Title: ERBB3-regulation of Bergmann glia proliferation is required for cerebellar lamination

Authors: *A. SATHYAMURTHY, D.-M. YIN, A. BARIK, C. SHEN, J. BEAN, W.-C. XIONG, L. MEI
Georgia Regents Univ., Augusta, GA

Abstract: The cerebellum controls motor movement and has recently been implicated in higher functions including cognition and emotion. Fundamental to cerebellar function is the unique laminar organization. During development, granule cell precursors (GCPs) proliferate in the external granule layer (EGL) beneath the glia limitans and migrate along the Bergman glial (BG) scaffold into the internal granule layer (IGL). Yet, little is known about BG proliferation and scaffold formation. We studied the role of ERBB3, a receptor of neuregulin 1 (NRG1), in cerebellar lamination. GFAP::Cre;Erbb3F/F mice that lack ERBB3 in both radial glia and neurons exhibited impairments in balance and motor-coordination. Cerebellar lamination was aberrant; Purkinje neurons (PNs) were misplaced; and granule neurons (GNs) failed to migrate into the IGL and formed ectopic clusters in the ML. Interestingly, these phenotypes were not observed in Math1::CreERT2; Erbb3F/F mice where the Erbb3 gene was deleted in GNs, suggesting that loss of Erbb3 in cells other than GNs and PNs contributes to lamination defects in GFAP::Cre;Erbb3F/F mice. Moreover, we found that ERBB3 was expressed in cerebellar astroglial cells and was required for their proliferation in culture. These observations support a working model where cerebellar BG require ERBB3 for proliferation. Diminished BG proliferation in the absence of ERBB3 causes reduction and disorganization of BG scaffold that is required for GN migration and cerebellar lamination. These observations identify a novel, cell autonomous role for ERBB3 in BG proliferation and cerebellar lamination.

Title: The motorized Rho GAP Myosin IXa is important for radial glia function

Authors: *S. THELEN, M. BÄHLER
Inst. for molecular cell biology, Westfalian Wilhelms Univ., Muenster, Germany

Abstract: Proper function of neural progenitor cells depends on the development of specific cell-cell adhesion structures and the establishment of an apico-basal polarity. Coordinated distribution of plasma membrane components and dynamic reorganization of the actin cytoskeleton are crucial to establish and maintain this polarity. It is regulated by signaling networks and protein complexes that include Rho family GTPases and polarity complexes. Among the regulators of the GTPase RhoA is the mammalian class IX myosin Myo9a. Constitutive deletion of Myo9a expression in mice leads to severe postnatal hydrocephalus formation (Abouhamed et al., 2009). The underlying molecular mechanism is not exactly known. Leakage of lysophosphatidic acid (LPA) into embryonic brain tissue through traumatic injury of blood vessels has been proposed to induce hydrocephalus through the induction of neuronal rosettes. LPA can induce Rho activity just as the loss of a RhoGAP. Therefore, we examined the role of the motorized RhoGAP Myo9a during neurogenesis in the developing mouse cerebral cortex. In radial glia cells of the developing telencephalon Myo9a localizes to the contractile actin ring along the apical junctional complex. As revealed by immunofluorescence stainings and electron microscopy images, its loss leads to thickening of F-actin bundles and a reorganization of adherens junction (AJ) components. In WT cortices, N-Cadherin labeling appeared as a prominent apical band along the ventricular surface. Upon loss of Myo9a, the N-Cadherin band appeared diffuse, indicating loss of the normal AJ organization. Consistent with this, aberrant localization of megalin, an apical membrane receptor, was observed in Myo9a-/- radial glia. These results demonstrate that loss of the motorized RhoGAP Myo9a impairs the proper morphological arrangement of cell-polarity and cell-fate cues in radial glia cells. The numbers of basal mitotic progenitors originating from asymmetric cell divisions of radial glia cells were increased by 3-fold in Myo9a-/- cortices. However, the total numbers of Pax6+ radial glia and Tbr2+ basal progenitors were unaltered. Except for a few aberrantly positioned neurons in the developing telencephalon, loss of normal radial glia morphology did not grossly interfere with

neurogenesis as indicated by normal layering of the cortex at birth. Mere inhibition of the Rho downstream effector ROCK did not rescue the phenotype. In conclusion, Myo9a is important for proper morphology and division of neural precursor cells, but is dispensable for neurogenesis. The exact molecular mechanism(s) by which Myo9a-RhoGAP affects AJ in radial glial cells remains to be investigated.

Title: Gap junction channels has different patterns of distributtion and plays specific roles during the chick brain development

Authors: *V. PASCHON, G. S. V. HIGA, E. R. KINJO, C. M. FURTADO, N. V. SANTOS, A. H. KIHARA
Neurociência e Cognição, Univ. Federal Do ABC, São Bernardo Do Campo, Brazil

Abstract: Gap junction channels formed by connexins (Cx) may play essential roles in some processes that occur during neuronal development, such as apoptosis and calcium wave spread. Although Cx expression was described in the chick retina, their expression in the visual areas of the brain is largely unknown. The present study was undertaken to determine the distribution pattern of Cx36, Cx43, and Cx45 by immunofluorescence, Western Blot, and real time PCR during the development of the chick Optic Tectum (OTe). We also measured the coupling level in each age by scrape loading (dye uptake). Our results showed that Cx43 was mostly expressed in the adult chick OTe (P15 – 100%) co-localizing with radial glial cells, while E5 was only 15-30% ($P<0,05$). The Cx43 phosphorylated isoform was only present in P15 suggesting formation of functional gap junction channels. Cx36 was up-regulated during the development. We observed low levels at E5 (0,19% $P<0,05$), which increased during the development. At E15 and P15 we observed specific neuronal layers expressing Cx36. Cx45 was highly expressed in the beginning of the development and was maintained during the development. Our results about scrape loading showed that the neurobiotin dye was uptake in all developmental stages, while the

Lucifer Yellow dye was spread only after E15 showing a transient pattern. In addition, E10 neuronal and glial cell culture of chick OTe was incubated with quinine, a specific blocker for Cx36 50 and 100μM, for 24hours to observe specific changes related with neuritogeneses and synaptogenesis. In conclusion, we observed an important modulation of Cxs during the development, which is probably related to particular roles in the brain function and maintenance of homeostasis during development of the chick OTe. Cx45 may have important roles during the neurogenesis and in the control of proliferative processes. Cx36 is upregulated during the development revealing important roles in the late development. On the other hand, Cx43 may be important after cell differentiation. It was find functional gap junction channels in the hole development and adult. Finally, the blockade of specific Cxs alters the synaptogenesis and neuritogenesis *in vitro*. Financial **Support:** FAPESP.

Title: RNA Binding Protein Sfpq is required for the expression of schizophrenia-related long neuronal genes

Authors: *A. TAKEUCHI[1], K. IIDA[1], K. NINOMIYA[1], M. ITO[2], K. OHNO[2], M. HAGIWARA[1]
[1]Dept. of Anat. and Developmental Biol., Kyoto Univ. Grad. Sch. of Med., Sakyo-Ku, Kyoto, Japan; [2]Div. of Neurogenetics, Nagoya Univ. Grad. school of Med., Nagoya, Japan

Abstract: Mammalian neuronal cells express long pre-mRNAs which are vulnerable to misregualtion of transcriptional elongation or processing but the neuron-specific regulation of long pre-mRNAs is still largely unknown. Here we found that RNA-binding protein Sfpq (splicing factor, proline/glutaminerich) is essential for neuronal genes to fully express extremely long pre-mRNAs. Sfpq was specifically expressed in differentiated neurons during development and disruption of Sfpq caused massive apoptosis in embryonic mouse brains. Genome-wide Sfpq binding analysis using *in vivo* iCLIP (cross-linking immunoprecipitation) showed saw-tooth binding patterns on entire pre-mRNAs of more than 7400 genes with low sequence specificity, which suggests co-transcriptional binding of Sfpq to entire pre-mRNAs. In transcriptome analysis of Sfpq-/- brains, the expression of Sfpq-bound pre-mRNAs longer than 100 kilobases was significantly down-regulated. Gene Ontology analysis demonstrated these Sfpq target long genes have essential functions for late development stage of brains, including cell adhesion, neuronal migration, axon guidance, and synapse formation. Mutation of Sfpq target long genes are shown to have association with several neurodevelopmental disorders including schizophrenia. To further address the *in vivo* function of Sfpq, we examined the heterozygous mutant mice and performed comprehensive behavioral test battery. Sfpq-heterozygous mutant mice were viable and they appeared grossly normal, including the morphology of brains. However, Sfpq +/- mutant mice displayed schizophrenia-like abnormal behaviors in fear and anxiety-related behavioral test and Pre-pulse inhibition test. These data indicate that the RNA binding protein Sfpq is required for the expression of long pre-mRNAs which play essential roles for neuronal development and that the impairment of Sfpq-dependent gene expression could be a cause of neurodevelopmental and psychiatric disorders.

Title: Fgf signal transduction through frs in the developing telencephalon

Authors: *N. KAMATKAR[1,2], G. GUTIN[3], J. HÉBERT[2,3]
[2]Dept. of Neurosci., [3]Dept. of Genet., [1]Albert Einstein Col. of Med., Bronx, NY

Abstract: Fibroblast growth factors (FGFs) are a family of secreted proteins utilized for different processes including survival and specification of cells during embryonic brain development. How these factors induce these different processes in a spatial and temporal manner is an essential question in understanding FGF signaling. Our insight into FGF signal transduction has largely been deduced from *in vitro* experiments that have found several intracellular transducers that directly bind to the receptor including FGF Receptor Substrate proteins 2α/β (FRS2/3). To understand the underlying mechanism of FGF signaling in the developing telencephalon through FRS2/3, we inhibited signaling through FRS2/3 via two complementary approaches. First, we inhibited the binding of the adaptor proteins FRS2/3 to the receptor intracellularly, and we observed a severe phenotype in which the telencephalic precursor cells do not survive which results in a loss of the telencephalon. We suspect that there are other intracellular signaling transducers that are unable to bind to the mutated receptor since when we conditionally delete the adaptors FRS2/3 themselves, we find that there is a less severe phenotype in which the telencephalon is largely formed albeit reduced in size with failure to properly differentiate cells in the medial ganglionic eminence (MGE). Thus, FGF signaling through FRS2/3 during early development of the telencephalon is required for only a subset of functions including properly differentiating neurons in the MGE.

Title: Origin and secondary expansion of the transient subplate zone in the developing cerebrum of human and nonhuman primates

Authors: *A. DUQUE[1], Z. KRSNIK[3], P. RAKIC[2], I. KOSTOVIC[3]
[2]Neurobio. and Kavli Inst. for Neurosci., [1]Yale Univ. Sch. Med., New Haven, CT; [3]Croatian Inst. for Brain Research-School of Med., Univ. of Zagreb, Zagreb, Croatia

Abstract: Because of its exceptionally large size it may not be coincidence that the subplate (SP) was originally discovered, and its basic functions proposed, based on the analysis of the developing cortex in human and nonhuman primates (NHPs) (Kostovic and Moliver, 1974; Rakic, 1977). Furthermore, the generally accepted hypothesis that the SP evolves from the deeper stratum of the primordial preplate layer (PP) after it becomes separated from the marginal zone (MZ) neurons situated above, by the arrival of the cortical plate neurons from the ventricular zone (VZ), was also based on histological studies of human fetal brain tissue (Marin Padilla, 1978). However, most of the subsequent research on the genesis, function and fate of the SP was carried out in non-primate species such as rodents and carnivores (e.g. Allendoerfer and Shatz, 1994; Kanold and Luhmann, 2010) and its origin and evolutionary expansion in human remains elusive. Here we take advantage of the large and slowly developing SP in the macaque monkey to examine the time of origin, mode of migration, settling pattern and fate of the SP in primates. Monkey embryos were exposed to the DNA replication marker H3-Thymidine (TdR) at early embryonic ages and sacrificed at different intervals to follow changes in positions and fates of the postmitotic cells. Surprisingly, we found that most SP neurons generated in the VZ initially migrate radially to the cortical plate together with the prospective layer 6 neurons. Only subsequently, during mid-gestation, they become secondarily displaced within the widening SP zone which expands by growth of the neuropil, due mainly to invasion of basal forebrain, thalamocortical and cortico-cortical axons. Examination of the SP in the embryonic human cerebral wall at corresponding fetal ages, indicates even larger displacement of SP cells, particularly subjacent to the association cortical areas and underneath the summit of the folia which contains the voluminous contingent of early cortico-cortical connections. Overall our data sheds new insight into the origin and fate of the SP in primates, and illustrate the dynamic nature of this transient zone, which has been associated with disorders of the highest cognitive functions, such as autism and schizophrenia (Akbarian et al., 1996; Kostovic et al., 2011; Hoerder-Suabedissen et al., 2013).

Title: Implications of pax6 in pituitary gland function and development

Authors: *K. JOHNSON, C. BLATCHER, *. LAUDERDALE
Cell. Biol., Univ. of Georgia, Athens, GA

Abstract: Aniridia is a congenital condition characterized by the absence of the iris that is caused by a semidominant mutation in the transcription factor Pax6. The eye phenotypes of this disorder have been well characterized, but recent studies have shown that Aniridic patients over the age of 18 have a higher propensity for obesity, polycystic ovarian disease, infertility, and severe eczema when compared to their non-Aniridic siblings. It is possible that these symptoms are a result of a Pax6 deficiency in the neuroendocrine regions of the brain, such as the pituitary gland. During development, Pax6 expression in the pituitary gland begins at e9.0 in the primordial anterior pituitary gland (Rathke's Pouch). This expression becomes restricted to the dorsal anterior pituitary by e11.5 and persists into adulthood. Therefore, it is plausible that a reduction in PAX6 could result in a change in pituitary hormone cell numbers and thus explain the endocrine symptoms that affect people with Aniridia. To test this possibility, we have used flow cytometry to measure pituitary cell numbers in the mouse model for Aniridia, Small eye, which have a deficiency in one copy of Pax6. Our data suggests that in adult mice a reduction in levels of PAX6 does not result in significant differences in cell numbers when compared to wild-type. Previous studies have reported changes in levels of Adrenocorticotropin Hormone and Thyroid Stimulating Hormone levels in people with Aniridia. However, based on the data presented here, it is unlikely that the hormone changes are a consequence of an increase or reduction in hormone-producing cells of the pituitary gland. Alternatively, it may be that Pax6 is indirectly affecting hormone production and release by regulating the enzymes that are responsible for generating the active form of the hormones, prohormone convertase (PC) 1 and 2. Future studies will therefore focus on the potential relationship between Pax6 and PC 1 and PC2, and on the possibility that Pax 6 affects the hypothalamic hormones.

Title: The C-terminal region domain of reelin is required for arrest of cortical neuronal migration and formation of the hippocampal dentate gyrus

Authors: *S. HA[1], D. R. BEIER[1,2]
[1]Developmental Biol. and Regenerative Med., Seattle Children's Res. Inst., Seattle, WA;
[2]Brigham and Women's Hosp., Boston, MA

Abstract: We have previously described a forward genetic screen for cortical lamination defects and identification of a novel hypomorpic allele of *reelin* (Cereb. Cortex 2013 doi: 10.1093/cercor/bht209). This mutant, named *Reln* ^{CTRdel}, carries a splice-site mutation that results in a truncation of the C-terminal region (CTR) domain. The mutant expresses normal levels of secreted reelin protein, distinguishing *Reln* ^{CTRdel} from *Orleans reeler,* which has a larger C-terminal truncation that causes a secretion defect and phenocopies *reeler*. In contrast, *Reln* ^{CTRdel} displays remarkably distinct phenotypes from *reeler*. First, the size and foliation of the cerebellum is normal, and this mutant is not ataxic. Second, the mutant does not have the inversion of cortical layers; however, both superficial and deep layer neurons migrate beyond normal boundaries. This abnormality, in the absence of layer inversion, strongly supports the hypothesis that that *reelin* may act as a stop signal for migrating cortical neurons. Third, while lamination in *Cornu Ammonis* region of the hippocampus is normal, the dentate gyrus morphology is severely disturbed; most of the infrapyramidal blade is absent, while the suprapyramidal blade is present and better laminated compared to *reeler*. We are exploring the specific process that is disturbed in this mutant. We do observe increased *Dab1* expression, likely due to impaired negative feedback, which suggests defect in reelin signaling. In summary, CTR-truncated *reelin* still can carry out certain developmental processes (i.e. inside-out cortical lamination, normal cerebellar foliation and function, and development of the CA region and suprapyramidal blade). This unexpectedly enables us to elucidate a requirement of the *reelin* CTR domain in specific developmental processes: arrest of cortical neuronal migration and formation of dentate gyrus infrapyramidal blade.

Title: Changes in the functional organization of the neocortex following lesions to visual cortex early in development

Authors: *L. A. KRUBITZER[1], J. C. DOOLEY[2]
[1]UC Davis, DAVIS, CA; [2]UC Davis, Davis, CA

Abstract: The neocortex is a highly dynamic structure that can be functionally optimized both in its organization and connectivity to generate appropriate behavior in an ever-changing social and physical environment. While many factors are known to contribute to this plasticity, the limit of this plasticity following early cortical injury is not well known. To better understand the time-course and extent of recovery of the neocortex, our laboratory has previously used the short-tailed opossum (Monodelphis domestica) as a model organism to investigate cortical reorganization. Opossums are born extremely early in development, which has allowed us to investigate the effects of lesioning the caudal pole of cortex (which would normally develop into primary visual cortex and other visual areas) before thalamocortical afferents have innervated cortex (postnatal day 4, P4). We found that early lesions result in a rostrally-shifted, compressed representation of somatosensory and auditory cortex and a very small, caudally-located visual area when animals were examined as adults. Thalamocortical projections had also shifted rostrally so that inputs from the major sensory nuclei correctly projected to their cortical targets (Huffman et al., 1999). The studies presented here demonstrate if and how plastic changes to the neocortex differ when cortex is bilaterally lesioned just after thalamocortical axons have innervated the neocortex (P12 in opossums). Following lesions, animals were allowed to develop to adulthood, and the functional organization of the neocortex was accessed using electrophysiological recording techniques. Unlike animals lesioned at P4, P12 lesioned animals do not show a compression or a rostral shift of somatosensory, auditory and visual areas. Additionally, only a small portion of cortex in which neurons responded to visual stimulation was found at the caudal-most portion of remaining cortex in some, but not all cases. Somatosensory cortex in these animals had a normal topography, with body and forepaw representations located medially and the face representation located laterally within somatosensory cortex. These results indicate that the extent of cross-modal plasticity following cortical insult is severely restricted once thalamocortical afferents have innervated the cortical subplate. Importantly, the persistence of a visual cortex is highly dependent on when cortical injury occurs relative to the development of thalamocortical axons.

Title: Suppressor of Fused (SuFu) controls the development of cerebellar granule neurons

Authors: *T. JIWANI[1,2], J. J. KIM[1,3], L. ROTIN[1], N. D. ROSENBLUM[1,2,3]
[1]Program in Developmental and Stem Cell Biol., Hosp. For Sick Children, Toronto, ON, Canada; [2]Dept. of Lab. Med. and Pathobiology, [3]Dept. of Physiol., Univ. of Toronto, Toronto, ON, Canada

Abstract: Cerebellar granule cells (GCs) are neurons that coordinate motor function, memory and learning. GC development is tightly controlled by the Sonic Hedgehog (SHH) signaling pathway. The pathway regulator, Suppressor of Fused (SUFU) modulates the levels of SHH effectors by stabilizing GLI activators and promoting the synthesis of GLI3 repressor (Gli3R), in a context dependent manner. Genetic deficiency of SUFU in all cerebellar cells resulted in abnormal patterning and cell differentiation, and reduced cerebellar size, suggesting a deleterious effect on GCs (Kim et al., 2011). However, the mechanisms by which SUFU controls GC development, specifically, are undefined. Here we investigate our hypothesis that SUFU controls GC development by regulating the activity of the SHH signaling pathway. We deleted SuFu specifically from the GC lineage using Cre recombinase driven by the Math1 promoter in mice. Mutant cerebella contained an increased number of Pax6-positive GC precursors, with a higher rate of GC proliferation demonstrated via *in situ* BrdU incorporation assays. A subset of mutant GCs also failed to migrate to their final destination in the mature cerebellum (internal granule layer), though they correctly expressed differentiation markers, such as NeuN and Tag1. Interestingly, the GFAP-positive Bergmann glia (BG) scaffold, a regularly arranged meshwork of neuron-supportive cells, was consistently disrupted in areas containing GCs that failed to migrate. Ectopic BLBP-expressing BG cell bodies were also observed in the GC precursor zone (external granular layer) in mutant cerebella, suggesting defects in BG patterning and

differentiation. As SuFu was not deleted from the BG lineage, these findings uncover a novel non-cell autonomous function of SuFu. Finally, constitutively expressing GLI3R (transgenically) in SUFU deficient mice fully rescued defects in GC proliferation, but not migration, suggesting complex molecular interactions downstream of SUFU in GC development. We conclude that (i) SUFU controls the number of GC precursors by cell-autonomously regulating GC proliferation and migration, in a GLI3R-dependent and -independent manner, respectively; and (ii) SUFU non-cell autonomously regulates the patterning of the BG lineage. We speculate that SUFU controls cerebellar development via SHH-dependent and -independent mechanisms.

Title: Behavioral examinations of forebrain-specific Ctgf knockout mice

Authors: *H.-C. CHANG[1], K.-C. CHEN[2], I.-S. YU[3], L.-J. LEE[2,4]
[2]Grad. Inst. of Anat. and Cell Biol., [3]Dept. of Clin. Lab. Sci. and Med. Biotech., [4]Neurobio. and Cognitive Sci. Ctr., [1]Natl. Taiwan Univ., Taipei, Taiwan

Abstract: Connective tissue growth factor (CTGF), a member of CCN family, is important for the development of connective tissue. In the cerebral cortex, CTGF is expressed in subplate neurons. However, the roles of CTGF in the brain are still largely unknown. To evaluate the functions of CTGF in the brain, a forebrain-specific *Ctgf* knockout mouse model was generated by crossing *Ctgf*$^{flox/flox}$ mice with *Emx1-Cre* transgenic mice. In *Ctgf*$^{flox/flox}$; *Emx1-Cre* mice, the expression of Ctgf in the subplate was abolished while these mice are still fertile and develop normally. In the present study, the behavioral phenotypes of *Ctgf*$^{flox/flox}$; *Emx1-Cre* mice were examined. Wildtype and mutant mice exhibited comparable locomotor activity in an open field and similar sensorimotor gating ability in response to acoustic startle stimuli. The olfactory function was evaluated in buried food test and the latency to uncover food pellet was equivalent between genotypes. However, the mutant mice tended to spend more time in the closed arms of an elevated plus maze and display less immobility time in the forced swimming test. Since some emotion-related behaviors are affected in forebrain-specific *Ctgf* knockout mouse model, our data suggest a novel function of subplate-expressed Ctgf in adult brain.

Title: Role of hypoxic environment during neocortical development

Authors: *A. HONDA
Doshisha Univ., Kizugawa City, Kyoto, Japan

Abstract: During neocortical development, a multitude of cellular events must all occur with exquisite spatiotemporal control. Its location within the uterus when embryonic cardiovascular development and placental blood flow are not well-established, leads to a hypoxic environment. Despite this hypoxia, the embryonic cells are able to undergo remarkable growth and differentiation. Hypoxia-inducible factor (HIF) is known to play critical roles as molecular sensors of oxygen pressure, and HIF-1alpha has been reported to be crucial for normal brain development. Additionally, HIF may acts cooperatively with other signaling molecules such as Notch-Hes, thereby influencing a wide range of processes including tumor malignancy and neural progenitor maintenance and differentiation. In this study, at first we measured oxygen pressure level in the embryonic neocortex with needle type micro oxygen sensor. We found that the oxygen pressure level was around 1% to 2.5% at embryonic day of 12 (E12) to E15, and this oxygen level was generally known as physiological hypoxia. Next, a chemical reagent pimonidazole, which is activated in hypoxic cells, was utilized to confirm the localization of hypoxic cells in the developing neocortex, and we detected the activated pimonidazone around the ventricular zone. Furthermore, we performed transient transfection experiments in the mouse neuroblastoma Neuro2a cell line using plasmids containing HIF- responsive element (HIFRE) region fused to the luciferase reporter gene, and observed that HIFRE-luciferase activity was significantly increased in the hypoxic condition compared with that in the normoxic condition. Also, we found that hypoxic environment significantly increased Hes1 promoter activity, whereas hypoxia significantly suppressed both Neurogenin2 and NeuroD1 promoter activity in the Neuro2a cell line. In addition, the HIF target genes such as Igfbp5 preferentially expressed in the ventricular zone, and these HIF target genes were highly correlated with Notch-Hes

signaling. These results suggest that hypoxic environment plays a critical role in the regulation neural differentiation during neocortical development.

Title: Docosahexaenoic acid and its ethanolamide in the brain: Possible role in early development and neuroprotection of the dopaminergic system

Authors: *S. SONTI, S. J. GATLEY, R. I. DUCLOS, R. H. LORING, K. QIAN
Dept. of Pharmaceut. science, Northeastern Univ., BOSTON, MA

Abstract: Docosahexaenoic acid (DHA, 22:6), an omega-3 long chain fatty acid (LCFA), constitutes the primary structural LCFA of the brain. It is esterified as phosphatidylserine (PS) and phosphatidylethanolamine (PE) phospholipids localized primarily in the inner leaflet of cell membranes. Ca2+-independent phospholipase A2 (iPLA2) releases DHA from the membrane phospholipids, and DHA prevents apoptosis, promotes neuronal differentiation and activates neuronal gene expression by functioning as a ligand at the retinoid X receptor. DHA thereby plays an important role in neuronal survival and maturation. Due to its roles in both membrane architecture and cellular transcription, DHA is critical for proper development of brain. For example, recent evidence establishes the role of DHA in the development of the hippocampus and the dorsal root ganglia. Based on this background, we are investigating the possible role of DHA in the development and neuroprotection of the mid-brain. In parallel efforts, we are evaluating the uptake of exogenous DHA and related compounds by the brain *in vivo*, and the effects of DHA on a dopaminergic cell line. Our lab has previously shown that LCFA ethanolamides (N-acylethanolamines) enter the brain much faster than their corresponding free LCFA's (Abstract#: 639.25, 2012). In the brain, the ethanolamides are rapidly converted to free LCFA's by the enzyme fatty acid amide hydrolase (FAAH). DHA ethanolamide (DHEA) has been termed "synaptamide" (PMID: 21810478). We hypothesized that the ethanolamides might generally be useful to deliver LCFA's to the brain, in other words, to act as prodrugs. To test this

hypothesis, we synthesized the radiolabelled N-acylethanolamine of DHA, [C-14]docosahexaenoylethanolamine ([C-14]DHEA). Preliminary experiments confirmed that following intravenous administration the radiotracer was found in the mid-brain. Parallel *in vitro* studies on the IRB3AN27 (mesencephalic dopaminergic) cell line showed increased neuritogenesis following treatment with DHA, suggesting a possible role of DHA in the development and/or maturation of mid-brain dopaminergic system. Studies are in progress to confirm this role of DHA in the development of mid brain dopaminergic system and to evaluate the potential therapeutic effects of DHA and DHEA using a suitable animal model.

Title: The transcription factor ebf2 regulates gene expression driven by the murine prepro-orexin promoter

Authors: A. SANCHEZ-GARCIA[1], V. C. ZOMOSA-SIGNORET[1], C. DEVEZE[2], R. ORTIZ-LOPEZ[1], *R. VIDALTAMAYO[2]
[1]Bioquimica y Medicina Mol., Univ. Autonoma de Nuevo Leon, Monterrey, Mexico; [2]Basic Sci., Univ. of Monterrey, San Pedro, Mexico

Abstract: Orexins (hypocretins) are peptide neurotransmitters that regulate wake-sleep cycle and arousal, promoting wakefulness and inhibiting REM sleep. We have previously demonstrated that KO mice lacking ebf2, a member of the bHLH family of transcription factors, show a narcoleptic phenotype, characterized by direct to REM transitions from the wake state and cataplexic episodes. This phenotype is due to the loss of 80% of the orexinergic neurons in the lateral hypothalamus and decreased levels of expression of orexin A in the remnant cells. We also identified two olf1-like binding sites in the putative minimal promoter region (comprising

roughly 450 bp upstream of the transcription initiation site) of the prepro-orexin genes from several mammalian species. Here, we analyze the regulation of expression of luciferase driven by the putative promoter region of the murine prepro-orexin gene. We generated luciferase-expressing constructs based on the pNifty3-Lucia plasmid vector (Invivogen, CA) containing synthetic sequences derived from the publicly available prepro-orexin gene sequence (MGI ID 1202306, Hcrt; NCBI: NM_010410.2). We transfected our reporter constructs into a stable, modified HEK 293 cell line, overexpressing mouse ebf2. Ebf2-expressing cells show a 7-fold increase in luciferase signals over levels observed in Wt HEK293 cells (2091±243 vs. 293±24 luminescence units, respectively; mean ± SEM; $P<0.001$, Bonferroni-corrected ANOVA followed by Holm-Sidak post-hoc test). Deleting both putative olf1 sites in the prepro-orexin promoter prevents the increase in luciferase expression and luminescence reverts to near Wt levels (188±17; $P<0.001$ vs. ebf2 cells). Our results suggest that ebf2 regulates prepro-orexin gene expression through binding to olf1 sites present in its promoter region.

Title: Protocadherin 10 expression pattern in the developing mouse cerebellar cortex

Authors: S. VIBULYASECK[1], S. HIRANO[2], *I. SUGIHARA[1]
[1]Dept. of Systems Neurophysiol, Tokyo Med. & Dent. Univ. Sch. Med., Tokyo, Japan; [2]Dept. of Cell Biol., Kansai Med. Univ., Osaka, Japan

Abstract: The cerebellum is compartmentalized into some tens of areas that have distinct axonal projection patterns, and thus that are presumably involved in different functions. In each compartment, a subset of Purkinje cells will have distinct expression levels of certain molecules, such as aldolase C (=zebrin II), which can be used as markers for the compartment. Because aldolase C is expressed only in the mature cerebellum, we investigated whether protocadherin 10 (Pcdh10), which is expressed during cerebellar development, could also act as a molecular

marker. By using heterozygote samples of the knock-in mouse strain (OL-KO, Lexicon Pharmaceuticals, Inc., USA; Uemura et al., 2007), in which Pchd10 gene expression is visualized by the reporter molecule beta-galactosidase, we were able to follow the evolution of cerebellar compartments through successive developmental stages. Whole mount preparations of the cerebellum from embryonic day 13.5 up to adult were used to investigate the alternating striped pattern of Pcdh10 expression throughout development. In the mature cerebellum (~adult), high expression areas were clearly compartmentalized into multiple stripes mainly in the vermis, paravermis, and paraflocculus. Although these compartments could be roughly traced through development, they were differently organized in shape and were merged in some cases in the immature cerebellum (down to E13.5). Consequently, the appearance of the mature striped pattern of Pcdh10 expression in the adult cerebellum was quite different from that in the embryonic immature cerebellum. We are now investigating the details of the developmental changes in Pcdh10 compartments. We also compared Pcdh10 compartments and Aldolase C compartments precisely in serial sections at postnatal day 16, when Aldolase C compartments start to stabilize. We are studying the spatial relationship between Aldolase C and Pcdh10 compartments. Initial results suggest that the compartments defined by these markers are exactly matched in some areas but not in others. The results indicate that the fine molecular compartments of the adult cerebellar cortex have a developmental lineage from immature early compartments in the embryonic cerebellum.

Title: The role of FGF receptor adaptor proteins during embryonic brain development

Authors: *C. A. BLACKWOOD[1], G. GUTIN[1], N. KAMATKAR[1], K. LEE[2], F. WANG[3], G. FISHELL[4], M. GOLDFARB[2], J. HEBERT[1]

Abstract: During early development, the Fibroblast Growth Factor (FGF) signaling pathway is one of the major inductive pathways that contribute to the ability of cells to organize into complex structures such as the telencephalon and its dorsal derivative, the cortex. For example, in early development FGFs are required for the survival of telencephalic precursors, while at later stages they maintain "stem-cellness" of radial glial cells in the neocortex. However, the role of the adaptor proteins that interact with FGF receptors to transduce signals and promote these various functions remain poorly understood *in vivo*. The FGF signaling adaptor proteins, FRS and Crk, are leading candidates for transmitting FGF signals during telencephalon development. We utilized conditional FRS and Crk knockout mice to study the roles of FRS and Crk genes during early and late development of the telencephalon. We found that the FRS genes are not critical for all aspects of FGF signaling during telencephalon development.

Abstract: Abstract Cconnective tissue growth factor (CTGF), a critical player in connective tissue development, is exclusively expressed in the cortical subplate. To explore the function of CTGF in the brain, a forebrain-specific *Ctgf* knockout mouse model was generated by crossing *Ctgf* $^{flox/flox}$ mice with *Emx1-Cre* transgenic mice in which the expression of *Cre* is prenatally initiated. The expression of Ctgf in the subplate was abolished in *Ctgf* $^{flox/flox}$; *Emx1-Cre* mice. The densities of cortical neurons were estimated in adult mice (10-12 weeks and 16-18 weeks). Besides, since Ctgf-expressing subplate neurons send axons to the center of each cortical barrel in which spiny stellate cells preferentially orient their dendrites toward it. The dendritic arborization of layer 4 spiny stellate cells in the barrel cortex was revealed using Golgi stain and the morphometric parameters of dendrites were measured. The densities of cortical neurons and dendritic arbors of layer 4 spiny stellate cells in the barrel cortex were comparable between genotypes in adult mice. Our data indicated that the cytoarchetecture of barrel cortex in adult brain is not affected by forebrain-specific deletion of *Ctgf* from the embryonic period.

Title: Functional analysis of the Reelin-Dab1 signal pathway in the developing zebrafish nervous system

Authors: *S. KIKKAWA, T. SUMIMOTO, T. SUMI, Y. SAKIHAMA, T. TERASHIMA
Kobe Univ. Sch. of Med., Kobe, Japan

Abstract: Reelin is an extracellular matrix protein highly conserved among vertebrates and is known to control neuronal migration during mammalian brain development. The intracellular protein disabled homolog 1 (Dab1) has been identified as a downstream adaptor protein in the Reelin signal. Spontaneous mutants for reelin and dab1, as well as targeted knockout mice, have been reported to share their characteristic laminar malformation in the brain cortices, which includes the largely inverted outside-in structure of the cerebral neocortex and distinctive hypoplasia of the cerebellar cortex. Whereas a large body of evidence has been accumulating in mammals, little is known about the roles of these molecules in the neural development of non-mammalian vertebrates. Zebrafish embryo is an established model organism bearing robustness to experimental manipulation and transparency feasible for visualization of developmental processes, including neuronal migration, nerve nucleus formation, and axonal outgrowth, in a living organism. To investigate functions of the Reelin-Dab1 signal pathway in neural development of non-mammalian vertebrates, we cloned their zebrafish homologues, including reelin and dab1 (with two isoforms, dab1a and dab1b). Immunohistochemical studies revealed that the Reelin protein is highly expressed throughout the CNS, including the telencephalon, optic tectum, cerebellum, hindbrain, and spinal cord, and that the expression pattern changes dynamically during embryogenesis. Next, we found that gene silencing using morpholino antisense oligonucleotides (MOs) against reelin or dab1a, but not dab1b, causes migration defects in the facial and vagus motor neurons in the developing hindbrain, defects in peripheral nerve pathfinding and fasciculation, and defects in posterior migration of the lateral line neuromasts . We also observed migration defects in cerebellar Purkinje, but not granule, cells in reelin and dab1a morphants. In addition, these Purkinje cells seem to undergo the retarded neuronal differentiation and/or development. Our results demonstrate that the Reelin-Dab1 signal pathway, known to mainly control neuronal migration in mammals, plays more diverse roles in zebrafish neural development.

Title: Distal enhancers and chromatin state in forebrain development

Authors: ***A. S. NORD**, C. ATTANASIO, J. A. AKIYAMA, A. HOLT, R. HOSSEINI, S. PHOUANENAV, I. PLAJZER-FRICK, M. SHOUKRY, V. AFZAL, E. M. RUBIN, L. A. PENNACCHIO, A. VISEL
Genomics Div., LBNL, Berkeley, CA

Abstract: Control of gene expression is critical during brain development. This is evidenced by genetic studies of neurodevelopmental disorders, where implicated genes converge in transcriptional regulation and chromatin remodeling pathways. Enhancers are distal regulatory DNA elements that activate expression of target genes. The genome-wide location and activity of enhancers can be predicted via ChIP-seq targeting histone modifications. We profiled the enhancer-associated histone mark H3K27ac in mouse forebrain across seven developmental stages. Complementary to time course analysis, we use data from additional histone modifications (e.g. H3K4me1, H3K4me3, and H3K27me3) to identify active and repressed chromatin states in the embryonic forebrain, and used transgenic assays to validate enhancer activity *in vivo* in the mouse brain. The results reveal regulatory circuitry associated with processes such as neuronal proliferation, lineage specification, and synaptic development and provide an entry point for examining the role of regulatory control systems in evolution and disorders of the brain. This integrated functional genomic study implicated many thousands of non-coding sequences, as well as active and repressive chromatin states, in orchestrating transcriptional regulation underlying forebrain development and function.

Title: Mixed lineage leukemia 1 (MLL1) chromatin modifying factor maintains neural stem cell regional identity in the developing and postnatal mouse brain

Authors: *R. N. DELGADO, R. D. SALINAS, D. A. LIM
Neurosurg., UCSF, San Francisco, CA

Abstract: The adult subventricular (SVZ) zone contains neural stem cells (NSCs) that produce neurons throughout life. NSCs in the SVZ are regionally heterogeneous such that those located ventrally generate different subtypes of neurons than those located dorsally. Whether epigenetic mechanisms underlie the maintenance of the regional identity of NSCs is not known. Microarray analysis of dorsal and ventral V-SVZ NSCs revealed an enrichment of homeotic transcription factors consistent with the embryonic origins of each region. Specifically, ventral SVZ NSCs were enriched for Nkx2.1, a transcription factor required to specify the ventral telencephalon during embryogenesis. While sonic hedgehog (Shh) signaling is required to induce and maintain Nkx2.1 expression early in neural development, inhibition of Shh signaling by cyclopamine and vismodegib did not reduce Nkx2.1 expression in postnatal SVZ NSCs, suggesting that Nkx2.1 expression in the SVZ was being maintained epigenetically. Chromatin immunoprecipitation sequencing (ChIP-seq) analysis of dorsal and ventral SVZ NSCs revealed that many of the regionally expressed genes, including Nkx2.1, were enriched with H3K4me3, a chromatin mark associated with active transcription. Furthermore, Mixed-lineage leukemia 1 (MLL1) protein, a trithorax group member and H3K4 methytransferase, was enriched at the Nkx2.1 locus in ventral, but not dorsal SVZ NSCs. Conditional deletion of MLL1 in ventral SVZ NSC cultures resulted in loss of Nkx2.1 expression, but the Shh signaling pathway remained intact, indicating that MLL1 is required for the maintenance of Shh-independent Nkx2.1 expression. Using Nkx2.1-CreER fate tracing, we found that early embryonic Nkx2.1+ cells are direct precursors to

the Nkx2.1+ NSCs of the postnatal SVZ. We next investigated whether MLL1 is also required for Nkx2.1 expression during embryonic development. While conditional deletion of MLL1 with the Nestin-Cre transgene did not result in loss of Nkx2.1 expression at embryonic day 13.5 (E13.5), by E18.5, the expression of Nkx2.1 in the developing ventral telencephalon was greatly diminished. These data suggest that MLL1 is not required for the establishment, but rather the maintenance of Nkx2.1 expression in the embryonic and postnatal brain. These data thus illustrate how the positional information provided by extrinsic cellular signals such as morphogens becomes epigenetically encoded into regionally distinct cell types. More generally, these results help explain how complex developmental information is properly maintained despite rapid tissue growth and/or dynamic changes in morphogen gradients.

Title: Emerging cerebellar pathways in humans from newborns to young adults using high angular resolution diffusion MR tractography

Authors: T. J. RE[1,2], K. IM[3], M. J. PALDINO[4], A. RIGHINI[5], P. E. GRANT[4], *E. TAKAHASHI[3]
[1]Div. of Newborn Medicine, Boston Children's Hospital, Harvard Med. Sch., Boston, MA; [2]Dept. of Radiology, Univ. of Milan, Milan, Italy; [3]Div. of Newborn Med., Boston Childrens Hospital, Harvard Med. Sch., Boston, MA; [4]Dept. of Radiology, Boston Children's Hospital, Harvard Med. Sch., Boston, MA; [5]Dept. of Radiology, Buzzi Children's Hosp. of Milan, Milan, Italy

Abstract: We aimed to describe the evolution of the cerebellar pathways of the inferior (ICP), middle (MCP), and superior (SCP) cerebellar peduncles in developing human subjects ranging from newborn to young adult, using high angular resolution diffusion imaging (HARDI)

tractography. The ICP primarily contains fibers from/to the inferior olivary (IO) nucleus related to proprioceptive sensory and motor vestibular inputs as well as outputs for balance and posture maintenance. The MCP contains two dissociated pathways: 1) pathways from the rostral pons to the inferior cerebellum (MCP-1) attributed with a sensory-motor function and 2) pathways from the caudal pons to the superior cerebellum (MCP-2) attributed with a higher cognitive function. The SCP pathways are the primarily output pathways from the cerebellum. Number and volume of all studied pathways increased progressively with age with an initial plateau varying across pathways (approximately: ICP at 3Y, MCP-1 at 5Y, MCP-2 at 3Y, SCP at 3Y). MCP-1 and MCP-2 pathways were distinctly identifiable starting from the earliest ages, and the volume of MCP-1 was consistently greater than the volume of MCP-2 (2-way ANOVA, $p < 0.05$). Mean ADC for all studied pathways decreased in the first 5 years then plateaued. ADC values for ICP and SCP remained significantly higher than those of the MCP for all age groups ($p > 0.01$). Mean FA increased until a plateau of 5 years (chi-square test, $p < 0.05$). ICP showed significantly lower mean FA than all other tracks ($p < 0.01$), while MCP-1 showed significantly higher mean FA than all tracks ($p < 0.01$). ICP tracks were not detected until about 2 months (M) post-term and showed a surge in development from 2M to 6M post-term. At approximately 6 years of age, these tracks begin to branch more extensively. The absence of tractography pathways is likely to indicate lower myelination and lower density of axons, suggesting lower maturity of the pathways. Interestingly, the ICP, involving primary sensorimotor functions appear to begin maturing later, although complete more rapidly, than the SCP and MCP pathways. This may suggest that output pathways to the IO nucleus may play a role in the maturation of IO neurons and therefore axons which compose the ICP. Early extra-uterine proprioception and balance experiences may also contribute to the rapid development of the ICP 2M to 6M post-term. The dissociated maturation patterns of the two MCP pathways suggest that although there are pathways related to higher cognitive functions, primary motor functions are dominant in the cerebellum. We hope this work may represent an initial step towards the creation of an age-based reference atlas for developing cerebellar tracts.

Title: Emerging callosal pathways in mice and humans using high angular resolution diffusion MRI (HARDI) tractography

Authors: *J. W. SONG[1], G. DAI[2], A. C. R. SCOTT[3], E. TAKAHASHI[3]
[1]Radiology, Yale Univ. Sch. of Med., New Haven, CT; [2]Martinos Ctr. for Biomed. Imaging, Massachusetts Gen. Hospital, Harvard Med. Sch., Boston, MA; [3]Div. of Newborn Medicine, Dept. of Medicine, Boston Children's Hospital, Harvard Med. Sch., Boston, MA

Abstract: Little is understood about the early development of callosal connections in human brains. In mice, the corpus callosum pathways are thought to be pioneered by axons from the cingulate cortex, which help guide axons across the midline. Although extensive work has been carried out in mice, the spatiotemporal development of the callosal pathways in the developing human brain remains elusive. The aims of this study are to describe during human fetal, newborn, and toddler ages 1) the timing of the emergence of pioneer axons for callosal pathways and their course as they cross the midline, 2) specify the location within the mesial wall of the brain from where the pioneer axons for callosal pathways originate, 3) determine whether callosal axons are distinguishable from the population of pioneer axons by HARDI tractography, and 4) perform a comparative neuroanatomic analysis between mouse and human brains by tractography of the developing callosal connections. We first confirmed in mouse brains that the HARDI technique can detect pathways that likely correspond to pioneer axons and permanent callosal axons in the cingulate gyrus from embryonic day (E) 14.5. Overall axonal development patterns were consistent with previously reported orders and organization of emerging fiber pathways in mice. In humans at 15-17 gestational weeks (GW), most of the pathways running through the superior/inferior mesial wall were radially oriented to the brain surface and terminated in the ventricular zone. At 17GW, a few pathways from the superior mesial wall emerged and connected to the contralateral hemisphere through the corpus callosum. Interestingly, additional tractography pathways arising from more lateral regions of the brain also led to the corpus callosum. At 20GW, pathways connecting both hemispheres from/to the inferior mesial wall (cingulate gyrus) emerged and were observed in all of the anterior, middle, and posterior brain regions, while pathways from/to the superior mesial wall connecting both hemispheres were not observed at this stage. Only a few, local short pathways connecting the superior and inferior mesial walls within a hemisphere were observed. At 22GW, pathways corresponding to the callosal pathways from/to the cingulate gyrus emerged. At 30GW, short, local pathways were clearly identifiable by tractography. From 40GW to 2 years of age, tractography pathways from/to the superior/inferior mesial walls revealed a similar organization

as the 30GW. These results suggest that HARDI can image potential pioneer axons as early as 17GW in humans and identify developing pathways that correspond to permanent callosal pathways in the mesial wall of the brain.

Title: Maternal diabetes alters expression of microRNAs that regulate genes critical for neural tube development

Authors: *T. DHEEN, S. SHYAMASUNDAR, S. S. W. TAY, B. BAY
Anat., Natl. Univ. Singapo, Singapore, Singapore

Abstract: Maternal diabetes causes neural tube defects (NTDs) in embryos and neuropsychological deficits in infants. Over the years, several metabolic pathways and genes have been identified to be deregulated by maternal diabetes although the exact mechanism behind this remains unknown. Recently, micro RNAs have been shown to be critical for brain development and maturation. Therefore, we hypothesized that maternal diabetes alters the expression of miRNAs that regulate genes involved in biological pathways critical for neural tube development and closure. To address this, we performed miRNA expression profiling in neural stem cells (NSCs) isolated from the forebrain of embryos exposed to hyperglycemia *in vivo*. Since maternal diabetes results in fetal hypoglycemia/hyperglycemia or hypoxia (induced by hyperglycemia), we exposed NSCs *in vitro* to low glucose, high glucose or hypoxia. Distinct miRNA expression patterns were observed in NSCs from different groups. Pathway analysis identified biological pathways that were targeted by differentially expressed miRNAs in the different groups. From this, we identified 7 common pathways (namely MAPK signalling, focal adhesion, actin cytoskeleton, wnt signalling, neurotrophin signalling, ErbB signalling and axon guidance) that were predicted to be deregulated in NSCs from various groups. The biological pathways identified by pathway analysis have already been shown to be associated with or critical for neural tube development. Our results indicate that altered miRNA expression induced

by maternal diabetes may form the basis for deregulation of several metabolic pathways resulting in NTDs. Overall, our results provide novel insights into the mechanism of maternal diabetes induced NTDs and altered brain function in infants of diabetic mothers.

Title: Calcineurin regulated development of cortical interneurons

Authors: ***R. PRIYA**[1], I. GRAEF[2], G. FISHELL[1]
[1]New York Univ., NY, NY; [2]Stanford Sch. of Med., Stanford, CA

Abstract: Our laboratory has identified a role for activity in the maturation of specific classes of cortical interneurons. Neuronal activity typically functions through activation of calcium-signaling cascades, however the contribution of any specific calcium signaling cascade or a calcium effector molecule in the development of interneurons has yet to be established. We observe that Calcineurin, a calcium dependent serine threonine phosphatase, is expressed in both medial and caudal ganglionic eminence-derived cortical interneurons. Loss of Calcineurin using a pan interneuronal driver decreases the survival of the animal to an average lifespan of 21 days. The overall body size of the animal is smaller, however the removal has no effect on the brain size. Interestingly, while at P6 the numbers of cortical interneurons is unaffected in conditional Calcineurin animals, by P21 it is 20% higher than found in age matched wild type littermates. This result suggests that the increase in the number of cortical interneurons observed at P21 is due to disruption in intrinsic cell death. Interestingly, in calcineurin knockout animals despite the overall increase in interneuron numbers, none of the subtype specific markers seem to be increased. In fact, paradoxically Parvalbumin and Reelin markers was found to be reduced. This suggests that calcineurin removal is also affecting the maturation of interneurons.

Title: Neuronal cell death during the pre- to postnatal transition in mice

Authors: *M. MOSLEY, C. SHAH, N. FORGER
Neurosci., Georgia State Univ., Atlanta, GA

Abstract: Naturally occurring neuronal cell death is a widespread feature of brain development. Two waves of death have previously been described. The first occurs near proliferative zones, peaks around embryonic (E) day 14 in the mouse, and eliminates many neuronal precursor cells soon after they are generated. The second wave, known as postmitotic cell death, occurs after neurons have migrated and begun to make connections, and is thought to be largely postnatal. We previously generated an "atlas" of cell death in the postnatal mouse brain, using immunohistochemical detection of activated caspase-3 as a marker for dying cells (Ahern et al., 2013). Of the ~30 areas of the forebrain quantified from the atlas, many had elevated levels of cell death at postnatal day (P)1. This raised the question of whether peak cell death in these regions actually occurs prenatally; few studies have systematically examined cell death during the embryonic to postnatal transition. To address this, we generated timed-pregnant mice and collected male and female offspring on E17, E18, E19, P0 and P1. In most forebrain areas, there were very few activated caspase-3 cells prior to birth. This confirms that postmitotic cell death is predominantly postnatal in the forebrain. Of the regions in which postnatal cell death was previously quantified, the amygdala and hippocampus were the only areas to show appreciable levels of activated caspase-3 prenatally. In addition, however, we found striking accumulations of activated caspase-3 cells dorsal and ventral to the corpus callosum in the subcallosal sling and indusium griseum/cingulate cortex prenatally. Grayscale thresholding revealed significant effects of age in these regions ($p=0.0003$ and $p<0.0001$, respectively). The subcallosal sling showed a 2.5-fold increase between E17 and E18 and remained somewhat constant to P1. In the indusium grisium/cingulate cell group, a sharp, 3-fold, increase in caspase-3 immunoreactivity was observed between E17 and E18 followed by a return to baseline one day later. We also observed a significant age-by-sex interaction ($p<0.05$) in this region, due to higher cell death in males than in females on E18 and greater cell death in females on E19. Because microglia are suggested to play an active role in neuronal cell death, we stained adjacent sections for the microglial marker,

Iba1. We observed dense concentrations of microglia in the indusium griseum/cingulate cortex and subcallosal sling on both E18 and E19. We are currently determining the phenotype of the unusual clusters of dying cells, as well as effects of manipulating microglial activity on cell death in these regions.

Title: Glutathione content modulates the effect of reactive oxygen species produced during cerebellar granule neurons development

Authors: *J. MORAN, M. OLGUIN
Natl. Univ. of Mexico, Apdo. Postal 70-253, Mexico

Abstract: Reactive oxygen species (ROS) have been associated with neuropathologies and neurodegenerative diseases, as well as to different physiological processes in the nervous system acting as modulators of normal brain function. During development, ROS participate in some processes of neuronal differentiation and programmed cell death. In this study we evaluated the role of glutathione and the levels of ROS in neuronal development by using a model of cerebellar granule neurons (CGN). We cultured CGN from 0 to 8 days *in vitro* (DIV) under physiologic concentrations of KCl (5 mM, K5) or depolarizing concentrations of KCl (25 mM, K25) that is believed to mimic the presynaptic trophic action exerted by mossy fibers on the survival and maturation of CGN. We found a gradual increase in the levels of ROS during the first 2 DIV, which was sustained until 3 DIV under both K5 and K25 conditions. After this time (3 DIV), the levels of ROS returned to the basal levels in CGN cultured in K25, but not in K5, where ROS levels continued increasing from 3 to 5 DIV. In contrast to K25, and in coincidence with the increment of ROS levels observed in K5, the cell viability and the mitochondrial activity diminished significantly at 4 and 5 DIV. In addition, the levels of reduced glutathione (GSH)

increased two fold from 0 to 1 DIV under K5 and K25 conditions, preceding the peak of ROS observed at 2 and 3 DIV. These levels of GSH remained high in K25 until 5 DIV, and at 8 DIV they returned to the basal levels detected at 0 DIV. In contrast, the levels of GSH diminished from 3 to 5 DIV in K5. At 5 DIV, the levels of GSH were 30% higher in K25 than in K5. To determine the relevance of the transitory high GSH levels during CGN development, we inhibited the synthesis of GSH during different periods of time. When GSH synthesis was inhibited during 48 h, the totality of CGN died at 2 DIV, but no cell death occurs when treatment is delayed 1 or 2 DIV. This condition was completely reverted by the antioxidant Euk-134. On the other hand, when ROS levels were reduced by antioxidants or inhibitors of the ROS-producing complex NADPH-oxidase, the expression of the proteins MAP2 and TAU were reduced at 1 and 2 DIV, but not at 3 DIV. These results suggest that the regulation of ROS could influence different events of CGN development. At early times of development, the production of ROS, which is highly regulated by the GSH system, seems to be critical for neuronal maturation. During a second stage of CGN development, ROS levels reach a low basal state to allow cell survival, otherwise this would lead to the activation of the programmed cell death.

Title: Oxygen level-dependent effects of sod2 deficiency on the development of cultured cerebral cortical neurons

Authors: D. LU, Y. YANG, M. MATTSON, *A. CHENG
Lab. of Neurosciences, NATIONAL INSTITUTE ON AGING/ NATIONAL INSTITUTES OF HEALTH, BALTIMORE, MD

Abstract: Superoxide dismutases (SODs), including cytosolic and extracellular SODs (SOD1 and SOD3) and mitochondrial SOD (SOD2), are major antioxidant defense enzymes. Inactivation of SOD2 results in neonatal lethality. However, the function of SOD2 in early neuronal development is unknown. In the present study we found that deletion of SOD2 reduced embryonic brain development. During the first 24 hours in culture, primary cortical neurons established from embryonic day 15 wild type (WT) and SOD2-/- mice appeared morphologically

similar. During the ensuing two days in culture SOD2-/- neurons exhibited a profound reduction of neurite outgrowth and subsequently died such that less than 10% of the SOD2-/- neurons remained alive at culture day 5. Mitochondrial mass and mitochondrial distributions to neurites were significantly reduced and the level of reactive oxygen species was dramatically increased in SOD2-/- neurons on culture day 3 compared to WT neurons. Moreover, the expression of the mRNAs encoding PGC1alpha, a transcription factor critical for mitochondrial biogenesis, and NRF1 and TFAM (two PGC-1alpha[[Unsupported Character - Symbol Font ]]target genes) were significantly reduced. Attempts to rescue SOD2-/- neurons with neurotrophic factors (FGF2 and BDNF), antioxidants (N-acetylcysteine, TMP and Tiron), an alternative energy substrate (pyruvate) and a mitochondrial membrane permeability pore inhibitor (cyclosporine) failed. However, maintenance of the neurons in a reduced oxygen atmosphere (3% O_2) abolished the adverse effects of SOD2 deficiency on neurite outgrowth and cell survival that occurred in the usual 20% O_2 atmosphere. Relative to the O_2 level neurons are exposed to *in vivo* (2-5%), the 20% O_2 level typically used for cell cultures is hyperoxic . Our findings therefore suggest that SOD2 plays a particularly important role in enabling neurite outgrowth and cell survival under conditions where superoxide production is high. Supported by the Intramural Research Program of the National Institute on Aging. Key Words: SOD2, neurite outgrowth, mitochondrial biogenesis, neuronal death, ROS.

Title: Abhydrolase domain-containing protein 4 (ABHD4) controls adherens junction-dependent cell survival in radial glial cells

Authors: *Z. LELE[1,2,3], Z. I. LÁSZLÓ[1], A. J. DORNING[1], I. KATONA[1], G. M. SIMON[2], B. F. CRAVATT[2], S. S.-J. HU[3], K. MACKIE[3]

Abstract: Anandamide (AEA) is a lipid mediator, which exerts its physiological effects in the brain by activating CB1 cannabinoid receptors and the non-selective cation channel TRPV1. This endocannabinoid/endovanilloid molecule is also present in the embryonic forebrain and emerging evidence indicates that anandamide signaling regulates several fundamental aspects of cortical development including proliferation and neuroblast migration. Interestingly, NAPE-PLD, the enzyme which was proposed to be the predominant anandamide-synthesizing enzyme in the brain is not expressed until postnatal ages raising the possibility that anandamide may be synthesized via an alternative synthesis route in the developing forebrain. Therefore, in the present study, we first tested the hypothesis whether ABHD4, a serine hydrolase involved in the metabolism of N-acyl phospholipids, including a potential lipid precursor for anandamide is expressed in the embryonic forebrain. We found that ABHD4 mRNA expression is highly expressed by radial glial cells (RGCs) in the ventricular zone throughout prenatal development. Despite this restricted expression pattern, which was validated in ABHD4 knockout animals, we could not detect any defects in processes regulated by RGCs including proliferation, neuroblast migration or adult cortical lamination in ABHD4 knockout cortices. On the other hand, the disappearance of ABHD4 expression from sister neuroblasts implied that the function of ABHD4 may interfere with neuroblast migration. Indeed, ectopic expression of wild-type ABHD4, but not of a hydrolase-dead ABHD4 mutant in postmitotic neuroblasts arrested migration and induced cell death. Importantly, ABHD4-induced cell death did not require CB1 receptors or TRPV1 channels indicating that the pro-apoptotic function of ABHD4 is independent of endocannabinoid or endovanilloid signaling. Because the absence of ABHD4 alone did not cause developmental defects, but ABHD4 needs to be downregulated in the sister neuroblasts, we then asked the question whether this serine hydrolase controls a specific cell death process in radial glial cells. Notably, *in utero* disassembly of adherens junctions in the ventricular zone by using a dominant-negative version of N-cadherin induced robust cell death in wild-type, but not in ABHD knockout embryios. In contrast, basal developmental or genotoxic stress-induced apoptosis did not require ABHD4 activity. Taken together, these findings demonstrate that ABHD4 plays a specific stand-by guardian function in radial glial cells by controlling adherens-junction-dependent cell survival during cortical development.

Title: The small GTPase RhoQ is a target of the MLK-JNK-c-Jun pathway in sympathetic neurons

Authors: *J. HAM, M. KRISTIANSEN, R. HUGHES
Cancer Section, Developmental Biol. and Cancer Programme, UCL Inst. of Child Hlth., London, United Kingdom

Abstract: Developing sympathetic neurons depend on nerve growth factor (NGF) for survival and die by apoptosis after NGF withdrawal. This process requires *de novo* gene expression and we used Affymetrix exon arrays to study the pattern of expression of all known genes in sympathetic neurons at 16 hours after NGF withdrawal compared to +NGF as a control (Kristiansen et al., 2011, *BMC Genomics* 12: 551). We selected 16 hours because this was previously defined as the transcriptional commitment point and induced genes known to be required for NGF withdrawal-induced death, e.g. *c-jun, bim, egln3*, are expressed at a high level at this time. By including a mixed lineage kinase (MLK) inhibitor, CEP-11004, in our experimental design we identified which of the genes induced after NGF withdrawal are potential targets of the MLK-JNK-c-Jun pathway, which promotes apoptosis following NGF deprivation. In these microarray experiments we found that the level of the *rhoq* mRNA increased by 2.5 fold after NGF withdrawal and this increase was completely inhibited by CEP-11004 suggesting that the *rhoq* gene could be a downstream target of the JNK pathway. The *rhoq* gene encodes a small GTPase (RhoQ, ras homologue family member Q) similar to Cdc42 and Rac1 but with some distinct properties. The RhoQ protein can activate various effectors including protein kinases that activate the JNK pathway and this can increase the phosphorylation and transcriptional activity of c-Jun. We confirmed in real time Q-PCR experiments that the *rhoq* mRNA increases in level after NGF withdrawal. Furthermore, in immunoblotting and immunocytochemistry experiments we found that NGF withdrawal causes a significant increase in the level of the RhoQ protein. To investigate the function of RhoQ in this context, we microinjected a pcDNA1-RhoQ expression vector into sympathetic neurons. We observed that overexpression of RhoQ in the presence of NGF induces neuronal death as efficiently as expression of a constitutively active form of MLK3. Finally, bioinformatic analysis

of the DNA sequence upstream of the first exon of the rat *rhoq* gene identified conserved AP-1 and ATF sites, which are within regions bound by c-Jun in ChIP-seq experiments published by the ENCODE project consortium. These results suggest that *rhoq* could be a direct target of c-Jun in sympathetic neurons. We are currently studying the role of RhoQ in the NGF withdrawal-induced death pathway and will present the results of these experiments.

Title: Methylmercury exposure affects cell proliferation and death but not neural progenitor specification in xenopus laevis

Authors: *R. HUYCK[1], M. NAGARKAR[2], N. OLSEN[3], S. E. CLAMONS[1], M. S. SAHA[1]
[1]Col. of William and Mary, Williamsburg, VA; [2]Scripps Inst. of Oceanography, La Jolla, CA; [3]Virginia Commonwealth Univ., Richmond, VA

Abstract: Methylmercury (MeHg) is a ubiquitous environmental toxin with neurotoxic properties. To investigate the impact of MeHg exposure during early nervous system development, we exposed *Xenopus laevis* embryos to MeHg introduced in solution and assayed developmental response using a graded phenotype scale. We then evaluated the expression of the neural patterning genes Sox2, Delta, and En2, and the cell proliferation marker, PCNA, using *in situ* hybridization (ISH) and whole transcriptome microarray; and labeled patterns of apoptosis using TUNEL assay. *X. laevis* embryos showed a range of embryological disruption in both a dose and embryo density dependent manner, including failure of brain development, with a TD_{50} of ~0.05 microg/g MeHg and an LD_{50} of ~0.1 microg/g MeHg at densities of one embryo per ml of MeHg solution. Neural patterning genes did not show changes in gene expression even at the highest non-lethal doses by either ISH or microarray. In contrast, PCNA expression was

negatively correlated with MeHg dose at stages past gastrulation, while the amount of stained apoptotic cells in epithelial and neural regions was conversely increased. Partek pathway analysis on the differentially expressed genes identified by microarray similarly showed a significant impact of MeHg exposure on cell cycle and apoptotic pathways. These results suggest that disruption of neural development by MeHg may not be directly due to a loss of early neural patterning gene transcription, but rather related to impairment of cell proliferation during neurogenesis and an increase in cell death throughout the developing nervous system.

[1]Allen Inst. For Brain Sci., Seattle, WA; [2]Univ. of Oxford, Oxford, United Kingdom; [3]Univ. of Washington, Seattle, WA; [4]UC Davis, Davis, CA

Abstract: Existing gene expression atlases of the developing human brain have focused on attaining either fine spatial resolution at few timepoints or broader temporal resolution at low spatial resolution, largely due to tissue limitations. Non-human primates make ideal model systems for studying human brain development due to their close evolutionary proximity to humans, protracted development and maturation, and availability of multiple specimens from precisely specified ages. We present here a transcriptional atlas of the developing rhesus macaque brain that provides both high spatial and temporal resolution by using laser

microdissection and DNA microarray-based profiling across ten prenatal and postnatal timepoints, providing a window into understanding the role of genes associated with primate brain development, human evolution and neurodevelopmental diseases. A major focus was to probe the molecular underpinnings of events in cortical development, including progenitor and post-mitotic excitatory neuron development, thalamocortical projection specificity, and GABAergic neuron development by selectively assaying layers of several cortical areas (including V1) and associated subcortical structures including the dLGN and ganglionic eminences. Six prenatal time points correspond with ages of peak neurogenesis for different layers in V1, and four postnatal time points correspond to key phases of postnatal development: infancy, childhood, adolescence and early adulthood. We find extensive variation between cortical layers and across developmental stages, as well as evidence of a global transcriptional "clock," involving dramatic rates of gene expression change in all assayed regions throughout prenatal and early postnatal development. Interestingly, these rates were consistently 2 to 3-fold higher in macaque, mirroring the more rapid developmental trajectory compared to humans. We find a great deal of conservation of laminar and areal patterns between human and macaque, substantiating its value for studying the molecular basis of human cortical development. Finally, we used the anatomical specificity of connections between dLGN and layer 4Cb of V1 to search for genes that may mediate this connectivity, and find shared selective expression in parvocellular layers of dLGN and L4Cb of V1. Several of these genes (LRRTM1, EPHA3, CNTN5) have a known role in axon guidance and cell adhesion and may contribute to the target specificity of thalamocortical afferents in V1. This dataset is publicly accessible as part of the NIH Blueprint NHP Atlas at www.blueprintnhpatlas.org.

Title: The regulatory role of Pax6 on cortical progenitor cell proliferation

Authors: *Y.-T. HUANG[1,2], D. MI[2], K. RUISU[4], A. PANTAZI[3], J. O. MASON[2], D. J. PRICE[2]
[1]Sch. of Biomed. Sci., [2]Ctr. for Integrative Physiol., [3]Inst. of Genet. and Mol. Med., Univ. of Edinburgh, Edinburgh, United Kingdom; [4]Dept. of Developmental Biol., Univ. of Tartu, Tartu, Estonia

Abstract: Forebrain development is controlled by a set of transcription factors which are expressed in dynamic spatiotemporal patterns in the embryonic forebrain and are known to regulate complex gene networks. Pax6 is a transcription factor that regulates corticogenesis and mutations affecting Pax6 protein levels cause neurodevelopmental defects in eyes and forebrain in both humans and mice. In previous studies, it is shown that the graded expression pattern of Pax6 protein, which is high rostro-laterally to low caudo-medially in the cerebral cortex, is critical for its control of cell cycle progression and proliferation of cortical progenitors. However the underlying mechanisms are still unclear. Based on a microarray analysis, we identified a number of cell cycle-related candidate genes that may be affected by Pax6. One such gene, *Cell division cycle associated 7 (Cdca7)* is expressed in a counter-gradient against that of Pax6. In addition, *Cdca7* mRNA expressions is upregulated in *Pax6* null (*Small eye*) mutants and downregulated in mice that overexpress PAX6 (*PAX77*). There are several potential Pax6 binding motifs close to Cdca7 gene. One of them is proven to be physically bound by Pax6 *in vivo* by chromatin immunoprecipitation. Promoter luciferase assays using fragments combining four suspect binding motifs show that Pax6 is functionally critical. Cdca7 is a Myc and E2F1direct target and is upregulated in some tumours but its biological role is not fully understood. Current work using *in utero* electroporation to overexpress Cdca7 around the pallial-subpallial boundary (PSPB), where Cdca7 expression levels are normally lowest, to test the effects on the cell cycle of cortical progenitor cells in this region.

Title: A revised view of the regionalization of the ventral secondary prosencephalon based on morphogenetic analysis in zebrafish

Authors: *K. YAMAMOTO, P. AFFATICATI, B. RIZZI, C. BUREAU, N. PEYRIÉRAS, C. PASQUALINI, M. DEMARQUE, P. VERNIER
Neurobio. & Develop. (UPR3294), CNRS-Gif, Gif-sur-Yvette, France

Abstract: Regionalization of the forebrain is complex and highly dynamic event during the development. Since some of the processes are conserved among different vertebrate groups, notably at the developmental time point referred to as the “phylotypic stage”, we took advantage of zebrafish embryos to examine in 3D the secondary prosencephalon at 24, 30, and 48 hours post-fertilization. We systematically analyzed the i) localization of cells undergoing proliferation and differentiation and ii) expression of developmental genes, in relation to the ventricular organization. Based on the general distribution of DAPI staining in link with ventricular morphology, three distinct cellular masses were identified: ones containing future telencephalon, preoptic area, and hypothalamus. These regions were bordered by radial glia (GFAP+) and nerve fibers (acetylated tubulin+). The preoptic area was organized around the optic recess of the third ventricle, and the expression of ccna2 (marker of proliferating cells) and elavl3 (marker of differentiating cells) transcripts, and HuC/D protein (marker of differentiated cells) were organized in a centrifugal manner around the optic recess. A proneural gene neurogenin 1, transcription factors such as dlx2a and sim1a/otpb were also symmetrically expressed around the optic recess. These results suggest that the region containing the zebrafish preoptic area behaves as a morphogenetic unit, independent from the telencephalon and hypothalamus. We named this new morphogenetic unit the "ventral optic recess region" (vORR), as it is organized around the ventral part of the optic recess. Our results lead to reconsider the boundary of the telencephalon and the hypothalamus within the framework of the prosomeric model, and we propose possible homologous areas of the vORR between teleosts and tetrapods.

Title: The expression and function of Sonic hedgehog in the human fetal telencephalon

Authors: *F. MEMI, N. RADONJIC, J. A. ORTEGA, N. ZECEVIC
Neurosci., UCHC, Farmington, CT

Abstract: Sonic hedgehog (Shh) signalling plays a crucial role in the development of the mammalian nervous system regulating ventral patterning, proliferation, differentiation and survival of progenitor cells along the entire neuraxis. The expression pattern of Shh in the rodent ventral telencephalon and its role in the specification of GABAergic interneurons has been thoroughly characterized. Still, little is known about the expression and function of this morphogen in the human forebrain. Here, we provide, for the first time, a detailed description of the Shh expression pattern in the developing human brain, focusing in the dorsal (cortical) part of the telencephalon, using *in situ* hybridization. Furthermore, we identify the cells producing Shh to be projection and inhibitory neurons as well as neuronal progenitors such as Radial Glial Cells (RGCs), using a combination of *in situ* hybridization and cell-type specific immunostaining. Next, we determined Shh concentration in the human fetal brain and compared the levels of Shh between ventral and dorsal telencephalon. Finally, to reveal the role of Shh signalling in the developing human cerebral cortex, we treated enriched cortical RGCs *in vitro* with exogenous Shh and its inhibitor cyclopamine. Control dorsal RGCs generated cortical interneuron progenitors expressing Nkx2.1 and Lhx6, and calretinin-positive (CalR+) cells, the only GABAergic neurons present in RGC cultures at this developmental stage. Treatment of dorsal RGC cultures with exogenous Shh, increased the pool of Nkx2.1+ progenitors, decreased levels of Lhx6 expression, and suppressed the generation of CalR+ cells. On the other hand, the blockade of endogenous Shh signalling by cyclopamine led to an increase in number of CalR+ cells in dorsal RGCs cultures, but did not affect Nkx2.1 expression. These results support the idea that in human forebrain Shh plays an important role in specification of cortical interneuron progenitors generated from dorsal RGCs.

Title: Maternal hyposerotonemia alters placental physiology and biogenic amine function in fetal brain tissue of the B6.129(Cg)-SIc6a4tm1Kpl/J serotonin transporter knockout (SERT-KO) mouse line

Authors: *S. M. HEROD[1], E. HUGHES[1], K. FISH[1], E. EMERY[1], J. VELASQUEZ[2], A. BONNIN[2]
[1]Biol. & Chem., Azusa Pacific Univ., Azusa, CA; [2]Zilkha Neurogenetic Inst., Keck Sch. of Med. at the Univ. of Southern California, Los Angeles, CA

Abstract: Serotonin (5-HT) is a monoamine neurotransmitter fundamentally important for brain development, and recent studies have indicated the placenta, not the maternal blood or the fetal brain itself, is the source of 5-HT to the fetus in early development. Lower circulating levels of serotonin are associated with a variety of clinical psychopathologies including anxiety and depression. However, it is unclear how decreased circulating levels of 5-HT (hyposerotonemia) in mothers with such pathologies might affect placental levels of 5-HT and other biogenic amine signaling, or fetal brain development. Using a genetic mouse model for hyposerotonemia, B6.129(Cg)-*Slc6a*^{4tm1Kpl}*/J* serotonin transporter knockout (SERT-KO) mice were bred heterozygous (HET) by HET to generate wildtype (WT), HET, and knockout (KO) experimental genotypes. Females of each genotype were bred with HET males, and tissue was harvested at four different timepoints during embryonic development (E12.5, E14.5, E16.5, E18.5) as part of ongoing studies. High performance liquid chromatography (HPLC) analysis of forebrain, hindbrain, and placenta samples has measured concentrations of 11 biogenic amines, their precursors and metabolites in tissues. Thirty-three significant differences have been detected in biogenic amine levels when comparing maternal and fetal genotype combinations, indicating that SERT deletion has widespread effects on multiple neurotransmitter functions. Fetal brain tissue

from KO mothers had higher levels of both noradrenaline (NA) and 5-HIAA (main serotonin metabolite) than fetal brain tissue from HET mothers in a region specific manner. Increases in NA levels and higher concentrations of 5-HIAA, which indicates increased turnover rate of serotonin, are both associated with psychopathologies such as anxiety and depression. Placental tissues also showed marked decreases in 5-HT, NA, and 5-HTP in KO mothers as compared to HET mothers, regardless of fetal genotype, indicating a critical role for maternal availability of serotonin. Finding multiple differences in concentrations of biogenic amines due to 5-HT availability warrants further research regarding the effects of maternal 5-HT on placental physiology and fetal brain development.

Title: Morphological features of early born GABA hub neurons: From embryo to adulthood

Authors: *A. BAUDE[1], V. VILLETTE[1], P. GUIGUE[1], T. TRESSARD[1], M. A. PICARDO[2], R. COSSART[1]
[1]INMED INSERM, Marseilles Cx9, France; [2]Neurosci. Inst., New York, NY 10016, NY

Abstract: Early Born GABA neurons (EBGNs) are major components of the hippocampal circuit since at early postnatal stages they form a subpopulation of “hub neurons” transiently supporting CA3 network synchronization (Picardo et al., Neuron, 2011). One way to understand

the cellular mechanisms by which EBGNs coordinate neuronal activities as well as their developmental role is to examine the evolution of their connectome throughout life from the early perinatal period to adulthood. To this aim we have performed a thorough anatomical investigation of EBGNs labelled with EGFP/TdTomato using inducible genetic fate-mapping techniques. Postnatal day 3 appears to be a critical time point for the maturation of these cells, which coincides with the emergence of the first synapse-driven correlated activities within hippocampus. Indeed, we observed a spectacular development of the dendritic and axonal arborisation of EBGNs at P3, together with a higher expression of KCC2 at the membrane, further supporting their advanced maturation stage. EBGNs persist into adulthood. Locally, hippocampal EBGNs target principally dendrites of principal cells. Most importantly, hippocampal EBGNs include a significant proportion of cells with an extrahippocampal GABAergic projection to the septum but no other extrahippocampal target regions. Notably, half of the EBGNs from the dorsal CA1 at the rostral level project to the septum. Conversely, a quarter of EBGNs were targeted by septal afferents, as well as by inputs from the entorhinal cortex. Last, we found that some EBGNs outside from the hippocampus, like in the septum or the entorhinal cortex also displayed a long-range projection, this time to the hippocampus. We propose that a subpopulation of EBGNs develop into a network of GABAergic projection neurons in many brain areas, thus making them lifelong candidates to support information flow across distant structures

Title: Alterations of the forebrain in the Lhx2 and Lhx2/Lhx9 knockout mice

Authors: *A. ABELLAN[1], Y. ZHAO[2], E. DESFILIS[1], H. WESTPHAL[2], L. MEDINA[1]
[1]Univ. of Lleida - IRBLLEIDA, Lleida, Spain; [2]NIH/NICHD, Bethesda, MD

Abstract: The paralog genes Lhx2 and Lhx9 are expressed in specific and comparable patterns in the forebrain of different vertebrates. Studies in mouse and zebrafish showed that Lhx2 regulates forebrain development at multiple levels, including patterning, cell differentiation and proliferation, and axonal guidance (Porter et al., 1997; Seth et al., 2006; Saha et al., 2007; Zhao et al., 2010; Peukert et al., 2011). Lhx2 has been shown to be essential for the development of the neurohypophysis, the retina, and the telencephalon (Porter et al., 1997; Zhao et al., 2010). In the telencephalon of Lhx2-/- mice, there is agenesis of the hippocampal formation and severe malformation of the neocortex (Porter et al., 1997). In zebrafish, additional roles have been described for Lhx2 in the formation of the preoptic/commissural region (Seh et al., 2006), and for both Lhx2 and Lhx9 in the formation of the thalamus (Peukert et al., 2011). The roles of Lhx2 and/or Lhx9 in the thalamus, or Lhx2 in the preoptic region remain unexplored in mouse. We analyzed the role of both Lhx2 and Lhx9 in forebrain development by studying the mRNA expression of several developmental regulatory genes in the embryonic forebrain of Lhx2-/-, Lhx2-/-/Lhx9+/- and Lhx2-/-/Lhx9-/- mice. Our results show an enlargement of the ventrolateral pallium in the Lhx2-/- mouse, visualized with Dbx1, Tbr1, Lhx9 and Lmo3, accompanied by displacements of the boundaries separating this region from the subpallium or the dorsal pallium. We observed a distinct calretinin-immunolabeled area at the surface of the ventrolateral pallium, extending dorsally. This labelling does not include olfactory fibers (Saha et al, 2007), but possibly represents cells incoming from the enlarged prethalamic eminence. At the preoptic region, the anterior commissure was not formed. In the diencephalon of Lhx2-/- mice, the thalamic size was smaller compared to adjacent regions, although this region showed expression of Lef1. However, the thalamus was more severely affected in the absence of both Lhx2 and Lhx9, and showed no expression of Lef1 or Id4. The defect was accompanied of a ventricular enlargement. The malformation was more severe in the Lhx2-/-/Lhx9-/- than in Lhx2-/-/Lhx9+/-, suggesting a dose-dependent effect of Lhx9 in the formation of the thalamus.

Title: The regulation of Notch ligands Dll1 and Jag1 by Pax6 during cortical development

Authors: *E. F. DORA[1], I. SIMPSON[2], J. O. MASON[1], D. J. PRICE[1]
[1]Ctr. for Integrative Physiol., [2]Inst. for Adaptive and Neural Computation, Edinburgh Univ., Edinburgh, United Kingdom

Abstract: The regulation of gene expression resulting in the formation of the mammalian cerebral cortex is tightly regulated by a group of transcription factors. The deletion of any one of these transcription factors results in numerous defects whose nature and severity depends on the role of the transcription factor in the regulation of complex gene regulatory networks involved in development. There is currently relatively little knowledge about the gene networks that these transcription factors control and how they exert their regulatory effects. The paired-box transcription factor *Pax6* has been identified as a master regulator of gene networks involved in cortical development and its deletion results in numerous cortical defects such as an abnormally thin cortical plate and a vastly expanded proliferative zone. Previous work in our lab identified a list of candidate genes that are likely to be regulated by *Pax6* in the developing cortex. Members of the *Notch* signalling pathway were potential *Pax6* targets of particular interest since *Notch* signalling plays a crucial role in the maintenance of neural progenitor cells during development and consequently plays a critical role during corticogenesis. Our work aims to identify the regulatory relationship between *Pax6* and *Notch* ligands *Dll1* and *Jag1* during cortical development. Double label analysis of both gene and protein expression has provided insight into the relationship between *Pax6* and *Dll1* in progenitor cell subpopulations during cortical development. *In situ* hybridisation and qPCR results confirmed that loss of *Pax6* causes loss of *Dll1* expressing cells and downregulation of *Jag1*, indicating that both ligands are regulated by *Pax6.* Bioinformatic screening suggests that *Jag1* is a likely candidate to be a direct target of *Pax6.* Ongoing work aims to confirm *Jag1* as a direct target by visualisation of reporter gene expression produced by predicted enhancer elements driven by *Pax6*.

Title: The lateral cortical stream in embryonic and early fetal development of the human insular cortex

Authors: *G. MEYER, M. GONZALEZ-GOMEZ, C. MEDINA-BOLIVAR
Univ. La Laguna, La Laguna Tenerife, Spain

Abstract: The embryonic period sets the framework and pace for the subsequent patterning, proliferation and differentiation events of the cortex. The human insular lobe, thought to be important for sociocognitive processing, displays three main cytoarchitectonic divisions ranging from a ventral and rostral agranular neocortex (periallocortex), adjacent to the piriform cortex, to a dorsal and caudal granular neocortex, with transitional dysgranular areas in between. We study insula development in human embryos from Carnegie stage (CS) 16 (5.5 postconceptional weeks, PCW) to CS23 (8.5 PCW), and young fetuses (9-16PCW). CS17 marks the onset of the first, ventrally directed migration of Tbr1+ cells from the lateral edge of the pallial-subpallial boundary (PSB) toward piriform cortex and amygdala. In parallel, calretinin (CR) + interneurons migrate ventrally from the lateral ganglionic eminence (LGE). Both migrations form part of the lateral cortical stream (LCS). The LCS becomes more prominent in the following stages (CS 18-21) and contributes large numbers of Tbr1+ and CR+ cells to the prospective rostral insula, which is thus the earliest neocortical area to develop. At CS18, a subventricular zone (SVZ) appears in the cortex adjacent to the PSP, though not yet in dorsal and medial regions. Radial glia fibers guide the migration of the LCS toward the rostral insula. At CS 22/23, fibers of the internal capsule traverse LCS and PSB and enter the cortical intermediate zone. As the temporal horn of the lateral ventricle expands at 11/12 PCW, the PSB at the ventral ganglionic eminence gives rise to an ascending LCS which provides cells for the caudal insula, guided by radial glia from the PSB of the temporal lobe. Dorsal and ventral ganglionic eminences are connected by radial glia bridges which may serve as a substrate for neurons migrating in the LCR toward the prospective intermediate, dysgranular insula. At the posterior pole of the ganglionic eminences, the PSB is characterized by a highly developed SVZ, from where radial glia fibers direct migratory Tbr1/Tbr2+ neurons toward the caudal granular insula. We conclude that the agranular insula is the first neocortical region to develop; dysgranular and granular insular areas develop according to the progression of the ventricular system and the LCS, in concert with parietal and temporal areas. The agranular/dysgranular/granular character of the insula may be related to its proximity to the SVZ, with the dorsocaudal granular insula being closest to the highly developed SVZ of the parietal PSB.

Title: Regulation of the patterning and development of the hypothalamus and prethalamus by canonical Wnt signaling

Authors: *E. NEWMAN[1], H. WANG[1], D. WU[2], J. ZHANG[3], M. TAKETO[4], R. AWATRAMANI[5], S. BLACKSHAW[1]
[1]Neurosci., [3]Dept. of Radiology, [2]Johns Hopkins Univ., Baltimore, MD; [4]Dept. of Pharmacol., Kyoto Univ., Kyoto, Japan; [5]Northwestern Univ., Chicago, IL

Abstract: We tested the role of canonical Wnt signaling in hypothalamic and prethalamic patterning through loss and gain of function experiments using the canonical Wnt effector beta-catenin. We selectively eliminated beta-catenin from the hypothalamus using an Nkx2.1-Cre line, which we have previously shown to be active in posterioventral hypothalamus beginning at E9.5. We examined Nkx2.1-Cre; beta-cateninlox/lox embryos at E12.5 using *in situ* hybridization. With loss of beta-catenin, posterior structures were lost or reduced, and anterior structures were expanded. Gain of function studies using Shh-Cre; βcat(ex3)lox/+ showed a complementary phenotype, in which posterior hypothalamic structures were expanded at the expense of anterior structures. We next used the Foxd1-Cre line, which is expressed earlier in development throughout both the prethalamus and hypothalamus, to investigate the effects of gain and loss of function of beta-catenin. We found that Foxd1-Cre; βcat(ex3)lox/l+ mice lost expression of most, but not all, hypothalamic and prethalamic markers. However, some posterior hypothalamic markers such as Pitx2 and Lhx5 showed expanded domains of expression. These data suggest that canonical Wnt signaling is coordinately patterning both the hypothalamus and prethalamus.

Title: Role of differential heparan sulfate sulfation in mouse forebrain Fgf8 signalling

Authors: *W. CHAN, J. M. CLEGG, D. J. PRICE, T. PRATT
Ctr. of Integrative Physiol., Univ. of Edinburgh, Edinburgh, United Kingdom

Abstract: Heparan sulfate proteoglycans (HSPGs) are cell surface/secreted molecules expressed by all cells consisting of linear carbohydrate side-chains attached to a core protein. HSPGs are involved in regulating key signalling pathways in the developing mammalian brain via sugar-protein interactions. It has been hypothesised that the specificity for the interaction between the HSPGs and its particular signalling pathway is encoded by its heparan sulfate (HS) side-chain. HS has a variety of structures due to postsynthetic modification during its biosynthesis. Hs2st and Hs6st1 are two enzymes involved in generating various HS structures where the former catalyses the specific sulfation at the 2-carbon molecule of the sugar backbone while the latter catalyses the sulfation of the 6-carbon. Hs2st and Hs6st1 have been shown to be important for mouse forebrain development but interestingly, Hs2st and Hs6st1 each play a different role. Hs6st1 play a unique role in Fgf8 signalling while Hs2st does not providing support for the existence of a HS code. Fgf8 is a secreted morphogen crucial for forebrain development where it functions to pattern the forebrain via regulated gradient formation. Fgf8 protein levels and the interpretation of the Fgf8 protein gradient are important for Fgf8 signalling. HS has been previously shown to be involved in these processes however, the role differential sulfation plays in these processes and particularly, the molecular mechanism(s) behind this has not been clearly resolved. Fgf8 signalling has been widely studied and its signalling mechanism well characterised. Yet, the conventional model of its signalling mechanism could not fully explain the observations preliminary to this work where Hs6st1 mutants have disrupted Fgf8 distribution, presenting a gap in our current understand of Fgf8 signalling. To begin filling this gap, we test our hypothesis that differential HS sulfation is involved in Fgf8 signalling regulation. Here, we used a combined *in vivo* and *in vitro* approach to investigate the formation of Fgf8 gradient over time. Comparing these data between wild-type and Hs2st or Hs6st1 mutants reveals differences that indicate differential HS sulfation is important in the formation of Fgf8 gradient in the forebrain. Furthermore, the data revealed several key aspects of how differential sulfation is

affecting Fgf8 gradient interpretation. This provides us with further insight into the role of HS in the complex but precise regulation of mouse forebrain development.

Title: Fate-labeled Islet1 progenitor cells uniquely contribute to mature interneuron subtypes in mouse neocortex

Authors: *F. SIDDIQI[1], A. L. TRAKIMAS[3], D. J. JOSEPH[2], T. T. CLARKE[2], E. D. MARSH[2,4], J. H. WOLFE[2,5]
[1]Dept. of Neurol., [2]Neurol., Children's Hosp. of Philadelphia, Philadelphia, PA; [3]Biol., [4]Neurosci., [5]Pathobiology, Univ. of Pennsylvania, Philadelphia, PA

Abstract: The LIM homeodomain transcription factor, Islet1, is expressed in the ventral division of the lateral ganglionic eminence (vLGE) and is known to generate medium spiny neurons of striatum. It remains controversial whether or not Islet1-derived cells of the vLGE contribute to neocortical interneuron subtypes, which would indicate a larger unidentified role of Islet1 in forebrain development. Since Islet1 expression is mostly down-regulated in the postnatal brain, we used a Cre/loxP knock-in mouse line whereby the Islet1 gene locus drives expression of Cre recombinase crossed with a floxed R26-stop-CAG-tdTomato-WPRE mutant mouse line to trace the lineage of the Islet1-derived population. Results showed that at E11.5, tdTomato+ cells were localized to the LGE, yet three days later (E14.5) these DCX+ cells had tangentially migrated to the neocortex. Birth-dating with a S-phase marker showed many tdTomato+/EdU+ cells pulse labeled at E14.5. Co-staining with the MGE and CGE markers, Nkx-2.1 and CoupTF-II, respectively, showed that tdTomato+ cells did not overlap with these cortical interneuron progenitor pools. E14.5 isochronic transplantation of tdTomato+ microdissected tissue onto

littermate control organotypic slices showed that only LGE to LGE transplant resulted in cortical migration. In contrast, tdTomato+ cells isolated from the preoptic area only migrated locally in the basal ganglia. Lastly, phenotyping at P0 revealed labeled cells were present in olfactory bulb and at distinct locations from the known dLGE-derived ER81 interneuron pool. At P21 in the neocortex, tdTomato+ cells spanned layers II through VI and represented 18±1% of the larger GAD67+ population. A combination of neurochemical markers and electrophysiology determined that tdTomato+ cells were heterogeneous with fast spiking, regular spiking and rebound spiking cells within the population. Together, our data supports a model of the presence of a distinct Islet1+ progenitor population contributing to cortical interneuron diversity.

Title: Relationship between malformations of neuronal migration and variation of folia development in the cerebellar vermis of C57BL/6J mice

Authors: *S. VANDINE[1], N. YAN SIU[1,2], M. KHAN[2], J. AHSAN[2], R. L. RAMOS[1]
[1]Dept. of Biomed. Sci., New York Inst. of Technol. Col. of Osteop, Old Westbury, NY; [2]Dept. of Life Sci., New York Inst. of Technol., Old Westbury, NY

Abstract: The complex neuronal circuitry of the cerebellum is embedded within its lamina and folia, which together play an important role in sensory and motor function. Studies in mouse models demonstrate that cerebellar lamination and folia development are under genetic control. The cerebellar vermis of C57BL/6 mice exhibit normal variation in the organization of anterior folia (lobules I-V) as well as malformations of neuronal migration of posterior folia (lobules VIII and IX; molecular layer heterotopia). However, the relationship between naturally-occurring variations in foliation and the presence of heterotopia has not been directly examined. In the present report, we analyze the frequency with which folia variation and heterotopia occur, and demonstrate that folia variation is more commonly found to coincide with heterotopia than alone. These data are relevant toward understanding normal cerebellar development and disorders affecting cerebellar foliation and lamination.

Title: Autism-associated Met tyrosine kinase receptor influences frontal cortical size and neuronal generation

Authors: ***J. M. SMITH**, E. M. POWELL
Anat. and Neurobio., Univ. of Maryland, Baltimore, Baltimore, MD

Abstract: *MET*, the gene encoding the tyrosine kinase receptor for hepatocyte growth factor/scatter factor (HGF/SF), has been identified as a susceptibility locus for autism spectrum disorders (ASD). Both Met and HGF are expressed in the cerebral cortex during development, and HGF-Met signaling has been implicated in a number of cellular processes, including proliferation, migration, survival, and process formation. Alterations in HGF-Met signaling may therefore affect cortical development, potentially leading to neuroanatomical changes such as those thought to play a role in neurodevelopmental disorders such as ASD. We have previously found an expansion of the cortex at rostral levels in transgenic mice expressing a kinase-dead Met in the *Emx1* lineage. We have also found altered cortical lamination at the level of the somatosensory barrel fields. The embryonic loss of Met-signaling led to a permanent expansion of frontal cortical areas and increased white matter. We examined layer-specific marker expression in frontal cortex to determine if lamination was altered. To determine if the changes in cortical laminar structure could be due to changes the timing of neurogenesis, we also examined BrdU incorporation after a series of injections during early, middle, and late cortical neurogenesis. Our results suggest that prenatally impaired Met signaling alters neuronal generation and specification in a regionally-specific manner.

Paris Diderot, Paris, France; [6]Dept. of Biol., Howard Univ., Washington, DC; [7]Dept. of Anat., Univ. of California, San Francisco, CA

Abstract: The hypothalamus integrates information to coordinate the output of innate behaviors. However, the developmental programs for the generation of neural circuitry regulating these behaviors remains unknown. Here, we reveal that the homeodomain gene, Dbx1, is required for development of select subsets of hypothalamic neurons and innate behaviors. Despite widespread expression throughout the embryonic hypothalamic primordium, Dbx1 selectively functions in the specification of subgroups of neuronal populations within the feeding-associated arcuate and lateral hypothalamic nuclei. Consistent with this selective developmental role, Dbx1 hypothalamic-specific conditional knockout mice display sexually dimorphic alterations in energy homeostasis, without displaying defects in other hypothalamically regulated innate behaviors such as mating or conspecific aggression. Surprisingly, Dbx1-conditional knockout mice also have defects in innate fear responses. Thus, our findings link embryonic patterning to the emergence of subsets of motivational and aversive behaviors and suggest a common developmental genetic mechanism for specification of subsets of functionally related hypothalamic neurons.

Abstract: The mammalian cerebral cortex is subdivided into several tangential domains called functional areas, which are deputed to the elaboration of motor and sensory inputs, the selection and implementation of motor plans, and many other higher cognitive functions. Each functional area is constituted by six layers of projection glutamatergic neurons (PNs) with different morphologies, connectivity and molecular codes. Several transcription factors specifying different subclasses of neurons, such as callosal neurons (CPN, which target the contralateral neocortical hemisphere) and subcerebral projection neurons (SCPN, e.g. corticopontine and

corticospinal neurons) have been identified so far [1]. However, little is known about the mechanisms specifying their features in a time- and areal-specific manner. In this study, we show that a population of cells co-expressing molecular markers of CPN and SCPN neurons, such as Ctip2 and Satb2 (C/S+), becomes first specified in layers V and VI of rostro-medial mouse neocortex at perinatal stages and progressively increases between P0 and P21 in somatosensory areas. Since it was shown that Satb2 strongly inhibits the expression of Ctip2 [2, 3], we investigated the molecular mechanisms allowing their co-expression at different developmental stages and in different neocortical areas. Moreover, by the use of a transgenic line expressing GFP in layer V neurons and of vital dyes, we analysed morphology, connectivity and electrophysiological activity of this hybrid class of neurons at postnatal stages of development. Our study demonstrates that the co-expression of CPN and SCPN neuronal markers does not only characterize early phases of neuronal specification [1], but also defines a neuronal subpopulation with different areal-specific features and developmental timing in the mammalian neocortex. 1. Title: Analysis of heparan sulfate function in the developing mammalian forebrain using systematic gene expression analysis

Authors: *H. PARKIN, J. CLEGG, J. MASON, T. PRATT
Univ. of Edinburgh, Edinburgh, United Kingdom

Abstract: Heparan sulfate proteoglycans (HSPGs) are a family of molecules involved in regulating key signalling events required for normal mammalian brain development. It is thought that specificity of HSPGs for particular signalling processes is encoded by the heparan sulfate (HS) sugar side chains, which can be modified post-synthetically to yield huge variation in HS structure. Different sulfation patterns are generated by the action of enzymes such as the heparan sulfate sulfotransferases (HSTs) and sulfatases. Depending on the expression of these enzymes and the resulting heparan sulfate 'code', it is proposed that cells are then able to regulate signals they receive and send in the ligand rich extracellular environment of the developing forebrain. Following loss of the two HSTs Hs6st1 or Hs2st that add sulphate groups to specific positions on residues of the HS side chains, commissural tracts including the corpus callosum fail to develop normally during late mouse embryogenesis. The telencephalic midline environment is perturbed, with a striking mis-positioning of glial cell populations that normally act to guide axons towards the contralateral hemisphere. One hypothesis to explain this acallosal phenotype is a change in critical cell populations and processes at a time when the correct midline environment is being established, that may be identified by changes in gene expression. Given the function of HS these changes might correlate with alterations in signalling such as an increase in Fgf/ERK that has already been found. We performed RNA sequencing analysis on dissected midline regions of WT, Hs2st-/- and Hs6st1-/- mouse embryos at E16.5 and have identified lists of differentially expressed genes. We find changes in gene expression in cell populations that are known to be important for corpus callosum development, including callosal pioneer axons and the disrupted glial cells observed in HST-null embryos. By comparing the expression of these genes between WT and mutant embryos, we are gaining an insight into the underlying mechanisms of HS function.

Title: The molecular mechanism of thalamic pattern formation during development

Authors: *H. EBISU[1,2], L. IWAI[2], T. MOMOI[3], H. KAWASAKI[1,2]
[1]Grad. Sch. of Med. Sci., Kanazawa Univ., Ishikawa, Japan; [2]Grad. school of Med., The Univ. of Tokyo, Tokyo, Japan; [3]Ctr. for Med. Sci., Intl. Univ. of Hlth. and Welfare, Tochigi, Japan

Abstract: The mammalian thalamus is an important brain region that transfers sensory information to the cerebral cortex. The thalamus is located in the diencephalon and contains dozens of morphologically and functionally distinct thalamic nuclei. Although the thalamic primodium differentiates into these distinct nuclei during development, the mechanisms underlying the formation of thalamic nuclei are still unclear. Here, we searched for candidate molecules that could mediate thalamic pattern formation using the Allen brain atlas. We focused on transcription factors expressed in the thalamic primodium with a graded expression pattern. We found that the expression of Foxp2 was low in the anterior thalamus and high in the posterior thalamus at embryonic day 11 when the identities of the thalamic nuclei are about to be distinguished. Loss-of-function studies revealed that antero-medial thalamic nuclei expanded, whereas postero-lateral thalamic nuclei shrank in Foxp2-mutant mice. Furthermore, using *in utero* electroporation, we found that Fgf8 signaling, which is thought to be important for thalamic pattern formation, suppressed Foxp2 expression in the thalamic primoidum. Our results suggest that Foxp2 is important for establishing the identities of thalamic nuclei.

Title: EphA7 regulates striatal organization and function

Authors: C. J. GRIFFEY, *L. F. KROMER
Dept Neurosci, Georgetown Univ. Med. Ctr., WASHINGTON, DC

Abstract: In the developing nervous system, Eph receptor tyrosine kinases and their ephrin ligands regulate cellular interactions necessary to establish proper connections between brain regions, including neuronal migration, cell sorting, and axon guidance. However, the structural implications and correlated behaviors for which these molecules are responsible are less well known. For example, EphA7 receptors are reported to interact with ephrin-A5 ligands to regulate the topographic organization of thalamocortical and corticothalamic connections as well as the size of the somatosensory "barrel" cortex. In addition, neurons expressing EphA7 form a unique matrisome compartment within the striatum that exhibits a banded pattern. This distribution of EphA7+ matrisome neurons inversely correlates with the topographic organization of somatosensory inputs from ephrin-A5 expressing neurons in medial somatosensory (S1) cortex. However, it is currently unknown whether expression of EphA7 is essential for this organization of cortical afferents and whether EphA7 deletions result in behavioral abnormalities that are associated with corticostriatal functions. To address these questions, we evaluated anatomical changes within the striatum and identified behavioral abnormalities that occurred in EphA7-/- mice. Ephrin-A5 ligand binding histochemistry was used to evaluate changes in neuronal organization and axonal connections in the forebrain in the absence of EphA7 in 1-2 week postnatal mice (a time when EphA receptors are expressed at high levels in the forebrain). In EphA7-/- mice, there is a change from the normal striatal matrisome binding pattern observed in wild-type mice to a dispersed binding that extends across the entire striatal matrix compartment. Since all matrix neurons express EphA4, this suggests that EphA4 may function as a secondary binding partner for ephrin-A5 in the absence of EphA7. In addition, we observed that the pattern of ephrin-A5 binding is altered in the cortex, hippocampus and amygdala in EphA7-/- mice. Behavioral analysis of adult EphA7-/- mice indicates they exhibit motor impairments including hyperactivity and decreased coordination; diminished anxiety phenotypes in both elevated-plus maze and open field tests; and impaired contextual and cued fear conditioning. Taken together, these results support a developmental role for EphA7 in organizing striatal, limbic, and cortical structures and connections involved in regulating important cognitive and motor behaviors.

Title: Compensation during neural development following Notch signaling perturbation in X. laevis

Authors: *C. TOCHENY[1], B. RABE[2], M. MCDONOUGH[1], T. ARALERE[1], J. HINES[1], M. SAHA[1]

Abstract: During primary neurogenesis, the establishment of a balance between the proliferation of neural progenitor cells and the differentiation of neurons is crucial for the formation of a properly functioning nervous system. One of the pathways implicated in regulating this balance is the Notch pathway, a juxtacrine cell-signaling pathway that initiates the shift from a neural progenitor fate to a differentiated neuron through lateral inhibition. In order to determine the role of Notch signaling in neurotransmitter fate specification in Xenopus laevis, we unilaterally injected RNA constructs that overexpress or inactivate Notch signaling at the two cell stage. While these perturbations showed profound effects on the expression of neuronal gene markers at neural plate and neural tube stages of development on the injected side, expression of various neural marker genes equalized by the swimming tadpole stage, suggesting a compensatory response. To determine the molecular mechanism through which this compensation occurs during development, we performed microarray analysis as well as examining the expression patterns of early and late genes in the neural determination pathway. Our results suggest that the compensatory response involves both apoptosis to remove an excess of progenitor cells and a re-calibration of cell cycle dynamics, as well as modified regulation of genes involved in neuronal stabilization and determination.

Abstract: In the developing cerebral cortex the fibers of Radial Glia cells (RGCs) serve as guide and substrate for radially migrating neurons. In gyrencephalic species, like human and ferret, radial migration proceeds following the highly divergent trajectories of RG fibers, an arrangement that allows the expansion of the cerebral cortex in surface area and the formation of folds. This depends on the massive generation of basal Radial Glia Cells (bRGCs), particularly in the outer subventricular zone (OSVZ). Here we have investigated which are the cellular mechanisms involved in the generation of bRGCs in the developing ferret cortex. We find that at early postnatal stages bRGCs in the OSVZ are not produced by apical RGCs in the VZ (aRGCs), but only by self-amplification within the OSVZ. Unexpectedly, we find that this is completely different at embryonic stages, when aRGCs in the VZ undergo a brief period of massive generation of bRGC for both ISVZ and OSVZ. Hence, upon seeding the OSVZ with a small population of founder bRGCs, these establish a self-amplifying population independent from the VZ lineage. We are currently searching for molecules expressed differently in the VZ along cortical development that may underlie the transient generation of OSVZ-destined bRGCs. This is the first demonstration of the developmental origin of the OSVZ, and we identify for the first time the lineage independence between germinal layers within the developing mammalian cerebral cortex.

Title: Characterization of cells derived from adoptive transfer of hemocytes in crayfish brain

Authors: J. PLATTO, J. L. BENTON, *V. QUINAN, B. S. BELTZ
Neurosci. Program, Wellesley Col., Wellesley, MA

Abstract: As in mammals and other vertebrates, decapod crustaceans undergo life-long neurogenesis. In crayfish (Procambarus clarkii), the neuronal lineage underlying adult neurogenesis has been defined; this lineage is characterized by at least three generations of precursors that are spatially separated. The first-generation neuronal precursors are not self-renewing, but are never depleted; *in vitro* work has shown that hemocytes, and not other cell types, are attracted to and incorporated into the niche (Benton et al 2011). Thus, it has been hypothesized that neuronal precursors originate in a source extrinsic to the niche and that this source is part of the innate immune system. Adult-born neurons in the olfactory pathway in the crayfish brain differentiate by 6 weeks after BrdU labeling; these innervate the accessory and olfactory lobes (Sullivan and Beltz, 2005) and express appropriate transmitters (Sullivan et al., 2007). Labeled cells harvested from the hemolymph of donor crayfish and transferred to recipient crayfish become neuronal precursors. These go through the normal lineage events, and by 6 weeks after transfer express the transmitters appropriate to their locations in the brain. The current project seeks to characterize the morphology of the brain cells in P. clarkii that derive from adoptive transfers, by injection of dextran dyes into the accessory and olfactory lobes. These dyes retrogradely fill cells projecting to these regions, allowing visualization and characterization of the descendants of cells transferred from donor crayfish.

Title: The crustacean cytokine astakine 1: A link between the innate immune system and nervous system in crayfish

Authors: K. A. RAMOS[1], J. L. BENTON[1], J. LI[1], I. SÖDERHÄLL[3], *D. BAUER[2], B. S. BELTZ[1]
[1]Neurosci. Program, [2]Wellesley Col., Wellesley, MA; [3]Dept. of Comparative Physiol., Uppsala Univ., Uppsala, Sweden

Abstract: Freshwater crayfish (Pacifasticus leniusculus, Procambarus clarkii) live for up to twenty years and contain distinct hematopoietic tissues that synthesize hemocytes throughout the animal's lifetime. Astakines, crustacean cytokines belonging to the prokineticin family, are necessary for the synthesis and release of hemocytes from hematopoietic tissues (Lin et al., 2011, J Immunol 186:2073). In vertebrates, prokineticins are involved in diverse functions, including circadian regulation, angiogenesis, neuronal development, and adult neurogenesis. The goal of the present work is to define the role(s) of astakine 1 (AST1) in adult neurogenesis in the decapod crustacean brain. Immunoreactivity for AST1 was localized in the brains of crayfish using an antibody raised against the P. leniusculus form of the peptide. Fibers and varicosities within the olfactory and accessory lobes and associated interneuronal cell clusters express AST1 immunoreactivity. In both species, AST1 antibody also labels brain regions involved with circadian control. Immunoreactivities for AST1 and serotonin are generally expressed in the same synaptic areas in the brain, a finding that may be particularly relevant in the olfactory pathway, where adult-born neurons are integrated. The efficacy of recombinant P. leniusculus astakine (r-AST1) was tested in P. clarkii by injecting r-AST1 and sampling hemolymph at intervals after injection. At 12 hours post-r-AST1 injection, a ~75% increase in circulating hemocyte counts was documented. Western blot of P. clarkii AST1 shows that protein levels in the brain and hematopoietic tissue vary depending on time of day, with higher levels in the morning as previously reported for P. leniusculus (Watthanasurorot et al., 2011, Cell Mol Life Sci 68:315). R-AST1 injection also affects adult neurogenesis in the crayfish brain. The neuronal precursor lineage in adult crayfish is characterized by at least three generations of precursors that are spatially separated. R-AST1 regulates this lineage by increasing the total number of cells in the niche, as well as by increasing the numbers of 5-bromo-2'-deoxyuridine (BrdU)-labeled cells in all generations of the lineage. These studies demonstrate a close relationship between the innate immune system and adult neurogenesis in the crustacean brain. Further studies are examining the combined roles of serotonin and AST1 in regulating this link.

Title: Microglial proliferation in the developing rat neocortex

Authors: A. KREUTZ[1], J. KEITER[2], S. SAYLOR[2], V. MARTINEZ-CERDEÑO[3], *S. C. NOCTOR[2]
[1]Neurosci. Grad. Program, [2]Psych & Behavioral Sci., UC Davis, SACRAMENTO, CA; [3]Pathology, UC Davis, Sacramento, CA

Abstract: Microglia are the immune cells of the CNS. We have found that in the normally developing brain microglia play a critical role in regulating the number of neural precursor cells in the fetal neocortex. Microglia first enter the cortex during early stages of forebrain development. However, they do not accumulate in significant numbers until the end of the neurogenic period, when they colonize the proliferative zones and their number increases substantially. How the number of microglia rises substantially is not understood. Since microglia specifically colonize proliferative zones we considered whether microglial precursor cells preferentially divide in the cortical proliferative zones to produce cortical microglia. Alternatively, it is possible that microglial precursor cells divide in peripheral sites to produce microglia that enter the cortex. To address these possibilities we examined the proliferative status of microglia in the developing rat neocortex from E11 through postnatal ages. To determine when and where microglia proliferate, we mapped out the distribution of actively dividing microglia in the embryonic rat cerebral cortex. Mitotic microglia were identified based on co-expression of the M-phase marker phosphohistone-3 (PH-3) and the microglial marker Iba1. The laminar distribution of microglia was determined using cytoarchitectonics and Tbr2 expression to define proliferative zones. Our results show that microglia arrive in the rat neocortex by E11, and their number increases until E19 when the Iba1+ population expands dramatically. We found that a steady low proportion of microglia were proliferative in the rat neocortex from embryonic through early postnatal ages. Interestingly, the mitotic microglia were not restricted to the proliferative zones, but instead were located in laminae across the cortical wall. These data suggest that the rapid rise in microglial number at E19 results primarily from increased microglial entry into the cortex, not proliferation. Unlike other CNS cell types, we find no evidence for specific proliferative zones for microglia.

Title: Sleep deprivation effects over hippocampal neurogenesis and apoptosis after different recovery times in adult BalB/C male mice

Authors: *S. SOTO-RODRIGUEZ[1], G. LOPEZ-ARMAS[2], O. GONZALEZ-PEREZ[3], M. LUQUIN-DE ANDA[2], R. RAMOS-ZUÑIGA[2], R. GONZALEZ-CASTANEDA[2]
[1]Univ. De Guadalajara, Zapopan, Mexico; [2]Univ. de Guadalajara, Guadalajara, Mexico; [3]Univ. de Colima, Colima, Mexico

Abstract: Sleep deprivation (SD) is a stressful agent that actual society undergoes, with psychological and physio-logical repercussions. In mouse models it has been proven that SD affects the development in learning as well as memory tasks and it has been correlated with the decrease in the neurogenesis in the dentate gyrus (DG) but it remains unknown if this reduction is due to apoptosis and which cell line is the most affected. Most tests are applied immediately after SD, but it is unknown if these effects remain over long terms. The aim of this study was to analyze the effects of SD over proliferation in the DG at different stages of neurogenesis and gliogenesis in adult male mice, and evaluate the apoptosis in the hippocampus. SD was carried out in the inverted flowerpot for 72h, a single BrdU injection was applied at hour 70. After this time, animals were divided randomly in three groups. The first group was sacrificed immediately, and the remaining animals after a recovery period of 14 or 21 days. Neurogenesis was evaluated with inmmunohistochemistry (IHC) and apoptosis with a TUNEL test; brains were labeled to recognize between hemispheres. Progenitor cells and immature neurons were reduced in the SD animals, showing hemisphere differences. Apoptosis results showed no significant differences in DG, but there were differences in other hippocampal regions. Our results suggest that SD has a deleting effect in the dentate gyrus after 72h SD, affecting more one of the hemispheres, but this is not due to apoptosis, and this was persistent after a recovery period.

Title: Zinc-finger protein INSM1 regulates neurogenesis in spiral and vestibular ganglia and is transiently expressed in nascent outer hair cells

Authors: S. M. LORENZEN[1], *A. DUGGAN[1], A. OSIPOVICH[2], M. A. MAGNUSON[2], J. GARCÍA-AÑOVEROS[1]
[1]Anesthesiol, Northwestern Univ., CHICAGO, IL; [2]Mol. Physiol. and Biophysics, Vanderbilt, Nashville, TN

Abstract: Discussion of the development and differentiation of inner ear neurons and hair cells has centered on the bhlh transcription factors. These factors, while necessary, cannot alone account for proper differentiation of these cells. Furthermore, no factor has been described that is expressed by outer hair cells (OHCs) and not inner hair cells (IHCs) during early embryonic stages of inner ear development. INSM1 is a zinc-finger protein that is expressed throughout the developing nervous system in late neuronal progenitors and nascent neurons. In the embryonic cortex and olfactory epithelium, Insm1 promotes the transition of progenitors from apical, proliferative, and uncommitted to basal, terminally-dividing and neuron producing. In the embryonic mouse ear, not only is Insm1 expressed in neuronally committed progenitors and nascent neurons, but also in nascent OHCs. Insm1 expression pattern was assessed by *in situ* hybridization and Insm1GFP.Cre expression. Insm1 lineage analysis was conducted with Insm1GFP.Cre mouse crossed with reporter mice. Insm1 function was analyzed by comparing Insm1+/+ and Insm1-/- embryos. Immunohistochemistry was used to identify delaminating progenitors, nascent neurons, cells in mitosis, and cells undergoing apoptosis. In the otocyst,

delaminating and delaminated progenitors express Insm1, whereas, apically dividing progenitors do not. This pattern of expression is analogous to that in embryonic olfactory epithelium and cortex (basal/subventricular progenitors). Lineage analysis confirms that nearly all of the auditory and vestibular neurons come from cells which have expressed Insm1. In the absence of Insm1, spiral and vestibular ganglia have a 40% reduction in neurons, and accordingly the ganglia are smaller. To account for the decrease in neurons, we observe delaminated progenitors undergoing fewer mitoses, but no change in apoptosis in the progenitors or nascent neurons. We conclude that in the embryonic inner ear Insm1 regulates proliferation of delaminated neuronal progenitors and hence the production of neurons in the ear, a similar function to that in other embryonic neural epithelia. Unexpectedly, also found that nascent, but not mature, OHCs express Insm1, whereas IHCs never express Insm1. Thus far, we have not determined any abnormalities in the development of OHCs in the absence of Insm1. Insm1 is the earliest known gene expressed in OHCs versus IHCs, demonstrating that nascent OHCs initiate a unique differentiation program in the embryo, much earlier than previously believed. Furthermore, as a transcription factor, INSM1 may be an early regulator of the unique differentiation of OHCs.

Title: Developmental estrogen treatment selectively increases proliferative activity in the 3rd ventricle stem cell niche of female rats at weaning

Authors: *Z. HE[1], L. CUI[2], M. G. PAULE[1], S. A. FERGUSON[1]
[1]Div. of Neurotoxicology, Natl. Ctr. For Toxicology Res., Jefferson, AR; [2]Neurol., Univ. of Arkansas for Med. Sci., Little Rock, AR

Abstract: Developmental estrogen treatment enlarges the sexually-dimorphic nucleus of the preoptic area (SDN-POA) in male and female weanling rats (He et al., 2012). Because stem cell activity at least partially accounts for postweaning SDN-POA development (He et al., 2013), the present study determined if neural stem cell activity in the 3rd ventricle stem cell niche (3VSCN, rostral end of the 3rd ventricle labeled with nestin-immunoreactivity, He et al., 2013) responds to estrogen treatment. Methods: Pregnant Sprague-Dawley rats were gavaged with ethinyl estradiol (EE2, 10 µg/kg/day) or vehicle (0.3% carboxymethylcellulose sodium salt) on gestational days 6-21 followed by gavage of offspring with the same dose from postnatal day (PND) 1 until weaning on PND 21. On PND 21, neural stem cell activity in the 3VSCN was assessed in 1 pup/sex/litter (n=5-7/sex/group). Stem cell markers, including nestin, Ki67, phosphohistone H3 (PHH3) and doublecortin (DCX), were combined to investigate neural stem cell activity in the 3VSCN with reference to the caudal 3rd ventricle (within-subject control) and to other well-accepted neural stem cell niches [i.e., the subventricular zone (SVZ) and subgranular zone (SGZ)] as the within-subject positive controls for immunoreactivity. Results: The 3VSCN was characterized by reproducible nestin-labeling showing long straight projections perpendicular to the ventricular wall along the rostral end of the 3rd ventricle. The 3VSCN scarcely expressed DCX, while both the SVZ and SGZ displayed robust DCX expression: the former showing immunoreactivity along the ventricular wall and the latter showing the deposit along the base of granular layer as well as in the hippocampal hilus. The SVZ exhibited vigorous expression of Ki67- and PHH3-positive immunoreactivity, but the 3VSCN displayed only a few Ki67-positive and PHH3-positive cells. Nevertheless, Ki67-positive cell counts in the 3VSCN were 2.2 to 5.8 times that of the caudal 3rd ventricle in PND 21 female and male rats: 2798±565/mm3 vs. 1254±305/mm3 for females and 4365±1033/mm3 vs. 753±345/mm3 for males, $p<0.05$, respectively. Estrogen treatment increased Ki67-positive cell counts in both sexes in both regions: 8992±1880/mm3 vs. 1390±284/mm3 and 8219±2118/mm3 vs. 1322±324/mm3 (3VSCN vs. caudal 3rd ventricle, female and male respectively) and was significant for females ($p<0.05$). Conclusion: Developmental estrogen treatment selectively increased proliferative cell counts in the 3VSCN of female rats at weaning. Neural stem cell activity in the 3VSCN may be one of the driving forces in the postweaning development of the SDN-POA in rats.

Title: The function of Progranulin-a, a microglia-specific growth factor, during vertebrate retinal development

Authors: *C. WALSH[1,2], P. HITCHCOCK[2,1]
[1]Ophthalmology and Visual Sci., [2]The Univ. of Michigan, Ann Arbor, MI

Abstract: Progranulin is an evolutionarily conserved secreted growth factor well established for its role in embryogenesis, tumor development and wound repair. Although much is known about progranulin activity in non-neuronal tissues, the functions of progranulin within the central nervous system (CNS) are not well understood. In humans, mutations in the progranulin gene (*GRN*) cause neurodegeneration. In zebrafish, progranulin-a (*Pgrn-a*), syntenic to *GRN*, is expressed exclusively by peripheral macrophages and CNS microglia, and is strongly upregulated in retinal microglia after the selective death and regeneration of photoreceptors. There is a gap in our knowledge, however, regarding the functions of progranulin during developmental neurogenesis. Therefore, the purpose of this study was to determine how Pgrn-a regulates vertebrate retinal development, using zebrafish as a model. The work presented here combined reverse genetics and quantitative morphometric approaches, including *in vivo* and *in vitro* assays of cell proliferation and differentiation and expression studies, to elucidate the details by which Pgrn-a regulates retinal progenitor cell cycle. Knock down of Pgrn-a synthesis in zebrafish embryos results in the absence of neuronal differentiation in the retina, maintenance of retinal progenitors in a proliferating state, and altered cell cycle kinetics. Collectively, our data show Pgrn-a loss-of-function (LOF) lengthens retinal progenitor cell cycle. Specifically, the proportion of cells undergoing mitosis is significantly decreased in Pgrn-a LOF embryos. Relative to controls, the G2-phase, total cell cycle length and S-phase duration is significantly longer following Pgrn-a LOF. The expression of cell cycle promoters and inhibitors is correspondingly altered in experimental embryos. These data suggest that for retinal progenitors Pgrn-a functions as a mitogen to govern the transition from proliferation to differentiation, and that in the vertebrate retina, microglia-derived growth factors regulate aspects of developmental neurogenesis. Ongoing studies seek to elucidate the downstream signaling mechanism of Pgrn-a action on cell cycle kinetics.

Title: The role of direct neurogenesis in the development of the olfactory bulb

Authors: *A. CÁRDENAS[1], M. COGSWELL[2], C. DE JUAN ROMERO[1], A. TZIKA[3], M. MILINKOVITCH[3], L. MARTÍNEZ[1], M. TESSIER-LAVIGNE[4], S. RUSSEK[2], V. BORRELL[1]

Abstract: The olfactory bulb (OB) develops as a unique specialization of the rostral pallium (OB primordium) from early stages of development. The onset of OB development coincides with changes in progenitor cell cycle parameters and early neurogenesis locally within the OB primordium, which have been suggested to be key for its initial evagination and growth. Here we show that the distinction between OB and neocortical development starts at the onset of neurogenesis, with changes in progenitor cell cycle parameters such as cycle lengthening and increased cycle exit, producing within a short developmental period a prominent accumulation of neurons that bulge rostrally. We find that these changes in progenitor cell dynamics involve mainly apical progenitors, and are linked to an equally important accumulation of newborn pallial neurons within the VZ of the OB primordium, virtually absent in the neocortex. Time-course and time-lapse analyses of progenitor cell lineages demonstrate that these changes are preceded by significant OB progenitor cell dynamics, including the abundant occurrence of direct neurogenesis from Radial Glia cells, which we show is nearly anecdotic in the neocortex at those stages. Hence, whereas in the neocortex the majority of neurons are born from intermediate progenitor cells through indirect neurogenesis, in the OB we find that a significant fraction of neurons are produced directly from apical progenitors, while maintaining similar rates of indirect neurogenesis as in the neocortex. Direct neurogenesis in the OB primordium is paralleled by a reduced self-amplification of RGCs, coupling an increased neurogenesis with a reduction in apical surface, which leads to OB evagination. In summary, the development of the OB is initiated by a transient peak of neurogenesis in a short developmental period driven by a high incidence of direct neurogenesis from RGCs. We are currently searching for candidate genes

differentially expressed between OB and neocortex that may regulate cell cycle dynamics as well as the fate of Radial Glial Cells towards a direct neurogenetic lineage.

Abstract: Identifying the mechanisms behind non-pathological cognitive aging is a critical step for developing preventative and ameliorative treatments that maintain or improve quality of life in the elderly. The production of new hippocampal and olfactory bulb neurons can diminish with age, but whether age-related changes in neurogenesis in these regions occur concomitantly or in a region-specific manner is unclear. In addition, age-related declines in hippocampal neurogenesis have been linked to changes in central cytokine and chemokine levels but whether these factors also impact olfactory bulb neurogenesis is also unclear. Here we quantified central and circulating chemokines/cytokines and new neuron numbers in the olfactory bulbs and hippocampi of young (4-6mo), middle-aged (10-12mo) and aged (18-20mo) male Fischer 344 rats injected with the cell synthesis marker bromodeoxyuridine (BrdU; 50 mg/kg every 24h for 3 days) 2 weeks after the rats were trained and tested in a rapid water maze. Although similar proportions of immature (DCX+), transitioning (DCX/NeuN+) and mature (NeuN+) neurons

were detected across age groups, significantly fewer new cells were found in the olfactory bulbs and hippocampi of middle-aged and aged rats relative to their young counterparts. We are currently testing the relationships between age-related changes in olfactory bulb neurogenesis, hippocampal neurogenesis and levels of circulating and central cytokines in memory-impaired and memory-unimpaired rats. Our data will add to the picture of how neuroinflammation impacts neurogenesis and cognition across age.

Title: The role of Lhx2 in cortical neurogenesis

Authors: *H. CHIA-LING, L. CHIA-CHENG, N. SEAN, C. SHEN-JU
Inst. of Cell. and Organismic Biology, Acad, Taipei, Taiwan

Abstract: Abstract During corticogenesis, the balance between proliferation and differentiation of cortical progenitors is precisely regulated to give rise to an optimal number of cortical neurons. Lhx2, a LIM homeodomain transcription factor, was shown to be crucial for the formation of the cortex. Interestingly, *Lhx2* is expressed in a high-caudal-to-low-rostral gradient, which is opposite to the neurogenesis gradient in the developing dorsal telencephalon (dTel). Thus, it has been hypothesized that Lhx2 is involved in regulating cortical neurogenesis. The deletion of *Lhx2* in neural progenitors leads to a significantly smaller cortex with fewer progenitors and more neurons in the dorsal telencephalon at early developmental stages. We are currently comparing the proliferation and differentiation capacity of cortical progenitors from wild type and *Lhx2* conditional knockout (cKO) embryos. Our preliminary findings suggest that Lhx2 is required for the maintenance of cortical progenitors at their proliferative state. (This work is supported by NHRI-EX102-10260NI.)

Title: The roles of cytokinesis and kinesin Kif20b in regulating cerebral cortex growth

Authors: K. M. JANISCH[1], V. VOCK[2], A. SHRESTHA[2], J. DARDICK[2], M. FLEMING[2], T. CUPP[2], C. GRIMSLEY-MYERS[2], *N. DWYER[3]

Abstract: The proper development of the cerebral cortex depends upon precise temporal and spatial control of the cell divisions of neural stem cells. Early in development, sufficient numbers of symmetric divisions must occur to expand the neuroepithelium, and then asymmetric divisions must produce neurons with sequential layer fates and finally glia. During these divisions the neural stem cells maintain apical-basal polarity and epithelial integrity. It is thought that the fates of the daughter cells are determined by the partitioning of specific factors in the membrane and cytoplasm during cleavage. To control the segregation of fate determinants, the cells must precisely regulate mitotic spindle positioning, cytokinetic cleavage furrowing, and abscission. However, while many proteins affecting spindle orientation have been studied in mammalian cortex, much less is known about the cytokinesis events that actually carry out partitioning. This is crucial because neural stem cells undergo a special polarized form of cytokinesis. Their cleavage furrow ingresses from basal to apical, and forms a midbody at the apical membrane, which mediates abscission (severing of the daughter cells). We have undertaken quantitative analysis of cytokinesis in neural stem cells (apical progenitors) of the developing mouse cortex, and found differences between early and later stages of corticogenesis. Furthermore, we have identified a mouse mutant with microcephaly and defects in cytokinetic structures in the embryonic cortex. In mutant cortex, cytokinetic midbodies of dividing apical progenitors are often misaligned with the apical membrane. Those that are aligned tend to be wider than in controls. Apoptosis is increased four-fold in mutants. The subventricular zone and neuronal layers form, but are thin, and the mutants die at birth. The mutant has a hypomorphic mutation in

the vertebrate-specific Kinesin-6 family member Kif20b. This microtubule motor protein localizes within cleavage furrows and cytokinetic midbodies of control progenitor cells, but is reduced to undetectable levels in mutant cells. Kif20b was previously shown to be involved in cytokinetic abscission of human cells *in vitro*, but its precise function is not known. We hypothesize that in the developing cortex, Kif20b plays roles in midbody maturation and linkage to the apical membrane prior to abscission. In the Kif20b mutant, stochastic failures in abscission appear to lead to apoptosis, which depletes the progenitor pool and reduces neurogenesis. We are further analyzing the structure of neural progenitor midbodies, and testing whether candidate binding partners of Kif20b are mislocalized in mutant cells.

Title: Krüppel-like factor 5 plays important roles in self-renewal and differentiation of neural stem cells

Authors: A. KURODA[1], S. ISHIDA[1], *T. FUCHIGAMI[3], Y. HAYASHI[1], M. EMA[2], S. HITOSHI[1]
[1]Interactive Physiol., [2]Res. center for animal life science, Shiga university of medical science, Ohtsu, Japan; [3]Physiol., Japan, Ohtsu, Japan

Abstract: Krüppel-like factor (Klf) 5 is a member of Klf family of Zinc finger transcription factors, whose sequence and function are highly conserved in vertebrates. Among this family, Klf4 have been vigorously studied and there are so many reports about its roles in the induction of iPS cells by somatic cell reprogramming, in ES cell self-renewal, and in early embryogenesis, especially in inner-cell mass (ICM) development. In neural development, Klf4 also plays a significant role in the maintenance of neural stem cells (NSCs) by repressing proliferation of NSCs. Despite Klf5 can substitute, at least in part, for the roles of Klf4 in the early development, its roles in the neural development remain poorly understood. In this study, we performed the

neurosphere assay using Klf5 conditional knockout (cKO) mice and found that Klf5-deleted NSCs showed the impairment of self-renewal. We also observed that knockdown of Klf5 by *in utero* electroporation induced the premature differentiation and facilitated the radial migration of neural precursor cells of mouse embryonic brains. To understand the molecular mechanisms underlying the effects of Klf5 knockdown on the neurogenesis, microarray analysis was performed. Our results suggest that Klf5 plays important roles in the neural development and proliferation, migration and differentiation of neural precursor cells.

Title: Cells from the innate immune system generate adult-born neurons in crayfish

Authors: ***J. L. BENTON**[1], R. KERY[1], J. LI[1], C. NOONIN[2], I. SÖDERHÄLL[2], B. S. BELTZ[1]
[1]Neurosci. Program, Wellesley Col., Wellesley, MA; [2]Dept. of Comparative Physiol., Uppsala Univ., Uppsala, Sweden

Abstract: Neurogenesis continues in the brains of adult decapod crustaceans. However, the 1st-generation precursors that produce adult-born neurons, which reside in a neurogenic niche, are not self-renewing in the crayfish brain and must be replenished; the source of these neuronal precursors is unknown. Hemocytes, which are central players in innate defense mechanisms in crustaceans, are prime candidates. Here, we report that the number of cells composing the neurogenic niche in crayfish is tightly correlated with total hemocyte counts (THC) and can be manipulated by raising or lowering THC. Following adoptive transfer of ethynyl-2'-deoxyuridine (EdU)-labeled hemocytes, these cells populate the neurogenic niche containing the 1st-generation neuronal precursors. After a 7-week survival time, EdU-labeled cells are located

in brain clusters 9 and 10 where adult-born neurons differentiate, and express appropriate neurotransmitters. These findings demonstrate that the immune system is intimately involved in adult neurogenesis, and that adult-born neurons in crayfish can be derived from hemocytes *in vivo*.

Title: Neuronal precursors in the crayfish Procambarus clarkii are replenished from a non-neuronal source

Authors: J. LI, E. COCKEY, J. PLATTO, J. L. BENTON, *B. S. BELTZ
Neurosci. Program, Wellesley Col., WELLESLEY, MA

Abstract: Adult neurogenesis - the birth and integration of new neurons in the adult brain - is common in both vertebrate and invertebrate species. Investigations in mammalian models suggest that stem cells producing adult-born neurons are self-renewing. Previous investigations in the crayfish, Procambarus clarkii, have found that although the pool of first-generation neuronal precursors in the neurogenic niche is never depleted, these cells are NOT self-renewing. Therefore, there must be a source of neuronal precursors extrinsic to the niche. We propose that the innate immune (hematopoietic) system is this source, based on *in vitro* studies showing that hemocytes (and not other cell types) are attracted to the niche. We further tested this hypothesis by examining the turnover rate of two key hematopoietic regions, the posterior hematopoietic tissue (HPT) and the newly discovered anterior proliferation center (APC). Both of these regions are highly proliferative and are potential sources of neuronal precursors. The turnover rate of cells in HPT and APC was tracked after a single 5-bromo-2'-deoxyuridine (BrdU) injection to label S-phase cells, followed by immunohistochemical detection. An overall decrease in the

number of BrdU-labeled cells in hematopoietic regions was observed over time, as well as a temporally correlated increase in BrdU-labeled cells in the hemolymph. In the niche, BrdU-labeled cells were observed for 4 days following the labeling period. This initial labeling period is followed by a 3-day gap when the niche is devoid of BrdU labeling. Unexpectedly, BrdU-labeled cells were again observed in the niche between 8 and 14 days after the BrdU exposure. As BrdU is no longer available for renewed labeling of neuronal precursors in the niche at this time, our interpretation is that the "second wave" of labeled cells must have incorporated the nucleoside while still in their source tissue. Many mechanisms underlying adult neurogenesis are conserved across a broad range of vertebrate and invertebrate species. Therefore, this work may have important implications for other organisms, as well as for diseases associated with adult neurogenesis.

Title: Neurogenesis and *in vivo* cell cycle dynamics during the development of the DRG compared to the ENS

Authors: *D. G. GONSALVEZ, M. L. Y. FONG, K. N. CANE, L. A. STAMP, H. M. YOUNG, C. R. ANDERSON
Anat. and Neurosci., The Univ. of Melbourne, Parkville, Australia

Abstract: To understand the *in vivo* proliferative behaviour of neural stem and progenitor cells outside the CNS, we have examined the *in vivo* cell cycle dynamics of the developing mouse dorsal root ganglia (DRG) and enteric nervous system (ENS). We have modified an existing double S-phase labelling approach by combining it with multiple label immunofluorescence to identify *in vivo* cell cycle parameters in identified populations of cells. With this approach we can simultaneously identify the growth fraction (GF), S-phase length (Ts) and cell cycle length (Tc) for individual embryos. To identify neural crest progenitor cells, committed neurons and proliferating cells we used antisera to Sox10, Hu, and Ki67 respectively. The changes to GF, Tc and Ts, in the developing DRG and ENS are summarised in Table 1. In the DRG, only Sox10

cells were cycling. From E9.5 to E12.5, Tc and Ts both increase in proportion. On E13.5 Tc increases further but Ts decreases, corresponding with significant numbers of Sox10 cells exiting the cell cycle. For Sox10 cells in the ENS, there was a significant increase in the length of Tc from E10.5 to E12.5, which then remained constant through E16.5. Over this period, the vast majority of Sox10 cells remained in the cell cycle. Together with a previous study (Gonsalvez et al 2013, J. Neuroscience, 33(14); 5969), this study shows that neural crest derivatives forming different parts of the peripheral nervous system each have different patterns of proliferation, despite their common origin. The approach used can be applied to identify key proliferation parameters *in vivo* from different CNS and neural crest-derived tissues in a single embryo. This approach will be useful in studying how *in vivo* cell cycle dynamics are altered in a range of neurocristopathies. Table 1: Proliferation parameters of Sox10 and Hu cells the developing DRG and ENS

Title: Initiation mechanism for apical nuclear migration in radial glial progenitors

Authors: *A. BAFFET, D. HU, R. VALLEE
Columbia Univ., New York, NY

Abstract: In the developing neocortex, neurons are formed from the division of neuronal progenitor cells, also called Radial Glial Progenitors (RGPs). RGPs undergo a long-mysterious cell cycle-dependent process known as Interkinetic Nuclear Migration (INM), during which their nuclei oscillate between the apical and the basal regions of the ventricular zone. This movement is dependent on the microtubule cytoskeleton and tightly linked to the cell cycle: The kinesin KIFf1A transports the nucleus basally during G1 and dynein transports the nucleus apically during G2. We recently reported an essential role for two dynein recruitment pathways to the nuclear pores, acting sequentially to drive G2 apical nuclear migration (Hu et al, Cell, 2013). The RanBP2-BicD2 pathway is activated early in G2 and is involved in long-range nuclear migration to the ventricular surface, whereas the Nup133-CENP-F pathway contributes specifically to the late stages of migration. Strikingly, inhibition of these factors also blocked mitotic entry and neuronal production, revealing a tight relationship between cell cycle, INM, and neurogenesis. The current study was initiated to identify cell cycle-dependent regulatory mechanisms responsible for triggering apical nuclear migration during G2. Using multiple protein kinase

pharmacological inhibitors in live cultured embryonic rat brain slices we found acute Cdk1 inhibition to block apical nuclear migration at its earliest stages, phenocopying dynein and BicD2 knockdown. Cdk1 inhibition also rapidly and reversibly interfered with recruitment of BicD2 and dynein to the G2 nuclear envelope. Dynein recruitment could be rescued by constitutively targeting the dynein-binding region of BicD2 to the nuclear envelope, indicating that Cdk1 primarily modulates the RanBP2-BicD2 interaction. Using *in vitro* protein kinase assays, we identify novel Cdk1 phosphorylation sites in RanBP2, which strongly enhance BicD2 binding. These results identify a mechanism to control dynein recruitment to the G2 nuclear envelope and initiate apical nuclear migration in brain progenitor cells.

Title: Basal radial glia in outer subventricular zone contributes to late-bone neurons in the marmoset cerebral cortex

Authors: *A. MURAYAMA[1,2], J. OKAHARA[3], E. SASAKI[3], H. OKANO[1,2]
[1]Keio Univ. Sch. of Med., Tokyo, Japan; [2]RIKEN, BSI, Wako, Japan; [3]Central institute for experimental animal, Kawasaki, Japan

Abstract: The basal radial glia (bRG) is a type of progenitor in the subventricular zone (SVZ), which retains a basal process to the pial surface, sustains expression of radial glial markers and is capable of self-renewal. The bRGs occur at high relative abundance in the outer SVZ (OSVZ) of gyrencephalic animals, but lower of lissencephalic rodents, suggesting that the division of bRG in OSVZ is important to generate gyrencephalic brain. The common marmoset, Callithrix jacchus, is a primate that has a few gyrus and sulcus formations though the abundance of bRG cells is similar to that in human neocortex. In order to study the role of bRG in the developing marmoset brain, at first, we characterized the cell cycle of bRG using the technique of thymidine analog labeling, in combination with immunofluorescent staining. Secondary, we determined when the bRG cells build up in the OSVZ. Accordingly, the poor gyrification of marmoset's cerebral cortex is caused by the later birth of bRG than those of gyrencephalic animals such as macaque monkey. Furthermore, we labeled the dividing bRG with thymidine analogs when there

is an abundance of bRG in OSVZ according to previous data (Kelava et al., 2012). After birth, we performed histological analysis, showing that the bRG cells predominantly became the upper-layer neurons in the marmoset cerebral cortex.

Title: Coordinated cell cycle regulation by nucleotides and IGF-I in retinal progenitors

Authors: ***I. M. ORNELAS**, M. R. PEREIRA, T. M. SILVA, A. L. M. VENTURA
Neurobio., Fluminense Federal Univ., Niterói, Brazil

Abstract: Aim: ADP induces proliferation of retinal progenitors through activation of P2Y1 receptors, MAPK and PI3K. Recent studies have also suggested the participation of growth factors in purinergic signaling. Here we evaluated the role of ADP and IGF-I in controlling cell cycle of retinal progenitors. Methods and results:To evaluate signaling pathways activated by ADP and IGF-I in retinal cells, primary cultures obtained from 7-day-old chick embryos were stimulated for 5 minutes and protein levels detected by western blot. Cultures treated with 250 μM ADP and 100 ng/ml IGF-I showed increased levels of phospho-Erk. However, only IGF-I could stimulate phosphorylation of IGF-I receptor, Akt and 4E-BP1. Besides, after IGF-I treatment we could detect, by immunofluorescence, phospho-Akt and PCNA double-labeled cells, indicating that IGF-I stimulate PI3K/Akt pathway in progenitor cells. Since PI3K/Akt pathway is involved in CDK1 regulation and G2/M progression of retinal progenitors, we evaluated if IGF-I or ADP could regulate CDK1 levels by RT-PCR and western blot. IGF-I treatment, but not ADP, significantly increased CDK1 expression at mRNA and protein levels. Consistent with this data, IGF-I promoted a significant decrease in histone-H3 phosphorylation, which was partially prevented by the addition of PI3K inhibitor. S-phase entry was evaluated by

[3H]-thymidine incorporation in cultures treated with IGF-I and/or ADP for 24 h. When cultures were maintained in absence of FBS (fetal bovine serum) nor ADP or IGF-I could promote entry in S-phase. However, co-treatment with both agonists promoted a significant increase in [3H]-thymidine incorporation. Besides, in absence of FBS, concomitant treatment with both agonists could also increase Cyclin D1 and Cyclin E levels. Furthermore, in presence of FBS, ADP could stimulate entry in S-phase and this effect was totally prevented by IGF-I receptor inhibitor AG-1024. Conclusions: These data suggest that ADP and IGF-I are extracellular factors that regulate cell cycle in retinal progenitors. While IGF-I controls CDK1 expression and G2/M progression, both ADP and IGF-I are required to S-phase entry and expression of G1-phase cyclins.

Title: An intracellular mechanism integrating inputs from extracellular signals to activate hippocampal stem cells

Authors: *J. ANDERSEN[1], N. URBÁN[1], A. ITO[1], A. ACHIMASTOU[1], B. MARTYNOGA[1], M. LEBEL[1], C. GÖRITZ[2], J. FRISÉN[2], F. GUILLEMOT[1]

Abstract: Neural stem cells (or radial glia-like cells, RGLs) in the dentate gyrus (DG) of the adult hippocampus exist primarily in a quiescent state, in contrast to the highly proliferative NSCs in the embryonic nervous system. One of the main features of quiescent DG stem cells is their ability to re-enter the cell cycle upon reception of activation signals from the surrounding niche, and therefore, of their ability to respond to changing physiological demands as well as to aberrant pathological states. A number of environmental stimuli and signals have been shown to

influence stem cell activity. However, how stem cells integrate this information to generate an appropriate response is still unknown. Here we show that *Ascl1*, a member of the basic helix-loop-helix family of transcription factors known to promote progenitor fate commitment and differentiation in the developing mouse brain, is expressed by stem cells of the adult hippocampus, specifically when they become activated. Moreover, its expression is rapidly induced by neurogenic stimuli, with a faster kinetic than that of activation markers such as MCM2. Deleting *Ascl1* specifically in the neural stem cell population of the DG with a GlastCreERT2, tamoxifen-inducible line, results in the complete inability of RGLs to exit quiescence and divide, and consequently leads to an absolute block of neurogenesis in the adult DG. *Ascl1*-deficient cells remain in a state of quiescence over many months, and, most importantly, are unable to respond to neurogenic stimuli. By examining the genome-wide binding of *Ascl1* in adult hippocampal-derived neural stem cells, and the genes deregulated in *Ascl1*-deleted DG stem cells, we are learning how this factor controls stem cell activation and cell cycle progression. This work establishes the role of the transcription factor *Ascl1* in promoting the activation of neural stem cells and highlights the central function of *Ascl1* in integrating niche signals to regulate neural stem cell activity.

Title: Down-regulated necdin expression triggers the proliferation of postmitotic neurons of the rat cortex

Authors: *S. LIU, R. LIU, H. QUE, J. YANG, Q. LIN, Y. LIU, S. YANG, S. JING
Neurobio., Beijing Inst. of Basic Med. Sci., Beijing, China

Abstract: A widely accepted concept in neural biology field is that mature neurons are terminally differentiated cells and thus unable to re-enter cell cycles or to proliferate. The neurogenesis of the brains of adult animals reported by early articles is now believed to be the result of the proliferation of neural stem cells or neural progenitor cells. However, we found that down-regulated necdin expression by tri-iodo-L-thyronine (T3) and necdin RNAi can trigger the

proliferation of the purified primary neurons and the neurons *in situ* of adult rat cortex. The cultured primary neurons from fetal rat cortex were treated with (10^{-5} M) of arc-c for 96 hours and purified up to the concentration 99.99% and no nestin-positive cells is observed. The enriched primary neurons were then treated with T3 at different concentrations. Substantial amount of dividing neurons at different mitosis phases were observed. Low dose of T3 (2μg/ml) resulted in the division of parvocellular neurons and high dose of T3 (more than 50μg/ml) made magnocellular neurons proliferation. About 4.6±0.7% ShcC labeled neurons were checked out at G2M with flow cytometry when treated with 50μg/ml of T3. We further demonstrated that the dividing neurons possess various characteristics of postmitotic neurons, evidenced by specific markers, electrophysiology, ultrastructural and typical synapses between the dividing neurons and others. When different concentration of T3 was reversely administrated into the cortex of adult rat by microdialysis, a substantial amount of MAP2 and ShcC labeled neurons *in situ*, located around the microdialysis areas of layers III-VI, were triggered to divide. We further found that T3 triggers neuron division, is closely related to its ability to reduce the expression of necdin, alter the subcellular localization of E2F1, and to activate cyclin expression. Following, we demonstrated that down-regulation of necdin expression triggers the division of the enriched primary neurons and the cortex neurons *in situ* by necdin RNAi. The postmitotic neurons still possess the ability to proliferate under some conditions suggests the neurogenesis possibility and renews the hope in developing strategies for the cure of neural degenerative diseases. Key words: tri-iodo-L-thyronine, postmitotic neuron, proliferation

Title: Retinal progenitors are stem cells and Hmga2 facilitates their self-renewal

Authors: *I. AHMAD, S. PARAMESWARAN, X. XIA
Univ. Nebraska Med. Ctr., Omaha, NE

Abstract: Retinal progenitors unlike neural stem cells do not self-renew under normal culture conditions *in vitro*. This observation is counterintuitive to a prolonged retinal histogenesis, which necessitates retinal progenitors to self-renew to sustain the temporal generation of diverse cell types. Here, we have examined the premise that the self-renewal property of retinal progenitors requires contribution from others cells in the histogenic environment. In the absence of the identity of the contributing cells in the developing retina this notion was tested in the presence of endothelial cells, known to support stem cells in neural and extra-neural niches. We used conventional neurosphere assays, lentivirus-mediated perturbation of gene expression, and molecular and biochemical analyses to test the hypothesis. We observed that a small subset of retinal progenitors were capable of clonal propagation and maintain multipotentiality of their parents in the presence of endothelial cells. The self-renewing features, also observed *in vivo*, involved multiple inter-cellular signaling pathways. Microarray analysis revealed that these pathways recruited high-mobility group protein AT-hook2 (Hmga2), an epigenetic regulator, whose expression progressively decreased in the developing retina, as progenitors were exhausted. Perturbation of expression of Hmga2 both *in vitro* and *in vivo* revealed that it was functionally involved in mediating the cell-extrinsic influences on the self-renewal of retinal progenitors. Our observations suggest that retinal progenitors possess non-cell autonomous self-renewal property, which is regulated by a molecular axis, underpinned by Hmga2.

Title: Genomic DNA methylation program of a neural stem cells differentiation

Authors: *F. C. ZHOU[1], C.-L. LO[2], A. LOSSIE[3]
[1]Anat & Cell Biol, Indiana Univ. Sch. Med., INDIANAPOLIS, IN; [2]Anat. & Cell Biol., Indiana Univ. Sch. of Med., Indianapolis, IN; [3]Office of Behavioral and Social Sci. Res., NIH, Bethesda, DC

Abstract: The neural stem cell (NSC) restriction and differentiation require precise and orchestrated network of genetic transcription. What and how are the key genes transcribed from selected genome, and foremost what instructions are given to direct the complex transcription during neurulation is key to the understanding of the neuronal development. We have previously demonstrated that epigenomics of neural stem cells go through a critical DNA methylation diversification during initiation of differentiation (Zhou et al., 2011). In this study, comparing between undifferentiated and 3-day differentiated dorsal ganglia NSCs as model, we combined the analysis of genome-wide DNA methylation (by MeDIP-Chip) with the transcription (by microarray) to interrogate the involvement of the gene activities at epigenetic and transcriptional levels during the initial differentiation. The altered genes were further analyzed using Ingenuity pathway analysis (IPA) for canonical pathway and functional networking. We found that 691 genes were hypermethylated and 403 genes were hypomethylated in the differentiated cells as compared to the undifferentiated. Cross analysis of DNA methylation and transcription followed with IPA revealed a genes form a key network which involved critical cell signaling (including growth factors ECM protein, cytokines and hormone signaling pathways), cell cycle (e.g decrease of Cyclin D, Cyclin E), apoptosis (e.g. decrease of Bak, Bax), and Hedgehog, WNT, BMP, and TGF-β pathways. Our further analysis of neuronal specification pathways revealed many including Bmp4, Notch2, Hox and proneuron genes (ie. Ascl1) were also altered in expression or methylation. Finally, the influence of DNA methylation on transcription of a proneuron gene, Ascl1 was tested using miSeq methylation analysis followed by qRT-PCR to demonstrate the epigenetic influence of DNA methylation on transcription. Title: Neural differentiation of human adipose tissue-derived stem cells involves activation of the Wnt signalling

Authors: *S. JANG, J.-S. PARK, H.-S. JEONG
Physiol., Chonnam Natl. Univ. Med. Sch., Gwangju, Korea, Republic of

Abstract: Background: Stem cells are a powerful resource for cell-based transplantation therapies in neurodegenerative diseases, but understanding stem cell differentiation at the molecular level is not clear yet. Wnt signalling is involved in numerous events in animal development, including the proliferation of stem cells and the differentiation of stem cells to specific lineages. Based on this, we hypothesized that the Wnt pathway controls stem cell maintenance and neural differentiation. Results: We characterized the transcriptional expression of Wnt signalling genes during the neuronal differentiation of hADSCs followed our previous study. After neuronal induction, RT-PCR analysis was showed that the expressions of Wnt2, Wnt4, Wnt11 were decreased, but the expression of Wnt5a was increased compared with primary hADSCs. In addition, the expression level of most Fzds and LRP5/6 ligand were decreased, not Fzd3 and Fzd5. There were not changes the expression of b-catenin and GSK-3b. Interestingly, Wnt5a expression was highly increased in NI-hADSCs by real time RT-PCR analysis and western blot. Finally, we found that the JNK expression was increased after neuronal induction. Conclusion: Our studies indicate that the Wnt5a/JNK pathway modulated the neuronal differentiation binding Fzd3 and Fzd5 and directing Axin/GSK-3b in hADSCs.

Title: Global gene expression profiling of mesenchymal stem cells preconditioned with the neuroprotective agents lithium and valproic acid reveals involvement of novel genes and signaling pathways

Authors: *G. R. LINARES[1], D.-M. CHUANG[2]
[1]Mol. Neurobio., [2]NIH, Bethesda, MD

Abstract: Although stem cell-based therapy has emerged as a potential treatment for neurodegenerative diseases, donor cell loss after transplantation is a major drawback for this approach. One strategy to boost cell survival and efficacy is to precondition cells prior to transplantation with compounds that elicit a comprehensive increase in the expression of genes associated with trophic factors, energy metabolism, cell survival, and migration. Since the neuroprotective actions of the mood stabilizers lithium and valproic acid (VPA) induce multiple cell survival and anti-apoptotic pathways in neurons and other cell types, we hypothesized that preconditioning bone marrow-derived mesenchymal stem cells (MSCs) with lithium and VPA would enhance their biological and functional properties. To identify the genes and signaling pathways governing the beneficial effects of preconditioning, whole genome microarray analysis was performed on MSCs using an Agilent chip that contained 60,000 oligonucleotides. MSCs were incubated in the presence or absence of combined lithium and VPA (2.5 mM each) for 24 hrs. Of the 55,821 transcripts that hybridized to the array, 4,340 genes were differentially expressed with a fold change of 2.0 or higher ($P < 0.05$) in the lithium-VPA co-treatment group relative to control. Approximately 96% of the 4,340 genes were markedly upregulated, suggesting that lithium-VPA co-treatment exerts stimulatory biological effects on MSCs. The validity of the microarray data was confirmed with the increased expression of fibroblast growth factor-21 (2.3-fold) and matrix metallopeptidase related genes such as MMP-17 (2.6-fold) and Adam-2 (9.0-fold). Functional enrichment by gene ontology (GO) analysis revealed that genes clustered into 39 GO categories (false discovery rate p-value cut off = 0.10). We found robust expression (2-9 fold) of genes involved in growth factor, antioxidant, anti-apoptotic, chemokine/cytokine, migration, mitochondrial energy, and stress response signaling pathways compared to untreated MSCs. Furthermore, several expressed sequence tags (ESTs) and long non-coding RNAs (lncRNAs) with no known function were also identified as potential targets for lithium-VPA induced signaling pathways. Experiments are ongoing to validate the expression of selected genes by real time PCR. In conclusion, global gene expression profiling improved our understanding of the molecular pathways and mechanisms involved in mediating the beneficial actions of lithium-VPA on MSCs. Therefore, employing a preconditioning strategy utilizing these agents may prove useful for enhancing the therapeutic efficacy of stem cell-based therapy.

Title: HDAC3 controls G2/M progression in adult neural stem/progenitor cells by regulating CDK1 levels

Authors: Y. JIANG, *J. HSIEH
Mol. Biol., UT Southwestern Med. Ctr., DALLAS, TX

Abstract: The maintenance of the resident adult neural stem/progenitor cell (NSPC) pool depends on the precise balance of proliferation, differentiation, and maintenance of the undifferentiated state. Identifying the mechanisms that regulate this balance in adult hippocampal NSPCs can provide insight into basic stem cell self-renewal principles important for tissue homeostasis and preventing tumor formation. Pharmacological inhibition of histone deacetylases (HDACs), a class of histone-modifying enzymes, have promising effects in cancer cells, yet the specific roles of individual HDACs in stem cell proliferation is unclear. Here using conditional knockout (cKO) mice and *in vitro* cell culture, we show that histone deacetylase 3 (HDAC3) is required for the proliferation of adult NSPCs. Detailed cell cycle analysis of NSPCs from Hdac3 cKO mice reveals a defect in cell cycle progression through G2/M phase, but not S phase. Moreover, HDAC3 controls G2/M phase progression mainly through post-translational stabilization of the G2/M cyclin-dependent kinase-1 (CDK1). These results demonstrate that HDAC3 plays a critical role in maintaining the self-renewal of adult NSPC pool and suggest that strategies aimed at pharmacological modulation of HDAC3 may be beneficial for tissue regeneration and controlling tumor cell growth.

Abstract: Neurons of the mammalian neocortex are produced by proliferating cells located in the ventricular zone (VZ) lining the lateral ventricles. This is a complex and sequential process, requiring precise control of cell cycle progression, fate commitment and differentiation. We have analyzed publicly available databases from mouse and human to identify candidate genes that are potentially involved in regulating early neocortical development and neurogenesis. We used a mouse *in situ* hybridization dataset (The Allen Institute for Brain Science, ~2,100 genes) to identify 13 genes (Cdon, Celsr1, Dbi, E2f5, Eomes, Hmgn2, Neurog2, Notch1, Pcnt, Sox3, Ssrp1, Tead2, Tgif2) with high correlation of expression in both time and space in the proliferating cells of the VZ of the neocortex at early stages of cortical development (E13.5 and E15.5) and then significantly reduced at later stages of development (E17.5 and onwards). Consistent with this approach, we found that the human homologs of 10 of these genes also show high levels of expression in the ventricular and subventricular zones in the human developing brain (microarray data from the BrainSpan Atlas, ~58,700 probes). Using human transcriptomic data (RNAseq data from Yale University on deposit at the Allen Institute, ~52,400 genes), we further confirmed 7 of these 10 candidates as being highly expressed in human neocortex at 8-9 weeks post-conception (a comparable time point to mouse early cortical development used above) and greatly reduced by 12 weeks post-conception. We then extended this gene set by including other genes that are highly expressed either in the human neocortex or mouse VZ. A

gene ontology search for both of these extended sets of genes indicates that the majority of the genes considered are involved in transcriptional regulation. Validation of the candidate genes is provided by the reported involvement of Celsr1, Neurog2, Notch1, Sox3, and Tgif2 in either early neuronal development or diseases resulting from the disruption of neurogenesis, further suggesting that Hmgn2 and Tead2 are involved in the regulation of early neocortical development. Taken together, our knowledge-based discovery method has uncovered a conserved set of 7 genes that are highly expressed at the right time and place during neocortex development, allowing the identification of two novel potential regulators of early stages of cell proliferation in both human and mouse neurogenesis.

Title: Lipopolysaccharide-induced maternal cytokine changes and the effects on dopaminergic and serotonergic neuronal development

Authors: *S. WANG[1,2], K.-F. FAN[1], C.-Y. LIN[1]
[1]Inst. of Anat. and Cell Biol., Natl. Yang-Ming Univ., Taipei, Taiwan; [2]Dept. of Educ. and Res., Taipei City Hosp., Taipei, Taiwan

Abstract: Increasing evidences suggest that maternal infection during pregnancy may influence fetal brain development and leads to neurological disorders. In our previous studies we had used lipopolysaccharide (LPS) exposure to mimic maternal infection in rats. The offspring exposed to LPS during critical developmental window for dopaminergic and serotoninergic neurons showed a reduction in the number of dopaminergic and serotoninergic neurons and the dopamine (DA) and serotonin (5-HT) concentrations were decreased in various brain regions in adulthood. As a consequence, the offspring displayed more anxiety-like and depression-like behaviors and had increased corticosterone responses to stress; suggesting maternal immune activation during critical developmental window might pose a risk for psychiatric disorders in offspring. In the

current study, we set out to examine the maternal cytokine changes induced by LPS exposure and measured cytokine concentrations in the amniotic fluid. We also examined whether the developing dopaminergic and serotonergic neurons in embryo display cytokine receptors. The pregnant dams received a single *ip* injection of LPS on day 11 of gestation. Dams of the control group received a single *ip* injection of phosphate buffered saline (PBS) at the same time point. We collected maternal blood, amniotic fluid, and embryo samples at 2, 6, 12, 24 hours following LPS injection. The tissue narcosis factor α (TNFα), interleukin 1β (IL1β) and interleukin 6 (IL6) concentrations in the blood and amniotic fluid were determined by enzyme-linked immunosorbent assay (ELISA). In another group of dams we injected 5-bromo-2'-deoxyuridine (BrdU, 200 mg/kg, ip.) from E9-E11 (one injection per day) to label proliferating cells and had LPS or PBS injection on E12.We measured the number of serotoninergic and dopaminergic neurons and the number of BrdU-positive DA and 5-HT neurons on postnatal day 7, 14, 21 and 30. We found that there was a significant increase in TNFα, IL1β, and IL6 in maternal blood and amniotic fluid, however the peak time varies in each cytokine. The developing dopaminergic and serotonergic neurons express IL6 and TNFα receptors. There is a significant reduction in the proportion of BrdU-positive serotonergic and dopaminergic neurons in LPS rats; suggesting a reduction in cell proliferation. In summery, these data indicated that maternal cytokines induced by LPS exposure could reduce cell proliferation in DA and 5-HT neurons and the effect is long-lasting.

Title: Identification of small cell lung cancer (SCLC)-specific miRNAs in blood as a tumor marker for the detection of SCLC

Authors: *M. SHIMOJO[1], Y. SHUDO[2], S. ITO[1]
[1]Dept. of Med. Chem., [2]Psycosomatic Med., Kansai Med. Univ., Hirakata/Osaka, Japan

Abstract: Small cell lung cancer (SCLC) is a highly malignant form of cancer, which originates from primitive neuroendocrine cells in the lung. SCLC cells express several autocrine neurotransmitters and neuropeptides and their respective receptors. It was reported that the expression of these neuronal markers is regulated by RE1-silencing transcription factor (REST). In SCLC cells, an SCLC-specific isoform of REST (sREST) is highly expressed while full-length REST expression is too low to detect, suggesting that the expression of sREST correlates with the pathogenesis of SCLC. We previously reported that the neural-specific SR-related protein of 100 kDa (nSR100) abnormally activates the alternative splicing of REST (Mol. Cancer Res. 11, 1258 (2013)) in SCLC cells. There is recently increasing evidence that miRNA expression plays a fundamental role in gene regulation and may contribute substantially to cancer progression through translational repression. We analyzed the miRNA expression in SCLC cells using microarray analysis, suggesting that some of down-regulated miRNAs are predicted to interact with nSR100 mRNA. Analysis of these down-regulated miRNAs in patients' serum showed that the expression of a specific miRNA was significantly higher in SCLC patients than in other tumor patients. Furthermore we have found the miRNAs in SCLC patients' serum were selectively incorporated in the exosome. SCLC cells cultured on Matrigel in the condition which causes the up-regulation of nSR100 expression showed that the secretion of the miRNA in exosome was increased, while the intracellular miRNA significantly decreased. Taken together these results suggest that the miRNA targeting nSR100 might be a novel SCLC-specific biomarker.

Title: An axon enriched microRNA with a neurodevelopmental role within the rodent cortex

Authors: A. KOS, N. OLDE LOOHUIS, H. VAN BOKHOVEN, G. MARTENS, S. KOLK, *A. ASCHRAFI
Donders Inst. For Brain, Cognition, and Behaviour, Nijmegen, Netherlands

Abstract: MicroRNAs (miRs) are small non-coding RNAs which can regulate gene networks through post-transcriptional modulation of gene expression. An axon-enriched miR was previously identified as a regulator of axonal outgrowth and oligodendrocyte differentiation. However, the role of this miR within the central nervous system and more specifically the cortex remains largely unknown. In the current study we characterized the function of this miR in cortical development and dissected its downstream signaling pathways. To monitor the spatio-temporal expression of this miR we used qPCR analysis to examine the quantity of this gene within several brain regions. This revealed that this miR is dynamically expressed throughout development in a wide range of brain regions including the cortex. Following this, we established primary cortical cultures wherein we inhibited this miR using a viral based sponge. In-vitro inhibition of this miR throughout development resulted in a significant decrease in neuronal complexity. To complement these findings we employed in-utero electroporation (IUE) in order to manipulate this miR in the developing mouse brain. Brains in which this miR was either up or down regulated displayed several abnormalities potentially due to changes in the cell-cycle status of newborn neurons. A combination of whole transcriptome RNA-sequencing and gene network classification of the altered genes allowed us to pinpoint miR targets likely responsible for the observed phenotype. Our results indicate that this miR has an important role in early cortical development, and possibly is capable of affecting multiple stages of this process by regulation several key downstream mRNA targets.

Title: Using RNA interference to examine junctional communication within the adult neurogenic niche

Authors: *M. SORRELL[1], D. LINZ[2], Y. TOMOYASU[2], K. KILLIAN[2]
[1]Biol., Miami Univ., Latonia, KY; [2]Biol., Miami Univ., Oxford, OH

Abstract: In adult crickets, new neurons arise from two clusters of mitotic cells within the mushroom bodies. Within mammalian neurogenic niches, cell-cell interactions play a role in

regulating neurogenesis during both early development and adulthood. Within insect neurogenic niches, we propose that septate junctions mediate such cell-cell communication. We hypothesize that septate junctions maintain an active adult neurogenic niche and that disruption of this cell-cell communication will decrease the mitotic activity of progenitor cells, and lead to their terminal differentiation. To test this, we used RNA interference (RNAi) to experimentally knockdown expression of the septate junction protein Lachesin. We focused on this protein since it had been previously reported that mitotic cells of the cricket neurogenic niche label with anti-*lachesin* antibodies (Malaterre et al., 2002, *J. Comp. Neurol*. 452:215). Newly emerged (day one) adult male crickets were given a 2µl intra-abdominal injection of dsRNA. The optimal concentration for an effective knockdown, and the duration of knockdown, was determined by sacrificing control and experimental animals at different times post-injection. Effectiveness of the RNAi was validated using quantitative real-time PCR. Two days after injection of 2.5µg dsRNA against *lachesin* into adult male crickets (*n*=6), brain *lachesin* transcript levels were decreased by approximately 60% compared to control crickets injected with 2.5µg dsRNA against *dsRed2* (*n*=6), a gene not found in insects. This 60% decrease in *lachesin* expression was still evident 30 days later. Decreasing the dose of *lachesin* dsRNA to 1µg (*n*=6) or 0.5µg (*n*=6) resulted in a decrease in *lachesin* expression of 71% and 40%, respectively, 30 days post-injection. As RNAi was determined to produce a long-term decrease in *lachesin* expression, we examined the effects of this knockdown on adult neurogenesis. Again, on day one of adulthood, male crickets received an intra-abdominal injection of 2.5µg of *lachesin* dsRNA (*n*=6) or *dsRed2* dsRNA (*n*=5). Twenty-nine days later, all crickets were injected with 10µl of 40 mg/ml 5-bromo-2'-deoxyuridine (BrdU) in saline. After 2 hr, brains were dissected and processed for BrdU immunocytochemistry. Preliminary results support our hypothesis, since *lachesin* knockdown led to a significant, 15% reduction in the number of mitotic cells in the neurogenic niches (Student's T-test, *p*=0.03). We plan to examine the effect of *lachesin* RNAi on the structure of the niche and to determine its impact on behavioral plasticity. This study provides insight into the mechanisms by which stem cells in adult neurogenic niches remain mitotically active.

Title: Function analysis of centrosomes in the developing neocortex

Authors: *W. SHAO[1], R. INSOLERA[2], H. BAZZI[3], K. ANDERSON[3], S. SHI[3,2,1]
[1]Developmental Biol., [2]Neurosci., Weill Cornell Med. Col., New York, NY; [3]Developmental Biol., Mem. Sloan Kettering Cancer Ctr., New York, NY

Abstract: Centrosomes are essential for the proper development of the neocrotex, the dysfunction of which underlies several neurodevelopmental disorders, including microcephaly and ciliopathy. As demonstrated in our previous study, asymmetric inheritance of mature versus immature centrosomes dictates the cell fate of each daughter cell during asymmetric cell division of neuronal progenitors. Once neurons are born, the centrosome also directs neuronal migration by its repositioning into the leading process before nuclear translocation. However, the mechanisms underlying centrosomal behaviors in neurogenesis and neuronal migration remain elusive. I hypothesize centrosomes may regulate different aspects of neurogenesis and neuronal migration through different centirole-related structures in the developing neocortex. To begin with, we compared the phenotypes upon loss of primary cilia and centrosomes with a *Nestin::Cre* line to drive conditional knockout in the developing neocortex. In the cilia mutant *Ift88*$^{-/-}$, the cortex is surprisingly normal based on immunohistochemical analysis of neurogenesis and neuronal lamination. In contrast, the centrosomal mutant *Sas4*$^{-/-}$ is microcephalic with extensive apoptosis by E15.5. Upon full rescue by simultaneous removal of *p53*, Majority of Pax6+ cells cells delaminated and were ectopically present in the intermediate zones of the double mutant *Sas4*$^{-/-}$;*p53*$^{-/-}$. The ectopic progenitors do not possess any long processes and divide with randomized cleavage planes, indicating that they are not outer subventricular zone progenitors (oRGs). Further analysis demonstrated these progenitors are as capable as their normal counterparts in ventricular zone (VZ) to give rise to a more or less normal cortex. Taken together, centrosomes are required to anchor the radial glial progenitors and ensure a proper cleavage orientation. However, we also revealed that neuronal progenitors are remarkably plastic, in which they do not depend on the VZ as their essential stem cell niche and retain normal proliferation capability in spite of changed morphology and randomized cleavage orientations. We will examine *Sas4*$^{-/-}$;*p53*$^{-/-}$ mutant in more details to fully understand the functions of centrosomes in the developing neocortex.

Title: Differential roles of Nde1 and Ndel1 in rat cortical development

Authors: *D. DOOBIN, S. KEMAL, R. VALLEE
Pathology and Cell Biol., Columbia Univ., New York, NY

Abstract: Radial glial progenitor cells in the developing neocortex undergo cell cycle dependent interkinetic nuclear migration (INM). We have found apical nuclear migration to require cytoplasmic dynein, recruited to the nuclear envelope by sequential G2-specific mechanisms (Hu et al. Cell. 2013, 154:1300-13), and basal nuclear migration to involve kinesin-3 (Tsai et al. Nat. Neurosci. 2010, 13:1463-71). A number of dynein regulatory factors are involved in brain development, including LIS1, NudE, and NudEL. The latter two are closely related (55% identity; 70% similarity), but knockout mice exhibit distinct brain developmental phenotypes. Using *in utero* electroporation of Nde1 and Ndel1 shRNAs, followed by fixed and live cell imaging, we tested the effects of NudE and NudEL RNAi on neurogenesis and migration. NudE RNAi resulted in strong inhibition of INM, with severe defects specifically in apical nuclear migration, and a complete failure to enter mitosis. In contrast, NudEL RNAi had no effect on INM, and cell division at the ventricular surface persisted. Either NudE or NudEL RNAi, however, led to an accumulation of multipolar cells in the intermediate zone. Further migration of postmitotic neurons into the cortical plate was also diminished, an effect rescued by RNAi-insensitive NudE expression. These results identify a specific role for NudE in INM, and suggest common roles for both NudE and NudEL during the multipolar to bipolar transition and subsequent migration. Supp. by NIH HD40182.

Title: The role of rab18 in cerebellar development

Authors: *L.-S. KAO[1,3], P.-C. WU[3], H.-F. WU[1], C.-J. HONG[2]
[1]Dpt Life Sci. & Inst. Genome Sci., [2]Inst. of Brain Sci., Natl. Yang-Ming Univ., Taipei, Taiwan; [3]Brain Res. Ctr., Taipei, Taiwan

Abstract: Rab GTPase proteins belong to the superfamily of Ras small G protein family. They coordinate multiple processes of membrane trafficking, including regulation of vesicle formation, transport, budding, tethering and fusion. However, little is known about the physiological roles of Rab18 *in vivo*. Mutations of Rab18 are identified in patients with Warburg Micro Syndrome characterized by progressive limb spasticity, optic atrophy, hypoplasia of corpus callosum and cerebellum, suggesting that Rab18 is involved in neurodevelopment. Rab18 is also reported to be a candidate susceptibility gene of schizophrenia. Indeed, there is evidence for cerebellar pathology in schizophrenia, including decreased numbers of Purkinje cells and reduction of cerebellar volume. In cultured cells, Rab18 is shown to cycle between cytosol and secretory granules and interact with secretory granules to repress exocytosis upon activation of the regulated secretory pathway, suggesting a role of Rab18 as a brake for secretion. Therefore, it is possible that Rab18 may control some secretory factors crucial for neurodevelopment. In this study, the Rab18-mutant mice exhibited severe hind limbs ataxia and reduced cerebellar size by approximate 20%. We found that the foliation pattern of cerebellum was alterebd and the number of Purkinje cells was decreased in Rab18-mutant mice at P28. However, no significant differences were found in the thickness of granule cell layer and molecular layer as well as the Purkinje cell density. Furthermore, the proliferation of granule cells in the external granule cell layer of Rab18-mutant cerebella revealed no alterations. We will next focus on the deficits of cerebellum in Rab18-mutant mice and further elucidate functions and molecular mechanisms of Rab18. The study of the pathophysiological role of Rab18 during neurodevelopment will help to solve the mysteries of cerebellar malformations in human diseases.

Title: Promise of resveratrol for relieving cognitive and mood dysfunction, hippocampus oxidative stress and inflammation in gulf war illness

Authors: *B. HATTIANGADY[1,2,3], B. SHUAI[1,2,3], G. A. SHETTY[1,2,3], V. MISHRA[1,2,3], M. KODALI[1,2,3], X. RAO[1,2,3], A. K. SHETTY[1,2,3]

Abstract: Gulf war illness (GWI), a chronic multi-symptom heath problem, affects over a third of 700,000 veterans served in the Persian Gulf War-1. Memory problems and depression are the major symptoms related to brain. While the precise etiology is unknown, epidemiological studies imply that exposures to anti nerve gas agent pyridostigmine bromide (PB), pesticides such as DEET and permethrin, and stress during the war underlie GWI in a significant fraction of veterans. This supposition has been supported by studies in animal models. Our studies in a rat model have shown that exposures to these GWI-related chemicals (GWIR-Cs) and mild stress (5 min restraint stress) for 4 weeks is sufficient to cause memory and mood dysfunction associated with decreased hippocampus neurogenesis and increased oxidative stress and inflammation. Here, we investigated the efficacy of treating rats with resveratrol (RESV; a potent antioxidant and anti-inflammatory compound), a month after their exposure to GWIR-Cs and stress for improving memory, mood and dentate neurogenesis, and easing oxidative stress and inflammation. Adult male SD rats were exposed daily to GWIR-Cs DEET (40 mg/kg), permethrin (0.13 mg/kg) and PB (1.3 mg/kg) and 5-minutes of restraint stress for 4 weeks. A month later, a group of these rats received daily RESV (40 mg/kg, SQ) for four weeks while another group received vehicle (VEH). Both groups also received 5'-bromodeoxyuridine (BrdU) during the last 7 days of treatment for analyses of neurogenesis. Cognitive tests done two months after treatment showed improved memory function in RESV treated GWI-rats, in contrast to VEH treated GWI-rats. This comprised improved spatial learning and memory retrieval ability in a water maze test, proficiency for location and recognition memories in object location and novel object recognition tests. Moreover, RESV treated GWI-rats displayed better mood function, which was indicated through reduced latencies to eat food in novelty suppressed feeding test and reduced immobility times in forced swim test. Furthermore, in comparison to VEH-treated GWI-rats, the hippocampus of RESV treated GWI-rats presented greater level of neurogenesis when

quantified through BrdU, BrdU-NeuN and doublecortin assays, reduced expression of genes encoding oxidative stress response, reactive oxygen species metabolism and oxygen transporters, increased expression of antioxidant genes, and reduced numbers of ED-1+ activated microglia. Thus, RESV treatment has promise for reversing brain dysfunction in GWI. It appears that improved neurogenesis, decreased oxidative stress and inflammation mediated by RESV underlie the beneficial effects.

Title: Choline deficiency decreases proliferation of embryonic neural progenitor cells through inhibiting epidermal growth factor pathway

Authors: *Y. WANG, N. SURZENKO, M. MEHEDINT, K. CORBIN, S. ORENA, W. FRIDAY, S. ZEISEL
Nutr. Res. Inst. UNC Chapel Hill, Kannapolis, NC

Abstract: Choline deficiency can alter the development of fetal brain. Epidermal growth factor (EGF) is pivotal for neural progenitor cell (NPC) proliferation in the embryo. To address the possibility that EGF signaling pathway plays a functional role in the effect of choline deficiency, we cultured NPCs derived from E14 mouse hippocampus and cortex, then treated them with low choline (5 μM) or medium choline (70 μM). Low choline significantly suppressed the phosphorylation of EGF receptor (EGFR) and activation of downstream effectors ERK1/2 and Akt after stimulation of NPCs with EGF. Moreover, low choline decreased the EGFR protein expression and half-life in NPCs. There were no changes observed on the EGFR mRNA expression and degradation of EGFR protein. However, low choline remarkably inhibited the EGFR nascent protein synthesis. Pregnant Nestin-CFP transgenic mice were fed either a choline-deficient (CD) or control (CT) diet from days 11 to 17 of pregnancy and then E17 fetal brains were studied. In CD fetal cortex and hippocampus, expression of EGFR expression was

decreased. Similar decreased expression was observed in cell sorted CFP-positive cells using fluorescence-activated cell sorting (FACS). Our findings reveal that choline deficiency influences NPC proliferation by suppressing EGFR signaling pathway, which might have long-term effects in the brain.

Title: miR-7 promotes cell proliferation and migration by targeting KLF4

Authors: K. F. MEZA-SOSA[1], E. I. PÉREZ-GARCÍA[1], N. CAMACHO-CONCHA[1], O. LÓPEZ-GUTIÉRREZ[1], G. PEDRAZA-ALVA[1], *L. PEREZ-MARTINEZ[2]
[1]Medicina Mol. y Bioprocesos, IBt-Universidad Nacional Autonoma De Mexico, Cuernavaca, Mexico; [2]Medicina Mol. y Bioprocesos, Ibt-Universidad Nacional Autonoma De Mexico, Cuernavaca, Mexico

Abstract: Krüppel like factor 4 (KLF4) is a very versatile transcription factor (TF) that can act as an oncogene or as a tumor suppressor due to its ability of regulating the expression of several cell cycle regulators. The role of KLF4 during the central nervous system (CNS) development has been recently uncovered indicating that KLF4 protein levels decrease as the mouse brain develops and accordingly, KLF4 overexpression during early embryonic days affects the differentiation of ependymal cells causing hydrocephalus. Moreover, neural precursor cells (NPCs) derived from transgenic mice that overexpress KLF4 in the CNS, present a reduced proliferative ability and a preferential acquisition of a gliogenic fate over a neurogenic one. In

addition, neurons derived from KLF4-overexpressing NPCs fail to migrate and to differentiate adequately. These data suggest that KLF4 expression must be tightly regulated during the early CNS development. In this sense, microRNAs (miRNAs) are small RNAs (19-21 nt) that bind to the 3' untranslated region (3' UTR) of their target mRNAs and negatively regulate their expression at the post-transcriptional level. Additionally, miRNAs regulatory potential is crucial for differentiation of distinct cell types including neurons. Based on the dynamic KLF4 expression profile during the CNS development and on the KLF4 ability to control the cell cycle, we were interested on determining whether KLF4 expression is regulated by miRNAs during the early stages of neurogenesis. Bioinformatic, functional and molecular analyses revealed that KLF4 is a direct target of miR-7 and that regulation of KLF4 by miR-7 has functional implications in different cellular processes including cell proliferation and cell migration. In part, this result from misregulation of KLF4 target genes involved in cell cycle control such as p21 and Cyclin D. Taken together, these findings indicate that miR-7 can control cell cycle by directly regulating KLF4 expression and indirectly some of its target genes.

Title: Hedgehog signaling is required for and amplifies FGF2-induced formation of Muller Glia derived Progenitor cells in the avian retina

Authors: *L. J. TODD, A. J. FISCHER
The Ohio State Univ., Columbus, OH

Abstract: The capacity of retinal regeneration varies substantially across different vertebrate species, but consistently involves Müller glia as the cellular source for progenitors. Although retinal regeneration is robust in fish, the regeneration in birds and mammals is limited. After retinal injury, Müller glia in the avian retina can undergo de-differentiation, proliferation, some progeny differentiation as neurons, while most cells remain as undifferentiated progenitor-like

cells. The signaling pathways that influence the formation of Müller glia-derived progenitor cells (MGPCs) are slowly being revealed, whereas the coordination and cross-talk between these pathways remains largely unresolved. The purpose of this study was to investigate whether Hedgehog-signaling is a key node in the signaling network of MGPC formation. In NMDA-damaged retinas, we found that Hedgehog-signaling is dynamically up-regulated in Müller glia/MGPCs, and inhibition of Hedgehog-signaling decreases numbers of MGPCs. By comparison, activation of Hedgehog-signaling increases the formation of MGPCS in moderately damaged retinas, but is not sufficient to induce the formation of MGPCs in the absence of injury. Fibroblast growth factor 2 (FGF2) alone induces the formation of MGPCs in undamaged retina. We found that Hedgehog-signaling is necessary for FGF2-induced MGPCs as inhibition of Hedgehog-signaling with KAAD-cyclopamine, a SMO inhibitor, inhibits progenitor cell formation. Data is provided suggesting that KAAD-cyclopamine attenuates MGPC formation by preventing the accumulation of MAPK effectors in Müller glia. Additionally, co-application of a smoothened-agonist with FGF2 leads to an increase of MGPC formation. We conclude that Hedgehog-signaling stimulates the formation of proliferating MGPCs in acutely damaged retinas. Further, in undamaged retinas, our data indicate that FGF2/MAPK-signaling recruits Hedgehog-signaling to enable the de-differentiation and proliferation of MGPCs.

Title: Temporal dynamics of human cerebrospinal fluid vesicles

Authors: *D. M. FELICIANO, A. TIETJE, K. L. MARON, Y. WEI
Biol. Sci., Clemson Univ., Clemson, SC

Abstract: Elaboration of the cerebral cortex requires exquisite orchestration of cellular events through coordinated exchange of information between distally located cells. One mechanism by which intercellular communication is achieved is through the transfer of exosomes. Exosomes are vesicles that carry lipids, nucleic acids, and proteins and are detectable in most biological fluids including cerebrospinal fluid (CSF). Here we report that CSF vesicle concentrations, including that of exosomes, and vesicle content undergo age dependent fluctuations. CSF

vesicles encapsulated miRNAs that contain a conserved recognition sequence. We found that proteins important for miRNA recognition are found in vesicles produced by human choroid plexus epithelial cells and that they decreased with age in CSF. To determine the significance of declines in CSF exosomes in development we performed bioinformatic analysis of CSF vesicle miRNAs and *in vivo* inhibition of exosome release which support the hypothesis that exosomes mediate a developmental switch in signaling pathways. These results provide insight into exosomal exchange of miRNAs within the brain and a framework to understand how changes in exosomes may have an important impact on brain development.

Title: Laser-induced ATP dependent cortical calcium waves in E13-E15 mouse embryos ex utero

Authors: *M. YURYEV[1], C. PELLEGRINO[2], V. JOKINEN[3], S. KHIRUG[1], S. FRANSSILA[3], L. KHIROUG[1], C. RIVERA[1,2]
[1]Neurosci. Ctr., Univ. of Helsinki, Helsinki, Finland; [2]Inst. de Neurobiologie de la Mediterranee, Aix-Marseille Univ., Marseille, France; [3]Sch. of Chem. Technol., Aalto university, Espoo, Finland

Abstract: Calcium activity has been shown to have an effect on the cell cycle during brain development in *in vitro* and *ex vivo* conditions. The calcium activity in acute slices obtained from the embryonic brain has been shown to occur in different patterns such as singular events, synchronized coupled activity in neighboring cells as well as calcium waves. Calcium waves

have been found in the ventricular zone and shown mostly to be comprised in radial glia cells population, a transient cell type existing mainly in the period of active neurogenesis. In *ex vivo* conditions, it has been shown that calcium waves occur spontaneously and propagate by extracellular ATP rise and involve IP3-mediated intracellular calcium release. The disruption of the calcium waves during the peak of embryonic neurogenesis decreases cell proliferation *in vivo*. However, the properties of the calcium waves *in vivo* are poorly studied so far. Here we present the method for the calcium imaging in live mouse embryos connected to the mother at the age E13-E15. Prior to the imaging the embryos were injected with the acetoxymethyl ester form of different calcium dyes intraventricularly *in utero*. The embryos were positioned in a custom made chamber for stable fixation of the embryos that allows keeping the embryos connected to the anesthetized mother through the umbilical cord where two-photon imaging of the embryonic brains was performed. The physiological conditions of the embryos have been monitored by the blood flow level. Spontaneous singular calcium activity events were detected. To study the properties of the calcium wave propagation we stimulated a small group of cells (3-5) by means of high power laser emission from the same infrared laser as used for imaging. In the control conditions the stimulation of the cells caused calcium waves propagated through 340±240 cells/mm^2 (n=20) in the field of view. The strong stimulation of the cells always caused the calcium increase in the neighboring groups of cells. In case of injection of non-selective ATP receptors blocker suramin together with the calcium dye the calcium level increases were detected either confined in the zone of laser emission (3-5 cells) or recruiting significantly less number of cells (56±51 cells/mm^2; n=16) than under control conditions. On the contrary, the number of cells involved was increased after injection of caffeine (1190±370 cells/mm^2; n=15). Altogether, *in vivo* data demonstrates the possibility of calcium wave induction and propagation in the embryonic brain together with different pharmacological manipulations using the aforementioned method.

Title: Functional interaction between neural progenitors and the vasculature regulates neocortical interneuron production

Authors: *X. TAN, W. SHI, Z. LI, S. SHI
Mem. Sloan Kettering Inst., New York, NY

Abstract: Neurons in the neocortex can be classified into two primary groups, excitatory neurons and inhibitory interneurons, which are precisely and intricately interconnected to form functional circuits for various behavioral controls. Excitatory neurons in the neocortex are produced by radial glial cells (RGCs) in the ventricular zone of the dorsal telencephalon and they migrate radially along the radial glial processes into the cortical plate. In contrast, most if not all inhibitory interneurons are generated in the ganglionic eminence (GE) of the ventral telencephalon and they migrate tangentially over a long distance to reach the neocortex. Although extensive studies over the past decade have provided a comprehensive view on the production and positioning of excitatory neurons, our understanding of interneuron neurogenesis remains limited. Recently, we have identified the progenitor cells in the medial ganglionic eminence (MGE) responsible for producing more than 60% of neocortical interneurons are RGCs in nature, which typically exhibit a bipolar morphology with a ventricular endfoot and a long basal process. Using retroviral labeling, we found that most RGCs in the MGE possessed a highly diverse basal endfoot structure that was closely associated with nearby vasculature throughout the embryonic development. Further time-lapse imaging experiments indicated that the interaction between RGCs and vasculature was actively maintained and this interaction may be critical for the proliferation and maintenance of the interneuron radial glial progenitors. Amongst the large group of integrin receptors critical for cell-cell/ECM adhesion, integrin beta1 (Itgb1) has been shown to contribute to regulating the proliferation, maintenance and survival of neural stem cells. Our immunostaining results showed that Itgb1 was highly expressed in the RGCs in the MGE. Conditional knockout of Itgb1 specifically in the MGE led to a significant increase of RGCs that failed to interact with nearby vasculature. Furthermore, neocortical interneuron cell number was significantly decreased in Itgb1conditional knockout mice at P21, indicating the interaction between RGCs and vasculature mediated by integrins is important for proper interneuron production. We are continuing to analyze these defects in interneuron production and link these defects to the proliferation and maintenance of progenitors in the MGE.

