investigating auditory cognition in common marmosets

Authors: *C. TOARMINO[1], C. C. YEN[2], A. C. SILVA[2], C. T. MILLER[1]
[1]UC San Diego, San Diego, CA; [2]Natl. Inst. of Neural Disorders and Stroke, Bethesda, MD

Abstract: Beyond primary auditory cortex, relatively little is known about the role that higher areas of the auditory system play in perception and cognitive functions. To address this issue, here we report on the progress of the development an awake-behaving fMRI preparation to examine the contributions of the auditory belt regions in auditory cognition. Previously, we have

developed a method for imaging auditory cortex in the awake common marmoset (Callithrix jacchus) during passive listening using fMRI. Consistent with previous neurophysiology experiments, we found: 1) robust bilateral activity in auditory cortex to stimulation consisting of tones and band-passed noise, 2) regions selective to high and low frequencies along a caudal-rostral axis throughout the auditory core, and 3) responses to noise were greatest outside of the auditory core. Our goal here is to combine our previously established imaging paradigm with a behavioral training preparation we have also established in order to investigate brain areas involved in an auditory attention task. We trained marmosets to perform a frequency sweep discrimination task where the subject must discriminate an upward-directed frequency sweep (GO stimulus) from a downward-directed frequency sweep (NO-GO stimulus) by licking or withholding licking, respectively. Currently, we are integrating the imaging and behavioral preps in order to investigate brain areas that show activity during this task. Given the attentional demands of the task, particularly when subjects perform at threshold, analyses will focus on trials with high and low discriminability to determine whether attention modulates neural responses. We hypothesize that the frontoparietal network and auditory belts regions will be active during this task, including dorsolateral prefrontal cortex during threshold performance.

Title: A preparation for optogenetic photostimulation in marmoset cortex

Authors: M. MACDOUGALL[1], J. MITCHELL[2], S. SRINIVASAN[2], *C. T. MILLER[3]
[1]UC San Diego, La Jolla, CA; [2]Salk Inst., La Jolla, CA; [3]Psychology, UCSD, La Jolla, CA

Abstract: Marmosets are emerging as a powerful model for investigation of primate neurologic systems. Optogenetics offers relatively precise temporal and spatial control of neuronal activity. We employ awake, behaving head-fixed marmosets performing auditory discrimination tasks to evaluate marmoset cognition, auditory processing, and social behaviors. More could be learned about the underlying neural mechanisms of these complex primate features using optogenetic

manipulations of neurons to perturb the brain during auditory tasks. Here we sought to develop an optogenetic photostimulation preparation for marmoset cortex. This project comprised two components. The aim of the first component was to determine which viral constructs were most suitable for use in marmosets. Using various adeno-associated viral (AAV) capsids containing channel rhodopsin genes with varying promoters, we systematically examined various methods for creating a marmoset optogenetic preparation. We investigated the utility of AAV 1, 5, and 9, the promoters synapsin, CAMkII, and CAG, and we varied injection rate and volume into the marmoset cortex. The viruses were allowed to express for 6 weeks after injection and brains were harvested and examined microscopically using immunofluorescence. The channel rhodopsins also had fluorescent protein tags such as GFP, YFP or mCherry. Primary antibodies against NeuN, GABA, CD68, and GFAP were applied to fixed brain slices prior to application of secondary fluorescent antibodies. The results demonstrate excellent expression of channel rhodopsin for particular serotype/promoter combinations. Particular constructs expressed notably well in the long-tract axons of the corpus callosum and in white matter coursing through internal capsule and brainstem. The aim of the second phase of the project was to optimize photoexcitability in marmoset cortex using these constructs. We are currently refining these parameters in marmoset neocortex and will present these results. Our results here indicate that using optogenetic techniques in marmosets is a feasible and useful method of correlating neural activity with behavior in awake marmosets.

Title: Ontogeny of antiphonal calling in common marmosets

Authors: ***C. P. CHOW**, C. T. MILLER
UCSD, La Jolla, CA

Abstract: Common marmosets (Callithrix jacchus) are small, highly vocal New World primates native to the coastal rainforests of Northeastern Brazil. Many aspects of this highly voluble species' vocal behavior have been described (Bezerra and Souto, 2008), but relatively little remains known about the ontogenetic development of their vocal communication system. Nonhuman primates are commonly described as having a limited capacity for vocal control over the acoustic structure of vocalizations (Seyfarth and Cheney, 1997), but an ability to exert control over the usage of the same call types (Pistorio et al, 2006). To test whether common marmoset vocal development is consistent with this trend, we investigated the longitudinal changes in vocal development of the common marmoset from approximately 3 to 12 months during their naturally occurring antiphonal calling behavior. We recorded antiphonal calling interactions between twins as well as between those twins and their respective parents twice a month over the duration of the study period for 12 animals. Analyses focus on changes in vocal behavior and vocal signal over ontogeny. Preliminary analyses suggest significant changes in both aspects of communication over the first year of life.

Title: Studying the neural basis of vocal communication in a naturalistic environment using wireless neural recording technology in marmoset monkeys (Callithrix jacchus)

Authors: *L. ZHAO[1], H. YI[1,2], X. WANG[1]
[1]Dept. of Biomed. Engin., The Johns Hopkins Univ., Baltimore, MD; [2]Sch. of Biomed. Engin., Tianjin Med. Univ., Tianjin, China

Abstract: How the primate brain controls the production of speech and other species-specific vocalizations, especially when coordinating the multiple dynamic features of vocal signals, is largely unknown. Lesion studies in humans have shown that particular frontal cortical regions (such as Broca's area) are crucial for speech production, and local field potential recordings from the human brain suggest that different motor cortical regions generate specific signals associated with different phonetic elements. The generation of vocal signals involves temporally precise coordination of the larynx and other articulators and therefore likely requires organized activity

among areas within the frontal cortices. To uncover such mechanisms in the primate brain at the neuronal level, we have studied frontal cortical activities in marmoset monkeys (Callithrix jacchus), a small New-World primate species with a rich vocal repertoire, in a naturalistic environment. Using chronically implanted multi-electrode arrays with wireless neural recording technology, we examined single-unit activity from populations of neurons in premotor cortex of freely moving and vocalizing marmosets embedded in a large breeding colony. Neural dynamics of single-units showed temporal patterns related to different types of vocalizations, including correlations between neural activity and different call types or different acoustic features within a call type. These results provide evidence to help understand neural mechanisms underlying vocal control in the primate brain.

Title: Norm-based neural coding of conspecific vocalization in the macaque monkey

Authors: ***S. A. LOVE**[1], M. FUKUSHIMA[2], A. DOYLE[2], R. C. SAUNDERS[2], N. FUJII[3], P. BELIN[1], M. MISHKIN[2], D. A. LEOPOLD[2]
[1]Inst. de Neurosciences de La Timone, Marseille, France; [2]Lab. Neuropsychology, NIMH/NIH, Bethesda, MD; [3]Lab. Adaptive Intelligence, RIKEN Brain Sci. Inst., Saitama, Japan

Abstract: Person perception is a critical aspect of social interaction; subtle differences between individuals in vocal and/or facial features are used to identify conspecifics. In humans, norm-based coding explains the encoding of both the facial and the vocal identity of individuals (Latinus et al, 2011; Leopold et al, 2001; Valentine, 1991). Facial identity is represented in reference to an internal norm in both human (Loffler, et al 2005) and monkey (Leopold et al 2006) temporal cortex. Similarly, the human temporal voice area (Belin et al 2000) represents voice identity in reference to an internal norm (Latinus, et al 2013). Recent work also shows sensitivity to conspecific vocalizations in the temporal cortex of the monkey (Petkov et al, 2008). Here we asked whether a norm-based coding strategy could explain the neural coding of vocal

identity in the monkey. An average macaque voice was created by morphing together a coo from 7 macaques. 7 voice identity continua, containing 9 stimuli (-50 to 150% in steps of 25%), were created by morphing the average with each individual coo. Stimuli contained X% of information from the average coo and 100-X% from an individual coo. To record auditory evoked potentials, we used an electrocorticographic (ECoG) array chronically implanted in a macaque monkey. This ECoG array consisted of 256 recording sites for bipolar recording at 128 locations. The electrodes were located in the medial wall, the lateral surface, and the supratemporal plane (STP) in the lateral sulcus. We found robust auditory evoked responses to the vocalization stimuli in the recording site around the primary auditory cortex (A1) in STP. Norm-based tuning for voice did appear to develop over time in some recording sites. Specifically, some electrodes showed a stimulus-selective drop in frequency power that varied systematically based on the distance of a stimulus from the center of the "voice space". Consistent with models of norm-based coding, these power drops were most pronounced for the average voice and decreased along multiple identity trajectories at higher identity strength, and particularly the extreme (caricature) voices.

Abstract: The amygdala plays a key role in the processing of emotionally salient stimuli. Changes in the gamma-band oscillatory activity in the human amygdala have been related to the discrimination of emotion categories of visual stimuli (Oya et al., 2002), but less is known about amygdala responses to auditory stimuli carrying emotional information. We recorded intracranial field potentials with chronically implanted microelectrodes bilaterally in the amygdala and the caudolateral belt of the superior temporal gyrus (STGcb), and unilaterally in a control area, the visual cortex (V1), in three Rhesus monkeys while they listened to neutral, threatening and fearful monkey calls. We analyzed the responses in two time-windows (Window 1: 0-500 ms, Window 2: 500-970 ms from stimulus onset). In Window 1, event-related potentials to the three types of auditory stimuli differed from each other in the amygdala and STGcb, but not in V1. A two-way analysis of variance (ANOVA) (factors hemisphere and stimulus) of the auditory-stimulus-related oscillatory power in the amygdala and STGcb, and a one-way ANOVA in V1, showed a significant main effect of stimulus in the amygdala ($F(1,2) = 15{,}451$, $p < 0.05$), but not in STGcb and V1. The peak power in the gamma range (30-120 Hz) in amygdala to fearful calls was greater than to neutral and threatening calls (in both, $p < 0.05$, paired t-test). In Window 2, the mean power in the beta range (15-25 Hz) in amygdala also differed between the stimuli ($F(1,2) = 18.516$, $p < 0.05$); it was greater to the threatening calls than to fearful and neutral calls (in both, $p < 0.05$, paired t-test). In Window 2, there were no significant differences between the stimuli in the oscillatory power to the three types of stimuli in STGcb and V1. These results suggest a role for the amygdala in the processing of emotionally salient, naturalistic auditory stimuli.

Title: LFP's in the superior colliculus of an echolocating bat are timed with ongoing behaviors

Authors: *M. J. WOHLGEMUTH, III, C. MOSS
Johns Hopkins Univ., Baltimore, MD

Abstract: LFP SFN Abstract - 2300 characters max Our research examines local field potential (LFP) recordings in the superior colliculus (SC), a structure in the mammalian midbrain important in spatial navigation and orientation. The SC is a laminated structure, with superficial layers receiving sensory information, intermediate layers integrating sensory information into motor planning, and deeper layers directing motor actions for spatial orientation. Specifically, we are investigating how the LFP may convey circuit level sensory information into a distributed network of neurons engaged in motor planning. The echolocating bat is a particularly valuable model system, because it discretely samples its environment with sonar signals, which provide unparalleled temporal precision for correlating LFP signals with sensory processing and pre-motor commands. Chronic multichannel neural recordings were taken in the SC, while the echolocating bat tracked a moving insect from a stationary position. The recording device was a 4x4 grid of electrodes that sampled both action potentials and LFP's in a 300 square micron volume of the SC. We found a significant increase in the power of the LFP when the bat was actively tracking an object. Furthermore, the timing of sonar call production and the subsequent echo returns were tied to particular phases of the LFP. We also found that the amplitude of the LFP was highest in the medial extent of the SC, where activity is tied to sensory activation along the horizontal plane of the animal, and which corresponds with the location of the target throughout the approach vector. And lastly, we found that separate frequency bands of the LFP become phase-locked at specific times with respect to the bat's sonar behaviors. These results suggest that features of the LFP play an important role in the active sensing system of the echolocating bat, and demonstrate the utility of the bat as a model to study LFP's in the context of sensation and adaptive motor commands.

Title: Streaming of repeated embedded noise in ferret auditory cortex

Authors: *D. SADERI[1], J. H. MCDERMOTT[2], S. V. DAVID[1]
[1]Oregon Hearing Res. Ctr., Oregon Hlth. & Sci. Univ., Portland, OR; [2]Dept. of Brain and Cognitive Sci., MIT, Cambridge, MA

Abstract: To function in natural auditory environments, the brain must segregate different components of sound mixtures, a process known as auditory streaming. Many natural sounds contain repetitive patterns that provide a cue for auditory grouping. The present study sought first to test if ferrets can use temporal regularities to stream auditory stimuli and second to explore if a streaming effect can be measured at the level of the primary auditory cortex (A1). We trained two ferrets on a repetition embedded noise (REN) detection task. Stimuli consisted of the superposition of two broadband, spectrally overlapping signals, each composed of a continuous sequence of 300-ms noise samples with spectro-temporal correlations matched to natural sounds. The stimuli were perceived as a single stream until a target sample started to repeat in one of source signals, thereby generating a perceptually distinct foreground. We recorded extracellular responses in A1 of an awake behaving ferret during presentation of single and two simultaneous noise sequences. A simple test for streaming revealed preferential encoding of the repeated target relative to the random background stream. Specifically, the PSTH response to the repeated target in noise was more similar to the response to the target in isolation (measured by correlation coefficient) than the response to the non-repeated target in noise. Moreover, a linear classifier trained on autocorrelated responses of all cells recorded in A1 was able to robustly discriminate between the presence and absence of a repeating noise sample. This supports the idea that the information about the repeated target is present in A1 neurons, perhaps carried by an implicit temporal code. We conclude that ferrets provide a good animal model for studying the neurophysiological bases of repetition-based streaming, and representation of foreground/background segregation might be encoded at the level of A1. Ongoing studies are exploring whether the representation of the repeated foreground is more prominent in secondary areas of the auditory cortex (belt regions), known to display a more context-dependent response to behaviorally relevant sounds. We are also performing classification image (CIm) analysis on the behavioral data to shed light on the strategies used by the animal during the REN detection task.

Title: Audio-haptic coordination and multisensory integration in rat auditory cortex

Authors: *R. P. RAO[1], F. MIELKE[1], E. BOBROV[1,2], M. BRECHT[1]
[1]Bernstein Ctr. For Computat. Neurosci., Berlin, Germany; [2]Berlin Sch. of Mind and Brain, Humboldt Univ. of Berlin, Berlin, Germany

Abstract: During social interactions, rats employ complex multi-modal signaling and sensing. In this study, we investigate facial interactions between conspecifics. Specifically, we look at the coordination of whisking and ultrasonic vocalization and the integration of touch and sound in the auditory cortex. To this end, we use a combination of low- and high-speed videography, extracellular neuronal data acquisition and ultrasound recordings. We find that facial touch between conspecifics is associated with increased vocalization frequency, and this is modulated by sex and estrous state of the interacting partners. Interestingly, calls are emitted at the whisking frequency (~8 Hz) and are preferentially initiated in the retraction phase of whisking. In the auditory cortex, responses to ultrasonic vocalizations are mostly excitatory and tend to be very weak in regular-spiking but stronger in fast-spiking neurons. Interestingly, neurons of female rats tend to have higher basal firing rates which is not modulated by estrous state. Facial touch on the other hand induces inhibition in auditory cortex and off-responses after termination of touch. In addition, touch resulted in increased modulation in response to ultrasonic vocalizations. Facial interactions therefore appear to involve temporally orchestrated calling-whisking patterns. While regular-spiking neurons respond weakly to ultrasonic vocalizations, their modulation is increased during facial touch.

Title: Genetic dissection of infant vocalizations

Authors: *S. ROY[1], M. L. SCATTONI[2], D. H. HECK[1], L. LU[1], R. W. WILLIAMS[1]
[1]Anat. and Neurobio., Univ. Of Tennessee Hlth. Sci. Ctr., Memphis, TN; [2]Dept. of Cell Biol. and Neurosciences, Neurotoxicology and Neuroendocrinology Section, Inst. Superiore di Sanità, Rome, Italy

Abstract: Rodent pups produce series of brief ultrasonic vocalizations (USVs) when distressed or separated from their nest. As is humans, these separation-induced vocalizations are critical for parental care and infant survival. It is likely that the underlying genetic mechanisms and CNS circuitry are well conversed among many mammalian species, and we argue that the cries of a human infant and a mouse pup are true behavioral homologs. C57BL/6J (B6) and DBA/2J (D2) strains of mice differ significantly in qualitative and quantitative characteristics of separation induced USVs. We initiated a genetic dissection of USVs to discover sequence variants and brain circuitry that underlie this critical set of infant behaviors. We collected separation-induced USVs from 44 genotypes, including two common progenitor strains B6 and D2, their reciprocal F1 hybrids, and 40 BXD recombinant inbred (RI) strains on postnatal days 7, 8, and 9 (2 to 5 litters each with data on sex and weight). We scored 14 facets of vocalization and in all cases heritabilities were sufficiently high_from 20% to 50%_to warrant detailed genetic analysis. We did not detect any effects of sex or body weight. Heritabilities for ten distinct USV call types (relative numbers of upward, downward, chevrons, etc.) tended to be higher than those for quantitative traits (amplitude, duration, total number of calls, and frequency). Duration covaries positively with amplitude ($r = 0.39$, $p < .01$), but negatively with frequency ($r = -0.30$, $p < 0.05$). We mapped four primary quantitative USV traits and detected significant linkage for mean peak frequency to chromosome (Chr) 14 at 58 ± 3 Mb (LRS of ~18 and +3 kHz per *D* allele) corresponding to human Chr 13 from 19-25 Mb and Chr 14 from 22-24 Mb. This locus is

completely independent of call duration and amplitude. Duration and amplitude map jointly, but weakly to chromosomes 1, 4 ,and 9. Duration has independent linkage_but suggestive only_to proximal Chr 6 and distal Chr 8. Therefore we conclude that all of these functionally coupled vocalization traits are influenced by several genetic factors.

Title: Coding of vowels in the auditory midbrain of the budgerigar and rabbit

Authors: *K. S. HENRY[1], E. G. NEILANS[3], J. M. MCDONOUGH[2], L. H. CARNEY[1]
[1]Biomed. Engin., [2]Linguistics, Univ. of Rochester, Rochester, NY; [3]Psychology, Univ. at Buffalo, Buffalo, NY

Abstract: While speech plays an integral role in human social interactions, the neural mechanisms contributing to speech coding are not well understood, especially in the lower central nervous system. Here, we compare the neural mechanisms underlying differential responses to natural English vowels in the budgerigar, a vocal learner with human-like behavioral sensitivity to complex signals, and in the Dutch-belted rabbit, a species with more limited behavioral capabilities but greater cochlear similarity to humans. Neurophysiological recordings in awake animals were made from isolated cells of the auditory midbrain using chronically-implanted electrodes. Frequency response maps, modulation transfer functions, and vowel responses were recorded in each cell. Frequency response maps define a cell's tuning to audio frequencies while modulation transfer functions describe tuning to amplitude modulation frequencies. Modulation transfer functions fell into the same basic categories in the two species. Some cells showed an increase in firing rate in response to a limited range of modulation frequencies (i.e., band-pass modulation tuning) while others exhibited decreases in firing rate (e.g., band-reject and low-pass modulation tuned cells). Frequency response maps were also broadly similar, with both species exhibiting considerable variation in the bandwidth of audio

frequency tuning across cells of similar characteristic frequency. Neural responses to vowels in both species showed substantial differences in evoked firing rate across twelve different spoken English vowels from the Hillenbrand et al. (JASA 1995, 97:3099) database. The interactions of audio frequency tuning (i.e. characteristic frequency) and modulation tuning in explaining vowel responses were explored using a computational model of the auditory system. The model included an auditory-nerve component (Zilany et al., JASA 2014, 135:283) and interactions between the time course of excitation and inhibition in the auditory brainstem and midbrain to yield modulation tuning (Nelson and Carney, JASA 2004, 116:2173). The results allow detailed comparison of auditory midbrain function between birds and mammals. Furthermore, they suggest that both audio frequency tuning and modulation tuning may shape coding of vowels in the lower central nervous system.

Title: Encoding of complex natural sound in auditory midbrain by small neural groups

Authors: *D. LYZWA[1,2]
[1]Dep. Nonlinear Dynamics Max Planck Inst. For Dynamics and Self-Organization, Göttingen, Germany; [2]Informatics Forum, Univ. of Edinburgh, Inst. of Perception, Action and Behaviour, Edinburgh, United Kingdom

Abstract: How complex natural sounds are represented in the midbrain remains an open question. The central nucleus of inferior colliculus (ICC) is the main converging station in the auditory midbrain, and contains nearly all information about the sound. To better understand the functional organization of this nucleus, the spatial extent of the neural representation of vocalizations and their encoding by individual and groups of multi-units was explored. Spiking multi-unit activity was simultaneously recorded from 32 positions along and across isofrequency laminae of the ICC while presenting 11 species-specific vocalizations to guinea pigs. Using

neural discrimination and cross-correlation it was found that small groups of neurons reliably encode the spectrotemporally rich set of vocalizations. Combination of a few multi-units yielded improved discrimination over an individual unit, but temporal correlations between the units did not improve discrimination. Individual vocalizations with their specific spectral content are optimally encoded across large frequency regions and this should be beneficial in a behavioral context. The findings suggest a spatially broad distributed code for vocalizations in the mammalian inferior colliculus. Title: Reorganisation of V1 and the pulvinar nucleus following early life lesion of area MT

Authors: *J. A. BOURNE[1], I. MUNDINANO[1], H.-H. YU[2], C. WARNER[1], W. KWAN[1]
[1]Aust. Reg. Med. Inst., Monash University, Australia; [2]Dept. Physiol., Monash University, Australia

Abstract: The middle temporal (MT) area of the nonhuman primate visual cortex is a primary-like area which develops in parallel with the primary visual cortex (V1). Throughout development, area MT receives input primarily from the medial portion of the inferior pulvinar (PIm) and V1. The aim of this study was to investigate the impact of the ablation of area MT in early life on the remaining visual cortex, especially V1, and the retinopulvino-MT pathway. To analyse retinopulvino-MT connectivity in the absence of area MT early in life, we administered intraocular anterograde tracers (n=2) 12 months following the mechanical unilateral ablation of left area MT (n=5) in postnatal day 14 marmoset monkeys. Single-unit electrophysiological recordings in area V1 were also conducted in 3 animals 12 months following ablation. This was performed to observe if there were any changes to the physiological properties of V1 neurons

post-ablation. cFos immunoreactivity was also used to further quantify functional activation of neurones in V1. Pyramidal cell (neurofilament) and interneuron (calbindin and parvalbumin) markers were used to identify changes in neuronal cell populations in the visual cortex. Compared to age matched non-lesion controls, early life MT ablation resulted in an increase in retinal input into the ipsilateral PIm. Within the ipsilateral V1, a loss of cFos+ and calbindin+ cells in the lesion projection zone in layers V and VI were detected. In 2 out of 3 cases, where drifting gratings were used to characterize tuning properties of single units in V1, we observed unusually large numbers of units (>40%) with receptive fields located inside the affected part of the visual field that were not orientation selective. Other properties such as spatial frequency tuning, temporal frequency tuning, and size selectivity showed no obvious deviation from those observed in normal animals. In the third case, tuning properties were close to normal. These results suggest that the absence of MT results in a reduction of pruning within retinopulvinar connectivity. Furthermore, the absence of area MT during early life impacts on the function of V1 in adulthood.