Abstract: Regenerative processes in brain pathologies require the production of distinct neural cell populations from endogenous progenitor cells. To study how epigenetic factors regulate a regenerative response of parenchymal progenitors in white matter after hypoxia, we have used a mouse model of neonatal hypoxia that reproduces all the landmarks of brain injury observed in premature infants, including DWMI. In this model, we have previously demonstrated that - one week after hypoxia - the regenerative and proliferative response of oligodendrocyte progenitor cells (OPCs) was regulated by the Cdk2-p27Kip1 pathway. Since functional activity of cell cycle proteins is dependent on phosphorylation and acetylation status, we studied the role of Sirt1 (NAD dependent deacetylase) in the regulation of the Cdk2 signaling pathway in OPCs after hypoxia. Immunocytochemical studies demonstrated that hypoxia upregulated total number of Sirt1+ and NG2+Sirt1+, cells, as well as their proliferative potential. A higher expression of Sirt1 mRNA transcript was observed in FACS purified NG2+ cells after hypoxia. Furthermore, knockdown of Sirt1 protein or blockage of Sirt1 activity with sirtinol (Sirt1 inhibitor) caused a significant decrease in OPC proliferation after hypoxia. Finally, inactivation of Sirt1 also promoted OPC differentiation to oligodendrocytes. Molecular studies revealed that hypoxia enhanced Sirt1 levels and Sirt1/Cdk2 complex formation. Sirt1 deacetylated retinoblastoma (Rb) in the Cdk2/Rb/E2F1 complex, leading to dissociation of E2F1 and enhanced OPC proliferation. Blockage of Sirt1 activity in cultured cells enhanced expression of acetyl-lysine for Rb after hypoxia, indicating its lower acetylation status. Our results indicate that Sirt1 is an essential regulator of OPC proliferation and oligodendrocyte regeneration after neonatal brain injury. Therefore, enhancing Sirt1 activity may promote oligodendrocyte recovery after DWMI.

Title: Long-standing effects of exposure to gulf war illness related chemicals and mild stress on the expression of genes encoding oxidative stress and inflammation in the hippocampus

Authors: ***G. SHETTY**[1,2,3], B. HATTIANGADY[1,2,3], B. SHUAI[1,2,3], A. K. SHETTY[1,2,3]

Abstract: Impairments in cognition and mood are the major CNS related symptoms seen in Gulf war Illness (GWI), a chronic multi-symptom illness afflicting nearly 250,000 veterans who served in the 1991 Gulf War. Epidemiological studies have suggested that synergistic interaction of pyridostigmine bromide (PB, given to troops to shield against nerve gas agents) and pesticides such as DEET and permethrin (used copiously to protect against pest-borne diseases) with or without stress underlie GWI in a significant fraction of GW veterans. Our studies in a rat model have shown that exposures to these GWI-related chemicals (GWIR-Cs) and mild stress (5 min restraint stress) for 4 weeks cause hippocampus-dependent spatial and location memory impairments as well as a greatly declined neurogenesis. To understand mechanisms, we examined whether exposure to GWIR-Cs and mild stress causes enduring alterations in the expression of genes encoding oxidative stress and inflammation in the hippocampus. A group of adult male SD rats were exposed daily to DEET (40 mg/kg), permethrin (0.13 mg/kg) and PB (1.3 mg/kg), and 5-minutes of restraint stress for 4 weeks. Another group received VEH and handling. Six months later, hippocampi were analyzed for the expression of 84 genes relevant for oxidative stress via qRT-PCR array. Expression of multiple genes related to inflammation was also analyzed. Hippocampi from rats exposed to GWIR-Cs and stress displayed upregulation of

multiple genes related to oxidative stress response (Gpx1-3, Gpx5-6. Gclm, Txnip, Park7, Als2, Gsr, Gclc, Prdx1-2, Ercc6, Ctsb, Dhcr24, Txnrd2, Nudt1, Sqstm1, Cat, Hmox1, Nqo1, Txnrd1, Psmb5, Gpx4, Gpx7, Prdx6, Prnp, Sepp1, Apoe, Idh1, Tpo, Ercc2, Duox2, Mpo, Ucp3), ROS metabolism (Cyba, Noxo1, FMo2, Scd1, Ccs, Sod2-3, Ucp2), and oxygen transport (Mb, Cygb, Dnm2, Ift172, Slc38a1, Fancc, Ngb). Presence of increased oxidative stress was also revealed through upregulation of multiple antioxidant genes (Ptgs1, Prdx1-6, Gstk1, Gpx1-7, Sod3, Ehd2, Gstp1, Cat, Txnrd1, Srxn1, Gsr, Apc, Ctsb, Txnrd2, Ptgs1, Lpo). Furthermore, rats exposed to GWIR-Cs and stress showed up-regulation of several genes that promote inflammation (NF-κB, IL-1α, IL6, Csf2, Bcl6). Additionally, a gene encoding blood-brain-barrier leakage (Vegfa) was immensely upregulated and a gene having a role in maintaining Redox balance (Fox03) was severely downregulated. Genes encoding anti-inflammatory proteins (IL4 and IL10) were unaltered however. Thus, oxidative stress and inflammation likely underlie the persistent cognitive dysfunction observed in GWI. From this viewpoint, antioxidant and anti-inflammatory drug therapies seem ideal for treating GWI.

Title: Altered cellular responses in the juvenile and adult subventricular zone induced by epidermal growth factor

Authors: *G. KUHN, O. R. LINDBERG, A. BREDERLAU
Univ. of Gothenburg, Gothenburg, Sweden

Abstract: The ErbB receptor family mediates effects in numerous tissues and cellular contexts. Signaling through the ErbB receptors is often altered in cancers. Increased ErbB signaling, mainly ErbB1 (EGFR) and ErbB2, can lead to increased proliferation and invasiveness of tumor cells. Intracerebroventricular infusion of epidermal growth factor (EGF) induces hyperproliferative polyp-like dysplasia in the subventricular zone (SVZ) of the adult rodent brain. EGF induces a differentiation shift in the subventricular zone towards a highly proliferative glial cell type, while the generation of neuronal progenitor cell is strongly diminished. Interestingly, blood vessels develop in about 30% of the polyps after continuous EGF infusion for 14 days. Structurally, the newly formed vessels are of a disorganized and glomeruloid appearance, sometimes as bundles sprouting from a single SVZ blood vessel, and other times as a highly vascularized ventricle wall. These vessels are to a large extent covered by pericytes strongly expressing NG2. The angiogenic area shows multi-luminal vessels and signs of immaturity based on ultrastructural characteristics, such as a thickened endothelial cell layer. As polyp growths progresses, microglia/macrophages accumulate in the polyp core concurrent with increasing cell death. Both microglia/macrophage accumulation and cell death peak during angiogenesis and decline after polyp vascularization. EGF infusion into the adult rodent brain causes substantially reduced neuroblast production; however, after EGF infusion into the juvenile brain (starting at postnatal day P21) the number of neuroblasts (DCX) and glial progenitor cells (Sox2, Olig2) in the SVZ was not altered. In the juvenile brain the number of DCX was reduced, and the number of Sox-2 and Olig2 cells was increased only if animals had received whole brain irradiation at P9 (8Gy) prior to EGF treatment. Hyperproliferative polyps were formed after EGF infusion at both P21 and P80 in both naive and irradiated animals. This indicates that stem and progenitor cells capable of extensive proliferation are present even in the irradiated SVZ.

Title: Thyroid hormone acts locally to increases the rate of neurogenesis and dendritic arborization in the tadpole visual system

Authors: *C. K. THOMPSON, H. T. CLINE
The Scripps Res. Inst., La Jolla, CA

Abstract: Thyroid hormone is a critical regulator of brain development. For instance, low levels of maternal thyroid hormone during gestation leads to cretinism in humans. Nevertheless, the specific effects of direct action of thyroid hormone on different regions of the brain are not well understood. To address this issue we have developed a method for direct application of thyroid hormone to distinct parts of the Xenopus laevis tadpole visual system. Crystalline triiodothyronine (T3) was diluted into melted coconut oil, which was then injected via micropipette and picospritzer into either the 3rd ventricle near the optic tectum or into the eye. These animals were treated with CldU, a thymdine analogue, in order to label newly-divided cells and then sacrificed 2 days later. We found that T3 placed in the brain increased the rate of proliferation nearly tenfold relative to animals that received T3 in the eye. In contrast, T3 in the eye increased the rate of proliferation in the ciliary region by fivefold, whereas T3 in the brain had no effect on retinal proliferation. In another experiment, we electroporated the tectum with morpholinos against type 3 iodothyronine deiodinase (DIO3), which converts T3 to reverse T3, an inactive form of thyroid hormone. We found that DIO3-knockdown increased the rate of proliferation in the tectum, likely by increasing the local concentration of active T3. Combining DIO3 morpholino treatment with systemic exposure to methimizole, which blocks thyroid synthesis in the thyroid gland, prevented the increased proliferation seen with DIO3 morpholino alone. These experiments suggest that T3 acts locally in the tectal progenitor cells to regulate their proliferation. Last, we sought to examine the effects of local T3 on arborization of tectal neuron dendrites. We electroporated tectal neurons with GFP and after 7 days, when the neurons had already acquired a complex dendritic arbor, we injected T3 coconut oil into the 3rd ventricle. We imaged the GFP-expressing neurons with a 2-photon microscope the day before T3 delivery and each day afterward for 3 days. We found that T3 treatment significantly increased dendrite arbor length and branch tip number by 66% and 73%, respectively. These experiments demonstrate that thyroid hormone can act directly on specific neural circuits and have a substantial impact on brain development.

Title: Fate choice in the cranial neural crest

Authors: *R. CARR, A. GRAHAM
MRC Ctr. for Developmental Neurobio., King's Col. London, London, United Kingdom

Abstract: Neural crest cells (NCCs) are a transient embryonic population which diversify into many cell types, including peripheral neurons, pigment cells and the majority of the craniofacial skeleton. The mechanisms by which these fate choices are regulated remain elusive. Cranial NCCs enter the pharyngeal arches and switch to an ectomesenchymal fate, upregulating Dlx2. Those cranial NCCs that do not enter the arches maintain the expression of early crest markers, and will form non-ectomesenchymal derivatives, including those that contribute to the peripheral nervous system. Previous work has shown that this switch to an ectomesenchymal fate at least in part involves FGF signalling. However, NCCs are also exposed to other signalling pathways, including SHH, BMP and WNT, and it is unclear how they respond to these. We find that the presence of Wnt in NCC-explant cultures has clear effects causing huge depletion of NCC numbers; conversely, FGF allows survival and growth of NCC-explants in culture. We also show *in vivo* that although Shh is expressed in the pharyngeal arch epithelia, NCCs do not appear to respond to this signal. We have also shown that NCCs respond to BMP signalling *in vivo*, though a role of BMP in NCC fate switch has yet to be elucidated.

Title: The role of serotonin in running-induced neuronal activity

Authors: *C. HAINER[1], F. KLEMPIN[1], A. MACMAHON[2], M. BADER[1], N. ALENINA[1]
[1]MDC Berlin, Berlin, Germany; [2]Columbia Univ., New York, NY

Abstract: Serotonin (5-hydroxytryptamine) is a small biogenic amine with functions in the peripheral as well as the central nervous system (CNS). As neurotransmitter, serotonin was recently shown to be necessary for the running-induced increase in adult neurogenesis, the generation of new neurons in the dentate gyrus (DG). The mechanisms coupling physical activity with neuron formation via serotonin are not yet fully understood. This project aims at investigating brain areas that are affected by serotonin signaling during exercise. Mice lacking the enzyme TPH2 with central serotonin deficiency (TPH2 -/- mice) have been generated in the Bader lab and serve as an effective tool for this study. Analysis was done with TPH2 -/- mice in comparison to serotonin competent (TPH2 +/+) animals. Methods used in my study comprise 20 min sessions of forced running on a rodent treadmill. Neuronal firing was detected by labeling expression of the immediate early gene c-Fos on histological brain slices. Surprisingly, no changes in c-Fos expression have been observed in serotonergic neurons of the brain stem raphe nuclei. However, quantification of c-Fos expression in the DG revealed a significant increase in activated neurons in TPH2 +/+ as well as TPH2 -/- animals after running. These data show a condition rather than a genotype effect. Thus, the observed result seems to be serotonin independent and other neurotransmitters may mediate running-induced cell activation in the DG. Further analysis will be done for other brain regions. Studying intracellular signaling mechanisms is of great clinical importance for the development of novel therapeutic approaches.

Title: VGluT1+ neuronal glutamatergic signaling regulates postnatal developmental maturation of cortical protoplasmic astroglia

Authors: *M. TOLMAN, L. MOREL, H. HIGASHIMORI, Y. YANG
Tufts Univ., Boston, MA

Abstract: Functional maturation of astroglia is characterized by the development of a unique, ramified morphology and the induction of several important functional proteins, such as glutamate transporter GLT1. Although pathways regulating the early fate specification of astroglia have been characterized, mechanisms regulating postnatal maturation of astroglia remain essentially unknown. Here we employed a new *in vivo* approach to illustrate and quantitatively analyze developmental arborization of astroglial processes in multiple brain regions. Our analysis found a particularly high increase in the number of VGluT1+ neuronal glutamatergic synapses that are ensheathed by processes from individual developing astroglia from P14 to P26 when astroglia undergo dramatic postnatal maturation. Subsequent silencing of VGluT1+ synaptic activity in VGluT1 knockout (KO) mice significantly reduces astroglial domain growth and the induction of GLT1 in the cortex, but has no effect on astroglia in the hypothalamus where non-VGluT1+ synaptic signaling predominates. Electron microscopy (EM) was used to analyze the localization of GLT1 relative to the synapse showed that significantly fewer perisynaptic astrocytic contacts in the cortex of VGluT1 KO mice. To further determine whether synaptically released glutamate mediates VGluT1+ synaptic signaling, we pharmacologically inhibited and genetically ablated metabotropic glutamate receptors (mGluRs, especially mGluR5) in cortical astroglia and found that the developmental arborization of astroglial processes and expression of functional proteins such as GLT1 is significantly decreased. In summary, our genetic analysis provides new *in vivo* evidence that VGluT1+ glutamatergic signaling, mediated by the astroglial mGluR5 receptor, regulates the functional maturation of cortical astroglia during development. These results elucidate a new mechanism for regulating the developmental formation of functional neuron-glia synaptic units.

Title: New mouse strains for manipulating genetically defined subpopulations of central norepinephrine neurons

Authors: *N. PLUMMER[1], J. DE MARCHENA[1], D. D'AGOSTIN[1], S. D. ROBERTSON[1], C. J. TUCKER[2], P. JENSEN[1]
[1]Lab. of Neurobio., [2]Lab. of Signal Transduction, NIH/NIEHS, Research Triangle Park, NC

Abstract: Central norepinephrine (NE) neurons comprise a small yet diverse population of cells that vary in their anatomical location, connectivity, and response to disease and environmental insult. NE neurons project to virtually all areas of the central nervous system, and they play an essential role in a wide range of behavioral and physiological processes. Recently, we identified four NE neuron subpopulations derived from progenitors located in different rhombomeres of the embryonic hindbrain (Nat Neurosci 16:1016-23). Because they are defined genetically, these NE subpopulations are accessible for experimental manipulation in mice via a genetic intersectional strategy. Here we describe a suite of new mouse strains that will permit these experiments and can also be adapted to studies of other neuronal populations. A triple-recombinase responsive fluorescent indicator allele uses the Dre/rox, Flp/FRT, and cre/loxP recombinase systems to label neuron cell bodies and axons at the intersection of three distinct gene expression domains. This allele can therefore reveal additional diversity within the rhombomere-derived subpopulations, including the subpopulation derived from rhombomere 1 (r1) which encompasses the functionally important locus coeruleus (LoC). A similar strategy was used to generate a triple-recombinase responsive effector allele expressing the hM3Dq DREADD receptor, which will permit us to directly link structural and behavioral consequences of altered NE signaling during development to a specific subpopulation of NE neurons. Furthermore, two new recombinase driver alleles, a Dre recombinase knock-in allele of Engrailed 1 and a Dre-dependent cre knock-in of the dopamine β-hydroxylase gene, will allow any cre-responsive indicator, effector, or conditional knockout allele to be expressed in the r1-derived NE subpopulation, thus granting unprecedented ability to control locus coeruleus development and function.

Title: Sox17 promotes hedgehog-mediated oligodendroglial lineage survival in the subcortical white matter

Authors: *B. MCELLIN, M. CATRON, E. HONG, L.-J. CHEW, X. MING, V. GALLO
Neurosci., Children's Natl. Med. Ctr., Washington, DC

Abstract: Successful repair in demyelinating diseases, such as multiple sclerosis, is dependent on the development and maturation of oligodendrocyte progenitor cells (OPCs). A better understanding of molecular mechanisms of oligodendrocyte development through the study of its regulatory factors will provide important clues for potential therapeutic strategies. Our lab has previously identified the SRY-box containing gene 17 (Sox17) as a transiently expressed High Mobility Group-domain factor that positively regulates oligodendrocyte development *in vitro* by promoting cell cycle exit and differentiation of OPCs. To expand upon these studies, a novel CNPase-based conditional Sox17 knockout mouse (Sox17 cko) was used to study the effects of Sox17 ablation on oligodendrocyte development and remyelination in the subcortical white matter (SCWM). In the absence of injury, Sox17 knockout animals show reductions in both RNA and protein levels of myelin proteins, as well as increased numbers of delaminated axons by electron microscopy at P30. In addition, Sox17 cko mice show motor deficits on inclined beam tests relative to controls, suggesting that abnormalities in myelination are functionally significant. To understand how this phenotype arises, cellular analysis of the developing SCWM was performed. Results showed persistent deficits in total numbers of Olig2+ and CC1+ cells in Sox17 cko during development, likely due to apoptotic death in CC1+ cells, as a 4-5 fold increase in cleaved caspase3+/CC1+ positive cells was observed in Sox17 cko at P30. A pro-survival function for Sox17 in oligodendrocytes is supported by recently published data using in a CNP-Sox17 transgenic mouse (Ming et al., J. Neurosci 2013 33(30):12528-12542). In this study, oligodendrocytes with high Sox17 were resistant to lysolecithin-induced cell death, due to increased levels of Gli2 and its downstream effector Bcl2, an anti-apoptotic protein. Consistent with this data, Sox17 cko mice show reduced numbers of oligodendrocytes expressing Gli2 and Bcl2, indicating regulation of the SHH pathway during normal development. Ongoing work with Sox17 cko mice is also testing whether Sox17 has similar functions in remyelination following cuprizone- or lysolecithin-induced demyelination. Preliminary analysis suggests that Sox17 cko mice have fewer surviving, newly-born oligodendrocytes after 3 weeks of cuprizone treatment. Future experiments will determine whether this is due to impaired survival of newly formed oligodendrocytes and/or failure to mobilize OPCs for regeneration.

Title: Glial cells and neurons express fibroblast growth factor receptor 1 (FGFR1) in the cortex and hippocampus in the developing mouse brain

Authors: L. CHOUBEY[1], J. COLLETTE[3], *K. M. SMITH[2]
[1]Biol., [2]Univ. of Louisiana At Lafayette, Lafayette, LA; [3]Biol., Univ. of Louisiana at Lafayette, Lafayette, LA

Abstract: Fibroblast growth factors (Fgfs) and their receptors have various morphological, regulatory and endocrine effects on the developing and adult CNS. Inactivation of Fgfr1 results in reduced hippocampal volume, disruption of corpus callosum and hippocampal commissure due to abnormal midline glia development. A decrease in FGFR1 expression in the dorsal telencephalon leads to postnatal loss of cortical interneurons expressing parvalbumin (PV). Neuronal imbalances between excitatory and inhibitory neurons have been seen in patients with schizophrenia, autism, bipolar disorder, Tourette syndrome and attention-deficit/hyperactivity disorder. A previous study shows that FGFR1 is mostly expressed in neurons. Here, we use a transgenic reporter line, the tgFGFR1-EGFP BAC transgenic line (GENSTAT) where EGFP is regulated under the FGFR1 promoter, to demonstrate FGFR1 is expressed mostly in astrocytes, along with neurons, oligodendrocytes and Sox 2 positive cells. Previous staining of one month tgFGFR1-EGFP mice with antibodies against PV and GFP showed interneurons expressing PV did not colocalize with cells expressing GFP. We report that FGFR1 in E14.5 mice is strongly expressed in the hippocampal hem, choroid plexus and cortical ventricular zone, and weakly expressed in the medial ganglionic eminenece (MGE). FGFR1 is expressed in radial glial cells

undergoing soma translocation in P7 mice. In one month old mice, 57% ± 0.9% of cortical GFP positive cells colocalize with GFAP positive astrocytes and 25% ± .5% of cortical GFP positive cells colocalize with NueN positive neurons. Also SOX2 positive cells colocalize with GFP positive cells in the dentate gyrus of the hippocampus and subventricular zone of one-month old mice. Understanding which cell types express FGFR1 may elucidate its role in neuropsychiatric disorders and brain development.

Title: Patch-clamp study of Schwann cells in mouse sciatic nerve slice: Electrophysiological properties and neurotransmitter receptor expression

Authors: *N. FRÖHLICH, D. EISSLER, M. KUKLEY
Ctr. for Integrative Neurosci. (CIN), Tübingen, Germany

Abstract: Two Schwann cell (SC) types are present in the peripheral nervous system: myelinating and non-myelinating SCs. Both types originate from the same progenitor, the immature SC, which develops from neuronal crest cells. The sequential expression of transcription factors and developmental markers characterize the distinct SC types in the lineage. The electrophysiological properties of these cells are only rarely studied in *ex vivo* slices so far. First hint that SCs could express neurotransmitter receptors for glutamate was shown in invertebrates. Furthermore, neurotransmitters, including glutamate, are able to induce changes of SC membrane potential in the giant squid axons (Lieberman and Sanzenbacher, 1992; Villegas et al., 1987). Moreover, different studies done in cell culture (Liu and Bennett 2003) or with immunohistological methods (Dememes et al. 1995) show that SCs in vertebrates could express different types of glutamate receptors. We investigate the receptor expression on SCs in more natural conditions. In addition, we want to determine and characterize SCs in *ex vivo* slices. We

developed a new preparation of sciatic nerve slices of late embryonic (E16-18) and early postnatal mice (P0-P2). Using patch clamp recording and immunohistological analyses, we could (dependent on the age) characterize two (E16-E18) or three (P0-P2) electrophysiologically different SC types. These SC types differ in their expression of voltage-dependent sodium and potassium channels. First analyses show that they express tetraethylammonium (TEA) and 4-aminopyridine (4-AP) sensitive delayed rectifying potassium channels. During patch-clamp recordings we included a fluorescent dye into the pipette solution, so we could combine the electrophysiological properties of the different SC types with their morphological features. These analyses show that SCs before birth display higher number of processes and branches whereas SCs after birth have longer but a lower number of processes and less branches. Using the fast pressure-application system, we want to investigate whether SCs in acute slices express functional ionotropic glutamate receptors and whether SC types differ in their expression. Application of 1mM glutamate induced an inward current in at least two SC types and in both age groups. The evoked current is sensitive to the AMPA/kainate blocker GYKI53655, indicating that functional glutamate receptors of the AMPA/kainate type are expressed.

Title: How does glia-secreted sparc block synaptic development?

Authors: ***H. DINGSDALE**, A. PAMUKCU, S. SINGH, C. EROGLU
Duke Univ., Durham, NC

Abstract: Precise control of the formation, maintenance and turnover of synapses is critical for the correct functioning of the nervous system. Aberrant synaptogenesis, either congenital or due to injury, can underlie epilepsy, autism and other neurological diseases. We have previously shown that hevin is an astrocyte-secreted molecule that promotes the formation of synapses by

bridging pre- and post-synaptic molecules. Astrocytes and microglia secrete a close homolog of hevin, called SPARC (secreted protein, acidic and rich in cysteine). SPARC is not synaptogenic; on the contrary SPARC specifically blocks hevin-induced synapse formation, whilst having no effect on the pro-synaptogenic activities of other known promoters such as thrombospondins. SPARC has also been shown to downregulate AMPA receptors at the synaptic cleft, and reduce the size of the presynaptic vesicular pool at cholinergic synapses. Taken together, these findings indicate the SPARC is a pro-immaturity factor that blocks the formation and maturation of synapses in the CNS. This function of SPARC may be important for keeping synaptic connections plastic during critical developmental periods. The mechanism by which SPARC specifically inhibits the prosynaptogenic function of hevin has not yet been elucidated. Therefore, here we investigated three possible mechanisms by which SPARC may inhibit hevin-induced synaptogenesis: 1. SPARC binds to and sequesters hevin; 2. SPARC competes with hevin for binding of its synaptic receptor; 3. SPARC blocks hevin's synaptogenic signaling by activating an inhibitory signaling pathway within neurons. Determining the mechanism by which SPARC inhibits hevin during synaptogenesis will further our understanding of this critical process.

Title: Cortical neuronal damage stimulates a microRNA and epigenetic-associated transition in activated microglia that enhances neuronal differentiation and survival

Authors: A. K. JOHNSON[1], N. W. MATHY[1], M. TAPPATA[1], *A. SHIBATA[2]
[1]Biol., [2]Dept Biol, Creighton Univ., Omaha, NE

Abstract: Contribution of microglia to neurogenesis under different pathological conditions is unclear. Both pro and anti-neurogenic effects reflect the heterogeneity of microglial activation. We have utilized an *in vitro* model system to co-culture microglia with mechanically damaged or undamaged primary neurons. Accelerated and increased expression of Nestin, α-internexin, β-tubulin III, and NeuN was observed in damaged neurons co-cultured with activated microglia. Western blot analysis revealed an increase of 118.5 ± 21.3% (p=.064) in Nestin expression in damaged neurons co-cultured with activated microglia as compared to controls. Alpha-internexin expression increased 67.0 ± 27.1% (p=.009) and immunofluorescence increased 109 ± 2.1% (p=.0001) in neurons one day after damage and co-culture with activated microglia. β-tubulin III immunofluorescence increased 96.1 ± 1.9% (p=.0001) after one day of co-culture and 623.8 ± 7.22% (p=.0001) at four days of co-culture with activated microglia. By seven days of co-culture, GFAP expression decreased by 26.2 ± 8.4% (p=.028) and NeuN expression increased 40.2 ± 26.2% (p=.0069) in damaged neurons suggesting that neurogenesis and neuronal survival was enhanced in the absence of significant astrogliogensis. Transition to a neurogenic microglial phenotype may involve regulation of protein expression via non-coding RNAs and epigenetic modification. RT-RCR analysis of microRNA (miR) in microglia co-cultured with undamaged and damaged neurons revealed significant increases in let-7c, miR-124, and miR-9 expression. Co-culture of microglia with undamaged neurons increased let-7c expression by 8.5 fold ± 2.008 (p=.038) and miR-124 expression by 9.8 ± 1.29 (p=.002) as compared to control microglia. Co-culture of microglia with damaged neurons increased let-7c expression by 12.2 fold ± 3.94 (p=.009) and miR-124 expression by 9.9 ± 0.86 9(p=.0001) as compared to control microglia. MiR-9 expression is specifically increased (4.6± .64 fold) in microglia co-cultured with damaged neurons as compared to microglia co-cultured with undamaged neurons (p=.037) suggesting a specific regulatory role for miR-9 in neurogenic microglia. A 1.74 ± .02 fold increase (p=0.031) in H3K9me1 levels was seen in activated microglia co-cultured with damaged neurons. MiR9 and H3K9 methylation may regulate protein expression in microglia. RT-PCR and ELISA analysis confirmed significant decreases in Ccl3/MIP1-α and TNF-α mRNA and protein in co-cultures of activated microglia and damaged neurons. Our data suggests that microglia possess modifiable properties to become potential targets for neuroprotective therapies.

Title: Bidirectional signaling between neurons and astrocytes via neuroligin-1 and hevin

Authors: *J. A. STOGSDILL[1], S. K. SINGH[1], L.-J. PILAZ[2], D. L. SILVER[2], C. EROGLU[1]

Abstract: The dynamic communication between astrocytes and neurons is critical for synapse formation and maturation within the CNS. Defects in this bi-directional communication may underlie the pathology of neurological diseases such as autism, depression, and epilepsy. Hevin, an astrocyte-secreted synaptogenic protein, regulates the maturation of both pre- and post-synaptic specializations of excitatory synapses. Previously, we identified the post-synaptic cell adhesion molecule neuroligin (NL) as a post-synaptic receptor for hevin. NLs (1-3) are required for hevin-induced synapse formation of retinal ganglion cells *in vitro*; however, if NL/hevin interaction is important for synapse formation and maturation *in vivo* was not known. We found that, *in vivo*, hevin and NL1 co-localize in the mouse visual cortex. To determine if hevin-NL1 interactions control synapse formation in the visual cortex, we knocked down NL1 with shRNA in layer 2/3 cortical neurons by *in utero* electroporation (IUE) in wild type and hevin KO animals. We found that knockdown of NL1 in wild type brains reduces the density of all dendritic spines, in particular mature mushroom spines and increased the length of all spines types in layer 2/3 pyramidal neurons. In contrast, knockdown of NL1 in the hevin KO background resulted in no changes to dendritic spine length or density. These findings show that hevin and neuroligin-1 are required for proper dendritic spine formation and maturation within the visual cortex. Additionally, we find that hevin protein levels are profoundly elevated in wild type brains with reduced NL1. These data suggest that hevin is required for NL1-abundance dependent competitive synaptogenesis and may be regulated via activity-dependent mechanisms. In summary, our findings identify a mechanism whereby neurons and astrocytes communicate to establish the synaptic connectivity within the brain. Both hevin and NLs are linked to neurological disease, therefore, these data may give novel insight into neurodevelopmental disorders wherein the balance of neuroligin and/or hevin is altered such as in autism.

Title: PACAP induces differentiation of neural progenitor cells into glial lineage in cerebral cortex development

Authors: *J. WATANABE[1,2], H. OHTAKI[2], T. NAKAMACHI[2,3], Z. XU[2], K. SUGIYAMA[2], S. SASAKI[2], S. ARATA[1], S. SHIODA[2]

Abstract: Neural development is controlled by region-specific factors that regulate cell proliferation, migration and differentiation. Pituitary adenylate cyclase-activating polypeptide (PACAP) is a neuropeptide that exerts a wide range of effects on different cell types in the brain as early as the fetal stage. The distribution of PACAP and its specific receptor, PAC1-R mRNA during development suggests that PACAP is associated with differentiation or proliferation of neural progenitor cells (NPCs)1. However, little is known about the role of PACAP in NPCs. Previously, we reported that PACAP induced differentiation of cultured mouse embryonic NPCs into astrocytes2. Here, we report that the effect of PACAP *in vivo* on the glial differentiation. We studied the localization of PAC1-R during neural development by use of immunohistochemistry. PAC1-R immunopositve cells were observed in the sub-ventricular zone in E14 mouse embryo. Double-immunostaining showed that immunoreactivity for PAC1-R was co-localized with cell proliferation marker, Ki67 and radial glia marker, vimentin. Astrocyte marker, GFAP-positive cells appeared around the ventricle from E16. GFAP-immunopositive cells appeared in the region where PAC1-R immunoreactivity was strongly expressed. These data suggest that endogenous PACAP leads NPCs to differentiate into radial glia then astrocytes. Addition of PACAP into primary cultured-NPCs increased the expression of another radial grail marker, GLAST after 4 days. The expression of GFAP was up-regulated 6 days after PACAP administration. Furthermore, intracerebroventricular injection of PACAP into the ventricle of telencephalon of E13 embryos *in utero* increased the number of GLAST immunopositive cells and decreased the number of nestin immunopositive cells. These data suggest that PACAP plays crucial roles in the differentiation of NPCs into astrocytes via radial grail lineage. 1 Watanabe J et al. Peptides. 2007; 28(9):1713-9. 2 Watanabe J et al. Title: Astrocyte-secreted hevin promotes synapse formation and maturation by trans-synapticallybridging neurexin 1-alpha and neuroligins

Authors: *S. SINGH[1], J. A. STOGSDILL[1], L.-J. PILAZ[2], H. DINGSDALE[1], A. PAMUKCU[1], D. L. SILVER[2], C. EROGLU[1]

Abstract: Establishment of synaptic adhesions is the critical first step in the construction of neuronal circuits. Interactions between presynaptic Neurexins (Nrxs), and postsynaptic Neuroligins (NLs) coordinate the formation of synaptic adhesions. An isoform/splice variant-dependent code determines the compatibility of Nrxs and NLs for interactions, and thereby contributes to the target recognition between axons and dendrites. However, the presence of synaptic linkers that can bridge incompatible Nrx-NL pairs across the synaptic cleft, thus strengthen the synaptic adhesions was unknown. Using a combination of *in vitro* and *in vivo* approaches we found that an astrocyte-secreted synaptogenic protein, hevin organizes pre- and post-synaptic specializations by interacting with Nrx1-alpha and NLs respectively. Mechanistically, hevin links Nrx1α and NL1 to each other transcellularly by bridging these otherwise incompatible isoforms. These findings show that astrocyte-secreted hevin is a synaptic linker protein that links Nrx1-alpha and NLs trans-synaptically and thereby control synapse formation and maturation.

Title: Perinatal protein malnutrition during the 10 first lactation days alters the vimentin and cell proliferation pattern of the dentate gyrus

Authors: *A. C. B. BARBOSA, P. L. GUEDES, M. L. M. ROCHA, P. BARRADAS, F. TENORIO
Depto. de Farmacolgia e Psicobiologia - IBRAG - UERJ, Uerj, Rio De Janeiro, Brazil

Abstract: Perinatal malnutrition can lead to permanent damage in brain morphology, physiology and neurochemistry. The hippocampus is a structure particularly sensitive to nutritional alterations during development. Dentate gyrus is characterized as the most proliferative hippocampal region. As hippocampus is a structure responsible for the mechanism of learning and memory, alterations in its astrocitary populations may affect this process. Besides their role in neuronal nutrition and support in ionic concentrations, other important function of astrocytes is related to the secretion of neurotrophic factors, that may be associated to neurogenesis. In this study, we evaluated the effect of protein malnutrition restricted to the 10 first lactation days on cell proliferation and precursor glial cells distribution in dentate gyrus. This study was approved by our University Ethics Committee (CEA/055/2009). Wistar male rats on postnatal day 5 (P5), 10 (P10), and 15 (P15) were used. The animals were settled in two groups: control group (CG) and malnourished group (MG). CG dams were fed ad libitum with a normoprotein diet (22% protein) during gestation. During the first 10 days of lactation MG received a 0% protein diet. On each age studied animals were anesthetized and perfused with saline solution 0,9%, paraformaldehyde (PF) 4% and PF 4% plus sucrose 10%. Sections of 20μm were immunostained using anti-vimentin and anti-Ki-67 antibodies, revealed with a secondary antibody conjugated with Alexa 555 and Alexa 488, respectively and observed at a fluorescence microscope. Our analyses show that during the development, vimentin positive cells tend to concentrate in the polimorfic and molecular layers. But, in MG, these cells can be seen through all the dentate gyrus and at age (P15), they are more visible in the polimorfic layer (PL) next to the granule layer, while the immunostainings of CG seem to be equally distribuited in this layer. The Ki-67+ cells are found disperse in both groups, but MG presents a much more difused distribuition than CG, that is more uniform and contains more imunostainned cells (CG - 99.80 ± 9.272 N=3; MG - 35.53 ± 9.327 N=3; $p<0,05$). At P10, with apparently lesser positive cells than the previous age,

it is possible to observe that the less stained layer is the molecular one in MG and the granular layer in CG. At P15, the densest area with Ki-67+ cells is the PL next to the granular layer to MG and the center of PL to CG. The present study demonstrates that protein restriction may modify the pattern of vimentin and cell proliferation in the dentate gyrus.

Title: Sustained learning and memory programmes modulate OPC proliferation and differentiation

Authors: *J. BOULANGER[1], C. MESSIER[2]
[1]Sch. of Psychology, [2]Univ. of Ottawa, Ottawa, ON, Canada

Abstract: Environmental enrichment and physical activity have been shown to upregulate OPC proliferation rates (Ehninger et al., 2011; Okuda et al., 2009; Simon et al., 2011). However, not all agree on the fate of these newly divided OPCs. We looked at rates of OPC proliferation and differentiation in response to a sustained programme of learning and conditioning that targeted multiple neural networks in the hopes of maximising the possible changes in OPC dynamics. BrdU was administered through the mice's drinking water. When looking strictly at OPC proliferation, 3-5 month old CD-1 mice were exposed to a programme consisting in a radial arm maze task, which utilizes reference and working memory, an operant conditioning task, and the Morris Water Maze, which draws on spatial memory. The training programme had to be modified for the NG2Cre/R26S-EYFP transgenic mice used to study differentiation as they showed increased levels of toxicity to BrdU. The programme administered in the differentiation phase of the study consisted in the Barnes Maze, which measures short- and long-term memory as well as spatial memory, and an operant condition task. Preliminary results show that a sustained programme of learning and conditioning increases the proportion of newly proliferated

OPCs in the cortex and that in response to such a programme, OPCs either remain undifferentiated or adopt an oligodendroglial phenotype.

Title: HMGN family proteins promote astrocyte differentiation of neural precursor cells

Authors: *M. NAGAO[1], D. LANJAKORNSIRIPAN[2], Y. ITOH[2], Y. KISHI[2], Y. GOTOH[2], T. OGATA[1]

Abstract: Astrocytes are the most abundant cell type in the mammalian brain and are important for the functions of the central nervous system (CNS). Although previous studies have shown that the STAT signaling pathway or its regulators promote the generation of astrocytes from multipotent neural precursor cells (NPCs) in the developing mammalian brain, the molecular mechanisms that regulate the astrocytic fate decision have still remained largely unclear. Here, we show that the high mobility group nucleosome-binding (HMGN) family proteins, HMGN1, 2 and 3, promote astrocyte differentiation of mouse NPCs during brain development. HMGN proteins were expressed in NPCs, Sox9+ glial progenitors and GFAP+ astrocytes in perinatal and adult mouse brains. Forced expression of either HMGN1, 2 or 3 in mouse NPCs in cultures or in the late embryonic neocortex increased the generation of astrocytes at the expense of neurons. Conversely, knockdown of either HMGN1, 2 or 3 in mouse NPCs suppressed astrocyte differentiation and promoted neuronal differentiation. Importantly, overexpression of HMGN proteins did not induce the phosphorylation of STAT3 or activate STAT reporter genes. In addition, HMGN family proteins did not enhance DNA demethylation and acetylation of histone H3 around the STAT-binding site of the gfap promoter. Moreover, knockdown of HMGN family proteins significantly reduced astrocyte differentiation induced by gliogenic signal ciliary

neurotrophic factor (CNTF), which activates the JAK-STAT pathway. Therefore, we propose that HMGN family proteins are novel chromatin regulatory factors that control astrocyte fate decision/differentiation in parallel with or downstream of the JAK-STAT pathway through modulation of the responsiveness to gliogenic signals.

Title: D-Serine influences the maturation of glutamatergic synapses and axonal refinement in the developing visual system of the Xenopus tadpole

Authors: *M. VAN HORN[1], L. POLLEGIONI[2], E. RUTHAZER[1]
[1]Neurol. and Neurosurg., McGill Univ., Montreal, QC, Canada; [2]Dept. of Biotech. and Life Sci., Univ. of Insubria, Varese, Italy

Abstract: D-Serine is an endogenous co-agonist for synaptic N-methyl-D-aspartate receptors (NMDAR). Here we examined the neurophysiological significance of D-serine, a known gliotransmitter, in regulating synaptic transmission and axonal remodeling in the developing visual system. Acute D-serine (100 μM) wash-on enhances NMDAR currents of optic tectal neurons. Conversely, degradation of D-serine by RgDAAO reduces evoked NMDAR currents. To investigate the pathways involved in modulating D-serine release in the optic tectum, we used D-serine-sensitive amperometric biosensors and found that α-amino-3-hydroxy-5-methyl-4-isoxazolepropionic acid (AMPA) application results in an increase in D-serine release, presumably by activating non-NMDARs on glial cells. These results indicate that in the retinotectal system, the NMDAR glycine site is not saturated under normal physiological conditions *in vivo*, D-serine is an endogenous agonist of the NMDAR and its release is modulated by AMPA receptor activation. We next tested whether chronically elevating D-serine

levels could influence the maturation of glutamatergic synapses. We find that tadpoles raised in elevated levels of D-serine (100 μM) for 2 days have higher frequencies of miniature excitatory postsynaptic AMPAR currents and higher retinotectal synaptic AMPA/NMDA ratios compared to control animals. To examine the effects of D-serine on axonal development, retinal ganglion cells were electroporated to express EGFP and 2-photon images were collected daily over 4 days. We found that increasing available D-serine results in less complex retinal axons arbors. These findings are consistent with the hypothesis that D-serine enhancement of NMDAR currents promotes synaptic maturation and leads to stabilization of axonal branches. Taken together, these results suggest that D-serine levels are modulated by glutamatergic neurotransmission *in vivo* and can influence the maturation of retinotectal synapses and circuit refinement.

Title: Unitary synaptic connections between GABAergic interneurons and NG2 cells in the developing somatosensory cortex

Authors: D. ORDUZ[1], P. P. MALDONADO[1], M. BALIA[1], M. VÉLEZ-FORT[1], V. DE SAARS[2], Y. YANAGAWA[3], V. EMILIANI[2], *M. C. ANGULO[1]
[1]INSERM U1128, Paris, France; [2]CNRS UMR 8250, Paris, France; [3]Gunma Univ. Grad. Sch. of Med., Dept. of Genet. and Behavioral Neurosci., Maebashi, Japan

Abstract: NG2-expressing cells, the main pool of progenitors in the CNS, have the primary role of generating myelinating oligodendrocytes in the developing brain. These progenitors are

unique non-neuronal cells that receive bona fide synaptic inputs from neurons. However, our understanding of synaptic physiology of NG2 cells is still limited because it derives only from studies based on averaged synaptic currents generated by the stimulation of unidentified neurons. In the developing somatosensory cortex, NG2 cells receive a major GABAergic synaptic input from interneurons, but how these progenitors are wired and integrate interneuronal networks remains unknown. By using paired recordings and holographic photolysis, we investigated the dynamics of synaptic transmission at the level of unitary interneuron-NG2 cell connections in acute somatosensory cortical slices of vGAT-Venus;NG2-DsRed transgenic mice during the second postnatal week. Among the heterogeneous cortical population of interneurons, we identified fast-spiking interneurons (FSIs) as a preferential presynaptic input of NG2 cells. Quantal analysis revealed that interneurons innervate NG2 cells through single or double release sites. Both fast-spiking (FSI) and non-fast-spiking cells (NFSI) contact NG2 cells, but these two neuronal populations target distinct anatomically segregated subcellular domains that differ on the postsynaptic receptor subunit composition. In addition, holographic photolysis was very effective in photo-activating interneurons at a single cell resolution in order to build connectivity maps of interneurons innervating NG2 cells. Using this technique, we found that the spatial arrangement of interneuron-NG2 cells connections is more local than those of interneuron-pyramidal cell connections, forming a specific subnetwork characterized by a local microarchitecture. Our findings on unitary interneuron-NG2 cell connections uncover specific rules of synaptic connectivity for these progenitors that differ from those of classical neuronal GABAergic synapses in the neocortex. Also suggest that FSIs, beyond their role in neocortical networks, play important roles in controlling NG2 cell function.

Title: Hoxb1 is required for the development of a subset of pontine norepinephrine neurons

Authors: *S. D. ROBERTSON, P. JENSEN
Natl. Inst. of Envrn. Hlth. Sci., Durham, NC

Abstract: Norepinephrine (NE) neurons in the central nervous system support a range of essential behaviors, including attention, stress, memory and appetite. The molecular mechanisms that contribute to this divergence of adult NE neuron function are unknown. Recently, we classified mature NE neurons based on differences in developmental gene expression history. We defined four subpopulations that differ in their anatomical location, efferent projection pattern and axon morphology. One of these subpopulations, defined by the expression of the homeobox gene Hoxb1, consists of NE neurons that are distributed across the pons and medulla. Interestingly, this Hoxb1-derived NE subpopulation has a propensity to project to key components of the central autonomic nervous system. However, it is unclear if Hoxb1 expression is required for the development of these NE neurons and therefore important for central autonomic function. A previous study by Gaufo et al 2004, suggested that Hoxb1 is required for the specification of medullary NE neurons based on the absence of Dbh mRNA within rhombomere 4 (r4) of the Hoxb1-null embryonic hindbrain. In the current study, we employed a recombinase-based intersectional genetic strategy to selectively label Hoxb1-derived NE neurons with eGFP, and all other NE neurons with mCherry, thus enabling us to trace the long-term fate of all NE neurons in the context of the Hoxb1-null mutation. We mapped these populations onto the mature anatomically defined pontine (Subcoeruleus (SubC), A5) and medullary (A1 and A2) NE nuclei and counted the number of mCherry and eGFP positive NE neurons. In the pontine SubC and A5 nuclei, we observed a striking absence of Hoxb1-derived NE neurons. In contrast, mapping of Hoxb1-null NE neurons onto the medullary A1 and A2 nuclei revealed a significant increase in the number of Hoxb1-derived NE neurons. This increase in the number of eGFP-positive NE neurons is likely due to the ectopic expression of cre which has been reported in Hoxb1-null embryos caudal to r4. In summary, we have demonstrated a requirement for Hoxb1 in the proper development of a subset of Hoxb1-derived NE neurons. Studies are ongoing to examine the effects of the Hoxb1-null mutation on NE neuron efferents throughout the brain, particularly in regions important for the regulation of central autonomic function. Results from these studies promise new insight into how Hoxb1 contributes to the generation of functionally divergent subsets of NE neurons

Title: Tridimensional *in situ* description of axonal branches contacting multi and uni-ciliated cells lying on the lateral wall of lateral ventricle, in adult Long-Evans rats

Authors: *C. S. HAEMMERLE, M. I. NOGUEIRA, I.-S. WATANABE
Anat., Univ. of Sao Paulo; Inst. of Biomed. S, Sao Paulo, Brazil

Abstract: Introduction: the canonical definition for the lining of brain ventricles introduce us to the single layer of multiciliated cells named ependyma; however, new findings specially at lateral ventricle has yielded information about additional and distinct cell elements further the multiciliated surface, influencing the cell proliferation in this neurogenic niche. In this field, the axonal signaling occurring on the lining epithelia seems to make an important contribution to the regulation of neurogenesis. Using a high-resolution and ultrastructural analysis provided by High-Resolution Scanning Electron Microscopy (HRSEM) and Transmission Electron Microscopy (TEM), we demonstrate the proper anatomical details about the innervation of different ciliated cells present on surface of neurogenic niche of lateral ventricle. Methods: we used adult male Long-Evans rats (n=10). For HRSEM, following a whole mounting dissection of lateral ventricle, the samples were post-fixed in OsO_4 1%, dehydrated, dried and covered with gold ions and examined in field emission scanning electron microscope. For TEM, the brains were perfused, reduced and immersed in modified-Karnovsky solution. After sectioning, post-fixation was done in OsO_4 1%, followed by dehydration and embedding in Spurr resin. Semi-thin sections confirmed the lining surface region and ultrathin sections were examined in TEM microscope. Results: we observed a heterogeneous pattern for cilia distribution throughout the different poles of the lateral ventricle surface. Besides the canonical definition about the multiciliated cells lying on the ventricular surface, we corroborate that the lateral ventricle lining also contains single/primary cilium and biciliated cells, with its peculiar lenghts; we also demonstrated axonal bundles and varicose axons on ependymal surface surrounding and contacting these cells, but not in its totality. The axonal contacts making synapses were also confirmed by TEM. Therefore, we provide a unique ultrastructural methodology that describes the tridimensional *in situ* organization of lateral ventricles lining, regarding to the discrete innervation on the surface elements, in a way to corroborate the available functional findings about the heterogeneity of factors regulating this neurogenic niche.

Abstract: While the localization and function of cannabinoid CB1 receptors in astroglia, and CB2R receptors in microglia are well established, the CB2 receptors expression and function in astroglia remains controversial. Primary mixed cultures of astrocytes and microglial cells were grown from 1-day old rat brain cortices. Once confluent, microglial cells grown on the bed of astrocytes were separated by mechanical shaking and were grown separately. The resulting astroglial and microglial cells were used for immunocytochemical, biochemical and pharmacological studies. Immunocytochemical double-labeling studies showed that cells expressing microglial specific marker CD11b were stained positive for CB2 receptors. Whereas, the astroglial cultures, expressing the specific marker, glial fibrillary acidic protein (GFAP) were also stained positive for the cannabinoid CB2 receptors besides CB1 receptors. Quantitative western blot analyses showed a single immunoreactive band at 62 KDa that increased with increase in cell lysate protein when probed with an anti-CB1R antibody. The cell lysate, when probed with an anti-CB2R antibody, showed a smaller, but prominent immunoreactive protein band at 40 KDa, the immunoreactivity of which was blocked by a CB2R blocking peptide, thus confirming it was indeed a CB2R protein band. To determine if the CB2R in astroglial cells is functional, the agonist-induced cAMP inhibition was measured. The mixed agonist WIN 55212-2 (1μM) inhibited about 61% of forskolin-induced cAMP accumulation (80.87±5.08 nmol/well) which was attenuated either by the CB1 receptor-selective antagonist /inverse agonist, AM 251(25 nM), or by the CB2 receptor-selective antagonist/inverse agonist, AM 630 (100nM). However the inhibition was not additive when both of these antagonists were added, suggesting an integrated signaling response. Our findings suggest that CB2 receptors are constitutively expressed in rat cortical astrocytes and microglial cells. Astroglial cells, by expressing both CB1 and CB2 receptors may integrate their signaling pathways when simultaneously activated by a CB1/CB2 agonist.

Title: Ultrastructural distribution of glycogen in hippocampal astrocytic processes

Authors: *C. CALI[1], J. BAGHABRA[1], H. LEHVASLAIHO[1], G. KNOTT[2], I. ALLAMAN[3], P. J. MAGISTRETTI[1]

Abstract: Glycogen is a major energy store in astrocytes that provides energy support and signals for plasticity to neurons under the form of lactate. While the biochemistry of glycogen is well known, the spatial distribution of glycogen granules within astrocytes remains largely unknown. To this purpose, we imaged a 220 μm^3 volume of adult mouse hippocampus neuropil using a FIB-SEM microscope. This technique allowed us to automatically acquire very thin serial section micrographs (5 nm) at very high resolution (5 nm). Perfect isotropy of resulting voxels allowed iLastik, a state of art semi-automated software for EM stacks segmentation, to rapidly reconstruct every axon, dendrite, and the astrocytic processes present within the volume. Glycogen granules inside an astrocyte were recognized by morphology, and manually reconstructed using TrakEM2, a widely used tool for manual segmentation of serial section electron micrographs. We then used Blender, a three-dimensional modeling software, to visualize the entire 3D model in the fully immersive virtual reality CAVE system. This detailed walk-in made it very clear that the apparently random cloud of glycogen granules in fact appeared in clusters. The DBSCAN algorithm, optimized with the help of Silhuette coefficient, determined the extent and number of glycogen clusters. Compared to other clustering algorithms, DBSCAN allows extraction of irregularly shaped clusters, and is much more sensitive to noise and outliers, making it a perfect choice for our case. We also used the Silhuette coefficient that allowed the optimal initialization parameters for DBSCAN, thus validating the clustering. In order to determine weather the clusters have a spatial relationship with the pre- or post- synaptic elements, we extracted all spines and boutons, as well as their size, using Neuromorph, a scientific package available as addons for Blender, designed for detailed morphological analysis of the neuropil. Preliminary results indicate a regular 3D organization of glycogen granules, and a slight preference for the glycogen granules in astrocytic processes close to presynaptic boutons compared to postsynaptic spines (75% vs 25%, respectively). We are aiming to repeat the

approach using samples from animals undergoing learning protocols in order to asses the plasticity of such an arrangement of glycogen granules within perisynaptic astrocytes.

Title: Neuron-astrocyte interplay: role of astrocytic DISC1 in neurodevelopment

Authors: *M. XIA[1,2], A. SHEVELKIN[1], C. YANG[1], M. V. PLETNIKOV[1]
[1]Dept. of Psychiatry and Behavioral Sci., The Johns Hopkins Univ. Sch. of Med., Baltimore, MD; [2]Sch. of Basic Med. Sci., Guangxi Univ. of Traditional Chinese Med., Nanning, China

Abstract: Astrocyte dysfunction has been implicated in the pathogenesis of psychiatric disorders. The role of candidate psychiatric genetic risk factors in astrocytes dysfunction remains poorly understood. Here, we studied the effect of dominant-negative mutant Disrupted-In-Schizophrenia-1 (DISC1) selectively expressed in astrocytes on neuronal maturation and differentiation using a co-culture approach. Primary embryonic hippocampal neurons and astrocytes were co-cultured using a cell insert system that allows for indirect co-culture of distinct cell populations in the absence of direct cell contacts. Neurons from wild-type embryos were cultured for 5 days and then were combined with primary control astrocytes or astrocytes that express mutant DISC1 . We found that neurons co-cultured with mutant DISC1 astrocytes exhibited significantly less elaborated dendritic tree as evidenced by decreased dendrites branch level and dendritic branch point after 5 days of co-culturing. Analysis of expression of pre-and postsynaptic markers of glutamatergic and GABA-ergic neurons as well as identification of putative astrocyte-secreted factors to affect neurodevelopment are in progress. We suggest that astrocytic DISC1 impacts neuronal maturation and contributes to risk of major mental illness.

Title: Myelination compensates for visual deprivation and diminished neurotransmission as a form of functional plasticity

Authors: *A. ETXEBERRIA[1], X.-L. CHOU[2], K. HOKANSON[3], S. R. MAYORAL[1], L. I. ZHANG[2], E. M. ULLIAN[3], H. W. TAO[2], J. R. CHAN[1]

Abstract: Underlying the remarkable versatility of the mammalian nervous system are numerous mechanisms for functional plasticity. Myelination of axons increase action potential conduction velocity, modulating network function; however current mechanisms of plasticity do not consider myelination of axons as a factor for functional plasticity. We demonstrate that after long-term monocular deprivation (MD) the latency of response in the deprived visual pathway is shortened and that this decrease correlates with an enhancement in the differentiation of oligodendrocytes and myelination of the optic tract. Our results suggest that oligodendrocyte differentiation and myelination are triggered by a reduction in sensory stimuli. Generating a conditional knockout of the vesicular glutamate transporter 2 (VGlut2) in retinal ganglion cells significantly decreases glutamate neurotransmission along the retinogeniculate pathway and phenocopies the changes in myelination detected after MD. Together our results indicate the existence of a feedback mechanism between neurons and oligodendroglial cells that tailors myelination to functional requirements.

Title: Short and long term consequences of maternal presence on *in vivo* physiology of the developing amygdala

Authors: *D. A. WILSON[1,2], E. C. SARRO[1,2], R. M. SULLIVAN[1,2]
[1]Child and Adolescent Psychiatry, NYU Sch. of Med., New York, NY; [2]Nathan Kline Inst., Emotional Brain Inst., Orangeburg, NY

Abstract: The survival of altricial infants depends upon the quality of caregiving, exerting both immediate and enduring neurobehavioral changes that determine individual differences, with maternal maltreatment of pups initiating the pathway to pathology. The mechanism for this neurobehavioral effect is incompletely understood. Here we explore one well-documented influence on brain development, brain oscillation and assess how the quality of maternal care influenced this neural activity. Here we addressed this by recording spontaneous neocortical local field potential (LFP) activity for 7 consecutive days in freely behaving infants (~postnatal days 12-19) in their natural environment during interactions with their mother. We have previously shown that infant cortical activity can be directly influenced by maternal presence and her behaviors in the nest, however it is unknown whether prior early-life trauma can modulate this maternal influence on infant brain activity. We implanted infant rat pups (PN12) with bipolar stainless steel electrodes, targeting the amygdaloid complex and connected to a wireless transmitter (DSI) implanted subcutaneously. Prior to implantation, one group of infants was reared from PN8-12 with a naturally abusive mother and another group were odor-shock conditioned at PN8-12. Both paradigms lead to long-term behavioral deficits. We recorded spontaneous amygdala LFP activity in freely behaving infants, specifically assessing changes in LFP activity during interactions with the mother and littermates, as well during periods of specific behavioral states (i.e., nursing, grooming, milk ejections). Fast Fourier Transform analysis (2.4 Hz bins) was used to quantify LFP oscillatory power in theta (5-15Hz), beta (15-35Hz) and gamma (35-80Hz) bands. We were particularly interested in whether recent trauma leads to modifications in the amygdala activity during interaction with the mother and littermates. In a separate experiment, we examined the long-term consequences of a learned abusive odor (naturalistic maternal odor or artificial conditioned odor) on amygdala LFP activity by presenting this odor in adulthood to animals from the same conditions. We show odor-specific enhancements in LFP power in response to the learned abusive odor, supporting the long-term behavioral influence that the learned maternal odor can impose on adult behavior. Given the important role of neural activity in shaping circuit development and refinement during

development, this suggests a powerful direct and long-term influence of maternal care on brain development. Key words: maternal care, development, local field potential, amygdala, telemetry

Title: Neurobehavioral development of fear and aggression following early life abuse

Authors: ***R. E. PERRY**[1,2,3,4], R. M. SULLIVAN[1,2,3]
[1]Emotional Brain Inst., Nathan Kline Inst., Orangeburg, NY; [2]Child and Adolescent Psychiatry, NYU Sch. of Med., New York, NY; [3]NYU Child Study Ctr., NYU Langone Med. Ctr., New York, NY; [4]Neurosci. and Physiol., NYU Sackler Inst. for Grad. Biomed. Sci., New York, NY

Abstract: Early life abuse produces increased sensitivity to threat and a heightened prevalence of aggressive and violent behaviors emerging by adolescence in humans. Here we use a rodent model of abuse to assess the neurobehavioral development of fear and aggression following early life abuse using a Resident Intruder Test (RIT), as well as a novel Threat Response Selection Test (TRST), which allows for the assay of active (i.e. fighting, exploration) and passive (i.e. freezing, hiding) defensive responses. Furthermore, we assess environmental enrichment as a possible way to attenuate abuse-induced deficits in response to threat. Rat pups were reared with a normal or abusive mother (postnatal days 8-12), and tested in the TRST at post-weaning (PN26-30), adolescence (PN40-45), and adulthood. In this test, individuals were placed in a center "start" chamber of a three chamber arena and given the option to approach a predator odor (fox urine), freeze, or hide in a shelter. The rat was allowed free roam of the apparatus for 5 minutes, and active and passive fear responses were assessed. In a separate group of animals, aggressive behaviors were assessed in the RIT. In this test, animals were single housed for one week before introducing a smaller, same-sex intruder into the home cage for 10 minutes.

Offensive and defensive aggressive behaviors were scored. At all ages, following the TRST or RIT, brains were removed for c-Fos immunohistochemistry analyses within the amygdala, prefrontal cortex, and hypothalamus. Lastly, the effects of housing animals in a socially and physically enriched environment (weaning until time of testing) were assessed on the adult response to threat (TRST) after abuse. In the TRST, post-weaning rats that were abused in infancy showed heightened avoidance of the predator odor, as well as increased hiding in the provided shelter. However, by adulthood, abused rats showed decreased time hiding, and increased approach and interaction with the predator odor, relative to control rats. Furthermore, early life abused animals show increased offensive behaviors in the RIT, including attacking, boxing, pinning, and chasing the intruder. Group differences were found in c-Fos expression following the TRST and RIT. Environmental enrichment prevents previously abused adult animals from approaching the predator odor in the TRST. Infant abuse alters later life responses to threatening stimuli throughout development, making it more likely for one to place itself in harm's way. Understanding the neurobiology of threat responding and its modulation by infant experience will provide insight for treatment of fear and aggression-related disorders that occur after abuse.

Title: Developmental disruption of rat social behavior following early life abuse is mediated by the amygdala and rescued by environmental enrichment

Authors: M. RINCÓN CORTÉS[1,2,3], *R. M. SULLIVAN[1,2,3,4]
[1]Emotional Brain Inst., NKI & NYU Sch. of Med., New York, NY; [2]Child and Adolescent Psychiatry, Child Study Ctr. at the NYU Langone Med. Ctr., New York, NY; [3]Neurosci. and

Physiol., NYU Sackler Inst. at the NYU Sch. of Med., New York, NY; [4]NYU Ctr. for Neural Sci., New York, NY

Abstract: Disrupted social behavior is a hallmark feature of numerous psychiatric disorders, including depression, anxiety and autism (Kennedy and Adolphs, 2012). Moreover, many of these disorders have origins in early life and may be exacerbated by infant experiences such as early life abuse (Rutter, 1984). Early life abuse negatively affects the development of the amygdala- a critical brain area for emotion, learning, and social behavior in both humans and other mammals (Phelps and LeDoux, 2005; Rincón-Cortés and Sullivan, 2014). Importantly, abnormal amygdala function is a common component of psychiatric disorders and has been implicated in the pathophysiology of depression (Anand and Shekhar, 2003; Whalen et al., 2002). Here we use a naturalistic rodent model of early life abuse associated with mother rats roughly handling pups when they are provided with insufficient bedding for nest building. We have previously shown that the effects of infant abuse include but are not limited to: disrupted attachment to the mother amygdala dysfunction and social behavior deficits (Raineki et al., 2012). However, while the amygdala has been implicated in social behavior (Félix-Ortiz and Tye, 2014), its exact contribution to social behavior deficits following infant abuse is currently unknown. Here, we explore the role of amygdala as a mediator of social behavior differences following abuse or normal rearing. To this end, infant rat pups were reared with either an abusive or normal caregiver from postnatal (PN) days 8-12, received age-appropriate social behavior tests throughout early development (infancy, preweaning, adolescence; n=6-8 p/g) and were assessed for c-FOS immunoreactivity within the amygdala following social behavior testing. Pups reared with an abusive mother from PN 8-12 demonstrated social behavior deficits, as indexed by reductions in social interaction time ($p<0.05$), and atypical amygdala activity compared to normally reared pups. However, these changes were only observable at preweaning (PN20) and adolescence (PN40-48), suggesting a developmental delay in the expression of these deficits. Thus, early life abuse produces long-lasting and persistent changes in social behavior and the amygdala that may contribute to the expression of depressive-like behavior during later life. However, an enriched social and physical environment during the postweaning period attenuates the neurobehavioral consequences of early life abuse, as animals receiving environmental enrichment treatment did not show social behavior deficits during adolescence.

Title: Reorganization of the axon terminations of accumbens neurons projecting to the ventral tegmental area between adolescence and adulthood

Authors: *L. YETNIKOFF, K. P. PARSELY, D. S. ZAHM
Dept. of Pharmacol. and Physiological Sci., St. Louis Univ. Sch. of Med., Saint Louis, MO

Abstract: The development of the mesocorticolimbic system has been studied extensively, but almost exclusively with regard to dopaminergic output. By comparison, the ontogeny of inputs to the ventral tegmental area (VTA), the source of mesocorticolimbic dopamine, is less studied. This is not a trivial oversight, as the activity of VTA neurons, which reflects the transmission of information about salient events, is sensitively modulated by their afferent connections. We recently compared the numbers of retrogradely labeled neurons in adolescent and adult rats following injections of the retrograde tracer, cholera toxin β subunit, into the VTA and found significantly fewer in the prefrontal cortex and ventral striatopallidum, including the nucleus accumbens (Acb), in adolescent as compared to adult brains (JCN 522: 1031-47, 2014). Here, we evaluated whether the protracted maturation of Acb inputs to the VTA is reflected in differences in the organization of the axonal terminations of Acb neurons in the VTA. Groups of four adolescent (postnatal day 29) and seven adult (> postnatal day 60) rats received injections of the anterograde tracer, Phaseolus vulgaris-leucoagglutinin (PHA-L), into the Acb shell. Ten days later, the rats were perfused and the brains sectioned at 50 μm. Three and five adjacent series of sections from the adolescent and adult brains, respectively, were collected. One series from each brain was immunoprocessed to show PHA-L, mounted in rostrocaudal sequence on glass slides and coverslipped. Numbers of varicosities in the VTA were estimated by the optical fractionator method with the aid of the StereoInvestigator hardware-software platform (MBF Bioscience, Williston, VT). The StereoInvestigator Cavalieri probe was used to assess the volume of the VTA innervated by Acb fibers. No difference in numbers or density of varicosities in the VTA between adult and adolescent rats was observed. Because overall numbers of Acb neurons do not differ in the adolescent and adult brain (JCN, cited above) and, as noted above, fewer Acb neurons project to the VTA during adolescence as compared to adulthood, this finding suggests that Acb neurons that do innervate the VTA during adolescence have more varicosities than do adult VTA-projecting Acb neurons. It follows that VTA neurons may be influenced differently by Acb inputs during adolescence and adulthood.

Title: Gestational stress produces hyperlocomotion and attenuated weight gain in adult male offspring

Authors: H. BAUERLE[1], *D. J. TOUFEXIS[2]
[1]Dept. of Psychological Sci., [2]Dept. of Psychology, Univ. of Vermont, BURLINGTON, VT

Abstract: Stress during the second trimester of pregnancy has been associated with the development of both schizophrenia and autistic spectrum disorder. This study examines the possible relationship between prenatal stress and schizophrenia by exposing pregnant Sprague-Dawley rats to three iterations of 45 minutes of restraint stress, from days 15 to 20 of pregnancy, and then examining behaviors similar to those commonly observed with schizophrenia in humans. Prenatal stress was associated with hyperlocomotion and attenuated weight gain in 90 day old male, but not 90 day old female, offspring of dams that were stressed during gestation. Baseline startle and prepulse inhibition were equivalent across all groups at this age. Cross-fostering male pups from gestation-stressed to non gestation-stressed dams on day 3 postpartum mitigated the hyperlocomotion and the attenuated weight gain observed in prenatally-stressed pups.The maternal behavior of gestation-stressed dams had no significant effect on pups cross-fostered from non gestation-stress dams. These data suggests that certain behavioral and physical changes that have been associated with schizophrenia are also observed in the adult male offspring birthed and raised by dams exposed to stress during gestation.

Engin., [4]Dept. of Psychiatry, [5]Dept. of Med., [6]Dept. of Med. Biophysics, Univ. of Toronto, Toronto, ON, Canada; [7]Sch. of Psychology, Univ. of Wollongong, Wollongong, Australia; [8]Program in Neurosci. and Mental Hlth., Hosp. for Sick Children, Toronto, ON, Canada

Abstract: INTRODUCTION The human memory circuit includes thin white matter projections (alveus and fimbria), which emanate from inside the hippocampus (HC) and lead out of the medial temporal lobe via the fornix. The volumetric trajectory of the HC subfields and, in particular, the above-mentioned white matter structures (WM) have received little attention with respect to healthy aging. Using precise manual and automatic segmentation methods, our aim was to identify if any volumetric changes in constituents of this circuit are associated with healthy aging. METHODS High-resolution T1 and T2-weighted MRI images were acquired for 5 healthy controls (mean age=37 years). A novel tracing protocol that identified the alveus, fimbria, fornix, and mammillary bodies was created and used in conjunction with the Winterburn HC subfield atlas (Fig A). MAGeT Brain segmentation, previously validated for use in medial temporal lobe, was used to automatically segment WM and HC subfields using the high-resolution atlases on 297 healthy individuals aged 19-94 (mean age=44.85 ± 23.43) from the OASIS dataset (See Fig A for sample output segmentation). RESULTS A general linear model accounting for sex, and intracranial volume indicated a significant decrease in left and right fornix volume with age (respectively; $t=-3.27$, $p<0.001$; $t=-4.11$, $p<0.001$). The left and right alveus (respectively; $t=7.16$, $p<0.001$; $t=6.58$, $p<0.001$) and left CA1 subfield ($t=4.75$, $p<0.001$) demonstrated significant increases in volume across age, maintaining the largest effect sizes (Fig B). No significant differences were observed in the fimbria, whole-HC or combined WM volumes. CONCLUSION Here we present evidence of bilateral increases in CA1 and alveus volumes and decreased fornix volume during healthy aging. Previous studies have demonstrated preservation of the CA1 subfield in healthy aging; however, the volumetric trajectory of HC WM remains relatively elusive. Our results suggest preservation of such structures may be linked to a decreased likelihood of developing neuropsychiatric disorders (e.g. Alzheimer's Disease).

Title: Environmental enrichment differentially affects the perinatal and adult mouse brain

Authors: *R. ALLEMANG-GRAND[1,2], J. SCHOLZ[1], E. LANGILLE[1], D. FERNANDES[1,2], J. P. LERCH[1,2]
[1]Mouse Imaging Ctr., Toronto, ON, Canada; [2]Dept. of Med. Biophysics, Univ. of Toronto, Toronto, ON, Canada

Abstract: Introduction: Physically and cognitively stimulating environments affect the nervous system throughout the lifespan. During perinatal life, housing in an enriched environment (EE) accelerates the maturation of cellular and behavioural measures of murine brain development. Additionally, exposing adult mice to EE triggers neurogenesis and neuroplasticity. In this study, *in vivo* magnetic resonance imaging (MRI) is used to compare the neuroanatomical changes that occur following exposure to EE during perinatal life and in adulthood. Methods: Pregnant CD-1 dams were housed in enriched environments (multi-level maze and running wheel in a large rat

cage) or standard housing (no maze or wheel) conditions. Pups lived in the cage until weaning, at which point they were assigned into the same environment they were raised. Pups were longitudinally scanned at 2.5, 3.5 and 5 weeks of age with a manganese-enhanced MRI (MEMRI) protocol to acquire high-resolution images of the brain. Images acquired at each time point were registered and deformed to generate a consensus average. A mixed effects model was computed at each voxel relating the volume to the fixed effects of age and group. Multiple comparisons controlled for with a false discovery rate (FDR). In the second part of the study, 7 week old C57Bl6 mice were exposed to EE for 3 weeks and scanned with MEMRI. Results: At 2.5 weeks of age, enriched pups had volume increases in regions of the hippocampus and cerebellum as well as volume reductions in the cortex (10% FDR). Interestingly, the trajectory of these differences between enriched and control mice did not change by 3.5 and 5 weeks of age. Separately in adults, a significant interaction (time point by group) was found in the hippocampus and retrosplenial cortex between the two imaging time points in mice exposed to EE. We are currently attempting to replicate these findings in adult CD-1 mice for comparative purposes with the cohort of perinatal EE CD-1 mice. Future work: We are currently scanning 1 week old pups to determine whether the early life neuroanatomical changes are caused by exploration in the enriched cage, or developmentally programmed via an epigenetic mechanism. Our findings suggest that perinatal EE increases the volume of the hippocampus and decreases the volume of the cortex, while adult EE leads to localized volume increases in the hippocampus and retrosplenial cortex.

Title: Maternal programming of mice offspring by prenatal exposure to predator odor

Authors: *S. ST-CYR, P. O. MCGOWAN
Cell and Systems Biol., Univ. of Toronto, Toronto, ON, Canada

Abstract: In rodents, maternal programming of offspring phenotype using classical stressors (e.g. restraint, handling) or of combinations of multiple stressors (chronic variable stress) has been extensively documented. Imposing these stressors during development of early life typically leads to offspring that show an increase in anxiety-like behavior and alterations in related neural pathways. However, the precise somatosensory impact or ecological relevance of these stressors is not always clear. In this study, we used a prenatal stressor that is evolutionarily and ecologically relevant to mice, uniform in its intensity, psychological and unconditioned: predator odor. Pregnant mice dams were exposed to 3 different predator odors daily or distilled water (control) over the second half of their pregnancy when the fetal stress axis is developing. Subsequently, levels of maternal behavior in dams were measured. Furthermore, anxiety-like, sociality and anti-predatory behaviors as well as endocrine stress axis reactivity and gene expression levels were assessed in stress-related brain areas in adult male and female offspring. Predator odor exposure lead to an increase in maternal nest quality while offspring in adulthood showed an increase in anxiety-like behavior in a standardized test (EPM), increased social investigation and affiliation, increased anti-predator behavior and stress axis reactivity in response to predator odor exposure. A number of genes were also found to differ in their expression in key limbic structures, the hippocampus and amygdala. Some genes which showed altered expression are documented targets of early-postnatal stress while others constitute novel markers potentially specific to prenatal predator odor exposure. Consequently, prenatal exposure to a potent ecologically relevant stressor leads to an altered integrative phenotype on a behavioral, physiological and functional genetic level. Future work will examine potential epigenetic mechanisms mediating the persistent effects of prenatal predator odor exposure on the adult phenotype.

Abstract: The impact of spinal cord inflammation on the operation of locomotor networks during development is poorly understood. We show that the kinin-induced changes to central sensitization of spinal nociceptive networks occur perinatally. Furthermore, conditions of the plasticity of kinin receptors induced functional changes in spinal locomotor networks. We investigated the role of kinins (bradykinin (BK) and des-Arg9-bradykinin (DABK)) and their receptors (Bradykinin-2 receptor (B2R) and Bradykinin-1 receptor (B1R)), a neurotrophin (glial cell-derived neurotrophic factor (GDNF)) and transient receptor potential vanilloid 1 (TRPV1) in altering sensorimotor function. Immunohistochemical and pharmacological evidence showed expression of B2R, but not B1R, in the dorsal and ventral horns of naïve animals. Basal B2R expression was downregulated following either an intrathecal or an *in vitro* spinal cord application of BK (B2R agonist). Basal B1R expression was upregulated by an intrathecal injection of GDNF. In hind limb attached to spinal cord (HL) preparations, application of a noxious heat stimulus (> 42 °C) to the hind paw with simultaneous activation of B2R by BK in the spinal cord resulted in a transient disruption of the locomotor rhythm. Conversely, application of noxious heat to the hind paw in the presence of DABK, a B1R agonist, caused a sustained disruption of the locomotor rhythm in spinal cords with upregulated B1R. The BK- or DABK-induced hypersensitivity of locomotor networks to noxious heat was abolished in the HL preparations from trpv1-/- mice. B2R- or B1R-induced hypersensitivity was inhibited in the presence of the protein kinase C blocker, chelerythrine. Using a neonatal model of spinal cord injury, we are characterizing the changes in the expression of GDNF, kinin receptors and activation of glia. These results suggest that early injury and plasticity in the sensorimotor networks may impact normal development of sensorimotor function.

Title: Molecular architecture of the developing and adult human hippocampal formation

Authors: *S.-L. DING, J. J. ROYALL, A. BONGAARTS, R. DALLEY, P. D. PARKER, M. HAWRYLYCZ, A. R. JONES, E. S. LEIN, J. G. HOHMANN

Abstract: The hippocampal formation (HF) including the dentate gyrus (DG), hippocampus proper (CA1-4), and subicular complex [prosubiculum (ProS), subiculum (Sub), presubiculum/postsubiculum (PrS/PoS) and parasubiculum (PaS)] is well established for its importance in learning and memory, and in the processing of emotion and anxiety. The HF is also implicated in many major neurological and psychiatric diseases such as Alzheimer's disease, epilepsy and schizophrenia. Although intensive studies have been carried out in normal and abnormal conditions for various species, there remains very limited information on the molecular architecture of the different components in the developing and adult human HF. To gain insight into molecular cell types across sub-regions, layers, anterior-posterior axis and developmental stages of human HF, we have investigated and compared gene expression patterns of mid-gestational, postnatal and adult human HF using *in situ* hybridization data from the Allen Human Brain Atlas and Brainspan Atlas of the Developing Human Brain. In mid-gestation (post-conception week15-21), many genes are expressed in the cortical plate of HF including FADS2, FOXG1, FOXP1, ENC1, NRGN, LMO4, GAP43, ETV1 and FEZF2, although region-specific expression is not obvious. In adult, conspicuous region-specific gene expression was observed in the DG (NPY1R, CALB1, PDYN, PCP4, BDNF, CD8, TRHR, GABRD, GRM1 and GRM7), CA3 (SLC1A1, CNR1, GRIN2A, BDNF, GRIK5 and HTR2C), CA2 (CALB1, PCP4 and RGS4), CA1 (HTR2A and CARTPT), ProS (TH and NTS), Sub (GFRA1, RGS4, ABAT, CDH11, HTR2C, GRIK1 and GRIK2), PrS/PoS (PDYN, PENK, GRIA4, NEUROD6 and HTR2A,) and PaS (MAOB and HTR2C). Sub-layer enriched gene expression was also detected in the principal layers of CA1 (HTR1A and HTR2C in the upper part, and PCP4 in the deep part) and Sub (NEUROD6 in the upper part, and PCP4 & CHRM2 in the deep part). Some genes (e.g. PDYN, CARTPT, HTR1A and GABRG1) were expressed preferentially in the most anterior (uncal) portion of HF while others were enriched in more posterior HF. During postnatal development (3 months -17years), expression patterns of certain genes (CALB1 and PDYN) were similar to that in adult, while others (PENK and HTR2C) differed between the developing and adult HF. All data for this study is publicly available at www.brain-map.org.

Abstract: Innate behaviors in mammals are mediated by a connected circuit of limbic system structures, which most prominently includes the olfactory system, bed nucleus of stria terminalis (BNST), medial amygdala (MeA) and hypothalamus. As innate behaviors are inborn, there must be embryonic genetic mechanisms that encode establishment of innate circuits. However, how these circuits are established from development remains unknown. Our previous work (Hirata et al., Nature Neuroscience, 2009; Carney et al., Neural Development, 2010) revealed a one to one relationship between a specialized ventral telencephalic progenitor niche marked by expression of the developmentally regulated homeodomain transcription factor Dbx1, and the generation of an electrophysiologically homogenous population of neurons in the MeA. Here we further demonstrate that Dbx1-derived neurons express a unique profile of genes implicated in sexually dimorphic behaviors, and in a complementary pattern to genes expressed by neighboring FoxP2+ MeA neurons. Furthermore, consistent with their restricted electrophysiological and molecular

profiles, Dbx1-derived neurons are selectively activated by restricted subsets of innate behaviors. Thus, parcellation of MeA subpopulations based on developmental genetics predicts electrophysiological, molecular and behavioral specificity.

Title: Identification of the central extended amygdala of chicken based on gene expression patterns and fate mapping analysis

Authors: A. VICARIO, A. ABELLÁN, *L. MEDINA
Univ. Lleida-IRBLLEIDA, Lleida, Spain

Abstract: In mammals, the central extended amygdala is a cell corridor of the basal telencephalon involved in control of fear responses. Developmental data in mouse have demonstrated that it shows a mosaic-like organization with different neurons coming from distinct embryonic domains and showing a different genetic profile (Waclaw et al., 2010; Bupesh et al., 2011). In the central amygdala neurons coming from the dorsal lateral ganglionic eminence (dLGE) express Pax6 and primarily populate the capsular subdivision, overlapping with pre-proenkephalinergic (ppENK) neurons; those coming from the ventral lateral ganglionic eminence (vLGE) express Islet1 and populate lateral and medial subdivisions, partially overlapping with different peptidergic neurons, including those expressing corticotropin-releasing factor (CRF); neurons coming from the medial ganglionic eminence (MGE) express Nkx2.1 and somatostatin (SOM), and primarily concentrate in the medial subdivision. The avian central extended amygdala is poorly known, and a central amygdalar nucleus has not been found yet. Our aim was to identify the components of the central extended amygdala in the developing

brain of chicken by analyzing the expression of cPax6, cIslet1, cppENK, cCRF and cSOM, and by experimental fate mapping. We observed two distinct cell masses at caudal telencephalic levels expressing either Pax6 or Islet1 that appeared to derive from the dLGE-like or vLGE-like striatal domains, respectively. We called these two chicken subdivisions the central capsule (CeC, rich in Pax6) and the oval central nucleus (Ce-ov, rich in Islet1). Both subdivisions include neuron subpopulations expressing either cppENK or cCRF. Another cell mass, the perioval zone, appeared to extend from the pallidal domain into the central amygdala, and became interposed between the CeC and the Ce-ov. This area contains many cppENK- and some cSOM-expressing cells. Our *in vitro* migration assays combined with immunofluorescence showed that the dorsal striatal domain produces cPax6-expressing neurons that mainly populate the CeC, whereas the ventral striatal domain produces cIslet1-expressing cells, populating the Ce-ov. Regarding the chicken lateral bed nucleus of the stria terminalis (BSTL), like that of mammals, it also contains neuron subpopulations coming from the pallidal or the striatal subdivisions (both dLGE- and vLGE-like), although in different proportions and locations. In conclusion, we identified the central amygdala and the BSTL in chicken, having subcomponents similar to those present in mammals based on genetic profile and embryonic origin.

Title: Developmental differences in psychophysiological responses to music

Authors: J. ANCELLE, R. TIETZE, S. WEINBERGER-LITMAN, *D. A. HUNTER
Psychology Dept., Marymount Manhattan Col., New York, NY

Abstract: The use of music as a therapeutic tool can be traced to ancient preliterate cultures. However, it was not until recently that music therapy was recognized as an effective treatment for various neurological disorders such as non-fluent aphasia, memory and communication deficits associated with dementia and limited emotional processing in autism. Research in the field has been steadily growing since, but much still needs to be understood regarding the effects

of music on the brain and body. During early adolescence, the rapidly maturing limbic system parallels the increasing capacity to create emotions. The prefrontal cortex, responsible for the ability to make rational judgments is one of the last regions to mature. Therefore, the regulation of emotions is less restrained and often contributes to long lasting and robust emotional relationships made during this time. The objective of this study was to determine which time period (adolescence or adulthood) evokes the strongest emotions to self-selected music using psychophysiological measures (heart rate-HR and electrodermal responses -EDR) as a measure of quantifying emotions. To this end, male or female participants ranged in age from 18-72 years of age (N=16) Participants were asked to complete a background questionnaire that consisted of demographic questions and a request for a list of 4 songs that they developed a strong connection to during adolescence (12 to 17 years of age) and adulthood (>18). Two songs were randomly selected from each category and played to the participants in a randomized order while simultaneous recordings of psychophysiological responses were recorded. Psychophysiological responses were compared with a self-report questionnaire accessing subjective evaluations of felt emotions to music selections. Preliminary results show that music altered HR and EDR relative to baseline and there was trend reflecting stronger EDR responses to music that corresponded to the participant's adolescence. A better understanding of psychophysiological responses to self-selected music should help design better therapeutic approaches to treating individuals using music therapy to help alleviate deficits incurred via neurological damage.

Abstract: Activation of sensory circuits regulates the number of interneurons that express specific neurotransmitters (NT) in the brain, as shown in the hypothalamus following stimulation of the retino-hypothalamic projection and more recently in accessory olfactory bulb (AOB) interneurons after activation of the olfactory nervous system. Frogs use olfactory-mediated kin recognition to distinguish siblings from non-siblings via kinship cues; 4-day old Xenopus larvae display attraction/aversion behavior to water-borne kin (K)/nonkin (NK) odorants, respectively. AOB interneurons were identified by immunocytochemical markers for dopamine (tyrosine hydroxylase, TH) and GABA. Following 48 hr exposure to K (sibling condition) or NK (non-sibling condition) odorants, the extent of TH and GABA expression in the AOB changed dramatically, compared to odorant deprivation (orphan condition, O). We found that altering the ratio of dopamine/GABA coexpression in AOB interneurons, as well as blocking their receptors, reverses kinship recognition behavior. To identify the signalling molecules that mediate kinship recognition we performed comparative mass spectrometry analysis of K- and NK-conditioned water samples. We identified two vitellogenin-derived peptides (PP1, AVILNGFPESGLS; PP2, VVVNPHEAQAS) that were uniquely present in kinship-conditioned samples of one genotype. Behavioral tests showed that PP1 is sufficient to elicit aversion behavior in NK larvae and that its signaling specificity is lost when the amino acid sequence is scrambled or swapped. MicroRNA (miR) regulates many aspects of development. To test miR involvement in regulating NT switching we sequenced RNA from AOB tissue of animals exposed to K, NK, and O conditions and identified 183 miRs based on their predicted targets, 20 of which were differentially regulated across conditions. The miRs showing a substantial fold change matching the up- or down-regulation expected according to the kinship-dependent NT phenotype switch were selected for qPCR validation. To screen validated miR candidates for their role in NT respecification *in vivo*, locked nucleic acid (LNA) miR inhibitors were delivered via electroporation in the AOB during the sensory-induced changes in NT expression. Our results show that miR-375 is a potent inhibitory regulator of the dopaminergic phenotype. We are currently testing miR candidates expected to regulate the GABA phenotype. Understanding the molecular machinery regulating this form of chemosensory-induced neuroplasticity affecting behavior may be relevant to behavioral states associated with neurological disorders that involve abnormal expression of NTs.

Title: Neurotransmitter switching in single neurons in the adult rat brain

Authors: *D. MENG[1,2], D. DULCIS[1,2], S. LEUTGEB[1,2], K. DEISSEROTH[3], N. C. SPITZER[1,2]
[1]Div. of Biol. Sci., UC San Diego, La Jolla, CA; [2]Kavli Inst. for Brain and Mind, UC San Diego, La Jolla, CA; [3]Dept. of Bioengineering, Dept. of Psychiatry & Behavioral Sci., Stanford Univ., Stanford, CA

Abstract: The nervous system responds to changes in endogenous activity and the external environment by modulating its function through various forms of neuroplasticity, many of which occur at synapses. However, it has been believed that neurotransmitters are fixed and invariant in the brain. Recent work has demonstrated activity-dependent transmitter respecification in neuronal populations both in the developing and adult nervous system. For example, the numbers of dopaminergic (DA) neurons and somatostatin (SST) neurons in the hypothalamus of the adult rat change in response to altered photoperiods. Long days (19hr:5hr L:D) decrease the number of DA neurons and increase the number of SST neurons by the same amount, which leads to depression-like behaviors. Short days (5L:19D) elicit the opposite effects. Can single neurons switch their transmitter? Despite evidence demonstrating transmitter switching in neuronal populations, it remains unclear whether this form of plasticity takes place by single neuron reprogramming in the adult brain. We have taken a genetic approach to permanently label DA neurons, by injecting the hypothalamic paraventricular nuclei (PaVN) of tyrosine hydroxylase (TH)::Cre rats with a Cre-dependent AAV virus expressing EYFP. The originally inverted viral EYFP sequence is flipped in neurons expressing TH, and EYFP expression is driven by an internal promoter independent of Cre. Since EYFP expression persists during long-day exposure when PaVN DA neurons lose TH expression, formerly DA neurons can be identified. Following viral injection and long-day exposure, brains were stained for TH and SST and compared to controls (12L:12D). If transmitter switching takes place only within single neurons, the formerly DA neurons (EYFP+) will lose TH and express SST instead. In contrast, if transmitter switching occurs only at the population level, the formerly DA population and the newly acquired SST population will remain separate. Our results indicate that EYFP+SST+TH- neurons are present following 19L:5D exposure, indicating that these formerly DA neurons have acquired the SST phenotype. Additionally, EYFP+SST-TH- neurons and EYFP-SST+TH- neurons are also present, consistent with switching at the population level. We are quantifying these results with multichannel fluorescence stereology. These findings identify an unexpected flexibility of the hardwired connectome. Since transmitter respecification can involve a switch between excitatory

and inhibitory transmitters that alters behavior, this activity-dependent plasticity may explain a variety of normal behaviors and neurological disorders.

Abstract: The emergence of bigger brains with enormous numbers of neurons is an evolutionary innovation in amniotes, particularly mammals and birds. However, the corresponding changes in cortical developmental programs during amniote evolution are poorly understood. In the developing mammalian neocortex, neural stem/progenitors in the ventricular zone give rise to basal progenitors (BPs) including Tbr2-positive intermediate progenitors and Pax6-positive outer radial glial cells (oRGs), which contribute to enhanced neurogenesis and encephalization. Here we show that various progenitor populations also exist in the developing avian pallium. Interestingly, avian BPs exhibit mammalian oRGs characteristics, which are distiguished from Tbr2-positive cell population. Manipulation of regulatory genes for progenitor dynamics such as CDK4/CyclinD1 provided distinct outcomes in the mammalian and avian pallium. Furthermore, we identified basal mitotic cells in non-avian reptiles and also amphibians, which implies the origins of progenitor diversities. Our results suggest that specific BPs have evolved

independently in mammalian and avian lineages, by modifying ancestral regulatory mechanisms for neural stem/progenitor maintenance during amniote evolution.

Abstract: Although the basic morphological characteristics of neurons in the cerebellar cortex have been documented in several species, virtually nothing is known about the quantitative morphological characteristics of these neurons across different taxa. To that end, the present study investigated cerebellar neuronal morphology among eight different, large-brained mammalian species comprising a broad phylogenetic range: afrotherians (African elephant, Florida manatee), carnivores (Siberian tiger, clouded leopard), cetartiodactyls (humpback whale, giraffe) and primates (human, common chimpanzee). Specifically, several neuron types (e.g., stellate, basket, Lugaro, Golgi, and granule neurons; N = 317) of the cerebellar cortex were stained with a modified rapid Golgi technique and quantified on a computer-assisted microscopy system. There was a 64-fold variation in brain mass across species in our sample (from clouded leopard to the elephant) and a 103-fold variation in cerebellar volume. Most dendritic measures tended to increase with cerebellar volume. The cerebellar cortex in these species exhibited the trilaminate pattern common to all mammals. Morphologically, neuron types in the cerebellar cortex were generally consistent with those described in primates (Fox et al., 1967) and rodents (Palay and Chan-Palay, 1974), although there was substantial quantitative variation across species. In particular, Lugaro neurons in the elephant appeared to be disproportionately larger than those in other species. To explore potential quantitative differences in dendritic measures across species, MARSplines analyses were used to evaluate whether species could be differentiated from each other based on dendritic characteristics alone. Results of these analyses indicated that there were significant differences among all species in dendritic measures.

Ctr., Atlanta, GA; [4]Fishberg Dept. of Neurosci. and Friedman Brain Inst., Icahn Sch. of Med. at Mount Sinai, New York, NY; [5]Anthrop., The George Washington Univ., Washington, DC

Abstract: Gradients in developmental maturation across the rostro-caudal axis of the isocortex align with gradients in adult anatomical features as well as a hierarchy in cognitive processing. The maturation (e.g., myelination) of the frontal cortex is protracted compared with more caudal regions (e.g., occipital cortex). By adulthood, neurons have more elaborate dendritic branches towards the frontal cortex and it mediates more abstract processing than more caudal regions. However, very little is known about how evolutionary changes across these developmental gradients account for systematic changes in connections across the isocortex. To that end, we used HARDI (high-angular resolution diffusion MRI) tractography to compare the strength of connections across the isocortex of several primate species (e.g., marmoset, *Callithrix jacchus*; chimpanzee, *Pan troglodytes*; orangutan, *Pongo pygmaeus*; human, *Homo sapiens*). These species were chosen because they vary in their brain size and length of developmental schedules. We placed regions of interest through the frontal, temporal, parietal and occipital lobes and estimated the density of connections within and between each of these lobes. We found that as brains expand and overall developmental schedules lengthen, proportionally more tracts arise and terminate within the frontal cortex than in more caudally situated regions (e.g., occipital lobe). Lengthened developmental schedules may promote increased time for the formation of within-frontal cortical connections, resulting in increased frontal lobe within-connectivity in adulthood. More generally, these findings highlight that, as primate brains expand, the isocortex increases the integration of information within the frontal cortex.

Title: Uncovering the genetic differences of hemispheric lateralization in humans

Authors: *G. MUNTANÉ[1,2], G. SANTPERE[1], A. VERENDEEV[2], A. BAUERNFEIND[3], A. NAVARRO[1], W. D. HOPKINS[4], C. C. SHERWOOD[2]

Abstract: A prominent asymmetrical brain function in humans is preferential handedness, with more than 90% of the population showing more skillful usage of the right hand, which is controlled by the left hemisphere. The left hemisphere is also dominant for language, whereas the right hemisphere excels in spatial recognition. Even though genetic models of human handedness and language have been proposed, the actual gene that underlie these functions in humans have not yet been identified. In the current project we used microarrays in both humans and macaque monkeys to examine gene expression profiles in three cortical regions involved in language or handedness: inferior frontal cortex and posterior superior temporal cortex (which in humans correspond to Broca's area and Wernicke's area, respectively) and primary motor cortex. As follow up, levels of candidate genes were confirmed using other techniques such as RT-PCR and immunohistochemistry. The results demonstrated that the overall pattern of gene expression is very similar between hemispheres in both humans and macaques. Therefore, weighted gene correlation network analysis (WGCNA) was used to find clusters (modules) of highly correlated genes. WGCNA showed that human inferior frontal cortex and posterior superior temporal cortex present weaker module preservation between hemispheres. The method also facilitated the identification of hub genes in these modules. In sum, bioinformatic analyses of these data revealed that the human and macaque monkey's interhemispheric expression profiles are very similar, although subtle differences appear in human Wernicke's and Broca's areas at the level of gene co-expression networks.

Title: Asymmetry in the inferior parietal lobe in chimpanzees and its relationship with handedness

Authors: *L. D. REYES[1,2], C. C. SHERWOOD[3,1], W. D. HOPKINS[4,5]
[1]Ctr. for the Advanced Study of Hominid Paleobiology, [2]Hominid Paleobiology Program, [3]Dept. of Anthrop., The George Washington Univ., Washington, DC; [4]Neurosci. Inst., Georgia State Univ., Atlanta, GA; [5]Div. of Developmental and Cognitive Neurosci., Yerkes Natl. Primate Res. Ctr., Atlanta, GA

Abstract: The inferior parietal lobe (IPL) is associated with tool-use in humans and non-human primates and can be divided into rostral and caudal regions. The rostral portion is involved in the execution and observation of grasping, and the caudal portion that is active during visually guided arm and hand movements. Previous studies have indicated that areas associated with tool-use such as the planum temporale (PT) and parietal operculum (PO) have population-wide leftward asymmetry in chimpanzees and humans, with an increased magnitude of leftward PT asymmetry for right-handed individuals. This study examines if the chimpanzee IPL and its rostral and caudal parts show a similar pattern of asymmetry and link with handedness. The sample consisted of T1-weighted structural MRI scans from 30 chimpanzees from Yerkes National Primate Research Center (23F, 7M, age = 22.1 +/- 2.7 yrs). Volume was calculated for the whole IPL, rostral IPL, and caudal IPL bilaterally. IPL regions of interest were based on Bailey et al. (1950)'s map of histologically parcellated areas in the chimpanzee brain. Asymmetry quotients (AQ) were calculated for each measure using the formula (R-L)/[(R+L)/0.5]. Handedness was based on hand preference for a simulated termite fishing task. Chimpanzees exhibit population-wide leftward asymmetry for the entire IPL and caudal IPL, and rightward asymmetry for the rostral IPL. IPL asymmetries were not correlated with handedness, and there was no relationship between magnitude of IPL asymmetry and handedness. The IPL and PO appear to follow a similar pattern of population-wide asymmetry that is not correlated with handedness. Although tool-use relies on the use of the hand and arm, the processing of sensory and motor information is highly integrative and relies on interconnectivity with other brain regions. This interconnectivity may have resulted in hemispheric specialization in tool-use circuits independent of handedness.

Abstract: We performed high-throughput mass spectrometry in individual regions (anterior cingulate, primary motor, primary sensory, and primary visual) and layers (III, IV, and V) of the neocortex, in the cerebellum (granule cell layer), as well as in the caudate nucleus in humans and chimpanzees. A total of 39 mass spectrometry peaks were matched with probable protein identifications in both species, allowing for a direct interspecific comparison. We explored how the pattern of expression of these proteins varies across regions and cortical layers to provide insights into the differences in biological function of these neural structures between species. Molecular signatures in the expression of proteins differed principally in a regional and laminar-specific pattern, while the expression of proteins that differentiate species were less pronounced. Specifically, human and chimpanzee brains are fundamentally similar in their distribution of proteins related to the regulation of transcription and enzyme activity but differ more markedly in their expression of proteins supporting aerobic metabolism. While most work of molecular expression differences in the brains of primates has been performed on gene transcripts, our unique dataset extends current understanding of differential molecular expression patterns that may underlie human cognitive specializations.

Title: Differences in serotonin transporter expression in the amygdala of bonobos (Pan paniscus) and chimpanzees (Pan troglodytes): Implications for behavior

Authors: *C. D. STIMPSON[1], W. D. HOPKINS[2,3], J. P. TAGLIALATELA[4,3], N. BARGER[5], P. R. HOF[6], C. C. SHERWOOD[7]

Abstract: Human's closest living relatives are the bonobo (Pan paniscus) and chimpanzee (Pan troglodytes), sharing over 98% of our genetic material with the genus Pan. Bonobos and chimpanzees themselves are over 99% genetically similar, but despite this, differ greatly in behavior and social structure. Bonobos are considered much more tolerant, bond strongly with one another and often mediate conflicts through sexual interactions. Chimpanzees, on the other hand, form hunting parties, patrol territories and resolve conflicts between and within troops through aggression. Recent studies have identified volumetric and neuronal differences between the two species in the amygdala, an area of the brain related to social cognition. The amygdala serves a role in decision making, memory, attention and emotional responses. In the current study, we sought to determine whether the amygdala shows a measureable difference in serotonin transporter (SERT) expression between bonobos (N=6) and chimpanzees (N=6). SERT is known to regulate the responsiveness of the amygdala to stimuli that provoke fear and aggression, with lower levels of expression associated with increased aggression. We labeled SERT-containing axons using immunohistochemistry and employed stereological methods to estimate their length density. We found that bonobos express a significantly greater density of SERT-immunoreactive axons across the entire amygdala, at levels twice those observed in chimpanzees (Mann-Whitney U, $p = 0.008$). These findings suggest that variation in serotonin levels in the amygdala mediate, in part, the remarkable differences in social behavior exhibited by bonobos and chimpanzees.

Abstract: Humans are uniquely susceptible to age-related neurodegenerative pathologies, such as Alzheimer's disease. This vulnerability is likely the result of evolutionary changes related to increased brain size and longevity compared to other primates. In humans, healthy aging is marked by varying degrees of neural deterioration and cognitive impairment. One region particularly affected by aging is the hippocampus, which exhibits a decrease in total volume and an increase in glial cell population and activation. Prior studies of great apes, including chimpanzees, did not find an age-associated decrease in hippocampus volume or a substantial neuronal loss in the CA1 subregion. These reports suggest the great ape brain may age differently than the normal human brain. The objective of the present analysis was to examine the effect of age on neuronal and glial densities in the hippocampus of chimpanzees, our closest living relatives. Using Nissl-stained sections and stereological methods, we quantified neuron and glial density in the CA1 and CA3 fields of the hippocampus in a sample of 16 chimpanzees (ages 12-58 years). Overall, CA3 possessed higher neuron and glial densities relative to CA1 (Mann-Whitney, $p < 0.01$). Variation in neuron densities was associated with age in both hippocampal subregions (CA1: $p = 0.02$, $r2 = 0.32$; CA3: $p < 0.01$, $r2 = 0.49$), while variation in glial densities was only correlated with age in the CA3 field ($p = 0.030$, $r2 = 0.296$). The ratio of glia to neurons in CA1 and CA3 was not altered with age in chimpanzees. Our preliminary results demonstrate a moderate, age-related decline of both neuron and glial densities for CA3 and neuron densities for CA1. Future analyses will reveal if this association remains with an increased sample size and is related to neurodegenerative pathologies in these individuals.

Title: Heritable anatomical variation in chimpanzee brains. Implications for human evolution

Authors: *A. GOMEZ-ROBLES[1], W. D. HOPKINS[2,3], C. C. SHERWOOD[1]
[1]Dept. of Anthrop., The George Washington Univ., Washington, DC; [2]Neurosci. Inst., Georgia State Univ., Atlanta, GA; [3]Div. of Developmental and Cognitive Neurosci., Yerkes Natl. Primate Res. Ctr., Atlanta, GA

Abstract: The brain phenotype of the last common ancestor of chimpanzees and humans is unknown, but it is usually assumed that humans have undergone a much more dramatic divergence from the ancestral condition. Therefore, chimpanzee brains provide the closest available model of the expected phenotype from which human brains evolved. The evolutionary modifications experienced during human evolution must have been determined by genetic variation influencing different brain regions. We address this question by combining morphometric analyses with quantitative genetics in order to evaluate the proportion of phenotypic variation in different brain areas that is heritable and, therefore, available to modification by natural selection. Quantitative genetics uses phenotypic affinities in pedigreed populations to estimate the genetic component of phenotypic variation from similarities between kin-related individuals. We used a sample of more than 200 chimpanzees for which a well-documented pedigree is available. Brain anatomy was characterized by means of a set of homologous landmarks and some linear distances defined between them. Preliminary results show that variables related to primary sensory and motor cortical areas show higher heritabilities,

whereas cortical association areas, especially inferior frontal regions, show the lowest heritability values. Our results underscore the importance that non-genetic, plastic variation in inferior frontal association areas may have had in primate brain evolution and development. Interestingly, parietal areas, which have been proposed to show increased levels of plasticity in modern human brains, show higher heritability than inferior frontal areas in chimpanzees, perhaps pointing to increased plasticity in parietal regions as a late acquisition in human brain evolution.

Title: Evo-devo of cortical association pathways: Allometric and systematic variation across primates

Authors: *C. SHERWOOD[1], E. TAKAHASHI[2], A. VAN DER KOUWE[3], W. D. HOPKINS[4], P. R. HOF[5], C. J. CHARVET[2]
[1]Anthrop., George Washington Univ., WASHINGTON, DC; [2]Div. of Newborn Medicine, Dept. of Med., Boston Children's Hospital, Harvard Med. Sch., Boston, MA; [3]Martinos Ctr. for Biomed. Imaging, Massachusetts Gen. Hospital, Harvard Med. Sch., Boston, MA; [4]Neurosci. Inst. and Language Res. Ctr., Georgia State Univ., Atlanta, GA; [5]Fishberg Dept. of Neurosci. and Friedman Brain Inst., Icahn Sch. of Med. at Mount Sinai, New York, NY

Abstract: Several cortical association pathways differ in humans compared with other primates. In particular, the finding that the arcuate fasciculus is more prominent in humans than in chimpanzees and macaques has been used to argue that its expansion is tied to the emergence of language. However, it is not clear whether the arcuate fasciculus expanded in isolation or in concert with other cortical association pathways in primate evolution. Moreover, the developmental mechanisms accounting for the expansion of the arcuate fasciculus in humans

relative to other primates have gone unexplored. To that end, we used HARDI (high-angular resolution diffusion MRI) tractography of brains to compare cortical association pathways (e.g., arcuate fasciculus, inferior fronto-occipital tract, inferior longitudinal fasciculus,) in several adult and developing primates (e.g., marmoset, Callithrix jacchus; chimpanzee, Pan troglodytes; orangutan, Pongo pygmaeus; human, Homo sapiens). We found that each cortical association pathway enlarges with a different allometry as developmental schedules lengthen and brains expand. The arcuate fasciculus becomes disproportionately enlarged as overall brain size increases and overall developmental schedules lengthen. In development, the studied cortical association pathways follow a similar sequence of maturation in chimpanzees and in humans. For instance, the maturation of the arcuate fasciculus is protracted compared with many other association pathways. The lengthened developmental time course of brain maturation in humans may give rise to the particularly disproportionate expansion of tracts that mature late in development. Taken together, these findings demonstrate that the disproportionate expansion of the arcuate fasciculus may be a by-product of lengthened developmental schedules.

Title: Statistical model of evolution of brain regions

Authors: *D. D. FERRANTE, Y. WEI, A. KOULAKOV
Cold Spring Harbor Labs., Cold Spring Harbor, NY

Abstract: We study the distribution of brain and cortical area sizes (parcellation units (PUs)) obtained for three species: mouse, macaque, and human. We find that in all these animals the observed distribution of PU sizes is close to log normal. We analyze the model of evolution of brain PUs through splitting or fragmentation. We define splitting statistically, by assuming that each existing PU has a probability to be split into two more specialized regions that depends on PU size only. We show that such a splitting process defined statistically can explain the

distributions of PU sizes observed in three species, including lognormality and the scale of standard deviations. Similar statistical models have been analyzed previously to describe the process of explosive shell fracturing and rock grinding, however, in these models fracturing occurs independently for different fragments. In contrast, the model that we describe for PU fragmentation does not consider PU splitting to be independent for different regions. We find that the model that best captures the observed PU distributions includes fracturing that is independent on the PU size. This finding suggests that, in the course of brain evolution, PUs have approximately similar probability to be split into more specialized regions. The evolutionary pressure to specialize, described statistically, applies equally to large and small brain regions.

Title: Are the foundations for embodied activity already embedded in heterogeneous laminar networks?

Authors: *E. L. OHAYON, A. K. LEE, A. LAM
Neurolinx Res. Inst., The Green Neurosci. Lab., La Jolla, CA

Abstract: What are the neural foundations necessary for movement in the environment? In this study we use embodied computational models to examine the relation of network structure to movement in artificial autonomous agents. Previous studies by members of our group have found that random networks tend to settle to a fixed-point state or limit cycle, oscillatory, behavior reminiscent of seizures. These behaviors could be quickly evolved into embodied movement by applying genetic algorithms to the connectivity. In another set of studies, spatial, laminar networks were shown to support persistent activity in cases where density was varied and connectivity made heterogeneous. However, the question of how the spatial features of laminar network architecture would contribute to interactions with the environment remained open. As such, we connected the laminar networks to a chassis and observed the behavior. RoHS

compliant materials and open source platforms were used in building the embodied agents. Specifically, the Arduino platform was used to interface the neural networks running on an external computer. The chassis was equipped with servo motors for output motion. Sensory input included photoresistors and contact switches. The spatial networks were multi-layered and consisted of up to 100,000 spiking units. Simulations included both inhibitory and excitatory units connected in columnar geometries. Network density was varied by adding or removing units and their connections at 10% increments. Neural activity was initiated with a single initial contact to a touch receptor. Unlike the results in random networks, many of the embodied spatial networks immediately began to show movement, requiring no learning or evolutionary interventions. Specifically, in heterogeneous networks (e.g., density of 60%), embodied forward and turning movements correlated to the persistent propagating activity seen in the isolated networks. These initial observations suggest that the heterogeneous laminar structure is sufficient to generate movements that are reminiscent of nascent embodied motion seen in early development and evolution. The results of this study may thus help illuminate why (i) laminar architectures and (ii) changes in density are important neural features that appear repeatedly in evolution and development.

Title: Decoupled schedules of neural and somatic development during embryogenesis across species

Authors: *A. HALLEY
Univ. of California, Berkeley, Berkeley, CA

Abstract: Significant evolutionary differences exist across species in terms of relative brain structure size, functional architecture, connectivity, and degrees of encephalization, among other

forms of variation (Streidter 2006). While investigations into brain evolution have traditionally examined species differences in adult brains, recent research has increasingly aimed to describe the developmental mechanisms responsible for lineage-unique adult neuroanatomy. Embryonic development, when progenitor cell pools are established and neurogenesis begins, is of primary interest for comparative neurological investigations. Comparative embryology generally utilizes staging techniques (e.g. the Carnegie system; O'Rahilly & Muller 1999) based primarily on the appearance of somatic features to establish morphological equivalence in embryonic development. However, staging obscures differences across species in the relative rate of neural and somatic development, which is central to understanding early alterations to brain development across species. Here we describe interspecies differences in the decoupling of neural and somatic development, based on three approaches: (1) our own meta-analysis of embryonic literature on the appearance of embryonic traits, combined with those described by recent work in Barbara Finlay's lab (Clancy et al. 2001; Workman et al. 2013; www.translatingtime.org); (2) comparative brain morphology at equivalent stages; and (3) allometric measurements of brain/body growth during embryonic development. Comparison across available species shows that a variety of events in embryonic brain development - e.g. neurogenesis, tract formation, etc. - occur significantly earlier in rodent species relative to somatic events when compared against non-rodent mammals. Corresponding differences in both embryonic brain morphology and brain/body allometry are also examined. These findings are discussed in relation to developmental shifts in corticogenesis observed in glires (Workman 2013), as well as potential evolutionary pressures and developmental mechanisms underlying the developmental decoupling of somatic and neural events.

Title: FGF2-induced gyrification in the mouse brain: An evolutionary perspective from mice to humans

Authors: *S. TOMASI[1], G. COPPOLA[1], F. M. VACCARINO[1,2,3]
[1]Child Study Ctr., [2]Dept. of Neurobio., [3]Kavli Inst. for Neurosci., Yale Univ., New Haven, CT

Abstract: During the course of evolution, selective expansion of different cortical areas of the cortex is a major requirement to increase the complexity of information processing. Indeed, gyrification, the folding of the cortical mantle which generates sulci and convolutions, represents an optimal evolutionary strategy to increase neuronal populations without increasing head size, and is one of the most distinctive morphological features of the brain of primates and humans. Understanding the molecular underpinnings of gyrencephaly represents a major challenge in neurobiology, and may potentially increase our understanding of brain growth under normal and pathological conditions. We previously reported that a single microinjection of Fibroblast Growth Factor 2 (FGF2), but not FGF8, into lateral ventricles of mouse embryos before the onset of neurogenesis (E11.5) resulted in the appearance of rostrolateral, fully-layered gyri in the normally non-convoluted adult mouse brain, which was reminiscent of morphological features of gyrencephalic species. In order to investigate the mechanisms of FGF2-induced gyrification, we set out to analyze gene expression profiles at different time points after FGF2 injections by means of *in situ* hybridization, real-time quantitative PCR and next-generation RNA sequencing, and correlated these data with morphological findings and proliferative dynamics in the region undergoing the cortical enlargement. Interestingly, we found that FGF2 did not seem to alter the cell cycle or cell survival, but modulated the expression profiles of several proneural genes (including Ngn1, Ngn2, NeuroD2, NeuroD4 and NeuroD6) as early as 48 hours after injections. As FGF signaling is a known modulator of other signaling pathways, including Wnt and Notch, we carried out a series of experiments aimed at understanding the nature of this crosstalk. Strikingly, we found that few hours after injection, FGF2 regulated the expression gradients of Notch ligands, and that altered expression corresponded to the region undergoing the cortical expansion, suggesting that FGF2 can shift the timing of neurogenesis and the determination of VZ-SVZ cell identities. Consistently, several FGFs and Notch-related genes are co-expressed in a spatially and temporally-restricted manner during early stages of neurogenesis in humans.

Title: A new dimension of neurobiology in a novel cell type

Authors: *P. H. FREDERIKSE, A. NANDANOOR, C. KASINATHAN
Rutgers SDM BHS, Newark, NJ

Abstract: Extensive similarities shown between neurons and elongated fiber cells in eye lens include the ultrastructure of their microtubule vesicle transport machinery and the membrane protrusions/dendritic spines along their lateral surfaces. These membrane structures have similar size and shape, and share expression of a number of key gene products and associated molecular regulatory mechanisms first shown to work as a unit in neurons at dendritic spines. We showed that AMPA and NMDA glutamate receptors and a core set of associated molecular mechanisms that coordinate their regulation at the DNA, RNA and protein levels also occur in lens. Others showed both membrane structures express clathrin and AP-2 on their surface and contain F-actin, which forms a scaffold in dendritic spines. Lens AMPARs include its pivotal GluA2 subunit which also undergoes Q/R RNA editing, analogous to neurons. We showed NMDAR NR1, NR2A, and NR2B in lenses, and identified p-Tyr GluA2 and p-Tyr 1472 NR2B that are phosphorylated at clathrin/AP-2 interaction sites which block endocytosis. Conversely, we showed STEP Tyr-phosphatase in fiber cells that promotes receptor internalization. Greater STEP and excess AMPAR/ NMDAR endocytosis are key factors in primary neural disorders and important drug targets. Extracellular GluA2 domain is a principal binding partner for GAPDH moonlighting protein at dendritic spine surfaces, and GAPDH internalization has a critical role in neuronal cell death mechanisms. IF *in situ* studies demonstrated overlapping focal distributions of STEP, GAPDH, p-Tyr-GluA2, clathrin, actin, and AP-2 at the perimeter of lens fiber cells at membrane spines in lenses of healthy adult rabbits. In disease, we measured greater STEP61 and decreased p-Tyr-GluA2 in lenses of adult diabetic rabbits together with disrupted fiber cell morphology typical in the rabbit model. We speculate that AMPA and NMDA glutamate receptors actions in lens focus on the remarkably precise nature of its morphogenesis required to produce an optically useful organ. Detailed similarities between lens fiber cells and neurons may also relate to observations first made in the 1970's that neurons can trans-differentiate into lens. In light of speculations first made by W. Gehring (CH) that sensory organs which include the eye and lens preceded the evolution of a brain, these findings in lens provide further evidence of a unique relationship in the evolution and development of lens fiber cells and neurons, and support the further hypothesis that AMPAR/NMDAR functions and regulation in lens may have been antecedents of more dynamic activities that define neuronal functions.

Title: Social isolation and brain development in the eusocial ant species camponotus floridanus

Authors: *E. JUNGE[1], M. A. SEID[2]
[2]Biol. Dept., [1]The Univ. of Scranton, Scranton, PA

Abstract: Social interaction plays a key role in the healthy development of social animals. This effect can be seen throughout the mammalian family and is most pronounced in species with complex social networks. When developing offspring do not receive proper social interaction they show developmental impairments. This effect is well documented in mammalian species but controversial in social insects. It has been hypothesized that the enlarged mushroom bodies, responsible for learning, memory and sensory integration, observed in social insect species are needed for maintaining the large social networks or due to other confounding factors such as the demands of parasitism or task related behavior. This study examines the impact of social isolation on the development of mushroom bodies of the eusocial ant species Camponotus floridanus. Ants raised in isolation were shown to exhibit impairment in the growth of the mushroom bodies as well as behavioral deficits when compared to ants raised in small social groups beyond the factors that have been previously shown to influence mushroom body growth during development. These results indicate that social interaction is necessary for the proper development of C. floridanus mushroom bodies.

Title: The rod photoreceptors originate from S-opsin expressing cone precursor cells in the mammalian retina

Authors: *J.-W. KIM, H.-J. YANG, M. J. BROOKS, A. SWAROOP
NIH, Natl. Eye Inst. (NEI), Bethesda, MD

Abstract: Cone and rod photoreceptors in the retina are specialized light-sensing neurons for day and night vision, respectively. Developmental defects or death of photoreceptors can lead to retinal neurodegeneration and consequently blindness. Loss of *Nrl*, a transcription factor essential for rod cell fate determination, results in a mouse retina with only S-(blue or uv sensitive) cone photoreceptors instead of rods. Based on multiple lines of evidence, we proposed that rod photoreceptors are generated from S-cone precursor cells that have developmental plasticity and generate rods when NRL is dominant and active. To test this hypothesis and find possible 'footprints of S-cone precursors', we purified the rod cells using fluorescence activated cell sorter (FACS) from *Nrl*-GFP transgenic mouse retina (from P2 to P28; peak of rod birth to matured rod) that expresses GFP specifically in rod photoreceptors. We performed global transcriptome analysis of flow-sorted developing and mature rods using RNAseq. The RNAseq data revealed no expression of genes specific for non-photoreceptor neurons; however, cone-specific genes, such as *Opn1sw* and *Gnb3*, are highly expressed in rods from early stages of differentiation and their expression decreased as the rods matured. We then examined the epigenetic landscape of rod photoreceptors by reduced-representation bisulfite sequencing (RRBS) for DNA methylation and ChIPseq for histone methylation patterns (H3K4me3 and H3K27me3). The epigenome data demonstrated active epigenetic marks (low levels of DNA methylation, high H3K4me3, low H3K27me3) on cone-specific genes at early development stages but the patterns reversed in mature rod photoreceptors. To further test our hypothesis, we performed lineage tracing by marking S-cone cell specific lineage using *Opn1sw*-Cre;ROSA26-AP (Alkaline phosphatase). Surprisingly, rod photoreceptors also exhibited high AP activity along with S-cones. Taken together, our studies provide strong evidence in support of evolution of rods from S-cone photoreceptors.

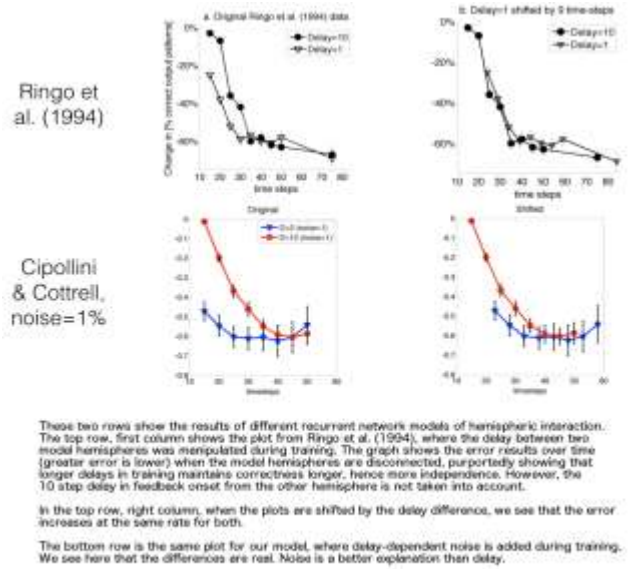
Title: A developmental approach to long-distance connectivity and interhemispheric collaboration

Authors: *B. N. CIPOLLINI, G. COTTRELL
Cognitive Sci., UC San Diego, La Jolla, CA

Abstract: Cerebral lateralization is intertwined with virtually every cognitive function that we think makes us human, yet a clear dichotomy in a leading theory about its origins remains unexplained. Though lateralized processing has been suggested to be due to independent, local development of neural circuits (Ringo et al., 1994; Rilling & Insel, 1999a), these intrahemispheric circuits tend to be complementary (not independent) and show extremely strong functional coupling, suggest robust interhemispheric interactions in the lateralized human brain. Here, we review literature and present modeling evidence suggesting that: (1) previous modeling work that concluded that conduction delay leads to hemispheric independence is overstated and misinterpreted, and is inconsistent with experimental data on the development of lateralization and the corpus callosum. (2) Variability in conduction delays, present in early development due to thin, unmyelinated white matter fibers (Faisal et al., 2008), can bias infant learning towards the use of shorter, local connections, and this effect can drive hemispheric independence. (3) This early bias towards local circuits suppresses lateralization of perceptual processing and enhances lateralization in unilateral motor production (e.g. handedness). These results are consistent with developmental data showing that lateralization increases during development, where communication migrates from local circuits to long-distance circuits. We argue that this effect is greatest in humans, due to a trade-off between maximizing adult brain size while minimizing brain size at birth as indicated by the uniquely human post-natal growth trajectory (Martin, 1983). This suggests that, counter to previous proposals, the physiology of interhemispheric communication in humans may not be a pure function of brain size shared across mammals, but instead is related to the uniquely human problem of birthing a large-brained fetus through a narrow walking pelvis.



These two rows show the results of different recurrent network models of hemispheric interaction. The top row, first column shows the plot from Ringo et al. (1994), where the delay between two model hemispheres was manipulated during training. The graph shows the error results over time (greater error is lower) when the model hemispheres are disconnected, purportedly showing that longer delays in training maintains correctness longer, hence more independence. However, the 10 step delay in feedback onset from the other hemisphere is not taken into account.

In the top row, right column, when the plots are shifted by the delay difference, we see that the error increases at the same rate for both.

The bottom row is the same plot for our model, where delay-dependent noise is added during training. We see here that the differences are real. Noise is a better explanation than delay.

Title: Comparing human and macaque cortical development through differential gene coexpression analysis

Authors: *M. C. OLDHAM
Neurol., UCSF, San Francisco, CA

Abstract: Unique aspects of human brain development underlie our species' remarkable cognitive abilities and our vulnerability to malformations of brain circuitry, which likely contribute to many neuropsychiatric disorders. However, our understanding of the cellular and

molecular bases of brain development is predominantly based on studies of model organisms. This situation has begun to change with the advent of techniques such as laser micro-dissection (LMD) and transcriptional profiling, which can be combined to generate highly multivariate, quantitative, and precise information about the molecular composition of a single tissue specimen. This approach has recently been used in conjunction with stereotyped sampling strategies to generate atlases of gene expression in the developing brains of humans and rhesus macaque monkeys, providing an unprecedented opportunity to test the hypothesis that changes in the regulation of gene expression were central to the evolution of many unique human qualities, including our expanded neocortex. The present work describes a multivariate analytical strategy for comparing transcriptome organization between humans and macaques during prenatal cortical development. Application of this strategy to LMD samples from cingulate cortex and primary visual cortex of both species reveals conserved and distinct patterns of gene activity, many of which are driven by specific cell types. These results provide an integrated functional context for studying genes that have been implicated in cortical development, while simultaneously identifying novel candidate genes whose activity may distinguish cortical development in humans from other primate species.

Abstract: Commissural axons exist in all Bilateria, but the development of novel commissural circuits or the modification of existing ones has accompanied the emergence of key neurobiological features in vertebrate evolution, such as depth perception, hearing, lung-based breathing and limb-derived locomotion. In most Bilateria, specific sets of cells occupy the midline and express axon guidance molecules, which regulate crossing. Two ligand/receptor molecular partners play a major role in this process: Netrin-1/DCC (Deleted in Colorectal Cancer) which mediates the attraction of commissural axons towards the midline and Slit/Robo (Roundabout) which mediate repulsion of post-crossing axons away from the midline and prevent ipsilaterally projecting neurons from crossing it. In vertebrates, a key role in midline guidance is played by the divergent Robo family member Robo3. Robo3 is expressed by commissural axons of the mouse spinal cord and hindbrain before and during crossing of the midline floor plate, and many commissures fail to develop in mice and humans lacking Robo3. We provide evidence for positive selection of the Robo3 receptor during mammalian evolution that subverted its mechanism of action. Unlike other Robo receptors, including Robo3 in non-mammalian vertebrates, mammalian Robo3 is not a high affinity receptor for Slits, a difference attributable to a few substituted residues. Moreover, Robo3 regulates responses to the chemoattractant Netrin-1, as Netrin-1 selectively triggers phosphorylation of mammalian Robo3, pontine neurons lacking Robo3 fail to migrate towards a Netrin-1 source, and loss of Robo3 attenuates Netrin-1-induced spinal commissural axon outgrowth. Midline pontine neuron attraction is restored in Robo3 knockout mice expressing mammalian but not non-mammalian Robo3. We propose that Robo3 evolution was key to sculpting mammalian motor circuits by converting a receptor for Slit repulsion into one that both represses Slit repulsion and potentiates Netrin attraction.

Title: A human accelerated enhancer of FZD8 regulates corticogenesis

Authors: *D. L. SILVER[1], G. WRAY[2], S. SKOVE[1], L. BOYD[1]
[1]Mol. Genet. and Microbiology, Duke Univ. Med. Ctr., Durham, NC; [2]Biol., Duke Univ., Durham, NC

Abstract: The human neocortex differs from that of other great apes in several notable regards including altered cell cycle, prolonged corticogenesis, and massively increased overall size. While these evolutionary changes likely contributed to the origin of distinctively human cognitive faculties, their genetic basis remains almost entirely unknown. Highly conserved non-coding regions that show rapid sequence changes along the human lineage are candidate loci for the development and evolution of uniquely human traits. Here we report the discovery of a human-accelerated regulatory enhancer (*HARE5*) of *FZD8,* a member of the frizzled family of WNT receptors implicated in brain development and size. Although *Fzd8* is expressed throughout the developing embryo, *HARE5* drives expression primarily in neural stem cells and neurons of the neocortex. Using transgenic mice, we demonstrate striking differences in human and chimpanzee *HARE5* activity, with human *HARE5* driving precocious and more robust expression at the onset of corticogenesis. Chromosome conformation capture assays reveal mouse *HARE5* physically and specifically contacts the core *Fzd8* promoter in embryonic neocortices. To assess the phenotypic consequences of *HARE5* activity, we generated transgenic mice in which *Fzd8* expression is under control of either human or chimpanzee *HARE5*. In comparison to chimpanzee *HARE5*, human *HARE5*-driven expression of *Fzd8* induced a larger fraction of neural stem cells in S and G2/M phases of the cell cycle. Changes in *HARE5* function that are unique to humans thus alter cell cycle state of a critical population of stem cells during corticogenesis, and may therefore underlie some of the distinctive anatomical features of the human brain.

Title: Differing residues in the highly conserved transmembrane domain of β2 and β4 nAChR subunits contribute to differences in function and agonist efficacy of α4β2 and α4β4 receptors

Authors: *M. NEWHOFF[1], C. LI[2], J. B. EATON[1], R. J. LUKAS[1], A. P. KOZIKOWSKI[3], Y. CHANG[1]
[1]Barrow Neurolog. Inst., Phoenix, AZ; [2]Xinxiang Med. Univ., Henan, China; [3]Univ. of Illinois at Chicago, Chicago, IL

Abstract: Neuronal heteromeric nicotinic acetylcholine receptors (nAChRs) composed of α4 and β2 subunits form pentameric ligand-gated cation channels in high-sensitivity (HS) (α4)2(β2)3 and low-sensitivity (LS) (α4)3(β2)2 isoforms. A4 can also form functional HS and LS receptors in conjunction with β4, a lesser-studied nAChR subunit whose presence has been detected in primate brain. Despite a high sequence homology between β2 and β4 subunits, α4β2 and a4β4 nAChRs differ markedly in total function, as well as in the potency and efficacy of agonists including Sazetidine-A (AMOP). Using chimeras of the β2 subunit with the C-terminal domain or the M3-M4 intracellular loop swapped with the corresponding region in β4 and two-electrode voltage-clamp in the oocyte expression system, we demonstrated that the structural determinant for these differences is located in the transmembrane domain (C-terminal domain, excluding the large intracellular loop), suggesting they are potentially due to a gating effect. In comparing sequences of the channel lining domain M2 and the coupling region of β2 and β4 subunits, we found two residues which differ between the two subunits: one in the 13' position of the M2 domain, and one at the end of M2-M3 linker near the "hinge". Point mutations interchanging these two residues in the wild-type subunits altered efficacies for the agonist AMOP and other related compounds towards those of the alternate wild type receptor. Receptor function was also affected: while our WT α4β2 receptors had lower function than our WT α4β4 receptors, we found that the V253F and V272I mutations in β2 increased function dramatically, such that the mutant receptor function more closely resembled that of WT α4β4 than of WT α4β2. Our results suggest that differences in gating and coupling efficiency between β2 and β4

subunits can influence agonist efficacy. (Supported by NIH Grant R01GM085237 to YC and U19 MH085193 to APK, RJL, and YC)

Title: MTS modification of substituted cysteines in the β2 nachr subunit reduces dFBr potentiation of α4β2 receptors

Authors: ***Y. HUANG**[1], R. M. CERCHIO, Jr[1], R. A. GLENNON[2], M. K. SCHULTE[1]
[1]pharmacology and Toxicology, Univ. of Sci., Philadelphia, PA; [2]Dept. of Medicinal Chem., Virginia Commonwealth Univ., Richmond, VA

Abstract: Neuronal nicotinic acetylcholine receptors (nAChRs) are members of the Cys-loop super family of ligand gated ion channels (LGIC) and play a critical role in synaptic transmission. Changes in receptor expression resulting from neurodegenerative and epigenetic processes produce a range of neurological disorders including Autism, Alzheimer's and Parkinson's disease. Unfortunately, few drugs are available for treatment of these neurological disorders. Desformylflustrabromine (dFBr) is a natural product originally purified from the marine bryozoan Flustra foliacea. Using a synthetic form of dFBr, we previously determined that dFBr is a selective allosteric modulator of the nicotinic α4β2 receptor. When co-applied with acetylcholine on these receptors, dFBr produces a 265% increase in efficacy compared to acetylcholine alone. The EC50 for potentiation by dFBr is 1μM; however, at dFBr concentrations greater than 3μM, acetylcholine induced responses are inhibited in the presence of dFBr, producing a "bell shaped" dose response curve. The precise binding site for dFBr and the mechanism of potentiation remain unknown. In this study we use substituted cysteine accessibility method (SCAM) to determine if dFBr binds at the β2+/α4- interface of the α4β2 receptor. To prevent modification of the two endogenous cysteines located on the intracellular M1-M2 loop by MTS we mutated these residues on both the α4 and β2 subunits to serine and

glycine (C262S and C269G). We have previously shown that these mutations produce no effect on acetylcholine responses on mutant α4β2 receptors (pseudo wt). While these mutations did block potentiation by calcium, no effect on dFBr potentiation was observed, thus calcium and dFBr potentiation appear to involve different mechanisms. Using these "pseudo wt" receptors, we introduced single point cysteine mutations in the B and C loops of the β+ subunits. Mutation of β2D217 of loop C to cysteine produced no effect on either acetylcholine responses or dFBr's ability to potentiate acetylcholine responses. Modification of D217C by MTS also produced no observable effect on the acetylcholine response but reduced the potentiation produced on co-application of dFBr by 80%. As MTS modification of the cysteine introduced at position 217 would block dFBr access to β2+/α4- interface, these data support our hypothesis that dFBr binds at this position to produce potentiation.

Title: Properties of extracellular domain α3β2 nicotinic acetylcholine receptors with a protease site inserted upstream of M1

Authors: *G. B. WELLS, V. L. FRANKOVICH, A. M. PERSON
Mol. & Cell. Med., Texas A&M Univ. Hlth. Sci. Ctr., COLLEGE STATION, TX

Abstract: Background: Water-soluble extracellular domain human nicotinic acetylcholine receptors (ECD nAChRs) would be useful for understanding how human nAChR work. Their production, however, remains elusive and appears to need initial expression with the first transmembrane domain (M1). Because of that requirement, post-expression proteolysis to remove M1 is a potential path to water-soluble ECD nAChRs. The path requires that ECD nAChRs tolerate an inserted protease site upstream of M1. Indeed, α7 ECD nAChR and α4β2 ECD nAChR with inserted protease sites upstream of M1 have high structural fidelity to full length receptors. Thus, a proteolysis strategy might have general utility for many or even all

nAChRs. **Goal and Objective**: The goal is to determine whether human α3-containing ECD nAChRs, like α7 and α4β2 ECD nAChRs, are suitable for post-expression proteolysis to produce water soluble receptors. The objective is to measure properties of human α3-containing ECD nAChRs containing inserted amino acid residues, including a site-specific protease site, upstream of M1. **Methods**: Human α3 and β2 cDNAs were truncated after M1 (α3M1 and β2M1). Mutagenesis placed a heterologous 5-residue sequence (adding two restriction sites; α3M1RE and β2M1RE) or a 7-residue TEV protease site (α3M1TEV) at the ECD-M1 interface. Subunits were expressed in *Xenopus* oocytes. Immunoblotting and affinity and yield of [^{3}H]epibatidine binding sites assessed effects of inserted residues on expression and structural fidelity. **Results**: Immunoblotting showed expression of α3M1, β2M1, α3M1RE, β2M1RE, and α3M1TEV. The dissociation constant of [^{3}H]epibatidine with α3M1/β2M1 ECD nAChR was similar to the dissociation constant with full length α3β2 nAChR. With heterologous sequences inserted at the ECD-M1 interface, α3M1RE/β2M1RE and α3M1TEV/β2M1RE produced yields of high affinity [^{3}H]epibatidine binding sites comparable to the yield of α3M1/β2M1 ECD nAChR. **Conclusions:** Based on dissociation constants with [^{3}H]epibatidine, the α3 nicotinic subunit forms α3M1/β2M1 ECD nAChR with high structural fidelity to full length α3β2 nAChR. Based on yield of high affinity [^{3}H]epibatidine binding sites, the α3M1 subunit tolerates heterologous residues, including a TEV protease site, inserted immediately upstream of M1. These results suggest that α3β2 ECD nAChR, like α7 and α4β2 ECD nAChRs, might be suitable for post-expression proteolysis to produce water soluble receptors.

Title: Biophysical and pharmacological properties of native human α6β4 nicotinic acetylcholine receptors

Authors: *A. J. HONE[1], J. MCINTOSH[3,4], J. PASSAS[5], A. ALBILLOS[2]
[1]Neurosci., [2]Pharmaoclogy and Therapeut., Univ. Autonoma De Madrid, Madrid, Spain; [3]Biol., Univ. of Utah, Salt Lake City, UT; [4]Psychiatry, George E. Wahlen Veterans Affairs Med. Ctr., Salt Lake City, UT; [5]Urology, Hosp. Doce de Octubre, Madrid, Spain

Abstract: Human adrenal chromaffin cells express nicotinic acetylcholine receptors (nAChR) that facilitate the release of catecholamines when activated. The two main receptor subtypes expressed by these cells are α6β4 and α7. The α7 subtype has been widely studied in other cells and expression systems but much less is known about the α6β4 subtype in part because of its sparse expression in the nervous system and relatively poor expression in heterologous systems. Consequently, very little is known about the pharmacological and biophysical properties of this subtype. We performed whole-cell voltage-clamp electrophysiology on isolated human chromaffin cells obtained from organ donors to elucidate these properties. Several agonists were tested to determine their activities on α6β4 nAChRs including acetylcholine, nicotine, varenicline, DMPP, and 5-I-A-85380. The rank order potency of these ligands was 5-I-A-85380 = DMPP = varenicline > nicotine = acetylcholine and all had EC50 values in the low micromolar range. The relative efficacies of these agonists also differed. Varenicline and 5-I-A-85380 were both full agonists whereas nicotine and DMPP were partial agonists relative to acetylcholine. Desensitization experiments with acetylcholine and nicotine revealed that chromaffin cell α6β4 nAChRs rapidly desensitized during continuous exposure to EC50 concentrations of either agonist. Furthermore, these receptors recovered relatively rapidly after complete desensitization by nicotine. The pharmacological properties observed were not due to the presence of receptors that contained a β2 binding site because the acetylcholine-evoked currents were relatively insensitive to inhibition by a β2-selective antagonist, an analog of α-conotoxin LvIA, and could be completely abolished by the β4-selective antagonist α-conotoxin BuIA(T5A,P6O). Additional experiments were performed to examine the current-voltage relationship and calcium permeability of α6β4 nAChRs. These results provide valuable information on the properties of native human α6β4 nAChRs.

Title: Roles for N-terminal domains of nicotinic acetylcholine receptor (nAChR) β3 subunits in enhanced functional expression of mouse α6β2β3- and α6β4β3-nAChRs

Authors: *B. DASH[1], R. J. LUKAS[2], M. D. LI[1]
[1]Psychiatry and Neurobehavioral Sci., Univ. of Virginia, Charlottesville, VA; [2]Neurobio., Barrow Neurolog. Inst., Phoenix, AZ

Abstract: Functional heterologous expression of naturally-expressed mouse α6*-nicotinic acetylcholine receptors (mα6*-nAChRs; where '*' indicates presence of additional subunits) has been difficult. Here we expressed and characterized wild-type (WT), gain-of-function, chimeric or gain-of-function chimeric nAChRs, sometimes as hybrid nAChRs containing both human (h) and mouse (m) subunits, in Xenopus oocytes. Hybrid mα6mβ4hβ3- (~5-8 fold) or WT mα6mβ4mβ3-nAChRs (~2 fold) yield higher function than mα6mβ4-nAChRs. Function is not detected when mα6 and mβ2 subunits are expressed together or in the additional presence of hβ3 or mβ3 subunits. However, function emerges upon expression of mα6mβ2mβ3(V9'S)-nAChRs containing β3 subunits having gain-of-function, V9'S [valine(V)-to-serine(S)] mutations in their transmembrane segment II 9' residues and is ~89% lower than those of mα6mβ2hβ3(V9'S)-nAChRs. Studies involving WT or gain-of-function chimeric mouse/human β3 subunits indicate involvement of N-terminal and other segments/domains of β3 subunits in their differential effects on function of mα6*- nAChRs. Using hβ3 subunits as templates, site directed mutagenesis studies indicate that substitution with mβ3 subunit residues in putative "β2-β3" (Q94 and E101), "β5-β6" (Loop E: S144 and S148) or "β9-β10" (loop C: E221 and F223) loops increases function of mα6mβ2*- (~2-3 fold) or mα6mβ4*- (~2-4 fold) nAChRs. EC50 values for nicotine at mα6mβ4hβ3-, mα6mβ4mβ3-, mα6mβ4mβ3(S144V+S148V)-, mα6mβ4mβ3(E221D)- and mα6mβ4mβ3(E221D+F223V)- nAChRs are same ($p > 0.05$). Thus, amino acid residues located on the putative primary (loop C) or complementary (β2-β3 or E loops) faces of β3 subunits are some of the molecular impediments for functional expression of mα6mβ2mβ3- or mα6mβ4mβ3-nAChRs.

Title: Molecular interaction of α-conotoxin RgIA with α9α10 nAChR

Authors: *L. AZAM[1], J. MCINTOSH[2]
[1]Biol., Univ. of Utah, SALT LAKE CITY, UT; [2]Dept. of Pyschiatry & Biol., Veterans Affairs Med. Ctr. & Univ. of Utah, Salt Lake City, UT

Abstract: The α9α10 nAChR was first identified in the auditory system, where it mediates synaptic transmission between efferent olivocochlear cholinergic fibers and hair cells of the cochlea. This receptor has gained further recent attention due to its potential role in chronic pain, breast and lung cancers. We previously showed that α-conotoxin RgIA, one of the few α9α10 selective ligands identified to date, is 300-fold less potent on human vs. rat α9α10 nAChR. This species difference was conferred by only one residue in the (-) complementary, rather than (+) principal, binding region of the α9 subunit. In light of this unexpected discovery, we sought to determine other residues that interact with α-conotoxin RgIA. A recent molecular modeling study concluded that RgIA interacts with Glu194, Pro197 and Asp198 on the (+) face of the α9 subunit and Glu58 and Asp114 of (-) face of the α10 subunit (1). However, mutations of these nAChR subunit residues had little or no effect on toxin block of α9α10 nAChR function. In contrast, mutation of homologous residues in the opposing nAChR subunits resulted in loss of toxin activity ranging from 19 to ≥1700-fold. The results of the present study demonstrate interaction of α-conotoxin RgIA with an α10/α9 rather than α9/α10 nAChR subunit interface. These findings may help guide the development of other selective ligands of therapeutic potential. 1 Pérez EG, Cassels BK, Zapata-Torres G. Title: What non-natural conotoxin can tell us about α7 nAChRs

Authors: *F. MARGER[1], T. SCHAER[2], C. HEINIS[3], D. BERTRAND[4]
[1]Hiqscreen, Vésenaz, Switzerland; [2]HiQscreen, Geneva, Switzerland; [3]LABORATORY OF THERAPEUTIC PROTEINS AND PEPTIDES, EPFL, Lausanne, Switzerland; [4]hiQscreen, Geneva, Switzerland

Abstract: The finding that the α-conotoxin ImI binds with high affinity the α7 nAChRs opened new possibilities to investigate the structure function of these nicotinic acetylcholine receptors. As expected for a complex protein-protein interaction, binding affinity was found to depend upon the tridimentional structure of the conotoxin (Ulens et al., 2006). Examples, obtained with the α-conotoxin PnIA have shown that exchange of a single amino acid residue at position 10 in the conotoxin was sufficient to switch its activity from antagonist at the α7L'9T to agonist indicating the exquisite structural sensitivity required to stabilize the active state (Hogg et al., 2003). Based on these initial observations we postulated that even small structural changes of the α conotoxin might modify their functional effects. Taking advantage of the automated HiClamp system, which allows electrophysiological recordings in small volumes we examined the effects of a series of small conformational changes on the pharmacological properties of non-natural α conotoxins ImI. Determination of the dose-response activity revealed that inhibition of ACh evoked current strongly depends upon the α-conotoxin structure and that as much as a ten fold increase in affinity at α7 nAChRs can be obtained with an IC50 down to 50 nM. Further characterization of the most relevant conformations provides additional information about the conserved selectivity of these α7 conotoxin on the different nAChRs subtypes. In conclusion this work provides new insights for the understanding of the binding site of nAChRs, the importance of conserved residues in the N-terminal domain of the receptor opening new possibilities to engineer small protein of interest for drug development. Title: Allosteric modulation of α7 nicotinic acetylcholine receptors is altered by transmembrane mutations

Authors: *A. CHATZIDAKI[1], J. M. D'OYLEY[2], T. D. SHEPPARD[2], N. S. MILLAR[1]
[1]NPP, [2]Chem., Univ. Col. London, London, United Kingdom

Abstract: Acetylcholine activates nicotinic acetylcholine receptors (nAChRs) by binding at an extracellular orthosteric site, located at the interface between two adjacent subunits. In the case of homomeric α7 nAChRs, activation by acetylcholine, or by other orthosteric agonists, results in rapid desensitisation. Previous studies have described a series of positive allosteric modulators (PAMs) that are selective for homomeric α7 nAChRs. These include Type I PAMs, that exert little or no effect on the rate of receptor desensitisation after activation by an orthosteric agonist, and Type II PAMs that cause a dramatic loss of agonist-induced desensitisation. A binding site for both Type I and Type II PAMs has been identified within the transmembrane domain of α7 nAChRs. In addition, there is evidence that nAChRs can be activated by ligands (allosteric agonists) binding to a similar allosteric transmembrane site. In the case of α7 nAChRs, activation by allosteric agonists has been found to induce a much lower level of desensitisation than that which occurs after activation by orthosteric agonists. Here we report evidence that transmembrane mutations in α7 nAChRs have interesting and diverse effects on receptor activation and desensitisation by allosteric ligands. It has been reported previously that the L247T mutation (located in the second transmembrane domain) confers increased potency to acetylcholine and reduced levels of desensitisation. In contrast, the M260L mutation (located higher up in the second transmembrane domain) does not show any difference in the acetylcholine potency and desensitisation profile compared to wild-type receptors. We have found that in receptors containing the L247T mutation, both Type I PAMs and Type II PAMs are converted into non-desensitising agonists. In contrast, in receptors containing the M260L mutation, this effect is seen only with Type II PAMs. These findings, indicating that the M260L mutation has a selective effect on Type II PAMs, have been confirmed both with a series of previously described PAMs and also with a series of novel α7-selective PAMs. The novel PAMs examined in this study have close chemical similarity but diverse pharmacological properties.

For example, they include compounds displaying effects on receptor desensitisation that are typical of classical Type I and Type II PAMs but, in addition, they include compounds with intermediate properties. It is hoped that studies examining the effects of a series of transmembrane mutations on PAMs with diverse pharmacological effects will help to provide an insight into the mechanism of action of nAChR allosteric modulators.

Title: Chimeric acetylcholine binding proteins provide insight to the structure and function of human nicotinic receptors

Authors: *T. T. TALLEY[1,2], J. LINDSTROM[3], J. LUO[3], J. BOBANGO[1], M. WILSON[1], K. GALLEGOS[1], P. TAYLOR[2]
[1]Dept. of Biomed. and Pharmaceut. Sci., Idaho State Univ. Col. of Pharm., Meridian, ID;

Abstract: Since the first report of the acetylcholine binding protein (AChBP) and its structure by Sixma and colleagues in 2001, crystal structures of many complexes have been analyzed in relation to ligand selectivity. However, AChBPs define a sub-species of a nicotinic acetylcholine receptor (nAChR) ectodomain, whose sequence and ligand selectivity are distinct from nAChR subtypes. While providing an atomic resolution view of how nicotinic ligands interact with their binding sites and similar general patterns of “nicotinic” activity, AChBP selectivity differs from specific subtypes of nAChRs and might be treated as one member of a wide family of extracellular domains. To enhance correlation between native nAChRs and the AChBPs, we have generated several chimeric constructs wherein specific regions of the AChBP primary

sequence are replaced with amino acids that correspond with specific nAChR subtypes. In addition to replacing loop C of the AChBP with the sequence of each of the human α and β subtypes we have modified other regions of the subunit interfacial binding site to mimic more closely the binding affinities observed for human nAChRs. We have also modified surface regions that correspond with the area of the muscle α1 subunit implicated in the autoimmune myasthenia gravis (MG). Distinct sequences in the main immunogenic region (MIR) of the α1 subunit have been substituted into the corresponding position of the AChBP sequence. The expressed protein demonstrates an antibody profile directly comparable to that observed in MG patients. To further understanding of the antibody/receptor interactions, we have generated several X-ray structures of our MIR/AChBP chimera. Both C loop and MIR substitutions have enhanced crystallization of several ligand-AChBP complexes yielding valuable information on binding determinants and poses. While we continue to strive for structures of the antibody in complex with this construct the current structures provide a structural template for the development of small molecule or peptidomimetic disrupters of the antibody interaction.

Title: Active when closed? Coupling to heterotrimeric G proteins enable α7 nAChR mediated calcium store release

Authors: *J. KING, J. NORDMAN, S. P. BRIDGES, M. LIN, N. KABBANI
George Mason Univ., Fairfax, VA

Abstract: α7-nicotinic acetylcholine receptors (α7 nAChRs) are pentameric ligand gated channels that enable calcium entry into cells. Although the α7 nAChR is known to rapidly desensitize in response to ligands, its function is critical for long-lasting changes in neuronal activity and structure. To date little is know about the mechanism by which α7 nAChRs mediate persistent changes in cells. Recent studies suggest a role for α7 nAChRs in the regulation of intracellular calcium stores in hippocampal neurons. We have examined the ability of α7 nAChRs to couple heterotrimeric G proteins in developing neural cells. We find that specific residues in the intracellular M3-M4 loop are critical for G protein binding and modulation of IP3 receptor calcium store release. In particular, ligand activation of the α7 nAChR appears to promote an increase in intracellular calcium well beyond the established time frame of channel activation, a process blocked by xestospongin C and attenuated by G protein blockers. The findings support the involvement of G protein signaling in nAChR function and suggest a new framework for considering α7 nAChR driven neuronal modulation.

Title: AChBP/insect chimeras as tools for the analysis and development of safer insecticides

Authors: *J. BOBANGO[1], M. WILSON[1], K. GALLEGOS[1], P. TAYLOR[2], T. TALLEY[1]
[1]Dept. of Biomed. and Pharmaceut. Sci., Idaho State Univ., Meridian, ID; [2]Skaggs Sch. of Pharm. and Pharmaceut. Sci., Univ. of California, San Diego, CA

Abstract: The nicotinic acetylcholine receptors (nAChRs), members of the Cys-Loop ligand gated ion channel superfamily, are the primary target of insecticides. Selectivity and resistance

issues of current insecticides dictate a need to research new compounds. Due to the inability to heterologously express insect nAChRs, current assay techniques involve utilizing either truly hybrid receptors or a heterogeneous mix of the binding targets from crude tissue preparations. To circumvent these issues, the soluble acetylcholine binding protein (AChBP) from the mollusk *Aplysia* californica, a good structural surrogate for insect nAChR, is recombinantly expressed and utilized for high throughput assays of binding affinity. Radioligand competition binding assays is utilized to determine the binding affinity differences of wild-type, insect like constructs, and AChBP constructs designed to mimic human nAChR subtypes. This combined with *in situ* Click Chemistry can be used to develop and evaluate analogs of neonicotinoid pesticides. Further, the ability to crystallize the AChBP constructs in the presence of novel ligands allows for structure-guided compound design. In the current study we have generated AChBP/insect chimeras by site-directed mutagenesis in the loop C region of the AChBPs for subtype and species selectivity to mimic target and off-target insects. This was completed for the following insects: *Drosophila* melanogaster (fruit fly), Myzus persicae (green peach aphid), Heliothis virescens (moth), Anopheles gambiae (mosquito), and the off-target honey bee Apis mellifera. We have assayed the affinity of the AChBP/insect chimeras for the nicotinoids nicotine and epibatidine, the neonicotinoids imidacloprid and thiocloprid, and the pyrazinoylimino and trifluoroacetylimino extended neonicotinoid analogs. We have contrasted the affinities relative to wild-type and humanized AChBP. This information will aid the development of new insecticides with greater potency and specificity including a novel series of analogs developed through Click Chemistry.

Title: Development and validation of a population patch clamp-based assay for subtype-selective profiling of nicotinic acetylcholine receptors

Authors: G. KIRSCH, Y. KURYSHEV, Z. LIU, L. ARMSTRONG, *C. MATHES, A. M. BROWN
Chantest Corp., Cleveland, OH

Abstract: Neuronal nicotinic acetylcholine receptors (nAChRs) belong to a family of pentameric, membrane-bound receptors which function as ionic channels and mediate cholinergic modulation of neurotransmission. Subtypes within the family of neuronal nAChRs are defined by their α- and β-subunit composition, and functional properties such as ligand-sensitivity, pharmacologic profile, Ca^{2+} permeability, and desensitization kinetics. Homopentameric α7 and heteropentameric α4β2 subtypes, in particular, are prominent in brain and have been investigated as therapeutic targets for various neurologic indications including depression, tobacco addiction, neuroinflammation, cognition impairment related to schizophrenia and Alzheimer's disease, and neurodegeneration related to Parkinson's disease. Here we describe development, optimization and validation of medium throughput population patch clamp-based assays for human nicotinic subtypes, $\alpha_3\beta_4$, α_7, $\alpha_4\beta_2$, and $\alpha_3\beta_4\alpha_5$, stably expressed in Chinese hamster ovary (CHO) cells. Cell line development and characterization were performed in both a fluorescent imaging plate reader (FLIPR Tetra) and the IonWorks Barracuda (IWB) automated patch clamp system; only the patch clamp assays are presented here. The cell lines were pharmacologically characterized by both subtype-selective and non-selective reference compounds, including agonists, pore blockers, competitive antagonists and positive allosteric modulators. An IWB platform in 384-well population patch clamp format supported development and validation of automated patch clamp assays in the four different nAChR subtypes. The validation results showed that biophysical characteristics of the receptors (agonist sensitivity and acute desensitization) measured in the IWB system were comparable to those obtained by conventional electrophysiological assays. The potency of reference antagonists for inhibition of the receptor-channels and selectivity of positive allosteric modulators also were very similar between IWB and published conventional voltage clamp results. All four assays were found to be very robust and reproducible, suitable for subtype profiling and medium-throughput screening of compound libraries in agonist, antagonist or positive allosteric modulator modes. The discovery of selective modulators may facilitate development of new therapeutics or adjuvant therapies for treatment of disease conditions such as cognition impairment, depression, addiction, and inflammation.

Title: [125I]-iodo-ASEM: A New radioligand for measuring α7 nicotinic receptors

Authors: *T. T. OLSON[1], C. ONONGAYA[1], Y. XIAO[1], Y. GAO[2], R. MEASE[2], M. POMPER[2], A. G. HORTI[2], K. J. KELLAR[1]
[1]Dept. of Pharmacol. & Physiol., Georgetown Univ. Sch. of Med., Washington, DC; [2]Dept. of Radiology, John Hopkins Univ. Sch. of Med., Baltimore, MD

Abstract: Neuronal nicotinic acetylcholine receptors (nAChRs) are pentameric ligand-gated, nonselective cation channels composed of varying α and β subunits. Combinations of these subunits define the nAChR subtypes. Heteromeric nAChRs are composed of α subunits (α2 – α10) in combination with β subunits (β2 – β4), while the α7 subunit forms a homomeric receptor. The homomeric α7 nAChR is found throughout the brain and is believed to play an important role in memory, cognition, schizophrenia, and Alzheimer's disease. Studying the α7 receptor has been difficult due to the limited number of selective ligands available. Currently and historically the most important and selective ligands and tools for studying α7 nAChRs are α-bungarotoxin, which is a protein harvested from Taiwanese krait snake venom, and certain α-conotoxin peptides (Johnson et al. *Mol. Pharmacol*. 1995; Pereira et al., *J Pharmacol Exp Ther*, 1995), which are based on the venom of marine predatory cone snails. These proteins do not readily enter the brain, and therefore are not usually very useful for *in vivo* studies. Moreover, they are sometimes difficult to obtain and/or available only in relatively small quantities. More recently, methyllycaconitine, a norditerpenoid isolated from delphinium seeds has proven to be another excellent high affinity probe for α7 nAChRs (Davies et al., *Neuropharmacolgy*, 1999). Here we investigated iodo-ASEM, a novel selective high affinity α7 ligand (Gao et al., *J Med Chem*,

2013; Horti et al., *J Nucl Med*, 2014) that has the potential to be an excellent ligand for studying α7 nAChRs *in vitro* and *in vivo*. In radioligand binding assays, [^{125}I]-iodo-ASEM demonstrated high binding affinity (<300 pM) and selectivity for α7 nAChRs stably expressed in HEK cells, as well as in solubilized receptors from rat hippocampus (K_d ~3 nM), which expresses a high density of α7 receptors. In radioligand binding competition assays using [^{3}H]-epibatidine to label nAChR binding sites in membranes from cells stably transfected with different nAChR subunit combinations, we further demonstrate the selectivity of iodo-ASEM for the α7 nicotinic receptor compared to other rat and human nicotinic receptor subtypes. [^{18}F]-ASEM has recently been shown to be useful for PET imaging of α7 nAChRs in baboon brain (Horti et al. 2014), indicating its potential as a PET probe for α7 nAChRs in human brain. Further investigation of this new α7-specific ligand should facilitate studies that target the α7 nicotinic receptor and its involvement in neural functions and diseases.

Title: Comparative pharmacology of human α4β2β4 nicotinic acetylcholine receptor subtypes expressed in HEK293 cells using sazetidine-A and AT-1001

Authors: *K. DEDOMINICIS, H. HWANG, M. UDDIN, S. LEE, T. T. OLSON, N. SAHIBZADA, Y. XIAO, B. B. WOLFE, K. J. KELLAR, R. P. YASUDA
Pharmacol., Dept. of Pharmacology/Georgetown Univ., Washington, DC

Abstract: Neuronal nicotinic acetylcholine receptors (nAChRs) are present in the central and peripheral nervous system where they mediate and modulate neurotransmission. nAChRs are pentameric ligand gated cation channels that assemble from combinations of different subunits: α2-α10 and β2-β4. These channels can be heteromeric, as in the α4β2 or α3β4 subtypes, or

homomeric, as in the α7 subtype. In this work, we examine the pharmacology of two different ligands, sazetidine-A and AT-1001, at heteromeric nAChRs composed of α4, β2 and β4 subunits. Radioligand binding experiments were performed on membrane homogenates prepared from HEK293 cells expressing α4β2 or α4β4 nAChRs. Both sazetidine-A and AT-1001 compete for [3H]-Epibatidine binding sites on α4β2 and α4β4 homogenates; however, they do so with different affinities. Sazetidine-A competes for α4β2 receptors with a higher affinity than for α4β4 receptors. In contrast, AT-1001 competes for α4β4 receptors with higher affinity than for α4β2 receptors. This is consistent with published data, which has demonstrated that sazetidine-A is selective for β2 containing nAChRs and AT-1001 is selective for β4 containing nAChRs. To further elucidate the binding pharmacology of α4β2 and α4β4 nAChRs with sazetidine-A and AT-1001, we constructed pentameric concatamers using alanine-glycine-serine repeat linkers. The use of concatenated constructs allows us to examine binding parameters of sazetidine-A and AT-1001 at complex nAChR stoichiometries composed of α4, β2 and β4 subunits. Competition binding with sazetidine-A against [3H]-Epibatidine at membrane homogenates from α4β2β4 concatamers fit best to a two-site non-linear regression model, consistent with the selectivity of sazetidine-A for β2 over β4 containing binding sites. The same two-site model was found for competition binding using AT-1001 at these concatamers, with AT-1001 being more selective for β4 over β2 containing binding sites. Further binding studies in conjunction with electrophysiology recordings from these concatameric pentamers expressed in HEK293 cells may provide insight into binding pharmacology for unique α4β2β4 containing nAChRs. The use of these concatameric constructs may facilitate development of ligands with specificity for these complex heteromeric receptors that may be important in some brain regions and/or in certain disease states.

Title: Mass spectrometric investigation of human α7-nicotinic acetylcholine receptor interacting proteins in SH-SY5Y cells

Authors: M. J. MULCAHY, *E. HAWROT
Mol Pharmacol, Physiol & Biotechnol, Brown Univ., PROVIDENCE, RI

Abstract: The α7-nicotinic acetylcholine receptor (α7-nAChR) is a ligand-gated ion channel widely expressed in the mammalian CNS and is associated with numerous biological functions and diseases such as Alzheimer's. The α7-nAChR is also the principal high-affinity α-bungarotoxin (bgtx) binding protein in the mammalian CNS. The high-selectivity of bgtx for α7-nAChRs is a powerful tool which has been utilized to specifically isolate the receptor for investigation. SH-SY5Y is a human clonal cell line used to model neurons which endogenously expresses α7-nAChRs. Receptor interacting proteins are associated with the regulation and function of ligand-gated ion channels. To identify α7-nAChR interacting proteins, bgtx-sensitive protein complexes were isolated from SH-SY5Y using bgtx-conjugated affinity resin. Protein was specifically eluted with nicotinic receptor agonist, reduced and alkylated prior to digestion with trypsin in-solution. Proteins isolated and treated by the same method but with affinity resin

lacking bgtx served as controls. Tryptic peptides were separated using high-performance liquid chromatography and analyzed with a Thermo Scientific™ Q Exactive™ hybrid quadrupole-orbitrap mass spectrometer. Spectra were matched to proteins using the Mascot algorithm and resulting data analyzed using ProteoIQ™. A total of 78 proteins, including the α7-nAChR subunit, were identified (1% FDR, >90% probability of correct assignment, identified in multiple replicates, 0% probability in controls). This is the first study in which the α7-nAChR was detected along with its interacting proteins in an endogenous human neuronal model using mass spectrometry. Identified human α7-nAChR interacting proteins are associated with a diverse array of functions which may contribute to the expression, localization, function, or modulation of α7-nAChRs. Identification of endogenous human α7-nAChR-protein interactions provides a foundation to investigate how these interactions may contribute to human disease.

Title: Arylguanidines as potential alpha7 negative allosteric modulators

Authors: *S. N. KHATRI[1], O. ALWASSIL[2], Z. BAZARSKY[3], M. DUKAT[2], M. SCHULTE[3]
[1]Pharmacol. and toxicology, Univ. of Sci., Philadelphia, PA; [2]Dept. of Medicinal Chem., Sch. of Pharmacy, Virginia Commonwealth Univ., Richmond, VA; [3]Dept. of Pharmaceut. Sci., Philadelphia Col. of Pharmacy, Univ. of Sci., Philadelphia, PA

Abstract: Nicotinic acetylcholine receptors (nAChRs) are pentameric, transmembrane, ligand gated ion channels and members of the Cys-loop superfamily of receptors. Varied combinations of α (α2-α10) and β (β2-β4) subunits create different subtypes of neuronal nAChRs. The homomeric alpha7 subtype is expressed in important brain regions mediating learning, memory, and cognition, making them potential drug targets for the treatment of schizophrenia, Alzheimer's and other neurological disorders. They are also implicated in immune system function, angiogenesis, and nociception. meta-Chlorophenylguanidine (MD-354), synthesized by Dr Dukat's laboratory, has been shown to be a partial agonist of the serotonin type 3A (5HT3A)

receptor (EC50 = 3.1 μM) and a negative allosteric modulator (NAM) of the α7 nAChR (IC50 = 41.51 μM). Using a tail flick assay in a mouse model, MD-354 was found to antagonize the antinociceptive effects of nicotine mediated by α7 receptors. The goal of this study was to identify the structural features of MD-354 that are responsible for its action as a negative allosteric modulator at α7 nACh receptors. A series of MD-354 analogs with varying electronic and lipophilic character was synthesized and evaluated for its ability to inhibit ACh-induced responses of Xenopus levies oocytes expressing human α7 nACh receptors in a two electrode voltage clamp assay. Halogen substitution at the meta position of MD-354 was found to increase IC50 values relative to their increasing polarizability (from 21.8 μM to 53.6 μM). A meta-methyl substituent decreased potency (IC50 = 118.4 μM) significantly compared to the halogen-substituted analogs. Methoxy and trifluromethyl substitution produced no significant change as compared to MD-354. Also, the analog with no meta substituent decreased minimal potency (IC50 = 59.8 μM). meta-Substitution seems to have a minimal, yet complex, effect on alpha7 NAM action.

Title: Monitoring pentameric ligand-gated ion channel functionality along the affinity purification process

Authors: *A. V. PANDHARE[1], N. MNATSAKANYAN[1], S. RIELA[2], M. P. BLANTON[3], M. JANSEN[1]

Abstract: *Xenopus laevis* oocytes are widely used as a heterologous expression system for the study of membrane transport proteins. Most commonly, expression is initiated by the microinjection of poly(A)-cRNA. A unique variant of the oocyte microinjection/expression system, however, utilizes the micro-transplantation of preassembled membrane proteins in vesicles that then integrate into the oocytes plasma-membrane. Our goal is to utilize the latter

system to assess the functionality of affinity-purified and lipid-reconstituted pentameric ligand-gated ion channels (pLGIC), including α4β2 and α3β4 nicotinic acetylcholine receptors (nAChRs), and the *Gloeobacter violaceus* ligand-gated ion channel (GLIC). First, we micro-transplanted HEK-293 cell membranes containing α4β2 or α3β4 nAChRs into oocytes and monitored incorporation into the oocyte plasma-membrane, receptor functionality and pharmacology using two-electrode voltage-clamp (TEVC) recordings. For α4β2 and α3β4 nAChRs, the acetylcholine (ACh) dose-response curves yielded EC_{50} values of 2.28 μM and 147.7 μM, respectively. The EC_{50} values determined for these micro-transplanted neuronal receptors are consistent with those from previously published data. Next, using protein transplantation into oocytes, we also have established an optimal set of conditions for detergent solubilization, affinity purification, and membrane reconstitution that preserves the functionality of a number of pLGICs.

Title: Differential functional contributions of α4(+)/(-)β2 agonist binding sites in α4β2-nicotinic receptor isoforms

Authors: *P. WHITEAKER[1], J. EATON[1], Y. CHANG[1], J. F. COOPER[2], J. M. LINDSTROM[2], R. J. LUKAS[1], L. M. LUCERO[1]
[1]Div. Neurobiol, St. Joseph's Hosp, PHOENIX, AZ; [2]Dept. of Neurosci., Med. Sch. of the Univ. of Pennsylvania, Philadelphia, PA

Abstract: Selected nicotinic agonists were used to activate and desensitize high-sensitivity (HS; (α4)2(β2)3) or low-sensitivity (LS; (α4)3(β2)2) isoforms of human α4β2-nicotinic acetylcholine receptors (nAChR). Function was assessed using two-electrode voltage-clamp electrophysiology in Xenopus oocytes expressing concatenated pentameric HS or LS α4β2-nAChR constructs (HSP and LSP). Unlike for previously-studied agonists, desensitization induced by the highly-selective agonists A-85380 and sazetidine-A (Saz-A) preferentially reduced α4β2-nAChR HS-phase vs. LS-phase responses. The concatenated-nAChR experiments confirmed that ≈20% of LS-isoform ACh-induced function occurs in an HS-like phase, which is abolished by Saz-A preincubation. Six mutant LSP were generated, each removing a conserved agonist-binding residue within the LS-isoform-only α4(+)/(-)α4 interface agonist binding site. Every mutation reduced the percentage of LS-phase function, demonstrating that this agonist site underpins LS-phase function. Oocyte-surface expression of the HSP and each of the LSP constructs was statistically indistinguishable, as measured using β2-subunit-specific [125I]mAb295 labeling (the presence of two vs. three β2 subunits in HSP vs. LSP nAChR was accounted for). However, maximum function was approximately 5x greater on a "per receptor" basis for unmodified-LSP vs. HSP α4β2-nAChR. Thus, recruitment of the α4(+)/(-)α4 site at higher agonist concentrations appears to augment otherwise-similar function mediated by the pair of α4(+)/(-)β2 sites shared by both isoforms. Further studies modified selected residues implicated in agonist binding at specific α4(+)/(-)α4 or α4(+)/(-)β2 subunit interfaces within HSP and LSP constructs. Significantly, the same mutations applied to one or the other of the nominally-identical α4(+)/(-)β2 agonist binding sites within an HSP construct produced different functional outcomes. Thus, the two α4(+)/(-)β2 agonist binding sites contribute asymmetrically to the function of α4β2 nAChR. These studies elucidate subunit interface bases for differences in pharmacology of α4β2-nAChR isoforms and illustrate new opportunities to selectively manipulate HS vs. LS α4β2-nAChR activity. In turn, since α4β2 nAChR are the predominant neuronal subtype, these discoveries may provide important insights for drug discovery and development.

Title: Single-channel kinetic analyses of the mouse neuronal nicotinic acetylcholine receptor channels containing α3 and β4 subunits in hek293 cells

Authors: *P. G. PUROHIT
Physiol. and Biophysics, SUNY At Buffalo, BUFFALO, NY

Abstract: Background: Neuronal nicotinic acetylcholine receptors (nAChRs), contribute in excitatory transmission, are increasingly receiving attention as therapeutic targets; however, their physiological roles remain elusive. Seventeen homologous subunits organize in unique stoichiometries to form the native pentamers. The agonist concentration-response relationship of these receptors depends on the subunit composition that determines subtype-specific receptor pharmacology. The issue is rarely addressed at single-molecule level. Therefore, here I present kinetic modeling approach on nAChRs containing putative (α-3β-4)2α-3 and (α-3β-4)2β-4 stoichiometries, at single-channel level. Methods: HEK293 cells were transiently co-transfected (15 h) with cDNAs for α-3:β-4 subunits (1:6 ratio) and GFP using calcium phosphate precipitation method. Electrophysiological data were recorded for the next 2 days (23∘C, cell-attached, PBS). Single-channel data were low-pass filtered at 20- and digitized at 50-kHz. QuB suit was used to acquire and analyze the data. Results: Single-channel recordings were generated for acetylcholine, epibatidine, anabasine, choline and TC2559 at multiple concentrations. At sub-micromolar concentrations all agonists, except choline, showed isolated openings/burst with two distinct current amplitudes (L, low and H, high). Open-channel life-times of L-type events were approximately longer compared to the H-type openings. Analyses of only acetylcholine data are presented here. A partially conducting state was observed at lower concentrations; the lifetime and frequency of which decreases at increasing concentrations, from 0.1 to 30 μM. The Closed-Open events (at >100 μM) were clustered and separated by sojourns in long C periods. Based on the intra-cluster open probability (Po) difference, the L- and H-type datasets were segregated using SKM. Single-channel current amplitudes (pA±S.D.) at 100, 300 and 500 μM acetylcholine were 3.2±0.1, 3.1±0.1 and 2.3±0.15 (L) and 5.3±0.3, 5.2±0.1 and 4.9±0.0.4 (H). The intra-clusters dwell times (for L and H) were fitted with one open and three closed exponentials; a predominant C component (95%) likely corresponds to the main gating event. The Po was reduced at increasing concentrations in both populations. Conclusions: 1. The low- and high-Po clusters may represent activity from (α-3β-4)2α-3 and (α-3β-4)2β-4 combinations, respectively. 2. Determination of gating rate and equilibrium constants is experimentally feasible as single C/O components are apparent. 3. The inverse correlation between the agonist concentrations and Po may be due to agonist-induced open channel block.

Abstract: Bupropion is clinically used as an antidepressant, as well as smoking-cessation aid. It is known to act as a non-competitive antagonist of nicotinic acetylcholine receptors (nAChRs). Previously, we used the photoreactive bupropion analogue (±)-2-(N-tert-butylamino)-3'-[^{125}I]-iodo-4'-azidopropiophenone ([^{125}I]-SADU-3-72) to identify binding sites in the *Torpedo* (muscle-type) nAChR. To extend our study we investigated bupropion's effect on proton-induced currents in *Gloeobacter violaceus* ligand-gated ion channel (GLIC), a prokaryotic homologue of pentameric ligand-gated ion channels, after expression in *Xenopus laevis* oocytes with two-electrode voltage-clamp recordings. Co-application of bupropion resulted in reduction of pH-induced currents with an IC_{50} value of 25 μM. Affinity-purified and detergent solubilized GLIC expressed in *E. coli* was photolabeled with [^{125}I]-SADU-3-72. In preliminary experiments, we have established bupropion-specific photo-incorporation in the GLIC subunits. Further studies are in progress to identify site(s) of labeling in GLIC, which can be conserved across the eukaryotic members of pLGICs.

Title: Atomistic views of positive allosteric modulators acting on the α7 nAChR

Authors: V. BONDARENKO[1], D. D. MOWREY[1], T. S. TILLMAN[1], E. SEYOUM[1], Y. XU[1], *P. TANG[2]
[1]Univ. of Pittsburgh Sch. of Med., Pittsburgh, PA; [2]Anesthesiol., Univ. of Pittsburgh, Pittsburgh, PA

Abstract: α7-nAChR plays an important role in memory, learning, and cognition. It is also a therapeutic target for neurological disorders, such as schizophrenia and Alzheimer's disease. Positive allosteric modulators (PAMs) of α7-nAChR hold therapeutic promise. 1-(5-chloro-2,4-dimethoxyphenyl)-3-(5-methylisoxazol-3-yl)urea (PNU-120596) and 3a,4,5,9b-Tetrahydro-4-(1-naphthalenyl)-3H-cyclopentan[c]quinoline-8-sulfonamide (TQS) are potent and selective PAMs for α7-nAChR. They were thought to act through binding to the transmembrane domain (TMD) of α7-nAChR, but the precise binding sites were uncertain. Here, we applied high-resolution nuclear magnetic resonance spectroscopy (NMR) and surface plasmon resonance (SPR) to determine the binding sites and affinities of PNU-120596 and TQS. Ivermectin, a ligand potentiating α7-nAChR and activating the α7-nAChR TMD channel, was also included in the studies. Three nAChR constructs, including the full-length human α7-nAChR, the TMD alone, and the TMD with the intracellular domain (TMD+ICD), were expressed in E. coli and purified using NiNTA affinity chromatography. The steady-state SPR responses of ligand binding to immobilized α7-nAChR constructs as a function of ligand concentration were measured at 25°C using a Biacore 3000 with the NTA sensor chip. Dissociation constants were derived by non-linear regression analysis using a Langmuir isotherm equation. In agreement with previous functional data, the SPR results show that, among the three tested ligands, PNU-120596 has the highest affinity to α7-nAChR, followed by TQS and ivermectin. Moreover, each ligand has a similar binding affinity to the full-length α7-nAChR, the TMD and the TMD+ICD, confirming that the ligand binding sites are within the TMD. NMR experiments were performed on the α7-nAChR TMD, which forms functional channels that can be activated by ivermectin and potentiated by PNU-120596 and TQS. NOESY and 2D saturation transfer NMR spectra, as well as ligand-induced chemical shifts, revealed intra-subunit binding sites for TQS and PNU-120596

that are located towards the extra- and intra-cellular ends of the TMD, respectively. Although the observed site for PNU-120596 was similar to that suggested previously by mutagenesis data, the TQS site is novel. Ivermectin was also found in a novel site formed between TM3 and TM4 of a single subunit and the surrounding lipids. The atomistic views of PNU-120596, TQS, and ivermectin acting on α7-nAChR are invaluable for the development of new PAMs of therapeutic potentials. This work was supported by NIH (R01GM56257 and R01GM66358 to P.T. and R37GM049202 to Y.X.).

Title: Effects of α-conotoxins from the venom of Conus purpurascens on the *Drosophila* α7 nicotinic acetylcholine receptor

Authors: *A. M. RODRIGUEZ, M. HEGHINIAN, T. A. GODENSCHWEGE, F. MARÍ
Florida Atlantic Univ., Boca Raton, FL

Abstract: The venom of *Conus purpurascens* contains several novel α-conotoxins, which are a conserved family of conopeptides that inhibit nicotinic acetylcholine receptors (nAChRs). The decreased functionality of nAChRs is associated with several diseases, including Alzheimer's disease, Parkinson's disease, and nicotine addiction. α7 nAChRs are expressed in the giant fiber system (GFS) of *Drosophila melanogaster*, which is a well-characterized neuromuscular circuit that is responsible for the escape response of the fly. We have developed a *Drosophila* based electrophysiological assay that allows us to characterize α-conotoxins. In this study, conopeptides from *C. purpurascens* were extracted from live specimens using a milking procedure and separated by reverse-phase high performance liquid chromatography (RP-HPLC). A panel of known α-conotoxins, PIA, PIB, and PIC, as well as novel conopeptides, were identified using bioanalytical techniques (Edman degradation, MS, and NMR). Paired nanoinjection of purified conotoxins into *D. melanogaster* with simultaneous

electrophysiological recording of the two muscles used in the escape response was used to screen the compounds. Our findings show that some novel conotoxins from the venom of *C. purpurascens* alter the synaptic transmission of the α7 nAChR-dependent D. *melanogaster* GFS pathway. The continued effort to characterize α-conotoxins is of great importance, as they can be used as probes to study disease pathways and neurodegeneration.

Title: The modular character of nicotinic agonists: Minimal pharmacophores and transposable motifs for selectivity and silent agonism

Authors: *N. HORENSTEIN[1], K. CHOJNACKA[1], R. PAPKE[2]
[1]Chem., [2]Pharmacol. and Therapeut., Univ. Florida, Gainesville, FL

Abstract: Tetramethylammonium (tetMA) is the minimal structure that will effectively activate the ion channel of neuronal nicotinic acetylcholine receptors (nAChR). Dimethyldiethylammonium (diMdiEA) is the minimal structure which will selectively activate homomeric alpha7 nAChR. The minimal structure which will produce activation of alpha7 nAChR that is manifest only when the conformational landscape of the receptor has been altered by the binding of a type II positive allosteric modulator (silent agonism) is tetraethylammonium (tetEA). We have tested a series of simple amines and five additional sets of compounds with progressively larger core structures and determined that, for the essential cationic center, single methyl groups are transposable elements that can impart quantal changes in pharmacology. We identify a critical size for the core ammonium group to be approximately 150 Å3, such that analogs with solvent-excluded volume larger than this have profoundly reduced efficacy under normal conditions but may still function as silent agonists. We have previously shown that the selectivity motif of diMdiEA is one of three such motifs which can be placed in a naturally non-selective agonist in order to generate an analog that selectively activates alpha7 nAChR. We now

report that the properties of the core cationic center in a nonselective agonist within much larger global structure, such as 1,1-dimethyl-4-phenylpiperazine (diMPP) , can be modified in the same manner as the simpler amines to establish alpha7 selectivity by extending the N-methyl group to an ethyl group. Replacing the remaining N-methyl group with an ethyl group creates a tetEA substructure within the original diMPP framework that then becomes an alpha7-selective silent agonist. We have extended this approach to three other pairs of diMPP analogs, and our data support the characterization of a transposable core cationic center which is the key regulator of the detailed pharmacological property of nicotinic agonists with extended structures. These data suggest that while the ligand binding domain is tolerant of large molecules, presumably accommodated in the subunit interface, within the subdomain of the core cation recognition center there are stringent requirements for molecules to activate the ion channel and/or induce the conformational changes associated with the desensitized states that can be converted to conducting states by a type II positive allosteric modulator.

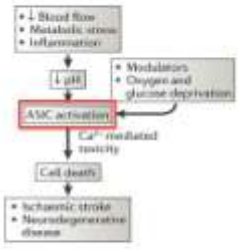
Title: Acid-sensing ion channel proton sensitivity is modulated by a guanidine containing dietary supplement

Authors: *A. AGHARKAR[1], R. N. SMITH[1], E. B. GONZALES[1,2,3]
[1]Pharmacol. & Neurosci., UNT Hlth. Sci. Ctr., Fort Worth, TX; [2]Inst. for Aging and Alzheimer's Dis. Res., Fort Worth, TX; [3]Cardiovasc. Res. Inst., Fort Worth, TX

Abstract: Dietary supplements have been the focus of research to identify novel therapeutics for a variety of pathologies, including the prevention of long-term consequences of stroke and reducing pain. Ion channels offer a growing group of molecular targets for treatment, which includes the acid-sensing ion channels (ASICs). The ASICs are sodium selective channels that

are sensitive to changes in extracellular pH, specifically those changes following injury and ischemia. These channels are expressed most prominently in central and peripheral nervous system. The ASIC1a has been implicated centrally in the neurodegeneration following ischemic stroke while ASIC3 is involved in pain sensation. The extracellular domain of ASIC offers several sites for interacting with protons and guanidine compounds. We identified an over the counter dietary supplement (DS) which can modulate the activity of ASICs by altering the channel's proton sensitivity using whole-cell patch-clamp electrophysiology. The dietary supplement increased the ASIC1a pH50 values at physiologically relevant supplement concentrations consistent with suggested dietary supplementation. Our preliminary data show that ASIC3 peak current amplitude is reduced in the presence of the dietary supplement. Future studies will focus on the full characterization of the dietary supplement actions on ASICs. Our findings suggest that dietary supplement may be



neuroprotective.

Title: Acid-sensing ion channel modulation by nonproton ligands: the influence of divalent cations

Authors: *R. N. SMITH, E. B. GONZALES
Pharmacol. & Neurosci., UNT Hlth. Sci. Ctr., Fort Worth, TX

Abstract: Acid-sensing ion channels (ASICs) are sodium-selective ion channels activated by extracellular protons. These sodium channels are important components of physiological processes, like action potential propagation, as well as pathophysiological conditions, such as pain and ischemic stroke. Multiple subtypes exist that are widely distributed throughout human physiology and these subtypes respond differently to concentrations of protons in the extracellular space. Crystal structures of ASIC1 revealed that these channels are trimeric and possess a large extracellular domain likely organized for interaction with ligands more complex than protons. In particular, nonproton ligands like 2-guanidine-4-methylquinazoline (GMQ) and divalent cations (Ca2+) can interact with these acid-sensing ion channels to modulate channel activity. Previous electrophysiological studies indicate that reducing extracellular calcium concentrations can activate ASIC3. Calcium appears to lock the channel in a closed state and this calcium block must be removed before the channel can activate with protons or other ligands, like GMQ. The concentration-dependent activation of ASIC3 via GMQ application likewise is dependent on the removal of the calcium block before interacting with the nonproton ligand sensor domain. Here, we probed the role of the calcium block site in GMQ activation of ASIC3. Using full-length ASIC1, ASIC3 and ASIC1/ASIC3 chimeric receptors, we observed that there is a sequential step in the removal of calcium before GMQ activation. To fully resolve these steps, we will substitute other divalent cations for calcium (such as Cd2+, Co2+, Ba2+) and assess the changes in GMQ ASIC activation using patch clamp electrophysiology. We anticipate that higher affinity divalent cations (such as Cd2+) for the ASIC calcium block site will slow GMQ activation. Thus, our work will elucidate the role of divalents and GMQ on ASIC3.

Title: Tobramycin inhibits acid sensing ion channel (ASIC) homomers 1a, 1b and 2a expressed in CHO cells

Authors: *A. M. ORTEGA[1], K. PÉREZ-TIERRA[1], M. A. GANDINI[2], R. FELIX[2], R. VEGA[1], E. SOTO[1]
[1]Insituto De Fisiología, Benémerita Univ. Autónoma De Puebla, Puebla, Mexico; [2]Dept. of Cell Biology, Ctr. for Res. and Advanced Studies of the Natl. Polytechnic Inst. (Cinvestav-IPN), México City, Mexico

Abstract: Acid-sensing ion channels (ASICs) are ligand-gated cation channels that respond to acidic stimuli, over the years they have taken great relevance because they are involved in a number of neurological diseases such as pain, ischemic stroke, multiple sclerosis. The ASICs are homotrimers or heterotrimers of four ASIC subunits (1...4), each channel conformation displaying distinct properties. The extracellular portion of the pore of the ASIC has negatively charged regions and it is believed that this region facilitates an accumulation of cations near the pore. Tobramycin (Tbr) is a polycationic molecule, fact that makes feasible its binding to the ASIC, modulating the ionic current. In this work we recorded the acid gated current in CHO cells transfected with ASIC1a, 1b and 2a subunits. We found that the Tbr are capable to inhibit the ASIC current depending on the type of ASIC subunit and the state of the channel (open or closed). Tobramycin (100 μm) inhibits the ASIC1b current when it interacts with the channel in closed state (pre-application) (32 ± 5%), and have no significant effect when interaction with the channel is in open state (co-application); in contrast Tbr has an effect on ASIC2a current when co-applied (50 ± 8%). In the case of ASIC1a we noted an inhibition of the peak current in both conditions, pre- and co-application (33 ± 2% and 14 ± 7% respectively). These results suggest that the Tbr is a relevant tool for the study of the ASIC and that analogues of this molecule may constitute be new and valuable drug family.

Abstract: Acid-sensing ion channels (ASICs) are abundantly expressed membrane-bound cation channels that activate upon acidosis of the extracellular fluid. Evidence indicates that ASIC1a, a critical subunit of the ASIC1 channel, is expressed at relatively high levels in the nucleus accumbens (NA), a region known to regulate drug addiction-related behaviors. The present study investigated whether ASIC1a, especially in the NA, regulates two addiction-related behaviors: cocaine conditioned place preference (CPP) and cocaine self-administration. In order to examine the contribution of ASIC1a to cocaine-associated learning and memory, ASIC expression was disrupted globally using Asic1a-/- mice. Mice then underwent CPP, in which they were administered cocaine (10 mg/kg, diluted in 0.9% saline, i.p.) and confined to one side of a two-sided chamber (the cocaine-associated context). During testing, Asic1a-/- mice showed significantly greater cocaine CPP relative to controls. To determine whether the NA was responsible for these effects, ASIC1a expression was restored in the NA of Asic1a-/- mice by injecting 0.5 µl of 70% AAV-Asic1a and 30% AAV-eGFP bilaterally into the NA. Restoring ASIC1a in the NA of Asic1a-/- mice reversed the increased CPP found in the knockout mice. To further confirm the NA as the responsible brain region, site-specific disruption of ASIC1a was achieved by using Asic1aloxP/loxP mice and bilaterally injecting AAV-Cre into the NA. Selective disruption of ASIC1a in the NA also significantly increased preference on the CPP test compared to control mice. These findings suggested that ASIC1a in the NA plays a role in regulating the rewarding/reinforcing properties of cocaine. To determine whether this was the case using a self-administration model, ASIC1a was overexpressed in rats by injecting 0.5 µl of AAV2/1-CMV-Asic1a(mouse) bilaterally into the NA core. Rats were trained to self-administer cocaine in daily two-hour sessions during which active lever presses resulted in an intrajugular cocaine infusion. Rats underwent one day of self-administration with each of five cocaine doses (300, 90, 30, 9, 3 µg/infusion) to create a dose-response curve. Overexpression of ASIC1a in the NA of rats reduced cocaine self-administration relative to AAV2/1-CMV-eGFP controls and produced a rightward shift in the dose-response curve, suggesting that increasing ASIC1a expression and activity in the NA reduced the reinforcing properties of cocaine. Together, these results suggest that ASIC1a in the NA is involved in the rewarding properties of cocaine and, moreover, point to a novel potential therapeutic target for drug addiction.

Abstract: Motivated behaviors, such as food-gathering, mate-seeking, predator-evasion, and harm-avoidance, are necessary for the propagation and survival of most species, particularly animal species. However, when environmental factors or stimuli subvert the neural mechanisms underlying these adaptive behaviors, maladaptive behaviors and disease states can arise, such as addiction in response to drugs of abuse. For example, in mammals, it is well-documented that most psychoactive drugs of abuse impinge upon the mesolimbic dopamine pathway that plays a vital role in countless motivated behaviors. The intricacy of the mammalian nervous system and the rich behavioral variety of which mammals are capable add layers of complexity to the study of addiction biology. As the hermaphroditic nematode, Caenorhabditis elegans, is capable of self-fertilization, their motivated behaviors are limited largely to foraging and avoidance behaviors. For example, *C. elegans* will move up the gradient of chemicals associated with or predictive of a food source. Meanwhile, these worms will crawl down a gradient of noxious chemicals and will avoid areas of high osmolarity or irradiated with high intensity light. Moreover, myriad studies have demonstrated that *C. elegans* is sensitive to a number of plant alkaloids frequently abused by humans and other mammals, including nicotine and cocaine, among others. In addition to the constrained behaviors *C. elegans* exhibits, the hermaphrodite nervous system consists of only 302 neurons, with a reliably complete and long-established connectome. Furthermore, the genetic amenability and short generation time of these nematodes makes them an attractive model for investigating the manner in which drugs of abuse usurp adaptive neural mechanisms to elicit maladaptive behavioral outcomes. Accordingly, we have developed a behavioral paradigm that allows us to screen mutant worms rapidly for both canonical and novel targets for drugs of abuse, such as acid-sensing ion channels, transient receptor potential channels, and epithelial sodium channels.

Title: The acid-sensing ion channel (ASIC)

Authors: *D. C. BERTRAND[1], S. BERTRAND[1], Y. GAUTSCHI[2], L. SCHILD[2]
[1]Hiqscreen, Vesenaz - GE, Switzerland; [2]Dept. of Pharmacol., Univ., Lausanne, Switzerland

Abstract: Acid-sensing (proton-gated) ion channels belong to the ENaC/degen (Lv et al., 2011)erin superfamily of sodium (Na+) channels that includes the epithelial Na+ channel (ENac). ASIC channels are multimeric channels made of homologous subunits; the subunits ASIC1-4 are encoded by four different genes ACCN1-4 genes.. Evidence support the role of ASICs in pain sensation, expression of fear, neurodegenerarion after ischemia (see for review Wemmie 2013) Spontaneous mutations in ASIC1a have been associated to genetically transmissible diseases such as temporal lobe epilepsies . Activated by low pH, ASIC's display a fast response onset and rapid desensitization. Sharing similarities to other ligand gated such as the neuronal nicotinic acetylcholine receptors, ASIC1 are inactivated (desensitized) by sustained exposure to a condition that otherwise produces activation. Namely, desensitization occurs at pH that are higher (more alkaline) than those causing its activation, which results in activation and desensitization profiles that do not necessarily overlap or yield the so call window currents. Probing ASIC channels function was conducted using heterologous expression in Xenopus oocytes as well as in patch clamp in transfected cells (Vallet et al., 1998;Waldmann et al., 1997;Li et al., 2012). Development of HiClamp, an automated electrophysiological system using expression in Xenopus oocytes offers fast drug application and minimal compound volume allowing multiple measurements in 230 µL of solution and was shown to be optimum for functional investigation of ligand gated channels. In this work we present the latest developments of automated recordings for ASIC1a channels expressed in Xenopus oocytes and revisit physiological and pharmacological properties of this important class of ion channels. Offering new possibilities for functional screening of these rapidly desensitizing channels this work illustrates how to probe effects of libraries of compound in an unattended manner. Title: Synaptic availability of GluN2A subunit of NMDA receptors: The role of Rabphilin 3A

Authors: *F. GARDONI[1], J. STANIC[1], M. CARTA[2], A. A. GENAZZANI[3], C. MULLE[2], M. DI LUCA[1]

Abstract: NMDA receptor subunit composition commands receptor function and pharmacological responses. The identity of the GluN2 subunit regulates biophysical and pharmacological properties of the receptor and influences receptor assembly, signaling and localization. Recently, a two-hybrid screening has highlighted Rabphilin 3A (Rph3A) as a new GluN2A partner. Rph3A is a synaptic vesicle-associated protein first identified as a binding partner of Rab3A. Moreover, different studies have indicated that Rph3A can regulate exo- and endocytosis processes at presynaptic sites. Our goal was to characterize Rph3A interaction with GluN2A at postsynaptic sites and to assess its function. Subcellular fractionation assays revealed that Rph3A is present in postsynaptic density (PSD) fractions. Immunofluorescence studies performed in neuronal hippocampal cultures revealed Rph3A colocalization with PSD-95 and GluN2A. With co-immunoprecipitation and GST-pulldown assays, we found Rph3A to be interacting with GluN2A(1349-1389) as well as PSD-95(PDZ3) domains. Therefore, we

designed a cell permeable peptide containing GluN2A(1349-1389) sequence (Tat-2A-40) that disrupts the interaction between Rph3A and GluN2A, reduces the expression of GluN2A in dendritic spines and its surface expression and acutely reduces the amplitude of NMDAR-mediated currents. Moreover, we observed a decrease of hippocampal GluN2B-to-GluN2A developmental perturbation at postsynaptic sites in pups injected with Tat-2A-40 at that crucial development stages. These results demonstrate the presence of Rph3A in the PSD compartment and indicate a function of Rph3A in the modulation of GluN2A localization through the formation of a triple complex with GluN2A and PSD-95.

Title: Structural and functional study of N-Methyl-D-Aspartate Receptor-specific antagonistic peptides from Conus species of marine snails: ConPr1, 2, 3, and ConRlB

Authors: ***S. KUNDA**[1,2], T. SNOW[1,2], J. CHERIYAN[2], M. HUR[2], R. BALSARA[1,2], F. J. CASTELLINO[1,2]

Abstract: Conantokins are naturally occurring, gamma-carboxyglutamate (gla)-containing neuroactive peptides found in the venom of marine snails, which have been studied for their highly selective antagonistic activity towards N-Methyl-D-Aspartate Receptors (NMDAR). Here we report the characterization of peptides from *Conus parius* and *Conus rolani* species of snail identified as Conus parius1, 2, and 3 (ConPr1, 2, 3) and conantokinRlB (ConRlB), which uniquely differs from other conantokins by the presence of a 4-transhydroxyproline (Hyp 'O') residue. These conantokins have been studied for their structural α-helical conformation in the presence or absence of divalent ions, as well as their biological effects downstream of NMDAR activation. ConPr1 and ConPr2 showed an increase in α-helicity on addition of Mg^{2+} ions,

whereas native-apo-ConPr3 is inherently helical. ConRlB displays 62% α-helicity when compared to ConG (100%), in presence of Mg^{2+}. Further elucidation of backbone structure of Mg^{2+}-ConRlB by ^{1}H NMR and TALOSplus software has predicted a disruption in the helix due to the presence of Hyp at position 10. Robust inhibition of intracellular calcium influx [iCa^{2+}] and whole cell recordings was observed in GluN2A$^{-/-}$ mice cortical neurons, but not in GluN2B$^{-/-}$ neurons, revealed GluN2B subunit specific activity of Con Pr peptides and ConRlB. Synthesis of mutant peptides to assess the role of Hyp in 10^{th} position in ConRlB was aimed at elaborating the molecular requisites required by these peptides for their unique structural and functional attributes. ConG[Insert 10 'O'] and ConRl-B[K8N,A9Q,ΔO] behave functionally and structurally similar to their respective parent peptides, ConG and ConRlB, calling to attention the role played by amino acids other than the second inter-gla fragment. In addition, ConPr1, 2, 3 and ConRl-B peptides mildly inhibited NMDA-mediated phosphorylation of CREB at Ser133, a transcription factor required for maintaining long term synaptic activity. Therefore, inhibitory properties displayed by the conantokins antagonize NMDAR-directed current and iCa^{2+} influx, while maintaining the receptor-coupled CREB signaling pathway. Similar experiments were performed with GluN2C$^{-/-}$ and GluN2D$^{-/-}$ neurons. A significant inhibition of iCa^{2+} influx was observed by ConG and ConRlB in DIV9 GluN2D$^{-/-}$ neurons, but not in DIV13-15 GluN2D$^{-/-}$ neurons. In conclusion, biophysical and cellular characterization in conjunction with genetic studies enables correlations of the structure-function relationships of conantokins as allosteric inhibitors of NMDAR.

Title: Rapid antidepressant stimulates decoupling of GABAB receptors from GIRK/KIR channels through 14-3-3η

Authors: *E. WORKMAN[1], P. C. G. HADDICK[2], G. DILLY[1], B. ZEMELMAN[1], K. RAAB-GRAHAM[1]
[1]Inst. for Neurosci., The Univ. of Texas At Austin, Austin, TX; [2]Div. of Res., Genentech, South San Francisco, CA

Abstract: A single injection of NMDAR antagonists produces a rapid antidepressant response. Lasting changes in synapse structure and composition underlie the effectiveness of these drugs. However, little is known about the molecular and biochemical mechanisms which initiate these systemic changes. We recently discovered that rapid antidepressants cause a shift in the $GABA_BR$ signaling pathway. With NMDAR antagonists, $GABA_BR$ activation shifts from opening potassium channels to increasing resting dendritic calcium signal and mTOR activity. Herein, we find that $GABA_BR$ signaling to Kir3 (GIRK) channels is reduced with NMDAR blockade. Consistent with these findings, *in vivo* administration of the rapid antidepressant AP5, decreases hippocampal expression levels of Kir3.2 while increasing $GABA_BR2$. Relieving NMDA-dependent repression of 14-3-3η protein expression promotes the decoupling of $GABA_BR$ signaling from Kir3 and is required for the rapid antidepressant efficacy. Taken together, these data suggest that the shift in $GABA_BR$ function requires a loss of $GABA_BR$-Kir3 channel activity mediated by 14-3-3η. Our findings support a central role for 14-3-3η in the efficacy of rapid antidepressants and define a critical molecular mechanism for activity-dependent alterations in $GABA_BR$ signaling.

Title: Investigating the role of NMDA receptor expression in the developmental integration of hippocampal neurogliaform cells

Authors: *E. S. BARKSDALE, R. CHITTAJALLU, X. YUAN, D. COLLINS, K. PELKEY, C. MCBAIN
NICHD/NIH, Bethesda, MD

Abstract: Appropriate development of interneurons is essential in ensuring normal CNS function. Indeed, the precipitation of a number of neurological disorders can be linked to interneuron dysfunction. Together, the neurogliaform cell (NGFC) and the closely related Ivy cell comprise the most abundant group of interneurons in the CA1 hippocampal region, and their recruitment results in widespread GABA volume transmission. Thus NGFCs/Ivy cells have the potential to impart an inhibitory influence on large numbers of neurons within the hippocampal circuitry. However, in contrast to other interneuron subtypes, relatively little is known about NGFC function and in particular the developmental aspects of their circuit integration. NMDA receptors (NMDARs) have been implicated in a wide variety of cellular phenomena from proliferation/migration through to synaptic refinement/plasticity and recruitment. NGFCs located in the stratum lacunosum moleculare (S-LM) receive excitatory input from the entorhinal cortex via the temporoammonic pathway (TA) and serve as pure feed-forward interneurons, inhibiting distal dendrites of CA1 pyramidal cells. In the current study we show that upon TA stimulation, S-LM NGFCs possess unusually large NMDAR-mediated responses when compared to other CA1 interneuron subtypes. This prompted us to focus on the possible roles of NMDAR expression on varying aspects of NGFC development. The majority of S-LM NGFCs arise from progenitors in the caudal ganglionic eminence (CGE) that specifically express the $5HT_{3A}$ serotonergic receptor. Crossing floxed NR1 knockout mice with mice in which the $5HT_{3A}$ promoter drives expression of both Cre and tdTomato (Ai14 reporter) allowed us to generate deletion of NMDARs in NGFCs. Initial data indicate a decreased density of S-LM NGFCs in $5HT_{3A}Cre:NR1^{-/-}$ when compared to wild-type mice across a number of developmental time points. Furthermore, NGFCs in which functional NMDAR-mediated currents were abolished using our genetic strategy demonstrated a significantly larger AMPA sEPSC frequency but no change in peak amplitude. Importantly, the paired pulse ratio of TA-evoked AMPA EPSCs was unchanged in $5HT_{3A}Cre:NR1^{-/-}$ compared to WT indicating similar release probabilities at TA inputs to WT and NR1 knockout NGFCs. Altogether these data suggest NMDARs play a crucial role in varying aspects of NGFC development including regulating functional synapse formation. We are currently expanding on these data to confirm our initial findings and also to fully investigate the underlying mechanisms involved.

Institute, Technion-Israel Inst. of Technol., Haifa, Israel; [4]Ctr. de Psychiatrie et Neurosciences, Univ. Paris Descartes, Paris, France

Abstract: The N-methyl-D-aspartate receptors (NMDARs) are glutamate-gated ionotropic receptors which play a crucial role in synaptic plasticity and cognitive functions. When their function is altered these receptors are also involved in a broad range of neurologic and psychiatric disorders. NMDA receptors activation requires the binding of glutamate and of a coagonist that could be glycine or D-serine. Here we investigated the respective contribution of glycine and D-serine in controlling NMDARs activity in CA1 and dentate gyrus (DG) subregions of the rat hippocampus, a brain area underlying synaptic plasticity and memory formations. To that purpose we recorded NMDAR-mediated field excitatory post-synaptic potentials (fEPSPs) elicited at CA3-CA1 synapses and in DG *stratum moleculare* in response to the stimulation of Schaffer collaterals and to medial Perforant Path fibers respectively in acute hippocampal slices. Selective depletion of endogenous D-serine with applied recombinant D-amino acid oxidase (DAAO) dramatically reduced NMDAR-fEPSPs in the CA1 but not in the DG. Conversely, application of glycine oxidase (GO) to selectively deplete endogenous glycine had no significant effect in CA1 while it significantly impacted NMDA-fEPSPs in the DG. We next showed that pharmacological inhibition of the DAAO potentiated responses in the CA1 but not in the DG, further demonstrating that glycine is the major coagonist for NMDARs in the DG whereas D-serine is the preferred one at CA3-CA1 synapses. This regional compartmentalisation of the coagonist identity is associated to a specific subtype of GluN1/GluN2A or 2B-containing

NMDARs as evidenced by the use of specific antagonists and immunoblot analyses. Strikingly, both amino acids are mandatory for long-term changes in synaptic plasticity. Indeed, enzymatic ablation of their functions occluded the induction and expression of Long Term Potentiation in both DG and CA1. We finally performed experiments in juvenile rats (P9-P14) at the time where GluN1/GluN2B-containing NMDARs over numbered GluN1/GluN2A NMDARs at CA3-CA1 synapses as compared to mature synapses. Here we revealed a developmental switch in the identity of the coagonist since glycine and not D-serine is the preferred coagonist in immature CA3-CA1 synapses. Accordingly, pharmacological inhibition of DAAO at immature CA3-CA1 synapses failed in potentiating NMDA-fEPSPs as compared to mature synapses. Altogether, our observations revealed an unprecedented developmentally and regionally switch in the identity of the coagonist at synaptic NMDARs.

Title: Using fMRI in awake rats to differentiate NMDA receptor antagonists

Authors: *K. MOORE[1], P. KULKARNI[1], M. NEDELMAN[2], C. F. FERRIS[1]
[1]Ctr. for translational neuroimaging, Northeastern Univ., Boston, MA; [2]Ekam Imaging, Boston, MA

Abstract: BOLD imaging at 7.0 Tesla was performed on awake rats to examine the dose-dependent changes in brain activity with the NMDA antagonists ketamine and CP101-606. Human and animal studies using 2DG, cFos, PET and MRI have identified several key areas that comprise the ketamine sensitive neural network . With dose escalation the activity of this network shows increasing positive BOLD for both ketamine and CP101-606 in limbic cortex and brain areas associated with emotion and cognition. The pattern of positive BOLD signal change is very similar for both antagonists across a broad range of doses (0.1 - 10mg/kg)(Fig 1). However, at low doses of both drugs (0.1mg/kg) the pattern of negative BOLD signal change is

significantly different. Treatment with CP101-606 results in a robust negative BOLD signal change localized primarily to pontine, cerebellar and brainstem areas. CP101-606 (Traxoprodil) is selective for the NR2B subunit of the NMDA receptor and shown to have neuroprotective effects in Parkinson's models with some evidence of having rapid antidepressant effects similar to ketamine. Given the similarity in positive BOLD between both antagonists it is likely that activation of a common neural circuitry is responsible for antidepression effects while the unique inhibition in brain activity by CP101-606 in the pons, cerebellum and medulla oblongata may provide protection in animals models of neurodegeneration.

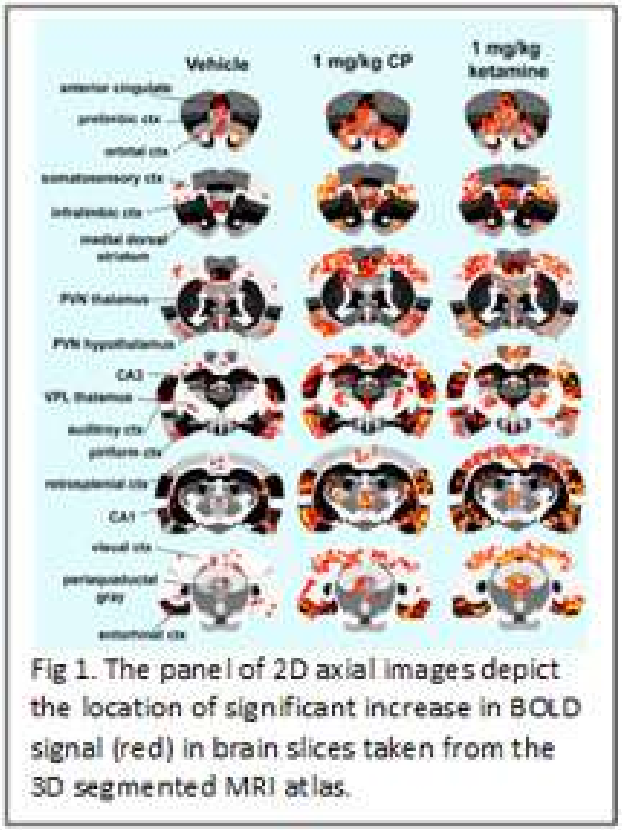

Fig 1. The panel of 2D axial images depict the location of significant increase in BOLD signal (red) in brain slices taken from the 3D segmented MRI atlas.

Title: A GRIN2A de novo mutation associated with epilepsy and intellectual disability reduces NMDA receptor currents and Mg^{2+} block in cultured primary cortical neurons

Authors: *K. MARWICK, P. A. SKEHEL, G. E. HARDINGHAM, D. J. A. WYLLIE
Univ. of Edinburgh, Edinburgh, United Kingdom

Abstract: *GRIN2A* encodes the GluN2A subunit of the NMDA receptor, a subtype of ionotropic glutamate receptor that displays voltage-dependent block by Mg^{2+} and a high permeability to Ca^{2+}; these receptors play important roles in synaptogenesis and synaptic plasticity. Recently individuals with a range of childhood onset epilepsies and intellectual disability have been found to carry heterozygous missense mutations in this gene, including a *de novo* mutation substituting lysine for an asparagine in the NMDA receptor M2 pore region ($GluN2A^{N615K}$). We hypothesised that this mutation underlies the carrier's early onset epilepsy and severe intellectual disability and sought to explore its functional consequences. As the altered residue comprises part of the ion permeation pathway, we made two-electrode voltage clamp recordings from *Xenopus laevis* oocytes expressing GluN1/$GluN2A^{N615K}$ NMDARs and compared these to wild-type (WT) GluN1/GluN2A NMDARs to assess this mutation's effect on the potency of voltage-dependent Mg^{2+} inhibition. As might be anticipated given the location and nature of the mutation we found that Mg^{2+} (1 mM) block of GluN1/$GluN2A^{N615K}$ mediated currents, at -60 mV, was significantly decreased (5 ± 2% (N615K, n = 13); 89 ± 1% (WT, n = 15)). Furthermore, block by memantine (10 μM) and amantadine (100 μM) was also reduced at GluN1/$GluN2A^{N615K}$ NMDARs compared to WT NMDARs (memantine: 26 ± 1% (N615K, n = 17); 75 ± 2% (WT, n = 17), amantadine: 18 ± 1% (N615K, n = 17); 44 ± 3% (WT, n = 17)). Intriguingly, block by ketamine was unaffected by the mutation, whereas we observed a significant increase in the block produced by dextromethorphan (56 ± 3% (N615K, n = 9); 44 ± 2% (WT, n = 8)). We next used whole-cell patch-clamp recordings to evaluate NMDAR-mediated currents in mouse primary cortical pyramidal neurons that were transfected with either $GluN2A^{WT}$ or $GluN2A^{N651K}$ subunits. We observed a significant decrease in Mg^{2+} (1mM) sensitivity (50 ± 5% (N615K, n = 10); 93 ± 2% (WT, n = 9)) and a significant decrease in current density (36 ± 6% (N615K, n = 10); 61 ± 2% (WT, n = 9)). In summary, the disease associated mutation $GluN2A^{N615K}$ has substantial effects on NMDA receptor inhibition by both endogenous and exogenous channel blockers. **Acknowledgements**: This work was funded by The Wellcome Trust via an Edinburgh Clinical Academic Training PhD Fellowship.

Title: Voltage dependence of NMDA receptor inhibition by memantine and by ketamine depend on duration of glutamate application and on receptor subtype

Authors: ***N. G. GLASGOW**[1], J. W. JOHNSON[2]
[1]Dept. of Neurosci., [2]Neurosci., Univ. of Pittsburgh, Pittsburgh, PA

Abstract: NMDA receptors (NMDARs) are a class of ionotropic glutamate receptor that are essential for neuronal development, synaptic plasticity, learning, memory formation, and cell survival. NMDARs are typically composed of GluN1 and GluN2 subunits. There are 8 GluN1 splice variants arising from a single gene and 4 GluN2 subunits (GluN2A-GluN2D) expressed from 4 separate genes. NMDAR subtypes are defined by the identities of the subunits present in the receptor (e.g. the GluN1/2A NMDAR subtype contains two GluN1 and two GluN2A subunits). NMDARs play critical roles in normal neuronal physiology, and NMDAR dysregulation is implicated in many neurological disorders including Alzheimer's disease, schizophrenia, depression, and neuropathic pain. Inhibition of NMDARs with open channel blockers, such as memantine, which is approved for treatment of Alzheimer's disease, has broad potential for treatment of neurological disorders. Another NMDAR open channel blocker, ketamine, has shown promise as a rapidly-acting antidepressant and as a treatment for neuropathic pain. Although memantine and ketamine share similar voltage dependence, kinetics and IC50s at NMDARs, their clinical effects vary significantly, suggesting that their mechanisms of NMDAR inhibition may differ in ways that are not yet well understood. There has been recent debate over the efficacy of inhibition by memantine and ketamine when NMDARs are activated by synaptic glutamate release as opposed to when NMDARs are activated under steady-state conditions (e.g., Xia et al., 2010; Emnett et al., 2013). Further, whether memantine and ketamine

exhibit similar voltage dependence during synaptic activation and during steady-state activation is unknown. Therefore, we compared inhibition of heterologously expressed GluN1/2A and GluN1/2B receptors activated by synaptic-like glutamate applications (2-4 ms) and by long (>10 s) glutamate applications at 3 membrane voltages (Vms): -65, -45, and -25 mV. We focused on NMDARs containing GluN2A and GluN2B subunits because they are the GluN2 subunits most commonly expressed at synapses. We have previously shown at a holding Vm of -65 mV that memantine and ketamine display NMDAR subtype-dependent inhibition during synaptic-like glutamate activations. At holding Vms of -45 and -25 mV we found for both memantine and for ketamine that inhibition did not depend on NMDAR subtype, or on whether responses were activated by synaptic-like or by long glutamate applications. Thus, voltage dependence of NMDAR inhibition by memantine and by ketamine depends both on duration of glutamate application and on NMDAR subtype.

Title: Transmembrane conformational signaling at NMDA receptors independent of ion flow during synaptic plasticity

Authors: *K. B. DORE, J. AOW, R. MALINOW
Neurosciences, UCSD, La Jolla, CA

Abstract: Traditionally, ion-channels achieve signaling through transmembrane passage of ions. Whether ion-channels can transmit transmembrane conformational information in the absence of ion passage is not well established. Here we use Förster resonance energy transfer (FRET) imaging of fluorescently tagged proteins expressed in neurons to monitor conformational changes within the NMDA receptor (R) complex. We show that extracellular ligand binding to the NMDAR drives a rapid ion-flow independent conformational change in its cytoplasmic domain (cd). In conditions that produce LTD, a form of synaptic plasticity, ligand binding to the NMDAR is sufficient to drive a transient FRET reduction between NMDARcd and phosphatase

1 (PP1) as well as a long-lasting FRET reduction between NMDARcd and calcium/calmodulin-dependent protein kinase II (CaMKII) that depends on PP1 activity. These results demonstrate a novel signaling mechanism for ion channels and suggest that ligand binding to the NMDAR drives NMDARcd-complexed PP1 to dephosphorylate and redirect NMDARcd-bound CaMKII during LTD.

Title: Classification of neuronal cell types in the mouse brainstem through cell specific constellations

Authors: *S. RAGHURAMAN[1], A. GARCIA[2], K. J. CURTICE[1], R. TEICHERT[1], J.-M. RAMIREZ[2], B. OLIVERA[1]
[1]Dept. of Biol., Univ. of Utah, Salt Lake City, UT; [2]Ctr. for Integrative Brain Res., Seattle Children's Res. Inst., Seattle, WA

Abstract: The mammalian brain consists of an extraordinary number of cell types. A deeper understanding of circuits, networks and behavior requires that we identify and study specific neuronal cell types. Comprehensive classification of these cell types is impeded partly by their molecular complexity and by the inability to identify each cell type by multiple molecular markers. Here we describe an approach to resolve these issues, which allowed us to define different cell types and to refine their molecular characterization by using target-selective conotoxins. We studied a heterogeneous population of cells obtained from a network in mouse brainstem that generates breathing rhythm. To classify cell types in this region, we used an approach that we call constellation pharmacology. The ventral respiratory columns from mice were isolated and dissociated to obtain a heterogeneous cell population. Using calcium imaging, we then monitored the simultaneous responses of ~200 cells to a panel of pharmacological challenges. The responses to such pharmacological perturbations enabled us to categorize these cells into three major cell classes and subclasses based on the constellations of ion channels and

receptors expressed by each cell. We found that a subset of these cells that responded to substance P, putatively inspiratory pre-Bötzinger complex (preBötC) neurons, also responded to histamine and bradykinin. We further examined the existence of these cell classes in an intact slice through electrophysiological studies and confirmed that the preBötC neurons responsive to substance P in an intact slice exhibited similar responsiveness to bradykinin and histamine. Thus, this approach provided a platform to classify cell types with crucial physiological roles in behavior and to generate hypotheses to test the roles of modulatory inputs to these defined cell classes in an intact system. To further refine the definition of these cell classes, we used target-selective conotoxins that differentiated between complex molecular isoforms. For example, NMDA receptors that are found in various combinations of subunits are difficult to study due to the lack of target selective tools. Using conantokin-Rl-B, a conotoxin that selectively targets NR2B subunits of NMDA receptors, we demonstrate its expression only in a specific subset of the defined cell types. Thus, using constellation pharmacology as our approach, we defined various cell types within the ventral respiratory column of the mouse brainstem and studied the expression of complex NMDAR isoforms within these cell types using target selective conotoxins.

Title: PSD-95 differentially regulates trafficking of NMDA receptors based on their subunit composition

Authors: *S. H. STANDLEY[1], M. AVETISYAN[1], M. RONILO[2]
[1]Grad. Col. of Biomed. Sci., Western Univ. of Hlth. Sci., Pomona, CA; [2]Biol., California State University, Fullerton, Fullerton, CA

Abstract: The function of PSD-95 has been viewed primarily as restricting NMDA or AMPA receptors to synapses. We report that the splice variants of the NR1 subunit impart unique trafficking and targeting properties on both individual subunits, and assembled full-length NMDA receptors, in the context of PSD-95. NR2B/NR1-3/4 receptors in the presence of PSD-95

are targeted to the trans-Golgi network (TGN) and directly to synapses, reconstituting the effect of AP5 on NMDA receptor targeting. NR2B/NR1-1/2 receptors are clustered on the cell surface in the presence of PSD-95 and found in recycling endosomes at lower expression levels. PSD-95 PDZ-binding to NR1-3 or NR1-4 triggers a differential interaction between PSD-95 and NR1 that blocks clustering and imparts TGN and synaptic targeting. On the other hand, PSD-95 binding to the NR2B PDZ-binding domain and sequences upstream causes well-characterized clustering, and recycling endosomal localization. These results, along with prior work related to SAP97, another PSD-95 family MAGUK, suggest these proteins may generally operate as trafficking switches, employing ligand-specific architectures to mediate differential sorting and targeting of their respective binding partners.

Title: Autocrine boost of NMDAR current in hippocampal CA1 pyramidal neurons by a PMCA-dependent pH shift

Authors: *H.-Y. CHEN[1], M. CHESLER[2]
[1]NEUROSURGERY, [2]PHYSIOLOGY & NEUROSCIENCE AND NEUROSURGERY, NYU SCHOOL OF MEDICINE, NEW YORK, NY

Abstract: Neural activity causes a surface membrane alkalosis due to activation of the plasma membrane calcium ATPase (PMCA), a transporter that extrudes calcium in exchange for two protons from the extracellular space. We previously showed that increasing effective buffering with exogenous carbonic anhydrase (XCAR, which reduces the surface alkaline shift) can significantly diminish the NMDAR-EPSC of a singly-activated, hippocampal, CA1 pyramidal neuron (PN). This suggested that an alkalosis is normally responsible for a large fraction of NMDAR current, and that this surface pH shift originates locally, from the recorded cell. The pH-dependent modulation of the NMDAR would accordingly be regarded as an autocrine effect. Indeed, splice variants of PMCA2 have been localized to dendritic spines and associated with

post-synaptic density proteins (1,2), placing them in close proximity to post-synaptic NMDARs. Here, we have further tested this autocrine hypothesis. Whole cell recordings of pure NMDAR EPSCs (VH = +50 mV) were obtained from CA1 PNs in juvenile mouse hippocampal slices. To assess locality of the modulation, we reduced stimulus intensity to generate responses of just 30 - 55 pA. The addition of XCAR reduced these EPSCs by 25 +/- 3.2 % ($n = 9$, $p < 0.001$), which was no different from its effect on larger EPSCs of ranging 166 - 386 pA ($p = 0.6$). AMPAR EPSCs of similar small size (32 - 49 pA) were unaffected by XCAR (VH = -70 mV). To directly test the autocrine nature of the modulation, we blocked activation of the PMCA in the recorded cell. When patch pipettes contained 20 mM BAPTA, after 12 min. of dialysis the NMDAR EPSCs were reduced by 23 +/- 4.2 % ($n=7$, $p < 0.001$) compared to responses at breakthrough. Moreover, after reduction of the EPSCs by BAPTA, external XCAR had no effect on EPSC amplitude. Similarly, when pipettes contained the PMCA inhibitor carboxyeosin (1 μM), EPSCs were reduced by 19 +/- 4 % after 12 min. of dialysis ($n = 7$, $p < 0.01$), and the effect of XCAR again was occluded. These data link the effects of XCAR to activation of the PMCA, and indicate that the alkaline boost of NMDAR currents is an autocrine effect that likely occurs at the level of single boutons. Title: Ischemia-induced excitoxicity is attenuated by GluN2B-specific conantokin-G in a rat model of focal brain ischemia

Authors: *T. SNOW[1,2], R. BALSARA[1,2], A. DANG[1], D. DONAHUE[2], F. J. CASTELLINO[1,2]

Abstract: Conantokin-G (ConG) is a GluN2B-specific potent N-methyl-D-aspartate receptor (NMDAR) antagonist, which displays neuroprotective activity on neurons that have

extrasynaptically activated NMDAR. The neuroprotective effect of ConG was tested in an *in vivo* rat model of Middle Carotid Artery Occlusion (MCAO) with 2 μM ConG administered intrathecally 30 min post occlusion. The animals were evaluated at 4 hr and 26 hr after injury induction. A 30% reduction in edema volume and a 50% reduction in infarct size were observed at 4 hr post-MCAO. Though, reduction in edema and infarct size was not observed at 26 hr post-MCAO, neurological recovery was significant at this time point. ConG treated rats showed significant recovery of the brain cytoarchitecture and neuronal integrity in the penumbra region as demonstrated by hematoxylin & eosin staining and Microtubule Assisted Protein-2 immunostaining. This was accompanied by decreased number of degenerated neurons by con-G at both 4 and 26 hr in the ipsilateral penumbra. MCAO-induced loss of GluN1 and GluN2B localization around the soma and proximal dendrites was reinstituted by ConG administration at 4 and 26 hr, but ConG had no effect on restoring MCAO-induced loss of GluN2A localization, which showed increased perinuclear presence in the brains of ConG treated rats. These data provide evidence that ConG ameliorates the detrimental effects of ischemic stroke via the NMDARs by repairing certain neurological and neuroarchitectural deficits, as well as reconstituting neuronal localization of GluN1 and GluN2B subunits in the penumbra.

Title: Activity-induced synaptic delivery of GluN2A-containing NMDA receptors is mediated by endoplasmic reticulum chaperone Bip and participates in fear memory

Authors: ***B. ZHANG**[1,2,3,3,3], X. ZHANG[1,3,3,3,3,3], X. YAN[1,3,3,3], M. YE[1], Q. YANG[1], W. CAO[1], W. QIANG[1], L. ZHU[1], X. XU[1], J. WANG[1], J. LUO[1,3]

[1]Dept. of neurobiology, Inst. of Neurosci. of Zhejiang Univ., Zhejiang, China; [2]Dept. of neurobiology, [3]Inst. of neuroscience, Hangzhou, China

Abstract: The N-methyl-D-aspartate receptor (NMDAR) is mainly composed of GluN1 and GluN2A or GluN2B subunits in hippocampus and cortex. Since the GluN2A- and GluN2B-containing NMDARs possess distinct functional properties, their relative amount and dynamic regulation on these synapses play a major role in controlling Ca2+-dependent signaling and synaptic plasticity. Previous studies have suggested that neurons occupy multiple trafficking pathways and intracellular reserve pools for synaptic receptor transport. So far, accumulative evidence reveals that KIF17 selectively mediates GluN2B transport along microtubules and tyrosine phosphorylation regulates surface level of GluN2B-containg NMDARs, although its relevance to physiology has not been established. However, the mechanism of rapid increase of synaptic GluN2A-containing NMDARs remains unknown, and as well does its implication in learning and memory. We found in this study that newly-inserted synaptic GluN2A-containing NMDARs in response to neuronal activity were directly assembled and delivered from dendritic ER. We identified a well-studied ER chaperone protein Bip to retain GluN2A subunits in dendritic ER through the selective interaction between them and mediate the activity-induced synaptic delivery of the GluN2A-containing NMDAR. And interestingly, this regulatory process was effectively abolished by interrupting the interaction between Bip and GluN2A. Furthermore, *in vivo* application (i.p.) of the interfering peptide before training effectively disrupted the fear memory formation in mice. These findings uncover a new mechanism for activity-induced supply of synaptic GluN2A-containing NMDARs that are initially from a reserve pool of GluN2A subunit in a Bip-bond form in dendritic ER, and demonstrate a relevance of this process to memory formation.

Title: Novel reagents for cell biological and biochemical assessment of ketamine targets

Authors: *C. M. EMNETT[1], H. LI[2], A. BENZ[1], X. JIANG[1], J. BOGGIANO[1], C. ZORUMSKI[1], D. WOZNIAK[1], D. REICHERT[2], S. MENNERICK[1,3]
[1]Psychiatry, [2]Radiology, [3]Anat. and Neurobio., Washington Univ., Saint Louis, MO

Abstract: Ketamine is of interest in neuropsychiatry as a rapidly acting antidepressant. Although NMDAR antagonism is likely relevant for triggering antidepressant effects of ketamine, other cellular and biochemical targets could also be important. Ketamine is rapidly metabolized into norketamine, which has a longer half-life (~12 h vs ~3 h) and biological activity possibly similar to ketamine. Here we offer new chemical biological tools that may help identify novel targets of ketamine and norketamine. We first explored actions of (R,S)ketamine and (R,S)norketamine in the forced swim test (FST). Ketamine significantly reduced immobility in C57BL/6J mice at 3 ($p=0.021$) and 10 mg/kg ($p=0.002$), during the FST after a 3 h post-injection delay. These doses did not affect locomotor activity. Norketamine also reduced immobility at 3 ($p=0.039$) and 10 mg/kg ($p=0.003$) using the same test parameters. Thus, norketamine had a similar behavioral effect as ketamine in this antidepressant screen. We examined NMDAR actions of ketamine, norketamine and first-generation chemical biology analogs in hippocampal cultures. We found that norketamine was active but ~4-fold less potent than ketamine at native NMDARs. Norketamine exhibited slower kinetics of block and more steady-state voltage dependence. At 10 μM, both compounds suppressed the peak of NMDAR EPSCs by ~20%, but ketamine more strongly accelerated EPSC decay time constants. These results confirm the potential relevance of norketamine and suggest that analogs of ketamine/norketamine would be useful. To that end, we exploited the versatility of bio-orthogonal click chemistry to develop bi-functional analogues of ketamine/norketamine to probe intracellular targets. We introduced an alkyne “click” handle into the ketamine/norketamine structure (alkyne-norketamine) at the key nitrogen atom via alkylation with 5-iodo-1-pentyne. Alkyne-norketamine exhibited potency equivalent to norketamine and voltage dependence similar to ketamine, thereby yielding an NMDAR-active, bi-functional probe. Introducing the alkyne with an amide linkage abolished NMDAR antagonism, presumably by interacting with nitrogen protonation. Imaging neurons following incubation in 10 μM alkyne-norketamine revealed intracellular labeling following Cu2+ catalyzed cycloaddition of azide-AlexaFluor488, demonstrating the utility of the probe for cell biological studies and revealing the potential for relevant intracellular targets. Thus, we advance first-generation chemical biology tools to aid identification and characterization of cellular and molecular targets of ketamine/norketamine relevant to antidepressant effects.

Title: CaMKII-α is necessary for normal development of NMDA receptors on zebrafish Mauthner cells

Authors: *B. ROY, D. W. ALI
Dept. of Biol. Sci., Univ. of Alberta, Edmonton, AB, Canada

Abstract: Calcium/calmodulin dependent protein kinase 2 (CaMKII) is a multifunctional protein that is highly enriched in the synapse. It plays important roles in neuronal functions such as synaptic plasticity, synaptogenesis and neural development. Gene duplication in zebrafish has resulted in the occurrence of seven CaMKII genes (*camk2a*, *camk2b1*, *camk2b2, camk2d1, camk2d2, camk2g1* and *camk2g2*) that are expressed in a developmentally regulated manner. In this study, we used single cell, real-time quantitative PCR to investigate the expression of CaMKII genes in individual Mauthner cells (M-cells) of 2 days post fertilization (dpf) zebrafish embryos. We found that out of seven different CaMKII genes, only CaMKII-α was expressed in the M-cells at detectable levels, while all other isoforms were undetectable. To investigate a developmental role for CaMKII-α, we used two separate antisense morpholino oligonucleotides to knock down CaMKII-α expression in embryonic zebrafish; one was targeted to block the translation of mRNA and the other was designed to disrupt proper splicing of pre-mRNA. We recorded miniature excitatory postsynaptic currents (mEPSCs) mediated by NMDA receptors, which exhibited a biexponential decay with a τ_{fast} of ~30 ms and τ_{slow} of ~300 ms. Morpholino knockdown of CaMKII-α resulted in a 40% reduction in the amplitude of the slow component of the mEPSCs, with very little effect on either the amplitude of the fast component, the frequency or kinetics of the mEPSCs. These results suggest that CaMKII-α is present in embryonic M-cells and that it plays a role in the normal development of excitatory synapses. Our findings pave the way for determining the function of specific CaMKII isoforms during the early stages of M-cell development.

Title: Differential localization of NMDA receptors in cerebellar stellate cells

Authors: *C. DUBOIS[1], L. SUN[1], M. MISHINA[2], S. J. LIU[1]
[1]Dept. of Cell Biol. and Anat., LSUHSC, New Orleans, LA; [2]Brain Sci. Lab., The Res. Organization of Sci. and Technology, Ritsumeikan university, Shiga, Japan

Abstract: Modification of the strength of excitatory synapses has been long thought to be the neural basis for learning and memory. Nonetheless, it is now accepted that inhibitory synapses can also undergo plasticity and probably contribute to most forms of experience-dependent plasticity by altering the balance between excitatory and inhibitory inputs. Therefore, understanding the crosstalk between these inputs is essential. We and others have shown that activation of extrasynaptic NMDA receptors in cerebellar GABAergic interneurons leads to both short and long term changes in the strength of GABAergic synapses. Here we determined the effects of NMDAR subunit specific inhibitors on somatic and dendritic NMDA receptors in stellate cells. Previous data from our lab using GluN2D KO mice indicated the presence of GluN2B and Glun2D subunits in cerebellar stellate cells. First we applied 0.1 μM PPDA and 0.2 μM CPP to outside-out patches excised from the soma of cerebellar Purkinje and Golgi neurons that express di-heteromeric GluN2D and tri-heteromeric GluN2B/2D NMDA receptors, respectively. Our results showed that PPDA inhibited GluN2D-containing NMDA receptors, whereas CPP selectively blocked tri-heteromeric GluN2B/2D NMDA receptors. Using these antagonists as well as the GluN2B antagonist Ifenprodil (3 μM), we then characterized NMDA receptors located in the soma of stellate cells. We found that PPDA and Ifenprodil inhibited NMDA-evoked currents in outside-out patches excised from the soma of stellate cells, whereas 0.2 μM CPP had no effect. Our data suggests that stellate cells express both GluN2B and GluN2D di-heteromeric NMDA receptors in the soma. Finally, we activated dendritic NMDARs by repetitive stimulation of parallel fibers and recorded dendritic currents recorded at +40 mV in the presence of the AMPA receptor antagonist NBQX. We found that PPDA and Ifenprodil

reduced dendritic currents by ~40% and in contrast CPP only blocked less than 20% of the NMDAR currents. Thus di-heteromeric GluN2B and GluN2D NMDA receptors, but not tri-heteromeric GluN2B/2D NMDA receptors, are located in the soma and the dendrites of stellate cells. Because a low concentration of CPP blocked an NMDAR-dependent increase in GABA release, the tri-heteromeric GluN2B/2D receptors appear to be mostly restricted to the axons of these cells. This differential subcellular distribution of NMDA receptors with distinct pharmacological and electrophysiological properties may function to finely tune the crosstalk between excitation and inhibition in the molecular layer of the cerebellar cortex.

Title: GluN3A expression restricts the localization of NMDA receptors to synapses via modulation of surface dynamics

Authors: I. M. GONZÁLEZ-GONZÁLEZ[1], J. A. GRAY[2], R. A. NICOLL[2], L. GROC[3], *I. PEREZ-OTANO[1]
[1]Ctr. For Applied Med. Res. (CIMA) and Univ. of Navarra., Pamplona, Spain; [2]Dept. of Cell. and Mol. Pharmacol., Univ. of California, San Francisco, CA; [3]Interdisciplinary Inst. for Neuroscience, Univ. de Bordeaux, Bordeaux, France

Abstract: NMDA-type glutamate receptors (NMDARs) guide the activity-dependent remodeling of excitatory synapses and associated dendritic spines during critical periods of postnatal brain development. Whereas mature NMDARs composed of GluN1 and GluN2 subunits mediate synapse plasticity and promote spine growth and stabilization, juvenile NMDARs containing

GluN3A subunits are thought to inhibit these processes via yet unknown mechanisms. One key factor controlling the synaptic concentration of NMDARs is their ability to swap in and out of synapses via lateral diffusion. This ability depends on the type of GluN2 subunits comprising the receptor complex; whereas GluN2A subunits confer stability to NMDARs, GluN2B-containing subtypes are more mobile. Because GluN2A levels progressively increase during postnatal brain development, it has been hypothesized that the replacement of GluN2B by GluN2A subunits underlies the stabilization of NMDARs at synapses and the associated consolidation of neural networks. Information regarding the mobility of GluN3A-containing subtypes has been conspicuously lacking, despite biochemical and EM evidence suggesting that overexpression or down-regulation of GluN3A might modify receptor localization and stability. By taking advantage of high resolution live cell imaging, native GluN2 were followed using a single-molecule tracking based on the detection of quantum dots (QDs) in cultured hippocampal neurons. Here we report that variations in GluN3A expression differentially modulate the surface dynamics of NMDARs depending on the type of GluN2 subunit, and thereby drive developmental changes in the synaptic enrichment of GluN2-NMDARs.

Title: Peculiarities of homocysteine as an agonist of NMDA receptors

Authors: *D. A. SIBAROV[1], P. A. ABUSHIK[1], R. GINIATULLIN[2], S. M. ANTONOV[1]
[1]Sechenov Inst. of Evolutionary Physiol. and Biochem., Saint-Petersburg, Russian Federation; [2]Dept. of Neurobio., A. I. Virtanen Inst. for Mol. Sciences, Univ. of Eastern Finland, Kuopio, Finland

Abstract: High level of homocysteine (HCY) in blood or in cerebrospinal fluid, often originating from distorted methionine metabolism, is a significant risk factor for the heart attack, stroke and neurodegenerative disorders. In central and peripheral nervous systems HCY acts as an agonist of NMDA receptors (NMDARs) and metabotropic (mGluR5) glutamate receptors. Previously we showed that the neurotoxic effect of HCY in rat cotrical and trigeminal sensory neurons is determined by intracellular Ca2+ oscillations (doi:10.1111/jnc.12615). Pro-apoptotic action of HCY in neurons results from cumulative effect of Ca2+ entry via NMDA receptors and mGluR5 provoked secondary release of Ca2+ from intracellular stores. Here, using whole cell patch-clamp recording from rat cortical neurons in primary culture we studied the agonist properties of HCY in comparison with NMDA. A fraction of neurons responding to 30 μM NMDA, generated inward currents also to HCY (100 μM) application. In neurons exhibiting comparable peak currents to both NMDA and HCY, the amplitude of late HCY-induced steady-state current was 2-folds magnitude lower than for NMDA. The EC50 value for HCY measured at the steady state currents was as low as 14.4 ± 1.3 μM. In the nominal absence of extracellular Ca2+ NMDA-induced currents did not reveal the receptor desensitization. In contrast, HCY-induced currents demonstrated the same degree of desensitization independently on the presence of extracellular Ca2+. Both Mg2+, as a noncompetitive, and AP5 as the competitive NMDARs antagonist, inhibited HCY induced currents. Interestingly, HCY-induced currents were insensitive to ifenprodil, the selective inhibitor of GluN2B subunit of NMDARs. NMDA-induced currents of neurons that did not respond to HCY were almost completely blocked by ifenprodil. Taking together these observations allow us to suggest, that HCY does not act on GluN2B subunits. Based on known predominant expression of GluN2A and GluN2B subunits in cortical neurons, we hypothesize that HCY selectively interacts with the binding site of the GluN2A subunit containing NMDARs. Thus, HCY acts as an effective agonist of NMDARs, causing Ca2+ independent rapid desensitization with the low amplitude of the steady-state currents. HCY can strongly interfere with the NMDARs-mediated synaptic transmission in concentrations comparable with those which occur *in vivo* during hyperhomocysteinemia.

Title: D-Cycloserine selectively alters kinetics of evoked NMDA responses in the rat entorhinal cortex

Authors: A. M. LENCH, P. V. MASSEY, *R. S. JONES
Dept Of Pharm. and Pharmacol., Univ. of Bath, Bath, United Kingdom

Abstract: The NMDA receptor (NMDAr) coagonist binding site partial agonist D-cycloserine (DCS) has been implicated as a potential therapeutic target in a number of CNS diseases. In particular the anticonvulsant effects of DCS have been identified but are yet to be fully explored and may point to novel approaches for the treatment of epilepsy. We have examined the effects of DCS, applied cumulatively from 1 to 30 μM, on evoked NMDA receptor responses (eNMDAr), recorded under voltage clamp in neurones of the entorhinal cortex in rat brain slices. Interestingly, DCS had no observable effect on the amplitude of these responses (e.g. at 30 μM, mean amplitude was 187.6±54.1pA compared to 174.7±34.2 pA in control) but significantly decreased their decay time (Emax=65.8±5.0% control, IC50 = 2.1μM, n=6). When a saturating concentration of D-serine (1mM) was applied following DCS (10μM) the amplitude of eNMDAr increased to 122.1±4.9% control (n=7). As D-serine is a full agonist, this indicated that the endogenous level of binding was 81.9±3.2% of maximum. This value is very similar to the reported efficacy of DCS at NR2A/NR2B containing receptors. This indicates that the lack of effect of DCS on eNMDAr amplitude is due to a match between this efficacy and the endogenous level of activation. The low efficacy partial agonist, 1-Aminocyclobutane-1-carboxylic acid, was seen to decrease eNMDAr amplitude and decay time, supporting this conclusion. It is plausible that the kinetic effect underlies the anticonvulsant properties of DCS. We show this computationally using a Pinksy-Rinzel network model, demonstrating that a 35% reduction in NMDAR decay time results in large reductions in predicted durations of bursting activity. The allosteric properties of NMDAr coagonist binding site partial agonists have been extensively described though it is remarkable that in an endogenous situation the kinetic effects of DCS occur selectively at synaptic NMDA receptors. These allosteric effects may therefore underlie the anticonvulsant effect of DCS by reducing the ability of neuronal networks to sustain rhythmic activity.

Title: Chronic GluN2B inhibition reduced axon length and sphere of axonal arborization in dentate/hilar border interneurons, but did not affect GABAergic synapses onto dentate granule cells

Authors: *S. B. BAUSCH, Y. WANG, D. LAPIDES, K. QUINN
Dept Pharmacology, Rm C2007, Uniformed Services Univ. Sch. of Med., BETHESDA, MD

Abstract: We showed previously that chronic treatment with distinct classes of N-methyl-D-aspartate receptor (NMDAR) antagonists exerted differential effects on seizure-like events (SLE) in organotypic hippocampal slice cultures. SLE involving dentate granule cells were dramatically reduced following chronic treatment (17-21 days) with the GluN2B-selective antagonist, Ro25,6981, but were increased in cultures treated with the non-subtype-selective antagonists, memantine or D-APV. Since GABAergic transmission plays a critical role in the regulation of hippocampal activity, we hypothesized that chronic Ro25,6981 would promote expansion of interneuron axonal fields as well as the number of GABAergic synapses onto dentate granule cells, while memantine or D-APV would elicit opposite effects. To investigate potential changes in morphology, interneurons at the dentate/hilar border were filled with neurobiotin and digitally reconstructed. Treatment with Ro25,698, but not the other NMDAR antagonists dramatically reduced total axonal length and sphere of axonal arborization. Axonal branch points and putative boutons mirrored these results, but branch point and bouton density were unchanged. Dendritic length and sphere of dendritic arborization also were reduced following chronic Ro25,6981, but this reduction was not specific to GluN2B inhibition as other NMDAR antagonists caused similar reductions. Double immunofluorescence for GAD 65/67 (GABA synthetic enzymes) and NeuN (for somata) or MAP2 (for dendrites) was then performed to quantify neuron number and numbers of putative GABAergic synaptic boutons apposed to granule cell somata and dendrites, respectively. Quantification showed that the number of neurons and putative GABAergic synapses onto granule cells were lower following D-APV or memantine treatment compared to vehicle. Similar decreases have been described in epilepsy models and may contribute to the increased SLE expression in slice cultures following chronic treatment with D-APV and memantine. In contrast, we found equivalent numbers of putative GABAergic synapses onto granule cells in vehicle- and Ro25,6981-treated cultures, despite reduced axonal fields in individual interneurons and no change in the number of GABAergic neurons. These changes together with electrophysiological results suggest that one possible mechanism for reduced SLE following chronic Ro25,6981 is that individual interneurons may have a reduced ability to synchronize activity across widespread populations of neurons.

Title: Combined effect of genetic variants in GRIN2B on prefrontal function during working memory performance

Authors: ***G. PERGOLA**[1], P. DI CARLO[1], L. FAZIO[1], A. RAIO[1], R. MASELLIS[1,2], B. GELAO[1], A. RAMPINO[1,2], G. BLASI[2], A. BERTOLINO[1,2]
[1]Basic Med. Science, Neurosci. and Sense Organs, Univ. of Bari 'Aldo Moro', Bari, Italy; [2]Psychiatry Unit, Bari Univ. Hosp., Bari, Italy

Abstract: N-methyl-D-aspartate receptors (NMDAR) are important modulators of prefrontal activity during working memory processing. Furthermore, they concur in mediating glutamate-dependent neural plasticity and are involved in neurodevelopmental processes. For example, among the subunits composing NMDAR, GluN2B are more abundant during neurodevelopmental stages than they are in adults - in which GluN2A is prevalent. Here, we tested the combined effect of genetic variants in the GluN2B gene (GRIN2B) on GRIN2B prefrontal mRNA expression. Once this effect was detected, we also investigated how these genetic variants together affect prefrontal activity during working memory in healthy human subjects. SNPs were identified using Braincloud (http://braincloud.jhmi.edu/). We found five SNPs significantly associated with GRIN2B expression: rs2160517, rs219931, rs11055792, rs17833967, rs12814951 (all $p < .05$, corrected with Benjamini-Hochberg FDR). Thus, based on signal detection theory, we computed a composite genetic score to account for the combined effect of these SNPs on expression. Machine learning indicated that this score was negatively correlated with gene expression ($N = 148$, $R^2 = .17$, $p < 10^{-6}$). Then, we genotyped the SNPs of interest in 134 healthy individuals (56 females; mean age ± SD was 28 ± 7 years (range 19-53) and determined the associated genetic score. Functional magnetic resonance images were also acquired while these participants performed a working memory task (n-back). We estimated the association of genetic score with dorsolateral prefrontal cortex activation using linear regression models, controlling for age, gender, IQ, socioeconomic status, and handedness. With this aim,

we performed an ROI analysis including bilateral Brodmann Areas 8, 9, and 46. We found a significant cluster of 157 voxels in the left superior frontal gyrus (Brodmann Area 8; $z = 3.9$; $p < .05$, peak-level family-wise error correction; coordinates in MNI space: $x = -32$; $y = 20$; $z = 58$). In particular, results suggested that activation was negatively correlated with GRIN2B genetic score. Adding behavioral performances as nuisance variables in the statistical analysis did not modify the results. This study suggests that genetic variants in GRIN2B have additive effects on gene expression. The combined effect of these genetic variants is also associated with more distal and complex phenotypes related to prefrontal function and cognitive processing. These findings may help to shed light on the biological basis of brain disorders with a complex genetic background.

Title: Synthesis, mechanism of action, and structural determinants for a novel class of GluN2C/D-selective NMDA receptor antagonists

Authors: *S. A. SWANGER[1], S. S. ZIMMERMAN[2], T. M. ACKER[2], K. M. VANCE[1], C. A. MOSLEY[2], D. C. LIOTTA[2], S. F. TRAYNELIS[1]

Abstract: NMDA receptors are ionotropic glutamate receptors that mediate excitatory synaptic transmission and are involved in many neurological disorders. These tetrameric receptors are

composed of two GluN1 and two GluN2 subunits (GluN2A-2D), and the GluN2 subunits exhibit distinct developmental and regional expression patterns in the brain. Therefore, subunit-selective pharmacological modulation of NMDA receptors is a promising strategy for studying NMDA receptor function in specific neuronal circuits and for developing therapies for neurological disorders. We have discovered a novel class of GluN2C/D-selective antagonists (class 1063) that are >500-fold selective for GluN2C/D-containing receptors over GluN2A/B-containing receptors. The 1063 compounds had low micromolar potencies at GluN2C- and GluN2D-containing receptors, when tested on recombinant NMDA receptors in Xenopus oocytes. Furthermore, inhibition of GluN2C/D-containing receptors by 1063 is voltage-independent and could not be surmounted by increasing concentrations of agonists; this is consistent with a noncompetitive mechanism of action. Using GluN2A/D chimeric receptors, we identified a critical region for 1063 inhibition near the first transmembrane domain of the GluN2 subunit. Mutation of a single residue (C590) that is not conserved between GluN2C/D and GluN2A/B blocks inhibition, suggesting this region may be a molecular determinant of action. In addition, 1063 compounds inhibited triheteromeric receptors containing GluN1/GluN2A/GluN2C subunits, which may enhance their utility for studying neural circuits. Importantly, the 1063 series of NMDA receptor antagonists inhibited GluN2C/D-containing NMDA receptors in transiently transfected cultured rat neurons. These data suggest that this new class of GluN2C/D-selective antagonists may be a valuable tool for studying NMDA receptor function, and could be further developed for potential use in treating neurological disease. This research was supported by funding from NIH-NINDS [NS065371 (SFT), NS086368 (SAS), NS071802 (TMA), T32-NS007480 (KMV)].

Title: Distributed kinetic effects of oxysterol positive modulators on NMDA channels

Authors: *A. J. LINSENBARDT[1], S. M. PAUL[3,4], J. J. DOHERTY[4], C. F. ZORUMSKI[2], S. MENNERICK[2]

Abstract: N-methyl-D-aspartate receptors (NMDARs) are essential for learning and memory and are important in neuropsychiatric disorders including Alzheimer's disease and schizophrenia. NMDAR gating can be manipulated by allosteric modulators, resulting in the alteration of channel opening probability (Po). Recently, we reported on a novel endogenous oxysterol NMDAR positive allosteric modulator, 24(S)-hydroxycholesterol (24(S)-HC), and we showed that synthetic oxysterol analogs potentiate NMDARs with high specificity and potency. Oxysterol potentiation increases agonist efficacy and channel Po. Here we explored biophysical mechanisms of potentiation by analyzing the activity of individual GluN1a/GluN2A channels in transfected HEK293 cells. At saturating agonist concentration (300 μM NMDA), single channels in cell-attached patch recordings exhibited three clearly resolved closed states and two open states, consistent with observations from previous studies. Application of the oxysterol analog SGE-301 (2 μM) decreased the mean duration of long channel closures and increased the mean duration of both short and long channel openings. There was no change in the relative contributions of various closed-time and open-time components. We observed minimal modal channel behavior, examined by time-binned Po analysis. We interpreted oxysterol-induced changes by applying several five-state kinetic models from previous work to our data. Fits to a linear gating scheme produced a paradoxical slowing of the rate of forward transition between the two open states and slowing of several backward rate constants. Together, these changes produced the expected potentiation of simulated macroscopic steady-state currents. Two five-state branched gating models were indistinguishable from the linear model by log likelihood values. Like the linear model, both predicted distributed changes to multiple rate constants. The linear model better mimicked synaptic-like pulses of agonist and modulation by SGE-301 than the branched models. Taken together, we show that oxysterols have distributed effects on several aspects of channel behavior. Our results elucidate the mechanism by which oxysterols augment NMDAR function and contribute to novel therapeutic interventions.

Coimbra, Coimbra, Portugal

Abstract: Repeated stress elicits neurochemical and neuroanatomical changes that negatively impact on brain functioning and constitute a trigger or risk factor for psychiatric disorders such as depression and neurodegenerative disorders involving cognitive impairment in both humans and animal models. Since caffeine consumption (adenosine receptor antagonist) correlates inversely with depression and adenosine A2A receptor (A2AR) antagonists normalize aberrant plasticity and afford neuroprotection, we tested the role of A2AR in the control of the behavioural, electrophysiological and neurochemical modifications caused by chronic unpredictable stress (CUS, composed by uncontrollable daily stressors such as tilted cage, food/water deprivation, foot shock, paired caging, continuous light, wet bedding) for 3 weeks in adult mice. CUS led to an up-regulation of A2AR selectively in glutamatergic terminals in the hippocampus, increased the morning plasma levels of corticosterone, induced anxiogenic (open field, elevated plus maze) and depressive-like behaviour (forced swimming, tail suspension, sucrose preference) and decreased memory performance (object displacement, object recognition, modified Y maze, Morris water maze). These behavioural changes were accompanied by a decrease of synaptic plasticity (long term potentiation) and a reduced density of synaptic proteins (SNAP-25, syntaxin and vesicular glutamate transporters type 1, vGluT1) in the hippocampus without overt neuronal damage (Cresyl violet and FluoroJade C) or microgliosis (CD11b immunoreactivity). All these CUS-induced changes were prevented by each of the following treatments: 1) caffeine (1 g/L, p.o., starting 3 weeks before and throughout CUS); 2) KW6002 (3 mg/kg, p.o.; selective A2AR antagonist, starting 4 days before and throughout CUS); 3) global genetic deletion of A2AR; 4) selective A2AR deletion in forebrain neurons. Notably, A2AR blockade was not only prophylactic but also therapeutically relevant since, after the end of the CUS protocol, a 3-weeks treatment with the A2AR antagonist SCH58261 (0.1 mg/kg, i.p.) reversed the mood and memory impairments as well as the synaptic dysfunction caused by CUS. These results herald a key role of neuronal A2AR in the control of chronic stress-induced modifications and prompt the hypothesis that A2AR may be an attractive and effective target for the development of novel corrective strategies for brain disorders that involve a synaptic dysfunction, as now observed for the maladaptive responses to chronic stress.

Abstract: Anxiety is one of the most prevalent comorbidities associated with acute lung injury (ALI) and acute respiratory distress syndrome (ARDS). Activation of the innate immune system is a known inducer of anxiety-like behaviors. Adult male BALB/cJ mice were exposed to 6% oxygen for 2 hours (hypoxia). We found that hypoxia increased circulating adenosine concentration by more than two-fold. Moreover, we see that hypoxia induced a four-fold increase in staining for active caspase-1 in the amygdala when compared to normoxic controls in wild type but not A2A adenosine receptor (AR) KO. Finally, hypoxia increased anxiety-like behaviors in wild-type mice by 45% in the open field test and 86% in the elevated zero-maze, while A2A AR KO mice were resistant to hypoxia-induced anxiety-like behaviors. Our results indicate that hypoxia induces anxiety-like behaviors, at least in part, by increasing adenosine signaling via A2A AR to increase caspase-1 activity.

Title: Intracellular control of A2A receptor signaling and behavior as revealed by optoA2AR approach

Authors: X. HOU[1,2], M. P. SURPRIS[1], P. LI[1], J. ZHENG[2], *J.-F. CHEN[1]
[1]Neurol., Boston Univ. Sch. Med., BOSTON, MA; [2]Neurol., Xinqiao Hospital/3rd Med. Univ., Chongqing, China

Abstract: Adenosine A2A receptors (A2ARs) in the nucleus accumbens (Acb) play an important role in control of motor, sleep and addiction. A2AR can exert its biological responses through G-protein-dependent as well as G-protein independent signaling pathways. Recently, at least six G-protein accessory proteins have been identified to bind to the C-terminus of A2ARs to affect A2AR signaling. This raises a possibility that the interaction between the intracellular domain of A2AR and G proteins and G-protein accessary proteins can directly affect down-stream cellular signaling and function. To specifically define the role of the intracellular domain of the A2AR in dictating intracellular signaling and behavior in Acb, we have developed a chimeric rhodopsin-A2AR (optoA2AR) protein which confers light responsiveness with the extracellular and transmembrane domains of rhodopsin and A2AR signaling with the intracellular domains of the A2AR. In this study, we selectively expressed the optoA2AR in the striatopallidal neurons by injecting the Cre-dependent AAV-optoA2AR-mCherry into the Acb of Adora2a-Cre mice. The striatopallidal neuron-specific expression pattern was confirmed by the localization of optoA2AR in enkephalin-positive, but not substance P-positive cells in the striatum. Light activation of optoA2AR in the striatopallidal neurons triggered MAPK phosphorylation in the striatum and suppressed motor activity, but had no effect on recognition memory when light was delivered during the training or immediately after the training. These findings illustrate the utility of the optoA2AR approach to investigate the intracellular control of A2AR signaling in behaving animals, and suggest that the intracellular domain of the A2AR may be important in dictating A2AR signaling and behavioral responses.

Abstract: Caffeine and adenosine A2A receptors (A2AR) control stress-induced emotional and memory alterations that involve information processing in the prelimbic medial prefrontal cortex (PLmPFC). A2AR control synaptic plasticity in different brain regions and can form heteromers and antagonize dopamine D2-like receptors (D2R). However, the role of A2AR in the PFC is essentially unknown and may underlie the ability of caffeine to restore cognitive flexibility in an animal model of attention deficit and hyperactivity disorder (ADHD). Thus, we now tested if A2AR blockade with its selective antagonist (SCH58261) controlled synaptic transmission and plasticity in the PFC and if the effects of A2AR depend on D2R function, a critical modulator of PFC function. We recorded population spikes in layer V of slices from male Wistar rats (6 weeks) upon stimulation of layer II/III and long-term potentiation (LTP) was induced by 1 priming 100Hz (0.5s duration) train, followed 15 min later by 4 trains of 100Hz (0.5s duration, every 10s). SCH58261 (50nM) was devoid of effects on basal synaptic transmission but decreased LTP amplitude (23.5±3.8% over basal with SCH58261 versus 40.3±5.3% in control slices, n=6, $p<0.05$). Silencing A2AR selectively in the mPFC (with a lentivirus expressing a shRNA downregulating A2AR, shA2AR) triggered an impulsive phenotype, evaluated in a delayed reward paradigm (34.5±3.3% of larger reward choices in shA2AR versus 64.0±6.7% in control rats, n=8, $p<0.01$). Since impulsive phenotype has also been linked to loss of D2R function and A2AR and D2R can heteromerize, we tested if D2R impacted PLmPFC LTP and interacted with A2AR. D2R blockade with supiride (10μM) decreased LTP amplitude

(26.8±6.7% with sulpiride versus 40.7±6.5% in control, n=6, P<0.05), as did A2AR blockade. Furthermore, with the simultaneous blockade of A2AR and D2R, LTP amplitude (20.7±5.1%, n=5) was not significantly different from SCH58261 or sulpiride (p>0.05), revealing mutually occlusive effects. These results document a novel role of A2AR in the control of adaptive plastic changes in the PFC in tight interaction with D2R, with relevance for the control impulsivity in conditions such as ADHD in view of the clear impulsive phenotype in rats with silenced A2AR.

Title: Caffeine potentiates D-aspartate-mediated GABA release in the developing chick retina

Authors: *D. D. FERREIRA[1], B. STUTZ[2], R. A. M. REIS[2], F. G. DE MELLO[2], R. C. C. KUBRUSLY[1]
[1]Federal Fluminense Univ., Niteroi, Brazil; [2]IBCCF, Federal Univ. of Rio de Janeiro, Rio de Janeiro, Brazil

Abstract: Aim: We are investigating the effects of caffeine in GABAergic system, analyzing the purinergic receptors influence in regulating NMDA receptor (NMDAR) activity in retinal explants of chick embryo. Methods and Results: Retinas from 13-day-old chick embryo (Gallus gallus domesticus) were used for [3H]-GABA uptake and release, high performance liquid chromatography and cAMP assay. All experiments were approved by the Ethics Committee of CCS-UFRJ. D-aspartate (500µM) (D-asp) increased GABA-release in 4.5 fold when compared to basal levels (B) (B=2.21±0.05, n=6; D-Asp=9.95±0.24, n=6). Caffeine (500µM) (Caf+D-Asp)

elevated D-asp-induced GABA release in 60% (Caf+D-Asp=16.10±2.29, n=7). The release was inhibited in the presence of NNC-711 (NNC), GABA transporter-1 (GAT-1) blocker (NNC=2.42±0.33, n=3), and MK-801 (MK), NMDAR antagonist (MK=3.18±0.58, n=3). Caffeine did not modify [3H]-GABA uptake in 5, 30 and 60min (5min:Ctrl=96.14±1.73; Caf=101.4±11.84; 30min:Ctrl=290.2±58.58; Caf= 247.4±29.65; 60min:Ctrl=312.1±6.76; Caf=313.3±36.13; n=2) and did not increase the release of D-asp (Ctrl=9.64±1.45, Caf= 8.78±1.22) or glutamate at basal (Ctrl=14.29±2.98, Caf=12.94±2.61; n=6) or stimulated conditions (Ctrl=15.40±3.23, Caf=11.66±3.31; n=6). Caffeine's effect was mimicked by the adenosine A1 receptor DPCPX (DPCPX=21.95±1.42, n=4) and by the adenylyl cyclase activator forskolin (FK) (FK=18.76±1.82, n=4); and was blocked by the PKA inhibitor, H-89 (H-89=11.58±0.98, n=4), tyrosine kinase inhibitor genistein (Gen=9.19±0.31, n=3) and src family kinase (SFK) inhibitor PP1 (PP1=9.76±0.42, n=3). Forskolin-stimulated cAMP levels (F) were reduced in the presence of the A1 receptor agonist CHA (F=2317±447, n=3; CHA=1094±420, n=2). The GluN2B subunit-containing NMDAR antagonist ifenprodil (IF) inhibited caffeine's effect at 10uM (IF=8.78±0.35; n=6). Conclusion: Our data suggest that caffeine potentiates D-asp-induced GABA release, which is mediated through reversion of GAT-1 and is dependent of NMDAR. Caffeine seems to promote this effect by antagonizing the adenosine A1 receptor and cAMP levels and PKA may be involved in it. Additionally, phosphorylation of the GluN2B containing-NMDAR by SFK may participate in the potentiation of D-asp-induced GABA release by caffeine.

Title: Modulation of ERK phosphorylation by A1 adenosine receptor in cultures of avian retinal glial cells: Involvement of PKC and Src kinase

Authors: *A. DOS SANTOS-RODRIGUES[1], M. R. PEREIRA[1], I. L. A. DA SILVA[1], S. A. RODRIGUES[1], L. R. LEÃO-FERREIRA[2], R. PAES-DE-CARVALHO[1]

Abstract: Adenosine is an important modulator of neuronal survival and differentiation and also participates in neuroprotection mechanisms. Besides its classical role in the regulation of adenylyl cyclase activity, increasing evidence indicates that adenosine receptors regulate different signaling pathways including MAP kinase cascade which appear to have important roles in several neural and glial functions. Glial cells play fundamental roles in the CNS such as regulation of synaptic transmission as well as neurotransmitter uptake and metabolism. In the present work expression of adenosine A1 receptors and regulation of extracellular-regulated kinase (ERK) activity of cultured retinal glial cells by adenosine was evaluated. Expression of A1 receptor in purified cultures of glial cells obtained from 11 day-old chick embryo retinas was detected by (3H) DPCPX binding and western blot. Purified cultures were incubated with selective kinase inhibitors and adenosine receptor selective agonists or antagonists for determination of phosphorylated ERK (pERK) level by western blotting or immunocytochemistry. Incubation of cultured glial cells with adenosine deaminase (0.5 U/ml) or DPCPX (10 μM), an A1 receptor-selective antagonist, reduced basal pERK level by approximately 50% indicating that endogenous adenosine regulates ERK phosphorylation through activation of A1 receptor. Incubation with CHA (1 μM), an A1 receptor-selective agonist, induced an increase of 120% in pERK levels, an effect completely blocked by DPCPX. Basal pERK level was also reduced 30-50% by PD98059, a MEK inhibitor, PP1, a Src inhibitor, or Chelerythrine chloride (100 nM), a PKC inhibitor. Furthermore, these selective inhibitors completely blocked CHA-induced ERK phosphorylation. Immunocytochemistry data revealed that A1 receptor-induced increase in pERK level is mainly localized in the cytosol. These results demonstrate that A1 adenosine receptor is expressed in retinal glial cells and modulate ERK signaling through a pathway involving PKC and Src kinase.

Title: Adenosine-based anticonvulsant mechanisms underlying ketogenic diet

Authors: *M. KAWAMURA[1], D. N. RUSKIN[2], S. A. MASINO[2]
[1]Dept Pharmacol, Jikei Univ. Sch. Med., Tokyo, Japan; [2]Neurosci. Program/Psychology Dept., Trinity Col., Hartford, CT

Abstract: A ketogenic diet (a low-carbohydrate high-fat protocol) was designed in the 1920s to mimic fasting to treat epilepsy. In recent decades, ketogenic diet has increasingly been noted as a useful therapy for medically-refractory epilepsy using antiepileptic drugs. Despite decades of clinical use, the neural mechanisms underlying the anticonvulsant effects of a ketogenic diet are poorly understood, and to date there has been no established *in vitro* preparation recapitulating its neural effects *in vivo*. To elucidate this, we used a complementary approach which included *in vivo* dietary treatment followed by characterizing acute brain slices using electrophysiology. We fed rats and mice a ketogenic or control diet for 2-3 weeks, prepared acute hippocampal slices, and performed electrophysiology and pharmacology in the seizure-prone CA3 region of hippocampus. Slices from ketogenic diet-fed animals showed reduced excitability, and seizure propensity depended on maintaining a reduced extracellular glucose level. This reduced excitability was not observed from control diet-fed rats and mice. The effects of the ketogenic diet could be reversed with blockers of adenosine A_1 receptors and were absent in slices obtained from ketogenic diet-fed mice lacking adenosine A_1 receptors, thus identifying specific mechanisms mobilized by the diet that influenced neuronal activity. These results suggest that the reduction of neuronal activity through activation of adenosine A_1 receptor is one of the key mechanisms underlying anticonvulsant effects of ketogenic diet.

Title: A novel role of adenosine A2B receptors in mediating calcium-activated small conductance potassium (SK) channel function at the synapse

Authors: *A. K. GARSKE[1], L.-R. B. WEITZEL[1], R. J. TRAYSTMAN[2], P. S. HERSON[1]

Abstract: After ischemic injury adenosine levels are highly elevated in the brain. The role of adenosine receptors in ischemic injury has been studied, however very little is known about the A2B adenosine in the brain. In peripheral organ ischemia-reperfusion causes the upregulation of A2B receptors and organ protection. In contrast, we made the remarkable observation that inhibition of A2B receptors provides robust protection against stroke injury in mice. Therefore, we used electrophysiology methods to explore potential mechanisms to explain the injurious role of A2B receptors in brain ischemia. Patch clamp recordings from adult mouse hippocampus demonstrate that pharmacologic activation of the A2B receptor leads to a reduction in SK channel mediated current. Synaptic recordings implicate this A2B regulation of SK channels is present at the synapse. Additionally, our findings suggest that this potential interaction between A2B receptor and SK channel activity may be mediated by a mechanism involving protein kinase A (PKA) dependent signaling. These findings propose a novel signaling interaction between A2B receptor signaling and SK channel functional activity, which may provide an improved understanding of SK channel regulation at the synapse. Further, these observations may have implications in neuronal excitability and efficacy of synaptic transmission, particularly after ischemic injury.

Title: The GAIN domain of the adhesion GPCR BAI1 regulates the constitutive activity of the receptor

Authors: *R. H. PURCELL, R. A. HALL
Emory Univ., Atlanta, GA

Abstract: Adhesion GPCRs are a family of more than 30 receptors that undergo autoproteolytic cleavage to separate their long, extracellular N termini (NT) from their 7-transmembrane regions. These receptors share a conserved G protein Autoproteolysis-Inducing (GAIN) domain, which mediates this proteolytic activity (Arac et al. 2013). Previous studies have shown that loss of the NT augments receptor signaling activity in several adhesion GPCR family members including brain-specific angiogenesis inhibitor 1 (BAI1), a Galpha12/13-coupled receptor that has been shown to regulate dendritic spine morphology in hippocampal neurons (Duman et al. 2013) and signal to the Rho, Rac, and ERK pathways (Duman et al., 2013; Stephenson et al. 2013, Park et al. 2007). BAI1 exhibits significant constitutive activity in cultured cells, but the mechanisms regulating receptor activity are currently unknown. We hypothesized that the GAIN domain of BAI1 might be a key regulator of receptor signaling activity. We prepared a Flag-tagged BAI1 GAIN domain construct and found that the GAIN domain binds robustly to both the BAI1-NT and full-length BAI1. Moreover, we found that co-transfection of the BAI1 GAIN domain modulates the constitutive activity of the full-length receptor, as assessed in multiple distinct assays. These data suggest that the constitutive activity of BAI1 is regulated by GAIN domain binding, which has implications for understanding how this receptor is activated in native cell types in the brain.

Title: The subcellular localization and local function of Gs-linked receptor GPR3 in neuronal cells

Authors: *T. MIYAGI[1], S. TANAKA[2], I. HIDE[2], T. SHIRAFUJI[2], N. SAKAI[2]
[1]Pharmacol Neurosci, Grad Sch. of Biomed & Hlth. Sc, Hiroshima, Japan; [2]Pharmacol Neurosci, Inst. of Biomed & Hlth. Sci., Hiroshima, Japan

Abstract: G-protein coupled receptor (GPR) 3 is a member of GPRs that constitutively activates adenylate cyclase. We have reported that the expression of GPR3 in cerebellar granular neurons (CGNs) enhances neurite outgrowth and modulates proliferation of CGNs. However, the subcellular localization and local function of GPR3 have not been fully elucidated. In the present study, we investigated the distribution of GPR3 in the CNS utilizing the GPR3 knockout LacZ knock-in mouse. X-gal staining for these mice revealed that GPR3 was distributed in the cortex, striatum, hippocampus, medial habenular nucleus, and cerebellum. We further determined the subcellular localization of GPR3 in cerebellar granular neurons (CGNs) using fluorescent-tagged GPR3. In CGNs, GPR3 was distributed along the plasma membrane and in endoplasmic reticulum and goldi body. To precisely analyze time-dependent distribution of GPR3 *in vivo*, we examined the distribution of GPR3 in CGNs using time-lapse imaging. Surprisingly, fluorescent punctae of GPR3 were translocated along the neurite in both directions. Moreover, translocation of GFP-GPR3 punctae was completely abrogated by administration of blebbistatin, which is a potential myosinIIinhibitor. We further asked if local distribution of GPR3 affects local activation of cAMP-PKA signaling pathway. PKA FRET indictor (AKAR3EV) analyses revealed that up-regulation of GPR3 resulted in activation of PKA in cell body and neurites, whereas local activation of PKA in the tips of neurite was inhibited by administration of blebbistatin or transfection of GPR3 siRNA in SH-SY5Y cells. There results thus indicated that GPR3 may be related with local PKA activation, thereby affect neurite outgrowth and neuronal polarization.

Title: Pharmacological implications of A2AR-D2R heteromerization; significance for Parkinson's disease

Authors: *C. N. HATCHER-SOLIS[1], D. E. LOGOTHETIS[2]
[2]Physiol. and Biophysics, [1]Virginia Commonwealth Univ., Richmond, VA

Abstract: Appreciation of the existence of oligomeric G protein-coupled receptor (GPCR) complexes with distinct signaling properties from their homomeric counterparts is growing. Yet, the effect of heteromerization on the pharmacology of many GPCR homomers remains unknown. We have undertaken the task to examine the effect of heteromerization on G_s signaling through the adenosine 2A receptor ($A_{2A}R$) and G_i signaling through the dopamine receptor type 2 (D_2R). Signaling through the $A_{2A}R$-D_2R heteromeric complex is of great interest as this heteromer is an emerging therapeutic target for Parkinson's disease. Previous work suggests the $A_{2A}R$ and D_2R display reciprocal antagonism, with $A_{2A}R$-mediated negative allosteric modulation of the D_2R and D_2R-mediated negative allosteric modulation of the $A_{2A}R$. We sought to develop an electrophysiological assay for $A_{2A}R$-D_2R heteromer and homomer signaling. Our objective is to determine using this assay whether combining D_2R full agonists and $A_{2A}R$ inverse agonists targeting the $A_{2A}R$-D_2R heteromer will potentiate dopaminergic, G_i signaling more than sole stimulation of the D_2R. We heterologously expressed GIRK channels that can serve as reporters for GPCR signaling through G_i and G_s. *Xenopus laevis* oocytes injected with cRNA for GIRK1, GIRK2, D_2R, $A_{2A}R$, and $G_{\alpha s}$ were used for our heterologous expression system and currents were measured using two-electrode voltage-clamp. GIRK channels were used as reporters for GPCR signaling because GPCR activation leads to direct $G\beta\gamma$-mediated stimulation of the GIRK current. Preliminary data have demonstrated that heteromer formation decreases dopamine-elicited G_i signaling through the D_2R and CGS-21680-elicited G_s signaling through the $A_{2A}R$. Furthermore, this reciprocal antagonism seemed to occur through a wide cRNA GPCR injection ratio. Currently, we are examining crosstalk by assessing whether addition of agonists or inverse agonists to the $A_{2A}R$ is able to decrease or increase respectively the D_2R-mediated G_i

signaling through the $A_{2A}R$-D_2R heteromer. Modulation of G_s signaling through the $A_{2A}R$ by D_2R ligands is also being examined. Once we have characterized G_s and G_i signaling through the $A_{2A}R$-D_2R heteromer in our heterologous expression system, we will validate the results in native cells to ensure the physiological relevance of such signaling. Characterization of the signaling pathway through the $A_{2A}R$-D_2R heteromer will provide insight into what ligands optimize dopaminergic signaling, which may advance Parkinson's disease pharmacotherapy.

Title: Design and synthesis of N-substituted indoles as selective hMT2 melatonin receptor ligands

Authors: *M. L. DUBOCOVICH[1], E. B. NARANJO-RODRIGUEZ[2], A. LIRA-ROCHA[2], O. ESPEJO-GONZALEZ[2], R. V. RAJNARAYANAN[1]
[1]Dept. of Pharmacol. and Toxicology, Sch. of Med. and Biomed. Sciences, Univ. at Buffalo, Buffalo, NY; [2]Dept. of Pharmacy, Facultad de Química, Univ. Nacional Autónoma de México, Mexico City, Mexico

Abstract: The goal of this study was to design, synthesize and iteratively optimize a mini-library of N-substituted indoles with high selectivity for the MT_2 melatonin receptors. Theoretical models of human melatonin receptors were generated using the x-ray crystal structures of rhodopsin [PDB ID: 1L9H] and beta-2 adrenergic G-protein-coupled receptor [2RH1; 3NYA; 3SN6]. To enhance the predictability of these models, a curated list of ligands with affinity for melatonin receptors were used to generate pseudo-receptor spaces (PRS) and as shape/volume filters of 3D melatonin receptor models. An ensemble of functionally relevant receptor conformations of melatonin receptors were generated by high-throughput hierarchical helical search by translation and rotation of transmembrane helices followed by combinatorial docking

of PRS of active melatonin ligands. A total of ~15 million ligand-melatonin receptor complexes were analyzed to gauge the conformational dynamics and ligand induced changes in receptor architecture. MT_1 receptor rotamers with TM3 and TM5 at 330 and 240 degrees positioned H195, S110 and S114 to provide space within the binding site to accommodate melatonin. A further translation in the x-direction was required to enhance melatonin binding through H-bonding interactions with S110 and S114. Using these predictive MT_1 and MT_2 melatonin receptor models we designed, synthesized and iteratively optimized a mini-library of N-substituted indoles. In silico analysis of the top MT_2 ligand, with Ki values of 17.0 $\pm$ 1.4 nM (n=6) and 1848$\pm$1.4 nM (n=6) for MT_2 and MT_1 receptor, respectively [MT_1/MT_2 affinity ratio = 115] revealed several residue clashes [VAL111, ILE112, ILE115 and PHE116] in the MT_1 receptor binding pocket and none in the MT_2 receptor pocket, indicative of MT_2 selectivity. The high number of ligands with MT_2 selectivity in this library can be attributed to the ring stacking interactions with W264, F209, H208 and hydrophobic interactions with M120, V124, I125, F129, L172, Y183, F192, V205 and L267. Furthermore, the MT_2 melatonin receptor binding constants of these compounds was proportional to the hydrophobicity of the N-aryl substituent. Optimization of this lead molecule could result in highly selective MT_2 melatonin receptor ligands.

Title: Differential expression of cannabinoid receptors, monoacylglycerol lipase and fatty acid amide hydrolase in neurons and glia cells

Authors: M. ENGELSKIRCHEN[1], N. PASQUARELLI[1,2], H. BAYER[1], J. HANSELMANN[1], *P. WEYDT[1], B. FERGER[2], A. WITTING[1]

[1]Neurol., Ulm Univ., Ulm, Germany; [2]CNS Dis. Res., Boehringer Ingelheim Pharma GmbH & Co. KG, Biberach/Riß, Germany

Abstract: The endocannabinoid system (ECS) represents a potential therapeutic target for neurodegenerative diseases. ECS consists of the cannabinoid receptors CB_1 and CB_2, the endocannabinoids (eCBs) and the enzymes involved in synthesis and degradation of the eCBs. In our study we investigated the expression of CB_1 and CB_2 and of the endocannabinoid hydrolyzing enzymes monoacylglycerol lipase (MAGL) and fatty acid amide hydrolase (FAAH) in different cell types of the brain. The expression levels of CB_1, CB_2, FAAH and MAGL were quantified in primary mouse neurons, astrocytes, oligodendrocytes and microglia on mRNA level by qPCR and on protein level by Western blot. The cellular localization of CB_1, CB_2, FAAH and MAGL was investigated by immunocytochemistry. We found that CB_1 receptors were highly expressed in neurons and CB_2 receptors were highly expressed in microglia. MAGL and FAAH were mostly expressed in astrocytes, whereas microglia expressed relatively low levels of MAGL and FAAH. Our results confirm that CB_2 ligands will mainly induce an effect on microglia, whereas CB_1 ligands will mainly induce effects in neurons. Inhibitors of MAGL and FAAH will target mainly astrocytes that might play a key role in mediating neuroprotective and anti-inflammatory effects related to MAGL and/or FAAH inhibition.

Title: Activating the histamine H1 receptor induces gamma oscillations in the rat hippocampus

Authors: *R. H. ANDERSSON[1,2], D. PAPADIA[2], D. GALTER[1], A. FISAHN[2]
[1]Karolinska Institute, Dept. of Neurosci., Stockholm, Sweden; [2]Neurobiology, Care Sci. and Society, Karolinska Inst., Huddinge, Sweden

Abstract: From a neurophysiological perspective wakefulness is characterized by mild depolarization of principal neurons of cortical structures and parts of the thalamus and the cessation of slow-wave activity. Histamine is a biogenic amine, which is a key transmitter in the arousal and wakefulness system of the mammalian brain. It has been shown to have largely excitatory actions in the hippocampus where it promotes burst firing in pyramidal cells. Because the hippocampal area CA3 has a strong tendency to generate gamma oscillations (30-80Hz) when exposed to an excitatory neurotransmitter we hypothesized that histamine may promote such rhythmic network activity. Indeed we found that histamine dose-dependently elicits gamma oscillations and this histamine-induced rhythmogenesis depends on the H1 receptor but not H2 or H3. We also showed that rhythmogenesis was independent of indirect release of acetylcholine. Using *in-situ* hybridization with probes for the H1, H2 and H3 receptors respectively, we observed that they were all expressed in *stratum pyramidale* with little expression outside this layer. The H2 and H3 receptors were also expressed in CA1 whereas the H1 receptors were almost exclusively expressed in CA3, suggesting that they might have a specialized role there. Both pyramidal cells and fast-spiking interneurons exhibited a depolarization as well as a decrease in membrane resistance in response to histamine. We did not observe any effect on synaptic charge transfer for excitatory or inhibitory postsynaptic currents recorded in pyramidal cells. Rather, it was an increased synchronization of inhibitory postsynaptic currents that seems to underlie the rhythmogenic effect of histamine.

Title: Molecular recognition of ketamine by discrete olfactory G-protein coupled receptors

Authors: *J. HO[1], L. GAO[3], J. M. PEREZ-AGUILAR[4], J. G. SAVEN[3], R. ECKENHOFF[5], H. MATSUNAMI[2]

Col., New York, NY; [5]Dept. of Anesthesiol. and Critical Care, Perelman Sch. of Medicine, Univ. of Pennsylvania, Pennsylvania, PA

Abstract: Ketamine is a well-known N-Methyl-D-aspartate (NMDA) receptor antagonist with a wide variety of pharmacological effects, including sedation, analgesia, hallucinations, and general anesthesia. However, the underlying molecular mechanisms that mediate these effects, particularly the anesthetic effects, remain unknown. Specifically, ketamine's interactions with G-protein coupled receptors (GPCRs) have been little studied. We aim to use olfactory GPCRs (ORs) as a model to study the ketamine-GPCR interaction by taking advantage of their ligand-binding diversity and sequence and structural similarity for insights into the ketamine binding pocket. Using an in-vitro screen for OR ligand activation, we identified 4 ORs (MOR136-1, MOR136-3, MOR136-5 and MOR139-1) that respond to ketamine in a dose-dependent manner. We then applied a combination of molecular homology modeling and site-directed mutagenesis to examine key ketamine binding residues in the MOR136-1, and were able to increase (D109), reduce (S105) and abolish (S112) its ketamine response via single site mutations at the indicated residues. Finally we were able to introduce ketamine response in a non-responder, MOR136-4, again by a single site mutation at Y104. All four residues are located in the third transmembrane domain (TM3), suggesting its importance in ketamine binding and response. Our results suggest that GPCRs could, at the minimum, serve as functional targets for ketamine, and our ability to abolish and introduce responsiveness in specific receptors suggest a signature binding pocket that can be used to further explore other protein structures for more candidate ketamine receptors.

Title: When entourage gets in the way: The curious case of 2-og and 2-lg

Authors: *N. MURATAEVA, K. MACKIE, A. STRAIKER
Indiana Univ., Bloomington, IN

Abstract: 2-Arachidonoylglycerol (2-AG) is the most abundant endogenous cannabinoid in the brain and is a high efficacy agonist at both cannabinoid receptors (CB1 and CB2). Over the past years the synthesis, degradation and signaling of 2-AG have been investigated in some detail. However, several other endogenous monoacylglycerols have been isolated from various tissues, but their pharmacology has not been fully explored. Two of these are 2-linoleoylglycerol (2-LG) and 2-oleoylglycerol (2-OG), also a GPR119 agonist. The current data suggest that these compounds do not bind to the cannabinoid receptors. Nor do they affect intracellular free Ca2+ levels or adenylyl cyclase activity in a CB1-dependent manner. However, the presence of these compounds has been reported to potentiate the activity of 2-AG and slow its degradation, possibly through competitive inhibition of 2-AG degradation. This phenomenon has been dubbed the 'entourage effect' and may be a means to regulate synaptic activity. To clarify the activity of these lipids at the CB1 receptor we employed patch-clamp and cell-based assays. For the former we used cultured autaptic hippocampal neurons, i.e. self-synapsing neurons that have the necessary cellular machinery for several forms of endocannabinoid-mediated synaptic plasticity. This includes the 2-AG-, CB1-, and MAGL-dependent retrograde form of neuronal signaling known as depolarization-induced suppression of excitation (DSE), making it a useful model to test for a potential entourage effect. Our electrophysiological data show that 2-OG and 2-LG do not inhibit neurotransmission via CB1 when applied to autaptic neurons. However, these compounds fail to potentiate the 2-AG-dependent DSE. Instead 2-OG and 2-LG behave as antagonists at the CB1 receptor, attenuating DSE. This result is inconsistent with an 'entourage effect'. Interestingly 2-OG and 2-LG do internalize CB1 receptors in CB1-HEK cells, as shown by an on-cell western assay, indicating that these compounds do activate CB1 receptors under some conditions. Our results suggest 1) that these compounds may serve as functional antagonists under certain conditions and, interestingly, 2) that these compounds may exhibit functional selectivity in their signaling. Our results suggest that the relationship between 2-AG and its congeners may be more nuanced than previously appreciated.

Title: Functional G-protein coupled receptor 35 (GPR35) in rat hippocampal CA1 stratum radiatum interneurons

Authors: *M. ALKONDON, E. F. R. PEREIRA, S. W. TODD, M. LANE, E. X. ALBUQUERQUE

Abstract: G-protein coupled receptor 35 (GPR35) was de-orphanized after the discovery that kynurenic acid (KYNA) acts as an agonist of this receptor. Abundant evidence supports that GPR35 exists primarily in peripheral tissues. Here, we tested the hypothesis that GPR35 exists in the hippocampus and remains a molecular target for the actions of KYNA in the CNS. Fluorescence immunohistochemical staining using an antibody anti-NeuN (a neuronal marker), an antibody anti-GFAP (a glial marker), and an antibody anti-GPR35 revealed that neurons in the stratum oriens, stratum pyramidale and stratum radiatum of the CA1 field of the hippocampus express GPR35. To determine whether these receptors are functional, we tested the effects of various GPR35 agonists on the frequency of spontaneous action potentials recorded as fast current transients (CTs) from stratum radiatum interneurons (SRIs) under cell-attached configuration in rat hippocampal slices. Bath application of the GPR35 agonists zaprinast (1-10 μM), dicumarol (50-200 μM), pamoic acid (500-1000 μM), and amlexanox (3 μM) produced a concentration- and time-dependent reduction in the frequency of CTs. Superfusion of the hippocampal slices with the GPR35 antagonist ML145 (1 μM) increased the frequency of CTs and reduced the inhibitory effect of zaprinast and dicumarol. At concentrations ranging from 200 nM to 1000 nM, KYNA also decreased the frequency of CTs. The present results demonstrate that functional GPR35s are expressed by CA1 SRIs and suggest that these receptors can be molecular targets for KYNA's actions in the hippocampus.

Title: The role of CB2 cannabinoid receptors in regulating synaptic transmission

Authors: *J. KIM
Georgia Regents Univ., Augusta, GA

Abstract: Major endocannabinoids (e.g., 2-arachidonoylglycerol, anandamide) and cannabis components (e.g., Δ9-tetrahydrocannabinol) can activate two types of cannabinoid receptors--CB1 and CB2 receptors (CB1R and CB2R, respectively). In the brain, the effects of cannabinoids have been studied mostly in relation to CB1R in part because early evidence indicated that CB2R was present in the immune system but not in the brain. However, CB2Rs have been recently discovered in the brain and implicated in various neuropsychiatric phenotypes, suggesting their involvement in a variety of brain functions such as anxiety, addiction, depression and schizophrenic behaviors. Despite recent information about the presence and behavioral effects of CB2Rs, it is largely unknown how CB2Rs regulate neuronal functions at the cellular level. In the hippocampus, CB2Rs are located in the soma and dendrites of neurons, especially near synaptic contacts, as well as in microglia, but the role of CB2Rs in modulating synaptic function remains elusive. The objective of this study is to determine the role of CB2Rs in regulating synaptic transmission. Postsynaptic currents were recorded from CA1 pyramidal neurons in organotypic cultures of the rat hippocampus. CB2R agonists were found to change the properties of glutamatergic synapses via extracellular signal-regulated kinases. This study reveals a novel function of CB2 receptors in the hippocampus. It will be interesting to further identify the signaling cascade and CB2R location that are involved in the synaptic regulation.

Title: Subcellular mobility of the trans-Golgi-associated PDZ protein PIST in endocrine cells

Authors: W. ALSHAFIE[1], Y. PAN[1], H. J. KREIENKAMP[2], *T. STROH[1]
[1]Neurol. and Neurosurg., Montreal Neurolog. Institute, McGill Univ., Montreal, QC, Canada;
[2]Inst. fuer Humangenetik, Universitaetsklinikum Hamburg-Eppendorf, Hamburg, Germany

Abstract: The Protein Interacting Specifically with Tc10 (PIST) is a Golgi resident PDZ protein implicated in sorting at the trans-Golgi-network (TGN). For instance, PIST protects Somatostatin (SOM) Receptor subtype 5 (sst5) from lysosomal degradation by trapping it in the Golgi before its engagement in the recycling pathway (Bauch et al, 2014). Here we used immuno labelling and confocal microscopy followed by fluorescence intensity profile analysis to examine the effect of somatostatinergic agonists on PIST subcellular distribution and its association with trafficking adaptors in the endocrine AtT20 cell line that endogenously expresses several SOM receptor subtypes (sst1, 2, 4, and 5). As expected, we observed a high peak of PIST immunofluorescence at the TGN under control non-stimulated conditions. Interestingly, following stimulation with the sst2-selective agonist L779,976 (0 to 60 minutes), while the main peak of PIST was still associated with the Golgi, over time smaller fluorescence peaks appeared at the cell periphery associated with PIST-positive vesicular structures. They appeared to be located just beneath the plasma membrane as visualized by immuno labelling for the sst2A receptor. This apparent mobilization of PIST positive structures from TGN to the cell periphery appeared to rely on sst2 activation since L779,976 is highly selective for sst2 over other SOM receptor subtypes. We also observed an increased co-localization of PIST and a recycling adaptor, Rab11a, following sst2 stimulation suggesting a possible role for PIST in the recycling pathway. Based on these observations, we propose an important role for PIST in the regulation of trafficking from the Golgi compartment including the regulation of recycling.

Title: Contribution of adenosine A1 and A2A receptors to hypoxia-reperfusion synaptic potentiation in rat hippocampus

Authors: *J. STOCKWELL, Z. MING, Z. CHEN, F. S. CAYABYAB
Dept. of Physiol., Univ. of Saskatchewan, Saskatoon, SK, Canada

Abstract: Adenosine is a principal regulator of synaptic depression in various neuronal insults such as hypoxia/ischemia. Hypoxic insult to the vulnerable hippocampus induces a substantial increase in extracellular adenosine and subsequent synaptic depression, which is mediated by activation of the adenosine A1 receptor. The inhibitory adenosine A1 receptors are widely believed to be neuroprotective in these insults, whereas the excitatory A2A receptors promote neurotoxicity. We previously showed that a 20-minute hypoxic insult followed by a 45-minute normoxic reperfusion period induced rapid synaptic depression in hypoxia followed by significant post-hypoxic potentiation during reintroduction of oxygen. Accordingly, we showed that A1 receptors mediate synaptic depression through internalization of AMPA glutamate receptors, namely GluA1 and GluA2 AMPA receptor subunits. We hypothesized that the significant post-hypoxic potentiation is caused by A2A receptor activation, which we have shown causes increased GluA1-AMPA receptor surface expression. We tested hippocampal slices incubated in SCH 442416, an A2A receptor antagonist, and DPCPX, an A1 receptor antagonist followed by a 20-minute hypoxic insult and a 45-minute normoxic washout. Electrophysiological fEPSP recordings show that SCH 442416 prevented post-hypoxic potentiation, allowing fEPSPs to recover to baseline levels, and was accompanied by less GluA1 upregulation compared to control, as shown by biochemical analysis. Paired-pulse ratio (PPR) analysis showed significant paired-pulse facilitation in hypoxia in presence of SCH 442416 (decreased probability of neurotransmitter release), similar to control. However, during reperfusion of normoxic solutions, SCH 442416 caused recovery of PPR to baseline levels, while control slices showed paired-pulse depression (increased probability of transmitter release). Interestingly, DPCPX not only reduced hypoxia-induced synaptic depression, but also prevented post-hypoxic potentiation and GluA1 surface expression. These results suggest that a cross-talk between the adenosine A1 and A2A receptors primes A2A receptors for adenosine-mediated excitotoxic potential in cerebral ischemia/reperfusion injury.

Abstract: Reports from the last decade overwhelmingly implicate synaptic dysfunction in most, if not all, Autism Spectrum Disorders (ASD). Synaptic structure and function are tightly coordinated by signal exchange between both glia and neurons. Understanding the mechanism(s) through which glia and neurons regulate synaptic transmission is critical to understanding ASD-associated synaptic deficits. Several groups report finding astrocyte activation and neuronal hyperexcitability in ASD mouse models. Interestingly, activated astrocytes release matrix metalloproteinases (MMPs), a family of extracellular matrix protein proteases. MMPs may potentiate neuronal excitability through activation of glial-neuronal signaling, which may contribute to the hyperexcitability phenotype found in ASD. MMP-1 is known to activate protease-activated receptor 1 (PAR1), a G-protein-coupled receptor (GPCR) that is highly expressed in both astrocytes and neurons. Previous studies have shown activation of astrocytic PAR1 canonical G protein signaling triggers a Ca^{2+}-dependent release of glutamate that potentiates neighboring neurons. Therefore, we questioned whether astrocyte-derived factors play a role in astrocyte to neuron signaling *in vitro* and *in vivo*. More specifically, we investigated the astrocytic modulation of neuronal responses via MMP-1 mediated activation of PAR1. In the present study, we utilized novel transgenic mice that overexpress the potent PAR1 activating protein, human MMP-1 (hMMP1), under the direction of an astrocyte specific promoter to assess astrocyte to neuron signaling. First, we use a combination of complementary mass spectrometric methods to measure MMP-1 specific activation of PAR1. Next, we examine the role mobilization of intracellular astrocyte calcium plays in the release of glial glutamate with

several calcium imaging experiments. Lastly, we employ the use of multielectrode arrays (MEAs) to study the effect of astrocyte-derived factors on neuronal action potential frequency. MMP1-mediated activation of PAR1 in astrocytes has not yet been reported in the context of neurodevelopmental disorders, thus this proposal offers an innovative approach to assess the therapeutic potential of PAR1 inhibitors.

Abstract: Extracellular nucleotides acting at Gq- and Gi-coupled P2Y receptors (P2YRs) modulate biological processes in many organs and tissues. We explore novel P2YR agonists and antagonists, to identify selective agents as pharmacological probes and potential therapeutic agents. We designed fluorescent conjugates of functionalized congeners that display high P2YR

affinity, for characterization of these GPCRs in living cells by flow cytometry and in cell membranes. Fluorescent agonists are mostly internalized consistent with agonist-induced receptor internalization, and this labeling is attenuated by specific P2YR ligands. Examples are MRS4129 and MRS4162, which are fluorescent pyrimidine nucleotides, respectively, selective for the P2Y6R (EC50 9 nM, phospholipase C activation) and high affinity pan-agonist at P2Y2R,P2Y4R and P2Y6R (expressed in astrocytoma cells). We synthesized P2Y14R fluorescent antagonists based on potent and highly selective 2-naphthoic acid derivative PPTN. We modeled the hP2Y14R based on recent hP2Y12R X-ray structures and simulated docking, suggesting that a piperidine of PPTN is accessible for tethering fluorophores. Click chemistry was used to conjugate functionalized PPTN alkyne derivatives and azide-bearing fluorophores. Flow cytometry showed high specific P2Y14R binding of AlexaFluor488 derivative MRS4174 (Ki 80 pM, cAMP inhibition in P2Y14R-expressing CHO cells). Known P2Y ligands inhibited cell labeling consistently with affinity order. Thus, the 3D knowledge of ligand recognition in GPCRs promises to enable drug discovery through design of fluorescent molecular probes for P2YRs. This approach demonstrates the predictive power of GPCR homology modeling and the value of applying newly determined X-ray structures to the medicinal chemistry of GPCRs.

Title: Novel insights on the allosteric mechanism of alfaxolone interaction with rP2X4 receptor opening, lessons from structural biology analysis

Authors: *J. T. GARCÍA-HUIDOBRO[1,2], N. ALVEAL[3], C. H. NAVARRETE[3], N. P. BARRERA[3]

[1]Fisiologia, Facultad Ciencias Biológicas, Pontificia Univ. Católica De Chile, Santiago, Chile, Chile; [2]Dept. de Biologia, Lab. de Nucleotidos, facultad de Quimica y Biologia, Univ. de Santiago de Chile, Santiago de Chile, Chile; [3]Lab. de Proteinas de membrana y señalizacion celular, Dept. de Fisiologia., Pontificia Univ. Catolica de Chile, Santiago de Chile, Chile

Abstract: Danio rerio P2X4 receptor crystals (zfP2X4R) with and without ATP in the orthosteric site offered the possibility of understanding at the structural/atomic level the function of this receptor channel. Alfaxolone, a prototype neurosteroid, elicited a positive allosteric modulation of the rP2X4R through an interaction occurring likely in the transmembrane (TM) rP2X4R domain; larger steroid concentrations elicited per se an ionic current, suggesting pore opening in the absence of ATP (Codocedo et al., 2009). We aimed at characterizing the steroid binding site and understand how the structure of the pore changes in response to alfaxolone binding to the TM domain of rP2X4R. Based on the crystallized zfP2X4R in the apo and holo (ATP-bound) states, corresponding rP2X4R models of the extracellular and TM domains for both states were built, including the modelling of the N and C-terminus cytoplasmic tails which are absent in the crystallized zfP2X4R. The rP2X4R model was embedded in an artificial lipid membrane environment; all atom molecular dynamics (MD) simulations with three docked alfaxolone molecules were developed during 100 nanoseconds. MD calculations not only allowed identifying the steroid binding site, but also the eventual conformational alternations elicited by steroid binding. Results reveal that in the apo state, 3 alfaxolone molecules interact with the TM domain throughout the simulation; however, only a single steroid forms hydrogen bonds across the subunit interface of the TM, while the other two steroid molecules only bind to the TM domain of the binding subunit. Channel activation involved the separation between the TM helices of neighboring subunits (Hattori & Gouaux, 2012). Single alfaxolone binding may partially open the rP2X4R pore, as evidenced by the increases in the solvent accessible surface area for Val-47 (subunit A) and Asn-338 (subunit C) when comparing the apo state with alfaxolone and apo state without alfaxolone, a feature also observed between the apo and holo structures of rP2X4R and zfP2X4R. These data provides insights of the direct alfaxolone effect, helping to understand the motion of the pore during rP2X4R channel gating. The interaction of neurosteroids eliciting a negative allosteric modulation will be promptly examined on the rP2X4R.

Title: When BigLEN met GPR171: A tale of a recently deorphanized neuropeptide/receptor system

Authors: *E. N. BOBECK, J. WARDMAN, I. GOMES, L. DEVI
Icahn Sch. of Med. at Mount Sinai, New York, NY

Abstract: Receptor systems of the hypothalamus are considered attractive targets for the development of therapeutics regulating food intake, satiety and body weight regulation. Recent neuropeptidomics studies have demonstrated that ProSAAS-derived peptides are among the most abundant peptides present in the hypothalamus; these peptides are greatly enriched in the agouti related peptide neurons of the arcuate nucleus. Additional studies have implicated Big LEN (b-LEN), the peptide derived from ProSAAS in acute feeding. Recently we deorphanized GPR171, as a hypothalamic G protein-coupled receptor for b-LEN. GPR171 is a Gαi/o coupled receptor activated by the C-terminal region of b-LEN. Overexpression of GPR171 leads to an increase and knock-down leads to a decrease in b-LEN-binding and signaling. In the hypothalamus GPR171 expression complements the expression of b-LEN; the levels and activity of GPR171 are elevated in mice lacking b-LEN. Lentiviral shRNA-mediated knock-down of GPR171 in the hypothalamus leads to alterations in food intake and metabolism. To further investigate the role of GPR171 in the orexigenic properties within the arcuate nucleus, a designer receptor exclusively activated by designer drugs (DREADD) approach was used targeting b-LEN containing, agouti related peptide neurons. Activation of these neurons with clozapine-N-oxide induced food intake; the role of b-LEN and other neuropeptides released from these neurons in food intake is currently being investigated. To explore the physiological involvement of GPR171 in modulating additional behaviors, we examined its distribution in mouse brain and find expression in dentate gyrus, pedunculopontine nucleus, and preriaqueductal gray suggesting potential role for GPR171 on a number of behavioral outcomes. Further studies are underway to investigate the role of GPR171 in addiction, Parkinson’s disease, and pain processing. This work

Title: Potential association between a mutation in the brain-expressed receptor GPR37L1 and a novel inherited neurological disorder

Authors: ***M. M. GIDDENS**[1], E. G. FARROW[2], S. E. SODEN[2], R. A. HALL[1]
[1]Pharmacol., Emory Univ. Sch. of Med., Atlanta, GA; [2]Dept. of Pediatrics, Ctr. for Pediatric Genomic Med., Children's Mercy Hosp. and Clinics, Kansas City, MO

Abstract: GPR37-like-1 (GPR37L1) is a G protein-coupled receptor that is expressed almost exclusively in the central nervous system. This receptor has been previously shown by our lab to be activated by prosaposin, a secreted factor with neuroprotective and glioprotective actions (Meyer et al., Proc. Natl. Acad. Sci. USA, 2013). Stimulation of GPR37L1 by prosaposin mediates cytoprotective signaling in astrocytes and other cell types in the brain. Recently, exome mapping in a large, consanguineous family of Middle Eastern descent has identified a point mutation in the GPR37L1 gene as the single candidate mutation for inheritance of a previously-undescribed recessive monogenic disorder. Affected children develop severe migraines and seizures around the onset of puberty, which is followed by cortical atrophy and ultimately death by the late teens. The mutation in the GPR37L1 gene results in a lysine to asparagine substitution (K349N) in the middle of the receptor's third cytoplasmic loop. To better understand the functional consequences of the GPR37L1 K349N mutation and assess whether this mutation underlies the pathology observed in the affected family, we have created a GPR37L1 expression construct with the K349N mutation. Ongoing studies are assessing the expression, trafficking, signaling and function of the K349N mutant receptor in transfected cells. These studies will shed new light on the fundamental properties of GPR37L1 and potentially provide insights regarding potential treatment options for the affected family.

Emory Univ. Sch. of Med., Atlanta, GA

Abstract: GPR37 is an orphan G protein-coupled receptor that is highly expressed in the brain. Previous work from our lab has shown that GPR37 is a receptor for the secreted neuroprotective and glioprotective factor prosaposin and that prosaposin acts through GPR37 to protect cultured astrocytes from oxidative stress-induced cell death (Meyer et al., Proc. Natl. Acad. USA, 2013). Interestingly, several reports indicate that GPR37 is expressed at particularly high levels in oligodendrocytes (Imai et al., Cell, 2001; Cahoy et al., J. Neurosci., 2008). Furthermore, prosaposin has also been shown to enhance the survival of oligodendroglia *in vitro* and also promote myelination *in vivo* (Hiraiwa et al., Proc. Natl. Acad. Sci. USA, 1997; Hiraiwa et al., Glia, 1999). However, despite the aforementioned evidence for GPR37 expression in oligodendroglia, the role(s) that GPR37 and its ligand prosaposin may play in oligodendroglial biology remain uncharacterized. Using enriched oligodendrocyte cultures and mixed glial cultures generated from either wild type (WT) or GPR37 knockout (GPR37KO) C57Bl/6 neonatal mice, we investigated the role of GPR37 in oligodendroglial survival. We found that oligodendrocytes generated from GPR37KO mice are less viable in culture than oligodendrocytes generated from WT mice. Furthermore, we also observed that GPR37KO oligodendrocytes are more susceptible than their WT counterparts to death induced by oxidative stress via hydrogen peroxide treatment. Together, these data suggest that GPR37 is important for oligodendroglial survival and protection against insults. Ongoing studies in this area seek to elucidate the signaling pathways downstream of GPR37 that promote the survival of oligodendroglia.

Title: Guanyl nucleotide modulation of the dopamine D3 receptor in rat brain cerebellum lobule 9&10

Authors: *N. C. STRATMAN, C. J. SCHMIDT
Neurosci. Res. Unit, Pfizer Inc., Cambridge, MA

Abstract: The functional nature of the dopamine D3 receptor (D3R) has typically been investigated in recombinant cell lines, and many studies have identified weak or nonexistent G-protein dependent coupling in these systems. It has not been clear if recombinant cells lines have the appropriate G-proteins or secondary messenger systems necessary for adequate responses of D3R activation. As such, investigation of the D3R in its native environment may provide insights into to the mechanisms needed to elicit intracellular responses. Since the D3R is only moderately expressed in the same brain regions of high levels of dopamine D2 receptors (D2R) such as in the ventral striatum, discrimination between the two receptors has proved difficult with non-selective ligands. However, the D3Rs are moderately expressed in cerebellum lobules 9 and 10 without the presence of the D2R. The current investigation profiled the binding of radiolabeled D3R agonists in rat cerebellum lobules 9 and 10 in the absence or presence of guanyl nucleotides to identify modulation of the D3R as an indication of activation of the receptor through coupling to native G-proteins. Autoradiography has been utilized to provide the most sensitive method to quantify changes in radioligand binding.

Title: GPCR-Gs-NCS/Rapgef2 coupling: A novel pathway to ERK activation in neuroendocrine cells

Authors: M. V. EIDEN[1], A. C. EMERY[2], *L. E. EIDEN[2]
[1]Sec Directed Gene Transfer, [2]Sec Molec Neurosci, NIH, NIMH-IRP, BETHESDA, MD

Abstract: It is generally accepted that G-protein coupled receptors (GPCRs) that engage Gs and activate adenylate cyclase exert effects on neuronal function through the activation of multiple cAMP sensors, including protein kinase A, the Rap guanine nucleotide exchange factors Epac1 and 2, cyclic nucleotide-gated calcium channels, and cyclic nucleotide-gated potassium channels. We have characterized a cAMP-dependent factor mediating neuritogenesis through ERK phosphorylation, initiated by PACAP occupancy of the family B GPCR PAC1, and termed this the neuritogenic cAMP sensor (NCS). We have recently identified the NCS as the protein product of the Rapgef2 gene. We now report on some new features of NCS/Rapgef2 function in neuroendocrine cells, based on the creation of a 293 cell line expressing hRapgef2, and preliminary results on NCS/Rapgef2 coupling to GPCRs in addition to the PAC1 receptor. We have reported that functional full-length Rapgef2 is expressed in cell lines of neuroendocrine lineage, but not in several non-neuroendocrine cell lines commonly used for high-throughput GPCR ligand and antagonist screening (Emery et al., *Science Signaling* **6**: ra51, 2013). To study the role of this protein in GPCR-initiated cAMP signaling, *in cellula,* we have therefore created a series of indicator cell lines based on the 293_CREB-luciferase reporter gene line (Promega), and a 293_Elk-luciferase reporter gene line constructed via sequential retroviral transduction/limiting dilution cell cloning, in which we have transduced various human GPCRs, and/or hRapgef2, each under the control of the CMV promoter, via introduction as retroviral vector integrants. We have also introduced GPCRs via retroviral gene delivery into rat neuroendocrine NS-1 cells, in which neurite extension caused by elevation of cAMP is mediated exclusively through the NCS/Rapgef2->Rap->Raf->MEK->ERK signaling pathway. We find that a diverse array of family B (PAC1, VPAC1, VPAC2) GPCRs, and a family A (D1) Gs-coupled GPCR, cause either ERK-dependent neuritogenesis in NS-1 cells, or ERK activation sensitive to adenylate cyclase inhibition in 293 cells only when expressing both hRapgef2 and the appropriate GPCR, when cells are stimulated by the cognate receptor ligand PACAP, VIP or SKF 81297. The availability of cell lines expressing GPCR and hRapgef2 from single-copy genes, to avoid both receptor reserve, and signaling pathway misactivation, and amenable to high-throughput screening for GPCR-initiated activation of ERK, should be useful tools in GPCR-based CNS drug discovery.

Title: Tricyclic and tetracyclic antidepressants activate LPA_1 lysophosphatidic acid receptor signaling in glial cells

Authors: *P. ONALI, S. DEDONI, M. C. OLIANAS
Biomed. Sci., Univ. of Cagliari, Monserrato, Italy

Abstract: Although inhibition of presynaptic monoamine reuptake or metabolism is generally considered the main mechanism of action of antidepressants (AD), there is a large body of evidence indicating that the pharmacological actions of these drugs can also derive from their direct interaction with additional molecular targets. We have previously reported that different classes of AD can activate LPA_1 lysophosphatidic acid (LPA) receptor in Chinese hamster ovary cells to induce growth factor receptor transactivation. In the present study we extended this observation by examining the ability of different AD to induce LPA_1 signaling in glial cells, which are considered a relevant cellular target of AD therapeutic action. We found that in C6 glioma cells the tricyclic AD amitriptyline, desipramine, imipramine and nortriptyline, the tetracyclic AD mianserin and mirtazapine increased the phosphorylation state of extracellular signal-regulated kinases 1 and 2 (ERK1/2) in a pertussis toxin (PTX)-sensitive manner. The $LPA_{1/3}$ antagonist Ki16425 and the selective LPA_1 antagonist AM966 reduced the stimulatory effect on ERK1/2 phosphorylation elicited by either amitriptyline, mianserin or LPA. The LPA receptor antagonists also counteracted the increased phosphorylation of the transcription factor CREB and the prosurvival protein kinase Akt induced by either amitriptyline or mianserin. Similar results were obtained in rat cortical astrocytes, where amitriptyline and mianserin activated ERK1/2 in a manner sensitive to PTX, Ki16425 and AM966. Moreover, treatment of C6 glioma cells with LPA_1 siRNA inhibited ERK1/2 phosphorylation by amitriptyline and mianserin. The data provide evidence that in glial cells tricyclic and tetracyclic AD activate LPA_1 receptor coupled to signaling pathways regulating cell survival and differentiation.

Title: Dopamine and serotonin transporter release activity of phenmetrazine analogs

Authors: *A. M. DECKER[1], A. LANDAVAZO[1], J. S. PARTILLA[2], B. E. BLOUGH[1], M. H. BAUMANN[2], R. B. ROTHMAN[2]
[1]RTI Intl., RTP, NC; [2]Natl. Inst. on Drug Abuse, Baltimore, MD

Abstract: Monoamine releasers represent one class of compounds currently being evaluated as potential agonist medications to treat psychostimulant addictions. However, due to activation of dopamine neurons, these agonist medications are often abused. Previous evidence suggests that serotonin elevations can counteract the stimulant and reinforcing effects of dopamine. Additional research indicates that withdrawal from drugs of abuse is associated with deficits in both dopamine and serotonin. One possible advantage of using dual dopamine/serotonin releasers as agonist medications is their combined ability to provide the necessary stimulant-like properties (dopamine release) while reducing abuse liability (serotonin release). Recently, the monoamine releaser (+)-phenmetrazine produced favorable results in cocaine discrimination and self-administration studies in rhesus monkeys. Phenmetrazine was once approved as an appetite suppressant but was discontinued due to its high abuse liability. Our study set out to evaluate the dopamine and serotonin transporter release activity of a series of phenmetrazine analogs with the goal of identifying compounds that have dual dopamine/serotonin release activity. The analogs were synthesized using either an epoxide opening-cyclization method or a Grignard addition-cyclization method. Dopamine and serotonin transporter release activity was measured in freshly prepared rat brain synaptosomes. Our results show that several analogs are more potent dual dopamine/serotonin releasers than phenmetrazine, especially in the 5-methyl-2-phenylmorpholine series. We further demonstrate that compounds with the (2*S*,5*S*) configuration in this series produced the most effective dopamine and serotonin release activity. In conclusion, our results indicate that the (2*S*,5*S*)-5-methyl-2-phenylmorpholine series represents a good lead in our efforts to identify dual dopamine/serotonin releasers that could potentially be used as agonist medications for psychostimulant abuse.

Title: Gat1 expression in human brain: alternate transcript validation and expression analysis of novel RNAs in patients with schizophrenia

Authors: ***H. MITCHELL**, M. I. MIGHDOLL, G. URSINI, J. SHIN, A. JAFFE, R. TAO, D. R. WEINBERGER, J. E. KLEINMAN, T. M. HYDE
Lieber Inst. For Brain Develop., Baltimore, MD

Abstract: Abnormal GABA-mediated neurotransmission is a consistent postmortem finding in schizophrenia. In the dorsolateral prefrontal cortex (DLPFC) of subjects with schizophrenia, studies have revealed alterations in GABA signaling, and lower expression of GABA transporter 1 (GAT1) mRNA compared to healthy controls. GAT1 is a widely expressed GABA reuptake transporter in neuronal and glial membranes of the neocortex. Here we examined GAT1 mRNA expression and alternative splicing in the DLPFC. PolyA enriched RNA was extracted from post-mortem human DLPFC grey matter (n=107 controls, n=107 patients with schizophrenia) and then purified and enriched with PCR to create a final cDNA library for high throughput sequencing using the Illumina HiSeq2000. The Illumina Real Time Analysis module was used to perform image analysis and base calling, followed by the BCL Converter to generate FASTQ files containing sequence reads. Pair-end reads of cDNA sequences obtained by the HiSeq2000 were aligned to the human genome reference (UCSC hg19) by splice-read mapper (TopHat v2.0.4), providing known transcripts from Ensembl Build GRCh37.67. Multiple novel RNA species were identified in the GAT1 locus. Specifically, we detected 50 novel splicing events. Although no differences were found in the global expression of the GAT1 gene between controls

and patients with schizophrenia, the expression of a novel exon located between exons 7 and 8 was greater in patients (p=0.04). Two novel exons, that partially overlap known exons, were also over expressed in patients, based on a junction analysis (chr3:11034616-11058805; p=.02468, chr3:11072966-11075082; p=.00096). Finally, we detected novel non- coding RNAs spanning the GAT3 and GAT1 loci. Our RNA sequencing analysis identified multiple novel RNAs in the GAT1 locus, demonstrating the complexity of the transcriptional regulation of this gene. Preliminary analyses also suggest that those novel transcripts predicted to alter the protein coding sequence are over expressed in patients with schizophrenia.

Title: Revised ion/substrate coupling stoichiometry of GABA transporters

Authors: S. L. WILLFORD, C. M. ANDERSON, S. R. SPENCER, *S. ESKANDARI
Biol. Sci., California State Polytechnic Univ. Pomona, POMONA, CA

Abstract: Plasma membrane γ-aminobutyric acid (GABA) transporters (GAT) are electrogenic transport proteins that couple the cotranslocation of Na^+, Cl^-, and GABA across the plasma membrane of neurons and glia. GATs regulate the synaptic and extrasynaptic concentrations of GABA in the brain and, thus, they modulate inhibitory GABAergic signaling in the nervous system. A fundamental property of the transporter that determines its ability to concentrate

GABA in neurons and glia and, hence, reduce synaptic and extrasynaptic GABA concentrations, is the ion/substrate coupling stoichiometry. An accurate knowledge of the stoichiometry is essential to understanding the contribution of GATs to GABAergic signaling in health and disease. The currently accepted GAT stoichiometry is 2 Na^+ : 1 Cl^- : 1 GABA, however, this model is inconsistent with several experimental results. In the present study, we expressed GAT1 and GAT3 in *Xenopus laevis* oocytes and utilized a thermodynamic approach, as well as uptake under voltage clamp experiments, in order to determine a definitive stoichiometry for the GABA transporters. Voltage-clamped GAT1-expressing oocytes were preloaded with GABA and then superfused with solutions containing different external concentrations of Na^+, Cl^-, or GABA (while the concentrations of the other two co-substrates remained the same). For any given substrate concentration, the reversal potential (V_{rev}) of transporter-mediated current was recorded. The shifts in V_{rev} for a 10-fold change in the external Na^+, Cl^-, and GABA concentration were 84 ± 4 mV, 30 ± 1 mV, and 29 ± 1 mV, respectively. We then measured Na^+, Cl^-, and GABA fluxes under voltage clamp in GAT3-expressing cells in order to determine the ratio of charge flux to substrate flux. We found that for every Na^+ ion translocated across the plasma membrane by GAT3, 0.7 ± 0.1 elementary charge enters the cell. For every Cl^- ion translocated across the plasma membrane, 2.0 ± 0.2 elementary charges enter the cell. For every GABA molecule translocated across the plasma membrane, 2.1 ± 0.1 elementary charges enter the cell. Altogether, the thermodynamic and flux measurements are inconsistent with the currently-accepted 2 Na^+ : 1 Cl^- : 1 GABA stoichiometry model, but rather strongly suggest a 3 Na^+ : 1 Cl^- : 1 GABA coupling stoichiometry for the GABA transporters. The revised stoichiometry has important implications for the role of the GABA transporters in establishing the resting concentration of GABA in the brain, as well as for the contribution of these proteins to regulating GABAergic synaptic activity.

Title: Reduction of GAT-3 expression is responsible of tonic inhibition in globus pallidus neurons in experimental parkinsonism

Authors: *M. CHAZALON[1], C. MIGUELEZ[2], S. MORIN[1], S. CRISTÓVÃO-FERREIRA[3], S. H. VAZ[3], A. M. SEBASTIAO[3], J. BAUFRETON[1]
[1]neuroscience, Inst. Des Maladies Neurodegeneratives, Bordeaux, France; [2]Univ. of the Basque Country, Fac. of Pharmacy, Dept. of Pharmacol., Vitoria-Gasteiz, Spain; [3]Fac. of Medicine, and Unit of Neurosci., Inst. of Pharmacol. and Neurosciences, Inst. of Mol. Med., Lisbon, Portugal

Abstract: The external globus pallidus (GPe, equivalent of GP in rodents) is the first relay of the indirect pathway of the basal ganglia network and receives its main source of inhibition from the striatum. In Parkinson's disease, the striato-pallidal pathway is believe to become hyperactive, leading to an increase of extracellular GABA levels ([GABA]e) in the GP which contribute to the hypoactivity of pallidal neurons observed in animal-models of the disease. The molecular mechanisms involved in the hypoactivity of GP neurons remain however poorly understood, we thus undertaken series of experiments to better characterize the impact of dopamine-deprivation on GABAergic inhibition properties in GP. Using patch-clamp recordings in acute brain slices, we found the presence of a permanent form of inhibition, commonly called tonic inhibition (TI) but only in GP neurons of 6-hydroxydopamine-treated (6-OHDA) rats or mice. Interestingly, TI persisted in dopamine-depleted slices in presence of tetrodotoxin (TTX, 1μM) suggesting that it is independent of neuronal activity and not the consequence of striatal neuron's hyperactivity. Using pharmacology and δ-knock-out mice, we demonstrated that TI is mediated by δ-containing GABAA receptors in GP neurons, but that these receptors are not overexpressed in 6-OHDA animals. We thus investigated the contribution of neuronal and glial GABA transporters, called GAT-1 and GAT-3, respectively. GAT-1 blockade lead to the same change in the magnitude of TI in control and dopamine-depleted conditions suggesting that this transporter is important in the regulation of [GABA]e but is not implicated in the TI observed in 6-OHDA rodents. On the other hand, whereas GAT-3 blockade produces a substantial increase in TI in control rats, it didn't significantly increase TI in dopamine-depleted animals suggesting that glial uptake of GABA is impaired in experimental Parkinsonism. Immunohistochemistry experiments showed a reduction of GAT-3 staining in GP astrocytes in 6-OHDA rats suggesting a down-expression of the transporter. We are currently testing that GAT-3 expression is reduced in astrocytes in 6-OHDA-treated rats using western blot analysis. In addition, we are investigating the impact of tonic inhibition on the excitability and pattern of GP neurons in acute brain slices using extracellular multi-electrode recordings. Taken together these results suggest that the increase of [GABA]e observed in experimental Parkinsonism in GP is caused, at least in part, by a dysfunction of GAT-3 transporters leading to a persistent form of inhibition in pallidal neurons.

Title: CB1 and GPR55 receptors regulate GABA uptake in gliosomes and synaptosomes respectively in the rat globus pallidus

Authors: ***M. MUNOZ ARENAS**[1], R. SANCHEZ-ZAVALETA[2], A. BAEZ-CORDERO[3], F. PAZ-BERMUDEZ[2], D. LIMON[1], B. FLORAN[2]
[1]Lab. De Neurofarmacologia, Puebla, Mexico; [2]Physiology, Biophysics and Neurosciences, CINVESTAV-IPN, México. D.F., Mexico; [3]Lab. de Neurofarmacología, BUAP, Puebla, Mexico

Abstract: Globus pallidus express GABA transporters: GAT-1 and GAT-3 in neural terminals and glial cells respectively. GABA concentration in the synaptic cleft is regulated by these transporters and regulates motor behavior. In addition, it has been shown that GABA uptake is modulated by the different compounds acting on cannabinoid receptors. Therefore, the aim of this work was to study the role of CB1 and GPR55 receptors on the activity of GAT-1 and GAT-3 in the globus pallidus of the rat. [^{3}H]GABA uptake was measured after activating the CB1 and GPR55 receptors in synaptosomes (nerve terminals) and gliosomes (enriched astrocytes membrane somas) from globus pallidus of normal rats. We found that CB1 receptor activation inhibits [^{3}H]GABA uptake mediated by GAT-3 in gliosomes, while compounds with selectivity of GPR55 inhibit [^{3}H]GABA uptake mediated by GAT-1 in synaptosomes. We propose that cannabinoid compounds blocks GABA uptake at GAT-1 and GAT-3 in the GP by means of the different location of transporters in cellular elements. This study also shows the importance of the endocannabinoid system in the control of the GABAergic transmission of the globus pallidus.

Title: The astrocytic transporter Slc7a10 (Asc-1) is required for glycinergic inhibitory function

Authors: *J. T. EHMSEN[1], Y. LIU[2], Y. WANG[2], J. D. ROTHSTEIN[1], S. H. SNYDER[1], M. P. MATTSON[1], A. HOKE[1]
[1]Johns Hopkins, BALTIMORE, MD; [2]Natl. Inst. of Aging, Baltimore, MD

Abstract: Slc7a10 (Asc-1) is a sodium-independent neutral amino acid transporter known to be the primary mediator of D-serine transport in the brain. Slc7a10 transports a number of additional amino acids including glycine, L-alanine, L-serine, and L-cysteine, as well as their D-enantiomers. We find that Slc7a10 is enriched in cerebellar Bergmann glia and within a subset of astrocytes of the caudal brain and spinal cord, in a distribution corresponding to high densities of glycinergic inhibitory synapses. Accordingly, we find that spinal cord glycine levels are significantly reduced in Slc7a10-null mice and that spontaneous glycinergic postsynaptic currents in motor neurons of mice lacking Slc7a10 show substantially diminished amplitude, identifying the likely etiology of sustained myoclonus and early postnatal lethality previously described for these animals. These observations establish a critical role for astrocytic Slc7a10 in glycinergic inhibitory function in the central nervous system, and implicate SLC7A10 as a candidate gene in human hyperekplexia and stiff person syndrome.

Title: Outer-gate residues determine species-specific differences in recognition of MDMA as a substrate by the serotonin transporter

Authors: *B. FELTS[1], E. L. BARKER[2], L. K. HENRY[1]
[1]Univ. of North Dakota Sch. of Med. & He, Grand Forks, ND; [2]Dept. of Medicinal Chem. and Mol. Pharmacol., Purdue Univ., Lafayette, IN

Abstract: The Na^+/Cl^-–dependent serotonin transporter (SERT) functions to reuptake serotonin (5-HT) into pre-synaptic terminals following neurotransmission. In addition, SERT is also the target of the drug of abuse 3,4-methylenedioxymethamphetamine (MDMA, ecstasy). MDMA is recognized as a substrate by human SERT (hSERT) and transported into presynaptic neurons, where it mediates robust reverse transport (efflux) of 5-HT through SERT and into the synapse. Previously published work has demonstrated that, unlike hSERT, MDMA is not recognized as a substrate by *Drosophila* SERT (dSERT), as MDMA is unable to elicit substrate-induced currents or produce measurable substrate efflux. However, MDMA is able to bind to dSERT and antagonize 5-HT uptake, as revealed through competitive uptake analysis, albeit with an eight-fold drop in potency when compared to hSERT. Importantly, hSERT and dSERT display similar K_M values for 5-HT transport, suggesting that differences in substrate recognition are not universal for all SERT substrates. As substrate recognition occurs at the molecular level, we focused on amino acid differences between hSERT and dSERT that reside in the proposed permeation pathway. Interestingly, there is divergence in the residues that form the outer gate structure, which in hSERT is composed of R104 and E493 and likely form a salt-bridge. In dSERT, the Arg is conserved (R99) but the charged Glu is replaced by a polar Asn (N484). We found that a reciprocal switch of this single differential amino acid in hSERT and dSERT resulted in both a gain of function for dSERT, where dSERT N484E was able to recognize and transport MDMA, and a loss of function for hSERT, where hSERT E493N can no longer transport MDMA. These reciprocal mutants retained 5-HT transport competency. Our findings suggest a negative charge opposite of the Arg at the outer gate may be necessary for recognition

of MDMA as a substrate. To further characterize the role of the outer-gate residues in MDMA recognition we investigated SERT from *C. elegans* (ceSERT), as its outer gate is composed of the universally conserved Arg (R125) and an Asp (D517). Like in hSERT, this forms a true salt bridge at the extracellular gate, however the variation in acidic residues between hSERT and ceSERT has not been examined for its effect on MDMA recognition. Our aim is to utilize the functional similarities and differences between hSERT, dSERT and ceSERT to unravel the role of the salt bridge in MDMA recognition as a substrate.

Title: Dissecting the role of integrins in the modulation of the serotonin synapse

Authors: *M. MAZALOUSKAS, A. M. CARNEIRO
Pharmacol., Vanderbilt Univ., Nashville, TN

Abstract: Recent evidence from our laboratory has indicated that obligate integrin heterodimers containing the β3-subunit (ITGB3) influence the serotonin system in platelets. Whereas fibrinogen, an activator of αIIbβ3 (also known as glycoprotein GPIIb/IIIa), enhances the activity of the antidepressant-sensitive serotonin (5-hydroxytryptamine, 5-HT) transporters (SERTs, SLC6A4) in platelets, the genetic disruption of integrin β3 in mice diminishes platelet SERT activity. Thus the SERT•β3 complex appears to serve as an important regulatory element in 5-HT signaling. Recent studies from our group and others have begun to elucidate a functional interaction between SERT and β3 integrin in the central nervous system, where integrin signaling contributes to neuronal migration and synaptic differentiation during development, as well as aids in the synaptic plasticity of mature neurons. Whereas chronic administration of the selective serotonin reuptake inhibitor (SSRI) paroxetine has been shown to enhance the levels of integrin β3 mRNA in cultured cells, the SSRI fluoxetine has been shown to induce increases in synaptogenesis in rat hippocampal CA1 and CA3 subfields. Given that SSRIs may indirectly influence 5-HT1A receptors to increase integrin expression and the formation of new synapses,

we examined the role of SERT•β3 complexes in serotonergic synapses in the raphe nuclei of the midbrain, the major source of 5-HT neurons in the brain. Our immunohistochemical analyses of the raphe nuclei indicate that integrin β3 is expressed in approximately 1/3 of serotonergic synapses. We find that the absence of integrin β3 in the midbrain of β3 null mice (Itgb3-/-) results in a decrease in the number of serotonergic synapses without affecting the total number of neurons, thus implicating integrin β3 in serotonergic synaptogenesis. Utilizing mouse lines expressing a gain-of-function mutant form of integrin β3, we will examine whether newly formed synapses express integrin β3 and assess the activation state and downstream signaling of integrin β3 using biochemical approaches. Proteomic approaches will be utilized to further identify key determinants of serotonergic synaptogenesis on fluorescence-activated cell sorted serotonergic synaptosomes containing integrin β3. Elucidating the role of integrins in governing serotonergic synaptogenesis may provide insight into the molecular mechanisms that underlie neuropsychiatric disorders and reveal novel, druggable targets for the treatment of several psychiatric illnesses.

Title: Regulation of serotonin transporters by focal adhesion proteins

Authors: *M. DOHN, A. CARNEIRO
Pharmacol., Vanderbilt Univ., Nashville, TN

Abstract: The monoamine serotonin is a critical mediator of a broad range of physiological and behavioral functions. Serotonin plays roles in platelet aggregation, cardiac function, and digestion, whereas dysfunction of serotonin neurotransmission has been implicated in depression, anxiety, and autism spectrum disorders. While serotonin signaling is transduced by a large family of receptors, extracellular clearance, and thus inhibition, of serotonin occurs primarily via one protein, the serotonin transporter (SERT). SERT has been shown to interact both genetically and physically with components of focal adhesion (FA) complexes. FAs are

large multiprotein complexes that connect the cytoskeleton to the extracellular matrix via transmembrane integrin proteins. Interactions between synaptosomal and FA proteins are thought to modulate synaptogenesis and synaptic function. In platelets, FA formation modulates SERT function via the association of adaptor proteins with the carboxy-terminus of SERT, followed by inactivation of the transporter and translocation to endocytosis-ready membranes. The FA adaptor protein Hic-5 is a key modulatory protein, and Hic-5/SERT associations depend on the activation of intracellular signaling pathways. While functional interactions of SERTs with FAs have been established in platelets, little is known on the role of these proteins in neurons. Here we dissect the effect of these interactions on SERT function. Using serotonin uptake assays in HEK293 cells transduced to express SERT and Hic-5, we demonstrate that Hic-5 suppresses SERT transporter activity. Deletion and point mutants are also utilized to uncouple protein-protein interactions and map potential interaction domains. We will then extend those studies to primary neuronal cultures to decipher how the association of SERT with FA complexes modulates SERT trafficking to axons, plasma membrane insertion, and uptake capacity. From these studies we aim to provide a greater understanding of SERT regulation by FA proteins.

Title: Cellular and ultrastructural localization of organic cation transporter 3 suggest a dendritic and glial monoamine clearance mechanism

Authors: *P. J. GASSER[1], J. CHAN[2], J. E. HILL[1], M. HURLEY[1], V. M. PICKEL[2]
[1]Biomed. Sci., Marquette Univ., Milwaukee, WI; [2]Brain & Mind Res. Inst., Weill Cornell Med. Col., New York, NY

Abstract: Transporter-mediated uptake determines the duration and extent of diffusion of released monoamines. Most studies of monoamine clearance have focused on the presynaptic reuptake transporters SERT, NET and DAT. We have recently demonstrated the expression of an additional, largely uncharacterized, high-capacity monoamine clearance mechanism, OCT3 (organic cation transporter 3), throughout the rat brain. In contrast to DAT, NET and SERT,

OCT3 has higher capacity and lower affinity for substrates, is sodium-independent and multi-specific, with the capacity to transport dopamine, norepinephrine, and serotonin. OCT3 is insensitive to inhibition by cocaine and antidepressants, but is inhibited by corticosterone. Thus, OCT3 represents a novel, glucocorticoid-sensitive monoamine clearance mechanism. However, little is known about the subcellular localization of the transporter and its proximity to sites of monoamine release. This information is critical for the integration of OCT3 into models of the regulation of monoaminergic neurotransmission. In this study, we used immunochemical techniques at both the light and electron microscopic level to examine the distribution and phenotype of OCT3-expressing cells, and the subcellular localization of OCT3 in the rodent amygdala and retrosplenial cortex (RSC). OCT3-immunoreactive perikarya and punctae were observed throughout the BLA and RSC, with particularly high densities in the intercalated cell groups of the amygdala and the granular RSC. In both areas, dense perinuclear staining was observed. Dual immunofluorescence revealed OCT3 expression in close proximity to, but not on fibers expressing either tyrosine-hydroxylase or dopamine-beta-hydroxylase. In the BLA, OCT3 immunoreactive punctae were observed in close proximity to D1 receptor + punctae. OCT3-was observed in neurons and glia in both areas. Immuno-electron microscopy revealed similar patterns of OCT3-like immunoreactivity in BLA and RSC. OCT3 immunostaining was associated with plasma membranes of dendritic spines adjacent to putative monoamine release sites. In several dendrites, dense OCT3 immunostaining was associated with mitochondria adjacent to the plasma membrane. In addition to dendritic staining, OCT3 immunostaining was observed in glial processes, and in a small number of presynaptic terminals. In both RSC and BLA, dense OCT3-immunostaining was associated with the nuclear envelope. These data suggest that represents a post- or peri-synaptic clearance mechanism, and raise interesting questions regarding potential roles of this transporter in the intracellular disposition and metabolism of substrates.

Title: Mechanisms contributing to lack of antidepressant efficacy in juveniles and adolescents

Authors: *N. MITCHELL[1], R. FRASER[2], W. OWENS[1], R. HORTON[1], M. VITELA[1], G. GOULD[1], W. KOEK[3], L. DAWS[1]
[1]Physiol., [2]Pharmacol., [3]Psychiatry, Univ. of Texas Hlth. Sci. Ctr. At San Antonio, San Antonio, TX

Abstract: Depression is a major health problem for which most patients are not effectively treated. This problem is further compounded in children and adolescents where only two antidepressant drugs are currently approved for clinical use. Both are selective serotonin (5-HT) reuptake inhibitors (SSRIs), which are often less therapeutically efficacious in this young population compared to adults. Consistent with clinical literature, we found that antidepressant-like effects of SSRIs in mice aged 21 days post-partum (P21, juvenile) was reduced relative to adult mice; however, there was no difference in expression of hippocampal 5-HT transporter (SERT), the target protein of SSRIs, to account for the reduced SSRI efficacy. The increase in extracellular 5-HT following SSRI administration is thought to trigger downstream events required for therapeutic effects. Thus, our data raise the possibility that transporters capable of 5-HT uptake other than SERT may be present in disproportionately higher levels during juvenile and adolescent periods thereby preventing extracellular 5-HT from climbing to therapeutically relevant levels following SSRI treatment. Decynium-22 (D22) is a blocker of organic cation transporters (OCTs) and the plasma membrane monoamine transporter (PMAT), low affinity, but high capacity transporters for 5-HT. We found that in juvenile and adolescent mice, the density of [3H]D22 binding sites in hippocampus are greater than in adults. Western blot analysis using specific antibodies revealed that increased [3H] D22 binding was most likely driven by increased PMAT expression in young mice relative to adults. These data suggest that D22 may have antidepressant activity in juvenile and adolescent mice. In our preliminary studies we found that D22 (0.01mg/kg) produced antidepressant-like effects in juvenile but not adult mice. Using *in vivo* chronoamperometry, an electrochemical technique which allows for sub-second measurements of region specific 5-HT clearance in brain, studies are underway to determine whether the antidepressant-like effects of D22 are related to its ability to inhibit 5-HT clearance. Our results suggest that significant uptake of 5-HT by PMAT and/or OCTs may limit the therapeutic efficacy of SSRIs, providing a mechanistic basis for poor treatment response to SSRIs particularly in juveniles and adolescents.

Title: Contributions of interleukin-1β signaling to the enduring effects of early-life stress: A serotonin connection?

Authors: *N. L. BAGANZ[1,2], J. T. SMITH[1], L. J. HARBOM[1], M. J. ROBSON[1,2], R. D. BLAKELY[1,2,3]

Abstract: Early-life stress during childhood, if sustained, can have an enduring impact on the quality of life and social interactions, and lead to lifelong risk for cognitive disability and mood disorders, such as major depression. A growing awareness of the role of neuroimmune signaling in the adaptive and maladaptive responses to stress-mediated behaviors encouraged us to explore the contribution of inflammatory signaling in the risk for depressive symptoms in a mouse maternal separation (MS) model. In our MS model, we imposed a daily 3 hr separation of mouse pups from their mother over a 2-week period. As others have demonstrated, we detected long-lasting consequences on behavior, including heightened anxiety- and depressive-like behavior of adult animals subjected to MS. Additionally, we found that MS lead to adult elevations in the expression of multiple inflammatory signaling molecules (e.g. IL-1β and IL-6) in both the brain and periphery. Remarkably, when animals deprived of IL-1β signaling via a constitutive IL-1 receptor KO (IL-1R KO) were assessed for enduring behavioral effects of MS, these animals were found to lack the anxiety and depressive symptoms of their wild type, MS treated littermates. Moreover, the MS-induced elevations in inflammatory cytokine levels were absent. As IL-1β signaling can modulate serotonin (5-HT) transporter (SERT) activity (Zhu et al, 2006), effects that are also lost in the IL-1R KO (Zhu et al, 2010), and SSRI treatments can reverse MS-induced changes in behavior (El Khoury et al, 2006; Levine et al, 2012; Couto et al, 2012; Yoo et al, 2013) we hypothesize that one determinant of MS-induced behavioral changes may involve IL-1β alterations in SERT expression and/or function. Finally, using conditional IL-1R KO mice,

we are investigating whether early and/or later-life IL-1β signaling is required for MS-induced behavioral changes and to what degree these changes depend on IL-1β modulation of 5-HT signaling.

Title: Molecular basis for interactions of the dopamine transporter with G protein βγ subunits

Authors: ***J. GARCIA-OLIVARES**[1], D. TORRES-SALAZAR[1], S. G. AMARA[1], G. E. TORRES[2]
[1]Natl. Inst. of Mental Health/NIH, Bethesda, MD; [2]Neurobio., Univ. of Pittsburgh, Pittsburgh, PA

Abstract: Proper function of reward circuitry within the brain requires that the presynaptic dopamine transporter (DAT) efficiently recaptures dopamine (DA). DAT function can be regulated by many intracellular mechanisms including phosphorylation, ubiquitination, and protein-protein interactions. We recently reported a novel mechanism describing the regulation of DAT by heterotrimeric G-proteins. We found that Gβγ subunits bind directly to the C-terminus of DAT (residues 582-620), and upon G-protein activation, the release of Gβγ results in a decrease in DA uptake. To explore the molecular basis of this interaction, we generated a peptide library containing a series of sequential alanine and/or glycine substitutions from residues 582 to 620 of the sequence of the human DAT. Using an *in vitro* binding assay with this peptide library, we identified the putative binding site in the region 582 to 595. We measured DA uptake and efflux in HEK-293 cells expressing mutated DAT to corroborate the functional impact of the elimination of the putative Gβγ subunit binding site. The fusion of the potential binding site with a TAT-peptide to generate a cell permeant peptide, blocked the effect of the Gβγ activator mSIRK. We also explore how other known regulators of DAT, such as PKC and CamKII, play a role in the Gβγ binding and functional regulation. Taken together, our results

suggest that Gβγ subunits directly regulate DA transport through DAT. This novel mechanism could have important implications for the actions of amphetamine and other psychostimulants as well as for the regulation of the dopaminergic tone within the brain.

Title: Chronic methamphetamine exposure leads to diminished short-term memory

Authors: *A. NORTH[1], S. GOODWIN[2], H. KHOSHBOUEI[3]
[1]Neurosci. and Pharmacol., [2]Biochem. and Cancer Biol., Meharry Med. Col., Nashville, TN; [3]Neurosci. and Pharmacol., Univ. of Florida, Gainesville, FL

Abstract: Methamphetamine (METH) is a highly addictive and abused psychostimulant known for its long-lasting euphoric and neurotoxic effects. Its use in humans is often associated with addiction, neurocognitive impairment, and a disruption in brain function. Despite the negative consequences of METH use, it is used in FDA approved drugs that include Ritalin® and weight loss supplements. Recently, we have shown that METH increases the baseline synaptic transmission and diminishes LTP in the hippocampal CA1 region of young mice (Swant et al, 2011). In this study, we tested the hypothesis that a repeated neurotoxic regimen of METH exposure in adolescent mice decreases hippocampal synaptic plasticity and produces a deficit in short-term memory. Contrary to our prediction, after 14 days of METH exposure, we found no change in the hippocampal plasticity or short-term memory. However, we found that following 21 days of drug abstinence, METH-exposed mice displayed a deficit in the spatial memory and a decrease in hippocampal plasticity. Our findings support the hypothesis that the negative cognitive consequences of neurotoxic regiment of METH exposure can persist long after drug

abstinence. Thus, short-term and long-term consequences of methamphetamine exposure need to be studied in order to develop novel therapeutic approaches for methamphetamine use.

Title: Dopamine transporter endocytic braking requires the non-receptor tyrosine kinase Ack downstream of cdc42 activation

Authors: ***S. WU**[1], H. E. MELIKIAN[2]
[1]Grad. Program in Neurosci., [2]Brudnick Neuropsychiatric Res. Institute, Dept. of Psychiatry, Univ. of Massachusetts Med. Sch., Worcester, MA

Abstract: Dopaminergic neurotransmission is essential for movement, reward and cognition, and dopamine (DA) signaling is implicated in Parkinson's disease, addiction and schizophrenia. The presynaptic Na^+/Cl^--dependent DA transporter (DAT) recaptures released DA, thereby temporally and spatially sculpting DAergic neurotransmission. DAT is potently inhibited by addictive (cocaine, amphetamine) and therapeutic (methylphenidate) psychostimulants. Thus, intrinsic cellular mechanisms modulating DAT availability are likewise predicted to robustly impact DAergic neurotransmission. DAT surface levels are acutely modulated by endocytic trafficking, and both PKC activation and AMPH exposure rapidly decrease DAT surface expression. DAT surface stability is governed by an endocytic braking mechanism that requires both the DAT amino and carboxy termini, but whose mechanistic underpinnings are not defined. We recently reported that 1) Rin GTPase activity is required for PKC-stimulated release of the DAT endocytic brake and 2) DAT endocytic recycling relies on a dynamin/actin-dependent mechanism. Both Rin and the actin cytoskeleton are intimately coupled to the Rho GTPase cdc42, suggesting that cdc42 may play a critical role in DAT endocytic trafficking. In the current study we used small molecule cdc42 inhibitors to test this possibility. Acute cdc42 inhibition with small molecules pirl1 and casin significantly decreased DAT surface expression in SK-N-MC cells and in mouse striatal slices. DAT surface losses were due to a striking and significant

increase in the DAT endocytic rate, suggesting that cdc42 activity is required to maintain the DAT endocytic brake. However, acute cdc42 inhibition did not alter SERT basal internalization rate, indicating a DAT-specific mechanism. Recent studies indicate that the non-receptor tyrosine kinase Ack is directly activated by cdc42 and is a negative regulator of endocytosis, raising the possibility that Ack participates in DAT endocytic braking downstream of cdc42. Studies examining Ack activation via Y284 autophosphorylation revealed that both PKC activation and cdc42 inhibition robustly diminish pY284-Ack levels. To test whether Ack activation impacts DAT activity and trafficking, we took advantage of a highly specific Ack inhibitor, AIM-100. AIM-100 treatment decreased both DA uptake and Y284 Ack autophosphorylation levels in a dose-dependent manner. Moreover, Ack inhibition increased constitutive DAT internalization rates, consistent with release of the DAT endocytic brake. Studies using cdc42 mutants and Ack mutants will elucidate the role of these proteins in regulated DAT endocytic trafficking.

Title: Pharmacological chaperone activity of bupropion on monoamine transporters

Authors: *P. BEEREPOOT, A. SALAHPOUR
Pharmacol., Univ. of Toronto, Toronto, ON, Canada

Abstract: Monoamine transporters are essential for recycling monoamine neurotransmitters and regulating extracellular neurotransmitter concentrations. Recently we have discovered that the commonly prescribed dopamine/norepinephrine transporter blocker bupropion can increase dopamine transporter (DAT) protein and function in HEK293 cells. Furthermore, chronic bupropion treatment can increase DAT protein and amphetamine response in mice. By using inhibitors of different steps in the DAT lifecycle, we have determined that the effect of

bupropion is post-translational. We hypothesize that bupropion modulates interaction between DAT and ER-resident chaperone proteins, and are currently exploring this hypothesis by immunoprecipitation and bioluminescence resonance energy transfer approaches. We have also tested bupropion on cells expressing other transporters, and have found that bupropion has similar activity on the serotonin, but not the GABA transporter. Lastly, we are investigating the activity of a number of bupropion analogues to determine structure-activity relationships. So far we have discovered that the primary metabolite of bupropion, hydroxybupropion, also increases DAT surface expression. Our data show that bupropion may have activity that has previously not been appreciated, which could be of significance for the clinical use of this drug. Furthermore, the action of bupropion and related compounds as pharmacological chaperones of monoamine transporters could be exploited therapeutically for pathological conditions involving reduced monoamine transporter function.

Title: Dopamine transporter deregulation impacts retinal physiology

Authors: *H. DAI[1], C. JACKSON[1], G. DAVIS[2], R. BLAKELY[3], D. MCMAHON[1]
[1]Biol. Sci., [2]Neurosci. program, [3]Dept. of Pharmacol., Vanderbilt Univ., Nashville, TN

Abstract: Retinal dopamine reconfigures retinal circuits for light adaptation and high-resolution vision .Retina-specific disruption of dopamine synthesis leads to deficits in light-adapted electroretinogram (ERG) responses, contrast sensitivity and acuity. In addition to the synthesis pathway, extracellular dopamine levels are regulated by dopamine reuptake, which is mediated by dopamine transporter (DAT). To gain insight into the role of DAT in the retinal dopaminergic system and visual function, here we used a mouse strain carrying a human DAT (SLC6A3 gene) coding variant, Ala559Val (A559V), originally described in human ADHD subjects.This DAT variant exhibits an anomalous outward “leak” of cytoplasmic dopamine when pre-loaded with dopamine. We measured retinal mass electrical responses to light stimuli by electroretinogram

(ERG) in WT, heterozygous, homozygous DAT A559V littermates. Homozygous animals showed increased light-adapted b-wave amplitudes, but dark-adapted responses did not differ, compared to WT and heterozygotes. This elevated amplitude of the photopic ERG could be mimicked by applying D1 and D4 dopamine receptor agonists by i.p. injection to WT mice, suggesting that is due to increased light-adapted retinal dopamine levels in DAT homozygous mutant mice. However, visual acuity and contrast sensitivity, as measured by optokinetic tracking, and tissue dopamine levels in the dark, as measured by HPLC, were maintained at normal levels in the homozygous mice. Taken together these data suggest that alteration of dopamine clearance by DAT can influence light-adapted retinal responses.

Abstract: With ADHD being the most common childhood psychiatric disorder, and one that, left untreated, is associated with low socio-economic status, addiction and/or incarceration, a better understanding of ADHD etiology is critical. ADHD has long been associated with disruptions in dopamine (DA) signaling. Moreover, the main pharmacological treatments for ADHD (Ritalin (methylphenidate, MPH)) and Adderall (amphetamine, AMPH)) target the DA transporter (DAT). As current genetic models of ADHD lack construct validity, we screened subjects for the presence of functional DAT coding variation, identifying the variant DAT Val559 in two boys and small kindred, a variant previously identified in a girl with bipolar disorder. *In vitro* studies

that demonstrated anomalous DA efflux (ADE), as well as an anomalous response to AMPH, encouraged us to explore the impact of the variant *in vivo* via the generation of the DAT Val559 knock-in mouse. The DAT Val559 knock-in mouse has normal transporter protein expression and DA uptake *in vivo*, as predicted from *in vitro* studies. Striatal microdialysis studies reveal an elevation in basal extracellular DA levels in DAT Val559 animals and a blunted ability of AMPH to elevate these levels. Although DAT Val559 animals are not spontaneously hyperactive, they exhibit elevated escape speed with imminent handling (darting). Moreover, Val559 mice show a blunted locomotor response to both AMPH and MPH compared to wild-type mice. DAT Val559 animals also display a blunted rearing response to AMPH. Ongoing studies seek to determine what cellular and circuit level plasticities derive from lifelong expression of the DAT Val559 variant and whether other phenotypes, e.g. impulsivity, attention deficits, social behavior disruption, arise in these animals and respond to chronic psychostimulant treatments. Title: Five in a million: Analysis of changes in dopamine transporter function in dat-1 coding variants derived from the *C. elegans* million mutation project

Authors: *P. FREEMAN[1,3], S. M. WHITAKER[1], S. B. ROBINSON[1], R. D. BLAKELY[2]
[1]Pharmacol., [2]Pharmacol. and Psychiatry, Vanderbilt Univ., Nashville, TN; [3]Biol., Fisk Univ., Nashville, TN

Abstract: The dopamine (DA) transporter (DAT) is critical for the termination of extracellular DA signaling as well as presynaptic recapture of DA for re-release. The orthologous *Caenorhabditis elegans* protein (DAT-1) plays an equivalent role at worm DA synapses, presenting an opportunity to gain a better understanding of the transporter's structure, function and regulation by use of the powerful forward and reverse genetic tools available with the worm

model. Recently, The Million Mutation Project (MMP, http://genome.sfu.ca/mmp/) represents a library of ~2,000 mutagenized worm strains where sequencing at a depth of 15X genome coverage reveals the presence of, on average, ~9 new non-synonymous alleles per gene, whose characterization can reveal novel links to protein structure and function. Thirteen such coding variants are present in the MMP. We have initiated a functional characterization of these variants, focusing initially on five lines that bear amino acid changes (D8N, P9L, M20T, P596S, P609S) at highly conserved locations and/or that are associated with regions suspected to confer/support DAT activity or regulation based on mammalian DAT studies. To date, we have confirmed behavior of four of these lines consistent with DAT-1 loss of function, assessed by the presence of Swimming-induced paralysis (Swip). Additionally, we observe differential changes in the ability of amphetamine to include Swip. Following successful backcrossing of these mutants, we will pursue additional worm and mammalian cell studies to expand the opportunity to understand the impact of structural changes in DAT for DAT trafficking, function and contributions to DA-linked behaviors *in vivo*. Title: Discovery of a novel, conserved MAP kinase required for dopamine neuron function in *C. elegans*

Authors: *D. BERMINGHAM[1,2], J. A. HARDAWAY[2], S. WHITAKER[3], S. SNIDER[1], R. BLAKELY[3,4]
[2]Neurosci., [3]Pharmacol., [4]Psychiatry, [1]Vanderbilt Univ., Nashville, TN

Abstract: The dopamine (DA) transporter (DAT) acts across phylogeny to modulate DA signaling and behavior. We performed a forward genetic screen based on a hyperdopaminergic phenotype, “Swimming-induced paralysis” (Swip) that is displayed by animals with loss of *the C. elegans* DAT ortholog, DAT-1. One mutant that we recovered in this effort, *vt32*, was localized by SNP mapping and whole genome sequencing to an uncharacterized gene, here designated *swip-13*. We find that *swip-13* mutations result in significantly reduced sensitivity to the neurotoxic *dat-1* substrate 6-OHDA, supporting a role for *swip-13* in sustaining DAT-1 protein expression, surface trafficking and/or activity. Importantly, DA neuron-specific expression of the wild-type *swip-13* gene restores normal swimming behavior in *swip-13* animals, consistent with expression of SWIP-13 protein by DA neurons as key to kinase-modulation of DA signaling. Fluorescently-tagged, functional *swip-13* protein localizes to DA terminals, consistent with a presynaptic contribution to DA signaling. Implementation of an *in vivo*, FRAP-based approach reveals that *swip-13* animals display normal basal rates of vesicle DA release, whereas epistasis studies suggest that *swip-13* and *dat-1* function in the same pathway, possibly via kinase-modulation of DAT-1 trafficking or function. SWIP-13 is highly conserved, likely representing the nematode ortholog of a mammalian atypical MAP kinase, designated ERK7 in mouse), ERK8 in humans. Excitingly, ERK8/DAT co-expression in human neuroblastoma cells increases DA uptake capacity. Ongoing efforts seek to uncover the mechanism(s) by which SWIP-13 and ERK7/8 modulate DA signaling with an eye towards how our findings may provide insights into disorders linked to perturbed DA signaling.

Title: Abnormal dopaminergic signaling in mice expressing the ADHD-associated dopamine transporter variant DAT Val559

Authors: *R. GOWRISHANKAR[1], M. A. MERGY[1], S. C. GANTZ[2], P. J. GRESCH[1], G. L. DAVIS[1], J. T. WILLIAMS[2], M. K. HAHN[1], R. D. BLAKELY[1]

Abstract: Attention-Deficit/Hyperactivity Disorder (ADHD) is a widespread developmental neuropsychiatric disorder that has been associated with perturbations in dopamine (DA) signaling pathways. The presynaptic DA transporter (DAT) is the target for the most common pharmacological therapies for ADHD, amphetamine (AMPH) and methylphenidate (MPH) and is responsible for terminating DA signaling via reuptake of DA into the presynaptic terminal. Previous work in the lab revealed the presence of a heritable, functional DAT coding variant (DAT Val559) in subjects with ADHD and demonstrated that cells expressing DAT Val559 exhibit anomalous basal outward DA efflux (ADE) that can be blocked by AMPH and MPH. Owing to the striking phenotype of DAT Val559 *in vitro*, and the lack of ADHD mouse models with good construct validity, we engineered knock-in mice expressing the DAT Val559 variant. *In vivo* microdialysis studies of DAT Val559 mice revealed a pronounced elevation in basal, extracellular DA levels along with a significantly blunted efflux of DA evoked by locally infused AMPH, supportive of our heterologous expression studies. To probe the neuronal impact of the DAT Val559 variant, we first interrogated the cellular properties of DA neurons in the substantia nigra (SN) and found a prolongation of the decay of evoked, somatodendritic DA D2 autoreceptor (D2AR)-mediated IPSCs (D2-IPSCs), indicative of disruptions in DA homeostasis. We also observed a reduction in the amplitude of D2-IPSCs in AMPH. In striatal slices, we observed a near-complete loss of DAT-dependent AMPH-induced [3H]-DA release as well as a significant reduction in depolarization-evoked vesicular [3H]-DA release. The latter effect appears to derive from constitutive presynaptic D2AR activity, sustained by ADE, as the effects of the D2R agonist quinpirole to reduce [3H]-DA release is lost in slices from DAT Val559 mice, whereas release can be normalized with pre-treatment of slices with the D2R antagonist raclopride. Together, our studies confirm a functional impact of the DAT Val559 variant on DA neuron physiology and on both vesicular and AMPH-mediated DA release, providing potential insights into ADHD etiology and its treatment.

Title: An autism-derived de novo mutation in the dopamine transporter displays anomalous function that can be improved upon exposure to zinc

Authors: *P. J. HAMILTON[1], F. HERBORG HANSEN[5], N. G. CAMPBELL[1], C. SAUNDERS[2], A. N. BELOVICH[2], J. S. SUTCLIFFE[3], U. GETHER[5], H. J. G. MATTHIES[4], K. ERREGER[4], A. GALLI[4]

Abstract: De novo genetic variation is an important class of risk factors for autism spectrum disorder (ASD). Recently, whole exome sequencing of ASD families has identified a novel de novo missense mutation in the human dopamine (DA) transporter (hDAT) gene, which results in a Thr to Met substitution at site 356 (hDAT T356M). The DAT is a presynaptic transmembrane protein that regulates dopaminergic tone in the central nervous system by mediating the high-affinity re-uptake of synaptically released DA, making it a crucial regulator of DA homeostasis. We have previously reported a functional, structural, and behavioral characterization of this ASD-associated de novo mutation in the hDAT. We demonstrate that the hDAT T356M displays anomalous function, characterized as a reduction in DA uptake (substrate influx), a reduction in the amphetamine(AMPH)-induced DA efflux, and a persistent reverse transport of DA (substrate efflux). In the bacterial homolog leucine transporter, substitution of A289 (the homologous site to T356) with a Met promotes an outward-facing conformation upon substrate binding. In *Drosophila* melanogaster, expression of hDAT T356M in DA neurons lacking *Drosophila* DAT leads to hyperlocomotion, a trait associated with DA dysfunction and ASD. Here, we have demonstrated that exposure to micromolar quantities of Zn2+ improves the function of the hDAT T356M in terms of DA uptake. Importantly, Zn2+ also partially restores the ability of AMPH to cause DA efflux in hDAT T356M. Taken together, our findings demonstrate that alterations in DA homeostasis, mediated by aberrant hDAT T356M functions may stem from altered conformational equilibrium of the hDAT protein, possibly supporting risk for ASD and related neuropsychiatric conditions.

Title: Maybe not a story about the dopamine transporter: A novel role of PICK1 in regulating dopamine D1 receptor signaling in response to cocaine?

Authors: M. RICKHAG[1], M. RATHJE[1], G. SØRENSEN[1], A. H. R. THOMSEN[1], D. DENKCER[2], I. AMMENDRUP-JOHNSEN[1], K. ERREGER[3], A. GALLI[3], A. FINK-JENSEN[2], G. WÖRTHWEIN[4], K. L. MADSEN[1], *U. GETHER[1]

Abstract: Psychostimulants such as cocaine and amphetamine exert their action through their high affinity interaction with the presynaptic dopamine transporter (DAT), thereby increasing extracellular levels of dopamine. DAT belongs to the family of neurotransmitter:sodium symporters and plays a key role in maintaining dopamine homeostasis by mediating reuptake of dopamine from the synaptic cleft. DAT contains a C-terminal PDZ-domain binding sequence that can bind the PDZ domain of the scaffolding protein PICK1, as well as conceivably other yet unidentified PDZ-domain proteins. Our recent analyses of DAT knock-in mouse strains expressing DAT mutants incapable of interacting with PDZ domain proteins supported an essential role of PDZ domain interactions for distribution of DAT to striatal structures. However, a detailed analysis of PICK1 knock-out (KO) mice provided no evidence for a role of PICK1 in DAT regulation except from around 20% reduction in synaptosomal dopamine uptake.

Compared to WT mice, we found no change in DAT expression or distribution according to immunohistochemistry and western blotting experiments. In addition, surface biotinylation experiments showed no change in surface expression of DAT, amperometry experiments in striatal slices showed no change in amphetamine-induced dopamine efflux and sucrose density gradients centrifugation of striatal extracts showed no evidence for altered membrane raft association. Nonetheless, PICK1-KO mice were characterized by markedly reduced locomotor response to acute cocaine and amphetamine stimulation. Moreover, we observed impairment of behavioral sensitization as well as decreased self-administration of cocaine. Interestingly, stimulation with a selective dopamine D1 receptor agonists suggested that the reduced response to psychostimulants is caused by impaired postsynaptic dopamine D1 receptor signaling. A role of PICK1 in postsynaptic D1 receptor signaling was further supported by altered phosphorylation of DA- and cAMP regulated phosphoprotein (DARPP-32) in PICK1 KO mice. Summarized, our data suggest a hitherto unknown role of PICK1 in regulating downstream signaling in dopamine D1 receptor positive neurons.

Title: A novel dopamine transporter (DAT) variant (ΔN336) associated with autism ablates dopamine transport function

Authors: ***N. CAMPBELL**, A. N. BELOVICH, P. J. HAMILTON, A. SHEKAR, K. ERREGER, A. GALLI, J. S. SUTCLIFFE
Ctr. for Mol. Neurosci., Vanderbilt Univ., Nashville, TN

Abstract: Autism spectrum disorder (ASD) is a neuropsychiatric condition affecting approximately 1% of the population and is characterized by a spectrum of impairments in social interactions and communication, and patterns of rigid-compulsive behaviors. ASD risk is

predominantly determined by genetic factors, however, this etiological architecture is highly complex. Rare, functional genetic variation (both de novo and inherited) is widely accepted as a significant contributor to susceptibility, and that multiple alleles within a particular gene can harbor coding or structural variants predisposing an individual to disease risk. Our recent discoveries on the functional consequences of a de novo missense mutation (T356M) within the dopamine (DA) transporter (DAT) gene (SLC6A3) in an ASD proband have strongly implicated disruption of DA transport as a potential biological risk factor in ASD. Here we report a novel, SLC6A3 variant, also identified in an ASD proband from whole exome sequencing (WES). The genetic variant is an in-frame deletion of three nucelotides resulting in a deletion of amino acid N336. Located in the third intracellular loop, N336 is conserved from human to *Drosophila*, and in silico algorithms predict a functionally damaging effect. Expression of ΔN336 DAT in Chinese hamster ovary (CHO) cells revealed a near absence of DAT-dependent DA uptake relative to wildtype DAT, yet surface expression was not affected. These results, when taken together with prior association of abnormal DAT function with attention deficit-hyperactivity disorder (ADHD), may inform the link between ASD and ADHD, which co-occurs in ~40% of people with ASD. Most importantly, this work adds to the growing body of literature implicating altered regulation of DA homeostasis/transport as a potential biological mechanism underlying liability to ASD.

Title: SLC6A3 coding variant Ala559Val found in two autism probands alters dopamine transporter function and trafficking

Authors: E. BOWTON[1], C. SAUNDERS[2], I. A. REDDY[1], N. G. CAMPBELL[1], P. J. HAMILTON[1], L. K. HENRY[4], H. COON[5], D. SAKRIKAR[2], J. M. VEENSTRA-VANDERWEELE[3], R. D. BLAKELY[2], J. S. SUTCLIFFE[1], H. J. MATTHIES[1], *K. ERREGER[1], A. GALLI[1]

Abstract: Emerging evidence associates dysfunction in the dopamine (DA) transporter (DAT) with the pathophysiology of autism spectrum disorder (ASD). The human DAT (hDAT; SLC6A3) rare variant with an Ala to Val substitution at amino acid 559 (hDAT A559V) was previously reported in individuals with bipolar disorder or attention-deficit hyperactivity disorder (ADHD). We have demonstrated that this variant is hyper-phosphorylated at N-terminal serine (Ser) residues and exhibits an anomalous DA efflux (ADE) phenotype. Here, we report the novel identification of hDAT A559V in two unrelated ASD subjects and provide the first mechanistic description of its impaired trafficking phenotype. DAT surface expression is dynamically regulated by DAT substrates including the psychostimulant amphetamine (AMPH), which causes hDAT trafficking away from the plasma membrane. The integrity of DAT trafficking directly impacts DA transport capacity and therefore dopaminergic neurotransmission. Here, we show that hDAT A559V is resistant to AMPH-induced cell surface redistribution. This unique trafficking phenotype is conferred by altered protein kinase C β (PKCβ) activity. Cells expressing hDAT A559V exhibit constitutively elevated PKCβ activity, inhibition of which restores the AMPH-induced hDAT A559V membrane redistribution. Mechanistically, we link the inability of hDAT A559V to traffic in response to AMPH to the phosphorylation of the five most distal DAT N-terminal Ser. Mutation of these N-terminal Ser to Ala restores AMPH-induced trafficking. Furthermore, hDAT A559V has a diminished ability to transport AMPH, and therefore lacks AMPH-induced DA efflux. Pharmacological inhibition of PKCβ or Ser to Ala substitution in the hDAT A559V background restores AMPH-induced DA efflux. Although hDAT A559V is a rare variant, it has been found in multiple probands with neuropsychiatric disorders associated with imbalances in DA neurotransmission, including ADHD, bipolar disorder, and now ASD. These findings provide valuable insight into a new cellular phenotype (altered hDAT trafficking) supporting dysregulated DA function in these disorders. They also provide a novel potential target (PKCβ) for therapeutic interventions in individuals with ASD.

Title: An autism-associated variant at position 346 of the dopamine transporter impairs dopamine uptake while increasing transporter membrane expression

Authors: *I. REDDY[1,2], N. G. CAMPBELL[2], J. S. SUTCLIFFE[2], A. GALLI[2]
[1]Vanderbilt Univ. Sch. of Med. - VBI, Nashville, TN; [2]Mol. Physiol. and Biophysics, Vanderbilt Univ. Sch. of Med., Nashville, TN

Abstract: The dopamine (DA) transporter (DAT) acts to recycle released DA back into terminals and thus regulates extracellular DA levels. The DAT is also the primary target of the psychostimulant drugs amphetamine and cocaine. A small number of rare variants in the DAT gene (SLC6A3) have recently been linked to autism spectrum disorder (ASD). Here we report on a novel, SLC6A3 ASD variant identified via high-throughput exome sequencing in an affected individual belonging to the ARRA Autism Sequencing Consortium. This variant results in an alanine to a valine missense substitution at position 346 (A346V). We found that Chinese hamster ovary (CHO) cells expressing human DAT (hDAT) A346V exhibit a significant reduction in the Vmax of [3H]DA uptake but unaltered Km with respect to hDAT expressing cells. Somewhat surprisingly, this reduction in uptake was associated with a 44.3% increase in hDAT A346V membrane surface expression ($p<0.05$). Given that A346 is located within a conserved region of transmembrane domain 7 thought to interact with cholesterol, even a conservative amino acid change at this position could be responsible for increasing basal surface expression through altered interactions with the plasma membrane. Altered surface expression patterns might, in turn, disrupt DAT function and responsiveness to psychostimulants. Continuing work to identify the mechanisms behind such dysfunction will allow us to create new molecular models of disease and therapeutics for ASD.

Title: Dopamine transporter variant associated with autism spectrum disorder displays impaired interaction with plasma membrane phospholipids

Authors: *A. N. BELOVICH[1], N. G. CAMPBELL[2], P. J. HAMILTON[2], A. M. POE[3], K. ERREGER[3], H. J. G. MATTHIES[3], J. S. SUTCLIFFE[4], A. GALLI[3]
[1]Pharmacol., [2]Neurosci. Program in Substance Abuse, [3]Mol. Physiol. and Biophysics, [4]Psychiatry, Vanderbilt Univ. Med. Ctr., Nashville, TN

Abstract: Autism spectrum disorder (ASD) represents a group of developmental disorders characterized by deficits in social and communication skills, patterns of rigid-compulsive behaviors, and in many instances, an array of impaired motor functions. ASD is often comorbid with several other neuropsychiatric conditions, including ADHD and schizophrenia. ASD has devastating effects on the affected individuals and their caretakers, and represents a tremendous societal concern. The dopamine (DA) transporter (DAT) is a presynaptic membrane protein that clears extracellular DA through an active reuptake mechanism. Recently, we have demonstrated that a de novo mutation in the human DAT (hDAT) gene (SLC6A3) affects function of the hDAT and is associated with ASD (Thr to Met substitution at site 356: hDAT T356M). This suggests that DA neurotransmission can play an important role in the neural underpinnings of ASD pathology. Here, we show that a private, novel, heritable, ASD-associated genetic variation in hDAT (Arg to Trp substitution at site 51: hDAT R51W), displays significant functional deficits in sustaining reverse transport DA, as assessed using amperometry. However, the ability of the hDAT R51W to uptake DA is indistinguishable from wild type hDAT, suggesting this novel variant selectively impacts reverse DA transport. Using co-immunoprecipitation experiments, we demonstrate that the hDAT R51W has a significantly impaired interaction with phosphoinositol (4,5)-bisphosphate (PIP2), which has been previously demonstrated to be a key player in AMPH-induced DA efflux. hDAT R51W may therefore shed light on the importance of the N-terminus of hDAT and its interaction with the plasma membrane for neuropathologies, such as ASD. Taken together with our work on several novel ASD hDAT variants, these results strongly suggest that altered regulation of DA transport is a biological liability for ASD risk. A.N. Belovich and N.G. Campbell contributed equally to this work. J.S. Sutcliffe and A. Galli contributed equally to this work.

Title: P38 mitogen-activated protein kinase mediated norepinephrine transporter regulation modulates cocaine sensitization and conditioned place preference

Authors: *P. MANNANGATTI[1], K. NARASIMHA NAIDU[2], M. I. DAMAJ[2], S. RAMAMOORTHY[2], L. D. JAYANTHI[2]

Abstract: The noradrenergic and p38 mitogen activated protein kinase (p38 MAPK) systems have been implicated in behavioral effects of cocaine. The psychostimulant drug cocaine targets the presynaptic norepinephrine transporter (NET), and in part contributes to cocaine-mediated behaviors. Previously, we demonstrated a role for p38 MAPK mediated NET-T30 phosphorylation in cocaine upregulation of NET (Mannangatti et al, 2011 JBC). The present study explored the functional interaction between p38 MAPK mediated T30-phosphorylation dependent NET regulation and cocaine-induced behaviors. *In vitro* cocaine treatment of mouse prefrontal cortex (PFC) synaptosomes upregulated NET function, surface expression and phosphorylation. These cocaine-mediated effects are sensitive to both p38 MAPK inhibition and manipulation of NET-T30 phosphorylation suggesting the involvement of p38 MAPK mediated NET phosphorylation in cocaine upregulation of mouse NET. *In vivo* administration of p38 MAPK inhibitor SB203580 completely blocked cocaine-induced NET upregulation and p38 MAPK activation in the mouse PFC. Furthermore, *in vivo* administration of TAT-NET-T30 WT peptide but not the T30A mutant peptide completely abolished cocaine-induced NET upregulation. When tested for cocaine-induced locomotor sensitization and conditioned place preference (CPP), mice receiving SB203580 exhibited reduced cocaine-mediated locomotor sensitization and CPP compared to those receiving the vehicle. Similarly, mice receiving TAT-NET-T30 WT peptide but not the T30A mutant peptide exhibited blunted locomotor sensitization and CPP in response to cocaine. These findings indicate that selective interference of cocaine regulation of NET by either p38 MAPK inhibition or TAT-NET-T30 peptide strategy

attenuates cocaine locomotor sensitization and CPP revealing an important role for p38 MAPK mediated NET regulation in cocaine-elicited behaviors.

Title: Modulation of serotonin transporter function by kappa opioid receptor ligands

Authors: *S. SUNDARAMURTHY[1], S. RAMAMOORTHY[1], L. JAYANTHI[2]
[1]pharmacology and toxicology, Virginia Commonwealth Univ., Richmond, VA; [2]pharmacology and toxicology, virginia commonwealth university, richmond, VA

Abstract: Kappa opioid receptor (KOR) agonists produce dysphoria and psychotomimesis. While KOR agonists produce pro-depressant like effects, KOR antagonists produce anti-depressant-like effects in rodent models. The cellular mechanisms and downstream effector(s) by which KOR ligands produce these effects are not clear. KOR agonists modulate serotonin (5-HT) transmission in brain regions implicated in the regulation of mood and motivation. Presynaptic serotonin transporter (SERT) activity is critical in the modulation of synaptic 5-HT and hence in mood disorders. Detailing the molecular events of KOR-linked SERT regulation is important in view of the postulated role of this protein in mood disorders. The present study used heterologous expression systems and native tissue preparations to determine the cellular signaling cascades linked to KOR-mediated SERT regulation. KOR agonists U69,593 or U50,488 produced a concentration dependent, KOR antagonist-reversible decrease in SERT function. KOR-mediated functional down-regulation of SERT is sensitive to CamKII and Akt inhibition. The U69,593-evoked decrease in SERT activity is associated with decreased Vmax, increased SERT phosphorylation and cell surface expression. Furthermore, activation of KOR increases SERT-PP2Ac association, while SERT-syntaxin 1A association is decreased. These data demonstrate that KOR activation decreases SERT function. The decrease in function is likely due to alterations in SERT phosphorylation, trafficking and protein-protein interactions.

Interestingly, KOR-agonists exhibit differential influence on amine transporters in that they increase DAT function and decrease SERT function while having no effect on NET function. We hypothesize that the opposing effects of KOR agonists on SERT and DAT function may contribute to the pro-depressant and psychotomimetic effects of these agents.

Title: Role of neurokinin 1 signaling in amphetamine mediated norepinephrine transporter regulation

Authors: *L. D. JAYANTHI, P. MANNANGATTI, S. RAMAMOORTHY
Pharmacol. & Toxicology, Virginia Commonwealth Univ., Richmond, VA

Abstract: The functional expression of norepinephrine (NE) transporter (NET) is rapidly coupled to the dynamics of NET regulatory mechanisms. Post-translational mechanisms phosphorylation, trafficking, and protein-protein interactions have been the focus of our investigations addressing NET regulation. Our previous work has provided evidence linking Substance-P/Neurokinin-1 receptor (SP-NK1R) mediated NET downregulation to PKC-induced phosphorylation of NET-T258/S259 motif. Very recently, we have demonstrated that raft-mediated protein-protein interactions play an important role in facilitating NK1R mediated NET regulation. Previously, we have also shown that the PKC-resistant T258/S259 motif is required for amphetamine (AMPH) mediated NET downregulation. However, the physiological significance of NK1R mediated NET regulation as well as the involvement of T258/S259 trafficking motif in both NK1R and AMPH mediated NET down regulation are unclear. Interestingly, AMPH is known to facilitate *in vivo* release of SP in the rodent nucleus accumbens. In addition, it has been shown that SP enhances amphetamine induced motor behavior and NK1R antagonists decrease psychostimulant-induced locomotor activity. Given the fact that NK1R modulates NET, and that NET is effective in clearing synaptic NE, it is possible that the interaction of NET and NK1R signaling may contribute to the physiological responses

mediated by AMPH. Here we report that *in vivo* administration of selective NK1R agonist, GR73632 results in reduced NE transport and plasma membrane expression of NET in the rat VST synaptosomes. Administration of NK1R antagonist, aprepitant prior to GR73632 administration prevents these NK1R-mediated effects. We also show that *in vivo* administration of AMPH results in reduced NET function and expression in the rat VST synaptosomes. Immunoprecipitation experiments revealed stable physical complexes containing abundant NET and NK1R proteins in the ventral striatum. Studies are underway examining the role of SP-NK1R signaling in AMPH mediated NET regulation and the significance of such regulation in AMPH-elicited behavioral effects. Results from these studies will provide new insights into the role of neurokinins in AMPH-mediated NET regulation and its contribution to behavior.