Title: Spatio-temporal distribution of gamma power and coherence in primate middle temporal area of the visual cortex

Authors: ***S. S. SOLOMON**[1], S. C. CHEN[2], J. W. MORLEY[3], S. G. SOLOMON[4]
[1]Physiol., Univ. of Sydney, The University of Sydney, Australia; [2]Discipline of Physiol., The Univ. of Sydney, The University of Sydney, Australia; [3]Univ. of Western Sydney, Sydney, Australia; [4]Cognitive, Perceptual and Brain Sci. Res. Dept., Univ. Col. London, London, United Kingdom

Abstract: Recurrent networks are thought to play an important role in shaping the tuning properties of motion sensitive neurons in the middle temporal (MT) area of primate visual cortex. A signature of recurrent inhibitory networks is a bump of increased power in the local field potential (LFP), occupying a narrow band of frequencies in the gamma-range (16-100 Hz). In area MT, narrow-band gamma power is elevated during presentation of moving gratings. Presentation of moving dot-fields, however, brings about a large increase in LFP power over a broad range of frequencies, without a narrow band elevation. This might imply that recurrent inhibitory networks are not activated during presentation of dot fields, but could also arise if their LFP signature is subsumed by the broadband increase in power. To address this, we analysed coherence in LFP signals measured by multi-electrode arrays, hypothesizing that coherence in gamma-band provides a more sensitive indicator of recurrent inhibitory networks. Multi-electrode recordings were made from area MT of sufentanil-anaesthetised marmoset monkeys using planar arrays (5 animals) or laminar probes inserted perpendicular to the cortical surface (3 animals; 12 recording sites). The stimulus was a grey screen or a large field of moving dots presented for 2 s. We measured the power in the induced LFP at each electrode (n = 1315), and the coherence in the induced LFP between pairs of electrodes (n = 24191). The power spectra during maintained activity showed typical 1/*f* frequency-dependence, and presentation of dot fields increased power across a broad band of gamma frequencies, as expected. Coherence during maintained activity was stronger for pairs of nearby electrodes, and stronger if the electrodes were separated normal to the cortical surface than electrodes separated tangentially. For pairs of electrodes more than 1 mm apart, presentation of dot fields reduced coherence across the entire range of gamma frequencies. However, nearby electrodes showed increased coherence across a narrow band of gamma frequencies in most recordings (3 arrays, 10 probes); the centre frequency varied between animals. This narrow band of coherence decayed with distance and did not depend on whether electrodes were separated tangential or normal to the cortical surface. These observations suggest that dot fields do recruit recurrent inhibitory networks intrinsic to area MT, which may extend across both axes of the cortical sheet.

Title: Response decay kinetics in areas MT, MST, and VIP on the motion pathway in macaques

Authors: *F. VIEIRA[1], S. W. EGGER[2], K. H. BRITTEN[1]
[1]Univ. of California, Davis, Davis, CA; [2]MIT, Cambridge, MA

Abstract: It is known that visual response latencies increase in areas that are higher on the cortical processing hierarchy. While the fidelity of processing of rapidly varying stimuli will be as affected by response offset dynamics as by onset dynamics, these have received relatively little study. Here, we compared response offset dynamics of three areas on the dorsal motion pathway: the middle temporal area (MT), the medial superior temporal area (MST), and the ventral intraparietal area (VIP). We examined how the time-course of response offset was influenced by position in the cortical hierarchy and by stimulus type. Identical stimulus sequences of random-dot motion (0.5 s on, 0.5 s off, while monkeys maintained continuous fixation) were used for all three areas. Pattern motion was either linear or complex ("spiral space"). Decay dynamics were measured by fitting the post-stimulus epoch with an exponential function using maximum-likelihood methods. Decline to baseline after stimulus offset was slower for MST compared to MT by about a factor of five (81 vs. 17 ms; $p < .05$). Decay kinetics in VIP were similar to those in MST. From these observations, we conclude that decay dynamics are greatly influenced by the location of an area on the cortical hierarchy. The effect on decay dynamics is considerably larger than the effect of hierarchy on response onset latency; this averages about 5 ms between MT and MST. Therefore, it seems unlikely that the effects on decay dynamics are merely due to accumulated temporal imprecision with hierarchical processing. We consider it more likely that recurrent circuit connectivity, either within or between areas is involved in retarding response offsets. Whatever the mechanism, the slower kinetics could serve the purpose of averaging temporal noise in motion signals or be useful in predictive coding for guiding behavior.

Title: Realistic simulations of cortical population response for the evaluation of MT decoding models

Authors: *J. LOMBARDO, B. BAYER, L. OSBORNE, S. PALMER
Biol. Sci. Div., Univ. of Chicago, Chicago, IL

Abstract: Visual sensation arises from the activity of large populations of neurons, but sampling that population activity often involves trade-offs, either in the time resolution of the recording technique or in the sampling density. One approach to the analysis of population coding is to simulate ensemble data based on real neural responses in order to fill in the sampling gaps. Here we use the pursuit system as a model to test theories of cortical population coding of visual motion. Pursuit behavior offers a valuable performance metric for such a population model, since eye movement can be well characterized, the neural circuitry is well known, and pursuit initiation is tightly coupled to responses in the middle temporal area (MT). Neurons in visual area MT are tuned to the direction and speed of local image motion, enabling the perception of motion and the initiation of pursuit eye movements. The diversity of tuning bandwidths and temporal dynamics in the responses of individual MT neurons is key for transmitting a distributed population code that is robust to noisy, correlated inputs and outputs. Including realistic heterogeneity of responses in models of MT population activity provides a better estimate of information capacity and allows for a comparison of temporal responses to the timescales of pursuit behavior. Ultimately, we seek to understand how the extra information about motion direction encoded in heterogeneous populations can be reliably and flexibly decoded and thereby drive pursuit. In order to capture and characterize the richness of MT neuronal dynamics, we modeled the distribution of temporal responses across cells in a reduced-dimensionality space, from which we can pseudo-randomly draw realistic simulated responses. These synthetic populations are in good agreement with data recorded from real MT neurons, and can be used to test the viability of different decoding strategies for the estimation of image motion, which ultimately drives pursuit behavior. We use carefully quantified direction thresholds on pursuit and perception to test our models.

Title: Constraints on decoding of visual motion parameters for smooth pursuit from MT cortical population activity

Authors: *M. V. MACELLAIO, L. C. OSBORNE
Neurobio. Dept., Univ. of Chicago, Chicago, IL

Abstract: In pursuit, visual estimates of retinal image motion are translated to motor commands to smoothly counter-rotate the eye in order to stabilize the retinal image of a moving target. The visual inputs for pursuit behavior arise in the middle temporal cortical area (MT) where neuronal responses are tuned for motion direction and speed. Motion direction discrimination in pursuit is approximately a factor of ten lower than MT neuron discrimination thresholds, suggesting that visual motion estimates are derived from cortical population responses. In previous work, we have shown that variability in the initiation of pursuit arises from variability in motion estimation, as if visual estimates are decoded from cortical inputs with errors, but are then loyally translated to movement by the oculomotor system. Here we show that while a variety of population decoding models can reproduce the accuracy of pursuit eye speed and direction, reproducing the trial-to-trial eye movement variation places strong constraints on the coordinate frame and number of free parameters in the decoding model. Using both correlated and uncorrelated Poisson model neurons coupled to experimental measurements of actual pursuit behavior, we show that the most parsimonious decoding models operate in visual coordinates (direction, speed) rather than in motor coordinates aligned with the pulling direction of the eye muscles (i.e. horizontal, vertical). We also use data-based, realistic simulations of MT populations that preserve measured spike count statistics and the natural heterogeneity of tuning

and rate dynamics to further constrain the nature of cortical population decoding for smooth pursuit.

Title: Motion detection in Extrastriate Area 21a of the cat cortex

Authors: *H. ASLANYAN[1], A. KHACHATRYAN[2], D. KHACHVANKYAN[1], B. KOZAK-HARUTYUNIAN[1]
[1]Inst. of Applied Problems of Physics of NAS, Yerevan, Armenia; [2]Ophthalmology, SUNY Downstate Med. Ctr., Brooklyn, NY

Abstract: Using extracellular recording of spike activity from single neurons in Area 21a of extrastriate cortex, we examined in detail both the spatial stationary structure of neuron receptive fields (RF) and response patterns to moving visual stimuli. We found that a small group of visually sensitive neurons revealed no responses to stationary visual stimuli, while responding vigorously to moving images. The results of our experiments show that response patterns of these neurons to moving stimuli display a high degree of diversification and elaboration of incoming visual information. It is commonly accepted that static RF structure predetermines the pattern of neuron's response to moving visual images; in our investigation, we observed only a weak correlation and, in some cases, an almost complete lack of correlation between the RF stationary structures and response patterns to moving stimuli. In this study we present observations from a small group of neurons in extrastriate area 21a which did not react to a stationary flashing spot positioned in their RFs yet responded strongly to moving visual stimuli. We found significant qualitative and quantitative differences in the intensity of evoked discharges depending on the size, contrast and direction of applied visual stimuli. Thus, a high degree of information diversification appears to be taking place. We propose that these neurons may be specialized strictly in the detection and processing of visual information required for the perception of moving images. These results allow us to suggest that a small cluster of neurons in the central visual pathways, while being unresponsive to stationary visual stimuli, most likely specialize in motion detection governed by modulatory influences of activated adjacent neurons

with RFs overlapping with the RF of the neuron under investigation. Such interactions may be temporary events taking place during the time of image motion.

Title: Temporal dynamics of heading perception in the presence of moving objects

Authors: *O. W. LAYTON[1,2], B. FAJEN[3]
[1]Ctr. for computational neuroscience and neural technology, Boston Univ., Boston, MA; [2]Cognitive Sci., [3]Dept. of Cognitive Sci., Rensselaer Polytechnic Inst., Troy, NY

Abstract: When humans navigate in the presence of an independently moving object, judgments of about the direction of self-motion (heading) are sometimes biased (Warren & Saunders 1995, Layton & Fajen 2014). Models often exploit spatial patterns in the first-order optic flow vectors to explain the heading bias. The location of the singularity known as the focus of expansion (FoE) is estimated, which specifies the observer's direction of self-motion in the absence of the moving object. Differential motion models subtract motion vectors due to the object from those of the background to recover the FoE position (Royden 2002), and motion pooling models average object and background vectors (Warren & Saunders 1995). A key implicit prediction made by many models is that only the FoE position immediately prior to when the judgment is made influences heading perception - the time history of the object's trajectory should not matter. On the other hand, the neural model of Layton, Mingolla, and Browning (2012) requires temporal integration to replicate the human heading bias. The present study tests the temporal predictions made by these competing models. Human subjects viewed simulated self-motion for a number of durations (150, 300, 500, 750, 1050, and 1500 ms) in the presence of a moving object that approached in depth. The object moved such that its final distance relative to the observer and optical size remained the same. If the predictions made by the original Warren & Saunders (1995) and Royden (2002) models are correct, then heading judgments should be

equally biased irrespective of the trial duration because the instantaneous optic flow at the end of each trial is the same. Results indicate that the time history of the object's trajectory has a large impact on heading judgments. When the trial duration matched that used in other studies (Warren & Saunders 1995, Layton & Fajen 2014), we obtained a comparable bias of 1-2°. For the shorter viewing durations, the mean variability across subjects increased and the mean bias reached ~6°. Heading judgments were not biased in trials of the same duration that did not contain a moving object. Our results indicate that heading perception in the presence of moving objects is a spatio-temporal process, which is not compatible with a number of existing models. We successfully simulated the results using the model of Layton et al. (2012), which explains the increased bias and variability at shorter viewing durations through the dynamics of neurons in primate brain area MSTd.

Title: Processing of contrast-modulated second-order stimuli in mouse visual cortex

Authors: Z. KHASTKHODAEI, O. JURJUT, S. KATZNER, *L. BUSSE
Ctr. for Integrative Neurosci., Univ. of Tuebingen, Tuebingen, Germany

Abstract: In primates, visual processing in the ventral stream takes place across a hierarchy of areas, starting with representations of low-level features in primary visual cortex (V1), which are gradually transformed into high-level object representations in inferotemporal cortex (IT). In mice, extrastriate visual areas seem to form anatomically and functionally distinct groups, possibly constituting a pathway analogous to the ventral stream in other species. Whether in the mouse these areas support increasingly complex, cue-invariant representations of visual information remains an open question. To test this question we compared visual processing of

first-order gratings, characterized by changes in luminance, and second-order gratings, characterized by changes in contrast only. We recorded extracellular activity in areas V1 and LM of anesthetized mice and measured orientation tuning curves for first- and second-order gratings. We found that areas V1 and LM responded more strongly and selectively to luminance-modulated compared to contrast-modulated gratings. Among the visually responsive neurons in both areas, >90% showed significant responses to luminance gratings, while only ~70% of V1 neurons and ~30% of LM neurons were activated by contrast-modulated gratings. Even for neurons with significant responses to both types of gratings, peak firing rates for contrast-modulated gratings were lower by ~30% in V1 and by ~50% in LM. Importantly, the majority of neurons recorded in either visual area lacked clear orientation selectivity for contrast-modulated gratings. This lack of orientation-selectivity for contrast-modulated gratings in mouse visual cortex prompted us to test behaviorally whether mice can discriminate second-order orientation. We trained mice to perform a coarse orientation discrimination task. After mice reached stable orientation discrimination for luminance-modulated gratings we replaced the visual stimuli with a contrast-modulated gratings. We found a massive breakdown of performance with little generalization of orientation-discrimination across the two types of stimuli. This breakdown was not due to the lower root-mean-square (RMS) contrast of the contrast-modulated gratings: when switching back to a luminance-modulated grating with matched RMS contrast, discrimination performance returned to high. In summary, although mice can see contrast-modulated gratings their modest representation in visual cortex seems to allow only relatively poor behavioral discrimination of second-order orientation. We conclude that the mouse visual system seems to be specialized for luminance-based perception.

Title: Frequency-dependent spatiotemporal profiles of visual responses recorded with subdural electrodes in awake monkeys

Authors: *K. TAKAURA[1], N. TSUCHIYA[2,3], N. FUJII[1]
[1]RIKEN Brain Sci. Inst. - Wako, Wako City, Saitama, Japan; [2]Sch. of Psychological Sciences, Fac. of Medicine, Nursing and Hlth. Sciences, Monash Univ., Melbourne, Australia; [3]Decoding and Controlling Brain Information, Japan Sci. and Technol. Agency, Chiyoda-ku, Japan

Abstract: Electrocorticography (ECoG) constitutes a powerful and promising neural recording modality both in humans and animals. The ECoG signals are often decomposed into several frequency bands, among which so-called high-gamma band [80-250Hz] has been proposed as a reliable measure of the local cortical activity. It is typically assumed that the lower the frequency bands, the less specific the signal reflects about the local cortical activity. However, the differences across the frequency bands have not been systematically investigated. To address this issue, we obtained ECoG recordings from two awake monkeys during a retinotopic mapping task. We characterized the spatiotemporal profiles of the visual responses in the time-frequency domain. We defined the preferred spatial position, receptive field (RF) and the response latencies of each electrode in each frequency band (i.e., alpha [8-16 Hz], beta [16-30 Hz], low- [30-80 Hz] and high- gamma), and compared them across the bands. Across all the electrodes, spatial preferences were comparable across the bands. We observed that the RF of each electrode represents the contralateral visual field in all the frequency bands and that the high-gamma activity showed smaller RF than the other bands. However, a systematic difference arose in the temporal domain. The response latencies for the alpha band were always longer than the other bands. Comparison of the response profiles in both space and time within each region (V1, V4+ and TEO/TE) revealed regional idiosyncrasies. While in V1 and V4+, the latencies of the visual responses in the beta, low- and high-gamma bands were almost identical, in TEO/TE, the beta and low-gamma activity occurred 25 ms earlier than the high-gamma. Furthermore, TEO/TE exhibited a unique pattern in the spatial response profile; the high-gamma tended to prefer the foveal regions while the beta and low-gamma preferred peripheral visual fields with larger RFs. It suggests that neurons in TEO/TE first receives spatially less selective information via the beta and low-gamma, and later spatially more fine-tuned foveal information via the high-gamma. This result is consistent with a previously proposed hypothesis by Nakamura, Gattass, Desimone, Ungerleider (1993) that the visual processing in TEO/TE starts with coarse-grained information, which primes subsequent fine-grained information. In summary, our results demonstrate that the nature of computation carried out within each stage of the visual system can be learned more richly by incorporating knowledge of the spatiotemporal characteristics across all frequency bands of ECoG recordings.

Title: Activity propagation between early visual areas determines the awareness of phosphenes

Authors: *B. V. VUGT, B. DAGNINO, P. ROELFSEMA
Netherlands Inst. for Neurosci., Amsterdam, Netherlands

Abstract: Understanding how visual awareness emerges in the brain is one of the major challenges that remain to be addressed in neuroscience. What is the difference between information that reaches awareness and information that does not? Here we directly compared information transfer along the visual hierarchy between perceived and non-perceived phosphenes, elicited by electrical microstimulation (MS) of neurons in V1. To this aim we recorded activity from neurons in area V4 with receptive fields (RFs) that overlapped with a phosphene in a task where macaque monkeys had to report the delivery of MS to area V1. MS was given in 50% of the trials and the monkeys reported the detection of a phosphene by making a saccade to the phosphene location and the absence of a phosphene by making a saccade to another stimulus. We varied the MS current to keep performance at 80%, close the threshold for phosphene awareness, so that we could compare V4 activity between trains of MS pulses of equal strength that were either perceived by the monkey (correct eye movement to location of phosphene) or missed (incorrect eye movement to the other stimulus). Our results for two monkeys show very clear differences in V4 activity between seen and missed MS trials. MS trains that reached awareness elicited activity in V4 that was much stronger than MS trains that were missed. This difference in activity occurred almost immediately after MS, but was also maintained during a later, sustained response phase. We also examined activity of V4 neurons with RFs that did not overlap with the phosphene location, but found that their activity was a poor predictor of phosphene perception. We next compared V4 activity elicited by visual stimuli (low contrast gratings) presented in the neurons' RF that were perceived and that were not, and also observed a correlation between V4 activity and perception. As the stimulus in perceived and non-perceived trials is the same, our results suggest that the state of the cortex at the moment of

the stimulus determines visibility. To examine this possibility, we investigated the power of the LFP and found that low frequency power (4-12Hz) preceding the stimulus was indeed associated with higher visibility. Together, these results show that the cortical state preceding microstimulation or visual stimuli determines the propagation of activity from lower to higher visual areas and thereby whether a phosphene or a visual stimulus will be perceived or not.

Title: Rapid learning impacts noise correlation in monkey V4

Authors: ***Y. WANG**[1], V. DRAGOI[2]
[1]UT medical school at Houston, HOUSTON, TX; [2]Neurobio. and anatomy, UT medical school at Houston, Houston, TX

Abstract: Improvement in sensory discrimination after practice is a well-documented behavioral phenomenon. It has been previously reported that neurons in early and mid-level visual cortex change their response properties after perceptual learning, including the increase in tuning curve slopes and the increase in response gain. However, whether and how the information encoded in population activity changes after learning is not fully understood. The amount of information encoded by cortical circuits depends critically on the capacity of nearby neurons to exhibit trial-to-trial (noise) correlations in their responses. Therefore, we assessed the change in neurons' correlated variability induced by learning. To accomplish this goal, we used multiple electrode recording in alert macaque V4 to record single units before, during, and after a rapid learning task. Two monkey were trained to performed a 3-stage task: in the 1st and 3rd stages (during the same session) the monkey was required to perform a color change detection task on the hemifield that is contralateral to the receptive field locations. Simultaneously, unfamiliar natural images were passively presented at the receptive field locations. In the 2nd stage, the monkey was trained to indicate whether two successive images briefly flashed for 300 ms and separated by a 1000-ms delay were presented at the same or different orientation. The images in 2nd stage

were located at the receptive field location, and were identical to those presented in stages 1 and 3. We found that the monkey's image orientation discrimination threshold decreased significantly during the time course of learning (stage 2). We examined the extent to which the noise correlations between neurons changed after learning by comparing the Pearson correlation coefficients in the 1st and 3rd stage in each session. We examined 565 pairs originating from 133 single neurons recorded in both monkeys. Despite the fact that firing rates did not change as a result of learning, we found a significant decrease in noise correlation when stages 1 and 3 were compared (35% decrease during stimulus onset and 15% decrease during the entire 1 sec stimulus period, Wilcoxon rank test, $p < 0.00001$). The decrease in noise correlations caused a 30% increase in the population signal noise ratio. These findings indicate that rapid learning (tens of minutes) impacts noise correlations in V4 such as to enhance perceptual performance.

Title: Functional MRI mapping of IT single unit responses during natural vision

Authors: *S. PARK[1,2], B. E. RUSS[1], D. B. T. MCMAHON[1,3], H. D. ELNAIEM[1], D. A. LEOPOLD[1]

Abstract: In functional MRI, hemodynamic time courses measured throughout the brain are summarized into activity maps in a process that usually involves comparing each voxel's time series with a model. Models can be *a priori* and built into the stimulus design or can be extracted from some aspect of the stimulus or task, with an example of the latter being the mapping of particular features in natural videos (Russ et al., SFN Abstr., 2013). An alternative approach is to use neural signals themselves as models for fMRI mapping. An example of this approach is the use simultaneously measured neural and fMRI signals to map the functional distribution of

spontaneous activity at rest (Schölvinck et al., PNAS, 2010). In the present study, we combined the approaches by using stimulus-driven neural signals as models for fMRI mapping to investigate the diversity of single unit responses within a single voxel during the viewing of natural videos. We previously demonstrated that, when monkeys freely viewing 5-minute videos of complex social interaction, a population of neurons in the anterior fundus (AF) face patch within < $1mm^3$ showed a broad range of response time courses, many of which were uncorrelated, despite each being deterministically driven by the contents (Elnaiem et al., SFN Abstr., 2013). We asked whether this diversity can be explained by a differential pattern of functional interactions of individual neurons with other brain areas. To address this, we used a novel combination of fMRI and single unit recordings, where both fMRI responses from the whole brain and single unit activities from neurons in face patch AF were measured while the subjects freely and repeatedly watched 5-minute naturalistic movies. We then computed correlation coefficients between movie-driven signals recorded in these two methods. Specifically, we used spike density functions derived from each single unit as a regressor and obtained a functional picture of the whole-brain-network that is correlated to selective activity of individual neurons. In two monkeys, more than fifty single neurons resulted in correlation maps localized to visually responsive areas. We found that neurons located within a few hundred microns provided strikingly dissimilar maps, reflecting their distinct response patterns to the movie stimuli. This approach provides a means of relating the activity observed locally in single neurons to the patterns functional organization observed globally at the level of the whole brain.

Title: Effect of image familiarity on neuronal responses in areas V2 and V4 of monkey visual cortex

Authors: *S. RAMACHANDRAN[1,2], T. S. LEE[1,2], C. R. OLSON[2]
[1]Carnegie Mellon Univ., Pittsburgh, PA; [2]Ctr. for the Neural Basis of Cognition, Pittsburgh, PA

Abstract: Neurons in monkey inferotemporal cortex (IT) respond more weakly to images that are highly familiar than to novel images. Suppression is not instantaneous but rather develops at a latency of around 80 ms following response onset. This phenomenon has been assumed to have its origin in functional changes induced by visual experience at the level of IT. However, this idea has not been tested by recording at earlier stages of the ventral stream. To resolve this issue, we monitored neuronal activity, using a 32-electrode semi-chronic recording array, in a sector of areas V2 and V4 representing the lower parafoveal visual field. This approach allowed recording from 3-15 well isolated neurons per day. Over the course of twelve days, we repeatedly presented each of 25 images in superimposition on the collective receptive field of the neurons under the array. The 7.4° images, representing natural and manmade objects free of background, were of the same kind that we have used to induce the familiarization effect in IT. Although not tailored to the requirements of individual V2 or V4 neurons, the images evoked strong responses in both areas. On a subset of days (3, 8, 9, 10, 11, 12), we also presented novel images drawn from the same library as the images in the familiarization set. The novel images employed on a given day were used on that day only. On day 3, after 60 exposures to each familiar image, the strength of the population response to the familiar images was not measurably different from the strength of the population response to the novel images employed on that day. However, on day 8, after 200 exposures to each familiar image, and on every subsequent day, the trajectory of the population response differed between familiar and novel images. The familiar-image response was briefly stronger than the novel-image response but then underwent a sharp truncation so that the level of sustained activity was lower than for novel images. The truncation of the familiar-image response occurred earlier in V2 and V4 than in IT. This suggests that the effect occurred at or before level of V2 and V4 and was not simply the product of top-down feedback from IT.