Title: Akt mediated regulation of the serotonin transporter function, expression and phosphorylation

Authors: *J. RAJAMANICKAM[1], B. ANNAMALAI[3], L. D. JAYANTHI[2], S. RAMAMOORTHY[2]
[1]Dept. of Pharmacol. and Toxicology, [2]Pharmacol. and Toxicology, Virginia Commonwealth Univ., Richmond, VA; [3]Pathology & Lab. Med., Med. Univ. of South Carolina, Charleston, SC

Abstract: The serotonin (5-HT) transporter (SERT) controls serotonergic neurotransmission in the brain by rapid clearance of 5-HT from the synaptic cleft into presynaptic neurons. Altered SERT function is associated with psychiatric disorders and drug addiction. SERTs are primary targets for antidepressants and psychostimulants. The molecular basis for the alterations in SERT function in the mental illnesses or in drug abuse is largely unknown. Our previous studies have identified the involvement of several signaling pathways and protein kinases in regulating SERT function and expression. In this study, we investigated on the role of protein kinase B/Akt in regulating SERT function and expression. Treatment of human embryonic kidney (HEK 293)

cells expressing SERT with Akt phosphorylation inhibitor 'Akt inhibitor X' (AktX) significantly reduced 5-HT uptake in a time- and concentration- dependent fashion. AktX treatment reduced the levels of endogenously phosphorylated Akt. Furthermore, RNA interference targeted to Akt reduced total Akt, phospho-Akt levels as well as 5-HT uptake, confirming the involvement of active Akt in SERT regulation. Kinetic assay revealed reduced SERT Vmax and biotinylation experiments revealed reduced cell surface expression of SERT following AktX treatment that correlated with reduced SERT function. AktX treatment also reduced SERT exocytosis and SERT basal phosphorylation suggesting that reduced cell surface expression could arise from reduced plasma membrane delivery of the transporter protein that may be linked to regulation of SERT phosphorylation. These results collectively suggest that constitutively active Akt maintains functional expression of SERT and that any changes in the activation of Akt could alter SERT mediated 5-HT clearance and subsequently serotonergic neurotransmission.

Title: Mechanism of internalization of the dopamine transporter by amphetamine

Authors: *S. M. UNDERHILL[1], D. S. WHEELER[3], R. L. COLLIER[2], E. THIELS[3], S. G. AMARA[2]
[1]Lab. of Mol. and Cell. Neurobio., [2]NIH/NIMH, Bethesda, MD; [3]Univ. of Pittsburgh, Pittsburgh, PA

Abstract: Amphetamine (AMPH) and its derivatives are useful therapeutic agents, but also pose a danger as a consequence of their addictive properties. Acute AMPH exposure elevates extracellular dopamine by a variety of mechanisms including an increase in the rate of internalization of the plasma membrane dopamine transporter (DAT). In this study, we

investigated the mechanism of AMPH-mediated DAT endocytosis. We report here that AMPH-mediated DAT internalization is clathrin independent but requires dynamin and activation of the small GTPase RhoA. GFP-tagged clathrin light chain does not colocalize with mCherry-tagged DAT after AMPH treatment indicating a clathrin independent process. The dynamin inhibitors, Dynasore and Dynole-34-2, both attenuate AMPH-induced endocytosis of DAT. We also found that AMPH activates both of the small GTPases Rho and Rac and in recombinant expression systems, primary cultures and midbrain slices, activation of Rho and the downstream Rho-kinase (ROCK) triggers endocytosis of DAT. Inhibition of RhoA activity with a dominant negative mutant or introduction of the botulinum neurotoxin C3 prevents AMPH-induced DAT internalization. However, Rac1 inhibition has no significant effect on DAT trafficking. The ROCK inhibitor Y27632 also prevents AMPH-induced DAT internalization further supporting Rho activation in this phenomenon. Intriguingly, we found that AMPH must enter the cell to initiate this cascade, implicating an intracellular target in this event. Intracellular AMPH also increases cAMP leading to the serine phosphorylation of Rho by protein kinase A (PKA) that inactivates Rho and serves as a brake on DAT internalization, thus demonstrating an important interaction between PKA- and RhoA-dependent signaling in mediating the actions of AMPH. In agreement with our observations in cell lines and brain slices, we also found that the activation of D1/D5 receptors that couple to PKA in dopamine neurons within the brain *in vivo* can antagonize the DAT trafficking and behavioral effects of AMPH in mice. These observations reveal a novel intracellular target that mediates the effects of AMPH on Rho and cAMP signaling and suggest new pathways to target in order to better understand the mechanisms of action of AMPH.

Title: The sigma-1 receptor interacts with the dopamine transporter and regulates its activity

Authors: *D. O. SAMBO[1], M. LIN[1], D. ANGOLI[1], B. RICHARDSON[1], E. CARTIER[1], M. SCHWENDT[1], B. BLOUGH[2], J. KATZ[3], H. KHOSHBOUEI[1]

Abstract: The primary mechanism for terminating dopaminergic signaling in the brain is reuptake of dopamine (DA) via the dopamine transporter (DAT). This transporter is implicated in a variety of neurological disorders and is one of the main targets for highly addictive psychostimulants cocaine and methamphetamine (METH). METH acts as a substrate for DAT, increasing synaptic DA levels by competing with DA at the transporter as well as inducing efflux of DA into the synapse. Previous studies indicate that METH exposure causes up-regulation of an endoplasmic reticulum chaperone protein called the sigma-1 receptor in DAT-expressing regions of the brain. Upon activation, this protein can translocate to the plasma membrane where it has been shown to modulate the activity of various receptors and channels. We have shown that DAT and the sigma-1 receptor interact at the plasma membrane, and that this interaction is potentiated by treatment with METH. In this study, we investigated the functional consequence of the DAT/sigma-1 receptor interaction on the activity of the transporter. These results show that the up-regulation of the sigma-1 receptor reduces the METH blockade of DA uptake, decreases METH-induced DA efflux, and inhibits METH-induced firing activity in dopaminergic neurons. These data suggest that up-regulation of the sigma-1 receptor may provide compensatory mechanisms to reduce the effects of METH. Understanding the mechanism of sigma-1 receptor regulation of DAT activity may reveal a novel therapeutic target for the treatment of METH addiction.

Title: Imaging the cholesterol-dependent dopamine transporter nanodomains in the plasma-membrane

Authors: *T. RAHBEK-CLEMMENSEN, S. ERLENDSSON, J. ERIKSEN, F. VILHARDT, T. NYGAARD JØRGENSEN, U. GETHER
Dept. of Neurosci. and Pharmacol., Univ. of Copenhagen, Copenhagen N, Denmark

Abstract: The dopamine transporter (DAT) is an integral membrane protein that regulates dopamine homeostasis by mediating reuptake of released dopamine. Here we employ super-resolution microscopy techniques to investigate the cellular distribution of DAT at a resolution exceeding that of conventional fluorescence microscopy. Application of stochastic optical reconstruction microscopy (STORM), using an antibody directed against the DAT N-terminus, showed that DAT was not uniformly distributed in the plasma membrane of the neuronal extensions, varicosities and growth cones in cultured dopaminergic neurons but localized to discrete nanoscale domains with diameters of ~100-500 nm. The DAT signal appeared on either side of the extensions, permitting separation of two plasma membrnes sheets <95 nm apart. STORM imaging of catecholaminergic CAD cells transiently expressing DAT revealed a similar nanodomain distribution of the transporter. Moreover, a comparable nanodomain phenotype was seen with photoactivated localization microscopy (PALM) in CAD cells using photoswitchable Dronpa fused to the DAT N-terminus. Cholesterol-depletion with methyl-β-cyclodextrin decreased the number of DAT nanodomains in CAD cells while disrupting DAT clustering only in the varicosities and growth cones of the cultured neurons. The cytoskeleton disrupting agent cytochalasin D, however, showed a global effect on DAT clustering in dopaminergic neurons but only little or no effect in CAD cells. Summarized, we provide the first insight into the cellular distribution of DAT at subdiffracting resolution and obtain evidence for localization of DAT to discrete cholesterol-sensitive and cytoskeleton dependent nanodomains in dopaminergic neurons.

Title: Phosphorylation of PKC residues on the N-terminal of the dopamine transporter regulates amphetamine-stimulated dopamine efflux

Authors: *Q. WANG, N. BUBULA, P. VEZINA
Psychiatry, Univ. of Chicago, Chicago, IL

Abstract: Previously we showed that inhibiting PKC in the nucleus accumbens attenuates the ability of amphetamine to induce dopamine (DA) overflow in this site (Loweth et al., 2009). A role for the phosphorylation by PKC of the dopamine transporter (DAT) in this effect has been suggested by others showing that truncation of the first 22 amino acids of the N-terminal of the DAT also reduces amphetamine-induced DA efflux. This segment of the DAT N-terminal contains a number of putative PKC related residues including S4, S7, S12, and S13. Here we assessed the contribution of these residues to amphetamine-induced DA efflux by using serine to alanine (S-A) point mutations at each site on the DAT N-terminal. DATs with different S-A point mutations or combinations of S-A point mutations were transfected into HEK-293 cells and these were used to assess amphetamine-induced (10μM) DA efflux with an incubation procedure. WT-DATs were used as controls. In an initial experiment, we confirmed that inhibiting PKC with Go6976 (130nM) significantly reduced amphetamine-induced DA efflux. In follow-up experiments, cells transfected with the S12A, S13A, and S4,7,13A mutants showed a reduction of amphetamine-induced DA efflux similar to that observed with Go6976. The greatest reductions were observed with the S13A, and S4,7,13A mutants. Interestingly, cells transfected with the S7A mutant, identified by some as a PKC-PKA residue showed WT-DAT levels of amphetamine-induced DA efflux. These results suggest that multiple serine residues, either alone (S13) or in combination (S4,7,13), are targets for PKC phosphorylation during amphetamine-induced DA efflux.

Title: Characterization of human like dopaminergic neurons containing physiologically and pathologically relevant alpha-synuclein levels

Authors: *B. R. BUTLER, D. ANGOLI, H. KHOSHBOUEI
Univ. Of Florida, Gainesville, FL

Abstract: Dysregulation of dopaminergic signaling along with significant loss of midbrain dopaminergic neurons are pathological characteristics of Parkinson's disease (PD). Alpha-synuclein is a small neuronal protein whose physiological function has yet to be discovered. Alpha-synuclein has been implicated in the sporadic PD as it is a major component of the Lewy bodies, and point mutations of the protein along with locus triplication and duplication of the SNCA gene have shown to result in Familial PD. Here we seek to characterized the influence of alpha-synuclein overexpression in the dopamine neurons obtained from induced pluripotent stem cells (IPSCs) derived from control patients and those with triplication of alpha-synuclein that have been differentiated to dopaminergic neurons. Our preliminary results reveal that increased alpha-synuclein level in the human-like dopamine neurons 1) alters the resting membrane potential, where these neurons rest at a more depolarized state as compared with the neurons containing physiological level of alpha-synuclein. 2) Pathological level of alpha-synuclein influences the excitability of these neurons, 3) decreases the inward sodium current at voltages tested and 4) alters the amplitude of the action potential. These preliminary results suggest that the early stage alterations in the excitability of dopamine neurons mediated by increase alpha-synuclein may describe alpha-synuclein mediated pathologies in the long-term.

Title: Indole based structural analogs of modafinil inhibit the dopamine transporter

Authors: *C. EARLES OCHSNER, J. RUSSEL
Chem., St Norbert Col., DE PERE, WI

Abstract: Inhibition of the human dopamine transporter (hDAT) expressed in human embryonic kidney (HEK) by synthesized structural analogs of modafinil (2-[diphenylmethyl) sulfinyl] acetamide) was measured using rotating disk electrode voltammetry (RDEV). Our previous results using this technique show modafinil competitively inhibits the human dopamine

transporter in a manner similar to amphetamines. However, modafinil functionalized with reduced sulfur and an isopropylamide linkage inhibits the dopamine transporter in an uncompetitive manner similar to cocaine. These results lead us to functionalize the reduced sulfur isopropylamide arm with an indole instead of diphenylmethyl. The resulting compound did not inhibit transport, however, use of hydrophobic N-methyl in place of N-H indole inhibits the dopamine transporter in a dose dependent manner and appears to show competitive inhibition.

Title: The interaction between the dopamine transporter (DAT) and the SNARE protein syntaxin 1A is regulated by N-terminal phosphorylation of DAT

Authors: *K. L. MADSEN, T. FAURSCHOU ANDREASSEN, U. GETHER
Dept. of Neurosci. and Pharmacol., Univ. of Copenhagen, Copenhagen, Denmark

Abstract: Dopaminergic signaling serves multiple important cognitive functions including motor control and reward prediction. Correct regulation of DA homeostasis through tight temporal and spatial regulation is achieved by the release of stored DA containing vesicles and the subsequent reuptake into the presynaptic neuron by DAT. Improper regulation can lead to disease states such as Parkinson's disease, ADHD and schizophrenia. Moreover DAT is the principal target for multiple drugs of abuse including cocaine and amphetamine, which block the uptake of DA leading to increases the extra-synaptic concentration of DA as well as cellular responses such as trafficking and phosphorylation. The SNARE protein syntaxin 1A (STX1A) is a nervous system-specific; membrane bound protein implicated in the docking of synaptic vesicles to the plasma membrane. In addition to the role in synaptic release of neurotransmitters it has previously been implicated in regulating the function of DAT as co-expression of STX1A with DAT in heterologous cell cultures increases the AMPH induced efflux of DA. Despite the functional connection between STX1A and DAT the interaction site between the two proteins

are currently unresolved. Here we show, using a combination of FRET based assays in HEK293 cells and GST-pulldown that STX1A binds to the N-terminus of DAT and that specific phosphorylation sites on DAT are sufficient to regulate the interaction. Our results compliment previous findings on this interaction and provide a basis for the notion that proteins involved in the regulated exocytosis of neurotransmitters may regulate the reuptake in a dynamic, phophoregulated manner.

Title: Role of CaMKII in the persistence of *in vivo* hippocampal mossy fiber synaptic plasticity

Authors: *L. RAMOS-LANGUREN, Y. JUÁREZ, A. RIVERA-OLVERA, M. L. ESCOBAR
Fac Psicol,UNAM, Mexico City, Mexico

Abstract: Calcium/calmodulin-dependent protein kinase II (CaMKII) has been proposed as a suitable molecular substrate for long-term memory storage due to the capacity of this enzyme to maintain an active autophosporylated state even after the decay of the external stimuli. Recent work has demonstrated that CaMKII is necessary for the maintenance phase of long-term potentiation (LTP) in the CA1 synapses of hippocampal slices. The hippocampal mossy fiber-CA3 pathway (MF-CA3) is considered as a relevant area for acquisition and storage of different learning tasks. MF-LTP has been characterized by a slow initial increase in the EPSP slope that has been related to the independence of NMDA receptors activation. However, the molecular mechanisms that underlie the maintenance of long-lasting enhancement of synaptic transmission at MF pathway remain to be elucidated. Therefore, the aim of the present study was to evaluate the participation of CaMKII on the persistence of MF-LTP. Thus, we administrated acute microinfusions of the noncompetitive inhibitor of CaMKII (Myr-CaMKIINtide) in the hippocampal CA3 area of adult rats during the late-phase of *in vivo* MF-CA3 LTP. Our results show that CaMKII inhibition reverses MF potentiation in a persistent manner. These findings

support the idea that CaMKII is a key molecular substrate for the long-term synaptic plasticity maintenance.

Title: Ca2+-permeable AMPA receptors mediate functional compensation of cyclic GMP-dependent protein kinase II knockout in the hippocampus

Authors: *S. KIM[1], R. TITCOMBE[2], L. KHATRI[2], F. HOFMANN[3], E. B. ZIFF[4]
[1]Biochem., NYU Sch. Med., New York, NY; [2]NYU Med. Ctr., New York, NY; [3]Tech. Univ. of Munich, Munich, Germany; [4]NYU Sch. of Med., New York, NY

Abstract: Activity-dependent trafficking of GluA1-containing AMPA receptors (AMPARs) is an important mechanism for synaptic plasticity. Cyclic GMP-dependent protein kinase II (cGKII) is activated by the NMDA receptor (NMDAR)-nitric oxide (NO)-cGMP pathway, and promotes surface expression of GluA1 and LTP (long-term potentiation) through phosphorylation of GluA1 serine 845 [pGluA1(S845)]. While acute cGKII inhibition causes a robust reduction in LTP at CA1 synapses in the hippocampus, initial studies of the cGKII knockout (KO) mouse found no impairment of LTP. Thus, we hypothesize that cGKII KO, unlike acute inhibition, induces compensatory mechanisms that maintain normal hippocampal LTP. Here, we describe a functional compensation present in the cGKII KO based on the downregulation of phosphatase activity. The Ca2+-dependent phosphatase, calcineurin, dephosphorylates pGluA1(S845), which enables GluA1-containing AMPARs to be endocytosed from the plasma membrane during long-term depression. Reduction of calcineurin activity in cultured cortical neurons induces synaptic expression of Ca2+-permeable AMPARs (CPARs) during synaptic scaling. Furthermore, LTP is enhanced when CPARs are present at synapses. Thus, we hypothesized that cGKII KO maintains normal hippocampal LTP via expression of CPARs induced by a cGKII KO-mediated decrease in calcineurin activity. We determined

spontaneous synaptic transmission by measuring mEPSCs in DIV14-17 cultured hippocampal neurons obtained from cGKII KO mice. We found that the mEPSC amplitude was significantly increased in KO neurons, and this increase was inhibited by naspm (1-naphthyl acetyl spermine), a blocker of CPARs, suggesting synaptic CAPR expression in cGKII KO neurons. GluA1 and pGluA1(S845) levels were increased in PSD (post synaptic density) of cGKII KO hippocampus while GluA2 levels were decreased. Furthermore, surface GluA1 was increased but GluA2 was decreased in cultured cGKII KO neurons. Therefore, CPARs were expressed at synapses of cGKII KO hippocampus. We also determined that calcineurin activity was lower in mutant neurons, accounting for the increased pGluA1(S845). Using GCaMP5, a genetically encoded Ca2+ indicator, we confirmed that Ca2+ activity was lower in cGKII KO. Taken together, decreased Ca2+ activity in cGKII KO hippocampal neurons, reduces calcineurin activity, which in turn increased GluA1 phosphorylation and expressed synaptic CPARs, account for normal LTP in the mutant hippocampus. These findings suggest that genetic deletion of cGKII causes functional compensation at a molecular level that increases CPARs at synapses, which maintains normal hippocampal LTP.

Title: Post-translational regulation of Arc/Arg3.1 by Erk2

Authors: O. NIKOLAIENKO, M. S. ERIKSEN, *C. R. BRAMHAM
Dept Biomed and KG Jebsen Ctr. for Res. on Neuropsychiatric Disorders, Univ. of Bergen, N-5009 Bergen, Norway

Abstract: The immediate-early gene ARC (aka ARG3.1) is required for long-lasting synaptic plasticity and memory formation. Arc expression is precisely regulated in space and time by activation of extracellular signal-regulated kinase (Erk/MAPK). Here, we found that Erk2 also acts as a post-translational regulator of Arc. Using in silico tools Arc was predicted to bind Erk

family kinases and to contain several potential Erk phosphorylation sites. GST-fused Arc of rat origin was able to pull down endogenous Erk1 and Erk2 from rat hippocampal lysates. Using a cellulose-bound peptide array covering the Arc/Arg3.1 sequence, we mapped the binding site of purified Erk2 on Arc. Activated Erk2 phosphorylated bacterially expressed Arc *in vitro* at different sites, as confirmed by phospho-specific protein staining and subsequent LC-MS/MS analysis. We also raised rabbit polyclonal antibodies that specifically recognize S206-phosphorylated Arc and show that this residue is modified *in vivo* and that treatment with the mitogen-activated protein kinase kinase (MEK) inhibitor U0126 affects Arc S206 phosphorylation. The results identify Arc as an Erk substrate and further suggest a dual role for Erk signaling in regulating Arc expression and function.

Title: A critical time window for dopamine actions on the structural plasticity of dendritic spines

Authors: *S. YAGISHITA[1], A. HAYASHI-TAKAGI[1], G. C. R. ELLIS-DAVIES[2], H. URAKUBO[3], S. ISHII[3], H. KASAI[1]
[1]The Univ. of Tokyo, Tokyo, Japan; [2]Dept. of Neurosci., Mount Sinai Sch. of Med., New York, NY; [3]Dept. of Systems Science, Grad. Sch. of Informatics, Kyoto Univ., Uji, Kyoto, Japan

Abstract: Animal behaviors are reinforced by subsequent rewards that follow the behaviors within a narrow time window. The reward is coded by the phasic activity of dopaminergic neurons in the ventral tegmental area (VTA), which densely innervates the medium spiny neurons (MSNs) in the nucleus accumbens of the striatum, a key brain area for reinforcement

learning in mammals. Glutamatergic synapses on dendritic spines of the MSNs also receive sensorimotor inputs that evoke action potentials (APs). These concurrent neuronal activities of synaptic inputs and APs can induce spike-timing-dependent plasticity (STDP), a major Hebbian learning mechanism. Although dopamine may modulate the STDP, the slow kinetics of dopamine-regulated kinase signaling contradicts the ability to detect the narrow time sequence, and its mechanisms remain unknown. Here, we selectively stimulated dopaminergic and glutamatergic inputs on MSNs by optogenetic stimulation of dopaminergic fibres and two-photon uncaging of caged-glutamates paired with APs (STDP) in MSNs in acute slices of mouse brain. We found that dopamine markedly potentiated spine enlargement, but this only occurred within a narrow time window (0.3-2 s) closely following STDP, which is consistent with behavioural conditioning findings. FRET imaging of Ca2+/calmodulin-dependent protein kinase II (CaMKII) and protein-kinase A (PKA) revealed that the sequence detection involved molecular signaling upstream of PKA activation: Sufficient generation of cAMP for PKA activation occurred only when spikes preceded dopamine to prime adenylyl-cyclase (AC1), otherwise cAMP was effectively removed by a potent phosphodiesterase (PDE) activity in thin distal dendrites of MSNs due to a large surface-to-volume ratio. Therefore, PKA was activated only within the specific timing for reinforcement, which then activated CaMKII through the dopamine- and cAMP-regulated phosphoprotein 32 kDa (DARPP-32). Thus, we have clarified the molecular basis of reinforcement plasticity which is induced at the level of single dendritic spines.

Title: CaMKIIα is necessary and sufficient for NMDA receptor-mediated long-term potentiation at the hippocampal mossy fiber-to-CA3 pyramidal cell synapse

Authors: *P. A. HAEGER[1,2], T. J. YOUNTS[2], R. LUJAN[3], S. J. TAVALIN[4], J. W. HELL[5], P. E. CASTILLO[2]

Ctr., Memphis, TN; [5]Dept. of Pharmacol., Univ. of California at Davis, Davis, CA

Abstract: NMDA receptors (NMDARs) are heterotetrameric ligand-gated ion channels classically associated with controlling the induction of long-term plasticity of AMPA receptor-mediated synaptic transmission. Beyond this traditional role, our group recently identified a form of long-term potentiation (LTP) of NMDAR-mediated synaptic transmission expressed at the hippocampal mossy fiber (mf)-to-CA3 pyramidal cell (mf-CA3) synapse, termed NMDAR-mfLTP. To date, however, the molecular mechanisms underlying this form of plasticity are incompletely understood. NMDARs are typically composed of two GluN1 and two GluN2 (GluN2A or GluN2B) subunits. NMDAR subunit composition confers distinct functional properties to the channel, and imparts interaction specificity between the NMDAR and effector proteins like the Ca2+-sensitive enzyme Ca2+/calmodulin-dependent protein kinase IIα (CaMKIIα). CaMKIIα is a major constituent of excitatory synapses, interacts with the GluN2B subunit, and is central to the regulation and induction of classical AMPAR-LTP. In this study, we first examined NMDAR subunit expression at mf-CA3 synapses using electron microscopy and selective pharmacology. We then investigated the role of CaMKIIα in NMDAR-mfLTP using *in vitro* electrophysiology in rat and mouse hippocampal slices along with molecular manipulations that interfere with CaMKIIα signaling and the CaMKIIα-GluN2B interaction. We found that both GluN2A and GluN2B subunits are expressed at the mf-CA3 synapse. We also observed that the selective CaMKIIα inhibitor KN-93 blocked NMDAR-mfLTP whereas the inactive analog KN-92 had no effect. Likewise, when CA3 pyramidal neurons were loaded through the patch-pipette with a CaMKIIα inhibitory peptide (CaMKII-Ntide), which operates by a distinct mechanism from that of KN-93, we found that CaMKII-Ntide strongly inhibited NMDAR-mfLTP. Furthermore, we took advantage of a recently developed GluN2B knock-in mouse where the CaMKIIα-GluN2B interaction is impaired by two point mutations: L1298A and R1300Q. NMDAR-mfLTP was severely compromised in GluN2B-KI mice compared with littermate controls. Finally, by loading a constitutively active version of CaMKII(1-290) directly into CA3 pyramidal cells via the patch pipette, we found that CaMKIIα is sufficient to potentiate NMDAR-mediated mf-CA3 synaptic transmission. Together, these findings indicate CaMKIIα is

both necessary and sufficient for long-term plasticity at the mf-CA3 synapse and that the CaMKII-GluN2B interaction is a key step required for NMDAR-mfLTP. Our study supports the notion that CaMKIIα is an activity-dependent coordinator of synaptic NMDAR plasticity.

Title: Intracellular membrane association of *Aplysia* phosphodiesterase long- and short-form via different targeting mechanisms

Authors: Y.-W. JUN[1], J.-A. LEE[3], B.-K. KAANG[4], *D.-J. JANG[2]
[1]Kyungpook Natl. Univ., Sang-Ju, Korea, Republic of; [2]Dept. of Applied Biol., Kyungpook Natl. Univ., Sangju-si/gyeongsangbuk-Do, Korea, Republic of; [3]Hannam Univ., Daejeon, Korea, Republic of; [4]Seoul Natl. Univ., Seoul, Korea, Republic of

Abstract: Phosphodiesterases (PDEs) play key roles in the compartmentalization of cAMP in intracellular signaling processes through specific subcellular targeting. Previously, we have shown that *Aplysia* PDE4 (ApPDE4) long- and short-form, which were localized to distinct subacellular membrane organelles, play key roles in 5-HT-induced synaptic facilitation in *Aplysia* sensory to motor synapses. However, the molecular mechanism of the isoform-specific distinct subcellular membrane targeting was not clear. In this study, we further deciphered the molecular mechanism of the membrane targeting of ApPDE4 long- and short-form. We found that the membrane targeting of the long-form was mediated by hydrophobic interactions mainly via 16 amino acids at the N-terminal, whereas the short-form was targeted solely to the plasma membrane mainly by nonspecific electrostatic interactions between the N-terminal region and negatively charged lipids including PI4P and PI(4,5)P_2 in the plasma membrane. Moreover, oligomerization of the short-form by interaction of a truncated upstream conserved region 1 (UCR1) domain and a UCR2 domain enhanced the plasma membrane targeting of the short-form. These results suggest that ApPDE4 long- and short-form can be distinctly targeted to the intracellular membranes by direct membrane association via hydrophobic and electrostatic interactions, respectively.

Title: Phosphorylation and degradation of the CREB repressor ATF4 during long-lasting long-term potentiation

Authors: ***K. A. HAYNES**[1], W. XU[2], A. N. HEGDE[1]
[1]Neurobio. and Anat. Dept., Wake Forest Univ. Hlth. Sci., Winston Salem, NC; [2]Wake Forest Univ., Winston Salem, NC

Abstract: Activating transcription factor 4 (ATF4), the murine ortholog for human cAMP-response element binding protein 2 (CREB2), is a negative regulator of transcription. Previous work by others has shown that ATF4 phosphorylation at serine-219 is necessary for ubiquitination and degradation by the ubiquitin-proteasome pathway (UPP) (Lassot et al. 2001; Mol. Cell Biol. 21(6):2192-202). Using long-lasting chemically-induced long-term potentiation (LTP) and immunofluorescent labeling in coronal hippocampal slices from C57BL/6 mice, we endeavored to determine the time-course for ATF4 phosphorylation at serine-219 during LTP and the kinase responsible for this phosphorylation. We found that ATF4 phosphorylation at serine-219 peaks at 20 minutes after LTP induction, returning to control levels by 30 minutes. Furthermore, we determined that inhibition of the proteasome with beta-lactone blocks the decrease in ATF4 to baseline suggesting that the phosphorylation of ATF4 at serine-219 during LTP is indeed leading to the degradation of the transcriptional repressor via the UPP. Finally, we found that the serine-219 phosphorylation could be blocked with the general kinase inhibitor, staurosporine, suggesting a subset of likely candidates for the kinase responsible for marking ATF4 for ubiquitination and degradation by the UPP. Because de novo transcription is necessary for the maintenance of LTP, these results provide novel insight into the molecular mechanisms behind LTP regulation by the UPP through the degradation of transcriptional repressors such as ATF4.

Title: CaM Kinases are critical for activity-dependent gene expression in parvalbumin positive inhibitory interneurons

Authors: *S. M. COHEN, R. W. TSIEN
NYU Sch. of Med., New York, NY

Abstract: Transcriptional regulation via excitation-transcription (E-T) coupling is essential for the long-term adaptive changes that occur during brain development, learning and memory, and drug addiction. Recent work has demonstrated that experience induces plastic changes in parvalbumin (PV) positive interneurons to regulate adult learning. Environmental enrichment and fear conditioning induce opposite changes in levels of PV expression, with direct implications for memory consolidation and retrieval, excitatory-to-inhibitory synaptic-density ratios, and structural synaptic plasticity {{Donato, 2013}}. We study mechanisms of E-T coupling in PV+ interneurons, employing pharmacological, imaging, and immunocytochemical techniques on cultured rat cortical neurons. Depolarization of PV+ neurons for 2 min with a 40mM K+ solution resulted in a marked increase in PV and c-fos expression in PV+ cells. This increase was blocked by CaV1 (L-Type) blocker Nimodipine or Ca2+/CaM dependent Kinase (CaMK) blocker KN93. MEK1 inhibitor PD98059 partially inhibited this increase. To understand the mechanism underlying this activity dependent increase in PV, we focused on the steps leading to Ser133 phosphorylation of the transcription factor CREB (pCREB). Regulation of this key signaling event remains relatively unexplored in inhibitory interneurons. We showed that PV+ cells can employ CaMKs to trigger nuclear CREB phosphorylation. Nimodipine, KN93 and CaMKK inhibitor Sto609 prevented increases in pCREB after 30 seconds of K+-depolarization. Depolarization-induced Ca2+ entry via CaV1 channels triggered increases in the nuclear CaM in a manner correlated with increases in pCREB. However, interneurons displayed little immunoreactivity for CaMKIV (the CREB kinase in excitatory neurons). Our preliminary results suggest that CaMKI, which shares a high degree of homology with CaMKIV, translocates to the nucleus. CaMKI could serve as a CaM shuttle, or may itself phosphorylate CREB.

Interestingly, evidence points to the dysfunction of GABAergic transmission and of proteins involved in E-T coupling (CaV1, γCaMKII, βCaMKII, and Calcineurin) in numerous neuropsychiatric diseases. Specifically, disrupted expression of the activity-dependent genes GAD67 and PV is characteristic of schizophrenia. Understanding mechanisms of E-T coupling in PV+ cells will likely shed light on the cell biology underlying the experience regulated network plasticity important for learning, as well as the pathophysiology of neuropsychiatric disease.

Title: Palmitoylation of AKAP79/150 by the palmitoyl acyltransferase DHHC2 controls synaptic potentiation

Authors: *K. WOOLFREY, J. L. SANDERSON, M. L. DELL'ACQUA
Pharmacol., Univ. of Colorado Denver, Aurora, CO

Abstract: Glutamate receptor trafficking is a key plasticity mechanism for excitatory neurons found in the mammalian forebrain. Covalent modification of AMPA-type glutamate receptors by kinases and phosphatases is thought to play an essential role in controlling the channel properties and synaptic incorporation of these receptors during forms of synaptic plasticity such as LTP. Such signaling is coordinated by the synaptic scaffolding protein AKAP79/150 through its ability to bind and target PKA, PKC, calcineurin, receptors, ion channels and other scaffolding proteins. Posttranslational modification of AKAP79/150 by palmitoylation is a critical step in its targeting to recycling endosomes. These endosomes have recently been identified as important intracellular AMPA receptor repositories. Here, we explore mechanisms of AKAP79/150 palmitoylation and the cellular consequences of disrupting this signaling in neurons. We find that

the recycling endosome-resident palmitoyl acyltransferase DHHC2 is an enzyme critical for AKAP79 palmitoylation. RNAi-mediated knockdown of DHHC2 disrupts recycling endosome exocytosis, altering regulated delivery of AMPA receptors to synapses in hippocampal neurons. Accordingly, DHHC2 signaling through AKAP79/150 is crucial for the NMDA receptor-dependent synaptic strengthening that mediates LTP. Importantly, a palmitoylation-independent lipidated AKAP79 mutant is capable of restoring aspects of normal plasticity in DHHC2-deficient neurons. Thus, we demonstrate that DHHC2-AKAP79/150 signaling is an essential regulator of synaptic potentiation.

Title: Activated CaMKII immobilized in spines both at the PSD and away from the PSD as resolved by single-molecule tracking PALM

Authors: ***H. LU**[1,2], H. D. MACGILLAVRY[3,2], N. A. FROST[4,2], T. BLANPIED[2]
[1]Univ. Maryland, Baltimore, BALTIMORE, MD; [2]Physiol., Univ. of Maryland, Baltimore, Baltimore, MD; [3]Dept. of Biol., Utrecht Univ., Utrecht, Netherlands; [4]Dept. of Neurol., UCSF, San Francisco, CA

Abstract: Calcium/calmodulin-dependent kinase II (CaMKII) is essential for synaptic plasticity underlying memory formation. With stimuli that induce LTP, activated CaMKII translocates to the PSD and phosphorylates synaptic proteins including AMPA receptors. However, though many known CaMKII substrates that could regulate synaptic transmission lie away from the PSD, it is not likely that PSD-bound CaMKII could phosphorylate such targets. To clarify this, we sought evidence of potential subpopulations of bound CaMKII away from the synapse by examining its mobility within spines. Confocal imaging does not achieve the resolution necessary to distinguish subpopulations within the small volumes of a spine. Therefore, we used

live-cell photoactivated localization microscopy (PALM) to track single CaMKII molecules at a resolution of ~25 nm, mapping the spatial and kinetic heterogeneity of CaMKII within single, living spines. Cultured rat hippocampal neurons were transfected with mEos2-CaMKIIα and single molecules were imaged and localized. Molecules were tracked as they moved within the cell, and their effective diffusion coefficient, Deff was calculated. This showed that CaMKIIα exhibits at least three kinetic subpopulations even within spines. The Deff distribution could be altered by CaMKIIβ overexpression or by acute latrunculin application, demonstrating that at least one kinetic subpopulation is regulated by the actin cytoskeleton. To determine the spatial distribution of these subpopulations, we constructed maps of Deff across neurons and showed that CaMKII with slow Deff is typically enriched in spines compared to dendrites, consistent with the presence of a higher density of potential binding partners. Importantly, activation of CaMKII following NMDA receptor stimulation prompted the immobilization and presumed binding of CaMKII not only at PSDs (marked by PSD-95-Cerulean3) but also at other points in spines but outside of the PSD, suggesting that the activated kinase does not act only at the PSD. Finally, by visualizing immunostained phospho-T286 CaMKII at nanometer resolution via stochastic optical reconstruction microscopy (STORM), we found that endogenous, activated CaMKII concentrated in spines including points quite distant from the PSD. In conclusion, our results suggest that CaMKII mobility within spines is determined by association with multiple interacting proteins, even outside the PSD, suggesting diverse mechanisms by which CaMKII may regulate synaptic transmission.

Sci., Physiol. & Pharmacol., Neurology, Anesthesiol., SUNY Downstate Med. Center, Brooklyn, NY, BROOKLYN, NY; [4]Ctr. for Neural Sci., New York Univ., New York, NY

Abstract: Using pharmacological inhibitors or a dominant negative mutation, many studies have indicated that the persistent kinase activity of PKMζ--a brain-specific, constitutively active atypical protein kinase C isoform--is crucial for the maintenance of the protein synthesis-dependent phase of long-term potentiation (late-LTP or L-LTP) and for the consolidation of spatial long-term memory (LTM). However, recent genetic evidence from PKCζ/PKMζ null mice has questioned this hypothesis (Lee et al., Nature, 493:416, 2013; Volk et al., Nature, 493:420, 2013). Here we show that although the PKC/PKMζ null mice do initially learn, they consistently display an abnormal and inefficient behavioral strategy. Whereas wild-type mice rapidly move to the safest location in an active place avoidance arena, the KOs remain in the most dangerous region next to the shock zone, even though they show equivalent sensitivity to shock as the wild-type. This altered pattern of behavior in the KOs allows for effective learning and memory for ~2 days. When memory reaches asymptotic performance, however, further training and testing reveal a deficit compared to wild-type mice, as demonstrated by a significant difference for the KOs in errors on memory testing without shock. Prior studies on the PKCζ/PKMζ null mice had not reported an increased activation of PKCι/λ, the other ZIP-sensitive atypical PKC. But PKCι/λ activation had been examined in lysates from the whole brain of the KO. Using a "split-brain" preparation, we confirmed this result in lysates from KO hemibrains. But the contralateral isolated dorsal hippocampus from the same animals showed a ~400% increase in activated PKCι/λ. To avert this compensation, we used a conditional knockout approach, which involved AAV-Cre recombinase injections into the hippocampus of PKC/PKMζ-floxed mice. Conditional knockout showed no compensation by PKCι/λ and resulted in the disruption of both late-LTP and spatial LTM consolidation. Thus, under physiological conditions or when compensation is averted, PKMζ is crucial for consolidation of L-LTP and spatial LTM.

Title: A presynaptic role for PKA in synaptic tagging and memory

Authors: *A. J. PARK, R. HAVEKES, J. CHOI, V. LUCZAK, T. NIE, T. HUANG, T. ABEL
Biol., Univ. of Pennsylvania, Philadelphia, PA

Abstract: Protein kinase A (PKA) and other signaling molecules are spatially restricted within neurons by A-kinase anchoring proteins (AKAPs). Although studies on compartmentalized PKA signaling have focused on postsynaptic mechanisms, presynaptically anchored PKA may contribute to synaptic plasticity and memory because PKA also regulates presynaptic transmitter release. Here, we examine this issue using genetic and pharmacological application of Ht31, a PKA anchoring disrupting peptide. At the hippocampal Schaffer collateral CA3-CA1 synapse, Ht31 treatment elicits a rapid decay of synaptic responses to repetitive stimuli, indicating a fast depletion of the readily releasable pool of synaptic vesicles. The interaction between PKA and proteins involved in producing this pool of synaptic vesicles is supported by biochemical assays showing that synaptic vesicle protein 2 (SV2), Rim1, and SNAP25 are components of a complex that interacts with cAMP. Moreover, acute treatment with Ht31 reduces the levels of SV2. Finally, transgenic mouse lines expressing Ht31 in excitatory neurons at the Schaffer collateral CA3-CA1 synapse highlight a requirement for presynaptically anchored PKA in pathway-specific synaptic tagging and long-term contextual fear memory. These results suggest that a presynaptically compartmentalized PKA is critical for synaptic plasticity and memory by regulating the readily releasable pool of synaptic vesicles.

Title: GDPβs unsilences silent synapses in CA1 pyramidal cells by disinhibiting the protein kinase A activating pathway

Authors: *M. OUARDOUZ
Neurosci. Res. Advisory Co., Gatineau, QC, Canada

Abstract: During early brain developmental stages, excitatory synapses mediated by AMPA receptors are weak or silent. Activity dependent insertion of AMPA receptors into synapses depends on the activation of protein kinase A. In this work, we investigated the effect of GDPβS on excitatory and inhibitory synaptic currents in CA1 pyramidal cells of Wistar rats at postnatal days 9-12, using whole-cell patch-clamp recordings. GDPβS applied through the recording electrode induces an increase in excitatory synaptic current amplitude, but not in inhibitory synaptic current amplitude. An analysis of the change in excitatory synaptic current amplitude in the presence of GDPβS revealed a progressive increase, which is blocked by the protein kinase A inhibitor Rp-cAMP, suggesting that GDPβS inhibits G-protein with a tonic negative control on a protein kinase A activating pathway. To further characterise the mechanism of excitatory synaptic current amplitude increase, we monitored the amplitude and frequency of spontaneous excitatory synaptic currents in the presence of GDPβS. Although the frequency increased, no change in the amplitude was observed. In addition, GDPβS has no effect on paired-pulse facilitation, suggesting that the probability of glutamate release is not affected. Moreover, as GDPβS was applied to postsynaptic neurons, the increase in spontaneous excitatory postsynaptic current frequency could be related to changes at the postsynaptic side associated with turning on silent synapses. In conclusion, the results indicate that in juvenile hippocampal CA1 pyramidal cells, the tonic negative modulation of a protein kinase A activating pathway through the activation of a G-protein prevents the activation of silent or weak synapses.

Title: Simulations suggest pharmacological methods for rescuing long-term potentiation

Authors: *P. D. SMOLEN, D. A. BAXTER, J. H. BYRNE
Neurobio. and Anat., The Univ. of Texas Med. Sch., Houston, TX

Abstract: Congenital cognitive dysfunctions are frequently associated with deficits in molecular pathways that underlie the induction and/or maintenance of synaptic plasticity. For example, Rubinstein-Taybi syndrome (RTS) is commonly due to a mutation in *cbp*, which encodes the histone acetyltransferase CREB-binding protein (CBP) (Alarcon et al., 2004; Bourtchouladze et al., 2003). CBP is a transcriptional co-activator that binds to phosphorylated CREB, and the consequent induction of CREB-dependent transcription plays a key role in long-term memory formation. Here, we illustrate a strategy for the rational design of molecular therapeutic approaches for improving memory formation. The strategy uses computational models of the molecular processes that correlate with impairment of learning to simulate the effects of the underlying molecular lesions. We extended our previous model of long-term synaptic potentiation (LTP) to describe CBP-mediated histone acetylation, and simulated LTP impairment due to *cbp* mutation. By altering parameters, molecular targets were identified that may serve as pharmacological targets to restore RTS-mediated deficits in LTP. Single parameter variations of moderate amplitude (~30%) did not restore simulated LTP. However, a pair of parameter changes, that together simulated the effects of a phosphodiesterase inhibitor and a deacetylase inhibitor, was effective in restoring LTP while maintaining basal synaptic weight near its normal value. A pair that simulated the effects of a phosphodiesterase inhibitor and an acetylase activator was similarly effective. For both pairs, additive synergism was present, in that the effect of the combination was greater than the summed effect of the separate parameter changes. These results suggest that the strategy of combining modeling and empirical studies may lead to effective therapies for improving long-term synaptic plasticity and learning and memory in cognitive disorders.

Title: Mindbomb homolog 2 is involved in hippocampal synaptic plasticity

Authors: *T. KIM, S. KIM, H.-R. LEE, Y.-Y. KONG, B.-K. KAANG
Dept. of Biosci., Seoul Natl. Univ., Seoul, Korea, Republic of

Abstract: Mindbomb homolog 2(Mib2) is a protein strongly expressed in adult brain, heart, skeletal muscle and brain. Previous studies reported that Mib2 is down-regulated in malignant melanoma. However, the role of Mib2 in brain tissue has not been yet identified. Here, using Mib2 knockout mouse, we report the role of Mib2 in hippocampal synaptic plasticity using field recording and contextual fear conditioning. Mib2 KO animals showed less freezing behavior (WT: 34.87±2.4% n=8, KO: 23.47%±2.5, n=11) in contextual fear conditioning (0.4mA shock). Hippocampal slices from Mib2 KO mice showed impairment in long-term potentiation. With TBS protocol, impairment was seen in early-phase long-term potentiation (WT: 198.3%±16.4, n=13 slices, KO: 157.5%±6.7, n=14 slices) For basal synaptic transmission at SC-CA1 synapses, there was no change in Mib2 KO hippocampal slices(WT: n=12 slices, KO: n=5 slices). These results suggest that Mib2 protein is essential for contextual fear memory and synaptic plasticity in adult mouse brain. (T. Kim and S. Kim both contributed equally to this work)

Title: The integrin-regulated Abl2/Arg kinase modulates NMDA receptor activity and NMDAR-dependent plasticity

Authors: *X. XIAO, A. LEVY, S. WARREN, A. KOLESKE
MB&B, Yale Univ., New Haven, CT

Abstract: Integrin α3β1 adhesion receptor signaling through the Abl2/Arg nonreceptor tyrosine kinase is critical for dendrite and dendritic spine stability in excitatory forebrain neurons. Arg acts through p190RhoGAP to stabilize dendrite arbors, but the mechanism by which Arg regulates spine stability is unclear. N-methyl-D-aspartate receptors (NMDARs) are critical

determinants of dendritic spine stability and NMDAR antagonists suppress spine destabilization in Arg-deficient neurons, suggesting that Arg interacts functionally with NMDARs. We show here that arg-/- mice exhibit increased NMDAR function beginning at postnatal day 21 (P21), before spines are lost, and that the increased NMDAR currents are driven by GluN2B subunit-containing NMDARs and are regulated by Src family kinase signaling. While NMDAR subunit levels are unaltered, tyrosine phosphorylation of GluN2B, which increases NMDAR currents, is significantly increased in arg-/- hippocampi, suggesting the involvement of a phosphatase downstream of Arg. Finally, we demonstrate that NMDAR-dependent LTP and LTD are significantly altered by P42 in arg-/- mice. These plasticity changes are also governed by the modulation in GluN2B phosphorylation through Src family kinase. Together, these data demonstrate that the integrin-regulated Arg kinase modulates GluN2B phosphorylation to regulate NMDAR function and NMDAR-dependent synaptic plasticity.

Abstract: Hippocampal learning and memory function deteriorates with aging. MicroRNAs (miRNAs) are small noncoding endogenous RNA molecules that regulate multiple biological processes including neuronal regulation and synaptic plasticity mainly through post-transcriptional silencing of their mRNA targets. In order to gain an insight into how changes in expression patterns of miRNAs affect hippocampal function during aging, we performed small RNA profiling at seven different life stages of mouse hippocampus. From deep sequencing and

subsequent bioinformatical analysis of these small RNAs, we found that 54 (35 upregulated and 19 downregulated) miRNAs are differentially expressed showing more than two fold change between young (2M) and old (18M) mouse hippocampus, and predicted that their potential target mRNAs are important components in neuronal regulation pathways including axon guidance. Here we report that Eph/ephrin signaling pathway is significantly downregulated during adult normal aging in hippocampus. mRNA levels of key Eph/ephrin signaling molecules including EphB2, decreased and mRNA level of its inhibitory molecule, RhoA, increased between young(2M) and old(18M) stages as evidenced by qPCR validation. We found more pronounced differential expression at their protein levels by performing Western Blot analysis on three independent hippocampal tissues. One of upregulated miRNAs in old hippocampus specifically targets EphB2 and causes a reduced protein expression in hippocampal neurons, resulting in significantly decreased spine density of hippocampal cultured neurons. The spine density deficit was recovered to near normal level by specific inhibition of the miRNA targeting EphB2. These results suggest that the miRNA plays an important role in age dependent regulation of Eph/ephrin signaling pathway by targeting key receptor molecule EphB2 and provides a potential for therapeutic intervention for improved cognitive function in aged humans.

Title: miR-26a and miR-384-5p are required for LTP maintenance and spine enlargement

Authors: *Q. GU, H. SHEN
NIH, Bethesda, MD

Abstract: Long-term potentiation (LTP) is a form of synaptic plasticity leading to enhanced synaptic strength. It is associated with the formation and enlargement of dendritic spines, tiny protrusions accommodating excitatory synapses. Both LTP and spine remodeling are crucial processes for brain development, cognition, and the pathophysiology of neurological disorders. However, the mechanisms underlying their long-term maintenance are largely unclear. Using next-generation sequencing to profile miRNA transcriptomes, we found that miR-26a and miR-

384-5p specifically regulate the maintenance but not induction of LTP, and different stages of spine enlargement. Both miRNAs affects LTP by regulating the expression of RSK3. Using bioinformatics, we also determined the global effect of miRNA transcriptome changes during LTP on gene expression and cellular activities. This study reveals a novel miRNA-mediated mechanism for gene-specific regulation of translation in LTP, identifies two miRNAs required for long-lasting synaptic and spine plasticity, and presented a catalog of candidate "LTP miRNAs".

Abstract: Why dendritic growth, synaptogenesis, axon sprouting, and Long Term Potentiation (LTP) in rat hippocampus all undergo pronounced changes in the third post-natal week is poorly understood. There is, however, good agreement that actin management plays a key role in synapse formation, spine growth, and the generation of stable LTP. Accordingly, we carried out the first tests of whether the activity of actin regulatory proteins and actin dynamics change during the critical week. Western blot analyses of several such proteins indicated that concentrations of phosphorylated (inactive) cofilin, a factor that blocks actin polymerization when active, decreased precipitously during the third week. Conversely, phosphorylation of ARP2/3, a protein that elaborates and stabilizes actin networks, increased during the same period. Consonant with the cofilin results, filamentous actin (F-actin) within dendritic spines

decreased from post natal day 11 forward. The high levels of F-actin in the immature hippocampus were eliminated by a toxin that disrupts dynamic actin filaments and this was accompanied by depression of synaptic potentials, an effect not seen in adult slices. Theta burst stimulation triggered actin polymerization in spines, an event critical to LTP consolidation, at 21 days post-natal but not earlier. We propose that cofilin activation (dephosphorylation) during week three of post-natal development depresses the formation of dynamic actin filaments and thereby terminates spine formation and synaptogenesis. This, along with a rise in p-ARP2/3, are suggested to open the way for the synapse specific cytoskeletal changes required for consolidation of LTP and memory. Data relating to the causes of the opposing changes in cofilin vs. ARP2/3 phosphorylation are described.

Title: Melanocortin-4 receptor regulates hippocampal synaptic plasticity through a PKA-dependent mechanism

Authors: *Y. SHEN[1,2,3], W.-Y. FU[1,2,3], E. Y. L. CHENG[1,2,3], M. TIAN[1,2,3], A. K. Y. FU[1,2,3], N. Y. IP[1,2,3]

Abstract: Learning and memory require the orchestrated regulation of both neuronal connections and synaptic strength in the hippocampus. While neuropeptide alpha melanocyte-stimulating hormone (α-MSH) is implicated in memory acquisition and retention, the functional role of its cognate receptor, melanocortin-4 receptor (MC4R), in the hippocampus remains unclear. Our recent findings revealed that MC4R activation is important for hippocampal synaptic plasticity via the regulation of dendritic spine morphology as well as the abundance of postsynaptic glutamate receptors. While knockdown of MC4R in rat hippocampal neurons resulted in a reduction of mature dendritic spines, activation of the receptor stimulated the surface trafficking of AMPA receptor subunit GluA1 in a PKA-dependent manner. Blockade of the PKA signaling abolished the MC4R-stimulated enhancement of neurotransmission and formation of long-term potentiation (LTP) in hippocampal slices. Importantly, deletion of MC4R in the mouse hippocampal CA1 region led to the impairment of LTP, whereas *in vivo* delivery of MC4R agonist such deficit. These findings collectively demonstrate that postsynaptic MC4R signaling is critical for the regulation of structural and functional synaptic plasticity.

Title: STDP induced phase tuning in an oscillatory feed forward network

Authors: *Y. LUZ, M. SHAMIR
Physiol. and Neurobio., Ben-Gurion Univ., Be'er-Sheva, Israel

Abstract: Oscillations in neuronal activity are common in the brain, ranging from the Delta frequencies (below 4 Hz) and up to the Gamma frequencies (above 30 Hz). A population of neurons oscillating in synchrony induces an oscillating LFP with same frequency, and amplitude that depends on the amplitude and phase distribution of individual neurons in the population. It is yet unknown how this population oscillatory activity interacts with synaptic learning. Spike Timing Dependent Plasticity (STDP), is an experimentally observed learning rule that

strengthens or weakens synaptic connectivity based on the temporal distance of pre and post synaptic firing. Hence, one would expect the oscillations' frequency and phase to interact with the mechanisms responsible for STDP. Here, we study a possible role of STDP learning as a mechanism for input selectivity by phase tuning. For the case of learning a single synapse, we derived analytical mean field solution in the limit of weak coupling and extend our analytical results using numerical simulations. In this case our model demonstrates that STDP induces phase tuning, i.e., the fixed point of the learning dynamics (the asymptotic synaptic strength) as a function of the relative phase between pre and post synaptic firing is bell shaped. Next, we studied the case of a population of excitatory synaptic inputs with uniform phase distribution. Our simulations revealed that the STDP produced spontaneous symmetry breaking with bell shaped input selectivity by the input phase. However, we found that the arbitrary preferred phase is not stable and drifts in time due to the intrinsic delay between presynaptic activity and its effect on post synaptic firing. Our model so far could not find a stable solution, but rather suggests a limit cycle. We further investigate potential stabilizing mechanism to compensate for this drifting effect.

Title: Spike-timing-dependent plasticity shapes interval selectivity of electrosensory midbrain neurons

Authors: *C. A. BAKER, X. MA, B. A. CARLSON
Biol., Washington Univ. In St. Louis, St Louis, MO

Abstract: Spike-timing-dependent plasticity (STDP), in which the connection strength between two neurons can change based on the relative timing of pre- and postsynaptic spikes, has been implicated in visual, somatosensory, auditory, and electrosensory processing. Here we show that

STDP influences processing of communication signals among a network of midbrain electrosensory neurons. Mormyrid fish vary the interpulse intervals (IPIs) between electric pulses to communicate, and neurons in the posterior exterolateral nucleus (ELp) exhibit a wide range of IPI tuning. We previously found a dense excitatory network in ELp in which similarly tuned neurons are more likely to be connected and with stronger connections. Here we ask whether STDP contributes to this network topology in *Brevimyrus niger* and *Brienomyrus brachyistius*. Using a whole-brain *in vitro* preparation, we varied the delay between extracellular presynaptic fiber stimulation and a postsynaptic spike induced by intracellular current injection into an ELp neuron. The largest increases in postsynaptic potentials (PSPs) in ELp neurons occurred when presynaptic spikes led postsynaptic spikes by ~20 ms, and the largest decreases in PSPs occurred when presynaptic spikes trailed postsynaptic spikes by ~10 ms. The NMDA receptor antagonist APV eliminated both effects, indicating that STDP in ELp is NMDA-dependent. To test whether STDP can influence IPI tuning, we stimulated afferent inputs with different IPIs, but paired postsynaptic spikes at a potentiating delay with only one particular IPI. This led to a consistent shift in IPI tuning in the direction of the paired IPI. Next, to test whether natural patterns of spiking in this circuit can influence IPI tuning, we repeatedly stimulated afferent input using constant IPI trains without postsynaptic current injection. This caused the IPI tuning of ELp neurons to shift in the direction of the repeated IPI. Finally, we tested whether natural patterns of spiking can influence tuning *in vivo* by recording evoked potentials from ELp before and after presenting electrosensory pulses of constant IPI. In contrast to the *in vitro* results, IPI tuning shifted away from the repeated IPI. We hypothesize that the different observed effects *in vivo* versus *in vitro* reflect differential effects of inhibition. Whereas the afferent stimulation *in vitro* follows natural temporal patterns, it likely does not capture natural spatial patterns. This could result in stimulation of different amounts of excitation and inhibition *in vitro* versus *in vivo*. Collectively, our results suggest that STDP may alter the topology of this network to optimize the coding of changes in stimulus statistics.

Title: Interneuron effects on cholinergically-induced STDP in hippocampal CA1 network

Authors: *E. SUGISAKI[1,2], Y. FUKUSHIMA[3], T. AIHARA[2]
[1]Tamagawa Univ. Grad. Sch. of Engin., Tokyo, Japan; [2]Tamagawa Univ. Brain Sci. Inst., Tokyo, Japan; [3]Kawasaki Univ. of Med. Welfare, Kurashiki, Japan

Abstract: One of the neurotransmitters in diffuse modulatory system is an acetylcholine (ACh), and the cholinergic fibers from the medial septum are projected to the neurons in hippocampal CA1 region. It is known that the ACh is released from cholinergic terminals when in arousal and /or in attentional state *in vivo*. While the multimodal sensory inputs, such as visual, auditory, olfactory et cetera, are received in hippocampus via entorhinal cortex to play a crucial role in information processing. Previous study has shown that the synaptic plasticity induced by injection of spike timing-dependent plasticity (STDP) stimulation in CA1 region was influenced by ACh in GABAA receptor-blocked network. In order to investigate the ACh effect on STDP in CA1 network in more natural condition, the interneuron-activated rat hippocampal slices were used. As the results, ACh receptors (AChRs) not only on pyramidal neurons but also on interneurons were co-activated and the STDP was significantly enhanced both by positive and negative timing of STDP protocols in the presence of eserine, a cholinesterase inhibitor. According to these results, the question was raised which type of AChRs, muscarinic (mAChR) or nicotinic (nAChR), on pyramidal or interneuron was more effective to the STDP enhancement. The results brought in both timing in the GABAA-blocked network showed that the activation of mAChRs on pyramidal neuron were more effective to the enhancement of STDP than nAChR activation on pyramidal neuron. In addition, the similar experiments were performed in the interneuron-activated network, and the activation of mAChRs on interneuron was more sensitive than nAChRs on interneuron for preventing the expansion of cholinergically-induced STDP. These observations suggest that the calcium, which is important substance for the synaptic plasticity, is additionally influx due to the activation of mAChRs and nAChRs on pyramidal neuron. While the mAChRs and nAChRs on interneuron regulate the cholinergically-induced STDP by reducing the excitability of pyramidal neuron. We conclude that ACh is a critical neurotransmitter for learning and memory, furthermore, the appropriate magnitude of synaptic plasticity is decided by co-activation of AChRs not only on pyramidal neurons but also on interneurons.

Title: Presynaptic calcium entry into proximal boutons and 1st Ranvier node shapes backpropagating action potentials in L5 pyramidal neurons of visual cortex

Authors: *E. S. NIKITIN, P. M. BALABAN, M. ROSHCHIN
Inst. Higher Nervous Activity, Moscow, Russian Federation

Abstract: It is well documented that nonsynaptic as well as synaptic plasticity can be a substrate for long-term memory. Synaptic plasticity is widely regarded as the primary mechanism. Recently it has been demonstrated that global nonsynaptic changes can be linked to compartmentalized synaptic changes and increase in synaptic efficacy [Nikitin et al. 2013]. Little is known, however, about how the activation of efficient synapses can change the neuronal excitability of the presynaptic neuron in short-term at subcellular level. Large boutons (≥1 mkm) of axonal collaterals of L5 pyramidal neurons are typically regarded as presynaptic parts of functionally mature cortical synapses [Romand et al. 2011]. Also, a strong correlation between the size of active zones and the number of docked vesicles and postsynaptic density was reported in a number of publications [Schikorski, Stevens 1997]. In our experiments in rat visuial cortex (P18-P24) a morphological examination of L5 pyramidal neurons with an intracellularly loaded fluorescent morphological tracer demonstrated that the very first synaptic boutons emerged on the first collaterals at 7-12 mkm from the 1st node of Ranvier. We performed simultaneous calcium imaging of the first synaptic bouton and node with a line-scanning fast confocal microscope and a calcium sensor delivered through the patch pipette. Somatically induced action potentials (APs) evoked significantly larger calcium transients in the first boutons suggesting that there is a gradient of calcium elevation in the proximal part of axonal collaterals towards the node with peaks in the proximal boutons. Than we induced additional calcium elevation in the first proximal boutons close to the 1st node and in the node itself by Ca2+ uncaging with a blue laser under the confocal microscope. Ca2+ uncaging produced broadening of the APs recorded in the soma when prior calcium elevation was induced either in the bouton or node comparing to control flashing of background regions. There is evidence that axonal calcium-sensitive potassium channels (BK-type) can regulate the AP width in L5 pyramidal neurons of visual cortex [Yu 2010]. Presynaptic calcium elevation initiates release of neurotransmitters at synapses, and regulation of presynaptic Ca2+ channels has a powerful influence on synaptic

strength. Emerging evidence suggests a critical role of Ca2+ regulation in control of neurotransmission and in presynaptic plasticity [Catterall, Few 2008]. We propose a novel mechanism of how the presynaptic plasticity and changes in calcium elevation in proximal boutons can regulate the backpropagation of action potentials and tune the excitability of the presynaptic neuron.

Title: LTP induced by pairing subthreshold basal dendritic excitation with backpropagating apical dendritic evoked spike *in vivo*

Authors: C. LAW[1], T. FUNG[1], *L. LEUNG[2]
[1]Physiol. and Pharmacol., Univ. of Western Ontario, London, ON, Canada; [2]Univ. Western Ontario, London, ON, Canada

Abstract: Hippocampal CA1 pyramidal cells receive excitation of their basal and apical dendrites from different cells in CA3, and synaptic integration and plasticity may depend on the interaction between basal and apical dendritic excitation. In order to study the properties of long-term plasticity associated with spike timing dependent plasticity (STDP), subthreshold basal dendritic population excitation (E) in hippocampal CA1 was paired with a strong apical dendritic excitation that evoked a population spike (S) in urethane-anesthetized adult rats *in vivo*. Average field excitatory postsynaptic potentials were recorded in CA1 at 50 micron intervals by a 16-channel silicon probe, and analyzed as current source density. A strong stratum radiatum stimulus evoked a population spike that backpropagated into the basal dendrites. We hypothesize that excitation-spike (ES) pairing at positive intervals- generating a synaptic excitation before a spike - results in long-term potentiation (LTP), while pairing at a negative ES interval results in long-term depression (LTD), as has been shown for different preparations *in vitro*. ES-pairing (50 pairs at 5 Hz given in 5 segments each of 10 pairs) at ES interval of -10 ms resulted in significant LTP of the slope and amplitude of the basal dendritic excitatory sink for 2 h, while

pairing at +10 or +20 ms ES interval did not induce LTP or LTD. At 1 h after pairing, the basal-dendritic sink was 1.29 ± 0.12, 0.97 ± 0.07, and 0.96 ± 0.12 times of the pre-pairing baseline for ES interval of -10, +10 and +20 ms, respectively. The apical-dendritic sink was not significantly changed by pairing. Similar basal dendritic LTP was found for ES interval of 0 ms (synchronous) or -10 ms if the 50 pairs were given continuously. No LTP or LTD resulted from 50 stimuli of 5 Hz, evoking only an apical dendritic spike or only subthreshold basal dendritic excitation. No LTP was observed after pairing at ES -10 ms if the rats were pretreated with NMDA receptor antagonist CPP (10 mg/kg i.p.). Contrary to our hypothesis, we found that pairing at negative or zero ES interval resulted in LTP, while no LTP or LTD resulted from pairing at ES intervals of +10 and +20 ms. Pairing at ES interval of -10 ms may involve the coincidence of the weak basal dendritic excitation with the depolarizing afterpotential or spike burst following a backpropagated spike, thus opening NMDA receptor channels and resulting in subsequent LTP.

Title: Timing-dependent LTP can be induced by six repetitions of single pre- and postsynaptic spikes at CA3-CA1 synapses in acute hippocampal slices

Authors: E. CEPEDA-PRADO[1], V. LESSMANN[1,2], *E. EDELMANN[1]
[1]Inst. of Physiol., Otto-von-Guericke Univ., Magdeburg, Germany; [2]Ctr. of Behavioral Brain Sci. (CBBS), Magdeburg, Germany

Abstract: Long-term potentiation is thought to be a cellular correlate of learning and memory formation, which is often studied in field potential recordings by means of high frequency stimulation protocols. Here we analyse timing dependent (t-) LTP at the level of single postsynaptic CA1 neurons using few repeats of synaptic stimulation in a spike timing-dependent plasticity (STDP) paradigm, which most likely approximates more physiological synaptic

activation patterns. The canonical form of STDP is commonly induced with high repeat numbers (50-100 times) of precisely timed pre- and postsynaptic spike pairs at higher pairing frequency (up to 5 Hz) to induce timing-dependent long-term potentiation (t-LTP). Nevertheless, the STDP rules vary between synapses in different brain regions and are dependent on multiple factors. Our study now aimed at evaluating requirements of canonical STDP at CA3-CA1 synapses in acute hippocampal slices using minimal numbers of repetitions. Using patch clamp experiments in acute hippocampal slices of juvenile rats and mice, t-LTP at CA3-CA1 synapses was induced with different numbers of spike pairings of one presynaptically induced excitatory postsynaptic potential (EPSP) in combination with one postsynaptic AP (1EPSP/1AP) at positive delays between pre- and postsynaptic activation and at low pairing frequency. We achieved successful t-LTP by 1EPSP/1AP spike pairings, which were repeated 6 to 70 and 12 to 100 times in mice and rats, respectively. Efficiency of t-LTP amplitudes seemed to be inversely correlated to repeat numbers, but nevertheless all protocols produce reliable t-LTP. Lower repeat numbers such as 3x in mice (1.06±0.2) or 6x in rats (0.80±0.1) did not show any t-LTP and the resulting EPSP amplitudes were comparable to the values obtained from unpaired control experiments (mice: 0.95±0.1 or rats: 0.80±0.1, respectively). The 6-repeat t-LTP protocol which was successful at short intervals, did not elicit successful t-LTP at longer positive pairing delays, which fits to the asymmetric STDP curve described for 1EPSP/1AP pairings. Our results reveal a novel canonical STDP paradigm, which induced robust t-LTP in hippocampal CA1 region, generated by only six repeats of 1EPSP/1AP pairings at low frequency and follows the rules of classical t-LTP.

Title: Stable reinforcement learning via temporal competition between LTP and LTD traces

Authors: M. A. HUERTAS[1], S. SCHWETTMANN[2], *H. Z. SHOUVAL[1]
[1]Neurobiol & Anat, Univ. Tex Medl Schl Houston, HOUSTON, TX; [2]Computat. and Applied Math, Rice Univesity, Houston, TX

Abstract: Although synaptic plasticity is responsible for reinforcement learning in the brain, theories of reinforcement learning are generally abstract and involve neither neurons nor synapses. Here we describe a biophysically based theory of reinforcement-modulated synaptic plasticity. We postulate the existence of two eligibility traces, one corresponding to the induction of LTP, and the other to the induction of LTD. The traces have different temporal profiles: the LTP-associated eligibility trace, with a slow decay time constant on the order of several seconds, is larger than the corresponding decay time constant for the LTD-associated trace. Such assumptions are consistent with recent experimental results by He and Kirkwood (SFN abstracts 2013). The magnitude of these traces, at the synapse, depends on the activity of pre- and post-synaptic neurons. The traces decay individually over time, and their magnitude at the time of reward determines if synaptic modification will correspond to LTP or LTD. Due to the difference in their temporal profiles, the LTP and LTD traces can exhibit temporal competition at the reward time. We suggest that this competition provides a mechanism for stable reinforcement learning. To test this novel reinforcement-learning rule, we applied it to a model of a recurrent cortical network designed to reproduce the experimentally observed responses of neurons in the rodent visual cortex. In these experiments a visual stimuli is paired with delayed reward signals, resulting in neural responses that last significantly beyond the visual stimulation and correlated well with the expected time of reward. Previously we proposed a model to account for this phenomenon by using a plastic recurrent neural network with a learning rule that uses only a single eligibility trace that potentiates the synapses and a mechanism for inhibiting the reward signal in order to obtain stability. Our new approach uses two Hebbian eligibility traces with different time constants, which we show can also serve as a more biophysically plausible stability mechanism. Initially when the network responds primarily to the stimuli the LTP trace dominates at the time of reward due to its longer time constant, potentiating synapses and resulting in prolonged network activity. As activity is prolonged and approaches the reinforcement signal, the relative level of the LTD trace increases, until it completely balances the LTP trace. The proposed learning rule produces a stable network, with prolonged transient activity that terminates near the expected reward time.

Title: Non-genomic action of estradiol on a spinal cord neuromuscular reflex in female rat

Authors: *O. D. LARA GARCIA[1], M. LARA GARCÍA[1,2], Y. CRUZ[2], E. CUEVAS[2], M. MARTÍNEZ-GÓMEZ[2], P. PACHECO[3,1]
[1]Univ. Veracruzana, Xalapa, Mexico; [2]Univ. Autónoma de Tlaxcala, Tlaxcala, Mexico; [3]Univ. Nacional Autónoma de México, México, Mexico

Abstract: Pubococcygeus muscle (Pcm) reflex activity evoked by mechanical stimulation of clitoris (Clit) in female rat, results an interesting model to explore hormonal effects on its components. It is known that dermatome size of pudendal nerve which innervates the Clit, is increased by estrogen treatment or during the receptivity period of the estrous cycle. Here, we explored the characteristics of this reflex in diestrous (DE), proestrous (PE) and ovariectomized (Ovx) animals as well as the immediate estradiol action on this reflex after its subcutaneous injection. Methods: In DE, PE and Ovx animals deeply anesthetized with intraperitoneal urethane, the electromyography (EMG) characteristics of Pcm reflex were recorded using intramuscular stainless steel bipolar electrodes. Mechanical stimulation (pressure) was applied to Clit during 5-15 sec, before and after estradiol benzoate administration (40mg/kg). Results: EMG from Pcm fibers was compound of regular rhythmic firing of its corresponding motoneurons. Animals in DE and PE, during stimulation evoked a discharge rate of 15-20 pulses per second. After the end of stimulation, PE animals showed an afterdischarge of 20-100 sec. Ovx animals did not present reflex activity during or after stimulation; however, after 5-10 min of estradiol injection, the reflex activity appeared during and after Clit stimulation. In DE animals, after estradiol injection the afterdischarges also appeared. Discussion: Mammalian motoneurons including rat, display a repetitive rhythmic firing; then, it is likely that the EMG discharges of Pcm here described are in accordance with this motoneuronal property. Summation of currents from soma, dendrites and the initial axon segment had been implicated in the production of an afterhyperpolarization current which is supposed to trigger the motoneuronal repetitive firing that we have indirectly recorded in Pcm EMG. These motoneuronal areas can be activated by clitoral receptors which through interneurons evoke motoneuronal firing. Thus, neural components involved in Pcm reflex activity are modulated by estradiol. The short-time effect of estradiol here described, suggests the idea of a non-genomic modulatory effect which is rich, when blood levels of estradiol are high (PE) or poor when these are low (DE), or absent when there is a lack of estradiol (Ovx). Conclusions: Clitoral receptors are connected with their corresponding Pcm motoneurons. The EMG reflex activity evoked in the Pcm by mechanical stimulation of Clit is blocked by ovariectomy; however, it is immediately restored by the non-genomic effect produced after subcutaneous injection of estradiol.

Title: Eligibility traces in cortical synapses

Authors: ***K. HE**[1], A. KIRKWOOD[1,2]
[1]Mind/Brain Inst., [2]Dept. of Neurosci., The Johns Hopkins Univ., Baltimore, MD

Abstract: Eligibility trace has been proposed as the transient synaptic 'tag' that allows the brain reinforcement signal to identify the target neural activity underlying reward-based learning. Previously we have established an experimental approach to prove for the first time that the eligibility trace does exist and can be generated by correlated neuronal spiking activity in a polarity-specific manner. We have described eligibility trace that are transient, synapse-specific and can be consolidated by distinct catecholamines into long-term potentiation or depression. This novel neuromodulators-mediated consolidation of eligibility trace could be the candidate brain substrate for reinforcement learning. Here we extended our investigation to further understand the universality of this novel learning rule and the properties of the eligibility trace. Similar to what we have shown previously in the primary visual cortex, we found dopamine and serotonin respectively consolidate LTP and LTD eligibility traces in the medial prefrontal cortex. We are currently evaluating whether these elegibility traces are determined by kinase/phosphatase activity.

Title: Highly precise hippocampal synaptic plasticity

Authors: *C. BROMER[1,2,3], T. M. BARTOL[1], J. KINNEY[2], K. HARRIS[3], T. SEJNOWSKI[1]
[1]CNL, Salk Inst. For Biol. Studies, San Diego, CA; [2]Synthetic Neurobio. Group: MIT Ctr. for Neurobiological Engin., MIT, Boston, MA; [3]Section of Neurobiology; Ctr. for Learning and Memory; Inst. for Neurosci., The Univ. of Texas at Austin, Austin, TX

Abstract: Changes in the strengths of synapses drive changes in neuronal computation. The size of a dendritic spine head is highly correlated with the size of the presynaptic axon active zone and both are directly related to the strength of the synapse. In an electron microscopic reconstruction of the hippocampal neuropil, we analyzed the dimensions of the spine heads, the areas of postsynaptic densities, and the availability of presynaptic vesicles of neurotransmitter at synapses on CA1 apical dendrites and found that pairs of dendritic spines on the same dendritic branch receiving input from a single presynaptic axon are nearly identical in size (CV = 0.083). Despite a small sample size, the relationship is highly significant over a factor of 60 in spine head sizes, which implies 6 bits of accuracy. This does not occur for dendritic spines located on different dendrites but synapsing with the same presynaptic axon. Although there are numerous sources of variability in the responses of synapses, including low neurotransmitter release probabilities, the precision indicated here suggests that the biochemical pathways inside excitatory hippocampal synapses is tightly controlled and in particular must be able to average the impact of input spike trains over many minutes. If similar precision is found at excitatory synapses on pyramidal neurons in the cerebral cortex then the capacity of the brain to store information may be much higher than previously thought.

Title: E-S potentiation in CA1 rat hippocampal neurons is selectively induced during the lifespan and is dependent on L-type calcium channels

Authors: E. CARPENTER-HYLAND[1], E. BICHLER[2], *M. BENVENISTE[1]
[1]Neurosci. Inst., Morehouse Sch. of Med., Atlanta, GA; [2]Physiol., Emory Univ. Sch. of Med., Atlanta, GA

Abstract: Under certain conditions hippocampal LTP, a neurophysiological correlates to learning and memory, has been shown to abate with normal aging. Currently, little is known about alterations in non-synaptic forms of plasticity in normal aging, and if neurons in the adult employ such mechanisms to enhance plasticity as LTP declines. One relatively unexplored mechanism of non-synaptic plasticity involves the potential change in ability of a postsynaptic neuron to produce action potentials as a result of specific EPSP input strength . This would be a change in intrinsic excitability, or EPSP to spike (E-S) plasticity. E-S plasticity can be observed as an alteration in the probability of producing action potentials at given EPSP slopes. We have measured E-S plasticity in CA1 neurons from adult and juvenile rat hippocampal slices using whole-cell current clamp in conjunction with various LTP-induction protocols. We observed that E-S potentiation was more sensitive that LTP, being induced under conditions of weak stimulation when little or no LTP was produced (100 pairings of Schaffer collateral stimulation with spike-producing postsynaptic depolarization @ 0.3 Hz). E-S plasticity was differentiated from synaptic plasticity as it could be produced in conjunction with either LTP or LTD, although E-S potentiation and LTP become highly correlated under conditions when strong stimulation such as theta burst was used for LTP induction. Interestingly, E-S potentiation differed across the lifespan, appearing in adult rat CA1 (60-90 days) while being absent from young rats (13-26

days). Expression of E-S potentiation in adults was found to be unaffected by 100 μM APV and therefore NMDA receptor independent, but dependent on intracellular calcium since it was blocked when 30 mM BAPTA was present in the intracellular recording solution. In addition under strong stimulation induction using theta burst, L-type calcium blocker, nifedipine (10 μM), eliminated E-S potentiation in CA1 neurons in the adult, whereas robust LTP was fully preserved. These findings support a novel form of non-synaptic plasticity present in adult hippocampus that may eventually contribute to understanding memory deficits which can occur with normal aging.

Title: Coordinated distinct Ca2+ sources and mGluRs encode spike timing-dependent plasticity at mature hippocampal Schaffer collateral synapses

Authors: *C. M. TIGARET[1], J. H. L. SADOWSKI[1], T. J. O. GRIFFITH[2], K. TSANEVA-ATANASOVA[3], J. R. MELLOR[1]
[1]Sch. of Physiol. and Pharmacol., [2]Dept. of Engin. Mathematics, Univ. of Bristol, Bristol, United Kingdom; [3]Col. of Engineering, Mathematics and Physical Sci., Univ. of Exeter, Exeter, United Kingdom

Abstract: Induction of spike timing-dependent synaptic plasticity (STDP) at glutamatergic Schaffer collateral synapses onto CA1 hippocampal pyramidal neurons requires specific timing between synaptic input and post-synaptic action potentials (APs). The NMDA receptor-generated Ca^{2+} transients at the dendritic spines (EPSCaTs) are proposed to determine the direction of plasticity, with large Ca^{2+} transients elicited during near-coincident APs leading to potentiation, and small Ca^{2+} transients leading to depression (1,2). We evaluated STDP at Schaffer collateral to CA1 pyramidal neuron synapses in acute hippocampal slices from adult

rats, by pairing pre-synaptic stimuli delivered in the stratum radiatum with somatically-evoked APs. Using two-photon Ca^{2+} fluorescence imaging we recorded the EPSCaTs triggered by paired activity at apical dendritic spines and we correlated them with the ability of the pairing protocols to generate synaptic plasticity. Recordings were performed in whole-cell current clamp, at 36°C, under $GABA_A$ receptor inhibition. Single pre-synaptic stimuli paired with somatic APs elicited larger EPSCaTs when compared to unpaired stimuli. This effect was stronger when the pre-synaptic stimulus was paired with two back-propagated APs within 10 ms and was independent of the timing sign. In contrast, induction of NMDA receptor-dependent LTP required pairing of at least two back-propagated action potentials 10-50 ms following, but not preceding, a single pre-synaptic stimulus. Pairs of pre-synaptic stimuli at 100 Hz yielded larger EPSCaTs than the LTP-inducing pairing protocols but failed to induce plasticity, whereas pairing at 20 Hz induced LTD. Induction of spike timing-dependent LTP required the activation of T- and L-type voltage-sensitive Ca^{2+} channels, which contributed only partially to the EPSCaTs generated by the pairing protocol. LTP was specifically blocked by the $mGlu_1$ antagonist YM298198, which did not alter the magnitude of the EPSCaTs. Our data indicate that the coordinated activation of NMDA receptors, voltage-sensitive Ca^{2+} fluxes, and of mGlu1 receptors determine the induction of STDP at mature Schaffer collateral synapses, whereas the magnitude of EPSCaT is not sufficient to determine the direction of synaptic plasticity. Title: History-dependent changes in spiking patterns of cholinergic neurons in the medial septum

Authors: *E. D. MELONAKOS, J. A. WHITE, F. R. FERNANDEZ
Dept. of Bioengineering, Univ. of Utah, Salt Lake City, UT

Abstract: Hippocampal theta rhythms are sensitive to atropine, a muscarinic acetylcholine receptor antagonist. Cholinergic neurons from the medial septum target the hippocampus, and have thus been suggested as a neuromodulatory driver of hippocampal theta rhythms. An understanding of the role of medial septal cholinergic neurons in hippocampal theta rhythms requires a detailed description of their individual electrophysiological properties. An important electrophysiological characteristic of a neuron that influences spike phase-locking and rhythm generation is the neuronal sensitivity to current inputs or gain. In particular, changes in gain significantly influence spike phase-locking to weak sinusoidal inputs (Broicher et al., 2012). In our efforts to characterize cholinergic neurons, we found that these cells express a significant history- and voltage-dependent gain response. We found that changing the holding voltage from about -74 mV to about -44 mV led to a 5.5-fold increase in subsequent gain. Further investigation revealed that this effect resulted from a slow, likely potassium current with reversal potential around -80 mV. This current activates and inactivates at depolarized potentials and is deinactivated at hyperpolarized potentials. This unique property of cholinergic neurons in the medial septum may be important for determining the history-dependence of hippocampal cholinergic tone. Title: Perineuronal nets modulate neuronal physiology in the mouse barrel cortex

Authors: *P. CHU[1], K. BUDHU[2], J. C. BRUMBERG[3,4]
[2]Psychology, [1]Queens College, City Univ. of New York, Flushing, NY; [3]Psychology, City Univ. of New York, The Grad. Ctr., NY, NY; [4]Psychology and Neurosci. Major, Queens College, CUNY, Flushing, NY

Abstract: Perineuronal nets (PNNs) are an aggregated form of extracellular matrix that exists in the central nervous system. Although the presence of PNNs was reported by Camillo Golgi in the late 19th century, their functions have only recently begun to be elucidated. For example, removing components of PNNs genetically and enzymatically results in enhanced plasticity in adult animals. However, the mechanism for the enhancement is not well understood. We sought to determine the role of PNNs in regulating neuronal physiology through enzymatic digestion and *in vitro* whole cell patch clamping in the mouse barrel cortex. Following enzymatic digestion with chondroitinase ABC (ChABC), we recorded from cells in layers 2/3, 4 and 5. In response to hyperpolarizing and depolarizing current pulses, the intrinsic properties of putative excitatory neurons (electrophysiological identified as "regular spiking", RS) and putative inhibitory neurons (fast spiking, FS) are altered following digestion of the PNN with chABC. However, there was no change in the intrinsic properties of another putative class of GABAergic inhibitory interneurons, low threshold spiking cells. FS interneurons showed a 10-20% reduction in action potential amplitude and a decrease in input resistance. RS neurons did not show any changes in their action potential amplitude but did show a reduction in input resistance that was less than that for FS cells. Other intrinsic properties of the cells were not affected in any cell class (e.g. spike frequency, resting membrane potential, spike thresholds, first spike delays) suggesting that the impact of PNN digestion was specific to those properties and not due to non-specific effects of the enzyme. The greater effect on FS cells is consistent with anatomical data showing that PNNs preferentially ensheath fast-spiking parvalbumin+ interneurons. The effect of chABC on RS cells, not typically thought to express PNNs in large proportions, may be due to modulation by the PNNs expressed on neighboring FS cells. Overall our results suggest that Perineuronal nets are capable of modulating the intrinsic properties of neurons.

Title: Intracellular fibroblast growth factor 14 in the regulation and dysregulation of purkinje neuron excitability

Authors: *J. L. RANSDELL, M. XIAO, D. M. ORNITZ, J. M. NERBONNE
Washington Univ., Saint Louis, MO

Abstract: Intracellular fibroblast growth factor 14 (iFGF14) is a regulator of neuronal intrinsic excitability that is known to bind and modulate voltage gated sodium channels. In addition, *FGF14* is the locus of mutations responsible for spinal cerebellar ataxia 27 (SCA27), an autosomal dominant disease characterized by progressive ataxia and cognitive decline. A number of SCA27 linked mutations in *FGF14* have now been identified, of these, the first was the missense mutation $FGF14^{145S}$, identified in an extended Dutch family. Recent studies have demonstrated that $Fgf14^{-/-}$ Purkinje neurons have attenuated intrinsic excitability, but, repetitive firing properties similar to wild type Purkinje neurons can be rescued by prior membrane hyperpolarization, suggesting that attenuation of excitability may be caused by a change in the transient sodium current, I_{Na}, steady-state inactivation. To test this hypothesis directly, we used a recently developed voltage-clamp technique to obtain recordings of I_{Na} in Purkinje neurons in acute slice preparations from $Fgf14^{-/-}$ and $Fgf14^{+/-}$ animals, and compared them with wild type. Results in these studies indicate that steady-state inactivation of I_{Na} in $Fgf14^{-/-}$ Purkinje neurons is significantly more hyperpolarized than in wild type Purkinje neurons (wild type $V_{1/2}$ = -55mV, $Fgf14^{-/-}$ $V_{1/2}$= -73mV, $p<.001$). These data demonstrate directly that iFGF14 has an effect on I_{Na} steady-state inactivation in Purkinje neurons. To investigate directly the effects of the $FGF14^{145S}$ human mutant protein on Purkinje neuron excitability we developed a knockin mouse model. Results to date reveal a marked decrease in spontaneous firing in $FGF14^{145S\ +/-}$, consistent with the autosomal dominant / haploinsufficient genetics of SCA27. We also found $Fgf14^{+/-}$ Purkinje neuron spontaneous firing is attenuated when compared to wild type, demonstrating that iFGF14 haploinsufficiency also affects Purkinje neuron firing properties.

Title: Kv2 and BK channels in substantia nigra dopamine neurons differentially regulate spontaneous and burst-like firing

Authors: *C. KIMM, B. P. BEAN
Dept. of Neurobio., Harvard Med. Sch., Boston, MA

Abstract: Dopamine neurons of the *substantia nigra pars compacta* (SNc) have two major modes of activity: tonic slow pacemaking and higher-frequency bursts evoked by synaptic input. Substantial work has explored the ionic mechanisms underlying the spontaneous depolarization of these cells and the commencement and cessation of burst firing, but less is known about the voltage-dependent potassium currents contributing to spike repolarization and to the timing of action potentials within a burst. Performing action potential clamp experiments using acutely-dissociated mouse SNc dopamine neurons at 37°C, we found that the outward current flowing during spike repolarization included major contributions from BK calcium-activated potassium channels (sensitive to paxilline) and Kv2 channels (sensitive to GxTx-1E). Given the large BK current during action potentials, we were surprised that in current clamp experiments, application of paxilline had only a small effect on spike width (1.47 ± 0.14 ms in control to 1.89 ± 0.11 ms in 300 nM paxilline, mean ± S.E.M., n=16) and no clear effect on spontaneous firing frequency. Similarly, GxTx-1E also had small effects on spike width (1.60 ± 0.15 ms in control to 1.86 ± 0.17 ms in 100 nM GxTx-1E, n=18) and no clear effect on spontaneous firing frequency. However, co-application of paxilline and GxTx-1E produced a dramatic effect on spike width (1.57 ± 0.14 ms in control to 5.85 ± 0.87 ms in 300 nM paxilline + 100 nM GxTx-1E, n=24) and decreased firing rate from 7.4 ± 1.0 Hz to 4.2 ± 0.4 Hz (n=24). Further experiments revealed large “reserves” of both BK and Kv2 currents relative to the current activated during individual action potentials and showed that acute inhibition of either current led to additional recruitment of the other, minimizing changes in spike width. While inhibition of either Kv2 or BK channels alone had no effect on spontaneous firing frequency, higher-frequency firing evoked by current injection was differentially altered. Blocking BK channels resulted in reduction in maximal firing frequency and flattening of the F-I curve, while inhibiting Kv2 channels resulted in faster firing and steeper F-I curves. Thus, BK and Kv2 channels have a high degree of “redundancy” during spontaneous action potentials but differentially regulate evoked firing.

Title: Localization and characterization of the axon initial segment of *in vivo* labeled individual substantia nigra dopaminergic neurons in the mouse

Authors: *R. MEZA[1,2], A. OÑATE[1], N. M. DOIG[1], M. FAUNES[1], P. HENNY[1]
[1]Anatomy, Sch. of Med., [2]Physiological Sciences, Fac. of Biol. Sci., Pontificia Univ. Católica De Chile, Santiago, Chile

Abstract: Dopaminergic neurons of the substantia nigra compacta (SNc) play a key role in movement control, motivated behavior and learning. The electrical activity of dopaminergic neurons is characterized by low frequency, regular or irregular firing and is mostly controlled by intrinsic membrane properties. This tonic activity is punctuated by brief periods of high-frequency burst firing, as well as short pauses in firing, which are synaptically mediated and have been shown to encode behaviorally salient stimuli. In spite of these common firing characteristics, there exists a large variation in individual neurons activity and driven responses to stimuli. In most nigral dopaminergic neurons, the axon does not emerge from the cell body, but from primary or secondary dendrites. The most proximal region of the axon, the initial segment (AIS), is an unmyelinated structure and is where the action potentials are generated. The AIS is enriched in sodium channels and other voltage gated channels, as well as scaffolding proteins such as Ankyrin-G (Ank-G). The aim of this project is to examine whether the structural characteristics, including localization, of the AIS relate to the diverse activity patterns showed by these neurons. In order to address this question, dopaminergic SNc neurons were recorded in adult male mice under urethane anesthesia. Neurons were recorded during spontaneous basal activity and after the application of nociceptive somatosensory stimulation to the hind paw. Recorded neurons were labeled using the juxtacellular method with neurobiotin, after which animals were perfused and their brains removed and serially sectioned. Labeled neurons were revealed using streptavidin and identified as tyrosine hydroxylase positive using immunofluorescence. In order to reconstruct the neurons, Z-stacks of images from all sections containing labeled dendritic and local axon fragments were obtained using a confocal microscope. Fragments were traced and spliced to render a 3D reconstruction of the somato-dendritic and local axonal domain using Neurolucida (MBF). The localization of the AIS was inferred from reconstructions and further confirmed using immunofluorescence staining for Ank-

G. Preliminary results confirm a heterogeneous axon origin and AIS structure in these neurons, and analyses are being carried out to test a correlation of these parameters with spontaneous and driven firing patterns recorded *in vivo*.

Title: Burst-pause-burst pattern in striatal cholinergic interneurons: Can they pause without bursting?

Authors: ***A. ZUCCA**, S. AOKI, A. LIU, S. ZUCCA, J. WICKENS
Wickens Unit, Okinawa Inst. of Sci. and Technol., Kunigamigun, Japan

Abstract: Striatal cholinergic interneurons (sCINs) are local interneurons representing only 1-2% of neurons in the striatum of rodents. Although sparse, studies show that they have an important role in reinforcement-learning and movement. sCINs display tonic firing activity *in vivo* and electrophysiological recordings *in vivo* and *in vitro* reveal a burst-pause-burst pattern of firing. We are interested in understanding the functions of the pause for the rest of the striatum. Here we ask if we can alter and manipulate the burst-pause-burst pattern (i.e. Can we cause a pause without bursting?) and further examine rebound firing. Using transgenic rats that express cre-recombinase under the control of choline acetyltransferase (Witten, I. B. et al. Neuron 72, 721-733, 2011) and cre-dependent expression of opsins via AAV injection in the dorsal striatum, we analyzed the electrophysiological properties of sCINs. During hyperpolarization-induced rebound firing we manipulated their characteristic burst-pause-burst pattern with light in an acute slice preparation as a prequel to *in vivo* experimentation. In our condition, rebound firing of sCINs is dependent on several parameters: hyperpolarization potential, duration of hyperpolarization, resting membrane potential and shape of hyperpolarizing waveform.

Halorhodopsin and Archaerhodopsin hyperpolarize the membrane, creating a pause. This synchronous and strong hyperpolarization induces a robust burst after a square light pulse, possibly masking the effect of a pause alone. By being able to prevent firing after the pause, or induce a pause without inducing a burst, we hope to separately identify the role of the pause and burst on post-synaptic cells and during certain behaviors.

Title: Coupling compartmental models to live neurons to investigate action potential mechanisms

Authors: *M. A. NAVARRO[1], S. L. DEBS[2], L. S. MILESCU[1]
[1]Biol. Sci., Univ. of Missouri-Columbia, Columbia, MO; [2]Whitman Col., Walla Walla, WA

Abstract: In mammalian central neurons, action potentials are initiated in the axonal initial segment (AIS) by Nav1.2 and Nav1.6 channels, and shaped and terminated by other voltage-gated ion channels. From the AIS, the AP travels down the axon towards the presynaptic site, but also back-propagates towards the soma. The role of axonal sodium channels in AP initiation and propagation is still incompletely understood, mostly because it is difficult to record from these channels at the AIS. Instead, most experimental evidence of axonal activity is obtained indirectly, from electrical recordings at the soma. To better understand these mechanisms, we developed a real-time computational procedure where a compartmental model of the axon is coupled to a live neuron using dynamic clamp. The properties of this computational model (e.g., spatial distribution and kinetics of ion channels) are varied until the firing activity of the hybrid construct (neuron + axon compartmental model) best matches the normal activity of the neuron.

Title: Toad venoms resibufogenin and cinobufagin activate central neurons through a ouabain-like action

Authors: Z.-J. WANG, L. SUN, *T. HEINBOCKEL
Anat., Howard Univ. Coll Med, Anat., WASHINGTON, DC

Abstract: Cinobufagin and resibufogenin are two major effective bufadienolides of Chan su (toad venom) which is a Chinese medicine obtained from the skin venom gland of toads. It is used as a cardiotonic and CNS respiratory agent, as analgesic and anesthetic and as remedy for ulcers. Many clinical cases showed that Chan su and Chan su-containing formulations have severe side-effects on the CNS, causing shortness of breath, breathlessness, seizure, coma and cardiac arrhythmia. We used whole-cell recordings from brain slices to determine the effects of bufadienolides on excitability of a principal neuron in the main olfactory bulb, mitral cells, and the cellular mechanism underlying the excitation. At higher concentrations, cinobufagin and resibufogenin induced irreversible over-excitation of mitral cells indicating a toxic effect. At lower concentrations, they concentration-dependently increased spontaneous firing rate, depolarized the membrane potential of mitral cells, and elicited inward currents. The excitatory effects were due to a direct action on mitral cells rather than an indirect phasic action. Bufadienolides and ouabain had similar effects on the firing of mitral cells which suggested that bufadienolides activated neurons through a ouabain-like effect, most likely by inhibiting Na+/K+-ATPase. The direct action of bufadienolide on brain Na+ channels was tested by recordings from stably Nav1.2-transfected cells. Bufadienolides failed to make significant changes of the main properties of Nav1.2 channels in current amplitude, current-voltage (I-V)

relationships, activation and inactivation, suggesting that bufadienolide-evoked activation of neurons is not mediated by the Na+ channels. Our results suggest that inhibition of Na+/K+-ATPase may be involved in both the pharmacological and toxic effects of bufadienolide-evoked CNS excitation.

Title: Propylparaben decreases the neuronal excitability of Hippocampal CA1 pyramidal cells *in vitro*

Authors: *L. LARA, L. ROCHA, E. J. GALVÁN
Pharmacobiology, CINVESTAV SUR, Mexico City, Mexico

Abstract: Propylparaben (PPB) is an antimicrobial preservative widely used in food, cosmetics and pharmaceutics. Previous studies demonstrate that PPB blocks voltage-dependent sodium channels; virtual screening studies suggest that topological descriptors of PPB share similarities with certain antiepileptic drugs of clinical use. To further explore the effects of PPB, patch clamp experiments were carried out on acute hippocampal slices and changes in the intrinsic excitability of CA1 neurons were tested in the presence of PPB. In current clamp mode, cells were held at -65 mV and current steps (1 sec duration, 50 pA increase) were injected to generate burst of action potentials (APs). Increasing concentration of PPB (100, 200 and 500 μM) blocked the evoked APs in all the cells tested (n=34) in a concentration dependent manner. Systematically, PPB increased the rheobase current to evoke APs (Rheobase increase: 10 ± 9%; 80 ± 32% and 220 ± 23%, for 100, 200 and 500 μM, respectively) and decreased the input resistance of pyramidal cells (Rn decrease 14.6 ± 5.4% and 21.8 ± 5.6 for 200 and 500 μM, respectively). In another set of experiments, cells were clamped at -65 mV and slow voltage ramps (20 mV/s) from -98 to -28 mV were applied. In control ACSF, neurons elicited burst of

action currents (29 Hz). In the presence of PPB (200 μM), the action currents generated at -45 mV were abolished and conductance responses turned linear. Lastly, we assessed the antiepileptic potential of PPB. Gap-free activity was acquired in current clamp mode, and epileptiform activity was induced with 4-AP (100 μM) + Mg2+-free ACSF. Spontaneous APs were very rare during baseline (frequency was less than 0.01 Hz). The perfusion of 4-AP generated paroxysmal depolarizing shifts (PDS) with burst of APs (8.9 Hz). Both, PDS and AP burst were reverted by the perfusion of PPB (AP burst activity decreased to 0.7 Hz). We surmise that PPB blocks the voltage dependent sodium channels, therefore neuronal excitability decreases.

Abstract: In the absence of any environmental stimuli, the brain endogenously generates spontaneous electrical activity that can be recorded from the surface of the brain, as electroencephalographic (EEG) waves, and in individual neurons, as a complex barrage of excitatory and inhibitory synaptic potentials. This endogenous brain electrical activity varies as a function of vigilance states and can be dramatically altered during pathological states, such as epilepsies and comas. We have investigated by the means of surface EEG coupled with intracellular recordings in the rat *in vivo*, the impact of an oscillatory or tonic background synaptic activity on the membrane excitability and firing responses of somatosensory cortex

pyramidal neurons. The two network activities were induced by systemic injection of pentobarbital or fentanyl, allowing general analgesia and mimicking sleep- and waking-like cortical patterns, respectively. We compared the neuronal electrical properties in the two states to those acquired after complete removal of background activity by injection of high doses of pentobarbital, leading to isoelectric states in both neurons and EEG. Compared to the oscillatory state, the tonic spontaneous activity resulted in a more depolarized and less fluctuating membrane potential (Vm), a lower input resistance (Rm) and steeper relations of firing frequency versus injected current (F-I curves). Suppression of background synaptic activities caused a Vm hyperpolarization, without any change in Rm, and induced a rightward shift of F-I curves. Both types of synaptic drive generated a high variability in current-induced firing rate and pattern, which was much reduced after removal of spontaneous activity. These findings indicate that endogenous brain activity increases the sensitivity of cortical neurons to weak inputs and is responsible for a large variability in firing responses. The functional outcome of this differential modulation of cortical excitability as a function of background synaptic activities is currently investigated in our lab. We are analyzing and comparing, in the presence and absence of synaptic activity, the sensory responses evoked in somatosensory cortical neurons by the application of controlled air-puff stimuli to the whiskers. In collaboration with the Intensive Care Unit of the Hospital, we are also investigating the sensory reactivity of the isoelectric cortex in human patients suffering from “status epilepticus”, and maintained, for therapeutic purpose, in deep comatose with high doses of pentobarbital.

Title: Calbindin-D28K restores the intrinsic excitability properties of aged CA1 pyramidal neurons to young-like state

Authors: *D. SIMKIN, A. HOFFMAN, M. M. OH, J. F. DISTERHOFT
Physiology, Feinberg Sch. of Med., Northwestern Univ., Chicago, IL

Abstract: Aging- and Alzheimer's-related Ca2+ dysregulation is implicated in impaired synaptic plasticity and learning/memory (Khachaturian '94, Thibault, et al. '07). Activity-dependent Ca2+ influx is enhanced in CA1 pyramidal neurons from aged animals (Tombaugh, et al. '05) overwhelming endogenous Ca2+ binding/buffering proteins (CBP) leading to an enlarged Ca2+-dependent postburst-afterhyperpolarization (sAHP) in these neurons (Disterhoft and Oh '06, Tombaugh, et al. '05). Recently, we have discovered that the endogenous buffer capacity for Ca2+ is enhanced in aged CA1 neurons (Oh, et al. '13). Also, a previous report suggests that reductions in a classical CBP calbindin-D28K (CB) correlates with aging-related learning and memory deficits (Soontornniyomkij, et al. '12). Therefore, we hypothesize that enhancing endogenous Ca2+ buffer(s) will rescue aging-related intrinsic excitability and cognitive deficits. Although chemical Ca2+ chelators (e.g. BAPTA) have been shown to impact the intrinsic excitability of pyramidal neurons, it remains to be determined if increasing the endogenous CBP level will increase excitability of CA1 neurons by reducing the sAHP. Hence, we evaluated the intrinsic excitability properties (including: sAHP, spike frequency accommodation, and ability to fire trains of APs at θ-burst frequencies) of CA1 pyramidal neurons from young (2-4 mo) and aged (29-31 mo) rats after intracellular delivery (through internal pipette solution) of purified CBP (calbindin-D28K). We observed that CBPs reduce the sAHP and accommodation in aged CA1 pyramidal neurons to young-like levels. Therefore, these data suggest that aging-related intrinsic excitability and cognitive deficits could be ameliorated by increasing the endogenous CBPs by use of gene therapeutics (e. g. AAV-mediated gene transfer).

Title: Effects of oxytocin on intrinsic properties of pyramidal neurons in rat insular cortex

Authors: *J. A. VARELA, J. CHRISTIANSON
Psychology, Boston Col., Chestnut Hill, MA

Abstract: The neuropeptide oxytocin (OT) is a highly conserved neural modulator and is known to contribute to social, feeding, and fear behaviors. OT positive axons and OT receptors (OTR) are found in the insula but not in many adjacent cortical areas of adult male rats. The present study sought to describe the effects of OT on layer 5/6 pyramidal neurons of the insular cortex. Visualized whole cell patch clamp recordings were made from 300μm slices taken from 4 to 6 week old male Sprague Dawely rats (N=15, neurons N=30); cells were included for analysis if they were found in the deep layers of Agranular or Granular insular cortex 2.8mm (+/- .5mm) caudal to bregma and appeared to have pyramidal morphology (confirmed by biocytin staining). Active and passive membrane properties were determined first in conventional aCSF and 10 min after perfusion with aCSF containing 500nM OT. OT caused a number of significant changes(ps < 0.05), namely: Depolarization of the resting potential, increase in input resistance and rheobase, decrease in SAG ratio and membrane time constant, decrease in action potential (AP) amplitude and AP rise rate and increase in AP halfwidth. The input-output curve, measured as APs/s evoked by positive current injections was left-shifted. Simultaneous application of the phospholipase C (PLC) inhibitor, U 73122 (10 μM), prevented OT effects on AP amplitude, input resistance and the input-output curve. (N=5, neurons N = 5/group). Taken together these data suggest that the OT alters the intrinsic neuronal excitability in the insula through a GPCR/PLC mediated mechanism.

Title: Functionally distinct populations within anatomically similar CCK-expressing hippocampal interneurons due to different availability of potassium conductances

Authors: V. J. OLAH, *J. SZABADICS
Inst. of Exptl. Medicine, Hungarian Acad. of Sci., Budapest, Hungary

Abstract: Specific functions of various voltage-dependent ionic channels contribute to the functional divergence of GABAergic cell types. The firing properties are specific for distinct cell types and are important for their function within the neuronal networks as a general determinant of their integrative properties. Furthermore, the firing properties are often used for the identification of the recorded cell types because these complex properties are determined by the cell-type specific combinations of ionic channels. Here we provide evidence for an exception for the cell-type specific firing patterns by showing that within anatomically and functionally identified same cell types, individual GABAergic cells can have markedly different firing properties. Using whole-cell patch clamp recordings and anatomical identification, we distinguished two populations of CCK-expressing GABAergic cells (CCK-IN) in the CA3 region of the hippocampal acute slices based on the presence or the absence of state-dependent firing properties. In the first subset of CCK-INs, action potentials are inhibited at the onset when the firing patterns were evoked from hyperpolarized membrane potentials (at -80mV). However, this transient outward rectification (TOR) was absent in the same cells at depolarized membrane potentials (-60mV). The second subset of morphologically indistinguishable CCK-INs did not show state-dependent inhibition of action potential generation (non-TOR cells). Interestingly, the presence or absence of the state-dependent firing characteristic did not correlate with any of the previously known anatomical subdivision of CCK-expressing GABAergic cells (including VGlut3, SATB1 and calbindin expression, axonal arborization), thus the state dependent firing provide an novel level of complexity within this cell group. Voltage-clamp recordings revealed that TOR CCK-INs have substantial A-currents with leftward shifted activation and inactivation voltages, which can explain the state dependent firing. Furthermore, the state-dependent inhibition of firing was inhibited by high concentration of 4-AP; whereas TEA and low concentration of 4-AP did not change the onset firing suggesting the involvement of specific potassium channels (potentially Kv4.3 and KChIP). Altogether, the results revealed that different availability of an A-type potassium conductance can results in different functionality among anatomically homogeneous CCK-INs in the CA3 region.

Title: Effect of maternal bisphenol A exposure on network excitability in mouse hippocampal slices assessed by voltage-sensitive dye imaging

Authors: *Y. TOMINAGA[1], K. IGARASHI[2,3], M. I. OTSUKA[2,3], Y. FURUKAWA[3], J. KANNO[3], K. TANEMURA[4], T. TOMINAGA[1]

Abstract: There are increasing concerns about disruption of brain function due to exposure to environmental chemical substances, especially in early development. We aimed to develop a method to assess such effects on neuronal circuit activity. Bisphenol A (BPA), which is widely used in the production of polycarbonate plastics and epoxy resins, is a potentially hazardous chemical substance. BPA can bind to estrogen receptors and affect the signaling cascade of endogenous estradiol. A number of reports have indicated that estrogen affects synaptic plasticity in the hippocampal (HP) circuit in rats and mice. In particular, maternal exposure to BPA is a great concern owing to the associated risk of delayed emotional and cognitive deficits in the offspring. Here, we aimed to assay the effects of maternal exposure to BPA on neural circuit activity after development. Pairs of male and female mice were transferred for mating into cages supplied with BPA-containing drinking water at four different concentrations (0, 0.1, 1, and 10 ppm). On confirmation of pregnancy, the male mouse was removed, and BPA-containing drinking water was supplied until weaning. Male offspring were randomly chosen from mothers maintained under the same conditions. HP slices were made by standard procedures and analyzed after staining with voltage-sensitive dye (VSD: Di-4-ANEPPS) after at least 8 weeks. Three main pathways, namely the perforant, mossy fiber, and Schaffer collateral pathways, were stimulated under wide-field optics (THT-macroscope, BrainVision LLC), and the neuronal activation patterns were recorded by a CMOS high-speed imager (MiCAM Ultima, BrainVision LLC). The neuronal responses of the HP slices of control (0 ppm) and BPA-exposed mice (0.1, 1, and 10 ppm BPA) were tested in normal and Gabazine (10 μM)-containing artificial cerebrospinal fluid. Gabazine increased the peak amplitude and duration of the response to

strong stimulation in the HP slices of both control and BPA-exposed mice. In the HP slices of control mice, even very weak stimulation was sufficient to induce large and long responses in the entire CA3-CA1, whereas the HP slices of BPA-exposed mice did not exhibit such responses. This clear difference may indicate an alteration in the threshold of excitability of the cells. These modifications in the HP circuit may be different from the deficits in valproate-treated mice reported last year. These results highlight the benefits of VSD imaging assays when assessing environmental risk factors.

Title: Switching between cholinergic-dependent mnemonic and epileptiform responses in individual hippocampal CA1 pyramidal neurons in acute rat brain slice preparations

Authors: *B. KNAUER[1,2], M. YOSHIDA[1,2,3]
[1]Mercator Res. Group, Ruhr-University Bochum, Bochum, Germany; [2]Intl. Grad. Sch. of Neurosci., Bochum, Germany; [3]Fac. of Psychology, Bochum, Germany

Abstract: The cholinergic system supports memory but is also involved in mesial temporal lobe epilepsy. We previously showed that individual CA1 pyramidal neurons may support short-term maintenance of information by persistent firing which is action potential generation that outlasts the stimulation. Other groups have shown that CA1 pyramidal neurons engage in persistent activity which was accompanied by depolarization block and is termed here as epileptiform response. Both forms of responses require the activation of muscarinic acetylcholine receptors (mAChRs). Preventing epileptiform activity, while allowing the neurons to exhibit memory-related forms of activity may be of clinical interest. However, it remains unclear what distinguishes these two responses. In this study, we aim to clarify what down-stream

mechanisms of mAChR stimulation determine whether persistent firing or an epileptiform response is induced. We used *in vitro* whole-cell patch clamp recordings from hippocampal CA1 pyramidal neurons in acute brain slices from P14-24 Long-Evans rats. While recording, slices were submerged in 35±1°C artificial cerebrospinal fluid with ionotropic synaptic blockers (2 mM kynurenic acid, 0.1 mM picrotoxin). We first present that stronger activation of mAChRs (5, 10, 20 μM carbachol (Cch)) increased the likelihood of epileptiform responses. One of the down-stream effects of mAChR activation is the gating of transient receptor potential (TRPC) channels. We show that elevated concentrations of intracellular ATP (0, 2, 4, 10 mM) and the blockade of TRPC4/5 channels (20 μM ML204) depressed both persistent firing and epileptiform responses. This suggests that the TRPC channels support depolarization in both responses. Another down-stream effect of mAChR stimulation is the reduction of post-burst afterhyperpolarization (AHP). In the presence of Cch, additional blockade of the SK- (100 nM apamin) and/or M-channels (20 μM XE-991) often switched persistent firing to epileptiform responses. Under blockade of SK- and M-channels but in the absence of Cch, we observed depolarization block during the current injection. Neither the persistent firing nor the epileptiform response that outlasted the current injection was observed in this condition. These results suggest that TRPC channels and AHP currents (SK- and M current) both contribute to the transition between persistent firing and epileptiform response. Our results indicate that individual neurons may switch between persistent firing and epileptiform responses by modulating single cell properties down-stream of mAChR activation which may affect network activity *in vivo* and may have clinical implications.

Title: Ketamine differentially affects neuronal activity in primary and high order sensory cortex in mice

Authors: *C. M. FUNK[1,2], S. HONJOH[1], A. V. RODRIGUEZ[1,2], C. CIRELLI[1], G. TONONI[1]
[1]Dept. of Psychiatry, [2]Neurosci. Training Program, Univ. of Wisconsin-Madison, Madison, WI

Abstract: Ketamine anesthesia produces sensory disconnection from the environment that is associated with intense dreaming in humans. Ketamine induces varied effects on neuronal spiking both directly through antagonism of NMDA receptors and indirectly by disinhibition of excitatory neurons and alteration of the neuromodulatory milieu. These complex and often opposing effects undermine attempts to predict how ketamine may influence specific brain areas and necessitate *in vivo* recordings of neuronal activity in order to determine the overall response of a given brain region to ketamine. We performed laminar recordings in primary visual cortex (V1) and retrosplenial cortex (RS) in mice to examine whether ketamine differentially affects neuronal activity in primary and high order sensory cortex. We implanted adult male mice (n=4) with 16ch silicon laminar probes in V1 and/or RS. Following recovery from surgery, local field potentials and neuronal activity were recorded continuously along with epidural EEG and EMG. On experimental days (n=4, 1 per mouse), 100mg/kg ketamine was administered IP. Behavioral state was determined by assessing the righting reflex (RR) and other behaviors. Administration of ketamine led to two distinct behavioral phases. First, mice lost the RR and remained immobile for 821 +- 185 seconds. Upon recovery of the RR, mice exhibited locomotion that resembled crawling and a tendency to approach corners of the clear plastic cage, where they continued to perform crawling movements, as if attempting to "walk through" the wall. At the neurophysiological level, periods of neuronal silence (OFF periods) dominated throughout the first phase in both V1 and RS (54+-27% and 48+-9% time spent in OFF periods, respectively). However, neuronal firing levels during ON periods differed markedly between areas. In V1, spiking during ON periods was decreased by 80% compared to baseline wake ($p<0.05$), while in RS, ON period firing rates exceeded baseline levels by more than 100% ($p<0.005$). In the second phase, percent time OFF decreased in both areas ($p<0.05$ for both). In V1, ON period firing rates gradually increased toward baseline levels, with deep layers recovering more quickly than superficial layers. In RS, elevated ON period spiking persisted throughout the second phase. These findings reveal that ketamine attenuates V1 activity while triggering periods of intense firing in RS. This striking difference may reflect an imbalance in feedforward and feedback signaling, whereby weak feedforward activity in V1 is occluded by strong feedback signaling from RS, perhaps contributing to the sensory disconnection caused by ketamine.

Title: Effects of ambient neuromodulators in cerebrospinal fluid on neuronal activity in the hippocampus

Authors: *A. BJOREFELDT, U. ANDREASSON, J. DABORG, I. RIEBE, P. WASLING, H. ZETTERBERG, E. HANSE
Inst. for Neurosci. and Physiol., Gothenburg, Sweden

Abstract: Central neurons are surrounded by an extracellular fluid whose composition results from the continuous mixing of cerebrospinal fluid (CSF), occupying the ventricles and subarachnoid space, with interstitial fluid of the parenchyma. The CSF is known to harbor many different neuromodulatory substances at ambient levels, but whether they actually influence the activity of central neurons is still unknown. By using a matched artificial CSF as control, we show that human CSF (hCSF) strongly increases spontaneous excitatory, but not inhibitory, activity in the hippocampus. In CA1 neurons, hCSF lowers the action potential threshold and depolarizes the resting membrane potential to boost spontaneous firing. Clamping G-protein activity in CA1 neurons with GTPγS completely occluded these effects, suggesting that the neuromodulators in hCSF act specifically via G-protein coupled receptors to increase spontaneous excitatory activity. We also found an augmentation of evoked glutamatergic transmission that was associated with an increased release probability at CA3-CA1 synapses, and a slightly increased presynaptic axonal excitability. Taken together, these findings show that ambient neuromodulators in brain extracellular fluid potently increases the activity of pyramidal neurons, but not interneurons, and thus promote spontaneous excitatory activity. Our results may help explain differences in the level of spontaneous activity displayed by pyramidal neurons in *in vivo* and *in vitro* recordings.

Title: Amyloid β-protein induces hippocampal neuron hyperexcitability through A-type K+ current inhibition mediated by caspases and GSK-3 activation

Authors: F. SCALA[1], S. FUSCO[1], C. RIPOLI[1], R. PIACENTINI[1], D. D. LI PUMA[1], M. SPINELLI[1], F. LAEZZA[2], C. GRASSI[1], *M. D'ASCENZO[1]

Abstract: Amyloid β-protein (Aβ) pathologies have been linked to dysfunction of excitability in hippocampal neurons, but the molecular mechanisms underlying this process are still poorly understood. Here we applied whole-cell patch-clamp electrophysiology to primary hippocampal neurons and show that intracellular $A\beta_{42}$ delivery leads to increased spike discharge and action potential broadening through down-regulation of A-type K^+ currents. Pharmacological studies showed that caspases and GSK-3 activation are required for these $A\beta_{42}$-induced effects. Extracellular perfusion and subsequent internalization of $A\beta_{42}$ increase spike discharge and promote GSK-3-dependent phosphorylation of the Kv4.2 α-subunit, a molecular determinant of A-type K^+ currents, at Ser-616. In acute hippocampal slices derived from an adult triple-transgenic Alzheimer's mouse model (3xTg-AD), characterized by early intracellular accumulation of $A\beta_{42}$, CA1 pyramidal neurons exhibit hyperexcitability accompanied by increased phosphorylation of Kv4.2 at Ser-616. Collectively, these data suggest that intraneuronal $A\beta_{42}$ accumulation leads to an intracellular cascade culminating into caspases activation and GSK-3-dependent phosphorylation of Kv4.2 channels. Taken together these data provide novel insights into the toxic mechanisms triggered by intracellular $A\beta_{42}$ and offer potentially new therapeutic targets for Alzheimer's disease treatment.

Title: Overexpression of tau augments afterhyperpolarizations in rat CA1 hippocampal neurons

Authors: *T. W. CHURCH[1], J. T. BROWN[3], N. V. MARRION[2]
[2]Sch. of Physiol. & Pharmacol., [1]Univ. of Bristol, Bristol, United Kingdom; [3]Univ. of Exeter Med. Sch., Univ. of Exeter, Exeter, United Kingdom

Abstract: Cognitive impairment is seen in a number of diseases involving the alteration and physiological dysfunction of the microtubule-associated protein tau. These disease states, known as tauopathies, are characterised by progressive neurodegeneration, but it is unknown whether changes in excitability precede cell death to underlie cognitive decline in the early stages of disease. To examine the physiological effects of tau overexpression, rat organotypic hippocampal slices were infected with the Sindbis virus encoding the human 4R0N isoform of tau. Whole-cell current-clamp recordings were made from CA1 pyramidal neurons labelled with co-expressed eGFP. Hippocampal CA1 neurons, overexpressing wildtype tau, displayed an augmented afterhyperpolarization (AHP) following a train of 15 action potentials (APs). Both components of the AHP (medium and slow AHP respectively) increased in amplitude compared with control by 62% and 100% respectively. The effect of tau overexpression on the medium and slow AHP was reproduced by overexpression of a mutant form of tau with a single point mutation (P301L) that is found in frontotemporal dementia patients, shown by a 63% and 93% augmentation on the mAHP and sAHP, respectively. Passive and active properties of hippocampal CA1 neurons were examined in cells overexpressing eGFP and eGFP + tau. A small but significant increase in the membrane time constant was observed in cells overexpressing tau, correlating with an apparent change in cell morphology, specifically in the structure of the distal dendritic and axonal arbours. Furthermore, AP threshold was shifted to more hyperpolarized potentials, but no change in the AP rate of rise or duration was observed. Evoking AP firing from a resting potential of -75 mV resulted in a mAHP driven by activation of both SK and H current. Bathing infected slices in Ca2+-free extracellular solution showed that tau overexpression augmented the SK channel component of the mAHP. The dependence of the sAHP on extracellular Ca2+ was maintained in cells expressing tau. These data, together with the finding that intracellular cAMP was able to abolish the augmented sAHP, suggests that tau overexpression does not change the ion channel subtype that underlies the sAHP. These data

indicate that the overexpression of wild-type tau reduced hippocampal pyramidal cell excitability by enhancing AHPs that regulate cell firing. This effect might occur in concert with a change in cell morphology and suggests that dysregulation of tau expression could result in changes in excitability that may underlie cognitive impairment observed in the early stages of tauopathies.

Title: Activation of muscarinic receptors underlies cholinergic modulation of serotonergic neurons in the brainstem of ePet-EYFP mice

Authors: *Y. DAI[1], L. M. JORDAN[2]
[1]East China Normal Univ., Shanghai, China; [2]Dept. of Physioloy, Univ. of Manitoba, Winnipeg, MB, Canada

Abstract: 5-HT neurons in the parapyramidal region (PPR) of the medulla play an essential role in generating locomotion. It has been shown that stimulation of the PPR produces locomotion in the isolated neonatal rat brainstem-spinal cord preparation. However, little is known about the properties of these locomotor 5-HT neurons. Using brainstem slices from ePet-EYFP mice in which EYFP was expressed in 5-HT neurons we were able to perform whole cell patch-clamp recordings on EYFP+ neurons of the brainstem (PND 1 - PND 15). We had previously shown that the 5HT neurons received excitatory cholinergic input and displayed location-related responses to acetylcholine (ACh). Bath application of 15-30 μM ACh produced depolarization of the membrane potential in 76% of the 5-HT neurons (n=50) in PPR while 67% of 5-HT neurons (n=33) in the midline raphe nuclei (MRN) of the brainstem did not respond to ACh. In this study, we further investigated the cholinergic modulation of 5-HT neurons in the brainstem of ePet-EYFP mice with bath administration of muscarine (10-20 μM) and nicotine (10-15 μM). Muscarine could mimic the effects of ACh on 5-HT neurons in the medulla while nicotine did

not show any substantial effect on these neurons. Similar to ACh, muscarine induced depolarization of membrane potential in 70% of PPR 5-HT neurons (n=33) with decreases in rheobase (5.1±12 pA), input resistance (176.7±290 MΩ), action potential height (2.2±4 mV) and AHP depth (2.6±4 mV), whereas 72% of MRN 5-HT neurons (n=14) did not respond to muscarine. Similar to the observations with ACh, a small number of the PPR 5-HT neurons exhibited a hyperpolarization of membrane potential (6/33) or did not respond to muscarine (4/33), while a few MRN 5-HT neurons displayed depolarization (2/14) or hyperpolarization (2/14) in the presence of muscarine. Muscarine also induced or enhanced membrane oscillations in some of the 5-HT neurons. We further demonstrated that the effects of muscarine on PPR or MRN 5-HT neurons could be antagonized by 1-3 μM atropine (n=12), suggesting that the cholinergic modulation of 5-HT neurons in the brainstem of ePet-EYFP mice was mediated through activation of muscarinic receptors. Furthermore, we examined the subtype of muscarinic receptors with administration of antagonists of M1-M4 receptors (telenzepine 5-10 μM; methoctramine 5-10 μM; 4-DAMP 2-5 μM; PD102807 1-2 μM) in the presence of muscarine. Our data suggested that both M2 and M3 receptors were implicated in the muscarinic modulation of the 5-HT neurons. This study provides insight into the mechanisms underlying the cholinergic modulation of 5-HT neurons in the brainstem of ePet-EYFP mice.

Title: Hodgkin-Huxley model with fractional differentiation displays spike time adaptation

Authors: *W. W. TEKA, T. M. MARINOV, F. SANTAMARIA
UTSA Neurosciences Institute,, Univ. of Texas at San Antonio, San Antonio, TX

Abstract: The electrical activities of neurons have previously been described using biophysical models based on the Markov state of ion channels. Recent studies show that neuronal dynamics can be affected by the long term interactions between ion channels that have non-Markovian states. The temporal correlation and state distributions of the channels follow power law dynamics. Mathematical models with fractional (non-integer order) derivatives can be more effective than models with standard (integer order) derivatives in describing neuronal dynamics with power law distributions. In a previous paper, we showed that the emergent properties of spike time adaptation are modeled well by the Fractional Leaky Integrate- and-Fire (FLIF) model, which displays upward and downward spike adaptations without any additional adapting current. In the current study, we go beyond the functional model approach of the FLIF and apply fractional derivatives to actual biophysical models and develop the new Fractional Hodgkin-Huxley model (FHH). We find that spike time adaptation emerges from the fractional derivative of the biophysical models without any adapting potassium currents. From the Fractional Hodgkin-Huxley model emerges a temporal adapting process that is highly influenced by the integration of all the past activities (called memory trace). The effect of the memory trace on the adapting process becomes stronger when the fractional exponent is close to zero as seen in experimental data. The Fractional Hodgkin-Huxley model promises to be useful in the further study of spiking properties of neurons caused by the long term correlation of ion channels.

Title: Functional roles and noradrenergic modulation of calcium-dependent potassium conductances in identified subtypes of layer 5 pyramidal neurons from mouse somatosensory cortex

Authors: *R. C. FOEHRING, D. GUAN
Anat. & Neurobio., Univ. Tennessee Hlth. Sci., Memphis, TN

Abstract: We used BAC mouse lines that express EGFP in different subpopulations of layer 5 pyramidal neurons from somatosensory cortex to test whether functional differences between the two types of pyramidal cells were due to differential expression of calcium-dependent potassium channels. The mouse lines were (1) Tg(Etvl-EGFP)BZ192Gsat/Mmucd (*etv1*), where EGFP was only expressed in IT-type, layer 5A pyramidal neurons that had thin apical dendrites (Type 2 morphology); (2) Tg(Glt25d2-EGFP)BN20Gsat/Mmnc (*glt*), in which EGFP was expressed in PT-type, "thick-tufted" layer 5B pyramidal neurons (Type 1 morphology: Larkman and Mason, *J Neurosci* 10: 1407, 1990). We prepared acute brain slices from 2-4 week old mice. EGFP-positive cells were identified under epifluorescence and studied with whole-cell patch clamp current-clamp recordings (established using IR /DIC microscopy). E*tv1* pyramidal cells had significantly broader action potential half-width, lower dV/dt for spike polarization and repolarization, and larger slow afterhyperpolarizations as compared to *glt* pyramidal cells (Groh et al. *Cerebral Cortex* 20: 826, 2010). *Etv1* cells also exhibited greater spike frequency adaptation and reduced dc gain (lower f-I slope) for repetitive firing than *glt* cells. We found that calcium-dependent conductances contribute to functional differences between *glt* and *etv1* pyramidal cells. A large portion of the fast, medium and slow AHPs (fAHP, mAHP and sAHP, respectively) were Ca-dependent in both cell types. We did not find differences between *etv1* and *glt* cells in the effects of BK channel blockers. Whereas *glt* cells had significantly larger apamin-sensitive (sK-mediated) current, *etv1* cells had significantly larger slow AHP and I_{sAHP}. Consistent with the latter findings, apamin had a greater effect on repetitive firing in *glt* cells. The sAHP and I_{sAHP} were strongly inhibited by norepinephrine acting via β-receptors. Since the sAHP was much larger in *etv1* cells, NE had a dramatic effect on repetitive firing in *etv1* cells and almost no effect on firing in *glt* neurons. The f-I gain was increased and spike frequency adaptation reduced by NE. In the presence of NE, *etv1* cells fire similar to *glt* cells in the absence of modulation. Thus, in addition to pyramidal cells from layers 5A and 5B differing in terms of their morphology, thalamic inputs, cellular targets, and receptive field size (e.g. Manns et al. J Physiol 556: 601, 2004), they also differ in their response to neuromodulators such as NE. Additional experiments tested for differences in the expression of voltage-gated potassium conductances in *etv1* and *glt* neurons. Supported by NS44163 (to RCF).

Title: Small conductance calcium-activated potassium channels mediate nitric oxide effects on neuronal excitability via S-nitrosylation

Authors: *L. R. ARTINIAN, S. MCLEISH, J. EIDELMAN, V. REHDER
Biol., Georgia State Univ., Atlanta, GA

Abstract: Small conductance calcium-activated potassium channels (SK channels) play an important role in controlling the neuronal firing frequency, intrinsic excitability and synaptic integration. The regulation of these channels by neurotransmitters and neuromodulators is of great importance to their function. Nitric oxide (NO) is a gaseous neuromodulator that controls neuronal excitability. In mature B5 neurons of the fresh water snail, Helisoma trivolvis, NO increases neuronal spiking by depolarizing the membrane potential via inhibition of SK channels1, and, using this mechanism, controls neuronal excitability. We demonstrated that this effect of NO was cGMP-independent 2, suggesting that the inhibition of SK channels might be mediated by S-nitrosylation, a selective and reversible posttranslational modification of cysteine residues by NO. To address this possibility, we first cloned the Helisoma SK channel (HeliSK channel) from the snail CNS. The channel protein, composed of 564 amino acids, demonstrated a high homology with mammalian SK channels, especially in the calmodulin-binding site and transmembrane domains. The channel was then heterologously expressed in HEK 293 cells. Whole-cell voltage-clamp recordings with 2μM [Ca2+] inside of the recording pipette demonstrated a functional channel that could be blocked with the SK channel specific blocker apamin. The NO donor NOC-7 (100 μM) inhibited the HeliSK channel-mediated current. To evaluate the possible regulation of the SK channel by NO via S-nitrosylation, cysteine residues in the channel protein were identified and subsequently mutated to alanine residues. A single-point mutation of one of the eight cysteine residues prevented the NO-mediated inhibition of the channel current. Interestingly, this cysteine residue is conserved among species. Taken together, our data suggest that S-nitrosylation of the HeliSK channel serves as a major regulatory mechanism by which NO controls neuronal excitability. 1. Title: Contributions of calcium influx and calcium-induced calcium release (CICR) to the orexin-enhanced afterhyperpolarization (oeAHP) in dorsal raphe neurons

Authors: M. ISHIBASHI, E. LYNN, *C. S. LEONARD
Dept Physiol, New York Med. Coll, VALHALLA, NY

Abstract: Orexin (hypocretin) neuropeptides critically regulate sleep and waking behavior along with other homeostatic processes via extensive projections to brainstem targets including serotonergic dorsal raphe (DR) neurons. Previously, we reported that orexin not only depolarizes DR neurons, but also powerfully *enhances* their Ca^{2+}-dependent afterhyperpolarizations (AHPs) resulting in slowed firing and decreased firing variability. Since the oeAHP is blocked by buffering $[Ca^{2+}]_i$ with BAPTA (10mM), and is mediated, in part, by prolonging the apamin-sensitive SK-current, we considered three factors by which orexin might influence SK currents using simultaneous whole-cell voltage-clamp and Ca^{2+} imagining in mouse brain slices. First, since SK2 currents are prolonged by de-phosphorylation, we intracellularly applied okadaic acid (25 nM), an inhibitor of the SK2-associated protein phosphatase 2A (PP2A). This did not reduce the oeAHP current, suggesting that prolongation of SK currents by orexin does not require this de-phosphorylation. Second, since the oeAHP depends on PLC, but not PKC activation, and is sensitive to depletion of Ca^{2+} stores with CPA (10 μM), we examined whether store involvement was mediated by IP3 and/or ryanadine receptors (RyRs). Intracellular application of the IP3 receptor antagonists 2-APB (50 μM) or xestospongin C (1 μM) did not reduce the oeAHP, while the RyR antagonist, ruthenium red (100 μM) significantly reduced the oeAHP. This suggests that CICR rather than IP3 receptor activation contributes to the oeAHP. We next re-examined the possibility that Ca^{2+} influx was increased by orexin, although previously we did not detect changes in somatic Ca^{2+} indicator signals. Indeed, the Ca^{2+} action currents (CACs) evoked by our depolarizing voltage trains were enhanced by orexin. To test if this resulted from increased Ca^{2+} current, we applied orexin while measuring Ca^{2+} current with a Cs^{+}-rich patch solution. Ca^{2+} currents were not increased, although the Cs^{+} solution occluded enhancement of the CACs by orexin. Since the K^{+} channel blocker 4-AP (5 mM, but not 0.5 mM) also occluded enhancement of the CACs, we examined the effect of orexin on A-type K^{+} current in DR

neurons and found that this current was inhibited by orexin. Collectively, these findings suggest that orexin-enhanced activation of SK current, which occurs as part of the oeAHP, results from suppression of A-current, spike broadening and increased Ca^{2+} influx which is then amplified by CICR in DR neurons.

Title: Spikelets in cortical pyramidal neurons: Origin and functional consequences

Authors: ***M. MICHALIKOVA**[1], M. REMME[1], R. KEMPTER[1,2]
[1]Humboldt-Universitaet Zu Berlin, Berlin, Germany; [2]Bernstein Ctr. for Computat. Neurosci., Berlin, Germany

Abstract: Spikelets are transient, all-or-none depolarizations of small amplitude (< 15 mV), which can be measured in somatic intracellular recordings. In hippocampal CA1 pyramidal neurons, spikelets were reported in awake behaving (Epsztein et al., Science, 2010) and anesthetized animals (Chorev & Brecht, J Neurophysiol, 2012) whereas they are rarely observed *in vitro*. Both the mechanism underlying spikelet generation and their functional significance remain unknown. Here, we investigate the emergence of spikelets using mathematical analysis and numerical simulations of simplified neuron models consisting of an axon, an axon initial segment (AIS), and somato-dendritic compartments. Somatic spikelets are produced in the model upon orthodromic (dendritic or somatic) stimulation. We find that the generation of spikelets requires the combination of two main properties of the model cell: 1) a voltage shift of several millivolts (~10 mV) of the activation of somatic versus axonal sodium channels, and 2) sufficient electrical segregation of the axonal spike initiation zone from the somato-dendritic current sink. In this way, weak orthodromic stimuli trigger APs at the AIS that fail to activate somatic sodium

channels and manifest as somatic spikelets. Stronger stimuli lead to full-size APs at the soma, either through axonal APs that backpropagate to the soma ('shouldered APs') or direct somatic AP generation ('full-blown APs'). Through analysis and simulations we isolated the cell parameters that allow for spikelet generation. We hypothesize that spikelets occur rarely *in vitro* because the difference in activation voltages between somatic and axonal sodium channels under in-vitro conditions might be smaller than under in-vivo conditions. More precisely, the activation voltage of sodium channels might be controlled by neuronal activity, which is typically much higher *in vivo* than *in vitro*. Physiological regulation of these activation voltages, e.g., through various neuromodulators (dopamine, serotonin) acting via channel phosphorylation, was shown to differentially affect axonal versus somatic sodium-channel subtype. In our model, somatic spikelets represent APs that are only propagated down the axon, but are not backpropagated to the soma and the apical dendrites. Consequently, such a mechanism might be involved in the control of dendritic plasticity and/or in the homeostatic regulation of somato-dendritic firing rates without affecting the axonal output of a neuron.

Title: Cyclic AMP increases excitability at warm temperatures and decreases excitability at cold temperatures through activation of the hyperpolarization-activated current (Ih) in neurons from the bullfrog

Authors: ***J. SANTIN**[1], L. HARTZLER[2]
[1]Wright State Univ., Dayton, OH; [2]Wright State Univ., Dayon, OH

Abstract: Both endothermic and ectothermic animals experience changes in brain temperature that challenge the control of behavioral and physiological systems. Given the profound temperature-sensitivity neural signaling within the brain, changes in brain temperature pose a challenge to the normal-functioning CNS. Second messenger molecules like cyclic AMP (cAMP) play a critical role in modifying neuronal excitability, but limited consideration has been

given to the ability of second messenger systems to modulate neuronal firing at different temperatures. We hypothesized that increasing cAMP would exert temperature-specific effects on neuronal firing in locus coeruleus (LC) neurons of bullfrogs. Using whole-cell current clamp, we found that LC neurons containing 100μM cAMP had increased spontaneous firing rates compared to control LC neurons (0.78±0.13Hz *vs.* 2.79±0.47Hz; $P<0.05$). Intriguingly, as we have demonstrated in previous work, LC neurons increased firing during cooling from 20°C to 10°C (0.57±0.9Hz *vs*. 2.24±0.35Hz; $P<0.05$); however, in the presence of cAMP, firing was reduced by cooling (1.71±0.42Hz *vs.* 0.61±11Hz; $P<0.05$) in 80% (12/15) of neurons. cAMP, therefore, exerts opposite effects on excitability at 20°C and 10°C. Whole-cell voltage clamp experiments revealed that cAMP increased a hyperpolarization-activated current (I_h) at 20°C and 10°C by shifting voltage dependent activation to more depolarized potentials (20°C: $V_{0.5}$=-77.06±3.03 mV in control and -62.85±2.37mV with cAMP; 10°C: $V_{0.5}$=-95.09±2.35mV in control and -76.32±3.89mV with cAMP). In the presence of cAMP, inhibition of I_h using 2mM Cs^+ ([Cs^+] did not block K^+ currents) reduced firing at 20°C (2.16±0.48Hz *vs.* 0.4±0.19Hz; $P<0.05$), but converted firing decreases upon cooling into increases similar to those observed in neurons containing control intracellular solution. Finally, the 3 neurons that maintained cold-activated responses in the presence of cAMP had a lower I_h density compared to 5 neurons that reduced firing rates during cooling (-3.23±0.35pA/pF *vs.* -6.16±0.77pA/pF; $P<0.05$), but did not exhibit differences in voltage dependence of activation at 20° or 10°C, indicating that the ability of cAMP to modify excitability depends on the amount of I_h. I_h is carried by HCN channels that are expressed ubiquitously throughout the CNS and PNS in many animals that have been shown to undergo relatively large changes in temperature. These data provide evidence that activation of I_h by cAMP can exert opposite effects on neuronal excitability at different temperatures and therefore may have broad implications in normal and pathological neuronal function. Abstract: Although brain damage is one of the risk factors for acquired epilepsies, the underlying mechanism remains poorly understood. Various types of brain injuries often involve breakdown of blood-brain barrier. Albumin extravasation through compromised blood-brain barrier is known to be critical in the development of epilepsy, which is mediated by astrocytic uptake of albumin and in turn by the activation of transforming growth factor beta (TGF-β) signaling cascade. Since extracellular matrix (ECM) plays a key role in regulating synaptic plasticity and in control of excitatory/inhibitory neurotransmission balance, and astrocytes are a major source of ECM secretion, we hypothesize that astrocyte-induced ECM changes are a common phenomena in the pathophysiology of post-traumatic epileptogenesis. Here we compare transcriptome profiles following distinct types of damage-related epileptogenesis models - partial cortical isolation ("Undercut") and photothrombotic cortical stroke in rats. Using cDNA microarray analysis, we demonstrate that several ECM remodeling genes are commonly upregulated in both of the injury models. Similar changes were also found in rat brains following BBB disruption by deoxycholic acid, albumin treatment, and direct application of TGF-β. These genes include inhibitors of major proteases as well as chondroitin sulfate proteoglycans (CSPGs). In cortical astrocytes, albumin treatment increases transcription of various ECM related genes that can be blocked by TGF-β signaling inhibitors. These data suggest that albumin extravasation through compromised BBB may alter the provisional property of ECM around synapses via astrocytes, contributing to the development of epilepsy.

Title: Expression of insulin-like growth factors I and II and their receptors in iron-deficient murine astrocytes

Authors: E. MORALES-GONZÁLEZ, *I. CONTRERAS, J. A. ESTRADA
Neuroquimica, Univ. Autonoma del Estado De México, Toluca, Mexico

Abstract: Iron deficiency is an important public health problem worldwide, affecting vulnerable populations, such as children and pregnant women, causing developmental and functional alterations of the central nervous system. Growth factors, including the insulin-like growth factors I and II, act as neurotrophins, enhancing the survival and differentiation of neurons, thus having neuroprotective functions. However, the effect of iron deficiency on the expression of these growth factors has not been properly assessed. The objective of this study was to determine the expression of IGF-I, IGF-II, IGF-IR and IGF-IIR on murine astrocytes under iron-deficient conditions. To this end, we prepared primary mixed glial cultures from cerebral tissue from newborn mice (<24 hours old) and cultured them for 14 days. Astrocytes were dissociated from these cultures by treatment with trypsin/EDTA and cultured until 80% confluence was achieved. Two groups of cells were cultured: the first group was treated with deferoxamine (100 μM/mL) for 24 hours prior to analysis, to simulate iron-deficient conditions; the second group was maintained under standard culture conditions. After treatment, cells from both groups were lysed and their protein content was quantified using the Bradford method. Proteins were loaded in polyacrilamyde gels and IGF expression was analyzed by western blot. Our results showed decreased expression of IGF-II in iron-deficient astrocytes, compared to controls. IGF-I expression did not show differences in expression. IGF-IR and IGF-IIR expression was not altered either in iron-deficient conditions. Previous work has shown decreased expression of IGF-II in iron-deficient mixed glial cell cultures, accompanied by enhanced expression of IGF-IIR, with no discernible differences in the expression of these molecules in either isolated microglial or neuronal primary cultures. Together, our data suggest a differential regulation of IGF expression on neuronal and glial cells under iron deficient conditions, which may be important in the induction of neurological deficits in iron-deficient patients.

Title: Albumin-induced reactive astrocytosis following blood-brain barrier disruption: A model for age-related seizure susceptibility

Authors: *V. SENATOROV, JR, G. CHIN, N. JAHAN, D. KAUFER
UC Berkeley, Berkeley, CA

Abstract: Post-traumatic epilepsy (PTE), occurring after brain insult, is one of the most common epilepsies, affecting millions of people worldwide. The progression of PTE is marked by a period of neuronal network reorganization in which post-injury inflammatory responses are thought to contribute to a hyperexcitable neural environment, ultimately leading to chronic and spontaneous seizures. Since post-injury epilepsy is often resistant to current anti-seizure medications, elucidating the mechanisms of the "silent period" of epileptogenesis may reveal novel treatments to prevent seizures before onset. Our previous research developed a novel hypothesis for how vascular injury leads to epilepsy. We found that breakdown of the blood-brain barrier (BBB), as occurs during injury, allows the serum protein albumin from the blood to enter the brain. Once in the neuropil, albumin binds selectively to transforming growth factor beta receptors (TGF-βR) on astroglia, causing inflammatory TGF-β signaling and initiating a variety of effects including reactive astrocytosis, increased neuronal excitability and epileptogenesis. Furthermore, pharmacologically blocking TGF-β signaling prevented the onset of seizure activity in rodents exposed to albumin. Interestingly, an increase in reactive astrocytosis, pro-inflammatory TGF-β signaling and BBB permeability is found in the aging brain, suggesting that the elderly will be more susceptible to epileptogenesis mediated by BBB injury. Indeed, the incidence and prevalence of seizures significantly increases in the elderly, but the causes and mechanisms of age-related vulnerability are poorly studied and remain elusive. Therefore, investigating the identity of potentially epileptogenic astrocytes, along with probing their possible roles in causing susceptibility to seizure onset, may elucidate the cellular and molecular factors underlying epileptogenesis. We hypothesize that the aged brain will show heightened astrocytic reactivity to albumin signaling, resulting in increased vulnerability to albumin-induced epilepsy. To test this, we characterized the astrocyte response to albumin in both the young adult and aged mouse brain. We also quantified albumin signal transduction in both age groups, used specific transgenic approaches to analyze the spatio-temporal patterns of

reactive astrocytosis and block astrocytic TGF-β signaling, and assessed the effects of astrocyte signaling and age on seizure induction threshold. These experiments explore the potential for preventative treatments targeted at astrocyte reactivity before the onset of epilepsy.

Title: Glioma-induced astrocyte apoptosis: A new mechanism promoting glioma growth

Authors: ***Z. YE**[1,2], B. R. RANSOM[1], Y. ZHOU[2], R.-Y. LIN[2], W. WANG[2]
[1]Dept Neurol, Univ. Washington, SEATTLE, WA; [2]Ctr. for Neurosci. Res., Fujian Med. Univ., Fuzhou, China

Abstract: Glioma cells release glutamate and this behavior is believed to be an important mechanism underlying brain tumor-induced epilepsy and neuronal death. Excess glutamate is presumed to over-stimulate neurons promoting epileptiform discharge and/or killing them in a manner termed excitotoxicity. The end point of these glutamate effects is loss of neuronal tissue in and around the glioma mass, thus facilitating glioma expansion. The fate of normal astrocytes in and around gliomas, however, remains largely unknown. As shown in a previous report (sfn 2013, 131.03), astrocyte glutamate uptake is the chief mechanism counteracting glioma glutamate release, and can protect neurons from glioma glutamate excitotoxicity. Because the extracellular glutamate levels are determined by the equilibrium between glutamate release and glutamate uptake, the ratio between the numbers of astrocytes and glioma cells determines extracellular glutamate concentration. In glioma-astrocyte co-culture studies, however, we also found that when astrocytes are greatly outnumbered by glioma cells for periods greater than 24 hours, they can lose their ability to counteract glioma glutamate release, which is accompanied by astrocyte morphological changes, apoptosis and reduction in numbers. These results suggest that gliomas make room for tumor expansion by killing off both neurons and astrocytes. In fact,

the lethal effect on astrocytes might actually be permissive for neuronal destruction because it removes the main mechanism protecting neurons from excitotoxicity.

Title: Insulin signaling influences morphology and proteostasis in the aging of healthy and diseased neurons

Authors: H. N. CURREY[1], S. C. HUNTER[1], M. DRISCOLL[2], J. PARKER[3], C. NERI[4], *B. E. TAYLOR[1]
[1]Biol. & Wildlife, Univ. of Alaska Fairbanks, Fairbanks, AK; [2]Dept. of Mol. Biol. and Biochem., Rutgers, Piscataway, NJ; [3]Dept. of Neurosci., Univ. of Montreal, Montreal, QC, Canada; [4]Lab. of Neuronal Cell Biol., Sorbonnes Universites, Paris, France

Abstract: Aging of healthy brains is characterized by neuronal sprouting, synaptic deterioration and restructuring with little to no neuronal cell loss (Yankner, 2008). However, the physiological factors that affect the decline of neuronal morphology over time *in situ* remain poorly understood. This is true in particular at the single cell level. Insulin signaling has been shown to regulate the rate of aging in organisms ranging from yeast to mice, and there is evidence that in humans, single nucleotide polymorphisms (SNPs) of the FOXO transcription factor, an insulin signaling target, can predict whether an individual will reach the age of 100 (Suh et al, 2007). There are many aging related diseases, some of which are neurodegenerative, for example Huntington's disease. Huntington's is a dominantly inherited disorder caused by polyglutamine expansion in the N-terminus region of the huntingtin protein. This protein interacts with over 200 others and plays a major role in trafficking vesicles along axon microtubules (Schulte and Littleton, 2011). Here, we present an RNAi screen of insulin genes one through forty, in the wild

type and Huntington's neurodegeneration *C. elegans* models. Both the wild type control and the neurodegeneration model have six fluorescently labeled mechanosensory neurons, as well as huntingtin aggregates labeled with CFP in the neurodegeneration Huntington's model (Parker et al. 2001). Significant changes in neuronal morphology and aggregation were observed between insulin knockdowns and empty vector controls. In addition, differences in neuronal morphology were observed when comparing wild type and neurodegeneration models. Together, these RNAi screen findings shed light on the role of insulin signaling in the aging of healthy versus diseased neurons.

Title: Purinergic modulation of spinal neuroglial maladaptive plasticity following peripheral nerve injury

Authors: *M. PAPA[1], G. CIRILLO[2], C. DE LUCA[2], L. SAVARESE[2], L. ALBERGHINA[3], A. COLANGELO[4]

Abstract: Modulation of spinal reactive gliosis following peripheral nerve injury (PNI) is a promising strategy to restore synaptic homeostasis. Oxidized ATP a non-selective antagonist of P2X receptors has been reported to recover neuropathic behavior following PNI. We investigated the effect of intraperitoneal OxATP treatment in restoring the expression of neuronal and glial markers in the mouse spinal cord after sciatic spared nerve injury. Using *in vivo* two photon microscopy, we imaged Ca2+-transients in neurons and astrocytes of the dorsal horn spinal cord at rest and upon right hind-paw electrical stimulation in different groups: Control, SNI and OxATP-treated mice. Spinal cord was processed for analysis of glial markers (GFAP, Iba1), glial (GLT-1 and GLAST) and neuronal aminoacid transporters (EAAC1, vGLUT1), and GABAergic markers (vGAT and GAD65/67). Analysis revealed that SNI was associated with i) increased glial response (Iba1 and GFAP), paralleled by ii) decreased glial aminoacid transporters (GLAST and GLT1) and iii) increased levels of neuronal EAAC1 and vGAT. In SNI animals, *in vivo* analysis of spinal neurons and astrocytes showed a persistent increase of Ca2+ levels. Administration of OxATP reduced glial activation, modulated the expression of glial and neuronal transporters, restored neuronal and astrocytic Ca2+ levels. Reduced astrocytes proliferation and levels of ROS in neurons and astrocytes, in presence of OxATP, as vGLUT levels increase, comes out from *in vitro* studies. Data support the correlation between reactive gliosis, the mechanisms underlying the perturbation of the synaptic circuitry and the role played by the purinergic system in modulating spinal plasticity following PNI

Title: Effects of cortical freeze injury on primary cilia of glial cell populations

Authors: M. CORONEL, S. R. BHATTARAI, S. LEWIS, *H. D. SCHWARK, J. L. FUCHS Biol. Sci., Univ. of North Texas, Denton, TX

Abstract: Glial cells maintain homeostasis in the nervous system that is essential to neuronal function. Injury to the nervous system leads to the activation and proliferation of glial cells, which may contain damage and help restore homeostatic conditions. Sonic hedgehog signaling has been implicated in astrogliosis following injury. Sonic hedgehog signaling requires primary cilia, but there are few reports of primary cilia in glial cells, and glial cilia are currently thought to be rare. Primary cilia are microtubule-based organelles that arise from the centrosome, and are retracted when the centrosome nucleates the mitotic spindle prior to cell division. Among proteins concentrated in cilia are components of several proliferative, sensory and mechanosensory pathways. We investigated the effects of cortical freeze injury on the incidence of primary cilia in the wound region exhibiting reactive gliosis. Astrocytes, polydendrocytes and pericytes were classified by immunohistochemistry based on cell-type markers GFAP, NG2 and Olig2, and cilia were identified mainly by immunoreactivity for Arl13b. In normal adult mice, primary cilia were present in a majority of each cell type examined: astrocytes, 98±2%; polydendrocytes, 87±6%; and pericytes, 79±13% (mean ± SD). Three days post-injury, cilium incidence decreased by 24% in astrocytes ($p<0.008$) and 41% in polydendrocytes ($p<0.002$), but there was no significant effect in pericytes. Considering post-injury rates of proliferation for astrocytes and polydendrocytes, it appears that resorption of cilia during the cell cycle may account for much of the loss of cilia in polydendrocytes but is not sufficient to account for the loss of cilia in astrocytes. Losses in glial cilia might influence the capacity for recovery from injury in the CNS.

Title: A plasma membrane redox enzyme, cytochrome b5 reductase, can protect cells from insults through maintaining redox homeostasis

Authors: *D.-H. HYUN[1], H.-K. KIM[1], S.-K. KIM[1], M. P. MATTSON[2]
[1]Dept. of Life Sci., Ewha Womans Univ., Seoul, Korea, Republic of; [2]Lab. of Neurosciences, Natl. Inst. on Aging, Baltimore, MD

Abstract: The plasma membrane redox system (PMRS) contains several NADH-dependent enzymes and plays a key role in maintaining levels of NAD+/NADH and reduced coenzyme Q. Brain aging and neurodegenerative disorders involve impaired energy metabolism and oxidative damage, but the involvement of the PMRS in these processes is still unknown. In this study, neuronal cells overexpressing cytochrome b5 reductase (b5R) were used to investigate how the PMRS regulates cellular stress responses. Overexpression of b5R made cells more resistant to death induced by 2-deoxyglucose, KCN, H2O2 and MG132. The NAD+/NADH ratio was significantly increased in the b5R transfectants compared to the control cells, consistent with enhanced levels of b5R activity. Increased levels of b5R induced lower production of reactive oxygen species. Our data suggest that a higher NAD+/NADH ratio and lower ROS levels are closely related to ability of neural cells to maintain redox homeostasis under conditions of energetic stress. These results illustrate that an up-regulated PMRS can protect cells from insults due to an improved antioxidant capacity, and suggest important roles for the PMRS in protecting brain cells against age-related increases in oxidative and metabolic stress.

Title: The role of Sonic hedgehog signaling in reactive gliosis

Authors: *R. ALLAHYARI, A. D. R. GARCIA
Biol., Drexel Univ., Philadelphia, PA

Abstract: Understanding the process of neural repair is critical to developing therapeutic treatments and improving functional recovery following injury to the central nervous system (CNS). Astrocytes play an instrumental role in neural repair mechanisms. They undergo reactive gliosis, characterized by an increase in glial fibrillary acidic protein (GFAP) expression, and in severe injuries, undergo cell proliferation and glial scar formation. Reactive astrocytes segregate

the damaged tissue, in order to restrict secondary damage to surrounding tissue. The molecular mechanisms regulating these processes are poorly understood. In the adult forebrain, distinct astrocyte populations express the transcription factor, Gli1, indicating active and high level Sonic hedgehog (Shh) signaling. Disruption of Shh signaling in astrocytes leads to mild astrogliosis, suggesting that Shh is important in regulating normal astrocyte function. The functional significance of Shh signaling in astrocyte function is unknown. Here, we use a conditional knock out (CKO) approach in which the obligatory Shh receptor, Smoothened (Smo) is specifically ablated in GFAP-expressing cells. We performed a forebrain stab injury in *GFAPCre;Smo*$^{fl/fl}$ (GFAP Smo CKO) mice and subsequently investigated the effect on various measures of astrogliosis. Our data show that disrupting Shh signaling in astrocytes leads to reduced proliferation and smaller lesion volumes following an acute injury. In wild type mice, reactive astrocytes immediately adjacent to the lesion extend a single process directed towards the necrotic lesion core. Reactive astrocytes from GFAP Smo CKO mice fail to exhibit this morphological phenotype, suggesting that Shh signaling plays a role in regulating the morphology of these cells. Taken together, these data point to a critical role for astrocytic Shh signaling in mediating pathological processes following injury.

Title: Upregulation of astrocytic metabotropic glutamate receptor (mGluR) expression in a murine model of virus-induced epilepsy

Authors: *M. TAHERI, J. M. GEE, R. S. FUJINAMI, K. S. WILCOX, J. A. WHITE
Univ. of Utah, Salt Lake City, UT

Abstract: Increasing evidence suggests that astrocytes communicate bidirectionally with neurons, are central to information processing, and are involved in the initial stage or progression

of neurological disorders such as epilepsy. Astrocytes express metabotropic glutamate receptor (mGluR) types 3 (a group II mGluR) and 5 (a group I mGluR) that regulate a variety of intracellular signaling systems through G-protein activation and are thought to play important roles in maintaining synaptic homeostasis and synaptic activity. Studies on temporal lobe epilepsy (TLE) patients report an upregulation of mGluRs in hippocampal astrocytes and neurons. In particular, mGluR3 and mGluR5 are upregulated in these patients. These studies also report astrogliosis, in which astrocytes undergo changes in morphology and exhibit a dramatic increase in the expression of intermediate filament protein glial fibrillary acidic protein (GFAP). Similar astrogliosis and mGluR upregulation has also been observed in some animal models of epilepsy. From these studies, it is hypothesized that reactive astrocytes, through their upregulation of mGluR 3 and 5 and downstream release of bioactive molecules, may contribute to the hyperexcitability of neural networks and the development of behavioral seizures in epilepsy. In this study, we assessed levels of astrogliosis and astrocyte mGluR 3 and 5 expression during the development of epilepsy in the Theiler's Murine Encephalomyelitis Virus (TMEV)-induced seizure model in C57Bl/6 mice. This newly developed epilepsy model closely resembles infection-induced TLE in humans. TMEV-injected mice progress through three phases: acute symptomatic seizures; a latent period, in which no seizures are observed and epileptogenesis occurs; and chronic spontaneous and recurrent seizures. We are specifically interested in studying cortical and hippocampal astrocytes in TMEV-injected mice during the latent period. Using immunohistochemical techniques, we have confirmed the appearance of astrogliosis in the cortex and hippocampus of TMEV-injected mice, as well as increased expression of mGluR 3 and 5 in hippocampal GFAP-positive astrocytes. Furthermore, we found that mGluR3 expression is highly colocalized with GFAP expression during the latent period. Our present results suggest that changes in astrocyte phenotypic expression, in particular of mGluR expression, may be an important factor in the development of behavioral seizures in epilepsy and may be a potential pharmaceutical target for the treatment of this disorder.

Title: Glutamine synthetase inhibition and epileptic seizures

Authors: E. PEREZ[1], H. ZAVERI[1], H. WANG[1], E. DAMISAH[1], R. DHAHER[1], *T. EID[2]
[1]Yale Univ., New haven, CT; [2]Dept Lab. Med., Yale Univ., New Haven, CT

Abstract: We have previously demonstrated that glutamine synthetase (GS) is deficient in astrocytes in the epileptogenic hippocampal formation in patients with MTLE (Eid et al. Lancet 2004; 363: 28-37). We have also shown that recreating a state of chronic GS deficiency in rats by continuously infusing methionine-sulfoximine (MSO), an inhibitor of GS, into the entorhinal-hippocampal area leads to recurrent seizures. However, the exact role of GS deficiency in the development of MTLE (epileptogenesis) and the initiation of seizures remains unclear. Here we test the working hypothesis that chronic (28 days) but not acute (72 hrs) inhibition of GS in the entorhinal-hippocampal area is necessary to induce epileptogenesis and cause spontaneous recurrent (epileptic) seizures. A total of twenty-five rats were infused with MSO into the entorhinal-hippocampal area. Seven rats had the infusion continue for 28 days. Eighteen rats had the infusion stopped after 72 hours. All of the rats had seizures during the infusion. However, rats with infusion stopped after 72 hours typically had several weeks of no seizures followed by reappearance of spontaneous recurrent seizures. These results suggest that brief inhibition of GS in the entorhinal-hippocampal area is sufficient to start epileptogenesis. We expect that these studies can provide important insights into the role of astrocytes and GS inhibition in epileptogenesis in MTLE.

Title: Aryl hydrocarbon receptor differentially regulates curcumin-induces proinflammatory and neuroprotective factor expressions in astrocytes

Authors: *C.-H. LIN[1], M.-S. LIN[2], P.-C. HSU[3], Y.-J. HUANG[3], Y.-H. LEE[3]
[1]Kang-Ning Junior Col. of Med. Care and Mgmt., Taipei, Taiwan; [2]Dept. of Neurosurg., Taipei City Hospital, Zhong xiao Br., Taipei, Taiwan; [3]Inst. of Physiol., Natl. Yang-Ming Univ., Taipei, Taiwan

Abstract: Curcumin, a natural bioactive polyphenol, has been proposed to provide prevention of neurodegeneration via the regulation of the immune response in the central nervous system. Aryl hydrocarbon receptor (AhR) has also been found to mediate immune cell differentiation and maturation, but its role in the brain disorders remains unclear. Our previous study has shown that curcumin can provide neuroprotection by increasing neuroprotective chemokine RANTES secretion from astrocytes. In this study, we demonstrate that curcumin can activate astrocytic AhR.. Astrocytes treated with curcumin alone (1 μM) caused increase in luciferase activity driven by the dioxin response element (DRE), the DNA binding sequence of the ligand-activated AhR. Curcumin by itself not only increased RANTES but also the proinflammatory iNOS expression, but did not affect the expression of IL6, which has both proinflammatory and neuroprotective effects. Intriguingly, knockdown AhR expression by siRNA abolished the cucumin-induced iNOS, but great enhanced the curcumin-induced RANTES and IL-6 expressions. TET1, a member of Dioxygenases of the Ten-Eleven Translocation (TET) that is involved in the process of DNA demethylation. We found that curcumin can profoundly increase TET1 expression in astrocytes, and this effect was abolished by AhR knockdown. In summary, our preliminary results suggest that AhR is differentially involved in the expression of proinflammatory mediators in astrocytes that may also provide neuroprotection, and one of the possibilities might involve its upregulation of DNA demethylation machinery for epigenetic regulation.

Title: Effects of 6-hydroxydopamine on striatal and cortical mouse astrocyte cultures

Authors: *S. CARADONNA[1], B. WACHTER[2], J. ETSCHMANN[1], E. KÜPPERS[1]
[1]Inst. of Neuroanatomy, Univ. of Tuebingen, Tuebingen, Germany; [2]Inst. of Clin. Neurobiology, Univ. Hosp. Würzburg, Würzburg, Germany

Abstract: Intraventricular injection of 6-OHDA results in increased proliferation and de-differentiation of a subpopulation of $GFAP^+$ cortical astrocytes (Wachter *et al.*, 2010) towards a molecular phenotype resembling radial glia cells (expressing Pax6, Nestin Vimentin). Moreover, we observed a 15-fold increase in the number of tyrosine hydroxylase (TH)-positive somata in the temporo-parietal cortex of 6-OHDA lesioned animals. Most of these cells immunhistochemically co-stained for GAD or Calretinin, but the expression of glial and neuronal progenitor markers (Sox2, S100b, PSA-NCAM) in some TH^+ cells was also demonstrated. However, the design of the above mentioned study did not allow to discriminate if the observed effects were brought about directly by 6-OHDA or if they were due to the 6-OHDA-induced dopaminergic de-afferentiation. To investigate direct effects of 6-OHDA on glial and neuronal cells in dopaminergic target areas, we treated striatal and cortical mouse astrocytes with 15µM and 30µM of 6-OHDA, concentrations that have been shown not to affect the viability of the cells. Since after the intraventricular injection of the neurotoxin we observed *in vivo* an increase in proliferation of $GFAP^+$ cells, we investigated the effects of the 6-OHDA on the proliferation capability of striatal and cortical mouse astrocytes. Surprisingly treatment of the cultures with 6-OHDA inhibited proliferation in a dose-dependent manner at all timepoints investigated. Furthermore, immuncytochemistry at 2^{nd}-4^{th} and 6^{th} day after the treatment with 15µM of 6-OHDA revealed a significant lower expression of GFAP in cortical astrocyte cultures after 4 and 6 days *in vitro*. No effect of the toxin was to be seen on mRNA level. In contrast to the emergence of TH^+ cells in the temporo-parietal cortex following intraventricular injection of 6-OHDA, we could not detect any TH^+ cell neither in cortical nor in striatal astrocytes cultures at any time point investigated. Taken together, these results provide evidence that the observed de-differentiation of $GFAP^+$ cells as well as the occurrence of TH^+ cells *in vivo* following 6-OHDA lesion seem to be induced by the dopaminergic de-afferentiation rather than by direct effects of 6-OHDA. Further studies have to be performed in order to confirm this and to characterize the *in vitro* phenotype of the investigated subpopulation of $GFAP^+$ cortical astrocytes.

Title: Stalled capillary flow is a novel mechanism for hypoperfusion in Alzheimer's disease

Authors: *N. NISHIMURA[1], C. KERSBERGEN[1], J. CRUZ HERNANDEZ[1], I. IVASYK[1], Y. KANG[1], S. GHERKING[1], V. MUSE[1], J. ZHOU[1], J. D. BEVERLY[1], G. OTTE[1], T. P. SANTISAKULTARM[1], E. SLACK[1], C. IADECOLA[2], C. B. SCHAFFER[1]
[1]Biomed. Engin., Cornell Univ., Ithaca, NY; [2]Brain and Mind Res. Inst., Weill Cornell Med. Col., New York, NY

Abstract: Cerebral blood flow deficits of ~20-30% relative to healthy controls are observed in both patients and animal models of Alzheimer's disease (AD). We recently found that white blood cells often plug capillaries in the brains of AD mouse models. In AD mice, ~2% of brain capillaries are stalled while control animals have only 0.4% of capillaries stalled. We hypothesized that these plugged capillaries may be a cause of the drop in cortical perfusion. Using *in vivo* two-photon excited fluorescence imaging, we evaluate perfusion of capillaries in the cortex of AD mouse models (B6.Cg-Tg(APPswe,PSEN1dE9)85Dbo/J) and wildtype littermate controls. As a measure of overall blood flow to the cortex we quantified volume blood flux in individual penetrating arterioles. The majority of occlusions were caused by leukocytes, so to reduce the number of stalls, we injected antibodies against lymphocyte functional antigen-1 (LFA- 1, clone M17/4, 4 mg/kg, BD Biosciences) into AD mice. Using flow cytometry, we found that this treatment depletes circulating neutrophils (CX3CR1 macrophages) to 68% (57%) of the baseline value at 24 hours. We imaged these animals before and 24 hours after injection and quantified capillary stalls and measured blood flow speed in penetrating arterioles. In antibody-injected animals (n =6), the incidence of capillary stalling dropped to 47% +/- 18% of baseline ($p = 0.008$ from baseline) while saline injected controls remained nearly unchanged (average 119% +/- 42 of baseline, n=6, $p = 0.007$ from antibody treatment). Between the natural variability of the incidence of stalling and the decrease due to leukocyte depletion we were able to relate penetrating arteriole blood flow to the local incidence of capillary stalling. Volumetric blood flow increased to 120% of baseline when stalls dropped to near zero and decreased when stall rates increased. The brain blood flow increase we measured when capillary stalls were eliminated coincides with the observed deficiencies in blood flow measured in AD mice and patients, suggesting capillary plugging may contribute to brain hypoperfusion in AD.

Title: Early life exposure to noise permanently reduces mpfc astrocyte numbers and t-maze alternation/discrimination task performance in male rats

Authors: *Y. RUVALCABA DELGADILLO[1], T. MORALES SALCEDO[2], G. YAÑEZ DELGADILLO[3], P. HERNANDEZ CARRILLO[3], G. CHIPRES TINAJERO[3], R. RAMOS ZUÑIGA[3], A. FERIA VELASCO[3], J. GARCIA ESTRADA[4], S. LUQUIN[3], F. JAUREGUI-HUERTA[3]
[1]Univ. De Guadalajara, Guadalajara, Mexico; [2]Neurociencias, [3]Univ. de Guadalajara, Guadalajara, Mexico; [4]Inst. Mexicano del Seguro Social, Guadalajara, Mexico

Abstract: Environmental noise (EN) has become an important issue for modern societies. Its presence affects both, auditory and non-auditory functions. Non-auditory effects of noise are mostly due to annoyance and the subsequent activation of the stress response. Brain structure and function has been proposed as one of the main targets for the deleterious effects of noise outside the hearing organ. In this experiment, we evaluated the long-term effects of noise by assessing both, astrocyte changes in medial prefrontal cortex (mPFC) and mPFC related alternation/discrimination tasks. Methods: 21-day-old male Wistar rats were exposed to environmental noise in a 24-h fashion. We used for this purpose a standardized rats' audiogram-fitted adaptation of a human noisy environment. We measured corticosterone (CORT) serum levels at the end of the exposure and registered body weight gain during the first 7 weeks of the experiment. In order to assess non-auditory long-term effects of the early EN exposure, we assessed the rats' performance on T-Maze related PFC tasks 3 months after the end of the exposure. Astrocyte numbers and proliferative changes in mPFC were also evaluated 3 months later. We found that a 24-h EN exposure significantly increased serum CORT levels and negatively affected the body weight gain curve. Accordingly, enduring effects of noise were also demonstrated on mPFC structure and function. The ability to solve alternation/discrimination tasks were reduced as well as the numbers of astroglial cells. We also found a reduction on the cellular proliferation rate not related with astroglial lineage. Our results support the idea that early exposure to the widespread environmental stressor namely noise may have long-lasting consequences affecting complex cognitive processes. These results also suggest that glial changes may become an important element behind the cognitive and morphological alterations accompanying the PFC changes seen in some stress-related pathologies.

Title: Tolerance of hippocampal CA1 and CA3 interneurons to oxygen glucose deprivation

Authors: *G. BARRIONUEVO[1], N. V. POVYSHEVA[1], S. G. WEBER[2]
[1]Dept Neurosci, [2]Dept Chem., Univ. Pittsburgh, Pittsburgh, PA

Abstract: Neuronal populations as similar as hippocampal CA1 and CA3 pyramidal cells demonstrate different tolerance to hypoxic-ischemic insult, with the latter being substantially more resilient (Gee et al., 2006). In this study, we address the differential sensitivity of somatostatin (SST)-positive inhibitory neurons in hippocampal areas CA1 and CA3 to better understand the pathophysiological changes in the excitation/inhibition balance during ischemia. Whole-cell recordings were made from SST interneurons in coronal hippocampal slices of 4-7 months old transgenic mice with interneuron-specific GFP labeling FVBTg(GadGFP)45704Swn/J). SST interneurons were located in *strata pyramidale* and *oriens* of CA1 and CA3. SST interneurons from CA1 and CA3 had similar intrinsic membrane properties: spike duration (0.48±0.09 ms vs. 0.49±0.06 ms), firing without adaptation, time constant (19.4±5.5 ms vs. 21.1±9.2 ms), and input resistance (278±28 MΩ vs. 283±119 MΩ, respectively. During the oxygen-glucose deprivation (OGD) experiments, neurons were held at -70 mV at 32^{o}C. After recording of baseline responses in control conditions, the extracellular solution was changed to a solution containing sucrose (10 mM) substituted for glucose, and perfused with a mixture of 95% N_2/5% CO_2. The sucrose solution was applied for 10 minutes, and then switched to control solution for 15 minutes to explore the tolerance of cells to reperfusion. The neurons developed a strong inward current in OGD conditions or during reperfusion. We found that CA1 and CA3 SST interneurons had comparable latencies to onset of the OGD current (6.8±2.0 min, n=7 vs. 6.2±1.2 min, n=5), and comparable amplitudes of the OGD current (743±230 pA; n=7 vs. 521±460 pA; n=5). Four out of 6 CA1 and 4 out of 5 CA3 SST interneurons survived 10 min exposure to OGD. Two out of 4 CA1 and 2 out of 4 CA3 SST interneurons survived 15 min reperfusion. These preliminary data indicate that in contrast to pyramidal cells, SST-positive interneurons in CA1 and CA3 exhibit similar resilience to the hypoxic-ischemic insult. Further studies will address the involvement of SST-positive interneurons in the pathophysiology of hippocampal ischemia.

Title: The multiple roles of lysophosphatidic acid receptor-1 in the regulation of lipopolysaccharide-induced immune responses in reactive astrocytes

Authors: *F.-S. SHIE, J.-J. LIANG, C.-S. LU
Ctr. For Neuropsychiatric Research, Natl. Hlth. Res. Inst., Zhunan Town, Taiwan

Abstract: Increasing line of evidence suggest that reactivate astrocytes play an important role in the glia-mediated neuroinflammation in Alzheimer's disease (AD). Understanding the regulatory machinery of astrocyte reactivation may confer the molecular basis for the development of therapeutic approach for the disease. In this study, we demonstrate that immunoreactivity of lysophosphatidic acid receptor-1 (LPAR1) is present in reactive astrocytes in mice genetically engineered to develop AD and is increasing in parallel with the progression of the disease, whereas immunereactivity of LPAR1 is absent in the age-matched wild-type littermates. These findings lead us to speculate that LPAR1 may be involved in the regulation of immune responses in reactive astrocytes and alteration of LPAR1 expression may affect the pathogenesis of AD. Indeed, our data show that significant increases of immune responses are found in lipopolysaccharide (LPS)-activated primary astrocytes with siRNA against LPAR1 as compared to the controls. These immune responses include expressions of inducible nitric oxide synthase (iNOS), cyclooxygenase 2 (COX-2), IL-6, and TNFa. In contrast, overexpression of LPAR1 in primary astrocytes suppresses the LPS-induced immune responses. Intriguingly, the LPS-induced immune responses in primary astrocytes are partially inhibited by an LPAR1 antagonist, Ki16425. Taken together, our data suggest that multiple mechanisms may underlie the regulatory roles of LPAR1 in astrocytic immune responses.

Title: Glia limitans alterations in lipopolysaccharide induced parenchymal neuroinflammation

Authors: *I. TATAR[1,2], S. LULE[2], M. YEMISCI[2], M. HAYRAN[1], E. ERDEMLI[3], Y. OZDEMIR-GURSOY[2,4], T. DALKARA[2,4]

Sci. and Phychiatry, Ankara, Turkey, Ankara, Turkey; [3]Ankara University, Fac. of Medicine, Dept. of Histology-Embryology, Ankara, Turkey, Ankara, Turkey; [4]Hacettepe University, Fac. of Medicine, Dept. of Neurology, Ankara, Turkey, Ankara, Turkey

Abstract: Glia limitans (GL) is the outermost layer of the cerebral cortex and is formed by astrocytic end-feet and basal membrane surrounding vascular structures, thereby functioning like a modified blood-brain barrier for the regulation of the movement of molecules and cells to in and out of the brain parenchyma. Neuroinflammation (NI) in brain parenchyma leads to activation of microglia and astrocytes resulting in increased gene expression of many potentially neurotoxic chemoattractant molecules. Although the effects of systemic inflammation on GL are known, there are no data on how the parenchymal inflammation affects GL and the associated micro-vasculature. The aim of the study is to investigate the effects of parenchymal NI induced by intracerebroventricular (icv) injection of lipopolysaccharide (LPS) on GL by using immunohistochemical, confocal and electron microscopic methods. 2.5µg/2.5µl LPS (Sigma, E.coli (0127:B8)) or saline was applied icv to Swiss albino male mice (28-30g). After 2 hours, mice were perfused with 4% paraformaldehyde and 20 µm thick sagittal sections were taken from frozen brains, stained with antibodies against Iba-1, ALDH1L1, IL-1beta, TNF-alfa and visualised with a confocal microscope. Another set of sections were evaluated and imaged with transmission electron microscopy. Activation of microglia and astrocytes were observed in LPS treated mice, especially in the superficial GL. Surface associated astrocytic end-feet were hypertrophic and microglia were in reactive state. Increased expression of inflammatory cytokines, TNF-alfa and IL-1beta, were detected in GL and the underlying cortex with immunofluorescent staining. In electron microscopic studies; edematous changes were seen especially at astrocytic end-feet of vascular (internal) GL but interestingly endothelial cells were intact and micro-vessels were not compressed. There are studies showing the cellular migration from blood to the brain parenchyma via GL during NI, but there is no study showing how NI affects GL and the micro-vasculature. In this preliminary study, we demonstrated that inflammation triggered within the parenchyma could affect both the superficial GL and the associated micro-vasculature, leading increased inflammatory cytokine formation as well as structural changes.

Title: Local GABAergic regulation of cerebellar NG2 cell development is altered in perinatal diffuse white matter injury

Authors: *M. ZONOUZI[1], J. SCAFIDI[3], P. LI[3], L. HARVEY[4], D. SUN[5], S. CULL-CANDY[2], M. FARRANT[2], V. GALLO[6]
[1]Pharmacol., [2]Neuroscience, Physiol. and Pharmacol., Univ. Col. London, London, United Kingdom; [3]Ctr. for Neurosci. Res., Children's Natl. Med. Ctr., Washington DC, DC; [5]Dept. of Neurol., [4]Univ. of Pittsburgh, Pittsburgh, PA; [6]Ctr. for Neurosci. Res., C, Washington DC, DC

Abstract: Diffuse white matter injury (DWMI) is a common finding in children born very prematurely (<32 weeks of gestation) and is a leading contributor to neurodevelopmental disabilities. DWMI is characterized by significantly reduced myelination of the cerebral white matter (WM) by oligodendrocytes. Myelinating oligodendrocytes are formed from oligodendrocyte precursor cells (OPCs). The molecular mechanisms that control the proliferation and migration of OPCs, and thus the formation of myelinating oligodendrocytes, following WM damage remain unknown. Whilst the majority of studies on DWMI in neonates have focused on abnormalities occurring in the sub-cortical WM, there is evidence of significant injury to the cerebellum. In this study, we used an established rodent model of DWMI that mimics the disrupted pattern of brain development in very preterm neonates (chronic perinatal hypoxia; P3-P11). We examined the effects of chronic neonatal hypoxia on the number and distribution of WM GABAergic interneurons and NG2+-OPCs in the cerebellum at P7, P11, P15 and P30. We found that hypoxia resulted in 1) a significant increase in NG2+/Ki67+ OPCs and 2) a reduction in the number of Pax2+ immature interneurons. In a variety of brain regions NG2+-OPCs have

been shown to receive synaptic input from neurons during development. Using patch-clamp recording in acute brain slices we found a marked decrease in the prevalence and frequency of GABAergic synaptic input to NG2+-OPCs. As GABA signaling is known to regulate both neuronal and glia development, this loss may contribute to the NG2+-OPC disruption seen following neonatal hypoxia. There are currently no treatments for DWMI associated with very preterm birth. Thus understanding the mechanisms that control the properties of OPCs under pathological conditions is imperative.

Title: The role of sodium channel on ethanol-induced aquaporin-4 expression

Authors: ***R. KATADA**, K. SUGIMOTO, M. YOSHIDA, H. MATSUMOTO
Osaka Univ. Fac. of Med., Suita, Japan

Abstract: Ethanol is the bad player of traumatic brain injury (TBI). We previously reported that ethanol decreased survival rate to around half by brain edema augmentation after TBI. Aquaporin-4 (AQP4), an water channel protein, is involved in brain edema augmentation after TBI under ethanol consumption. We also reported that blood sodium ion concentration was decreased after TBI. AQP4 is regulated by Na-K ATPase, Na(+)-K(+)-2Cl(-) co-transporter. Ethanol is also involved in those channels. From these findings, sodium ion channel may affect AQP4 expression under ethanol condition. In this study, rat primary astrocyte was incubated in iso-sodium MEM (NaCl: 680 mg/dl) and hypo-sodium (NaCl: 410 mg/dl) or hyper-sodium MEM medium (NaCl: 950 mg/dl) with 10% calf serum for 30 min to 24 hr. Ethanol (25, 50, 100 mM) was added to each medium simultaneously. And it was exposed in ethanol (25, 50 mM) with tetrodotoxin (400 nM, 800 nM), voltage-gated sodium channel blocker, for 1 or 3 hr. After exposure, AQP4 protein expression was analyzed by western blotting and mRNA by real-time RT-PCR. Three hour hypo-sodium medium increased AQP4 expression. Hypo-sodium and

ethanol did not affect AQP4 expression, however, AQP4 expression was decreased by hyper-sodium and ethanol for 3 hr exposure, and was increased for 6 hr. Tetrodotoxin affected AQP4 expression under ethanol exposure. These findings indicate that AQP4 expression is involved in sodium ion channel with ethanol exposure.

Title: Systemic administration of ultra-low dose alpha2-adrenergic antagonist atipamezole attenuates morphine-induced gliosis associated with the development of tolerance

Authors: *P. GRENIER[1], B. MILNE[2], M. C. OLMSTEAD[3], C. M. CAHILL[1,4]
[1]Pharmacol. & Toxicology, [2]Anesthesiol. & Perioperative Care, [3]Psychology, Queen's Univ., Kingston, ON, Canada; [4]Anaesthesiology & Perioperative Care, Univ. of California, Irvine, Irvine, CA

Abstract: Background: Prolonged use of opioids is limited by the development of analgesic tolerance as increasing the dose exacerbates side effects such as constipation and opioid-induced hyperalgesia. Chronic opioid administration leads to spinal glial activation, causing a shift to a pro-inflammatory state. Spinal administration of ultra-low dose (ULD) α2 adrenergic receptor (AR) antagonists paradoxically enhances morphine effectiveness and attenuates analgesic tolerance in pain-naïve conditions. The mechanism through which ULD α2 antagonists attenuate opioid tolerance is unknown, but could involve changes in the activation states of spinal glia. Methods: Rats were treated once daily with morphine (5mg/kg, s.c.), morphine plus ULD atipamezole (5ng, s.c.), atipamezole alone or vehicle (saline) for seven days. Thermal tail flick responses were assessed daily before injection and thirty minutes post-injection (at peak drug effect), and a full two hour time course was performed on day 1 and day 7. Following the last

day of behavioural testing, all animals were perfused and spinal cords were collected for immunohistochemical analysis of gliosis. The L4-L5 lumbar region of the spinal cord was isolated and sectioned on a freezing microtome. Sections were incubated with primary antibodies for microglia (CD11b) and astrocytes (glial fibrillary acidic protein/GFAP). Images were captured within the deep and superficial dorsal horn on a confocal microscope, layered stacks were collapsed, converted to greyscale and mean grey values were quantified. Results: Animals administered morphine alone experienced rapid development of analgesic tolerance. Atipamezole administered on its own had no effect on thermal tail flick latencies, but when co-administered daily with morphine it attenuated the development of morphine tolerance. Morphine treatment induced astrogliosis in the spinal dorsal horn, which was prevented by concomitant ULD atipamezole administration. Astrocyte labeling in the animals that received ULD atipamezole alone was not different from saline. No differences in microglial labeling were observed across any of the groups. Conclusion: ULD α2 AR antagonists attenuate opioid tolerance through the attenuation of morphine-induced astrogliosis in the spinal dorsal horn.

Title: Valproic acid and other HDAC inhibitors regulate fibroblast growth factor 21 gene expression in astroglia

Authors: J. WANG, *Y. LENG, Z. WANG, H.-M. LIAO, P. LEEDS, D.-M. CHUANG
Mol. Neurobiol Section, Natl. Inst. Mental Health/NIH, Bethesda, MD

Abstract: Fibroblast growth factor 21 (FGF-21) is a newly identified regulator of glucose and lipid metabolism, and has been proposed as a potential target for treating diabetes, obesity, and hyperlipidemia. Valproic acid (VPA), a mood stabilizer and an anticonvulsant drug, is a histone deacetylase (HDAC) inhibitor, and regulates gene expression via chromatin remodeling through epigenetic mechanisms. Recently, our lab reported that FGF-21 mRNA and protein can be markedly induced in rat brain-derived neurons by combined treatment with the mood stabilizers

lithium and VPA (Leng et al., Mol Psychiatry 2014, advance online). We also documented that FGF-21 has robust neuroprotective properties against insults such as glutamate excitotoxicity, at least in part, by inhibiting glycogen synthase kinase-3 (GSK-3) and activating the cell survival factor Akt. Notably, VPA alone failed to induce FGF-21 in multiple types of primary neurons. The present study was undertaken to investigate whether VPA and related HDAC inhibitors regulate the expression of FGF-21 in non-neuronal cells such as rat C6 glioma cells and primary cortical astrocyte cultures. Incubation of C6 cells with VPA caused a dose and time-dependent increase in FGF-21mRNA levels with an approximately 30-fold increase at 3 mM after 7-day treatment. A comparable extent of FGF-21 mRNA elevation was also observed by treating C6 cells with two other HDAC inhibitors, phenylbutylate butyrate (PB) and sodium butyrate (SB), which are structurally and functionally similar to VPA. The effects of VPA on FGF-21 mRNA in C6 cells were associated with dose-dependent increases in the length of neurite-like processes and levels of histone acetylation, a marker of HDAC inhibition. In primary rat cortical astrocytes, VPA also induced a seven-fold increase in FGF-21 mRNA levels following incubation with 5 mM of the drug for 7 days. Together, our results suggest that HDAC inhibition by VPA and related compounds up-regulates FGF-21 mRNA in astroglial cells. The neurobiological significance of this up-regulation in glia requires further investigation.

Title: PKC activation is necessary and sufficient for astrocytic group I mGluR potentiation of astrocyte glutamate uptake

Authors: *I. M. HOLMAN[1], P. DEVARAJU[3], T. FIACCO[2]
[1]Neurosci., [2]Cell Biol. and Neurosci., UC Riverside, Riverside, CA; [3]St. Jude's Chidlren's Res. Hosp., Memphis, TN

Abstract: Uptake of synaptically released glutamate by astrocytes is essential for maintaining a healthy level of excitatory activity in the brain and for shaping neuronal synaptic currents. Yet the mechanisms by which astrocytic glutamate uptake is acutely modulated remain to be

clarified. It is known that during neuronal activity, astrocytic metabotropic glutamate receptors (mGluRs) and other G protein-coupled receptors (GPCRs) are activated. We have previously demonstrated that activating astrocytic mGluRs via a tetanic high-frequency stimulus (HFS) applied to Schaffer collaterals (SCs) in acute hippocampal slices leads to short-term potentiation of the synaptically evoked glutamate transporter currents (STCs). Furthermore, there is no similar potentiation of STCs in the presence of group I mGluR antagonists or during selective inhibition of astrocytic PKC, suggesting that HFS-induced potentiation of astrocyte glutamate uptake is dependent upon astrocytic group I mGluRs and PKC. New data indicate that dialysis of astrocytes with the PKC activator (-)Indolactam-V, but not the inactive enantiomer (+) Indolactam-V, results in potentiation of astrocyte glutamate transporter currents over a similar timecourse as observed following HFS of SCs. Astrocytic transporter current amplitude gradually increased over the course of the recording, peaking at 30 min. after cell break-in. Collectively, the findings suggest that astrocytic PKC is both necessary and sufficient for rapid potentiation of astrocyte glutamate uptake. Experiments are underway to determine if potentiation of astrocyte glutamate uptake following stimulation of a transgenic GPCR (MrgA1R) expressed exclusively in astrocytes, is also PKC-dependent. Additional studies will determine whether modulation of astrocyte glutamate uptake is bidirectional, as well as the effects of rapid modulation of astrocyte glutamate uptake on neuronal excitability, including extrasynaptic NMDA receptor currents and LTP.