Title: Maintenance of spatial information gates the processing of incoming visual information in area V4

Authors: Y. MERRIKHI[1], M. PARSA[2], E. ALBARRAN[3], *B. NOUDOOST[2]
[1]Sch. of Cognitive Sci., Inst. for Res. in Fundamental Sci., Tehran, Iran, Islamic Republic of; [2]Montana State Univ., Bozeman, MT; [3]Dept. of Neurobio., Stanford Univ., Stanford, CA

Abstract: When subjects remember a location, visual processing at that location is enhanced compared to elsewhere in space, as measured by visual discrimination performance. The feature selectivity of neurons in early visual areas makes these neurons a good candidate substrate for an enhanced visual representation underlying these changes in discrimination. However, the firing rates of neurons in extrastriate visual cortices such as V4 and V5 appear to be largely unaffected by spatial memory maintenance. An alternative hypothesis is that although the delay-period activity of these neurons is unaltered, spatial memory can still enhance their sensitivity to incoming visual information. To examine this idea, we recorded the neuronal responses of area V4 in awake rhesus monkeys while they performed a memory-guided saccade task. In this task, the target was presented for one second and the monkey had to remember the target location throughout a one second delay period while maintaining his fixation. The fixation point then disappeared, and the monkey moved his eyes to the remembered cue location to receive a reward. We measured the responses and mapped the receptive field of V4 neurons by presenting brief visual probes in a 7x7 grid of locations near one of the cue locations, both during fixation and during memory maintenance. We found that the centers of V4 receptive fields shifted towards the remembered location. This resulted in a larger number of V4 neurons responding to a given visual stimuli when remembering a nearby location (compared to the number of neurons responding to the same stimulus when remembering a location in the opposite visual hemifield). We further examined the effect of memory maintenance on noise correlations between simultaneously recorded pairs of V4 neurons, and found that remembering a location common to both V4 receptive fields decorrelates their activity. This effect of memory maintenance on visual cortical responses, which closely resembles the effect of covert spatial attention, could underlie the behavioral effects of memory maintenance on visual discrimination.

Title: Late responses of V2 neurons are enhanced by global scene context of natural movies

Authors: *J. M. SAMONDS[1], Y. LI[4], Y. ZHANG[2], T. LEE[3]
[1]Ctr. Neural Basis Cognition, Carnegie Mellon Univ., PITTSBURGH, PA; [2]Computer Sci., [3]Ctr. for the Neural Basis of Cognition and Computer Sci., Carnegie Mellon Univ., Pittsburgh, PA; [4]Dept. of Information Sci. and Electronic Engin., Zhejiang Univ., Hangzhou, China

Abstract: Cortical neurons receive inputs from other neurons within the same layer that have distinct receptive fields, as well as neurons in subsequent layers and areas with larger receptive fields. These inputs alter feed-forward input responses in interesting and complex ways that may contribute to statistical inference mechanisms. We measured the response properties of V2 neurons in awake, behaving macaques in response to natural movies and drifting sinusoidal gratings of varying aperture size to understand how spatiotemporal context of natural movies can influence the activities of V2 neurons. We found that the early stage of responses of the neurons (0-200 ms after stimulus onset) expressed surround suppression: the responses to stimuli presented in a larger aperture were smaller than to stimuli presented in a smaller aperture. This surround suppression was observed for apertures slightly larger than the receptive fields (1-2 degrees of visual angle) and saturated at 5-6 degrees of visual angle. In addition, we observed the selectivity of the tuning curve of the neurons to the spatiotemporal patterns in the movies also increased with an increase in aperture size, but the sharpness developed at a slower rate than surround suppression. Interestingly, when the aperture was increased to 9 degrees of visual angle or larger, the neurons' responses actually increased relative to the response to the same movies presented in smaller apertures. This enhancement was later than both surround suppression and sharpening of tuning and was only observed for natural scenes and not for gratings. Qualitatively, the enhancement occurs at the point at which the natural scenes could be recognized or interpreted. These findings have indirectly revealed properties of multiple distinct networks that contribute to the responses of V2 neurons. These surround inputs allow

information from other regions of the visual field as well as top-down expectations to facilitate the interpretation of the incoming visual evidence.

Title: Sparse and distributed representation of visual concepts in V1 and V2 neuronal populations

Authors: ***T. LEE**[1], C. MASSOT[2], G. PAPANDREOU[3], A. YUILLE[4]
[2]Ctr. for the Neural Basis of Cognition, [1]Carnegie Mellon Univ., Pittsburgh, PA; [3]Computer Sci., Toyota Technol. Inst., Chicago, IL; [4]Dept. of Statistics, Univ. of California, Los Angeles, Los Angeles, CA

Abstract: Earlier neurophysiological studies have showed that individual V2 neurons are selective for simple and complex artificial shape stimuli (Hegde and Van Essen 2003). Here, we studied whether and how neurons in early visual cortical areas are tuned to a more general set of visual concepts derived from natural images using statistical clustering techniques. In this study, we focused on 150 edge concepts, derived as cluster centers of aligned edge contour segments extracted from the human-annotated edge maps of the Berkeley segmentation database. Each of these edge concepts is associated with a set of contour patches and appearance patches of the cluster it represents. We presented the representative contour patch, the first principal component and/or prototype example of the appearance patches associated with each edge concept to the receptive fields of V1 and V2 neurons through a 3-degree smoothed aperture, recorded in awake behaving monkeys using a 32-channel recording array (Gray Matter Research), and 24-channel linear multi-electrode arrays (Alpha-Omega). In general, we found the responses of a majority of V1 and V2 neurons to the contour patterns and the appearance patterns were correlated (R =~0.4), suggesting that the neurons individually were tuned to more abstract concepts. On

average, V1 neurons exhibit stronger responses, are sparser and more selective in tunings, to contour patterns than to appearance patterns, while V2 neurons respond more strongly, with sparser and more selective tunings, to appearance patterns. These findings indicate V2 neurons prefer richer and more naturalistic stimuli than V1 neurons. While both V1 and V2 neurons exhibit some degree of sparseness in their tunings, their codes are also distributed as they responded moderately to many visual concepts. To investigate V1 and V2 codes at the population level, we have applied multidimensional scaling (MDS) and K-means clustering on V1 and V2 population response vectors. We have found that edge concepts in V1 are clustered according to their mean orientation. On the other hand V2 exhibits a clear clustering of the three types of stimuli (contour, mean appearance, example prototype). In addition, distinct clusters of visual concepts in the high dimensional space (T-Y-L junctions, lines, curves, simple and complex patterns) start to emerge in V2. These findings suggest that visual concepts that are not separable in V1 population become separable ("untangled" in the terms of DiCarlos and Cox 2007) in V2 neuronal population.

Title: Relating divisive normalization to spike count correlations between and within cortical areas

Authors: *D. MONTEZ[1], D. A. RUFF[2], M. R. COHEN[2]
[2]Neurosci., [1]Univ. of Pittsburgh, Pittsburgh, PA

Abstract: Normalization, in which a neuron's response is divisively scaled by the presence of stimuli that do not drive the cell when presented alone, is thought to be involved in a wide variety of neuronal computations. Although most normalization models are descriptive, the prevailing hypothesis is that normalization is a network phenomenon that is accomplished by scaling a neuron's response by the responses of a large pool of surrounding neurons. Even within the same brain area and under identical experimental conditions, neurons vary in the degree to which they exhibit normalization. For example, direction-selective neurons in area MT differ in the way they respond to pairs of stimuli moving in opposite directions within their receptive fields. Some neurons exhibit strong normalization, responding similarly to the average of their responses to the two stimuli alone. Others show no normalization, producing a response similar to the response to a preferred stimulus alone. We hypothesized that the extent to which a neuron exhibits normalization reflects its specific role in a cortical circuit, which might give rise to a distinctive pattern of interactions with neurons within the same cortical area and in other areas. One way to probe the interactions between a pair of neurons is by measuring the extent to which the trial-to-trial fluctuations in their responses are correlated (termed spike count correlations). We recorded simultaneously from several dozen neurons in primary visual cortex (V1) and from either a single neuron or a small group of neurons in area MT in two monkeys. We presented different combinations of moving stimuli and measured normalization and spike count correlations within and between the two areas. We also measured several different properties of each neuron we recorded, including its direction tuning, the size and location of its receptive field, the amount its responses were modulated by stimuli outside its classical receptive field and by shifts in spatial attention. We found that MT neurons that exhibited strong normalization typically had higher spike count correlations with V1 than neurons that did not show normalization. Our results suggest that neuron-to-neuron variability in normalization (and possibly other sensory and cognitive factors) can be explained by patterns of interactions between neurons across and within cortical areas. In general, our data support the idea that looking at interactions between neurons in multiple cortical areas might provide new insights into the mechanisms underlying neuronal computations.

Title: Spatio-temporal structure of shape-tuning in V4 receptive fields

Authors: *A. S. NANDY, J. H. REYNOLDS, J. F. MITCHELL
SNL-R, Salk Inst., La Jolla, CA

Abstract: Visual shape information is processed in the ventral cortical pathway, which progresses from the primary visual cortex (V1) through intermediate visual areas including V2, and V4, and into the inferotemporal cortex (TEO and TE). Shape is initially encoded primarily in terms of local orientation in V1, but by the final stages of visual processing in IT, neurons are selective for complex objects like faces. Area V4 lies at a critical juncture in mediating this transformation. In a previous study (Nandy et al., 2013) we have shown that V4 neurons exhibit a tradeoff between curvature tuning and spatial invariance. Neurons tuned to curved shapes exhibit very limited spatial invariance, while those that prefer straight contours show spatially invariant tuning. This diversity was explained by the fine-scale structure of the receptive fields (RFs). The fine-scale RF maps for neurons preferring curved shapes had heterogeneous local variation in orientation tuning. In contrast, these were homogeneous for neurons preferring straight contours. This previous analysis presented a temporally averaged static picture of the fine-scale RF structure. Here we show that these fine-scale RFs have an underlying intricate temporal structure as well. The temporal structure for neurons that showed statistically significant temporal shifts (80 out of 96), can be qualitatively grouped into three categories: (a) progressively shifting spatial kernels, (b) distinct spatial locations (sub-units) having distinct temporal signatures, and (c) spatial kernels that dissipate over time from the center to the edges. The temporal evolution of these fine-scale RF maps is concomitant with changes in shape-tuning over time. Taken together, our results suggest the presence of a rich spatio-temporal shape code in area V4.

Title: Converging encoding strategies in dorsal and ventral visual streams

Authors: *P. J. MINEAULT[1], T. P. ZANOS[2], C. C. PACK[2]
[1]Neurobio., [2]Neural Circuits Unit, Montreal Neurolog. Inst., Montreal, QC, Canada

Abstract: At the highest levels of the visual cortex, behaviourally relevant information, including object identity, pose, and heading, can be easily read via a simple linear decoding rule. This behaviourally relevant encoding is thought to emerge as the visual signal is iteratively re-encoded to ever more abstract, invariant, and selective representations as it processed by a hierarchy of areas. While the visual encoding of motion and shape is relatively well understood in primary visual cortex, how this signal is propagated and re-encoded in extrastriate cortex is less clear. Here, we analyze the recordings from macaque areas V2 and V4 of the ventral visual stream and areas MT and MST of the dorsal visual stream to understand how the visual signal is re-encoded in extrastriate cortex. We begin by analyzing receptive field organization in area V2 (Willmore et al. 2010). We find that V2 receptive field reflect balanced excitation and suppression in the space of orientation and spatial frequency energy. Convergence of excitatory inputs leads to invariance to scale and position, while tuned suppression and the threshold nonlinearity of neurons enhance the sparseness of the representation. The interplay of excitation, suppression and thresholding creates selectivity for unique combinations of features which occur in natural images, but not in noise with matched power spectrum. We find that a similar encoding occurs in area MT (Cui et al. 2013), where excitatory and suppressive influences to the velocity and direction of inputs are finely balanced, creating a selective, invariant, and sparse representation of visual motion. We then sought to determine how downstream areas take advantage of this novel representation. Using a novel supervised learning technique, we found a parametric transformation that captures the processing in areas V2 and MT, much like half-wave rectified Gabor filterbanks can capture the processing in simple cells. We find that the computations performed by V2 and MT neurons were essential to capture the selectivity of V4 and MST neurons to complex stimuli with naturalistic structure. These results show that early extrastriate areas of both the dorsal and ventral visual streams, despite operating on different domains, perform similar computations on their input. Furthermore, the emerging representations

are forwarded, preserved and further built on in later areas, lending strong support for hierarchical models of visual processing.

Title: Low-frequency oscillations in extrastriate cortex: Contributions of V1 and pulvinar

Authors: ***J. T. SCHMIEDT**[1], A. MAIER[2], R. C. SAUNDERS[3], D. A. LEOPOLD[3], M. C. SCHMID[1]
[1]Ernst Strüngmann Inst. (ESI) for Neurosci., Frankfurt Am Main, Germany; [2]Dept. of Psychology, Vanderbilt Univ., Nashville, TN; [3]NIMH, Bethesda, MD

Abstract: The local field potential (LFP) in visual cortex is often characterized by the following spectral pattern: before the onset of a visual stimulus, low frequency oscillations in the high alpha to low beta frequency range (13-20 Hz) typically dominate, whereas high-frequency fluctuations (>30 Hz) replace these low-frequency oscillations during stimulus presentation. However, the generative mechanisms of this alpha-beta activity *in vivo*, in particular the contributions of cortical versus thalamocortical input, remain unclear. To this end, we first longitudinally recorded LFP from chronically implanted multi-electrode arrays in extrastriate area V4 of two behaving macaques, before and after selective removal of primary visual cortex (V1). In the absence of V1 input, V4 low frequency oscillations were still present during active fixation periods indicating that V1 does not contribute to their generation. Visual stimulation with grating patterns after V1 removal however did not result in the typical ca. 30% reduction of alpha-beta power, but instead increased it by up to more than 50%. As this activity pattern was specific to stimulus locations affected by the V1 lesion, and was modulated by stimulus motion, it likely reflects unmasked input via V1-independent thalamocortical circuits. Indeed, in a second

set of recordings performed in behaving monkeys with intact V1, we found oscillatory LFP and spiking activity in the alpha-beta frequency range in the pulvinar nucleus that was enhanced by visual stimulation by ~30%. Due to the widespread and strong projections of pulvinar to visual cortex it is therefore conceivable that the pulvinar is a contributing source of the alpha-beta oscillations in extrastriate cortex.

Title: Neural noise correlations in visual area V4 of the rhesus macaque after V1 lesion

Authors: *K. SHAPCOTT[1], J. T. SCHMIEDT[1], A. MAIER[2], R. C. SAUNDERS[3], D. A. LEOPOLD[3], M. C. SCHMID[1]
[1]Ernst Strüngmann Inst., Frankfurt Am Main, Germany; [2]Dept. of Psychology, Vanderbilt Univ., Nashville, TN; [3]NIMH, Bethesda, MD

Abstract: Neuronal co-fluctuations in visual areas of the brain unrelated to a stimulus have been extensively described and are usually termed “noise correlations”. The presence of this correlation between neurons has important implications for the ability of the brain to optimally encode sensory stimuli[1]. Traditionally, noise correlations have been thought to indicate the presence of common feed-forward input[2]. However, they have also been shown to vary according to the nature of a task or the allocation of top-down attention, which could indicate a contributing component from higher cortical areas[3,4]. We longitudinally recorded from two rhesus macaques the single- and multi-unit activities from multi-electrode “Utah”-arrays chronically implanted at the 3 degrees eccentricity representation of extra-striate area V4. Recordings took place while the monkeys performed a basic fixation task with visual

stimulation. After a two-week period an aspiration lesion was performed of primary visual cortex (V1) grey matter covering the central 7 degrees. Neuronal recordings continued after a short recovery period using the same implanted array and behavioural task. Rate correlation magnitudes were then compared between the pre and post lesion period during the fixation baselines (no stimulus present). If noise correlations arose uniquely from common feed-forward input, it would be expected that they decrease after the removal of V1, which constitutes the major V4 input. However, the experimentally measured noise correlations instead showed a significant increase (139% in monkey B and 25% in monkey F) for multi-unit activity. Despite this clear increase in noise correlation due to the lesion, the generally described relationship of decreasing noise correlation with increasing electrode distance was preserved. These results point to an origin of neural noise correlation either locally in V4 or from unmasked input from other cortical or thalamic areas. 1. Shadlen, M. N., & Newsome, W. T. (1998). Title: Rhythmic neural activity during perceptual grouping in visual area V4 and its dependence on area V1 input

Authors: *R. KIENITZ[1], M. A. COX[2], J. T. SCHMIEDT[1], R. C. SAUNDERS[3], D. A. LEOPOLD[3], A. MAIER[2], M. C. SCHMID[1]
[1]Ernst Strüngmann Inst., Frankfurt am Main, Germany; [2]Dept. of Psychology, Vanderbilt Univ., Nashville, TN; [3]Lab. of Neuropsychology, NIMH, Bethesda, MD

Abstract: Perceptual grouping is a fundamental aspect of visual processing. However, the underlying neural mechanisms are not well understood. Here, we investigate the role of midlevel cortical area V4 neurons in perceptual grouping by tracking their responses during the presentation of the Kanizsa illusion in which perceptual grouping of inducer elements elicits the illusory percept of a visual surface. To this end, we recorded extracellular spiking activity and the local field potential (LFP) from chronically implanted multi-electrode arrays in V4 of two behaving macaque monkeys that passively viewed the Kanizsa illusion. We have previously found that neurons with their receptive field centered on the perceived surface (”surface cells”) preferably encode the Kanizsa illusion (Cox et al., PNAS, 2013). Here we extend this finding and report enhanced rhythmic spiking in the theta range (~4 - 6 Hz) of surface cells, when Kanizsa compared to control stimuli were shown. Analysis of the LFP showed the presence of gamma oscillations (30-40 Hz) in addition to those in the theta range. Interestingly, in the Kanizsa condition only, the emergence of gamma oscillations and associated spatial coherence in this frequency range was coupled in time to the phase of the theta cycle. In a second set of experiments, in which the two monkeys received a permanent V1 aspiration lesion resulting in severe perceptual deficits in the para-foveal part of the visual field, we assessed again the V4 neuronal activity in response to the Kanizsa illusion. With input from V1 largely removed, the V4 LFP showed transient activation shortly after the stimulus onset, ensuring that information reaches V4 via V1-bypassing pathways (e.g. through visual thalamus). However, the strong theta rhythm seen with intact V1 dramatically decreased after the lesion and did not differentiate between the Kanizsa and control conditions. At the same time, however, gamma oscillations did not change significantly in power, and presentation of the Kanizsa stimulus was still associated with stronger gamma power compared to control. Taken together, our results suggest an essential involvement of V1 in the generation of low-frequency rhythms in extra-striate cortex, and more generally, a role of neural rhythmicity in perceptual grouping.

Title: Differential response consistency in the macaque face processing system to the viewing of social and non-social movies

Authors: *B. E. RUSS[1], D. A. LEOPOLD[2]
[1]Section on Cognitive Neurophysiol. and Imaging, Lab. of Neuropsychology, NIMH/NIH, Bethesda, MD; [2]Section on Cognitive Neurophysiol. and Imaging, Lab. of Neuropsychology, NIH/NIMH, Bethesda, MD

Abstract: Conventional approaches to measuring the neural correlates of sensory and cognitive variables focus on isolating and controlling as many stimulus and task elements as possible. A complementary approach involves measuring the consistency of neural responses to multiple viewings of a complex, dynamic scene (Hasson et al, Science 2004). Inter-viewing correlations may be able to identify neural responses that participate in the interpretation of dynamic or contextual features of a scene that cannot be accurately modeled using a priori assumptions. Thus, this data-driven method has the potential to tap into aspects of cognition that are difficult to parameterize in more conventional paradigms. Here we use the inter-viewing method to investigate which regions of the macaque cortex are more consistently engaged by the presence of social stimuli, in this case animals, versus their absence. Five-minute movies varying in the amount of social content were shown repeatedly to two monkeys undergoing whole brain fMRI scanning. One set of movies contained clips of other animals, mostly macaques, interacting with each other or the environment, while a second set of movies contained natural dynamic scenes, such as storms, with a complete absence of animals. We produced brain-wide functional maps by computing each voxel's correlation across trials to repeated presentations of the same movies. The correlation value at each position thus reflected the extent to which a given area responded reliably to the content of a particular movie. We found that the majority of the ventral visual stream responded consistently to both the social and non-social movies. However we found that one bilateral region within the superior temporal sulcus was more consistently engaged by the presence of animals. This region overlapped the location of the middle face patch in both animals. Of the six identified face patches in each hemisphere, both the middle lateral and fundus face patches displayed a marked decrease in consistency when the subjects viewed movies that did not contain any animals. These results suggest that within the face processing system only the middle face patches were more sensitive to the presence of animals during natural viewing conditions.

Title: A sinc wavelet describes the receptive fields of neurons in the motion cortex

Authors: *S. G. ODAIBO[1,2,3]
[1]Quantum Lucid Res. Labs., Arlington, VA; [2]Ophthalmology, Howard Univ. Hosp., Washington, DC; [3]Ophthalmology and Visual Sci., Univ. of Michigan, Ann Arbor, MI

Abstract: Visual perception results from a systematic transformation of the information flowing through the visual system. In the neuronal hierarchy, the response properties of single neurons are determined by neurons located one level below, and in turn, determine the responses of neurons located one level above. Therefore in modeling receptive fields, it is essential to ensure that the response properties of neurons in a given level can be generated by combining the response models of neurons in its input levels. However, existing response models of neurons in the motion cortex do not inherently yield the temporal frequency filtering gradient (TFFG) property that is known to emerge along the V1 to MT motion processing stream. TFFG is the change from predominantly lowpass to predominantly bandpass temporal frequency filtering character along the V1 to MT pathway (Foster et al 1985; DeAngelis et al 1993; Hawken et al 1996). We devised a new model, the sinc wavelet model, which logically and efficiently generates the TFFG. The model replaces the Gabor function's sine wave carrier with a sinc (sin(x)/x) function, and has the same or fewer number of parameters as existing models. Because of its logical consistency with the emergent network property of TFFG, we conclude that the sinc wavelet is a better model for the receptive fields of motion cortex neurons. This model will provide new physiological insights into how the brain represents visual information.

Title: Modeling attention-induced reduction of spike synchrony in the visual cortex

Authors: *N. WAGATSUMA[1,3], R. VON DER HEYDT[2], E. NIEBUR[2]
[1]Krieger Mind/Brain Inst., [2]Johns Hopkins Univ., Baltimore, MD; [3]Tokyo Denki Univ., Saitama, Japan

Abstract: The mean firing rate of a border-ownership selective (BOS) neuron encodes where a foreground figure is located relative to its classical receptive field (Zhou et al, J. Neurosci 20:6594, 2000). In addition, the firing rate of these neurons is modulated by the effect of visual attention (Qiu et al., Nat. Neurosci 10:1492, 2007). Martin and von der Heydt (VSS Abstract J Vision 2013 13(9): 289) showed that top-down attention increases firing rates of BOS neurons and decreases spike synchrony between them. To understand the mechanisms of attentional modulation on mean rates and synchrony of BOS neurons, we developed a network model of spiking neurons. In the model, BOS neurons receive synaptic input from non-BOS feature-selective neurons which reflects visual input. The strength of the synaptic input is multiplicatively modulated by the activity of Grouping neurons (G) which receive their input

from BOS neurons and whose activity represents the location of visual objects in the scene (Craft et al, J. Neurophysiol. 97:4310, 2007; Mihalas et al, PNAS 18:7583, 2011). In addition, the mean firing rate of a G cell is increased when attention is directed to an object that is represented by it. Model simulations show that, in agreement with experimental findings, that attention to an object increases the mean firing rates of BOS neurons representing it while decreasing spike synchrony between pairs of such neurons. Our results thus suggest that top-down attention multiplicatively emphasizes synaptic currents due to bottom-up visual input. They furthermore suggest that attention exerts its influence on BOS cells by boosting the firing rates of G cells, rather than directly influencing the activity of BOS or other feature-selective neurons.