Title: AMPA receptors modulate changes in Bergmann glia morphology through calpain activation

Authors: *Y. BASTIAN[1], R. ROSAS-HERNÁNDEZ[2], J. MENDEZ[2]
[1]Univ. Autonoma De San Luis Potosí, San Luis Potosí, Mexico; [2]Inst. de Física, Univ. Autónoma de San Luis Potosí, San Luis Potosí, Mexico

Abstract: The cerebellum is important for fine and coordinated movement as well as motor learning and some cognitive functions. The cerebelar functions depends on the neural activity of Purkinje cells. The neural activity of Purkinje cells depends on the adaptive synaptic plasticity through the integration of excitatory synaptic inputs from the parallel and the climbing fibers. The lamellar processes of Bergmann glia tightly ensheath the Purkinje cells synapses. Bergmann glia AMPA receptors lack iGluR2 subunits, therefore their stimulation induces calcium entry. Remarkably, this calcium entry through AMPA receptors is essential for establishment and maintenance of Purkinje cells synapses. Furthermore, AMPAr inactivation in Bergmann glia induces an impairment in fine motor coordination triggered by the retraction of Bergmann glia processes. Given that calcium is important for this retraction and that processes like this involves changes in the cytoskelatal structure, we used coronal cerebelar acute slices treated with 200 μM glutamate to evaluate the involvement of the calcium-dependent cystein protease calpain, a well known modulator of cytoskeleton structure. A 10 min stimulation with glutamate induces the activation of calpain that is accompanied with a change in the morphology of Bergmann glia. This change in morphology is prevented by calpain blockade with calpeptin, a calpain inhibitor. Moreover, both the activation of calpain and the change in morfology were prevented when AMPAr were blocked with NBQX. We suggest that the effects of calpain in remodeling of cytoskeleton involves the cleavage of either spectrin, ankyrin or other proteins implicated in actin cytoskeleton organization, for instance the focal adhesion proteins.

Title: Ca2+ responses in astrocytes of unanesthetized mouse visual cortex

Authors: *R. GARCIA, M. GOARD, J. PETRAVICZ, M. SUR
Brain & Cognitive Sci., MIT, Cambridge, MA

Abstract: Astrocytic intracellular Ca^{2+} signaling has become a prominent feature in neuronal-glial interactions. The majority of data concerning astrocyte Ca^{2+} signaling come from either culture or *in situ* brain slices, approaches that rely on electrical stimulation or pharmacological methods to examine the spatial and temporal coding of astrocyte Ca^{2+} signals. Recently, several studies have utilized *in vivo* Ca^{2+} imaging in response to physiologically relevant stimuli or combined with electrical stimulation of brain nuclei to examine the role of astrocyte Ca^{2+} transients in intact circuits. Further, *in situ* data shows that localized Ca^{2+} elevations in distal processes of astrocytes occur at a higher frequency than somatic increases. This is difficult to examine *in vivo*; bulk loading of SR101 and OGB require anesthesia and allow for imaging primarily of somatic response, with limited detection of Ca^{2+} activity in processes. Additionally, anesthesia has been shown to influence both neuronal and astrocytic activity, which may alter the spatial and temporal coding of Ca^{2+} transients in response to stimuli. We are currently investigating visually evoked Ca^{2+} responses in visual cortex astrocytes of an awake, head-fixed animal using two-photon microscopy. To achieve this, we have generated a new astrocyte reporter line that expresses tdTomato in cortical astrocytes driven by the shortened human GFAP promoter, together with viral mediated delivery of a membrane-bound genetically encoded Ca^{2+} indicator, Lck-GCamp5G, to specifically target cortical astrocytes. We present evidence that Ca^{2+} transients in distal processes of cortical astrocytes are more frequent than has been observed for anesthetized preparation, with variable relationship to somatic responses. Furthermore, we are able to identify structurally identifiable regions of distal processes from single astrocytes that are responsive to visual stimuli and display orientation tuning. The combination of these technologies will allow us to further explore the functional role of astrocytes in the primary visual cortical circuit.

Title: A quantitative evaluation of optogenetically-induced calcium signaling in astrocytes

Authors: *L. BALACHANDAR, A. RAYMOND, M. NAIR, J. RIERA DIAZ
Florida Intl. Univ., Miami, FL

Abstract: Optogenetics is a modern technique used to understand functioning principles of targeted neurons and their circuits. Studies have shown opsin gene expression in neurons modulate neural activity by light stimulation, which has been expanded to non-neuronal cells (i.e. astrocytes, Figueiredo et al., 2010). However, the mechanisms by which light stimulation affects channelrhodopsins on astrocytes have not been quantified. The main purpose of this study is to provide a full protocol to evaluate light stimulation profiles and viral transduction parameters which are optimal to produce calcium signaling in rat astrocytes. A DNA plasmid with an optogenetic probe (from Addgene) having a Chr2 and GFAP promoter was used to specifically target astrocytes. Creation of the virus by transformation, packaging by transfection and expression studies by transduction after titration were done. Primary rat astrocytes (Sciencell) were transduced with different viral loads and varying durations. Transfected astrocytes were stained with Sulphorhodamine 101 and Fluo-4 to evaluate morphometric changes and light-induced calcium signaling measurement (Stimulation with 470-490 nm light flashes with different durations and intensities on a DV Elite microscope) Transductions of astrocytes *in vitro* at all loads are indicated in Fig. 1A. Transduction time and viral load played a crucial role in light-induced calcium signaling (Fig. 1B). Calcium signaling evoked optogenetically resembled patterns obtained with standard low-doses of exogenous glutamate. We used a model of calcium signaling in astrocytes to estimate the total flux of calcium ions entering the cytoplasm for each condition (Riera et al., 2011). We developed a method to quantify AAV/light-induced calcium signaling in astrocytes. We evaluated ideal stimulation parameters (e.g. intensity, duration, frequency) to evoke astrocytic calcium waves. This would thereby pave way in understanding one of our long-term goals of the role of changes in calcium activity in astrocytes, as a result of epileptic seizures.

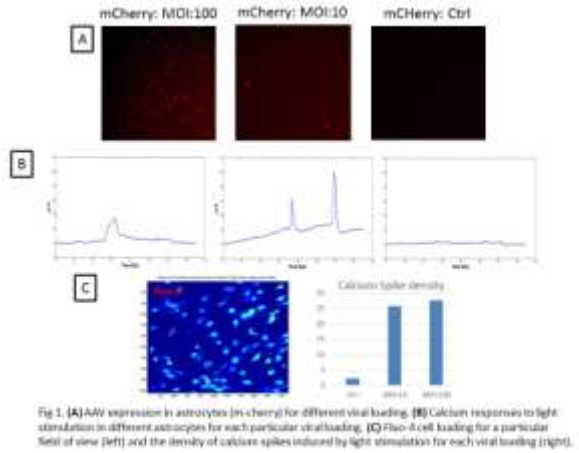

Fig 1. (A) AAV expression in astrocytes (m-cherry) for different viral loading. (B) Calcium responses to light stimulation in different astrocytes for each particular viral loading. (C) Fluo-4 cell loading for a particular field of view (left) and the density of calcium spikes induced by light stimulation for each viral loading (right).

Title: Cortical spreading depression induced optogenetically in awake mice

Authors: *S. M. BACA, A. BARTH, R. T. JONES, I. MODY, A. C. CHARLES
Neurol., UCLA, Los Angeles, CA

Abstract: Cortical spreading depression (CSD) is a wave of increased brain activity followed by a profound and lasting inhibition. CSD is a likely mechanism for migraine aura, and CSD is consistently observed when the brain is injured. Photostimulation of channelrhodopsin-2 receptor in astrocytes in awake mice triggered CSD with local field potential changes similar to those observed previously in anesthetized mice and brain slices. CSDs could be reliably elicited from the same location although the time needed to elicit subsequent CSDs varied. The minimally invasive approach of optogenetically triggering CSD in awake animals is a novel platform for studying basic mechanisms of CSD and may provide a translational platform to screen migraine therapeutics.

Title: Off targeted effects of aquaporin 4 RNA interference on connexin 43 expression via changes of microRNA expression

Authors: A. JULLIENNE[1], A. M. FUKUDA[2], N. NISHIYAMA[1], *J. BADAUT[4,3]
[2]Physiol., [3]Physiol. and Pediatrics, [1]Loma Linda Univ., Loma Linda, CA; [4]UMR 5287-Institut de Neurosciences Cognitives et Intégratives d'Aquitaine, CNRS- Bordeaux Univ., Bordeaux, France

Abstract: Background: Water movements in the brain are critical for cellular functions by regulating cell volume, and homeostasis in extracellular and intracellular compartments. We previously showed that with a 27% decrease of the water channel aquaporin 4 (AQP4) after intracortical injection of siRNA targeting AQP4 (siAQP4) in rat, water mobility was decreased by 50% as interpreted from apparent diffusion coefficient (ADC) value changes. In fact, it has been previously reported that siAQP4 also resulted in a decreased expression of the gap junction protein connexin 43 (Cx43) in primary astrocyte cultures. Interestingly, the absence of Cx43 and Cx30 has consequences on the distribution of AQP4 in astrocyte end feet. MicroRNA (miRNA) are small (21-22 nucleotides) noncoding RNA, which have a regulatory activity in animals. Several miRNA target both AQP4 and Cx43 mRNA and could therefore be good candidate to regulate simultaneously the level of expression of AQP4 and CX43. We hypothesized that the off target effects of siAQP4 on Cx43 expression occur via modifications of expression of miRNA targeting both proteins. Methods: P17 rats were intracortically injected with siAQP4, siCx43 or siGLO (control), on day 0 and day 2. On day 3, animals were euthanized after T2WI and DWI scans. One part of the animals was used for protein assessment (western blot and immunohistochemistry) and the other one was used for miRNA assessment (PCR). To determine miRNA targeting both AQP4 and Cx43 we used literature and databases (targetscan.org and microrna.org). We selected 6 miRNA among the most conserved between species. Results: Western blot and immunohistochemistry showed that siAQP4 injection indeed resulted in decreased levels of Cx43 *in vivo* compared to siGLO-injected rats and a decrease of ADC values. In contrast, injection of siCx43 did not change the levels of AQP4 and no changes in T2WI and ADC. The lower expression of Cx43 in siAQP4 treated animals compared with control animals is associated with an up-regulation of miR224. Discussion: The changes of miRNA expression could be one of the molecular mechanisms explaining in part the effect of siAQP4 on Cx43 expression. Decrease of CX43 is not enough to induce changes in ADC signal; AQP4 decrease is mandatory to observe ADC decrease.

Abstract: The major cell classes of the brain differ in their developmental processes, metabolism, signaling, and function. To better understand the functions and interactions of the cell types that comprise these classes, we prospectively purified representative populations of neurons, astrocytes, oligodendrocyte precursor cells, newly formed oligodendrocytes, myelinating oligodendrocytes, microglia, endothelial cells, and pericytes from the mouse cerebral cortex. We generated a transcriptome database for these 8 cell types by RNA sequencing and used a highly sensitive algorithm to detect alternative splicing events. Bioinformatic analyses identified thousands of new cell type-enriched genes and splicing isoforms that will provide novel markers for cell identification, tools for genetic manipulation, and insights into the biology of the brain. For example, our data provides clues as to how astrocytes dynamically regulate glycolytic flux and lactate generation. This dataset will provide a

powerful new tool for understanding the development and function of the brain. We are currently expanding our RNA-seq based transcriptome analysis to include human neurons and glia. We have developed an immunopanning-based method to purify neurons, astrocytes, oligodendrocytes, and microglia from fetal and postnatal human surgical brain samples. Astrocytes promote synapse formation and function in both rodent and human neurons, but whether human astrocytes are more potent stimulators of synapse formation remains unknown. Our gene profiling of human and rodent astrocytes is revealing many genes that are expressed specifically by human astrocytes. Thus, we are testing the function of several candidate synaptogenic molecules that are specific to human astrocytes to unveil functional differences between human and rodent astrocytes.

Title: SUMO-1 is an upstream regulator of NFκB-mediated inflammatory response of activated microglia

Authors: ***P. RANGARAJAN**[1], A. KARTHIKEYAN[2], B. TAN[2], E. A. LING[2], S. T. DHEEN[2]
[2]Anat., [1]Natl. Univ. of Singapore, Singapore, Singapore

Abstract: Microglial cells are the resident immune cells of the Central Nervous System. Chronic activation of microglia resulting in excessive release of cytokines has been implicated in several neurodegenerative disorders. Sumoylation, a post translational modification whereby the small ubiquitin like modifier - 1 (SUMO-1) is covalently attached to the target protein, has been identified as a key regulatory mechanism of several cellular processes including inflammation. The role of sumoylation in microglia-mediated inflammation has not been well established. In this study, we aim to characterize the function of SUMO-1 in activated microglia. SUMO-1 expression has been localized in microglia from tissue sections of early postnatal rat brains. Its expression was found to be increased in activated BV-2 microglia *in vitro*. Further, in activated

BV-2 microglia, the nuclear fraction of SUMO-1 was found to be significantly higher than the cytosolic fraction. It has been previously shown that sumoylation of NFκB essential modulator (NEMO) by SUMO-1 causes the activation and nuclear translocation of NFkB. In conjunction with this, our study showed that knockdown of SUMO-1 in activated BV-2 microglia decreased protein levels of NFκB and the proinflammatory cytokine, tumour necrosis factor-alpha (TNF-α). Nuclear translocation of NFκB has also been found to be decreased upon SUMO-1 knockdown in activated BV-2. In silico screening has identified other potential SUMO-1 targets like TRIKA1, TRAF6, IKKα, IKKβ, IκBα and p65 which are all involved in the NFκB-mediated inflammatory pathway. Our study suggests that SUMO-1 expression in microglia upon LPS stimulation appears to regulate the nuclear translocation of NFκB which activates the transcription of pro-inflammatory cytokines like TNF-α. Further studies are required to elucidate the role of sumoylation in the inflammatory pathway mediated by activated microglia.

Title: A potential role of TSPO in inflammasome activation

Authors: H. WANG[1,2], Q. YANG[3], J. YANG[3], W. WANG[4], S. CHAI[3], L. CUI[3], Y. HU[3], H. CHEN[3], W. HE[3], *J. ZHANG[5,3,2,1]

Sciences, Chinese Acad. of Med. Sci., Beijing, China; [4]Peking Union Med. Col. Hosp., Beijing, China; [5]Inst. For Cell Engineering, Johns Hopkins Univ., Baltimore, MD

Abstract: Neuronal damage induced by the activation of microglia through secreting inflammatory cytokines, such as IL-1β, TNF-α and IL-6, is a major causal contributor to

neurodegenerative diseases, such as Alzheimer's disease and Parkinson's disease. Inflammasome activation in microglia causes the neuroinflammation in the brain, which is also a critical step to initiate the innate immune responses. Previous studies shown that mitochondrial plays crucial roles in the inflammasome activation and regulation. Mitochondrial translocator protein (18kDa) (TSPO), an outer membrane mitochondrial protein, was originally described as a peripheral benzodiazepine receptor. TSPO participates in steroid biosynthesis by translocating cholesterol into mitochondria from cytoplasmic side, which is also involved in kinds of mitochondria functions and secondary signal transduction. Recently, many clinical studies demonstrate an association of TSPO with neuroinflammation. However, the roles of TSPO in inflammasome activation and neuroinflammation remain unclear. Here, we investigated the roles of TSPO in the activation of inflammasome. Our results showed that TSPO were mainly expressed in the monocytes and the platelets, which were sorted from human peripheral blood mononuclear cells by FACS. Low level of TSPO expression was observed in T cells, but not in granulocytes, B cells and NK cells. Lipopolysaccharide (LPS) treatment could significantly upregulate the expression of TSPO and two inflammasome proteins, Pro-caspase-1 and Pro-IL-1β, in a mouse microglia cell line BV2 cells. All inflammasome activators used in this study, including Nigericin, ATP, Alum, CPPD, MSU, Poly(I:C), Poly(dA:dT), Flagellin and MDP, could induce the release of IL-1β in murine peritoneal macrophages after primed 3h by 1μg/ml LPS, and all of which could be inhibited by a TSPO antagonist ligand Ro5-4864. However, another TSPO ligand PK11195 only displayed partial inhibitory effect, and neither of two ligands plays any roles in pyroptosis (inflammasome activation associated apoptosis) induced by Nigericin. Under confocal microscope, the colocolization of TSPO and NLRP3 could be decreased by TSPO ligands but significant increased by Nigericin in LPS-primed mouse microphages. All these results taken together indicate that TSPO could play a potential role in inflammasome activation producing IL-1β, but not pyroptosis. Furthermore, TSPO may be involved in the neuroinflammation in neurodegenerative diseases. Keywords: TSPO, Neuroinflammation, Inflammasome, PK11195, Ro5-4864.

Title: The Angiotensin II receptor blockers reduce LPS-mediated microglial activation via AT1 independent pathways

Authors: *K. O. AFFRAM, S. VILLAPOL, J. P. SHAH, K. MITCHELL, A. J. SYMES
Pharmacol., Uniformed Services Univ., Bethesda, MD

Abstract: Traumatic brain injury (TBI) can lead to chronic neuroinflammation. Drugs which reduce neuroinflammation after TBI should therefore be beneficial. Studies in our laboratory have shown that FDA-approved angiotensin II type I receptor (AT1R) blockers (ARBs) improve recovery from CCI in mice, suggesting they may be a potential treatment for patients with TBI. Mice treated with ARBs after TBI show reduced activation of microglia, pointing to anti-inflammatory actions of ARBs. However, it is not known whether angiotensin II acts directly through AT1Rs on microglia providing a target for ARB activity. ARBs not only block signaling through the AT1R but also act as agonists at PPAR-γ. Thus, ARBs may act to reduce inflammation in microglia either through blocking signaling by the AT1R or through directly stimulating PPAR-γ. We therefore investigated the expression of AT1Rs in primary microglia, and determined whether ARBs could reduce inflammation directly in cultured primary microglia from rats and wild type and AT1A knockout (KO) mice. Primary microglial cultures were pretreated with the ARBs, telmisartan (100μM) or candesartan (200μM) for two hours before addition of lipopolysaccharide (LPS) for 16 hours. RNA was isolated and gene expression determined by qPCR. AT1AR mRNA was expressed in primary microglia at low levels, and its expression was not altered by LPS treatment. As expected, LPS induced the expression of the pro-inflammatory genes, IL-1β and iNOS. Treatment with either telmisartan or candesartan or the PPAR-γ agonist rosiglitazone, reduced the LPS-stimulated induction of both IL-1β and iNOS in rat microglia showing that ARBs directly ameliorate LPS-induced microglial activation. Telmisartan and candesartan treatment of microglia derived from AT1A KO mice showed the same effect, reducing LPS stimulation of IL-1β and iNOS expression. These data show that this effect does not require the AT1 receptor and is therefore mediated by a non-angiotensin driven mechanism, possibly through stimulation of the PPAR-γ receptor. We continue to investigate the relative contribution of AT1R and PPAR-γ to the ARB-mediated reduction of LPS-stimulated gene expression. Our data show that multiple mechanisms may contribute to the ability of ARBs to ameliorate chronic neuroinflammation after TBI.

Title: Multiple separable mechanisms of statin treatment on primary cultured microglia

Authors: *M. A. CHURCHWARD[1], K. G. TODD[2]
[1]Psychiatry, [2]Ctr. for Neurosci. and Dept. of Psychiatry, Univ. of Alberta, Edmonton, AB, Canada

Abstract: As the primary immune cells of the central nervous system, microglia contribute to neural development, homeostatic mechanisms, and cellular and synaptic plasticity, in addition to their well characterized roles in the foreign body response and inflammation. Increasingly, inappropriate activation of microglia is being reported as a component of inflammation in a wide range of neurodegenerative and neuropsychiatric disorders. The statin class of cholesterol-lowering drugs have been observed to have anti-inflammatory and neuroprotective effects in both neurodegenerative diseases and ischemic stroke, and are suggested to act by attenuating microglial activity. We sought to investigate the effects of statin treatment on the secretory profile and phagocytic activity of primary cultured microglia, and to dissect the mechanism of action of statins on microglial activity. Statin treatment altered the release of cytokines and trophic factors from microglia, including interleukin-1-β, tumour necrosis factor-α, and brain derived neurotrophic factor in a cholesterol-dependent manner. Conversely, statins inhibited phagocytosis in microglia in a cholesterol-independent manner, suggesting the two effects occur through two distinct and separable molecular mechanisms.

Title: Soluble oligomeric Abeta42 affects microglia activation and mitochondrial respiration

Authors: *C. TAN, S. SARKAR, J. SIMPKINS
Physiol. and Pharmacol., West Virginia Univ. Hlth. Sci. Ctr., Morgantown, WV

Abstract: Microglia activation is associated with many neurodegenerative diseases such as Alzheimer's disease (AD). When activated, microglia cells change their morphology and become phagocytic. In the Alzheimer's brain, microglia play an important role in scavenging plaque-damaged cells and in clearing Aβ plagues. Soluble oligomeric Aβ42 is capable to stimulate microglia activation. In AD brain, microglia accumulate around senile plaques as a hallmark of the pathology and Aβ42 has been shown to rapidly activate microglia through the nuclear factor kappa-B (NFkB) pathway. We found that mitochondrial oxidative phosphorylation is affected in a dose-dependent manner in a microglia cell line (C8-B4). We demonstrated that basal, maximal and spare respiration capacities of mitochondria increase at low concentrations of oligomeric Aβ42 and decrease at higher concentrations. Flow cytometry for markers of microglial activation (Iba-1 upregulation) similarly shows a low dose increase and a high dose inhibition. In contrast, the Aβ42 stimulation does not alter mitochondrial oxidative phosphorylation in a mouse hippocampal neuronal cell line (HT22), suggesting a brain cell-specific response to Aβ42. Our experiment results suggest that at low concentrations of Aβ42, which would normally occur in healthy brains, microglia activation and phagocytosis are associated with increased mitochondrial function. In contract, at higher pathological levels of Aβ42, mitochondrial activation and its associated mitochondrial functions are inhibited, which may prevent phagocytosis and allow the accumulation of Aβ42. Title: Fosb gene products contribute to excitotoxic microglial activation by regulating the expression of complement C5a receptors in microglia

Authors: *H. NOMARU[1], K. SAKUMI[1,2], A. KATOGI[1], Y. N. OHNISHI[3], D. TSUCHIMOTO[1,2], E. J. NESTLER[3], Y. NAKABEPPU[1,2]

Abstract: The Fosb gene encodes subunits of the activator protein-1 transcription factor complex. Two mature mRNAs, Fosb and ΔFosb, encoding full-length FOSB and ΔFOSB proteins respectively, are formed by alternative splicing of Fosb mRNA. Fosb products are expressed in several brain regions. Moreover, Fosb-null mice exhibit depressive-like behaviors and adult-onset spontaneous epilepsy, demonstrating important roles in neurological and psychiatric disorders. Study of Fosb products has focused almost exclusively on neurons; their function in glial cells remains to be explored. In this study, we found that microglia express equivalent levels of Fosb and ΔFosb mRNAs to hippocampal neurons and, using microarray analysis, we identified six microglial genes whose expression is dependent on Fosb products. Of these genes, we focused on C5ar1 and C5ar2, which encode receptors for complement C5a. In isolated Fosb-null microglia, chemotactic responsiveness toward the truncated form of C5a was significantly lower than that in wild-type cells. Fosb-null mice were significantly resistant to kainate-induced seizures compared with wild-type mice. C5ar1 mRNA levels and C5aR1 immunoreactivity were increased in wild-type hippocampus 24 hours after kainate administration; however, such induction was significantly reduced in Fosb-null hippocampus. Furthermore, microglial activation after kainate administration was significantly diminished in Fosb-null hippocampus, as shown by significant reductions in CD68 immunoreactivity, morphological change and reduced levels of Il6 and Tnf mRNAs, although no increase in the number of Iba-1-positive cells was observed. These findings demonstrate that, under excitotoxicity, Fosb products contribute to a neuroinflammatory response in the hippocampus through regulation of microglial C5ar1 and C5ar2 expression.

Title: NFATc2 regulates microglial proinflammatory phenotype both *in vitro* and *in vivo*

Authors: *A. GHATAK, K. L. PUIG, C. K. COMBS
Basic Sci. Dept., Univ. of North Dakota, Grand Forks, ND

Abstract: Nuclear factor of activated T cells (NFAT) is known to play a critical role in initiating and regulating transcription of specific pro-inflammatory genes. Previous work from our laboratory described a role of NFAT in regulating stimulus-induced microglial activation. Based upon this, we hypothesized that a particular isoform of NFAT may represent an attractive target for microglial modulation strategies. Using primary murine microglial cultures, we observed that NFATc2 was the most abundantly expressed isoform. To evaluate the relative importance of NFATc2 activity in regulating microglial phenotype, we first compared primary microglial cultures from wild type and NFATc2 knockout mice. Although basal levels of cytokine secretion did not differ between the cultures, NFATc2 knockout cells had significantly attenuated TNFα and IL-6 secretion compared to wild type microglia in response to stimulation with either Aβ peptide or lipopolysaccharide. Consistent with the *in vitro* data, hippocampal lysate ELISAs from 8 month old NFATc2 knockout mice demonstrated significantly reduced cytokine levels compared to wild type controls. Surprisingly, immunohistochemistry demonstrated increased immunoreactivity for the microglial marker, Iba1, in the brains of NFATc2 knockout mice compared to controls. These findings were validated by western blotting results. Importantly, neither light/dark box testing nor Y maze spontaneous alternation behavior showed any significant behavioral differences between the two strains of mice indicating no dramatic behavioral compromise in NFATc2 knockout mice. Our findings demonstrate that NFATc2 has a positive role in regulating microglial cytokine secretion and phenotype *in vitro* and *in vivo*. These data support the idea that inhibiting microglial NFATc2 activity may represent a valid approach for limiting microgliosis.

Title: EP4 receptor-associated protein (EPRAP) in microglia promotes inflammation in the brain

Authors: *R. FUJIKAWA[1,2], M. MINAMI[1], S. HIGUCHI[1], M. YASUI[1], T. IKEDO[1], M. NAGATA[1], M. YOKODE[1]
[1]iACT, Kyoto Univ., Kyoto, Japan; [2]Res. Fellow of Japan Society for the Promotion of Sci., Tokyo, Japan

Abstract: Background and aims: EP4 receptor-associated protein (EPRAP) was isolated as a novel cytoplasmic signaling partner of EP4 receptor. Recently, we have generated EPRAP-deficient (EPRAP-KO) mice, and demonstrated that EPRAP attenuated macrophage activation in the periphery using various animal models of chronic inflammation. EPRAP also abundantly exists in the brain; however, little is known about the function of EPRAP in the central nervous system. In this study, we investigated the role of EPRAP in brain inflammation. Methods: The localization of EPRAP was assessed by immunohistochemical analyses. To explore the role of EPRAP in microglial activation, primary microglial cells from WT and EPRAP-KO mice were isolated and cultured: cytokine levels in cell-conditioned media were measured after 24-hour incubation with 10 ng/mL of lipopolysaccharide (LPS). In *in vivo* experiments, LPS was administered intraperitoneally at a dose of 100 mg/kg both in WT and EPRAP-KO mice, and the mRNA levels of pro-inflammatory cytokines in the cerebral cortex were measured 6-hour after the administration. In addition, to clarify the effect of EPRAP against neuronal cell death, kainic acid (0.2 μg in 4.0 μl of PBS) was injected intraventricularly in these mice, and brain samples were harvested 72-hour later. Sections including the CA1 field of the dorsal hippocampus were examined for karyopyknotic cells. Results: Immunohistochemical analyses demonstrated that EPRAP was colocalized in Iba1-positive microglial cells, suggesting that EPRAP is associated with inflammatory responses in the brain. EPRAP-deficiency markedly decreased LPS-induced expressions of pro-inflammatory cytokines and chemokines including TNFα, MCP-1 and IL-6 in primary microglial cells. Accordingly, EPRAP-KO mice showed less microglial accumulation

and pro-inflammatory cytokine expression in the cortex induced by intraperitoneal administration of LPS. Furthermore, compared with WT, EPRAP-KO mice showed less microglial activation as well as neuronal cell death in the hippocampus induced by intraventricular injection of kainic acid. Conclusion: Our results indicated that, in contrast to peripheral macrophage, EPRAP in microglia promoted pro-inflammatory activation and may be a key to deteriorate neuronal damages by brain inflammation. EPRAP could be a novel therapeutic target for inflammatory disorders of the central nervous system including Alzheimer's disease or stroke.

Title: Elderberry and its active polyphenol components on oxidative and anti-oxidative signaling pathways in microglial cells

Authors: *G. Y. SUN[1], Z. CHEN[2], D. AJIT[2], M. HANNINK[2], K. L. FRITSCHE[2], A. SIMONYI[2], A. L. THOMAS[1], Z. GU[3], D. L. LUBAHN[2]
[2]Biochem., [1]Univ. Missouri, Columbia, MO; [3]Sch. of Medicine,Univ Missouri, Columbia, MO

Abstract: Many edible berries are rich source of polyphenols with potent anti-oxidative properties, and have been shown to offer beneficial effects to promote human health. Elderberry (*Sambucus nigra*) is regarded as a medicinal plant for treatment of a number of maladies and for boosting the immune system. The action of elderberries and their active components on oxidative and anti-oxidative responses has not been investigated in microglial cells. In this study, we examined effects of freeze-dried ethanol extract of elderberry pomace and a few of its putative bioactive components (namely, quercetin, rutin, cyanidin, and cyanidin-3-glucoside) on liposaccharide (LPS)- induced oxidative and inflammatory pathways for induction of free radicals including NO and reactive oxygen species (ROS) in BV-2 microglial cells. While elderberry extract inhibited LPS-induced ROS production, its effect on induction of NO was

typically an inverted U shape curve. Among the active flavonol components, quercetin was the most potent in inhibiting LPS-induced NO and ROS. LPS also activated expression of heme oxygenase-1 (HO-1) via the anti-oxidant pathway involving Keap1/Nrf2. Interestingly, quercetin alone could induceHO-1, and quercetin exposure followed by stimulation with LPS further enhanced HO-1 protein expression. In addition, stimulation of HO-1 synthesis by quercetin and LPS was regulated by ERK1/2 and p38MAPK, indicating multiple modes of regulation of the Keap1/Nrf2 pathway. These results suggest that botanicals exhibiting electrophilic properties are capable of conferring resilience against the oxidative-inflammatory stress by upregulation of the anti-oxidative pathway.

Title: Investigating the effect of microglial α7 nicotinic receptor activation on lipopolysaccharide mediated tumor necrosis factor-α secretion

Authors: *H. PATEL[1], A. DUNAH[1], R. LORING[2]
[1]Neurol., Biogen Idec, Cambridge, MA; [2]Northeastern Univ., Boston, MA

Abstract: Microglia, the resident immune cells of the brain, plays an important role in inflammation in neurodegenerative diseases such as Alzheimer's and Parkinson's disease. Activating α7 nicotinic receptors on macrophages has anti-inflammatory effects in the peripheral nervous system, and α7 nicotinic receptors are also found in brain microglia, which share properties with macrophages. We hypothesize that activating α7 nicotinic receptors on microglia has anti-inflammatory properties. We studied whether α7 receptor activation of cultured rat microglia blocks lipopolysaccharide (LPS)-mediated secretion of the inflammatory cytokine, tumor necrosis factor-α (TNF). A five hour treatment of cultured rat microglia with LPS (1-10 ng/ml) significantly increased TNF levels in cell medium, measured using an enzyme-linked immunosorbent assay. Pretreatment with nicotine as well as the α7-selective agonist PNU282987 significantly inhibited LPS mediated TNF secretion, with no evidence of cell death. Nicotinic activation also changed the morphology of LPS activated microglia more towards a resting state

phenotype. Thus, our results imply that α7 nicotinic receptors have anti-inflammatory effects by significantly blocking TNF secretion in activated microglia. Future research should focus on examining the signaling interactions between α7 nicotinic receptors and TNF secretion and characterizing the α7 receptors expressed in microglia.

Title: Changes of microglial characters in response to extracellular stimulation

Authors: T. TANAKA, K. MURAKAMI, Y. BANDO, *S. YOSHIDA
Dept. of Functional Anat. and Neurosci., Asahikawa Med. Univ., Asahikawa, Hokkaido, Japan

Abstract: Microglia, generally considered to be immune cells of the central nervous system (CNS), are involved in many types of inflammatory processes in the brain. They are critical in developmental processes and are imperative for the maintenance of neuronal homeostasis. Recent studies have demonstrated that under specific polarization conditions microglia develop into different phenotypes, termed M1 and M2. However, the characterization of M1- and M2-polarized microglia and the mechanisms for regulating polarization are largely unknown. Here, we examined the characterization of LPS-treated M1 and IL-4-treated M2 microglia *in vitro*. The addition of M2 microglial conditioned media (CM) resulted in elongated neurite length compared with M1 microglial CM due to promotion of expression of neurotrophic factors and inhibition of toxic factors from M2 microglia. M2 microglia exhibited greater phagocytic capacity than M1 microglia. Morphology of M1 microglia were characterized by larger soma and that of M2 microglia were characterized by long processes. These characterization were converted in response to polarization switches. These results suggest that endogenous molecule in microglia control a dramatic phenotypic change but not originally different population. We found that interferon regulatory factor (IRF) 7 and IRF9 were elevated during M2-to-M1

microglia *in vitro* and *in vivo*. Thus, our findings reveal that endogenous IRF signaling including IRF7 and IRF9 implicated in switching the microglial polarization.

Title: A potential role of TSPO in inflammasome activation

Authors: J. ZHANG[1,2,3], Q. YANG[1,2], J. YANG[1,2], W. WANG[4], S. CHAI[1,2], L. CUI[1,2], Y. HU[1,2], H. CHEN[1,2], W. HE[1,2], *H. WANG[1,2]

Abstract: Neuronal damage induced by the activation of microglia through secreting inflammatory cytokines, such as IL-1β, TNF-α and IL-6, is a major causal contributor to neurodegenerative diseases, such as Alzheimer's disease and Parkinson's disease. Inflammasome activation in microglia causes the neuroinflammation in the brain, which is also a critical step to initiate the innate immune responses. Previous studies shown that mitochondrial plays crucial roles in the inflammasome activation and regulation. Mitochondrial translocator protein (18kDa) (TSPO), an outer membrane mitochondrial protein, was originally described as a peripheral benzodiazepine receptor. TSPO participates in steroid biosynthesis by translocating cholesterol into mitochondria from cytoplasmic side, which is also involved in kinds of mitochondria functions and secondary signal transduction. Recently, many clinical studies demonstrate an association of TSPO with neuroinflammation. However, the roles of TSPO in inflammasome activation and neuroinflammation remain unclear. Here, we investigated the roles of TSPO in the activation of inflammasome. Our results showed that TSPO were mainly expressed in the monocytes and the platelets, which were sorted from human peripheral blood mononuclear cells

by FACS. Low level of TSPO expression was observed in T cells, but not in granulocytes, B cells and NK cells. Lipopolysaccharide (LPS) treatment could significantly upregulate the expression of TSPO and two inflammasome proteins, Pro-caspase-1 and Pro-IL-1β, in a mouse microglia cell line BV2 cells. All inflammasome activators used in this study, including Nigericin, ATP, Alum, CPPD, MSU, Poly(I:C), Poly(dA:dT), Flagellin and MDP, could induce the release of IL-1β in murine peritoneal macrophages after primed 3h by 1μg/ml LPS, and all of which could be inhibited by a TSPO antagonist ligand Ro5-4864. However, another TSPO ligand PK11195 only displayed partial inhibitory effect, and neither of two ligands plays any roles in pyroptosis (inflammasome activation associated apoptosis) induced by Nigericin. Under confocal microscope, the colocolization of TSPO and NLRP3 could be decreased by TSPO ligands but significant increased by Nigericin in LPS-primed mouse microphages. All these results taken together indicate that TSPO could play a potential role in inflammasome activation producing IL-1β, but not pyroptosis. Furthermore, TSPO may be involved in the neuroinflammation in neurodegenerative diseases. Keywords: TSPO, Neuroinflammation, Inflammasome, PK11195, Ro5-4864.

Title: Analysis of MAP kinase cascade in M-CSF-dependent microglial proliferation

Authors: *S. YAMAMOTO[1], S. KOHSAKA[2], K. NAKAJIMA[1]
[1]Dept. of Bioinformatics, Fac. of Engineering, Soka Univ., Tokyo, Japan; [2]Dept. of Neurochemistry, Natl. Inst. of Neurosci., Tokyo, Japan

Abstract: Transection of rat facial nerve leads to an increase of microglial cell number in the ipsilateral facial nucleus. In the previous study, we demonstrated that up-regulated macrophage-colony stimulating factor (M-CSF) in the transected facial nucleus triggers the induction of cFms (receptor for M-CSF), proliferating cell nuclear antigen (PCNA) and cell cycle-associated proteins, including cyclins, cyclin-dependent protein kinases (Cdks) and Cdk inhibitors (CdkIs) in microglia and causes the microglia to divide. The microglial proliferation was found to be

regulated by the interactions among cyclin A, cyclin D, Cdk2, Cdk4 and p21, and the induction of cyclins/PCNA and cFms, which are requisite for microglial proliferation, was found to be differentially regulated by c-Jun N-terminal kinase (JNK) and p38 MAP kinase (p38) in M-CSF-stimulated microglia. However, the knowledge about signaling mechanism for M-CSF-dependent microglial proliferation is largely limited. In the present study, we analyzed the MAP kinase cascade in M-CSF-triggered microglial proliferation. We first confirmed that cFms transmembrane receptor is phosphorylated just after M-CSF stimulation. Subsequently, both JNK and p38 were phosphorylated. These activations were significantly suppressed by pretreatment with cFms inhibitor, suggesting that JNK and p38 are downstream of cFms. The upstream kinases of JNK and p38, MKK4 and MKK3/6, were also recognized to be activated by stimulation with M-CSF. Furthermore, we demonstrated that mitogen activated protein kinase activated protein kinase-2 (MAPKAPK-2), cyclic AMP responsive element binding protein (CREB), mitogen-and stress-activated protein kinase-1 (MSK-1) and ETS family of transcription factor (ETS-1) are all activated in M-CSF stimulated microglia. Our results indicated that M-CSF/cFms signaling in microglia is linked to MKK4-JNK and MKK3/6-p38 cascades, and at downstream of these MAP kinases MAPKAPK-2, CREB, MSK-1 and ETS-1 are serving for the induction of cyclins and cFms.

Title: A new tracer [11C]DPA713 tops a conventional tracer [11C]PK11195 in visualizing activated microglia in the living human brain

Authors: *M. YOKOKURA[1], Y. OUCHI[2], K. TAKEBAYASHI[1], E. YOSHIKAWA[3], M. FUTATSUBASHI[3], Y. IWATA[1], T. TERADA[2], K. NAKAIZUMI[1], N. MORI[1]
[1]Psychiatry and Neurol., Hamamatsu Univ. Sch. of Med., Hamamatsu, Japan; [2]Biofunctional Imaging, Hamamatsu Univ. Sch. of Med., Hamamatsu, Japan; [3]Hamamatsu Photonics KK, Hamamatsu, Japan

Abstract: Introduction; Translocator protein (TSPO) or a peripheral benzodiazepine receptor is established as a marker of microglial activation in the process of neuroinflammation in the brain. Activated microglia have been reported to increase in number with age in many studies with the most common TSPO PET tracer [11C]PK11195. This tracer, however, is reputed to suffer from high nonspecific binding. In contrast, a new TSPO PET tracer [11C]DPA713 has been recently reported to bind to TSPO more specifically than [11C]PK11195. To examine the power of [11C]DPA713 in their depiction, we estimated binding potentials (BPs) of [11C]DPA713 for the multiple brain regions in young and old healthy adults and compared them with [11C]PK11195 BPs. Methods; Thirteen healthy young (mean age 21.5±1.8 years old) and 12 healthy elderly (71.6±2.6) adults underwent [11C]DPA713 PET and MRI measurements. In a different group, 13 healthy young (mean age 21.4±2.0 years old) and 10 healthy elderly (72.2±8.1) adults also underwent [11C]PK11195 PET and MRI measurements. BP was estimated by a simplified reference tissue model analysis in which a normalized normal input was used as a reference tissue time activity curve as reported previously. We manually set regions of interest (ROIs) bilaterally on multiple brain regions in individual MRI images and obtained the values of BP by transferring ROIs onto corresponding PET BP images. Then, we compared [11C]DPA713 and [11C]PK11195 BP levels between young and old subjects in all ROIs and also examined the differences in magnitude between [11C]DPA713 and [11C]PK11195 BP. Results; In all ROIs, the levels of [11C]DPA713 BP were significant higher in old subjects than in young subjects. There are no significant differences in the levels of [11C]PK11195 BP between young and old subjects. Comparison between two tracers showed that levels of [11C]DPA713 BP in the healthy old subjects were significantly higher than those of [11C]PK11195 BP in a different set of healthy old subjects. Discussion; A new tracer [11C]DPA713 can depict a greater activation of microglia in the brains of old subjects than in young counterparts. Because [11C]DPA713 has a higher binding capacity to activated microglia than [11C]PK11195 in old subjects, [11C]DPA713 would suit for delineation of activated microglia occurring in the elderly brains irrespective of normal or disease states.

Title: Mechanism of TLR4-mediated survival of microglia: Roles of GM-CSF self-production and the activation of JAK2/STAT5 signaling pathways

Authors: *M. KAMIGAKI[1], I. HIDE[2], Y. YANASE[3], S. TANAKA[2], T. SHIRAFUJI[2], M. HIDE[3], N. SAKAI[2]
[1]Pharmacol Neurosci, Grad Sch. of Biomed & Hlth. Sci., [2]Pharmacol Neurosci, Inst. of Biomed & Hlth. Sci., [3]Dept of Dermatol, Inst. of Biomed & Hlth. Sci., Hiroshima Univ., Hiroshima, Japan

Abstract: The activation of Toll-like receptor 4 (TLR4) of rat primary cultured microglia by lipopolysaccharide (LPS) induced rapid death in a concentration dependent manner. Subpopulation of microglia escaped from death and survived for much longer than control cells, which gradually underwent death within two day. Survival of microglia is generally dependent on astrocyte-derived survival factors, such as macrophage colony-stimulating factor (M-CSF) and granulocyte macrophage colony-stimulating factor (GM-CSF). It is not clear, however, how LPS-stimulated microglia could keep surviving after the isolation from astrocytes. To clarify the mechanism underlying TLR4-mediated survival, we examined the possibility that microglia can produce their survival factors by themselves in response to LPS. The mRNA expression of M-CSF and GM-CSF in rat primary microglia after TLR4 activation were measured by using real-time PCR. The mRNA levels of M-CSF were not affected by LPS stimulation. On the other hand, LPS induced a marked increase in GM-CSF mRNA expression from the basal levels which was nearly undetectable in microglia. Moreover, the M-CSF receptor α subunit (GM-CSFRα) mRNA expression was also elevated in LPS-stimulated microglia. To explore the role of JAK2/STAT5 signaling pathway downstream GM-CSFR activation in LPS-stimulated microglial survival, the activation of STAT5 was tested by Western blot analysis. The TLR4 activation of microglia by LPS resulted in the phosphorylation of STAT5. Furthermore, pre-treatment with a specific JAK2 inhibitor, NVP-BSK805, suppressed both STAT5 phosphorylation and survival in microglia after LPS stimulation. These results suggest that TLR4 activation may enhance survival of a subpopulation of microglia at least through self-production of GM-CSF and up-regulation of GM-CSFR. This GM-CSF autocrine pathway may promote the activation of downstream signals including JAK2/STAT5 which controls transcription of survival-related genes.

Title: LRRK2 and the MAPK pathway: Friend or foe during neuroinflammation?

Authors: *J. M. PUCCINI[1], D. F. MARKER[2], J. BARBIERI[2], V. S. GOODFELLOW[3], S.-M. LU[2], H. A. GELBARD[2]
[1]Ctr. for Neural Develop. and Dis., [2]Univ. of Rochester Med. Ctr., Rochester, NY; [3]Califia Bio Inc., San Diego, CA

Abstract: Leucine rich repeat kinase 2 (LRRK2) is a known regulator of microglial activation during neuroinflammation in the central nervous system (CNS). However, the signaling mechanisms used by LRRK2 remain largely unknown. Given the homology of the LRRK2 kinase domain with mitogen activated protein kinases (MAPKs), we became interested in possible interactions between LRRK2 and the MAPK signaling pathway. In order to further elucidate these mechanisms, we employed a panel of small molecule kinase inhibitors which target LRRK2 and/or mixed lineage kinase 3 (MLK3), a MAPK known to be involved in neurodegenerative disease, such as Human Immunodeficiency Virus 1 (HIV-1) associated neurocognitive disorders (HAND) and Parkinson's disease (PD). We hypothesize that LRRK2 and MAPK signaling are intertwined and as a result can alter neuroinflammation within the CNS. We can induce inflammation in the BV-2 murine microglia cell line using either lipopolysaccharide (LPS) or the HIV-1 Trans activator of transcription (Tat) protein, both of which induce phosphorylation of LRRK2 at serine 935 (pS935-LRRK2), which is directly linked to LRRK2 kinase activity. Upon co-treatment with our inhibitors we can attenuate pS935-LRRK2 to varying degrees based on the targets of the given inhibitor. Specifically, LRRK2-IN-1, which inhibits LRRK2 but not MLK3, causes a significant decrease in pS935-LRRK2, as does URMC-099, which inhibits both LRRK2 and MLK3. Interestingly, our most recent data show that Califia Compound A, which inhibits MLK3 but not LRRK2, causes an increase in pS935-LRRK2. We have also found that LRRK2-IN-1 decreases phosphorylated p38 and c-Jun N-terminal kinase (JNK), which are downstream from MLK3. These results demonstrate that while

MLK3 inhibition increases LRRK2 kinase activity, LRRK2 inhibition decreases MAPK signaling. Further research will involve determining how these interactions effect neuroinflammation by analyzing microglial activation via cytokine expression and phagocytosis. Thus, we conclude that the interactions between LRRK2 and the MAPK pathway may be of high importance in the treatment of neurodegenerative disease, including both HAND and PD.

Title: NFκb pathway mediates down regulation of Transforming Growth Factor β receptor 1 expression and inhibition of canonical TGF-β signaling in activated microglia

Authors: K. O. AFFRAM, *K. MITCHELL, J. P. SHAH, A. J. SYMES
Pharmacol., USUHS, Bethesda, MD

Abstract: Chronic neuroinflammation mediated by persistent microglial activation has been associated with neurodegeneration. TGF-β1 is an anti-inflammatory cytokine that plays a major role in maintaining microglial quiescence. Our previous studies demonstrated that TGF-β1 signaling is suppressed in LPS-activated microglia thereby allowing chronic activation of microglia. We also showed that the TGF-β receptor, TβR1 is significantly downregulated by LPS treatment. We therefore sought to understand the pathways and molecular mechanisms by which TGF-β1 signaling is suppressed by LPS signaling in activated microglia. We showed that the rapid LPS-mediated downregulation of TβR1 mRNA was prevented by inhibition of the NFκb pathway with Bay 11-7082, but not by inhibition of the MAP Kinase pathway using PD 98059. The reduction of TβR1 mRNA, which required de novo transcription within the first 3 h as determined by actinomycin D treatment, was further suppressed via transcriptional-independent mechanisms at later time points. We also observed induction of negative regulators of TGF-β1 signaling in LPS-activated microglia including BAMBI and SnoN. Suprisingly, Smad7, which is commonly induced in other cell types in an NFκb-dependent mechanism to negatively regulate

TGF-β signaling was not upregulated in LPS-activated microglia. Finally, we assessed the effect of other pathologically relevant microglial activators like Amyloid β oligomer (Aβ) on primary microglia. We demonstrated that, in Aβ-activated primary microglia, TβR1 is downregulated, and TGF-β1 is less able to suppress expression of pro-inflammatory cytokines. Aβ treatment also reduced the amount of microglial cell death induced by TGF-β1. In conclusion, we have demonstrated that in microglia LPS suppresses TβR1 expression through an NFκb-dependent pathway and also induces the expression of negative regulators of TGF-β signaling, Bambi and SnoN. Aβ also inhibit TGF-β signaling and downregulate TβR1. Thus, we have identified a common mechanism for microglia activators and their associated pathways to prolong activation of microglia. Identifying ways to restore TGF-β1 signaling in activated microglia may yield novel strategies for reducing chronic neuroinflammation and ameliorating the associated neurodegeneration.

Title: c-Maf is a p53-dependent anti-inflammatory factor that regulates adult microglia behavior in response to neuroinflammation

Authors: *W. SU[1], B. SOPHER[1], D. J. KANG[2], M. S. ALOI[3], S. HOPKINS[1], G. A. GARDEN[1]
[1]Dept. of Neurol., [2]Dept. of Biol., [3]Dept. of Pathology, Univ. of Washington, Seattle, WA

Abstract: Neuroinflammation is observed in acute and chronic CNS injury, including stroke, traumatic brain injury and neurodegenerative diseases. Microglia are a specialized population of resident myeloid cells that mediate CNS innate immune responses to disease relevant stimuli, such as reactive oxygen species (ROS). Previously we described a novel mechanism by which p53, a ROS responsive transcription factor, modulates microglia behaviors *in vitro* and *in vivo*, promoting pro-inflammatory functions and suppressing down-regulation of the inflammatory response and tissue repair. We demonstrated that p53 negatively regulates the anti-inflammatory transcription factor c-Maf through two micro RNA (miRNA)-mediated pathways in cultured

neonatal microglia and a macrophage cell line. We observed that p53 is required for pro-inflammatory induction of miR-155, a suppressor of c-Maf mRNA and p53 promotes transcription of miR-34a and miR-145, which both suppress expression of Twist-2, a transcriptional activator of c-Maf. We observed that microglia extracted from adult p53 deficient mice expressed increased mRNA for c-Maf, supporting the hypothesis that this regulatory pathway was not unique to cultured neonatal microglia. To determine if c-Maf is a critical target for p53 dependent modulation of microglia function in the adult brain, we successfully developed Adeno-Associated Virus (AAV) serotype 2 as a gene transfer vector to express a c-Maf transcriptional reporter construct and modulate expression of c-Maf. Compared to lentiviral gene transfer, AAV infection yields reduced inflammatory responses and decreased toxicity in both neonatal and adult microglia. Using AAV for gene transfer, we were able to successfully study the effect of modulating c-Maf expression in adult microglia. We observed the effects of c-Maf overexpression and c-Maf shRNA on markers of activation phenotype, phagocytosis of apoptotic cells and cytokine release in both adult and neonatal microglia. Taken together our findings support the hypothesis that in the adult brain, p53 activation by local ROS or accumulated DNA damage influences microglia function, at least in part, through miRNA mediated modulation of c-Maf expression.

Title: Microglia expression of activation markers in iron-deficient conditions

Authors: *J. A. ESTRADA, M. A. LEÓN-DÁVILA, I. CONTRERAS
Neurochemistry, Univ. Autonoma Del Estado De Mexico, Toluca, Mexico

Abstract: Iron deficiency is the most common nutritional deficiency in the world. It is estimated that, in developed countries, 20-60% of children under 4 years old and up to 50% of pregnant and fertile age women suffer from this pathology. Iron is involved in the immune system as a co-factor in the formation of oxygen radicals and the proliferation and effector functions of leukocytes in general. Microglia represent the resident arm of the immune system in the central

nervous system (CNS). These cells are essential for immune surveillance in the CNS and the activation of innate and adaptive immune responses within this tissue. The effect of iron deficiency on the phenotype and functions of these cells has not been determined. The objective of this study was to determine the expression of the activation markers MHC class I and II, CD80 and CD86, by microglia from iron deficient mice. BALB/c mice were separated in two groups before mating: Control (standard diet, 100ppm iron) and Iron deficient (iron deficient diet, 10ppm iron). Mice born from mothers in each group were further subdivided in four more groups: two Basal groups (21 days old, control and iron-deficient) and two Adult groups (60 days old, control and iron deficient). Each group was maintained with the corresponding diet. Central nervous systems were dissected from mice sacrificed by anesthetic overdose for mononuclear cell purification. Purified cells were stained with fluorochrome-conjugated antibodies for the surface markers CD11b and CD45, to identify the microglial population, as well as for MHC-I, MHC-II, CD80 and CD86. The analysis was performed by flow cytometry. Our results show an overall decrease in the percentage and number of cells expressing activation markers in microglia from iron-deficient mice, compared to controls. However, the mean fluorescence intensity was increased in the same population. Our results suggest that iron deficiency increases the expression of cell surface markers of activation in microglia, although the number of cells expressing these markers is lower. These results may have important implications for the capacity of microglia to induce an adaptive immune response in the CNS of iron deficient individuals; however, the functional phenotype of these cells must be explored further.

Technol. Organisation, Sydney, Australia; [3]Med. Imaging & Radiation Sciences, Fac. of Hlth. Science, Univ. of Sydney, Sydney, Australia; [4]Ctr. for Translational Neuroscience, Univ. of Wollongong, Wollongong, Australia

Abstract: The evolutionarily conserved mitochondrial peripheral benzodiazepine receptor (PBR), or 18 kDa translocator protein (TSPO), is widely accepted as indispensable for life. Evidence accrued over 30 years ascribes to the PBR/TSPO an essential role in the translocation of cholesterol across the outer mitochondrial membrane, the vital rate-limiting step of steroid biogenesis. This regulatory function of the PBR/TSPO in steroid biogenesis is the common explanation for its involvement in disease and the mechanism of action of PBR/TSPO-binding drugs. The PBR/TSPO is extensively investigated as a biomarker of "neuroinflammation" due to its disease-dependent expression in activated microglia and a therapeutic drug target in neoplastic, inflammatory, metabolic, neurodegenerative, and behavioural disease. Here we show that global *Tspo* gene knockout mice (C57BL/6-*Tspo*$^{tm1GuWu(GuwiyangWurra)}$) are viable with normal cholesterol transport, blood pregnenolone concentration, fertility, protoporphyrin IX metabolism and under healthy conditions without overt clinical impairment. However, on high fat diet, homozygous *Tspo* knockouts, unlike wild-type mice, showed less than the expected weight gain. At the cellular level, the absence of the PBR/TSPO resulted in a substantially increased proton leak thereby reducing mitochondrial ATP synthesis. The PBR/TSPO appears to contribute to the efficient coupling of mitochondrial respiration and ATP synthesis and thus co-regulate the balance between energy intake and expenditure. Further, we demonstrate the high selectivity of both the isoquinoline PK11195, originally used to pharmacologically describe the PBR/TSPO, and the imidazopyridines CLINDE and PBR111 for the PBR/TSPO *in vitro* and *in vivo*. The global *Tspo* gene knockout animal model provides a crucial tool to evaluate, under naturalistic conditions, the diagnostic and therapeutic selectivity of existing and new chemical compounds with affinity to the PBR/TSPO. Reducing the reliance on conjecture, it enables a broad range of fundamental experiments into the controversially discussed pathways of steroid biogenesis, steroid-dependent systemic effects, including behavior, as well as mitochondrial energy production and the mechanisms of diet-induced obesity.

Title: Microglia: Synaptic scavengers in the healthy and diseased juvenile brain

Authors: *D. P. SCHAFER, C. T. HELLER, C. GORDON, L. LITVINA, C. CHEN, B. STEVENS
Boston Children's Hospital/Harvard Med. Sch., Boston, MA

Abstract: Abnormal glial cells and synaptic circuits have emerged as hallmarks of several neurodevelopmental disorders. However, it has remained a mystery whether these two abnormalities may be linked. Recently, we demonstrated in the healthy, developing brain that microglia, a highly specialized innate immune cell, play a key role in activity-dependent synaptic pruning in the early, postnatal (P5) mouse thalamus. Specifically, we showed that microglia engulf a subset of synapses in a manner dependent upon neural activity and the classical complement cascade. Here, we provide new data that, in the absence of any inflammation, microglia-mediated synaptic engulfment can be re-activated much later postnatally (P40). This engulfment occurs precisely at time points and locations where late-stage, fine-scale structural synapse elimination occurs in the healthy, juvenile brain. In addition, we provide evidence that late-stage synaptic engulfment is aberrantly upregulated in a neurodevelopmental disorder with late-onset and widespread synaptic abnormalities, Rett Syndrome (RTT). In mice deficient in the gene underlying RTT, Mecp2-/-, microglia-synapse interactions appear normal until late-stage

synaptic pruning (P40). During this later period, engulfment of synapses is aberrantly upregulated and is coincident with a weakening of synaptic connectivity and symptom onset. Taken together, we provide evidence that microglia-mediated engulfment of synapses in the healthy brain can be reactivated during multiple developmental windows. Furthermore, during a specific developmental window in RTT syndrome, microglia appear to be playing key roles in synaptic circuit abnormalities associated with the disease.

Title: Polarization of microglia through functionally distinct cannabinoid compounds

Authors: *C. PRESLEY, B. M. MOORE, II
Univ. of Tennessee Hlth. Sci. Ctr., Memphis, TN

Abstract: Microglia, as the brain's primary immunomodulators, can throw the brain's homeostasis into turmoil following classical activation (M1), a state associated with inflammatory neurodegenerative disorders. However, microglia may move along an activation continuum and polarize toward an anti-inflammatory or alternative activation state (M2) following the influence of anti-inflammatory cytokines such as interleukin 4 (IL-4) or cannabinoid compounds. We have established a new electrochemiluminescent platform to evaluate murine microglial polarization markers such as CD16/32, Fc γ receptor II/III, CD206, the mannose receptor, as well as cannabinoid receptors 1 and 2 (CB1, CB2) after a polarizing stimuli such as lipopolysaccharide (LPS) for an M1 state or IL-4 for an M2 state. Additionally, we have established the effect of cannabinoid compounds such as CP55,940, SR141716A, SR144528, as well as novel cannabinergic compounds on these same markers following polarization to either an M1 or an M2 state.

Title: Characterization of kynurenine pathway metabolite production in rat primary microglia

Authors: *M. E. HAMBY[1], D. P. BUDAC[2], E. CHARYCH[1], T. MÖLLER[1], B. M. CAMPBELL[1]
[1]Neuroinflam., [2]Bioanalysis and Physiol., Lundbeck Res. USA, Paramus, NJ

Abstract: Levels of metabolites in the kynurenine (KYN) pathway, the major route of tryptophan catabolism, are altered in several central nervous system (CNS) disorders. Alterations in metabolite levels by neuroinflammation or changes in central substrate (i.e., L-KYN) availability due to peripheral inflammation may be protective in or contribute to disease, depending on the context and disease/disorder under study. Evidence suggests that the pathway is partially segregated by cell type. KYN aminotransferase II (KATII) produces kynurenic acid (KYNA) primarily in astrocytes, whereas KYN 3-monooxygenase (KMO) produces 3-hydroxykynurenine (3-HK) predominantly in microglia. While 3-HK, through 3-hydroxyanthranilic acid (3-HAA), can be converted to the NMDAR agonist quinolinic acid, 3-HK and 3-HAA can also be oxidized to produce free radicals that contribute to oxidative stress. The present study examined KYN metabolite production in primary rat microglia, as measured via LC-MS, under basal, substrate supplemented (L-KYN) or toll-like receptor 4 (TLR4) activated (control standard endotoxin, (CSE)) conditions. Under basal conditions (48 hr), rat primary microglia produced 3-HK and small amounts of anthranilic acid (AA) and KYNA. Initial studies using a high concentration of L-KYN (500 μM; 48 hr) demonstrated a heightened production of 3-HK, KYNA and 3-HAA relative to non-L-KYN-treated microglia. The increases in KYNA, 3-HK and 3-HAA occurred in an L-KYN concentration-dependent manner (10-1000 μM; 48 hr). The production of 3-HK and 3-HAA, but not KYNA, elicited by exposure to 10 μM L-KYN was inhibited in a concentration-dependent manner by the KMO inhibitors UPF 648 and RO 61-8048 (0.01-30 μM; 48 hr), suggesting that 3-HAA is derived from 3-HK and not AA under non-inflammatory conditions in rat microglia. To test whether activation of the canonical pro-inflammatory signaling pathway TLR4 might alter KYN metabolite production in microglia, primary cultures were exposed to CSE. CSE (300 EU/ml; 48 hr) triggered an increase in KYN and 3-HK production; however, AA, KYNA and 3-HAA levels were largely unaffected. Similar

to L-KYN-treated cultures, the CSE-induced increase in 3-HK was attenuated by the KMO inhibitors RO 61-8048 and UPF 648 (10 μM; 48 hr). In sum, these studies demonstrate that the capacity of microglia to metabolize KYN and its metabolites varies based on the experimental conditions or environment. Current studies are underway to evaluate the functional significance of these changes in KYN metabolite levels in relation to oxidative stress in microglia and neurons.

Title: Opposite effects of BDNF and proBDNF on NO release from activated rodent microglial cells

Authors: *Y. MIZOGUCHI, H. NABETA, Y. IMAMURA, Y. HARAGUCHI, A. MONJI
Dept. Psychiatry, Fac. Medicine, Saga Univ., Saga, Japan

Abstract: Microglia are immune cells which release many factors, including proinflammatory cytokines, nitric oxide (NO) and neurotrophins, when they are activated after the disturbance in the brain. There is increasing evidence suggesting that pathophysiology of neuropsychiatric disorders is related to the inflammatory responses mediated by microglia. Brain-derived neurotrophic factor (BDNF) is a neurotrophin well known for its roles in the activation of microglia as well as in the pathophysiology and/or the treatment of neuropsychiatric disorders. We have previously reported that pretreatment of BDNF significantly suppressed the release of NO from activated microglial cells, possibly mediated by sustained store-operated calcium entry (SOCE) induced by BDNF. Although BDNF is initially translated as the precursor proBDNF, which binds p75 neurotrophin receptor (NTR), it remains obscure whether proBDNF affects the release of NO from activated microglial cells. In this study, we observed that pretreatment of proBDNF significantly potentiated the release of NO from activated microglial cells. RT-PCR and immunocytochemical techniques revealed that p75NTR were highly expressed in rodent microglial cells. Opposite effects of BDNF and proBDNF on microglial function might

contribute to the dichotomy of BDNF actions on neuroinflammation and also be involved in the pathophysiology and/or the treatment of neuropsychiatric disorders.

Title: Role of microglia in the hippocampus of chronic stressed mice

Authors: *A. M. CARNEIRO, B. BASSETT, S. VARNEY, C. CHUNG
Pharmacol., Vanderbilt Univ., Nashville, TN

Abstract: Chronic stress elicits biological changes that may have deleterious consequences upon higher brain functioning, thus influencing risk for several psychiatric disorders, including depression and anxiety. The adverse consequences of chronic stress, likely arise from alterations in modulatory neurotransmitter systems such as serotonin and noradrenaline. Cognitive symptoms of depression are associated with decreased neurogenesis and synaptogenesis in the hippocampus, which can be prevented by the concomitant administration of drugs targeting these systems, such as selective serotonin reuptake inhibitors (SSRIs). One of the early events triggered by chronic stress exposure is the activation of the immune system, in the brain represented by microglia. Recent studies indicate that chronic stress increases microglial activation, effects that can be normalized by SSRI administration. Here, we examine how chronic stress influences hippocampal microglial activation. We exposed mice to the chronic unpredictable stress model for three weeks to elicit behavioral responses associated with depression. After three weeks, mice were tested behaviorally in the forced swim and novelty-suppressed feeding tests, and tissue collected for neuroanatomical staining and quantification of tissue levels of monoamines by HPLC. Three weeks of chronic stress resulted in significant decreases in monoamine levels in cortices, higher immobility time in the forced swim test, and a larger latency to feed in the novelty-suppressed feeding test. Immunofluorescence analysis of hippocampal slices revealed that stress modifies specific microglial populations in the hippocampus. While stress elicited no changes in the number of microglia, it induced significant increases in microglial activation in the hippocampus. To identify hippocampal regions sensitive

to microglial response, we performed neuroanatomical analysis of microglia in the dentate gyrus, CA1 and CA3 regions of the hippocampus. Here we identified differential responses to chronic stress in dorsal versus ventral hippocampus, with increased microglial activation in the dentate gyrus. We further explored the role of microglia in the hippocampus by testing whether activated microglia contained neuronal fragments. We observed a significantly higher percentage of microglia containing neuronal fragments in the ventral hippocampi of stressed mice, compared to control animals. These studies provide evidence of a region-specific increase of neuronal phagocytosis by activated microglia in the hippocampus.

Title: Hv1 proton channels in spinal microglia contribute to astrocyte activation and neuropathic pain in mice

Authors: *J. PENG[1], H.-J. JEONG[4], P. SWIATKOWSKI[1], U. B. EYO[1], N. GU[1], S. GANATRA[2], Y. HUANG[3], C. F. DREYFUS[3], Y. REN[2], S. OH[4], L.-J. WU[1]

Abstract: Activation of spinal cord microglia contributes to peripheral nerve damage-induced neuropathic pain development. However, molecular mechanisms underlying microglia in neuropathic pain are not fully understood. Using a single cell gene array screen technique, we identified that the expression of the HVCN1 gene encoding the voltage-gated proton channel Hv1 was significantly increased in spinal cord microglia after spinal nerve transection (SNT). Hv1 channels mediated functional voltage-gated proton currents in spinal microglial and mice

lacking Hv1 (Hv1 KO) displayed attenuated pain hypersensitivities after SNT, especially in the later maintenance phase compared with wildtype (WT) mice. Consistently, microglial production of reactive oxygen species (ROS) and subsequent astrocyte activation in the spinal cord was reduced in Hv1 KO mice after SNT. Cytokine screening and immunostaining further revealed that IFN-γ expression was comprised in spinal astrocytes of Hv1 KO compared with WT mice. Intrathecal neutralization of IFN-γ reversed mechanical allodynia in WT but not Hv1 KO mice, while exogenous IFN-γ transiently rescued SNT-induced allodynia in Hv1 KO mice. These results demonstrate that the Hv1 proton channel contributes to microglial ROS production, astrocyte activation, IFN-γ upregulation, and subsequent pain hypersensitivities after SNT. Therefore, this study provides a rational for microglial Hv1 proton channel as a novel therapeutic target for alleviating neuropathic pain.

Abstract: Microglia become activated in response to peripheral nerve injury, and microglia activation, accompanied by global changes in gene expression, contributes to develop neuropathic pain. Here we employed microarray assay of individually collected pools of 10 cells to identify changes in microglia-specific gene expression that may be associated with microglial activation after peripheral nerve injury. With microglia located on superficial dorsal horn from

spinal cord slices of CX3CR1$^{+/GFP}$ mice after L4 spinal nerve transection, post-operative day (POD)1 and POD7 microglia were compared to sham-operated microglia, respectively. We found that microglia were highly heterogeneous at single-cell level, and while the variability of gene profile generally tended to increase over time after nerve injury, there existed 64 microglial genes showing lower variation, potentially linked to neuropathic pain. Our results also indicate that early microglia and late microglia exhibit significant differences in gene expression profile and recruit distinctive signaling pathways following peripheral nerve injury, possibly leading to phenotype changes during development and maintenance of neuropathic pain.

Title: Radiation-induced fatigue linked with microglial activation not with skeletal muscle alterations

Authors: G. HOLDER[1], Z. YU[2], L. N. SALIGAN[1], *K. FUKUHARA[1]
[1]Natl. Inst. of Nursing Reseach, [2]Natl. Heart, Blood, and Lung Inst., NIH, Bethesda, MD

Abstract: Background: Fatigue related to cancer and its therapy is a persistent sense of tiredness that negatively affects the overall quality of life of patients. We developed a mouse model to mechanistically investigate the relationship of radiation-induced fatigue with skeletal muscle alternations and microglial activation. **Methods:** 24 male Hsd:ICR (CD1), 10-week old mice were assigned to 3 different groups: non-irradiated control group (N=12), where 6/12 mice were sacrificed on day 7 for tissue collection, one day before start of irradiation; and two groups of irradiated mice sacrificed on day 13 (D13, N=6) and day 25 (D25, N=6). The irradiated mice received a total of 18 Gy to their lower abdomen administered at 6 Gy/day on days 8, 9, and 10. Voluntary wheel running was measured from days 7-25. Histological integrity of skeletal muscles were examined using hematoxylin and eosin stainings, and Iba-1 staining of CA1 and CA3 hippocampal regions were used to detect microglial activation. **Results:** Irradiated mice

(D13 and D25) had lower wheel running activity than non-irradiated (D7) mice, (D13, F=25.5, $p<0.001$; D25, F=13.4, $p<0.001$). There was no evidence of inflammation, damage or histological alterations in all skeletal muscle samples from each group. D13 mice reached nadir in wheel running activity 3 days after incremental irradiation and had reduced lba-1 expression (mean count per high power field (HPF)=9) compared with D7 (mean/hpf)=20) and D25 mice (mean/hpf=19). **Conclusion:** Histological skeletal muscle alterations are not observed in irradiation-related fatigue. However, acute but not chronic irradiation-related fatigue is influence microglial activation.

Title: Increases in microglial Iba1 immunoreactivity in the frontal cortex and hippocampus in response to chronic sleep restriction in rats

Authors: *S. HALL[1], S. DEURVEILHER[1], J. BURNS[1], K. SEMBA[1,2,3]
[1]Med. Neurosci., [2]Psychology & Neurosci., [3]Psychiatry, Dalhousie Univ., Halifax, NS, Canada

Abstract: Chronic sleep restriction (CSR) has negative consequences on cognitive performance, as well as cardiovascular, metabolic, and immune functions. Although the neurobiological mechanisms underlying these impairments are unclear, emerging evidence suggests a role of neuroinflammation, which is mediated by microglia, the resident immune cells in the brain. In this study, we examined changes in immunohistochemically-identified microglia in the rat brain during a '3/1' protocol of CSR, which features continuous cycles of 3 h of sleep deprivation using slowly rotating wheels and 1 h of sleep opportunity, for 4 days. We previously showed that this protocol induced both homeostatic and adaptive changes in sleep patterns, sustained attention performance, and the levels of brain-derived neurotrophic factor and FosB family transcription factor proteins. Adult male Wistar rats were randomly assigned to 4 groups (n = 2-5/group): two CSR groups were housed in motorized wheels and underwent the 3/1 protocol for 27 or 99 h, and two locked wheel control groups were kept in stationary wheels for corresponding intervals.

Following perfusion at the end of the experimental protocols, microglia in the brain were visualized using an antibody against ionized calcium-binding adaptor molecule 1 (Iba1) and a standard ABC/DAB-Ni method. Iba1-positive cell bodies were counted and the density of Iba1 immunoreactivity (percentage of immunoreactive area in a total area of analysis) was measured in selected brain regions known to be responsive to sleep loss, including the prelimbic cortex, hippocampus, and perifornical lateral hypothalamic area, using ImageJ software. The number of Iba1-immunoreactive cells and the density of Iba1 immunoreactivity in the prelimbic cortex and hippocampus tended to increase above control levels after 27 h, with a slight decline after 99 h, of CSR. The number of Iba1-immunoreactive cells and the density of immunoreactivity were positively correlated in each of the two regions (r=0.80 and 0.83). No changes were apparent in the perifornical lateral hypothalamic area. Analyses of the morphology of immunoreactive microglia are in progress. These preliminary results indicate an increase in the number of microglia in the cortex and hippocampus in response to CSR, suggesting that CSR initiates neuroinflammatory processes. These changes could contribute to cognitive and other impairments associated with CSR.

Title: NOX2 inhibition modulates microglial polarization, improves functional recovery and reduces chronic neurodegeneration following experimental TBI

Authors: *A. KUMAR, B. A. STOICA, F. TCHANTCHOU, A. I. FADEN
Univ. of Maryland, Baltimore, MD

Abstract: Signals from the microenvironment polarize microglia toward either a classical (M1) or alternative (M2) activation state, which mediates post-traumatic neuroinflammation or promotes tissue repair, respectively. Activation of NADPH oxidase (NOX2) is an important mechanism that initiates pro-inflammatory signaling in microglia. We have recently demonstrated that NOX2 is chronically expressed in M1-polarized microglia that surround the

lesion at 1 year following experimental traumatic brain injury (TBI) in mice. In the present study we used wild-type (gp91phox+/+) and NOX2-deficient (gp91phox-/-) mice to investigate the role of NOX2 in microglial polarization following TBI. Three-month old gp91phox+/+ and gp91phox-/- male mice were subjected to controlled cortical impact (6m/sec, 2mm depth) and cohorts of mice were followed for 1d, 3d, 7d and 21d post-injury. Changes in M1/M2 polarization were analyzed by qPCR, flow cytometry and immunohistochemical analyses. Long-term motor function recovery was assessed through 21d post-injury using a beam walk test, and lesion volume and cortical neurodegeneration was assessed by stereological methods. Flow cytometry analysis found no differences in the total numbers of activated microglia (CD11b+ cells) or infiltrating macrophages (CD11b+/CD45high) in gp91phox+/+ and gp91phox-/- mice following TBI. In contrast, genetic ablation of NOX2 modulated M1/M2 polarization: at 1d post-injury M1 gene expression (eg. TNFα & iNOS) was significantly reduced whereas M2 gene expression (eg. Ym1, Arg1, Fizz1, IL-4Rα) was significantly increased in the cortex of gp91phox-/- TBI mice compared to gp91phox+/+ TBI mice. Similar changes in protein expression of M1 (iNOS) and M2 (Ym1, Arg1, TGFβ) markers were confirmed by flow cytometry at 3d post-injury in MACS purified CD11b+ cells from the TBI cortex. Further, immunohistochemical analysis demonstrated that there was reduced expression of M1 microglia (CD16/32+ Iba1+) at 7d post-injury and increased expression of M2 microglia (Ym1+) at 21d post-injury in the cortex of gp91phox-/- TBI mice compared to gp91phox+/+ TBI mice. The dominant M2 polarization in gp91phox-/- TBI mice was accompanied by improved motor function recovery and significantly reduced lesion volume and cortical neurodegeneration at 21d post-injury. Our data indicate that NOX2 drives the M1 polarization of microglia following experimental TBI. The repolarization of microglia towards an M2 activation state in gp91phox-/- TBI mice may be in part responsible for reduced neurodegeneration and improved functional recovery.

Title: Microglial responses to cortical cell death during a two-day alcohol exposure in neonatal mice

Authors: *K. AHLERS, F. OOI, K. MAH, J. KERSIGO, B. FRITZSCH, S. H. GREEN, M. E. DAILEY
Biol., Univ. of Iowa, Iowa City, IA

Abstract: Brief episodes of high alcohol exposure during critical periods of brain development can induce widespread neuroapoptosis and microglial activation in the neocortex and other brain regions. We previously reported (Ahlers et al., Soc. Neurosci. Abstr. 2013) that a single day of alcohol exposure (5 g/kg alcohol administered via 2 intraperitoneal injections spaced 2 h apart) in postnatal day (P) 7 or P8 mice leads to robust but transient microglial activation and changes in the expression of proinflammatory factors. Work in BAX-null mice demonstrated that microglial activation in this model was strongly linked to BAX-dependent neuroapoptosis, not the alcohol. Remarkably, most dead cells were cleared and microglia began to de-activate within 2 d of the initial insult. Given that alcohol exposure on either P7 or P8 induces comparable levels of neuroapoptosis and microglial activation, we hypothesized that alcohol exposure on two sequential days (P7 and P8) would exacerbate neuroapoptosis and extend the period of microglial activation. Instead, we found that the period of neuroapoptosis and microglial activation was similar after a 1 d alcohol exposure on P7 or after a 2 d exposure on both P7 and P8. This was also observed at lower alcohol levels (3 g/kg) that show reduced levels of neuroapoptosis. Potentially the low cell death produced by the second injection in a two-day alcohol exposure model may be due to neuroprotective mechanisms elicited by the first injection. In support of this idea, a preliminary microarray analysis of cortical gene expression 12 and 24 h after exposure to 5 g/kg alcohol showed a decrease in expression of several pro-apoptotic factors and concomitant increase in expression of pro-survival factors, including neurotrophins. Of particular interest, the microarray showed a 15 fold increase in BDNF expression at 24 h (confirmed by qPCR) and *in situ* hybridization showed strong BDNF expression in cortical regions showing high levels of cell death. Future studies will be needed to extend the analysis of microglial activation states in this two-day injection model and to further explore the possibility that increased levels of BDNF following an initial alcohol exposure enact neuroprotective mechanisms against a second insult.

Title: Microglia inhibition is a potential mechanism underlying neuropathic pain prevention by Botulinum Toxin A

Authors: *W. XIE[1,2], X. FENG[2], Z. ZHOU[2], Y. QIU[2], L. XIAO[3]
[1]Res. Ctr. For Neural Engin., Shenzhen, China; [2]Shenzhen Inst. of Advanced Technology(SIAT), Chinese Acad. of Sci., Shenzhen, China; [3]Nanshan Hosp., Shenzhen, China

Abstract: Botulinum toxin A (BoTN/A) has shown long-term symptomatic anti-nociceptive efficacy against neuropathic pain in clinical applications, such as postherpetic neuralgia and diabetic neuropathic pain. The BoTN/A analgesic mechanism currently focuses on release inhibitory of neurotransmitters in peripheral and/or central terminals of somatosensory neuronal system. To identify if neuroglia related mechanism involved in BoTN/A induced analgesia, primary cultured rat microglia were incubated with BoTN/A. The BoTN/A pretreated microglia displayed slight morphological changes after LPS activation compared with untreated control group. Moreover, the real-time RCR results indicated LPS induced up-regulation tendency of inflammatory cytokines mRNA expression level, significantly decreased in BoTN/A pretreated microglia. Microglia activation in pathological condition, is believed has pivotal role in chronic neuropathic pain origin and maintenance. Then, we confirmed BoTN/A pre-intrathecal injection were able to inhibit initiation of neuropathic pain like behaviors including mechanical allodynia and thermal hyperalgesia in rat partial sciatic nerve ligation model. The immunofluorescence and western blot results indicated peripheral injury causing spinal microglia activation was partially blocked by BoTN/A pre-intrathecal injection. These *in vitro* and *in vivo* experimental results suggest besides neuronal release inhibition, suppressing microglia activation may underlie the analgesic efficacy of BoTN/A, which shows a promising preventive possibility on neuropathic pain. Further investigation related this latent capacity of BoTN/A is needed to be completed.

Title: Modeling of the glial scar through 3D hydrogel cultures

Authors: A. F. JEFFERY[1], M. A. CHURCHWARD[2], A. L. ELIAS[1], *K. G. TODD[3]
[1]Dept. of Chem. and Materials Engin., [2]Psychiatry, Univ. of Alberta, Edmonton, AB, Canada; [3]Psychiatry, Univ. Alberta, Edmonton, AB, Canada

Abstract: Neural interfacing often requires electrode implantation into the central nervous system (CNS). These electrodes must be biocompatible (elicit a minimal foreign body response) to optimize long-term safety and functionality. Glial scarring, initiated by the native immune cells of the CNS (microglia and astrocytes) is believed to be a major contributing factor to the loss in electrode functionality. Due to variability, expense and time required for *in vivo* testing, a parallel *in vitro* model is desired. This model must not only support microglia and astrocytes, but also mimic the mechanical properties of the CNS. Our study investigates the use of a three-dimensional culture technique to analyze glial scarring in response to a microwire. The three-dimensional culture was based on methacrylated hyaluronic acid, a hydrogel capable of photocrosslinking. Gels were formed at four macromer concentrations (0.5, 0.75, 1.0, and 1.5 % (w/v)). Stiffness of the hydrogels was shown to increase with increasing macromer concentrations via compressive strain analysis. A macromer weight fraction of 1.0 % (w/v) had a modulus similar to adult rat brain tested under identical conditions. Hydrogel structure was analyzed using Cryo Scanning Electron Microscopy. Although no significant difference in pore size was observed, scaffold walls appeared thicker with increasing macromer weight fraction. Microglia and astrocytes isolated from whole brain were then encapsulated in the HA scaffolds to assess cell viability, density and morphology. Of the cell seeding densities tested, 1x10^7 cells/mL was the most consistent and stable and was therefore used for all further studies. Cultures were viable at all macromer weight fractions tested though the 1.5 % (w/v) sample was significantly lower than other gels tested (0.5, 0.75 and 1.0 % (w/v)). The temporal response of mixed glial cultures to a microelectrode was followed over a period of 2 weeks. Microglia responded first to the electrode, exhibiting an activated morphology at 3 days, while a layer of astrocytes was observed around the electrode at day 6. This cellular response is similar to results reported for *in vivo* trials and appeared to model acute glial scarring. A 3D HA hydrogel culture model will allow *in vitro* testing of the physical and chemical properties of neural interfacing electrodes in *in vivo*-like conditions. This model will enable robust and repeatable comparisons of glial scarring to electrodes as well as other foreign bodies in the CNS.

Title: Microglia accelerate the maturation of barrier function of blood brain barrier

Authors: ***K. SATO**, Y. SHIGEMOTO-MOGAMI, K. HOSHIKAWA, Y. SEKINO
Div. Pharmacol, Natl. Inst. Hlth. Sci., Tokyo, Japan

Abstract: The blood-brain barrier (BBB) restricts the transport of substances between vasculature and brain. It is not known whether microglia have roles in the BBB development. In this study, we investigated the role of microglia in the maturation of barrier function of BBB using in *in vitro* BBB model. Co-existence of non-stimulated microglia with astrocytes in the brain side during the maturation period of *in vitro* BBB model significantly increased the trans-endothelial electrical resistance (TEER) and the expression levels of tight junction proteins. On the contrary, co-existence of LPS-stimulated microglia significantly decreased the TEER and the expression levels of tight junction proteins. These results suggest that microglia accelerate the

maturation of barrier function of BBB but their effects are reversed in the pathological conditions. We also discovered that BBB acquired the capability of ejecting extracellular L-Glu in the brain. Further, addition of non-stimulated microglia significantly increased the capability of ejecting L-Glu via increasing the expression levels of GLAST and GLT1 in endothelial cells. However, addition of LPS-stimulated microglia reversed the effects. These results strongly suggest that microglia is important for the maturation of the barrier function of BBB and reveal negative effects in the pathological conditions. In this study, we have developed the novel *in vitro* BBB model including microglia. The investigation of the precise role of microglia in the maturation of BBB barrier function is currently being undertaken.

Title: Inflammation increases axonal structural remodeling in a developing neural circuit

Authors: *N. FAROOQI[1], E. S. RUTHAZER[2]
[1]Montreal Neurolog. Inst., Montreal, QC, Canada; [2]McGill Univ., Montreal, QC, Canada

Abstract: Multiple lines of evidence implicate immune genes and immune/inflammatory activation in the development of neuropsychiatric disease. We investigated the effects of inflammation on a developing neural circuit *in vivo* by exposing larval zebrafish to bacterial lipopolysaccharide (LPS) to induce an innate inflammatory response. We demonstrate that exposure to LPS upregulates transcription of pro-inflammatory cytokines and induces morphological activation of microglia, confirming an active immune response. We subsequently expressed EGFP under a retinal ganglion cell (RGC) promoter to sparsely label axons arborising in the tectum and performed *in vivo* two-photon microscopy at high spatio-temporal resolution. Morphometric analysis of RGC axon arborization before and after exposure to LPS or a control solution demonstrates that an inflammatory insult increases structural remodelling as measured by rates of RGC axonal branch addition and retraction. Axons in larvae exposed to LPS also

demonstrate greater increases in overall axon arbor length than controls. These findings may reflect a failure to stabilize synaptic contacts and may underlie aberrant circuit formation. Microglia are key regulators of inflammatory responses in the CNS and have been implicated as having roles in normal neural development. The SpI1/Pu.1 transcription factor is necessary for normal differentiation of the myeloid lineage, including microglia and macrophages. One-cell stage injection of a morpholino oligonucleotide against SpI1/Pu.1 produces morphant animals lacking microglia and macrophages. We confirmed this effect and demonstrated that the increased remodelling of axonal arbors in response to LPS does not occur in SpI1/Pu.1 morphants. Myeloid-cell mediated responses are therefore necessary for the effect of an inflammatory stimulus on neuronal development. Funding sources: CIHR Vanier (NF), CIHR (ESR)

Title: Microglia rapidly change their morphological and dynamic properties during metabolic stress

Authors: ***L.-P. BERNIER**, L. DISSING-OLESEN, B. MACVICAR
Psychiatry, Univ. of British Columbia, Vancouver, BC, Canada

Abstract: Microglia are highly motile cells that play a pivotal role in monitoring brain homeostasis by constantly probing the environment and responding to extracellular cues. They are involved in stroke-related pathologies, mediating a nonspecific neuroinflammatory reaction that could lead to long-term deleterious effects following transient ischemia. However, the acute functional response of microglia during ischemic periods remains unclear. Here, we used real-time two-photon imaging in acute brain slices to monitor the initial effect of anoxic and

aglycemic insults on the morphological phenotype and dynamic properties of microglia. Microglia in resting conditions display a highly branched morphology with motile processes, however oxygen depletion induces a rapid, actin-dependent retraction of processes that is fully reversible upon reoxygenation. This finding indicates that microglia sense decreased oxygen levels in brain tissue within minutes. The rapid loss of major processes, normally needed by microglia to probe the environment, translates into a significant change in microglia function. Under normal conditions, microglia quickly extend their major processes towards focal injury, however this mechanism is inhibited during anoxia. We show that this phenotype is mimicked by multiple signaling molecules hypothesized to be released during brain anoxia, indicating a common intracellular pathway is activated to induce microglial process retraction. Characterizing the molecular cues responsible for this functional switch of microglial behaviour will likely provide valid targets for stroke treatment.

Abstract: Microglial cells play a key role in the patomechanism of neurodegenerative disorders. They can enter into metabolically different compartments in the CNS. We investigated, which compounds can serve as metabolic fuels for these cells. Cells were incubated in Artificial Cerebrospinal Fluid (ACSF) supplemented with those substrates, which are available for the

cells in the CSF: glutamine, glucose, lactate, pyruvate or ketone bodies. The oxygen consumption rate (OCR) and extracellular acidification rate (ECAR) was measured on primary microglial cells and on the BV-2 microglial cell-line with Seahorse Extracellular Flux Analyzer (Seahorse). ECAR was considered as a parameter of glycolytic activity. Cell viability was determined using MTT, Annexin/Calcein and Tunel essays. All of the substrates applied supported the metabolism of the cells and none of them influenced their viability negatively. In the presence of glutamine the basal rate of respiration was increased. However in the presence of glucose the OCR was decreased, the ECAR raised and the addition of a lactate dehydrogenase inhibitor after glucose was able to reverse this effect. Adding a mitochondrial fatty acid transporter inhibitor further increased the ECAR in the presence of glucose. We conclude that microglial cells show high metabolic plasticity, using wide range of substrates. From the ECAR results we claim, that these cells show high glycolytic capacity. Furthermore it was found that besides glucose glutamine is the most preferred substrate for microglial cells.

Title: Inhibition of microglial tyrosine kinases, Hck and Syk, impairs phagocytic activation and exacerbates Alzheimer’s disease-like neuropathology

Authors: *S.-L. LIM, C. J. RODRIGUEZ-ORTIZ, M. KITAZAWA
Univ. of California, Merced, Merced, CA

Abstract: Growing evidence has shown that microglia - the resident macrophage in the brain - plays a key role in regulating neuroinflammation and removing amyloid-beta (Aβ) species by phagocytosis. These beneficial activities of microglia are thought to protect one from developing Alzheimer’s disease (AD). However, functional inactivation and improper senescence of

microglia significantly impair its ability to clear Aβ, leading to a pathological buildup of Aβ and the onset of AD. Hematopoietic cell kinase (Hck) is a member of the Src family tyrosine kinases which mediate immunoreceptor-induced phagocytic activation in microglia upon Aβ stimulation, while spleen tyrosine kinase (Syk) is a non-receptor tyrosine kinase acting downstream of the Src family tyrosine kinases. We hypothesize that inactivation of Hck and Syk impairs microglial phagocytosis and Aβ clearance, leading to the development of AD neuropathology and cognitive decline. Murine microglial/macrophage cells (BV-2) were stimulated by naturally secreted oligomers (AβO) from 7PA2 cells, opsonized zymosan (mOZ) and lipopolysaccharide (LPS) in the presence or absence of Src-pan inhibitor (PP2) or Syk-specific inhibitor (BAY 61-3606). AβO markedly activated phagocytosis in BV-2 cells, and its activation was significantly inhibited by the Src and Syk inhibitors. This signified that the activation of BV-2 cells phagocytic activity by AβO stimulation was mediated by the Src family tyrosine kinases and Syk pathways, and inactivation of either kinase significantly attenuated the phagocytic capacity of BV-2 cells. We then examined whether a deficiency of Hck impacted cognition and Aβ pathology in Tg2576 mice. Behavioral studies on the Tg2576/Hck-knockout (KO) mice showed exacerbated cognitive decline in hippocampal-dependent spatial memory tests as compared with age-matched Tg2576, Hck-KO, and wild-type (WT) mice. The *in vivo* studies provided evidence that the inactivation of Hck and subsequent functional impairment of microglia may precede the buildup of Aβ and downstream AD neuropathology. Our data demonstrate that Hck and Syk are neuroprotective and important for AβO-stimulated microglial phagocytosis and clearance. These findings are imperative in delineating the contribution of microglial dysfunctionality in AD progression.

Title: Sex differences in developmental gene expression patterns in hippocampal microglia of mice: Relevance for neurodevelopmental disorders

Authors: *R. HANAMSAGAR[1], J. BOLTON[1], M. ALTER[2], S. BILBO[1]
[1]Duke Univ. Med. Ctr., Durham, NC; [2]Univ. of Pennsylvania, Philadelphia, PA

Abstract: Several neuropsychiatric disorders have been associated with immune abnormalities that likely originate during development. Many such disorders exhibit a marked sex difference in their prevalence and age of onset. Males are more likely to have disorders that present early in childhood, including autism and learning disabilities. Females are more often diagnosed with disorders that arise around or after the onset of puberty, including anxiety and depression. We have shown that microglial activation induced by early-life infection can adversely impact cognition in adult males, but not in females corelating to increased number of amoeboid microglia observed in male hippocampus (HP) during early post-natal developmental stages. However, the functional differences between male and female microglia at a basal level have not been studied. We performed whole transcriptome profiling using microarray and measured gene expression levels in microglia purified from HP of male and female at embryonic day 18 (E18), postnatal day 4 (P4), P14, P30 and P60. Data was examined with principal components analysis (PCA). The first 8 principal components accounted for 94% of the variance in gene expression levels (Fig). With respect to males and females, the first 3 principal component scores accounted for 53% of the variance and behaved similarly in males and females. The 4th through 8th principal component scores accounted for 41% of the variance and behaved differently in males and females. We hypothesize that sex-related functional differences are related to sex-based differential gene expression that follow PCA4-8. On-going studies on a bigger cohort of male and female mice will also involve treating mice at P60 with either lipopolysaccharide or saline (i.p.) to assess how a systemic inflammatory response can induce differential changes in microglial gene expression in males and females. These studies will help us understand how male and female microglia are intrinsically different, and will help explain sex-based differences in behavioral and cognitive outcomes.

Title: ATP stimulation induces plasma membrane budding and shedding of the human microglia cell line CHME-5: A good model for studying microvesicles biology

Authors: ***F. COLOMBO**, A. FINARDI, G. RACCHETTI, J. MELDOLESI*, R. FURLAN
Inst. Scientifico San Raffaele, Milano, Italy

Abstract: Cell-to-cell communication is probably one of the most studied and promising field of the current cell biology since the recent demonstration that molecular information (protein and nucleic acids) can be stored and transferred among cells by lipid particles of different size known as microvesicles. Their first descriptions date back decades ago nevertheless they were considered artifacts until recently thanks to some observations reporting the specificity of their genesis and their crucial roles in physiological and pathological conditions, which rely on the messages they carry. Exosomes and shedding microvesicles (SVs) are the two main types of microvesicles isolated up to now thanks to their diffent size (10-100 nm the former, 150-1500 nm the latter) and density. Exosomes are particles of endosomal origin released upon the fusion of multivesicular bodies with the plasma membrane whereas SVs derive by the budding of the plasma membrane, a process also known as ectocytosis. The biology of SVs is still very mysterious starting from the molecular actors governing their formation and release to the processes involved in the sorting of the content inside the nascent vesicle. Recently our group has observed a strong enrichment of myeloid-derived SVs in the cerebrospinal fluid of multiple schlerosis patients, with a strong correlation between the microvesicles number and the disease severity; this opened the possibility to use SVs as a reliable marker for monitoring neuroinflammatory disorders. In order to study some aspects of the biology of SVs in the contest of human brain pathology we chose as model a microglia cell line derived from human embryonal brain, namely CHME-5. Here I report the panel of methods I used for describing in detail the ability of CHME-5 cells to release SVs upon ATP or cytokine treatment, conditions that properly mimick the inflammed tissues. The methods presented here include flow cytometry (FCS) and western blotting for microvesicles quantitation, transmission and scanning electron microscopy (SEM, TEM) along with dynamic light scattering (DLS) for the measurements of the particles diameter. Therefore the crucial advantage of using this cell line would be the possibility to isolate enough amounts of SVs to perform OMICS analysis in order to reveal their content and perhaps their functions.

Title: GABAergic signaling evokes calcium oscillations and glutamate release in cortical astrocytes

Authors: L. MARIOTTI[1], *G. LOSI[1], M. SESSOLO[1], I. MARCON[1], S. BOVETTI[2], T. FELLIN[2], G. CARMIGNOTO[1]
[1]Neurosci. Institute-Cnr and Univ. of Padova, Padova, Italy; [2]Dept. of Neurosci. and Brain Technologies, Inst. Italiano di Tecnologia, Genova, Italy

Abstract: During the last decade, there has been an increasing interest in the reciprocal signalling between principal excitatory neurons and astrocytes. Conversely, the signalling between inhibitory interneurons and astrocytes remains largely unexplored. The main goal of our study was to identify and characterize the astrocytic response to GABAergic signals. We used slice preparations from the somatosensory cortex of P14-P22 mice loaded with the Ca2+ indicator Fluo-4 AM and the astrocytic marker SR101-AM. We found that i) about 60% of layer V astrocytes showed large amplitude somatic Ca2+ increases in response to GABA or baclofen (Bac), a GABAB receptor agonist; ii) blocking Gi/o proteins by pertussis toxin prevented Bac-mediated Ca2+ transients in astrocytes; iii) both GABA and Bac failed to induce Ca2+ events in mice lacking the inositol-1,4,5-trisphosphate (IP3) receptor type 2 in astrocytes. These results reveal an involvement of the Gq/IP3 cascade and suggest possible Gi/o-Gq protein interactions in the astrocyte response to GABA signals. Optogenetic stimulation of ChR2-expressing parvalbumin fast-spiking (Pv-FS) interneurons also evoked astrocytic Ca2+ events, and current pulse depolarization of single Pv-FS or a somatostatin (Som) interneurons increased Ca2+ peaks in nearby astrocytes from 0.41 ± 0.04 to 0.65 ± 0.08 (events/minute; $p<0.05$) and from 0.10 ± 0.31 to 1.09 ± 0.16 ($p<0.001$), respectively. Patch-clamp recordings in the presence of TTX showed that GABAB activation triggered glutamate release in astrocytes and NMDAR-mediated slow inward currents (SICs) in nearby neurons. The frequency of SICs was strongly increased both in Pv-FS interneurons (from 0.15 ± 0.06 to 0.46 ± 0.04 event/min) and pyramidal neurons (from 0.30 ± 0.07 to 0.79 ± 0.17 event/min). The increase in SIC frequency lasted for about three minutes, outlasting the time of GABA agonist applications. Due to the intrinsic membrane properties, GABAB mediated SICs were more effective in inducing action potential firing in pyramidal neurons than in Pv-FS interneurons, suggesting that in local circuits astrocytes activated by GABAergic interneurons convert a transient inhibition into a delayed excitation. The activation of astrocytes by two of the major GABAergic interneurons in the brain (Pv and

Som) and the consequent gliotransmitter release represent a new form of homeostatic control of local network excitability.

Title: Nerve Growth Factor regulates astrocyte and microglia physiology *in vitro* and *in vivo*

Authors: N. M. CARUCCI[1], C. RIZZI[1], L. GALLI-RESTA[2], S. CAPSONI[1], *A. CATTANEO[1]
[1]Scuola Normale Superiore, Pisa, Italy; [2]Inst. of Neuroscience, CNR, Pisa, Italy

Abstract: Cholinergic neurons of the basal forebrain are considered the main target cell population of NGF in the CNS. Selectively inhibiting the activity of mature NGF in the brain with a recombinant anti NGF antibody determines a more widespread, progressive neurodegeneration that recapitulates many hallmarks of AD. Also, intranasally delivery of NGF has been shown to rescue behavioural memory deficits and neuropathological alterations in APP based FAD mouse models, that show no cholinergic deficits. Here we show that neutralization of mature NGF in the AD11 mouse model induces, in an age-dependent manner, a marked astrocytic morphological change, which is reversed by intranasal NGF administration, showing a specific dependence on mature NGF deprivation. NGF neutralization determines also an early disregulated expression of mRNAs related to neuroinflammation, prior to the onset of any evident neurodegeneration. As both astrocytes and microglia cells are the principal mediators of neuroinflammatory states, we studied the effects of NGF neutralization in primary cell cultures of astrocyte or microglia. In these cells we confirmed the presence of NGF receptors TrkA and p75NTR. When incubated with NGF, we found an activation of both TrkA and p75NTR signaling pathways. *In vitro* neutralization of NGF with anti NGF mAb alfaD11 causes astrocyte morphological changes that are fully superimposable to those observed *in vivo* in AD11 mice. Moreover, in response to acute NGF deprivation, cultured astrocytes show changes in phosphorylation of TrkA, p75, Plcγ, Akt and modifications in their calcium dynamics. We demonstrated that the selective neutralization of mature NGF in the brain of AD11 mice, concomitantly to these astrocytes changes, also determines an early decrease in immune and

synaptic markers expression. Concomitantly, we found a decreased number of inhibitory interneurons in AD11 mice. To dissect the role of NGF receptors in microglia cells, these cells were incubated with NGF, in the presence/absence of p75NTR and TrkA immunoadhesins, or of the TrkA neutralizing antibody MNAC13. We observed a modulation of some inflammatory proteins and mRNA that are also modulated in the AD11 mouse. Microglia cells are known to phagocyte beta-amyloid. We found that NGF significantly increases the ability of microglial cell to phagocyte aggregated beta amyloid42. In conclusion we showed that NGF plays a significant role in the maintenance of astrocyte and microglia functions and homeostasis *in vivo* and *in vitro*. This physiological dependence could have a physiopathological consequence as well as a therapeutical implication, broadening the spectrum of NGF target cells in the brain.

Title: Release of lactate via connexin hemichannels

Authors: *A. KARAGIANNIS[1], S. SYLANTYEV[2], S. KASPAROV[3], A. V. GOURINE[1]
[1]Neuroscience, Physiol. and Pharmacol., UCL, London, United Kingdom; [2]Clin. and Exptl. Epilepsy, UCL, Inst. of neurology, London, United Kingdom; [3]Physiol. and Pharmacol., Univ. of Bristol, Bristol, United Kingdom

Abstract: Neurons require constant and appropriate supply of energy to meet their metabolic demands. Astrocyte-to-neuron lactate shuttle hypothesis suggests that neuronal activity is fuelled by lactate provided by the neighbouring astrocytes. This mechanism requires an efficient transport system of lactate across plasma membrane. Monocarboxylate transporters (MCT) have been implicated by the majority of studies, but their existence does not exclude the involvement of other potential mechanisms. In this study we tested the hypothesis that lactate could be released via opening of the connexin hemichannels. Lactate biosensors were used to record tonic and hypoxia-induced release of lactate by the acute slices of the brainstem, cortex, and the

hippocampus. Connexin hemichannels open when extracellular [Ca^{2+}] decreases. In our experiments we found that reduction of extracellular [Ca^{2+}] (from 2 mM to 0 mM) increased tonic release of lactate (by ~50%) suggesting that connexin hemichannels contribute to this release. Compounds known to block connexins (carbenoxolone, 100 μM; NPPB 200 μM) reduced lactate tone (by ~40%) while MCTs blocker 4-CIN (250 μM) had no effect. Hypoxia-induced lactate release by brainstem slices was significantly reduced (by ~50%) in the presence of either connexin or MCT blockers. Stimulation of Schaffer collateral fibers in hippocampal slices triggered release of lactate in the vicinity of the patch-clamped CA1 neurons. Lactate release in CA1 in response to stimulation of Schaffer collaterals was increased in low [Ca^{2+}] (0.5 mM) conditions, reduced by carbenoxolone (200 μM) and abolished by lactate dehydrogenase inhibitor oxamate (20mM). These results suggest that release of lactate in the central nervous system may occur via the mechanisms other than MCTs. We show that connexin hemichannels may function as a conduit of lactate release and this mechanism is recruited during hypoxia or enhanced neuronal activity.

Title: Imaging intracellular Calcium Waves in astrocytes of FGFR1 knockout mice

Authors: *D. J. ROGERS, P. ACHI, J. COLLETTE, G. WATSON, K. M. SMITH
Univ. of Louisiana at Lafayette, Lafayette, LA

Abstract: Fibroblast Growth Factor Receptor 1 (FGFR1) is a tyrosine receptor kinase. Its primary ligand is Fibroblast Growth Factor 2 (FGF2), which binds to its extracellular domain along with Heparin. In addition to signaling from the lipid bilayer, the entire FGF2/FGFR1 complex may become internalized and transported to the nucleus to stimulate transcription of proliferation promoting genes. One of the main substrates of FGFR1 is Phospholipase C γ (PLCγ). PLCγ activates IP3, which causes the release of calcium from the intracellular stores,

primarily from the endoplasmic reticulum. An increase of cytoplasmic calcium facilitates the exocytosis of gliotransmitters and also other ionic signaling through gap junctions. Calcium released from the endoplasmic reticulum may also enter the nucleus to aid in transcription of calcium-dependent genes. We compared internal calcium waves in astrocyte tissue cultures prepared from P2-P4 $FGFR1^{Flox/Flox;NestinCre}$ knockout mice and Control littermates using Fluo2-AM. We observed prominent calcium waves throughout the cortical astrocyte cultures in both the control and $FGFR1^{Flox/Flox;NestinCre}$ groups. The mean number of intracellular waves observed in 60 seconds was not significantly different between the control and $FGFR1^{Flox/Flox;NestinCre}$ groups. Cell nuclei fluoresced the brightest during a calcium wave, and returned to a basal fluorescence level at the end of the wave. There was a nonsignificant trend that the $FGFR1^{Flox/Flox;NestinCre}$ astrocytes demonstrated less intensity at the peak of the calcium wave than the littermate controls. $FGFR1^{Flox/Flox;NestinCre}$ mean intensity difference from baseline = 39 grey values ± 35.8. ; control mean intensity difference from baseline = 63 grey values ± 44.6 p=0.06. The calcium wave duration at the nucleus was compared. The $FGFR1^{Flox/Flox;NestinCre}$ astrocytes exhibited about a 4 times slower wave than the control. $FGFR1^{Flox/Flox;NestinCre}$ wave duration = 14.1 sec ± 5.6. Control wave duration = 3.7 sec ± 2.34 $p=1.98x10^{-11}$. This highly-significant difference in wave duration diminished by the second and third calcium waves; showing no significant differences between the two groups. These results indicate that FGFR1 has a significant role in intracellular calcium signaling throughout the astrocyte and possibly, the movement of calcium into the nuclear space.

Title: Extracellular potassium tunes astrocytic glutamate clearance efficiency

Authors: T. S. RIMMELE, A.-B. ROCHER, *J.-Y. CHATTON
Univ. Lausanne, Lausanne, Switzerland

Abstract: Glutamate is released in the synaptic cleft during neuronal activity. Glutamate clearance is mainly performed by Na^+-dependent glutamate transporters of astrocytes. Astrocytes are also involved in the regulation of extracellular potassium concentration ($[K^+]_o$) which significantly increases during the repolarization phase of neurons firing action potentials. In this study, we evaluated how these two fundamental functions of astrocytes, directly associated with neuronal activity, coexist and if they interact. We investigated the impact of altering $[K^+]_o$ on glutamate transporter activity measuring the intracellular sodium concentration ($[Na^+]_i$) by microspectrofluorimetry in primary astrocytes and glutamate transporter currents in cortical slices. Glutamate uptake caused a reversible rise in $[Na^+]_i$, which was tightly modulated both in amplitude and rate of rise by $[K^+]_o$. Astrocyte glutamate transporter currents evoked in acute slices also showed amplitude modulation by $[K^+]_o$. Because the Na^+/K^+ ATPase constantly attempts to regulate intracellular Na^+, we inhibited it using ouabain in order to single out the impact of $[K^+]_o$ fluctuations on the kinetics of the glutamate transporter. Under these conditions, low $[K^+]_o$ enhanced transport activity, whereas high $[K^+]_o$ markedly slowed down glutamate capture, indicating that $[K^+]_o$ directly modulates the kinetics of glutamate transporters. We then found that these $[K^+]_o$ alterations had bioenergetic consequences directly proportional with the degree of glutamate transporter activation. Overall, these results indicate that high $[K^+]_o$ exerts a negative feedback on glutamate uptake in astrocytes, while lowered $[K^+]_o$ potentiates glutamate transporter activity. The physiological consequences of these findings have to be considered in the context of K^+ buffering, maintenance of neurotransmitter, and energy homeostasis.

Title: CREB regulates calcium excitability in astrocytes via mitochondria

Authors: A. ERASO[1], E. VICARIO[1,2], R. VILLALONGA[1], L. PARDO[1], *E. GALEA[1], R. MASGRAU[1]

Abstract: HYPOTHESIS: Astrocytes are calcium-based excitable cells that modulate neurotransmission, learning and memory, although how they do it is not completely understood. Our working hypothesis is that experience induces CREB-mediated long-lasting changes in astrocytes that, in turn, modulate the activity of astrocyte-neuronal circuitries. In this study we have aimed at finding support for this idea by asking the straight question of whether CREB modulates the gliotransmitter-elicited increases in cytosolic calcium in rat cortical astrocyte cultures. METHODS: CREB-dependent transcription was triggered either by 1 hour-pulses with norepinephrine (NE 10 μM) or ATP (100 μM), which we have previously shown to CREB-dependent transcription in astrocytes within 6 hours, or by virally transducing a constitutively active form of CREB (VP16-CREB). Cytosolic calcium was assessed by calcium imaging in Fluo-4-loaded astrocytes (4 μM) challenged by gliotransmitters (100 μM ATP , 10 μM NE and 100 nM ET-1). RESULTS: Pre-stimulation with gliotransmitters reduced the calcium responses to the second stimulation with gliotransmitters by 15-38 %. Likewise, VP16-CREB caused a 27 % decrease in gliotransmitter-induced calcium response, as compared to astrocytes infected with an empty virus (Null). There were no alterations in resting cytosolic calcium levels. The CREB-induced decrease in calcium transients was still observed in the presence of EGTA but not if mitochondrial calcium uptake was blocked by the mitochondrial proton gradient uncoupler FCCP (5 μM). These results suggested that the CREB-induced decrease in cytosolic calcium transients was due to increased uptake by mitochondria rather than by reduced entry of external calcium. In agreement, ATP-induced mitochondrial calcium rises, monitored with 10 μM Rhod-2, were around 3 times higher in VP16-CREB-overexpressing than in Null astrocytes. CONCLUSION: CREB changes the calcium excitability of astrocytes by altering calcium compartimentalization between cytosol and mitochondria.

Title: Purines released from astrocytes inhibit excitatory synaptic transmission in the ventral horn of the spinal cord

Authors: E. M. M. CARLSEN[1], *J.-F. PERRIER[2]
[1]Neurosci. and Pharmacol., Univ. of Copenhagen, Copenhagen, Denmark; [2]INF, Univ. Copenhagen, Copenhagen, Denmark

Abstract: Spinal neuronal networks are essential for motor function. They are involved in the integration of sensory inputs and the generation of rhythmic motor outputs. They continuously adapt their activity to the internal state of the organism and to the environment. This plasticity can be provided by different neuromodulators. These substances are usually thought of being released by dedicated neurons. However, in other networks from the central nervous system synaptic transmission is also modulated by transmitters released from astrocytes. The star-shaped glial cell responds to neurotransmitters by releasing gliotransmitters, which in turn modulate synaptic transmission. Here we investigated if astrocytes present in the ventral horn of the spinal cord modulate synaptic transmission. We evoked synaptic inputs in ventral horn neurons recorded in a slice preparation from the spinal cord of neonatal mice. Neurons responded to electrical stimulation by monosynaptic EPSCs. We used mice expressing the enhanced green fluorescent protein under the promoter of the glial fibrillary acidic protein to identify astrocytes. Chelating calcium with BAPTA in a single neighboring astrocyte increased the amplitude of synaptic currents. In contrast, when we selectively stimulated astrocytes by activating PAR-1 receptors with the peptide TFLLR, the amplitude of EPSCs evoked by a paired stimulation protocol was reduced. The paired-pulse ratio was increased, suggesting an inhibition occurring at the presynaptic side of synapses. In the presence of blockers for extracellular ectonucleotidases, TFLLR did not induce presynaptic inhibition. Puffing adenosine reproduced the effect of TFLLR and blocking adenosine A1 receptors with DPCPX prevented it. Altogether our results show that ventral horn astrocytes are responsible for a tonic and a phasic inhibition of excitatory synaptic transmission by releasing ATP, which gets converted into adenosine that binds to inhibitory presynaptic A1 receptors.

Title: Astrocyte-neuron communication properties during aging

Authors: *M. MARTIN-FERNADEZ[1], M. GOMEZ-GONZALO[2], G. PEREA[2], A. ARAQUE[1]
[1]Univ. of Minnesota, Minneapolis, MN; [2]Inst. Cajal, Madrid, Spain

Abstract: The tripartite synapse is synaptic physiology concept, where astrocytes sense and control neuronal and synaptic activity. This concept is supported by studies from young animals. However the possible alteration of this functional unit during adulthood and aging is still unknown. Using electrophysiological and calcium imaging techniques we have investigated the bidirectional signaling between neurons and astrocytes in hippocampal and cortical slices of 0.5, 5, 12, and 20 months age mice. Astrocytes displayed spontaneous calcium elevations that were independent of neuronal activity. The local application of transmitter receptor agonist (ATP, ACh and DHPG), PAR1 agonist (TFLLR) or nerve electrical stimulation could induce calcium elevations. Electrophysiological recordings in neurons of adult and aged mice reveal the presence of slow inward currents (SICs) mediated by the activation of NMDA receptors by the released gliotransmitter glutamate. Therefore, during aging astrocytes are still able to affect neuronal excitability releasing the gliotransmitter glutamate. Furthermore, theses SICs can be induced after local application of agonists that activate astrocytes. These results reveal the existence of reciprocal signaling between neurons and astrocytes in adult and aged mice.

Title: Potential role of NF-κB p50 in astrocyte-neural progenitor cell communication within the neurogenic niche

Authors: *V. BORTOLOTTO, S. CVIJETIC, S. LOVECCHIO, P. L. CANONICO, M. GRILLI
Dept. of Pharmaceut. Sciences-Unipmn, Novara, Italy

Abstract: One of the areas in which adult neurogenesis occurs is the SubGranular Zone (SGZ) in the dentate gyrus of the hippocampus. This region is characterized by the presence of the neurogenic niche, a highly specialized microenvironment which profoundly influences the neurogenic process. Previous work in our laboratory showed that members of the NF-κB family of transcription factors are expressed in zone of active neurogenesis and that NF-κB p50 knockout (KO) mice display impaired adult hippocampal neurogenesis, likely occurring at the transition stage between neuroblasts and mature neurons. However, when adult hippocampal neural progenitor cells (NPC) derived from wild type (WT) and p50 KO mice are cultured *in vitro*, no significant differences can be observed in their neuronal differentiation rate. These data suggest a potential contribution of other cell subpopulations present in the neurogenic niche, like astrocytes, to the defective neurogenesis in p50 KO mice. Recently, we have set up primary astrocyte cultures from cortex and hippocampi of p50 KO and WT neonatal mice and studied their interaction with WT and p50 KO NPC by using astrocyte-conditioned medium (ACM). When WT NPC where exposed to WT ACM, an increased differentiation towards both neuronal and glial lineages was observed, compared to standard medium. Conversely, p50 KO ACM was able to significantly increase the percentage of newly generated astrocytes, but devoid of proneurogenic effects. Additionally, WT ACM had no proneurogenic effect on p50 KO NPC. In all experimental settings both WT and p50 KO ACM had no significant effect on the survival rate of NPC and their progeny in both genotypes. These preliminary data revealed a complex role for the NF-κB p50 subunit in the NPC-astrocyte cross-talk. In addition, they suggested that neurogenic defects in p50 KO mice cannot be merely ascribed to neural progenitor cell autonomous effects, but that they may also involve glial cells. At present, we are actively pursuing the identification of the astrocyte-derived soluble factor(s) which may be responsible of the different proneurogenic potential of WT and p50 KO ACM.

Title: Excitatory synaptic depolarizations induce Ca2+ elevations in NG2 cells

Authors: *W. SUN, D. DIETRICH
Dept. of Neurosurg., Univ. Clin. Bonn, Bonn, Germany

Abstract: As the fourth major type of glia cells in central nervous system (CNS), NG2 expressing oligodendrocyte precursor cells attracted much attention in the last decade because they receive direct synaptic input from neurons. NG2 cells themselves also express prominent levels of voltage gated ion channels (VGCs), including A-type and delay rectifier type potassium channels, and fast voltage-activated sodium channels. So far it has not been elucidated how presynaptic activity may trigger signaling pathways in postsynaptic NG2 cells potentially important for their proliferation and differentiation. In particular, it is unclear whether direct synaptic transmission can induce post-synaptic Ca^{2+} elevations in NG2 cells. In this study, we are investigating whether excitatory synaptic depolarizations are capable of triggering Ca^{2+} signaling in NG2 cells, and how VGCs modulate the Ca^{2+} elevation. We patched NG2 cells in the hippocampal CA1 region of NG2-DsRed mice (8-15 days old) in current clamp mode and held the membrane potential at -85mV. Intracellular calcium was monitored with 2-photon laser scanning microscopy. Excitatory post-synaptic potentials (EPSPs) were evoked by injecting mock excitatory post-synaptic current (moEPSCs) waveforms derived from miniature synaptic currents recorded in NG2 cells. moEPSC amplitudes were matched to the individual cell's passive properties. We did not detect any Ca^{2+} elevation in NG2 cells when single EPSCs were injected (N = 7). However, when we injected a burst of 10 moEPSCs at 100Hz, clear Ca^{2+} signals were observed which rose during the stimulation, peaked at 12.4 ± 2% $\Delta F/F$ and showed a 50%-decay-time of 2.3 ± 0.5 s in the proximal dendrite (N = 7). Combined application of 300 µM $CdCl_2$ and 200 µM $NiCl_2$ completely blocked the Ca^{2+} signal induced by burst moEPSCs injection (N =5). In striking contrast, in the presence of the A-type potassium channel blocker, 4-Aminopyridine (4-AP), 50% of NG2 cells showed Ca^{2+} elevation with only a single moEPSC injection (4 out of 8 cells), and the Ca^{2+} elevation in response to burst moEPSCs injection

significantly increased to 24.5 ± 6% in proximal dendrites. Our data suggest that excitatory synaptic depolarizations in NG2 cells are able to trigger Ca^{2+} elevation through the activation of voltage gated calcium channels. In addition, A-type potassium channels seem to be important for gating Ca2+ entry into NG2 cells.

Title: Lactate stimulates NMDA receptor-mediated Erk signaling cascade to regulate plasticity-related gene expression

Authors: *I. ALLAMAN[1], E. RUCHTI[1,2], P. JOURDAIN[1,3], J. YANG[1], G. GRENNINGLOH[1], J.-M. PETIT[1,3], P. J. MAGISTRETTI[1,2,3]

Abstract: Glycogen-derived lactate release by astrocytes is required for long-term memory formation (Suzuki et al, 2011). Here we report that in primary cultures of mouse cortical neurons L-lactate significantly stimulates mRNA expression of key immediate early genes (IEGs) involved in plasticity-related processes, in a time- and concentration-dependent manner. Following one hour of treatment with 20 mM L-lactate, Arc, Zif268 and c-Fos mRNA levels were increased by 5.2-, 3.7- and 8.2-fold, respectively. In addition, the increased IEGs mRNA expression levels induced by L-lactate are correlated at the protein level with respectively 5.5, 4.0 and 3.2 fold increase compared to control values. These effects were specific for L-lactate,

since D-lactate, L-pyruvate and D-glucose had no effect on gene expression. The effects of L-lactate involved potentiation of NMDA receptor activity and its downstream signaling cascade Erk1/2, as they were prevented in the presence of specific inhibitors of NMDA receptors (MK801, APV and the glycine site blocker L-689.560) and of Erk1/2 kinases (U0126). We also observed that L-lactate potentiated NMDA receptor-mediated currents (induced by co-application of glutamate and glycine) and the ensuing increase in intracellular calcium. Consistent with a direct modulation of NMDA receptor activity by L-lactate, NMDA application results in an increased IEGs expression that is potentiated by L-lactate. All effects of L-lactate are mimicked by NADH, suggesting that changes in redox state of neurons following conversion of L-lactate to L-pyruvate are involved in the effect of L-lactate. Taken together these findings demonstrate that L-lactate acts as a direct signaling molecule which regulates neuronal plasticity-related IEGs expression. Interestingly, the underlying mechanism of action of L-lactate involves NMDA receptors and changes in the redox state. This set of observations therefore reveals a novel signaling role of lactate which may represent a mechanism underlying the role of astrocytic-derived L-lactate on long term memory formation.

Title: Brain extracellular glucose and lactate levels in the mouse motor cortex: Effects of running and peripheral injections of glucose and insulin

Authors: *C. MESSIER, J. LARCHER
Sch. of Psychology, Univ. of Ottawa, Ottawa, ON, Canada

Abstract: There are some uncertainties about the relative contribution of lactate and glucose to brain metabolism. A long-standing theory suggests that the brain uses primarily glucose that transits from the blood to the brain extracellular space and then enters brain cells. Another theory posits that glucose enters the brain extracellular space and is taken up immediately by astrocytes

that eventually release lactate. Lactate is taken up by neurons and used as metabolic fuel. In the present experiment, we aimed bilateral electrochemical electrodes measuring glucose (right side) and lactate (left side) at the primary motor cortex of CD-1 mice. Brain extracellular glucose and lactate were recorded in freely-moving animals that could use a running wheel. Sustained running wheel activity and locomotion were associated with up to 50% increases in lactate and glucose levels in the primary motor cortex. Lactate rose from 0.65 mmol to 0.9 mmol when mice initiated running and returned to baseline 4 min after the end of running. When mice were injected with 2g/kg ip glucose, lactate increases during locomotion were blunted and there was a monotonic brain extracellular glucose increase (190% from baseline) proportional to blood levels. When mice received a 0.4U/kg ip insulin injection, brain extracellular glucose levels decreased (3%) and lactate levels increased (10%), 1-2 min after the injection. When the mice ran in the running wheel after the peripheral glucose injection, brain lactate extracellular levels rises were blunted. Conversely, when mice ran after the peripheral insulin injection, glucose extracellular rises were blunted and exercise-related extracellular lactate levels rises were more prominent. The results show that glucose and lactate extracellular levels closely follow each other during neuronal activation in the motor cortex. Rises in blood and brain extracellular glucose levels appear to reduce the amount of lactate present in the extracellular space and blunt the lactate increase following neuronal activation. Decreases in blood and brain extracellular glucose levels appear to increase the amount of lactate present in the extracellular space and potentiate the lactate increase following neuronal activation. The results suggest that both glucose and lactate may contribute to neuronal metabolism but their relative role may depend on blood and brain glucose availability.

Title: Proteolytic regulation of synaptic plasticity in the mouse primary visual cortex- analysis of mmp-9 deficient mice

Authors: *E. A. KELLY[1], A. MAJEWSKA[2]
[1]Neurobiol & Anat., Univ. Rochester, Rochester, NY; [2]Univ. of Rochester, Rochester, NY

Abstract: Matrix metalloproteinases (MMPs) constitute a large family of proteases which contribute to extracellular matrix degradation. MMP-9 is one of the most prevalent MMPs in the mammalian cerebral cortex and is known to participate in dendritic and synaptic remodeling. We have shown previously that MMP-9 is involved in the regulation of the intercellular adhesion molecule, ICAM-5 (telencephalin), and is responsible for its cleavage and subsequent removal, resulting in dendritic spine maturation. To investigate further the role of MMP-9 and extracellular matrix remodeling in activity-driven plasticity, we explored cortical plasticity in adolescent MMP9 null mice. We induced ocular dominance plasticity at P28 by monocularly depriving the contralateral eye of vision for a period 4-7 days. We then used intrinsic signal optical imaging to monitor the ocular dominance shift induced by monocular deprivation. We found that this shift was attenuated in MMP-9 KO mice following deprivation, suggesting that MMP-9 may play an important role in activity-dependent remodeling in the cortex. To evaluate the possible mechanisms of MMP-9 action during plasticity we evaluated the involvement of MMP-9 in several pathways that contribute to ocular dominance plasticity. Since MMP-9 has been shown to regulate dendritic structure and plastic changes involve dendritic spine remodeling, we next investigated anatomical changes at the level of the dendritic spine in MMP9 KO/GFP-M mice using a combination of two-photon and confocal microscopy. We also examined changes in extracellular matrix composition in MMP-9 KO mice using immunohistochemical techniques. Lastly, because MMP-9 is expressed in microglia and microglia have recently been shown to play an important role in ocular dominance plasticity, we quantified microglial morphology using immunohistochemistry and electron microscopy. Our preliminary findings suggest that loss of MMP-9 does not induce widespread changes in dendritic spine morphology or microglial morphology. Hence we conclude that MMP-9 loss affects activity-dependent plasticity through pathways that are distinct from the regulation of synapse and microglial morphology.

Abstract: Cellular mechanisms underlying the blood oxygen-level dependent (BOLD) signal measured in fMRI are poorly understood. There is evidence that astrocytes - the highly abundant glial cells of the CNS - are responsible for triggering changes in local blood flow following bursts of neuronal activity. Here we present data indicating that the principal astrocytic signalling molecule ATP is critically involved in the mechanisms underlying BOLD response. To interfere with ATP-mediated signalling we used a lentiviral vector to drive the expression of a potent ectonucleotidase - transmembrane prostatic acid phosphatase (TMPAP) on the cell surface membranes to accelerate breakdown of extracellular ATP. 21 days prior to MRI experiments, rats underwent bilateral viral injections targeted to the forepaw region of the somatosensory (SSFP) cortex. One hemisphere was transduced to express TMPAP-GFP while the other hemisphere was transduced to express green fluorescent protein (GFP). Bilateral electrical forepaw stimulation triggered significantly smaller BOLD responses in the cortex transduced to express TMPAP-GFP in comparison to the hemisphere transduced to express GFP (n=11) as measured by an experimentator unaware of the nature of transgene expressed on either side. Facilitated ATP breakdown potentially could lead to adenosine accumulation which may affect neuronal activity. However systemic treatment with A1 adenosine receptor antagonist DPCPX (1mgkg-1) further reduced, rather than increased the magnitude of fMRI signal in the hemisphere expressing TMPAP (n=9). To determine whether neuronal responses are affected by TMPAP expression we assessed the minimum amplitude of stimulation required to evoke multiunit activity in the SSFP cortex and also evaluated the amplitude of this response under the same stimulation parameters as used in the fMRI protocol. In both cases, no significant differences were observed between cortices (n=9). In summary, suppression of ATP-mediated signalling results in marked suppression of the BOLD response, indicating that purinergic signalling plays an important role in neurovascular coupling.

Title: Regulation of astrocytic glutamate transporter expression by peroxisome proliferator-activated receptor alpha

Authors: Y.-T. HSIEH[1], W.-T. CHIU[2], *J.-Y. C. HSU[3], S.-F. TZENG[1]
[1]Dept. of Life Sciences, Col. of Biol. Sci. and Biotechnology, Natl. Cheng Kung Univ., Tainan, Taiwan; [2]Dept. of Biomed. Engineering, Natl. Cheng Kung Univ., Tainan, Taiwan; [3]Cell Biol. & Anat., Natl. Cheng-Kung Univ. Col. of Med., Tainan, Taiwan

Abstract: Astrocytes play a crucial role in modulating extracellular glutamate concentrations to maintain low and non-toxic levels in the CNS. Glutamate transporter 1 (GLT-1)/EAAT-2 and glutamate aspirate transporter (GLAST) are the most important glutamate transporter subtypes found in rat astrocytes. The expression of two glutamate transporters can be regulated by microenvironmental factors in developmental and injured brain. Peroxisome proliferator-activated receptor-α (PPARα) can interact with RXRs, and then cooperatively regulate PPARα-target genes. For instance, 9-cis RA and PPARα agonists can downregulate the production of proinflammatory mediators in astrocytes. By examine the promoter sequences of GLAST and GLT-1 through the analysis using the promoter transcription factor binding site prediction software, we found rat GLAST and rat GLT-1 promoter regions contain 2 and 5 RXRα:PPARα binding sites, respectively. In the present study, we found that exposure to the PPARα agonists (WY 14,643 and GW 7647) significantly upregulated GLT-1 mRNA expression in astrocytes in the presence of dibutyryl cAMP (dbcAMP) or inflammagen lipopolysaccharide (LPS). In contrast, the two PPARα agonists reduced GLAST mRNA expression in dbcAMP-treated astrocytes, whereas PPARα agonists caused no significant change in GLAST gene expression by exposure of astrocytes to LPS. Thus, the activation of PPARα upregulated GLT-1 mRNA in astrocytes under the influence of intracellular cAMP rise and inflammagen. The PPARα/RXRα-mediated mechanism in the regulation of GLT-1 expression is currently under investigation.

Title: Role of astrocytes in the development of synchronized bursting behavior in neuronal networks

Authors: K. R. SANCHEZ, N. AGBAZUE, M. HARRINGTON, *M. TEMBURNI
Biol., Delaware State Univ., Dover, DE

Abstract: Synchronous oscillations are thought to be necessary for establishing functional neuronal networks for normal vertebrate brain development - although the mechanisms of synchronization are not fully understood. Existing models of synchronous activity assume that it is a process intrinsic to neurons. However, glia have been shown to modulate oscillatory activity in networks of neurons during sleep, during prodromal oscillations of neurons preceding spreading depression, and the slow inward currents (SICs) resulting in synchronous activity in hippocampal neurons, thalamus and nucleus accumbens. Recently glial cells, particularly astrocytes, have been shown to participate in neuronal communication by releasing "gliotransmitters" like glutamate, ATP and D-serine. We hypothesize that astrocyte-neuron interactions are crucial for the development of synchronous activity seen in the developing vertebrate brain. We test this hypothesis by establishing pure and mixed (astrocyte and neuronal) cultures from the developing chicken brain (optic tectum) and recording total neuronal activity using the multi-electrode array system, MED64. Pure neuronal cultures were obtained by treating cultures with the mitotic inhibitor 5-fluorodeoxyuridine (FUdR) which kills mitotically active astrocytes but spares post-mitotic neurons. Neurons were kept alive in the absence of astrocytes by supplementing the culture medium with 50% astrocyte conditioned medium. Typically mixed cultures of astrocytes and neurons show random spiking activity in one week and synchronous activity in two weeks. Our initial results indicate that pure neuron only cultures show random spiking activity without synchronization even after two weeks thus clearly establishing a role for astrocytes in the development of synchronous activity. To further dissect the molecular pathways involved we will target three pathways within astrocytes that have been demonstrated to be crucial for communication with neurons - metabotropic glutamate receptor (mGluR), purinergic (P2Y1) receptor and GABAB receptor. Activation of these G-protein coupled receptors by their respective neurotransmitters mobilizes intracellular calcium release leading to exocytosis of

either glutamate or ATP. Using lentiviral vectors, we propose to express dominant negative peptides designed to disrupt downstream signaling pathways of these receptors and thereby calcium mobilization and exocytosis of gliotransmitters in chick embryo astrocytes.

Title: Epidural glutamate produces long-lasting allodynia in rats: Role of glutamate actions in nearby dorsal root ganglia or intervertebral disc nerve endings

Authors: *R. WHITEHEAD, N. LAM, M. SUN, K. TUFFLI, W. ORNATOWSKI, F. HARRINGTON, H. MARTIN, E. MILLIGAN
Univ. of New Mexico, Albuquerque, NM

Abstract: Low back pain (LBP) is the leading cause of adult disability and arises from chronic intervertebral disc degeneration in the majority of cases. In the absence of physical pressure on nerve roots, the primary excitatory neurotransmitter glutamate is produced from herniated discs via enzymatic breakdown of nucleus pulposus matrix aggrecan proteins, yielding elevated ambient glutamate concentrations in LBP patients. Infusion of epidural glutamate over a 72 hour period results in thermal and mechanical hindpaw hypersensitivity, putatively via focal activation of glutamate receptors expressed on nearby dorsal root ganglia (DRG). However, it is not known whether: (1) epidural glutamate triggers peripheral and/or central sensitization after the time of passive glutamate clearance, (2) if elevated epidural glutamate is a required or chief component of discogenic LBP, and (3) which focal sites glutamate activates following enzymatic breakdown of matrix aggrecan. Here we sought to determine whether a single epidural injection of glutamate in rats would result in prolonged mechanical allodynia. One end of an indwelling catheter was

threaded epidurally to the level L5 DRG, and fastened at midpoint to the L2 spinous process. The opposite end was externalized and contained in a catheter holder sutured to the lumbar dorsal muscle. Following a 7-day recovery and monitoring period, rats received a 10 µl injection over 2-min of either 0.2mM HCL, 0.2mM L-glutamate or equivolume physiological saline. Mechanical allodynia was assessed using a blinded and randomized experimental design by systematically applying calibrated von Frey monofiliments to rat hindpaws to determine 50% threshold responses. Results revealed a single injection of 0.2mM glutamate produced significant bilateral allodynia lasting 10 days (2-way ANOVA: Left $F(2,14)=18.10$, $P<0.0001$; Right $F(2,14)=12.85$, $P=0.002$). Post hoc analysis showed peak effect on day 3 post injection bilaterally ($P<0.0001$; Multiple t-test using Holm-Sidak method). Injection of either 0.2mM HCL or saline failed to generate responses that differed from baseline levels, eliminating injection pressure and acidity as confounds ($P>0.05$). Indwelling catheter tip placements were confirmed at time of tissue harvest. Elevated epidural glutamate produces long lasting bilateral allodynia in rats. Ongoing studies are examining epidural glutamate-induced peripheral and/or central sensitization and excitotoxicity by measuring levels of pronociceptive neurotransmitters (Substance P & calcitonin gene-related peptide), pro-inflammatory mediators, and markers of cell apoptosis and necrosis in discs, DRG and spinal cord.

Title: Aldolase C is secreted by forebrain astrocytes in an exosome fraction

Authors: A. LUARTE[1], C. GOMEZ-MOLINA[1], *C. VERGARA[2], U. WYNEKEN[1]
[1]Univ. de los Andes, Santiago, Chile; [2]Biol., Univ. of Chile, Santiago, Chile

Abstract: Antidepressant drugs induce slow adaptations at glutamatergic synapses, which are enwrapped by astrocytes in the forebrain. However, the underlying signaling mechanisms involved in these adaptations are not completely understood. Besides their role as glycolitic

enzymes, aldolases have been reported to play secondary, “moonlight” functions mediated by their binding to F-actin and RNA species. Aldolase C (AldoC) is an astrocyte-specific enzyme in the forebrain. We previously showed that repetitive fluoxetine treatment in rats triggered AldoC up-regulation in a microsomal fraction derived from the forebrain. To get insight into the functional meaning of such increases, we performed studies in fluoxetine-treated animals and in astrocyte cell cultures. We found that fluoxetine treatment induces the secretion of AldoC into the extracellular space and that its content increases in the cerebrospinal fluid of fluoxetine-treated animals. Moreover, exosomes isolated from the cerebrospinal fluid contain AldoC. In astrocyte primary cell cultures, AldoC colocalizes with exosome markers. In addition, exosomes isolated from the conditioned medium of astrocyte cultures that express GFP-AldoC contain the recombinant protein. It is possible that AldoC in exosomes play a “moonlight” function, e.g. by regulating the stability or transfer of RNA species. The target cells of such microvesicles remain to be determined and will shed light on signaling mechanisms that participate in fluoxetine-mediated adaptations mediated by astrocytes.

Title: Astrocytic calciium signaling plays an important role for generation of retroaxonal barrage firing in hippocampalNPY interneurons

Authors: *T. DEEMYAD, N. SPRUSTON
Howard Hughes Med. Institute/Janelia Farm, Ashburn, VA

Abstract: A subset of inhibitory GABAergic interneurons in the CA1 area of the hippocampus exhibits persistent firing asa result of integrating action potential firing over the course of tens of seconds to minutes (Sheffield et al. 2011,Krook-Magnuson et al. 2011). Such retroaxonal barrage (RaB) firing could play an important role in regulating circuit excitability in the hippocampus. A few lines of evidence suggest that calcium ions play a role in the generation of RaB firing; namely, a decrease in extracellular calcium concentration or blocking voltage-gated calcium channels inhibit induction of RaB firing (Sheffield et al. 2013). In contrast, loading interneurons

with intracellular BAPTA had no effect on RaB firing. Inhibiting gap junctions also prevented generation of RaB firing, but mice lacking the connexin 36 subunit, which mediates gap junctions between interneurons, exhibited normal RaB firing (Sheffield et al. 2013). Together, these findings suggest a role for calcium signaling outside the interneurons in the induction of RaB firing. We tested the possibility that astrocytes may be the locus of these effects, by using a combination of electrophysiological recording from NPY cells and astrocytes as well as calcium imaging in astrocytes. All experiments were performed in hippocampal slices prepared from mice expressing GFP under the NPY promoter. First, double recordings from an NPY interneuron and a nearby astrocyte indicated that ~30% of astrocytes depolarized >10 mV few seconds before or after the onset of RaB firing (10-40mV, n=8/28). Second, induction of RaB firing was facilitated by depolarizing astrocytes with bath application of 100 uM BaCl2 (30-40 mV depolarization; n=6/6), a selective blocker of inwardly rectifying potassium (Kir) channel in astrocytes (<5 mV depolarization in interneurons), without any affect on the duration and frequency of RaB firing. Third, no RaB firing was observed in interneurons when astrocytic calcium was chelated by intracellular BAPTA during double recording from NPY cells and astrocyte (n=5/5 pairs).Furthermore, in additional experiments, RaB firing was first generated in interneurons and a nearby astrocyte was subsequently patched using pipettes containing BAPTA. In some cases this resulted in complete block ofRaB (n=2/25) or an increase in the number of spikes required for induction of RaB firing (n=5/25). Finally, using a calcium-sensitive dye, we observed, in some astrocytes, an increase in fluorescence preceding the onset ofRaB firing in NPY interneurons (n=3/9). Together, these findings suggest that a subset of astrocytes interact with NPY interneurons in a manner that promotes the generation of RaB firing.

Title: Heterogeneous astrocyte dynamics: Diurnal morphological changes in the dentate gyrus and suprachiasmatic nucleus

Authors: S. J. IRVING[1], H. J. ROSENBERG[1], *J. W. MITCHELL[2], G. NASERI KOUZEHGARANI[3], J. L. CHU[2], J. S. RHODES[4], M. U. GILLETTE[2]

Abstract: While brain information processing is thought to reside in interactions of complex neuronal circuits, a critical role for astrocytic glia in shaping brain physiology and behavior has emerged. Astrocytes participate at synaptic, cellular, and network levels, and their contributions to brain function by modulating synaptic transmission have received considerable attention. At cellular and network levels, astrocytes modulate the environment and form syncytia that permit rapid trans-network propagation of K+ and small metabolites. When challenged acutely, hypothalamic astrocytes can undergo morphological changes that alter relationships with surrounding cells and coordinate neurohormone release. We asked whether morphological change occurs under resting physiological conditions on a daily basis, the period over which brain physiology normally fluctuates. We evaluated the morphometrics of the astrocyte cytoskeleton, measured via immunofluorescence of the intermediate filament glial fibrillary acidic protein (GFAP), and of cell volume, determined via dye-filling of individual cells. We performed unbiased, computer-based analysis using Imaris software. We found robust diurnal patterns of morphological change in astrocytes of both the hippocampal dentate gyrus (DG) and hypothalamic suprachiasmatic nucleus (SCN). The complexity of GFAP structure and cell volume wax and wane in a rhythmic pattern over the 24-h cycle. GFAP branch terminal-points are significantly more numerous in the SCN than DG, differing by 4-fold at peak times. Terminal-point complexities oscillate in anti-phase, such that GFAP branching peaks at early night in the DG, but at early day in the SCN. In both regions, these daily changes in cytoskeleton architecture are mediated by reorganization of GFAP protein, not turnover. These findings add a new dimension to these cells with the discovery that the morphology of single astrocytes does not reside in a 'resting' basal state. Rather, astrocyte morphology in these regions of hippocampus and hypothalamus is highly dynamic even in unstimulated conditions.

Title: Transcriptional regulation of human transforming growth factor-α by NF-κB, Sp1 and YY1

Authors: P. KARKI[1], K. SMITH[1], J. JOHNSON JR[1], D.-S. SON[1], *E.-S. Y. LEE[2]
[1]Meharry Med. Col., Nashville, TN; [2]Physiol., Meharry Med. Col., Nashville, TN

Abstract: Transforming growth factor-alpha (TGF-α) play multifunctional roles in the central nervous system including its neuroprotection against excitotoxicity and oxidative stress. TGF-α has also been reported to mediate the neuroprotective effects of estrogen and selective estrogen receptor modulators but the regulation of TGF-α at the transcription level remains poorly understood. We attempted to identify critical transcription factors and signaling pathways for TGF-α regulation in rat primary astrocytes. We identified that the human TGF-αα promoter contains consensus sites for NF-kB, CREB, Sp1, and YY1. The results showed that overexpression of NF-kB p65 increased, whereas mutation in NF-kB binding sites of the TGF-α promoter reduced its promoter activity significantly. Accordingly, pharmacological inhibition of NF-kB abolished TGF-α promoter activity. Dexamethasone (Dx) and dibutyryl-cAMP (dbcAMP) increased TGF-α promoter activity, but their effects were significantly reduced when NF-kB binding sites were mutated. The electrophoretic mobility shift assay revealed that NF-kB binds to the TGF-α promoter directly. Sp1 also appears to be a critical positive regulator of the TGF-α promoter as its overexpression increased, but mutation of Sp1 binding sites decreased TGF-α promoter activity. On the other hand, YY1 is a critical negative regulator of the TGF-α promoter as overexpression of YY1 decreased, but mutation of YY1 binding sites in the promoter increased TGF-α promoter activity. On analyzing the signaling pathways involved in the regulation of TGF-α expression, Dx-enhanced TGF-α promoter activity and mRNA levels were abolished by inhibition of MAPK, PI3K/Akt, and PKA signaling. Taken together, our results suggest that NF-kB and Sp1 are critical positive regulators, whereas YY1 is a critical negative regulator of the TGF-α promoter. Dx enhances TGF-α promoter activity via NF-kB and several signaling pathways. These findings will significantly contribute to identifying the molecular mechanism for transcriptional regulation of TGF-α which induces neuroprotection.

Title: Anatomical arrangement of astrocytes in ferret visual cortex

Authors: *M. LOPEZ-HIDALGO, W. HOOVER, J. SCHUMMERS
Max Planck Florida Inst. For Neurosci., Jupiter, FL

Abstract: There is now abundant evidence that astrocytes are active elements in the proper function of neural circuits. An understanding of how astrocytes interact with the functional organization of different neural circuits will require a description of the anatomical arrangement of astrocytes within each specific neural circuit. Each astrocyte sends densely branching processes which define a territory, or domain, of neural tissue with which it can interact. Within their territory, astrocytes perform metabolic and hemodynamic functions as well as regulate neural activity. In the hippocampus, astrocyte domains have been shown to parcel out the gray matter with minimal overlap between neighboring domains.VIn the present study, we studied the spatial organization and morphology of astrocytes in ferret visual cortex, using a combination of *in vivo* and histological approaches. Astrocyte cell bodies (identified with SR101 *in vivo* or with S100 immunoreactivity in fixed tissue) were more numerous per unit of volume than their counterparts in mouse, through all cortical layers. Analysis of nearest neighbor distances revealed a non-random distribution of astrocyte locations, with a median distance of ~30 microns.VIn order to analyze the morphological characteristics of astrocyte territories, we performed *in vivo* targeted single-cell electroporation with large molecular weight fluorophores to enable high contrast imaging of the extent of astrocyte processes. We were able to image astrocyte morphology *in vivo*, as well as to recover the same astrocytes in fixed tissue for analysis by confocal microscopy. By comparing measurements between ferret and mouse visual cortex, we have found that ferret astrocytes are significantly bigger, more complex and that neighboring astrocytes overlap considerably more. In agreement with this observation, the mean distance of neighboring astrocytes is less than the size of astrocytes excluding the possibility of non-overlapping territories.VThe present study reinforces the growing attention to the diversity of astrocytes and calls into question the extrapolation of data from rodent hippocampus to other species and brain regions.

Title: Astrocytic gq-gpcr signaling contributes to classical conditioning

Authors: ***A. MADAYAG**, K. BOYT, R. LADD, K. D. MCCARTHY
Pharmacol., UNC Chapel Hill, Chapel Hill, NC

Abstract: Astrocytes are the most abundant cell type in the mammalian brain. These cells exist in close proximity to other cells of the central nervous system, including neurons. Our laboratory previously reported that astrocytes express Gq G-protein coupled receptors (GqGPCRs) that allow them to sense and respond to neuronal activity with intracellular Ca2+ fluxes. New data from our laboratory posits astrocyte GqGPCR signaling, including Ca2+ fluxes, as a significant regulator of classical conditioning such as fear conditioning, conditioned place preference, and conditioned place aversion. Previous studies have used pharmacological methods to determine astrocytic contributions to behavior. Unfortunately, this approach does not allow for specific targeting of astrocytes as the pharmacological approaches rely on compounds that can directly affect neuronal activity. Accurate investigation into the role of astrocytes in behavior requires the use of highly specific techniques that allow for selective perturbation of astrocyte signaling without direct effects on other cell types. Our laboratory has developed a mouse line that expresses Gq-linked Designer Receptor Exclusively Activated by Designer Drugs (Gq DREADD) in cells expressing glial fibrillary acidic protein (GFAP). With this model, we can activate Gq-GPCR signaling specifically in GFAP+ cells, primarily astrocytes, by injecting the otherwise inert compound clozapine-N-oxide (CNO). In a fear conditioning paradigm, we observe that activating astrocytic GqGPCR by CNO injection (0.5mg/Kg, IP) immediately after conditioning diminishes contextual, but not cue, freezing. Further, activating astrocytic GqGPCR signaling induces conditioned place aversion when the conditioned stimulus (CS+ chamber) is coupled to GqDREADD activation. Astrocytes are unique from other cells of the central nervous

system in part because they mobilize IP3-dependent Ca2+ stores by activating IP3 receptor type II (IP3R2). We sought to determine if mice lacking astrocytic IP3-dependent calcium responses (IP3R2 KO) exhibit deficits in classical conditioning. Indeed, we found that IP3R2 KO mice exhibit almost ablated conditioned place preference to cocaine as well as diminished contextual freezing to fear conditioning. Our findings suggest that intact astrocyte Gq GPCR signaling is essential to stabilizing behavioral output. Future studies should seek to determine mechanisms by which astrocyte Gq GPCR signaling regulates behavior as well as potential roles in neuropathology.

Title: TAMRA-conjugated spermine is selectively taken up by astrocytes in the rodent hippocampus

Authors: J. BENEDIKT[1], A. ZAYAS-SANTIAGO[1], Y. RIVERA[1], M. INYUSHIN[1], Y. V. KUCHERYAVYKH[1], L. Y. KUCHERYAVYKH[1], L. A. CUBANO[1], M. J. EATON[1], R. W. VEH[3], *S. N. SKATCHKOV[2]
[2]Biochem & Physiol., [1]Univ. Central Del Caribe, Bayamon, PR; [3]Charite, Inst. of Integrative Anat., Berlin, Germany

Abstract: The polyamines (PAs) spermine (SPM) and spermidine (SPD) are endogenous molecules stored almost exclusively in astrocytes in the adult rodent brain, but not in neurons.

Because of the lack of biosynthetic enzymes for SPM and SPD in glia, we hypothesize that these PAs are taken up by a yet unknown mechanism. To visualize the uptake of SPM in rodent brain slices, we used SPM covalently tagged with fluorescent 5(6)-carboxytetramethylrhodamine (TAMRA). We perfused rat and mouse hippocampal slices with an extracellular solution containing 10 μM SPM-TAMRA and observed robust uptake of fluorescent SPM into astrocytes, but not into neurons or blood vessels. When 10 μM of unconjugated TAMRA was perfused, there was no visible staining of any type of cells in the hippocampus, suggesting the presence of a specific mechanism for SPM uptake. Pre-application of 20 μM Gd3+ did not show any effect on SPM-TAMRA uptake, thus ruling out a glial Cx43 hemichannels as an uptake pathway when calcium and magnesium concentrations were physiological. When 10 μM SPM-TAMRA was injected with the patch pipette into a single astrocyte in the stratum radiatum region of CA1 hippocampus, it rapidly diffused through the astroglial syncytium propagating through the CA1 pyramidal layer into the stratum oriens, and eventually staining hundreds of astrocytes in a 10 min time interval. The same experiments were performed with 10 μM unconjugated TAMRA as control and this resulted in a very low level of dye propagation (33 cells on average). In both cases, pre-application of 200 μM carbenoxolone (gap-junction blocker) effectively abolished the propagation of the fluorescent compounds, implicating a gap-junction mediated mechanism. Taken together, our data suggest that *in vitro*, SPM-TAMRA is specifically taken up by hippocampal astrocytes and rapidly propagated through their syncitium. Because PAs are substrates for organic cation transporters (OCTs) which take up many of the endogenous and synthetic PAs (Sala-Rabanal et al., 2013), using RT-PCR analysis we found OCT1 and OCT3 transporters in astrocytes cultured from rat brain and thus SPM may be taken up by OCTs .

Title: Astrocyte mediated synapse model for spike timing-dependent depression

Authors: Y. NISHIMURA[1], Y. KAKIMOTO[1], *O. ARAKI[2]
[2]Dept. of Applied Physics, [1]Tokyo Univ. of Sci., Tokyo, Japan

Abstract: Recent findings have shown that neuronal activities are influenced by not only neuronal electrical activities but also astrocytic chemical signals. These findings insisted the effect of the astrocyte on variety of cognitive functions. Min and Nevian (2012) reported the contribution of the astrocyte to the memory function. In their study, it was observed that astrocytic calcium transients were induced by endocannabinoids which have been well known as essential material for induction of spike timing dependent LTD (t-LTD) and that disrupting calcium dynamics in astrocyte by calcium clamp inhibits the t-LTD. Based on their experimental results, they proposed a hypothesis of the synapse-astrocyte network for the t-LTD mechanism. In this model, post synaptic action potential leads calcium influx into the postsynaptic neuron. If this calcium influx is followed by a presynaptic action potential, PLC is activated in the postsynaptic neuron. The PLC leads to synthesis of endocannabinoids and these endocannabinoids act on astrocytic calcium transient. This in turn results in glutamate release from the astrocyte, which is thought to induce LTD. The aim of the present study is further investigation to the astrocyte mediated t-LTD by computational simulations. We proposed an astrocyte mediated synapse model constructed by two neurons model which represents dendritic calcium dynamics and emission of the neurotransmitter respectively, and an astrocyte model which represents astrocytic calcium dynamics and emission of the gliotransmitter. We also introduced the PLC activity as the input to the astrocyte. The calcium concentration influx in the postsynaptic neuron is represented by a differential equation, and the PLC activity is proportional to the calcium concentration defined by the temporal difference between postsynaptic and presynaptic action potentials in our model. Simulation results showed that if the postsynaptic action potential was followed by the presynaptic action potential, the PLC was activated and the gliotransmitter was emitted. The PLC activity and the emission of the gliotransmitter were large when the time interval was small. Additionally, they gradually decrease as the time interval increases. These results support that astrocytes are involved in the t-LTD mechanisms and suggest that the astrocytic t-LTD reported by the research of Min and Nevian might be correspondent to the standard STDP graph observed in Bi and Poo (1998).

Title: Endocannabinoid signaling induces lateral long-term potentiation of transmitter release through stimulation of astrocytes

Authors: *A. COVELO[1], M. GOMEZ-GONZALO[2], M. NAVARRETE[2], G. PEREA[2], A. ARAQUE[1]
[1]Univ. of Minnesota, Minneapolis, MN; [2]Inst. Cajal (CSIC), Madrid, Spain

Abstract: Endocannabinoids (ECBs) play key roles in brain function, acting as modulatory signals in synaptic transmission and plasticity. They are recognized as retrograde messengers that mediate long-term synaptic depression (LTD) through activation of presynaptic CB1Rs, but unable to induce the long-term potentiation (LTP) of synaptic transmission. Here we show that ECB signaling induces the long-term enhancement of synaptic transmitter release (eLTP) at single hippocampal synapses through stimulation of astrocytes when coincident with postsynaptic activity. This eLTP requires the coordinated activity of the three elements of the tripartite synapse: 1) ECB-evoked astrocyte calcium signal that stimulates glutamate release; 2) postsynaptic nitric oxide production; and 3) activation of presynaptic group I metabotropic glutamate receptors and protein kinase C. Evidence obtained by immunoelectron microscopy confirms the location of group I mGluRs at presynaptic sites. Therefore, while ECBs act as retrograde signals to depress homoneuronal synapses, they serve as lateral messengers to induce LTP in distant heteroneuronal synapses through stimulation of astrocytes. Present results show that endocannabinoids can trigger LTP of synaptic transmission through stimulation of astrocyte-neuron signaling, revealing novel cellular mechanisms of endocannabinoid effects on synaptic plasticity and brain function.

Title: Column- and layer-specific heterosynaptic depression mediated by astrocytes in neocortex

Authors: A. DIEZ, *A. ARAQUE
Dept. Neuroscience, Univ. of Minnesota, Minneapolis, MN

Abstract: The existence of reciprocal communication between neurons and astrocytes has been demonstrated in different brain areas, including hippocampus, ventrobasal thalamus, cerebellum, retina, etc. However, the presence and properties of this bidirectional communication in the neocortex is poorly known. Moreover, whether functional astrocyte-neuron interactions are widely diffuse or spatially constrained remain unknown. This is especially relevant in the neocortex, where the structural arrangement of cells is highly organized in layers and columns, because the spatially diffuse or synapse-specific astrocytic regulation of synaptic transmission may have important consequences on cortical function. Using combined electrophysiological and calcium imaging techniques in cortical slices from wildtype and transgenic mice, we have investigated the spatial properties of the endocannabinoid-induced astrocyte signalling and their consequences on the spatial regulation of synaptic function by astrocytes in the primary somatosensory cortex. We performed paired recordings from either two layer 5 pyramidal neurons or two layer 4 neurons while recording excitatory synaptic currents evoked by electrical stimulation of layer 2/3. We have found that endocannabinoids (ecbs) released by depolarization of layer 5 pyramidal neurons transiently depressed synaptic transmission in homosynapses as well as heterosynapses in adjacent pyramidal neurons. While homosynaptic depression was directly mediated by presynaptic CB1R activation, heterosynaptic depression required astrocyte calcium elevations and was mediated by activation of presynaptic A1 receptors. Astrocyte-mediated heterosynaptic depression exclusively occurred between layer 5 pyramidal neurons located within the same cortical column but was absent in neurons belonging to adjacent columns. Moreover, heterosynaptic depression recorded between layer 5 pyramidal neurons was never observed between layer 4 neurons located within the same cortical column. These results indicate astrocytes stimulated by an endogenous signal (i.e., ecbs) regulate cortical synaptic transmission through gliotransmitter release and activation of presynaptic purinergic receptors. Furthermore, the astrocyte-mediated heterosynaptic depression is column- and layer-specific, suggesting that astrocytic modulation of cortical synaptic transmission is spatially controlled and synapse-specific, which may have important consequences on the astrocyte regulation of cortical

function. Supported by University of Minnesota, MINECO (CSD2010-00045), and Cajal Blue Brain. AD is a JAE-CSIC predoctoral fellow.

Title: Regulation of glial Ca2+ signaling in *Drosophila* and its impact on neuronal activity and function

Authors: ***S. WEISS**[1], J. E. MELOM[2], T. J. LITTLETON[1]
[1]The Picower Inst. For Learning and Memory, MIT, Cambridge, MA; [2]The Picower Inst. fot Learning and Memory, MIT, Cambridge, MA

Abstract: Seizures are thought to involve reduced activity in inhibitory networks and increased activity in recurrent excitatory networks, often stemming from abnormalities in voltage-sensitive ion channels or GABAergic signaling. Large-scale screens for TS behavioral mutants to identify *Drosophila* temperature-sensitive (TS) paralytic mutations have been an important tool in the genetic dissection of membrane excitability, endocytosis and exocytosis. The goal of these screens is to generate thermolabile proteins or uncover thermosensitive processes important in neuronal signaling pathways that alter neuronal excitability when disrupted. Previous work in our lab identified Zydeco (Zyd), a glial Sodium-Calcium-Potassium exchanger (NCKX) which is involved in maintaining normal neural excitability in *Drosophila*. Mutation in zyd predisposes the flies to temperature-sensitive seizures. Zydeco was shown to be exclusively expressed in a specific glial subtype called cortex glia. Cortex glia exhibit spatial segregation reminiscent of mammalian astrocytes, with each glial cell ensheathing multiple neuronal soma. The basal intracellular calcium level in zyd mutants was shown to be elevated relative to wt, and near-membrane microdomain calcium oscillation, present in wt *Drosophila* glia, was abolished. Very little is known about the function of cortex glia in the mature nervous system. This work suggests that disruption of glial calcium regulation underlies seizure susceptibility in zyd1 mutants. To test the hypothesis that glial microdomain Ca2+ activity acutely regulates neuronal signaling, we used the zydeco mutation to dissect the mechanism(s) by which glia acutely communicate with neurons to regulate their firing properties. To probe the mechanism by which

altered glial Ca2+ regulation in zyd mutants affects neuronal excitability, we performed an RNAi screen for suppression or enhancement of zyd seizures. We knocked down, specifically in zyd1 glia, ~1000 candidate genes involved in vesicular trafficking and regulation, membrane receptors and secreted signaling ligands, participants in Ca2+ homeostasis and signaling pathways and genes that are enriched in *Drosophila* glia. This screen revealed several genes implicated in vesicle trafficking and in Ca2+ dependent cellular signaling as genetic suppressors, and components of the store operated Ca2+ entry (SOCE) pathway and genes implicated in cellular Ca2+ regulation as genetic enhancers of the zydeco TS phenotype.

Title: Remodeling of Bergmann glia actin cytoskeleton during glutamatergic neurotransmission in the cerebellum

Authors: *R. R. HERNANDEZ, Y. BASTIÁN, J. MENDEZ
Univ. Autónoma De San Luis Potosí, San Luis Potosí, Mexico

Abstract: The cerebellum participates, among other things, in fine motor control, motor learning and vestibular function through adaptive synaptic plasticity. The cerebelar functions are coded by the electrical activity of Purkinje cells. These neurons integrate the information received via synapses established with the parallel and climbing fibers within the cerebelar cortex. These incoming synapses are finely wrapped by the lamellar processes of the Bergmann glial cells (BGC). Given that BGC also express ionotropic glutamatergic receptors, during cerebelar glutamatergic neurotransmission BGC also becomes depolarized. Strikingly, inhibition of calcium entry trough AMPA receptors into the BGC, induces a retraction of Bergman glia lamellar processes. This causes glutamate to stay longer within the synaptic cleft and the synchronization of cerebelar glutamate neurotransmission is lost. Therefore, paradoxically the

correct function of Purkinje neuronal transmission depends on the correct functioning of AMPA receptors located onto the Bergman glia. RhoA is a small GTPase protein that regulates changes in the structure of cytoskeleton through the modulation of cofilin. RhoA is highly expressed in BGC and is activated after stimulation of Bergmann glial AMPA receptors. With the goal of determining the signal pathways that modulates the dynamics of actin cytoskeleton in Bergman glia. We stimulated coronal mouse cerebelar slices using 200 μM glutamate. We found that the levels of active RhoA increases after 10 minutes of glutamate treatment. The activation of RhoA was induced by GTP-γ-S as well as prevented with Inhibitor I, a RhoA inhibitor. Moreover, using a fluorescent-labeled Phalloidin we were able to observe changes in both the organization and level of actin polymerization. These results show that the activation of RhoA plays a role in the modulation of actin cytoskeleton in Bergmann glia. We suggest that activation of RhoA depends on PKC, PI-3K or FAK, which become active after AMPA receptor are stimulated in Bergmann glia cells.

Title: Local astrocyte influences on axonal properties and transmitter synchrony of hippocampal pyramidal neurons

Authors: *C. A. SOBIESKI, X. JIANG, S. MENNERICK
Dept of Psychiatry, Washington Univ. In St Louis, St Louis, MO

Abstract: The role of astrocytes in supporting neurotransmission has been extensively characterized at the synaptic level, but less is known about astrocytes' role in upstream events involved in neurotransmission. Furthermore, while global astrocyte factors have been emphasized, much less is known about local astrocytic roles. Recently our lab has uncovered a

novel role of astrocytes in axonal function. We observe large-scale (supraquantal), stereotyped asynchronous glutamate release in autaptic hippocampal pyramidal neurons when local astrocytic support is removed, but no change in GABA release (Sobieski et al., 2013). Here we investigate axonal differences in glutamatergic neurons void of local astrocytic support (-astrocyte neurons) compared to their astrocyte-rich counterparts (+astrocyte neurons) grown nearby that may explain this effect. Immunolabeling for sodium channels and for ankyrin-G showed no difference in the number, length, or intensity of labeling of the axon initial segment between +astrocyte and -astrocyte glutamatergic neurons. Total axon area and labeling intensity, measured by the axonal neurofilament marker SMI312, also did not differ. Because we detected no difference in axonal structural properties and previously detected only subtle differences in somatic excitability, we hypothesized differences in axon excitability. Specifically, we explored differences in Kv7 channels and Kv1 channels, known to be selectively localized to axons of principal neurons. +Astrocyte EPSCs were significantly more sensitive to XE991 (10 μM), a Kv7 antagonist, than -astrocyte EPSCs (17.2 ± 5.6% increase in peak EPSC vs. 2.0 ± 1.6% increase; $p < 0.03$, $n = 6, 8$). Consistent with a deficit in Kv7-like channels, the rheobase of -astrocyte glutamatergic neurons was slightly lower than the rheobase of +astrocyte controls (36.6 ± 5.2 pA vs. 57.4 ± 8.5 pA; $p < 0.05$, $n=10, 9$). By contrast both +astrocyte and -astrocyte neurons exhibited similar EPSC potentiation by another axonal K+ channel (Kv1) inhibitor, dendrotoxin (100 nM, 16.1 ± 6.0 % and 10.4 ± 3.9% increases, respectively, $p=0.44$). We conclude that axonal Kv7 deficits may participate in large-scale asynchrony of glutamate release in the absence of local astrocyte support.

Title: Neuroimaging analysis of the dopamine basis for apathetic behaviors in an MPTP-lesioned primate model

Authors: *L. TIAN, Y. XIA, H. FLORES, M. CAMPBELL, S. MOERLEIN, J. PERLMUTTER
Neurol., Washington Univ. Sch. of Med., Saint Louis, MO

Abstract: Apathy commonly occurs in Parkinson disease (PD) patients; however, the role of dopamine in the pathophysiology of apathy remains elusive. We previously demonstrated that dopaminergic dysfunction within the ventral tegmental area (VTA)-nucleus accumbens (NAcc) pathway contributes to the manifestation of apathetic behaviors in monkeys treated with the selective dopaminergic neurotoxin 1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine (MPTP). In the present study, we identified dysfunction of other dopaminergic pathways that correlate with development of apathetic behaviors. Specifically, we measured the effects of MPTP on monkeys' willingness to attempt goal directed behaviors, which is distinct from their ability to perform tasks. A total of 16 monkeys had magnetic resonance imaging (MRI) and baseline positron emission tomography (PET), using 6-[18F]fluorodopa (FD), [11C]dihydrotetrabenazine (DTBZ), and 2β-[11C]carbomethoxy-3β-(4-fluorophenyl)tropane (CFT). The monkeys received unilateral infusion of different doses of MPTP (0 - 0.31mg/kg), which produced stable hemiparkisonism by 3 weeks. After 8 weeks, PET scans were repeated and animals were euthanized. Apathetic behavior and motor impairments were assessed both pre- and post- MPTP infusion. Apathy scores were compared to motor scores, *in vitro* and *in vivo* dopaminergic measures. Apathy scores increased following MPTP. Apathy scores correlated with the non-displaceable binding potential (BPND) of DTBZ ($r_s = -0.51$, $p < 0.05$) and CFT BPND ($r_s = -0.67$, $p < 0.005$) in the dorsal lateral prefrontal cortex (DLPFC), with CFT BPND ($r_s = -0.73$, $p < 0.005$) in the ventromedial prefrontal cortex (VMPFC), and with DTBZ BPND ($r_s = -0.76$, $p < 0.005$), CFT BPND ($r_s = -0.80$, $p < 0.005$) in the insular cortex (IC), but did not correlate for any tracer in the anterior cingulate cortex (ACC) or the posterior cingulate cortex (PCC). Among all the cortical regions assessed, forward step-wise regression analyses indicated that only VTA cell count predicts IC CFT uptake better than neuropathological changes in the mesocortical network. Our findings suggest that dopaminergic dysfunction within the VTA-IC pathway plays a role in the manifestation of apathetic behaviors in MPTP-lesioned primates.

Title: *In vivo* MRI reveals early structural changes in a mouse model of α-synucleinopathy

Authors: *K. DEDUCK[1], M. DESCOTEAUX[2], K. C. LUK[3], B. J. BEDELL[1]
[1]Montreal Neurolog. Institute/McGill Univ., Montreal, QC, Canada; [2]Sherbrooke Univ., Sherbrooke, QC, Canada; [3]Dept. of Pathology and Lab. Med., Univ. of Pennsylvania Perelman Sch. of Med., Philadelphia, PA

Abstract: Introduction: Mutant A53T α-synuclein (α-syn) has been linked to familial forms of Parkinson's disease. Mice overexpressing human A53T α-syn under the mouse prion promoter (line M83) develop motor impairment and Lewy-body-like inclusions. While these behavioral and pathological alterations typically do not develop before 6 months of age, it is possible that other alterations may occur earlier. As such, the objective of this study was to use magnetic resonance imaging (MRI) to investigate differences in cortical thickness, regional volume, and white matter microstructure in young M83 mice. Methods: *In vivo* MRI scans were acquired from three month-old, male, homozygous M83 mice (TG) and wild-type littermates (WT). Anatomical scans (N = 9 TG, 7 WT) were acquired using a 3D balanced Steady-State Free Precession (bSSFP) sequence and diffusion tensor imaging (DTI) scans (N = 8 TG, 5 WT) were acquired using a customized pulse sequence. Regional volumes, cortical thickness, and DTI parametric measures (fractional anisotropy (FA) and mean/axial/radial diffusivity) were generated using a fully automated processing pipeline. Results: Regional cortical thickness was significantly reduced in TG mice in most regions, compared to WT mice, with the greatest reductions in auditory cortex, insula, and posterior cingulate cortex ($p \leq 0.005$). Reduced volumes were also observed in several cortical regions, including frontal cortex, insula, and visual cortex ($p \leq 0.05$). Notably, motor cortex was the only cortical region with increased volume in TG mice compared to WT ($p = 0.009$). TG mice also showed significantly increased volumes in the lateral ventricles and brainstem ($p \leq 0.03$). Diffusion imaging revealed significantly reduced FA in TG mice ($p = 0.04$) in the anterior portion of the corpus callosum. Conclusion: The increased lateral ventricular volume, decreased cortical thickness and volume, and reduced FA in anterior corpus callosum indicate cortical atrophy months prior to development of previously reported pathology. Interestingly, the brainstem volume was increased, and this is an area known to develop dense Lewy-body-like pathology in older M83 mice. This early increase in volume may be reflective of neuronal hypertrophy and/or gliosis. Correlative studies with quantitative immunohistochemistry (qIHC) are currently underway to investigate the cellular changes underlying these MRI-defined macrostructural alterations.

Title: Voxel-based morphometry, resting-state functional connectivity MRI and histological analysis for evaluating structural and functional changes in a rat model of Parkinson's disease

Authors: ***R. WESTPHAL**[1], C. SIMMONS[1], T. C. WOOD[1], M. B. MESQUITA[1], R. JOULES[1], S. C. R. WILLIAMS[1], A. VERNON[2], D. CASH[1]
[1]Neuroimaging, [2]Psychosis Studies, Inst. of Psychiatry, London, United Kingdom

Abstract: Introduction The neurotoxin 6-hydroxydopamine (6OHDA), when administered into the medial forebrain bundle (mfb) of rats, damages the dopaminergic nigrostriatal pathway. This models parkinsonian features such as reduced dopamine in the striatum1. The 6OHDA rat has been widely used as a test-bed for many therapeutic agents. The aim of this study was to further evaluate the 6OHDA rat in terms of structural and functional brain abnormalities in order to identify new biomarkers and targets for therapeutic interventions. Methods & Results Three weeks after unilateral 6OHDA lesioning of the mfb, male adult Sprague-Dawley rats (n=12-16 per group, full lesions were confirmed by apomorphine induced rotations) were imaged *in vivo* by structural (T2 weighted fast spin echo, resolution 0.25x0.125x0.5mm) and functional (gradient echo EPI TR=1s, resolution = 0.5x0.5x1mm) MRI. Structural images were analyzed using automated unbiased voxel-based morphometry2. Resulting statistical parametric maps revealed significant structural differences between the lesioned and sham groups. In particular, there was a reduction of grey matter volume ($p<0.05$, FDR corrected) in the ipsilateral (lesioned) hemisphere in the motor, sensorimotor, cingulate and temporal cortices. Grey matter volume loss was also present in the ipsilateral dorsal striatum and the substantia nigra ($p<0.01$, uncorrected). Functional images were analysed for resting-state connectivity using graph theoretical analysis and pattern recognition technique3. This demonstrated decreased connectivity between the ipsilateral motor and sensory cortex (including S1, S1 UlP and S2) with the contralateral parts of the brain. Dopaminergic neuronal loss and denervation was confirmed post-mortem by tyrosine

hydroxylase immunohistochemistry in the nigrostriatal and cortical areas as highlighted by MRI analysis. Conclusions Studies to identify neuroprotective interventions in Parkinson's disease have been hampered by the lack of clinically relevant animal models and the difficulty to detect brain pathology *in vivo*. This work demonstrates structural and functional brain changes on a topographic scale beyond the nigrostriatal tract in the 6OHDA rat by means of non-invasive and clinically relevant MRI protocols in conjunction with behaviour and histological methods. This highlights the beneficial use of the latest multiparametric MRI in animal models that allows the translational comparison between preclinical and clinical imaging and improves the predictive validity of the 6OHDA model. Title: Information theoretic metrics as biomarkers of parkinsonian symptom severity

Authors: ***C. ANDERSON**, A. DORVAL
Univ. of Utah, Salt Lake City, UT

Abstract: Deep Brain Stimulation (DBS) is a late-stage surgical intervention used to treat the symptoms of Parkinson's Disease (PD) once the therapeutic window of dopamine replacement has closed. Further probing of the mechanisms of DBS, and how stimulation modifies neural biomarkers of symptom severity, may lead to improved treatments for parkinsonism. Typical biomarkers studied - dopamine concentration, neuronal firing rates, neural coherence, etc - do not correlate strongly with symptom severity. We propose that information theoretic measures, including neuronal entropy and directed information, could serve as robust biomarkers for PD symptom severity. In this work, we use a 6-OHDA rodent model of PD to quantify spike train entropy and directed information within and across the substantia nigra reticulata (SNr) and ventral anterior thalamus (VA), as a function of symptom severity. Long Evans rats were

implanted with microwire recording arrays in the SNr and VA, in addition to microelectrode stimulating arrays in the subthalamic nucleus (STN). Under healthy, hemi-parkinsonian (via 6-OHDA injection to the medial forebrain bundle), and DBS conditions, unit activity and local field potentials were recorded simultaneously in the SNr and VA using a multichannel neural recording system. Symptom severity was measured using free-rotation tasks. Inter-spike intervals were binned logarithmically, entropy was computed for each unit in each condition, and mutual information between all pairs of simultaneously recorded neurons was determined. Spike train entropy in the SNr and VA covaried with symptom severity, while mutual information across all pair types decreased with increased symptom severity. Qualitatively, entropy increases in the PD condition were seen through an increase in bursting, while decreases in the DBS condition follow from unit regularization as the neurons phase lock to stimulation. Information may decrease in the PD condition due to cells being less responsive to inputs during sustained burst-like behavior. Information may increase due to regularization provided by DBS, restoring neuronal ability to respond to synaptic inputs. As the brain shifts from healthy to parkinsonian, neural units in the basal ganglia become more disordered, generating activity that drives symptoms by masking signals that drive healthy behavior. Information transmitted between neurons decreases, making individual neural unit activity more independent. This independence reflects a decrease in transmission of signals from basal ganglia to thalamus that drive healthy behavior, resulting in hypokinetic symptoms of PD, such as akinesia, bradykinesia, rigidity, etc.

Title: Cineradiographic analysis of respiratory function in a murine model mimicking the initial stages of Parkinson’s Disease

Authors: P. S. DE CAMPOS[1], K. HASEGAWA[2], Y. KUMEI[3], *J. L. ZEREDO[1]
[1]Univ. of Brasilia, Brasilia, Brazil; [2]JAXA, Sagamihara, Japan; [3]Tokyo Med. and Dent. Univ., Tokyo, Japan

Abstract: Parkinson's disease (PD) is known to cause respiratory alterations including shortening of operational volumes and reduced velocity of respiratory-muscle contraction. It has been proposed that such changes are secondary changes in posture and osteoarticular degeneration, leading into an alteration in the spinal axis that in turn could affect breathing mechanics. In this study, we aimed at testing the hypothesis that respiratory symptoms are associated with primary postural changes in the initial stages of PD.We employed a murine model of a mild hemi-Parkinson's Disease. C57BL/6J mice (n=23) were used. Under surgical anesthesia, PD mice received an injection of 6-OHDA solution (10 µg 6-OHDA in 0.9% NaCl with 0.02% ascorbic acid, infused at 0.5 µl/min) to the left nigro-striatal pathway though a stereotaxically driven microsyringe. These were compared to control mice, which received an injection of saline under the same conditions. Two weeks after surgery, all mice had their respiratory movements recorded by video x-rays on two incidences (lateral and horizontal) without restraint. Conventional behavioral tests were performed to assess the severity of the 6-OHDA lesion (pole test, cylinder test, and nest-building test). As a result, behavioral tests confirmed mild motor impairments in PD mice as compared to controls. Likewise, parameters of respiratory function (diaphragm displacement and ribcage volume) showed mild alterations in the PD group. These results suggest that respiratory alterations in PD may emerge simultaneously to other motor symptoms, and not as a consequence of the latter. Supported by grants from JSPS (Japan) to KH, YK, and JLZ.

Title: Transient potencial, kinin and purinergic receptors in Parkinson's disease

Authors: *L. M. DATI, A. S. ALVES, A. H. ULRICH, L. R. G. BRITTO
Univ. of Sao Paulo, Sao Paulo, Brazil

Abstract: Parkinson's disease (PD) is a progressive neurological disorder characterized by motor and non-motor deficits. Although there are a lot of studies about the mechanisms of Parkinson's disease, the involvement of purinergic, kinin and transient potential receptors (TRP) is still unknown. Here we studied the expression of those receptors in a Parkinson's disease model. Fifty C57BL/6 male mice aged 90 days were stereotaxically injected in to the right striatum (CPu) with 6-hydroxydopamine (6-OHDA) (Parkinson's disease - PD) while the left striatum (CPu) received saline injections (Control). After 15 days the animals were sacrificed and brains were dissected or perfused. The levels of tyrosine hydroxylase (TH), kinin receptors (B2 receptor), purinergic receptors (P2X2, P2X4, P2X7, P2Y1, P2Y4) and TRP channels (TRPM7) were determined in the CPu and substantia nigra (SN) from PD and controls by using both immunohistochemistry and immunoblotting. Data are presented as means ± SEM. The Tukey test was used to compare results from control and PD, with significance set at $p<0.05$. In both SN and CPu we found a 50% decrease in the levels of TH ($p<0.05$) in PD compared to control. The levels of TRPM7 increased around 60% ($p<0.05$) in the SN while in the CPu we observed a significant 80% increase for this receptor. The purinergic receptor P2X2 was increased into SN by about 100% ($p<0.001$); however, no difference was observed in the CPu. Higher levels of P2X4 were found in both SN and CPu (20% and 30%, respectively) in PD brains. The P2X7 receptor levels increased by 45% in the SN of PD ($p<0.05$), but no changes were observed in CPu. There was no difference in the levels of P2Y1 receptor in SN between the groups; however, we observed a 65% ($p<0.05$) increase of this receptor in the CPu. The P2Y4 receptor showed an increase around 230% in the SN of DP group, but no differences were found in the CPu. Finally, the B2 receptor increased by 72% in the SN, but no changes were seen in the CPu of the PD group. The results of this study show that kinin, purinergic and TRP receptors may all be involved in PD, but further studies about their brain localization and exact roles are necessary to better clarify this issue.

Title: A pathophysiological role of aquaporin-9 in parkinson's disease

Authors: K. STAHL, A. PRYDZ, T. B. LEERGAARD, *O. OTTERSEN, M. AMIRY-MOGHADDAM
Inst. Basic Med. Sci. Univ. Oslo, N-0317 Oslo, Norway

Abstract: Parkinson's disease is a relatively new disease, discovered as late as in 1817. It has been found to be clearly associated with environmental toxins, which lead to a selective degeneration of dopaminergic cells in the substantia nigra (SN). To date, however, the factors making these neurons selectively vulnerable are unknown. Aquaporin-9 (AQP9) is an aquaglyceroporin with particularly broad substance permeability, as it is permeable to water, glycerol, monocarboxylates and arsenite, among others (Torres-Avila et al., 2009). The channel is expressed in several tissues, including liver, testis and brain. In mouse brain, AQP9 is selectively expressed on catecholaminergic neurons in the SN, where it is localized both on plasma membranes and inner mitochondrial membranes (Amiry-Moghaddam et al., 2005, Mylonakou et al., 2009). This selective localization together with the broad substance permeability suggest that AQP9 may serve as a gateway for exogenous compounds to enter dopaminergic neurons in the SN. Based on this assumption, we hypothesize that the selective vulnerability of dopaminergic neurons to certain toxins could be attributed to AQP9, implying that this channel may play a role in the pathophysiology of Parkinson's disease. In this study, we investigated whether targeted deletion of the AQP9 gene interferes with 1-methyl-4-pyridinium ion (MPP+) toxicity using stereotaxic surgery. The toxin was infused unilaterally into the striatum of AQP9-/- animals and WT littermates, followed by several behavioral assessments. Following the lesion,all animals displayed a distinct ipsilateral rotational behavior, indicating a disruption of the motoric system. When quantified by means of apomorphine rotation test and cylinder test, AQP9-/- animals showed significantly less rotational behavior and ipsilateral paw preference, respectively, than WT littermates, indicating less motoric disruption in these animals. After seven days, animals were sacrificed by cardiac perfusion with 4 % paraformaldehyde, the brains were dissected out, and the midbrain was stained with antibodies against tyrosine hydroxylase (TH). We are currently using stereological cell counting to quantify whether these behavioral patterns are due to a reduced TH+ cell loss in AQP9-/- animals.

Abstract: Emerging evidence suggests that synaptic dysfunction is an early event in the pathogenesis of Parkinson disease (PD) occurring prior to the onset of symptoms. In order to develop more effective therapeutic strategies, we need a better understanding of the underlying mechanisms of synaptic dysfunction of PD. Mutations in the leucine-rich repeat kinase 2 (LRRK2) gene are the most prevalent causes of familial and sporadic PD, demonstrating an unprecedented significant role in PD pathogenesis. Recently a transgenic (TG) mouse model with over-expression of human LRRK2-R1441G has been shown to recapitulate the robust motor behavioral, neurochemical and pathological features of PD (Li et al., 2009). In this study, we used a battery of tests to characterize evoked dopamine release by fast cyclic voltammetry and amperometry in acute corticostriatal slices of 3, 5 and 10 month old transgenic R1441G-LRRK2 mice and their wild type (WT) littermates. We found age-dependent deficits in dopamine release in the striatum in this model. Specifically, we found that vesicle trafficking and recycling in hLRRK2-R1441G TG mice is slower compared to that of WT and that this deficit starts at 5 months of age prior to the onset of behavior deficits. To determine whether the LRRK2-R1441G mutation resulted in changes to vesicle distribution and density within dopamine axon terminals, we also examined 6 pairs of the 10 month group by electron microscopy in the dorsolateral striatum. To date, no changes have been observed in the mean vesicle density nor in the mean distance of vesicles to the synapse between WT and TG animals. There were, however, some emerging trends for alterations in minimum distance to the synapse and maximal vesicle density. While the data support the conclusion that LRRK2 plays a key role in regulating dopamine release and recycling, further investigations of the underlying mechanisms and how this dysfunction leads to axonal degeneration are ongoing (Supported by MJFF).

Title: The biguanide metformin alters phosphoproteomic profiling in mouse brain

Authors: *R. KHANG[1], C. PARK[2], J.-H. SHIN[1]
[1]Div. of Pharmacol., [2]Res. Core Facility, Sungkyunkwan Univ., Suwon, Korea, Republic of

Abstract: Metformin, a potent antihyperglycaemic agent is recommended as the first-line oral therapy for type2 diabetes (T2D). Recently, metformin has been reported to be beneficial to neurodegenerative disease models. However, the putative mechanisms underlying the neuroprotective effects of metformin in disease models are unknown. Thus, we applied LC-MS/MS-based pattern analysis and two-dimensional electrophoresis (2DE) -based proteomic approach to understand the global phosphoproteomic alteration in the brain of metformin-administrated mice. Collectively, pattern analysis reveals that 41 phosphoproteins were upregulated and 22 phosphoproteins were downregulated in the brain of metformin-administrated mice. In addition, 5 differentially expressed phosphoproteins were identified upon metformin administration by 2DE coupled with mass spectrometry. The phosphorylation status of metabolic enzymes was decreased while that of mitochondrial proteins was increased by metformin. Taken together, our results might shed light on understanding the pharmacological effect of metformin on brain function.

Title: Early changes in the endocannabinoid system after 1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine (MPTP) treatment in mice

Authors: *N. PASQUARELLI[1,2], C. PORAZIK[1,2], P. WEYDT[1], A. WITTING[1], B. FERGER[2]

Abstract: The modulation of the brain endocannabinoid system has been identified as an option to treat neurodegenerative diseases including Parkinson's disease (PD). Here, we investigate early changes in the endocannabinoid system preceding neuron loss of tyrosine hydroxylase positive neurons in the substantia nigra using the dopaminergic neurotoxin 1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine (MPTP) mouse model of PD. Male adult C57BL/6JRj mice were treated with MPTP (2 x 20 mg/kg MPTP in a 4-hour interval). After one day, changes in striatal gene expression of the cannabinoid receptors (CB_1, CB_2), the endocannabinoid enzymes monoacylglycerol lipase (MAGL) and fatty acid amide hydrolase (FAAH) were determined using qPCR. Additionally, striatal gene expression of tumor necrosis factor α (TNFα) and interleukin 6 (IL6) was quantified. The principal endocannabinoid signaling molecules 2-arachidonoylglycerol (2-AG) and anandamide as well as the endocannabinoid metabolite arachidonic acid were measured by liquid chromatography coupled with tandem mass spectrometry (LC-MS/MS). Monoamine neurotransmitter and metabolite levels were determined using HPLC in combination with electrochemical detection. MPTP treatment led to a slight decrease in CB_1 receptor expression and to a pronounced increase in CB_2 receptor expression whereas MAGL and FAAH expression as well as 2-AG, anandamide and arachidonic acid levels were not affected by MPTP treatment. TNFα expression was substantially increased. In contrast, IL6 expression was not affected after MPTP treatment. As expected, MPTP treatment induced a significant decrease in striatal dopamine and dopamine metabolites without affecting serotonin. In summary, our data show that administration of MPTP in mice leads to diverse early changes in parts of the endocannabinoid system and warrants further investigation at later time points.

Abstract: Parkinson's disease (PD) is characterized by the loss of dopamine-producing neurons in the nigrostriatal system. Numerous researchers in the past have attempted to track the progression of dopaminergic depletion in PD. We applied a quantitative non-invasive PET imaging technique to follow this degeneration process in a 6-OHDA-induced rat model of PD. The VMAT ligand DTBZ was used as a radioactive tracer in our imaging experiments to monitor the changes of the dopaminergic system. Intracerebral (caudate nucleus) administration of neurotoxin was delivered to rat to induce hemiparkinsonism. Our results indicate a significant decline in the levels of striatal dopamine. Images obtained by positron emission tomography revealed uptake of DTBZ in the rat striatum. However, reduction in radioligand was evident in the striatum of hemiparkinsonism rats as compared with the control group. Immunohistochemical analysis further confirmed PET imaging results and indicated the progressive loss of dopaminergic neurons in treated animals compared with the control counterparts. Our findings suggest that 6-OHDA model is appropriate to follow the degeneration of dopaminergic system.