Title: Using optogenetics to probe neural circuit mechanisms underlying biased competition and de-correlation with attention

Authors: *J. H. REYNOLDS, A. S. NANDY, J. J. NASSI
Salk Inst., LA JOLLA, CA

Abstract: A typical visual scene contains more information than our visual system can process at any moment in time. The brain utilizes attention to preferentially process behaviorally relevant stimuli. The physiological signatures of spatial attention have been well-studied in cortical area V4 of the macaque, where increases in gain, reductions in low-frequency correlated activity and a biasing of competition between nearby stimuli have all been implicated with attention. Together, these effects are thought to increase the signal-to-noise ratio of behaviorally relevant stimuli at the attended location, while largely filtering out activity associated with behaviorally irrelevant distracters. The neural circuit mechanisms underlying these effects remain poorly understood. Here, we describe experiments in which we have used optogenetic depolarization of

excitatory neurons in macaque V4 to probe attentional mechanisms. Given that optogenetic stimulation bypasses the retina, LGN and other cortical inputs, this enables us to directly perturb and test the V4 circuit in attention, without indirect effects inherited from afferent visual areas. We find evidence that optogenetic depolarization of excitatory neurons activates competitive circuits and modulates response variability. This positions us to test whether attention can bias this competition in favor of the visual stimulus and reduce optogenetic-induced correlated variability within V4.

Title: Using saccadic eye movement tasks to differentiate attention-deficit hyperactivity disorder from bipolar disorder

Authors: *S. SONCIN, D. BRIEN, A. MARIN, D. MUNOZ
Ctr. for Neurosci. Studies, Queen's Univ., Kingston, ON, Canada

Abstract: Differentiating symptoms between Attention-Deficit Hyperactivity Disorder (ADHD) and Bipolar Disorder (BD) is difficult because the core features of ADHD are quite similar to the symptoms of BD. Executive function deficits are typical for these groups, where individuals with ADHD have problems with response inhibition and those with BD have emotion processing deficits. Response inhibition can be measured using eye movement tasks. The antisaccade task requires participants to inhibit a prepotent saccade toward a peripheral target and instead generate a voluntary response in the opposite direction. This task can be combined with emotional stimuli (faces) in order to differentiate ADHD and BD from each other and from controls. Adult subjects (18-62 years old; 22 ADHD, 20 BD, and 22 Control) performed an interleaved pro and antisaccade task (look toward vs away from peripheral target, respectively). Task instruction (pro vs anti) was conveyed by the colour of the central fixation spot. Standardized emotional faces (fear, happy, sad, neutral) were incorporated into the task along with control images (an object and no image). The images were presented behind the central fixation point shortly before (200ms) appearance of the peripheral target. In all conditions, Controls had faster mean saccadic reaction times compared to ADHD and BD groups while the

ADHD group was faster than the BD group. Controls also made less direction errors (prosaccades on antisaccade trials) than both patient groups. Emotion effects were group dependent: fear increased direction errors and saccadic reaction times for ADHD subjects while neutral had the same effect on BD subjects. The BD group had the greatest percentage of trials with multiple eye movements to reach the target while ADHD had the least, even when compared to controls. Additionally, the ADHD group produced the fewest corrective saccades, while BD made the most. Therefore, certain measures distinguish the patient groups from controls and others still show greater differences between ADHD and BD. In conclusion, these response patterns indicate that there are specific response profiles that can characterize each of these disorders. Emotions differentially affect each group implying that both response inhibition and emotion processing deficits may be valid as biomarkers for these disorders. Therefore, combining executive control and emotional processing into eye movement tasks may provide an objective measure that could be used for differential diagnosis.

Title: Saccade-related modulation of acoustic activity recorded from the external ear canal

Authors: *K. GRUTERS[1], C. A. SHERA[4], J. M. GROH[1,2,3]
[1]Psychology & Neurosci., [2]Neurobio., [3]Ctr. for Cognitive Neurosci., Duke Univ., Durham, NC; [4]Hlth. Sci. & Technol., Harvard Med. Sch. Massachusetts Eye & Ear Infirmary, Cambridge, MA

Abstract: Saccadic eye movements can quickly and substantially change the relationship between eye-centered visual space and head-centered auditory space, a relationship that must be "known" by the brain in order to coordinate a unified sense of audio-visual space. Previous research has found that saccades can evoke activity in auditory neurons located in the inferior colliculus (Porter et al., 2007; Bulkin and Groh, 2012), the lateral/medial banks of the

intraparietal sulcus (Mullette-Gillman et al., 2009), and superior colliculus (Lee and Groh, 2014). Presumably, this activity helps the auditory system calculate the hybrid reference frame that has been identified throughout the system (e.g. Mullette-Gillman et al., 2005; Porter et al., 2006; Lee and Groh, 2012). However, it is not clear at what level of the auditory system, or on what time scale, saccadic eye movement first influences auditory processes. We sought to test this question by determining whether acoustic signals recorded from ear canal display systematic peri-saccadic gain modulation. We measured sound pressure level in the external ear canal of monkeys (n=3) and humans (n=7) as they made saccades from a central fixation point to various locations along the horizontal azimuth. Sound pressure measured in this fashion reflects otoacoustic emissions generated by outer hair cells, activity of the middle-ear muscles, and possible influences from muscles near, but not necessarily specific to, the ear. Both monkeys and humans exhibited statistically significant changes in the peri-saccadic acoustic signal within individuals and at the population level (Monte Carlo simulation and ANOVA, $p<0.05$). These results indicate that eye movements influence auditory activity at the very periphery of the auditory system. Importantly, they suggest that whether or not the oculomotor system sends signals directly to the auditory system, eye movements systematically change the acoustic properties of the ear. Such changes are likely sufficient to pass eye position information throughout the entire auditory system and support a variety of interactions between vision and audition.

Title: How do patients with strabismus locate visual targets?

Authors: *J. R. ECONOMIDES, D. L. ADAMS, J. C. HORTON
Beckman Vision Ctr., UCSF, San Francisco, CA

Abstract: In subjects with strabismus either eye could potentially inform the brain about the location of a visual target, so that an accurate saccade can be made. It is unknown if the eye used

to acquire a target is also the eye that provides information regarding the target's location. Alternatively, the other eye could serve as the source for this information. To address this issue, 16 subjects with alternating exotropia and no amblyopia wore red/blue filter glasses for dichoptic stimulation while viewing stimuli on a tangent screen. Each trial began with a fixation cross, visible to either the right or left eye. After the subject fixated the cross, a peripheral stimulus appeared for 200 msec, visible to either the right or left eye. The subject's task was to look at it. Although the spot disappeared before the eye arrived, a saccade landing within a 5° window was rewarded with a tone, to motivate the subject. There were 2 main results: 1) the eye that saw the target was usually the eye that was used to fixate it; 2) when stimuli were presented in the far nasal field of the perceiving eye, subjects occasionally performed a "cross-over" saccade by placing the other eye on the target, to avoid having to make a large adducting saccade. In such cases, information about target location was obtained in one eye and used to program a saccade for the other eye. These cross-over saccades had a longer latency and were less accurate. In 10/16 subjects, purple spots were included as peripheral stimuli to test which eye was used to fixate targets that were potentially visible to either eye. First, binocular sensory maps were compiled to delineate the portions of the visual field perceived with each eye. Then the subjects' oculomotor behavior was studied by randomly interleaving red, blue, and purple peripheral stimuli. There was a close match between suppression scotoma maps and the eye used to acquire the peripheral stimulus. In other words, the target was perceived via the eye that was used to fixate it. These studies provide new information regarding the strategies used by patients with strabismus to fixate accurately visual targets, despite misalignment of the eyes.

Title: Optimal control of saccades in patients with ataxia-telangiectasia

Authors: *T. O. CRAWFORD[1], P. VASWANI[2], J. M. WRIGHT[3], H. M. LEDERMAN[3], R. SHADMEHR[4]
[1]Dept Neurol, Johns Hopkins Univ. Med. Sch., BALTIMORE, MD; [2]Dept. of Neurosci., [3]Div. of Pediatric Allergy and Immunol., [4]Dept. of Biomed. Engin., Johns Hopkins Univ. Sch. of Med., Baltimore, MD

Abstract: Ataxia-telangiectasia (A-T) is an autosomal recessive developmental disorder in which patients manifest neurodegeneration, ocular and cutaneous telangiectasia, and immunodeficiency. Among the prominent neurologic features, individuals with A-T have significant impairments in their oculomotor system, including difficulty with gaze holding, VOR, OKN, smooth pursuit, and saccades, though they have normal visual acuity. We assessed rapid eye movements of subjects with A-T. We asked 10 subjects with A-T and 30 control participants to make saccades to targets placed 10° to 40° apart on the horizontal axis. Recordings from control subjects demonstrated an initial saccade directly to, or near to, the target, while A-T subjects made a converging series of saccades that achieved the target with 3-4 movements. Prior work hypothesized this behavior is due to a deficit in the oculomotor system. Lewis et al. (1999) proposed that A-T individuals' saccades intend to move to the target, but are prematurely terminated, resulting in the series of saccades observed. We examined saccade dynamics and observed that peak velocity, early saccade velocity, duration, and skew were comparable to controls. Dynamics were appropriate for the saccade amplitude, but not for the target distance, suggesting that the A-T subjects' saccade hypometria is intentional. An optimal feedback controller (OFC) provides an alternate explanation for subjects' behavior. We hypothesized that A-T subjects make a series of saccades as an optimal policy given an increase in the signal dependent noise of their oculomotor system. An OFC that seeks to fixate the target accurately but also incurs a time cost makes two testable predictions. First, if there is a substantial increase in the signal dependent noise, the optimal policy is to make 3-4 saccades. Second, if visual feedback is available, these saccades will form a converging series; in the absence of visual feedback, when saccades must be planned in advance, equal amplitude saccades are predicted. Both control and A-T subjects displayed a signal dependent increase in the variance of saccade amplitudes, but the increase was 3.4 fold larger in A-T subjects. The intersaccadic interval in controls (413±12 ms) and A-T subjects (388±18 ms) was sufficient for the use of visual feedback. Given these parameters, the OFC predicts that A-T subjects should make a converging series of saccades with significantly reduced gain, as we observed. Individuals with A-T make a series of saccades that is optimal for the signal dependent noise in their oculomotor system. The "abnormality" observed in their saccades is not a primary deficit, but rather an adaptive, optimal policy.

Title: Saccade performance in children with and without dyslexia during reading tasks

Authors: *N. Z. AL DAHHAN, D. C. BRIEN, J. R. KIRBY, D. P. MUNOZ
Queen's Univ. Ctr. for Neurosci. Studies, Kingston, ON, Canada

Abstract: Eye movement recording is a valuable tool to investigate cognitive processes involved during reading and uncovering the cognitive and perceptual skills of average readers. It is then useful to apply these same ideas and technology of eye movement research to study readers with dyslexia. Despite dyslexia being one of the most common reading disabilities, its aetiologies are still unclear. Naming speed (NS) deficits, impaired timing mechanisms that affect reading fluency, are characteristic of reading difficulty from the early stages of reading into adulthood. NS tasks measure how quickly and accurately subjects can name sets of highly familiar stimuli (e.g., letters) randomly presented in a visual array. We used a letter NS task and three variants that were either phonologically and/or visually similar while participants' eye movements and articulations were recorded. We examined how these manipulations influenced performance and whether there were differences with increased reading acquisition from ages 6-10 and between dyslexic and average readers. Participants were in three groups (n=15/group): dyslexics (age 9-10), chronological-age controls (CA; age 9-10), and reading-level controls (RL; age 6-7). NS manipulations were associated with specific patterns of performance which were influenced by visual rather than phonological similarity. When the task was both visually and phonologically similar all groups had longer naming times and fixation durations, more naming errors, more frequent and shorter saccades, and had shorter eye-voice spans. Compared to CA controls, dyslexics performed more like RL controls and were less efficient, had longer articulation times, pause times, and fixation durations, shorter eye-voice spans, and made more errors, saccades, and regressions. Regression analyses indicated that pause time and fixation duration were the most powerful predictors of reading: longer pause times reflect more processing needed to process stimuli and prepare the correct response, and longer fixation durations reflect the greater amount of time needed to acquire visual information from stimuli. Overall, there were clear developmental changes in behavior and saccade performance in normally achieving children from ages 6-10 that appear to occur more slowly for dyslexics.

Title: Saccade planning in ambiguous situations

Authors: ***H. GERTZ**, K. FIEHLER
Justus-Liebig Univ. Giessen, Exptl. Psychology, Giessen, Germany

Abstract: In a recent human fMRI study, we applied a pro-/anti-reach task and varied the point in time when the context rule (pro or anti) was given. The context rule had to be combined with a spatial cue in order to infer the reach goal. Thereby, we created specified conditions with the spatial cue and the context rule given before a delay period, and underspecified conditions with only the spatial cue given before the delay. We showed that movement goals (and not the physical location of the spatial cue) are represented in reach-related posterior parietal regions in both specified and underspecified conditions during the delay period. However, in underspecified conditions activation was substantially reduced. Moreover, activation in the dorsal premotor cortex observed in the specified conditions was lacking in underspecified conditions. In this study, we used the same experimental design to study saccade planning in conditions with specified and underspecified saccade goals. In the specified conditions, we presented 1 or 2 spatial cues and a context rule (pro or anti) before a variable delay period. Afterwards, participants performed pro- and anti-saccades accordingly. In underspecified conditions, only the spatial cue was given before the delay period, while the context rule was specified after the delay. A specific saccade goal could thus not be inferred before the end of the delay period. As shown in previous studies, saccade planning in specified conditions led to activation in a frontoparietal network including the frontal eye fields, the supplementary eye fields, the superior parietal lobule, and the intraparietal sulcus. Comparing the planning period of pro- and anti-saccades, we found higher activation for the planning of anti-saccades in the superior parietal lobule. Moreover, we observed activation in a similar saccade network in the underspecified condition when the context rule was unknown before the delay. In contrast to our

previous findings on reaching, the observed cortical network and the activation strength were comparable for specified and underspecified conditions. These results suggest that saccades similar to reaches are even planned *in situ*ations where the saccade goal is ambiguous.

Title: Temporal stability and training effects in "express saccade makers"

Authors: *P. C. KNOX[1], F. D. A. WOLOHAN[2]
[1]Eye & Vision Sci., Univ. Liverpool, Liverpool, United Kingdom; [2]Eye & Vision Sci., Univ. of Liverpool, Liverpool, United Kingdom

Abstract: A gap between fixation target offset and saccade target onset encourages the production of express saccades (ES; latency 80-130ms). “Express saccade makers” (ESMs) produce almost exclusively ES in gap trials, and in overlap trials (fixation target present when the saccade target appears), a large proportion (>30%) of their saccades are ES. We investigated performance stability in ESM and nonESM participants over time and the effect of repeated exposure to gap and overlap tasks. Experiment 1. 113 participants (59 ESMs) completed two blocks of 200 overlap trials in the first session (T1). Sixty provided data on a second occasion (T2; 27 ESMs; 200 trials; mean of 87 days later) and 30 provided data on a third occasion (T3; 13 ESMs; 200 trials; mean of 94 days later). Eye movements were recorded using an infrared reflectance eye tracker. For each participant, the percentage of saccades with latencies of 80ms to 130ms (%ES) was calculated for all saccades with latencies between 50ms and 500ms. Participants displayed the same relative performance both within (T1, Block 1 vs 2: ICC=0.97, $p<0.001$) and between (T1 vs T2: ICC=0.95, $p<0.001$; T1 vs T2 vs T3: ICC=0.97, $p<0.001$) sessions, thereby demonstrating high temporal stability. Experiment 2. We exposed 5 ESMs and 5 nonESMs to repeated exposure (“training”) with gap and overlap tasks (administered separately, approx. 6 weeks apart; order counterbalanced). After baseline measurement, gap training consisted of 400 gap trials completed on five consecutive days. Participants returned on

day 8 and completed 400 overlap and 400 gap trials ('probe' trials); this pattern was repeated for overlap training. While gap training produced a small but significant increase in %ES on the overlap task for both groups ($F=11.3$, $p=0.01$; mean increase: ESM=15±11%, Non-ESM=7±10%; see Figure) overlap training did not ($F=1.9$, $p=0.21$; mean increase: ESM=0.4±8%, Non-ESM=6±7%; Figure). These observations show that the performance of ESMs is stable over time and that the overproduction of ES on the overlap task in ESMs is unlikely to be a product of some environmental exposure.

Title: Saccadic adaptation violates Hering's law of equal innervation on multiple timescales

Authors: *T. KNAPEN[1], T. BEEMSTERBOER[2]
[1]VU Amsterdam, Amsterdam, Netherlands; [2]Psychology, Univ. of Amsterdam, Amsterdam, Netherlands

Abstract: Saccades are commonly thought to be planned conjugately, a principle referred to as Hering's law of equal innervation of the two eyes. Here, we investigated the extent to which saccadic adaptation in one eye influences saccades made with the other eye. According to Hering's law, the two eyes should fully share their states of saccadic adaptation. We adopted a saccadic adaptation protocol with 6 blocks of alternating gain-up and gain-down adaptation. In two conditions, participants made saccades either with both eyes in all blocks (binocular), or with one eye patched (monocular). Importantly, the eye that was patched alternated with the blocks, ensuring that one eye would receive only gain-up adaptation and the other only gain-down adaptation. Any difference between binocular and monocular conditions in the course of adaptation across blocks would indicate a violation of Hering's law. Per-block data were fitted with both exponential and power-law adaptation functions, with the power-law fits consistently explaining more variance. This points to the existence of multiple timescales of adaptation in the single-block timecourses. Over the timecourse of the full experiment, gain-down adaptation on a long timescale decreased saccadic gain across all blocks for both conditions, pointing to a binocular adapting trace. In the monocular condition, adaptation state at the start of blocks was less influenced by the preceding adaptation in the other eye than in the binocular condition. This points to incomplete overlap of adaptation states in the two eyes. We used an extended multi-rate adaptation model to quantify this overlap, and find that fast and slow timescales show differences in binocular sharing of adaptation. Our results indicate that saccadic adaptation occurs in part at monocular levels of saccade planning and calibration, violating Hering's law.

Title: The effect of prosaccade training on antisaccade latency and accuracy

Authors: S. MONTENEGRO, *J. A. EDELMAN
Dept Biol, City Col. of New York, NEW YORK, NY

Abstract: Prosaccades are saccadic eye movements made reflexively in response to the sudden appearance of visual stimuli; those with latencies under 120 milliseconds have been referred to as “express saccades.” Bibi and Edelman (2009) demonstrated that decreases in reaction time resulting from training express saccades along one axis (horizontal or vertical) could transfer to saccades made in perpendicular directions. . To help determine the visuomotor processes underlying this facilitation, we trained subjects to make prosaccades and probed performance on antisaccade trials, in which prosaccades are suppressed and voluntary saccades made in the direction opposite the target. Eye movements of five subjects were recorded using an Eyelink II video eyetracker interfaced with computer routines written using Experiment Builder (SR Research). Subjects trained at making prosaccades over several weeks and were probed at three phases of the training (before training, after six sessions and after twelve sessions) to examine how training affected the ability to make antisaccades. We consider three possible outcomes: 1) A finding that prosaccade training increases errors in antisaccade trials would indicate that prosaccade training facilitates visual processes, making it more difficult for reflexive visuomotor processes to be suppressed during an antisaccade trial. 2) A finding that training increases antisaccade latency would suggest that prosaccade training suppresses voluntary saccade production. 3) A finding that prosaccade training decreases antisaccade reaction time would suggest that prosaccade training has a general effect to facilitate saccade production in reaction time tasks. As in previous work (Bibi and Edelman, 2009), training resulted in the shortening of prosaccade reaction time, with a greater percentage of saccades in the express latency range. Subjects exhibited an overall decrease in reaction time in antisaccade trials after training, while the percentage of errors in the antisaccade task increased only slightly (statistically significant in only 1/5 subjects). These findings suggest prosaccade training has a generalized effect on the saccadic system, allowing it to more quickly generate saccades (pro-and anti) in reaction time tasks.

Title: Visual attention and individual miniature saccadic eye movements generated during car driving

Authors: T. HIRAYAMA[1], T. OGURI[4], *K. INAGAKI[2,3], Y. HIRATA[3]
[1]Computer Sci., [2]Inst. of Sci. and Technol. Res., Chubu Univ., Kasugai, Aichi, Japan; [3]Robotic Sci. and Technol., Chubu Univ., Kasugai, Japan; [4]DENSO Corp., Nisshin, Japan

Abstract: A microsaccade (MSC) is a rapid miniature eye movement generated when we are fixating on a small visual target. It has been studied in well-controlled (or unnatural) laboratory environment, and shown to reflect location of visual attention in its statistical properties such as generation rates and direction distributions. Previously, we demonstrated that MSC-like miniature rapid eye movements were evoked in human subjects during real car driving, and the number of the evoked MSC-like eye movements increased when pedestrians and/or other vehicles were in their field of view (Miki & Hirata, 2013). Presently we repeated the same driving experiment with a new subject in addition to the same 3 subjects who participated in the previous study. The driving experiment was conducted on the campus road in Chubu University Kasugai Campus, lasting for 5 to 9 minutes with the maximum speed of 30 km/h. Binocular eye movements were measured with a video-oculography (EyeSeeCam) at the frame rate of 220 fps. First, we confirmed that the results obtained in our previous study (Miki & Hirata, 2013) were reproduced in all the 4 subjects. Then we analyzed individual MSC-like eye movements, rather than their statistical properties, in conjunction with larger saccades. It was found that most (> 87 %) of individual MSC-like eye movements preceded a gaze shift driven by a saccade in a short period of time (< 0.6 sec). When they were not followed by a saccade, they were followed by another MSC-like eye movement with a short interval (< 0.9 sec) that is shorter than the average interval (> 2.5 sec) calculated over the entire driving time. As saccades are known to accompany with spatial shift of attention, these results suggest that an individual MSC-like eye movement reflects spatial shift of subject's attention. However, the MSCs that preceded a saccade did not show clear directional correspondence with the landing position of the saccade, i.e., the location to which attention was presumably directed (53.6% in the same direction, 46.4% in the opposite direction). Further experiments and analyses are required to address the relationship between the direction of individual MSC and that of attentional shift.

Title: Contribution of dorsolateral prefrontal cortex to attentional and mnemonic processes in visual search

Authors: *B. BELBECK, S. G. LOMBER, S. EVERLING, K. JOHNSTON
The Univ. of Western Ontario, London, ON, Canada

Abstract: At any moment, we are faced with many more visual stimuli than can be processed at one time. Thus, a prerequisite for successful behaviour is the ability to selectively attend to relevant stimuli while ignoring irrelevant ones. A key characteristic of visual selective attention is that it may be deployed on the basis of our knowledge or the goals of the task at hand. Such may be the case when the behavioural relevance of stimuli varies frequently or when a representation of a relevant stimulus must be retained within working memory to guide visual selection. The prefrontal cortex (PFC) is thought to play a prominent role in attentional processes, as well as behavioural flexibility and working memory. Here, we used cryogenic deactivation to investigate the contribution of the dorsolateral PFC (DLPFC) to cognitive processes related to the deployment of attention using visual search tasks. Macaque monkeys performed four visual search tasks that required them to make a single saccade to a target amongst distracters, and which varied with respect to their cognitive demands. The first was a simple 'pop-out' feature search, in which the target stimulus was defined by colour. The other three tasks were variants of a conjunction search in which the target was defined by colour and shape. In these tasks, the target either remained constant throughout an experimental session, varied within-session on a trial-by-trial basis - requiring cognitive flexibility, or varied within-session with the addition of a memory delay - requiring working memory. In each experimental session, animals performed one of these tasks while the DLPFC was bilaterally deactivated. Both control and experimental behavioural data were collected within each session. A 15-minute deactivation epoch was preceded and followed by 15-minute control epochs. Deactivation resulted in minimal changes in response accuracy across tasks, but increased saccadic reaction times. These results suggest the DLPFC is involved in the deployment of attention to a target, and also contributes to the flexible and mnemonic processes needed when the search target changes or temporary retention is required. These findings are generally consistent with the notion that the PFC sends bias signals to other brain areas to guide attention during visual search.