Title: Ultrastructural localization of Myr-Akt in the nigro-striatal pathway, *in vivo*, following AAV transduction of neurons of the substantia nigra (SN)

Authors: *A.-S. ROLLAND, A. TAGLIAFERRO, T. KAREVA, N. KHOLODILOV, R. E. BURKE
Columbia Univ., New York, NY

Abstract: We have observed that increased Akt/mTor signaling in dopamine neurons of the substantia nigra (SN), achieved by transduction with AAV myristoylated-Akt (Myr-Akt), a constitutively active mutant, induces axon re-growth weeks after their destruction by neurotoxin (Kim et al, 2011). While the myristoylation tag has been believed to target Akt to the inner plasma membrane, and this has been confirmed *in vitro*, the subcellular distribution of the mutant Myr-Akt transgene *in vivo* is unknown. To examine its ultrastructural localization, we fused Myr-Akt with either Flag or GFP as a tag and transduced SN neurons by intra-nigral injection. We then performed electron microscopy on the nigro-striatal pathway, e.g. the SN, the medial forebrain bundle (MFB) and the striatum, by immunoperoxidase or gold particle detection. In the neuronal soma we confirmed the presence of Myr-Akt at the plasma membrane, as reported *in vitro*. However, Myr-Akt was also found to be associated with other structures, including the outer membrane of mitochondria, the Golgi apparatus and associated vesicles, the endoplasmic reticulum and with cytoskeleton. We also detected Myr-Akt throughout the nucleus. In dendrites, Myr-Akt was observed to be attached to the cytoskeleton and mitochondria. Myr-Akt was also identified outside the neuronal soma, in the axons of the MFB as well as in the axon terminals in the striatum. We conclude that *in vivo* Myr-Akt localizes not just to the inner surface of the plasma membrane, as emphasized in *in vitro* studies, but also extensively to discrete intracellular organelles. Their identification will shed light on the mechanisms by which Myr-Akt induces axon growth.

Title: Different involvement of opioid receptors in motor control and levodopa induced dyskinesia

Authors: *S. SGROI[1,2], C. CAPPER-LOUP[1], A. KAELIN-LANG[3,4]
[1]Exptl. Neurol., Inselspital Univ. Hosp., Bern, Switzerland; [2]Univ. of Bern, Bern, Switzerland; [3]Neurocentre of Southern Switzerland, Lugano, Switzerland; [4]Inselspital Univ. Hosp. and Univ. of Bern, Bern, Switzerland

Abstract: Locomotor disorders like bradykinesia are a hallmark of Parkinson's disease (PD). Levodopa (L-DOPA) remains the most effective treatment for PD symptoms although chronic L-DOPA treatment is responsible for the development of motor fluctuations ("ON/OFF" phenomena) and dyskinesia (called "abnormal involuntary movements" AIMs in animals). Opioidergic transmission is involved in basal ganglia function and is mediated by striatal endogenous peptides such as enkephalin (ENK) and dynorphin (DYN) acting through several opioid receptors (μ, δ, κ). Changes in ENK and DYN expression have been described in both untreated and L-DOPA treated PD animals but the role of the striatal opiodergic system in PD symptoms is largely unknown. Based on our previous studies, we hypothesized here that changes in the expression of opioid receptors and in the ENK and DYN mRNA levels are specifically linked with secondary compensatory mechanisms leading to changes in spontaneous motor activity and to the development of dyskinesia in PD rats under L-DOPA treatment. The purpose of this study was thus to investigate whether the opioid receptors expression and the ENK and DYN mRNA levels are correlated with the locomotor activity or the severity of dyskinetic movements. Immunohistochemistry for the anti-μ and anti-δ opioid receptors and *in situ* hybridization analysis were performed in three groups of PD rats, treated with chronic injections of L-DOPA 8 mg/kg, 6 mg/kg and Saline, respectively. The motor activity of all groups was evaluated by an "Open Field test" at several phases of L-DOPA treatment. The rats were also rated for AIMs. The immunohistochemical analysis showed a higher localization of μ receptors

in the striosomes of striatum, compared to a homogeneous distribution of δ receptors in the matrix. All PD rats showed a reduction of μ opioid receptors density in the striosomes of the lesioned striatum, compared to the not lesioned side. The expression of μ receptors was correlated to the motor symptoms, while the expression of δ receptors was correlated to the dyskinetic movements. Differences was also found in the levels of DYN and ENK mRNA between lesioned and not lesioned side, together with a different correlation with motor activity and dyskinetic movements, respectively. We conclude that the locomotor responses and dyskinesia are differently modulated by μ and δ opioid receptors and by their related DYN and ENK in PD rats under L-DOPA treatment.

Title: rAAV-Mediated Nurr1 overexpression in striatal neurons results in enhanced levodopa-induced dyskinesias in the 6-OHDA rat model of Parkinson’s disease

Authors: R. C. SELLNOW[1,2], K. STEECE-COLLIER[1], N. M. KANAAN[1], C. E. SORTWELL[1], T. J. COLLIER[1], A. COLE-STRAUSS[1], J. W. LIPTON[1], *F. P. MANFREDSSON[1]
[1]Translational Sci. & Mol. Med., Michigan State Univ., Grand Rapids, MI; [2]Cell and Mol. Biol. Program, Michigan State Univ., East Lansing, MI

Abstract: Primary motor symptoms in Parkinson’s disease (PD) arise due to a loss of dopaminergic innervation in the striatum (caudate/putamen). Administration of levodopa (L-DOPA) as a neurotransmitter replacement therapy is widely used to treat such motor symptoms by improving dopamine (DA) signaling. However, a significant proportion of patients receiving

L-DOPA treatment develop a series of debilitating hyperkinetic and dystonic movements known as L-DOPA-induced dyskinesias (LIDs). The molecular mechanism(s) driving LID genesis is not clear, and, it is not currently understood why some patients develop LIDs, but other patients on comparable doses of L-DOPA do not. In an attempt to identify transcriptional differences between LID responders (LID+) and LID non-responders (LID-) in the rat parkinsonian 6-OHDA model, we performed a full genome array to identify differential transcript expression between these two groups. The orphan nuclear receptor, Nurr1, was one transcript was expressed at significantly higher levels--greater than 30 fold--in LID+ animals when compared to LID- animals. In this study, we sought to determine if elevated expression of Nurr1 is a causative factor in dyskinesogenesis, or simply a cellular response to LIDs. Adult male Sprague-Dawley rats were rendered parkinsonian using 6-hydroxydopamine. Following the establishment of a stable lesion (4 weeks) animals received recombinant adeno-associated virus type 2/5 overexpressing either Nurr1 or GFP in the denervated striatum. Four weeks following vector injection, animals received escalating doses (0mg/kg - 24mg.kg) of L-DOPA every other day (M-Fr), and were evaluated for LIDs at 25 min intervals for 2-4 hours using our abnormal involuntary movement (AIM) rating scale. No off-time LID or significant differences in LID severity occurred at low doses of L-DOPA. At doses equal to or exceeding 12mg/kg, rAAV-Nurr1 treated animals exhibited both more severe LIDs as well as LIDs that persisted for longer than their rAAV-GFP control counterparts. Current studies are underway that will determine whether Nurr1 overexpression results in increased frequency of LIDs. These results demonstrate that overexpression of Nurr1 in the DA-depleted striatum of parkinsonian rats has a causative role in the expression of LIDs. These data suggest that the maladaptive upregulation of Nurr1 in striatal neurons is a core event in the formation of LIDs.

Title: Striatal cholinergic cell ablation attenuates l-dopa induced dyskinesia in parkinsonian mice

Authors: *U. J. KANG[1,2], L. WON[2], Y. DING[1,2], P. SINGH[1]
[1]Dept Neurol., Columbia Univ., New York, NY; [2]Neurol., Univ. of Chicago, Chicago, IL

Abstract: 3,4-Dihydroxyphenyl-L-alanine (L-DOPA)-induced dyskinesia (LID) is a debilitating side effect of long-term dopamine replacement therapy in Parkinson's Disease. At present, there are few therapeutic options for treatment of LID and mechanisms contributing to the development and maintenance of these drug-induced motor complications are not well understood. We have previously shown that pharmacological reduction of cholinergic tone attenuates the expression of LID in parkinsonian mice with established dyskinesia after chronic L-DOPA treatment. The present study was undertaken to provide anatomically specific evidence for the role of striatal cholinergic interneurons by ablating them before initiation of L-DOPA treatment and determining whether it decreases LID. We used a novel approach to ablate striatal cholinergic interneurons (ChIs) via Cre-dependent viral expression of the diphtheria toxin A subunit (DT-A) in hemiparkinsonian transgenic mice expressing Cre recombinase under control of the choline acetyltransferase promoter.Weshow that Cre recombinase-mediated DT-A ablation selectively eliminated ChIs when injected into striatum. The depletion of ChIs markedly attenuated LID without compromising the therapeutic efficacy of L-DOPA. These results provide evidence that ChIs play a key and selective role in LID and that strategies to reduce striatal cholinergic tone may represent a promising approach to decreasing L-DOPAinduced motor complications in Parkinson's disease.

Title: Role of nitrergic system in L-DOPA-induced dyskinesia in a mouse model of Parkinson's disease

Authors: O. SOLIS[1,2], I. ESPADAS[1,2], Y. TIZABI[3], E. DEL-BEL[4], *R. MORATALLA[1,2]
[1]Cajal Institute, CSIC, Madrid, Spain; [2]CIBERNED, ISCIII, Madrid, Spain; [3]Pharmacol., Howard Univ. Col. of Med., Washington, DC; [4]Behavioral Neurosci., Med. School, Univ. of São Paulo, São Paulo, Brazil

Abstract: Nitric oxide (NO), a gaseous neurotransmitter synthesized by nitric oxide synthase (NOS), plays a pivotal role in integrating dopamine transmission in the basal ganglia and has been implicated as a key player in the pathogenesis of Parkinson's disease (PD). In order to study the role of nitrergic system on L-DOPA-induced dyskinesia (LID), we assessed the effects of 7-nitroindazole (7-NI, neuronal NOS inhibitor), molsidomine (an NO donor) and zaprinast (cGMP phosphodiesterase 5- PDE5- inhibitor) on LID in Pitx3−/− (aphakia), a well-established mouse model of PD. Our hypothesis was that decreasing the level of NO by 7-NI would reduce LID and increasing NO by either molsidomine or zaprinast will exacerbate LID. To test this hypothesis, aphakia mice were treated with L-DOPA daily (10 mg/kg, ip) for 10 days to induce LID. On the last day of L-DOPA treatment some of these mice were administered 7-NI (30 mg/kg ip) or zaprinast 30 min before L-DOPA, or molsidomine, 10 min before L-DOPA to evaluate their effects on LID. Controls received vehicle. Front paw, hind paw, three paw and four paw dyskinetic movements were evaluated as abnormal involuntary movements, whereas locomotor activity and rotarod test were used as a measure of the antiparkinsonian effect of L-DOPA. Moreover, alterations in FosB, histone (H3) and pERK activation, molecular markers of LID, were examined by immunohistochemistry 1 hour after the last L-DOPA injection. 7-NI decreased LID, without affecting the beneficial antiparkinsonian effect of L-DOPA. In addition, expressions of FosB, pAcH3 and ERK correlated positively with LID. However, 7-NI attenuated FosB and pAcH3 expression only. Surprisingly, increasing the NO/cGMP signaling pathway with molsidomine or zaprinast also significantly diminished LID. However, these drugs also reduced the antiparkinsonian effect of L-DOPA. Thus, here we have demonstrated that NO/cGMP signaling pathway can modify both the behavioral and molecular consequences of L-DOPA treatment. Hence, targeting these molecular pathways might offer a novel pharmacological intervention in treatment of PD. Abstract: Parkinson's disease is a progressive and continuous neurodegenerative disorder, with onset of the disease occurring around 55 years of age. Symptoms are attributed to a loss of dopaminergic neurons within the nigrostriatal pathway, which leads to a significant decrease of dopamine in the patient's striatum. Transplantation of human embryonic dopaminergic progenitors within the striata of Parkinson's disease patients has given the field encouraging results, but ethical concerns and tissue availability limit this approach. The use of mesenchymal stem cells (MSCs) and induced pluripotent stem cells as an alternative cell source for transplantation circumvents the ethical issues, and provides a readily available source of cells, as they are derived from adult tissue. This study explored the use of MSCs as a cell source for DA neuronal induction prior to transplantation as a means to increase integration within the striatum. To this end, our lab developed a novel adenovirus for the polycistronic expression of multiple genes (Ascl1, Lmx1a, and Nurr1) that are involved in dopaminergic differentiation and used gfp to track transfection. MSCs were cultured with the adenovirus, which resulted in morphological changes as well as expression of GFP as evidenced by fluorescence microscopy. The presence of the viral DNA within the transfected cells was confirmed with PCR. Immunocytochemistry and RT-PCR analyses revealed that, cells expressing GFP have nuclear co-labeling of NURR1 and LMX1a, as well as an up-regulation of these genes, along with an up-regulation of downstream

gene targets, such as tyrosine hydroxylase, and the dopamine transporter. These results are indicative of active NURR1 and LMX1a promoting dopaminergic differentiation. Therefore, electrophysiology experiments were performed on these cells to examine their ability to produce action potentials, and dopamine release was quantified utilizing high performance liquid chromatography. Our results suggest that the approach used in this study may provide a new means of facilitating cell replacement therapy.

Title: Evaluation of a possible role for the GTPase Rap1B in the induction of new axon growth in the adult nigrostriatal dopaminergic system

Authors: *S. PADMANABHAN[1], T. KAREVA[2], O. YARYGINA[2], T. F. OO[2], N. KHOLODILOV[2], R. E. BURKE[2]
[2]Neurol., [1]Columbia Univ., New York, NY

Abstract: A number of extrinsic factors have been found to induce axon growth in dopamine neurons of the substantia nigra (SN) during development, including trophic factors such as GDNF. However, not much is known about the intrinsic mediators of axon growth in this system. Emerging data suggest that the extrinsic and intrinsic control of axon growth during development may also play a significant role in axon growth and regeneration after injury in adulthood. We have previously established a role for such developmental intrinsic mediators, the

kinase Akt and the GTPase Rheb, in the induction of axon growth following axon destruction in a parkinson mouse model. Other signaling pathways have essential roles in a number of aspects of neuronal polarization and axon growth during development. Of these, the Ras-related protein 1 (Rap1B) has been shown to play an important role in axon formation in embryonic hippocampal neurons in culture. We analyzed the expression of Rap1B in dopamine neurons in the SN in adult mice. We detected Rap1B mRNA expression in neurons of the SNpc by in-situ hybridization. Immunoperoxidase staining for Rap1B protein revealed expression in neurons of the SN and double immunofluorescence staining with tyrosine hydroxylase (TH) indicated that it was present in dopamine neurons. In order to investigate the potential of Rap1B to induce axon growth in the adult nigrostriatal dopaminergic system, we generated an AAV2/1 based viral vector containing the constitutively active form of Rap1B (Rap1BG12V) to enhance the activity of Rap1B. Transduction of SNpc neurons with Rap1BG12V caused no toxicity to the dopamine neurons or axons in the medial forebrain bundle (MFB) or striatum as assessed by TH immunostaining. At four weeks post AAV-Rap1BG12V injection into the SNpc, we observed efficient transduction of neurons, demonstrated by immunoperoxidase staining for Flag. We observed expression in the soma of neurons in the SN, in axons in the MFB and in the terminal fields in the striatum. In addition, double immunofluorescence labeling for TH and FLAG demonstrated expression of the transgene within dopamine neurons of the SNpc. Current studies are aimed at testing the role of Rap1B in inducing new axon growth following unilateral destruction of dopaminergic axons in the intra-striatal 6-OHDA mouse model of Parkinson's disease.

Pleasant, MI; [4]Col. of Med., Central Michigan Univ., Mt. Pleasant, MI; [5]Field Neurosciences Institute, 4677 Towne Ctr. Rd. Suite 101, Saginaw, MI

Abstract: Parkinson's disease is a neurodegenerative disorder characterized by the loss of dopaminergic neurons from the substantia nigra that innervate the striatum through the nigrostrial pathway. Loss of this pathway leads to significant motor impairments and affective symptoms. Although an effective long-term therapy has not been developed, extensive research focusing on the use of stem cell transplantations as a regenerative therapy for PD is being pursued, including the use of mesenchymal stem cells (MSCs) for this purpose. MSCs can be easily isolated and expanded from different adult tissues, including bone marrow, peripheral blood, vasculature, adipose tissue, and umbilical cord blood. Further, studies have shown that they also have the ability to differentiate *in vivo* and *in vitro* into neural-like stem cells and, more specifically, into dopamine-producing cells using growth factors and morphogens. However, there are discrepancies among studies regarding the optimal time and method for dopaminergic induction *in vitro*. In the current study, we compared the ability of early and later passaged rat bone marrow-derived MSCs to differentiate into dopaminergic-neurons when using two growth-factor based approaches: a single-stage induction (SSI) using sonic hedgehog (SHH) and fibroblast growth factor -8 (FGF-8) and a multiple-stage induction (MSI) using basic fibroblast growth factor (bFGF) epidermal growth factor (EGF), SHH, and FGF-8. Results from flow cytometry, and immunocytochemistry (ICC) analyses indicated that treatment of both early and later passaged MSCs with bFGF and EGF induced neurosphere-like formation, expressing the neural progenitor markers doublecortin (DCX) and nestin. Also, early passaged MSCs that underwent both the SSI and MSI exhibited a change in morphology toward a neuronal phenotype, and exhibited an increase in the expression of the neuronal markers neuron specific nuclear protein (NeuN) and class III β-tubulin (β-III), as determined by flow cytometry, ICC, and reverse transcriptase polymerase chain reaction (RT-PCR). Further, both early and later passaged MSCs, that were exposed to the MSI, showed an increase in the expression of the dopaminergic markers tyrosine hydroxylase (TH), dopamine transporter (DAT), and the nuclear receptor related 1 protein (Nurr1), following treatment with SHH and FGF-8, as evidenced by ICC and RT-PCR. Overall, findings from this study indicate that MSCs have the ability to differentiate into neuronal-like cells, and more specifically, early and later passaged rat MSCs, which have undergone a MSI, have the potential to differentiate into dopaminergic-neurons.

Title: Characterization of a novel PPAR-γ agonist as a neuroprotective agent in Parkinson's disease

Authors: *A. R. CARTA[1], D. K. NEVIN[2], D. LECCA[1], G. SACCHETTI[3], D. FAYNE[2]
[1]Biomed. Sci., Univ. of Cagliari, Cagliari, Italy; [2]Sch. of Biochem. & Immunol., Trinity Col., Dublin, Ireland; [3]Life Sci. and Biotech., Univ. of Ferrara, Ferrara, Italy

Abstract: Evidence has pointed to PPAR-γ as a pharmacological target of disease-modifying drugs in Parkinson's disease. However, currently available PPAR-γ agonists thiazolidinediones (TZDs) present limitations due to a low blood brain barrier permeability and concerns relating to potential increases in cardiovascular or cancer risks. Here, we have characterized the *in vitro* and *in vivo* neuroprotective efficacy of a novel thiobarbituric-based (TBA) compound MDG548, which shows high affinity PPAR-γ activity with increased BBB permeability compared to TZDs. Cell viability assays showed a dose-dependent effect of MDG548 that displayed cytotoxicity in neonate rat cortical neurons only at the high doses (25-50 μM), whilst it was void of effects in the range 100nM-10 μM. Therefore, this dose-range was used to further investigate *in vitro* effects of the compound. First, neuroprotection on H2O2-induced neurotoxicity was evaluated. Rat cortical neurons were pre-exposed for 24 hours to MDG548 prior to H2O2, or were co-treated with MDG548/H2O2 on the same time-point. In both instances, MDG548 dose-dependently increased cell viability as compared to H2O2. Moreover, MDG548 effects on NF-kB activation was investigated in order to assess its anti-inflammatory activity. HEK-Blue-hTLR4 cells were treated with varying concentrations of MDG548 for 24 hours prior to LPS (100 ng/100 ml) stimulation. MDG548 dose-dependently decreased LPS-induced NF-kB activation. Importantly, MDG548 effects in both *in vitro* assays were fully inhibited by PPAR-γ antagonist GW9662. In addition, MDG548 was not genotoxic based on Ames test performed with Salmonella typhimurium TA100 and TA98 strains, with and without metabolic activation (S9). *In vivo*, the neuroprotective effect of MDG548 was tested in a sub-acute MPTP model of

PD in mice. BL/6J mice were treated with MPTP (20 mg/kg i.p. once/day for 4 days) in conjunction with saline, MDG548 (2, 5, 10 mg/kg i.p.) or MDG548 plus GW9662 (10 mg/kg i.p.). Stereological counting showed a reduction in the number of TH-positive cells in the substantia nigra compacta after MPTP treatment, which was abrogated by MDG548 co-administration at all doses tested. Neuroprotection was PPAR-γ-mediated, since GW9662 antagonized the effects. Results suggest that the novel PPAR-γ agonist MDG548 exhibits neuroprotective efficacy *in vitro* and in an *in vivo* model of PD. Being a TBA compound, MDG548 may offer an effective alternative to TZDs in the search for safer PPAR-γ agonists to be utilized as disease-modifying drugs in PD. More investigations are warranted to further assess *in vivo* neuroprotection and molecular mechanisms mediating this effect.

Title: Evaluation of isradipine for neuroprotection in the MPTP/p mouse model of Parkinson's disease

Authors: *C. J. PRICE[1], M. L. SUTHERLAND[2], J. M. MATHEWS[1], T. R. FENNELL[1], S. R. BLACK[1], S. L. WATSON[1], R. W. SNYDER[1], R. C. SWITZER, III[3], S. O. AHMAD[4]

Abstract: Isradipine (ISR), a Cav1.3 Ca^{2+} channel blocker and anti-hypertensive, has been previously reported as neuroprotective in rodent neurotoxin models of Parkinson's disease. In the present studies, young male C57BL/6 mice were implanted on study day zero with placebo or ISR-loaded pellets delivering a target dose of 3 mg/kg/day, sc. On day 7, mice were terminated

for analysis of ISR (plasma; brain) or given a single MPTP/p treatment and terminated to assess ISR effects on: (a) MPTP and MPP^+ toxicokinetics (plasma; striatum); and (b) MPTP/p-induced changes in dopamine (DA) neurochemistry (striatum). On day 7, mice assigned to the main neuroprotection study received the 1st of 10 biweekly injections of vehicle or MPTP/p [probenecid (250 mg/kg, ip) followed 30 min later by MPTP·HCl (25 mg/kg, sc)]. Groups (N=12 per group) included: placebo + vehicle; placebo + MPTP/p; ISR + vehicle; ISR + MPTP/p. On day 44, mice were terminated for ISR analysis (plasma) and neuropathology of substantia nigra-pars compacta (SNpc). Immunohistochemical stains included tyrosine hydroxylase (TH) + AgNOR counter stain for DA neurons, GFAP for astrocytes, Iba-1 for microglia, alpha-synuclein (alpha-syn), and pSER129 for phosphorylated alpha-syn. On day 7, the mean plasma ISR was 18.8 ng/mL (range = 9.10 to 31.7 ng/mL) and the brain:plasma ratio was 0.509 (0.335 to 0.934). On day 44, plasma ISR declined to 10.8 ng/mL (8.42 to 16.2 ng/mL) in ISR+vehicle mice or 13.2 ng/mL (8.38 to 18.9 ng/mL) in ISR+MPTP/p mice. On day 7, baseline striatal DA was 47% higher in ISR vs. placebo mice, but ISR did not alter striatal MPP^+ or DA concentrations at 0.5, 1, 2, 3, or 6 h after MPTP. By day 44, mortality in MPTP/p-treated mice (3/12 placebo vs. 1/12 ISR) suggested some ISR-mediated protection against systemic MPTP/p toxicity. Mild body wt deficits and characteristic neurotoxicity occurred in MPTP/p-treated mice. As expected, striatal DA and number of TH^+ neurons in SNpc were reduced, TH staining intensity decreased, and % area stained by GFAP or Iba1 increased in MPTP/p-treated mice. ISR administration, however, failed to attenuate these indicators of MPTP/p-induced neurodegeneration. For alpha-syn and pSER129, staining intensity was not affected. In conclusion, previously reported neuroprotective effects of ISR were not replicated herein, in spite of well-controlled ISR delivery and internal exposures similar to earlier studies. Dose-response studies may be necessary to reliably demonstrate ISR's neuroprotective effect in the MPTP/p mouse model.

Title: HDAC inhibition protects dopaminergic neurons in a transgenic mouse model of multiple system atrophy

Authors: *E. STURM, P. HOCKL, W. POEWE, G. K. WENNING, N. STEFANOVA
Innsbruck Med. University, Dept. Neurol., Innsbruck, Austria

Abstract: Within the last years, histone deacetylases (HDACs) have been implicated to play an important role in the pathogenesis of neurodegenerative diseases. It has been shown that their inhibition protects neurons in models of Parkinson's disease (Roy, A. et al., 2012) and amyotrophic lateral sclerosis (Cudkowicz, M. E. et al., 2009). Multiple system atrophy (MSA) is an atypical parkinsonian disorder associated with oligodendroglial alpha-synuclein inclusions, selective neuronal loss and gliosis. MSA has rash progression and lacks treatment. In an attempt to identify new therapeutic targets for this disease in the current project we address the effects of HDAC inhibition by sodium phenylbutyrate (NaPB), a non-selective pan-HDAC inhibitor, in a transgenic mouse model of MSA. Transgenic PLP-alpha-Synuclein MSA mice with targeted overexpression of alpha-synuclein in oligodendroglia received daily intraperitoneal injections of either NaPB (200mg/kg) or saline over a period of two months. Wild type C57Bl/6 mice receiving saline served as healthy controls. Behavioral tests were performed in order to assess progression of motor deficits. Immunohistochemistry and biochemical analysis, including western blotting, were applied to identify the effects of NaPB treatment in selected neurodegenerating regions of the MSA brain. MSA transgenic mice showed reduced acetylation of the nucleosome core protein H3 as compared to healthy wild type mice. NaPB treatment of MSA mice resulted in increased H3 acetylation up to levels of healthy controls. Furthermore, NaPB treatment in the transgenic MSA mouse model was associated with neuroprotection of nigral dopaminergic neurons, reduced oligodendroglial alpha-synuclein inclusion density and a reduction of astrogliosis. We identified that treatment of MSA mice with NaPB led to increased expression of DJ-1, a protein that is an indicator for anti-oxidant and gene-regulatory activity of NaPB. Our data suggest that the pan-HDAC-inhibitor NaPB has a significant neuroprotective effect on nigral dopaminergic neurons of transgenic MSA mice. Epigenetic mechanisms including histone modifications should be investigated further as potential targets in MSA therapy. Acknowledgement: Austrian Science Funds (FWF) F4404 and P25161. Title: Lovastatin activates SREBP nuclear translocation and modulates dopamine transport system in SH-SY5Y cells

Authors: M. SCHMITT[1,2], B. DEHAY[2], E. BEZARD[2], *F. GARCIA-LADONA[1]
[1]Neurosci. TA, UCB Biopharma Sprl, Braine L'Alleud, Belgium; [2]Inst. des Maladies Neurodégénératives UMR5293, Univ. of Bordeaux, Bordeaux, France

Abstract: Sterol response element binding protein (SREBP) is a transcription factor regulating the expression of several gene families. Disinhibition of SREBP-dependent gene expression could be at the base of some pharmacological actions attributed to statins such as the lower incidence of Parkinson's disease and dementia in population under statin treatment. Experimental data in Parkinson's models have further shown neuroprotective effects as well as functional modulation of the dopaminergic system. Using immunocytochemistry and high content imaging, we have investigated the effects of HMG-CoA inhibition on the nuclear translocation of SREBP in SH-SY5Y human neuroblastoma cells. The expression of the main presynaptic elements of dopamine (DA) transport system, synaptogyrin-3 (SYNGR3), DA-transporter (DAT) and vesicular monoamine transporter-2 (VMAT-2) were studied using quantitative PCR (qPCR), SDS-PAGE electrophoresis and immunocytochemistry. Changes in the functional activity of the cellular DA transport system were investigated using radio-isotopic method. In undifferentiated SH-SY5Y cells, lovastatin induced a time-dependent and dose-dependent increase of SREBP nuclear translocation with maximal effects observed at 48hr of incubation. Gene expression analysis shows that the treatment of SH-SY5Y cells with lovastatin induced a time-dependent increase of mRNA levels coding for SYNGR3 and VMAT-2 proteins after 6hr incubation. No significant changes of DAT mRNA levels were observed at any time. Western blot analysis showed significant increases of a 75kDa VMAT-2- and a 24kDa SYNGR3-protein bands while no changes were observed for DAT (68kDa) band. DA transport experiments using [^{3}H]DA in whole cells showed a reduction of DA transport uptake activity after 24h of treatment with lovastatin. Our data demonstrate an statin-dependent induction of SREBP translocation into the nucleus concomitant with changes in the gene expression of VMAT2 and SYNGR3 proteins and a modification of the DA-transport capacity in SH-SY5Y

cells. Present findings suggest a potential molecular mechanism of action of statins on the dopaminergic system.

Title: Inhibition of the microglial response is essential for the neuroprotective effects of Rho-Kinase inhibitors on MPTP-induced dopaminergic cell death

Authors: A. I. ANA I. RODRIGUEZ-PEREZ[1], A. BORRAJO[1], B. VILLAR-CHEDA[1], R. VALENZUELA[1], M. J. GUERRA[1], *J. L. LABANDEIRA-GARCIA[2,1]
[1]Cimus, CIBERNED, Santiago de Compostela, Spain; [2]Fac Med., Santiago Compostela, Spain

Abstract: Several recent studies have shown that activation of the RhoA/Rho-associated kinase (ROCK) pathway is involved in the MPTP-induced dopaminergic cell degeneration and possibly in Parkinson’s disease. ROCK inhibitors have been suggested as candidate neuroprotective drugs for Parkinson’s disease. However, the mechanism responsible for the increased survival of

dopaminergic neurons after treatment with ROCK inhibitors is not clear. We exposed primary (neuron-glia) mesencephalic cultures, cultures of the MES23.5 dopaminergic neuron cell line and primary mesencephalic cultures lacking microglial cells to the dopaminergic neurotoxin MPP^+ and the ROCK inhibitor Y-27632 in order to study the effects of ROCK inhibition on dopaminergic cell loss and the length of neurites of surviving dopaminergic neurons. In primary (neuron-glia) cultures, simultaneous treatment with MPP^+ and the ROCK inhibitor significantly reduced the loss of dopaminergic neurons. In the absence of microglia, treatment with the ROCK inhibitor did not induce a significant reduction in the dopaminergic cell loss. Treatment with the ROCK inhibitor induced a significant decrease in axonal retraction in primary cultures with and without microglia and in cultures of the MES23.5 cell line. In conclusion, inhibition of microglial ROCK is essential for the neuroprotective effects of ROCK inhibitors against cell death induced by the dopaminergic neurotoxin MPP^+. In addition, ROCK inhibition induced a direct effect against axonal retraction in surviving neurons. However, the latter effect was not sufficient to cause a significant increase in the survival of dopaminergic neurons after treatment with MPP^+.

Title: Neuronal nitric oxide synthase inhibitor modifies glial reaction trigged by L-DOPA treatment in rat model of Parkinson’s disease

Authors: *M. BORTOLANZA[1], R. CAVALCANTI-KIWIATKOSKI[1], F. E. PADOVAN-NETO[1], C. A. DA-SILVA[1], M. MITKOVISKI[2], R. RAISMAN-VOZARI[3], E. DEL BEL[1]
[1]Physiol., Univ. of São Paulo, Ribeirão Preto, Brazil; [2]Max-Planck-Institute of Exptl. Med., Göttingen, Germany; [3]Inst. de Cerveau et de la Moelle Epinière, Paris, France

Abstract: Parkinson's disease is a movement disorder characterized by the dopamine depletion in dopaminergic nigrostriatal system. The most common treatment is with L-3,4-dihydroxyphenylalanine (L-DOPA). However, the use of this drug is severely limited by the motor (dyskinesia) or cognitive (psychosis) side effects it causes. We hypothesize that dyskinesia may be accompanied by alterations of the inflammatory cascade components. To analyze this hypothesis we investigate the inducible nitric oxide synthase (NOS) enzyme, microglia and astrocytes expression in the striatum of rats with L-DOPA-induced dyskinesia. Male Wistar rats were lesioned unilaterally with the 6-hydroxydopamine (6-OHDA), neurotoxin microinjection in the medial forebrain bundle. After 3 weeks, the animals were then treated daily with either the inhibitor of nitric oxide synthase 7-nitroindazole (7-NI, 30mg/kg/day) or vehicle (saline-DMSO 50%) followed (30 minutes later) by L-DOPA (30mg/kg plus benserazide 7.5 mg/kg/ -21 days) or saline. L-DOPA administration brought dyskinesia, which was blocked by 7-NI. An increase in the immunoreactivity of the inducible NOS, the glial fibrillary acidic protein (GFAP) labeling astrocytes and of the anti-CD11b antibody/equivalent protein (clone OX-42) labeling microglia was observed in the lesioned striatum. 7-NI decreased expression of inducible NOS and suppressed astrocytic and microglial activation. Our results provide, for the first time, evidence that glial activation, an actor of inflammatory processes, could play a role on L-DOPA induced dyskinesia in parkinsonian rats. The NOS inhibitor may overcome dyskinesia at least in part via the inhibition of glial cells activation and inducible NOS expression. It furthest settles NOS inhibitor therapeutic potential for control L-DOPA induced dyskinesia.

Title: Neuroprotection and neurorestoration by inducible Akt in Parkinson's disease

Authors: *S. PARK[1], O. LEVY[1], A. TAGLIAFERRO[1], T. KAREVA[1], T. FRANKE[2], R. BURKE[1], L. GREENE[1]
[1]Columbia Univ., New York, NY; [2]NYU Langone Med. Ctr., New York, NY

Abstract: Parkinson's disease (PD) is a common progressive neurodegenerative disorder. Existing treatments only help to manage symptoms and do not impede progression of the disease or reverse its course. Thus, there is great demand for treatments that will provide neuroprotection as well as restoration of function. Signaling by the serine threonine kinase Akt, the main effector of the PI3K pathway, has been shown to mediate both neuroprotection and regeneration of axons in PD toxin models. Furthermore, studies of postmortem sporadic PD brains and genetic PD models have suggested that a deficiency in Akt signaling is involved in the neuronal degeneration that is key to progression of PD. Based on these lines of evidence, we have chosen Akt as a promising neuroprotective and neurorestorative target for study in PD models. Because unregulated Akt activity may lead to undesirable side effects such as excess neuronal sprouting and proliferation of non-neuronal cells, we have devised a strategy to deliver a regulatable form of this protein. Here, we utilize an inducible protein stabilization system (Iwamoto et al, 2010) to control the activity of Akt by fusing a constitutively active Akt (CA-Akt, E40K) to a destabilization domain (DD). The DD, derived from E. coli dihydrofolate reductase (DHFR), causes the chimeric DD-CA-Akt to be degraded in proteasomes. The addition of the DHFR ligand, trimethoprim (TMP), rapidly stabilizes the kinase, allowing it to accumulate in the cell and activate downstream signaling cascades. This method thus allows tunable regulation of Akt activity using a ligand that is commonly used as an antibiotic in humans and readily crosses the blood-brain barrier. We have demonstrated that the system successfully confers inducibility of Akt activation at levels comparable to or greater than that of endogenous Akt in HEK293 cells, neuronal PC12 cells, and primary cortical neurons. Additionally, this activation is dose-dependent, reversible, and reaches its maximum within 24 hours of TMP treatment in cell culture. Survival experiments using lentiviral vectors to deliver DD-CA-Akt to neuronal PC12 cells demonstrate that TMP treatment significantly improves survival against the PD-mimetic toxin 6-OHDA, comparable to survival seen with myr-Akt. No protection is seen in absence of TMP or by TMP alone. We are presently testing the inducible system *in vivo* in 6-OHDA treated mouse models. If successful, this inducible system will provide a strategy for gene therapy in PD that has the potential to halt or slow progression of the disease and to lead to functional restoration of damaged neurons.

Title: Fibroblast-derived neurospheres as a therapeutic option to restore dopaminergic neuronal loss in a mouse model of Parkinson's Disease

Authors: *C. D. GUOYNES[1], J. CHO[2], K. LUTFY[3], Y. HONG[2]
[2]Col. of Vet. Med., [3]Col. of Pharm., [1]Western Univ. of Hlth. Sci., Pomona, CA

Abstract: Parkinson's Disease (PD) is characterized by the selective loss of dopaminergic (DA) neurons_as the disease progresses, more and more DA neurons are lost and PD becomes fatal. In order to reduce the progression of the disease and increase patient life expectancy, cells from a patient can be transdifferentiated *in vitro* and injected to restore the lost dopaminergic neurons. Our *in vitro* method involved deriving fibroblasts from mouse ear clip samples and transdifferentiating them into neurospheres using knockout serum replacer (KSR) media supplemented with Sox2 replacer small molecules. Neurospheres were then injected in the substantia nigra of mice with a unilateral 6-hydroxydopamine (6-OH-DA) lesion to assess the viability and transdifferentiation of these cells to dopaminergic neurons. Our results showed that an injection of 6-OH-DA into the striatum caused a significant loss of dopaminergic neurons in the substantia nigra compared to non-lesioned side. Furthermore, animals with unilateral 6-OH-DA lesion exhibited a significant increase in the number of contralateral rotations following apomorphine injection compared to sham-lesioned animals or animals with 6-OH-DA lesions in the nucleus accumbens. Studies are in progress to evaluate the viability and transdifferentiation of neurospheres to dopaminergic neurons in the control and lesioned animals. The results of the current studies will open a new avenue of research for PD cell therapy.

Title: Exercise confers neuroprotection and improved behavior in a sex-dependent manner to the $LRRK2^{R1441G}$ mouse model of Parkinson's disease

Authors: *J. JANG, H. NOH, T. KIM, M. JEONG, J. JEON, H. SEO
Dept. of Mol. and Life Sci., Hanyang Univ., Ansan, Korea, Republic of

Abstract: Physical exercise has been studied as a potential therapeutic approach to treat patients with Parkinson's disease (PD). In this study, we determined the effects of regular swimming exercise on the PD-related behaviors of male and female $LRRK2^{R1441G}$ transgenic mice (MT). Regular swimming exercise significantly improved the latent periods until falling in the rota rod test in male MT mice. In the open field test, swimming exercise increased the locomotor counts of crossing in both female and male littermate control mice (LM), but did not change the locomotor counts of crossing, rearing, or grooming for either female or male MT mice. Interestingly, swimming exercise increased locomotor counts of wall rearing in female LM mice, but decreased locomotor counts of wall rearing in male LM and MT mice. Regarding spatial learning, swimming exercise did not alter escape latency, as assessed by the Morris swim maze, in both female and male MT mice. Swimming exercise did not change olfactory activity in an odorant avoidance test, in any group of mice tested in this study. Immunohistochemical data supported the neuroprotective effects of swimming exercise, with an increased number of cholinergic neurons observed in the medial septum (MS) of female MT mice, and increased number of dopaminergic neurons in the substantia nigra pars compacta (SNpc) of female and male MT mice after swimming exercise. These data suggest that the therapeutic application of swimming exercise can potentially be considered, in a sex-dependent manner.

Title: Acute theta-burst stimulation exerts distinct therapeutic effects in early and late experimental parkinsonism

Authors: *V. GHIGLIERI[1], F. CACACE[1], V. PENDOLINO[1], A. VANNELLI[1], M. MANCINI[1], B. PICCONI[1], P. CALABRESI[2]

Abstract: In experimental Parkinson's disease (PD), different degrees of degeneration of nigrostriatal dopaminergic neurons produce distinct alterations of dopamine-dependent corticostriatal synaptic plasticity. Several lines of evidence indicate that repetitive transcranial magnetic stimulation (rTMS) induces a selective increase of dopamine in the vicinity of highly active corticostriatal terminals, suggesting that it may alleviate symptoms and improve the response to therapy in PD patients. However, the mechanisms underlying effects of rTMS on subcortical regions are not known and its effects on striatal plasticity have not been clarified either in healthy or in PD brain. Using intracellular recordings from corticostriatal slices of 6-hydroxydopamine (6-OHDA)-lesioned rats, modelling early and late PD, we show that a single session of *in vivo* cortical rTMS, using intermittent theta-burst stimulation (iTBS) protocol, was able to rescue a form of corticostriatal plasticity sensitive to low levels of DA, such as long term depression in fully-lesioned rats. The same treatment was able to induce a recovery of corticostriatal long term potentiation in partially-lesioned rats. These data indicate that acute iTBS may overcome effects of striatal DA denervation and may have a significant impact on neuronal activity of subcortical regions, providing experimental support for its use in clinical settings.

Title: Zonisamide prevents neurodegeneration in nigrostriatal dopaminergic neurons in a mouse genetic model of Parkinson's disease through brain-derived neurotrophic factor signaling pathway

Authors: *H. SANO[1], M. MURATA[2], A. NAMBU[1]
[1]Syst. Neurophysiol., Nat Inst. for Physiol Sci., Okazaki, Japan; [2]Dept. of Neurol., Natl. Ctr. Hospital, Natl. Ctr. of Neurol. and Psychiatry, Kodaira, Japan

Abstract: Parkinson's disease (PD) is a neurodegenerative disorder characterized by the progressive loss of nigrostriatal dopaminergic neurons, and consequent motor dysfunction. Zonisamide (ZNS; 1,2-benzisoxazole-3-methanesulfonamide), which was originally developed as an antiepileptic drug, was shown to also improve motor functions in PD. Although the pharmacological mechanisms behind the beneficial actions of ZNS in PD are not fully understood, some effects, such as the elevation of tyrosine hydroxylase activity, the increase in dopamine turnover and the inhibition of monoamine oxidase B, were suggested. Furthermore, ZNS attenuated cell death induced by seizure and ischemia, and showed neuroprotective effects on nigrostriatal dopaminergic neurons injured by dopaminergic neurotoxins. To clarify the pharmacological mechanisms of ZNS in PD, we have evaluated the neuroprotective effects of ZNS on nigrostriatal dopaminergic neurons of Engrailed mutant mice, which was shown resemble pathological features of PD. Chronic administration of ZNS to Engrailed mutant mice has improved the survival of nigrostriatal dopaminergic neurons compared with those under saline treatment. Although the number of dopaminergic neurons in the substantia nigra of ZNS - treated Engrailed mutant mice have not reached that of control mice, dopaminergic terminals in the striatum and the motor functions have been improved to the levels of those in control mice. To investigate the mechanism of the neuroprotective effect of ZNS, we have measured the contents of neurotrophic factors, such as glial cell-line derived neurotrophic factor (GDNF) and brain-derived neurotrophic factor (BDNF) in the striatum and ventral midbrain after chronic administration of ZNS. BDNF content has been increased in the ZNS-treated mice compared to

saline-treated mice, although GDNF content has remained unchanged. These findings indicate that ZNS prevents nigrostriatal dopaminergic cell death through BDNF signaling and may have similar beneficial effects in human PD patients as well.

Title: The deleterious effects of High Mobility Group Box 1 in the MPTP model and Parkinson's disease can be attenuated by glycyrrhizin

Authors: *P. TEISMANN[1], K. SATHE[1], P. STATHAKOS[1], H. L. MARTIN[1], M. A. HOBERT[2], T. W. RATTAY[2], T. GASSER[2], D. BERG[2], K. J. TRACEY[3], W. MAETZLER[2]
[1]Univ. of Aberdeen, Aberdeen, United Kingdom; [2]Hertie-Institute for Clin. Brain Res., Univ. of Tuebingen, Tuebingen, Germany; [3]Feinstein Inst. For Med. Res., New York, NY

Abstract: High-Mobility Group Box 1 (HMGB1) is a nuclear and cytosolic protein that can be released into the extracellular space from immune and non-immune cells -including microglia and neurons - in response to various stimuli. Extracellular HMGB1 has been shown to contribute to progression of numerous chronic inflammatory and autoimmune diseases which is, among other receptors, mediated by interaction with the receptor for advanced glycation endproducts (RAGE). With regard to Parkinson's disease (PD), there is increasing evidence from in-vitro studies that HMGB1 is a promising candidate for bridging the two main pathophysiological components, i.e. progressive dopaminergic degeneration and chronic neuroinflammation, as a mechanistic basis of PD progression. This study assessed the role of HMGB1 in biospecimen of PD and in the chronic 1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine (MPTP) mouse model. We found an increase in HMGB1 protein and RNA expression in the substantia nigra of postmortem PD patients as well as in cerebrospinal fluid and serum. A neutralizing antibody for HMGB1

partly inhibited MPTP-induced dopaminergic cell death, as well as reduction in dopaminergic striatal fibers. In parallel MPTP-induced increase of RAGE and tumor necrosis factor-alpha was attenuated. Glycyrrhizin, a component from liquorice root which can directly bind to HMGB1, reduced MPTP-induced dopaminergic cell death dose-dependently and effectively. This was accompanied by reduction of MPTP-induced protein expressions of HMGB1 and RAGE. Taken together this study provides evidence for a potential role of HMGB1 in the progressive dopaminergic neurodegeneration as seen in PD and the observed chronic neuroinflammation. Thus, HMGB1 might be a suitable and effective target for a potential neuroprotective therapy for PD.

Title: Therapeutic potentials of human adipose-derived stem cells in mouse model of Parkinson’s disease

Authors: ***H. KIM**[1], H. CHOI[2], Y.-H. SUH[2]
[1]Res. Div., Korea Brain Res. Inst. (KBRI), Daegu, Korea, Republic of; [2]Korea Brain Res. Inst., Daegu, Korea, Republic of

Abstract: Human adipose-derived stem cells (hASCs), a kind of mesenchymal stem cells (MSCs) isolated from adipose tissue, are well known for their pluripotent ability to differentiate into various cell types including adipocytes, osteocytes, cartilage cells, and muscle cells. Furthermore, the differentiation potential of hASCs into neuron-like cells was reported in the recent studies. Autologous hASCs have significant advantages, such as the lack of immune rejection responses, tumorigenesis, or ethical problems. However, for the stability of hASCs transplantation, the consistency and high reliability of the experimental results verified by the animal models of diseases have been considered greatly important factors. Therefore, the aim of

this study is to investigate preventive and therapeutic potential of hASCs for Parkinson's disease (PD). hASCs was intravenously injected into tail vein of Parkinson's disease mouse model induced by 6-hydroxydopamine (6-OHDA). In our previous study, we found that intravenously transplanted hASCs passed through the blood brain barrier (BBB) and migrated into the injuries of the brain. Consequently, the behavioral performances were significantly improved at 3 weeks after the intravenous injection of hASCs in PD mouse model.

Abstract: In clinical practice, deep brain stimulation (DBS) is effective for the treatment of motor symptoms in Parkinson's disease (PD). However, the mechanisms have not been understood completely. There are some reports that electrical stimulation exerts neuroprotective effects on the central nervous system disorders including cerebral ischemia, head trauma, epilepsy and PD; meanwhile, there are only few reports on neuroprotective effects of spinal cord stimulation (SCS). In the present study, we investigated neuroprotective effects of SCS on PD model of rats. Adult female Sprague-Dawley rats received hour-long SCS (2, 50 or 200Hz) with an epidural electrode at C1-2 level for 16 consecutive days. At 2 days after initial SCS, 6-hydroxydopamine (6-OHDA), a neurotoxin of dopaminergic neurons, was injected into the right striatum of rats. Behavioral evaluations of PD symptoms, including cylinder test and amphetamine-induced rotation test, were performed at 1-2 weeks after 6-OHDA injection. Animals were subsequently euthanized for immunohistochemical investigations. In order to explore neurotrophic and growth factor upregulation induced by SCS, another cohort of rats that received 50Hz SCS was euthanized at 1 and 2 weeks after lesion for protein assays. Behavioral tests revealed that the number of amphetamine-induced rotations decreased in SCS groups. Immunohistochemically, tyrosine hydroxylase (TH)-positive fibers in the striatum were

significantly preserved in SCS groups. TH-positive neurons in the substantia nigra pars compacta were significantly preserved in 50Hz SCS group. The level of vascular endothelial growth factor (VEGF) was upregulated by SCS at 1 week after the lesion. These results suggest that SCS exerts neuroprotection in PD model of rats, at least partially by upregulation of VEGF. SCS is supposed to suppress or delay Parkinson's disease progression and might become a less invasive therapeutic option for PD patients.

Title: Lymphocytes improve clinical outcome in the 6-OHDA parkinson mouse model

Authors: *C. IP, S. BECK, J. VOLKMANN
Univ. of Wuerzburg, Wuerzburg, Germany

Abstract: Objective: Neuroinflammation is an important feature of neurodegenerative diseases. The role of microglia in the pathogenesis of Parkinson's disease (PD) has been extensively investigated in human brain tissue and different rodent models. Although lymphocyte populations were found in autopsies material of PD patients and also in the MPTP Parkinson mouse model, there is currently no data on the role of lymphocytes in the 6-OHDA toxin model, which represents the most common rodent model of Parkinson's disease. To evaluate a possible role of the adaptive immune system in the progression of Parkinson' s disease, we used an unilateral 6-OHDA mouse model by injection into the medial forebrain bundle and compared the motor outcome of wt to RAG-1 deficient mice, that do not possess mature lymphocytes. Methods: Clinical examination in 6-OHDA and control mice (4 groups: wt 6-OHDA, RAG-1 -/- 6-OHDA, wt sham, RAG-1 -/- sham) was longitudinally performed by open field and rotarod analysis until day 30 after 6-OHDA injection. Immunohistochemical stainings were performed to analyze lymphocyte infiltration into the striatum. Results: After unilateral 6-OHDA injection RAG-1 -/- mice showed a significantly reduced velocity and exploration path in the open field compared to wildtype mice. Rotarod analysis exhibited a shorter time to fall in RAG-1 -/- mice

during the first 2 weeks after 6-OHDA injection. Wildtype bone marrow reconstitution into RAG-1 -/- recipients led to improvement of the clinical deterioration in RAG-1 -/- 6-OHDA treated animals. Immunohistochemical analysis im wildtype mice demonstrated a significantly higher CD8+ T-cell density in the striatum ispsilateral to the 6-OHDA lesion (right) compared to the untreated hemisphere (left) as well as a higher CD8+ T cell number in the right striatum of 6-OHDA treated mice compared to the sham group (NaCl injection). By contrast CD4+ T-cell number did not change significantly. Conclusion: Our preliminary data indicate that lymphocytes attenuate the clinical effect of 6-OHDA injection into the medial forebrain bundle and thus may play a protective role in this toxic PD mouse model.

Abstract: Impairment of autophagy-lysosomal pathways, an essential pathway for maintainance of proper protein and organelle quantity and quality within cells, is increasingly regarded as a major pathogenic event in neurodegenerative diseases, including Parkinson's disease (PD). Consequently, the possibility that enhancement/restoratoration of lysosomal-mediated degradation may prove beneficial for PD has been raised. We here report that poly (DL-lactide-co-glycolide) (PLGA) nanoparticles delivered to lysosomes within 24 hours after treatment, lower lysosomal pH and rescue chloroquine-induced cell death, but does not rescue from bafilomycin A-induced lysosomal pH loss. Treatment with PLGA nanoparticles of two disease-related *in vitro* models of PD with profound lysosomal dysfunctions, i.e. ATP13A2-knockdown dopaminergic cell lines and fibroblasts from PD patient carrying ATP13A2 mutations, restores lysosomal function and attenuates cell death. Moreover, PLGA nanoparticles are detected in

neurons after *in vivo* intracerebral injections, suggesting a translational opportunity. Taken together, our results reinforce the concept that restoration of normal lysosomal function might be beneficial in neurological disorders associated with lysosomal impairments.

Abstract: Increasing evidence indicates that impairment of lysosomal function may contribute to the pathogenesis of several neurodegenerative diseases, including Parkinson's Disease (PD). Autophagy-lysosome pathways alterations are observed in sporadic and familial forms of PD as well as in toxic and genetic rodent models of PD-related neurodegeneration. In this regard, enhancement or restoration of lysosomal-mediated degradation may prove beneficial for PD. Transcription factor EB (TFEB) has been recently identified as a new master regulator of lysosomal biogenesis and function and its activation has been shown to attenuate 1-methyl-4-phenylpyridinium -induced cell death in an *in vitro* setting. ZKSCAN3, a zinc finger family DNA-binding protein, has been recently characterized as a master transcriptional repressor of autophagy. To investigate the neuroprotective effect of enhancement of lysosomal biogenesis in an *in vivo* model, we used a genetic model of PD based on the overexpression of human mutant A53T synuclein (A53TSyn) by adeno-associated virus serotype 9 (AAV2/9) in the rat midbrain. We here report that unilateral AAV2/9-mediated overexpression of TFEB or repression of ZKSCAN3 through silencing strategy in the substantia nigra pars compacta (SNpc) reverse the toxicity of α-synuclein in the AAV2/9-A53TSyn rat model. Both overexpression of TFEB and silencing of ZKSCAN3 restored left paw use in cylinder test. Histological analyses performed at

the level of SNpc dopaminergic neuron cell bodies and striatal dopaminergic terminals were used to assess extent of dopaminergic lesion as well as occurrence of α-synuclein pathology. In order to assess the translational value of such strategies, the neuroprotective effect was also tested in a primate model of PD.

Title: Beta-estradiol protects against 1-methyl-4-phenylpyridinium induced-Parkinsonism in rat by activation of endogenous antioxidant system

Authors: Y. AGUIRRE-VIDAL[1], N. L. CHÁVEZ-GARCÍA[2], A. MONROY-NOYOLA[1], *S. MONTES[2]
[1]Facultad de Farmacia Univ. Autónoma del Estado de Morelos, Cuernavaca, Morelos, Mexico; [2]Natl. Inst. Neurol. Neurosurg, Mexico City, Mexico

Abstract: Steroids are bio-synthetized from cholesterol in different tissues including the brain. Specifically, estradiol (E2) can be produced from circulating testosterone or cholesterol by neurons and astrocytes. It is well known that E2 is involved in regulating neural development, synaptic plasticity and cell survival. Therefore, it has been linked with protection in neurodegenerative diseases including Parkinson disease (PD). However, the mechanism by which E2 protects dopaminergic neurons in PD it is not clear. PD is characterized by the progressive degeneration of dopaminergic neurons in substantia nigra pars compacta probably as a result of increased oxidative stress. The objective of the present work was to determine whether estradiol (given as beta-estradiol-3-benzoate) protects dopaminergic neurons through mechanisms related to antioxidant enzymes such as glutathione peroxidase (GPx), superoxide dismutase (SOD) and paraoxonase (PON) in a Parkinson's disease rodent model. Male Wistar rats (200-250 g) were gonadectomized and 30 days later, divided into 4 experimental groups: control group (C), MPP+ group (M), beta-estradiol-3-benzoate group (B) and beta-estradiol-3-

benzoate/MPP+ group (BM). The estrogen was dosed 100 µg every 48 h for 11 days (s.c.) in corn oil as vehicle. On day 6 of estradiol treatment, animals were infused with the neurotoxin MPP+ (10 µg/8 µl) or saline into the right striatum. Twenty four hours after the last dose of estradiol, rats were administered with apomorphine (1 mg/kg, s.c.) to evaluate circling behavior. The following day, animals were killed to determine dopamine in the right striatum. For the determination of antioxidant enzymes, rats were sacrificed 2 h after MPP+ injury. Estradiol treatment prevented by 80 % the decrease of striatal DA levels induced by MPP+. It also diminished by 50 % the turns induced by apomorphin in parkinsonic animals. Estradiol partially preserved glutathione (GSH) levels from oxidation by MPP+. These preliminary results suggest that estradiol protects from oxidative damage in the MPP+ PD experimental model.

Title: Botulinum neurotoxin A subtype 2 reduces pathological behaviors more effectively and confers greater safety than subtype 1 in a rat Parkinson's disease model

Authors: *M. ITAKURA[1], H. NAKAJIMA[1], T. KOHDA[2], T. KUBO[1], Y. SEMI[1], K. NISHIYAMA[1], Y.-T. AZUMA[1], S. KOZAKI[2], T. TKEUCHI[1]
[1]Vet. Pharmacol., [2]Vet. Epidemiology, Osaka Prefecture Univ., Osaka, Japan

Abstract: Botulinum neurotoxin type A (BoNT/A) acts on cholinergic neurons, cleaves presynaptic protein SNAP-25 (a 25 kDa synaptosomal-associated protein) and interrupts the release of acetylcholine. The type A organisms have been classified into five subtypes (A1 to A5). Among them, BoNT/A1 and BoNT/A2 cleave SNAP-25 more efficiently than that of other subtypes. Recent studies imply the clinical benefits of BoNT/A in neurological disorders. Parkinson’s disease (PD) is characterized by imbalanced cholinergic hyperactivity in the

striatum. Some reports suggest the interruption of acetylcholine release by intrastriatal injection of BoNT/A in a rat Parkinson's disease model. It is, however, not clear which subtype of BoNT/As has the greatest efficacy for treatment with PD. Therefore, we compared the effect of BoNT/A1 with that of BoNT/A2 on pathologic rotation behavior which was induced by the treatment with methamphetamine in the 6-hydroxydopamine-induced PD rat model. Intrastriatal treatment with BoNT/A1 or BoNT/A2 significantly reduced the pathologic rotation behavior in a dose-dependent manner. While the highest tested dose of BoNT/A1 (1 ng) resulted in significant reduction of the pathologic behavior, all of tested does of BoNT/A2 (0.1, 0.5 or 1 ng) did well. We next examined the localization of cleaved SNAP-25 in the BoNT/A-treated striatum by immunohistological analysis. Treatment with 0.1 ng BoNT/A1 did not change the level of cleaved SNAP-25 in the striatum compared with that of the vehicle-treated group. In contrast, treatment with 0.1 ng BoNT/A2 significantly increased the level of cleaved SNAP-25. Interestingly, SNAP-25 cleaved by BoNT/A2 was strictly localized to the striatum on the injected side although SNAP-25 cleaved by BoNT/A1 diffused contralaterally. Furthermore, treatment with BoNT/A1 caused a significant reduction in body weight, while BoNT/A2 treatment did not. Taken together, these findings suggest that BoNT/A2 is beneficial for clinical application against Parkinson's disease, compared to BoNT/A1

Title: Mithramycin A blocks the induction of the pro-apoptotic gene Trib3 and protects from cell death induced by the Parkinson's disease mimetics 6-OHDA and MPP+

Authors: *P. AIME[1], O. LEVY[2], A. V. RAO[1], L. A. GREENE[1]
[1]Pathology and Cell biology, [2]Neurol., Columbia Univ., New York, NY

Abstract: Parkinson's disease (PD) is characterized by the progressive loss of several neuronal populations, including dopaminergic neurons of the substantia nigra pars compacta (SNpc). We have reported in abstract form that the pro-death gene Trib3 is elevated in a subset of dopaminergic neurons of the SNpc of PD patients and that Trib3 is up-regulated in cellular models of PD, including neuronal PC12 cells and postnatally-derived dopaminergic ventral midbrain (VM DA) neurons treated with 6-OHDA, 1-methyl-4-phenylpyridinium (MPP+) or alpha-synuclein fibrils (aSYN). Trib3 overexpression is sufficient to induce death of neuronal PC12 cells and VM DA neurons. In cellular models of PD, Trib3 is also necessary to trigger neuronal death since Trib3 knock-down protects neuronal PC12 cells and VM DA neurons from 6-OHDA, MPP+ or aSYN and VM DA neurons from Trib3 null mice are partially protected against PD toxins. Taken together, our previous work suggests that Trib3 contributes to neuronal death in PD models. Understanding the regulation of Trib3 induction by PD-relevant stressors may identify novel pathways to target in order to reduce Trib3 levels. In the present work, we found multiple putative binding sites in the Trib3 promoter for Specificity protein 1 (Sp1) and related family members. Sp1 and its family members are zinc finger transcription factors that bind to GC-rich motifs of many promoters. Sp1 protein levels and DNA-binding activity are increased during oxidative stress. Mithramycin A (mTm) is an anti-neoplastic agent that blocks the binding of Sp1 family members to DNA and that has been shown to play a protective role against stress in different cellular models. We therefore tested the ability of mTm to block Trib3 induction and to protect in cellular models of PD. We found that mTm blocks activation of the Trib3 promoter and completely abolishes the increase of Trib3 mRNA levels induced by PD toxins in neuronal PC12 cells. We also demonstrated that mTm treatment protects VM DA neurons from cell death induced by 6-OHDA and MPP+. These data indicate that Sp1 binding sites in the Trib3 promoter are required for induction of Trib3 in cellular models of PD. Furthermore, interventions that interfere with Sp1 family binding, such as mTm, may be a potential therapeutic strategy to block Trib3 induction and arrest neuronal degeneration in Parkinson's disease.

Abstract: Glial cell line-derived neurotrophic factor (GDNF) gene therapy is a promising therapeutic approach for CNS disorders such as Parkinson's disease (PD) since it could provide a renewable source of GDNF within the brain while avoiding the need for repeated dosing. Current approaches largely rely on viral vectors to carry the gene into cells and most require direct intracranial injection. The immunogenicity of viral vectors and the invasiveness of surgical intervention are serious limitations. Thus, we are investigating the intranasal route of administration of PEGylated lysine 30-mer (PEG-CK30) DNA nanoparticles (NPs) encoding hGDNF. These NPs developed by Copernicus Therapeutics, Inc. compact single molecules of the expression plasmid and have minimal cross-sectional diameters of ~10 nm. We have shown that DNA NPs co-expressing enhanced green fluorescent protein (eGFP) and hGDNF (pUGG) successfully transfect neural cells *in vitro* and brain cells *in vivo*. The goal of this study was to assess *in vivo* transfection in brain after intranasal administration of Copernicus' hGDNF DNA NPs. GDNF ELISA was carried out on a series of rostral-caudal brain slabs 7 days post-treatment. Results showed significant increases in GDNF levels throughout the brains of rats given intranasal pGDNF relative to controls. To examine cellular transfection patterns, eGFP immunohistochemistry (IHC) was performed on brain sections from rats that received intranasal doses of pUGG NPs, naked pUGG, or saline. The number of cells expressing eGFP was significantly higher across brain regions in rats given intranasal pUGG NPs versus saline controls, with the highest number of eGFP positive cells in the midbrain. Double label IHC was also carried out for both eGFP and either rat endothelial cell antigen (RECA-1) or glial fibrillary acidic protein (GFAP). Most of the eGFP positive cells found in brain 7 days after intranasal delivery of pUGG NPs were immediately adjacent and abluminal to capillary endothelial cells staining for RECA-1. Preliminary results show a similar distribution of eGFP positive cells adjacent to capillaries enwrapped by GFAP positive astrocytic endfeet. This pattern suggests that pericytes may have been preferentially transfected after intranasal administration of these DNA NPs, consistent with distribution by the perivascular transport system. Collectively, these results confirm successful delivery and transfection of cells in rat brain after intranasal administration of Copernicus' DNA NPs, and they support the use of intranasal delivery of hGDNF NPs as a non-invasive means of gene therapy for PD and other CNS disorders.

Title: Neural restoration via loop-based reinforcement: A mechanism of therapeutic high frequency stimulation in Parkinson's disease

Authors: *S. SANTANIELLO[1], M. M. MCCARTHY[2], E. B. MONTGOMERY, Jr[3], J. T. GALE[4], N. KOPELL[2], S. V. SARMA[1]
[1] Biomedical Engineering - Institute For Computational Medicine, Johns Hopkins University, Baltimore, MD; [2]Boston Univ., Boston, MA; [3]Greenville Neuromodulation Ctr., Greenville, PA; [4]Cleveland Clin., Cleveland, OH

Abstract: Deep brain stimulation (DBS) is a clinically recognized treatment for movement disorders in Parkinson's disease but its mechanisms remain elusive. Two questions have hampered our understanding of the mechanisms of DBS so far: (1) Why is DBS therapeutic only when the frequency of stimulation belongs to a specific high range (i.e., 130-180 Hz)? (2) What is the fundamental mechanism that keeps high frequency DBS therapeutic even if the stimulation target is moved across distinct (and physiologically different) structures in the brain? To answer these questions, we developed a detailed computational model (880 single-compartment neurons) of the direct pathway in the motor loop, including the motor cortex, ventro-lateral thalamus, striatum, and internal globus pallidus, and we validated the neuronal activity of each structure with single unit recordings from non-human primates and rats, both in normal and parkinsonian conditions. Then, we used the model to study the effects of several DBS settings

(i.e., DBS frequency ranged from 20Hz to 180Hz, both regular and irregular DBS pattern) via numerical simulations. Regarding to 1), we show that, differently from what is currently hypothesized, the therapeutic effects of DBS do not entirely stem from local changes of the neuronal activity in the stimulation target but they also depend, in part, on the fact that the motor loop is a closed reentrant system. Due to the closed-loop nature, the perturbations induced by consecutive DBS pulses may travel along the system both forward and backward through multiple pathways, they can rendezvous, and positively overlap if the pulses are constantly spaced (i.e., DBS is regular) and close enough one to one another (i.e., DBS is high frequency). This suggests that (i) DBS globally impacts the entire loop, (ii) the therapeutic merit of clinically-used DBS settings depends on the anatomical properties of the treated system, and (iii) DBS in different individuals may require slightly different settings, which is consistent with clinical practice. Regarding to 2), we show that the rendezvous of consecutive DBS-elicited perturbations occurs in the striatum and may determine a dominant discharge pattern that percolates through the basal ganglia, projects towards the thalamus, and restores the normal function of the thalamo-cortical sub-system, which is primarily involved in the selective dis-inhibition of motor commands. Because the rendezvous exploits the closed-loop nature of the system and the fact that perturbations move both forward and backward, we show that the therapeutic effects may be preserved even though the entry point of the DBS input is moved along the loop.

Title: Effect of molecular tweezers treatment in a transgenic mouse model of amyotrophic lateral sclerosis

Authors: *C. V. FONTANILLA, B. CHAN, R. ROSALES, M. CHATTOPADHYAY, T. T. VU, A. ATTAR, J. S. VALENTINE, M. H. WIEDAU-PAZOS, G. BITAN

Abstract: Amyotrophic lateral sclerosis (ALS) is an incurable, neurodegenerative disease characterized by progressive motor neuron loss, occurring in both sporadic and familial forms and leading to paralysis and ultimately death within 2–5 years after symptom onset. Currently, there are no effective treatments for ALS. Abnormal protein aggregation is thought to play an important role in the underlying pathogenic mechanisms of ALS, yet whether protein aggregation actually causes motor neuron death is an open question. The objective of this study was to examine whether prevention of protein aggregation leads to improvement in disease symptoms of ALS or lifespan. In this context, the best-characterized system has been the assembly of Cu/Zn-superoxide dismutase 1 (SOD1) into neurotoxic oligomers and aggregates. The current study investigated the effect of the "molecular tweezer" (MT), CLR01 – a broad-spectrum, "process-specific" inhibitor of amyloidogenic proteins' self-assembly and toxicity, in a transgenic mouse model. Initial data show that CLR01 inhibits both wild type and mutant SOD1 aggregation, dissociates pre-formed SOD1 fibrils and attenuates cell death in a neuronal cell line expressing the SOD1-G93A variant. Based on these data, we evaluated the effect of CLR01 administration on symptom onset, survival, limb muscle strength, and pulmonary function in male and female SOD1-G93A mice in a gender-balanced, investigator-blinded study. Daily treatment with CLR01 (0.5 or 5 mg/kg) from 50 days of age until death did not extend lifespan significantly in CLR01-treated mice as compared to saline-treated animals, regardless of sex. Around the time of onset, differences appeared among the three treatment groups, yet they disappeared after several days and overall, the differences in limb muscle strength, as assessed by wire test and Rotarod, or pulmonary function, as measured using unrestrained, whole-body plethysmography, were not statistically significant. The data suggest that although CLR01 treatment did not result in overall improvement in the animals over time, the treatment may have an effect on the onset of disease rather than its progression. Title: Pur alpha: A potential therapy for ALS due to the C9ORF72 expanded repeat

Authors: *E. W. GODFREY[1], J. ORIANS[2], E. M. JOHNSON[3], D. C. DANIEL[3]
[2]Pathology and Anat., [3]Microbiology and Mol. Cell Biol., [1]Eastern Virginia Med. Sch., Norfolk, VA

Abstract: Amyotrophic lateral sclerosis (ALS) is a neurodegenerative disease that results in paralysis due to loss of motor neurons in the cortex and spinal cord. The most common genetic cause of ALS is an expanded hexanucleotide repeat (GGGGCC) in a non-coding region of the C9ORF72 gene, which encodes a protein involved in endocytosis and autophagy. Patients with this mutation have hundreds to thousands of copies of this repeat sequence. Repeat sequence RNA aggregates in nuclear foci that can be detected by fluorescent *in situ* hybridization (FISH). The mechanism by which the C9ORF72 repeat causes ALS is unknown, but a prominent hypothesis is that the repeat sequence in the RNA sequesters RNA-binding proteins. Disturbing the content of RNA-binding proteins in the cell can affect transcription, translation, and splicing of many mRNAs, resulting in expression of altered RNAs and reduction in RNA content. We hypothesize that overexpression of Pur-alpha, an abundant RNA- and DNA-binding protein that binds to GGGGCC repeats, or a peptide with a generic Pur family repeat may be therapeutic in C9ORF72 ALS. Overexpression of Pur alpha in *Drosophila* or neuronal cells with 30 copies of the repeat resulted in a reduction in neurodegeneration (Xu et al., 2012). We are using cells from C9ORF72 ALS patients to test the effects of Pur alpha on cellular pathology. We labeled autophagosomes in virally transformed lymphocytes from patients and controls with an antibody to p62, a protein that binds to the autophagosome membrane. These organelles are involved in removal of proteins that misfold and aggregate in the cytoplasm of neurons in ALS. Lymphoblasts from C9ORF72 patients had significantly more p62-labeled organelles than control cells. Transfection of Pur alpha or treatment of cells with the peptide resulted in a significant reduction in p62-positive puncta in C9ORF72 lymphoblasts, but did not reduce the amount of p62 protein in cells. These results suggest that Pur proteins and the peptide may reduce autophagy and ameliorate cellular pathology in this form of ALS. Additional experiments are underway to test the efficacy of the peptide in reducing cellular pathology in patient fibroblasts and in motor neurons differentiated from iPS cells of C9ORF72 ALS patients.

Title: Role of the ALS spinal cord environment on human astrocyte engraftment and differentiation

Authors: *A. M. HAIDET-PHILLIPS[1], A. DORESWAMY[1], X. P. TANG[1], S. K. GROSS[1], J. T. CAMPANELLI[2], N. J. MARAGAKIS[1]

Abstract: Amyotrophic Lateral Sclerosis (ALS) is a neurodegenerative disease characterized by the death of upper and lower motor neurons. Recent studies have highlighted a role for not only neurons, but also glia in disease pathogenesis. Therefore, strategies which replace or supplement the diseased astrocyte population with healthy astrocytes may protect against motor neuron degeneration. Our studies have sought to evaluate astrocyte replacement using glial-restricted progenitors (GRPs) which are lineage-restricted precursors capable of differentiating to astrocytes after transplantation. We have previously demonstrated that rodent GRPs can provide therapeutic efficacy in the ALS rat model. However, in all of our previous studies, the GRPs were transplanted into the diseased ALS spinal cord environment. The goal of our current study was to evaluate how transplantation to the diseased ALS spinal cord versus a healthy, wild-type spinal cord may affect the engraftment and differentiation of human GRPs. Human fetal-derived GRPs were transplanted into the spinal cord of either the ALS SOD1 G93A mouse model (n=19) or wild-type littermate mice (n=17). Mice were sacrificed for analysis at either the onset of ALS (90 days of age) or at the endstage of disease (>125 days of age). Immunohistochemical analyses

were used to quantify survival, migration, proliferation, and differentiation of the transplanted GRPs. No gross differences were found for any of these measures; however, proliferation of the human GRPs was slightly enhanced in the ALS spinal cord versus transplantation into the wild-type spinal cord. Between 80-90% of the transplanted GRPs differentiated into glial fibrillary acidic protein (GFAP)+ astrocytes with no differences found after transplantation to the ALS spinal cord versus the wild-type spinal cord. NanoString® gene profiling was used to analyze human-specific gene expression from the transplanted human cells in the mouse spinal cord. A panel of genes expressed by astrocytes as well as genes expressed by other cell lineages present in the central nervous system was assessed. No major differences were found in gene expression from the engrafted cells in the ALS spinal cord versus the wild-type spinal cord. Overall, these results suggest that the diseased ALS spinal cord environment does not inherently change the engraftment and differentiation of human GRPs. These findings are of interest given that human GRPs are currently in clinical development for spinal cord transplantation into ALS patients.

Title: Amyotrophic lateral sclerosis affects the extracellular matrix: detection of its components could serve as a disease marker

Authors: P. JENDELOVA[1], *S. FOROSTYAK[1,2], J. C. F. KWOK[3], A. HOMOLA, PhD[2], J. FAWCETT[3], E. SYKOVA[1,2]
[1]Inst. of Exptl. Med. ASCR, Prague, Czech Republic; [2]Neurosci., Charles Univ. in Prague, 2nd Fac. of Med., Prague, Czech Republic; [3]Dept. of Clin. Neurosciences, John van Geest Ctr. for Brain Repair (BRC), Univ. of Cambridge, Cambridge, United Kingdom

Abstract: Aims: 1) To study changes in the spinal extracellular matrix (ECM), particularly the perineuronal nets (PNNs), of transgenic rats harboring the superoxide dismutase 1 (SOD1) gene, during the course of ALS and after the application of human stem cells (SCs); 2) To evaluate the expression of ECM molecules in the cerebrospinal fluid (CSF) of rats and human patients (ALS and non-ALS). SOD1G93A rats were used as an *in vivo* model of ALS. Motor function of the rats was tested behaviorally during the whole course of the disease. Immunohistochemistry was used to visualize spinal PNNs and their components and to study the fate of the delivered human SCs. Western Blot was used to analyze spinal cord and CSF PNNs components at the presymptomatic, symptomatic and terminal stages of the disease in transgenic rats and wild-type (WT) littermates. The mRNA expression of PNN compounds were analyzed using RT-qPCR. Spinal cord tissues were used for *in situ* hybridization with several DIG-labeled chondroitin sulphate proteoglycans (CSPGs). Human CSF and serum were used for the evaluation of CSPGs content. SOD1G93A rats have an abnormal PNN structure around their spinal motoneurons, which appears with the onset of initial disease symptoms; this is indicated by disorganized Wisteria floribunda agglutinin staining and different immunohistological and western blot profiles of CSPGs. The spinal cord of SOD1 animals had a different expression of CSPG genes (Versican, Hapln1, Neurocan and Tenascin-R), whereas Aggrecan and Brevican profiles remained unchanged. The application of SCs preserved PNN structure and resulted in significantly better survival of motoneurons accompanied with higher motor activity. SC-treated rats lived significantly longer compared to sham-treated littermates. We found that CSPGs could be detected in the CSF of healthy and SOD1-rats, however at the symptomatic stage transgenic rats had a significantly higher amount of spinal and CSF CSPGs compared to the presymptomatic or age-related WT animals. At the terminal stage animals lost considerably more CSPGs in the spinal cord. We evaluated CSPGs in the CSF of patients with a confirmed diagnosis of ALS and non-ALS controls. Our results confirmed that CSPGs are present in the human CSF. We can conclude that the ECM is involved in the pathogenesis of ALS in SOD1-transgenic rat models of the disease. Detection of CSPGs in the CSF could potentially serve as biological markers for the diagnosis, assessment of treatment efficacy and prognosis of ALS. The administration of SCs safeguards PNNs and remodels the recipients' pattern of CSPGs gene expression. Human CSF contains CSPGs and some of them could serve as a biological marker of ALS.

Title: Preservation of forelimb function by UPF1 gene therapy: Potential regulation of UPF1 in TDP-43 toxicity

Authors: K. L. JACKSON[1], R. D. DAYTON[1], S. E. LOPEZ[1], E. A. ORCHARD[1], L. E. MAQUAT[2], S. JU[3], D. RINGE[4], G. A. PETSKO[5], *R. L. KLEIN[1]

Abstract: Nonsense mediated mRNA decay is an RNA surveillance mechanism that requires upframeshift protein one (UPF1). We demonstrate here that UPF1 expression exerts protective effects in a rat paralysis model based transactive response DNA binding protein 43 kDa (TDP-43). TDP-43 is an RNA binding protein involved in the processing of RNA and DNA. In amyotrophic lateral sclerosis (ALS), TDP-43 abnormally aggregates into pathological lesions. Here we use an adeno-associated virus vector (AAV9) to express TDP-43 throughout the spinal cord of rats to induce reproducible paralysis of the limbs mimicking paralysis in ALS. We selected UPF1 for therapeutic testing based on results obtained from a genetic screen of yeast. The overexpression of human TDP-43 or UPF1 in the spinal cord was titrated to less than twofold the level of their endogenous rat counterpart. AAV9 UPF1 clearly improved overall motor scores in rats also expressing TDP-43. The gene therapy effect of UPF1 was specific and reproducible when compared to groups receiving TDP-43 combined with either an empty vector or a green fluorescent protein (GFP) vector, which controlled for vector dose or foreign transgene. The UPF1 treatment was relevant in that it maintained forelimb motor function in rats that would otherwise become quadriplegic. We observed a reduction in UPF1 expression in the spinal cord by TDP-43, suggesting that UPF1 dysfunction may have a role in TDP-43's toxic action. This work helps validate UPF1 as a novel therapeutic target for ALS and other TDP-43-related diseases and hints UPF1 and NMD involvement in underlying disease mechanisms.

Title: Cell therapy in a murine model of amiotrophic lateral sclerosis: Functional and histological approach

Authors: ***I. B. PEREIRA**, F. GUBERT, A. DECOTELLI, M. SANTIAGO, R. MENDEZ-OTERO
Univ. Federal Do Rio De Janeiro, Rio De Janeiro, Brazil

Abstract: Amyotrophic lateral sclerosis is a fatal neurodegenerative disorder which affects motorneurons primarily leading to axonal retraction and cell death. The symptoms are tremors, spasms, loss of muscular strength and tonus until total loss of movement.Patient death occurs from 3 to 5 years after diagnosis. About 90% of the cases are sporadic, with unknown causes, and 10% have a genetic origin. In this work, we used the animal model of the disease and tested a possible therapy using bone-marrow mononuclear cells injected intravenously and/or intramuscular. These animals were evaluated in order to assess their motor capacity and their survival. We performed histological analyses to quantify the number of motorneurons, microglia and the denervation of motor plates one week after the last injection or at the end stage of the disease in order to evaluate if the therapy had any effect on these parameters. The cells remained on the injection site at least until seven days after the procedure, when a mild injury was made on

the target muscle. The therapies were able to delay the motor deficit with no effect on survival. The protocol combining on intravenously and intramuscular injections was able to reduce the motor plate denervation and microglial cell numbers, although it did not had any effect on neuronal survival. We concluded that the injection of bone-marrow mononuclear cells following the protocols studied was capable to reduce motor plate denervation, reduce microglial cell numbers and delay the motor deficit in this model. However, more studies need to be conducted in order to investigate whether the intravenous injection is required for a better result of the treatment.

Title: iPSC-derived neural stem cells act via kinase inhibition to exert neuroprotective effects in SMARD1

Authors: C. SIMONE[1], M. NIZZARDO[1], F. RIZZO[1], M. RUGGIERI[1], G. RIBOLDI[1], S. SALANI[1], M. BUCCHIA[1], P. RINCHETTI[1], F. PORRO[1], N. BRESOLIN[1], G. P. COMI[1], *S. CORTI[2]
[1]Dept. of Physiopathology and Transplant, [2]Univ. of Milan, Milan, Italy

Abstract: Currently there is no cure for spinal muscular atrophy with respiratory distress type 1 (SMARD1), which is a hereditary motor neuron disease caused by mutations in the IGHMBP2 gene. The aim of this study was to demonstrate that neural stem cells (NSCs) derived from human induced pluripotent stem cells (iPSCs) have therapeutic potential in the context of SMARD1. Using human skin fibroblasts, iPSC cell lines were derived with a non-viral non integrating method, based on the expression of reprogramming factors with episomal vectors. The iPSCs were differentiated based on a protocol to stimulate neural stem cell and motor neuronal fate. The phenotype of these cells was analyzed by morphological, gene expression, and protein analysis. Finally, nmd mice (an animal model of SMARD1) were injected with iPSC-

purified NSCs by intraspinal cord injection. NSCs from iPSCs are self-renewing, multipotent, and can differentiate *in vitro* into the three neuroectodermal lineages, as well as into motor neurons. We show that, upon transplantation, NSCs can appropriately engraft and differentiate into the spinal cord of SMARD1 animals and, thus, ameliorate their disease phenotype by protecting their endogenous motor neurons. The effect of NSCs in the context of human disease was evaluated using human SMARD1-iPSCs motor neurons with significantly reduced survival and axon length. Notably, the disease features were ameliorated when they were co-cultured with NSCs. This observation is attributed to the production of neurotrophic factors and their dual inhibition of GSK-3 and HGK kinases. Our data support the role of iPSCs as a SMARD1 disease model and potential for cell-mediated therapies in motor neuron disorders using pluripotent stem cells.

Title: Restoring function to paralysed muscles by transplanting optogenetically-active embryonic stem cell-derived motor neurons in mice

Authors: *J. BRYSON[1], C. BARCELLOS MACHADO[3], I. LIEBERAM[3], L. GREENSMITH[2]
[1]Sobell Dept. of Motor Neurosci. and Movement Disorders, [2]Sobell Dept. & MRC Ctr. for Neuromuscular Dis., UCL, Inst. of Neurol., London, United Kingdom; [3]MRC Ctr. for Developmental Neurobio., King's Col. London, London, United Kingdom

Abstract: Traumatic brain and spinal cord injury (SCI), as well as diseases that cause degeneration of motor neurons, such as amyotrophic lateral sclerosis (ALS), can block the transmission of motor signals from the CNS to skeletal muscles resulting in paralysis. Currently,

strategies to repair neurological damage or halt neurodegenerative diseases are extremely limited and any muscle paralysis that ensues from these disorders is typically permanent. We have recently developed a novel strategy that employed a synthesis of stem cell-derived neural tissue replacement and optogenetics, which results in restoration of controllable function to muscles that had been paralyzed (Bryson, *et al*. 2014). Following ligation of the sciatic nerve in mice, to model permanent muscle denervation, we transplanted stem cell derived motor neurons into specific nerve branches, distal to the injury site. These motor neurons had been modified to express the light-sensitive ion channel, channelrhodopsin-2 (ChR2) to enable optogenetic control of their activity, as well as glial derived neurotrophic factor (Gdnf) to promote their survival *in vivo*. The transplanted motor neurons not only robustly reinnervated the muscles that lie distally along the specific nerve branches, but, importantly, upon optical activation with a blue LED light-source, these neurons were capable of initiating finely controllable muscle contraction. We are currently developing this approach to enable long-term *in vivo* stimulation, using an implantable fiber-optic nerve cuff to chronically activate the muscle in awake mice and to promote maturation of neuromuscular junctions (NMJs), thereby preventing muscle atrophy. A similar approach has been shown to be effective in rats following viral expression of ChR2 in motor neurons (Towne, *et al*. 2013). Additionally, we are also investigating whether these modified motor neurons are capable of surviving and reinnervating muscles when transplanted into post-symptom onset $SOD1^{G93A}$ mice, which model ALS. These investigations are essential to advance the translational potential of this novel strategy to restore function to paralyzed muscles.

Abstract: Amyotrophic lateral sclerosis (ALS) is a devastating neurodegenerative disease of the motor neuron system. Apart from riluzole, an anti-glutamatergic drug which prolongs survival of ALS patients up to 3 months, no treatment is available so far. Endocannabinoids like 2-arachidonoylglycerol (2-AG) induce neuroprotective and anti-inflammatory effects through cannabinoid receptor (CB) signaling. In ALS, 2-AG levels increase and CB_2 expression increases on activated microglia suggesting that these disease-associated changes might counteract the occurring neurodegeneration. Therefore, enhancing the disease-related 2-AG increase by pharmacological inhibition of the 2-AG-degrading enzyme monoacylglycerol lipase (MAGL) might be desirable for the treatment of ALS. In addition, inhibition of 2-AG degradation by MAGL is linked to decreases in arachidonic acid and prostaglandins, possibly leading to further benefits. In our study, we pharmacologically inhibited MAGL by the highly selective MAGL inhibitor KML29 in the low-copy $SOD1^{G93A}$ (B6SJL-Tg(SOD1*G93A)^{dl}1Gur/J) mouse model of ALS. For this purpose, we orally treated male and female mice with 10 mg/kg KML29 three times a week from postnatal day 150 until disease end stage. Furthermore, we monitored running wheel activity from postnatal day 140 and body weight from postnatal day. Post mortem, we investigated the endocannabinoid system and the inflammation by quantifying the expression of CB_1 and CB_2, the endocannabinoid-degrading enzymes MAGL and fatty acid amide hydrolase (FAAH), cytokines like tumor necrosis factor α (TNFα) and interleukin 6 (IL6) by qPCR. We also analyzed the principal endocannabinoid signaling molecules 2-AG and anandamide as well as the metabolites arachidonic acid and prostaglandins by liquid chromatography coupled with tandem mass spectrometry (LC-MS/MS). In female $SOD1^{G93A}$ mice, KML29 delayed the disease onset by 35 days, the occurrence of first pareses by 49.5 days and the disease end stage by 33 days. In male mice, the effect of KML29 on onset, first pareses and end stage was lower, producing a delay ranging from 16 to 18 days. Furthermore, KML29 had a beneficial effect on the disease-related body weight reduction. In addition, we could show that KML29 increased 2-AG levels particularly in the spinal cord, the diseased tissue in ALS. In summary, our therapeutic application of KML29 in the $SOD1^{G93A}$ mouse model evidences MAGL as a valuable target for the treatment of ALS.

Title: Methyl pyruvate rescues mitochondrial degeneration by sigma-1 receptor mutation in amyotrophic lateral sclerosis

Authors: *K. FUKUNAGA, H. TAGASHIRA, Y. SHINODA
Tohoku Univ. Grad Sch. Pharm Sci., Sendai, Japan

Abstract: [Objective] Recently, sigma-1 receptor mutation (Sig-1R^{E102Q}) was discovered in gene of amyotrophic lateral sclerosis (ALS) patient. The Sig-1R^{E102Q} aggravated ER stress-induced motor neuronal cell death (Ann Neurol 2011;70:913). We here addressed whether treatment with methyl pyruvate, a mitochondrial substrate rescues the mitochondrial damages in neuro2A cells overexpressed mutant of Sig-1R^{E102Q}. **[Methods]** Neuro2A cells overexpressed Sig-1R^{E102Q} were treated with methyl pyruvate for 48 hrs and were assessed aggregation of Sig-1R^{E102Q} and cytoplasmic accumulation of TDP-43. **[Results]** Since σ_1R is critical for mitochondrial Ca^{2+} transport through IP_3 receptor and mitochondrial ATP production (Shioda and Fukunaga: J Biol Chem 2012;287:23318), overexpression of Sig-1R^{E102Q} decreased mitochondrial Ca^{2+} transport and ATP production. Dissociation of Sig-1R^{E102Q} from IP_3 receptor promoted the accumulation and aggregation of Sig-1R^{E102Q} in neuronal cytoplasm. We hypothesized that the impaired mitochondrial ATP production by the mutation causes neuronal cytoplasmic accumulation and inclusions of TDP-43. The methyl pyruvate treatment with 5 μM improved the ATP production and cytoplasmic accumulation of TDP-43 under ER stress condition. The methyl pyruvate treatment also prevented ER stress-induced apoptosis. **[Conclusion]** The decreased ATP production by Sig-1R^{E102Q} mutation is causative for the cytoplasmic accumulation and inclusions of TDP-43 under ER stress condition. The methyl pyruvate rescues the mitochondrial damages induced by Sig-1R^{E102Q}. **[Acknowledgements]** This work was supported by KAKENHI 24659024 (KF).

Title: Microglia migration and interactions with dendrimer in brain in the presence of neuroinflammation

Authors: *F. ZHANG[1,2], E. NANCE[2,3], Y. ALNASSER[3], K. RANGARAMANUJAM[2], S. KANNAN[2,3]
[1]The Johns Hopkins Univ., Baltimore, MD; [2]Ctr. for Nanomedicine, Dept. of Ophthalmology, [3]Dept. of Anesthesiol. and Critical Care Med., Johns Hopkins Med. Institutions, Baltimore, MD

Abstract: Introduction: Neuroinflammation mediated by activated microglia has been implicated to play a crucial role in the pathology of neurodevelopmental disorders such as cerebral palsy (CP). There is no effective cure for cerebral palsy currently. We have previously reported hydroxyl terminated PAMAM dendrimer can target activated microglia in a rabbit model of cerebral palsy. Understanding the dynamics of microglia in the presence of CP and their interactions with dendrimer can help improve and sustain the efficacy of dendrimer-based nano-therapeutics. The objective of this study is to understand microglia function in a rabbit model of CP by evaluating their morphology change, migration pattern and their dendrimer uptake, through an *ex vivo* study of rabbit brain slices. **Materials and Methods:** We established brain slice culture platform from postnatal day 1 (PND1) rabbits to analyze microglial migration and morphology. Live imaging technique was then used for observing the morphology, migration and dendrimer interaction. We also quantitatively measured the microglial cells migration and interaction with dendrimer using MATLAB and Imaris Software. **Results and Discussion:** The measurement of LDH level and microglial surface to volume ratio indicated brain slices from healthy/CP neonatal rabbit have good viability and retained their physiologically activated/resting state in the first day of incubation, when all other experiments were conducted. Our study showed the microglia cells from the CP brain slices have higher mean square displacement <MSD> when comparing with the microglia from healthy brain slices, indicating the impairment of their normal function that can be related to surveillance under in the presence of brain injury. In the dendrimer uptake assessment, activated microglia cells from CP brain slices show not only a faster uptake during the first 4 hours, but also 2.5 fold higher uptakes after (at 1 hour) and 4 fold higher uptake (at 4, 12 hours) after exposure to dendrimer,

when comparing with those from healthy controls. These results suggest pro-inflammatory or 'activated' microglia in the CP brain has an increased ability of phagocytizing xenobiotics. **Figure 1.** (A) Mean square displacement <MSD> of microglia cells (B) Representative trajectories. **Conclusions:** This study showed that pro-inflammatory or 'activated' microglia may have an impairment of their normal function that can be related to surveillance. These results may also explain why dendrimers show selective uptake and retain *in vivo*, delivering drugs to the activated microglia cells, producing dramatic motor function improvements.

Title: AAV-based GLT1 overexpression in the SOD1G93A mouse cervical spinal cord does not protect respiratory phrenic motor neurons, preserve histological or functional diaphragm innervation, or extend disease phenotype

Authors: *M. URBAN[1], K. LI[1], T. J. HALA[1], D. J. POULSEN[2], M. C. WRIGHT[3], A. LEPORE[1]
[1]Thomas Jefferson University, Farber Inst. For, Philadelphia, PA; [2]Dept. of Biomed. and Pharmceutical Sci., Univ. of Montana, Missoula, MT; [3]Dept. of Biol., Arcadia Univ., Glenside, PA

Abstract: Amyotrophic lateral sclerosis (ALS) is characterized by relatively rapid degeneration of both upper and lower motor neurons, with death normally occurring 2-5 years following diagnosis primarily due to respiratory paralysis resulting from phrenic motor neuron (PhMN) loss and consequent diaphragm denervation. In ALS, cellular abnormalities are not limited to MNs. For example, decreased levels and aberrant functioning of the major central nervous system (CNS) glutamate transporter, GLT1, occur in spinal cord and motor cortex astrocytes of both humans with ALS and in SOD1G93A rodents, a widely studied ALS animal model. This results in dysregulation of extracellular glutamate homeostasis and consequent glutamate

excitotoxicity, a primary mechanism responsible for MN loss in ALS animal models and in the human disease. Given these observations of GLT1 dysfunction in areas of MN loss, as well as the importance of testing therapeutic strategies for preserving PhMNs in ALS, we evaluated intraspinal delivery of an adeno-associated virus type 8 (AAV8)-Gfa2 vector to the cervical spinal cord ventral horn of SOD1G93A ALS mice for focally restoring intraspinal GLT1 expression. AAV8 was specifically injected into the ventral horn bilaterally throughout the cervical enlargement at 90 days of age, a clinically-relevant time point coinciding with phenotypic/symptomatic disease onset. Intraspinal delivery of AAV8-Gfa2-GLT1 resulted in robust transduction primarily of GFAP+ astrocytes that persisted until disease endstage, as well as a 2-3-fold increase in total intraspinal GLT1 protein expression in the ventral horn. Despite this robust level of astrocyte transduction and GLT1 elevation, GLT1 overexpression did not protect PhMNs, preserve histological PhMN innervation of the diaphragm NMJ, or prevent decline in diaphragmatic respiratory function as assessed by phrenic nerve-diaphragm compound muscle action potential (CMAP) recordings compared to control AAV8-Gfa2-eGFP injected mice. In addition, AAV-based increase in GLT1 expression in the cervical spinal cord did not delay forelimb disease onset, extend disease duration (i.e. time from either forelimb or hindlimb disease onsets to endstage) or prolong overall animal survival. These findings suggest that focal restoration of GLT1 expression in astrocytes of the cervical spinal cord using AAV delivery is not an effective therapy for ALS.

Title: Liposome-encapsulated H-ferritin improves survival in a SOD1 mutant mouse model of amyotrophic lateral sclerosis

Authors: *A. M. SNYDER[1], A. B. MADHANKUMAR[1], E. B. NEELY[1], E. RIZK[1], O. M. HESS[3], Z. SIMMONS[2], J. R. CONNOR[1]

[1]Neurosurgery, MC H110, [2]Neurol., Penn State Univ. Coll Med., Hershey, PA; [3]Mechanicsburg Area High Sch., Mechanicsburg, PA

Abstract: The misregulation of iron and subsequent oxidative stress are consistent features shared between humans with Amyotrophic Lateral Sclerosis (ALS) and in animal models of the disease. The iron sequestration protein H-ferritin has ferroxidase activity and limits the toxic potential of iron, making it an attractive therapy to pursue in ALS. One of the disadvantages of most systemically-delivered treatments for neurological diseases is that they exert their biological effects not only at their target sites but also at peripheral tissue and cells. This often results in dilution of the agent below therapeutic levels to the target tissue; a way to increase efficacy and reduce the amount of agent administered is to utilize liposomal drug carriers. The objective of this work is to determine if infusion of liposome-encapsulated iron-poor H-ferritin has neurorescue properties in a murine model of ALS. Two types of liposomes were used: those that were not directed to any specific cell type and those that were directed to microglia by the presence of lipopolysaccharide (LPS). At 90 days of age, mice with the SOD1G93A mutation underwent surgery allow for continuous infusion of liposome-encapsulated H-ferritin into the lateral ventricle. Disease onset was assessed by performance on the rotarod apparatus, and endpoint was determined by the inability of the animal to right itself. A significant impact on lifespan occurred in mice treated with H-ferritin encapsulated by non-targeted liposomes, resulting in a 10.5 day extension of survival as compared to untreated SOD1G93A mice (median values). Specific delivery of H-ferritin to microglia was of limited benefit in extending lifespan. A plausible explanation for this outcome is over-stimulation of microglia by accessing them through the TL4 receptor. Indeed, histological examination of lumbar spinal cord sections indicated less extensive microglial activation at end-stage in the group of mice treated with non-targeted liposomes carrying H-ferritin as compared to the group of animals treated with the LPS-directed liposomes. Furthermore, the motor neurons that remained at end-state in the non-targeted liposomal group had thick, extensively branched projections: features not seen in the LPS-targeted group. Our intervention in the animal model is of particular relevance to the clinical population because our intervention occurs at the peri-symptomatic stage of the disease; this would correlate to the time in which human patients would begin to notice symptoms and seek treatment in the clinic. Therefore, our therapy may be of greater clinical benefit than those compounds tested while animals are asymptomatic.

Title: Post-mortem assessment of potential ALS biological predictors: An analysis of 51 patient autopsies

Authors: *G. COAN[1], J. GLASS[2], C. S. MITCHELL[1]
[1]Georgia Inst. of Technol., Atlanta, GA; [2]Emory Univ., Atlanta, GA

Abstract: In an effort to identify both biological predictors for the onset and progression of Amyotrophic Lateral Sclerosis (ALS) as well its clinically relevant cellular underpinnings, we perform a retrospective meta-analysis of 51 autopsies conducted on patients with a confirmed diagnosis of ALS. All autopsies were performed at Emory University Hospital. Both the Internal Review Boards of Georgia Institute of Technology and Emory University approved this study. The analysis was focused on 71 distinct parameters, ranging in nature from the temporal (patient survival past the onset of the first symptom of ALS, survival past the date of ALS diagnosis, ALS symptom onset age, etc.), to the microscopic (severity of loss of neurons in a variety of regions, findings of numerous immunohistochemical tests, severity of loss of Purkinje cells, cytoplasmic accumulation of TDP-43, etc.), to the gross anatomical (localized atrophy of the brain and spinal cord, occlusions, etc.). Numerical scales were developed for the classification of the non-quantitative parameters, such as the severity of the loss of neurons in a given region of the brain. A cross-correlational analysis was performed in order to identify and prioritize possible relationships among assessed measures and immunohistochemistry test outcomes. A number of unique and potentially insightful relationships were identified that could be of potential future research interest.

Abstract: Abstract Mutations in two ubiquitously expressed nucleic-acid binding proteins, TDP-43 (TAR-DNA binding protein-43 KDa) and FUS/TLS (fused in sarcoma/translocated in liposarcoma), cause amyotrophic lateral sclerosis (ALS) and frontotemporal dementia (FTD). Abnormal aggregates of these two proteins are present in inherited and sporadic ALS, FTD, and other neurodegenerative diseases, independent of mutations in either gene. We show here that broad expression within the nervous system of wild type or either of two ALS-linked mutants of human FUS/TLS produces progressive motor phenotypes accompanied by characteristic ALS-like pathology. FUS/TLS levels are demonstrated to be autoregulated, as expression of wild type or ALS-linked mutants of human FUS/TLS downregulates endogenous mouse FUS/TLS expression at both mRNA and protein levels. A modest increase in expression of FUS/TLS achieved by saturating the autoregulatory mechanism in homozygote or double heterozygote transgenic mice produces rapidly progressive neurological phenotypes and dose-dependent lethality. Increased expression of FUS/TLS inhibits autophagy and causes splicing defects and reduction of long pre-mRNAs similar to the alteration observed in knockdown of FUS/TLS. Genome-wide expression analysis reveals mis-regulation of genes involved in ALS pathogenesis. Taken together, our results demonstrate that (1) mice expressing FUS/TLS develop progressive motor deficits and early mortality, (2) a surprisingly small increase in increased expression of wild type FUS/TLS sharply accelerate neurodegeneration, providing a basis for FUS/TLS involvement in pathogenesis in the absence of mutation, and (3) disturbance in both protein homeostasis and RNA processing contribute to FUS/TLS-mediated toxicity.

Title: H63D HFE modifies disease pathophysiology in animal models of amyotrophic lateral sclerosis

Authors: *W. NANDAR[1], E. B. NEELY[1], Z. SIMMONS[2], J. R. CONNOR[1]
[1]Dept. of Neurosurg., [2]Dept. of Neurol., The Pennsylvania State University, M. S. Hershey Med. Ctr., Hershey, PA

Abstract: The H63D HFE gene variant is present in as many as 30% of individuals with amyotrophic lateral sclerosis (ALS). H63D HFE is associated with disease processes implicated in ALS such as iron dyshomeostasis and oxidative stress. Thus, H63D HFE is proposed to be a genetic modifier for the risk of ALS. To determine how H63D HFE impacts ALS pathogenesis, we generated a double transgenic mouse line (SOD1/H67D) carrying the H67D HFE (homologue of human H63D) and SOD1(G93A) mutations. The double transgenic mice have shorter survival and accelerated disease progression. To determine mechanisms underlying accelerated disease observed in double transgenic mice, we examined parameters in the lumbar spinal cord of double transgenic mice at 90 days (presymptomatic), 110 days (symptomatic) and end-stage. Transferrin receptor and L-ferritin expression, both indicators of iron status, were altered in double transgenic and SOD1 mice starting at 90 days, indicating iron dyshomeostasis in these mice. However, double transgenic mice had higher L-ferritin expression than SOD1 mice suggesting higher iron in double transgenic mice. In addition to increased L-ferritin, double transgenic mice exhibited increased Iba-1 immunoreactivity and caspase-3 levels, indicating

increased microglial activation. Although both SOD1 and double transgenic mice had increased GFAP expression, the magnitude of the increase was higher in double transgenic mice at 110 days, suggesting increased gliosis in these mice. Increased hemeoxygeanse-1 and decreased nuclear factor E2-related factor 2 levels in double transgenic mice strongly suggest the accelerated disease process could be associated with increased oxidative stress. There was no evidence of TDP-3 mislocalization to the cytoplasm in double transgenic mice. However, there was evidence suggesting neurofilament disruption, which has been reported in ALS. Our findings indicate H63D HFE modifies ALS pathophysiology via pathways involving oxidative stress, gliosis and disruption of cellular function. Thus, we hypothesize that H63D HFE increases the risk of ALS by promoting the convergence of disease processes implicated in ALS.

Title: A meta-analysis of rotarod experimental protocols in the G93A SOD1 transgenic ALS mouse

Authors: *S. PFOHL[1], M. HALICEK[2], C. S. MITCHELL[3]
[1]Georiga Inst. of Technol., Atlanta, GA; [3]Biomed. Engin., [2]Georgia Inst. of Technol., Atlanta, GA

Abstract: The rotarod is a frequently used tool for the evaluation of disease progression in the G93A superoxide dismutase-1 (SOD1) transgenic mouse model of Amyotrophic Lateral Sclerosis (ALS). The methods employed by researchers in the field are not homogenous, which makes it difficult to directly compare results from different studies. The ability to compare ALS transgenic mouse studies, including cellular mechanistic studies and assessments of potential ALS treatment, is critical to forward progress in the field. By performing a meta-analysis from a pool of over 250 peer-reviewed articles, we assess rotarod as a predictor for disease onset, loss of

motor function, and survival for the G93A transgenic mouse. Moreover, we quantify the effect and dependency of experimental factors such as mouse sex, transgenic strain, and rotarod experimental parameters (actual speed, accelerating rotarod versus constant rotarod, etc.) on systemic output variables. We propose a regression model capable of comparing mouse survival times from different G93A experimental protocols, including mouse age at disease onset, rotarod parameters, and rotarod latency at a particular age.

Title: HMG-CoA reductase inhibitors negatively impact amyotrophic lateral sclerosis via mitochondrial mechanisms

Authors: *X. W. SU[1], W. NANDAR[1], E. B. NEELY[1], Z. SIMMONS[2], J. R. CONNOR[1]
[1]Neurosurg., [2]Neurol., Penn State Col. of Med., Hershey, PA

Abstract: Background: HMG-CoA reductase inhibitors (statins) may increase ALS risk or accelerate disease progression. Mitochondrial dysfunction contributes to ALS, and statins are known to perturb mitochondrial enzymes. Objectives: To determine if statins accelerate disease progression or decrease survival in ALS mice, and if statin-induced mitochondrial dysfunction mediates these effects. Methods: SOD1 G93A and wild type (WT) mice balanced for gender were used in accordance with IACUC guidelines. For the survival study, animals were administered daily 2 mg/kg simvastatin or vehicle beginning at disease onset, which was determined by rotarod, and allowed to reach endstage. Disease progression was measured by gripstrength. Plasma cholesterol and ferritin levels were measured by colorimetric assay or

ELISA. Western blot of mitochondrial fractions from gastrocnemius muscle and lumbar spine was conducted. For the mechanism study, animals were administered simvastatin in a similar fashion, gastrocnemius muscle and lumbar spine was collected at the symptomatic 120-day timepoint, and Western blots were conducted as above. For the rescue study, animals were administered daily 2 mg/kg simvastatin, 10 mg/kg coenzyme Q10, or the combination beginning at disease onset and allowed to reach endstage. SAS 9.3 or NCSS 9 was used for statistical analyses. Results: Animals administered simvastatin had physiologically relevant decreases in cholesterol. ALS mice had increased ferritin levels compared to WT mice. ALS mice administered simvastatin had accelerated disease progression as measured by gripstrength and decreased survival by Kaplan-Meier analysis compared to ALS mice administered vehicle. At 120 days and endstage, ALS mice had significantly decreased levels of complexes I and IV of the electron transport chain; cytochrome c; and the VDAC1 mitochondrial anion channel in gastrocnemius muscle and lumbar spine compared to WT mice. At 120 days, mice administered statin had increased complex I and VDAC1, as well as decreased cytochrome c, in lumbar spine compared to mice administered vehicle. At endstage, there were no statin-induced differences in ALS mice, possibly reflecting a floor effect at this advanced timepoint. Coenzyme Q10 administration did not rescue the statin-induced decrease in survival in ALS mice. Conclusions: Statins accelerate disease progression and decrease survival in ALS mice, effects mediated by perturbations in mitochondrial enzymes and which are not reversed by coenzyme Q10 supplementation. These results suggest statin therapy in patients with ALS should be investigated for a possible negative effect on disease progression.

Tokyo, Tokyo, Japan; [3]Dept. Physiol., Jichi Med. Univ., Tochigi, Japan; [4]Dept. Neurol., Jichi Med. Univ., Tochigi, Japan; [5]Clin. Res. Cent. Med., Intnatl. Univ. Hlth. Welfare, Chiba, Japan

Abstract: Motor neurons of patients with sporadic amyotrophic lateral sclerosis (ALS) express abundant GluA2 that has glutamine at the glutamine/arginine (Q/R) site. All of the GluA2 expressed in the central neurons have arginine at this site due to adenosine to inosine conversion (RNA editing), which is specifically catalyzed by adenosine deaminase acting on RNA 2 (ADAR2), and motor neurons devoid of ADAR2 activity express abnormally Ca^{2+}-permeable AMPA receptors that contain Q/R site-unedited GluA2. We developed conditional ADAR2 knockout (AR2) mice, in which the ADAR2 gene was targeted in cholinergic neurons including spinal motor neurons. Because lack of ADAR2 causes death of motor neurons by failure to edit this site in AR2 mice, it is likely that ADAR2 underactivity is involved in ALS-like progressive motor dysfunction resulting from death of motor neurons. Therefore, enhancement of ADAR2 activity in the motor neurons would be a therapeutic strategy for ALS, and we attempt to deliver the ADAR2 gene to the mouse motor neurons using an adeno-associated virus serotype 9 (AAV9) vector. One-shot intravenous injection of AAV9-ADAR2 vector rescued ALS-like progressive motor dysfunction and effectively prevented motor neurons from death in AR2 mice. Moreover, ALS-like TDP-43 pathology observed in motor neurons of untreated AR2 mice was rescued and motor neurons that expressed exogenous ADAR2 exhibited exclusively nuclear TDP-43 immunoreactivity in the treated AR2 mice. This AAV9-mediated ADAR2 gene delivery may therefore enable the development of a gene therapy for ALS.

Abstract: Amyotrophic lateral sclerosis (ALS) is a neurodegenerative disease accompanied by the loss of motor neurons, leading to paralysis and death. Glial cell line-derived neurotrophic factor (GDNF) promotes neuron health and function and has been proposed as a therapeutic treatment for ALS. GDNF protein expression in skeletal muscle is regulated by physical activity. The aim of this study was to determine if low intensity exercise would increase GDNF expression in skeletal muscle and slow degeneration of motor neurons in a mouse model of ALS. Following the first sign of disease onset, transgenic ALS mice were randomly assigned to one of three groups: sedentary control, involuntary low intensity exercise, and involuntary low intensity exercise with anti-GDNF injections, twice daily. Anti-GDNF injections were administered to determine if neutralizing GDNF inhibited the beneficial effects of exercise on the motor nervous system. Neurological score was tested daily throughout the exercise protocol, and animals were euthanized at 115 days of age. Lumbar spinal cord and soleus, extensor digitorum longus (EDL), and pectoralis major muscles were removed and analyzed for GDNF content by enzyme-linked immunosorbant assay. Immunohistochemical analysis of spinal cord was performed to assess motor neuron cell body count. Histological analysis of skeletal muscle was performed to examine endplate area and location of GDNF. Onset of neurological symptoms appeared to be delayed in the exercise group, when compared to the sedentary control and exercise with anti-GDNF treatment groups, although this was determined not to be statistically significant. GDNF content was not significantly affected in spinal cord, soleus, EDL, or pectoralis major, although there was a trend towards an increase in the exercised group compared to the control and anti-GDNF group. Histological analysis of spinal cord sections revealed a significant ($p<0.05$) increase in motor neuron number in the exercised animals (6.7 ± 0.7 ChAT positive cells per section) compared to the anti-GDNF treated animals (4.0 ± 0.6 ChAT positive cells per section). These results suggest that exercise protects against motor neuron loss and that neutralization of GDNF blocks this protective effect. This suggests that the neuroprotective effect of exercise may be related to the activity dependent expression on GDNF and that GDNF may have implications as a therapeutic agent in neurodegenerative disease. This work was supported by NIH grant 1 R15 AG022908-01A2 and NSF grant DBI 0552517.

Title: Age-dependent and mutant-enhanced synaptic deficit caused by als-ftd-linked fus/tls

Authors: *S.-H. TYAN[1,3], Q. WU[2], D. W. CLEVELAND[4,5,3], E. H. KOO[1,3], S.-C. LING[2,3,4]

Abstract: Amyotrophic lateral sclerosis (ALS) and frontotemporal dementia (FTD), two adult-onset neurodegenerative diseases, have traditionally felt to be different disorders with different mechanisms. Recent studies have shown that they share overlapping clinical, genetic, and pathological features. For example, mutations in FUS/TLS cause a disease with features of both ALS and FTD and where pathological inclusions contain FUS/TLS irrespective of the presence or absence of FUS/TLS mutations. In the companion abstract (Ling et al.,), we showed that transgenic mice expressing wild type or either of two ALS-linked mutants of human FUS/TLS produce ALS-like pathology and phenotype. To investigate the cortical phenotypes expected of these mutations, we extend here our analysis of hippocampus synaptic plasticity and found that FUS/TLS play a role in synaptic plasticity and contribute to synaptotoxicity. Specifically, we analyzed the basal synaptic transmission, pair-pulse facilitation (PPF) and long-term potentiation (LTP) in acute hippocampal slices of wild type and FUS mutants in young (6 months) and older (12 months) mice. Similar to the ALS-like phenotype and pathology, the mice expressing moderate levels of wild-type human FUS/TLS demonstrated age-dependent synaptic dysfunction (e.g., basal transmission and LTP) in hippocampus but were more severe in those hippocampi of mice expressing FUS mutants. Morphological and behavioral analyses of these mice are currently underway. Taken together, our results demonstrate that mice overexpressing wild type and mutant FUS/TLS develop age-dependent synaptic deficits that would be predicted based on the cortical symptoms seen in the human disease.

Title: Kit is important for ALS mouse survival independent of mast cells

Authors: *K. A. STAATS[1,2,3], S. SCHONEFELDT[2], M. VAN RILLAER[2], L. VAN HELLEPUTTE[3], Y. LAMPI[2], W. ROBBERECHT[3], L. VAN DEN BOSCH[3], A. LISTON[2]

Abstract: Amyotrophic Lateral Sclerosis (ALS) is a devastating neurodegenerative disease leading to progressive and lethal paralysis. The disease is multi-factorial and is characterized with specific motor neuron degeneration. Increasing growth factors in ALS can increase survival of ALS mice. C-kit is a growth factor, also present in the spinal cord, of which its role in ALS mouse survival is unknown. To dissect the role of c-kit in ALS we interbred SOD1G93A mice with kitw-sh/w-sh mice that have an approx. 70% decrease of kit gene expression in the spinal cord. kitw-sh/w-sh SOD1G93A mice survive shorter than SOD1G93A mice, while the amount of (motor) neurons at end stage is similar. By means of grip strength and nerve conductance analysis we show that kitw-sh/w-sh mice are less strong and have a slightly impaired CMAP latency, although the number of (motor) neurons is similar across genotypes. To exclude whether the decrease in survival of SOD1G93A mice by kitw-sh/w-sh is (additionally) by the lack of mast cells, we administered ketotifen to ALS mice. This did not alter disease survival. Decreasing kit gene expression in ALS mice is detrimental and our results imply that this is independent of mast cells. Additionally, we detect a decrease in strength and motoric EMG abnormalities in kitw-sh/w-sh mice. These mice are often used to assess the role of mast cells, also in neurodegenerative disorders. To conclude, our data confirms the protective role of growth factors in ALS, as decreasing kit by approx. 70% is detrimental in ALS mice.

Abstract: The application of adeno-associated virus (AAV) in gene therapy has multiple advantages due to its long-term expression in the central nervous system (CNS) and low immunoreactivity in humans. Gene therapy strategies in CNS include Canavan's disease, Alzheimer's disease and motor neuron diseases such as amyotrophic lateral sclerosis (ALS). Targeting only the vulnerable neuron populations without affecting other neuron types within the cerebral cortex is a major obstacle for translational neuroscience. This applies to ALS, in which the corticospinal motors neurons (CSMN; a.k.a upper motor neurons) show selective vulnerability and progressive degeneration. In this study, seven different AAV serotypes that harbor the eGFP gene were tested for their ability to transduce CSMN upon direct injection into the layer V of the motor cortex. CSMN transduction was confirmed by immunocytochemistry to CTIP2 and with red fluorescent microsphere labeling of CSMN after injection into the corticospinal tract (CST). Large pyramidal neurons located in layer V showed higher tropism for

AAV2-2. In an effort to increase the selective transduction of CSMN by AAV, we used capsid proteins that are engineered, and different promoters to drive the eGFP expression. Our ongoing studies suggest that the choice of the promoter is critically important to enhance selectivity of gene expression in CSMN. Identification of AAV serotypes that transduce only a select set of neuron populations, even upon direct cortical injection is critically important to develop effective and long-term gene therapy approaches in the cerebral cortex.

Title: A high-throughput genome-wide RNAi screen for novel modifiers of survival of motor neuron (SMN) protein levels

Authors: ***E. S. ARNOLD**[1], R. M. GIBBS[1], D. Y. KWON[1], S. E. MARTIN[2], E. BUEHLER[2], R. HUANG[1], B. REDAN[2], K. H. FISCHBECK[1], B. G. BURNETT[3]

Abstract: Spinal muscular atrophy is caused by a deficiency of the survival of motor neuron (SMN) protein due to deletion or loss of function mutations in the survival of motor neuron 1 (SMN1) gene. The severity of the disease is modulated by the number of copies of the SMN2 gene, a near duplicate of the SMN1 gene that is present in humans. SMN2 produces an unstable, rapidly degraded gene product, but higher copy numbers of SMN2 produce sufficient full length SMN protein to rescue the SMA phenotype. The mechanisms that regulate SMN protein stability remain largely unknown. In collaboration with NCATS, we conducted a genome-wide RNAi screen to identify protective modifiers of SMN protein levels using a cell line stably expressing an SMN2 mini-gene that produces an SMN-luciferase fusion protein. We identified 106 genetic modifiers whose depletion increased the level of SMN-luciferase activity. These modifiers

represent genes involved in multiple cellular processes. In particular, we find high representation of genes involved in RNA processing, trafficking, and transport. Additionally, we identified genes in other functional categories, including post-translational modifications. Based on previous work from our group and others, SMN is known to be ubiquitinated and degraded by the UPS. The identification of additional genes involved in the ubiquitination of proteins may yield further insights into the post-translational regulation of SMN protein stability.

Title: Regulation of SMN and other key pathogenetic events in Spinal Muscular Atrophy (SMA): Moving to RNA-Based treatment strategies

Authors: ***M. BUCCHIA**[1], M. NIZZARDO[1], C. SIMONE[1], F. RIZZO[1], G. ULZI[1], S. DAMETTI[1], A. RAMIREZ[1], E. FRATTINI[1], S. PAGLIARANI[1], N. BRESOLIN[1], F. PAGANI[2], G. P. COMI[1], S. CORTI[1]

Abstract: SMA is a genetic motor neuron disorder caused by mutations of the survival motor neuron gene (SMN1). Currently, there is no effective treatment; however, regulation of SMN levels through antisense mechanisms has shown promising results. Induced pluripotent stem cell (iPSC) lines were reprogrammed from SMA/wild-type human fibroblasts, using a non-viral non-integrating method or lentiviral constructs. The iPSCs were differentiated based on a protocol to stimulate motor neuronal commitment. The phenotype of these cells was analyzed by morphological, functional, gene expression, and protein analysis. SMN levels and Fas activation were modulated *in vitro* in iPS and differentiated cells by antisense morpholino or engineered U1 small nuclear RNA (U1). Compared with wild-type subject iPSC lines, we confirm that SMA cultures present progressively fewer and smaller motor neurons, features that recapitulate human

disease. In the SMA motor neurons treated with antisense morpholino or U1, which increase SMN levels, these phenotypeswere rescued. During motor neuron development, SMA lines exhibited an up-regulation of Fas ligand-mediated apoptosis and increased caspase-8 activation. Importantly, this could be mitigated by Fas silencing. Our data support the utility of SMA iPSCs as an*in vitro* disease model and suggest that RNA-based therapies can be considered in the treatment of SMA.

Title: Single chain antibodies against TDP-43 for treatment of ALS

Authors: ***S. POZZI**, K. DUTTA, C. GRAVEL, J. KRIZ, J.-P. JULIEN
CRIUSMQ, Québec, QC, Canada

Abstract: TDP-43 represents a major component of ubiquitinated cytoplasmic inclusions of brain and spinal cord in sporadic ALS cases (1). Although different mutations have been identified in ALS patients, nowadays the real cause of TDP-43-induced pathology is still unknown thereby necessitating further studies. Recently, it has been reported that TDP-43 can induce inflammatory events by interacting with p65, the main subunit of NF-kB (2). The two proteins interact in spinal cords of sporadic ALS patients and of mice overexpressing the human WT or a mutated TDP-43 protein. Co-transfection experiments demonstrated that, by interacting with p65 through its RRM1 domain, TDP-43 acts as a co-activator of NF-kB. Moreover, it is now emerging that TDP-43 proteinopathy is mainly determined by RRM1 domain alterations. Indeed, oxidation (3) or misfolding (4) of the RRM1 domain trigger irreversible protein aggregation, impaired nucleic acid binding activity together with TDP-43 cytosolic mislocalization and motor neuron toxicity. The project is aimed to develop a possible therapy that would involve delivery of single chain antibodies (scFv), enclosed in viral vectors (5), that

can target specifically the cytoplasmic and nuclear RRM1 domain of TDP-43 with the dual function of (i) inhibiting TDP-43-mediated NF-kB hyperactivation during the early stages of the disease and (ii) preventing the cytoplasmic aggregation by the end stage in TDP-43 mutant mice. Among nine different clones of anti-RRM1 monoclonal antibodies analyzed, three of them are able to recognize TDP-43 and immunoprecipitate both TDP-43 and phospho-p65 in nuclear extract of LPS-activated microglial cells and, more importantly, to inhibit their interaction. Vectors, encoding for single chain antibodies obtained from the selected clones, have been produced by cloning the variable heavy (VH) and light (LH) chains together with Igk secretory signal and myc reporter. Single chain antibodies can be efficiently released in the medium of transfected cells. Moreover, their signal can be detected in cells treated with ScFv antibody containing media, confirming the capacity of these antibodies to cross the cellular membrane. ScFv antibodies against the RRM1 domain of TDP-43 will be used to establish a novel antibody-based therapy that specifically targets TDP-43-induced inflammation and proteinopathy. Moreover, it will constitute a new and useful tool to better elucidate the mechanisms of TDP-43 toxicity. **References** (1) Neumann M, et al. Science 2006. (2) Swarup V, et al. JEM 2011. Title: Mecp2: A novel regulator of tissue-resident macrophage function and survival

Authors: *J. CRONK[1], N. C. DERECKI[2], I. SMIRNOV[2], E. JI[2], G. T. NORRIS[2], N. CODDINGTON[2], S. UPADHYAY[2], Y. WOLF[3], T. H. HARRIS[2], S. JUNG[3], J. KIPNIS[1]
[2]Neurosci., [1]Univ. of Virginia, Charlottesville, VA; [3]Immunol., Weizmann Inst. of Sci., Rehovot, Israel

Abstract: Methyl-CpG-binding protein 2 (MeCP2) is an important regulator of gene transcription, and mutations in MeCP2 are the major cause of Rett syndrome. Rett features prominent neurologic sequelae, thus research has been focused on the role of MeCP2 in neuronal function. Recent studies, however, have suggested the importance of glial cells in Rett syndrome. Our lab previously showed that wild type bone marrow transplant into Mecp2-null mice, including engraftment of wild type microglia-like cells into the brain, significantly improves lifespan and disease outcomes. Here we report Mecp2 as a novel regulator of function and survival in microglia and other tissue-resident macrophages. We found that multiple tissue-resident macrophage populations express high levels of Mecp2. Mecp2-null mice at the peak of disease display a 30% to 50% diminution of several tissue-resident macrophage populations, including microglia. In the periphery, impairment of tissue-resident macrophages in bone marrow is associated with neutrophilia, and eventual hematopoietic stem cell niche collapse. Attenuation of neutrophil load by anti-GCSF treatment slows down peripheral disease progression, extending lifespan by an average of about two weeks, but does not provide full rescue. In the brain, microglia are significantly reduced in numbers as disease progresses. Microglia from Mecp2-null mice exhibit abnormal morphology, as observed in fixed sections and confirmed with *in vivo* live imaging by two-photon microscopy. Selective expression of Mecp2 in tissue-resident macrophages using CX3CR1Cre in cross with Mecp2lox-stop results in a surprisingly robust disease arrest, significantly improving lifespan and disease scores, in addition to full rescue of somatic growth deficits. Further, specific rescue of microglia using tamoxifen-inducible CX3CR1CreER crossed to Mecp2Lox-stop results in significant increase in lifespan, implicating microglia specifically in the pathogenesis of Mecp2 deficiency. Together, these findings suggest a novel role for Mecp2 in tissue-resident macrophage survival and function, which may in part explain pathologies seen in Rett syndrome.

Title: Chronic ketamine treatment ameliorates cortical function in Rett Syndrome mouse model

Authors: *N. PICARD[1], A. PATRIZI[1], A. J. SIMON[1], G. GUNNER[2], N. A. ANDREWS[2], M. FAGIOLINI[1]
[1]Neurol., Boston Children's Hospital-Harvard Med. Sch., Boston, MA; [2]Boston Children's Hospital-Neurodevelopmental Behavior Core., Boston, MA

Abstract: Mice deficient in Mecp2 recapitulate many of the symptomatic features of Rett Syndrome (RTT), a devastating neurodevelopmental disorder affecting 1 in 10,000 girls. Visual circuits rapidly decline after an initial apparent normal development that directly correlates with the onset of the RTT phenotype. Genetic reduction of the excitatory NMDA receptor subunit GluN2A prevents such regression including the hyper-connectivity of parvalbumin-positive (PV) interneurons, loss of spontaneous and evoked neuronal activities associated with the decline in visual cortical function. Acute ketamine administration is sufficient to restore basal c-fos level in the forebrain of KO mice. Together, these findings suggest that targeting NMDA receptor may provide a new therapeutic approach for RTT. Here, we tested whether chronic ketamine treatment at low dosage (8mg/kg/day, i.p.) was sufficient to attenuate RTT visual cortical defects. Pharmacokinetic analysis of ketamine administration from plasma and brain samples demonstrated brain penetration (TMax=5min; Cmax=12uM post i.p. injection) and a rapid elimination from plasma (below LOD after 120 min). Two paradigms of administration were conducted: one starting from P15, when PV hyper connectivity first emerges, and one from P30, when visual function begins to regress and general RTT phenotypes appear. Both treatments were effective in ameliorating visual circuit deficits at adulthood (P55). *In vivo* single-units recordings of pyramidal cells, in response to visual stimulation, revealed that spontaneous and maximal evoked activities were restored to WT levels after ketamine treatment. Moreover, ketamine treated-Mecp2 KO mice exhibited improved optomotor visual acuity compared to controls. Notably, both treatments improve some of the RTT general phenotypes (like hindlimb clasping) in a subset of KO treated mice. However, only the ketamine treatment starting from P30 to adulthood enhanced performance on the accelerating rotarod test in KO mice. Overall, our results support the use of a therapeutic treatment targeting NMDA receptors to prevent or delay regression in a mouse model for RTT.

Title: An isogenic human induced pluripotent stem cell model of Rett Syndrome reveals early alterations in microRNA expression patterns and downstream neuronal maturation

Authors: *D. A. FELDMAN[1], N. MELLIOS[1], S. D. SHERIDAN[2], S. KWOK[1], B. ROSEN[1], B. CRAWFORD[1], S. HAGGARTY[2], M. SUR[1]

Abstract: Rett Syndrome (RTT) is an X-linked developmental disorder that is predominantly caused by mutations in methyl CpG-binding protein 2 (MECP2). Clinical features of RTT include a period of normal development lasting up to 6-18 months followed by stagnation of both neurological and general growth development. As this is a disorder of early development, it has proven difficult to elucidate phenotypes and/or molecular signatures at a pre-symptomatic stage. We have generated human induced pluripotent stem cell (iPSC) lines in which to study molecular and functional phenotypes *in vitro* at various stages of neural development. We took advantage of clonal X-inactivation from RTT patient lines in addition to shRNA knockdown of MECP2 in control lines to generate pairs of isogenic cell lines. Neural progenitors were generated from iPSCs via dual-SMAD inhibition and subsequently differentiated into cortical neurons, which exhibited intrinsic membrane excitability and spontaneous post-synaptic activity as observed via whole-cell patch clamp and functional calcium imaging. In this study, we aimed to identify key miRNA and molecular signatures at early stages of neuronal differentiation and in neural progenitors using these isogenic patient-derived and MECP2 knockdown cell lines. We screened for affected miRNAs and discovered a distinct miRNA family of interest that is robustly augmented in RTT patient-derived cell lines. Our results were subsequently confirmed

in MECP2 knockdown cell lines and embryonic mouse brain tissue. In parallel, components of the mitogen-activated protein kinase (MAPK) pathway that are known targets of the upregulated miRNA family were found to be misregulated in RTT lines. Such pathways are known to converge on key processes of neuronal development, thus leading to observed maturation deficits in early RTT neurons. Downregulation of aforementioned miRNAs in MECP2 knockdown neural progenitors ameliorated downstream neuronal maturation. Ongoing experiments are focused on elucidating the mechanisms of disease-related impairments of neurogenesis in a mouse model of RTT. Our data highly supports the hypothesis that the expression of a key miRNA family is altered in a human model of RTT and has significant effects on downstream signaling pathways implicated in RTT pathogenesis.

Title: Gabaergic contributions to neural deficits in a genetic model of rett syndrome

Authors: J. M. MOSSNER, R. BATISTA-BRITO, *J. A. CARDIN
Dept. of Neurobio., Yale Univ., New Haven, CT

Abstract: Autism Spectrum Disorders (ASDs) affect approximately 1% of the world's population and are associated with cognitive deficits in perception, social interaction, and communication, all functions served by the cerebral cortex. Recent evidence has suggested an association of these disorders with a disruption of GABAergic inhibitory interneurons in the brain. Genetic studies of ASD patients have identified several candidate genes including MeCP2, a transcriptional regulator that plays a role in synaptic development. Mutations in MeCP2 are strongly associated with Rett Syndrome, an X-linked ASD characterized by loss of language skills, deficits in social interaction and sensory processing, repetitive movements, and mental retardation. MeCP2 is strongly expressed in GABAergic cells in the brain, and deletion of MeCP2 specifically from inhibitory interneurons replicates many behavioral phenotypes of the

global knockout, including repetitive behaviors, impaired social interactions, deficits in spatial learning, and increased PPI. However, the cell type-specific role of MeCP2 signaling and the contributions of specific interneuron populations to these phenotypes remain unclear. Using Cre-dependent conditional deletion of MeCP2 from targeted neural populations, we compared mice lacking MeCP2 specifically in parvalbumin- (PV) and somatostatin- (SOM) expressing interneurons. To assess the role of MeCP2 signaling in cortical activity patterns, we recorded spontaneous and visually evoked activity in primary visual cortex (V1) of awake behaving mice. In each experiment, we used tetrode arrays to record local field potentials (LFP) and isolated single units across all layers of cortex. In a subset of experiments, we used optogenetic tagging to record the activity of identified interneurons from target populations. We further used a series of behavioral assays to elucidate the contributions of each interneuron population to previously reported behavioral deficits in this genetic model. Our preliminary data suggest that deletion of MeCP2 from PV and SOM interneurons may contribute to discrete elements of the overall phenotype observed in this model of Rett Syndrome. We find that PV and SOM deletion mice exhibit different patterns of cortical activity and seizure incidence. Additionally, these groups show distinct patterns of locomotor activity during behavioral tests. Overall, our data suggest that MeCP2 signaling contributes to the function of the two largest populations of inhibitory interneurons, and deletion of this gene impacts both cortical network activity and behavior in a cell type-specific manner.

Abstract: Mutations in the transcriptional regulatory gene, MECP2, generate Rett Syndrome (RTT), a neurodevelopmental disorder characterized by an initial normal developmental period, followed by stagnation and regression at 12-18 months. We recently discovered that Mecp2 deletion engenders sensory processing defects in the visual system, including reduced spontaneous and evoked single-unit activity in visual cortex. Additionally, mRNA transcripts from visual cortex reveal a significant increase in the ratio of the NR2A to NR2B subunit of the N-methyl-D-aspartate receptor (NMDAR) in Mecp2 KO mice. Normalizing the NR2A/NR2B ratio genetically by creating a Mecp2 KO / NR2A-heterozygous mouse model is sufficient to rescue visual cortical defects. Importantly, NMDAR density in cortical tissue of post-mortem RTT patients is also increased. Together these data support the hypothesis that NMDAR subunit dysregulation may contribute to the sensory deficits of Rett Syndrome. To create a comprehensive picture of NMDAR subunit dysfunction in Rett Syndrome, we took a high resolution, unbiased, mass spectrometry-based approach. By immunoprecipitating (IP) the NR2A and NR2B subunits from visual cortex homogenate and using spectral counting techniques and/or heavy isotope labeled peptides for absolute quantification (AQUA), we analyzed protein quantity, post-translational modification (PTM), and interacting partners at the onset of regression in a Mecp2 KO mouse (postnatal day 30, P30). We found that, in the absence of Mecp2, NR2B and NR1 protein levels remained unchanged compared to WT levels while NR2A expression was increased. In addition, among the 60 C-terminal peptides that we were able to measure, 10% of them were differentially modified in the KO visual cortex. Interestingly, their PTM profile was renormalized in the Mecp2 KO / NR2A-heterozygous rescue mouse similar to a wild-type status. Finally, NR2A and NR2B co-immunoprecipitate analysis detected multiple kinases and proteins known to be localized at the synapse. Several proteins common to both the Mecp2 KO NR2A and NR2B co-IPs showed opposite abundance trends when compared to the WT levels. Overall, our data indicates that Mecp2 deletion induces a differential regulation of NR2A and NR2B subunits and postsynaptic composition. Using small molecules to target kinases and phosphatases that modify NR2A and NR2B could represent a new therapeutic approach to Rett Syndrome.

Title: Remacemide eliminates apneic breathing in a mouse model of Rett syndrome

Authors: R. J. MATHER[1], I. ADAMS[2], M. LANG[2], *J. DUNLOP[1], E. ABERG[3], M. C. QUIRK[1], D. M. KATZ[2]

Abstract: Patients with Rett syndrome (RTT), a severe disorder caused by mutations in the MECP2 gene exhibit postnatal neurological regression leading to motor and cognitive impairments, respiratory and autonomic dysregulation, seizures and autism-like behaviors. Studies in the Katz laboratory demonstrated that a sub-anesthetic dose of the non-selective NMDA antagonist ketamine acutely reverses cortical hypofunction in Mecp2 null and heterozygous mice (Kron et al., 2012), suggesting the potential utility of NMDA antagonists for treatment of RTT. Therefore, the present study was designed to evaluate more selective NMDA antagonists in rodents for their ability to alleviate symptoms likely to be of clinical relevance for RTT patients. In particular, we examined remacemide and its active metabolite, desglycinyl remacemide, which are moderate to low affinity (0.5 to 68 uM) NMDA channel blockers previously in clinical development for the treatment of epilepsy and ischemic brain damage. Behavioral and physiological testing in wildtype rats and mice (seizure suppression, EEG-biomarker, anxiety/depression) and Mecp2tm1.1Jae mutant mice (plethysmographic analysis of breathing) were used to characterize the potential utility of remacemide for the treatment of RTT symptoms. Studies in wildtype animals demonstrated that remacemide and desglycinyl remacemide attenuate electroconvulsive-induced seizures (MES-test) and reduce the acute stress response in a forced-swim test at doses (8-30 mg/kg) associated with measurable changes in cortical gamma band EEG. Furthermore, both compounds acutely reverse the apneic breathing phenotype in Mecp2 mice at doses corresponding to clinically relevant and well tolerated exposures. Specifically, a single intraperitoneal injection of remacemide (60 mg/kg) or desglycinyl remacemide (30 mg/kg) in 12-16 week old female heterozygous Mecp2tm1.1Jae mice reduced spontaneous apneas (defined as respiratory pauses longer than twice the average duration of expiration) to wildtype levels within 3 hours of treatment. These preliminary studies, combined with human data demonstrating positive effects of remacemide as an adjunctive treatment for refractory epilepsy (Baesag et al., 2001; Chadwick et al., 2002; Devinsky et al., 2002) suggest that remacemide or related compounds may have therapeutic value in the treatment of RTT patients. Inst., Chevy Chase, MD

Abstract: *MECP2* duplication syndrome is a condition that manifests almost exclusively in males and is characterized by autism, intellectual disability, anxiety, hypotonia, epilepsy, recurrent respiratory tract infections and premature death. The disease is the result of duplications of genetic material on chromosome Xq28 with minimal region of overlap spanning

MECP2 and *IRAK1*. Mice overexpressing human *MECP2* at 2X (*Mecp2*-Tg1) replicate many phenotypes of the duplication syndrome including hypoactivity, increased anxiety, decreased social behavior, and abnormal motor coordination. Reversibility in adult mice has been demonstrated in a handful of mouse models of neurodevelopmental disorders including Rett syndrome, but whether the duplication is treatable remains unknown. To determine whether the phenotypes of *MECP2* duplication are reversible upon normalization of MeCP2 levels, we generated and characterized a new mouse model that over-expresses a conditional allele of *Mecp2* that could be deleted in the adult animal. Upon normalization of MeCP2 in 8 weeks symptomatic mice, several phenotypes were rescued including hypoactivity in the open field (n = 10-15, $P = 0.0016$), anxiety in the elevated plus-maze test (n = 10-15, $P = 0.03$), social behavior in the 3-chamber test (n = 10-15, $P = 0.05$), and motor coordination in the rotarod (n = 10-15, $P = 0.0003$). In addition, genes abnormally expressed in the brain of *MECP2*-overexpressing mice such as Crh, Gamt, Agrp, Prl2c2 and Rcor2, were normalized. These data demonstrate that developmental overexpression of MeCP2 in mice does not irreversibly damages neural function, and suggests that correcting the expression level of MeCP2 can potentially reverse some aspects of the *MECP2* duplication syndrome pathology. Abstract: The Cyclin-dependent kinase-like 5 (CDKL5) gene encodes for a serine-threonine kinase sharing homology to Mitogen-activated kinases (MAPKs) and Cyclin-dependent kinases (CDKs). Recently, mutations in the CDKL5 gene have been identified in the patients with neurodevelopmental disorders associated with epilepsies, such as West syndrome or atypical Rett syndrome, suggesting its critical role in neurodevelopment. However, neither its molecular functions or pathomechanisms caused by its mutations are largely unknown. Aiming to elucidate these problems, we have taken multidimensional strategies, combining an unbiased interactome approach and a targeted loss-of-function (LOF) approach. For the interactome approach, we performed the yeast two-hybrid screening and identified several CDKL5 interacting proteins. For the LOF approach, we have generated the Cdkl5 knockout mouse and analyzed the neurological phenotypes. The combination of these approaches suggested us possible mechanisms of CDKL5 regulating neural functions during development.

Title: Altered nicotinic receptor expression and nicotinic receptor mediated changes in open field locomotor behaviour in a mouse model of Rett syndrome

Authors: D. MCPHEE, A. RENDA, J. LEUNG, *K. R. DELANEY, R. NAHSMI
Univ. of Victoria, Victoria, BC, Canada

Abstract: Rett syndrome (RTT) results from loss of function of the X-linked transcription factor MECP2. In the Jaenisch RTT mouse model, a deletion of exon 3 eliminates the methylated DNA binding domain, leading to loss of MeCP2 function. Several studies have indicated that cholinergic hypofunction is one of the consequences of MeCP2 mutation in mice and humans. In WT mice, acute nicotine (NIC) decreases the open field movement (OFM) of males and females in a dose-dependent manner, with reduced movement evident at 1 mg/kg and immobility at 2 mg/kg. We therefore tested whether injection of NIC would induce similar behavioural effects in RTT mice. NIC injected male RTT mice showed significantly increased OFM compared to saline injection at 0.5 mg/kg, no difference at 1 mg/kg, with a large decrease at 2 mg/kg. Responses in presymptomatic (≈ 6 wks) female RTT mice were variable but nonetheless showed less suppression of locomotion at 1mg/kg compared to WT females. qRT-PCR of thalamus and midbrain tissue of male mice showed a 3.6-fold reduction in α4 nAChR expression in the RTT brain compared to WT littermates ($p=0.0054$, n= 5 WT; 5 RTT). We therefore tested the effect of TC-2559 (Tocris), an agonist with selectivity for α4 and α6 containing receptors. WT OFM was suppressed by TC-2559 above 1 mg/kg with saturating effects at 2.5 mg/kg but, unlike NIC, complete locomotor suppression was not produced by doses up to 10 mg/kg. Analysis of locomotor paths taken by WT in the test chamber revealed significant changes in pattern. Normally, mice circulate mainly around the perimeter of the test chamber reversing direction occasionally and crossing the centre at 10-20 sec intervals. WT mice injected with TC-2559, in addition to walking slower and stopping more, increased the proportion of time spent in the centre, away from the walls. RTT mice injected with 2.5 mg/kg showed a dramatic doubling of average velocity during the 5 min post injection test period with no change in the pattern of locomotion. Seizure activity was not observed in response to NIC or TC-2559 at the doses used. Our data suggest that the pathophysiology of RTT may be influenced by a decreased expression of the α4 (and/or α6) nAChR subunits resulting in altered response to nAChR agonists in the RTT brain.

Abstract: The X-linked gene cyclin-dependent kinase-like 5 (CDKL5) is mutated in many severe neurodevelopmental disorders, including some forms of atypical Rett syndrome. It has been suggested that CDKL5 could interact with synaptic proteins important for the organization of the postsynaptic density and dendritic spine morphology, however an *in vivo* analysis of the role of CDKL5 in dendritic spine dynamics and synaptic molecular organization is still lacking. To answer these question we performed *in vivo* two-photon imaging of dendritic tufts of layer V pyramidal neurons in the somatosensory cortex of male CDKL5 null mice. We found that adult mutant mice (imaged from P50 until P80) show a significant reduction in spine density that remained substantially stable during the observation period. Short-term spine turnover was unaffected, however the percentage of stable spines persisting for one month was significantly reduced. Spine deficits were accompanied by synaptic deficits consisting in a reduction of the expression of synaptic PSD95 and impaired LTP maintenance. The analysis of young CDKL5 null mice (P27-P28) revealed that spine density and levels of synaptic PSD95 already begin to be reduced at this age. Moreover, repeated *in vivo* imaging showed a dramatic increase in short-term spine elimination but normal spine formation, suggesting a crucial role of CDKL5 in spine stability in developing mice. To explore a possible therapeutical approach to reverse synaptic deficits, we administered IGF1 to juvenile mutant mice and we found that both spine density and spine loss rate were rescued to control levels. These data demonstrate that dendritic spine stabilization is a cellular process dramatically affected by CDKL5 deletion. Loss of stabilization, albeit with different time constants, is present both in juvenile and adult animals suggesting that CDKL5 role in synaptic maintenance is not restricted to development. Moreover, our data suggest that IGF1 treatment could be a promising candidate for clinical trials in CDKL5 patients.

Title: Abnormal arousal to auditory stimulation in Mecp2 mutant mice is reversed by treatment with LM22A-4, a small molecule partial TrkB agonist

Authors: *D. M. KATZ[1], M. LANG[1], I. ADAMS[1], F. M. LONGO[2]

Abstract: Complex respiratory disturbances are a prominent feature of Rett syndrome (RTT), a severe neurodevelopmental disorder caused by mutations in the MECP2 gene. Moreover, the severity of breathing dysfunction in RTT patients is strongly influenced by behavioral state, as respiratory phenotypes worsen when patients are agitated and improve with relaxation or sleep (reviewed in Ramirez et al., 2013). However, mechanisms that underlie behavioral state-dependent respiratory dysfunction in RTT are unknown and no treatments are currently available. We therefore sought to determine if breathing abnormalities associated with behavioral arousal could be modeled in Mecp2 mutant mice and if so, whether such abnormalities might be useful endpoints for preclinical evaluation of potential RTT therapeutics. To approach this issue we compared the respiratory component of the orienting reflex (OR) in wildtype (Wt) and Mecp2tm1.1Jae null mice. The OR, which is elicited by sensory stimuli that are sub-threshold for evoking a startle response but sufficient to draw attention to the stimulus is normally accompanied by a transient increase in breathing frequency (Nalivaiko et al., 2012). 6-8 week old animals were exposed to a brief auditory stimulus (50 ms, 80 dB white noise) during plethysmographic recording of respiration. Wt mice exhibited a transient increase in respiratory frequency in response to the auditory stimulus that returned to baseline within a few seconds. In contrast, null mice exhibited an increase in frequency that was significantly larger than Wt and remained significantly elevated above baseline for at least one minute after the stimulus. We therefore sought to determine whether or not the arousal breathing phenotype in nulls could be ameliorated by activation of the BDNF/TrkB signaling pathway, which we previously showed reduces excitability in the brainstem respiratory network (Katz, 2014). To approach this issue,

mice were treated with saline or LM22A-4 (150 mg/kg, i.p.), a BDNF loop domain mimetic with partial TrkB agonist activity (Massa et al., 2010), one hour prior to testing. LM22A-4 treatment completely restored the breathing response in nulls to Wt levels and had no effect in Wt mice. These data demonstrate that Mecp2 mutants exhibit an arousal breathing phenotype reminiscent of behavioral disruptions of breathing in RTT and suggest that treatments aimed at restoring BDNF/TrkB signaling may be effective at normalizing state-dependent changes in respiration in RTT patients. COI: F.M. Longo has intellectual property interest in LM22A-4 and equity interest in PharmatrophiX, a company developing small molecule ligands.

Title: Loss of MeCP2 in forebrain GABAergic neurons modulates striatal dopamine synthesis in a region-specific and non-cell autonomous manner

Authors: *W.-L. LIAO, F.-C. KAO, Y.-B. HUANG
Institue of Neurosci., Natl. Cheng-Chi Univ., Taipei, Taiwan

Abstract: The methyl-CpG binding protein 2 (MeCP2) is highly expressed in mature neurons and is involved in regulating target gene transcription. Mutations of *MECP2* gene cause more than 90% cases of Rett syndrome (RTT), a neurodevelopmental disorder featured by striking psychomotor dysfunction. Mice lacking MeCP2 recapitulate symptoms of RTT, including late onset hypoactivity and deficits in motor coordination and motor skill learning. We previously found that psychomotor deficits in *Mecp2*-null mice are associated with aberrant dopamine content in the striatum, which is composed of more than 98% GABAergic neurons. To investigate the causal roles of MeCP2 in modulation of striatal dopamine content, we selectively

removed MeCP2 in the forebrain GABAergic neurons, predominantly in the striatum, and measured dopamine content by HPLC. We uncovered that the amount of dopamine was significantly reduced in the rostral striatum (ST-r), increased in the caudal striatum (ST-c), but not altered in the ventral midbrain (VMB) of *Mecp2* $^{flox/y;Dlx5/6\text{-}Cre}$ (cKO) mice compared to littermate controls. To study the mechanism underlying the dopamine alterations, we next examined the protein expression of the rate-limiting enzyme for dopamine synthesis, tyrosine hydroxylase (TH) and its active form, phosphorylated TH at serine 40 (pTH-Ser40), in the striatum and VMB. We found that the total amount of TH protein remained unchanged in the ST-r, but increased in the ST-c of cKO mice. The level of pTH-Ser40 that indicates TH activity, however, was significantly reduced in the ST-r but increased in the ST-c of cKO mice. No change was found in total TH or pTH-Ser40 levels in the VMB of cKO mice compared to controls. Given that the phosphorylation of TH is inhibited by activation of dopamine D2 receptor (DRD2), we also examined the expression of DRD2 protein in the striatum of cKO mice. Consistently, the DRD2 expression was selectively elevated in the ST-r of cKO mice. Together, these results suggest that loss of MeCP2 in forebrain GABAergic neurons leads to region-specific alterations of protein expression of DRD2 and TH, as well as altered enzymatic activity of TH and ultimate changes of dopamine content in the striatum, without changing the dopamine features in the VMB. Therefore, MeCP2 in the striatal GABAergic neurons non-cell autonomously modulates dopamine synthesis in a sub-region specific manner.

Title: Identification of a novel pathway involved in MECP2 disease-relevant cellular phenotypes using *Drosophila*

Authors: *A. WILLIAMS[1], C. DUCH[1,2]
[1]Arizona State Univ., Tempe, AZ; [2]Zoology, Johannes Gutenberg-Universität, Mainz, Germany

Abstract: Methyl-CpG binding protein 2 (MECP2) is a widely abundant, multifunctional regulator of gene expression with highest levels of expression in mature neurons. In humans, both loss-and gain-of-function mutations of MECP2 cause mental retardation and motor dysfunction classified as either Rett Syndrome (RTT, loss-of-function) or MECP2 Duplication Syndrome (MDS, gain-of-function). There are currently no effective treatments for these conditions. At the cellular level, misregulation of MECP2 leads to both synaptic and dendritic defects; however, the underlying molecular pathways and cellular mechanisms are unknown. Here, we have used *Drosophila* as a model system to investigate the mechanisms affected by MECP2 gain-of-function involved in the regulation of dendritic growth. We have previously shown that expression of human MECP2 (hMECP2) in *Drosophila* leads to impairments in dendritic branching in an identified flight motoneuron (MN5), and used RNA-sequencing technology to determine genes differentially expressed with hMECP2 expression that may be involved in this process. We have subsequently identified Kibra, a gene associated with learning and memory in humans, as a top target from this screen. Kibra also activates the Hippo kinase cascade, a pathway involved in the regulation of dendritic growth in both *Drosophila* and mammals. We used quantitative PCR to confirm upregulation of kibra with expression of hMECP2, and have found that RNAi mediated knockdown of kibra partially rescues hMECP2 induced dendritic defects in MN5. We find that kibra knockdown does not increase dendritic growth independently of hMECP2 expression. Furthermore, over-expression of kibra alone does not phenocopy the hMECP2 induced cellular phenotype in MN5. Thus, we conclude that increased expression of kibra is necessary for the dendritic reduction with hMECP2 over-expression, but not sufficient to disrupt dendritic morphology alone. We are currently working to validate these findings in mouse primary neuron culture. The investigation of MECP2 targets identified in *Drosophila* may ultimately lead to novel therapeutic strategies for RTT and MDS.

Title: MeCP2 isoforms and neurological disorders

Authors: *M. RASTEGAR
Biochem. and Med. Genet., Univ. of Manitoba, Winnipeg, MB, Canada

Abstract: MeCP2 is an important protein in brain, and its altered expression causes neurodevelopmental disorders including Rett syndrome and autism. Alternative splicing of a single gene gives rise to two protein isoforms (MeCP2E1 and MeCP2E2). Deregulation of either isoform is implicated in neurological complications and impaired brain function. Currently, MeCP2-associated disorders have no cure and the mechanisms by which MeCP2 isoforms are controlled are not fully understood. We were the first group to develop isoform-specific MECP2 gene therapy vectors and to study the functional role of MeCP2E1 and MeCP2E2 in neuronal maturation. By developing isoform-specific anti-MeCP2E1 and anti-MeCP2E2 antibodies, we reported that MeCP2E1 and MeCP2E2 expression are cell type-, and brain region-specific. Further, we showed that DNA methylation impacts MeCP2 isoform-specific expression in differentiating brain-derived neural stem cells during brain development and in the adult murine brain in a brain-region specific manner. MeCP2 expression is important in different brain cell types, and disease-associated phenotypes are proven to be cell type-specific. Here, we will discuss our recent results on the MeCP2 isoform-specific regulation and functional role in neurons. We have exciting novel data on the epigenetic control of MeCP2 isoforms in brain-derived neural stem cells and different brain cells. Our results will have significant implications for future therapeutic strategies of MeCP2-associated neurological disorders.

Abstract: Rett syndrome (RTT) is a neurodevelopmental disorder that is caused primarily by mutations in the X-linked gene encoding methyl-CpG binding protein 2 (MeCP2). Pathological studies of human RTT cases have all shown a reduction in brain size, increased cell packing density, and aberrant dendrite structure. The major barrier toward developing an effective therapy for RTT is the lack of neuronal phenotypes to test in discovery platforms capable of supporting high throughput screening (HTS). In our studies with a unique mouse model (MeCP2-A140V "knock-in" human mutation) developed in our laboratory, we have identified decreased dendritic branching of cortical layer III pyramidal neurons, and increased cell packing density in several brain regions. Here, we detail the measurements of neuronal soma and nuclear size in cultured neurons from A140V and wild type (WT) mice. Our previous observations in cultured hippocampal neurons indicated that there was significant reduction in neuronal soma size, which was observable as early as 3 DIV. Further, the reduction in soma size was associated with decrease in nuclear size. To further validate this observation in a homogenous cell population, we quantified soma and nuclear size in primary cerebellar granule neuronal (CGN) cultures from wild type and MeCP2 A140V mutant mice. We found that the soma size of CGN (measured as cross-sectional area) was significantly smaller in mutant MeCP2 mice (55.94 ± 2.849 μm2) compared to wild type mice (65.06 ± 2.5 μm2). In addition, we also found that CGN nuclear size was decreased in MeCP2 A140 mice (28.50 ± 1.076 μm2) compared to wild type mice (31.97 ± 1.068 μm2). In our studies, we also found that mTORC2 pathway is significantly downregulated in MeCP2-A140V model, suggesting MeCP2 influences neuronal size via the mTORC2 pathway. The "soma size" phenotype in cultured neurons was rescued by treatment with recombinant IGF-1 *in vitro*. Neuronal size in such homogeneous CGN cultures is a predictable neuronal phenotype. Our findings suggest that soma/nuclear size can be used as biomarker in a high throughput screening assay for identification of potential therapeutic agents for Rett syndrome.

Title: Alterations in astrocytic gene expression in pre-symptomatic MeCP2-deficient mice

Authors: *N. L. PACHECO[1], M. L. OLSEN[2]
[1]Univ. of Alabama At Birmingham, Birmingham, AL; [2]Univ. of Alabama at Birmingham, Birmingham, AL

Abstract: Rett syndrome (RTT) is an X-linked neurodevelopmental disorder characterized by a decline in motor and language functions (6-18 months), breathing abnormalities and seizures. RTT is caused by mutations in the methyl CpG binding protein 2 (*MECP2*) gene, a transcriptional regulator. Expression of *MeCP2* specifically in astrocytes in a *MeCP2*-deficient mouse model ameliorated deficits associated with RTT. This coupled with findings that *MeCP2*-deficient astrocytes induced a RTT phenotype in wild type neurons suggests that astrocytes contribute to RTT pathology. We recently demonstrated that MeCP2 is a positive transcriptional regulator of the glial specific inwardly-rectifying potassium channel Kir4.1. Kir4.1 is highly expressed in gray matter astrocytes and is implicated in extracellular potassium homeostasis. Furthermore, Kir4.1 contributes to the hyperpolarized resting membrane potential and high resting K+ conductance observed in gray matter astrocytes. The importance of this channel for normal brain functioning is underscored by studies in Kir4.1 knock-out mice which develop ataxia, seizures, show altered synaptic plasticity and die during early postnatal development. Strikingly similar to individuals with RTT, knockout or mutation of *KCNJ10*, the gene that codes for Kir4.1, causes seizures, ataxia, and developmental deficits in humans alike. Our previous study demonstrated that *MeCP2*-deficient mice have decreased Kir4.1 protein and mRNA levels, which correlated with aberrant Kir4.1 function in astrocytes and increased neuronal excitability. However, this study focused exclusively on symptomatic *MeCP2*-deficient mice. It is unclear if reduced levels of Kir4.1 protein are a result of the disease process or contribute to the pathogenesis in *MeCP2*-deficient mice. Here we aim to address this by examining Kir4.1 expression and function in pre-symptomatic animals.

Title: Aberrant redox homeostasis in RETT syndrome affects cytosol and mitochondria

Authors: K. CAN[1], J. TOLÖ[2], S. KÜGLER[2], *M. MUELLER[1]
[1]Zentrum Physiologie & Pathophysiologie, [2]Univ. Goettingen, Goettingen, Germany, Germany

Abstract: Rett syndrome is associated with mitochondrial impairment, chronic oxidant challenge, and aberrant cellular redox homeostasis. Since mitochondria are partly uncoupled and show increased respiratory turnover rates, they may underlie the oxidative burden in MeCP2-deficient (Mecp2-/y) brain tissue. Since these alterations manifest early in life, they may facilitate or even underlie disease progression in Rett syndrome. Earlier we reported exaggerated responses of Mecp2-/y hippocampus to redox challenge and mitochondrial inhibition, and showed that extramitochondrial ROS production is not intensified. To decipher the molecular causes of redox imbalance in more detail, we now took advantage of viral constructs expressing the genetically-encoded optical redox sensor roGFP1 specifically in neurons. For subcellular analyses in hippocampal cell and slice cultures, roGFP1 was targeted to either the cytosol or the mitochondrial matrix. To enable quantitative recordings, the ratiometric response ranges of mito-roGFP1 and cyto-roGFP1 were calibrated to full oxidation and reduction. The response dynamics clearly differed between dissociated cell cultures and the more complex organotypic slices. Genotypic differences occurred especially in the slice cultures: both mitochondria and cytosol showed slightly more oxidized redox baselines in Mecp2-/y than in wildtype neurons. In addition, the redox balance of both compartments was less stable in Mecp2-/y hippocampus. Severe hypoxia caused more pronounced reducing shifts and acute oxidant challenge by 200 µM H2O2 elicited more intense oxidizing transients in Mecp2-/y neurons. Block of superoxide dismutase evoked only dampened oxidizing responses in Mecp2-/y cytosol and mitochondria. In conclusion, mito-roGFP1 and cyto-roGFP1 respond reliably to oxidation and reduction, thereby allowing analyses of subcompartmental redox dynamics. Genotypic differences among wildtype and Mecp2-/y mice are evident not only in the cytosolic but also the mitochondrial compartment. Since mitochondria are the primary cellular source of reactive oxygen species, this supports our hypothesis that it is especially the mitochondrial dysfunction which underlies the oxidative burden in Rett syndrome.

Title: Loss of MeCP2 affects normal development of hippocampal glutamatergic neurons by altering axonal and dendritic outgrowths

Authors: *C. SAMPATHKUMAR, T. TRIMBUCH, C. ROSENMUND
Charité - Universitätsmedizin Berlin, Berlin, Germany

Abstract: Methyl CpG – binding protein 2 (MeCP2) is a transcriptional regulator whose loss-of-function mutations result in neurodevelopmental disorders such as Rett syndrome. The objective of the study is to understand the role of MeCP2 in regulating synapse formation in hippocampal glutamatergic neurons during development. *Mecp2*$^{Null/y}$ and *Mecp2*^{Tg1} male mice were used and hippocampal neurons were plated on glial micro islands to study synapse formation at a single-cell level. We characterized MeCP2 wild type (WT) expression levels in autaptic murine glutamatergic neurons from the hippocampus and found that MeCP2 endogenous levels correlated to the number of synapses formed during peak synaptogenesis and synapse maturation. Additionally, we observed a developmental defect in glutamatergic MeCP2-null neurons. Loss of MeCP2 resulted in reduced axonal outgrowths as well as shorter dendritic structures compared to their WT littermates. Furthermore, the soma size of these neurons was significantly reduced. Interestingly, the MeCP2 overexpressing neurons (Tg1) did not display any of these developmental defects and were identical to WT neurons although synapse number was significantly increased. Restoring MeCP2 to WT levels in MeCP2 null neurons resulted in rescue of dendritic outgrowth comparable to WT neurons. In order to study the importance of MeCP2 during various stages of synapse formation, MeCP2 null neurons were treated with Cre recombinase at various time points during synaptogenesis to rescue MeCP2 to WT levels and synaptic output was measured. We observed that evoked excitatory postsynaptic current amplitude, pool size of readily releasable vesicles and frequency of spontaneous miniature events were significantly rescued to WT levels when MeCP2 was restored at early stages of synapse formation. Moderate rescue was seen also when MeCP2 was restored during synapse maturation. Taken all together, this study shows that abnormal axonal and dendritic outgrowths may contribute in part to the pathophysiology of the Rett syndrome. Furthermore, MeCP2 is critical throughout synapse formation as well as maintenance.

Title: Analysis of whole-brain X-chromosome inactivation within MeCP2 mutant and wild type mice

Authors: *E. SZELENYI, Y. KIM, K. U. VENKATARAJU, P. OSTEN
Cold Spring Harbor Lab., Cold Spring Harbor, NY

Abstract: Rett syndrome (RTT) is an X-linked neurodevelopmental disorder caused by mutations in the methyl-CpG-binding protein 2 (MECP2) gene. Unfavorable skewing of X chromosome inactivation is proposed to contribute to the severity of clinical symptoms in females with RTT. Here we examine X chromosome skewing of MeCP2 using whole-brain imaging of MeCP2-GFP reporter allele (Lyst et al., 2013, Nat Neurosci 16(7):898-902) crossed from the maternal or paternal side into wild type or MeCP2 mutant genetic background. The brains are imaged as 280 coronal section datasets by serial two-photon (STP) tomography (Ragan et al., 2012, Nat Methods 9(3): 255-258), the location of MeCP2-GFP+ cells is detected by convolutional neural network and watershed based algorithms, and the datasets are registered to the a 2-photon based Allen Mouse Brain Atlas with whole brain anatomical segmentation. This analysis revealed a lateralization-based skewing in some wild type mice, replicating a recent finding from different X-chromosome reporter mice (Wu et al., Neuron, 2014. 81(1): 103-19). Currently, our analysis focuses on mapping the distribution of MeCP2-GFP+ cells in the MeCP2 mutant background in female mice MeCP2GFP/null and MeCP2GFP/308X with the GFP allele introduced either from the maternal or paternal side.

Title: The BDNF val-66-met polymorphism impairs dendritic complexity and dendritic spine density and form in hippocampal neurons of Mecp2 knockout mice

Authors: *X. XU[1], J. GARCIA[2], R. EWALT[2], L. POZZO-MILLER[2]
[1]Neurobio., Univ. of Alabama At Birmingham, Birmingham, AL; [2]Neurobio., The Univ. of Alabama at Birmingham, Birmingham, AL

Abstract: Brain-derived neurotrophic factor (BDNF) has been highlighted in Rett syndrome (RTT), an X-linked neurodevelopmental disorder caused by loss-of-function mutations in MECP2. Bdnf mRNA and protein levels are lower in MeCP2-deficient models and RTT individuals, and its overexpression rescues cellular and behavioral deficits. The human BDNF gene has a single nucleotide polymorphism (SNP) - a methionine (met) substitution for valine (val) at codon 66 - that results in cognitive impairments because it affects BDNF trafficking and activity-dependent release; thus, it is highly relevant to know whether this BDNF SNP contributes to RTT pathophysiology. To examine the consequences of the BDNF SNP on dendritic and dendritic spine morphology, human val-BDNF or met-BDNF (tagged with GFP for their subcellular localization) were co-transfected with soluble GFP (to image neuronal morphology) in 6-8 DIV cultured hippocampal neurons prepared from P1 wildtype (wt) and Mecp2 knockout (ko) mice. After 48hs of expression, transfected neurons were fixed, processed for GFP immunocytochemistry, imaged in a laser-scanning confocal microscope, and analyzed with the Filament Tracing and Surface Rendering modules of Imaris software. We confirmed that met-BDNF fails to be properly transported in hippocampal neurons, being restricted to somata and proximal areas of primary dendrites, while val-BDNF is transported to more distal regions of primary and secondary dendrites. In wt neurons, met-BDNF fails to promote dendritic growth and branching, as val-BDNF does ($P<0.05$). In addition, met-BDNF does not increase dendritic spine density and the volume of individual spines in wt neurons, like val-BDNF does ($P<0.01$; K-S test). Of relevance to RTT, we found that Mecp2 ko neurons have impaired dendritic complexity, which is significantly improved by val-BDNF ($P<0.01$); on the other hand, met-BDNF reduces dendritic complexity in Mecp2 ko neurons. Lastly, Mecp2 ko neurons have lower spine density, while the volume of individual spines are larger than in wt neurons (see Li and Pozzo-Miller SfN 2014). Interestingly, val-BDNF increases dendritic spine density and individual spine volumes, while met-BDNF decreases dendritic spine volume ($P<0.001$; K-S test). These findings revealed a deleterious consequence of the human BDNF val-66-met SNP on

dendritic and dendritic spine morphology in Mecp2 ko neurons, suggesting that this BDNF variant contributes to RTT pathophysiology, and that BDNF-based therapies may not be equally effective in all RTT individuals.

Title: Phenotypic improvement in Mecp2-deficient mice after i.v. injection of a self-complementary AAV9 construct expressing a codon-optimized Mecp2 transgene

Authors: *V. MATAGNE, L. VILLARD, J.-C. ROUX
Aix Marseille Universite, UMRS 910, Marseille, France

Abstract: Rett syndrome (RTT) is an X-linked neurodevelopmental disorder that is primarily caused by a loss of function of methyl CpG binding protein 2 (MECP2) whose main function is that of a global transcriptional repressor. RTT is a disease affecting not only CNS functions (profound cognitive and motor deficits) but also peripheral functions (severe breathing abnormalities, autonomic dysfunction). The recent findings that reactivation of Mecp2 rescued adult diseased RTT mice not only indicates that MECP2 is needed for normal adult function (Robinson et al 2012) but also that gene therapy might be beneficial for RTT patients, even after the disease has started. Proof-of-principle that gene therapy was beneficial in a RTT mouse model (Mecp2 deficient or KO mice) has been recently reported by 2 different research teams (Gadalla et al 2013; Garg et al 2013). Although both studies reported an improvement in RTT symptoms, the therapeutic benefits seemed to depend on the age at which the virus was administered as well as the promoter driving the expression of Mecp2. In order to try and improve vector delivery and expression, we designed 2 plasmid constructs expressing GFP (control virus) or a codon-optimized version of Mecp2 (termed MCO) under the regulation of the mouse Mecp2 short promoter (pMe). These construct were used to generate self-complementary AAV9 (scAAV9) viruses. We first tested the scAAV9-pMe-GFP control vector after IV injection through the tail vein of 30-day-old male wild-type (WT) mice (5X10E12 vg/kg BW).

As reported by other groups (Foust et al 2009; Duque et al 2009), we found that this virus transduced CNS cells, although GFP was only expressed in neurons in the case of scAAV9-pMe-GFP. Given the low GFP expression (8.7±0.8 and 13.7±1.9 cells/0,6mm2 in frontal cortex (FC) and putamen-putamen area (CP), respectively, n=5), we elected to carry out a preliminary study injecting scAAV9-pMe-MCO at 5X10E13 vg/kg BW in Mecp2 KO mice. Twenty-five days after injection, mice were sacrificed and Mecp2 expression was quantified by IHC. Compared to WT mice (100% expression, n=3), we found that 8.6%±1% (FC) and 9.7%±1.5% (CP) cells expressed Mecp2 in Mecp2 KO mice (n=2). Despite this low percentage of Mecp2-expressing cells, we did find an improvement in spontaneous activity and sensorimotor coordination as measured in the open-field and rotarod tests. These encouraging preliminary data indicate that even a low level Mecp2 expression can improve RTT symptoms in Mecp2-deficient mice. Further studies will aim at confirming these data and investigating the potential therapeutic effect of scAAV9-pMe-MCO injection in female RTT mice (Mecp2 heterozygous females).

Title: Mechanisms of prefrontal cortical dysfunction in mecp2 null mice

Authors: ***M. P. SCENIAK**[1,2], M. LANG[2], A. C. ENOMOTO[2], C. J. HOWELL[2], D. M. KATZ[2]
[2]Neurosci., [1]Case Western Reserve Univ., Cleveland, OH

Abstract: Limbic cortical dysfunction is thought to contribute to cognitive and behavioral features of diverse neurodevelopmental disorders, including those on the autism spectrum. However, underlying synaptic and circuit-level mechanisms remain undefined. We recently found that loss of *Mecp2*, the gene mutated in Rett syndrome (RTT) is associated with a marked decrease in neuronal expression of Fos protein, an index of neuronal activity, in midline limbic cortices, including the cingulate and retrosplenial and the pre- and infralimbic subdivisions of the medial prefrontal cortex (mPFC; Kron et al., 2012), suggesting that these regions are hypofunctional in *Mecp2* mutants. The present study was undertaken to test this hypothesis by

defining synaptic and circuit function in the mPFC of *Mecp2*$^{tm1.1Jae}$ null mice using acute brain slices. Compared to Wt, layer 5 excitatory neurons in the mutant mPFC exhibit significant reductions in 1) excitatory postsynaptic currents, 2) the duration of excitatory UP states, 3) the ratio of NMDA/AMPA currents and 4) evoked population activity in layers 2/3 and 5. These functional changes are associated with significant reductions in the density of excitatory dendritic spines, the ratio of vesicular glutamate (VGLUT1) to vesicular GABA (VGAT) transporters and the level of NMDA receptor subunit 1 expression. In addition we found circuit abnormalities that differ markedly from those previously described in other cortical regions of *Mecp2* mutants. Specifically, we saw no effect of *Mecp2* genotype on 1) inhibitory synaptic currents, which are increased in primary sensory cortices in *Mecp2* nulls (Dani *et al.* 2005; Dani and Nelson 2009) or 2) expression of the interneuron marker parvalbumin, which is increased in the visual cortex of *Mecp2* nulls (Durand et al., 2013). In addition, we observed a significant increase in the NR2B component of NMDA currents, which is decreased in visual cortex of *Mecp2* nulls (Durand et al., 2013). These data support the hypothesis that loss of *Mecp2* function is associated with reduced activation of excitatory neurons in the mPFC. Moreover, our data, together with previous reports from other laboratories highlight the fact that synaptic and circuit-level phenotypes associated with loss of MeCP2 differ among brain regions. Taking this heterogeneity into account will be critical for designing therapeutic interventions aimed at restoring excitatory/inhibitory synaptic balance in RTT and related disorders. Supported by NINDS (DMK).

Inst., Houston, TX

Abstract: Deep brain stimulation (DBS) is an established therapy for several neurological disorders. By stimulating disease-specific target regions of the brain, DBS in both human patients and animal models has been shown to improve symptoms in Parkinson's disease, obsessive-compulsive disorder, depression, schizophrenia as well as improve cognitive deficits in Alzheimer's disease (AD) and epilepsy. However, the mechanistic dissection of DBS is rare, especially in awake, freely moving transgenic mouse models. A recent study in AD patients suggested that DBS in the fornix, a fiber tract containing cholinergic input from the medial septum to the hippocampus, reduces memory decline and improves cognitive function. Accordingly, we proposed that forniceal DBS will improve cognitive function in female mice heterozygous for a Mecp2 null allele (Rett mouse model). Here we show that unilateral DBS in the fimbria-fornix enhances the retrieval of contextual fear memory in both wild type and MeCP+/- mice, a model of Rett syndrome. Therefore, forniceal DBS rescues the impairment of contextual fear memory retrieval in Rett mice. To examine the cholinergic involvement of forniceal DBS on memory, we bilaterally infused the muscarinic cholinergic blocker atropine into the dorsal hippocampus. DBS-induced memory enhancement was abolished by atropine, compared with saline control. These results suggest that forniceal DBS might improve hippocampus-dependent memory retrieval via modulation of the cholinergic system. Forniceal DBS may serve as a therapeutic intervention to rescue the cognitive deficits of developmental neurological diseases.

Title: Astrocyte dysfunction in a mouse model of Rett syndrome

Authors: *M. L. OLSEN, V. A. CUDDAPAH, N. PACHECO, S. NWAOBI
Univ. of Alabama At Birmingham, Birmingham, AL

Abstract: Rett Syndrome is an X-linked neurodevelopmental disorder, caused by mutations in methyl-CpG-binding protein 2 (MeCP2) in > 95% of cases. RTT is typified by normal development until 6-18 months of age, when motor and communicative skills regress and hand stereotypies, autonomic symptoms, and seizures begin to present. Restoration of MeCP2 function selectively to astrocytes reversed several phenotypes in a murine model of RTT, but the mechanism of this rescue is unknown. Astrocytes serve to dampen neuronal excitability through maintenance of the extracellular concentration of K+, ([K+]o). In frontal brain regions dysregulation of [K+]o can lead to hyperexcitability and seizures, while in brain structures such as the brainstem, autonomic function may be disrupted. Given the high prevalence of seizures in girls with Rett and symptoms which originate from brain stem dysfunction, we hypothesized that MeCP2 loss may lead to disrupted [K+]o. Whole-cell patch clamp experiments of cortical astrocytes from symptomatic MeCP2-/y mice revealed a >50% deficiency in Ba2+-sensitive K+ currents attributable to Kir4.1, an inwardly-rectifying K+ channel implicated in the maintenance of [K+]o in the brain. K+-sensitive microelectrode recordings demonstrated that the baseline [K+]o was elevated by 1 mM in MeCP2-/y mice, and was associated with enhanced intrinsic excitability of layer II/III pyramidal neurons. Kir4.1 protein and mRNA were significantly downregulated in the cortex and brainstem. CHiP analysis revealed that Kir4.1 is a direct molecular target of MeCP2. Our data demonstrate that the loss of MeCP2 impairs astrocytic K+ homeostasis and provide novel mechanistic insight explaining how astrocytic dysfunction may contribute to RTT.

Title: A splicing-regulatory pathway controls neuronal excitation in Rett syndrome

Authors: *L. CHEN[1,2], P. YU[1,2], W. WANG[1,2], C. SHAW[1], H. Y. ZOGHBI[1,2,3]
[1]Baylor Col. of Med., Houston, TX; [2]Jan and Dan Duncan Neurolog. Res. Inst., Houston, TX; [3]Howard Hughes Med. Inst., Houston, TX

Abstract: Alternative splicing is prevalent in the mammalian nervous system, producing structurally and functionally distinct mRNA isoforms to modulate diverse neuronal processes. Although disruption in alternative splicing has been implicated in human brain disorders, the identity and the neuronal function of RNA variants involved in diseases are largely unknown, and the molecular basis for such aberrant alternative splicing remains poorly understood. Here we develop an algorism to reliably identify whole-genome alternative splicing events based on RNA sequencing (RNA-Seq) data. We apply this strategy and discover comprehensive alternative splicing events that are altered in the mouse models of Rett syndrome and MECP2 duplication syndrome. Notably, we identify numerous alternative splicing changes altering proteins involved in synaptic transmission and neuronal excitation. Molecular and genetic experiments reveal that the splicing regulator Rbfox1 functions downstream of MeCP2. In the absence of MeCP2, the expression of Rbfox1 is increased, whereas upon doubling MeCP2 levels the expression of Rbfox1 is decreased. To determine if some of the splicing alterations contribute to the phenotypes of MeCP2 null mice, we bred Mecp2+/- mice to Rbfox1+/- mice and found that heterozygous loss of Rbfox1 in the nervous system rescues alternative splicing and neuronal excitation abnormalities in MeCP2 null animals. We further provide evidence that MeCP2 directly represses the expression of Rbfox1 via remodeling its promoter to a closed chromatin state. Our study delineates a novel molecular pathway in mediating complex alternative splicing networks to control neuronal excitation in the brain.

Title: Bioenergetic dysregulation in MeCP2-null microglia secondary to glutamine transporter SNAT1 overexpression

Authors: *I. MAEZAWA[1], M. HORIUCHI[1], H. WULFF[2], G. CORTOPASSI[3], J. D. ERICKSON[4], L.-W. JIN[1]
[1]M.I.N.D. Inst, UC Davis, Sacramento, CA; [2]Pharmacol., [3]Mol. Biosci., UC Davis, Davis, CA; [4]Louisiana State Univ., New Orleans, LA

Abstract: Rett syndrome is an autism spectrum disorder caused by loss-of-function mutations in the gene encoding MeCP2, an epigenetic modulator that binds the methyl CpG dinucleotide in target genes to regulate transcription. Previously we and others reported a role of microglia in the pathophysiology of RTT. Therefore, how epigenetic dysregulation due to MeCP2 deficiency causes functional impairment in microglia becomes a significant research topic. Our ChIP-seq data using a specific anti-MeCP2 identified a MeCP2 target gene *SLC38A1*, which encodes a major glutamine transporter SNAT1. To understand the possible role of SNAT1 in MeCP2-deficient microglia, we analyzed its regulation and impact on cellular functions using cultured primary microglia, microglia acutely isolated from juvenile *Mecp2*-null and wild-type mice, and BV-2 microglia cells with MeCP2 knockdown or SNAT1 overexpression. Using qPCR and Western blotting, we showed that MeCP2 acts as a transcriptional repressor for the *SNAT1* gene in microglia, but does not affect the expression of a related system A transporter gene *SNAT2*, supporting the SNAT1-targeted regulation by MeCP2. Because glutamine is mainly metabolized in the mitochondria, where it is used as an energy substrate and a precursor for glutamate production, we hypothesize that SNAT1 over-expression would impair the glutamine homeostasis in MeCP2-deficient microglia, resulting in mitochondrial dysfunction as well as microglial neurotoxicity due to glutamate over-production. Supporting this hypothesis, we found that MeCP2 downregulation or SNAT1 overexpression in microglia resulted in (1) glutamine-dependent death of BV-2 cells; (2) proliferation of mitochondria and enhanced mitochondrial production of reactive oxygen species; (3) increased oxygen consumption but decreased ATP production; and (4) over-production of glutamate that caused NMDA receptor-dependent neurotoxicity. Interestingly, the above abnormalities could be rectified by the general anti-oxidant vitamin E as well as mitochondria specific approaches such as the mitochondria-targeted expression of catalase (mCAT) and a cell permeable, mitochondria-targeted peptide antioxidant Szeto-Schiller 31 (SS-31). Our results reveal a novel mechanism via which MeCP2 regulates bioenergetic pathways in microglia.

Title: Alterations of h-currents and voltage-gated Na+ currents in mesencephalic trigeminal propriosensory neurons increase excitability in a mouse model for Rett Syndrome

Authors: ***M. F. OGINSKY**, N. CUI, W. ZHONG, C. JIANG
Biol., Georgia State Univ., Atlanta, GA

Abstract: People with Rett syndrome (RTT) have motor defects in addition to autistic symptoms, which are also seen in *Mecp2*-null mice. It is known that normal motor function relies on motor neurons as well as propriosensory neurons. Whereas motor neurons have been studied for possible roles in the development of movement problems in RTT, much less attention has been given to the propriosensory neurons whose excitability changes can affect the essential feedback to motor neurons required for coordinated movement. To address this issue, we studied the mesencephalic trigeminal (Me5) neurons. In whole-cell current clamp, these propriosensory neurons responded to hyperpolarizing currents with a large sag and post-inhibitory rebound (PIR) suggesting the presence of the hyperpolarization–activated current (I_H). I_H plays a role in membrane excitability, pacemaking and bursting of action potentials. The sag and PIR were reduced in *Mecp2*-null mice by ~35% and ~20%, respectively. In voltage clamp, the I_H density was reduced by ~33%, the steady state activation was shifted by ~10mV toward more depolarization, and the activation time constant was slower in the *Mecp2*-null mice. Changes in the firing activity were studied by injecting depolarizing currents as the Me5 neurons did not fire spontaneously. We found that the Me5 neurons in *Mecp2*-null mice were more excitable than those in the WT despite the major deficiency in I_H. The density of the voltage-gated Na+ currents (I_{Na}) was unchanged but the I_{Na} steady state activation was shifted by ~5mV toward hyperpolarization in *Mecp2*-null mice. Consistently, the firing threshold measured from PIR was ~5mV less in the *Mecp2*-null neurons, while the latency to first spike was unchanged. These data suggest that the *Mecp2* knockout causes a major deficiency in I_H in Me5 neurons, and such

seemingly depressive effect was compensated by I_{Na} by unknown mechanisms making the cells more excitable instead.

Title: Defective GABAergic neurotransmission in the nucleus tractus solitarius in Mecp2-null mice

Authors: ***L.-W. JIN**[1], Y.-C. LIN[1], M. A. ROGAWSKI[2], C.-C. LIEN[4], I. MAEZAWA[1], C.-Y. CHEN[3]

Abstract: Respiratory dysfunction is one of the major clinical features of Rett syndrome (RTT), a devastating neurodevelopmental disorder caused by loss-of-function mutations in the X-linked methyl-CpG binding protein 2 (*Mecp2*) gene. GABAergic dysfunction has been implicated contributing to the respiratory dysfunction. The NTS is the first central site receives and integrates respiratory sensory inputs. Plasticity in the NTS can change the nature of the reflex output. We test the hypothesis that deficiency in *Mecp2* gene reduces GABAergic neurotransmission in NTS. Using whole cell patch clamp technique, we recorded spontaneous inhibitory postsynaptic currents (sIPSCs), miniature IPSCs (mIPSCs), evoked IPSCs (eIPSCs), and agonist-induced whole cell currents from NTS neurons in brainstem slices acutely prepared from age-matched male *Mecp2*-null mice and wild-type littermates. Using qPCR, we determined GABA-A receptor subunit gene expression from NTS punches. Compared to those from wild-type mice (n=11), NTS neurons from *Mecp2*-null mice (n=12) had significantly ($P<0.05$) smaller sIPSC and mIPSC amplitudes without significant changes in frequencies. There was no

significant difference in eIPSC amplitude and pair pulse ratio (PPR) between WT and *Mecp2*-null mice (n=4-6) albeit a greater PPR variability was observed in *Mecp2*-null mice. *Mecp2*-null mice had enhanced response to exogenous GABA-A agonist application (n=4-6) and elevated GABRA1 gene expression (n=3) in the NTS. The data suggest that reduced GABAergic signaling via a post-synaptic mechanism(s) in the NTS contributes to respiratory dysfunction in RTT.

Abstract: Down syndrome (DS) is the most common genetic chromosomal disorder and is associated with intellectual disability and the early onset of Alzheimer's disease. DS is caused by an extra copy of chromosome 21 (Hsa21) and the increased expression of the encoded genes. Hsa21 contains approximately 160 protein-coding genes, the orthologs of which map to

segments of mouse chromosomes 16, 17 and 10 (Mmu16, 17, 10). While several mouse models trisomic for segments of the Mmu16 segment have been studied in detail, little is known about the Dp(10)1Yey (Dp10) mice that are trisomic for the 40 protein coding genes mapping to Mmu10. Here, we compare protein levels and related pathologies in the hippocampus, cortex and cerebellum of 5.5, 8 and 16 month old Dp10 mice, to their age-matched wildtype (WT) littermate controls. In 16 month, but not 5.5. month-old Dp10 mice, by Western blot (WB), we observed significantly elevated astrocytic S100β and pre-synaptic synaptophysin protein levels and significantly less post-synaptic PSD95; GFAP levels were significantly lower in Dp10 vs. WT mice at both ages. By reverse phase protein arrays, we measured levels of ~100 proteins/protein modifications in 8 month old male and female mice. Approximately 40% of proteins showed abnormal levels, including components of MAP kinase and MTOR pathways, glutamate receptors and immediate early gene proteins. We observed both brain region- and gender-specific abnormalities: males showed more perturbations in hippocampus and females more in cerebellum. By immunohistochemistry, in 5.5 and 16 month old mice, no Aβ deposition was observed, however, by stereological analysis of NeuN- positive neurons at 16 months, Dp10 mice showed increased numbers of hippocampal CA1, but not dentate gyrus, neurons. Together these data show that trisomy of Hsa21 orthologs of the Mmu10 region causes age-related cell and molecular changes in brain. These observations are important because male Dp10 mice have shown no learning/memory impairment at 2-4 months of age. Therefore, it is critical to analyze these mice at older ages to determine if age and/or gender-specific abnormalities exist and potentially contribute to the DS phenotype and/or to drug responses.