Title: Saccadic suppression of visual sensitivity in frontal eye field neurons

Authors: *R. M. KROCK[1], T. MOORE[2]
[1]Stanford Univ., San Francisco, CA; [2]Neurobio., Stanford Univ., Stanford, CA

Abstract: Saccadic suppression is a profound loss of visual sensitivity around the time of saccadic eye movements that is presumed to aid in constructing a stable visual percept by minimizing self-generated motion signals. The frontal eye field (FEF) is an oculomotor structure that plays a key role in visual sensorimotor integration, and yet its role in saccadic suppression is unknown. We investigated changes in visual sensitivity of FEF neurons before saccades using extracellular recording with 16-channel linear electrode arrays in rhesus macaques. We presented brief (16 ms), full-field visual probes during fixation or shortly (<130 ms) before saccades. The probe consisted of a field of pseudorandomly positioned, 1 dva grayscale circles with contrast varying from 2 to 32% Michelson contrast across trials. Visual responses to presaccadic probes were significantly reduced compared to probes presented during fixation across the population of visually responsive cells. Visual sensitivity, as measured by d', was also markedly reduced across the range of stimulus contrast values tested. We also measured the time course of suppression and examined presaccadic sensitivity to chromatic stimuli. Our results demonstrate that FEF neurons exhibit robust suppression of visual sensitivity around the time of saccades.

Title: Bilateral anterior cingulate cortex deactivation reduces switch costs in the macaque monkey

Authors: *J. L. CHAN, K. JOHNSTON, S. G. LOMBER, S. EVERLING
Univ. of Western Ontario, London, ON, Canada

Abstract: The ability to flexibly switch behavior in a goal-directed manner is integral to cognitive control. The anterior cingulate cortex (ACC) is thought to play a critical role in this control. Although lesion, functional imaging, and neurophysiological studies have implicated this area in a variety of cognitive functions, including conflict monitoring, performance monitoring, action selection, and decision making, ACC function remains poorly understood. In this study, the role of the ACC in top-down control was investigated by applying reversible cryogenic deactivation bilaterally to the dorsal ACC (area 24c) of a rhesus macaque monkey performing a task that required switching between two behavioral rules. The task consisted of randomly interleaved pro- and anti-saccade trials, and enabled error rates and reaction times to be examined on trials where the task rule was the same as (repeat trial) or different from (switch trial) the previous trial. Each trial began with a grey central fixation point that changed to a colored instruction stimulus to indicate the task rule. After a random interval of 500 to 700 ms, the instruction stimulus was extinguished for 200 ms prior to the onset of a peripheral stimulus (gap task). The monkey was required to make a saccade either toward or away from the stimulus on pro- and anti-saccade trials respectively. Consistent with previous studies, switch costs were observed in this interleaved saccade task. Switches to pro-saccade trials had longer saccadic reaction times than repeat pro-saccade trials, and switches to anti-saccade trials had higher error rates than repeat anti-saccade trials. These switch costs were eliminated during ACC deactivation. In addition, ACC deactivation significantly decreased error rates for both pro- and anti-saccades. Thus, the absence of ACC activity may facilitate cognitive flexibility when a task requires frequent changes in behavior. These results suggest that the ACC may play a role in tracking previously rewarded behaviors.

Title: Theta-band coherent activity is involved in transmission of task relevant information between frontal eye field and anterior cingulate cortex

Authors: *S. BABAPOOR-FARROKHRAN[1], T. WOMELSDORF[2], M. VINCK[3], K. JOHNSTON[4], S. EVERLING[1]
[1]Neurosci., Western Univ., London, ON, Canada; [2]Biol., York University, Ctr. for Vision Res., Toronto, ON, Canada; [3]Neurobio., Yale University, Kavli Inst. for Neurosci., New Haven, CT; [4]Physiol. and Pharmacol., Westen Univ., London, ON, Canada

Abstract: Anterior cingulate cortex (ACC) is involved in a variety of motor and cognitive functions and frontal eye field (FEF) is involved in the generation of saccades. Previous literature suggests a role for ACC in saccade control by virtue of its anatomical and functional connectivity with FEF and other saccade-related brain areas. The mechanism of information transfer between these areas has not been completely understood and involves complex interactions of different types of oscillatory and neuronal signals. It has been suggested that brain areas communicate through synchronization and this facilitates the transmission of relevant information between brain areas. In the current study, we have investigated the potential mechanisms by which information is transferred between ACC and FEF during performance of oculomotor tasks. We carried out simultaneous local field potential (LFP) recordings in the FEF and ACC of macaque monkeys (Macaca fascicularis and Macaca mulatta) while they performed memory-guided saccades and a pro/anti saccade task. In the memory-guided saccade task, the monkeys performed saccades towards the remembered target location 1000 milliseconds after a brief presentation of the target stimulus. In pro/anti saccade task, the monkeys performed saccades toward (pro-saccade) or to the opposite side of (anti-saccades) the presented stimulus. The results indicate that theta-band coherence with the frequencies between 3 to 9 Hz is modulated during the preparatory period before stimulus onset in the pro/anti saccade task. Furthermore, theta-band coherence between FEF and ACC is enhanced when visual stimuli are presented in the contralateral visual field. Our results suggest that theta-band coherent activity is

involved in the rule-specific information transmission between FEF and ACC which might facilitate task-dependent stimulus-response mappings.

Title: Electrophysiological correlates of the saccadic preparation cognitive processes in the experimental scheme with distractors at stimulation of the leading and unleading eye

Authors: *V. MOISEEVA[1,2], M. SLAVUTSKAYA[1], V. SHULGOVSKIY[1], N. FONSOVA[1]
[1]Lomonosov Moscow State Univ., Moscow, Russian Federation; [2]Ctr. for Cognition & Decision Making, Higher Sch. of Econ., Moscow, Russian Federation

Abstract: To attend relevant stimuli in the visual field while ignoring distracter elements is crucial for successful goal-directed behaviour. The oculomotor system can be used as a model to study the competition between different elements in the visual space. The goal of our research was to analyse spatial-temporal parameters of saccades and presaccadic EEG-potentials at the simultaneous presentation of the target and distracting stimuli to the leading and unleading eye. 14 healthy right-handed volunteers participated in the study. Target and distracting peripheral visual stimuli were presented simultaneous monocularly on the monitor in various spatial combinations. Eye movements were recorded using the electro-oculogram. Possible combinations of visual stimuli in the same or in different visual hemifields. The complex of the positive and negative potentials was revealed in the saccade latent period. Latency of all components was shorter upon presentation of stimuli to the left, unleading eye, that may indicate the earlier saccade preparation. At the same time LP saccades were longer in this conditions

($p<0.05$). The main asymmetry in saccadic LP was revealed at the presentation of target and distracting stimuli in the left visual hemyfield at the distance 5 degrees between them. The results show that early potentials N1 and P1 were higher in amplitude and dominated in medial and controlateral parietal-occipital areas. It can be reflection of visual sensory processing and processes of motor preparation at the same time. The amplitude of the later negative potential N2 at the stimulation of the right eye increased in the case when target stimulus was at the same location than at the previous realisation. It's possible that N2 component is connected with processes of preliminary extracting of motor programme from memory together with attention processes. N2 amplitude was higher when the distance between target and distracting stimuli was 15 degrees in comparison with the minimal distance 5 degrees. It's corresponded with LP data. The findings show an active role of attention and decision-making processes in saccade programming. The work was executed at the support of RFBR (the projects № 14-04-01634 and № 12-04-00719) and it's a part of the Basic Research Program at the National Research University Higher School of Economics (HSE).

Title: How do frontal eye field neurons ignore distractors while selecting target-relevant features in natural scenes?

Authors: *D. K. WOOD[1], P. RAMKUMAR[2], J. I. GLASER[2], P. N. LAWLOR[2], K. P. KORDING[2], M. A. SEGRAVES[1]
[1]Northwestern Univ., Evanston, IL; [2]Rehabil. Inst. of Chicago, Chicago, IL

Abstract: While searching for targets in natural scenes, two strategies may be adopted: selectively attend to locations that share features with the target (target enhancement), or selectively avoid locations that do not (distractor suppression). We want to understand how these strategies are implemented in the frontal eye fields (FEF). To this end, we trained macaques to

search for a target (e.g. a vertical Gabor) in a natural scene that also contained a distractor (e.g. a horizontal Gabor). To ensure that distractor suppression is behaviorally advantageous, we rewarded monkeys for saccading to the target, and punished them (the trial was aborted) for saccading to the distractor. We tested whether monkeys used both strategies by asking if fixation prediction could be enhanced by using both target and distractor-based priority maps. We then modeled spike trains and local field potentials (LFPs) using generalized linear models (GLMs) comprising target and distractor relevance maps, as well as bottom-up saliency and movement direction. We found neural activity that encoded target features, distractor features, both, or neither. Our results suggest that FEF may play a role in both target enhancement and distractor suppression during natural scene search.

Title: The frontal eye field reflects task demands in natural scenes

Authors: *J. I. GLASER[1,2], P. N. LAWLOR[1,2], D. K. WOOD[2], P. RAMKUMAR[1,2], S. CADDIGAN[2], J. DRAPEKIN[2], B. FRICK[2], B. QIN[2], K. P. KORDING[1,2], M. A. SEGRAVES[2]
[1]Rehabil. Inst. of Chicago, Chicago, IL; [2]Northwestern Univ., Evanston, IL

Abstract: Primates make thousands of eye movements (saccades) per hour, but it is still an open question how the brain chooses fixation locations. Many factors are thought to influence saccadic locations, including visual "bottom-up" features like salience and goal-dependent "top-down" features. It is unknown how the visual system encodes the priority of these natural scene features, and whether they are encoded in a task-dependent manner. Studies with artificial stimuli suggested that the frontal eye field (FEF) encodes both visual salience and goal-dependent (relevant) features, but other studies using natural scenes did not replicate this effect. Here, we record eye movements, spike trains, and local field potentials (LFPs) from the macaque FEF during two tasks designed to disambiguate the effects of salience and goal-dependent

features in natural scenes: tasks with and without known search targets. We used generalized linear models (GLMs) to predict neural activity as a function of visual features and movement direction around the peri-saccadic interval. Using this method, we found that some FEF neurons differentially encoded salience and relevance between the two tasks. Our results demonstrate that the FEF encodes visual features according to their priority for the task.

Title: Gating of visual input to prefrontal cortex: Orthodromic activation of FEF neurons by V4 stimulation

Authors: ***K. L. CLARK**, B. NOUDOOST
Montana State Univ., Bozeman, MT

Abstract: Visually guided behavior is achieved in part via the interaction between oculomotor structures and visual areas. To understand how these areas interact with each other we studied dynamic changes in the efficacy of inputs from visual area V4 to the frontal eye field (FEF), which project directly to one another. We electrically stimulated V4 sites while recording from FEF neurons with overlapping response fields, and identified FEF neurons that were orthodromically activated by V4 stimulation. We were particularly interested in examining the changes in the functional relationship of FEF-V4 neurons during memory encoding, memory maintenance, and saccade execution. Various computational models suggest that areas that maintain information during working memory (such as FEF) should be differentially sensitive to inputs from sensory areas (e.g. V4) during memory encoding and maintenance. Changes in functional connectivity between FEF and V4 around the time of saccades could also help explain the difference in the magnitude of presaccadic receptive field shifts between the two areas. By stimulating V4 during different epochs of the memory-guided saccade (MGS) task, we

quantified the strength of functional connectivity between V4 and FEF during these cognitive states. In the MGS task, the animal is presented with a visual cue and must remember that location, while maintaining fixation, throughout a blank delay period, then saccade to the remembered location to receive a reward. We stimulated V4 during the fixation, cue, memory, and saccade periods of the task, and quantified the stimulation efficacy, timing and reliability of evoked spikes, and synchrony between pairs of simultaneously recorded FEF neurons. We examine the relationship between the functional properties of FEF neurons and their sensitivity to V4 input, as well as how sensitivity to V4 stimulation varies as a function of LFP power and phase. These provide direct neurophysiological measures of the gating of visual information during different epochs of a cognitive task.

Title: Cognitive modulation of neuronal activity in the frontal cortex of monkeys performing a simple reaction-time task with reward bias

Authors: *C. K. HAUSER, D. ZHU, M. COSTELLO, E. SALINAS, T. STANFORD
Wake Forest Sch. of Med., Winston Salem, NC

Abstract: Reward availability is key for guiding goal-directed actions and has profound effects on sensory and motor signals throughout the central nervous system. For saccades, reward contingency can influence choice, reaction time (RT), and saccade metrics. We investigated how

these changes relate to neuronal activity in the frontal eye field (FEF), focusing on how perceptual processing and motor planning are modulated by the internal expectation of reward. We used a simple RT variant of the one-direction-rewarded (1DR) task developed by Hikosaka and colleagues. Monkeys were trained to maintain fixation at a central spot and make a saccade when an eccentric stimulus appeared at one of 4 possible locations. Crucially, on a given block of trials, only one such location (the "rewarded location") was associated with the primary reinforcer, water. At each block transition, a new rewarded location was chosen and monkeys relearned the location-reward association. Strong effects on RT were observed: relative to the mean RT in a control task (191 ms, all directions rewarded), saccades to rewarded locations were faster (161 ms) and those to unrewarded locations were markedly slower (261 ms). Moreover, the spread of RTs for unrewarded locations was much larger than for the rewarded. These differences developed quickly, within approximately 5 trials of a switch. We exploited the large spread in RT and the spatially distinct reward conditions in the 1DR task to study how FEF responses related to behavior. We found that FEF activity covaried strongly with RT and was robustly modulated by reward contingency, particularly in the case of neurons traditionally classified as visuomotor (VM); that is, units that exhibit both a visually-driven response to the onset of a stimulus in the response field and an increase in activity preceding a saccade to it. The VM neurons showed three prominent effects: (1) large changes in baseline activity (during fixation) that correlated tightly with RT and/or reward location, (2) brisk presaccadic responses that peaked early and started declining a few tens of ms before saccade onset, and (3) an extremely attenuated presaccadic activation for saccades into the response field when the rewarded location was diametrically opposite. Thus, signals that would be traditionally attributed to motor preparation (e.g., in a standard delayed-saccade task) instead reflected other cognitive processes _ possibly the locus of attention _ that are typically aligned with the saccadic vector. By comparing neuronal activity across tasks with varying attentional and perceptual demands, ongoing experiments aim to further characterize the functional role of such activity.

Title: MST neurons contribute to perceiving the visual world as continuous across saccades by memory remapping of moving visual stimuli

Authors: *N. INABA[1,2], K. KAWANO[1]
[1]Dept. of Integrative Brain Sci., [2]Res. and Educational Unit of LIMS, C-PIER, Kyoto Univ., Kyoto, Japan

Abstract: We perceive the visual world as stable and continuous despite abrupt retinal image shifts induced by eye movements. To examine how the visual system deals with the spatial localization of moving visual stimuli across saccades, we recorded activities of motion sensitive neurons at middle temporal (MT) and medial superior temporal (MST) areas in awake monkeys. The monkeys performed fixation and saccade tasks in which a spatially stable moving stimulus was presented at various visual fields. When the moving stimulus was presented throughout the periods of the saccades, the location of the receptive fields (RFs) moved with the shifts of eye position due to saccades, indicating that motion-sensitive neurons in both areas have retinotopic RFs across the saccades. When we compared the latency of the post-saccadic response from saccade-offset to the visual response latency of each neuron, most MST neurons had significantly shorter latencies from saccade-offset than the visual response latencies. In contrast, for MT neurons, the former was significantly longer than the latter, suggesting the impact of saccadic suppression. As a result, although the MT neurons' visual response latencies were significantly shorter than the MST neurons', the MST neurons' post-saccadic response latencies were significantly shorter than the MT neurons'. When the moving stimulus was presented and turned off before the saccades, most MST neurons, but no MT neurons, increased their firing rates when a saccade brought into their RFs the location of the visual stimulus, which had been visible only before the saccade. It suggests that the responses of such MST neurons after the saccades were evoked by a memory of the stimulus that had pre-existed in the post-saccadic RFs, i.e., "memory remapping". These findings suggest that the post-saccadic responses in MST evoked by the "memory remapping" might be used to fill the missing vision due to saccadic suppression in MT and contribute to the continuous and stable visual perception.

Title: The role of the superior colliculus in the coordination of the pupil orienting response

Authors: *C.-A. WANG, D. P. MUNOZ
Queens Univ., Kingston, ON, Canada

Abstract: Pupil size, as a component of orienting, changes rapidly in response to local salient events in the environment in addition to an illumination-dependent modulation. A growing body of evidence suggests that the superior colliculus (SC) encodes stimuli based upon saliency to coordinate the orienting response. Although the SC is involved causally in the initiation of saccadic eye movements and attention, its role in coordinating other components of orienting is less understood. Here, we examined how pupil dynamics are modulated by the SC and stimulus saliency. While requiring subjects to maintain central fixation, we either presented a salient visual, auditory, multisensory stimulus or delivered weak electrical microstimulation to the intermediate SC layers (saccades were not evoked). Transient pupil dilation was elicited after presentation of salient stimuli, and this dilation was qualitatively similar to that evoked by SC microstimulation. Moreover, the timing and magnitude of evoked pupil responses scaled with the level of stimulus saliency, with significantly faster and larger pupil responses observed for more salient stimuli. The same modulation of stimulus saliency was demonstrated in human subjects. Importantly, the pupil response onset latencies for salient stimuli were comparable to those produced by the pupillary light reflex and much faster than the pupillary darkness reflex, suggesting that the initial component of pupil dilation is more likely mediated by inhibition of the parasympathetic pathway. Together, the results suggest that the transient pupil orienting response is modulated by stimulus saliency, and the SC is a likely neural substrate coordinating these pupil orienting responses.

Title: Neurons in the human medial temporal lobe encode target saliency during visual search

Authors: *S. WANG[1], A. N. MAMELAK[3], R. ADOLPHS[1,2], U. RUTISHAUSER[3,2]
[1]Computation and Neural Systems, [2]Div. of Biol. and Biol. Engin., Caltech, Pasadena, CA;
[3]Dept. of Neurosurg., Cedars-Sinai Med. Ctr., Los Angeles, CA

Abstract: A key function of selective visual attention is to direct our gaze rapidly to objects of interest in the visual environment. The human medial temporal lobe plays a key role in recognizing, categorizing, and learning visual objects and is though to convey saliency and object selection signals through its dense network with other brain regions. To investigate this issue at the single-neuron level, we employed a visual search task with both social (faces and people with different postures, emotions, ages, and genders) and non-social targets (e.g., electronics, food, utensils), which participants were asked to find in an array of 24 objects. With concurrent eye tracking, we recorded from over 150 single neurons in the amygdalae and hippocampi of four neurosurgical patients (five sessions) with implanted depth electrodes. Behaviorally, we found patients rapidly oriented to, and persistently searched amongst, target-congruent objects. Trial-by-trial analysis showed that 11.7% (8.3% for amygdala and 16.7% for hippocampus) of neurons responded only when a target was found. Fixation analysis revealed neurons that responded only when a fixation fell on a target but not a distractor. By comparing the average number of spikes in a time window of the entire fixation duration between fixations on targets and distractors, we selected 24.2% of these target neurons (9.7% for amygdala and 45.8% for hippocampus; two-tailed t-test at $p<0.05$; among which 82.3% increased firing rate to targets and 17.2% decreased). Since the same objects can be either targets or distractors on

different trials, this reveals the top-down driven nature of the response, which suggests that task-relevant target saliency was encoded by a subset of neurons. We further conducted two control experiments in the same patients: one ruled out motor confounds by applying a fixed duration of search in the same task without button press, and the second ruled out working memory or object matching confounds by employing a pop-out search task in which the target was defined as one face among vehicles or one vehicle among faces (thus no predefined target). We also found 21.7% (27.8% for amygdala and 12.5% for hippocampus) of neurons that responded more to social objects than to non-social objects. Interestingly, there was a small population (4%) of target-responsive neurons that differentiated social vs. non-social objects both during single target presentation and subsequent target detection in the search array. Taken together, we found compelling evidence that neurons in the human medial temporal lobe encode object categories and saliency signals that contribute to attention.

Title: Modulation of fixational event-related potentials by low-level image features during free-viewing

Authors: *C. DEVIA[1,2], R. MAYOL-TRONCOSO[2], R. MONTEFUSCO-SIEGMUND[3], J. P. OSSANDÓN[4], A. V. HELO[5], P. E. MALDONADO[2]
[1]Pontificia Univ. Católica, Santiago, Chile; [2]ICBM, BNI, CENEM, Univ. de Chile, Santiago, Chile; [3]Ctr. for Vision Research, York Univ., Department of Psychology, ON, Canada; [4]Univ. Osnabrück, Inst. für Kognitionswissenschaft, Osnabrück, Germany; [5]Lab. Psychologie de la Perception, Univ. Paris Descartes, Paris, France

Abstract: During natural vision we explore the visual world with a fast sequence of self-initiated saccadic eye movements, which occur unconsciously about four times per second. However, most of our knowledge of visual processing originates from studies where subjects fix the gaze on a screen and are exposed to a series of visual stimuli that trigger brain activity mainly through bottom-up mechanisms. These flashed stimuli elicit an unanticipated brain activity, thus occluding ongoing and top-down processes, predictive mechanisms at work in natural vision. One way to study the features of brain ongoing mechanisms is measuring fERP, the event-related potentials locked to fixation onset. In this work, we compared fERPs at occipital sites when subjects freely explored scenes with different low-level characteristics. On seven volunteer, we recorded EEG and eye tracking when they scanned 5 categories of gray-scale images: Landscape, fractals, pink noise, gray and black images. To analyze the data we first performed an ICA decomposition to remove ocular artifacts from scalp EEG signals and then calculated the fERP. We found that a fERP was elicited at fixation onset along image exploration (landscape, fractal and pink noise), it was composed by a positive and consecutive negative deflection localized at occipital sites, and it was visible at single trial. In black images, this fERP was absent showing its cortical origin as subjects also moved their eyes in this category. Even though gray images had more luminance than the other categories, the fERP was almost absent showing a weak modulation by luminance. Finally, we verified that frequency content of the images was similar, except for gray and black categories, and that partially explained fERP amplitude modulation at different categories. We showed here in a free-viewing task that fERP at occipital sites is partially explained by low-level image features like luminance and frequency content while also high-level image features, such as familiarity, congruency and emotional content modulate fERP signals. These results suggest that both bottom-up and as well as top-down processes modulate early visual cortex activity during natural vision.

Title: Target selection in primate Superior Colliculus: Simultaneous recordings of single unit and local field potential

Authors: *T. IKEDA, B. J. WHITE, D. P. MUNOZ
Ctr. for Neurosci. Studies, Queen's Univ., Kingston, ON, Canada

Abstract: The Superior Colliculus (SC) coordinates the orienting response, which converts sensory information into motor commands for the eyes and the head. The intermediate layers of the SC (SCi) integrate inputs from various brain regions to select an appropriate target. We have previously reported that single unit activity (SUA) in the SCi represents target selection processes in a color discrimination task having two separate mechanisms: one linked to the arrival time of visual signals and the other linked to the visual selection process (White and Munoz, 2011). The results showed that saccade reaction time (SRT) was determined by integrating these two mechanisms. We hypothesize that local circuitry within the SCi is playing an important role in this integrative process, and analyzed the local field potential (LFP) simultaneously recorded with SUA. The LFP is thought to represent the sum of postsynaptic potentials of neighboring neurons (Mitzdorf, 1985), and thus may reveal local processing in the SCi. Two monkeys were trained to perform a color-singleton selection task with three conditions in which luminance and color of the items were independently manipulated. 1) target and distractors were isoluminant with the background and had highly different chromaticity making the target easy to discriminate (iso-easy), 2) same target disciminability as previous condition except all items had added luminance contrast relative to the background (lum-easy), 3) target and distractors were isoluminant with the background but the chromatic difference between target and distractors was less making the target difficult to discriminate (iso-diff). SUA and LFP showed a similar phasic visual response with shorter visual onset latency for luminant (SUA: 51±11ms, LFP: 55±11ms) versus isoluminant stimuli (SUA: 68±15ms, LFP: 73±15ms). This suggests that luminance information arrives earlier than the chromatic information to the SC. However, the target discrimination time was different between SUA and LFP. SUA discriminated the target from distractors at almost the same time in condition 1 (103±38ms) and 2 (103±35ms) and much later in condition 3 (118±44ms). In contrast, LFPs showed a significant difference in discrimination time across all three conditions (condition 1: 120±37ms, 2: 104±32ms, 3: 130±32ms), which paralleled the SRTs (condition 1: 160±10ms, 2: 145±10ms, 3: 165±12ms). The results suggest that while the SUA discrimination time represents the visual selection, the LFP discrimination time might be more related to the integrated selection signals from neighboring neurons which triggers the saccadic motor command.