Title: Fluency semantic measures in young Down syndrome adults correlate with amyloidosis plasma biomarkers

Authors: L. XICOTA[1,2,3], L. DEL HOYO[1,4], G. SÁNCHEZ-BENAVIDES[1], S. DE SOLA[1,2], A. CUENCA[1], J. RODRÍGUEZ[1], M. FARRÉ[1], M. DIERSSEN[2,3], *R. DE LA TORRE[5,3]

Abstract: Down syndrome (DS) patients are known to develop early onset of Alzheimer-like disease (AD). The overexpression of the APP gene combined with the modulation of DYRK1A, that phosphorylates APP, results in an increased Aβ peptides production. Aβ plasma concentrations are increased in young DS adults; nevertheless their correlation with the cognitive performance remains unexplored. Previous studies performed in elderly DS population have successfully linked Aβ plasma concentrations and cognitive decline. Semantic verbal fluency task, developed as a measure of semantic memory and executive function, requires the generation of as many animal names as possible in one minute. Total number of words and its clustering provide an indirect measure of the organization of semantic representations, while word retrieval strategies, such as switching, yield information about set shifting ability. The objective of this study is to understand whether amyloidosis plasma biomarkers correlate with semantic fluency measures. A DS population comprised of 86 (44 males and 42 females) DS subjects aged 17-34 y (mean 23.4 y) were evaluated according to standard scoring rules. Blood samples were obtained from DS patients to evaluate Aβ plasma concentrations (Inno-bia plasma Abeta forms,Innogenetics). An inverse correlation was found between Aβ42 concentrations, the total number of correct words ($r=-0.448, p=0.001$), the number of switchings ($r=-0.337$, $p=0.017$), and the total number of words produced in the last 45s ($r=-0.378$, $p=0.006$) in DS. The last variable is the period in which prototypical items are exhausted and additional search strategies should be engaged. To our knowledge this is the first time Aβ plasma concentrations have been correlated with fluency outcomes in DS patients. Because higher Aβ concentrations translate into worse cognitive performance, not only in the semantic organisation, but also in the set- shifting ability, and these patients still do not have any sign of AD, the scores obtained in the fluency tasks could be considered a first sign of the decline. However, more work is needed to confirm this hypothesis.

Title: Physical exercise rescues adult neurogenesis, synaptic plasticity and memory in Down syndrome mice

Authors: *M. PARRINI[1], D. GHEZZI[2], G. DEIDDA[2], L. MEDRIHAN[2], F. BENFENATI[2], P. BALDELLI[2], L. CANCEDDA[2], A. CONTESTABILE[2]

Abstract: Down syndrome (DS), caused by the triplication of human chromosome 21, is the most frequent genetic cause of mental retardation. The Ts65Dn mouse model of DS show many neurological similarities to the human syndrome, including decreased hippocampal neurogenesis and cognitive impairment. In this study, we have investigated the effect of aerobic physical exercise on adult neurogenesis, synaptic plasticity and memory in Ts65Dn mice. Exposure of adult Ts65Dn mice to running wheels for one month increased the proliferation of neuronal precursor cell and stimulated adult neurogenesis in the hippocampal dentate gyrus. Moreover, physical exercise promoted the recovery of hippocampal synaptic plasticity and, most importantly, fully restored learning and memory in different behavioral task in trisomic mice. These findings demonstrate that Ts65Dn mice benefit from voluntary wheel running and provide evidence that physical exercise could represent a valuable complementary therapy for pharmacological interventions aimed at rescuing cognitive disabilities in DS patients.

Title: Diffusion MRI signature of Down syndrome brain abnormal trajectories

Authors: *E. D. HAMLETT[1], X. NIE[2], A.-C. GRANHOLM[3], H. A. BOGER[3], M. F. FALANGOLA[2]
[2]Radiology, [3]Neurosciences, [1]MUSC, Charleston, SC

Abstract: The Ts65Dn mouse model (TS) of Down syndrome (DS) is widely studied, developing neuropathology and cognitive impairment with age similar to that seen in the brain of humans with DS. These mice exhibit abnormal development and maturation of the brain with changes in dendritic structure and abnormal synaptic plasticity. Although TS mice have been well characterized cognitively and morphologically, little has been published using *in vivo* neuroimaging. Diffusional kurtosis imaging (DKI) is a diffusion MRI technique that extends

diffusion tensor imaging (DTI) by quantifying the non-Gaussian behavior of water diffusion, improving the characterization of the neurite cytoarchitecture. This study investigates the ability of DKI to detect the progressive abnormal developmental brain changes that have been well documented in TS mice. Mice (TS, n=8) and normosomic mice (NS, littermates, n=8) were studied at 2, 5 and 8 months of age. DKI experiments were performed on a 7T Bruker MR system. From DKI, mean kurtosis (MK), axial ($K_{//}$) and radial ($K_{\perp}$) kurtosis metrics were extracted. Regions of interest at the level of the frontal cortex (FC), striatum and hippocampus (HC) were manually drawn using NIH-ImageJ. One-way ANOVA corrected for multiple comparisons using Bonferroni was performed to assess group differences in DKI metrics (statistically significant at $p < 0.05$). The slopes of two group trajectories were compared, with a probability value of less than 0.05 indicating significant differences. Mouse behavior was measured at 8 months of age and the TS group exhibited alterations consistent with previous findings from our group, indicating hyperactivity and behavioral perseverance in a working memory task (novel object recognition). Our DKI results detected significant changes in the FC of the TS mice compared to NS already at 2 months of age (increased MK and $K_{//}$ ($p< 0.03$). At 5 months old, TS mice showed decrease in $K_{\perp}$ in the striatum ($p< 0.03$) and $K_{//}$ in the dorsal hippocampus (DH) ($p< 0.02$), which persisted in the 8 months old mice. Particularly in the DH, the slopes of two group trajectories were significantly different for MK ($p< 0.04$) and $K_{//}$ ($p< 0.03$). Although preliminary, these results validate that DKI metrics can detect TS brain developmental abnormalities; FC diffusion changes may represent less coherence in neurite orientations and abnormal cortical lamination, which may be affecting the myelination process, represented by the decrease in $K_{\perp}$ in the striatum, and triggering defects in axonal spread, represented by the decrease of $K_{//}$ in the dorsal hippocampus. Future studies will correlate DKI findings with specific morphological assessments.

Title: Peripheral biomarkers in Down syndrome follow the same pattern as in Alzheimer ’s disease

Authors: V. VASILEVKO[1], N. MOVSESYAN[2], E. DORAN[2], *I. T. LOTT[2,3]
[1]MIND Inst., Univ. of California, Irvine, Irvine, CA; [2]Pediatrics, UC Irvine Med. Ctr., Orange, CA; [3]Neurol., UC Irvine, Irvine, CA

Abstract: Deposition of amyloid and neuritic plaques in brain parenchyma and cerebral vasculature is a characteristic feature of Alzheimer’s disease (AD). The amyloid-beta protein is a main component of this pathological marker. The process of amyloid brain deposition is paralleled to a significant decrease of amyloid in the periphery which is an eminent biomarker of AD progression. In individuals with Down syndrome (DS) the amyloid precursor protein gene, the source of amyloid-beta, is triplicated. There is strong evidence that in individuals with DS there is an excessive production of amyloid-beta which results in accelerated amyloid plaque deposition and neurotoxicity and development of AD symptoms as early as 40 years of age. In the current study we tested the hypothesis that AD progression in DS is following the same pattern as in the general population and could be detected with traditional biomarker panel. We analyzed CSF and plasma from patients with DS with or without AD as well as MCI, AD and normal controls from the general population. We used MSD multiplex platform for amyloid detection and Millipore Milliplex kit for cytokine/chemokines. We found that amyloid-beta in CSF and plasma of individuals with DS is significantly elevated compared to DS+AD and general population samples. During the disease progression in DS amyloid-beta CSF levels significantly dropped while plasma levels remained stable. Three major groups of cytokines/chemokines in CSF were affected with AD progression in DS individuals. The most significant increase in immune system related factors was observed in IL-6 cytokine, as well as sCD40L and RANTES. Trophic factors IL-7, G-CSF and PDGF-BB were increased also. Angiogenic factor FGF-2 was increased in the CSF of individuals with DS+AD. In plasma changes in cytokine/chemokines levels were not as dramatic as detected in CSF, however, immune system related factors were increased in IL-6 cytokine, IL-8 and MCP-1. Trophic factors G-CSF and PDGF-BB were also increased in DS+AD vs DS individuals. The most remarkable increase in angiogenic factors in plasma was observed in IL-8 cytokine with disease progression. These dramatic changes in immune, trophic and angiogenic factors are, probably, associated with the pathological processes of neurodegeneration, cerebrovascular impairments, apoptosis and misbalanced reaction of the organism to slow down/reverse these changes. Remarkably, cytokine/chemokine changes in CSF are more revealing about the disease progression than plasma levels. Our data suggest that AD is a systemic disorder and the disease progression in individuals with DS follow the same pattern as in general population.

Title: Delayed development of visual acuity in the mouse model of Down syndrome Ts65Dn

Authors: M. R. STASKO[1], D. HERRERO[2], J. J. SCOTT-MCKEAN[3], *A. C. COSTA[3]
[1]Div. of Pediatric Neurology, Dept. of Pediatrics, Case Western Reserve Reserve Univ., Cleveland, OH; [2]Dept. de Saúde Materno Infantil, Univ. of São Paulo Sch. Publ. Hlth., Sao Paulo, Brazil; [3]Div. of Pediatric Neurology, Dept. of Pediatrics, Case Western Reserve Univ., Cleveland, OH

Abstract: Down syndrome (DS), which is caused by the trisomy of chromosome 21, is the most common genetically defined cause of intellectual disability. This genetic disorder also affects the visual system in a variety of ways, which include high incidence of refractive errors, accommodative inaccuracy, amblyopia, strabismus, nystagmus, abnormal oculomotor and vestibular functions, decreased visual acuity, and decreased color and contrast sensitivities. In a previous study (Scott-McKean et al., IOVS 51: 3300- 3308, 2010), we demonstrated that adult mice Ts65Dn (a murine model of DS) exhibit deficits in luminance threshold, spatial resolution, and contrast threshold, compared with euploid control mice, as assessed electrophysiologically by pattern visual evoked potentials. Here, we investigated visual thresholds of optokinetic tracking (OKT), a fundamental visual behavior that facilitates the relative stabilization of retinal images. Using the methods originally described in detail by Prusky el al. (IOVS 45:4611-4616, 2004), we were able to quantify OKT thresholds in untrained and freely moving Ts65Dn and control euploid mice, daily from eye opening (postnatal day 14) to 35 days of age, and then in longer intervals (5-10 days), until the animals were 60-day old. We found that Ts65Dn mice show a significant delay in the maturation of the visual system. Whereas the mean spatial frequency sensitivity to a 100% contrast grating projected on a virtual cylinder for 14-day old euploid control mice was 0.21 c/deg, the mean value of this measure was 0.08 c/deg for Ts65Dn

mice. Ts65Dn mice were only able to achieve a mean spatial frequency sensitivity of 0.21 c/deg at 16 days of age. At age 45 days, the measured values of mean spatial frequency sensitivity were 0.45 and 0.43 c/deg for control euploid and Ts65Dn mice, respectively. The observed delay in the maturation of the visual system in a mouse model of DS mimics the qualitative features of the same phenomenon seen in young persons with DS. This study provides us with a new surrogate endpoint for the emerging field of translational research of potential pharmacotherapies designed to enhance the cognitive and adaptive skills of persons with DS.

Title: Effects of epigallocatechin-3-gallate treatment on cognitive deficits in an adolescent Down Syndrome mouse model

Authors: M. E. STRINGER[1], I. S. ABEYSEKERA[2], R. J. ROPER[2], *C. R. GOODLETT[3]
[1]Psychology, [2]Biol., [3]IUPUI, INDIANAPOLIS, IN

Abstract: Down syndrome (DS) is caused by three copies of human chromosome 21 (Hsa21) and results in a constellation of phenotypes that include intellectual disability (ID) and skeletal abnormalities. Ts65Dn mice, the most extensively studied model of DS, have three copies of approximately half the genes homologous to Hsa21 and display many of the phenotypes including skeletal and ID deficits. DYRK1A is found in three copies in humans with Trisomy 21 and has increased expression in a number of tissues. Dyrk1a is also found in three copies in Ts65Dn mice, shows similar increased expression, and has been shown to be involved in a number of critical pathways including CNS development and osteoclastogenesis. Epigallocatechin-3-gallate (EGCG), the main polyphenol compound found in green tea, is an inhibitor of Dyrk1a activity. We have previously shown that a three week treatment with EGCG during adolescence normalizes skeletal abnormalities in Ts65Dn mice. We hypothesize that a similar EGCG treatment will also rescue cognitive deficits observed in Ts65Dn mice. Trisomic

mice and euploid littermates were given ~10mg/kg/day EGCG or water (control) beginning on postnatal day 24, and the treatments continued either for three weeks or throughout subsequent behavioral testing. Beginning at six weeks of age, the mice were tested on locomotor activity (LMA, two daily 30-min sessions in an activity chamber), novel object recognition (NOR), acquisition of delayed non-matching to place in a T-maze (DNMP) and Morris water maze spatial memory task. Results to date indicate that the Ts65Dn mice were not different from controls on LMA, but showed deficits on NOR (reduced discrimination index for the novel object), the DNMP task (more trials to acquisition criterion), and the MWM task (longer acquisition latencies and reduced time in the target location on probe trials). The EGCG treatment did not significantly improve performance of the Ts65Dn mice on these cognitive tasks. These preliminary results indicate that neither a three-week nor continuous treatment with a low dose of EGCG during adolescence was sufficient to alleviate learning and memory deficits in the Ts65Dn mouse. Supported by Research Support Grant Funds from the IUPUI Office of the Vice Chancellor of Research.

Title: Aging brain in Down syndrome mouse models: Lessons from the cerebellum?

Authors: *N. CREAU[1], S. BENNAI[1], B. SOUCHET[1], E. CABET[1], A. DUCHON[2], J. DELABAR[1], Y. HERAULT[2], F. DAUBIGNEY[1]
[1]Functional and Adaptive Biol., CNRS UMR8251, Paris, France; [2]AneuPath21, Inst. de Génétique Biologie Moléculaire et Cellulaire, Illkirch, France

Abstract: In Down syndrome, the different organization/ connections of the brain, due to 3 copy genes, may impact the aging processes and induce vulnerability to Alzheimer disease. In the aging mouse, the neurons in the cerebellum are altered earlier than those in the hippocampus (Woodruff-Pak et al., 2010), suggesting that analysis of the cerebellum may bring information on

the aging processes at an earlier age. To highlight pathways involved in DS aging, we studied the Ts1Cje model which has a trisomy of MMU16 containing 80 genes, orthologs of HSA21 genes, and in a range of ages that may correspond from young (25y) to mature (55y) adults in humans. We have analyzed the cerebellum of the Ts1Cje at 3 ages: adult (4months), middle-aged (12months) and aged (18months), in parallel to control of the same ages. Neuronal and glial molecular markers were quantified by the slot-blot method to evaluate the effect of age and genotype. Already at middle-age, changes in the levels of several molecular markers (up or down) were identified in the controls that were amplified further in aging. In the Ts1Cje, some of them were altered in the same direction; but, some appeared to be specifically altered. The level of the glial marker, GFAP, was found to increase with age in the controls while less in the Ts1Cje (age and genotype effects). These age and genotype effects were also observed at the transcript level. Interestingly, at the same age, in the cerebellum of TgPCP4 (Mouton-Liger et al., 2014) no increase of GFAP was found suggesting that the overexpression of the neuronal calpacitin Pcp4 (in 3 copies in the Ts1Cje) may counteract the age-related glial alteration. Moreover, changes in neuronal (ex:inositol 1,4,5-trisphosphate receptor, type 1 ITPR1) and glial (ex : S100 calcium binding protein B, S100B) markers during aging highlighted calcium signaling pathways as important modifiers of cerebellum function with age, particularly in the DS model. Additionally, the kinase DYRK1A (in 3 copies in the Ts1Cje) a potential player in Alzheimer disease, was found increased in the controls and trisomics already at middle-age though still following the gene dosage ; this increase was also observed in the forebrain of the same mice at the same age. Current analysis by immunohistochemistry, also in the Ts65Dn, is performed to precise the localization of these molecular markers and of their changes and defined the cell populations and the mechanisms involved. This work was supported by Univ. Paris Diderot, CNRS and grants from the « Fondation Jérôme Lejeune » and the « Association Française de la Recherche sur la Trisomie 21 ».

Title: Cognitive flexibility and receptive vocabulary in Down syndrome

Authors: B. CASTILLO-IGNACIO[1], N. ARIAS-TREJO[1], *O. GARCIA[2], M. MAYORAL-RAMÍREZ[3]
[1]Facultad de Psicología, UNAM, México, Mexico; [2]Psicofisiologia, Facultad de Psicologia, UNAM, Mexico, D.F., Mexico; [3]Integración Down, I. A. P., México, Mexico

Abstract: Down syndrome (DS) is the most prevalent genetic cause of intellectual disability. Lower performance, in comparison to children with typical development or other disabilities, in tasks measuring cognitive flexibility is typically reported. However, preserved language comprehension skills can be found. Although a significant relationship between cognitive flexibility and receptive vocabulary has been reported, little is known regarding the factors involved in such a relationship. The present research aimed to investigate the association between the receptive vocabulary of children with DS and their cognitive flexibility. Fourteen participants (9M, 5F; mean chronological age = 11.66 years; SD = 2.41) performed two tasks: the Card Sorting Task, extracted from the Frontal Lobes and Executive Functions Battery (BANFE), and the Peabody Picture Vocabulary Test (PPVT-III). The results from PPVT-III indicated a receptive vocabulary score of 3.10 years (SD= 0.66). Results from the Card Sorting Task yielded a mean standard score of correct responses of 6.71 (SD = 1.858), and 3.57 (SD= 2.848) in perseverations. According to the BANFE scale of the Card Sorting Task, 71.4% of the participants reached normal performance, 21.4% showed a mild-moderate deficit level and 7.1% a severe detriment level; while for perseverations 7.1% reached normal performance, 35.7% mild-moderate deficit level and 57.1% a severe detriment level. The mean performance time in the Card Sorting Task was 736.9 seconds; according to the BANFE scale, 14.3% of the participants reached normal performance, 14.3% showed a mild-moderate deficit level and 71.4% of the participants could not be classified since their performance mean time exceeded the 600 seconds permitted to respond. Correlations between receptive vocabulary from PPVT-III, mean correct responses and performance time in the Sort Card Task revealed that the receptive vocabulary score was positively correlated with the standard score of correct answers ($r=.639$, $p<0.05$) and negatively with performance time ($r=-.541$, $p<0.05$). Moreover, chronological age only correlated with receptive vocabulary ($r=.535$, $p<0.05$). The current results suggest a preserved ability, by DS children, to generate in a spontaneous manner a classification criterion (by color, shape); however, they showed deficits to change in a flexible manner the classification criteria. Also, in most of the cases the time to solve the task of cognitive flexibility was longer than expected. Finally, cognitive flexibility in DS children is not linked to receptive vocabulary, thus intervention strategies centered in executive functions improvements are deem prudent.

Abstract: Down syndrome (DS), human trisomy 21, is the most common genetic cause of intellectual disability in children and young adults. The genomic regions on human chromosome 21 (Hsa21) are syntenic to the three regions in the mouse genome, located on mouse chromosome 10 (Mmu10), Mmu16, and Mmu17. We examined Dp(16)1Yey/+ (Dp16) mice, a recently created genetic model of DS which harbors a third copy of ~113 genes located on 22.9 Mb segment syntenic to Hsa21 on Mmu16. In comparison to Ts65Dn, Dp16 mice carry three copies of 16 additional Hsa21 genes and do not have triplication of the subcentromeric Mmu17 region. Previously, we reported that Dp16 mouse model exhibits DS-related neurological defects, including impaired hippocampal-mediated learning and memory (Morris water maze and contextual fear conditioning tests) and reduced hippocampal long-term potentiation (Yu et al.,

2010). In this study, we explored DS-related phenotypes in Dp16 mice with the age ranging from 21 days to 17 months. We assessed locomotor and cognitive behaviors, hippocampal electrophysiology and brain morphology, as well as biochemistry. Compared to wild type (WT) mice, there was a reduction in the body weight starting at 10 months old ($p = 0.02$) that continued to 17 months old ($p = 0.01$). Brain weight was at first reduced at 10 months ($p = 0.02$) in Dp16 mice. Abnormalities in the Y-maze test were evident from 21 days of age ($p = 0.007$) and were still detected at 8 months ($p = 0.002$). Novel object recognition with a 24 hours delay just showed deficits in 17 months Dp16 mice ($p = 0.005$). No changes were found in locomotor activity at 10 or 17 months of age (total distance traveled: $p = 0.42$, $p = 0.33$, respectively). CA1 hippocampal LTP was reduced at 3 months of age in Dp16 mice ($p = 0.013$). Hippocampal volume was significantly reduced at 10 months ($p = 0.028$) and the cholinergic phenotype was evident at the same age with a reduction in the area of ChAT+ cell ($p = 0.048$) and the number of ChAT+ neurons ($p = 0.066$) in medial septum. In conclusion, Dp16 mice conservate many of the phenotypes of the Ts65Dn mice but demonstrate changes in the onset of time deficits. Dp16 mice thus provide an excellent model for the future studies of neurobiology of DS.

Title: The cortical landscape of the Down’s syndrome brain with and without Alzheimer’s disease neuropathology

Authors: *T. ANNUS[1], L. R. WILSON[1], J. ACOSTA-CABRONERO[2], A. CARDENAS-BLANCO[2], S. ZAMAN[1], A. J. HOLLAND[1], P. J. NESTOR[2]

Abstract: Post mortem and morphometric studies have shown distinctive gross anatomical differences between the brains of people with Down's syndrome (DS) and typically developing individuals. Furthermore, studies have investigated the effects of early development of Alzheimer's disease (AD) neuropathology on DS brain morphometry and volume, which resembles the neuropathological pattern seen in sporadic AD. However to our knowledge, there are no studies that have reported the differences in the cortical landscape of the DS brain with respect to the typically developing brain and the subsequent changes that emerge with the development of AD neuropathology in this population. The aim of this study is to provide a detailed account of the pattern of cortical thickness in the DS brain at baseline (without amyloidosis) and to investigate how this is affected by the development of AD neuropathology. We measured cortical thickness using a set of automated tools (Freesurfer) to reconstruct the brain's cortical surface from T1-weighted structural MRI data (MPRAGE) in 34 subjects with DS, of which 10 were positive for fibrillar β-amyloid on PiB-PET scans, and 30 age-matched healthy controls. Regression analysis with age was performed using SPM8. Compared to cognitively normal subjects, adults with DS without amyloidosis had thinner cortex primarily in bilateral motor cortex and right retrosplenial cortex. Cortical thickening was visible in bilateral prefrontal, primary sensory, posterior cingulate and occipito-temporal cortex in those subjects with DS. In comparison to healthy controls, the 10 oldest subjects with DS without amyloidosis showed cortical thinning in bilateral, motor cortex, left superior temporal gyrus and right retrosplenial cortex, whereas cortical thickening was localised to bilateral prefrontal, primary sensory, posterior cingulate and occipital cortex. Adults with DS with amyloidosis had thinner cortex in bilateral retrosplenial, motor, lateral parieto-temporal and left subcollosal cortex and thicker cortex in prefrontal cortex, when compared to healthy controls. Age had no effect on the cortical thickness in subjects with DS without amyloidosis (single group regression corrected for TIV, FWE=0.05). The results of this study provide evidence of the detailed pattern of cortical thickness in DS brain at baseline and how it deviates from the cortical anatomy of the healthy control brain. With the development of AD neuropathology and amyloid deposition, a further change of cortical thickness from the baseline is visible, providing insights into the effects of AD neuropathology and amyloid deposition on cortical thickness in adults with DS.

Title: Nicotine treatment improves neural and cognitive measures of memory in adults with down syndrome: An open-label pilot study

Authors: *A. R. KAMKWALALA[1], A. KEY[2], E. DYKENS[2], D. JONES[2], V. C. GAU[1], A. POTTER[3], P. A. NEWHOUSE[1]
[1]Psychiatry, Vanderbilt Univ. Sch. of Med., Nashville, TN; [2]Kennedy Ctr., Vanderbilt Univ., Nashville, TN; [3]Clin. Neurosci. Res. Unit, Univ. of Vermont Col. of Med., Burlington, VT

Abstract: Adults with Down Syndrome (DS) are at higher risk for age-related cognitive changes and dementias, and experience age-related cognitive changes up to 20 years earlier than normally developed individuals. The heightened risk of Alzheimer's disease (AD) in DS is conferred by a partial or full duplication of chromosome 21, which includes the amyloid precursor protein, APP. Cognitive symptoms of AD are associated with progressive damage to the cholinergic receptor system, thus cholinergic receptors and projections decrease as cognitive status worsens. Prior studies in our lab have shown that activation of remaining nicotinic receptors with chronic transdermal nicotine has positive cognitive effects on adults with mild-cognitive impairment (MCI), a prodromal disorder to AD (Newhouse et al, Neurology 78: 91-101). We hypothesized that treatment with nicotine may have similar benefits in middle-aged adults with DS, by improving memory and attention with chronic treatment. We administered 4 weeks of a low-to-moderate dose (7-14mg) of nicotine via transdermal patch to adults (25 years+) with DS. Participants were tested on a cognitive battery to assess working memory, attention, and visual event-related potentials (ERP) at Baseline, Day 14, Day 28, and a post-treatment follow-up at Day 42. Safety and tolerability measures were assessed at all visits, to monitor side-effects of the drug. Modified Buschke Selective Reminding task results show an increase in 'consistency', a measure of ability to hold words in working memory, at Day 28 vs. Baseline. On the Choice Reaction Time task, one individual's performance showed a promising decrease in reaction time from baseline to Day 28 that persisted to Day 42. Preliminary ERP analyses show that nicotine treatment caused increased amplitude of visual ERP P600 wave in response to a repeated stimulus during a passive memory task at Day 28 and Day 42 vs. Baseline, an indication of visual recognition/memory. Vital signs responded as expected, with decreases in weight by Day 28. Blood pressure remained stable across study duration, within normal ranges. Nicotine

treatment was well tolerated, safety results suggest that slower titration of dose is ideal in this population. This study provides evidence that chronic administration of nicotine may have the potential for beneficial CNS effects on attention and memory processes in adults with DS.

Title: Neural correlates of reading comprehension pre- and post-intervention in struggling readers

Authors: ***M. A. ROE**[1], J. E. MARTINEZ[1], J. A. MUMFORD[1], J. J. JURANEK[3], L. A. OLMEDO[1], R. A. POLDRACK[1], S. R. VAUGHN[2], J. M. FLETCHER[4], J. A. CHURCH[1]
[1]Psychology: Cognitive Neurosci., [2]Education: Special Educ., Univ. of Texas At Austin, Austin, TX; [3]Pediatrics, Univ. of Texas Med. Sch. at Houston, Houston, TX; [4]Psychology, Univ. of Texas at Houston, Houston, TX

Abstract: One way to assess a reading intervention is to look for functional brain changes between pre- and post-intervention. We are part of a large, multi-city, in-school 4th grade reading intervention project that focuses on reading comprehension and its interactions with attention skills. We thus investigated the neural processes of reading comprehension and inhibition as part of an evaluation of the intervention. Children (ages 8-11 years), identified as struggling or typical readers, participated in a dual-site pilot neuroimaging study: the University of Texas at Austin and the University of Texas Medical School at Houston. At the UT Austin site, 20 struggling readers completed an fMRI session before intervention, 16 struggling readers completed an fMRI session after the first year of intervention - 11 subjects completed both fMRI sessions - and 23 typical readers completed one fMRI session. From these data, a subset of subjects (who performed sufficiently, and had low enough movement) was included in each task analysis. Participants performed a sentence comprehension task (SC) and a stop-signal task (SST). The SC task (3 runs, 32 sentences/run) included four sentence categories: active sensible,

active non-sensible, passive sensible, and passive non-sensible. Subjects indicated if the sentence was sensible or non-sensible. The SST (2 runs; 96 “go” trials and 32 “stop” trials each run) included a visual stop signal staircased to maintain stop accuracy performance at 50%. Subjects were excluded from the SC fMRI analyses if accuracy on the task was <60%. SST exclusion criteria and calculations were based on Congdon et al. 2012. fMRI analyses of the SC task suggest struggling readers show more similar brain activity to typical readers after one year of reading intervention relative to pre-intervention measurements in numerous reading-related regions. Looking within just the struggling readers from whom we had repeated measures, the greatest changes during sentence comprehension were in putative task control regions (including anterior cingulate and bilateral insula). During the SST “stop” trials, we observe sub-threshold differences in right temporoparietal junction (TPJ) and right superior temporal sulcus (STS) in struggling readers relative to typical readers. During SST “go” trials we observe differences between pre-intervention and post year-1 intervention scans in struggling readers in putative task control regions. Our results are interpreted in the context of both reading and task control literatures, and suggest that changes in task control may precede behavioral and reading-related changes.

Title: Manipulation of cue switching variables in children and adults

Authors: *J.-R. BAUER, J. E. MARTINEZ, M. A. ROE, J. A. CHURCH
Univ. of Texas at Austin, Austin, TX

Abstract: Cognitive flexibility, the ability to adjust to new tasks and demands, is one of the last executive functions to develop and is also one of the most taxing (Diamond, 2013). We examined the relative impact of different manipulations on task switching across development with two goals in mind. First, we aimed to reduce differences in adult and child performance, thus reducing behavioral confounds observed in previous imaging studies. To that end, we

created a computer-based cue-target task consisting of nine runs of increasing difficulty via manipulations of response mapping consistency, stimulus congruency, number of tasks, and number of possible responses. Second, we wanted to measure short-term learning within the task paradigm as a function of age. To quantify learning, we added a tenth run identical in difficulty to the easiest first run. We collected behavioral data from 60 children aged 6-16 years and 60 adults aged 18-27 years in Study 1 and 33 children aged 7-15 years and 46 adults aged 18-25 years for Study 2. In Study 1, response mappings remained on the screen when the target appeared to potentially reduce difficulty for children. Study 2 induced greater cognitive load by having the onscreen reminders of response mappings disappear when the target arrived. With respect to our first goal, attempts to reduce differences in adult and child performance were largely unsuccessful; children were slower, less accurate, and more affected by the task-level manipulations than adults. However, in Study 1 we found a critical transition where children 12 years and up displayed more adult-like responses relative to younger children. In Study 2, we found a similar transition, but later, occurring around 15 years. We also found an interaction between switch costs and response-mapping manipulations where runs with mixed mappings had equal switch and repeat costs. Further, in runs with more than two response choices, repeat trials were more costly than switch trials for participants across age, while the opposite held true when there were only two response choices. Relevant to our second goal, we found similar amounts of behavioral improvement for both age groups, despite high starting levels of performance in adults. As a result of the higher cognitive load in Study 2, there was greater relative improvement in both age groups compared to Study 1. These results support the idea that more challenging tasks can promote higher degrees of short-term learning. Both studies show evidence of the ability to temporarily train and improve task-switching abilities in children within a single session, and have relevance for the study of atypical developmental populations in the future.

Title: Support vector machine classification of pediatric Tourette syndrome using resting state functional connectivity

Authors: *D. J. GREENE[1], J. A. CHURCH[5], B. ADEYEMO[2], B. NARDOS[2], K. J. BLACK[3], B. L. SCHLAGGAR[4]
[1]Radiology, [2]Neurol., [3]Psychiatry, [4]Neurology, Radiology, Washington Univ. Sch. of Med., Saint Louis, MO; [5]Psychology, The Univ. of Texas at Austin, Austin, TX

Abstract: Tourette syndrome (TS) is a childhood-onset neuropsychiatric disorder characterized by motor and vocal tics. While tics constitute the major diagnostic symptom, TS is quite heterogeneous. Not only does tic severity vary widely across individuals, but TS also commonly involves other psychiatric and cognitive symptoms, has a waxing and waning profile of symptoms, and has a long-term prognosis that is difficult to accurately estimate. Current understanding of the brain mechanisms underlying TS is based on research that often treats individuals with TS as essentially homogenous. Thus, approaches that can capture the underlying features of an individual's particular presentation would be immensely beneficial to the field. In the present study, we aimed to take a first step toward this goal and make diagnostic predictions about individuals using resting state functional connectivity (RSFC) MRI. We applied support vector machine (SVM) classification to test whether patterns in whole-brain RSFC could predict diagnostic group membership. SVM classification takes a multivariate approach that can be sensitive to detecting group differences in patterns of data that may go unseen by traditional univariate analyses. RSFC data from 42 children with TS (8-15 yrs) and 42 tic-free controls matched for age, IQ, and in-scanner movement were included in the study. Data underwent strict volume censoring and preprocessing procedures to minimize motion-related effects. Correlations between a large set of RSFC-derived ROIs that covers the whole brain were submitted to both traditional univariate t-tests (corrected for multiple comparisons) and to the SVM classification algorithm. While univariate tests revealed no significant group differences, SVM was able to classify group membership with 74% accuracy ($p < .001$). Interrogation of the RSFC features driving the classification revealed an aggregation of functional connections that were both within and between RSFC-derived brain networks. These results support the contention that multivariate methods may be necessary to capture the complexity of some brain disorders, and hold promise for predicting prognosis and treatment outcome for individuals with TS.

Title: Altered synaptic plasticity in Tourette's syndrome and its relationship to motor skill learning

Authors: *V. C. BRANDT[1], E. NIESSEN[2], C. GANOS[3], T. BÄUMER[1], A. MÜNCHAU[1]
[1]Univ. Clin. Schleswig-Holstein, Lübeck, Lübeck, Germany; [2]Inst. of Neurosci. and Medicine, Res. Ctr. Jülich, Jülich, Germany; [3]Sobell Dept. of Motor Neurosci. and Movement Disorders, Univ. Col. London, London, United Kingdom

Abstract: Gilles de la Tourette syndrome (GTS) is a neuropsychiatric disorder characterized by motor and phonic tics that can be considered motor responses to preceding inner urges. It has been shown that GTS patients have inferior performance in some motor learning tasks and reduced synaptic plasticity induced by transcranial magnetic stimulation. However, it has not been investigated whether altered synaptic plasticity is directly linked to impaired motor skill acquisition in GTS patients. In this study, cortical plasticity was assessed by measuring motor-evoked potentials before and after paired associative stimulation (PAS) in 14 GTS patients (13 male; age 18 - 39) and 15 healthy controls (12 male; age 18 - 33). Tic and urge severity were assessed using the Yale Global Tic Severity Scale and the Premonitory Urges for Tic Disorders Scale. Motor learning was assessed 45 mins after inducing synaptic plasticity and 9 months later, using the rotary pursuit task. On average, long-term potentiation-like effects in response to the paired associative stimulation were present in healthy controls but not in patients. In GTS patients, long-term potentiation-like effects were associated with more and long-term depression-like effects with less severe urges and tics. While motor learning did not differ between patients and healthy controls 45 mins after PAS (figure 1a), the learning curve of the healthy controls started at a significantly higher level than the Tourette patients' 9 months later (figure 1c). Induced synaptic plasticity correlated positively with motor skills in healthy controls 9 months later (figure 4d). The present study confirms previously found long-term improvement in motor performance after PAS in healthy controls but not in GTS patients. Patients did not show long-term potentiation in response to PAS and showed reduced levels of motor skill consolidation after 9 months compared to healthy controls. Moreover, long-term depression-like effects in GTS patients were related to superior motor skill learning (figure 1b) and to fewer symptoms, suggesting a compensatory mechanism.

Title: Treatment-related changes in EEG activation in Tourette's syndrome

Authors: *M. MIYAKOSHI[1], S. MAKEIG[1], J. PIACENTINI[2], P. WALSHAW[2], S. CHANG[2], J. MCCRACKEN[2], S. K. LOO[2]
[1]Swartz Ctr. For Computat. Neuroscience, INC, UCSD, La Jolla, CA; [2]Dept. of Psychiatry and Biobehavioral Sci., Univ. of California Los Angeles, Los Angeles, CA

Abstract: Background The challenge in studying cortical activity in Tourette's Syndrome is involuntary movements that prohibit the use of MRI due to movement artifacts. We propose the use of EEG measurement with computational data mining as a promising alternative. Materials and Methods 21 patients of chronic tic disorder participated, and 17 of them underwent two sessions before and after Habit Reversal Training. We administered three 5-minute sessions: tic freely; verbal instruction to suppress tic; the same but with $10 reward. Tic severity was evaluated using Yale Global Tic Severity Scale. EEG was recorded from 40 scalp channels. EEG data were annotated with tic onset markers and analyzed with EEGLAB (SCCN, UCSD). Results Tic counts during tic freely condition was average 29 (SD 15); verbal suppression 14 (8); reward suppression 13 (10). Independent component clustering analysis found a cluster centered at [0 13 43] in Talairach coordinates, which we identified to be supplementary motor area, to which 12/17 participants contributed. The inter-trial phase coherence of this cluster after training was significantly associated with treatment-related behavioral improvement in tic severity and frequency ($r = 0.78$, $p < 0.005$). Conclusion We found treatment-related changes in EEG activation in Tourette's Syndrome. We demonstrated the usefulness of EEG measurement with this neurological disorder, and revealed the electrophysiological representation of pre-tic brain dynamics in the supplementary motor area.

Title: Distinct cortical and subcortical networks drive myoclonic and vocal tics in the nonhuman primate model of Tourette syndrome: A PET and electrophysiological study

Authors: ***K. W. MCCAIRN**[1], Y. NAGAI[2], Y. HORI[2], A. IRIKI[3], M. TAKADA[1], T. MINAMIMOTO[2], M. ISODA[4], M. MATSUMOTO[5]

Abstract: Myoclonic and vocal tics, believed to arise from abnormalities in the cortico-basal ganglia (CBG) system, are primary symptoms associated with Tourette syndrome (TS). We used a nonhuman primate model of TS to investigate the neurophysiological and behavioral dynamics of myoclonic and vocal tics. Tourettisms were induced through bicuculline (GABA antagonist) disinhibition of different functional territories in the CBG system. Specifically, bicuculline targeted to the sensorimotor territory of the striatum (putamen) led to repetitive myoclonic tics, while placement in the limbic territory (nucleus accumbens) induced persistent vocalizations. Using video, electromyographic (EMG), local field potential (LFP) recordings, and PET scanning, we demonstrate that simple myoclonic and vocal tics exhibit partly similar but largely distinct properties with respect to the emergence of pathological behavior and brain states. Critically, myoclonic tics showed a faster expression rate and had a longer duration period than vocal tics. At the cortical level, the amplitude of LFP spikes in the primary motor cortex (M1) and the anterior cingulate cortex (ACC), major origins of the CBG system, characterized the two behavioral conditions. Tic-associated cortical LFP spikes were larger for simple myoclonic than vocal tics. In addition, simple myoclonic tics were associated with a strong 1:1 relationship between the LFP spikes in the M1 and EMG activity, while the relationship to vocal tics and the LFP spikes in the ACC was more complex. Although there was a strong correlation between the emergence of LFP spikes in the ACC and vocalizaion, it was also observed that the LFP spikes during vocal tics could occur at variable latencies prior to and after vocalization. However, reduction of regional cerebral blood flow was seen in both the M1 and the ACC during the peak effects of bicuculline-induced tourettisms, possibly reflecting silencing of cortical activity during inter-tic intervals. The present findings indicate that different CBG network alterations underlie the major symptom subtypes of TS (myoclonic vs. vocal tics), and this segregation opens the possibility of discrete therapeutic targeting to suppress individual symptom subtypes in TS.

Title: Integrative analysis of gene expression and rare single nucleotide variations in RNAseq data of the striatum in Tourette syndrome

Authors: *G. COPPOLA[1], J. B. LENNINGTON[1], Y. KATAOKA-SASAKI[1], T. FERNANDEZ[1], D. PALEJEV[1], Y. LI[1], A. HUTTNER[2], M. PLETIKOS[3], N. ŠESTAN[3], J. F. LECKMAN[1], F. M. VACCARINO[1]
[1]Child Study Ctr., [2]Dept. of Pathology, [3]Dept. of Neurobio., Yale Univ., New Haven, CT

Abstract: The etiology of Tourette syndrome (TS) is unknown. Despite a high population prevalence and substantial genetic contribution, attempts to identify common gene variants through genome wide association studies have not revealed candidates above threshold significance. Here we focused on evaluating transcriptional differences in the striatum (caudate and putamen), a brain region highly implicated in TS. We sequenced RNA isolated from post-mortem tissue of 9 individuals that had severe persistent TS symptoms in adulthood compared to 9 matched controls. Differential gene expression analysis revealed 309 down-regulated genes related primarily to neuronal signaling, specifically of striatal interneurons, and 822 up-regulated genes, mainly encoding for inflammatory and immune-related proteins. Weighted gene co-expression network analysis and gene set enrichment analysis revealed 17 gene co-expression modules associated with TS. The top-scoring down- and up- regulated modules were enriched in striatal interneuron-related genes and immune-related genes, respectively. Immunohistochemical studies of fixed tissue series further confirmed that three classes of striatal interneurons are significantly reduced in TS: (1) cholinergic and (2) parvalbumin^{+}-GABAergic interneurons, which had been previously reported; and (3) nitric oxide synthase1(NOS)$^{+}$/neuropeptide Y(NPY)$^{+}$/somatostatin(SST)$^{+}$-GABAergic interneurons. Reductions in these classes of interneurons were also indicated by significant decreased striatal expression of CHAT, CHRM2, SLC5A7 and several other cholinergic-related genes, and several GABAergic-related genes including GAD1, NOS1, NPY, and SST. These data strongly implicate disrupted interneuron signaling in the pathophysiology of severe TS. However, we found a lack of correlation between the expression of interneuron-related and immune system-related classes of transcripts, suggesting that these two signatures may independently contribute to TS pathophysiology. We

also evaluated the intersection of the network modules with genomic variants. Intersection of our network modules with genes implicated in a recent study of TS-associated copy number variants revealed enrichment in interneuron- and protocadherin- related gene modules. Analysis of rare single nucleotide variants (SNVs) from the RNA seq data revealed significant association of UTR SNVs within the immune-related gene module with TS, and marginal association of non-synonymous SNVs within the protocadherin-related gene module. Together these genomic alterations implicate cell adhesion and immune function loci in TS.

Title: Oscillations and plasticity in Tourette Syndrome

Authors: *R. HASHEMIYOON
Univ. of Miami, Coral Gables, FL

Abstract: Aberrations of synchronous neuronal activity have been correlated with a multitude of neurological disorders, including Parkinson's disease (PD), tinnitus, schizophrenia, autism spectrum disorder, and Tourette syndrome (TS). While the pathophysiology of these and other brain disorders is both distinct and unresolved, pathological hypersynchronization of neuronal groups has been consistently reported. Human, animal, and theoretical studies have further demonstrated a shift back towards physiological state concomitant with desynchronization of the abnormal activity. Additionally, models of plasticity have been derived to simulate and explain network dynamics with high levels of synchronization. One type of plasticity in particular, spike time dependent plasticity (STDP), has been explored and extrapolated to disorders of hypersynchrony such as PD and tinnitus. Circuit function with respect to disorders of synchrony, however, must also include hyposynchrony such as described in TS; yet, there are virtually no reports addressing this regime. Our recent study using deep brain stimulation (DBS) electrodes to record from the human thalamus demonstrated a correlation between low synchrony in the gamma band and positive symptoms of the disorder (tics). Despite being persistent, tic

expression waxes and wanes, however the mechanism by which this occurs is unclear. I propose here that the governing dynamic is one of alternation between strongly and weakly synchronized states, representing the waning and the waxing modes of tic expression, respectively. Furthermore, by considering STDP in this regime, the two states coexist in the network with synaptic strength dictating the level of synchrony. A model for this bistability has been described as the Sisyphus Effect, in which a network is characterized by spontaneous fluctuations between the two levels of synchrony. Mechanisms of STDP may also be useful for producing therapeutic changes in TS pathophysiology. Under conditions of STDP, a network can be moved into either a synchronized, desynchronized, or bistable state. Additionally, by means of feed forward inhibition, such as occurs in the recurrent loop of TS, GABA can control STDP by reversing its polarity. Either or both of these processes can be used or manipulated to increase neuronal coordination from the hyposynchronized pathological state seen in TS to a normal physiologic one.

Title: Individual differences in implicit learning abilities in young children: Implications for autism treatment predictors

Authors: *R. M. JONES[1,2], C. LORD[2]
[1]Rebecca Jones, NEW YORK, NY; [2]Psychiatry Dept., Weill Cornell Med. Col., New York, NY

Abstract: Implicit associative learning is an individual's ability to form connections between objects or stimuli without conscious awareness. There is inconsistency in the literature as to whether individuals with Autism Spectrum Disorder (ASD) have difficulties with such learning. Some suggest that there is impairment, while others report no differences compared to typically developing (TD) individuals. We hypothesize that the discrepancy is not simply explained by

methodological differences across studies, but reflects variability within ASD for implicit learning. Building upon the implicit learning literature, we designed a child-friendly task that measures differences in reaction time (RT) behavior and accuracy to a target stimulus predicted by two cues at differing probabilities. In each trial, children were instructed to touch a target image presented on an iPad but to refrain from touching the cues and distractor image. Unbeknownst to the participants, one of the cues predicted the target image at a high probability (75%), while the other cue preceded the target at a low probability (25%); the distractor appeared when the target was not presented. Trials were divided into thirds (early, middle and late) in order to assess learning differences. Preliminary results (N = 8; 2M; 3-6 years of age; Mean IQ = 113) are reported in TD children. All children demonstrated an increase in false alarms (incorrectly pressing the distractor) when presented with the high probability cue versus the low probability cue. All children show speeding in reaction times by the late trials to the target when preceded by the 75% cue compared to the 25% cue. Some children, regardless of age, demonstrate this pattern during middle trials, suggesting individual differences in implicit learning. Interestingly, after the task, only 2 of 8 children correctly matched the target image with the 75% cue image, suggesting learning occurred without conscious awareness. Preliminary data suggest, all TD children regardless of age, form associations during an implicit probabilistic learning task. Individual differences in how quickly children learn the patterns may be important for predicting intervention success in young children with ASD. Ongoing research in TD children, TD children who have a sibling with ASD and children with ASD will categorize individual variability in implicit learning abilities both within and across groups of children. The behavioral findings will be the foundation for future research with this task during functional Magnetic Resonance Imaging to understand the neural underpinnings of individual variability in implicit learning abilities in young children with ASD.

Abstract: Background: Little is known about the cognitive profiles of high-functioning autism spectrum disorder (ASD) and attention deficit hyperactivity disorder (ADHD) in adults based on the Wechsler Intelligence Scale III (WAIS-III). Objectives: To examine cognitive profiles of adults with no intellectual disability (IQ > 70), and in adults with ASD (Asperger's disorder (AD), High-Functioning Autism (HFA)) and ADHD using the WAIS-III. Methods: The clinical group of this study comprised outpatients at Showa University Hospital attending a diagnostic outpatient clinic for adults 18 years of age and older with suspected ASD. All patients were referred by physicians from other clinics. Inclusion criteria were WAIS-III FIQ ≥ 70; age of 18 to 60 years; no current use of anti-psychotics; and formal diagnosis of ASD, including autistic disorder, AS, and ADHD based on the DSM-IV-TR. To assess the presence of autistic traits, the Japanese version of the Autism-Spectrum Quotient (AQ) and Pervasive Developmental Disorders Autism Society Japan Rating Scale (PARS). Results: Verbal Intelligence (VIQ) - Performance Intelligence (PIQ) differences were detected between the two groups. Some subtest scores were significantly higher in ASD than in ADHD. Conclusions: The findings demonstrated cognitive profiles characteristic of adults with high-functioning ASD and ADHD.

Title: Functional connectivity of the visual cortex in children with neurofibromatosis type 1 and reading disability during single word reading

Authors: *L. A. BARQUERO, K. SWETT, S. K. BAILEY, S. S. BURNS, L. E. CUTTING
Vanderbilt Univ., Nashville, TN

Abstract: Neurofibromatosis Type 1 (NF1) is a genetic disorder with a prevalence of about 1:3500. Reading disabilities (RD) and visuospatial deficits are commonly associated with NF1, yet few investigations have characterized differences between RD in NF1 and idiopathic RD. A previous behavioral study indicated that reading interventions in populations with NF1 helped remediate both reading and visuospatial processes, raising questions about the contribution of visual systems in NF1 reading deficits. The purpose of this study was to explore functional connectivity of the visual cortex during reading, comparing children with NF1 and RD (NF+RD) to children with idiopathic RD. Participants were 39 children and adolescents (8-14 yrs) comprising three groups: NF+RD (n = 11), RD only (n = 13), and typically developing readers (TD; n = 15). During fMRI, participants performed a single word reading task, reading words that varied along dimensions of concreteness ("door" vs. "need") and spelling regularity ("came" vs. "clothes"). Connectivity analyses revealed significant differences in functional connectivity in readers with NF1. When reading abstract words, the NF+RD group alone showed decreased connectivity of the visual cortex (BA 17, 18, 19) with the left dorsolateral prefrontal cortex (p<0.001, uncorrected; k> 90), an area that has been implicated in visuospatial attention. Further analyses comparing conditions of regularly spelled vs. irregularly spelled abstract words revealed that the irregular condition appears to drive the connectivity difference observed for NF+RD in the left dorsolateral prefrontal cortex. In addition, when reading irregular abstract words, the NF+RD group exhibited decreased functional connectivity between visual cortex and left angular gyrus (p<0.001, uncorrected; k> 90), a semantic association area, and this difference was not observed in RD. Results suggest that reading deficits associated with NF1 may have underlying neurobiological differences as compared to idiopathic RD, and these differences are potentially related to visuospatial deficits commonly associated with NF1.

Title: Rhythm in music: Improving auditory processing in an animal model of developmental dyslexia

Authors: A. D. GRIFFIN, K. A. MCGINNIS, *A. H. BRADY
Psychology and Neurosci., St. Mary's Col. of Maryland, St Marys City, MD

Abstract: Language processing abilities are believed to be driven by the capacity to efficiently process rapidly presented auditory stimuli. Deficits in rapid auditory processing have been associated with language learning disorders such as developmental dyslexia. The induction of cortical microgyria via freeze lesion surgery leads to rapid auditory processing deficits as well as neuroanatomical abnormalities similar to those observed in post-mortem dyslexic brains, and has been proposed as an animal model of developmental dyslexia. Music exposure has previously been found to be effective in alleviation of auditory processing deficits in humans. In the present study, we investigated the degree to which passive music exposure with manipulated rhythms was effective in alleviation of these auditory processing deficits in rats with induced microgyria. Rats received either freeze lesion surgery or sham surgery on postnatal day 1, and began passive music exposure for three hours a day at postnatal day 11. We compared the effectiveness of music with simple, regular rhythms against music with complex, irregular rhythms. Beginning at postnatal day 26, a series of startle response paradigms was used to test juvenile rats' ability to process auditory stimuli, namely the ability of a subthreshold cue or gap to suppress the acoustic startle response. The first day of behavioral testing consisted of a Normal Single Tone procedure which measured a baseline ability to process auditory stimuli. These startle response scores were used to account for individual differences in startle testing in later procedures. The following four days of testing consisted of a Long Silent Gap procedure and the last four days of testing consisted of a Short Silent Gap procedure which measured the rats' ability to detect varying gap durations. The results of this study supported previous findings that while all rats were able to process auditory stimuli presented at slower speeds, the microgyric juvenile rats were significantly impaired at processing rapidly auditory stimuli in comparison to sham-treated animals. Furthermore, although sham-treated animals were relatively unaffected by music exposure, rapid auditory processing deficits in microgyric rats were alleviated by exposure to either music condition, with slightly stronger effects in the simple rhythm condition. These results may suggest that passive music exposure starting as early as infancy may benefit rapid auditory processing skills in humans at risk for developmental dyslexia.

Title: What is the role of dyslexia susceptibility candidate gene KIAA0319-Like in mouse cortical development?

Authors: *M. BAILEY[1], L. GUIDI[1,2], I. MARTINEZ GARAY[1], Z. HOLLOWAY[2], A. VELAYOS-BAEZA[2], A. P. MONACO[2,3], Z. MOLNÁR[1]
[1]Physiology, Anat. and Genet., Univ. of Oxford, Oxford, United Kingdom; [2]Wellcome Trust Ctr. for Human Genet., Oxford, United Kingdom; [3]Tufts Univ., Boston, MA

Abstract: Developmental dyslexia (DD) is a common childhood learning disorder characterised by significant impairments in reading abilities, despite adequate intelligence and educational opportunity [1]. The biological mechanisms underlying DD still remain poorly understood, although different pieces of evidence suggest that impaired neuronal migration may be a cellular antecedent [2]. Genetic studies have identified 9 *loci* (*DYX1-DYX9*) and up to 14 candidate genes [3]. Among these, *KIAA0319-Like* (*KIAA0319L*) has been proposed as a candidate gene for *DYX8 locus* supported by its homology to the *DYX6 locus* candidate *KIAA0319* [4]. The expression pattern of *KIAA0319L* suggests its role is not restricted to the nervous system. What this role is in brain is important to understand its putative involvement in dyslexia. Little is known about it except the KIAA0319L protein has been reported to interact with the axon guidance protein Nogo Receptor 1 [5], the mouse homologue is expressed in adult brain [6] and, similarly to other dyslexia candidates, rat *in utero* knockdown suggests its involvement in neuronal migration [7]. To investigate the putative function of this gene in cortical development, we generated mice where exon 3 of *Kiaa0319L* was targeted. Homozygous KO mice are viable, fertile and with no apparent phenotype. Analysis of the distribution of mitotic profiles, early transcription factor expression in the germinal zone and layer-specific marker expression, as well as overall morphological structure, showed no important differences between KO and wild-type mice. We have performed qRT-PCR at several developmental stages (E15, E18, P2, P10) to have a clear picture of *Kiaa0319* and *Kiaa0319L* brain expression pattern. This analysis will help

identifying regions of interest for development and analysis of specific conditional KO mice. We are also investigating if *Kiaa0319L* is involved in later events during development, such as dendritogenesis and spine formation, after acute elimination by *in utero* Cre electroporation into floxed mice. Our results suggest that, contrary to the shRNAi-mediated knockdown findings in rat, neuronal migration is not affected by disruption of the *Kiaa0319L* gene. This is a similar result to those found in KO mice for other dyslexia candidate homologous genes such as *Kiaa0319* (unpublished) and *Dcdc2* [8], and contributes to the mounting evidence that neuronal migration is neither an essential nor an exclusive function of these genes in the mouse cerebral cortex. 1. Title: Phenotyping the dihydropyrimidine dehydrogenase knockout mouse

Authors: ***S. SPRING**[1], L. NUTTER[2], A. M. FLENNIKEN[3], I. VUKOBRADOVIC[3], C. MCKERLIE[3,2], J. P. LERCH[1]
[1]Mouse Imaging Ctr., Hosp. For Sick Children, Toronto, ON, Canada; [2]Canadian Mouse Mutant Repository, Hosp. for Sick Children, Toronto, ON, Canada; [3]Ctr. for Modeling Human Dis., Mount Sinai Hosp., Toronto, ON, Canada

Abstract: Dihydropyrimidine dehydrogenase (Dpyd) deficiency is an autosomal recessive disease in humans characterized by excess quantities of uracil and thymine in the blood, urine and cerebrospinal fluid. Homozygous deficiency in patients has been associated with a variable clinical phenotype with the most common symptoms including convulsive disorders, motor retardation and mental retardation. Less frequent symptoms include autism, microcephaly and ocular abnormalities. To investigate the relationship between genotype and expressed phenotype, a Dpyd knockout mouse (*Mus musculus*) was produced on an isogenic C57BL/6NCrl

background. To study the phenotype associated with homozygous deficiency of Dpyd in the mouse, assays were conducted as per the standardized phenotyping protocols implemented by the International Mouse Phenotyping Resource of Standardised Screens (IMPReSS, www.mousephenotype.org/impress/). Some of these results are discussed here. A "knockout-first, conditional-ready" approach (1) was used to produce the cre-excised deletion of a critical exon in *Dpyd* resulting in a tm1b null allele. The open field test was used on male and female homozygous mutant mice at 9 weeks to assay general locomoter activity levels and anxiety compared to co-raised wild-type counterparts. A minimum of 7 mice per experimental group were used. Each mouse was placed in the middle of a peripheral zone of an arena facing the wall and allowed to explore the apparatus freely for 20 minutes. The activity of each mouse was measured in each of the arena zones in 5 minute bins. Clinical blood chemistry analysis was also conducted on test groups at 16 weeks of age with at least 7 mice per group. The open field test showed the Dpyd mutant mice had higher whole arena average speed, higher number of rears, higher latency to center entry, higher periphery average speed and higher distance traveled measurements. These results are indicative of hyperactivity, increased vertical activity and abnormal behaviours. Preliminary results also indicate significant differences in blood creatinine levels between Dpyd null mice and wild-type counterparts. Magnetic resonance imaging of fixed brain samples of Dpyd null mice is ongoing. The results of this work will assess brain morphometry changes associated with Dpyd deficiency and combined with the IMPReSS results will provide a thorough characterization of the Dpyd deficiency phenotype. Title: Monoaminergic interactions between lisdexamfetamine and duloxetine determined by dual-probe intracerebral microdialysis in freely-moving rats

Authors: *D. J. HEAL[1], H. L. ROWLEY[1], R. S. KULKARNI[1], P. H. HUTSON[2]
[1]RenaSci Ltd, Nottingham, United Kingdom; [2]Shire Develop. Inc, Wayne, PA

Abstract: Lisdexamfetamine dimesylate (LDX) is a prodrug of *d*-amphetamine that is approved to treat ADHD. In this study, we have investigated the effects of combining LDX with the SNRI, duloxetine, on monoaminergic changes in several regions of the rat brain. Male Sprague-Dawley rats were stereotaxically implanted with two concentric microdialysis probes into hippocampus [HIPP] (4 mm tip, AP: -4.8 mm; L: +/-4.8 mm relative to bregma; V: -7.8 mm relative to the skull surface) and nucleus accumbens [ACC] (2 mm tip, AP: +2.2 mm; L: +/-1.5 mm; V: -8.0 mm) or prefrontal cortex [PFC] (2 mm tip, AP: +3.2 mm; L: +/-2.5 mm; V: -4.0 mm) and striatum [STR] (4 mm tip, AP: +0.2 mm; L: +/-3.0 mm; V: -7.8 mm (2). The following day after collection of 3 basal samples, rats (n = 7-8) were given vehicle (po)/vehicle (ip), LDX (1.5 mg/kg *d*-amphetamine base po)/vehicle (ip); vehicle (po)/duloxetine (5 mg/kg ip) or LDX (1.5 mg/kg po)/duloxetine (5 mg/kg ip). Noradrenaline, dopamine and 5-HT were quantified by reverse-phase, ion-pair, HPLC-ECD. Duloxetine increased the efflux of noradrenaline and 5-HT in PFC (AUC[0-3.0hr] = 293%, $p<0.01$; 168%, $p<0.05$, respectively) and HIPP (274%, $p<0.05$; 650%, $p<0.001$, respectively) and 5-HT in STR (479%; $p<0.01$). Duloxetine also increased extracellular dopamine in PFC (218%, $p<0.05$) and HIPP (220%, $p<0.001$). LDX increased extracellular noradrenaline and dopamine in PFC (449%; $p<0.001$; 264%, $p<0.01$, respectively). It increased dopamine, but not noradrenaline, efflux in HIPP (263%; $p<0.001$), ACC (282%; $p<0.001$) and STR (197%; $p<0.001$). Combining LDX with duloxetine increased extracellular noradrenaline and dopamine in PFC, all three monoamines in HIPP, dopamine and 5-HT in STR and dopamine in ACC. Thus, when administered in combination, the complementary actions of LDX and duloxetine on monoaminergic neurotransmission were realised in all regions. The possible exception was the PFC where the findings were equivocal. There was a synergistic augmentation of LDX-induced dopamine efflux in ACC (377%; $p<0.05$) and STR (315%; $p<0.001$). LDX contributes increased dopaminergic neurotransmission in PFC, HIPP, ACC and STR to complement the increases of noradrenaline and 5-HT in PFC and HIPP, and 5-HT in STR evoked by duloxetine. Combining duloxetine with LDX synergistically augmented the effect of LDX on dopamine efflux in ACC and STR. Together, these findings suggest that the combination of duloxetine and LDX may enhance monoaminegic transmission more extensively in the CNS than duloxetine alone. Title: The effect of maternal separation on striatal protein levels is strain dependent: A proteomic study

Authors: *J. S. WOMERSLEY[1], L. A. KELLAWAY[2], D. J. STEIN[3], M. VLOK[4], V. A. RUSSELL[2]
[2]Human Biol., [3]Psychiatry and Mental Hlth., [4]Ctr. for Proteomic and Genomic Res., [1]Univ. of Cape Town, Cape Town, South Africa

Abstract: Introduction: The spontaneously hypertensive rat (SHR) is a well-validated model of attention-deficit/hyperactivity disorder (ADHD), a developmental disorder characterised by poor sustained attention, hyperactivity and impulsivity. Previous research has indicated that the effects of maternal separation, a model of mild chronic developmental stress, are strain dependent with SHR appearing to be behaviourally resilient to the anxiogenic effects of MS when compared to the Wistar-Kyoto (WKY) and Sprague-Dawley comparator strains. Therefore we sought to investigate the underlying differences in protein expression in the striatum, an area of the brain implicated in ADHD and involved in motor activity, orientation to salient stimuli and reward processing. Methods: Maternally separated (MS) SHR, WKY and Sprague-Dawley (SD) litters were removed from the dam for 3 hours per day between postnatal days 2 and 14, as opposed to non-maternally separated (nMS) litters, which stayed with the dam at all times. On postnatal day 60, rats were decapitated and the striata rapidly removed and snap frozen in liquid nitrogen.

Supernatant from striatal samples (n=4 per group) were analysed by isobaric Tag for Relative and Absolute Quantification (iTraq) of the proteome with matrix-assisted laser desorption/ ionization (MALDI) tandem mass spectrometry analysis of peptides. Mass spectrometry data were analysed using ProteinPilot 4.0 and the Uniprot Rattus rattus database. Significant differences in protein expression were calculated using Student's unpaired t test. Results: Proteomic analysis of striatal tissue from MS and nMS SHR, WKY and SD revealed multiple differences in proteins relating primarily to energy metabolism, signalling and cell structure. Strain differences in protein expression were found primarily between SHR and the control WKY and SD strains, suggesting that these differences contribute to the ADHD-like phenotype of SHR. The minimal number of differences found between WKY and SD suggest that both of these strains are suitable controls for SHR. Comparison of proteins affected by MS in more than one strain revealed that developmental stress had opposite effects on SHR and WKY, consistent with their different behavioural responses to developmental stress. Conclusion: WKY and SD rats are suitable controls for SHR. MS produced opposite effects on protein expression in SHR and the comparator strains, WKY and SD, consistent with previous research that suggests that the effect of developmental stress is strain-dependent.

Title: Modulation of cognitive performance in dyslexic children and adolescents with transcranial direct current stimulation

Authors: *D. MENGHINI[1], F. COSTANZO[1], S. ROSSI[1], C. VARUZZA[1], S. SDOIA[1], M. OLIVERI[2], G. KOCH[2], S. VICARI[1]
[1]Neurosci., Children Hosp. Bambino Gesù, Rome, Italy; [2]Santa Lucia Fndn., Rome, Italy

Abstract: Traditional remedial treatment for dyslexics increases their reading ability and modifies brain activation patterns in critical cortical areas, such as the left inferior parietal lobule.

One open question is whether a direct intervention on the same areas of the brain can affect reading ability. Non-invasive brain stimulation offers the possibility to investigate this topic. It induces excitability alterations in cortical areas and it may result in positive modulation of cognitive performance (an increase of accuracy or decrease of response time). The effect of transcranial direct current stimulation (tDCS) on cognitive performance and reading of dyslexic children and adolescents is still under-investigated. To test the effect of tDCS on dyslexic performance, reading (word, non-word and text reading) and cognitive measures (lexical decision, working memory, verbal fluency) have been assessed in 14 dyslexic children and adolescents (age range 12-18) in different conditions of stimulation. The polarities of tDCS over the left inferior parietal lobule were manipulated according to the following conditions: 1) left anodal/right cathodal tDCS, 2) right anodal/left cathodal tDCS, 3) sham tDCS and 4) in a baseline condition without tDCS. Stimulation was delivered for 20 minutes in each condition and set at 1 mA. tDCS was well tolerated from all participants. Preliminary results in dyslexics showed a better performance in text reading ($p < 0.05$) and in lexical decision ($p < 0.05$) after left anodal/ right cathodal tDCS compared to the baseline. In conclusion, our result document that tDCS transitorily improves the performance of dyslexic children and adolescents. Although preliminary, these findings suggest new brain-based perspectives in the treatment of dyslexia during childhood and adolescence.

Title: Activity in putamen an indicator of dysfluent state in stuttering

Authors: *E. L. CONNALLY[1], D. WARD[2], C. PLIATSIKAS[3], K. E. WATKINS[1]
[1]Exptl. Psychology & Oxford Ctr. for Functional MRI of the Brain (FMRIB), Univ. of Oxford,

Oxford, United Kingdom; [2]Clin. Language Sci., [3]Ctr. for Integrative Neurosci. and Nuerodynamics, Univ. of Reading, Reading, United Kingdom

Abstract: Several brain regions are implicated in developmental stuttering, these include the basal ganglia, frontal opercular and auditory cortex and cerebellum. The extent to which the dysfluent state relates to abnormal function in these brain regions is unknown. We used functional MRI to address this question by (i) examining differences between groups of adults who stutter who were either fluent or dysfluent during scanning and (ii) comparing percent signal change in regions showing group differences to percent signal change in fluent controls (CON). We collected overt speech samples and related BOLD activity under two conditions (picture description and sentence reading) using sparse-sampling functional MRI (3T, 32 axial slices 4 mm3, TR=9s, TA=2s, TE=30ms) in 17 adults who stutter (aged 19 - 54 yrs, 4 females) and 17 CON (aged 19-53 years, 3 females). Each condition was contrasted with a silent baseline and average percent signal change was extracted for three regions of interest based on group results. For the between-subjects analysis, we divided our sample into individuals who were mostly fluent (FLU, n=8) or dysfluent (DYS, n=9) based on an arbitrary cutoff of 10 dysfluent utterances per scan session. Strikingly, during overt speech production (i.e. both conditions), the DYS group showed no regions with greater activity than the FLU group. The DYS group had less activity than FLU in the putamen bilaterally, left posterior cerebellum and right central operculum during picture description and sentence reading. We probed for differences between adults who stutter and CON in those regions, collapsed across condition. Only the putamen showed a significant main effect of group (after accounting for age and structure volume), with the general pattern of DYS < CON < FLU. These data support the putamen as a candidate structure that shows abnormal function during both fluency and dysfluency in people who stutter. The pattern of activation and deactivation during different fluency states might explain variability in findings across studies with respect to abnormal basal ganglia activations.

Title: Effect of physical exercise on attentional function and social behavior: Comparison with psychostimulants and implications for ADHD

Authors: *D. J. BUCCI, A. M. ROBINSON
Dartmouth Col., HANOVER, NH

Abstract: Psychostimulants continue to be the primary treatment for the overt behavioral symptoms associated with Attention-Deficit/Hyperactivity Disorder (ADHD). However, growing research has identified important limitations of their use, such as concerns over the negative consequences of long-term use on the developing brain. Moreover, psychostimulants are often ineffective in treating the cognitive impairments that are now thought to be central to ADHD (e.g., behavioral inhibition, inattention). In addition, it is unclear how these therapies affect often-observed, yet rarely researched, hyper-social behavior associated with ADHD. Thus, there is currently great research interest in developing adjunctive or replacement therapies for psychostimulants. Our prior research using an animal model of ADHD, the Spontaneously Hypertensive Rat strain (SHR), demonstrated that exercise reduces distractibility and hyper-social behavior in SHRs compared to a normo-active control strain. Here we determined the duration of exercise that is needed to affect attentional function and social behavior and compared the effects of exercise to the standard of care pharmacotherapy, methylphenidate. Attentional function was assessed by measuring the amount of orienting behavior (i.e., rearing up on the hind legs) during the repeated presentation of a non-reinforced visual cue (a light). Normo-active rats initially exhibit a high level of orienting behavior that habituates over the course of several non-reinforced presentations of the light. Social behavior was assessed using a procedure adapted from File and colleagues in which a rat is allowed to freely explore a large arena containing an unfamiliar conspecific rat located in a restrainer in the center of the arena. Consistent with their hyper-responsive phenotypes, non-exercising SHRs exhibited a high level of orienting to the light, little habituation of the orienting response, and excessive social interaction compared to normoactive rats. Exercise and methylphenidate decreased orienting behavior and social behavior in SHRs in a dose-dependent fashion. In addition, a group of rats received a combination of both exercise and methylphenidate, using the doses of each that alone

were ineffective in altering orienting behavior. We found that these does of exercise and methylphenidate, when combined, now had a significant effect on orienting behavior. These data indicate that physical exercise is at least as effective as methylphenidate in reducing distractibility and hyper-social behavior in SHRs, and that smaller doses of drug can be used in combination with moderate amounts of exercise to reduce distractibility.

Abstract: S-Nitrosylation is a critical mechanism mediated by neuronal nitric oxide synthase (nNOS) which governs diverse signaling cascades that regulate neuronal functions. Although it has been studied extensively *in vitro* and in invertebrate animals, effects on mammalian brain development and underlying mechanisms remain poorly understood. Here we report that genetic deletion of nNOS disrupts dendritic development in the prefrontal cortex (PFC). S-nitrosylation

of nuclear distribution element-like 1 (NDEL1), a protein involved in multiple developmental processes, accelerates dendritic arborization in the PFC. This posttranslational modification is enhanced by NMDA receptor-mediated neuronal activity, a main regulator of dendritic formation. These findings highlight S-nitrosylation as a key activity-dependent mechanism underlying brain maturation.

Program, New Haven, CT; [7]Neurobio., New Haven, CT; [8]Psychology, New Haven, CT

Abstract: Tourette syndrome (TS) represents the most severe end of a spectrum of tic disorders that, in aggregate, affect 5% of the population and produce great morbidity. Existing somatic treatments are of limited efficacy. Convergent evidence implicates the cortico-basal ganglia

circuitry in the genesis of tics, but pathophysiological details are not well understood. Recent post-mortem work has revealed that specific interneuronal populations are abnormal in patients with severe, refractory TS. Cholinergic interneurons (ChAT), also known as tonically active neurons (TANs), constitute only about 1% of the neurons in the striatum, but they are critical regulators of striatal function. Abnormalities in ChAT interneurons in the ventral striatum have been reported in schizophrenia, but deficits in the dorsal striatum (the caudate and putamen) have only been described in TS. We tested the hypothesis that ChAT interneuron disruption in the dorsolateral striatum is sufficient to produce tics, using a novel approach for targeted ablation of these cells in mice. We exposed ChAT-ablated animals to acute mild stress. ChAT-ablated mice exhibited no behavioral abnormalities prior to the stressor, but increased grooming during the startle block. There was also a nominal increase in grooming in the 30 minutes after the block of startle stimuli, though it did not reach statistical significance. In contrast, mice with ChAT ablation in the DMS showed no alteration in acute stress-induced repetitive behaviors. Following amphetamine administration, the ChAT-ablated animals showed repetitive movements that last longer and reaching higher levels, while DMS-ChAT ablated mice showed enhanced locomotor activation but no change in stereotypy. We tested ChAT-ablated mice on the rotorod, which assays both baseline motor performance and improvement over time. Mice with a DLS ChAT lesion showed a marked deficit in baseline rotorod performance but rapidly improved with practice to a level of performance indistinguishable from controls. We tested ChAT-ablated mice and found no PPI deficit. These results support the importance of cholinergic dysregulation to the pathophysiology of TS and establish a new model system in which the consequences of this dysregulation can be examined.

Title: Deficiency of glutamate transporter in astrocyte increases brain excitability and induces Tourette's Syndrome-like excessive repetitive behaviours in mice

Authors: T. AIDA[1], J. YOSHIDA[1], M. NOMURA[2], A. TANIMURA[3], Y. IINO[1], M. SOMA[1], N. BAI[1], Y. ITO[1], W. CUI[1], H. AIZAWA[1], T. NAGAI[4], N. TAKATA[4], R. TAKAYANAGI[2], M. KANO[3], M. GÖTZ[5], H. HIRASE[4], *K. TANAKA[1,6]

Abstract: Brain hyperexcitability has been suggested to cause neuropsychiatric disorders including autism, obsessive-compulsive disorder (OCD), and Tourette's syndrome. Brain excitability is controlled by both neurons and astrocytes. In astrocytes, the glutamate transporters GLT1 and GLAST are critical for regulating brain excitability. However, the role of glial glutamate transporters in the pathogenesis of neuropsychiatric disorders remains unknown. Here, we show that GLT1 inducible knockout [GLAST(CreERT2/+)&GLT1(flox/flox), iKO] mice developed severe cervicofacial skin lesions and exhibited pathologic repetitive behaviours including excessive self-grooming and motor tics that resemble Tourette's syndrome. In iKO mice, seizure sensitivity and excitatory transmission at the corticostriatal synapses after repetitive stimulation were increased. Furthermore, treatment with an N-methyl-D-aspartate (NMDA) receptor antagonist memantine ameliorated the pathologic repetitive behaviours in iKO mice. These results suggest that iKO mice as a novel animal model for Tourette's syndrome and suppression of brain hyperexcitability by NMDA receptor blockade or glial glutamate transporter activation may be novel therapeutics for Tourette's syndrome. Further, because the repetitive behaviours are common core symptoms of autism, OCD and Tourette's syndrome, iKO mouse is a useful tool for understanding a common mechanism underlying these psychiatric disorders.

Title: Identifying novel biomarkers of naturally occurring social impairments in male rhesus monkeys

Authors: *O. OZTAN[1], J. P. GARNER[1], K. CHUN[2], S. A. HYDE[1], E. H. SHERR[3], J. P. CAPITANIO[2], K. J. PARKER[1]
[1]Stanford Univ., Stanford, CA; [2]Univ. of California, Davis, Davis, CA; [3]Univ. of California, San Francisco, San Francisco, CA

Abstract: Autism spectrum disorder (ASD) is characterized by core social impairments, but its basic biology remains poorly understood. Progress has been impeded by the difficulty of obtaining relevant tissue samples from patients and matched controls. In mouse models, while tissue is available, there is frequently discordance between complex human behavior and laboratory-based mouse behavior, even with shared genetic etiologies. These limitations underscore the tremendous value in developing a monkey model of social impairments with more reliable behavioral and biological correlates to the human disease. Like humans, rhesus monkeys (Macaca mulatta) are highly social, and both species display stable and pronounced individual differences in social functioning. At the behavioral extremes, low social compared to high social male monkeys initiate fewer affiliative interactions and display more inappropriate social behavior, suggesting both lower social motivation and poorer social skills. Study subjects were male rhesus monkeys aged 2-5 years (N=42). Subjects were selected on the basis of archived behavioral data thought to predict later low (N=21) or high (N=21) social functioning. Quantitative social behavior data and personality assessments were collected by blinded observers using established protocols. After completion of behavioral phenotyping, monkeys with the most extreme scores (N=15 low social monkeys and N=15 high social monkeys) were

selected for biological sample collection. Cerebrospinal fluid (CSF) and blood were drawn, respectively, from the cisterna magna and femoral vein during the same session to test whether candidate biomarkers [e.g., arginine-vasopressin (AVP) and oxytocin (OXT) peptide and receptor mRNA levels] were associated with social functioning, and whether the degree of biomarker dysregulation co-varied with the degree of social deficits. Low social monkeys were judged to be less affiliative, less contact seeking, more isolated/withdrawn, and more socially avoidant than high social monkeys. Preliminary biomarker data indicate that CSF AVP concentrations predict group classification, such that low social monkeys had diminished CSF AVP concentrations compared to high social monkeys. CSF AVP concentrations also positively predicted initiation but not receipt of social grooming for all monkeys. With continued investigation this research program may lead to the discovery of novel "drugable" targets and the streamlined development of the first effective therapeutics to treat social impairments in people with ASD. Research supported by NIH and the Simons Foundation.

Title: Changes in hippocampal proteins involved in glutamate and GABA transmission following early life stress in a rat model of ADHD, the spontaneously hypertensive rat

Authors: *V. A. RUSSELL[1], T.-L. STERLEY[2], F. M. HOWELLS[3]
[2]Dept. of Human Biol., [3]Dept. of Psychiatry, [1]Univ. Cape Town, Cape Town, South Africa

Abstract: Background: Experiencing stress early in life increases the risk of developing a psychiatric disorder. Maternal separation is an animal model used in research to mimic early life stress in humans. The spontaneously hypertensive rat (SHR) is the most widely used animal model of ADHD, exhibiting the three major characteristics of ADHD. We have previously shown opposite effects of maternal separation on $GABA_A$ receptor-mediated inhibition of glutamate-stimulated release of norepinephrine in hippocampus of SHR compared to Wistar-

Kyoto rats (WKY). The present study investigated the hippocampal protein profile of WKY, SHR and Sprague-Dawley rats (SD), and how these profiles were affected by maternal separation. Methods: Rat litters were subjected to maternal separation or non-maternal separation from postnatal day 2 to 14. On postnatal day 31-35, rats were decapitated and the hippocampus dissected. Proteomic analysis (iTRAQ) of hippocampal proteins was followed by Western blot analysis to confirm differential expression of 2 key proteins: glutamate transporter GLT1 and solute carrier family 12 member 5 (KCC2). Results: Main proteomics findings were that energy-related proteins were increased in SHR hippocampus compared to WKY and SD, and reduced in WKY hippocampus compared to SD. GLT1b (splice variant of GLT1) and KCC2 levels were increased in SHR hippocampus compared to WKY, and reduced in WKY hippocampus compared to SD. Maternal separation increased energy-related proteins in WKY hippocampus and reduced them in SHR hippocampus. Maternal separation reduced GLT1b in SHR hippocampus. Western blot analysis of GLT1 and KCC2 showed that GLT1 was reduced, while KCC2 was increased, in SHR hippocampus compared to WKY and SD. Maternal separation increased GLT1 in WKY, SD and SHR right hippocampus. Conclusion: Reduced GLT1 in SHR hippocampus possibly led to increased extracellular glutamate, inducing a compensatory increase in GLT1b. The increase in GLT1 in SHR hippocampus caused by maternal separation possibly reduced extracellular levels of glutamate, and thereby removed the induction of GLT1b, reducing GLT1b in SHR hippocampus only. KCC2 is responsible for establishing the Cl^- balance across the neuronal membrane and by so doing, determines the functioning of $GABA_A$ receptors. Increased KCC2 in SHR hippocampus was possibly a compensatory attempt to increase inhibitory GABAergic signalling.

Title: Functional analysis of FAM107B, a newly identified stress hormone responsive molecule

Authors: *K. KOIZUMI[1], M. ITO[1], K. NAKAO[2], H. NAKAJIMA[3,4]
[1]Ctr. for Child Mental Develop., Kanazawa Univ., Kanazawa-Shi, Japan; [2]Saitama Med. Univ.,

Moroyama-Shi, Japan; [3]Kumamoto Univ., Kumamoto-Shi, Japan; [4]Ageo Central Gen. Hosp., Ageo-Shi, Japan

Abstract: Numbers of studies indicate exposure to stress hormone, glucocorticoid (GC) during prenatal period affects neural development and causes abnormal behaviors in animals. The effects of GC may be also critical for prenatal brain development of human and cause psychiatric disorders such as depression (Neurosci Biobehav Rev. 43: 137-162) and autism (Neuroscience and Biobehavioral Reviews 32: 1519-1532, 2008). Here, we show a new GC responsive molecule, FAM107B. Treatment with GC agonist, DEX, or restraint stress on pregnant mice resulted in reduction of FAM107B in the brain of their embryos. To figure out its function, we study effects of RNAi or over expression of FAM107B in neuron-like PC12 cells and mouse neural cells. Transwell assay indicates reduction of FAM107B by RNAi accelerated PC12 cells migration induced by NGF while the over expression did opposite effect. Neurite outgrowth study in both PC12 and primary neurons showed FAM107B inhibits neurite outgrowth by over expression. Co-localization of F-actin and FAM107B was observed in outer membrane ruffles after NGF induction. FAM107B may have some roles in actin assembly and affect neural migration and neurite outgrowth. To study *in vivo* function, we also tried gene transfer of FAM107B *in utero* and found defects of migration in the brain cortex. Interestingly, exposure to DEX also showed similar effects on PC12 cells migration and neurite outgrowth. Possibly, FAM107B is one of the key molecules that responds to GC and gives critical effects on neural development in the embryonic brain that cause psychiatric disorders after birth.

Abstract: Increasing evidence implicates host-microbe interactions at virtually all system levels within the body including the central nervous system (CNS) and new data implicates the microbiota in neurodevelopmental and stress-related disorders such as autism and anxiety. Our lab could recently show that, mice that have been raised in a sterile environment (germ-free, GF), demonstrate a marked lack of pro-social behaviour in the well-established three-chamber social interaction test (3SIT). Alterations in brain function and cognition are suggested to be mediated via the microbiota-gut-brain axis, the bidirectional communication pathways between the CNS and intestinal organs. However, the underlying mechanisms of this interaction and the nature of the pathways are only insufficiently understood. We recently proposed a likely role for dynamic transcriptional regulation in those brain regions involved in social behaviour, including the amygdala, and by using the 3SIT, we have identified key response genes to social interaction exposure in the amygdala and compared these to data derived from analyses in the hippocampus. Furthermore, exploiting state-of the art transcriptional profiling combined with new bioinformatic techniques, we have determined modifications of the amygdala transcriptomes of conventionally raised and GF mice and GF mice that have been colonised after weaning to elucidate the effect of the microbiota on gene expression. Finally, plastic chromatin modifications have recently been identified to play an important role in cognitive processes during health and disease by regulating gene expression in the brain. However, the role of epigenetics in mediating host-microbe interactions, has received little attention. We therefore investigated the potential of the microbiota to influence histone acetylation in the brain. Together, data from these experiments have identified a novel mechanism by which the microbiota can affect social behaviour, which may have far reaching implications for human neurodevelopmental disorders such as autism.

Title: Brain MR relaxation times in an animal model recapitulating features of autism spectrum disorders

Authors: *L. M. COLON-PEREZ[1,2], M. KHARITON[3], L. VON ZABERN[4], P. CHAKRABARTY[5], M. FEBO[2]

Abstract: Valproic acid (VPA) has been used clinically as an anticonvulsant medication during pregnancy; however, it poses a neurodevelopmental risk of fetal malformations and autism spectrum disorders (ASD). VPA treatment in pregnant rats results in birth defects similar to human conditions and thus provides a useful tool to model ASD. It has been shown that VPA treated rats show greater increases in BOLD signal response to social stimulus, lower social interaction and greater locomotor activity compared to controls. In humans, voxel based relaxometry has shown increased values in transverse relaxation times in patients with autism. Diffusion tensor imaging (DTI) studies report conflicting results of DTI metrics and its correlations to ASD. On one hand, a study comparing sedated autistic children to naturally asleep typically developing children reported decreased FA values in autistic children. On the other hand, a study of a control group compared to autistic children and their typically developing siblings found no difference between autistic children and their typically developing siblings but there was a considerable difference between control kids to autistic children and their siblings. Barnea-Goraly et. al. suggests that reduced FA values is a potential biomarker for genetic risk for autism. A factor not accounted for in these DTI studies is the increase in transverse relaxation times observed in autistic children; this will alter the MRI images SNR and it is a possible confound when comparing autistic children to its control counterparts. In order to create a proper comparison between autistic and typically developing children, MRI experiments must account for these changes. In this study, rats treated with VPA (n = 5) during development were imaged and their MR relaxation rates were compared to controls rats (n = 4). Excised rat brains were scanned at the Advanced Magnetic Resonance Imaging and Spectroscopy (AMRIS) facility of the McKnight Brain Institute at the University of Florida in a 17.6T magnet. T1 values were estimated from a RARE sequence with 8 TR's and T2 values from a multi echo sequence with 8 echos. An image resolution of 90 x 90 x 280 μm3 was obtained for both scans. Mean T1 and T2 values were obtained over masks covering: entire brain, genu and splenium of corpus callosum, inferior colliculus, visual cortex, fimbria and internal capsule. VPA brains displayed significantly increased transverse relaxation times over the entire brain (T2 = 54.9 ± 3.6 ms) compared to controls (T2 = 41.9 ± 4.3 ms), as well in all other brain regions. However, no differences were obtained for longitudinal relaxation times. Our results agree with previous autism human studies.

Title: The role of Promoter IV-driven BDNF expression in fear extinction

Authors: *J. L. HILL[1], D. V. JIMENEZ[1], K. R. MAYNARD[1], R. J. SCHLOESSER[1,2], K. MARTINOWICH[1,3,4]
[1]Lieber Inst. For Brain Develop., Baltimore, MD; [2]Psychiatry, Univ. of Marlyand Sch. of Med., Baltimore, MD; [3]Psychiatry and Behavioral Sci., [4]Neurosci., Johns Hopkins Univ. Sch. of Med., Baltimore, MD

Abstract: The neural substrates of fear-related behavior have been well-studied. However, the molecular and cellular signaling cascades that are responsible for fear expression and its extinction are still not completely understood. The ability to extinguish, or decrease fear expression to a no longer aversive signal, has been consistently linked to expression of Brain-Derived Neurotrophic Factor (BDNF). The *Bdnf* gene is highly regulated, with different promoters driving expression in both a spatially and temporally unique pattern. The gene has nine promoters, each driving transcription from an alternative 5′ untranslated exon, which is spliced to a common 3′ coding exon. *Bdnf* promoter IV is highly responsive to induction of neural activity, and alterations in *Bdnf* expression from promoter IV have been observed in key regions of the fear circuitry during auditory fear conditioning and extinction. Previous data established that mice genetically altered to attenuate activity-dependent expression or activity-dependent secretion of BDNF show deficits in the ability to extinguish conditioned fear. We conducted a series of experiments to further investigate how disruption of BDNF expression specifically from promoter IV (BDNF-e4 mice) can affect fear extinction. First, we developed an extinction paradigm in which mice were extinguished 24h following conditioning, and found that homozygous BDNF-e4 mice show highly increased levels of freezing relative to wild-type animals after extinction trials while heterozygous BDNF-e4 animals show an intermediate extinction deficit. Mice with a genetic alteration that leads to a reduction in activity-dependent secretion of BDNF show deficits in extinction when extinction trials are conducted immediately

following conditioning suggesting that local release of BDNF is required to facilitate immediate extinction. In BDNF-e4 mice, activity-dependent production of BDNF from promoter IV rather than activity-dependent extinction is impaired. Thus, we hypothesized that immediate extinction should be intact in our animals. Mice underwent extinction training 5min post-conditioning; this time point was chosen because it is prior to conditioning-related increases in *Bdnf* transcription from promoter IV. We found no difference in levels of freezing between wild-type and BDNF-e4 mice. In summary, mice in which BDNF expression is disrupted from promoter IV possess a delayed, but not an immediate extinction deficit, contributing to the hypothesis that local secretion of BDNF is required to mediate successful fear extinction.

Title: Prenatal exposure to a 'double-dose' of valproic acid alters lifelong behavior and global methylation patterns: Modeling differing severities of autism spectrum disorder

Authors: *S. RAZA, A. HARKER, C. NIEHAUS, B. KOLB, R. GIBB
Univ. of Lethbridge, Lethbridge, AB, Canada

Abstract: Autism spectrum disorder (ASD) is an umbrella term used to designate a broad spectrum of neurodevelopmental disorders ranging from mild, including Asperger's and high-functioning autism, to severe symptomology. Due to heightened awareness and shifting diagnosis, the prevalence of ASD has significantly risen, now affecting 1 in every 55 children. While current animal research models appear to parallel the anatomical, functional, and behavioral pathology as reported in human cases of high-functioning autism, translation to the entire spectrum of autistic disorders is less well explored. That is, current animal models have been unable to entirely simulate the human condition, specifically cases of severe or low-functioning autism. One viable animal model of ASD is the valproic acid (VPA) rodent model, whereby prenatal exposure of VPA produces striking similarities to ASD symptomology in

humans. As such, modifications to such an animal model of ASD to better simulate severe, or low-functioning, autism may allow for greater understanding of the functional pathology that is representative of autistic individuals on an extreme end of the spectrum. The current study utilizes the widely used VPA rodent model of autism. While a single dose of VPA, *in utero,* produces autistic-like anomalies in rodents, the symptoms are relatively mild. We hypothesized that two does of VPA, *in utero*, would better simulate characteristics of low-functioning autistics. Using a within-litter design, pregnant Long-Evans rats were exposed to VPA on gestational days 10 and 12.5 (800mg/kg on each day, respectively), a period of fetal embryogenesis. Subsets of the offspring prenatally exposed to VPA (a single or 'double dose' of VPA) were sacrificed at weaning, and DNA from the medial prefrontal cortex (mPFC), amygdala, hippocampus, and cerebellum were extracted for global DNA methylation analysis. The remaining offspring underwent behavioral testing at three developmental milestones: pre-weaning (P7-P15), juvenile (P30+), and in adulthood (P95+). Several behavioral tasks designed to assess motor, emotional, and cognitive domains were administered. The results will not only serve as a plausible translational rodent model for low-functioning autism, but also shed light on the etiology of the multifaceted diagnoses of ASD.

Title: Cognitive disability in the Cntnap2 mouse model of ASD

Authors: H. L. H. RUTZ, *L. A. ROTHBLAT
Psychology, George Washington Univ., Washington, DC

Abstract: Cortical dysplasia-focal epilepsy syndrome (CDFE), a syndromic form of autism spectrum disorder (ASD), is caused by recessive mutations in *contactin associated protein-like 2* (*CNTNAP2*). Along with abnormalities in neuronal migration and early-onset focal epilepsy, children with CDFE present with language regression, intellectual disability, and impaired social

abilities. Single nucleotide polymorphisms in the *CNTNAP2* gene have been identified as risk alleles for language deficiencies and ASD. Moreover, recent brain imaging studies report significantly altered cortical connections in children with predisposing alleles, whether autistic or neurotypical. As with other syndromic forms of ASD, there now is a mouse model that replicates many features of the human disorder. *Cntnap2* knockout (KO) mice show migration abnormalities in cortical projection neurons and a reduction in the number of GABAergic interneurons (Penagarikano et al., 2011). Along with these morphological anomalies, these mice demonstrate reduced cortical synchrony and develop epileptic seizures at around 6 months of age. In addition, *Cntnap2* KO mice display some behavioral traits seen in ASD including repetitive grooming behavior, impaired communication (ultrasonic vocalizations), and decreased social interaction. To assess the role of *Cntnap2* deletion on cognitive ability, we tested 3-month old *Cntnap2* KO, heterozygous (HET), and wildtype (WT) mice (The Jackson Laboratory) on a series of tasks using computer automated touchscreen procedures. Compared to WT and HET littermates, most--though not all--KO mice exhibit significant deficits learning and reversing a visual discrimination. The striking cognitive impairment seen in KO mice occurred despite the fact that we saw no evidence of seizure activity even in mice over 12 months old.

Title: Noradrenergic mechanisms mediate the effects of physical exercise on attentional function in a rat model of ADHD

Authors: *A. M. ROBINSON[1], J. T. GREEN[2], T. R. BUTTOLPH[3], D. J. BUCCI[1]
[1]Psychological and Brain Sci., Dartmouth Col., Hanover, NH; [2]Psychology, [3]Dept. of Neurolog. Sci., Univ. of Vermont, Burlington, VT

Abstract: Recent studies in our laboratory indicate that physical exercise (access to a running wheel) can ameliorate attentional dysfunction in an animal model of ADHD, the Spontaneously Hypertensive Rat strain (SHR). Attentional function was assessed by measuring the amount of

orienting behavior (i.e., rearing up on the hind legs) during the repeated presentation of a non-reinforced visual cue (a light). Normo-active rats initially exhibit a high level of orienting behavior that habituates over the course of several non-reinforced presentations of the light. Consistent with their hyper-responsive phenotypes, control SHRs exhibited a high level of orienting to the light and no habituation of orienting behavior, suggesting that they continue to be distracted by the irrelevant visual stimulus. However, 5, 10, or 21 days of access to a running wheel significantly reduced hyper-orienting behavior to the level of normo-active control rats while 2 days of wheel access had no effect. Here, we tested the hypothesis that the effects of exercise were mediated by changes in noradrenergic neurotransmission. First, we measured the levels of norepinephrine transporter (NET) in the prefrontal cortex of SHRs that had access to a running wheel or remained sedentary. We found that exercise produced a dose-dependent reduction in NET, reflecting an increase in NE levels in exercising rats. In the second experiment, we tested the causal nature of this relationship by implanting propranolol pellets subcutaneously in exercising and non-exercising SHRs. Rats then had access to a running wheel for 10 days, or remained in the home cage with no wheel. Other groups received a sham surgery in which no pellet was implanted. We found that blocking noradrenergic receptors with propranolol had no effect on orienting behavior in the sedentary rats. In contrast, propranolol significantly attenuated the effects of exercise on orienting behavior compared to the sham-surgery exercising group. These data indicate that physical exercise alters NE levels in the prefrontal cortex and that changes in NE mediate the effects of exercise on distractibility in the SHR model of ADHD.

Title: The schizophrenia and autism associated gene, transcription factor 4 (TCF4), regulates the intrinsic excitability of prefrontal cortical neurons

Authors: M. D. RANNALS, S. CERCEO-PAGE, M. N. CAMPBELL, A. BRILEY, A. E. JAFFE, R. TAO, T. M. HYDE, J. E. KLEINMAN, D. R. WEINBERGER, *B. J. MAHER
Lieber Inst. For Brain Develop., Baltimore, MD

Abstract: Schizophrenia is a neurodevelopmental disorder with unknown pathophysiology. Genome-wide association studies (GWAS) have identified a number of loci associated with increase risk for SZ and several of these risk variants are located within introns of TCF4. In addition, autosomal dominant mutations in TCF4 result in Pitt Hopkins Syndrome (PTHS), a rare neurodevelopmental disorder characterized by a spectrum of symptoms including hyperventilation, seizures, autistic behaviors, intellectual disability, and brain malformations. Currently, the molecular mechanisms and underlying pathophysiology responsible for these two disorders are not understood. Our goal is to determine the function of TCF4 during cortical development and to understand the molecular mechanism of risk that is associated with genetic variants of TCF4. To test the function of TCF4 in the developing neocortex we altered its expression by transfecting layer 2/3 pyramidal cells in the rat prefrontal cortex by *in utero* electroporation. We knockdown TCF4 expression using two shRNA constructs that target independent sequences within the TCF4 transcript. Embryonic knockdown of TCF4 decreased action potential output and resulted in the ectopic appearance of spike-frequency adaptation in layer 2/3 pyramidal neurons ($p<0.002$; TCF4 shRNA n=24, Con shRNA n=32). These phenotypes were associated with an increase in the afterhyperpolarization (AHP) amplitude ($p<0.01$; TCF4 shRNA n=29, Con shRNA n=26) and suggested knockdown of TCF4 may increase the activity of Ca^{2+}-activated K^{+} channels. We tested this hypothesis by first rescuing action potential output by manipulating intra- and extracellular Ca^{2+} levels. We demonstrate that intracellular application of the Ca^{2+} chelator BAPTA ($p<0.002$; BAPTA n= 23; TCF4 shRNA n=18) or application of the L-type Ca^{2+} channel blocker nimodipine was effective at rescuing these phenotypes ($p<0.05$; n=8). To identify specific Ca^{2+}-activated conductances responsible for these phenotypes we performed voltage-clamp experiments and found that TCF4 knockdown results in a significant enhancement of the slow AHP (sAHP; $p<0.006$; TCF4 shRNA n=14; Con shRNA n=15). We further validated this result by rescuing the TCF4-dependent decrease in action potential output via application of carbachol, a M1/M3 agonist that is known to activate signaling pathways that inhibit the sAHP. Overall, these results suggest the dosage of TCF4 expression is critical for modulating neuronal excitability by regulating the expression of genes associated with the sAHP, and therefore could hypothetically explain cognitive deficits observed in PTHS and schizophrenia.

Title: Effect of docosahexaenoic acid (DHA) on a gene/prenatal stress autistic mouse model

Authors: *F. MATSUI, P. HECHT, E. JASAREVIC, K. FRITSCHE, D. BEVERSDORF
Univ. of Missouri, Columbia, MO

Abstract: Autism Spectrum Disorder (ASD) is characterized by impairments in social interaction and social communication, and repetitive and stereotyped behaviors. While genetics is thought to play a large role in the disorder, environmental factors, such as stress are also thought to contribute to it. We previously reported that prenatal stress exposure in stress-susceptible heterozygous serotonin transporter (SERT) KO pregnant dams in a mouse model altered social interaction in the offspring. The present study additionally found impaired social recognition as measured by the olfactory habituation/dishabituation test but not repetitive behavior as measured by the time spent self-grooming in a novel environment and the marble burying test in the mice. Moreover, the maternal docosahexaenoic acid (DHA) level on postpartum day 21 (P21) in frontal cortex in the mice was significantly reduced, indicating a decrease during gestation and lactation periods. Interestingly, DHA level in only prenatal stress mice (wild type) at P21 was also significantly reduced, while the level in SERT mice (no prenatal stress) was not significantly reduced. DHA, one of the major omega-3 polyunsaturated fatty acids (PUFAs), plays an important role in the functioning and development of the brain and central nervous system and a deficiency or an insufficient intake of omega-3 PUFAs can cause developmental abnormalities. We administrated a DHA rich diet to the offspring just after weaning and assessed their social behavior and fatty acid levels during adulthood. DHA improved their social interaction but not social recognition. The omega-3 PUFAs level in frontal cortex was significantly increased, while the omega-6 PUFAs level was significantly reduced. The results indicate that some behavioral aspects of autism-associated behavior can be reversed with DHA in the stress-susceptible genotype/prenatal stress mouse model. Future studies will need to further study the potential role of DHA in autism.

Title: Maternal immune activation and juvenile social motivation in mice

Authors: *J. J. SCHWARTZER, K. O. SUEN, K. A. GILL, P. NANDA, L. A. ALTOMARE, R. D. SANCHEZ
Psychology & Educ., Mount Holyoke Col., South Hadley, MA

Abstract: Activation of the mother's immune system during pregnancy is associated with neurodevelopmental disorders including Autism and Schizophrenia. These disorders are characterized by a broad range of impairments in social-emotional behaviors that manifest from alterations in one of several social brain networks, including disruptions in social cognitive and/or social motivational processes. Mouse models have repeatedly demonstrated that maternal immune activation results in deficits in social approach behavior in the three-chambered social approach task. However, it remains unknown which neurobehavioral processes are contributing to the social approach deficits. Specifically, it is hypothesized that reductions in social approach behavior in offspring of MIA dams are due to deficits in social motivation (i.e. the rewarding value associated with social interactions). To test this, pregnant mice were treated with the viral mimic polyinosinic:polycytidylic acid (polyI:C) or vehicle on gestational day 12.5 and juvenile offspring were measured for changes in social motivation using a social conditioned place preference task. Additionally, to determine whether MIA alters species-typical play behaviors in juvenile mice, offspring of polyI:C-treated and control dams were tested in the reciprocal social interactions task. Data provide insight into which neurobehavioral processes within the social brain network are disrupted by maternal immune activation.

Abstract: The interior of the neuronal cell nucleus is a highly organized 3-dimensional (3D) structure in which regions of the genome that are millions of bases apart participate in specialized sub-structures with dedicated functions. To investigate neuronal chromatin organization and dynamics *in vivo*, we generated bitransgenic mice that express histone GFP-tagged H2B in principal neurons of the forebrain. Surprisingly, the expression of this chimeric histone in mature neurons causes chromocenter declustering and disrupts the association of heterochromatin with the nuclear lamina. The loss of these structures does not affect neuronal viability but is associated with specific transcriptional and behavioral deficits related to serotonergic dysfunction. Overall, our results demonstrate that the 3D-organization of chromatin in the neuronal nucleus supports an additional level of epigenetic regulation of gene expression that critically influences neuronal function and indicate that some loci associated with neuropsychiatric disorders may be particularly sensitive to changes in chromatin architecture.

Title: Decreased protein synthesis in a mouse model of Tuberous Sclerosis Complex: unexpected consequences of mTORC1 activation

Authors: *R. M. REITH, T. HUANG, M. QIN, C. BEEBE SMITH
Natl. Inst. of Mental Hlth., Bethesda, MD

Abstract: Tuberous Sclerosis Complex (TSC) is an autosomal dominant neurogenetic disorder affecting about 1 in 6,000 people, leading to benign growths throughout the brain and other vital organs. TSC usually has effects on the central nervous system manifested by a high incidence of seizures, intellectual disability, and autism. TSC is caused by mutations in either TSC1 or TSC2, which encode for proteins that form a complex and interact with a small GTP-binding protein, RHEB, to inhibit mammalian target of rapamycin complex 1 (mTORC1). mTORC1 is a central regulator of ribosomal biogenesis and translation initiation, and loss of TSC1/2 function results in increased activity of mTORC1. Therefore, we hypothesized that haploinsufficiency of Tsc2 (Tsc2+/-) in mice would lead to increased regional rates of cerebral protein synthesis (rCPS). We measured rCPS in freely-moving awake male Tsc2+/- mice (age 3 months) with the quantitative autoradiographic L-[1-14C]leucine method. We compared rCPS in 16 brain regions in 11 Tsc2+/- mice with 10 control mice. Unexpectedly, we found statistically significant decreased rates of protein synthesis in many brain regions, including hippocampus (-17%), cortex (-16.5%), thalamus (-16%), and hypothalamus (-20%). These results suggest a possible novel role/ regulation of protein synthesis in the brain.

Title: Transient changes in the number of parvalbumin-immunoreactive neurons in the prefrontal cortex of malnourished rats

Authors: *R. J. CRUZ-RIZZOLO[1], L. L. LIMIERI[1], I. R. PAIVA[1], J. O. BARBOSA-RIBEIRO[1], E. ERVOLINO[1], L. PINATO[2], E. A. LIBERTI[3]
[1]São Paulo State Univ., Aracatuba, SP, Brazil; [2]São Paulo State Univ., Marilia, SP, Brazil; [3]São Paulo Univ., São Paulo, SP, Brazil

Abstract: Perinatal protein malnutrition (PPM) is considered a serious public health concern, affecting a significant portion of the world's population. Epidemiological studies indicate that protein perinatal deprivation may represent risk factors for the late onset of some mental and psychiatric disorders, fundamentally schizophrenia, condition where the prefrontal cortex plays a fundamental role. In view of the correlation between these neuropsychiatric conditions and PPM, it remains to be determined if some of the structural changes found mainly in the prefrontal cortex of patients in these situations may be reproduced in PPM experimental models. Between the structural changes observed in schizophrenic patients, it has been reported alterations in the GABAergic system, and particularly in the number of parvalbumin positive neurons, a GABAergic subpopulation of the cerebral cortex. Thus, in the present study, using a model of rat PPM, immunohistochemical techniques, and unbiased stereological analysis we quantified the neuronal population of parvalbumin-immunoreactive neurons (Pv+) and the total neuronal population revealed by NeuN immunohistochemistry in the rat medial prefrontal cortex (mPFC). Twenty-four young males rats (Rattus norvegicus; Wistar) were divided in control (C) and malnourished (M) groups. The two groups were fed with proteic or hypoproteic diets (20% and 5% casein, respectively) from one week before conception to the end of the experiment. At postnatal ages day 21 and 60 (P21, P60) twelve animals of each group were anesthetized and transcardially perfused with paraformaldehyde. After perfusion, brains were removed, cryoprotected, frozen and sectioned at 50 μm on the coronal plane. Free-floating sections were

processed for NeuN and Pv immunohistochemistry. The total neuron numbers was estimated using the optical fractionator, with the region of interest (ROI) including all layers and areas of the mPFC. Our stereological analysis showed that PPM did not significantly alter the number of NeuN+ neurons in the rat mPFC in any of the ages studied (P21: C, 527,200±61,290; M, 499,800±62,180; p>0.05. P60: C, 488,600±50,990; M, 493,500±100,500; p>0.05). However, we observed a significant decrease in the number of Pv+ neurons in the mPFC at P21 (C: 29,530±2,650; M 24,780±4,478; p0.05). Considering that there are no differences in the total number of neurons in the mPFC of control and malnourished rats, the changes found in the number of Pv+ neurons indicate a decrease in the synthesis of this protein in the early stages of development.

Title: The schizophrenia and autism associated gene, Transcription Factor 4 (TCF4), regulates cortical column formation in the prefrontal cortex

Authors: *S. C. PAGE, M. D. RANNALS, M. N. CAMPBELL, A. BRILEY, R. A. GALLO, B. MAYFIELD, B. N. PHAN, A. E. JAFFE, R. TAO, J. SHIN, T. M. HYDE, J. KLEINMAN, D. R. WEINBERGER, B. J. MAHER
Lieber Inst. For Brain Develop., BALTIMORE, MD

Abstract: Schizophrenia is a debilitating disease with a complex genetic pathophysiology. Genome-wide association studies (GWAS) have identified a number of loci associated with increased risk for SZ and several of these risk variants are located within introns of TCF4 (E2-2, SEF2, ITF2). In addition, autosomal dominant mutations in TCF4 result in Pitt Hopkins Syndrome (PTHS), a rare neurodevelopmental disorder characterized by a spectrum of

symptoms including hyperventilation, seizures, autistic behaviors, intellectual disability, and brain malformations. TCF4 is a basic helix-loop-helix (bHLH) transcription factor that is critical for brain development but whose function is largely unknown. Therefore, we are altering TCF4 expression in the developing rat prefrontal cortex using *in utero* electroporation to transfect neuroprogenitor cells that are giving rise to layer 2/3 pyramidal neurons. We observe that overexpression of the full-length human isoform TCF4B significantly accelerates neuronal differentiation and migration. In addition, expression of either TCF4B or a shorter isoform TCF4A, which lacks a nuclear localization sequence, results in the formation of aberrant cortical microcolumns. These abnormal cortical structures are not observed from expression of a PTHS variant that contains a single point mutation in the bHLH domain that does not permit DNA binding. TCF4B-dependent microcolumn formation is rescued by co-expressing calmodulin (CaM) with TCF4B, and this rescue appears to be dependent on Ca^{2+}, because rescue is prevented when a mutant calmodulin (CaM1,2,3,4) that is incapable of binding Ca^{2+} is co-expressed with TCF4B. Furthermore, analysis of human RNAseq data from postmortem dorsal lateral prefrontal cortex (DLPFC) identified a single TCF4 5' exon that showed significantly decreased expression in schizophrenia patients compared to controls. This differentially expressed exon is unique to TCF4H and *in utero* transfection of this isoform does not produce abnormal cortical microcolumns. We are currently investigating the molecular mechanisms responsible for these phenotypes. Overall, these results suggest the dosage of TCF4 expression is critical for the proper formation of the proposed cortical processing unit, the cortical column, and therefore could hypothetically explain the cognitive deficits observed in Pitt-Hopkins syndrome and schizophrenia patients.

Title: Analysis of a novel 17p13 duplication locus causing human cerebellar malformation

Authors: *V. V. CHIZHIKOV, E. STESHINA
Univ. of Tennessee Hlth. Sci. Ctr., Memphis, TN

Abstract: Malformations of the cerebellum affect 1 in every 4,000 births and are an important cause of ataxia, mental retardation, autism and other handicaps. The most common human cerebellar malformation is Dandy-Walker malformation, which is characterized by a small and upwardly rotated cerebellar vermis and enlarged posterior fossa. Currently the genetic basis of most Dandy-Walker cases is unknown, and the molecular mechanisms contributing to Dandy-Walker malformation are poorly understood. Recently we identified a novel locus on human chromosome 17p13, duplication of which is associated with Dandy-Walker malformation. By mapping 17p13 duplications in patients, we defined "most likely" Dandy-Walker critical region, which contains only nine genes, none of which have been previously implicated in cerebellar development or Dandy-Walker malformation. To model Dandy-Walker malformation of individuals with 17p13 duplication, we created BAC transgenic mice, carrying three of the most promising genes located within our most likely 17p13 Dandy-Walker critical region. These BAC transgenic mice recapitulated several features of the human Dandy-Walker brain phenotype, suggesting that at least one of the three human genes present in their genome is a Dandy-Walker causative gene. By analyzing these BAC transgenic mice, we will determine which of our candidate genes is a Dandy Walker causative gene and will identify new molecular mechanisms of cerebellar development and Dandy-Walker malformation.

Title: Disruption of Brain-Derived Neurotrophic Factor (BDNF) from promoters I and II, but not IV and VI, leads to increased aggression and altered serotonin signaling in male mice

Authors: *K. R. MAYNARD[1], B. LU[2], L. TESSAROLLO[3], R. J. SCHLOESSER[4,1], K. MARTINOWICH[1,5]
[1]Lieber Inst., Baltimore, MD; [2]Tsingua Univ., Beijing, China; [3]Natl. Cancer Inst., Frederick, MD; [4]Dept. of Psychiatry, Univ. of Maryland, Baltimore, MD; [5]Departments of Psychiatry & Behavioral Sci. and Neurosci., Johns Hopkins Univ. Sch. of Med., Baltimore, MD

Abstract: Transcription of *Bdnf* is controlled by several promoters, which drive expression of multiple transcripts encoding an identical protein. Promoters I and IV contribute significantly to activity-dependent *Bdnf* transcription. The existence of unique *Bdnf* transcripts allows for precise temporal, spatial, and stimulus-specific regulation of BDNF production, but the functional consequences of multiple transcripts encoding the same protein remains to be elucidated. We studied mice in which the production of BDNF from promoters I (BDNF-e1), II (BDNF-e2), IV (BDNF-e4), and VI (BDNF-e6) was specifically disrupted. We tested male mice for deficits in social interaction and used quantitative RT-PCR to analyze serotonin transporter and receptor expression in multiple brain regions associated with mood regulation. In a cagemate paradigm of aggression, BDNF-e1 and BDNF-e2 animals displayed decreased latency to attack, increased number of fights, and increased number of tail rattles compared to wild-type controls. Increases in aggression in BDNF-e1 and BDNF-e2 mice were also observed in the home cage requiring separation of mutant animals by 5-6 weeks of age. These behavioral changes were accompanied by increased mRNA expression of the serotonin transporter and $5HT_{2A}$, $5HT_{2B}$, and $5HT_{2C}$ receptors in the hypothalamus, medial prefrontal cortex, and hippocampus of BDNF-e1 and BDNF-e2 mice. In comparison, BDNF-e4 and BDNF-e6 animals did not show signs of enhanced aggressiveness in their home cage or a cagemate paradigm of aggression. Furthermore, BDNF-e4 and BDNF-e6 mice displayed divergent impairments in the 5HT system. These results indicate that *Bdnf* promoters I and II play a critical role in regulating aggressive behavior in male mice, likely through interaction with the serotonin system. Furthermore, our data suggest that BDNF produced from different activity-regulated promoters may have unique functions in neurodevelopment, plasticity, and behavior.

Abstract: Brain maturation is a dynamic and complex process in which many genetic factors for a wide range of neuropsychiatric disorders play diverse roles. Thus, elucidation of the precise molecular mechanisms of how genetic insults provoke aberrant brain development, resulting in subsequent disease-related functional deficits, is critical. We report that postnatal suppression of Disrupted-in-Schizophrenia-1 (DISC1) expression in the prefrontal cortex, drives disturbances of synaptic GABA function and dendritic development in pyramidal neurons, as well as abnormalities in sensorimotor gating, albeit without profound memory deficits. DISC1 regulates $GABA_A$ receptors function specifically in immature developing neurons, but not after full maturation. Notably, transient pharmacological intervention with subtype-selective $GABA_A$ receptor positive allosteric modulators during the postnatal period ameliorates dendritic deficits induced by suppression of DISC1. These findings highlight a critical role of DISC1-mediated postnatal GABA signaling for proper prefrontal cortex maturation and function, and suggest that the postnatal developmental phase may ultimately be considered an important strategic target of treatment for neurodevelopmental conditions.

Abstract: Attention deficit hyperactivity disorder (ADHD) is a heterogeneous syndrome manifesting symptoms including hyperactivity, impulsivity and inattention. The incidence of these symptoms typically changes with age, and often persists into adulthood. Dopamine transporter (DAT) knockout (KO) mice exhibit remarkable hyperactivity, and therefore have been widely considered as an animal model of ADHD. Although developmental processes may be involved in the pathogenesis of ADHD, there have been few studies evaluating developmental processes in this mouse model. We have thus tested locomotor activity of juvenile (4 weeks old) vs adult (12 to 20 weeks old) DAT KO and wildtype (WT) littermate mice in a novel environment after pretreatment with methylphenidate (a non-selective dopamine/norepinephrine transporter inhibitor), nisoxetine (a selective norepinephrine transporter inhibitor), methamphetamine (a relatively non-selective monoamine releaser) or saline. The results showed that 3, 10, 30, or 60 mg/kg methylphenidate failed to reduce locomotion in young DAT KO mice, whereas 10, 30, or 60 mg/kg nisoxetine and 2 mg/kg methamphetamine significantly

decreased hyperactivity in young DAT KO mice. By contrast, both methylphenidate (3, 10, 30, or 60 mg/kg) and methamphetamine (2.0mg/kg) were able to significantly decrease hyperactivity of adult DAT KO mice. The effects of methylphenidate or methamphetamine did not differ in WT mice regardless of age and in all cases produced locomotor stimulation, while nisoxetine (10, 30, or 60 mg/kg), exerted no significant effects on locomotor activity in WT mice. Methylphenidate differs from methamphetamine in its primary mechanism of action, which seems to affect the sensitivity of young DAT KO mice to these drugs. Curiously, the selective NET blocker nisoxetine was effective in both young and adult DAT KO mice, while methylphenidate was not, suggesting that they might have different mechanisms of action. These data indicate that pharmacological effects on locomotor activity in DAT KO mice have a specific neurodevelopmental basis that influences their response to ADHD medications that act through different mechanisms. Considering that methylphenidate was ineffective in juvenile mice, this may indicate that certain ADHD medications may have differential efficacy depending on age.

Title: Striatal Gad67 knockout induces spatial learning and social behavior deficits

Authors: K. ZHANG[1], S. LABAK[1], K. HILL[1], G. BLATT[2], *J.-J. SOGHOMONIAN[1]
[1]Anat. and Neurobio., Boston Univ. Sch. of Med., Boston, MA; [2]Hussman Insitute for Autism, Catonsville, MD

Abstract: GABA is the neurotransmitter of striatal projection neurons, however the contribution of the striatal GABAergic output to behavior is not well understood. We assessed motor function, spatial learning, social and olfactory preference in a conditional mouse model lacking the GABA-synthesizing enzyme glutamic acid decarboxylase, Gad67, in striatal neurons. Gad67-

deficient mice show no impairments in motor coordination and balance on the rotarod and the pole test, but exhibit enhanced locomotor activity, lack of anxious phenotype and stereotypic grooming behavior on the elevated maze and the open-field. Furthermore, Gad67-deficient mice show impairments in spatial learning and social behavior as assessed in the tri-chambers test and impairments in preference for social odors. These findings provide original evidence that striatal Gad67 expression is involved in the modulation of learning and social behavior. Some of the behavioral abnormalities observed in Gad67-deficient mice are reminiscent of Autism-Spectrum-Disorders (ASD) deficits, suggesting that abnormal striatal GABAergic output may contribute to behavioral deficits in ASD

Title: Ketogenic diet attenuates behavioral abnormalities and alters brain mitochondrial respiration in the BTBR mouse model of autism

Authors: *Y. AHN, N. CHENG, R. MYCHASIUK, J. SMITH, R. TOBIAS, J. M. RHO
Pediatrics, Alberta Children'S Hosp. Res. Inst., Calgary, AB, Canada

Abstract: Autism spectrum disorder (ASD) is an increasingly prevalent neurodevelopmental disorder characterized by three core symptoms: abnormal social interactions, communication deficits, and repetitive/stereotyped behaviors. Further, ASD is a chronic condition that can impair gastrointestinal, immune, hepatic, and endocrine systems. In the U.S., the prevalence of ASD is now as high as 1 in 68 children, a 30% increase over two years (CDC 2014). The BTBR T+tf/J (BTBR) mouse is a robust model of ASD and displays all three core behavioral features compared to C57 mice. Earlier, it was shown that the ketogenic diet (KD) can enhance mitochondrial bioenergetics in normal rats (PMID: 16807920) and reduces autistic behaviors in BTBR mice (PMID: 23755170). Here, we asked whether the behavioral improvements induced by the KD are associated with changes in mitochondrial metabolism. Mice were administered either the KD or a standard diet (SD) for 10-14 days from weaning at P21 (C57/SD, C57/KD, BTBR/SD, and BTBR/KD; N>8/group), at which point mice underwent the 3-chamber

sociability test and the inchworming test (P35) (Smith et al, 2014). In the 3-chamber test, BTBR mice spent less time in the chamber with the stranger mouse (340±18 vs. 230±51 sec; p=0.072), but more time in the empty chamber, compared to C57 mice (180±15 vs. 310±54 sec; p=0.039). After KD treatment, BTBR mice spent increased time in the stranger chamber (SD vs. KD in BTBR mice = 230±51 vs. 400±14 sec; p=0.003) and decreased time in the empty chamber (310±54 vs. 160±15 sec; p=0.01). To assess inchworming, we placed an intra-strain pair of mice in a 30x30 cm Plexiglas chamber containing sawdust bedding (~1 inch deep) in a quiet darkened room. Activity was recorded for 10 min sessions. Compared to C57 controls, BTBR mice exhibited longer and more frequent inchworming activity, and a shorter latency to initiate this behavior (13 vs. 300 sec for duration, 2 vs. 33 for frequency, 250 vs. 3 sec for latency to inchworming; $p<0.01$). After KD treatment, inchworming in BTBR mice was significantly decreased (SD vs. KD in BTBR mice = 190 vs. 110 for duration, 35 vs. 21 for frequency, and 3.5 vs. 30 for latency to inchworming; $p<0.01$). Next, we studied mitochondrial respiration with the Seahorse XF24 extracellular analyzer. BTBR mice showed higher oxygen consumption rates (OCRs) than C57 controls (94±1.1 vs. 120±1.3; $p<0.01$), whereas the KD decreased OCR levels in BTBR mice (120±1.3 vs. 88±1.0; $p<0.01$; N=7/group). While these results are clearly correlative, we conclude that the KD may trigger alterations in brain mitochondrial bioenergetics in BTBR mice and that these changes may underlie in part the beneficial behavioral effects of this diet.

Title: *In utero* hypoxia-ischemia and inflammation results in complex white matter abnormalities and gait deficits in young adult rats

Authors: *L. L. JANTZIE[1], S. ROBINSON[2]
[1]Neurol., Dept. of Pediatrics, UNM, Albuquerque, NM; [2]Neurosurg., Boston Children's Hosp. and Harvard Med. Sch., Boston, MA

Abstract: Infants born preterm commonly suffer from a combination of hypoxic-ischemic (HI) and infectious perinatal inflammatory insults that lead to cerebral palsy, cognitive delay, behavioural issues and epilepsy. Using a novel rat model of combined late gestation HI and lipopolysaccharide (LPS)-induced inflammation, we tested our hypothesis that inflammation from HI and LPS differentially impact white matter development and motor impairment during the first postnatal month. Pregnant rats underwent laparotomy on embryonic day 18 and transient systemic HI (TSHI) and/or intra-amniotic LPS injection. Shams had laparotomy and anesthesia, but no TSHI or LPS. Pups were born at term (n=11-18/group). Immunohistochemistry and Western blots were performed for myelin basic protein (MBP) and neurofilament (NF) expression. White matter erythropoietin (EPO) ligand and receptor levels were quantified using qPCR. Digigait analysis detected gait deficits. Statistical analysis was performed with one-way ANOVA and post-hoc Bonferonni correction. At P15, MBP expression is reduced by 31% in TSHI+LPS pups compared to shams ($p< 0.05$), whereas TSHI alone leads to only a 13% reduction in MBP. By P28, white matter injury shifts from the acute injury pattern to a chronic injury pattern in TSHI pups only. Both MBP expression ($p<0.01$) and the pNF/NF ratio, a marker of axonal dysfunction, are reduced in P28 TSHI pups ($p<0.001$). EPO ligand to receptor ratios differ between brains exposed to TSHI and LPS. Gait analyses reveal that all groups (TSHI, LPS and TSHI+LPS) are ataxic with deficits in stride, paw placement, gait consistency and coordination (all $p<0.001$). Prenatal TSHI and TSHI+LPS lead to different patterns of injury with respect to myelination, axon integrity and gait deficits. Further study will contribute to stratification of injury mechanisms in preterm infants, and guide the use of promising therapeutic interventions.

Title: Targeting the PI3K/Akt/mTOR pathway in an *in vitro* model of cortical dysplasia

Authors: *G. D'ARCANGELO, I. NIKOLAEVA, B. CROWELL, T. KAZDOBA
Cell Biol. & Neurosci., Rutgers, The State Univ. of New Jersey, PISCATAWAY, NJ

Abstract: Cortical dysplasia is a group of developmental brain disorders characterized by anatomical malformations of the cerebral cortex and cellular overgrowth. These malformations are highly associated with intellectual disability and childhood epilepsy. The activity of the PI3K/Akt/mTOR pathway is elevated in dysplastic brain regions as a result of genetic or somatic mutations in several genes in this signaling cascade. To mimic this condition in the developing mouse forebrain, we conditionally disrupted the *Pten* gene that normally suppresses PI3K/Akt/mTOR signaling specifically in excitatory neurons of the forebrain. Homozygous knock out mice (NEX-Pten) exhibit megalencephaly and activation of the PI3K/Akt/mTOR pathway in forebrain neurons, and die shortly after birth. Forebrain neuronal cultures derived from mutant embryos exhibit dramatic cellular hypertrophy, including increased soma size and dendrite complexity. Cultured neurons also exhibit the expected activation of PI3K/Akt/mTOR signaling. In this study we first characterized NEX-Pten forebrain cultures by measuring morphometric parameters of cellular growth and the level of PI3K/Akt/mTOR signaling in mutant and control neurons at different stages of development and maturation. Second, we tested known compounds that inhibit these specific pathway components to identify agents that reduce the growth abnormalities of NEX-Pten neurons. We used FDA-approved compounds, such as the Akt inhibitor MK2206 and the mTORC1 inhibitor RAD001 (a rapamycin analog), alone or in combination, to establish the most effective form of intervention that suppresses the phenotype and restores normal signaling without affecting neuronal viability. These findings will help to develop novel pharmacological treatments for children affected by cortical dysplasia. This work is supported in part by multiprogrammatic grant CBIR12MIG011 from the New Jersey Commission on Brain Injury Research, and by Exploration-Hypothesis Development Award #TS110033 from the Department of Defense - CDMRP - TSCRP (G.D.).

Title: Delayed post-treatment with bone marrow-derived mesenchymal stem cells is neurorestorative of striatal medium-spiny projection neurons and improves motor function after neonatal rat hypoxia-ischemia

Authors: *D. E. OORSCHOT, A. J. ALWAKEEL, L. GODDARD, C. E. HOBBS, E. K. GOWING, E. R. BARNETT, S. E. KOHE, R. J. SIZEMORE, S. H. CAMERON
Univ. Otago Sch. Med. Sci., Dunedin Otago, New Zealand

Abstract: Perinatal hypoxia-ischemia is a major cause of striatal injury and may lead to cerebral palsy. We investigated whether delayed administration of bone marrow-derived mesenchymal stem cells (MSCs), at one week after neonatal rat hypoxia-ischemia, was neurorestorative of striatal medium-spiny projection neurons and improved motor function. The effect of a subcutaneous injection of a high-dose, or a low-dose, of MSCs was investigated in stereological studies. Postnatal day (PN) 7 pups were subjected to hypoxia-ischemia. At PN14, pups received treatment with either MSCs or diluent. A subset of high-dose pups, and their diluent control pups, were also injected intraperitoneally with bromodeoxyuridine, every 24h, on PN15, PN16 and PN17. This permitted tracking of the migration and survival of neuroblasts originating from the subventricular zone into the adjacent injured striatum. Pups were euthanized on PN21 and the absolute number of striatal medium-spiny projection neurons was measured using stereological methods after immunostaining for DARPP-32 (dopamine- and cAMP-regulated phosphoprotein-32), double immunostaining for bromodeoxyuridine and DARPP-32, and after cresyl violet staining alone. The absolute number of striatal immunostained calretinin interneurons was also measured. There was a statistically significant increase in the absolute number of DARPP-positive, bromodeoxyuridine/DARPP-32-positive, and cresyl violet-stained striatal medium-spiny projection neurons, and fewer striatal calretinin interneurons, in the high-dose MSCs group compared to their diluent counterparts. Compared with previous stereological data on the absolute number of cresyl violet-stained striatal medium-spiny projection neurons in the normal uninjured brain, a high-dose of MSCs restored the absolute number of these neurons to normal uninjured levels. For the low-dose experiment, in which cresyl violet-stained striatal medium-spiny neurons alone were measured, there was a lower statistically significant increase in their absolute number in the MSCs group compared to their diluent controls. Investigation of behaviour in another cohort of animals showed that delayed administration of a high-dose of bone marrow-derived MSCs, at one week after neonatal rat hypoxia-ischemia, improved long-term motor function on the staircase test and the cylinder test. Thus, delayed therapy with a high- or low-dose of adult MSCs, at one week after injury, is effective in restoring the loss of striatal

medium-spiny projection neurons after neonatal rat hypoxia-ischemia and a high-dose of MSCs improved motor function. Funded by Lottery Health New Zealand.

Title: Combined effects of prenatal stress and maternal genotype on interneuron development

Authors: *P. HECHT[1], E. JASAREVIC[2], F. MATSUI[1], L. WELBY[1], J. MINK[1], M. WILL[1], D. BEVERSDORF[1]
[1]Univ. of Missouri, Columbia, MO; [2]Univ. of Pennsylvania, Philadelphia, PA

Abstract: Prenatal stress has been shown to have a profound and lasting impact on neurodevelopment and leads to an increased risk for several neuropsychiatric conditions, including autism spectrum disorder (ASD). It is crucial to understand how genetics may interact with this environmental trigger to identify those most susceptible to the increased risk and to create a better understanding of the underlying mechanisms and potential treatments of such disorders. A 44 base-pair deletion polymorphism located in the promoter region (5-HTTLPR) of the serotonin transporter gene (SLC6A4) results in decreased gene expression and has been associated with several anxiety related disorders. In an animal model, pregnant dams heterozygous for the serotonin transporter gene (Slc6a4 +/-) exposed to stress produced offspring that exhibited several autistic-like behaviors. It has been suggested that the GABAergic system plays a key role in the underlying pathophysiological process of ASD. Previous research has shown that prenatal stress and manipulation of the serotonergic system affects the proper development of the GABAergic system individually. However, the combined effects are unknown. In the present study, wild-type female mice and females heterozygous for the serotonin transporter gene (Slc6a4 +/-) were bred with wild-type males. Upon detection of a mating plug, mice were either placed in a prenatal stress or control condition. In the stress condition, animals were exposed to restraint stress beginning on embryonic day 12 and continued every day until embryo tissue collection or parturition. GABAergic interneuron development was

then analyzed using immunofluorescence. Results suggest that manipulations of the maternal serotoninergic system further exacerbate the deleterious effects of stress on the developing brain. Embryonic tissue in this group exhibited delayed interneuron migration and abnormal cortical layering into the cortex. These findings begin to reveal how stress exposure and genetics may interact to impact the development of neural circuits believed to be critical for social interaction.

Title: Learning and memory deficits in a novel mouse model of non-syndromic intellectual disability and autism spectrum disorder

Authors: A. W. OAKS[1], S. DI COSTANZO[1], D. E. TAMBUNAN[2], H. L. POND[1], D. GONZALEZ[2], C. A. WALSH[2], *M. MANZINI[1]

Abstract: Autosomal recessive loss of function mutations in the *CC2D1A* gene cause a spectrum of fully penetrant cognitive phenotypes including mild to severe intellectual disability (ID), autism spectrum disorder (ASD), as well as seizures, suggesting that these conditions have shared developmental mechanisms. Cognitive and behavioral deficits are often attributed to hypomorphic or *de novo* heterozygous mutations, however complete loss of *CC2D1A* function identifies this gene as a critical participant in neurodevelopmental processes without any additional syndromic presentation. CC2D1A is an important regulator of endosomal trafficking and signaling and these functions appear to be essential for normal cognitive development. Previous attempts to identify the developmental role of this gene by genetic removal in mice have been partially prevented due to perinatal lethality in *Cc2d1a*-deficient animals. In order to overcome this challenge and to further elucidate the role of *CC2D1A* in humans, we generated a conditional knockout (cKO) line to remove *Cc2d1a* in the brain at different times. In these

animals the floxed *Cc2d1a* gene is disrupted following expression of a cre recombinase driven by the *nestin* or *CamKIIa* promoter. While the Cc2d1a^{nestin} cKO animals still die at birth, conditional postnatal removal of Cc2d1a in the forebrain via CamKII-cre generates animals which are viable and fertile and show grossly normal growth and development. Brain anatomy and basic behavioral function are comparable to wild type in adult Cc2d1a^{CamKII} cKO mice, but these animals display deficits in spatial learning and memory and a tendency toward hyperactivity and excessive grooming, which are consistent with other ASD/ID models. As detailed morphological and electrophysiological characterization is underway, we propose that the Cc2d1a^{CamKII} cKO mice could provide much needed insight into the developmental mechanisms underlying non-syndromic cognitive deficits.

Title: Absence of H3K4 demethylase rbr-2 in *C. elegans* results in defective GABAergic network morphology and function

Authors: A. J. RODRIGUES[1], C. BESSA[1], F. MARQUES[1], A. AMORIM[1], F. LOPES[1], *P. E. MACIEL[1,2]
[1]Life and Hlth. Sci. Res. Inst. (ICVS), Braga, Portugal; [2]ICVS/3B's - PT Government Associate Lab., Braga, Portugal

Abstract: Intellectual disability (ID) is one of the most frequent and disabling neurological impairments with an estimated prevalence of 1.5-2% in Western countries. Technological advances such as the use of array comparative genomic hybridization (aCGH) and massive parallel sequencing have allowed the identification of novel genetic causes of ID. This large-scale analysis originates an incredible number of novel genetic associations that most often require functional validation. We are using the simple round worm Caenorhabditis elegans (*C. elegans*) as a platform to functionally validate ID genetic associations and to better understand

the importance of target genes and proteins in the nervous system and neuronal function. So far, we have studied 35 mutant strains that correspond to 29 orthologues of human genes previously linked to ID. Absence of one candidate, rbr-2, the orthologue of human KDM5C/JARID1C, leads to anatomical reproductive defects, developmental delay (larval arrest), increased embryonic lethality and decreased life span. Interestingly, rbr-2 mutant worms also present several behavioural deficits which suggest an impairment of neuronal functions. Of notice, worms exhibit increased motor uncoordination and abnormal sensory chemotactic responses. By crossing the rbr-2 knock-out strain with reporter strains expressing GFP in specific neuronal sub-types, we found an increased occurrence of GABAergic network defects - namely abnormal neuronal process positioning and migration. In addition, these animals were more sensitive to Pentylenetetrazol (PTZ - a GABA antagonist) than wild-type worms. This correlates well with expression analysis of genes related to GABA metabolism or transport, some of which were found be altered in mutant worms. Overall, our data suggests that rbr-2, which encodes for a histone demethylase, plays a relevant role in nervous system development and specifically in GABA-dependent neuronal functions.

Title: Shank2 mutation in a rat model decreases social interaction and increases hyperactivity and motivated behavior

Authors: *M. E. MODI[1], M. SCHMEISSER[2], D. REIM[2], T. BOECKERS[2], T. KISS[1], D. L. BUHL[1]
[1]Pfizer Inc., Cambridge, MA; [2]Univ. of Ulm, Ulm, Germany

Abstract: Many genes identified as anomalous in genetic screens of the autism population encode proteins that regulate synaptic plasticity, including the *SHANK* family of genes. The link between mutation of ubiquitously expressed synaptic genes and the social impairments of autism, though, is unclear. To investigate the relationship between decreased synaptic function and social impairment, the behavioral and molecular phenotype of transgenic rats expressing a

truncation mutation of the *Shank2* gene was characterized. *Shank2 m*utation resulted in alterations in social behavior throughout development. *Shank2* mutant rats engaged in less juvenile play than wild type rats (WTs), which was maintained into adulthood as evidenced by decreased social investigation and social recognition. Unlike *Shank2* deletion in the mouse, a decrease in social approach was not observed in *Shank2* mutant rats. *Shank2* mutant rats also exhibited several forms of hyperactive and repetitive behaviors, including increased locomotion and abnormal circling and checking behaviors. Independent of the hyperactivity, *Shank2* mutant rats showed increased motivation in a progressive ratio operant response task relative to WT rats, despite impairment in the initial acquisition of the task. Both increased circling and operant responses were significantly diminished by either dopamine D1 or D2 receptor antagonists. The observed hyperactivity/hypermotivation phenotypes may be due to the observed upregulation of mGluR1 and SHANK3 in the striatum. The alterations of mGluR1 expression are observed only in male mutant rats. Despite the alterations in locomotor behavior and synaptic receptor expression, *Shank2* mutant rats do not have any overt alterations in cortical EEG activity or in the sleep/wake cycle. However, as SHANK2 mutant rats display many of the behavioral features of autism, further investigation into behaviorally induced neuronal activity within neurocircuits associated with emotion will be explored for the development of electrophysiological endophenotypes of autism-related impairments.

Title: Maternal exposure to sleep apnea-featured intermittent hypoxia leads to oxidative stress and perinatal white matter deficits in mouse brains

Authors: X. LI[1,3], R. WU[1], C. TUONG[1], D. GOZAL[4], *J. CAI[2]
[1]Pediatrics, [2]Pediatrics/KCH Res. Inst., Univ. Louisville, LOUISVILLE, KY; [3]Neonatal Dept., Qilu Children's Hospital, Shandong Univ., Jinan, China; [4]Pediatrics, Comer Children's Hospital, Univ. of Chicago, Chicago, IL

Abstract: Pregnancy has emerged as an important risk factor for sleep-disordered breathing (SDB). Little is known about the impact of untreated gestational SDB on the fetus/newborn. We hypothesize that maternal SDB during gestation will result in hypoxic/oxidative stress and white matter injury (WMI) in perinatal brains. To test this hypothesis, we examined hypoxic status/oxidative response and WM development in perinatal brains using maternal mouse models of sleep apnea-featured intermittent hypoxia (IH). Pulse oxyhemoglobin saturation (SpO2) changed in a recurrent manner and produced similar nadir hemoglobin oxygen saturations (60%~70%) as observed in moderate to severe sleep apnea patients. Earlier delivery occurred with small litter size in IH-exposed pregnant mice. The gestational IH-insulted neonates showed retarded somatic growth after birth. Hypoxic cells in fetal brain were dramatically labeled with tissue hypoxia marker-pimonidazole hydrochloride. Expressions of iNOS and eNOS, but not nNOS, were enhanced in maternal IH-exposed fetal brains. Intriguingly, p67phox and gp91phox, the cytosolic and membrane-bound components of NADPH oxidase, were significantly elevated in fetal/neonatal brains subjected to maternal IH exposures. Although barely detectable SOD2 was slightly increased in IH-insulted fetal brains, a large amount of superoxide was produced, coinciding with increased endogenous apoptosis in multiple brain regions. Furthermore, maternal IH exposures inhibited myelin synthesis and axonal maturation in offspring after birth, especially in the areas of corpus callosum and cerebellum, which may result in long-term neurobehavioral sequelae. The findings suggest that hypoxic/oxidative stress may play an important role in the pathogenesis of adverse fetal outcomes, including perinatal WMI.

Title: The role of lysophosphatidic acid signaling in initiating premature infantile post-hemorrhagic hydrocephalus

Authors: *N. C. STODDARD[1,2]
[1]Chun Lab., The Scripps Res. Inst., La Jolla, CA; [2]Biomed. Sci., UCSD, La Jolla, CA

Abstract: Post-hemorrhagic hydrocephalus (PHH) is a disease caused by intraventricular hemorrhage that presents with increased intracranial pressure leading to ventriculomegaly, severe cognitive disability, and possible death. This is a leading childhood neurological disorder, affecting 1 in 1500 newborns, with only palliative treatment options. Recent studies have linked the bioactive lipid, LPA, through its cognate receptors (LPARs) to the initiation of PHH during embryonic life. This lipid is a small molecule existing in cells and circulating at high concentrations within the blood. Here, we present a new LPA-induced mouse model of PHH that implicates LPA signaling at a much later period of human development. This is especially relevant, as premature infants have fragile vasculature in the subventricular zone and surrounding the brain, making them a high risk group for PHH. Neonatal mice, approximating infants born at 20-32 weeks, were injected intracranially with LPA, blood, serum, or vehicle. LPAR signaling initiated by intraventricular hemorrhage caused drastically altered ventricular morphology, disrupted ependymal lining, and decreased cell number surrounding the ventricles. Importantly, these effects are distinct from the fetal PHH model based on age of LPA exposure, maturity and localization of neural cell types, and spatiotemporal LPAR expression. Ongoing studies include identification of receptor selectivity along with efforts to determine the therapeutic usefulness of targeting these GPCRs as a preventative measure against PHH development.

Title: Cognitive flexibility and frontal cortical BDNF-TrkB signaling following prenatal cocaine exposure

Authors: *D. M. MC CARTHY[1], M. N. HUIZENGA[2], G. BELL[3], E. N. CANNON[1], K. P. LEE[1], J. ZHU[1], D. A. FADOOL[3], G. SADRI-VAKILI[2], P. G. BHIDE[1]

Abstract: Prenatal exposure to cocaine produces lasting changes in brain structure and function. Studies using animal models of prenatal cocaine exposure have focused mainly on behavioral outcomes relevant to reward and addiction such as behavioral sensitization and conditioned place preference. However, prenatal cocaine exposure is likely to impact other cognitive functions such as working memory and cognitive flexibility, which are components of attentional and executive function networks. To address this gap in our knowledge, we used an olfactory reversal learning paradigm to assay cognitive flexibility in prenatally cocaine exposed adult mice. Water-deprived, adult (postnatal day 90) mice from prenatal cocaine- or saline-exposed groups were operant trained to associate water reward with a reinforcing odor (S+) and no reward with a non-reinforcing odor (S-). Following training, when the S+ and S- odors were reversed, the prenatally cocaine exposed mice demonstrated significant inability to elicit the correct responses, indicating deficiencies in cognitive flexibility. Plasticity in dopaminergic and GABAergic neuronal circuits in the prefrontal cortex is critical for cognitive flexibility. The neurotrophin BDNF plays critical roles in neuronal plasticity. Cocaine is known to alter BDNF signaling in multiple brain regions, including the frontal cortex. Therefore, we hypothesized that BDNF signaling via the TrkB receptor plays an essential role in mediating the effects of prenatal cocaine exposure on cognitive flexibility. We found that BDNF protein and mRNA as well as well as TrkB phosphorylation were significantly increased in the frontal cortex of prenatally cocaine exposed adult mice. Together our data show that prenatal cocaine exposure leads to lasting deficits in cognitive flexibility, which appear to be associated with alterations in BDNF signaling. Prenatal cocaine exposure also produces lasting changes in dopamine and GABA neuronal networks. Therefore, currently we are exploring whether the changes in cognitive flexibility are mediated solely by the elevated BDNF-TrkB signaling or whether other mechanisms such as frontal cortical dopamine and GABA neurotransmitter signaling are also involved.

Title: Perinatal high fat diet leads to DNMT1 deficits in the offspring prefrontal cortex: mRNA overexpression, reduced activity and cytoplasmic sequestration

Authors: *S. MCKEE, N. M. GRISSOM, N. BOWMAN, T. M. REYES
Univ. of Pennsylvania, Philadelphia, PA

Abstract: Maternal obesity and excess gestational weight gain increase the risk of mental disorders, including schizophrenia, autism, and attention deficit/hyperactivity disorder (ADHD). These disorders of cognition and attention implicate prefrontal cortex (PFC), a region important for action selection, executive function, and inhibitory control. Previously, we have shown that offspring of a maternal high-fat diet (HFD) have reduced whole-genome DNA methylation in multiple brain regions, including the PFC, coupled with promoter-specific hypomethylation and dysregulated gene expression. This suggests that DNA methylation deficits may contribute to the neurodevelopmental programming deficits induced by gestational exposure to a high-fat diet. Therefore, the present experiments were designed to systematically examine the expression and function of DNA methylation machinery in offspring born to dams fed a HFD during pregnancy and lactation. DNA methyltransferase 1 (DNMT1) was overexpressed in all examined brain regions, with the largest fold change observed in the PFC. In contrast, expression of DNMT3a and 3b was unchanged by maternal diet. Experimentally induced DNMT1 overexpression is typically associated with DNA hypermethylation, suggesting that the observed DNA hypomethylation in this model was due to impairments in DNMT1 function. In the PFC of HFD offspring, DNMT1 protein was elevated, while DNMT3a protein was unchanged. Via immunohistochemistry, we identified high levels of cytoplasmic DNMT1 in HFD offspring, while DNMT1 was largely contained in the nucleus in the PFC of control offspring. Methyltransferase activity of nuclear extracts of PFC was unchanged between HFD and control offspring, but the methyltransferase activity of cytoplasmic extracts was significantly lower in HFD offspring, suggesting that mechanisms impairing DNMT1 nuclear localization also impair its catalytic activity. Immunoprecipitation experiments revealed that DNMT1 from HFD offspring PFC was significantly less associated with the kinases AKT and casein kinase, both of which regulate DNMT1 nuclear import and catalytic function. Overall, these data indicate a profound impairment in the function of DNMT1 protein in adult PFC neurons due to gestational HFD. DNMT1 overexpression has been repeatedly observed in PFC in schizophrenia, and neuronal DNMT1 cytoplasmic sequestration has been noted in several forms of dementia. These

findings demonstrate that early life events can permanently alter the function of DNMT1 into adulthood, possibly predisposing to mental disorder.

Title: Developmental HCN/h-channel deficiency in the murine forebrain models structural and functional brain disorders

Authors: ***A. SCHLUSCHE**[1], A. MERSEBURG[1], A. NEU[2], S. SANDKE[2], D. ISBRANDT[1]
[1]Inst. for Exptl. Neurophysiol., DZNE Bonn, Hamburg, Germany; [2]Exptl. Neuropediatrics, Ctr. for Mol. Neurobio., Hamburg, Germany

Abstract: The hyperpolarization-activated cyclic nucleotide-gated nonselective cation (HCN) channels mediate I(h) and are important determinants of the biophysical properties of neurons. Changes in expression patterns, subcellular localization, or biophysical characteristics of HCN channels have been associated with neurological dysfunctions ranging from motor learning deficits to diseases such as epilepsy. Recently, de novo mutations in the HCN1 gene in human patients have been linked to epileptic encephalopathy with concomitant neurological abnormalities, including autistic features, ADHD, absence of language, behavioral disturbances, ataxia, and delay of motor development (1). We generated HCN/h channel-deficient mice in which we functionally suppressed I(h) in different developmental stages. The mice developed phenotypes that were dependent on the age of onset of I(h) suppression and that partially resembled comorbidities observed in human patients with different de novo mutations in the HCN1 gene (1). HCN/h channels are homo- or heterotetramers of HCN 1-4 subunits. By transgenic expression of a dominant-negative (non-conducting) HCN subunit (HCN-DN), we generated mice with a conditional and subunit-unspecific functional knock-out of I(h). HCN-DN

expression under the control of either the EMX1 or CaMKII alpha promoters enabled prenatal or peri-/postnatal ablation of I(h) in forebrain projection neurons. EMX1 promoter-mediated early prenatal ablation of the HCN/h current resulted in severe morphological abnormalities in the developing brain. Brain volume and cortex thickness were strongly reduced in HCN-DN-expressing mice. In contrast, CaMKII alpha promoter-driven early postnatal suppression of HCN channel-activity did not affect brain morphology, but resulted in behavioral abnormalities. HCN-DN mice displayed delayed somatosensory development with respect to sensorimotor reflexes, cognitive deficits in working memory and spatial learning and memory, as well as hyperactivity. Post-weaning onset of HCN-DN expression resulted in slight learning and memory deficits, but no hyperactivity. Our results demonstrate distinct roles of HCN/h-channel activity during pre- and postnatal development of the central nervous system of the mouse. The different age-dependent developmental phenotypes observed in our I(h)-deficient mice may provide a model to investigate the range and variability of neurological dysfunctions associated with HCN1 mutations in human patients. Title: Developmental exposure to dexamethasone induces alterations in circadian rhythms which precede depression-like behaviour

Authors: *S. SPULBER[1], M. CONTI[2], C. DUPONT[2], N. ONISHCHENKO[2], S. CECCATELLI[2]
[1]Karolinska Institutet, Dept. of Neurosci., Stockholm, Sweden; [2]Neurosci., Karolinska Institutet, Stockholm, Sweden

Abstract: Glucocorticoids play a critical role during development, but foetal exposure to high levels increases the risk of cardiovascular, metabolic, neuroendocrine and psychiatric disorders

later in life. The aim of this study was to characterise the early and long-term behavioural alterations induced by prenatal exposure to a synthetic glucocorticoid analogue (dexamethasone, DEX). Pregnant female C57Bl/6 mice were exposed to 0.05 mg/kg/day DEX from gestational day (GD) 14 until delivery. The offspring underwent a battery of behavioural tests to assess spontaneous locomotion, social interactions, and depression-like behaviour, between 1 and 12 months of age. We found that DEX-exposed males were hyperactive and displayed impaired social recognition between 1 and 5 months of age. At 12 months, but not earlier, the DEX-exposed mice displayed depression-like behaviour in the forced-swimming test and impaired hippocampal neurogenesis, which were not reversed by chronic antidepressant treatment with fluoxetine. In humans, mutations in the clock genes have beebn associated with depression. Therefore, we investigated the circadian and ultradian rhythms at 1, 3, 5, and 12 months of age to identify possible alterations that could predict the depression-like phenotype. To this end we monitored the locomotor activity in the homecage using the TraffiCage™ system. The data were analysed offline for assessing the rhythmicity and complexity of fluctuations in spontaneous activity. We found that control mice have fractal-like scale-invariant fluctuations in spontaneous activity. In contrast, starting from 3 months of age, DEX-exposed mice display alterations in circadian and ultradian rhythms suggestive for defective internal clock function. In agreement with the behavioural data, the cyclic expression of clock genes was abolished in the hippocampi of DEX-exposed mice. In conclusion, we found that developmental exposure to DEX induces subtle alterations in the circadian and ultradian rhythms that can predict depression-like behaviour later in life.

Title: Brain pathology in a nonhuman primate model of maternal immune activation

Authors: *R. K. WEIR[1], R. FORGHANY[2], A. K. MCALLISTER[2], P. H. PATTERSON[3], C. M. SCHUMANN[4], M. D. BAUMAN[4]
[1]Univ. of California, Davis, Sacramento, CA; [2]Univ. of California, Davis, Davis, CA; [3]California Inst. of Technol., Pasadena, CA; [4]Univ. California, Davis, Davis, CA

Abstract: Maternal infection during pregnancy is associated with an increased risk of having a child later develop autism or schizophrenia. Rodent models have played a critical role in establishing causal relationships and identifying mechanisms of altered brain development and behavior in pups prenatally exposed to maternal immune activation (MIA). To bridge the gap between rodent models and human patient populations, we have developed a novel, nonhuman primate model of MIA using a modified form of the viral mimic, polyIC. Pregnant rhesus monkeys (Macaca mulatta) received polyICLC injections at the end of the first trimester to produce a transient innate inflammatory response. A separate control group of pregnant rhesus monkeys received saline injections at these time points. Behavioral data from a large cohort of MIA-treated and control macaque offspring demonstrates that MIA in the rhesus monkey yields offspring with abnormal repetitive behaviors, communication, and social interactions. Despite these intriguing behavioral findings, we do not know the mechanisms by which MIA alters brain development in the nonhuman primate. Here we present our initial assessment of brain pathology in the nonhuman primate MIA model using archived brain tissue from a smaller cohort of MIA-treated and control offspring that were used to establish dosing parameters. Tissue from 8 animals (4 MIA-treated, 4 control) was processed using the Golgi-Cox method that stains approximately 2-5% of neurons in the cortex in an apparent random selection of cells. In brief, tissue blocks were placed in a solution of 1% potassium dichromate, 1% mercuric chloride and 0.8% potassium chromate for 10 weeks. Blocks were then embedded in parlodion, cut into 150μm coronal sections on a sliding microtome and mounted. For each case, 10 pyramidal cells in layer III of the dorso-lateral pre-frontal cortex (BA46) cortex were traced in their entirety using the Neurolucida software package, including all apical, oblique and basal dendrites and their spines. In addition, a more in-depth analysis of the apical dendrite was completed for 30 neurons/case by quantifying diameter, spine density and number of branches in a 30μm section located 100±10μm from the soma. While no significant group differences were found from the 10 neurons traced in their entirety, significant differences were detected in the more in depth analysis of apical dendrite morphology. Compared to controls, the apical dendrites of MIA-treated offspring were smaller in diameter and had a greater number of oblique dendrites. The data provide the first evidence that prenatal exposure to MIA alters dendritic morphology in a nonhuman primate MIA model.

Abstract: Background - The androgen receptor (AndR) is a transcription factor that is crucial for sexual development. AndR is linked to several disorders, including ADHD, Autism, and AIS. Mice bearing humanized AndR genes (h/mAr) with varying lengths of a polymorphic N-terminal glutamine (Q) tract have been created. The length of the Q tract is inversely proportional to the AndR activity. **Objectives –** To determine the behavioral and neuroanatomical phenotype of the AndR mouseline, which can lead to a better understanding of the initiation, progression, and treatment of androgen related disorders, as well as sex-related differences. **Methods –** *Mice* – Three separate mouselines have previously been created with varying Q tract lengths: 12Q, 21Q, and 48Q. Two separate cohorts of mice were used. The first cohort was naïve and sacrificed at P60 for MRI scanning; this cohort consisted of male hemizygotes, and female hetero- and homozygotes for each mouseline. The second cohort consisted of only male hemizygotes and were bred to ~P60 and subjected to 4 different behavior tests, sacrificed and set to undergo further MRI scanning to examine brain/behavior correlations *MRI Acquisition* - Scan parameters: T2- weighted, 3D fast spin-echo sequence (TR - 2000 ms, TEs - 14 ms, 6 echoes, 2 averages, FOV - 14 x 14 x 25 mm3, Matrix size = 250 x 250 x 450). This sequence yielded an image with 0.056 mm isotropic voxels (3D pixel). The same sequence was used on both the naïve and behavioral tested cohorts. *Behavioral Testing* - Tests were used to assess grooming (timed observation), anxiety (open field), sociability (3 chamber test), and compulsive behaviors (marble burying). **Results –** *Volume* - Measurements revealed that the hemizygote 12Q and

homozygote 48Q mice display the most volume differences compared to the WT, with the differences in the homozygote 48Q the most severe with 43 of the 62 regions found to be larger in size. The opposite was found in the hemizygote 12Q mice with 15 of the 62 regions smaller. *Behavior* – A dosage-effect with the 12Q and 48Q mice expressing an non- and anxious (respectively) phenotype was expected. This was affirmed in all measures of the open field test, repudiated by the marble burying and grooming measures, and the sociability test showed a trend towards it. **Conclusions** – The difference in Q tract length of the androgen receptor affects the brain differently in males versus females, with increase androgen activity causing decreases in the male brain and decrease androgen activity causing increases in the female brain. Behavioral investigation revealed a possible role for androgen activity both in anxiety-related and social behaviors, but not repetitive behaviors.

Title: Pharmacological and behavioral assessment of a selectively bred hyperactive mouse line to model ADHD

Authors: *P. MAJDAK, J. R. OSSYRA, J. M. OSSYRA, A. J. COBERT, T. K. BHATTACHARYA, J. S. RHODES
UIUC, Urbana, IL

Abstract: Attention deficit-hyperactivity disorder (ADHD) is a relatively common behavioral disorder characterized by developmentally inappropriate levels of hyperactivity, inattention and impulsivity. It is highly heritable, with broad sense heritability estimates approaching 75%. However, the specific genes and neurobiological risk factors remain a mystery, partly due to the fact that few animal models have been generated for the purpose of exploring the neurobiological

changes underlying a hyperactive phenotype. The goal of this study was to evaluate a line of mice selectively bred for increased locomotor activity in the home cage for face and construct validity as an animal model for ADHD. Following Zombeck et al. (2011) two lines of mice were maintained for over 15 generations. One line, referred to as High-Active, was subjected to within family selection each generation for increased total distance traveled in the home cage on days 5 and 6 of a six day test. Video tracking was used to precisely measure horizontal distance traveled continuously in the home cage over 6 days. The other line, referred to as unselected Control, were randomly bred (avoiding sibling mating) each generation. The purpose of the first experiment was to test face validity of the model by determining whether the High-Active mice also display impulsivity using the operant Go/No-go task as compared to Controls. The purpose of the second experiment was to test the construct validity of the model by determining whether administration of 0.25 mg/kg d-amphetamine during adolescence and adulthood ameliorates hyperactivity and impulsive behavior in the High-Active mice relative to Controls. Current evidence suggest that High-Active mice demonstrate significantly more impulsive behavior relative to Controls in the Go/No-go task, and that amphetamine administration produces a trend in alleviating hyperactivity of the High-Active mice. These preliminary results encourage the continued evaluation of our High-Active line as a potential model for ADHD.

Title: Metabolic effects of creatine transporter deficiency in mice

Authors: A. N. KOKENGE[1], K. N. MILES[1], G. J. PYNE-GEITHMAN[2], Z. KHUCHUA[3], J. F. CLARK[4], *M. R. SKELTON[1]
[1]Neurol., [2]Radiology, [3]Mol. Cardio. Bio., Cincinnati Childrens Res. Fndn., CINCINNATI, OH; [4]Univ. of Cincinnati, Cincinnaiti, OH

Abstract: Creatine (Cr) is a guanidino compound required for rapid replenishment of ATP in cells with a high-energy demand. In humans, mutations in the Cr transporter (CrT;SLC6A8) prevent Cr entry into tissue and result in significant intellectual impairment, epilepsy, and

aphasia. CrT knockout ($CrT^{-/y}$) mice, a high-fidelty model of human CrT deficiency in that they lack brain Cr and show severe cognitive impairments, were used to evaluate the effect of a lack of Cr on both whole body and cellular metabolism. In regards to whole body metabolism, $CrT^{-/y}$ mice weigh significantly less than their WT counterparts though both groups of animals consume similar amounts of food. Paradoxically, $CrT^{-/y}$ mice have a two-fold increase in body fat percentage as measured by ECHO-MRI. $CrT^{-/y}$ mice have an increase in energy expenditure compared with WT mice both in a homecage environment and during treadmill running. Consistent with the increases in whole-body metabolic function, $CrT^{-/y}$ mice show changes in cellular metabolism as well. Increased mitochondrial respiration was observed in skeletal muscle fibers from $CrT^{-/y}$ mice. In cardiac fibers, reductions in mitochondrial respiration were observed. In regards to neurometabolism, mitochondrial respiration was increased in hippocampal lysates from $CrT^{-/y}$ mice. Despite the increase in mitochondrial respiration, ATP levels were significantly reduced in the brain. In order to begin to understand the molecular regulation of these metabolic changes within the hippocampus, next generation RNA sequencing (RNA-seq) was performed. RNA-seq analysis revealed that many genes involved with glycogenolysis, including glycogen phosphorylase, were up-regulated in the hippocampus of $CrT^{-/y}$ mice. Gene expression changes were also observed in mitochondrial proteins, antioxidant synthesis proteins, and monocarboxylate transporters. The results of these studies suggest that the loss of Cr has a significant effect on both whole-body and cellular metabolism. Future studies will be conducted to determine if the changes observed are related to cognitive deficits seen in $CrT^{-/y}$ mice and CTD patients.

Title: Glucocorticoid programming of neural development involves a Tet3-dependent regulation of Wnt signaling and DNA methylation

Authors: *R. K. BOSE[1], S. SPULBER[1], P. KILIAN[1], N. HELDRING[1], P. LÖNNERBERG[2], A. JOHNSSON[2], O. HERMANSON[1], S. CECCATELLI[1]

Abstract: Glucocorticoids (GC) play a critical role during development. However, fetal exposure to excess GC increase the risk of cardiovascular, metabolic, neuroendocrine and psychiatric disorders later in life. We have previously shown that exposure to dexamethasone (Dex, a synthetic GC analogue) decreases proliferation and neuronal differentiation in neural stem cells (NSCs) with concomitant senescence. These effects are heritable and associated with changes in global DNA methylation. Here we performed a genome-wide analysis of differentially methylated DNA regions (DMRs) in embryonic cortex-derived NSCs by immunoprecipitation of methylated DNA enriched by methyl binding domain protein 2, followed by next generation sequencing. We found that Dex induced genome-wide DNA hypomethylation in cortical NSCs *in vitro*, and global hypomethylation in cerebral cortex of 3 day-old mouse pups exposed to Dex *in utero*. We validated selected genes of particular interest by qPCR and methylation-specific PCR in proliferating NSCs.We found that Dex exposure up-regulated Dkk1, a negative regulator of Wnt-signaling, and that the DNA hypomethylation was associated withTet1-3 up-regulation and Dnmt3a down-regulation. These alterations persisted in daughter cells never directly exposed to Dex, and were confirmed *in vivo*.The upregulation of Tet3 was required for the up-regulation on Dkk1 and for the down-regulation of Dnmt3a induced by Dex in NSCs. In summary, we propose that GC elicit strong effects on genome-wide DNA methylation in fetal NSCs including a Tet3-dependent regulation of Wnt signaling.

Title: Prenatal viral immune challenge to mimic autism-like behavioral and electrophysiological phenotypes in mice

Authors: S. M. LANDINO[1], Y. LI[1], *B. C. FINGER[1], V. Y. BOLSHAKOV[1], C. J. MCDOUGLE[2], W. A. CARLEZON, Jr[1]
[1]Dept. of Psychiatry, Harvard Med. School, McLean Hosp., Belmont, MA; [2]Lurie Ctr. for Autism, Massachusetts Gen. Hosp., Lexington, MA

Abstract: Clinical studies have demonstrated associations between maternal infection and inflammation during pregnancy and increased risk of autism. Furthermore, preclinical investigations of maternal immune activation and the development of autism-like phenotypes support the hypothesis of immunological involvement in the etiology of at least some forms of autism. Alterations in neural connectivity and abnormal functioning of numerous brain regions, such as the medial prefrontal cortex (mPFC), have been reported in autism spectrum disorders (ASDs). Further examination of the biological consequences of *in utero* infection may elucidate the specific role of the immune system in the onset of ASDs. To investigate whether *in utero* infection alters function of the prelimibic (PL) division of the mPFC in C57BL/6J mice, we administered the viral mimic polyinosinic:polycytidylic acid (Poly I:C) (20 mg/kg) or vehicle (phosphate buffered saline) to female C57BL/6J mice on day 12.5 of pregnancy. The offspring were tested for core behavioral features of autism, including deficits in communication (measured by analysis of ultrasonic vocalizations in early childhood and in adulthood), diminished social behavior (measured in the social interaction test), and increases in repetitive or stereotyped behaviors (measured in open field and marble burying tests). Following these behavioral tests, we conducted electrophysiology studies in brain slices of representative mice from both treatment conditions to examine the consequences of maternal immune activation on membrane excitability and glutamatergic synaptic transmission in the PL mPFC. Although membrane excitability of PL neurons remained unchanged, Poly I:C treated offspring had reductions in the amplitude of NMDA receptor-mediated synaptic responses at inputs to PL neurons without affecting AMPA receptor-mediated synaptic responses. Examining the behavioral consequences of *in utero* inflammatory responses together with cellular and molecular consequences may provide evidence for an etiologic subtype of neurodevelopmental disorders triggered by insults (e.g. exposure to viruses or bacteria, stress, toxins) that cause immune activation. Our results provide evidence that early immune challenge can trigger behavioral changes that share features with the core signs of autism and corresponding changes in brain glutamate function. Establishing cause-effect relationships among these findings may facilitate the development of interventions that target the immune system to more effectively treat, or even prevent, certain types of ASDs.

Title: Complex neurological phenotype in mutant mice lacking Tsc2 in excitatory neurons of the developing forebrain

Authors: *V. DAL POZZO, B. CROWELL, G. LEE, G. D'ARCANGELO
Rutgers, the State Univ. of New Jersey, Piscataway, NJ

Abstract: Tuberous Sclerosis Complex (TSC) is a genetic disease resulting from mutations in either the *TSC1* or the *TSC2* gene. The disease is characterized by a high frequency of epilepsy, intellectual disability and autism, and by the presence of brain malformations (tubers), frequent tumors and lesions in other organs. The TSC gene products form a complex that inhibits the growth-promoting complex mTORC1. This cellular mechanism may account for tumor susceptibility and growth abnormalities, however, it is not clear whether it underlies cognitive dysfunction in TSC patients. To better understand the role of TSC2 in forebrain development we generated a conditional mutant mouse line (NEX-Tsc2), which lacks *Tsc2* expression specifically in postmitotic excitatory neurons of the developing forebrain. Homozygous mutant mice exhibited neuroanatomical abnormalities in the cerebral cortex and hippocampus, became runt and mostly die during the second-third postnatal week. Mutants also displayed expected abnormalities in Akt and mTOR signaling, but no detectable alterations in glutamate receptor expression. Surprisingly, the mutants exhibited striking cellular abnormalities in non-neuronal populations of the brain, which were not directly affected by the gene knock out strategy. These findings provide new insights into the role of Tsc2 in the development of excitatory neurons, and in mechanisms controlling neuron-glia communication during brain development. This work is supported by Exploration-Hypothesis Development Award #TS110033 from the Department of Defense - CDMRP - TSCRP (G.D.).

Title: Pharmacological reversal of autism spectrum disorder social deficits in the SERT Ala56 mouse via p38α MAPK blockade

Authors: *M. J. ROBSON[1], D. M. WATTERSON[3], J. VEENSTRA-VANDERWEELE[2], A. M. POCH[1], R. D. BLAKELY[2]
[1]Pharmacol., [2]Pharmacol. and Psychiatry, Vanderbilt Univ. Sch. of Med., Nashville, TN; [3]Pharmacol., Northwestern Univ. Sch. of Med., Chicago, IL

Abstract: The reported incidence of autism spectrum disorders (ASD) in the United States pediatric population is currently 1 in 68 children. Exacerbating this problem is a lack of pharmacotherapies aimed at ameliorating aberrant behaviors relevant to ASD. One of the oldest biomarkers of ASD is peripheral hyperserotonemia, an effect linked to serotonin (5-HT) transporter (SERT) activity on platelets. Central 5-HT signaling is tightly regulated by SERT and changes in SERT expression and/or activity are linked to multiple neuropsychiatric disorders, including ASD. Genetic gain-of-function (GOF) variants in SERT have been identified in ASD, specifically in the context of rigid-compulsive behaviors and sensory aversion (Sutcliffe et al. 2005). Mice expressing the most prevalent of these GOF variants, SERT Ala56, display behavioral and biochemical phenotypes characteristic of ASD, including hyperserotonemia, social and communication deficits, and repetitive behaviors (Veenstra-Vanderweele et al. 2012). Additionally, SERT Ala56 animals display a p38 MAPK-dependent hyperphosphorylation of SERT within the CNS (Veenstra-Vanderweele et al. 2012). Pathways involving p38α MAPK signaling are important for responses to stressors and immune system activation and may represent a convergence point between environmental and genetic risk factors. Therefore, we asked whether pharmacological inhibition of p38α MAPK signaling attenuates ASD-like behaviors in the SERT Ala56 model. *In vitro* studies using CHO cells revealed that a novel,

selective p38α MAPK inhibitor, MW108 blocks anisomycin-induced increases in p38 MAPK phosphorylation. Furthermore, MW108 treatment was found to mitigate p38α MAPK-induced increases in SERT uptake in human SERT stably transfected SK-N-MC cells, providing evidence that human SERT is regulated in a similar manner by p38α MAPK as mouse SERT *in vitro*. Consistent with this idea, MW090, a p38α MAPK specific inhibitor with 10-fold lower potency than MW108, required a 10-fold higher concentration to attenuate p38α MAPK-induced increases in SERT activity in SK-N-MC cells. Importantly, *in vivo* behavioral studies revealed that chronic i.p. injections of MW108, as well as the less selective p38α/β MAPK inhibitor SB203580, reverse social behavior deficits in male SERT Ala56 mice in the Tube Test for Social Dominance. To our knowledge, our studies are the first to demonstrate pharmacologic rescue of ASD-like phenotypes by modulating p38α MAPK signaling, suggesting an ongoing versus developmental contribution of the pathway to social behavior deficits and the potential utility of p38α MAPK-based treatments for adult ASD subjects.

Abstract: Autism is a neurodevelopmental condition diagnosed by impaired social interaction, abnormal communication and stereotyped behaviors. In rodents *in utero* exposure to valproic acid (VPA) also causes neurodevelopmental abnormalities and is an important model of autism. In the present study, we aimed to investigate the effect of prenatal administration of VPA (500 mg/kg) at E12.5 on the social interaction behavior linked with electroencephalographic activity (EEG) in hippocampus (HIPP) and prefrontal cortex (PFC). At PD90, control (n 8) and *in utero* exposure to VPA rats (n 8), were stereotaxically implanted in both HIPP and PFC. Social interaction test was performed in pairs simultaneously with EEG recording, experiment was filmed to analyze the social behaviors. EEG activity was acquired on-line (300 Hz sampling rate) using an analog/digital conversion system (ADQCH4) designed in our laboratory. Frequency domain analysis of each chanel recording was performed off-line on the signals. Number, cumulative interaction time and latency of interaction behaviors were analyzed. Power numerical values were normalized against the maximum power of each band: 1-4 Hz, 5-12 Hz and 13-30 Hz and were averaged in 10 minutes epochs, We used the standard fast Fourier transform (FFT) to analyze long periods and the short FFT for short periods. The VPA rats showed an increase in the emission of social behaviors and an increased in latency to explore compared to the control group. Intra-group difference in latency to inactivity was showed in VPA group. The EEG power spectra of left HIPP decreased in the VPA animals in all bands. VPA rats showed an increase in the left PFC power in the 1-4 Hz band. Our study allows link specific brain activity with behavioral manifestations of autism and its changes during development, as well as, being consistent with the results obtained in the study of brain morphology and microcircuitry.

Abstract: Human neocortical molecular layer heterotopia consist of aggregations of hundreds of neurons and glia in the molecular layer (layer I) and are indicative of neuronal migration defect. Despite having been associated with dyslexia, epilepsy, cobblestone lissencephaly, polymicrogyria, and Fukuyama muscular dystrophy, a complete understanding of the cellular and axonal constituents of molecular layer heterotopia is lacking. Using C57BL/6J mice as a model, we identify diverse excitatory and inhibitory/GABAergic neurons as well as glia in heterotopia based on molecular profiles. Using immunocytochemistry, we identify diverse afferents in heterotopia from subcortical neuromodulatory centers. Finally, we document intracortical projections to/from heterotopia including callosal projections. These data are relevant toward understanding how heterotopia affect brain function in diverse neurodevelopmental disorders.

Title: Mode of delivery at birth and behavioural outcomes: Rewiring of the brain-gut-microbiome axis?

Authors: *Y. E. BORRE[1], L. HECKE MORAIS[1], A. V. GOLUBEVA[1], E. PATTERSON[3], F. CRISPIE[3], R. D. MOLONEY[1], K. A. SCOTT[1], R. STILLING[1], N. P. HYLAND[1], G. CLARKE[2], C. STANTON[3], P. D. COTTER[3], T. G. DINAN[2,1], J. F. CRYAN[1]
[1]Alimentary Pharmabiotic Ctr., [2]Psychiatry, Univ. Col. Cork, Cork, Ireland; [3]Teagasc Food Res. Ctr., Carlow, Ireland

Abstract: Mode of delivery has been shown to impact the development of the microbiota and immune system in newborns with negative health associations being reported. Specifically, children delivered by Caesarean section (C-section) are more likely to suffer from immune and metabolic disorders including allergies, obesity and diabetes, which have been linked to the disrupted microbiota maturation. We and others, have shown that early-life perturbations of the developing gut microbiota can affect neurodevelopment and potentially lead to adverse mental health outcomes later in life. However, the relationship between the mode of delivery and behavioural function across lifespan remains to be fully elucidated. To investigate this question, we applied an inter-disciplinary approach using a mouse model of C-section, and consisting of several behavioural assays combined with microbiota, metabolic, immune and transcriptome analyses. Our studies establish that male C-section offspring exhibit stereotypical, anxiety- and-depression- like symptoms, social deficits, disrupted hypothalamic-pituitary-adrenal axis responsivity and perturbed intestinal permeability. Using high throughput DNA sequencing, we monitored the gut microbial composition and diversity, and assessed metabolic and immune consequences of the mode of delivery in the offspring. In addition, we examined the effects of C-section on gene expression within brain limbic structures that play a key role in emotion, stress response and cognition. Furthermore, we evaluated crucial changes in the systemic and mucosal immunity, which may play a role in rewiring the brain-gut-microbiota axis following a C-section. Taken together, these findings support a microbiome-gut-brain connection in a mouse model of C-section and identify potential novel mechanisms by which mode of delivery may contribute to rewiring the developing brain, and susceptibility to neurodevelopmental disorders.

Title: Npas4 contributes to stress-induced changes in the prefrontal cortex of mice

Authors: *L. COUTELLIER[1], R. SHEPARD[2]
[1]Dept. of Psychology, [2]Psychology, Ohio State Univ., Columbus, OH

Abstract: The prefrontal cortex (PFC) is a brain structure strongly implicated in psychiatric conditions such as schizophrenia and depression. Many studies report that stress during childhood and adolescence induces changes in the PFC that could be responsible for the onset of the symptoms of these disorders. However, the molecular mechanisms underlying postnatal PFC development and its vulnerability to stressful events remain unknown. Here we suggest that the transcription factor Npas4 could play a significant role in PFC vulnerability to stress in early life. We first observed significant age-dependent changes in the level of Npas4 mRNA in the PFC of mice, with a significant increase from 3 weeks of age to adolescence and then to adulthood. Then, to determine whether low level of Npas4 in the brain during adolescence affects sensitivity to stress and adult PFC-dependent cognitive functions we used Npas4 heterozygotes (HET) and wild-type (WT) mice. WT and HET mice were exposed to chronic mild stress during adolescence (from 4 to 6 weeks old) or kept in standard rearing conditions (control). PFC-dependent memory was assessed in adulthood (10 weeks old) using the spontaneous alternation test and object/context mismatch test. We observed that WT mice were not affected by the chronic mild stress situation and have normal cognitive function in adulthood. However, adult Npas4 HET mice exposed to chronic mild stress during adolescence display severe PFC-dependent cognitive deficits, while they have only minor impairments when raised in standard conditions. Altogether, these findings support the importance of Npas4 for the development of the PFC during adolescence, and that disturbance of Npas4 expression, associated with stress can affect cognitive functions that rely on the PFC.

Title: Hypoxic-ischemic injury alters auditory cortex function in neonatal rats

Authors: *A. SHEIKH[1], J. LIU[1], A. ISAIAH[2], P. KANOLD[1]
[1]Biol., Univ. of Maryland, College Park, MD; [2]Med. Sch., Univ. of Maryland Baltimore, Baltimore, MD

Abstract: Subplate neurons (SPNs) are required for the formation and functional refinement of thalamocortical connections (Kanold & Luhmann 2010; Tolner, Sheikh et al. 2012). SPNs are selectively vulnerable to neonatal hypoxic-ischemic (HI) insults (McQuillen et al. 2003) and such insults impair critical period plasticity, at least in the visual cortex (Failor 2010). HI insults in human can give rise to auditory impairments, as well as a multitude of other developmental language disorders. Thus we investigated the consequences of developmental HI on auditory cortex function in rodents. HI was performed on rat pups on postnatal day (P) 1-2 and SPN loss was assessed at P5-P8 by immunohistochemistry to complexin 3, a SPN specific marker. We performed extracellular single-unit recordings in the auditory cortex of anesthetized control and HI animals between P20-33. The pure tone evoked response properties of auditory cortex neurons were altered consequent to HI suggesting either functional changes to cortical neurons or altered connectivity between neurons. To distinguish between these possibilities and to get a more in-depth understanding of the *in vivo* results on a cellular level, whole-cell patch clamp recordings were performed from layer 4 neurons between P18-23. We find that intrinsic properties of layer 4 cells are not significantly altered. Thus, the changes observed in-vivo may be due to differences in synaptic connectivity. Together our observations imply that SPNs are necessary for normal functional development of the auditory cortex.

Title: Effects of Foxp2 disruption in selected brain regions and in adulthood

Authors: *C. A. FRENCH[1], A. GOMEZ-MARIN[1], M. CORREIA[1], C. FELICIANO[1], V. B. PAIXÃO[1], X. JIN[2], S. E. FISHER[3], R. M. COSTA[1]

Abstract: Disruptions of the FOXP2 gene cause a rare speech and language disorder. A core feature of this disorder is difficulty in producing the sequences of orofacial motor movements necessary for fluent speech, although other expressive and receptive language problems are also present. Imaging studies have shown structural abnormalities in the caudate nucleus and ventral cerebellum, as well as altered patterns of activation during language-based tasks. FOXP2 encodes a transcription factor which is expressed in the cortico-striatal and cortico-cerebellar circuits required for sensorimotor integration and motor-skill learning. This neural expression pattern, and the FOXP2 protein sequence, are highly conserved in other vertebrate species such as mice and songbirds. Mice carrying a heterozygous point mutation in Foxp2 (the KE-family mutation) have motor-skill learning deficits and lack striatal long-term depression. We also found aberrant striatal activity *in vivo* during the learning of a motor task. Juvenile zebra finches show increased FoxP2 expression in AreaX of the striatum during the song learning-period, and FoxP2 knockdown in AreaX results in inaccurate and incomplete imitation of the tutor bird's song. FoxP2 knockdown in AreaX of mature birds abolishes the mediation of song by social context and suggests that FoxP2 function is important in adulthood as well as during development. We previously generated a conditional Foxp2 line and have used it to disrupt Foxp2 in selected brain regions (cortex, striatum or cerebellar Purkinje cells), and at a defined time point (adulthood). This genetic approach is being combined with an operant motor-sequence learning task where mice must complete a sequence of 8 lever presses to obtain a food reward. After 12 days a time constraint is added and the sequence must be performed at increasingly high speeds. Both cerebellar and striatal Foxp2 mutants show a reduced rate of lever pressing during training compared to controls. However, analyses of behavioural microstructure revealed that whilst pressing of all speeds is altered in cerebellar mutants, in striatal mutants it is primarily rapid pressing that is affected. These data indicate that Foxp2 function in distinct subcircuits differentially affects motor-skill learning. We disrupted Foxp2 globally in adult mice using a tamoxifen-inducible Cre. Preliminary data indicate that homozygous adult knockouts are viable, unlike other Foxp2 homozygous mutants which die at 3-4 weeks of age. Work is ongoing to investigate motor-sequence learning and other aspects of behaviour in these animals.

Title: Group B streptococcus infection during gestation leads to gender specific neurodevelopmental and behavioural impairments

Authors: *M.-J. ALLARD[1], J. BERGERON[1], L.-C. FORTIER[1], C. POYART[2], G. SÉBIRE[1,3]
[1]Univ. de Sherbrooke, Sherbrooke, QC, Canada; [2]Univ. René Descartes, Paris, France; [3]McGill Univ., Montréal, QC, Canada

Abstract: Background: A new preclinical animal (rat) model of gestational inflammation showed that exposure to inactivated Group B streptococcus (GBS) during gestation leads to perinatal brain injuries resulting in gender specific neurobehavioural impairments. To increase the clinical relevance, we refined this model by replacing inactivated by live GBS. The hypothesis is that GBS-induced gestational inflammation has a deleterious neurodevelopmental impact on offspring through a maternofoetal inflammatory response. **Methods:** Pregnant rats were intra-peritoneally injected at gestational day 19 with serotype 1a GBS (10^8 CFU) or saline. The maternal and foetal blood and placentas will be studied by ELISA and immunohistochemistry to characterize inflammatory responses. Brains were collected at postnatal day 40 (P40) for histological studies. Behavioural tests were performed from P7 to P40 to assess maternal attachment and neonatal communication (nest-seeking task, ultrasonic vocalizations), exploratory abilities (open field), social interactions and anxiety (elevated-plus-maze). **Results:** A decrease in body weight gain of dams exposed to GBS was noticed. An intra-uterine growth retardation was present in male, but not in female, pups at P1, and persisted until P4. An increased mortality was observed in GBS-exposed males as reflected by an unbalanced sex-ratio in GBS-exposed litters. GBS-exposed placentas displayed an increase of polymorphonuclear cells (PMN) compared to control; this PMN infiltration was more prominent in male than female. An increase of lateral ventricle size and a decrease of the corpus callosum thickness were detected in GBS-exposed males, but not females, at P40. An increase of myelin basic protein (MBP) detection was observed in the external capsule of GBS-exposed rats at P40. GBS-exposed males, but not females, at P7 showed a decrease of ultrasonic vocalisations. GBS-exposed males at P20 and GBS-exposed females at P25 showed hyperactivity, disorganised exploratory behaviour and decreased level of anxiety, compared to control. **Conclusion:** GBS-

induced inflammation resulted in gender dichotomic neurodevelopmental and behavioural impairments. Communication and social interactions will be further characterized by ongoing studies. Such neurobehavioural characterization correlated to inflammatory mechanistic studies will help to target future neuroprotective strategies.

Title: Systemic endotoxin exposure exacerbates longterm neurobehavioral deficits after neonatal cerebral ischemia

Authors: M. SHABANINIA[1], M. PORAMBO[1], J. MARX[1], M. BUELOW[1], J. CRAWFORD[2], M. PLETNIKOV[2], M. V. JOHNSTON[1], *A. FATEMI[3]

Abstract: Background: We recently reported an ischemic mouse model of Neonatal White Matter Injury (NWMI) induced by unilateral neonatal carotid artery ligation. Several studies have suggested that neuroinflamation has a critical role in the development of NWMI. The aim of this study was to investigate the combinatorial effect of neonatal ischemia with systemic inflammation on longterm neurobehavioral outcomes. Methods: At postnatal days P4/P5, 54 CD1 mouse pups were stratified in 4 groups, they received either an intraperitoneal injection of lipopolysaccharide (LPS, 1 mg/kg) (LPS group, N=18), or underwent neonatal unilateral carotid artery ligation and intraperitoneal injection of PBS (ISCH group, N=18), or unilateral carotid artery ligation and intraperitoneal injection of LPS 1 mg/kg (LPS+ISCH group, N=18), or were injected with PBS only (control group). The effects of these interventions were evaluated by Rotarod, Y-maze, prepulse inhibition (PPI) and open field testing at 8 weeks. Results: On rotarod testing, LPS group preformed significantly worse than controls, while ISCH group did not, however, the LPS+ISCH group performed dramatically worse compared to controls. ISCH and ISCH+LPS groups spent significantly less time in the novel arm of Y maze compared to

controls, while the LPS group did not. Total activity in open field testing was significantly lower in all injury groups and comparable within these three groups. On PPI testing, LPS group did not show a significant difference while ISCH group showed a significant decrease in startle amplitude. This decrease was most pronounced in the LPS+ISCH group. Conclusion: Mice undergoing neonatal ischemia combined with systemic inflammation express a pronounced phenotype with higher deterioration of motor learning skills, spatial memory, and sensorimotor gating. This animal model can facilitate the study of disease pathogenesis and conduction of trials to identify candidate therapeutic for NWMI.

Title: An N-terminal domain essential for PKG- and p38 MAPK-mediated regulation of the serotonin transporter revealed by studies of inbred mouse strain variation in transporter structure

Authors: ***M. A. QUINLAN**[1], R. YE[1,2], Z. JIN[1], R. D. BLAKELY[1,2,3]
[1]Pharmacol., [2]Silvio O. Conte Ctr. for Neurosci. Res., [3]Psychiatry, Vanderbilt, Nashville, TN

Abstract: Disruption of serotonin (5-HT) signaling is implicated in multiple neuropsychiatric and neurodevelopmental disorders, including anxiety and major depressive disorder, obsessive-compulsive disorder, and autism spectrum disorder (ASD). Regulation of 5-HT levels at the synaptic cleft is tightly controlled by high-affinity 5-HT uptake through the presynaptic, antidepressant-sensitive 5-HT transporter (*SLC6A4*, SERT). Studies of human SERT (hSERT) have shown that activation of PKG- and p38-MAPK signaling pathways lead to increases in SERT activity, changes made constitutive by multiple SERT coding variants associated from

individuals with ASD, including SERT Ala56. Our previous studies revealed various pharmacological, neurochemical, and neurobehavioral differences between mouse strains carrying the ER (DBA/2J = E39, R152) and GK (C57BL/6J = G39, K152) SERT. Additionally, site-directed mutagenesis studies of mouse SERT (mSERT) indicated that E39 in the transporter N-terminus dictates functional variation between the two mouse inbred strains. In the present study, we report that these mSERT haplotypes dictate PKG- and p38 MAPK-dependent regulation of SERT activity. Specifically, PKG- and p38 MAPK-dependent regulation is abolished in the ER mSERT, despite the fact that hSERT also encodes E39 and R152 at their corresponding positions. In an attempt to explain the latter discrepancy, we employed a species-scanning-mutagenesis strategy, converting the 15 residues of the N terminus of mSERT to their corresponding identifies in hSERT while maintaining the ER haplotype. *In vitro* 5-HT uptake analysis of the ER mSERT mutants reveal that multiple residues in the hSERT N-terminus overcome the inhibitory influence of E39 to permit regulation via PKG- and p38-MAPK-mediated pathways. Interestingly, this structural domain is localized around SERT Ala56, in which PKG- and p38-MAPK-dependent regulation of SERT is constitutive, consistent with the region as important in PKG/p38MAPK regulation of the transporter. Ongoing studies seek to build on these findings to elucidate sequence-specific interactions of this region with regulatory proteins.