Title: Sensory priming influences form-based perceptual decision-making and superior colliculus population activity

Authors: ***T. B. CRAPSE**, M. A. BASSO
Psychiatry and Biobehavioral Sci., UCLA, Los Angeles, CA

Abstract: Earlier studies uncovered decision-making activity in a number of sensorimotor areas including the superior colliculus (SC), a subcortical area important for eye movements and attentional allocation. Most of the studies in the monkey focus on spatial decision making tasks, eg., random dot motion discrimination with choice targets that remained fixed relative to motion direction. Here we asked whether decision-making activity in the SC extends to form-based decisions with non-spatially fixed choice target locations and whether the activity is affected by sensory priming, i.e. repetitive presentation of one stimulus. To address this, we trained a monkey on a Glass pattern (Glass, 1969) yes-no task in which the monkey had to answer whether or not it perceived structure in a briefly presented stimulus (800-1200 ms). We manipulated whether the stimulus contained structure by varying the coherence in the Glass pattern stimuli. We trained the monkey on 5 coherence levels: 100%, 51%, 26%, 13%, and 0%. If the monkey perceived no structure in the display, it made a saccade to a red peripheral target. If the monkey perceived structure, it made a saccade to a green peripheral target. The location of the choice targets varied randomly on each trial. Once trained, we introduced blocks of noise priming trials. For these sessions, we first collected ~200 trials of 'baseline' data during performance of the Yes/No task. This block was followed by a noise priming block consisting of 200 Yes/No trials in which the coherence was either 0% or 100%. Seventy-five percent of the

trials were 0% coherence. This block was followed by a final block of trials to assess the effects of the sensory priming. We found that sensory priming produced a rightward shift and a change in slope of the psychometric function indicating a change in behavioral threshold and bias. Preliminary recordings from SC neurons reveal first, that neuronal activity scales directly with difficulty level; 0% coherence exhibited the highest degree of activity, followed by 13%, 26%, etc. Second, priming with a noise stimulus amplifies this scaling. Third, the variability of neuronal responses increases following sensory priming. Finally, we find that noise correlations increase among simultaneously recorded neurons following sensory priming, suggesting heightened communication among neighboring neurons. These results suggest that form-based decision making involves mechanisms distinct from spatial-based decision making mechanisms, and points to the role of neuronal pooling mechanisms as a means of implementing sensory priming.

Title: Correlates of saccade target selection in simultaneously-recorded frontal eye field and superior colliculus local field potentials

Authors: *R. M. MCPEEK[1], S. RAY[2], J. PARK[1]
[1]Biol. Sci., SUNY Optometry, New York, NY; [2]Ctr. of Behavioural and Cognitive Sci., Univ. of Allahabad, Allahabad, India

Abstract: In contrast to single-unit recordings, local field potential (LFP) recordings incorporate potentials pooled over a larger area and are sensitive to dendritic synaptic activity. Saccade target selection in the superior colliculus (SC) has been studied extensively using single-unit recordings, but few studies have investigated the LFP correlates of selection in the SC. Moreover, although the SC and frontal eye field (FEF) communicate bidirectionally, to our knowledge no previous study has analyzed simultaneously recorded LFP activity from both areas. We trained macaques to perform a target selection task in which they were rewarded for

making a saccade to a color-oddball target presented with distractors, and we recorded LFPs simultaneously in the SC and FEF during the task. In agreement with earlier reports, we found that in both the SC (e.g., Ikeda et al. 2011) and FEF (e.g., Monosov et al. 2008; Purcell et al. 2013), LFPs recorded after stimulus onset in the target selection task initially did not discriminate the target from a distractor, but over time evolved to signal the target location. Overall, the magnitude of target discrimination tended to be higher in the SC than in the FEF, perhaps due to greater clustering of neurons with similar tuning and functional properties in the SC. In the frequency domain, target selection became evident in SC and FEF LFPs earliest through modest increases in power in the beta (at 25 Hz) and gamma (typically at 40 Hz in SC and 50 Hz in FEF) bands. The SC also showed a decrease in power in the alpha band (at 10 Hz), while an increase in power at this frequency was observed for some FEF sites. We also searched for evidence of phase synchrony (coherence) between simultaneously-recorded SC and FEF sites, since coherence is thought to be an important mechanism for gating communication between areas. We found that during the time of target selection, there was an increase in beta-band coherence between some SC and FEF sites with overlapping receptive fields. We conclude that robust correlates of target selection can be observed in LFPs in both SC and FEF, and that beta-band coherence may provide a mechanism for coordinating SC and FEF activity.

Title: Layer-specific influences of microsaccades on spatial vision in the primate superior colliculus

Authors: ***C.-Y. CHEN**[1,2], Z. M. HAFED[1]
[1]Werner Reichardt Ctr. For Integrative Neurosci., Tübingen, Germany; [2]Grad. Sch. of Neural and Behavioural Sciences, Intl. Max Planck Res. Sch., Tuebingen, Germany

Abstract: Saccadic suppression refers to reduced visual sensitivity around saccades/microsaccades. The sources of saccadic suppression remain elusive. One component of

suppression could occur because of retinal response properties to rapid image motion. Another component is believed to arise extra-retinally through corollary discharge. Here we studied saccadic suppression in superior colliculus, SC, an area that receives both direct and indirect retinal input. We analyzed saccadic suppression across spatial frequency (SF) channels in the most superficial layers (putatively receiving direct retinal input) and compared it to deeper layers receiving visual input only indirectly. We recorded from 87 neurons of 2 monkeys fixating a white spot over a gray background. Inside a neuron's RF, a stationary, vertical Gabor grating (0.56, 1.11, 2.22, 4.44, or 11.11 cpd) appeared. We measured peak neuronal activity 30-150 ms after grating onset. We characterized superficial-layer visual (V) and intermediate-layer visual-motor (VM) neurons. Trials when gratings appeared >100 ms before or after microsaccades served as baseline. We compared these to trials with gratings appearing <50 ms after microsaccades, a period in which maximal saccadic suppression occurs. In separate behavioral sessions, we measured reaction times (RT) when monkeys made visually-guided saccades to the gratings. During initial fixation, we detected microsaccades in real-time and then presented the gratings at specific times (0 to 200 ms) after detection. This allowed us to get a time course of saccadic suppression influences on subsequent RT. We analyzed 32 V and 55 VM neurons (covering 1-24 deg). 85/87 neurons showed significant suppression in at least 1 SF. VM neurons were twice as strongly suppressed as V neurons. Moreover, there was a SF-dependent suppression for VM neurons: it was strongest in the lower SFs and weakened for higher ones. Suppression was constant across SF for V neurons. Behaviorally, suppression mirrored the VM neurons: RT increased strongly during maximal suppression (immediately after microsaccades) and gradually returned to baseline, but this effect disappeared for high SFs. Thus, superficial layer neurons receiving direct retinal input exhibited weak suppression that was not SF dependent. Deeper layer neurons showed strong suppression that weakened with higher SFs. Deeper layer neurons were more correlated with behavioral effects, and they were also consistent with human studies for large saccades. Such human results hypothesized that the SF dependence arises from magno-/parvocellular LGN segregation, which could explain the lack of it in superficial SC layers.

Title: Inactivation of the prelimbic rather than infralimbic cortex impairs acquisition and expression of formalin-induced conditioned place avoidance

Authors: *J.-Y. WANG, Z.-C. JIANG, F. LUO
Key Lab. of Mental Hlth., Inst. Psychol, Chin Acad Sci., Beijing, China

Abstract: Conditioned place avoidance (CPA) paradigm has been used to investigate the affective component of pain. Although the anterior cingulate cortex (ACC) has been demonstrated to play an important role in the affective aspect of pain, whether the other prefrontal subdivisions are involved in pain-related aversion is unknown. The present study investigated the role of the prelimbic cortex (PL) and infralimbic cortex (IL) in the acquisition and expression of formalin-induced CPA (F-CPA) in rats. GABAA receptor agonist muscimol was bilaterally microinjected into PL/IL before or after the formalin-paired training, to explore the effect of temporary inactivation of PL/IL on the acquisition and expression of F-CPA, respectively. The results showed that inactivation of PL rather than IL impaired the acquisition and expression of F-CPA. Moreover, the PL inactivation did not block the acquisition of LiCl-induced CPA, suggesting that PL is specifically implicated in the coding of pain emotion. Inactivation of PL also disrupted the expression of LiCl-CPA, indicating that PL may be involved in a general memory retrieval function.. In summary, our study demonstrated that temporary inactivation of PL rather than IL blocked the acquisition and expression of F-CPA.The results revealed the critical role of PL in the pain-related aversion, and provided new evidence for the differential roles of PL and IL in pain emotion. Future studies should be designed to investigate the role of IL in the extinction of F-CPA, so as to better understand the involvement of the prefrontal cortex in emotional pain.

Title: Enhanced pain behavior observed in mice lacking interleukin-27

Authors: *T. YASAKA[1], T. SASAGURI[2], Y. MURATA[1], H. HARA[3], A. ISHIKAWA[2], T. FUJITA[1], E. KUMAMOTO[1], S. MASUKO[1], N. HIRAKAWA[2], H. YOSHIDA[3]

Abstract: Interleukin (IL)-27 is a member of the IL-12 cytokine family and has been shown to have an immunosuppressive and anti-inflammatory role. The immunosuppressive effect of IL-27 is thought to depend on inhibition of the development of Th 17 cells (a newly identified inflammatory T-helper population) and on induction of IL-10 production. On the other hand, one of recent developments in pain research is the finding that cytokines, including IL-1β, IL-6, TNFα, IL-17 and IL-10, have an important role in pain regulation. For example, IL-17 induces pain behavior, while IL-10 has an anti-nociceptive effect. Because of its potent ability to negatively regulate IL-17 (which is pro-nociceptive) and to promote the production of IL-10 (anti-nociceptive), we hypothesized that IL-27 could have a major impact in the control of pain and tested pain behavior of mice which carry a null mutation in IL-27 or IL-27 receptor gene(s). IL-27 is a heterodimer of EBI3 and p28, while the IL-27 receptor consists of a specific receptor WSX-1, together with gp130, which can also be coupled with other cytokine receptors, such as the IL-6 receptor. We used 3 different mouse strains, each lacking one of these genes (apart from gp130). These mice appeared healthy and had no obvious abnormality by visual inspection. We also observed that WSX-1 knockout mice were indistinguishable from wild type mice in the open-field test, indicating that null mutation of this gene would not affect locomotor activity (total distance traveled) or anxiety level (time spend in the center area of the field). Interestingly, we found that they exhibited enhanced responses in various assessments of pain behavior, including the hotplate, von Frey and formalin tests. Furthermore intraperitoneal injection of recombinant IL-27 (rIL-27) normalized the pain threshold in EBI3 but not WSX-1 knockout mice indicating that the normalized effect of rIL-27 was WSX-1-dependent, and that phenotypes observed in knockout mice did not result from irreversible developmental changes. These results suggest that IL-27 might contribute to regulating normal sensation of pain even in healthy conditions without inflammation.

Title: Chronic pain-related depression of behavior: Effects of intraplantar formalin and complete freund's adjuvant on intracranial self-stimulation (ICSS) and endogenous kappa opioid biomarkers in rats

Authors: *M. LEITL[1], D. N. POTTER[2], K. CHENG[3], K. C. RICE[3], W. A. CARLEZON JR[2], S. NEGUS[1]
[1]Pharmacol. and Toxicology, Virginia Commonwealth Univ., Richmond, VA; [2]Behavioral Genet. Lab., McLean Hospital, Harvard Med. Sch., Belmont, MA; [3]Chem. Biol. Res. Branch, Natl. Inst. on Drug Abuse, NIH, Bethesda, MD

Abstract: Intraplantar injection of complete Freund's Adjuvant (CFA) and formalin are two common chemical challenges for induction of chronic pain states in rodents. CFA is a heat-killed bacterial suspension that elicits an immune response at the site of its injection. Formalin is an aqueous solution of formaldehyde, a cell toxin that cross links proteins to disrupt dynamic protein interactions critical to cell viability. Both stimuli elicit hypersensitive withdrawal responses that often serve as a behavioral indicator of "pain." However, clinically relevant pain states also often include depression of behavior and mood, and preclinical evaluation of pain-related behavioral depression is an emerging area of research. This study compared effects of intraplantar CFA and formalin on the behavior of intracranial self-stimulation in rats. Male Sprague-Dawley rats were equipped with intracranial electrodes in the medial forebrain bundle and trained to lever press for pulses of electrical brain stimulation delivered across a range of 10 frequencies (56-158 Hz). Prior to intraplantar treatment, brain stimulation maintained a frequency-dependent increase in ICSS rates. Rats then received bilateral intraplantar treatment with 100 µl CFA or formalin. Pain-related depression of ICSS was evaluated for its sensitivity to reversal by the mu opioid analgesic morphine. In addition, pain-related depression of ICSS was evaluated for its relationship to central biomarkers of the endogenous kappa opioid system and its sensitivity to the kappa antagonist norbinaltorphimine (norBNI), because some other stressors

depress behavior by activating central kappa systems. There were four main findings. First, in agreement with previous studies, both CFA and formalin produced similar degrees of paw swelling and mechanical hypersensitivity. Second, CFA produced only weak and transient depression of ICSS, whereas formalin produced a robust, concentration-dependent and sustained depression of ICSS that lasted as least 14 days. Third, formalin-induced depression of ICSS was reversed by morphine doses that had no significant effect on ICSS in saline-treated rats, suggesting that formalin effects on ICSS can be interpreted as an example of pain-related and analgesic-reversible depression of behavior. Finally, formalin-induced depression of ICSS was not associated with changes in central biomarkers for activation of endogenous kappa opioid systems and was not blocked by the norBNI. These results suggest that formalin-induced depression of ICSS may serve as a useful procedure for research on neurobiology and treatment of chronic pain-related depression of behavior.

Title: Effects of nicotine on pain-stimulated and pain-depressed behavior in rats

Authors: K. FREITAS, *S. S. NEGUS
Pharmacol, Toxicol, Virginia Commonwealth Univ., Richmond, VA

Abstract: Agonists at nicotinic acetylcholine receptors (nAChRs) constitute one drug class being evaluated as candidate analgesics for treatment of pain. Preclinical studies to evaluate antinociceptive effects of nicotine and other nAChR agonists have relied exclusively on assays of pain-stimulated behavior, which measure behaviors that increase in frequency, rate or intensity after presentation of a noxious and putatively painful stimulus. However, drug effects in assays of pain-stimulated behavior have poor predictive validity for clinical analgesia in humans. Novel assays of pain-depressed behavior measure behaviors that decrease in frequency, rate or intensity after presentation of a pain stimulus. Pain-depressed behaviors play a key role in pain

diagnosis in both human and veterinary medicine, and procedures that measure pain-depressed behaviors may improve translational validity in tests of candidate analgesics. However, the effects of nAChR agonists have not been examined in assays of pain-depressed behavior. Accordingly, our study was designed to compare effects of nicotine in assays of pain-stimulated and pain-depressed behavior in rats. IP injection of dilute lactic acid (1.8% in 1 ml/kg) served as an acute noxious stimulus to stimulate a stretching response or depress intracranial self-stimulation (ICSS) in adult male Sprague Dawley rats. For ICSS studies, rats were implanted with electrodes targeting the medial forebrain bundle at the level of the lateral hypothalamus, and they were trained to respond under a fixed-ratio 1 schedule for a range of brain stimulation frequencies (158-56 Hz) during daily experimental sessions. Pretreatment with nicotine (0.032-1.0 mg/kg) produced a dose-dependent blockade of both acid-stimulated stretching and acid-induced depression of ICSS. Nicotine antinociception was blocked in both procedures by the nonselective nAChR antagonist mecamylamine (1.0 mg/kg). In a separate study, nicotine was also evaluated for its effects on chronic pain-related depression of ICSS induced by bilateral intraplantar injection of 5% formalin or saline (100 µl per paw). Seven days after intraplantar treatment, ICSS was depressed in the formalin-treated rats in comparison to the saline controls, and nicotine (0.01-0.32 mg/kg) produced a dose-dependent reversal of formalin-induced depression of ICSS. Doses of nicotine that blocked acid-induced depression of ICSS or reversed formalin-induced depression of ICSS produced little or no change in ICSS in the absence of the noxious stimulus. These results support a role for nicotine acting at nAChRs to alleviate pain-related depression of behavior in rats.

Title: Morphine antinociception is resistant to tolerance in an assay of pain-depressed intracranial self-stimulation

Authors: *A. ALTARIFI[1], S. NEGUS[2]
[1]Pharmacol., Jordan Univ. of Sci. and Technol., Zarqa, Jordan; [2]Pharmacol. and Toxicology, Virginia Commonwealth Univ., Richmond, VA

Abstract: Mu opioid receptor agonists (such as morphine) are commonly prescribed for management of acute and chronic pain. Although analgesic tolerance can be an obstacle to clinical effectiveness of mu agonists, many chronic pain patients can be maintained for long periods on stable opioid doses, suggesting that analgesic tolerance is often modest or absent. In preclinical studies, we showed previously that acute administration of morphine or other mu agonists produced antinociception in procedures in which IP injection of dilute lactic acid served as a noxious stimulus either to stimulate a stretching response or to depress intracranial self-stimulation (ICSS) in rats. The present study compared the development of tolerance to morphine antinociception for these two distinct pain-related endpoints. Test groups received daily injections of either saline (Chronic Saline) or escalating morphine doses to a terminal maintenance dose of 10 mg/kg/day (Chronic Morphine). Afterward, subjects from both groups were tested with a sequence of four treatments: (1) morphine vehicle + acid vehicle, (2) morphine vehicle + 1.8% lactic acid, (3) 1.0 mg/kg morphine + acid vehicle, or (4) 1.0 mg/kg morphine + 1.8% lactic acid. Morphine or its vehicle was administered 30 min before acid or its vehicle, and treatment order was randomized in a Latin-square design across animals. Separate groups of rats (N=6-7 per group) were used to assess morphine effects on acid-stimulated stretching and acid-induced depression of ICSS. In the stretching procedure, acid alone increased stretching, and acid effects were greater in the Chronic Morphine group. Morphine blocked acid-stimulated stretching in the Chronic Saline group but not in the Chronic Morphine group. In the assay of acid-depressed ICSS, rats equipped with electrodes targeting the medial forebrain bundle were trained to respond under a fixed-ratio 1 schedule for 0.5 sec trains of electrical stimulation (56-158 Hz in 0.05 log increments during each 30-min session). Acid alone depressed ICSS, and acid effects were again greater in the Chronic Morphine group. However, morphine blocked acid-induced depression of ICSS in both the Chronic Saline and Chronic Morphine groups. Morphine alone produced a small but significant increase in ICSS in the Chronic Morphine group only. In summary, tolerance developed to morphine antinociception in the assay of acid-stimulated stretching but not in the assay of acid-induced depression of ICSS. These data suggest that tolerance develops at different rates to different measures of morphine antinociception in rats, and morphine antinociception is resistant to tolerance in an assay of pain-depressed behavior.

Title: A rat model for sciatic endometriosis

Authors: S. CHEN[1,2], W. XIE[2], J. A. STRONG[2], J. JIANG[1], *J.-M. ZHANG[2]
[1]Obstetrics and Gynecology, Qilu Hospital, Shandong Univ., Jian, China; [2]Dept Anesthesiol, Univ. Cincinnati Coll Med., Cincinnati, OH

Abstract: Aim of Investigation: Clinical case reports show that endometriosis of the sciatic nerve can cause mild to severe chronic leg pain, often fluctuating with the menstrual cycle. In the current study, we aimed to develop an animal model of endometriosis of the sciatic nerve for the study of its underlying mechanisms. Methods: A model of endometriosis of sciatic nerve was established in female rats by surgically implanting autologous uterine tissue adjacent to the sciatic nerve at the mid-thigh level. In some experiments the implanted tissue was removed on postoperative day (POD) 21. Estrous cycles were tested everyday for 14 days. Mechanical sensitivity of the hindpaws was assessed with von Frey filaments, and mechanical allodynia was scored by responses to a light brush stroke cross the ventral surface of the hindpaws. The ectopic tissue and adjacent ipsilateral sciatic nerve were harvested for H&E staining. Results: The sciatic nerve endometriosis model was successfully established in rats, regardless of which phase of the estrous cycle rats were in at the time of surgery. Pain behaviors were first evident on POD 5-7, and lasted approximately 10 weeks, peaking between week 3 and week 4. Pain behavior showed no correlation with the estrous cycle. In rats with the implanted tissue remove on POD 21, the mechanical hypersensitivity gradually returned to the baseline. H&E staining of implanted tissue and adjacent sciatic nerve displayed signs of robust inflammatory responses and tissue damage. Conclusions: In humans, endometriosis of sciatic nerve can cause chronic leg pain, which can be reversed by a resection of ectopic tissue. This study suggests that one possible mechanism is local inflammation at the site of lesion caused by the ectopic tissues. Further studies will focus on the ectopic activity of the affected sciatic nerve and other possible causes. This is the first report of an animal model of endometriosis of sciatic nerve.

Title: Analysis of sleep disorders under pain using an optogenetic tool: possible involvement of the activation of dorsal raphe nucleus-serotonergic neurons

Authors: *H. ITO[1], M. YANASE[2], A. YAMASHITA[2], C. KITABATAKE[2], A. HAMADA[2], Y. SUHARA[2], M. NARITA[2], D. IKEGAMI[2], H. SAKAI[2], M. YAMAZAKI[1], M. NARITA[2]
[1]Anesthesiol., Univ. of Toyama, Toyama, Japan; [2]Pharmacol., Hoshi Univ. Sch. of Pharm. and Pharmaceut. Sci., Sinagawa, Tokyo, Japan

Abstract: Introduction: Several etiological reports have shown that chronic pain significantly interferes with sleep. Inadequate sleep due to chronic pain may contribute to the stressful negative consequences of living with pain. However, the neurophysiological mechanism by which chronic pain affects sleep-arousal patterns is as yet unknown. Although serotonin was proposed to be responsible for sleep regulation, whether the activity of serotonergic neurons in the dorsal raphe nucleus (DRN) is affected by chronic pain has been studied only infrequently. On the other hand, the recent development of optogenetical tools has provided a valuable opportunity to regulate the activity in genetically targeted neural populations with high spatial and temporal precision. In the present study, we investigated whether chronic pain could induce sleep disorders while changing the activity of DRN-serotonergic neurons. Furthermore, we sought to physiologically activate the DRN-serotonergic neurons with channelrhodopsin-2 to identify a causal role for the DRN-serotonin system in promoting and maintaining wakefulness using optogenetics. Methodology: We produced a sciatic nerve ligation model by tying a tight ligature around the partial sciatic nerve. In mice with nerve ligation, we investigated a sleep patterns monitored by electroencephalogram for 24 hr. To evaluate the effect of neuropathic pain on DRN-serotonergic neurons, we performed an *in vivo* microdialysis study. Using optogenetic tools, we investigated a causal relationship among DRN-serotonergic neurons firing and sleep/wake condition in freely moving mice. Results: We found an increase in wakefulness and a decrease in non-REM sleep monitored by electroencephalogram in nerve-ligated mice. In an *in vivo* microdialysis study, extracellular serotonin levels released in the prefrontal cortex by the electrical stimulation of DRN were significantly increased in nerve-ligated mice. The optogenetical activation of DRN-serotonergic neurons produced a significant increase in wakefulness and a decrease in non-REM sleep. Furthermore, the duration of non-REM sleep episode was significantly decreased during optical stimulation. Conclusions: These results suggest that neuropathic pain accelerates the activity of DRN-5-serotonergic neurons. Although further loss-of-function experiments are required, we hypothesize that this activation in DRN neurons may, at least in part, correlate with sleep disorders under a neuropathic pain-like state.

Title: Further characterization of a rodent headache model with video analysis and EEG recording

Authors: A. MELO-CARILLO[1], C. ALEXANDRE[2], A. LOPEZ-AVILA[3], R. BURSTEIN[1], *A. M. STRASSMAN[1]
[1]Dept. Anesthesia, [2]Dept. Neurol., Beth Israel Deaconess Med. Ctr., BOSTON, MA; [3]Lab. de Neurofisiologia de la Percepcion, Inst. Nacional de Psiquiatria Ramon de la Fuente Muniz, Mexico City, Mexico

Abstract: It has been argued that there is a need for improved behavioral models of ongoing pain, as opposed to stimulus-evoked hypersensitivity, for better modeling of clinical conditions and more effective testing of new therapies. In a new behavioral model of ongoing headache pain, Melo-Carrillo and Lopez-Avila found that application of inflammatory mediators to the cranial dura in rats produced a decrease in total exploratory behavior and a concomitant increase in resting behavior, during a 45-min. observation period, compared to saline control animals (Cephalalgia 33:1096, 2013). No difference was found in total time spent body grooming. The present study pursued these observations further by investigating possible differences in the pattern of body grooming, and by using EEG recording to characterize possible differences in behavioral state during the resting periods. Following a 7-day pre-surgery habituation period, male Wistar rats (250-300g) maintained on an inverted light-dark cycle were chronically implanted with a cannula sterotaxically positioned over a 1-mm diameter craniotomy in the frontal bone, as well as EEG electrodes. After a 2-day recovery, 2ul of a mixture of

inflammatory mediators (histamine, serotonin, bradykinin 1mM, and prostaglandin E2 0.1mM) was delivered to the dura through the cannula. Control rats received saline. Video and EEG recordings were made for 15 min. before and 45 min. after the dural infusion. Two differences were found in the stimulated rats: 1) a novel pattern of body grooming, not observed in control rats, in which episodes of face grooming were interspersed within the normal rostral-to-caudal grooming sequence (face-trunk-genitals-tail); and 2) a relative absence of slow-wave activity in the EEG during the resting periods, in contrast to the increased slow-wave activity present during resting periods in control animals. These findings indicate the induction of novel behaviors, not present in control animals, following dural stimulation. Such behaviors may serve as sensitive signs of ongoing headache pain.

Title: Brain neuroplastic changes accompany anxiety and memory deficits in a model of complex regional pain syndrome

Authors: *P. SAHBAIE[1,3], M. TAJERIAN[1,3], D. LEU[2,4], W. LI[1,3], W. S. KINGERY[5], T. HUANG[2,4], J. CLARK[1,3]
[1]Dept. of Anesthesia, [2]Dept. of Neurol. and Neurolog. Sci., Stanford Univ., Palo Alto, CA; [3]Anesthesiol., [4]Geriatrics Res. Educ. and Clin. Ctr., [5]Physical Med. and Rehabil. Service, Veterans Affairs Palo Alto Hlth. Care Syst., Palo Alto, CA

Abstract: Complex regional pain syndrome (CRPS) is a painful and often chronic condition with an incidence of about 50,000 cases in the US each year. It is a major cause of work-related disability, chronic pain after limb fractures and persistent pain after extremity surgery. In addition to pain, CRPS patients often experience cognitive changes, anxiety and depression. The supraspinal mechanisms linked to these CRPS-related comorbidities are not well understood. The present study was carried out with a well characterized mouse model of tibia fracture/cast

immobilization showing the principal stigmata of CRPS observed in humans. Our central hypothesis was that fracture/cast mice manifest changes in measures of nociception, working memory and anxiety attributable to neuroplastic changes in amygdala, perirhinal cortex, and hippocampus. We demonstrate that nociceptive sensitization in these mice is accompanied by altered thigmotactic behaviors in the zero maze but not open field assay, and working memory dysfunction in novel object recognition and social memory but not in novel object location recognition. Furthermore, we found evidence of structural changes and synaptic plasticity including changes in dendritic architecture and decreased levels of synaptophysin and brain derived neurotrophic factor (BDNF) in specific brain regions. Therefore, the present findings provide novel observations regarding behavioral changes and brain plasticity in a mouse model of CRPS. In addition to elucidating some of the supraspinal correlates of the syndrome, this work supports the potential use of therapeutic interventions that not only directly target sensory input and other peripheral mechanisms, but also attempt to ameliorate the broader pain experience by modifying its associated cognitive and emotional comorbidities.

Title: The Coy Operant Conflict System: Adaptations allow testing of mechanical and cold sensitivity in mice with a spinal nerve ligation (Chung model)

Authors: *S. M. CARLTON, S. ZHOU
Dept Neurosci Cell Biol., Univ. Texas Med. Br., Galveston, TX

Abstract: Pain perception involves sensory-discriminative, motivation-affective and cognitive components. To incorporate these into animal testing, complex behaviors involving supraspinal

processing are needed. We are modifying the Coy operant conflict system for rats (Coy Labs), to test mechanical and cold sensitivity in mice. The system has 3 consecutive chambers: a light (aversive), middle (stimulus) and dark (safe) chamber. Dependent measures are latency to exit (LTE) chamber 1 (emphasizing cognitive/motivation/affective components of pain) and duration (DUR) in chamber 2 (emphasizing sensory/discriminative components of pain). C57BL6 mice were made neuropathic using the Chung model which involves a tight ligation of the L5 and L6 spinal nerves (sham animals receive surgery but no nerve ligation). To test mechanical sensitivity, rough (grit 36) sandpaper was placed on the floor of chamber 2. To test cold sensitivity, an aluminum plate was cooled to 0°C and held in place under chamber 2 floor by a lab jack. This cooled chamber 2 to 17-18°C for about 10 min, but both end chambers remained at room temperature. Mice were acclimated and trained in the Coy operant conflict system for 5 days prior to nerve ligation surgery. During training to test mechanical sensitivity, the rough sandpaper was in place in chamber 2. During training to test cold sensitivity, chamber 2 was at 17-18°C. Following training, the baseline LTE and DUR were obtained for each mouse prior to surgery. Then, at 1 and 2 weeks post-surgery, mice were retested for changes in mechanical and cold sensitivity. For mechanical sensitivity, SNL mice (n = 6) had an increased LTE compared to sham (n = 5) at 1 and 2 weeks post-surgery, however, the difference was not significant. At 1 week, SNL mice spent considerably less time in the middle chamber compared to sham but this difference was not present at 2 weeks. For cold sensitivity, SNL mice (n = 10) showed no difference in LTE compared to sham (n = 9) at 1 week but showed a significant increase in LTE at 2 weeks ($p<0.05$), hesitating to leave the light chamber and enter the middle chamber when the floor was at 17-18°C. However, DUR in the middle chamber was not affected by SNL as these mice showed the same DUR as sham mice at 1 and 2 weeks post-surgery.These data demonstrate that the Coy operant conflict system can be adapted for testing mechanical and cold hypersensitivity in SNL mice. It appears that LTE is a more consistent measure than DUR in this nerve injury model, however, it is clear that an increase in Ns in the groups tested for mechanical sensitivity are also needed.

Title: Mechanisms of 16, 16 dimethyl prostaglandin (dmPGE2) in the sensitization of capsaicin induced mechanical allodynia in male Sprague Dawley rats (a model of hyperalgesic priming)

Authors: *S. M. JAFFAL
McGill Univ., Montreal, QC, Canada

Abstract: Inflammatory pain is one of the major health problems that impose burdens to society. Although acute inflammatory processes are short lived and contribute to the healing process, chronic inflammation is an unhealthy over-response that can be detected by enhanced responses to hyperalgesia and/or allodynia. Despite of the advances in pain researches, the mechanisms underlying the development of chronic pain are not fully determined. In this study, I used a model (hyperalgesic priming) for the transition from acute to chronic pain. The model involves injection of an inflammatory insult to sensitize nociceptors to a second inflammatory mediator. Specifically, I examined the effect of intraplantar injection of 5μM dmPGE2 (an analog of PGE2) on the mechanical allodynia that is induced by injection of 50μg capsaicin (TRPV1 agonist) in male Sprague Dawley rats. In all rats, the injections were intraplantar and ipsilateral and the mechanical allodynia was measured by von Frey anesthesiometer. The results show that dmPGE2 pre-injection aggravated and prolonged capsaicin induced mechanical allodynia to one week. It also enhanced the nocifensive and guarding behaviours compared to capsaicin injected animals. In addition, I found that the mechanism of dmPGE2 in the aggravation and the prolongation of capsaicin induced mechanical allodynia includes the novel PKC isoform (PKCε) and cAMP (in the initial phase of capsaicin induced mechanical allodynia), PKA (in the prolonged phase), PLC and two mitogen activated protein kinases (MAPKs): p38 and JNK pathways (in the initial and the prolonged phases). No significant effect was found for ERK-MAPK in dmPGE2-induced effect. Then, to characterize which receptor (among the 4 EP receptors of PGE2) is involved in dmPGE2 mediated responses, I injected the animals with different agonists of EP receptors followed by capsaicin injection and measurement of mechanical allodynia. I found that only EP1 agonist (17PGE2, 50μM) significantly aggravated and prolonged capsaicin effects to 5 days in a PKC dependent manner. The difference between the effect of dmPGE2 (7 days) and 17PGE2 (5 days) in the prolongation effect and the involvement of cAMP-PKA pathway in dmPGE2 mediated responses indicates that there could be a partial involvement of other subtypes of EP receptors. Also, the strong inhibition of 17PGE2 mediated effects by the general PKC inhibitor suggests the possibility of recruiting other isoforms of PKC to EP1 signalling mechanisms. Accordingly, continuing this research and identifying the exact mechanisms downstream EP receptors in TRPV1 sensitization can have therapeutic value for pain treatment in the future.

Title: Differential components relating to pain expectation were isolated after pain-related learning in a rodent model

Authors: ***N. WANG**, S.-G. LI, J.-Y. WANG, F. LUO
Inst. of Psychology, Chinese Acad. of Sciences; Key Lab. of Mental H, Beijing, China

Abstract: Previous studies have tried to separate the human brain responses associated with expectation of pain from those associated with direct experience of pain. Although there are many human studies focus on models of pain expectation, we still need animal models to explore the neuronal mechanisms. Our aim was to establish a rodent model to assess the cue-based expectancy and its effects on nociceptive behaviors. A novel balanced crossover design that commonly used in human disciplines was utilized to address these issues. On the basis of tone-laser paired trace conditioning paradigm, a series of tasks were conducted from simple conditioning to more difficult signal discrimination task in rats. We successfully isolated four component relating to pain expectation, including expectancy-based pain, expectancy of pain, pain, and normal state. Significant voluntary withdrawal behaviors in response to pain predictive

cues were brought about after a series of pain-related conditioning task with increasing cognitive load. Moreover, the presentation of pain cue followed by sham stimuli caused even stronger responses than those by no-pain cue followed by actual stimuli. The present findings suggest that the expectation per se could produce robust nocifensive behaviors that were comparable in magnitude to the responses elicited by actual noxious stimuli in normal animals. The current study may offer a new model to explore the neurophysiological and neurochemical mechanisms at molecular level underlying the pain expectation as well as the reciprocal modulatory effects between pain and expectation.

Title: Effect of tapentadol on neuropathic pain in arthritis models using automated and manual methods

Authors: V. GOURA, A. VUYYURU, R. ABRAHAM, *P. JAYARAJAN, R. NIROGI
Suven Life Sci. Ltd, Hyderabad, India

Abstract: Tapentadol is a new class of drug that possesses analgesic action, which results from contribution of μ-opioid receptor agonism and norepinephrine reuptake inhibition. It has been approved by US FDA for moderate to severe chronic pain and neuropathic pain associated with diabetic peripheral neuropathy. Pain and disability are the primary symptoms of arthritis. There is paucity in preclinical evaluation for Tapentadol on neuropathic pain in arthritis models. Hence we evaluated the effect of Tapentadol on Sodium Mono Iodoacetate (MIA) and Complete Freunds Adjuvant (CFA) induced osteoarthritis and rheumatoid arthritis respectively. We evaluated neuropathic pain conditions like hyperalgesia and allodynia using manual (von Frey monofilaments, Randal Selitto analgesymeter) and automated (Dynamic plantar aesthesiometer) methods. We observed significant efficacy of Tapentadol in both the manual and automated method of assessment in both osteoarthritis and rheumatoid arthritis pain models. The efficacy of tapentadol is in agreement with the clinical analgesic data of tapentadol in osteoarthritis induced pain. Similarly, the analgesic effect of tapentadol in rheumatoid arthritis induced pain in rats may be a viable option for clinical studies.

Title: Effects of 5-fluorouracil on stomatitis-induced pain in rats

Authors: K. YAMAGUCHI[1], *N. HARANO[3], S. HITOMI[2], K. ONO[2], T. SAGO[1], S. WATANABE[1], K. INENAGA[2]
[1]Dent. Anesthesiol., [2]physiology, Kyushu Dent. Univ., Kitakyushu, Japan; [3]Control of Physical Function, Kyusyu Dent. Univ., Kitakyusyu, Japan

Abstract: Stomatitis is frequently developed as a side effect of anti-cancer therapy in head and neck cancer patients and induces severe pain during eating and speaking. However, there are no effective treatments for stomatitis-induced pain. In this study, to examine relationship of anti-cancer drugs with stomatitis, we investigated effects of the representative anti-cancer drug 5-fluorouracil (5-FU) on stomatitis-induced pain in rats. We intraperitoneally (i.p.) administered 5-FU (40mg/ml/kg) or saline as control at three times in male Wistar rat (7-8 weeks old). To make stomatitis, rats were treated in the oral mucosa of the mandibular vestibule with a filter paper (9 mm^2), which was soaked into 50% acetic acid, for 30 seconds under anesthesia (pentobarbital 50mg/kg, i.p.). In the stomatitis model with and without pre-administration of 5-FU, a facial rubbing behavior that is a sign of orofacial pain was measured for 3 min following direct application of capsaicin solution in the oral mucosa by using the dropping method that we have recently developed for intraoral pain assessment in conscious rats. 5-FU administration decreased remarkably food consumption and body weight, compared with control group. Stomatitis with ulcer was observed in both groups on day 2 after acetic acid treatment. Until day

5, although stomatitis was visibly disappeared in the control group, it was still remained in the 5-FU group. Facial rubbing behavior following capsaicin application showed same level in both groups before making stomatitis and on day 2. However, the behavior was significantly increased in 5-FU group on day 5, compared with control group. From these results, 5-FU administration leads slow healing process of stomatitis and consequently induces long-lasting stomatitis-induced pain.

Title: Electrolytic lesion of the infralimbic cortex attenuates distraction analgesia in rats

Authors: *C. T. MCNABB[1], M. M. WHITE[1], C. A. SALCIDO[1], P. N. FUCHS[2]
[1]Psychology, [2]Psychology and Biol., Univ. of Texas at Arlington, Arlington, TX

Abstract: Distraction has been shown to reduce pain in clinical and experimental settings, but the underlying neurobiology of distraction's analgesic effect is not fully understood. In humans, the presentation of competing attentional stimuli (i.e. pain and cognitive tasks) has been associated with activation of the orbitofrontal cortex (OFC). There is evidence that the human OFC is functionally homologous to the infralimbic (IL) region of the medial prefrontal cortex in rats; however, the IL has never been selectively investigated in animal research of distraction analgesia. Therefore, this study utilized stereotaxic electrolytic lesions of the IL to elucidate the region's role in a rat model of distraction analgesia. One hundred eleven male Sprague Dawley rats between 7-9 months old were randomly assigned to receive either a bilateral electrolytic lesion to the IL or a sham surgical procedure. Rats were allowed one week to recover and were then habituated to an empty testing chamber for 10 minutes once a day for 7 days. On the eighth day, rats underwent a formalin test in the same chamber. Each rat was randomly assigned to receive a subcutaneous injection of .01 ml of either 1% or .5% formalin into the plantar surface of the left hindpaw. Each rat was immediately placed in the testing chamber, which was randomly assigned to either remain empty or to contain an upside down falcon tube to serve as a distracting object during the test. An observer quantified the amount of time spent with the paw

down, up, and licking/biting the paw in order to generate formalin pain scores organized into 5-minute time bins. Animal movement patterns were also recorded with behavioral tracking software. Repeated measures ANOVA of the formalin pain scores unexpectedly showed a main effect for lesion, $F(1, 103) = 5.27$, $p < .05$, as well as a lesion by distractor interaction, $F(1, 103) = 4.39$, $p < .05$. Posthoc comparisons revealed that the IL lesion was associated with significantly lower pain scores than the sham condition in the empty chamber, $p < .01$, indicating that the IL lesion reduced formalin pain. Additionally, there was a significant difference in formalin pain scores between empty and distractor conditions in the sham animals, $p < .05$, but not in the IL animals, $p = .45$, ns. These results demonstrate that the distractor had an analgesic effect on the sham animals, but that the distraction effect was absent in the IL animals. We conclude that the bilateral electrolytic IL lesion attenuated distraction analgesia and that the infralimbic cortex is a critical mediator of distraction analgesia in rats.

Title: Assessing the aversive nature of pain with an operant approach/avoidance paradigm

Authors: *C. A. SALCIDO, A. L. HARRIS, C. T. MCNABB, M. M. WHITE, P. N. FUCHS
Psychology, Univ. of Texas at Arlington, Arlington, TX

Abstract: Preclinical assessments of pain have been criticized for failing to adequately characterize the complexity of the clinical pain experience in humans. Recently developed preclinical pain assessments such as the Place Escape/Avoidance Paradigm (PEAP) have improved upon this shortcoming by quantifying the aversive component of pain more directly. Nevertheless, the PEAP is not designed to evaluate the impact of competing homeostatic drives, such as hunger, which may influence pain-related behavior. Therefore, we developed an approach-avoidance paradigm that measures the aversiveness of pain by allowing a rat to either satisfy hunger or avoid noxious stimulation. Twenty-six male Sprague Dawley rats were placed on a food-controlled diet and trained to lever-press for appetitive rewards in an operant chamber. On test day, animals were randomly assigned a subcutaneous injection into the plantar surface of

the hindpaw of either 1% carrageenan or normal saline. Animals were then placed in a modified operant chamber sitting atop a mesh platform, and a lever was presented for 10 seconds at 30-second intervals for a total of 30 minutes. During the test, lever presses were immediately followed by stimulation of the injected paw with a suprathreshold Von Frey filament. This presented the rat with an approach-avoidance conflict in which it had the opportunity to receive noxious mechanical stimulation to the injected paw in order to obtain appetitive reward or to avoid noxious stimulation and forego appetitive reward. Two separate one-way ANOVAs showed significant differences between carrageenan and saline groups in mean latency to lever-press, $F(1, 24) = 10.10$, $p < .01$, as well as the percentage of trials yielding lever-presses, $F(1, 24) = 7.02$, $p < .05$, respectively. The results of this study indicated that the noxious stimulation of carrageenan-induced inflammation resulted in the suppression of reward-seeking behavior and suggested that the motivation to avoid pain superseded the motivation to alleviate hunger. Future research should be conducted to further validate the paradigm and to investigate the neural mechanisms underlying approach-avoidance conflicts that are often present in pain patients.

Title: Clinically relevant endpoints in a recurrent nitroglycerin migraine model in rats

Authors: *K. J. SUFKA[1], S. M. STASZKO[2], A. P. JOHNSON[2], M. E. DAVIS[2], R. E. DAVIS[2], T. A. SMITHERMAN[2]
[1]Psychology & Pharmacol., [2]Psychology, Univ. of Mississippi, Oxford, MS

Abstract: Diagnostic criteria of migraine include a minimum of five recurrent episodes of severe unilateral head pain with sensitivity to light and sound, exacerbation by activity, and nausea/vomiting, among other signs; chronic migraineurs often show co-morbid stress-related disorders. Rodent models have induced migraine via nitroglycerin (NTG) and subsequently measured allodynia and/or hyperalgesia, but neither of these endpoints are diagnostic criteria. In a series of studies, we show in male Sprague-Dawley rats that, in contrast to a single NTG (10 mg/kg/2ml IP) administration, both 3 and 5 NTG injections over a 2 week period produce

decreased time in the light portion of and decreased photo-beam breaks (hypoactivity) in a light-dark (L/D) box compared to vehicle controls 2 hrs post final NTG administration. Patterns of weight change over this period were indicative of nausea and appetite loss. Interestingly, 1, 3, and 5 NTG injections did show modest changes in the rat grimace scale but did not affect responses on thermal allodynia measures; 3 and 5 NTG injections did not alter measures of anxiety (EPM) or depression (FST) 24 hrs post final NTG episode. Finally, we show that 0.3 and 1.0 mg/kg sumatriptan given IP 30 min after NTG produces a dose-dependent attenuation of both migraine hypo-activity and loss of body weight; time in light portion of L/D box under sumatriptan was in predicted direction but not significant. Collectively, the 3 or 5 NTG dosing migraine model with light-dark box measures of light sensitivity and activity and body weight changes may reflect a more clinically relevant episodic migraine simulation than existing rodent models.

Title: RGS4 modulates sensory and affective components of chronic pain states

Authors: *F. CARR[1], S. GASPARI[1], M. STRATINAKI[2], V. MITSI[1], V. ZACHARIOU[1]
[1]Neurosci., Mount Sinai Sch. of Med., New York, NY; [2]Pharmacol., Univ. of Crete, Heraklion, Greece

Abstract: Regulator of G protein signalling 4 (RGS4), an intracellular modulator of several monoamine and opioid receptors, is expressed at high levels in pain-associated CNS regions, including the dorsal horn and medial prefrontal cortex (mPFC). We have previously demonstrated a role for RGS4 in modulating analgesic properties of opiates in acute pain states, and efficacy of tricyclic antidepressants in chronic neuropathic pain. In the present study we investigated the contribution of RGS4 to both sensory and affective components of chronic inflammatory and neuropathic pain states. We used global RGS4 knockout mice and targeted

depletion using viral mediated gene transfer to examine the contribution of RGS4 to several pain models. The formalin test was used as a measure of sub-chronic pain, intraplantar injection of Complete Freund's adjuvant was used as a model of chronic inflammatory pain, and spared nerve injury (SNI) was used as a model of neuropathic pain. Several behavioural paradigms were then used to assess sensory symptoms (nociceptive licking behaviour in the formalin test, and mechanical allodynia and thermal hyperalgesia in the CFA and SNI models) and affective components (anxiety- and depression-like behaviours) in these pain models. Global RGS4 knockout mice displayed reduced nociceptive behaviours in the second, but not the first, phase of the formalin test. Although thermal nociception in the CFA model was unaffected by genotype, mechanical allodynia was significantly attenuated in RGS4 KO mice. RGS4 KO mice spent less time immobile in the forced swim test, and consumed more sucrose in the sucrose preference test at 3 weeks post CFA injection, indicating a reduction in depression-like behaviours associated with the inflammatory pain state. Analgesic efficacy of the delta opiate agonist SNC80 (5mg/kg, s.c.) was also increased in the RGS4 KO group, at 24h post CFA. In contrast to the pro-nociceptive role of RSG4 identified in inflammatory pain models, targeted depletion of RGS4 in the medial prefrontal cortex (mPFC) did not alter mechanical allodynia in neuropathic pain. In addition, mPFC specific depletion increased depression-like behaviours in the sucrose preference and social interaction tests, at 6 and 10 weeks post SNI. In conclusion, we have identified a complex role for RGS4 in modulating the sensory and affective dimensions of inflammatory and neuropathic pain.

Abstract: It is well known that oral mucosal pain in head and neck cancer patients treated with chemo-radiotherapy is persistent and intractable, resulting under-nutrition and low quality of life. Recently, it has clinically reported that Japanese herbal medicine Hangeshashinto is effective on the oral mucosal pain. However, mechanism of the analgesic effect has not well known. In this study, we investigated the oral ulcer-induced mucosal pain and efficacy of Hangeshashinto to the pain in rats using new behavioral technique to keep mouth open for direct stimulations. Treatment with acetic acid in the labial fornix region of the inferior incisors developed obvious oral ulcer, showing severe infiltration of inflammatory cells and epidermolysis in histology. Application of Hangeshashinto to oral ulcer region was not any changed the pain-related grooming behavior, suggesting Hangeshashinto does not have pungent effects on intraoral region. Head withdrawal threshold to mechanical stimulation to the oral mucosa was significantly decreased in oral ulcer compared to sham. The decrement of mechanical threshold was recovered to naive level from 30 minutes to 3 hours after topical application of Hangeshashinto to the oral ulcer region. From these results, Hangeshashinto recovered oral ulcer-induced mechanical allodynia long-lastingly.

Title: Chronic, mild stress prior to spinal cord injury increases post-injury allodynia in male Sprague Dawley rats

Authors: *A. MOHAIMANY-APONTE[1], M. T. ROBBINS[2], C. L. FLOYD[3]
[2]Dept. of Anesthesiol., [3]Dept. of Physical Med. and Rehabil., [1]Univ. of Alabama At Birmingham, Birmingham, AL

Abstract: Spinal cord injuries (SCI) affect 12,000 persons annually in the United States, and over 320,000 persons are currently living with chronic SCI. In addition to loss of motor and sensory function, SCI induces neuropathic pain in up to 66% of SCI patients. Neuropathic pain can be constant or episodic, and is a main contributor to lower quality of life. Although the underlying mechanisms and modulators of neuropathic pain are poorly understood, inflammation is hypothesized to contribute to the development and maintenance of neuropathic pain. Moreover, stressors have been shown to cause an inflammatory response and increase hypothalamic pituitary axis sensitivity; however, no studies have investigated the effects of chronic, mild stress (CMS) on subsequent development of neuropathic pain after SCI. Thus, the goal of this study was to evaluate the hypothesis that CMS prior to SCI may increase the incidence or severity of neuropathic pain in a clinically-relevant model of cervical SCI in adult male Sprague Dawley rats. Rats were divided into the following groups: Uninjured control (received laminectomy only; LAM) + CMS exposure or SCI + CMS exposure. Prior to the induction of SCI, rats in the CMS group were exposed to 30 intermittent foot shocks (1mA) for 15 minutes for 7 consecutive days. Rats in the no stress group were placed in the chambers without foot shocks. SCI groups received a hemicontusion at the fifth cervical region of the spinal cord. After SCI, assessments of pain and functional recovery occurred weekly on separate days for 30 days. Evaluations of neuropathic pain included thermal hyperalgesia (Hargreaves test), mechanical (Von Frey) and cold allodynia (acetone test). Motor function was assessed via dominant paw usage (cylinder test). We found that rats in the SCI group exhibited significantly decreased motor function in the ipsilateral forepaw compared to control groups; however, there was no stress effect on motor function. Rats that received CMS prior to SCI showed increased cold allodynic responses, but no stress effect in thermal hyperalgesia or mechanical allodynia was observed. These findings indicated that mild stress prior to SCI increases subsequent neuropathic pain. Future investigations will be conducted to elucidate potential mechanisms and therapeutics.

Title: Sleep deprivation potentiates neuropathic pain induced by chronic constriction injury of sciatic nerve in mice

Authors: *G. R. MOLSKA[1], L. I. G. PAULA FREIRE[2], C. E. N. GIRARDI[2], D. SUCHEKI[2]
[1]Psicobiologia, Univ. Federal De São Paulo, Sao Paulo, Brazil; [2]Univ. Federal de São Paulo, São Paulo, Brazil

Abstract: Previous studies have shown that sleep restriction or deprivation increases pain sensitivity in healthy volunteers and patients with painful diseases. In addition, sleep deprivation potentiates acute, inflammatory and chronic pain in animal models. The aim of this study was to investigate whether paradoxical sleep deprivation (PSD) enhances thermal and mechanical hypernociception in mice subjected to chronic constriction injury of the sciatic nerve (CCI). Male C57BL/6J mice (3 month-old, n = 20, 5/group) were submitted to CCI and after recovery (2 to 3 days), were subjected to sleep deprivation for 72 hours. Pain sensitivity was assessed by von Frey and hot plate tests before surgery (baseline measurement), immediately after PSD, and 1, 2 and 7 days after PSD. Analysis was done with the following groups: control naïve (CTL), CCI, PSD and CCI+PSD. Mice subjected to CCI, PSD and CCI+PSD showed a pain threshold lower than CTL. Sleep deprivation potentiated peripheral nerve injury-induced pain, since the pain threshold in CCI+PSD group was significantly lower compared to CCI and PSD groups, in both tests. These results demonstrate that animals with peripheral nerve injury submitted to paradoxical sleep deprivation have higher pain sensitivity. Based on these results, further studies will be conducted to elucidate the mechanisms involved in paradoxical sleep deprivation potentiation of hypernociception.

Title: Non-invasive, *in vivo* assessment of the modulating effect of persistent pain on the output of the mouse central pattern generator for mastication

Authors: *C. G. WIDMER[1], J. MORRIS-WIMAN[2]
[1]Orthodontics, Univ. of Florida, GAINESVILLE, FL; [2]West Virginia Sch. of Osteo. Med., Lewisburg, WV

Abstract: The masticatory central pattern generator (CPG) controls the activation rhythm and excitatory drive to masticatory motoneurons during incising and chewing with refinement of activity by peripheral sensory afferent input. Previous animal studies have evaluated the CPG after implantation of EMG electrodes or placement of a skull-mounted detector for jaw motion analysis. These studies evaluated a limited number of chewing/incising cycles and did not measure the forces generated during these activities. We have developed a non-invasive technique that can be used in the mouse home cage environment that evaluates three-dimensional incising forces over a 24 hour period. These data can be analyzed to determine the incising frequency, incising peak force and loading and unloading time, thus evaluating rhythm and excitatory drive of the CPG. We have also developed a masticatory muscle persistent pain model that causes a mild/moderate pain without muscle tissue destruction for a period of 4-5 weeks. The purpose of this study was to evaluate correlations of force output parameters in the absence and presence of persistent pain to determine the effect of pain on the CPG for mastication in the natural environment. *Methods:* CD-1 mice (n=4 females) were evaluated for incising force over a 24 hours period for two baseline and two pain time points (T7 and T14). Two injections (separated by five days) of acidic saline into the left masseter muscle created a persistent pain condition. Interspike intervals (ISI), peak amplitudes and temporal parameters (loading and unloading times) were assessed. Correlation coefficients were calculated using multiple linear regressions (Statistica 12, StatSoft, Inc.) with interspike interval as a dependent variable and peak forces and temporal parameters as independent variables. Partial correlation coefficients were calculated to determine the relative contributions by the independent variables. *Results:* During baseline conditions, variation in interspike intervals was significantly associated with the independent variables (peak force, temporal parameters) with correlation coefficients ranging from 0.13-0.87 (median = 0.53). ISI most commonly co-varied with peak 1 force amplitude and peak 2 load time duration. Pain was associated with modulation of the CPG output by slowing the rhythm of incising (mean reduction = 0.31 Hz) and was associated with higher correlations among the ISI and peak force and loading times (median = 0.61). *Conclusions:* Persistent

masticatory muscle pain affects the masticatory CPG by slowing incising rhythm and inhibiting afferent input to reduce variability of CPG output parameters.

Title: Behavioral characterization of a tamoxifen-inducible Nav1.7 KO mouse

Authors: *T. WU, L. DENG, K. SCEARCE-LEVIE, D. HACKOS
Neurosci., Genentech, South San Francisco, CA

Abstract: Selective inhibition of the voltage-gated sodium channel Nav1.7 has been proposed as a potentially effective novel therapeutic strategy for the treatment of pain. Strong support for Nav1.7 as a pain target comes from loss-of-function mutations in humans that result in congenital insensitivity to pain (CIP), as well as gain-of-function mutations that cause chronic painful disorders such as inherited erythromelalgia (IEM) and paroxysmal extreme pain disorder (PEPD). While total deletion of Nav1.7 in mice causes a lethal perinatal phenotype (possibly due to anosmia that also occurs in human CIP patients), nociceptor-specific knockout mice are viable and show increased pain thresholds. Here, we examined whether the absence-of-pain and anosmia phenotypes observed in human CIP patients can be replicated via an acute (as opposed to life-long) loss of the Nav1.7 channel from dorsal root ganglion neurons in adulthood by generating a tamoxifen-inducible Nav1.7-floxed mouse model. This conditional knockout model may mimic some aspects of therapeutic pharmacological inhibition of Nav1.7 in humans. Mice bearing a floxed version of the Nav1.7 gene were crossed with mice expressing CreERT under the control of the pCAAG promoter. A cohort of bigenic mice and Nav1.7-floxed single transgenic controls were dosed with tamoxifen at age 13 weeks to induce Cre-Lox recombination and Nav1.7 deletion. Pilot experiments using qPCR confirmed that this dosing regimen successfully knocks out Nav1.7 mRNA in DRG neurons in less than 1 week. Mice were behaviorally characterized before and after Nav1.7 deletion in assays of nociception (hot plate test) and olfactory function (hidden food test), as well as measures of general behavior, weight, locomotor activity, and grooming behavior. Nav1.7 cKO mice showed a reduced response to acute thermal stimuli on the hot plate test by 12 days post-dose, and a complete lack of response

by 26 days post-dose, confirming an inducible CIP-like phenotype. General health, activity, and behavior were not different between WT and cKO mice and remained unchanged with Nav1.7 deletion. Olfactory function also appeared to remain intact. We conclude that this model of Nav1.7 deletion in adulthood is sufficient to reduce pain responsiveness, providing proof-of-concept that pharmacological inhibition of this channel may reduce pain perception in humans.

Abstract: Bone is the third most common site for metastasis representing a poor prognosis in cancer patients. Metastases to the spine are common source of pain; fractures; hypercalcemia; and neurological deficits reducing patients' quality of life. Microfractures occur in metastatic regions of cancerous bone that can no longer handle ordinary loading, causing spine deformation and nerve impingement. As the disease progresses, pain increases and it becomes more difficult to treat. A key obstacle in the study of this disease is the lack of reliable, and reproducible animal models to study cancer pain. Behavioral evaluation was conducted in a group of 20 athymic rats: 6 spine tumor-implanted (human mammary adenocarcinoma); 7 sham and 7 control rats. Randal-Sellito test was used to evaluate the nociceptive response in rats. Tumor growth was monitored by BLI and CT. Pain response was significantly reduced (Day 45) in time (C= 11±6.8, S=11±8.2 and T=1.7±0.82 sec) and pressure (C=435±59, S=428±71 and T=320±58 grams) applied in

tumor rats compared with control or sham; a slight non-significant reduction was observed in the paw withdrawal in tumor implanted-rats. BLI imaging revealed severe tumor invasion in the lower spine that was qualitatively related with lytic lesions, characterized by a decrease in the density of the bone in lumbar spine consistent with tumor location on bioluminescence. There was near-complete ablation of the posterior elements of the spine. Locomotion gait analysis showed a disruption in the normal pattern of the rat's gait. Our intraspinal metastatic tumor model animals showed locomotor and sensory signs that are in accordance with some of the clinical manifestations in humans. These signs included a locomotor deficit and an increase in noxius sensation. Our model offers a reliable method to evaluate alternative approaches to treat pain in patients with metastatic spine disease.

Title: Assessment of pain outcomes in rodent models of severe spinal cord injury

Authors: C. A. G. LEE-KUBLI[1], M. INGVES[2], K. W. HENRY[2], M. TUSZYNSKI[1,3], *W. M. CAMPANA[2]

Abstract: Several candidate therapies for promoting regeneration after spinal cord injury are advancing toward clinical testing. It is essential that candidate therapies are evaluated for effects on pain outcomes, particularly because chronic neuropathic pain is a common problem after SCI and results at least in part from aberrant sprouting. Accordingly, regenerative strategies, by promoting axonal growth, could improve or worsen pain outcomes. Moreover, pain outcome testing should be performed in models of severe SCI which more accurately reflect the severity of most human injuries. We characterized pain-related behaviors and their associated cellular mechanisms in adult rats that underwent severe, T3 complete transection. This severe injury was associated with emergence of above-level neuropathic pain behaviors, including tactile allodynia and spontaneous forepaw lifting. This was associated with significantly greater expression of the activated microglial marker Iba1 ($P<0.05$) in the C8 spinal segment. GFAP expression also increased at C8 ($P<0.05$), suggesting that astrocytes may be involved in the maintenance of chronic pain. Complete T3 transection also resulted in enhanced withdrawal reflex to cold cutaneous stimuli in the hindpaws and prolongation of heat withdrawal latency, changes that likely reflect perturbations of local reflex circuits below the injury. Lumbar spinal cord segments exhibited significantly reduced GAD67 ($P<0.05$) and increased Iba1 ($P<0.05$) and CGRP ($P<0.05$) expression. While enhanced withdrawal reflexes below the level of the lesion may not impact the perception of pain in rats with a T3 full transection, they may be of concern if neural regenerative or neuroprotective therapies re-establish connectivity with the brain. These data begin to establish the pattern of changes that occur above and below the level of a severe spinal cord lesion site, and will be valuable for evaluating candidate therapies for SCI, including neural stem cell implants (Lu et al., Cell 2013). Studies underway are being extended to perhaps the most clinically relevant model of spinal cord injury, severe contusive injury.

Title: Closed head injury promotes a selective trigeminal hyper-nociception: implications for the acute emergence of posttraumatic headache

Authors: T. BENROMANO[1], R. DEFRIN[2], A. H. AHN[3], J. ZHAO[4], C. G. PICK[1], *D. LEVY[4]

Abstract: Headache is one of the most common symptoms following traumatic head injury, but the mechanisms underlying the emergence of such posttraumatic headache (PTH) remain unknown. These mechanisms may be related to local injury to deep cranial tissues leading to enhancement in cranial nociception, or could involve damage to supra-spinal pain processing pathways, as a result of brain injury. Here we tested the hypothesis that following head trauma there is an acute preferential enhancement of nociception from deep cranial tissues. We show that at 48 hours after an experimental model of closed head injury in mice, there was an acute enhancement in localized nociceptive responses to a noxious stimulus evoked by injection of dilute formalin into a deep cranial tissue, the calvarial periosteum. In parallel studies, we show that closed head injury did not lead to facilitation of the nociceptive responses following injection of formalin into an extracranial tissue, the hindpaw. Using a histological analysis of the calvarial periosteum 48 hours following closed head injury, we further demonstrate an increase in the number of activated mast cells, indicating a local inflammatory response. Our data provides evidence that mild head injury gives rise to enhanced processing of nociceptive information emanating from deep cranial tissues but does not affect nociceptive responses at non-cranial tissues. We therefore propose that in this head trauma model, there is peripheral sensitization of primary afferents innervating deep cranial tissues, such as the periosteum, rather than the enhancement of supra-spinal pain processing. Trauma evoked acute inflammatory responses within the calvarial periosteum could play a role in promoting cranial nociception and the emergence of PTH.

Title: Characterization of two animal models of orofacial pain

Authors: *H. DE BRITO GARIEPY, A. RAMSEY, E. PODBORITS, C. LEE, J. GIBBS
Col. of Dent. - Depart. Endodontics, NYU New York Univ., New York, NY

Abstract: Background: Orofacial pain is a common complaint that affects the lives of millions of people around the world. It impacts important physiological functions, such as chewing, swallowing, talking and laughing. Neuropathic pain in the trigeminal system is frequently observed clinically, but the mechanisms involved are still largely unknown. Microglia and astrocyte activation is believed to play a role, however this process is poorly understood, particularly in the trigeminal system. The present study was undertaken to characterize two murine models of orofacial pain. Methods: Under ketamine/xylezine anesthesia, mice received either bilateral ligation of the mental nerve (MNI) or a dental pulp injury (DPI) in the first maxillary molar. To measure mechanical pain, von Frey filaments were used with the up-down method. c-Fos expression was induced using a cold air burst either in the first maxillary molar (DPI) or directly onto the lower lip (MNI) in order to measure cold-evoked nociceptive input in the central nervous system. Quantitative PCR was performed to evaluate transcript levels of two nerve injury-associated genes, NPY and ATF-3, 21 days following either injury. Results: MNI and DPI mice showed persistent (>21 days) mechanical allodynia in the orofacial region, which was reversed by the anticonvulsant drug gabapentin (10mg/kg, i.p.). ATF-3 protein and mRNA and NPY mRNA expression was confirmed in the mandibular (MNI) and maxillary (DPI) division of the trigeminal ganglion by immunohistochemistry and PCR in injury vs control animals. GFAP and IBA-1, glial markers were increased in both models of orofacial pain in comparison to sham operated-mice. Repeated cold stimulation caused a significant increase of Fos expression in different areas of the trigeminal nucleus in both mice models. Conclusion and implication: Our results provide behavior and molecular data characterizing two murine models

of orofacial pain. Furthermore, the activation of glial cells in the trigeminal system are involved in the maintenance of orofacial mechanical allodynia. Characterizing differences between two animal models of orofacial pain will help develop a novel therapeutic target for neuropathic pain.

Title: NeurotropinR) ameliorates depression-like behavior in chronic pain via induction of brain-derived neurotrophic factor

Authors: *T. ISHIKAWA[1], S. YASUDA[1], H. FUJIMURA[1], K. FUKUHARA[1], K. ISHIKAWA[1], Y. IDA[1], Y. IWANAGA[1], T. IBUKI[2]
[1]Div. of Neurosciences, Yamaguchi Univ. Grad. Sch. Med., Yamaguchi, Japan; [2]Dept. of Anesthesilogy, Grad. Sch. of Med. Science, Kyoto Prefectural, Kyoto, Japan

Abstract: Background and Aims: Neurotropin (NTP) is a non-protein extract isolated from inflamed skin of rabbits inoculated with vaccinia virus, and used clinically for treatment of neuropathic pain. Moreover, NTP may activate the descending pain inhibitory system. Depression-like behavior is often complicated by chronic pain. However, little is known about NTP mediated preventing effect on mood disorder in chronic pain and its molecular mechanisms. We aimed to investigate the effects of NTP based on brain-derived neurotrophic factor (BDNF)-mediated signaling and gene expression in chronic pain. In addition, these effects of NTP were compared with other, pregabalin which is an anticonvulsant, anxiolytic analgesic used to treat neuropathic pain and fibromyalgia. Material and Methods: A chronic constriction injury (CCI) model was constructed in Sprague-Dawley rats. The pain response was assessed using the paw withdrawal latency (PWL) and depression was assessed by the immobility time in a forced swim test (FST). NTP was orally administered in dose of 50 NU (Neurotropin Unit) and 100 NU/kg for 7 days from day 7 after CCI. To ensure analgesic and anti-depressant effects of NTP, either anti-BDNF antibody, K252a (tyrosine kinase inhibitor) or 5,7-dihydroxy tryptamine (5,7-DHT, selective toxin of 5-HTergic neuron) was injected icv. Changes in pERK1/2 (immunohistochemistry), 5-HT and BDNF (ELISA), and BDNF mRNA (RT-PCR) were

measured in the anterior cingulate cortex (ACC) and rostral ventromedial medulla (RVM) 14 days after CCI. Results: After CCI, the rats showed a decrease in PWL associated with extension of the time of immobility. NTP reduced the decrease in PWL and the increased FST in a dose-dependent manner while pregabalin did not affect any of FST. These effects of NTP were reversed by anti-BDNF antibody, K252a, and 5,7-DHT, but analgesic effects of pregabalin were not reversed by K252a. NTP normalized the CCI-induced excessive activation of pERK1/2 associated with decreased pCREB and BDNF mRNA in ACC and RVM, and these changes were reversed by 5,7-DHT. In contrast, pregabalin did not affect them in chronic pain Conclusion: NTP ameliorated chronic pain and pain-related negative emotion by normalizing the induction of BDNF associated with 5-HTergic system. Pregabalin showed the analgesic effects and no anti-depressant effects without mediating BDNF pathway. These results suggest that NTP may represent the additional drug strategies against chronic pain associated with depression.

Title: Effects of chronic pain on activation of inflammatory brain mechanisms and development of depressive-like behaviors

Authors: M. CARDER, M. LEONG, M. LENDE, K. WATSON, R. FIRKINS, L. YUAN, *V. DURIC
Physiol. and Pharmacol., Des Moines Univ., Des Moines, IA

Abstract: Clinical reports indicate that many chronic pain patients also develop symptoms of mood disorders, especially major depressive disorder (MDD); however, the underlying neural mechanisms linking chronic pain conditions and depressive behaviors are still poorly understood. Our previous studies have demonstrated that rodent models of chronic pain mimic some of the stress-like alterations in intracellular signaling and cellular architecture (e.g., decreased MAPK signaling and reduced rate of neurogenesis) within the hippocampus, a limbic brain region involved in regulation of mood. Furthermore, recent reports suggest that stress-induced activation of interlukin-1-beta (IL-1ß)-mediated inflammatory mechanisms suppress

neurogenesis in the adult rat hippocampus and, therefore, may present novel factors contributing to the depressive-like effects observed in chronic stress models of depression. Thus, in this study, we examined the effects of persistent pain on activation of immune-inflammation processes in the limbic brain regions. Male rats were initially exposed to either injection of complete Freund's adjuvant (CFA; model of chronic inflammatory pain) or spared nerve injury (SNI; model of chronic neuropathic pain). Both pain models produced robust mechanical hypersensitivity over the 21 day period, accompanied by depressive-like phenotype. In parallel with the behavioral effects, exposure to pain also induced changes in expression of proteins involved in microglial pro-inflammatory signaling pathways that resemble previously observed responses to stress and depression. Preliminary results indicate that pain evoked upregulation of specific members of Nod-like receptor (NLR) family of inflammasome multiprotein complex within the hippocampus. The results of this study may ultimately contribute towards the identification of new treatment targets and the development of novel clinical strategies to diminish the mental health consequences of chronic pain.

Title: Acute ketamine attenuates long-lasting neuropathic pain-induced social avoidance in mice

Authors: *Z.-C. YANG, P. ZHANG, D.-J. GE
Huai'An First People's Hosp., Jiangsu, China

Abstract: Previous studies reported that chronic neuropathic pain induced depressive behaviors like anhedonia and despair which could be reversed by acute ketamine treatment both in animal and patients. Here, we found that long-lasting neuropathic pain also induce social avoidance, another core syndrome of major depressive disorder. In a chronic constriction injury (CCI) model of sciatic nerve in mice, we found that CCI surgery induced a long-lasting stable thermal hyperalgesia in the affected hindpaws when compared to unaffected hindpaws, or naïve control and sham animals. Twenty-eight days, but not 7 days following CCI surgery, mice developed significant social avoidance shown as decreasing interaction durations with a strange retired

aggressor, and increasing corner durations in social interaction test. And no significant changes were observed in the distances animals travelled and the mean velocity. A single low dose of ketamine (40mg/Kg or 20mg/Kg, intraperitoneal injection) administrated 24 hours before social interaction test significantly reversed CCI-induced decrement in interaction durations and increment in corner durations, but failed to affect the paw withdrawal latencies. In the future, we will investigate if CCI could induce social avoidance in mice to their littermate, and the underlying molecular mechanisms of neuropathic pain-induced social avoidance in the brain. This study indicates that long lasting neuropathic pain induces social avoidance behavior, and single low dose of ketamine maybe a potential rapid way to alleviate this behavior.

Title: Toll-like receptor 4 regulates central sensitization, touch-evoked itch, and inflammatory pain

Authors: *Q. HAN
DUKE UNIVERSITY, Durham, NC

Abstract: Toll-like receptors (TLRs) are typically expressed in immune cells and play a critical role in pathogen recognition and innate immunity activation. Our previous studies have shown that TLR3 and TLR7 are expressed by nociceptor neurons in the dorsal root ganglia to mediate itch sensation. TLR4 is the most investigated TLR family member and has been implicated in the pathogenesis of chronic pain via regulating glial activation in the spinal cord. However, the role of TLR4 in itch regulation has not been investigated. We examined histamine dependent and independent itch in wild-type and TLR4 knockout (KO) mice. We found compound 48/80-induced itch (histamine-dependent) is normal in TLR4-KO mice. Furthermore, chloroquine-

induced itch (histamine-independent) is also intact in TLR4-KO mice. We then investigated compound 48/80-induced alloknesis (touch-evoked itch), which is mediated by central sensitization. Strikingly, compound 48/80-induced alloknesis is abrogated in TLR4-KO mice. Consistently, formalin-induced second phase spontaneous pain, which is known to be mediated by central sensitization, is also abolished in TLR4-KO mice. Finally, spinal cord long-term potentiation (LTP) in intact mice following tetanic stimulation of the sciatic nerve is also impaired in TLR4-KO mice. Our data suggest that TLR4 contributes to central sensitization and the pathogenesis of inflammatory pain. Our data also suggest that TLR4 is not required for acute itch but essential for inducing central sensitization-mediated alloknesis. This study is supported by NIH grants RO1 DE17794, DE22743, and NS67686 to R.R.J.