Title: Effects of oxytocin on serotonin 1B agonist-induced social interaction deficits in mice

Authors: S. K. LAWSON, *N. S. WOEHRLE
Psychology Dept., Wittenberg Univ., Springfield, OH

Abstract: Autism spectrum disorder (ASD) is a group of developmental disabilities characterized by communication deficits, repetitive, compulsive behaviors with narrowed interests, and social difficulties. Despite the prevalence of ASD, few highly-valid animal models

and no pharmacological treatments for the social deficits in ASD currently exist. The serotonin system has been highly implicated in the pathophysiology of ASD, and, in particular, the serotonin 1B receptor may be involved. Drugs that activate the serotonin 1B receptor, such as FDA-approved treatments for migraine, have been shown to exacerbate ASD symptoms. Moreover, these same drugs induce ASD-like perseverative behavior in mice. Thus, serotonin 1B agonist-induced behavior may represent a novel pharmacological animal model of aspects of ASD. However, the effects of serotonin 1B receptor activation on social interaction behavior in mice have not been assessed. Here, we examine the effects of the serotonin 1B agonist RU24969 on social behavior in the three-chambered social test and on rearing behavior in the open field. ASD is associated with non-selective attention deficits, and rearing behavior is used as an index of non-selective attention in mice. In addition, we examine the effects of a putative treatment for ASD, oxytocin (OT), on serotonin 1B agonist-induced behavior. OT is a neuromodulator that has been linked to numerous pro-social behaviors including emotional bonding, affiliation, and social attachment. Moreover, OT has been proposed as a novel pharmacological treatment for the social deficits in ASD. Our results show that serotonin 1B agonist treatment induces deficits in sociability and social novelty, decreases rearing behavior, and increases locomotion and perseveration in mice. Moreover, we show that OT reverses serotonin 1B agonist-induced deficits in social novelty, but not sociability.

Title: Postnatal role for histone deacetylase 1 and 2 in behavioral and neuronal homeostasis

Authors: *M. MAHGOUB, M. ADACHI, L. M. MONTEGGIA
Dept. of Neurosci., UTSW Med. Ctr. At Dallas, Dallas, TX

Abstract: Histone deacetylases (HDACs) compress the chromatin structure, restricting access of transcription factors to the DNA and consequentially repressing gene expression. Previous studies using pharmacological agents have demonstrated that inhibition of Class I HDACs results in enhancements in learning and memory with recent attention focused on HDAC1 and HDAC2. Deletion of both HDAC1 and HDAC2 selectively in the brain during embryogenesis results in major structural abnormalities in cortical, hippocampal and cerebellar development with death at postnatal day 7, suggesting HDAC1 and HDAC2 together play a critical and redundant role during neuronal proliferation. More recent work has identified distinct roles for HDAC1 and HDAC2 in complex behaviors. Brain specific conditional HDAC2 knockout mice have enhanced learning and memory, as well as enhanced synaptic plasticity, with no effect on these measures observed in the conditional HDAC1 knockout mice. These data have generated interest in the development of HDAC2 selective inhibitors for enhancing learning and memory and as a possible therapeutic approach for neurodegenerative disorders such as Alzheimer's disease. However, given the high degree of sequence identity (85%) between HDAC1 and HDAC2, it is unknown whether the deletion of both of these genes in postnatal brain would be detrimental similar to the embryonic deletion or whether the late stage deletion would show beneficial effects on learning and memory. We generated conditional brain-specific HDAC1 and 2 double knockout (DKO) mice and found they die at approximately 9 weeks of age, although survival is not impacted in the single knockouts. The DKO mice have behavioral abnormalities including hypoactivity and heightened anxiety shortly after the deletion of HDAC1 and 2. Hematoxylin and Eosin (H&E) staining reveals abnormal neuronal morphology as represented by disruptions in cortical lamination and cell layering in the hippocampus. Additionally, the DKO mice have a significantly smaller brain mass that appears to be due to apoptosis in the brain. Further characterization of the DKO mice is on going in the laboratory and data will be discussed. Our results so far show redundant functions of HDAC1 and HDAC2 in postmortem brain and highlight the need for caution in the development of pharmacological inhibitors of HDAC1 and HDAC2 as therapeutic tools in treating symptoms of neurodegenerative diseases.

Abstract: The ENGRAILED 2 (EN2) gene, a homeobox transcription factor that is critical to normal hindbrain formation, is genetically associated with Autism Spectrum Disorder (ASD). En2 knockout (KO) mice exhibit behavioral and structural phenotypes relevant to neurodevelopmental disorders. Behavioral abnormalities in the KO include deficits in social interactions, fear conditioning, prepulse inhibition and spatial learning and memory (Brielmaier et al., 2012). In addition, we found reduced norepinephrine (NE) fiber innervation and neurotransmitter in the KO hippocampus. Given the importance of NE and the hippocampus in these behaviors, we hypothesized that the KO hippocampus would exhibit abnormal neuronal circuitry and function including GABA interneurons, synaptic activity and neurogenesis. One target population of NE in the hippocampus is GABA inhibitory neurons. Preliminary data indicate that GAD65+ interneuron number was unaffected in hippocampal subregions. However, GABA interneuron differentiation was apparently altered since there were 25% less parvalbumin+ cells, which might lead to functional changes. Indeed, acute recording from hippocampal slices in the KO revealed increased baseline synaptic transmission (+65%) associated with reduced paired pulse facilitation (-20%). Moreover, we previously defined dysregulation of hippocampal neurogenesis in the KO. We now find that newly generated Dcx+ neurons migrate 25% further from the KO subgranular zone than wild type, and some localize ectopically in the molecular layer. This enhanced outward migration is associated with decreased expression of the chemokine CXCR4 receptor that might underlie the phenotype. A similar migration abnormality occurs following kainate-induced seizures, a protocol to which the KO are especially sensitive (Tripathi et al., 2009). These studies identify reduced GABA interneurons, altered synaptic transmission and ectopic new born granule neurons in the KO hippocampus. These changes in the excitatory/inhibitory balance may be responsible for previously reported increased susceptibility of the KO to seizures, which are well-described comorbid symptoms in ASD (up to 35%) and other disorders. Since there are NE deficits in the KO forebrain, we are determining whether increasing NE pharmacologically can reverse reduced hippocampal inhibition. Interestingly, we recently found that NE re-uptake inhibitor desipramine reversed the En2 KO deficits in social and hippocampal dependent tasks (Brielmaier et al., 2014). Thus our studies of the En2 mutant identify neurobiological abnormalities that may be relevant to human neurodevelopmental disorders such as ASD.

Title: Characterization of the seizure phenotypes for the D1866Y Scn1a mouse model of genetic epilepsy with febrile seizures plus (GEFS+)

Authors: N. BROWDER[1], S. DUTTON[2], *A. ESCAYG[2]
[1]Agnes Scott Col., Decatur, GA; [2]Human Genet., Emory Univ., ATLANTA, GA

Abstract: Mutations in the *SCN1A* gene, which encodes the voltage-gated sodium channel (VGSC) $Na_V1.1$, have been linked to a variety of epilepsy conditions including genetic epilepsy with febrile seizures plus (GEFS+) and Dravet Syndrome. Within a GEFS+ family, affected members can display a variety of epilepsy phenotypes that differ in severity and age of onset. The D1866Y (DY) *SCN1A* GEFS+ mutation was first identified in an Italian family with four affected members displaying different epilepsy phenotypes. The DY mutation is located in the C-terminus of the channel and is predicted to alter channel function and possibly affect interaction with auxiliary β subunits. To gain a better understanding of the effect of this mutation on seizure susceptibility, mice containing the human GEFS+ DY mutation were generated and evaluated for their susceptibility to seizures induced by the proconvulsant flurothyl, the 6 Hz electroconvulsive paradigm, and hyperthermia. Heterozygous mutants exhibited increased seizure susceptibility to all three seizure-induction paradigms when compared to their wild type (WT) littermates. We also determined the effect of the DY mutation on mouse weight and survival by routine observations and weighing starting at postnatal day 5 (P5). All three genotypes gained weight at a similar rate until P23, after which homozygous mutants began to lose weight and exhibited

premature lethality. Heterozygous mutants and WT littermates exhibited normal lifespans and comparable body weights. Our findings demonstrate that the DY mutation alters the function of the $Na_v1.1$ channel, leading to increased seizure susceptibility in the heterozygous mutants and reduced lifespan of the homozygous mutants.

Title: Behavioral characterization of a zebrafish model of febrile seizures

Authors: *J. F. ULLMANN[1], G. LEANAGE[3], F. SEPEHRBAND[3], D. REUTENS[2]
[1]The Univ. of Queensland, St. Lucia, Australia; [2]Ctr. for Advanced Imaging, The Univ. of Queensland, Brisbane, Australia; [3]Ctr. for Advanced Imaging, Univ. of Queensland, Brisbane, Australia

Abstract: Febrile seizures (FS) are the most common type of seizures in humans, affecting up to 5% of children before the age of 5. Current evidence suggests a link between prolonged FS and an increased risk of developing temporal lobe epilepsy, although the magnitude of the risk is not accurately known. Animal models are a vital in the search for mechanisms underlying FS and their epileptogenic effects. The zebrafish has become an important model species for epilepsy (1) as they show similar sensitivity to a convulsants and anticonvulsants as mammalian models. A recent study by Hunt et al. (2) found that transient exposure of larval zebrafish to hyperthermia induces acute electrographic seizures. We extended the zebrafish FS model by identifying the optimum conditions for behavioral febrile seizures and characterizing the ictal behavioral phenotype in detail. **Method** Larval zebrafish were placed in embryo medium in well plates and exposed to increasing temperatures in an incubator bath. We examined the effects of larval age and rate of temperature increase. Trials were recorded and assessed for the percentage of larval zebrafish reaching each seizure stage, latency to seizure stages, temperature at seizure onset, duration of seizure bouts, and average number of seizure bouts. For detailed analysis of seizure phenotype, a high-speed camera was used to capture tail motion. Zebrafish were immobilized in agarose with the tail free and four types of behavior were compared: spontaneous swim behavior and escape response induced by an abrupt touch in controls, seizures induced by PTZ, and

seizures induced by hyperthermia. Custom software in MATLAB was used for analysis of tail movement with parameterization of deflection angle, speed, acceleration, and angular velocity. **Results** Macroscopic observations of zebrafish FS resembled the three-stage seizure behavior established in the literature. Zebrafish at 5 days post fertilization exhibited FS when exposed to a temperature increase of 2 °/min. The proportion of fish reaching Stage 2 and the duration of Stage 2 bouts showed a clear developmental trajectory. The latency to reach seizure Stage 2 was shortest at larval day 5 and temperature at each seizure stage onset was consistent across the larval ages with the average temperature reaching 36.2°C and 40.3°C for Stage 1 and 2. Analysis of tail movement showed that spontaneous swimming comprised symmetrical displacements with alternating right-left oscillations. In contrast PTZ-induced seizures produce a large, slow, and asymmetrical tail movement. **References** 1. Kalueff A et al. Prog Neuor-Pyschoph. 2014 PMID: 24593944. 2. Hunt R et al. Title: Mouse model of tetramethylenedisulfotetramine (TETS)-induced status epilepticus

Authors: *D. ZOLKOWSKA[1], H. WULFF[2], B. D. HAMMOCK[3], P. J. LEIN[4], M. A. ROGAWSKI[1]
[1]Dept. of Neurol., Sch. of Med., Univ. of California, Davis, Sacramento, CA; [2]Dept. of Pharmacology, Sch. of Med., [3]Dept. of of Entomology, Col. of Agr. and Envrn. Sci. and Cancer Ctr., [4]Dept. of Mol. Biosciences, Sch. of Vet. Med., Univ. of California, Davis, Davis, CA

Abstract: Tetramethylenedisulfotetramine (TETS) is a highly lethal convulsant toxin that acts by noncompetitive block of GABA-A receptors. Although TETS is banned throughout the world, accidental and intentional exposures are not uncommon. In humans, poisoning with TETS causes generalized clonic-tonic convulsions and persistent status epilepticus (SE) that is often refractory to treatment. Acute administration of TETS to mice and rats produces generalized convulsions

that are rapidly lethal. It has therefore been difficult to model TETS-induced SE in rodents. Here we report that pretreatment of mice with a single dose of riluzole (10 mg/kg IP) 10 min prior to administration of a lethal dose of TETS (0.2 mg/kg IP) reproducibly results in continuous seizure activity, characterized by a progression of behavioral seizure signs and EEG seizure discharges. Mice were implanted with right frontal and parietal cortical screw EEG recording electrodes. An EMG electrode was implanted in the neck. Recordings were conducted with respect to a screw reference electrode located in the left parietal cortex area. After a recovery period of 1 week, animals were treated with riluzole/TETS and monitored by video-EEG recording. Abnormal behavioral and EEG activity began approximately 3 min after TETS administration. During an initial period of about 20 min, the animals exhibited myoclonic jerks and isolated spikes, sharp waves, and spike and slow wave complexes, as well as isolated clonic seizures. Subsequently, merging seizures and continuous ictal discharges were observed for nearly 1 h. The EEG typically then transitioned into periodic epileptiform activity on a flat background and some animals died about 100 min after receiving TETS. Riluzole is an antiseizure agent that affects the function of many ion channels. It is known to inhibit voltage-gated sodium channels and it also activates small-conductance calcium-activated potassium channels. As is the case with other sodium channel blocking antiseizure agents, riluzole is weak or ineffective at preventing seizures induced by GABA-A receptor antagonists. However, riluzole can protect against the rapidly lethal effects of TETS in mice, allowing persistent SE. The utility of this model in the identification of therapeutic agents for the treatment of TETS-induced SE will be examined.

Title: Characterization of a novel model of neonatal hypoxia-induced seizures in mice

Authors: *N. RODRIGUEZ, E. JIMENEZ-MATEOS, D. HENSHALL
Royal Col. of Surgeons In Ireland, Dublin, Ireland

Abstract: Seizures are most prevalent in the neonatal period, with an incidence of 1-3.5/1,000 live births. Up to 60% of neonatal seizures are associated with hypoxic/ischaemic encephalopathy (HIE) (exposure to hypoxia or hypoxia/ischemia) and are related with later life epilepsy, neurological and/or cognitive deficits. The hippocampus is particularly vulnerable to damage in HIE, and injury may produce permanently enhanced excitability in the brain. Critically, no drug has been developed specifically for neonatal seizures, and a new therapeutic approach is required. Improved understanding of the pathophysiology and treatment of neonatal seizures would be achieved via the availability of a simple, reliable mouse model of neonatal hypoxia-induced seizures. Here, we present a characterization of a novel model of neonatal seizures induced by hypoxia in mice. Hypoxia was induced in post-natal (P7) mice by placing pups inside an air-tight chamber and exposing them to 100% N2 with the flow rate adjusted to create graded global hypoxia (4-6%) for 15 minutes. Seizure activity was detected using cortical EEG recordings from implanted subdermal electrodes and behavioral seizures induced by hypoxia were scored by a modified Morrison scale, specifically developed for immature mice . Levels of the immediate early gene *c-fos* were analyzed as a marker of seizure activity, and levels of vascular endothelial growth factor (VEGF) as a marker of hypoxia, using quantitative real-time PCR, and damage to the brain was assessed by Silver staining. Hypoxia was reliably induced and maintained in P7 mouse pups with minimal mortality or morbidity. 95% of mice displayed seizures during hypoxia which were characterized as brief bursts of epileptiform activity. Brain tissue from mice displayed increased markers of hypoxia, neuronal activity and neuronal injury but neuronal death was not evident. Also, we evaluated whether hypoxia during neonatal period results in an increase of long-term susceptibility to chemoconvulsant, kainic acid. We conclude that perinatal hypoxic seizures at P7 significantly increase susceptibility to later life kainate-induced seizures and demonstrate enhanced neuronal injury. Brief global hypoxia can be used to reliably elicit neonatal seizures in P7 mice. This model may be useful to investigate the pathophysiology of neonatal seizures and novel treatments and can be used to study transgenic mice.

Title: Epileptiform activity and psychiatric comorbidity in a mouse model of atypical absence epilepsy

Authors: *S. JUNG, D. JEON
Bio and Brain Engin., Korea Advanced Inst. of Sci. and Technol., Daejeon, Korea, Republic of

Abstract: Purpose: Atypical absence epilepsy (AAE) showing slow spike-and-wave discharges (SWD) is characterized by severely abnormal cognition and neurodevelopmental or neurological outcomes in humans. However, despite the severe behavioral outcomes in AAE, the relationship between AAE and social-behavioral dysfunctions and seizure development have not defined well, either experimentally or in patients with AAE. Experimentally, AAE can be produced by administering AY-9944 (AY), a cholesterol biosynthesis inhibitor. In this study, we characterized social behavior and epileptiform activity during the postnatal development in the AY mouse model of AAE. Method: AAE in the mouse was induced by repeated postnatal administration of AY every 6 days from postnatal day (P) 2 to P20. AY-treated mice performed tasks involving sociability/social novelty preference, social interaction with a juvenile conspecific, observational fear, and resident-intruder aggression. We also measured the electrophysiological properties of hippocampal CA1 neurons which are treated with AY-9944 using patch-clamp technique. Results: They showed behavioral dysfunction in social interactions with a juvenile conspecific and sociability/social novelty preference tasks. They also exhibited reduced social fear learning in observational fear conditioning. Interestingly, they showed increased levels of offensive behaviors in a resident-intruder task. However, AY-treated mice displayed normal levels of anxiety in light/dark transition and the elevated plus maze tasks, and showed slightly increased locomotor activity in an open-field task. AY-treatment on hippocampal slices changed membrane electrical property of hippocampal CA1 neurons toward increasing excitability resulting in abnormal action potential firing patterns during a long depolarization. Conclusion: These results demonstrate social dysfunction and epileptic activity during developmental stage in the AY-induced AAE model. Our study can also provide valuable information about Lennox-Gastaut syndrome, in which AAE is a component. Thus, our findings may help to understand behavioral pathogenesis or characteristics of patients with AAE.

Title: A mouse model of Xq22.1 deletion syndrome displays epilepsy and cortical circuit dysfunction

Authors: *E. M. GOLDBERG[1,2], J. ZHOU[3], C. YUE[1], P. J. WANG[3], D. A. COULTER[1]
[1]Neurol., Children's Hosp. of Philadelphia, Philadelphia, PA; [2]Neurol., The Perelman Sch. of Med. at The Univ. of Pennsylvania, Philadelphia, PA; [3]Animal Biol., The Univ. of Pennsylvania Sch. of Vet. Med., Philadelphia, PA

Abstract: X-linked inheritance is an increasingly recognized pattern of intellectual disability (ID) in humans, constituting ~10% of all cases; over 90 genes on the X chromosome are associated with intellectual disability. X-linked ID is often accompanied by epilepsy. Experimental models of epilepsy and ID provide an opportunity to investigate disease pathomechanisms. In this study, we aim to investigate the mechanisms of epilepsy in a novel mouse model of epilepsy due to a 1.1 Mb microdeletion of chromosome Xq22.1. This region in mouse is syntenic to the deleted region in human Xq22.1 deletion syndrome, which is characterized by developmental delay/ID, epilepsy, dysmorphic features, and an X-linked pattern of inheritance. Interestingly, the deleted region includes multiple members of the G-protein coupled receptor (GPCR) associated protein (GPRASP, or GASP) family, which regulate the trafficking of various GPCRs. Males harboring the deleted region of Xq22.1 exhibited respiratory failure, cleft palate, and neonatal lethality. Heterozygous females exhibited cleft palate and growth retardation; many (~75% of) females died in the first 3-4 weeks of life. Females surviving to post-natal day 30 exhibited epilepsy, including handling and stress-induced seizures as well as spontaneous seizures. 6-channel continuous intracranial electroencephalography confirmed that adult heterozygous females had, on average, 0.5 ± 0.2 seizures per 24 hours. Electrographic seizures appeared to initiate from the hippocampus. Histological analysis revealed normal anatomy and layering of the neocortex and hippocampus. Voltage sensitive dye imaging in brain slices prepared from heterozygous female mice revealed hyperexcitability in dentate gyrus in response to perforant path stimulation. In conclusion, we show that deletion of a 1.1 Mb region of Xq22.1 reproduces the salient features seen in patients harboring this deletion. Epilepsy in these mice may be due to dysfunctional trafficking of G-

protein coupled receptors leading to hyperexcitability in cortical networks. While Xq22.1 deletion syndrome is likely a very rare cause of epilepsy and ID, analysis of the mouse model may yield important insights into the role of GASP/GPRASPs in cortical excitability and mechanisms of epilepsy.

Abstract: Traumatic brain injury (TBI) is a significant cause of acquired epilepsies. After the initial damage by direct mechanical force to the head, secondary brain damage leads to molecular changes affecting reorganization of neuronal networks in epileptogenesis. We hypothesize that expression of genes that control formation of neuronal circuits alters network features after TBI in both, hippocampus and cortex, leading to increased seizure susceptibility and epilepsy.TBI was induced with lateral fluid-percussion injury to adult rats (n=5). Five sham-operated rats served as controls. At 3 months post-TBI two 2-mm-thick coronal slices were sectioned to sample the hippocampus and cortex for RNA extraction. Sequencing of

transcriptome was carried out with Illumina Genome Analyzer IIx. In the hippocampus, 4280 genes and cortex 176 genes were expressing differently when compared to controls (adj.p<0.05). The expression of 140 same genes was altered significantly in both brain areas. Most common functional terms in among of these differential expressing genes were glycoprotein, signal, plasma membrane and ion/metal/cation binding. Our result reveals long-lasting alternations after TBI in gene expression in the hippocampus and cortex.

Abstract: Traumatic brain injury (TBI) is estimated to cause 10-20% of all acquired epilepsies. After the initial damage caused by direct mechanical force to the head, secondary damage develops over time consisting of molecular changes that underlie the subsequent reorganization of neuronal networks. The little evidence available suggests that epigenetic regulation controls some part of the alterations found in the expression of hundreds of genes after TBI. We hypothesize that DNA methylation alters gene expression which regulates post-injury reorganization of neuronal circuits, eventually leading to the development of hyperexcitability

and epilepsy. TBI was induced with lateral fluid-percussion injury to adult rats (n=5). Five sham-operated rats served as controls. At 3 months after TBI sampling of the hippocampus and cortex was done for DNA extraction. Sequencing of methylome was carried out with Illumina Genome Analyzer IIx. After TBI, methylation was changed in the gene body area in 21 genes in the hippocampus and in 45 genes in the cortex (adj.p-value<0.05). Three promising candidate genes with altered gene expression and methylation level were identified for further validation. Our results demonstrate long-lasting change after TBI in DNA methylation which can explain altered gene expression levels.

Title: State-dependent respiratory effects of seizures contribute to death in a mouse model of SUDEP

Authors: K. I. CLAYCOMB, M. A. HAJEK, D. A. RAPPOPORT, *G. F. BUCHANAN
Neurol., Yale Univ., NEW HAVEN, CT

Abstract: Sudden unexpected death in epilepsy (SUDEP) is the leading cause of death in patients with chronic refractory epilepsy. SUDEP tends to occur at night, but the mechanisms of how this happens are unknown. It is known that seizure-related respiratory and cardiac arrest are the most-likely etiologies for SUDEP, and control of both breathing and cardiac function is subject to sleep state-dependent and circadian regulation. In addition, seizure themselves are modulated in a state- and circadian-dependent manner. Here we set out to determine whether there are state- and/or circadian-dependent effects of seizures on cardiac and respiratory function that contribute to seizure-related death. EEG, EMG and EKG electrodes were implanted in adult

male mice with or without a bipolar stimulating/recording electrode in the right centrolateral nucleus of the amygdala. Seizures were induced with maximal electroshock (MES; 50 mA, 200 ms, 60 Hz) or amygdala kindling (100-180 μA, 1 ms biphasic square wave, 1 s, 60 Hz) during wakefulness, non-rapid eye movement (NREM) sleep and rapid eye movement (REM) sleep, and EEG, EMG, EKG, and breathing were assessed. Vigilance state was determined on-line in real time based on EEG and EMG characteristics using standard parameters. A separate set of animals were made to spontaneously seize with pilocarpine (275-400 mg/kg, i.p.) induced status epilepticus and epileptogenesis. For these animals, seizures were analyzed post-hoc for vigilance state and circadian time of occurrence and effects on breathing and cardiac activity were assessed. In the MES model, seizures that occurred during sleep were more likely to be fatal, especially those induced during REM. Death was due to primary respiratory arrest. Seizures induced during NREM in the MES and kindling models were associated with increased respiratory rate variability and increased occurrence of apneas. Seizures were not readily induced during REM in the kindling model. Seizures occurred rarely during REM in the spontaneously seizing model, but those that did were associated with increased cardiac and respiratory variability. These data indicate that seizures that occur during sleep can have detrimental effects on breathing and cardiac activity, which may contribute to increased seizure related death.

Title: Postictal hypoventilation is a common cause of death in multiple mouse models for SUDEP

Authors: *Y. KIM[1,2], L. P. SOWERS[1], G. F. BUCHANAN[4], G. B. RICHERSON[1,3]
[1]Neurol., [2]Biomed. Engin., [3]Mol. Physiol. & Biophysics, Univ. of Iowa, Iowa City, IA; [4]Neurol., Yale Univ., New Haven, CT

Abstract: Sudden unexpected death in epilepsy (SUDEP) is the most common cause of death in chronic refractory epilepsy patients and is a great concern for the epilepsy community. The primary cause of SUDEP is unclear, because most cases occur at night without witnesses, and recordings of physiological data have rarely been obtained at the time of death. The recent MORTality in Epilepsy Monitoring Unit Study (MORTEMUS) reported the largest series of SUDEP cases that occurred in epilepsy monitoring units (EMUs), and included video, EEG, and EKG. For all of these cases breathing rate was estimated using post-hoc observation of the videos, but was not measured directly. Tidal volume, ventilation, oxygen saturation or other measurement of breathing were not made. Of 16 SUDEP cases, 100% occurred after a generalized seizure. All of these deaths associated with cardiac dysfunction, but it could not be determined whether the cardiac changes were the primary cause of death or were secondary to respiratory dysfunction and hypoxia. If data on breathing had been included, then it could have been easier to determine the primary mechanism of the SUDEP cases. Sudden death occurs in some mice after seizures. Investigation of sudden death after seizures in mouse models may help to define the primary mechanisms of SUDEP in humans. We designed and built a mouse EMU that included 2 EEG electrodes, nuchal EMG, EKG, animal movement, video, body temperature, chamber temperature and humidity, and whole-body plethysmography pressure (breathing) traces. We used multiple mouse models that are prone to sudden death in response to seizures, including both non-epileptic and epileptic mice: 1) audiogenic seizures induced in DBA/1 mice, 2) maximal electroshock (MES) seizures induced in $Lmx1b^{f/f/p}$ conditional knock-out mice, 3) MES seizures induced in C57BL6 mice, and 4) MES seizures induced in $Scn1a^{R1407X/+}$ mutant mice (Dravet Syndrome model). In sudden death cases, seizures caused respiratory arrest in all 4-mouse models. EKG activity was present for 3 to 5 minutes after terminal apnea. We interpret these data as indicating that the primary cause of sudden death was central apnea that began during the seizures, and the resulting hypoxia and hypercapnia later caused bradycardia and asystole. It is important to know whether different mouse models share the same mechanisms of SUDEP to investigate methods of prevention. To provide better understanding of SUDEP mechanisms, we now plan to expand these studies to epileptic mice in which SUDEP occurs spontaneously, since SUDEP in humans is due to spontaneous, not induced seizures.

Title: Infantile spasms: Rescue of an animal model

Authors: *K. JOSHI[1], L. SHEN[2], M. A. CORTEZ[2], J. H. EUBANKS[3], O. C. SNEAD 3RD[2]
[1]Neurosci. and Mental Hlth., The Hosp. For Sick Children, Toronto, ON, Canada; [2]Neurosci. and Mental Hlth., The Hosp. for Sick Children, Toronto, ON, Canada; [3]Physiol., Univ. Hlth. Network, Toronto Western Hospital, Krembil Discovery Tower, Toronto, ON, Canada

Abstract: Infantile spasms (IS) is a catastrophic childhood seizure disorder characterized by a distinct developmental window of onset [4-12 mos.], a unique clinical semiology [flexor and/or extensor spasms], electroencephalographic [EEG] signature [hypsarrythmia] and unique pharmacology. The latter consists of the sole effectiveness of ACTH or vigabatrin in IS. The mechanism/circuitry contributing to the fundamental pathogenesis of IS is unknown. Children with Down Syndrome (DS) are especially vulnerable to IS. Therefore we have chosen to use a genetic mouse model of DS, the Ts65Dn mutant mouse (Ts) as a substrate to develop an animal model of IS. We have demonstrated that administration of the GABABR/GIRK2 agonist, γ-hydroxybutrytic acid (GHB) to the Ts65Dn mouse results in an EEG behavioral/pharmacology phenotype that replicates IS in humans. One of the genes triplicated in the Ts mouse line is the Kcnj6/Girk2 gene. We hypothesize that the overexpression of GIRK2 (G-protein inward rectifying potassium channel) is necessary and sufficient for the GABABR/ GIRK2 agonist induced IS phenotype in the Ts mouse model. We reduced the GIRK2 channel activity in the Ts mice pharmacologically using a general GIRK 1-4 antagonist tertiapin Q (TPQ). The TPQ treated Ts mice were resistant to the IS-inducing effect of GHB. To further validate the role of GIRK2, we knocked down the GIRK2 gene in the Ts mouse. Specifically, we used GIRK2 null mice to engineer the Ts mouse to be disomic for the GIRK2 gene (Ts65Dn GIRK2+/+/-) and measured the difference in the GHB-induced IS-like behavioral and EEG seizure activity between theTs65Dn mice, Ts65Dn disomic mice and the Wild Type controls. We found that the genetically knocked down GIRK2 in the Ts mice rendered them resistant to the GHB-induced IS phenotype . In summary we have shown that the GHB-treated Ts model of IS can be rescued by knocking down GIRK2 function, either pharmacologically or genetically. The data suggest that overexpression of GIRK2 leading to excess hyperpolarization plays a major role in the pathogenesis of IS. We are now creating a transgenic GIRK2 overexpressing mouse line to further strengthen our hypothesis. We hypothesize that the GIRK2 overexpressed mice will be exquisitely sensitive to the IS-inducing effects of GHB. This study is important, as the GIRK2 expression profile information in various brain regions could help us identify the circuitry

involved in IS. This study also has important implications for future therapies for IS and Down's syndrome.

Title: Methyl-CpG-binding domain protein 3 (MBD3) in normal brain and in the rat model of temporal lobe epilepsy

Authors: *J. BEDNARCZYK, K. LUKASIUK
Nencki Inst. of Exptl. Biol., Warsaw, Poland

Abstract: MBD3 belongs to a family of nuclear proteins which are characterized by the presence of a methyl-CpG-binding domain. This multisubunit complex combines reading of DNA methylation marks with modifying histones participating in regulation of gene expression. The aim of this project was to define the composition of MBD3-containing protein complex in the brain, cellular localization of MBD3 mRNA and protein as well as a characterization of the expression pattern of MBD3 protein in normal rat brain and in the amygdala stimulation model of epilepsy. Epilepsy was induced in Sprague-Dawley rats by amygdala stimulation induced status epilepticus evoked by 100-ms train of 1-ms biphasic square-wave pulses (400 μA peak to peak) delivered at 60 Hz, every 0.5 s for 30 min. Animals were sacrificed 14 days after stimulation. Composition of MBD3-containing protein complex was studied with mass spectrometry using normal brain tissue. Obtained data was analyzed in the IPA and validated using Western-blot. To characterize the expression of mRNA MBD3 in the brain *in situ* hybridization for MBD3 combined with immunohistochemistry for markers of neurons (NeuN), oligodendrocytes (Olig2) or astrocytes (GFAP) was carried out. To determine cellular localization and level of expression of MDB3 protein immunofluorescent staining of control

(n=5) and stimulated (n=5) animals was performed. Cell number and staining intensity in the amygdala and piriform cortex were evaluated using ImageJ software. Mass spectrometry revealed that in the brain MBD3 is a part of conventional NuRD complex and immunoprecipitation combined with Western-blot confirmed that MBD3 co-precipitates with HDAC1 and MTA2 proteins. MBD3 mRNA is expressed in neurons and oligodendrocytes in the normal brain. In control and epileptic brains MBD3 immunoreactivity was observed in nuclei of neurons, astrocytes and oligodendrocytes but not in microglia. Analysis of expression pattern of MBD3 protein in the third layer of the piriform cortex, in the lateral and central nuclei of amygdala revealed that 98,5±1,41%, 99,3±0,52% and 99,7±0,67% of NeuN-positive neurons respectively contain MBD3 in their nuclei. The intensity of MBD3 immunofluorescence was significantly increased in epileptic group in the third layer of the piriform cortex (contra 230±48%; ipsi 208±24%, $P<0.01$, t-test), lateral nucleus of amygdala (contra 186±38%; ipsi 196±28%, $P<0.01$) and central nucleus of amygdala (contra 176±41%, $P<0.05$; ipsi 166±19%, $P<0.001$) compared to controls. MBD3 is expressed in the brain in cell specific manner, participates in conventional NuRD-containing MTA2 and HDAC1 complex and its expression is affected in epileptic brain.

Title: The mutant Γ2(Q390x) subunit protein was produced in the GABRG2(Q390X) knockin epilepsy mouse model

Authors: *J.-Q. KANG[1], W. SHEN[1], C. ZHOU[1], X. HUANG[2], D. XU[3], R. L. MACDONALD[1]
[1]Dept Neurol., [2]Neurosci. program, Vanderbilt Univ., Nashville, TN; [3]Departments of Computer Sci. and Christopher S. Bond Life Sci. Ctr., Univ. of Missouri, Columbia, TN

Abstract: GABRG2(Q390X) is a mutation associated with the most severe kind of epilepsy, Dravet syndrome in two independent pedigrees. We have previously demonstrated that the mutant γ2(Q390X) subunit produces dominant negative suppression on wildtype partnering subunits and the mutant subunit protein is stable and aggregated *in vitro*. Using protein structure modeling, the 4th hydrophobic, transmembrane α-helix (YARIFFPTAFCLFNLVYWVSYLYL) of the wildtype γ2 subunit was deleted and a new α-helix with many charged amino acids (KDKDKKKKNPAPTIDIRPRSATI) was found to assume its location in the mutant γ2(Q390X) subunit. The new α-helix was found to be unstable in the membrane, and the remaining hydrophobic surfaces in the α-helices of the mutant subunit were shown to become "sticky". To further understand the pathophysiology of GABAA receptor mutations and epilepsy, we created Gabrg2(Q390X) knockin mice. Similar to homozygous Gabrg2-/- knockout mice, homozygous Gabrg2(Q390X)/Q390X mice were not viable. Heterozygous Gabrg2 +/Q390X mice had spontaneous generalized tonic clonic seizures starting from about P20 and had increased mortality throughout life. Brain slice recording identified that GABAergic mIPSCs in the cortex layer VI neurons were reduced. Biochemistry and surface biotinylation has demonstrated that both surface and total wildtype γ2 and α1 subunits were reduced in the Gabrg2+/Q390X mice. Quantitative RT-PCR(qPCR) demonstrated that total mRNA of Gabrg2 in the mutant mice were not changed compared with the wildtype mice. Additionally, Gabrg2 mRNA abundance of the mutant allele was the same as the wildtype allele in the heterozygous Gabrg2 +/Q390X mice. This is likely due to the fact that since the mutation is located in the last exon of Gabrg2 gene, the mutant γ2 (Q390X) subunit mRNA is not degraded by nonsense mediated mRNA decay (NMD). Instead, the mutant γ2(Q390X) subunit protein was produced, accumulated intracellularly in heterozygous Gabrg2 +/Q390X mice.

Title: Seizure susceptibility in developing rats prenatally exposed to valproic acid

Authors: *A. A. PUIG LAGUNES, J.-S. MEDEL-MATUS, R. TOLEDO, J. MANZO, M.-L. LÓPEZ-MERAZ
Ctr. De Investigaciones Cerebrales, Univ., Xalapa, Mexico

Abstract: Epilepsy is a neurological condition characterized by recurrent epileptic seizures, whereas autism spectrum disorder (ASD) is a neurodevelopmental disorder characterized by social deficits, impaired communication, and stereotyped and repetitive behaviors. Clinical and epidemiologic evidence has shown comorbidity between ASD and epilepsy. Prenatal exposure to valproic acid (VPA) induces neural tube defects and impairment in social behaviors related to ASD in humans and rodents, which make it a useful animal model to study autism. The goal of this project was to evaluate seizure susceptibility in developing rats prenatally exposed to VPA (pregnant females were injected with 600 mg/Kg, i.p., during the twelfth embryonic day, E12), by using two epilepsy models, pentylenetetrazole (PTZ, 80 mg/Kg, i.p.) and lithium-pilocarpine (Li-Pilo, 3 mEq/Kg, i.p. and 100 mg/Kg, s.c., respectively). Control animals were expose to saline solution during E12. Seizures were induced in fourteen-days-old rat pups (both sex). Results showed two subgroups with different PTZ-induced seizure susceptibility in rats exposed to VPA ($p<0.0001$): a high susceptibility (HS) subgroup [28/42, seizure severity 4.9 ± 0.04, corresponding to generalized clonic-tonic seizures (GCTS)] and a low susceptibility (LS) subgroup [14/42, seizure severity 2.1 ± 0.01, displaying myoclonic seizures). There were not differences between HS subgroup and the control group (39/42, seizure severity 4.8 ± 0.1), but LS subgroup had less susceptibility to PTZ-induced convulsions when compared to the control group ($p<0.0001$). Animals exposed to VPA from the HS subgroup exhibited an increased latency ($p<0.0006$) to the GCTS (120.6 ± 5.2 s) when compared to control animals (106 ± 6.2 s). Additionally, HS animals had more that one GCTS (13/28, $p<0.05$) and status epilepticus (19/28, $p=0.006$) than control animals (10/42 and 14/42, respectively). When all animals exposed to VPA were considered (HS and LS subgroups), there was a decrease in the average PTZ-induced seizure severity (4.0 ± 0.2, corresponding to generalized clonic seizure; $p<0.01$) and in the number of rats displaying GCTS (27/42; $p=0.0018$) when compared to the control group [4.8 ± 0.1 (i.e. mostly GCTS) and 39/42, respectively]. No differences in seizure severity, latency or duration of status epilepticus induced by Li-Pilo were detected between VPA and control animals. In conclusion, prenatal expose to VPA in rats modifies the susceptibility to seizures induced by PTZ during the second week of age, but not the status epilepticus induced by Li-Pilo. This effect could involve an alteration in the GABAergic system.

Title: Development of epilepsy after spatially restricted viral vector-mediated silencing of parvalbumin-expressing GABAergic interneurons in the mouse

Authors: ***M. DREXEL**[1], S. WEGER[2], R. HEILBRONN[2], P. WULFF[3], R. O. TASAN[1], G. SPERK[1]
[1]Dept. of Pharmacol., Innsbruck Med. Univ., Innsbruck, Austria; [2]Inst. für Virologie, Charité – Universitätsmedizin Berlin, Berlin, Germany; [3]Inst. of Physiol., Christian-Albrechts-Universität zu Kiel, Kiel, Germany

Abstract: Parvalbumin (PV)-expressing GABAergic interneurons in the CA1 sector of the hippocampus and in the subiculum comprise basket cells and axo-axonic cells targeting the pyramidal cell soma and the axon initial segment, respectively. There they potently control the firing frequency and timing of pyramidal cells. In patients with temporal lobe epilepsy (TLE) and in animal models of TLE degeneration of PV-expressing interneurons in the hippocampal formation has been described. The goal of this study was to test the hypothesis that impaired function of PV-GABA interneurons in the hippocampal/parahippocampal region of mice may be causative for the development of epilepsy. Our approach was to specifically silence synaptic output of PV-expressing interneurons in different subregions of the hippocampal/parahippocampal region. This was achieved by locally restricted stereotaxic injection of an AAV-vector containing the GFP-tagged tetanus toxin light chain (TeLC) reading frame (inverted in a flip-excision (FLEX) cassette) into the brain of mice expressing Cre-recombinase under the PV promoter. TeLC-mediated cleaving of vesicle associated membrane protein 2 (VAMP2) stops vesicle fusion thereby inhibiting GABA release from PV-interneurons. Respective viral vectors containing GFP alone were used for control-injections. Mice were implanted with transmitters for telemetric EEG-recording and continuous video- and EEG-recordings were carried out for 30 (up to 50) days after virus-injection. Double-fluorescence

immunohistochemistry confirmed strong expression of TeLC in PV-expressing interneurons at the injection site. During the first 30 days after virus-injection, about 40% of mice developed at least 2 spontaneous recurrent seizures (latency 5 - 28 days). In these mice, the mean number of seizures per week was 2.2 ± 0.33. Each seizure was preceded by several minutes of low-frequency population spikes. Seizures occurred mostly in clusters followed by seizure-free intervals of 4-6 days. In animals recorded for 50 days (n = 4), seizure numbers per week did not increase over time although duration and intensity of individual seizures increased to some extent. The current results underline the crucial role of PV-expressing GABAergic interneurons for the control of principal cell firing in the hippocampal/parahippocampal region. We show that even a spatially restricted loss of function of these interneurons may lead to the development of spontaneous recurrent epileptic seizures. Malfunction or loss of PV-interneurons may also contribute to the development of human temporal lobe epilepsy.

Title: Scn1a mutation in parvalbumin-positive interneurons causes autistic-like social deficits in a mouse model of Dravet syndrome

Authors: ***S. HAN**, M. H. RUBINSTEIN, J.-Y. BAE, W. A. CATTERALL
Pharmacol., Univ. of Washington, Seattle, WA

Abstract: Autism spectrum disorders (ASDs) are developmental neuropsychiatric diseases with characteristic symptoms of impaired social interaction, stereotyped behaviors, and delayed language development, often accompanied by cognitive deficit. One hypothesis is that the core behavioral features of autism are caused by an imbalance of excitatory over inhibitory neurotransmission in the brain. Dravet Syndrome (DS) is caused by heterozygous loss-of-

function mutation of the Scn1a gene, which encodes brain specific voltage-gated sodium channel type 1. Mutation in Scn1a in forebrain inhibitory interneurons is sufficient to cause autistic-like behaviors and cognitive deficits in a mouse model of DS. More than 20 different classes of interneurons are involved in forebrain inhibitory circuits, yet it is not known which subtype(s) of interneurons are responsible for the autistic-like traits. To address this question, we generated conditional mutant mice for the Scn1a gene using the Cre-LoxP strategy, and we performed a battery of behavioral tests, including the three-chamber test for social interaction, the open field test for social interaction and repetitive behaviors, and the contextual fear conditioning test for spatial learning and memory. We observed that mice with heterozygous Scn1a mutation in paralbumin (PV)-positive interneurons display autistic-like social deficits, but not hyperactivity, whereas mice with heterozygous Scn1a mutation in somatostatin (SST)-positive interneurons display hyperactivity, but not social deficits. Mice with Scn1a mutation both in PV- and SST-expressing interneurons have both autistic-like social deficits and hyperactivity. Interestingly, neither PV- nor SST-selective heterozygous Scn1a mutant mice had deficits in fear-associated spatial learning and memory. Our results indicate that different classes of interneurons may be responsible for the different behavioral deficits in DS and other ASDs.

Title: A model of epilepsy based on optogenetic kindling

Authors: *E. CELA[1,2,3], A. J. CHUNG[1,3], P. J. SJÖSTRÖM[1,3]
[1]Neurol. and Neurosurg., Montreal Gen. Hosp., Montreal, QC, Canada; [2]Integrated Program in Neuroscience, McGill Univ., Montreal, QC, Canada; [3]Ctr. for Res. in Neurosci., The Res. Inst. of the McGill Univ. Hlth. Ctr., Montreal, QC, Canada

Abstract: Epilepsy is a neurological disease characterized by pathological firing of neurons. However, the local circuit changes that are associated with epileptogenesis are not clear. To study these changes, we developed a novel optogenetic animal model of epilepsy. Using this model, we tested the hypothesis that repeated high-frequency stimulation (kindling) might pathologically rewire local circuits by excessive recruitment of Hebbian learning. We first targeted Channelrhodopsin-2 (ChR2) to primary motor cortex (M1) of male C57BL/6J mice by stereotactic delivery of AAV-CaMKIIa-hChR2-E123T/T159C-p2A-EYFP. Following a 21-day recovery period, we began stimulating M1 with 445-nm laser pulses while recording EEG in awake behaving animals. Seizures were not elicited in early stimulation sessions, but seizures were consistently evoked (6 out of 6 animals) after ~15 sessions. Seizures were defined as periods longer than 3 seconds where EEG FFT power exceeded 0.3 standard deviations. In one representative animal, we observed no seizures in the first five sessions but 10.8 ± 1.4 seizures in the last five out of 26 sessions ($p < 0.01$). In the same animal, we also observed spontaneous seizures, a hallmark of epilepsy, after session 26 (1.67 ± 0.14 seizures/33 minutes, n=3 days). We quantified seizure duration by EEG, and their severity by a modified Racine scale in the same animal, and found that the duration ($r = 0.75$, $p < 0.001$) and severity ($r = 0.77$, $p< 0.001$) of seizures increased with stimulation sessions. This progressive development of seizures over sessions was qualitatively similar across animals. To our knowledge, our results are the first demonstration that repeated optogenetic stimulation can elicit epilepsy in awake behaving animals. This may occur through repeated recruitment of Hebbian plasticity by driving excessive neuronal activity. Our optogenetic approach allows the identification of directly activated cells, so that the role of specific cell populations in epileptogenesis can be investigated.

Title: Progressive remodeling of hippocampal mossy fibres and dentate gyrus granule neuron dendritic arbors in the brain-derived neurotrophic factor overexpressing mice

Authors: *C. ISGOR, P. COOMBS, K. GUTHRIE
Charles E. Schmidt Biomed Ctrr, Florida Atlantic Univ., BOCA RATON, FL

Abstract: Mice that overexpress brain-derived neurotrophic factor (BDNF) under the alpha-calcium/calmodulin-dependent protein kinase IIa promoter (termed TgBDNF mice) develop a mild cognitive deficit that is evident by 2-3 months of age that progresses to emergence of spontaneous seizures at ~6 months of age. Slow developing nature of behavioral disruptions observed in TgBDNF mice led to the hypothesis that chronic and sustained elevations in local BDNF are critical for progressive remodeling of hippocampal circuits implicated in epileptogenesis. We have previously shown that the mossy fibres (MF), axonal projections from the dentate gyrus granule neurons that innervate the CA3 field, are expanded in volume in TgBDNF mice compared to wildtype (WT) controls at 2-3 months of age. Using whole brain Golgi-Cox immersion technique and a computer-interfaced image analysis system (Neurolucida, Microbrighfield, VT), we also showed that granule neurons of 2-3 month-old TgBDNF mice had remarkably higher number of spines compared to WTs, even though dendritic complexity appeared to be comparable between genotypes. Detailed analyses showed that increase in number of spines was observable in mushroom-type spines, suggesting that excess BDNF may be associated with increased synaptic input from entorhinal cortex onto granule neuron dendritic arbors in mature circuitry even before seizure development. In this study, we challenged ~6 month-old mice with a subthreshold dose of pilocarpine (200 mg/kg) and observed that TgBDNF mice were susceptible to seizure induction at this low dose compared to WT conspecifics. We expanded our examination of MF terminal fields and granule neuron dendiritic arbors to include ~6 month-old time point to further delineate the progressive nature of structural remodeling. These studies map out comparisons between the early (2-3 month-old) and late (~6 month-old) circuit disruptions in the hippocampus of the TgBDNF mice; and morphological correlations with the intensity of seizures in response to a subthreshold dose of pilocarpine in the latter time point. This work is supported by a collaborative FAU Seed Grant awarded to Drs. Isgor & Guthrie.

Title: Mice lacking the xCT subunit of system x_c^- display delayed epileptogenesis in the self-sustained status epilepticus model

Authors: *R. KAMINSKI, M. NEVEUX, B. DARDENNE, K. KOSHIBU, I. JACQUES, K. LECLERCQ
UCB Pharma S.A., Braine-l´Alleud, Belgium

Abstract: System x_c^- is an amino acid antiporter that mediates the exchange of extracellular L-cystine and intracellular L-glutamate across the cellular plasma membranes. The xCT catalytic light chain is responsible for the transport function of the system x_c^- complex. Previously published data indicate that system x_c^- plays an important role in seizure susceptibility and may contribute to glutamate excitotoxicity in the hippocampus. In the present study we used mice lacking the xCT subunit (xCT KO) of system x_c^- to determine its role in epileptogenesis, which had not been studied so far. We used the self-sustained status epilepticus (SSSE) model, which is a well-established model of epileptogenesis induced by electrical stimulation. Briefly, the xCT KO mice and their wild-type (WT) littermates were surgically implanted with EEG electrodes: a bipolar stimulation electrode (basolateral amygdala) and a cortical monopolar electrode. After recovery from the surgery, mice underwent electrical stimulation through the amygdala-implanted electrode (monophasic train stimulation: duration - 1 s, single pulse duration - 1 ms, frequency - 50 Hz) to establish their afterdischarge threshold (ADT). An ascending series of current stimulations with 5 μA steps was applied once every 2 min until an afterdischarge of at least 5 s duration was elicited. Three days later SSSE was induced by a 90 min stimulation paradigm with 100 ms trains of 1 ms alternating current pulses (50 Hz), 2 trains per s and 250 μA peak current intensity. SSSE characterized by a continuous convulsive and electrographic activity was stopped after 150 min with diazepam (ip, 10mg/kg). Subsequently, the mice were continuously video-EEG monitored for 28 days. Eight mice of each genotype were included in the seizure monitoring studies. We did not observe any difference in seizure susceptibility and comparable ADT values were obtained in both xCT WT and KO mice. Also, there were no differences in either electrographic activity during the SSSE or convulsive seizure severity during this phase. Remarkably, however, the xCT KO displayed significantly longer latency to the onset of the first spontaneous seizure and displayed overall reduced number of spontaneous recurrent seizures during the 4-week monitoring period. Our data indicate that system x_c^- plays an important role in epileptogenesis and could be an attractive target for therapies aiming at the prevention of epilepsy. Acknowledgements: We are grateful to Prof. H. Sato from the Department of Food and Applied Life Sciences, Faculty of Agriculture, Yamagata University, Japan for providing access to the xCT KO mice.

Title: The effects of 1400W and diapocynin on the hippocampus in rat models of acute organophosphate toxicity: Electographic and immunohistochemical analyses

Authors: *S. SHARMA[1], S. PUTTACHARY[1], A. VELLAREDDY[2], B. KALYANARAMAN[3], A. G. KANTHASAMY[1], T. THIPPESWAMY[1]

Abstract: Diisopropylfluorophosphate (DFP), an organophosphate (OP), is considered as a surrogate to nerve gas soman. It is a potent seizurogenic neurotoxin, which causes irreversible brain damage due to hyper-excitability of neurons, reactive gliosis and neurodegeneration. If these are not adequately controlled at an early stage, they will lead to the development of epilepsy. The objective of this project is to prevent long term neurological effects of DFP intoxication by administering symptomatic drugs (atropine, 2-PAM, diazepam) with two novel neuroprotectants, 1400W (inducible nitric oxide synthase inhibitor) and diapocynin (NADPH oxidase inhibitor) to reverse neurological changes that follows the acute toxicity. We used two models of DFP intoxication in Sprague Dawley adult male rats (in accordance with IACUC). One with pyridostigmine (PST) pre-treatment and the other without to mimic military personnel (MP) and civilian population (CP) real-life OP intoxication scenarios. 2-PAM (25mg/kg, i.m.) and atropine (10mg/kg, i.p.) were given soon after DFP administration and seizures were scored

using modified Racine scale. Diazepam (10mg/kg, i.p.) was administered 2h later to mimic real-life scenario to control seizures and reduce mortality. 1400W (20mg/kg, i.p.) and diapocynin (300mg/kg, oral) were given twice a day for three days to reverse the damage produced by acute DFP exposure. Some rats were previously implanted with radiotransmitter telemetry device (DSI®), 10 days prior to DFP, and were video-EEG monitored continuously for 4 weeks. Rats were perfused with 4% paraformaldehyde under terminal anesthesia (pentobarbital, 100mg/kg, i.p.) and processed for immunohistochemistry (IHC). IHC and EEG were analyzed to reveal structural and functional changes in hippocampus at different time points. Increased EEG spike rate, reactive gliosis and neurodegeneration were observed 1 week after DFP exposure in both models. CP model rats showed similar behavioral and EEG changes as MP model, but at a 50% lower dose of DFP (n=3-5/group). FJB+NeuN and IHC staining revealed further neurodegenerative changes, astrogliosis and microgliosis in the hippocampus in spite of treating with symptomatic drugs. Both 1400W and diapocynin prevented these changes and significantly reduced the epileptiform spike rate during the first week of DFP exposure ($p<0.0001$) and reduced the number of spontaneous recurrent seizures (SRS) during the rest of the month ($p< 0.05$). 1400W and diapocynin, when given with symptomatic drugs, reduced neurodegeneration and gliosis in the hippocampus and reduced the number of SRS episodes demonstrated their therapeutic importance in OP toxicity.

Title: Dysfunction of hyperexcitable networks: Altered sensory processing accompanied by long-term biochemical and anatomical changes in neocortical epilepsy

Authors: *L. RESTANI[1], E. VANNINI[1,2], M. PIETRASANTA[1], O. ROSSETTO[3], S. MIDDEI[4], M. CALEO[1]
[1]CNR Neurosci. Inst., Pisa, Italy; [2]Scuola Normale Superiore, Pisa, Italy; [3]Dept. of Biomed. Sci., Univ. of Padua, Padua, Italy; [4]Cell. Biol. and Neurobio. Inst., CNR, Rome, Italy

Abstract: Epilepsy is characterized by a disruption in the balance of excitation and inhibition that leads to propensity for spontaneous seizures. Pathological remodeling of cortical circuitry may also lead to impaired information processing. However, how plastic rearrangements within the epileptic focus trigger cortical dysfunction and hyperexcitability is only partly understood. Here we have used a model of focal epilepsy induced by tetanus neurotoxin (TeNT) injection into the adult mouse visual cortex to examine alterations in sensory processing and underlying biochemical and neuroanatomical changes. In this model, spontaneous electrographic seizures are evident both during and at the completion of TeNT effects. We found persistent depletion of the TeNT substrate VAMP/synaptobrevin and upregulation of several GABAergic markers in epileptic mice as compared to vehicle-injected controls. At the anatomical level, there was a significant remodeling of the dendritic arbors of pyramidal neurons in superficial layers, with increased dendritic length and branching, and overall reduction in spine density but significant preservation of mushroom, mature spines. Functionally, spontaneous neuronal discharge was increased, and visual responses were dampened and less reliable in the epileptic cortex. Moreover, electrophysiological and behavioural visual acuity was consistently impaired in TeNT-treated mice. These data demonstrate robust, long-term remodelling of both inhibitory and excitatory circuitry associated with specific disturbances of neuronal function and visual perception in non-lesional neocortical epilepsy.

Title: Increased expression of growth associated protein 43 after seizures in rodent model of irradiation-induced cortical dysplasia

Authors: *A. NEMES[1,3], Z. YING[1], K. AYASOUFI[2], W. GUO[1], I. NAJM[1]
[1]Epilepsy Ctr., [2]Immunol., Cleveland Clin., Cleveland, OH; [3]Sch. of Biomed. Sci., Kent State Univ., Kent, OH

Abstract: Epilepsy is the fourth most common neurological disorder in the United States and 30-40% of patients are not responsive to pharmacological treatment. In many cases, patients with medically intractable epilepsy have underlying pathological abnormalities such as cortical dysplasia (CD). Patients with CD have a decreased threshold for seizures, and may become epileptic after a second hit such as trauma, infection or ischemia. Growth-associated protein 43 (GAP-43), a protein expressed in growth cones during axonal outgrowth and synaptogenesis, is up-regulated following stroke and traumatic brain injury. GAP-43 is also up-regulated in response to seizures, and may contribute to the process of epileptogenesis in CD brains. Methods Pregnant rats were irradiated with 145cGy of cesium-137 on E17. Pups were grown to adulthood and served as experimental models of CD. Rats were then injected with pentylenetetrazole (PTZ) at a sub-convulsive dose (40 mg/kg, i.p.) which does not typically cause seizures in normal rats, but because CD rats have a decreased threshold, they go into *status epilepticus.* Rats were monitored with chronic video/EEG. Seizures were analyzed and interictal spikes were counted until each endpoint. Rats were sacrificed at 2 days,15 days and 30 days following seizure induction to observe the acute and chronic expression of GAP-43. Immunohistochemistry was performed on brain slices and they were graded for staining intensity. Results The expression of GAP-43 is higher in CD rats than NL rats without PTZ in both the hippocampus and the cortex. Normal rats revealed an acute up-regulation of GAP-43 at day 2, which then decreased at days 15 and 30 suggesting a recovery. However, GAP-43 continued to be up-regulated from day 2 to day 15 and day 30 after PTZ injection in the CD rats. In addition at each time point, GAP-43 is always higher in the CD rats. In parallel of higher GAP-43 protein in CD rats, the interictal spikings are more frequent in CD rats than normal rats at each time point. Within CD rats, the interictal spikings continued to increase at each time point parallel to the trend of GAP-43 increase except for day 30. Conclusions CD rats have an intrinsic ability to up-regulate GAP-43 expression. The second hit (PTZ injection) only causes GAP-43 expression in an acute phase in normal rats; however it triggers continuous up-regulation of GAP-43 in CD rats. Interictal spiking (markers for potential epileptogenicity) correlates with higher GAP-43 not only between CD rats and normal rats but also among CD rats at each time point. The data suggests that GAP-43 contributes to the epileptogenic mechanisms and could be used as a bio-marker for epileptogenesis in CD.

Title: The regulation and function of the ATP-gated P2X7 receptor in epilepsy

Authors: *A. JIMENEZ PACHECO[1], A. SANZ[1], M. DIAZ-HERNANDEZ[2], T. ENGEL[1], D. C. HENSHALL[1]
[1]Physiol. and Med. Physics, Royal Col. of Surgeons In Ireland, Dublin, Ireland; [2]Biochem. and Mol. Biol., Univ. Complutense, Madrid, Spain

Abstract: Epilepsy is a common and disabling neurologic disorder which affects about 1% of the population. Seizures are the result of abnormal electrical activity in the brain and can be profoundly disabling, affecting work, social activity and increasing risk of harm. In at least 30-40 % of patients, treatment is inadequate, with patients continuing to experience seizures; therefore, there is an important need to develop new anti-epileptogenic drugs. Increased P2X7 receptor expression has been reported in the hippocampus and cortex after prolonged seizures in animal models and P2X7 receptor antagonists reduced seizure-induced damage to these brain regions. Here we show that P2X7 receptor mRNA and protein level is up-regulated in the hippocampus and cortex of epileptic mice. Using GFP-expressing P2X7 receptor reporter mice we localized the increased expression mainly to neuron and microglia in epileptic animals. In isolated synaptosomes, we observed increased presence and, using FURA-2 Ca+ imaging, functional activation of P2X7R in epileptic mice. These findings support a role for P2X7R in the pathophysiology of chronic epilepsy and suggest P2X7 receptor antagonists may have therapeutic effects against recurrent seizures or progression of disease pathology.

Title: Refractoriness of convulsive status epilepticus induced by soman, DFP and paraoxon to diazepam treatment

Authors: ***T. L. DAO**, J. A. LEUSCHNER, S. W. KASKI, L. J. SHUMWAY, L. J. SHUMWAY, C. R. BRAUE, R. K. KAN
USAMRICD, Edgewood, MD

Abstract: Organophosphates inhibit the enzyme acetylcholinesterase, cause accumulation of acetylcholine at the neuromuscular junctions and central synapses and induce seizures and status epilepticus in humans and animals. Diazepam is clinically used to control seizures induced by organophosphates. The present study evaluated the response of Sprague Dawley rats to diazepam treatment given at 40 min after the onset of seizures induced by soman, diisopropylfluorophosphate (DFP) and paraoxon. Rats were instrumented with cortical electrodes for monitoring electroencephalographic (EEG) activity 7 days prior to induction of seizures. Rats pretreated with HI-6 (125 mg/kg, ip) 30 min prior to soman challenge (180 ug/kg, sc) were treated with atropine methylnitrate (2.0 mg/kg, im) 1 min after soman administration. Rats pretreated with pyridostigmine bromide (0.026 mg/kg, ip) 30 min prior to DFP challenge (4.0 mg/kg, sc) were treated with atropine sulfate (AS; 0.2 mg/kg, im) and 2-PAM (25 mg/kg, im) 1 min after DFP injection. Rats exposed to paraoxon (1.05 mg/kg, sc) were treated with AS (2.0 mg/kg, im) and 2-PAM (25 mg/kg, im). All rats received diazepam (10 mg/kg, im) at 40 min after the onset of seizures. Rats that did not receive diazepam served as controls. While convulsive status epilepticus (CSE) induced by soman did not respond to diazepam treatment, DFP- and paraoxon-induced CSE was effectively treated with diazepam. Brain injury in rats treated with diazepam at 40 min after DFP- or paraoxon-induced CSE was reduced at 24 hr after seizure onset. In contrast, soman-exposed, diazepam-treated rats exhibited severe brain injury in the piriform cortex, amygdala and thalamus. Soman, DFP and paraoxon can induce CSE in rats, but only soman-induced CSE is refractory to diazepam treatment. DFP and paraoxon models were developed as surrogate animal models for chemical warfare nerve agent biomedical research for evaluation of putative therapeutics. The fact that only soman-induced CSE is refractory to diazepam treatment suggests that DFP and paraoxon are not suitable simulants for discovery of novel anticonvulsants to control on-going seizures. Initial screening of novel anticonvulsants using DFP and paraoxon may not be predictive of their effectiveness in terminating nerve agent-induced CSE.

Abstract: Exposure to nerve agents induces prolonged status epilepticus (SE), which can lead to death or cause brain damage. Diazepam (DZP) is the presently FDA-approved drug for the cessation of nerve agent-induced SE. Using a rat model of nerve agent exposure, we compared the efficacy of DZP with that of UBP302 –an antagonist of the kainate receptors that contain the GluK1 subunit– against seizures, neuropathology, and behavioral deficits induced by soman. DZP, administered 1 h or 2 h post-exposure, terminated the SE, but seizures returned; thus, in the DZP-treated group, the total duration of SE within 24 h after soman exposure was similar to (DZP at 1 h) or longer than (DZP at 2 h) in the soman-exposed rats that did not receive anticonvulsant treatment. UBP302 stopped SE with a slower time course than DZP, but reduced dramatically the total duration of SE within 24 h. UBP302, but not DZP, reduced neuronal degeneration in a number of brain regions, as well as neuronal loss in the basolateral amygdala and the CA1 hippocampal area, and prevented the loss of interneurons in the basolateral amygdala. Anxiety-like behavior, assessed in the open field and by the acoustic startle response, 30 days after soman exposure, was increased in the group that did not receive anticonvulsant treatment and the DZP-treated group, but not in the UBP302-treated group. The results argue against the use of DZP for the treatment of nerve agent-induced seizures and brain damage, and suggest that targeting GluK1-containing receptors is a more effective approach.

Title: LY293558 prevents soman-induced pathophysiological alterations in the basolateral amygdala and the development of anxiety

Authors: *T. H. FIGUEIREDO[1], E. M. PRAGER[1], R. P. LONG II[1], V. ARONIADOU-ANDERJASKA[1], J. P. APLAND[2], M. F. M. BRAGA[1]

Abstract: Without immediate treatment, nerve agent exposure can cause countless casualties, as it occurred in the recent sarin attack in Syria. Nerve agent-induced seizures become rapidly refractory to muscarinic antagonists, but also to benzodiazepines; therefore, novel treatments are necessary to stop seizures and prevent brain damage and the lasting health consequences of the exposure. We have previously shown that LY293558, a GluK1/AMPA receptor antagonist, is a very effective anticonvulsant and neuroprotectant against nerve agent exposure. In the present study, we examined if the protection against nerve agent-induced seizures and neuropathology conferred by LY293558 translates into protection against pathophysiological alterations in the basolateral amygdala (BLA) and the development of anxiety, which is the most prevalent behavioral deficit resulting from exposure. LY293558 (15 mg/kg) was administered to Sprague-Dawley rats along with atropine and the oxime HI-6, at 20 min after exposure to soman (1.2 x LD50). At 24 h, 7 days and 30 days after exposure, soman-exposed rats that did not receive LY293558 had small but prolonged evoked field potentials in the BLA, as well as increased paired-pulse ratio, reflecting neuronal damage and impaired synaptic inhibition. In contrast, rats that received LY293558 did not differ from control rats in these parameters. Similarly, long-term potentiation (LTP) of synaptic transmission was impaired at 7 days after exposure in the soman-exposed rats that did not receive anticonvulsant treatment, while this impairment was not present in the LY293558-treated rats. Anxiety-like behavior determined by the open field and acoustic

startle response tests was increased in the soman-exposed rats at 30 and 90 days after exposure, while soman-exposed rats treated with LY293558 did not differ from controls. These data substantiate the remarkable efficacy of LY293558 in counteracting nerve agent-induced seizures, neuropathology, pathophysiological alterations in the BLA, and anxiety-related behavioral deficits.

Title: The anticonvulsant, anti-epileptic and protective effects of midazolam and ketamine combination treatment after soman-induced seizures in rats

Authors: F. ROSSETTI[1], M. K. SCHULTZ[2], M. DE ARAUJO FURTADO[1], A. R. FURMAN[2], M. F. STONE[2], C. R. SCHULTZ[2], J. E. SCHWARTZ[2], A. R. BOURNE[2], M. C. MOFFETT[2], T. TURNER[2], L. K. WRIGHT[2], C. G. WASTERLAIN[3], *L. A. LUMLEY[2]
[1]Walter Reed Army Inst. of Res., Silver Spring, MD; [2]Neurobehavioral Toxicology, USAMRICD, GUNPOWDER, MD; [3]West Los Angeles VA Med. Center, UCLA, West Los Angeles, CA

Abstract: Introduction: Chemical warfare nerve agents (CWNA), such as soman (GD), produce *status epilepticus* (SE), resulting in extensive neuropathology and long-term performance deficits if seizures are not controlled. Current treatments for CWNA exposure increase survival, but are not fully protective. Although seizure is thought to be initiated by cholinergic mechanisms, the neuropathology resulting from CWNA exposure is believed to be due to glutamate release and subsequent excitotoxic damage. We investigated the neuroprotective effects of the noncompetitive NMDA antagonist ketamine in combination with the benzodiazepine midazolam in rats exposed to GD. **Material and Methods**: Rats (n=11-12/group) received 1.2 LD50 GD (0.6 ml/kg, 220 µg/ml); atropine (2 mg/kg, im) and HI-6 (93.6 mg/kg, im) 1 min after GD exposure; midazolam (MDZ, 3 mg/kg, ip) combined with ketamine

(KET, 30 mg/kg, ip) 40 min post-seizure onset , or MDZ or KET separately with vehicle (water). Amount of time spent in EEG seizures during the first 72 h after SE onset, power spectra of Delta (0.1-4Hz), Theta (4.1-8Hz), Alpha (8.1-12Hz) and Beta (12.1-25Hz) bands during the first 24 h, latency of the first EEG spontaneous recurrent seizures (SRS) appearance and number of SRS until 36 days were analyzed. Behavioral tests of motor activity (beam, home cage, open field), sensorimotor (acoustic startle response) and acquisition of spatial memory (Morris water maze) were conducted in the weeks after exposure. Neuropathology assessments included various histological stains. **Results:** The EEG analysis showed that combination MDZ/KET treatment increased the latency to first SRS appearance (26.49±7.00 days; X±SEM) and reduced the number of SRS (0.50±0.40) in comparison with MDZ or KET alone (MDZ: 10.82±2.47 days and 10.90±5.29; KET: 9.45±2.48 days and 17.1±8.77). Time spent in seizures during the first 72 h after GD exposure tended to be reduced in MDZ/KET-treated rats. The MDZ/KET combination treatment reduced Delta, Theta and Alpha bands power spectra during the 24-hour period after GD exposure compared to MDZ or KET treatment alone, and reduced the Theta and Alpha power spectra, but not Delta and Beta, in relation to baseline. MDZ/KET combination reduced GD-induced spatial memory impairment and reduced GD-induced hyperactivity that typically develops in the weeks after GD exposure. **Conclusion:** The antiepileptic, anticonvulsant, and protective effects of combination treatment with MDZ/KET compared to either treatment alone provide further support that combination therapy with an NMDA antagonist and a benzodiazepine is an effective therapeutic strategy against GD-induced SE and epileptogenesis.

Title: Modulation of NKCC1 and KCC2 co-transporters for control of catastrophic drug-resistant seizures

Authors: *V. I. DZHALA[1], Y. SAPONJIAN[2], Y. DE KONINCK[3], K. STALEY[1]
[1]Dept. of Neurol., Massachusetts Gen. Hospital, Harvard Med. Sch., Charlestown, MA; [2]Dept. of Neurol., Massachusetts Gen. Hosp., Charlestown, MA; [3]Cell. & Mol. Neurobio., Laval University, IUSMQ, Quebec, QC, Canada

Abstract: Epilepsy after brain injuries caused by hypoxia-ischemia or trauma respond poorly to anticonvulsants, including those that target the inhibitory chloride-permeable $GABA_A$ receptor ($GABA_A$-R). A low intracellular chloride concentration ($[Cl^-]_i$) is an important determinant of inhibitory postsynaptic $GABA_A$-R signaling. Both hypoxia and acute brain trauma are associated with large increases in $[Cl^-]_i$ and a consequent positive shift in the reversal potential for $GABA_A$-R mediated responses (E_{GABA}). Depolarizing shifts in E_{GABA} in populations of injured neurons may contribute to failure of inhibition, seizures, epileptogenesis and anticonvulsant resistance. The Na^+-K^--$2Cl^-$ co-transporter NKCC1 and K^+-Cl^- co-transporter KCC2 are responsible for the return of $[Cl^-]_i$ and E_{GABA} to baseline after synaptic signaling. Immediately after injury, NKCC1 and KCC2 may also contribute to cytoplasmic chloride increase. Suppressing NKCC1 activity acutely and/or chronically enhancing KCC2 activity may be a useful therapeutic strategy to reduce $[Cl^-]_i$, restore GABAergic inhibition in pathological neurons, suppress seizures and prevent epileptogenesis. We compared acute and chronic anticonvulsant efficacy of NKCC1 blocker bumetanide and KCC2 agonist CLP257 in *in vitro* model of post-traumatic epileptogenesis. We found that: (i) bumetanide reduced the frequency and power of early recurrent seizures; (ii) CLP257 abolished early recurrent seizures and reduced the frequency of interictal discharges in a concentration-dependent manner; (iii) KCC2 antagonist VU0726722 strongly potentiated spontaneous interictal and ictal-like discharges; (iv) CLP257 reduced the amount of late chronic seizure activity in a concentration-dependent manner, assayed by lactate and LDH production. Our results validate KCC2 as a promising target of investigation for anticonvulsive and antiepileptogenic therapies, and highlight the need to investigate the mechanism of positive modulators of membrane transport.

Title: Time course of the neuronal sodium concentration in post-traumatic epileptogenesis *in vitro*

Authors: *T. BALENA, K. J. STALEY
Massachusetts Gen. Hosp., Charlestown, MA

Abstract: Post-traumatic increases in intracellular Cl- can result in GABA becoming depolarizing, which could lead to disinhibition and early post-traumatic epileptic seizures. Increases in intracellular anions are likely to be balanced by an increase in intracellular cations, and the consequent salt accumulation could underlie cytotoxic edema. We investigated post-traumatic changes in intracellular Na+ concentration ([Na+]i) using acute hippocampal slices and organotypic hippocampal slice cultures from wild-type C57BL/6J mice, imaged with the Na+ dye SBFI. Two-photon imaging was used to excite SBFI at both Na+-sensitive and -insensitive wavelengths, allowing for the ratiometric determination of the [Na+]i. Propidium iodide (PI), an indicator of cell death, was used as a costain in most experiments to exclude damaged neurons from the analysis. In acute slices hippocampal neurons had significantly higher [Na+]i than has been reported in undamaged neurons, particularly near the cut surface of the slice. In organotypic slice cultures, [Na+]i returned to low levels ~2 days after slice trauma. At longer incubation times, during which slices become epileptic, [Na+]i increased to levels seen immediately post-trauma; blockage of seizure activity via chronic application of 3 mM kynurenate did not prevent the [Na+]i increase. By 20 days after trauma, [Na+]i returned to low levels. These trends were correlated with an increase in the number of PI-positive neurons. PI staining was also higher closer to the cut surface, and PI-positive neurons had very high [Na+]i. Acute perfusion of 10 μM of the Na+/K+ ATPase inhibitors ouabain and strophanthidin, 100 μM of the KCC2/NKCC1 antagonist furosemide, or 100 μM of the Na+/Ca2+ exchange antagonist benzamil increased [Na+]i. 10 μM of the NKCC1 antagonist bumetanide increased [Na+]i during the first ~10 days after trauma, and thereafter decreased [Na+]i. Thus, in the days after trauma NKCC1 and the Na+/Ca2+ exchanger operate in the reverse of their canonical directions by exporting Na+ and, presumably, the cotransported ions. Application of 8 μM fluorescein conjugated to large dextran molecules indicated severe membrane disruption in only a small number of neurons, but a moderate amount of damage in a larger number of neurons, particularly as epileptogenesis progresses. The correlation between the levels of [Na+]i and PI staining after acute trauma suggests that increased [Na+]i may represent an early step in, or serve as an early biomarker of, neuronal death in post-traumatic epileptogenesis. Increases in intracellular [Na+]i could alter the concentrations of cotransported ions and may contribute to cerebral edema and cell death.

Title: An *in vitro* screen for antiepileptogenic compounds utilizing organotypic hippocampal slice cultures

Authors: ***Y. SAPONJIAN**[1], Y. BERDICHEVSKY[2], W. SWIERCZ[1], K. STALEY[1]
[1]Neurol., Massachusetts Gen. Hosp., Charlestown, MA; [2]Lehigh Univ., Bethlehem, PA

Abstract: Traumatic brain injury (TBI) is a major cause of medically intractable acquired epilepsy. There is an urgent need to identify new therapeutic interventions. We utilized the accelerated course of epileptogenesis in the *in vitro* organotypic hippocampal slice culture model of severe post-traumatic epilepsy to conduct a moderate-throughput screen of an array of drugs for anticonvulsant, antiepileptic and neuroprotective effects. Organotypic hippocampal slice cultures were prepared from postnatal day 6 or 7 Sprague-Dawley rats and were maintained in poly-D-lysine coated 6-well tissue culture plates on a rocking platform in a humidified chamber at 37oC and 5% CO2. The culture medium consisted of Neurobasal-A, B27, 0.5 mM GlutaMAX, and 30 µg/ml Gentamicin and was changed every 3-4 days. Chronic-application experiments were carried out for 28 days *in vitro*. Drugs were dissolved in DMSO (final concentration 0.1%) and added to the media starting on DIV 3. All experiments included DMSO control slice cultures derived from the same animal. The lactate concentration in spent culture medium was strongly correlated with electrographic seizure activity and therefore used in subsequent experiments as an assay for seizure activity. The lactate dehydrogenase (LDH) concentration in spent culture medium was correlated with propidium iodide assays for cell death and used in subsequent experiments as an assay for the rate of cell death and neuroprotective effects. We investigated over 150 high-interest drugs, obtained primarily from the National Institute of Neurological Disorders and Stroke (NINDS) custom collection of known bioactives and FDA-approved drugs. Drugs were typically tested at 3 concentrations: the most likely effective concentration as well as

1 log above and below this concentration. Positive screens were repeated to confirm the findings. Drugs exhibiting significant anticonvulsant activity were further analyzed in wash-out experiments to differentiate anticonvulsant from antiepileptogenic effects. Several drugs exhibited dose-dependent anticonvulsive or proconvulsive effects, as well as neuroprotective or neurotoxic effects. The timing of drug application was an important determinant of the action of several drugs, supporting the idea that epileptogenesis results from a sequence of processes, each of which may respond to unique interventions. Anticonvulsant and neuroprotective effects were strongly correlated, presumably due to reductions in ictal cell death. This technology comprises a promising strategy for the rapid investigation of drug efficacy in chronic epilepsy, and could be further scaled with available robotic technologies.

Title: Carisbamate modifies the proteomic profile of the hippocampus in a model of temporal lobe epilepsy

Authors: *E. MARQUES-CARNEIRO[1,2], D. S. PERSIKE[1], J.-C. CASSEL[2], A. NEHLIG[3], M. J. S. FERNANDES[1]
[1]Unifesp, Sao Paulo, Brazil; [2]Lab. de Neurosciences Cognitives et Adaptative - UMR 7364 – IFR 37, Strasbourg, France; [3]Hôpital Necker - Univ. Paris Descartes, INSERM U1129, Paris, France

Abstract: *Purpose:* Epileptogenesis is a term used to define a series of events that occur between factors that causes symptomatic epilepsy and the appearance of the spontaneous seizure. In adult rats the administration of pilocarpine (Pilo) followed lithium reproduces most clinical and neuropathological features of human temporal lobe epilepsy (TLE). Carisbamate (CRS) is a drug with present neuroprotective and a potent epileptogenesis-modifying effect (François et al., 2011). Fifty percent of rats subjected to pilocarpine-induced *status epilepticus* (SE) develop absence-like seizure instead of motor seizures when treated with CRS. The mechanism of action of CRS is not yet known. The aim of this study was to perform a proteomic analysis of the

hippocampus of rats receiving lithium-pilocarpine presenting motor seizures or absence-like seizures following CRS treatment. *Methods*: Fifteen adult male Sprague-Dawley rats were used. SE was induced by pilocarpine injection (30 mg/kg, sc) associated with lithium (127.17mg/kg, i.p.). CRS treatment was initiated at 1 h after SE onset and maintained for 7 days. Four groups were obtained: Control (CT n=3), CRS with absence seizures (CRS-AE n=4), CRS with motor seizures (CRS-TLE n=4) and epileptic untreated (TLE n=4). Proteomic analysis was conducted by 2D-SDS-PAGE. Spots were analysed with PDQuest software. Analysis was conducted using UniProt website, GENEmania, QuickGO and IntAct systems, the entire data was integrated using the Cytoscape software. *Results*: Eight proteins linked to glycolysis pathway were down regulated in CRS-AE, such as aldolase-A; aldolase-C; glyceraldehyde-3-phosphate dehydrogenase; RGD1565368; enolase-2; pyruvate dehydrogenase; ATP synthase and aconitate hydratase, although two proteins were up-regulated, as Pyruvate-Kinase and L-lactate dehydrogenase, when compared to control group. *Conclusion*: The partial seizures occurrence is directly related to the energy consumption involving the excitatory/inhibitory balance. Te global reduction of glycolysis and ATP production found in CRS-AE rats is a finding which could explain, at least in part, the epileptogenesis-modifying effect of the Carisbamate.

Title: Pharmacological screening of the anticonvulsant activity of the (o-phenyl)-1,3-isoindolindione, a thalidomide analogue

Authors: *C. CAMPOS[1], S. ZAMUDIO[2], S. GUZMAN-VELAZQUEZ[2], J. TRUJILLO-FERRARA[3], E. RAMIREZ-SAN JUAN[2]
[1]Escuela Nacional de Ciencias Biologicas-IPN, Distrito Federal, Mexico; [2]Fisiologia, Escuela Nacional de Ciencias Biológicas-IPN, Ciudad de Mexico, Mexico; [3]Bioquimica, Escuela Superior de Medicina-IPN, Ciudad de Mexico, Mexico

Abstract: Thalidomide is a molecule consisting of a pthaloyl ring and a glutarimide ring, it was proven as antiepileptic drug, and recently has been confirmed this effect in preclinical and clinical research in epilepsy. In addition, it possesses pharmacological properties as antiemetic, sedative, hypnotic, and currently as immunomodulating and anti-inflammatory, however, it has caused congenital abnormalities which inhibited its use. Since thalidomide is an active molecule, nowadays scientists have synthetized new drugs based on thalidomide structure, such as (o-phenyl)-1,3-isoindolindione (OFI), synthesized with the aim of preserving the pharmacological effects on the central nervous system, particularly the effects of antiepileptic drugs, eradicating or reducing adverse effects. For the pharmacological screening, male CD1 mice of 25-30 g in weight were used, which were maintained with food and water ad libitum, in an environment with controlled conditions of temperature (22 ± 2 °C), humidity (55 ± 5%) and 12-hour light/dark cycle. We determined: 1) the effect of the OFI on locomotor activity and motor coordination; and 2) the anticonvulsant activity against seizures induced with pentylenetetrazole (PTZ; 80 mg/kg); strychnine (STR; 3 mg/kg) and pilocarpine (380 mg/kg) in different groups (n=12): control (vehicle OFI: corn oil; orally administrated.), groups that received doses of OFI (421.7 and 562.3 mg/kg, orally administrated) and one group was administrated with sodium valproate (300 or 550 mg/kg; given ip.). The results showed that 421.7 and 562.3 mg/kg doses of OFI significantly reduce the locomotor activity due to the distance traveled and the time of ambulation are decreased significantly with respect to the control; conversely resting time is increased significantly with respect to the control. OFI does not modify significantly the motor coordination of the mice at the doses tested in relation to the group treated with vehicle. The treatment with OFI do not antagonized meaningfully seizures induced by PTZ, STR and pilocarpine, since no dose significantly modifies the time to seizure onset, the number of seizures and/or the percentage of convulsing mice, the seizure total duration, or the death latency. In conclusion, the OFI induces a sedative effect from the dose of 421.69 mg/kg, it does not cause neurological deficit, and do not have anticonvulsant effect on the doses and models tested.

Title: Stiripentol and comorbidities in Dravet syndrome: Experimental approaches in animal models

Authors: *V. RIBAN, W. DEFFAINS, I. HEULARD, M. VERLEYE
Pharmacol., Biocodex, Compiegne, France

Abstract: Dravet syndrome or severe myoclonic epilepsy of infancy (SMEI) is an encephalopathy characterized by refractory epileptic seizures associated with cognitive and motor impairments. Autistic traits and Attention Deficits and Hyperactivity Disorder (ADHD) are also common comorbidities in this syndrome. Seizures management is achieved with a combination of antiepileptic drugs, classically an association of valproate, clobazam and stiripentol, a positive allosteric modulator of GABA-A receptors (Fisher, 2011) which was granted orphan drug status for Dravet syndrome in the European Union in 2001. The aim of this study was to assess the effects of acute or chronic stiripentol administration (at anticonvulsant doses) on two animal models predictive of the main comorbidities found in Dravet syndrome: the spontaneously hypertensive rat (SHR) for ADHD (Sagvolden, 2005), and rats prenatally exposed to sodium valproate (VPA) for social behavior impairments (Rodier, 1995). Acute intraperitoneal administration of stiripentol (200 mg/kg) in juvenile SHR rats decreased locomotor activity and the number of rearings measured in an actimetry test ($p < 0.05$). In the open field test, the number of rearings and zone changes was also decreased after 200mg/kg stiripentol administration. These effects of stiripentol were not observed in the control strain (Wistar Kyoto), and were dissociated from any myorelaxant effects, as measured in the grip test. In rats prenatally exposed to VPA, chronic oral administration of stiripentol (400 mg/kg, from P12 to P32) reversed the diminution of social contacts observed in this model whereas it did not have any effect in the control animals ($p<0.05$).These preliminary results show that, at anticonvulsant doses, stiripentol may have beneficial effects in two comorbidities associated with Dravet syndrome: hyperactivity and impaired social contacts.

Title: Effects of anti-seizure drugs on pro-inflammatory cytokines expression in the rat hippocampus

Authors: *C. D. GÓMEZ MARTÍNEZ, R. M. BUIJS, M. SITGES
Biología Celular y Fisiología, Inst. De Investigaciones Biomédicas. UNAM, Mexico, Mexico

Abstract: In the present study the effects of the two classical antiepileptic drugs, carbamazepine and valproic acid, and the non-classical anti-seizure drug, vinpocetine were investigated on the expression of the pro-inflammatory cytokines IL-1beta and TNF-alpha in the hippocampus of rats by PCR or Western blot after the administration of one or seven doses. Next, the effects of the anti-seizure drugs were investigated on the rise in cytokine expression induced by LPS inoculation *in vivo*. To validate our methods the changes induced by the pro-convulsive agents: 4-aminopyridine, pentylenetetrazole and pilocarpine were also tested. Finally, the effect of the anti-seizure drugs on seizures and on the concomitant rise in pro-inflammatory cytokine expression induced by 4-aminopyridine was explored. Results show that vinpocetine and carbamazepine reduced the expression of IL-1beta and TNF-alpha from basal conditions, and reduced the increase in both pro-inflammatory cytokines induced by LPS. In contrast, valproic acid, failed to reduce both, the expression of the cytokines from basal conditions and to prevent the rise in IL-1beta and TNF-alpha expression induced by LPS. Tonic-clonic seizures induced either by 4-aminopyridine, pentylenetetrazole or pilocarpine increased the expression of IL-1beta and TNF-alpha markedly. 4-aminopyridine-induced changes were reduced by all the tested anti-seizure drugs, although valproic acid was less effective. We conclude that the anti-seizure drugs, vinpocetine and carbamazepine, whose mechanisms of action involve a decrease in ion channels permeability, also reduce cerebral inflammation.

Title: Effects of Lacosamide and Eslicarbazepine acetate metabolites on voltage-gated sodium channel expressed in a neuroblastoma cell line

Authors: *P. GHISDAL, N. NOEL, Y. QUESNEL, I. NIESPODZIANY, C. WOLFF
UCB BioPharma SPRL, Braine l'Alleud, Belgium

Abstract: Lacosamide (LCM) is a third generation anti-epileptic drug with a molecular mode of action described to enhance slow inactivation of voltage-gated sodium channels (VGSC). Eslicarbazepine and its metabolites have also recently been shown to modulate VGSC gating properties. In this study we characterized and compared the effects of LCM and the active metabolites of eslicarbazepine acetate, S-licarbazepine (ESL) and R-licarbazepine (LIC), on the steady-state fast inactivation and slow inactivation properties of sodium current (I_{Na}) in mouse N1E-115 neuroblastoma cells. The whole-cell patch-clamp technique was used to evaluate and compare the effects of LCM and of the metabolites of Eslicarbazepine acetate (ESL and LIC) at different concentrations on VGSCs expressed in N1E-115 cell line. The sodium current (I_{Na}) recording was performed on an automated patch-clamp platform (PatchXpress 7000A, Molecular Devices). We have first evaluated the effect of compounds on the voltage dependency of the fast inactivation properties of VGSCs. Half inactivation potential of I_{Na} fast inactivation curve (V_{50}) was significantly shifted to hyperpolarized potentials after application of 100µM carbamazepine (-12mV±2mV, mean±SEM; n=5), or 300µM ESL (-8mV±1mV, n=7) or 300µM LIC (-8mV±1mV, n=6). The leftward shift of fast inactivation V_{50} measured in the 300µM LCM group (-4 mV±1mV, n=8) and the time-matched control group (-4mV±1mV, n=7) were not different. Voltage-dependent I_{Na} slow inactivation V_{50} value was significantly shifted by 300µM LCM (-42mV±4mV, n=6), ESL (-15mV±4mV, n=6) and LIC (-27mV±5mV, n=8) compared to the time-matched control group (-3 mV±4, n=6). Applied at a concentration of 100µM, LCM and ESL induced a I_{Na} slow inactivation V_{50} shift of -20 mV±1mV (n=4) and -6mV±1mV (n=7), respectively. Finally, we have tested the compounds efficacy on the tonic block of I_{Na} current when VGSCs were activated from a membrane potential corresponding to fast inactivation V_{50} of VGSCs individually measured for each recorded cell. A concentration of 300µM of either LCM, ESL, or LIC inhibited I_{Na} by 52±4% (n=6), 37±5% (n=6) and 24±5% (n=10), respectively. ESL 30µM had no effect on I_{Na} whilst 30µM LCM decreased it by 11±2% (n=6). In conclusion, this study revealed that both ESL and LIC, the minor metabolite of eslicarbazepine acetate, modulate fast and slow inactivation properties of VGSCs expressed in N1E-115 cells. Our results also confirmed that LCM enhances slow inactivation of VGSCs and does not modify their fast inactivation properties. Additionally, the slow inactivation was shown to be more significantly affected by LCM compared to ESL and LIC.

Title: Anticonvulsant effect of three artificial sweeteners on Pentylenetetrazole-induced seizures in mice

Authors: *B. I. ALDANA[1], A. ENRIQUE[2], A. TALEVI[2], L. BRUNO-BLANCH[2], L. ROCHA[1]
[1]Farmacobiología, Ctr. de Investigación y de Estudios Avanzados, Mexico City, Mexico; [2]Medicinal Chemistry, Dept. of Biol. Sciences,, Fac. of Exact Sciences, Natl. Univ. of La Plata, La Plata, Buenos Aires., Argentina

Abstract: Antiepileptic drugs (AEDs) with higher efficacy and lower toxicity are urgently needed as it is estimated that available medication does not adequately control seizures in up to 30% of individuals with epilepsy. In the search for new AEDs, a virtual screening campaign recently predicted several artificial sweeteners as potential anticonvulsants. The prediction was experimentally validated here by testing three artificial sweeteners (sodium cyclamate, saccharin, and acesulfame potassium) in the model of acute generalized tonic-clonic seizures induced by pentylenetetrazole (PTZ) in the mouse. With this purpose, the behavioral changes following PTZ administration at a convulsive dose of 60 mg/kg i.p. were visually evaluated during 30 min in animals pretreated i.p. either with the tree sweeteners at increasing doses or with the vehicle used to dissolve them (70% H2O/ 30% PEG 400). We found that cyclamate at the dose of 10 mg/kg increased the latency (293%) to the first myoclonic seizure induced by PTZ, compared with vehicle. At the dose of 30 mg/kg, cyclamate increased the latency to both myoclonic (285%) and generalized tonic-clonic seizure (434%); and avoided the generalized tonic-clonic seizures in 82% of the animals. Saccharin at a dose of 10 mg/kg increased the latency to PTZ-induced myoclonic (456%) and tonic-clonic (422%) seizures, and avoided the generalized seizures in 43% of the animals. Finally, acesulfame at a dose of 10 mg/kg, increased the latency to

myoclonic (403%) and tonic-clonic (274%) seizures induced by PTZ. In summary, the three artificial sweeteners studied here induce anticonvulsant effects being cyclamate the most effective of the compounds to reduce PTZ-induced seizures. Considering these results, it would be worthwhile to investigate the effect of these compounds in animal models of epilepsy.

Title: Fish oil supplementation decreased inflammatory markers in animal model of epilepsy

Authors: *F. SCORZA[1], M. NEJM[1], A. HAIDAR[1], M. MARQUES[1], A. HIRATA[1], M. NAFFAH-MAZACORATTI[1], R. CYSNEIROS[2], E. CAVALHEIRO[1]
[1]Sao Paulo Federal Univ., Sao Paulo, Brazil; [2]Mackenzie Presbyterian Univ., Sao Paulo, Brazil

Abstract: Sudden unexpected death in epilepsy (SUDEP) is the most common cause of death related in people with epilepsy. Its cause is still unknown. A number of studies have shown that pro-inflammatory and anti-inflammatory interleukins are able to orchestrate inflammatory responses in the heart. Regarding the importance of omega-3 on inflammation and immunomodulation we suggested that fish oil treatment could promote a reduction on pro-inflammatory interleukins expression in heart of rats with epilepsy. After 3h of SE the animals were randomly separated into the following groups: animals with epilepsy treated daily with vehicle (PV) or with 85mg/kg of fish oil (PO85) and control animals treated daily with vehicle

(CV) or with 85mg/kg of fish oil (CO85). After 90 days, it was investigated protein expression (western blot) of IL-6, IL-1β and TNF-α and protein level (ELISA) of IL-6 on the heart. The IL-6 expression was significantly higher in experimental group as compared to control ($F(1,12)=40.3$; $p<0.0001$) and fish oil treatment decreased it ($F(1,12)=6.8$; $p<0.05$) with no interaction between factors. The protein expression of TNF-α was significantly higher in experimental group as compared to control ($F(1,12)=5.6$; $p<0.05$), with no effect of treatment nor interaction between factors. The epileptic condition or treatment did not change the IL-1β expression. The IL-6 levels was significantly higher in experimental group comparatively to control ($F(1;16)=5.7$; $p<0.05$) and decreased under fish oil treatment ($F(1;16)=16.2$; $p<0.01$), with no interaction between factors. Proinflammatory cytokines are increased in heart of epileptic animals and fish oil decreased these cytokines, which could contribute to reducing the incidence of SUDEP.

Title: Oxidative stress in animal model of epilepsy induced by pilocarpine: Effect fish oil supplementation

Authors: *M. B. NEJM[1], A. HAIDAR[1], A. HIRATA[1], R. CYSNEIROS[2], E. CAVALHEIRO[1], F. SCORZA[1]
[1]Federal Univ. of Sao Paulo, Sao Paulo, Brazil; [2]Mackenzie Presbyterian Univ., Sao Paulo, Brazil

Abstract: Temporal lobe epilepsy (TLE) is the most common form of epilepsy. Brain injury observed in TLE may be the result of an overproduction of free radicals. NADPH oxidase

enzyme has emerged as a potential source of reactive oxygen species (ROS) generation in neurons. Previous studies of our group demonstrated that chronic treatment with fish oil in animal model of TLE exhibited neuroprotective and neuroplastic effects. This study evaluate if NAD(P)H oxidase expression is altered in TLE and if fish oil supplementation can exhibits protection effect against its ROS production. Animals were subjected to the animal model of TLE by pilocarpine administration (350 mg/kg, i.p) and the controls received saline. After 3h of SE the animals were randomly divided into the following groups: animals with epilepsy treated daily with vehicle (PV) or with 85mg/kg of fish oil (PO85) and control animals treated daily with vehicle (CV) or with 85mg/kg of fish oil (CO85). After 90 days, it was investigated the superoxide anion production using dihydroethidium (DHE) fluorescence dye in hippocampus, protein expression of NAD(P)H oxidase subunits (p47PHOX and gp91PHOX) by western blot and its RNAm expression. The superoxide anion production was significantly higher in CA1 and CA3 fields of the hippocampal formation of experimental group as compared to control ($F(1;16)=12.8$; $p<0.05$ and $F(1;16)=5.2$, $p<0.05$, respectively). The fish oil treatment significantly decreased the superoxide anion production as compared to vehicle in CA1 and CA3 fields of the hippocampal formation ($F(1;16)=5.7$; $p<0.05$ and $F(1;16)=5.8$, $p<0.05$, respectively). The protein expression of NAD(P)H oxidase subunit p47PHOX was significantly higher in experimental group as compared to control ($F(1;12)=8.3$; $p<0.05$), with no effect of treatment ($F(1;12)=1.5$; NS) nor interaction between factors. For the gp91PHOX expression, a significant effect of interaction was noted ($F(1;12)=6.6$; $p<0.05$). The gp91PHOX expression increased in the experimental group and decreased under the fish oil treatment. It was not found alteration on gene expression. The results shows that the expression of NADP(H) oxidase is increased in hippocampus of epileptic animals, being only mildly affected by the fish oil treatment and that the superoxide anion production increased in epileptic hippocampus and decreased by fish oil treatment.

Title: Effect of the most commonly-used antiepileptic drugs on the MTLE mouse model of human temporal lobe epilepsy: An EEG study

Authors: *C. ROUCARD[1], B. POUYATOS[1], C. BOUYSSIÈRES[1], C. DUMONT[1], A. DEPAULIS[2], V. DUVEAU[1]

Abstract: Mesial Temporal Lobe Epilepsy (MTLE) is the most common form of drug-refractory epilepsy. To better understand and treat this syndrome, the use of predictive drug-resistant animal models is mandatory. The MTLE mouse model induced by unilateral intrahippocampal injection of kainate reproduces most of the morphological and electroclinical features of human MTLE. Here, we present a comprehensive pharmacological characterization of the response of the MTLE mouse to the major antiepileptic drugs (AEDs) currently on the market. Using depth EEG recordings, we tested the dose-response effects of nine AEDs with different mechanisms of action on the occurrence of hippocampal paroxysmal discharges in the mouse model of MTLE. AEDs effects on ictal and interictal power spectra were as well studied using quantitative EEG methods. The MTLE mouse displayed a wide range of sensitivity to the tested AEDs. Depending on their effects on our model, AEDs can be classified in two categories. 1) Valproate, carbamazepine, lamotrigine and levetiracetam suppressed HPDs in a dose-dependent way, but only at high doses (10 to 20 times those used in patients) and associated with modifications of the general behaviour and/or EEG interictal activity for most of them. 2) Phenobarbital, pregabalin, tiagabine, vigabatrin and diazepam decreased in a dose-dependent manner the occurrence of HPDs at doses similar to the ones used in clinical practice and without obvious behavioural changes or interictal EEG perturbations. These data show that this mouse model of MTLE displays a specific pharmacology, with a resistance to several AEDs and sensitivity to others. This model provides a critical tool to identify new treatment for pharmacoresistant forms of focal epilepsy.

Title: Celecoxib reduced seizure activity and mrna expression of hmgb1 and tlr-4, in a model of recurrent seizures induced with kainic acid in developing rats

Authors: *M. MORALES[1], I. A. FERIA[2], A. VEGA[2], S. A. OROZCO[2]
[1]B, IMSS, Ixtapaluca, Mexico; [2]Neurosci., IMSS, Mexico City, Mexico

Abstract: Clinical and experimental evidence establishes inflammation as a key factor in epileptogenesis; it promotes in the brain an increase in neuronal excitability, reduces the seizure threshold and it's involved in molecular and structural changes of epileptogenesis. The functional role of brain inflammation has been influenced by the use of anti-inflammatory and inmunosupressive treatments during neonatal period, when the brain is more susceptible due to the anatomical and physiological features that facilitate the development of seizures. The aim of the present study was to evaluate the effect of the anti-inflammatory drug, celecoxib, on the mRNA expression of HMGB1 and TLR-4, and seizure activity in a model of recurrent seizures produced by kainic acid (AK) which induces epileptogenesis in developing rats. 48 male Sprague Dawley rats 10 days old were used. (20-25g).They were divided into six groups: Sham group (GC), Kainic Acid group (GAK), Celecoxib group (CCX), Experimental group 1 (AK+CCX), Experimental group 2 (AK+PB), Experimental group 3 (AK+CCX+PB). The AK was administred for 5 days (1.4mg/kg), to induce tonic-clonic seizures. Seizure activity was assessed during 60 minutes evaluation after administration of AK in each treatment. The hippocampus and cerebral cortex was removed and the RNA was extracted (Trizol® Reagent Protocol). cDNA was synthesized for analysis of gene expression by PCR. The results showed that celecoxib (AK+CCX) reduces the latency and frequency of tonic and tonic-clonic seizures. It also appeared to reduce the expression of the genes of proinflammatory proteins compared with AK group, in cerebral cortex and hippocampus ($p<0.05$). The results show that celecoxib has a neuroprotective effect on seizure activity and on the expression of proinflammatory proteins, in agreement with the hypothesis of the role of inflammation in epileptogenesis.

Title: Metabolic control of intractable epilepsy by LDH enzyme

Authors: N. YOSHIDA, *T. INOUE
Okayama Univ., Okayama, Japan

Abstract: Epilepsy is a neurological disorder caused by hyperexcitation of neurons in the brain. About 30% of epilepsy patients suffer from intractable drug-resistant epilepsy. To date, it is known that ketogenic diets are effective for intractable epilepsy. However, there are no antiepileptic drugs that mimic ketogenic diets. In this study, we therefore explored a metabolic enzyme which controls intractable epilepsy. To address this issue, we first explored a metabolic enzyme to control membrane potentials in hippocampal and subthalamic neurons, using slice patch-clamp techniques. Our *in vitro* recording revealed that neurons are hyperpolarized by application of oxamate, an LDH inhibitor. We then examined effects of LDH inhibition on seizure mouse models. *In vivo* recording revealed that LDH inhibition suppresses pilocarpine-induced generalized seizures. LDH inhibition also suppressed intractable epilepsy in a model of hippocampal sclerosis. We then explored clinically-used antiepileptic drugs that can inhibit the LDH enzyme. Enzymatic assay revealed that stiripentol, an orphan drug for Dravet syndrome, is a LDH inhibitor. These results show that LDH inhibition controls electrical activity in neurons and suppresses intractable epilepsy *in vivo*, and also that the LDH enzyme is inhibited by antiepileptic drug stiripentol.

Title: Targeting GSK-3 in the 6-Hz corneal kindling model

Authors: *I. J. SMOLDERS[1], N. AOURZ[1], L. WALRAVE[1], A. MASSIE[1], A. VAN EECKHAUT[1], C. V. ESGUERRA[2], P. A. M. DE WITTE[2], Y. MICHOTTE[1], A. D. CRAWFORD[2,3], F. VAN LEUVEN[2]

[1]Ctr. for Neurosci. C4N, Vrije Univ. Brussel, Brussels, Belgium; [2]KULeuven, Leuven, Belgium; [3]Univ. of Luxemburg, Luxemburg, Luxembourg

Abstract: GSK-3 is widely recognized as a key component of a surprisingly large number of cellular processes and is a tempting therapeutic target for several neurological and neurodegenerative disorders. Less than a handful of studies have linked increased GSK-3 activity to epileptic phenomena. Nevertheless, effects of GSK-3 pharmacological inhibition, of genetic deletion or overexpression in a model for epilepsy have never been investigated to date. We used the chronic 6-Hz corneal kindling model in which mice were stimulated (6 Hz, 3 s) twice daily at a predetermined fixed subconvulsive threshold current. Mice are considered kindled when they exhibit at least 10 consecutive generalized seizures (stage 3-5 Racine's scale). The selective and potent GSK-3 inhibitor BIO-acetoxime significantly reduced seizure severity in 6-Hz corneally kindled mice in a dose dependent manner. As such we here provide the first evidence for anticonvulsant actions of a selective GSK-3 inhibitor. We also compared differences in seizure susceptibility between GSK-3β neuronal knockout (GSK-3β $^{-/-}$) mice and their wild type littermates (GSK-3β $^{+/+}$), and between GSK-3β neuronal overexpression (GSK-3β OE) mice and their corresponding wild types (WT) in the same electrical kindling model. Although GSK-3β OE mice are more rapidly kindled, they display less severe seizures compared to their corresponding WT mice. Surprisingly, compared to GSK-3β $^{+/+}$ mice, GSK-3β $^{-/-}$ mice clearly show an increased susceptibility to the electrically-induced seizures. This observation raises the hypothesis that GSK-3β $^{-/-}$ mice develop a compensatory mechanism that might be responsible for their higher seizure susceptibility. Altogether our data sustain that GSK-3 is a complex and multi-faceted enzyme and that its potential role in epilepsy mechanisms is exciting and deserves further investigations.

Title: Real-time *in vivo* imaging of blast-induced mild traumatic brain injury reveals focal microglial activation, associated blood-brain barrier permeability and elevated cytokine responses

Authors: *B. R. HUBER[1,2], J. S. MEABON[1], K. MEEKER[3], B. KRAEMER[4], E. C. PETRIE[1,5], E. R. PESKIND[1,5], D. G. COOK[1,3,4]
[1]VA Puget Sound Hlth. Care Syst., Seattle, WA; [2]Psychiatry and Behavioral Sciences, Sch. of Med., [3]Pharmacol., [4]Div. of Geriatric Medicine, Sch. of Med., [5]Psychiatry and Behavioral Sci., Univ. of Washington, Seattle, WA

Abstract: Introduction: Many soldiers deployed to modern military conflicts have experienced repetitive mild traumatic brain injuries (mTBIs) caused by blast overpressure (BOP) events. There is great concern that such repetitive blast exposure may be similar to the repetitive subconcussive impacts that are common among boxers and football players that develop chronic traumatic encephalopathy (CTE). A growing body of evidence argues that persistent neuroinflammation plays a role in the pathophysiology of repetitive blast mTBI. In order to better understand the mechanism of pathogenesis in blast-induced mTBI we have developed a murine model of blast-mTBI and have used this model to evaluate microglia in the setting of single and repetitive blast exposure. Methods: *In vivo* experiments were performed with non-targeted Qdots 655 delivered intravenously to male CX3CR1-GFP+/- mice immediately prior to single BOP events. Repetitive blast exposure consisted of 3 BOP events with an interval of 24 hours between each blast. Following BOP exposure or sham treatment a thinned skull cranial window was introduced 2 mm posterior to the bregma and 2 mm lateral to the midline. Anesthetized mice were imaged with two-photon scanning confocal microscopy for periods of up to 6 hours. Morphologic and biochemical analyses were carried out using standard immunostaining and western blot methods. Results: At BOPs of 17 psi (7ms positive phase) 100% of the mice survived both single and repetitive blast exposure. Two photon imaging revealed increased regional blood-brain barrier permeability with increased Qdot florescence in the perivascular parenchyma, with markedly increased microglial uptake of Qdots in 8/8 BOP exposed mice. Microglia demonstrated a range of changes associated with activation including hyper- and de-ramified morphologies. Immunofluorescence microscopy of 50 um perfusion fixed sections demonstrated microglial morphologic changes (Iba-1 stain) after a single mild BOP exposure. Microglial processes (filaments) were shorter, occupy less volume and had a smaller surface area indicating partial activation. After a single blast exposure there is an increase in TNF-α at 24 hours. After two weeks only mice exposed to repetitive blast had significantly elevated TNF-α. Conclusion: These findings indicate repetitive blast results in persistent microglial activation and suggests that each additional blast exposure can enhance

expression of inflammatory cytokines from primed microglia leading to persistent elevation of inflammatory cytokines and microglial morphological changes long after the initial injury.

Byrd Alzheimer's Inst., Tampa, FL; [9]Dept. of Neurosurg. and Brain Repair, Univ. of South Florida Morsani Sch. of Medicine, Ctr. of Excellence for Aging and Brain Repair, Tampa, FL

Abstract: Millions of traumatic brain injuries (TBI) occur every year, 75% of which are considered mild traumatic brain injuries (mTBI). mTBIs are often seen in athletes, military personnel, and people involved in accidents. The cognitive effects of TBI are still untreatable. Neuronal loss and functional deficits are common attributes. Previous studies have suggested

that coffee/caffeine can have neuroprotective, and even therapeutic, potential for brain diseases such as Alzheimer's disease. Here, we investigated whether the beneficial effects of coffee may extend to treatments of mild TBI. There were 4 groups of mice: (1) vehicle + sham TBI; (2) vehicle + TBI; (3) coffee-treated + sham TBI; (4) coffee-treated + TBI. The coffee-treated mice were administered coffee nanoparticles (i.p.) at 30 minutes, 3 days, and 7 days following a mild TBI (a single 50 g weight drop-induced impact to the skull overlying the right temporal cortex). Brains were harvested 30 days following TBI. The Golgi impregnation method was used to visualize cortical layer V pyramids of the parietal cortex and the granule cells of the hippocampus for quantitative analysis of dendritic branching. Results showed that in the neocortex the dendritic domains of the layer V pyramids were significantly larger in both coffee groups (e.g., coffee + TBI and coffee + sham), suggesting either neuronal plasticity caused by the coffee nano-particles and/or compensatory dendritic hypertrophy associated with TBI-related neuronal death. Either - or both - events can occur independently of each other. In the hippocampus, both of the TBI groups had significantly less dendritic arbor than either of the sham TBI groups. This suggests TBI-related granule cell dendritic atrophy, but this cell population fails to exhibit any signs of neuroprotective properties in the coffee groups. Future stereology studies are planned to elucidate neuronal loss and compensatory mechanisms.

Title: Developmental changes in adult-born neurons following controlled cortical impact injury

Authors: *L. E. VILLASANA[1], K. N. KIM[2], R. MCCALLUM[3], G. L. WESTBROOK[4], E. SCHNELL[1,2]
[1]Anesthesiol. and Perioperative Med., Oregon Hlth. & Sci. Univ., PORTLAND, OR; [2]Portland VA Med. Ctr., Portland, OR; [3]Sch. of Medicine, OHSU, Portland, OR; [4]The Vollum Institute, OHSU, Portland, OR

Abstract: Traumatic brain injury (TBI) often results in long-term cognitive impairment. In mammals, the generation of adult-born hippocampal neurons persists into late adulthood, and experimental TBI increases the number of these newly-generated dentate granule cells. Because hippocampal neurogenesis is important for certain forms of memory, TBI-induced neurogenesis could reflect a compensatory mechanism contributing to cognitive recovery. However, it is unknown whether TBI-induced adult-born neurons functionally integrate into the existing hippocampal network. Additionally, as hippocampal neurons born after experimental seizures demonstrate altered maturation and integration, it is possible that neurons born after TBI aberrantly wire into the hippocampus. Here, we used 2-month-old male and female POMC-EGFP (C57Bl/6J) mice, which express EGFP in young adult-born hippocampal granule cells, to examine the development and integration of adult-born neurons following a controlled cortical impact injury (CCI). Mice were anesthetized with isoflurane and a 4 mm craniotomy was made on the right hemisphere between bregma and lambda. A 0.9 mm cortical deformation (speed 4.4 msec/ 3mm diameter) was made using an electromagnetic impact device in accordance with IACUC-approved protocols. Sham mice were anesthetized but did not undergo craniotomy or injury. Consistent with previous reports, the number of newborn neurons increased two weeks post-injury. Moreover, CCI enhanced the migration and dendritic arborization of adult-born dentate granule cells compared to sham-treated mice, suggesting that CCI alters the development of these new neurons. Whole-cell recordings demonstrated that these adult-born neurons integrate into the hippocampus. Their functional impact on the hippocampal circuitry is under investigation.

Title: Modulation of neuroprotective signaling and morphological changes in neurons after mild traumatic brain injury and treatment in mice

Authors: *B. A. CITRON[1,2], R. F. MERVIS[4,3], S. K. FOLEY[4,3], L. RACHMANY[5], V. RUBOVITCH[5], C. G. PICK[5], J. N. CHANG[1,2]

Laboratories, Inc., Tampa, FL; [5]Anat. and Anthrop., Sackler Sch. of Medicine, Tel Aviv Univ., Tel Aviv, Israel

Abstract: At least 0.5% of the population sustains a traumatic brain injury each year and the incidence is 30 times greater among deployed military service personnel. The majority of TBIs are mild and these can result in deleterious cognitive effects for which there are currently no effective treatments. Our targeting of specific transcription factors has produced improved outcomes after mild TBI. We have now characterized changes associated with neuronal health at the intracellular level and by measurements of changes in the dendritic arbors of neurons. Several different transcription factor modulators that we have tested have proven to be neuroprotective in an *in vitro* TBI model. For example, inhibiting p53, or c-Jun or upregulating PPARγ or Nrf2 has resulted in improved health of model neurons after injury. With a weight drop induced-closed head injury model that includes rotation we have significantly reduced memory loss by treatment with tBHQ (tertiary butylhydroquinone) to increase the activation of an inflammatory responsive transcription factor, Nrf2, beginning 30 minutes after injury and identified factors, e.g., HSP70, that participate in the neuroprotection. We will report the effects of the injury and treatment on dendrites and spines in the hippocampus and cortex, characterized by Golgi staining. To help distinguish between compensatory hypertrophy or preferential susceptibility that could account for phenomena such as higher levels of branching complexity that we found after TBI, but not after TBI plus treatment, we are complementing these examinations with stereological counts of the neurons. Overall, our goal is to help identify therapeutic approaches that would benefit individuals suffering mild traumatic brain injury.

Title: Identification of microstructural subdomains by diffusion MRI microscopy in the perilesional cortex following controlled cortical impact in the mouse

Authors: *E. B. HUTCHINSON[1], S. SCHWERIN[2], E. SHINDELL[2], M. KOMLOSH[1], A. AVRAM[1], S. JULIANO[2], C. PIERPAOLI[1]
[1]NICHD, Natl. Inst. of Hlth., Bethesda, MD; [2]APG, USUHS, Bethesda, MD

Abstract: Objectives: Following focal brain trauma, multiple and evolving cellular and tissue changes affect the microstructure of the perilesional brain tissue. Some of these changes indicate damage while others are associated with a protective or regenerative response. The purpose of this work was to use high resolution diffusion MRI of ex-vivo mouse brains taken at variable times following controlled cortical impact (CCI) to identify distinct MRI markers of tissue changes, validate them with histology in the same brains and characterize their spatial pattern and evolution after injury. Methods: A total of 19 perfusion-fixed mouse brains were obtained following mild CCI at 24 hours, 1 week, 4 weeks or 12 weeks, controls were surgically naive. For each brain, 297 diffusion weighted MRI volumes were collected with b-values ranging from 100 to 10,000 s/mm2. The resolution of these images was 100 microns isotropic. Standard diffusion tensor imaging (DTI) maps of fractional anisotropy (FA) and mean diffusion (MD) were calculated as well as mean apparent propagator (MAP) index maps, including return to the origin probability (RTOP), which probes water restriction. Histological processing is ongoing. Results: Both DTI and MAP-MRI revealed spatially distinct and highly reproducible abnormalities in the perilesional cortex (PLCX) following injury. Abnormal MD values were most prominent at 24 hours post-CCI with a central region of high MD surrounded by a region of low MD that extended for several mm. At the edge of this low MD region there was a distinct thin band of high RTOP. At later time points MD was low and RTOP was high in a thin band near the cavity. FA abnormalities were non-overlapping with MD and RTOP abnormalities. At

24 hours, FA was low on the side of injury, but at 1 week a distinct patch of increased FA was evident. At 4 and 12 weeks all brains demonstrated a region of high FA that encapsulated the cavity and extended several mm in all directions. Tissue orientation within this region was radial to the cavity wall and comparison with glial fibrillary protein (GFAP) indicated only partial overlap of oriented astrocytes and high FA. Conclusions: We have used high-resolution diffusion MRI to identify subregions within the perilesional cortex that differ in diffusion based metrics. In particular, MD, FA and RTOP appear to offer complementary and non-overlapping information about the altered structural environment. Ongoing histological validation promises to better define the source of diffusion changes in the identified subdomains. In this study, diffusion MRI microscopy has demonstrated sensitivity to the spatial organization of cellular changes that follow brain injury.

Title: Multi-channel neurophysiology of the hippocampus in awake behaving swine after diffuse brain injury

Authors: *P. KOCH[1], A. V. ULYANOVA[1], M. R. GROVOLA[1,2], D. K. CULLEN[1,2], J. A. WOLF[1,2]
[1]Dept. of Neurosurgery, Ctr. for Brain Injury and Repair, Univ. of Pennsylvania, Philadelphia, PA; [2]Philadelphia Veterans Affairs Med. Ctr., Philadelphia, PA

Abstract: We have recently developed acute recording methodology to interrogate hippocampal circuitry post diffuse brain injury in a swine model of rotational injury. However, these investigations are inherently limited by the anesthetized preparation. Furthermore, as diffuse TBI is predominantly a disease of the white matter, understanding how network level interactions

break down after injury is critical. Therefore we are developing a method of stereotactic multi-channel electrode implantation in order to examine these networks in swine and correlate activity to behavior post injury. To replicate the range of forces experienced at different injury levels by the brain during mild traumatic brain injury (mTBI), we utilize a range of coronal rotational accelerations (180260 rads/sec) that induce little or no loss of consciousness (< 15 min), yet exhibit axonal pathology. Acute multi-channel recordings in the hippocampus post injury revealed changes in synaptic function and excitability under anesthesia at terminal time points up to 14 days, as well as after repetitive injury. In order to capture both single unit activity and local field structure in the hippocampus, we developed a 32-channel electrode with an ideal configuration for the laminar structure of the hippocampus. Tetrodes are arranged in layer CA1 as well as in the dentate and hilus, with other contacts equally spaced in dendritic layers to examine changes in laminar structure and cortical EEG. We then modified a large animal stereotax to include skull pins for stereotaxic placement of this chronically implantable probe after injury. A surgical approach for sterile implantation was developed including a burr-hole craniotomy, and mapping of the hippocampus using tungsten electrodes prior to probe placement. Fixation of the connector and cable were achieved with Geristore acrylic, while leaving the electrode implanted in the brain parenchyma. Units >150uV were detected on the tetrodes and clearly separable. Unit and field recordings prior to and post electrode fixation were stable across this time period. Further histopathological examination will indicate potential tissue reaction to this implantation over the recording period. Successful development of this technique, combining awake behaving recordings with this injury model, may reveal changes in network function due to previously reported changes in hyperexcitability and axonal injury after diffuse brain injury. Furthermore, this paradigm may be useful in the future for multiple brain regions to correlate activity with behavioral changes post injury, potentially revealing network dysfunction underlying cognitive changes after mTBI.

Abstract: Animal models of abusive head trauma (AHT), especially for rotational-acceleration traumatic brain injury (TBI), are essential for testing novel hypotheses, pathological mechanisms and therapeutic interventions. Unfortunately the modeling of this unique TBI was not well developed. In this study, we introduced a new mouse model to generate rotational-acceleration brain injury. Eight postnatal day12 (P12) C57/BL6 mouse pups were culled from each litter and divided into two groups for exposure either to inflicted insult or to sham treatment as control. The animal was placed into an anesthesia box for 3 minutes that filled with 3% isoflurane that vaporized by 100% oxygen. The insulted mouse lay on a horizontal plate in a prone position and its head was firmly fixed by a rubber band in a head holder. The head holder was rotated when hit by a piston. The velocity of rotational acceleration and angle were adjusted by pneumatic pressure and moving distance of piston. One time rotational acceleration procedure was profiled as 60 psi for 60 times with ±35° rotational angle. The recovery of righting reflex was measured followed by whole brain dissection or behavioral examinations till P42 including rotarod, open field, elevated plus maze and Y maze tests. The recovery of righting reflex indicated that the animals insulted by repeated rotations needed more time to recover from the unconscious state. The subarachnoidal hemorrhage and BBB leak were found in the injured pups. Furthermore, the rotarod performance was significant lower than sham mice at P21 but completely recovered at late stages. However, the exploring function tested by Y maze dramatically declined at P40, not early stages. These findings collectively suggest that the inflicted traumatic brain injury may result in locomotor and cognitive deficits in developing mouse brain.

Title: Pairing vagus nerve stimulation with rehabilitative training enhances functional recovery after traumatic brain injury

Authors: *D. PRUITT, A. SCHMID, C. CHOUA, L. KIM, J. TRIEU, C. ABE, K. FLANAGAN, M. KILGARD, R. L. RENNAKER, II
The Univ. of Texas At Dallas, Richardson, TX

Abstract: Traumatic Brain Injury (TBI) is one of the largest health problems in the United States, and affects nearly two million people every year. The effects of TBI, including weakness and loss of coordination, can be observed years after the initial injury. We have developed a method by which we drive cortical plasticity through stimulation of the vagus nerve during rehabilitative therapy to enhance recovery from TBI. We trained rats to perform the isometric pull task - a task that measures volitional pull strength. After animals were proficient at the task they received a controlled-cortical impact (CCI) in the forelimb area of left motor cortex, and were then randomized into two treatment groups. The first group of animals received vagus nerve stimulation (VNS) paired with rehabilitative therapy, while another group received rehabilitative therapy alone. Following CCI, volitional forelimb strength in all animals was significantly reduced. Animals that received VNS paired with rehabilitative therapy over a period of five weeks achieved a significant but not a full recovery of both forelimb strength and success rate on the isometric pull task, while animals that received only rehabilitative training did not significantly recover forelimb strength. Our findings indicate that pairing VNS with rehabilitative therapy enhances functional recovery, and further research is warranted to investigate how VNS may transfer to clinical settings.

Title: Mitochondrial gene expression profiles and metabolic pathways in the amygdala associated with exaggerated fear in an animal model of PTSD

Authors: *H. LI[1], X. LI[2], S. SMERIN[1], L. ZHANG[1], M. JIA[1], G. XING[1], J. WEN[1], Y. SU[3], D. BENEDEK[1], R. URSANO[1]
[1]Psychiatry/USUHS, Bethesda, MD; [2]Dept. of Biostatistics, Bioinformatics, and Biomathematics,, Georgetown Univ. Med. Ctr., Washington, D.C., DC; [3]Dept. of Gene and Protein Biomarkers, GenProMarkers, Rockville, MD

Abstract: The metabolic mechanisms underlying the development of exaggerated fear in post-traumatic stress disorder (PTSD) are not well defined. In the present study, alteration in the expression of genes associated with mitochondrial function in the amygdala of an animal model of PTSD was determined. Amygdala tissue samples were excised from 10 nonstressed control rats and10 stressed rats, 14 days post stress treatment.. Total RNA was isolated, cDNA was synthesized, and gene expression levels were determined using a cDNA microarray. During the development of the exaggerated fear associated with PTSD, 48 genes were found to be significantly upregulated and 37 were significantly downregulated in the amygdala complex based on stringent criteria ($p<0.01$). Ingenuity Pathway Analysis (IPA) revealed up or down regulation in the amygdala complex of four signaling networks - one associated with inflammatory and apoptotic pathways, one with immune mediators and metabolism, one with transcriptional factors, and one with chromatin remodeling. Thus, informatics of a neuronal gene array allowed us to determine the expression profile of mitochondrial genes in the amygdala complex of an animal model of PTSD. The result is a further understanding of the metabolic and neuronal signaling mechanisms associated with delayed and exaggerated fear.

Title: Effects of a blueberry-enhanced diet on pre-pulse inhibition and beta amyloid after traumatic brain injury in rats

Authors: *C. J. GIBSON
Psychology Dept, Washington Col., Chestertown, MD

Abstract: Although there are multiple promising avenues of treatment for the pathologies associated with traumatic brain injury (TBI), few of these single manipulations have been successful in clinical trials, indicating a need for exploration of combined therapies, especially nutritional interventions (Erdman, Oria, & Pillsbury, 2011). Circumin, a strong antioxidant derived from the spice turmeric, normalized markers of inflammation when administered 30 minutes after controlled cortical impact TBI (Laird et al., 2010). Another promising nutritional strategy involves strong antioxidant foods such as blueberries. A blueberry-enhanced diet has been shown to be cognitively enhancing in aging, Alzheimer's, ischemia, and other studies. In this set of experiments, a 2% blueberry-enhanced diet was fed to rats for 6 weeks after they received a sham or mild TBI. Although no significant differences were found in Morris water maze (MWM) tests or acoustic startle, the blueberry-enhanced diet resulted in significant improvements in pre-pulse inhibition, a measure of cognitive gating where a warning tone dampens the startle response. Also, Beta amyloid increased in the cerebrospinal fluid of rats in this study between 3 weeks and 3 months post-injury. In a second study, the effects of a single 30-minute post-TBI circumin injection and a 2% blueberry enhanced diet beginning immediately post-TBI were combined. Additional findings on measures of MWM, acoustic startle, pre-pulse inhibition, and beta amyloid will be presented and the results will be discussed in the context of TBI pathologies such as oxidative stress and inflammation.

Title: Neuropathological and biochemical assessment of chimera: A novel closed-head impact model of engineered rotational acceleration

Authors: *D. R. NAMJOSHI, W. CHENG, K. MCINNES, J. FAN, A. WILKINSON, P. CRIPTON, C. WELLINGTON
The Univ. of British Columbia, Vancouver, BC, Canada

Abstract: Background: Traumatic brain injury (TBI) is a leading cause of death and disabilities worldwide. Despite promising outcomes from many preclinical studies, clinical studies so far have failed to identify effective pharmacological therapies for TBI, suggesting that the translational potential of preclinical models requires improvement. To address the challenge of generating a simple and reliable model of rodent TBI, we have developed a novel neurotrauma model called CHIMERA (Closed-Head Impact Model of Engineered Rotational Acceleration) that fully integrates biomechanical, behavioral, and neuropathological analyses. CHIMERA is distinct from existing rodent neurotrauma models in that it uses a completely non-surgical procedure to precisely deliver impacts of defined dynamic characteristics to intact animal head while allowing unconstrained head movement. Objective: In this study we characterized the acute neuropathological and biochemical outcomes of repeated TBI (rTBI) in mice using CHIMERA. Methods: Male, wild-type mice were subjected to two closed-head impacts spaced at 24 h. Microglial response was assessed by Iba-1 immunohistochemistry while axonal injury was assessed by silver staining at 48 h post-rTBI. Levels of proinflammatory cytokines, TNFα and IL-1β were measured at 6, 12 and 48 h post-rTBI using ELISA. Phosphorylation levels of endogenous tau protein were assessed in half-brains collected at 6, 12 and 48 h post-rTBI by Western blotting. Results: Injured brains showed significant widespread microglial activation with hypertrophic and bushy morphology in white matter areas at 48 h post-rTBI. Silver staining revealed axonal injury, as indicated by intense punctate and fiber-associated argyrophilic structures in white matter. High-magnification silver-stained images revealed numerous axonal varicosities, a characteristic histological feature of human axonal pathology. Protein levels of TNFα and IL-1β showed ~ 1.7- and 2-fold increase, respectively at 48 h following rTBI. Immunoblot analysis showed significantly increased (~1.5 to 3.5-fold) tau phosphorylation at all probed epitopes (pThr231, pSer396, pSer404 and pSer202), peaking at 12 h following rTBI compared to sham brains. The change in tau phosphorylation was due to a significant increase in ratio of phosphorylated tau : total tau, but not as a result of change in total tau level. Conclusion: CHIMERA is a simple and reliable model of murine TBI that replicates several aspects of human TBI such as neuroinflammation, axonal injury as well as tau hyperphosphorylation.

Title: Repetitive mild traumatic brain injury in mice with a vulnerable cholinergic system: Severe and lasting cholinergic-attentional impairments CHT+/- mice

Authors: *A. KOSHY CHERIAN[1], V. PARIKH[2], R. D. BLAKELY[3], M. SARTER[1]
[1]Psychology and Neurosci., Univ. of Michigan, Ann Arbor, MI; [2]Psychology and Neurosci., Temple Univ., Philadelphia, PA; [3]Pharmacol. and Psychiatry, Vanderbilt Univ. Sch. of Med., Nashville, TN

Abstract: Repetitive mild traumatic brain injury (rm-TBI), as sustained by athletes and military personnel, represent one of the most common types of brain injury. Because of the predominant impairments in attention, TBI has long been hypothesized to impact cortical cholinergic functioning. We hypothesized that choline transporter (CHT) heterozygosity bestows greater vulnerability to the effects of TBI because attenuated choline transport into cholinergic terminals has previously been speculated to interact with other pathological events to facilitate cholinergic neuronal membrane decline and thus cholinergic cell loss (for review see Sarter & Parikh, 2005). CHT+/+ and CHT+/- mice acquired the mouse version of the Sustained Attention Task (SAT; St.Peters et al., 2011) and then were subjected to rm-TBI using a modification of the method described by Kane et al. (2012). Mice practiced the SAT six days a week and were subjected to five TBI events separated by seven days. Rm-TBI impaired hit rates only in CHT+/- mice, reaching and then remained at chance level after the 5th TBI. Consistent with the selective effects of cholinergic lesions on the performance in this task, non-signal trial performance was unaffected by rm-TBI. Following 7 days of SAT practice after the 5th TBI, frontal cortices were harvested for saturation analyses of hemicholinium-sensitive choline uptake in frontal synaptosomes. Results indicate that in SAT-performing CHT+/- mice that experienced rm-TBI, the capacity for choline uptake was nearly completely abolished whereas choline uptake in CHT+/+ rm-TBI mice remained above levels observed in sham-treated CHT+/- mice. These results indicate a greater rm-TBI-induced loss of behaviors, such as SAT, that depend on CHT and cholinergic signaling (Parikh et al., 2013). This evidence indicates that rm-TBI has a relatively greater impact in mice with a compromised cholinergic system, suggesting the

possibility that humans with vulnerable cholinergic systems likewise experience more severe and lasting consequences of rm-TBI.

Title: Dysfunctional CA1 hippocampal networks in mice after repetitive closed-head injury

Authors: ***O. C. LOGUE**[1], N. P. CRAMER[2], X. XU[2], Z. GALDZICKI[2]
[2]Anatomy, Physiology, and Genet., [1]Uniformed Services Univ., BETHESDA, MD

Abstract: Traumatic brain injury (TBI) is the leading cause of death for persons under the age of 45. Military servicemembers, who have served on multiple combat deployments, and contact-sport athletes, are at particular risk of sustaining repetitive TBI (rTBI). Cognitive and behavioral deficits resulting from rTBI are well documented. Associative long-term potentiation (LTP), occurring in the CA1 hippocampal Schaffer collateral pathway, is required for both memory formation and retrieval. Utilizing our mouse model of rTBI, we hypothesize that a triple closed-head injury (3X CHI) will trigger alterations in hippocampal function. One week after 3X CHI, extracellular recordings were performed to evoke Schaffer collateral LTP in the CA1 area. Ipsilateral CA1 LTP is enhanced in mice from the 3X CHI treatment group. The intrinsic properties of CA1 neurons were evaluated with whole-cell patch-clamp recordings. 3X CHI ipsilateral CA1 neurons exhibit significant increases in action potential amplitude, maximum rise slope, and maximum decay slope, while the action potential width at half amplitude is decreased. Gap-free voltage clamp recordings of CA1 neuron postsynaptic currents were conducted to detect spontaneous excitatory (EPSCs) and inhibitory (IPSCs) and respective miniature currents (mEPSCs and mIPSCs). In the 3X CHI mice, the sEPSCs and sIPSCs of ipsilateral CA1 neurons have an increased frequency of events but decreased peak amplitudes. Conversely, 3X CHI alters

the action potential-independent miniature postsynaptic currents in a different manner. The mEPSCs of ipsilateral CA1 neurons display both an increased frequency of events and larger peak amplitudes. Moreover, the effect of 3X CHI on mIPSCs is opposite to that of the sIPSCs. That is, the frequency of events in the mIPSCs is decreased, while the peak amplitudes are increased. These results are consistent with our hypothesis that repetitive closed-head injury may affect CA1 hippocampal function by promoting an imbalance between excitatory and inhibitory synaptic inputs.

Abstract: Introduction : Traumatic brain injury (TBI) is a major environmental risk factor for Alzheimer's disease (AD) and is the leading cause of disability in North America for persons under 40 years of age. Intraneuronal neurofibrillary tangles, composed of abnormally hyperphosphorylated Tau protein is one of the characteristic features of AD. Tau pathology can be found in post-mortem brain many years after a single severe or repetitive mild TBI. Since Tau

hyperphosphorylation is suggested to play a major role in AD pathogenesis, induction of Tau hyperphosphorylation after injury may play a role TBI pathology. There are reports of acute phospho-Tau accumulation after experimental TBI using a controlled cortical impact (CCI) model. Here, we examined tau and phospho-Tau accumulation in a transgenic AD mouse model 2 and 4 weeks post-CCI to determine if these acute changes can persist chronically after injury in the mouse. Methods : 9 months old 3xTgAD mice were subjected to CCI (Leica ImpactOne, 5.25m/s, 2mm depth) and were euthanized at 2 or 4 weeks post-injury (n=10/timepoint). Tau phosphorylation (at the AT270, CP13, Thr205, AT8, Tau-1, Ser199, AT180, MC-6, PHF-1 and Ser422 epitopes), APP cleavage, Tau kinases activation and phosphatases expression were examined in the ipsilateral and contralateral striatum by western blot analysis. Results : An increase in Tau phosphorylation at the Thr205 residue was observed in the ipsilateral striatum of injured mice and was associated with Tau hyperphosphorylation at the AT8 and Ser422 epitopes 4 weeks post-injury. In this side, a sustained PKA activation was observed concomitantly with an increase of the activated form of Akt at 4 weeks. In the contralateral striatum, TBI induced a transient increase in Tau phosphorylation at the AT180 and Ser422 epitopes. This Tau hyperphosphorylation was associated with a temporary activation of Akt 2 weeks after CCI. The injured mice did not show any changes in either tau phosphatase levels or APP cleavage, as compared with sham mice. Conclusion : This work provide an extensive characterization of Tau phosphorylation in the CCI mouse model. We show that CCI results in different patterns of Tau hyperphosphorylation and Tau kinases activation in the striatum of 3xTgAD mice. Our data suggest that the hyperhosphorylation of Tau found in the ipsilateral striatum could be linked to sustained PKA activation, while transient Tau hyperphosphorylation observed in the contralateral side could be related to Akt activation. Moreover, these results provide further evidence for the independent relationship between Tau hyperphosphorylation and APP processing in the TBI context.

Title: Acute neuronal plasmalemmal disruptions in peri-vascular domains are exacerbated following repetitive closed head rotational acceleration traumatic brain injury in swine

Authors: E. KUO[1], C. J. MIETUS[1], K. D. BROWNE[1], J. P. HARRIS[1], L. A. STRUZYNA[1], J. A. WOLF[1], J. E. DUDA[2], *D. CULLEN[1]

Abstract: Repetitive traumatic brain injury (TBI) may result in a progressive neurodegenerative disease referred to as chronic traumatic encephalopathy (CTE). A curious neuropathological feature of CTE is a preferential distribution of cells exhibiting intracellular tau accumulations around mid-size blood vessels. The cause of these patterns is unknown, but one possible explanation is that micro-structural discontinuities at vasculature-brain tissue interfaces result in stress concentrations that exacerbate cellular damage during traumatic loading. Therefore, the objective of the current study was to determine if perivascular neural cells exhibited elevated immediate plasmalemmal damage and evolving degeneration in a large animal model of non-impact inertial TBI. Swine were subjected to sham conditions or rapid closed-head rotational acceleration using the HYGE pneumatic actuator, either a single injury or two injuries separated by 15 minutes or 7 days. To assess plasmalemmal compromise, Lucifer Yellow (LY), a small (457 Da) cell impermeant dye, was administered into the lateral ventricles to diffuse throughout the interstitium prior to injury. Animals were sacrificed within 15 minutes (those with LY injections), 8 hours, or 7 days post-injury (n=21 total). We found that closed-head inertial TBI induced acute plasmalemmal permeability in neural cells, virtually exclusively in neurons. In particular, LY+ cells were concentrated around blood vessels in the cerebral cortex, sub-cortical white matter and thalamus/midbrain following single or repetitive TBI (each $p<0.05$ vs. sham). Maximal perivascular cell permeability was observed following repetitive TBI separated by 7 days ($p<0.01$). This exacerbated cell permeability following delayed repetitive TBI corresponded with dramatic increases in astrocyte reactivity around blood vessels, suggesting that local astogliotic changes may create additional stress concentrations. Remarkably, approximately 11% of blood vessels were surrounded by LY+ cells following delayed repetitive TBI, versus 6% following same-day repetitive and 4% following single TBI (each $p<0.05$ vs. sham). These results suggest that micro-structural discontinuities at vasculature-brain tissue interfaces contribute to exacerbated plasmalemmal damage following TBI. Ongoing analyses will assess the co-occurrence of plasmalemmal damage with the emergence of tau pathology and evolving neurodegeneration. These results increase our understanding of the links between the physical and physiological consequences of TBI, and may identify periods of enhanced biomechanical vulnerability in perivascular domains.

Title: STAT3 signaling in perilesional nestin-expressing reactive astrocyte is required for cortical recovery after closed-head injury

Authors: ***M. MORITA**[1], A. WATANABE[2]
[1]Biol., Kobe Univ., Kobe Hyogo, Japan; [2]Kobe Univ., Kobe, Japan

Abstract: We have developed a novel closed-head injury model, photo-injury, and found that nestin-expressing reactive astrocyte accumulates perilesional recovering region (Suzuki et al, 2012). In order to address the roles of the perilesional reactive astrocyte in wound healing, STAT3, which is crucial for astrocyte activation, has been ablated in nestin-expressing cells by using Nestin-Cre/STAT3$^{flox/flox}$ mouse. Mice after more than seven days post-injury showed significantly less accumulation of perilesional reactive astrocytes, and larger lesion size in the STAT3-ablated group than in wild type group. The importance of STAT3 signaling was further confirmed by ablating SOCS3, which suppress cytokine mediated STAT3 activation, in the nestin-expressing reactive astrocyte by using Nestin-Cre/SOCS3$^{flox/flox}$ mouse. The SOCS3-ablated groups showed significantly smaller lesion size after more than seven days post-injury, as well as significantly larger region covered by perilesional reactive astrocyte, than corresponding wild type group. Our results indicates that cytokine-mediated STAT3 activation in perilesionl astrocytes leads to the accumulation of nestin-expressing reactive astrocyte, and then promote wound healing following closed-head injury.

Title: Long-term cognitive impairments and pathological alterations in a rat model of mild traumatic brain injury

Authors: *J. SHI, Y. LI, S. G. MASSA
Dept. of Neurol., Dept. of Veterans Affairs Med. Ctr. and Univ. of California, San Francisco, CA

Abstract: Mild traumatic brain injury (mTBI) accounts for the majority of all traumatic brain injuries and long-term consequences of mTBI have become increasingly recognized in individuals engaged in certain sports or in military operations. Many mTBI patients suffer chronic neurobehavioral impairments, however the underlying mechanisms are not clear. Recent studies have suggested that loss or dysfunction of neurons and neuronal precursors, activation of microglia, and proliferation of astrocytes in the hippocampus may contribute to memory deficits after traumatic brain injury. In order to expedite preclinical research and therapy development, there is a need for animal models that reflect the long-term cognitive and pathological features seen in patients. In the present study, we developed and characterized a rat model of mTBI, induced by controlled cortical impact (CCI) over the left frontal hemisphere with an electromagnetic stereotaxic impact device. Varying several impact parameters, we evaluated animals in several behavioral tests to define a mild TBI injury level without motor impairment. Animals receiving mTBI showed a significant impairments in spatial learning and memory as well as depression-like behavior. Moreover, a robust astrogliosis and activated microglia were observed upon histopathological examinations several months following TBI. These findings are consistent with the deficits and pathology associated with mTBI in humans and suggest this model may be of value in the evaluation of potential therapeutic approaches.

Title: Impaired synaptic vesicle docking is a novel contributor to reduced neurotransmission in a rat model of traumatic brain injury

Authors: *S. W. CARLSON, H. Q. YAN, C. E. DIXON
Neurosurg. and VA Pittsburgh Healthcare Syst., Univ. of Pittsburgh, Pittsburgh, PA

Abstract: Traumatic brain injury (TBI) impairs neuronal function and can culminate in lasting cognitive impairment. While impaired acetylcholine release has been well established after experimental TBI, little is known about the mechanisms underlying this consequence. We hypothesized that alterations in synaptic vesicle distribution and reduced vesicular docking at the pre-synaptic membrane contribute to impaired neurotransmission. To examine the ultrastructural distribution of synaptic vesicles, anesthetized adult male Sprague-Dawley rats received 2.7mm controlled cortical impact (CCI) or sham injury (n=6/group) and the brains were processed for transmission electron microscopy at 1 week post-injury. In each animal, 20 randomly selected synaptic nerve terminals from the molecular layer of the hippocampus were imaged at 100k magnification. Synaptic vesicle distribution was assessed by measuring the distance of each vesicle from the active zone for all terminals. CCI resulted in a significant reduction in vesicle frequency within 200nm of the active zone ($p<0.01$ compared to sham, repeated one-way ANOVA). Recent reports highlight that reduced vesicular density within 100nm of the active zone impairs vesicular docking and blunts neurotransmitter release. In a normal synapse, vesicular docking and neurotransmitter release requires formation of the SNARE complex. To examine the effect of TBI on the SNARE complex, rats received CCI or sham injury and were sacrificed at 6hr, 1d, 1, 2, or 4 weeks post-injury (n=6/injury/time). Immunoblotting of unboiled hippocampal homogenates showed that SNARE complex formation, identified by SNAP-25 and syntaxin immunoreactivity, was reduced by at least 48% at 1 week ($p<0.05$) and 2 weeks ($p<0.01$) after CCI. Neurotransmitter release deficits have been well characterized at 1 and 2 weeks post-injury, suggesting that changes in synaptic vesicle docking contributes to impaired neurotransmission. In this study, we provide the first evidence that TBI alters synaptic vesicle

distribution using quantitative ultrastructural analysis of electron micrographs. Our findings suggest that reductions in the standing pool of readily releasable vesicles and impaired SNARE complex formation are two novel mechanisms that contribute to the impaired neurotransmission after TBI.

Title: Nicotinamide treatment in a bilateral frontal model of traumatic brain injury: Effects on fear conditioning and memory

Authors: *S. F. BENNETT, B. E. ELMORE, M. R. HOANE
Southern Illinois Univ., Carbondale, IL

Abstract: In the United States 1.7 million people experience a traumatic brain injury (TBI) annually, and cognitive impairments are the leading cause of TBI-related disability. Despite the frequency of this major public health issue, there are currently no FDA approved pharmacological treatments available. Previous research has shown that a derivative of the B3 vitamin, nicotinamide (NAM), has therapeutic potential as neuroprotectant in various TBI models. The purpose of this study was to evaluate cognitive functioning and learning following NAM treatment in a bilateral frontal controlled cortical impact (CCI) model in 30 male Sprague-Dawley rats. It was hypothesized that NAM would improve recovery of function in a retrograde amnesia Morris water maze (MWM) paradigm and a passive avoidance assessment. Four days prior to surgery animals were tested in the MWM paradigm for four trials per day to assess baseline learning. On the day of surgery animals were assigned to a sham (uninjured), vehicle (0.9% saline), or NAM treatment condition (150 mg/kg). Injections were administered intraperitoneally at four hours post injury, and every 12 hours for 72 hours. The animals were tested for retention in the MWM on day 11 and tested in the passive avoidance task on days 12 and 13. Animals were perfused on day 13 and standard histological procedures were conducted to assess lesion volume. The results of this study found no therapeutic benefit from treatment in the utilized tasks. An injury effect was detected though, and these findings may contribute to the

repertoire of behavioral assessments used in TBI pharmaceutical evaluations and provide further evidence of the efficacy of NAM treatments.

Title: Effect of age on amount and distribution of diffuse axonal injury after rotational trauma

Authors: J. DAVIDSSON[1], M. ANGERIA[2], *M. G. RISLING[2]
[1]Div. of Vehicle Safety, Applied Mechanics, Chalmers Univ. of Technol., Göteborg, Sweden;
[2]Dept Neurosci, Karolinska Inst., Stockholm S-171 77, Sweden

Abstract: Traumatic brain injuries (TBI) are a major public health problem in term of suffering and cost for society. About 40% of the TBI patients admitted to hospitals are non-focal injuries, usually referred to as distributed brain injuries (DBI). Studies have hypothesized that the resulting strains in the brain tissue are the primary cause of neurological deficiencies following DBI. These strains commonly appear when the skull is accelerated and the brain mass, due to its inertia, lags behind or continues its motion relative the skull. It has been suggested that the severity of the injury correlates with the amplitude of the angular acceleration, or with the resulting angular velocity. Among DBI, diffuse axonal injury (DAI) is common and regularly results in unconsciousness or death. Past studies have suggested DAI injury criteria and thresholds that can be used with crash test dummies and mathematical models of the human. However, these past studies have been performed with rather young animals. In addition, some studies have shown that brain properties change as we grow older; it is likely that this have an effect on the risk of DAI following a rotational head injury. Therefore, the aim of this study is to investigate the distribution of axonal injuries in the brain following sagittal plane rotation trauma and to determine if the injury threshold changes when the subjects grow older. In this study rats were exposed to sagittal plane rotational acceleration head trauma and the outcome studied using Amyloid Precursor Protein to detect axonal injuries. For relatively young animals, DAI were found in and along the border of the corpus callosum and in the brainstem when rotational acceleration exceeded 1.1 Mrad/s2. Slightly older animals required higher accelerations to exhibit similar injury levels and the injury patterns were different. We hypothesise that the lower

injury scores for the older subjects could be due to differences in tolerance to tissue strains or, as indicated in the literature, that the differences were due to changes in the constitutive properties of the brain tissue. The latter suggests, in combination with the observed differences between older and younger individuals, that additional studies on brain tissue properties, and studies on rotational acceleration induced DAI, should be carried out using even younger and older animals than used in this study. In conclusion, a previous study showed that the onset of diffuse axonal injuries started to appear at 10 krad/s2 with a duration of 4 ms, when data were scaled for humans, whereas new data indicate that this onset is slightly higher for occupants that are approximately 15 years older.

Labs, Tampa, FL; [2]The Honors Col., [3]The Col. of Arts and Sci., Univ. of South Florida, Tampa, FL; [4]Dept. of Anat. and Anthrop., Sackler Sch. of Medicine, Tel Aviv Univ., Tel Aviv, Israel; [5]Dept. of Neurosurg. and Brain Repair, Univ. of South Florida Morsani Sch. of Medicine, Ctr. of Excellence for Aging and Brain Repair, Tampa, FL

Abstract: Traumatic brain injury (TBI) affects 10-20% of the veterans from the Iraq and Afghanistan wars, designating it as the signature injury of the conflict. 80% of those brain injuries are categorized as mild. Improvised explosive devices (IEDs) are often a major source of TBI to both combatants and civilians. Cognitive and emotional disorders are often a sequelae of such brain damage. The nature of blast-related TBI is unique and the neuropathology is poorly understood. Here we sought to characterize neuronal damage in a mouse model of blast TBI (bTBI) involving low-level blast pressure effects to the brain but without systemic injuries. Anesthetized 7 week-old mice were exposed to a single explosion which generated a pressure

wave of 5.5 psi (lbs/sq in) and sacrificed 72 hrs later. Using the Golgi impregnation technique, the dendritic arbor of cortical and hippocampal neurons were microscopically evaluated for alterations in dendritic branching which would reflect the extent of neuronal damage. From coded slides, dendritic branching of randomly selected Layer V and VI pyramids from the parietal and frontal cortices, along with hippocampal CA1s, were quantitatively evaluated. All neuronal populations were affected: CA1s lost 17% of their dendritic domains, cortical pyramids of the parietal cortex lost up to 30%, and cortical pyramids of the frontal cortex lost approximately 19%. Additional studies will determine if this damage is transient or long-lasting, but this is the first evidence to demonstrate that even mild blast-related TBI results in disruption of dendritic circuitry. This may serve as an anatomical basis for subsequent cognitive dysfunction and/or post-traumatic stress disorders. The implications of these findings to military who have served overseas and have been exposed to IEDs are ominous.

Title: The effect of focal brain injury on beta–amyloid plaque deposition, inflammation and synapses in the APP/PS1 mouse model of Alzheimer's disease

Authors: *J. COLLINS, A. E. KING, A. WOODHOUSE, M. T. K. KIRKCALDIE, J. C. VICKERS
Wicking Dementia Res. and Educ. Ctr., Univ. of Tasmania, Hobart, Australia

Abstract: Purpose: Traumatic brain injury has been proposed to increase the risk of Alzheimer’s disease (AD), however, the effect of such brain damage on the onset and progression of beta-amyloid plaque pathology is not well understood. This study utilized an *in vivo* model of focal brain injury to examine how structural cortical injury may alter the onset and progression of beta-amyloid plaque deposition as well as inflammatory and synaptic changes, in

a transgenic model of AD. **Methods:** The APPswe,PSEN1dE9 (APP/PS1) transgenic AD model was used for this study. Under isoflurane anaesthesia 3- and 9-month-old transgenic (Tg) and wild type (Wt) mice were subjected to a focal brain injury involving insertion of a needle into the somatosensory neocortex, or sham surgery (3-4 mice per group), and examined at 24hrs and 7d post-injury (PI). Sections were stained with thioflavine-S (Thio-S) or immunolabelled with the antibody MOAB-2, which specifically reacts with beta-amyloid but not APP. Microglial and synaptic responses were examined by quantification of the % area occupied by Iba-1 immunopositive microglia at the injury site and the number of synaptophysin-labelled puncta near and distant from the injury site, respectively. **Results:** Focal brain injury did not induce Thio-S stained or MOAB-2-labeled plaques at either 24hrs or 7d PI in 3-month-old Tg or Wt mice. Thio-S and MOAB-2 plaque load was not significantly ($p>0.05$) altered by brain injury in 9-month-old Tg mice compared to sham animals at 24hrs PI (0.09±0.02% vs 0.1±0.04% for Thio-S, 3.24±0.68% vs 2.8±061% for MOAB-2) or 7d PI (0.14±0.07% vs 0.09±0.02% for Thio-S, 3.00±0.52% vs 2.88±0.39% for MOAB-2). At 7 days PI, there was a significant ($p<0.001$) increase in the percent cortical area occupied by Iba-1 positive microglia in injured (24.72±1.41%) compared to sham mice (10.01±0.30%). However, there was no difference in this response between Tg and Wt mice ($p>0.05$). At 24hrs PI, there was a significant reduction ($p<0.01$) in the number of synaptophysin puncta near the injury site (1001±80) as compared to sites distant to the injury (1519±49) and sham mice (1533±50). At 7d PI, there was no significant difference ($p>0.05$) in the number of puncta near (1420±53) versus distant (1527±76) to the injury site or compared to sham mice (1571±41). Again, there was no significant effect of genotype on this response ($p>0.05$). **Conclusion:** These results indicate that focal brain injury and the associated microglial response do not alter beta-amyloid plaque deposition in the APP/PS1 mouse model. Furthermore the current study demonstrates that the brains of both Wt and Tg mice are capable of substantial synaptic remodeling post-injury.

Title: Expansion of peripheral lymphocytes following a fluid percussion traumatic brain injury in mice

Authors: *L. A. SHAPIRO[1,2,3], R. TOBIN[1], S. MUKHERJEE[1], J. KAIN[1], M. NEWELL-ROGERS[1,3]
[1]Dept Surgery & Neurosurg., Texas A&M Univ. COM, TEMPLE, TX; [2]Central Texas Veterans Hlth. Care Syst., Temple, TX; [3]Baylor Scott & White Hosp., Temple, TX

Abstract: Each year, traumatic Brain Injury (TBI) impacts millions of people worldwide. Despite the increased resources dedicated to understanding the complex series of physiological events that follow a TBI, effective diagnostic and treatment options are lacking. The majority of research on TBI has focused on the role of the central nervous system (CNS) in mediating disease manifestation. This "CNS-centric" approach has yielded a number of putative mechanisms involved in TBI pathogenesis. These include mechanisms of neuronal damage, dysfunction and death, loss of myelin, astrocyte and microglial contributions, neuroinflammation, endothelial cell alterations and blood brain barrier (BBB) breakdown. There is little doubt that most, if not all of these components are involved in the post-TBI phenotypes. However, accumulating evidence strongly supports peripheral contributions to the TBI conditions. It is well known that following TBI, numerous types of peripheral immune cells are mobilized and infiltrate into the CNS. Less understood is how TBI affects peripheral immune cell expansion and activation. For this study, we hypothesized that a fluid percussion TBI would induce rapid expansion and activation of B and T cells in the periphery, and that subsets of these cells would be observed in the CNS. Using flow cytometry and immunohistochemistry, our results demonstrate expansion of B and T cells in the periphery by 24 hours after injury. By 72 hours after injury, subsets of these cells are observed in the CNS. The appearance of activated T cells in both the periphery and in the CNS is highly suggestive of a switch from innate to adaptive immunity following TBI. Follow-up studies are warranted to test the putative mechanisms of these cell types on TBI-related pathology.

Abstract: Mild traumatic brain injury (mTBI) can occur from an exposure to blast shock waves (BSWs). Blasts are believed to be responsible for two-thirds of the combat related mTBI occurred in Operation Iraqi Freedom and Operation Enduring Freedom. While MRI scans and other imaging studies do not typically reveal obvious brain injury at interim post-exposure time points, blast-related mTBI can lead to memory and mood dysfunction several years after the incident. Animal studies have documented several immediate changes after an exposure to shock waves of a single blast or repeated blasts, with some studies implying that cognitive impairments recover spontaneously over time. In this study, using C57BL6 mice, we ascertained long-standing effects of an exposure to shock waves of a single blast on cognitive and mood function, hippocampus neurogenesis and white matter integrity. For inducing BSW mediated mTBI, we wrapped each mouse in a flexible Kevlar after anesthesia and placed inside a Schedule 80 PVC container designed to leave only the head exposed. The container was then fixed to the distal end of the shock tube apparatus. The head was exposed once to BSWs (11.79 ± 0.10 psi) through restrained rupture of a Mylar membrane, which separated the blast tube from a high-pressure chamber. Another cohort of age-matched mice served as sham controls, which were anesthetized and placed near the shock tube to receive only the sound. Six months following the exposure, animals were examined using different behavioral tests. Mice exposed to BSWs displayed inability for pattern separation function in a behavioral test that examined their ability for discriminating distinct familiar objects placed on a different floor pattern. These animals also showed memory impairments in water maze, object-in-place and novel object recognition tests and mood dysfunction in modified novelty suppressed feeding and forced swim tests. Imaging of fixed brains *ex vivo* through diffusion tensor imaging revealed significant corpus callosum white matter alterations in a subset of mice exposed to BSWs compared to sham controls. Radial diffusivity (a marker of myelin degradation) was increased 68% bilaterally but no changes in axial (axonal injury) or mean diffusivity (global tissue measures) were observed. Relative

anisotropy (asymmetry of water mobility) was decreased 42%. Moreover, measurement of doublecortin+ newly born neurons in the dentate gyrus revealed ~33% decrease in neurogenesis. These results suggest that 6-8 months after exposure to BSWs there are significant cognitive and mood impairments associated with declined hippocampus neurogenesis and ongoing myelin degradation in the corpus callosum.

Hosp., Toronto, ON, Canada

Abstract: **Introduction:** Concussions can result in a range of cognitive, psychiatric and physical symptoms and associated brain pathology. We recently reported that impulsivity correlated with white matter metrics of the uncinate fasciculus (UF), based on diffusion tensor imaging (DTI), in retired professional athletes (Goswami et al., 2014). However, it is not known whether DTI of the UF can be predictive of concussion history in single subjects. Here we determined if a machine learning classifier could be trained to discriminate concussed retired athletes from

healthy controls on the basis of DTI of the UF. **Methods:** DTI scans of 19 retired Canadian Football League players (50 ±12yo) with a history of concussions and 17 age-matched controls without concussion (46 ±10yo) were obtained using 3T MRI. Data were pre-processed using the standard FSL DTI pipeline and TBSS was used to generate spatial maps of the fractional anisotropy (FA), mean diffusivity (MD), axial diffusivity (AD), and radial diffusivity (RD) projected onto a common white matter skeleton. Whole-brain skeletons were restricted to the left and right UF by transforming probabilistic tractography-based segmentations of each subject's UF into standard space, averaging, thresholding and taking their intersection with the TBSS skeletons. Eight support vector machine (SVM) classifiers (4 DTI metrics x 2 hemispheres) were trained to discriminate athletes from controls based on voxels from each hemisphere's uncinate tract. Performance was optimized over algorithm meta-parameters by grid search. Leave-one-out cross validation computed accuracy and random label permutation tests assessed statistical significance. **Results:** Classifiers based on MD and RD measured at voxels of the right UF achieved statistical significance ($p=0.018$ and $p=0.04$, respectively), with an optimal operating point sensitivity/specificity of 84/82% for the former and 79/82% for the latter. The areas under the ROC curves were 0.81 and 0.80, respectively. The spatial pattern of classifier weights revealed MD and RD that were higher in concussed athletes than in controls at the orbitofrontal end of the UF, but lower in athletes compared to controls at the temporal end of the UF. **Conclusion:** These data provide evidence for the use of machine learning with DTI to assess spatial locations of white matter abnormalities in multiply-concussed athletes that may not be identifiable with standard DTI approaches. Furthermore, this approach has potential utility in the general assessment and diagnosis of brain abnormalities following concussion.

Title: The study of correlation between TBI severity and neurofilament level in CSF

Authors: *K. SUMIYOSHI, Y. TAKASATO
Neurosurg., Natl. Disaster Med. Ctr., Tachikawa, Japan

Abstract: Introduction Various biomarkers have reported to detect the severity of brain damage. The application of biomarkers is suitable for the assessment of TBI (traumatic brain injury) severity. However, this method do not detect the locational information of the injury. In this study, we examined a correlation between the neurofilament level in CSF and the ultimate severity of brain damage after TBI, and ask whether the neurofilament level enables to predict long-term consciousness state in TBI patients. Methods The patients who could not obey simple command within 3 days after head injury were examined. Those with severe local damage to the speech area, thalamus or brain stem were excluded. The CSF level of phosphorylated neurofilament H (pNF-H) were measured using ELISA at several time points from Days 1 to 70. The changes of brain parenchymal volume (BPV) and the state of consciousness were also observed. Results Five patients were observed (4 males, 1 female; age 19-73). Three of those recovered consciousness and obeyed simple command within 2 months after injury (early-recovered group), whereas, the other two still showed disturbed consciousness one year after injury (VS group). The pNF-H level showed different temporal pattern between these groups. Maximum level of pNF-H was found right after injury in early-recovered group, whereas, that in VS group was observed a few weeks after injury. The difference in reduction rate of BPV was not significant a month after injury between the groups, however the persistent reduction was also found in VS group after Day 30. Conclusion This preliminary study raises the possibility that pNF-H level in CSF enables to predict final brain damage in TBI patients. By combining this quantitative information with positional information from radiological examination, early prediction can be expected about long-term outcome of consciousness state.

Abstract: Working memory (WM) refers to our ability to maintain and manipulate information 'on-line' for a short period of time, and WM is frequently affected by mild traumatic brain injury (mTBI). Two constituent processes of working memory are capacity and manipulation. While a distributed network of brain regions has been shown to be involved in information processing associated with increased capacity and manipulation in both HCs and mTBIs, these two processes are frequently confounded in working memory paradigms. In order to better understand which aspects of working memory are affected in mTBI, we used a novel WM paradigm that allowed us to independently manipulate capacity and manipulation: the CapMan paradigm. Moreover, in order to assess changes in these constituent WM processes over time, we assessed working memory performance and brain activation at two time points: within 10 days after the injury and 4 months (+/- 2 two weeks) after the injury. 11 healthy controls and 7 individuals with mTBI participated in the current study. fMRI data was acquired with a 3T Siemens Trio scanner. The paradigm was presented in the scanner in a blocked design using E-Prime software. There were four task blocks, each lasting 64 seconds and each composed of four trials/conditions (high capacity and manipulation: CAP-MAN; high capacity, low manipulation: CAP-man; low capacity, high manipulation: cap-MAN; low capacity and manipulation: cap-man). fMRI data was analyzed with a 2x2x2x2 mixed ANOVA (Group: mTBI vs. HC; Session; time 1 vs. time 2; Capacity: high vs. low demand; Manipulation: high vs. low demand). All group-level statistical maps were thresholded at $p < 0.05$ (corrected for multiple comparisons). The analysis resulted in main effects of Group, Capacity, and Manipulation. We also observed a Group X Session and Group X Load interaction. Two cerebellar regions showed a Group X Session interaction. Cerebellum is reported to play a role in working memory and is thought to be responsible for inner vocalization/phonological storage (e.g. Marvel & Desmond, 2010). Four regions showed a Group X Load interaction: right lentiform nucleus, left superior temporal gyrus/inferior frontal gyrus, left posterior insula, right cerebellar tonsil. The significance of these effects and interactions will be discussed.

Title: Age related atrophy of white matter tracts in Veterans with TBI and PTSD

Authors: *M. M. ADAMSON[1], K. L. MAIN[1], S. SOMAN[2], J. L. KONG[1], A. NODA[4], B. HERNANDEZ[4], L. C. LAZZERONI[4], L. L. KINOSHITA[5], J. K. FAIRCHILD[3], A. J. FURST[1], J. YESAVAGE[1], J. L. TAYLOR[3], J. W. ASHFORD[1], P. J. BAYLEY[1]

Abstract: OBJECTIVES: Diffusion Tensor Imaging (DTI) fiber tractography has been used to assess the relationship between age and microstructural changes in white matter tracts (WMT). Such studies typically include healthy adults and commonly report measures of white matter integrity such as Fractional Anisotropy (FA). Our objective was to investigate WMT changes in a Veteran population with multiple health complaints including mild to moderate Traumatic Brain Injury (TBI) (68%) and/or Post Traumatic Stress Disorder (PTSD) (78%). METHODS: Participants were recruited from the War Related Illness and Injury Study Center, CA (WRIISC CA). Ninety-one participants (Control n=16, PTSD n=17, TBI n=11, PTSD+TBI n=47) were given a high-resolution T1 anatomical scan and a 30 direction DTI scan. DTI data were analyzed with custom software for the creation of tensor maps and white matter tractography that provided common DTI indices of FA for sixteen fibers of interest. RESULTS: Compared to controls, all three patient groups revealed a distinct pattern of aging (Figure 2).We focused on three fiber tracts that are implicated in trauma in both TBI & PTSD populations. There was an Age x TBI Interaction for Left Inferior Frontal Occipital Fasiculus (LIF), $F(1, 90) = 5.02$, $p < 0.05$. Results differed from previous work in healthy aging as bilateral cingulum and uncinate FA in our "control" population did not show a linear negative correlation with age (almost zero). In contrast, the correlations in both these tracts were very evident in the TBI population (R2 range = -0.3 to -0.6). Bilateral uncinate and cingulum had a negative correlation in both PTSD & TBI/PTSD population (R2 range = -0.1 to -0.5). RIF/LIF were also highly negatively correlated with age in all four groups (with only RIF in controls) whereas in previous research in civilian populations, R2 ranges are reported to be ~ 0.19. The only significant interaction was found in the TBI group where TBI (mild & moderate) appeared to amplify the effect of age on LIF. CONCLUSIONS: Aging effects related to TBI and PTSD were found. These effects were more pronounced in Veterans with one or more events of mild or moderate TBI, regardless of PTSD status andwere found in long association fibers (e.g., LIF), which are known to be particularly vulnerable to TBI. Veterans with PTSD, regardless of TBI, revealed compromised fiber integrity

in both cingulum and uncinate fibers - previously implicated in PTSD. This study demonstrates how DTI can illuminate the complex pathological substrates of WM changes with aging even with clinical scans that are initially read as “unremarkable”.

Title: Transplantation of adult subventricular zone-derived neural stem/progenitor cells to immune competent rats improves locomotor function after spinal cord injury

Authors: ***S. SANKAVARAM**, A. FROSTELL, J. GRIPENLAND, M. SVENSSON, L. BRUNDIN
Clin. Neurosci., Karolinska Institutet, Stockholm, Sweden

Abstract: Spinal cord injuries (SCI) are caused by trauma and leads to devastating and irreversible consequences like loss of sensory and motor functions below the injury. Adult NSCs have capacity to differentiate into cells of the CNS and constitute a potential source for therapy for SCI. Here we transplanted NSCs isolated from the SVZs of ubiquitin:EGFP transgenic Lewis rats into SCI of immune competent wild type litter mates 10 days after injury. Spinal contusion injury was made on the dorsal side of thoracic T11 level using IH impactor. A total of 230,000 neurospheres (≤40μm) in 5μl of medium were transplanted in two injection sites of the spinal cord at the epicenter of the injury. We assessed recovery of rats after NSC cell transplant with BBB score and kinematic apparatus. The majority of the NSCs survived after 15weeks of transplantation and differentiated into oligodendrocytes (APC), astrocytes (GFAP) and neurons

(Tuj-1). The NSCs filled the cyst and migrated into entire injured area. We identified regional differences in the differentiation of NSCs within the injured spinal cord. Transplanted NSCs differentiated into more neurons (Tuj-1) in dorsal funiculus compared to central region. Majority of the cells differentiated into functional oligodendrocytes (MBP) and some migrated into the white matter of the spinal cord. The NSC transplanted animals performed significantly better than the control animals after 28 days of post transplantation. We conclude that transplanted NSCs from SVZ will improve recovery after SCI by integration and differentiation into oligodendrocytes, neurons and astrocytes and the degree of improvement depends on the number of cells and survival of the cells with in the host tissue. *Funding: Swedish Medical Research council; Soderbergs foundation; Strat Regen KI.*

Title: Activation of lysophosphatidic acid receptor 1 (LPA1) contributes to pathophysiology of spinal cord injury

Abstract: Lysophosphatidic acid (LPA) is an extracellular lipid mediator with many physiological functions, which signals through 6 known G protein-coupled receptors (LPA1-6). A wide range of LPA effects have been identified in the CNS, including neural progenitor cell physiology, astrocyte and microglia activation, neuronal cell death, and axonal retraction. *In vivo* studies also show that LPA is involved in the etiology of fetal hydrocephalus, as well as the development of neuropathic pain after sciatic nerve injury and cerebral ischemia. Here we demonstrate for the first time that LPA acting via LPA1 contributes to secondary damage after spinal cord injury (SCI). Our data revealed that LPA levels increase ~10 fold in the contused spinal cord parenchyma. To assess the potential contribution of increased LPA levels in the spinal cord tissue, we injected 5 nmoles of LPA into the dorsal column of an intact spinal cord. The injection of LPA led to an inflammatory response and demyelination, suggesting that the increased levels of LPA observed in the contused spinal cord may contribute to tissue damage. We then assessed the expression of LPA receptors in the spinal cord, and found that LPA1 is the form expressed at higher constitutive levels. Intraspinal injection of LPA into the intact spinal cord of LPA1-null mice resulted in reduced myelin loss, although demyelination was not completely abrogated. Similar results were observed after injecting LPA and AM095 (a potent and selective LPA1 antagonist) into the spinal cord, suggesting that the demyelinating effects of LPA are partially mediated via LPA1. To study the mechanisms underlying the demyelinating response triggered by LPA through LPA1 signaling we exposed oligodendrocyte primary cultures to 1μM LPA for 24 hours. Survival of oligodendrocytes was reduced ~20% upon LPA stimulation; however, cell death was unchanged by the administration of AM095. Conditioned media of primary cultured microglial cells stimulated with LPA led to marked reduction in oligodendrocyte survival (~85%). However, cell survival was enhanced ~3 fold when microglial LPA1 was blocked with AM095, suggesting that the detrimental actions of LPA1 are mediated by microglial cells. We finally assessed whether LPA-LPA1 signaling contribute to secondary damage following spinal cord injury. Oral administration of AM095 resulted in reduced locomotor deficits and myelin loss after SCI. Overall, these results provide clear evidence that the increase in LPA levels that occurs after SCI contribute to demyelination, and that such detrimental effects are mediated, in part, by microglial activation via LPA1 signaling.

Title: Overexpression of the astrocyte glutamate transporter, GLT1, using AAV exacerbates phrenic motor neuron degeneration and diaphragm dysfunction following cervical contusion spinal cord injury

Authors: *A. C. LEPORE[1], K. LI[1], C. NICAISE[2], D. SANNIE[1], T. J. HALA[1], E. JAVED[1], J. L. PARKER[1], R. PUTATUNDA[1], K. A. REGAN[1], V. SUAIN[2], J.-P. BRION[2], F. RHODERICK[3], M. C. WRIGHT[4], D. J. POULSEN[3]
[1]Neurosci., Thomas Jefferson Univ. Med. Col., Philadelphia, PA; [2]Univ. Libre de Bruxelles, Bruxelles, Belgium; [3]Univ. of Montana, Missoula, MT; [4]Arcadia Univ., Glenside, PA

Abstract: A major portion of spinal cord injury (SCI) cases affect mid-cervical levels, the location of the phrenic motor neuron (PhMN) pool that innervates the diaphragm. While initial trauma is uncontrollable, a valuable opportunity exists in the hours-to-days following SCI for preventing PhMN loss and consequent respiratory dysfunction that occurs during secondary degeneration. One of the primary causes of secondary injury is excitotoxic cell death due to dysregulation of extracellular glutamate homeostasis. GLT1, mainly expressed by astrocytes, is responsible for the vast majority of functional uptake of extracellular glutamate in the CNS, particularly in spinal cord. We found that, in BAC-GLT1-eGFP reporter mice following unilateral mid-cervical (C4) contusion SCI, numbers of GLT1-expressing astrocytes in ventral horn and total intraspinal GLT1 protein expression were reduced early after injury and the decrease persisted for at least 6 weeks. We employed intraspinal delivery of adeno-associated virus type 8 (AAV8)-Gfa2 vector to rat cervical spinal cord ventral horn for targeting focal astrocyte GLT1 overexpression in areas of PhMN loss. Intraspinal delivery of AAV8-Gfa2-GLT1 resulted in transduction primarily of GFAP+ astrocytes that persisted for at least 6 weeks post-injury, as well as increased intraspinal GLT1 protein expression. Surprisingly, we found that astrocyte-targeted GLT1 overexpression increased lesion size, PhMN loss, phrenic nerve axonal degeneration, and diaphragm neuromuscular junction denervation, and resulted in reduced functional diaphragm innervation as assessed by phrenic nerve-diaphragm compound muscle action potential (CMAP) recordings. These results demonstrate that GLT1 overexpression via intraspinal AAV-Gfa2-GLT1 delivery exacerbates neuronal damage and increases respiratory impairment following cervical SCI.

Title: Transplantation of human iPS cell-derived astrocytes can be used as a therapeutic approach for delivering the glutamate transporter, GLT1, to injured cervical spinal cord

Authors: *A. FALNIKAR[1], K. LI[1], E. JAVED[1], T. J. HALA[1], J.-P. RICHARD[2], N. J. MARAGAKIS[2], A. C. LEPORE[1]

Abstract: Transplantation-based replacement of lost and/or dysfunctional astrocytes is a promising therapeutic approach for traumatic spinal cord injury (SCI) that has not been extensively explored, despite the integral roles played by astrocytes in the intact, injured and degenerative CNS. Induced pluripotent stem (iPS) cells are a clinically-relevant source of pluripotent cells generated from adult somatic cell types, avoiding ethical issues of embryonic stem cells. This technology also allows for homogeneous derivation of mature cell types in large quantities, potentially in an autologous fashion. Despite the promise of this approach, the iPS cell transplantation field is in its infancy with respect to evaluating *in vivo* graft integration and therapeutic usefulness in relevant SCI models. Astrocytes express the major CNS glutamate transporter, GLT1, which is responsible for the vast majority of functional glutamate uptake and plays a central role in regulating extracellular glutamate homeostasis in spinal cord. Following SCI, astrocyte loss and/or altered GLT1 expression/function can result in further susceptibility to glutamate excitotoxicity. Given these observations of GLT1 dysfunction, we evaluated intraspinal transplantation of hiPS cell-derived astrocytes into ventral horn following cervical contusion SCI as a novel therapeutic strategy for reconstituting GLT1 function. Transplant-

derived cells robustly survived for at least 5 weeks post-injection and efficiently differentiated into astrocytes in injured spinal cord of both immune suppressed mice and rats. However, the majority of transplant-derived astrocytes did not express GLT1, particularly at early time points post-injection. To enhance the ability of transplants to modulate extracellular glutamate levels, we engineered hiPS cell-derived astrocytes *in vitro* with lentivirus to overexpress GLT1. Overexpression resulted in significantly increased GLT1 protein and functional GLT1-mediated glutamate uptake levels following astrocyte differentiation *in vitro*. Following transplantation of GLT1-overexpressing cells into cervical contusion SCI, nearly all hiPS cell-derived astrocytes expressed high levels of GLT1 *in vivo*. Our findings demonstrate that hiPSA transplantation is a therapeutically-powerful and clinically-relevant approach for targeting astrocyte dysfunction in both SCI and other CNS diseases associated with astrocyte pathogenesis. Ongoing studies are aimed at determining therapeutic efficacy of these transplants for protecting respiratory motor neurons and preserving diaphragm function following cervical SCI.

Abstract: Approximately half of human traumatic spinal cord injury (SCI) cases affect cervical regions, resulting in significant and often chronic respiratory compromise. The majority of these injuries affect mid-cervical levels, the location of the important pool of phrenic motor neurons (PMNs) that innervates the diaphragm. A valuable opportunity exists in the hours-to-days following SCI for preventing PMN loss and consequent respiratory dysfunction that occurs during secondary degeneration. One of the primary causes of secondary injury is excitotoxic cell death due to dysregulation of extracellular glutamate homeostasis. Astrocytes express the major glutamate transporter, GLT1, which is responsible for the vast majority of glutamate clearance in the CNS. We find that in rodent models of unilateral mid-cervical (C4) contusion SCI, numbers of GLT1-expressing astrocytes in ventral horn and total intraspinal GLT1 protein expression are reduced soon after injury and persist for at least 6 weeks. Given these observations of GLT1 dysfunction, we aim to evaluate intraspinal transplantation of Glial-Restricted Precursors (GRPs) - a class of lineage-restricted astrocyte progenitors - into ventral horn following cervical contusion as a novel therapeutic strategy for reconstituting GLT1 function, preventing excitotoxicity, and consequently protecting PMNs. Following transplantation of GRPs derived from transgenic BAC-GLT1-eGFP promoter reporter mice, only a small percentage of transplant-derived astrocytes express GLT1 in injured spinal cord, particularly at early time points post-engraftment. To enhance the ability of transplants to modulate extracellular glutamate levels, we engineered GRPs *in vitro* with AAV8 vectors to overexpress GLT1 only in astrocytes using the astrocyte-specific GFA2 promoter. Overexpression resulted in significantly increased GLT1 protein expression and functional GLT1-mediated glutamate uptake following astrocyte differentiation *in vitro* and was restricted to only GFAP-expressing astrocytes. Following transplantation of GLT1-overexpressing cells into C4 contusion SCI, nearly all GRP-derived astrocytes expressed high levels of GLT1 *in vivo*. Compared to medium-only control and unmodified GRPs, GLT1-overexpressing transplants reduced lesion size, diaphragm neuromuscular junction denervation by PMNs, and diaphragm dysfunction. Our findings demonstrate that transplantation-based replacement of GLT1 is a promising therapeutic approach for SCI.

Abstract: Spinal cord injury (SCI) is a severely disabling neurotrauma that leads to the loss of sensory and motor function and currently affects approximately 273,000 people in the United States. Primary trauma typically sustained through contusion, compression, or laceration is exacerbated by secondary pathophysiological injury mechanisms which can significantly reduce vital sensory and motor function. Demyelination through both physical and chemical injury exposes and activates underlying juxtaparanodal K+ channels, which results in conduction block clinically observed as mobility loss in SCI victims. Functional restorative therapeutic strategies seek to reverse this pathology through application of K+ channel blockers (such as 4-AP or AMPYRA) has shown promised result. As such, 4-AP has been approved by FDA to treat multiple sclerosis (MS). In our recent investigation, we have shown that a 4-AP derivative, 4-aminopyridine-3-methanol (4-AP-3-MeOH), has a 10-fold increased potency and appears to be a new and alternative promising K+ channel blocker to treat not only MS but also SCI. Therefore, we sought to characterize and compare functional restoration of 4-AP-3-MeOH and 4-AP following SCI in both *in vitro* and *in vivo* preparation. Double sucrose gap electrophysiological recordings of complete rat spinal cord sections were employed to obtain functional data. In addition, behavioral assessments for motor function and neuropathic pain, using rotarod and mechanical allodynia tests, were also conducted. From our experiments, we showed that application of either 4-AP or 4-AP-3-MeOH significantly increased compound action potential (CAP) amplitude following mechanical and acrolein-mediated injury *in vitro*. Furthermore, motor function is significantly enhanced and neuropathic pain significantly alleviated with application of 4-AP-3-MeOH at 5 mg/kg *in vivo*. At lower concentrations, little improvement in motor function was noted for both chemicals, while 4-AP resulted in fatalities at 5 mg/kg. These results further indicate the potential for 4-AP-3-MeOH as a viable alternative for 4-AP which can overcome adverse side effects at higher and more effective dosage.

Title: Intercostal nerve-lumbar dorsal root anastomosis promotes axonal regeneration beyond a spinal cord injury

Authors: X. LIN[1,2,4], T. ZHAO[4], W. XIONG[2], S. LIN[1,4], C. WALKER[3], X. JIN[2], *X. M. XU[3], S. LIU[1]

Abstract: To promote axonal regeneration beyond a spinal cord injury (SCI), a nerve bypass strategy was conducted in adult female Sprague Dawley (SD) rats (n=24). After a right sided spinal cord hemisection was performed at the T13 level, the T11 and T12 intercostal nerves and the L2 and L3 dorsal roots were identified, isolated, and cut at their distal ends. The proximal stumps of the T11 and T12 intercostal nerves were then anastomosed to the proximal stumps of the L2 and L3 dorsal roots, respectively, on each side. At 18 weeks post-surgery, a second surgery was performed and the animals received a complete spinal transection (TX) at the previously hemisected site. Animals then received anterograde tracing of biotinylated-dextran amine (BDA, n=9), electrophysiological recordings (n=12), or retrograde tracing of Fluoro-Gold (FG) (n=5). Our results showed that: (1) the bypass promoted a significant improvement in hindlimb locomotor function assessed by Basso, Beattie, and Bresnahan (BBB) open field and contact placing scores at 6 months post-TX; (2) axons in the bypass penetrated through the dorsal root entry zoon (DREZ) of the L2-3 spinal segments, reinnervated the gray matter, and formed new synapses on host neurons; (3) regenerated axons were originated from motoneurons of the T11-12 segments above the TX; and (4) new functional circuit was established across the lesion gap, evidenced by electrophysiological recordings. Thus, our results provide strong evidence for a novel bypass strategy that leads to anatomical regeneration and functional recovery in a complete spinal cord transection model. Further investigation will be required to dissect out the mechanisms underlying plasticity and specificity of reinnervation in this model.

Title: Microtubule stabilization therapy promotes breathing outcomes after cervical spinal cord injury

Authors: *K. C. HOY[1], F. BRADKE[2], W. ALILAIN[1]
[1]Neurol., Metrohealth Med. Ctr., Cleveland, OH; [2]DZNE, Bonn, Germany

Abstract: More than half of all spinal cord injuries (SCI) are at the cervical level. These injuries can result in the disruption of the respiratory motor pathways leading to the innervation of the diaphragm, resulting in the need for mechanical ventilation. To examine the neuronal circuitry involved in cervical SCI and potential interventions, our laboratory utilizes a C2 lateral hemisection. This model induces paralysis of the hemi-diaphragm ipsilateral to the hemisection. By leaving one side of the diaphragm still active, this model allows us to examine the breathing circuitry affected and spared by cervical SCI without the need for mechanical ventilation of experimental subjects. A recent investigation has shown that the microtubule stabilizer paclitaxel (Taxol) can improve outcomes in thoracic injury. In the thoracic injury model, paclitaxel has been shown to reduce the perineuronal (PNN) net and increase serotonin (5-HT) after injury. However, its application in cervical injury is untested. Taken together, our central hypothesis is that microtubule stabilization will promote respiratory motor recovery after cervical spinal cord injury by 1) decreasing inhibition by reducing the PNN and 2) increasing 5-HT expression and sprouting after cervical injury. Here we examined the role of paclitaxel on the recovery of breathing after a C2 spinal hemisection. Subjects received various doses of paclitaxel for 6 weeks after injury. For recovery ventilation and diaphragmatic electromyographical (EMG) activity was assessed. Preliminary data indicate that cervical SCI subjects that receive Taxol have improved respiratory motor function compared to vehicle treated animals.

Title: Modulation of the pten/mtor pathway rescues respiratory motor function after cervical contusion injury

Authors: *D. V. GUTIERREZ, W. J. ALILAIN
NEUROSCIENCE, METROHEALTH MEDICAL CENTER, CLEVELAND, OH

Abstract: Cervical spinal cord injuries (SCI) can disrupt the descending bulbospinal fibers originating from the medullary rostral ventral respiratory group (rVRG) and which innervate phrenic motor neurons (PMNs; located C3-C6). Injuries at this level are quite significant and often result in diaphragm paralysis leading to mechanical ventilation to support breathing and survival. These patients have a diminished quality of life. Given that current regenerative therapies do not completely restore motor function, gaining a more comprehensive understanding of the cellular mechanisms that influence plasticity and recovery in the injured spinal cord is crucial to the development of novel treatment interventions. An ideal strategy would target intrinsic factors known to initiate synaptic plasticity, promote an enhanced regenerative environment and augment the sprouting of spared pathways. One key signaling component in axonal regeneration is phosphatase and tensin homolog (PTEN). Deletion of PTEN can robustly enhance axonal regeneration through the upregulation of mTOR and phosphorylated S6. Furthermore, deletion of PTEN and upregulation of mTOR leads to enhanced neurotransmission. The present study seeks to determine the functional outcome of pharmacologically modulating PTEN activity after a high cervical lesion. Specifically, adult rodents underwent a C3/4 unilateral contusion model of SCI and were treated with bisperoxovanadium (bpV[pic]) to inhibit PTEN. Animals were then exposed to a delayed (3 weeks post contusion) contralateral C2 hemisection to directly investigate treatment efficacy on spared and injured pathways. We hypothesize that inhibiting PTEN after cervical contusion will enhance the regeneration and sprouting of injured rVRG axons, improve neurotransmission, and augment phrenic motor neuron dendritic arborization. Futhermore, this plasticity will support the rescue of respiratory motor function. Excitingly, data obtained from diaphragm electromyogram (EMG) recordings revealed that bpV[pic] treatment significantly influenced the length of breathing time and frequency post-hemisection. Additionally, bpV[pic] therapy bilaterally enhanced the overall breathing amplitude. Improvements in breathing output were not present in saline treated animals. The

results obtained thus far suggest that bpV[pic] mediated modulation of the PTEN/mTOR pathway rescues the ability to breathe after cervical SCI by making injured pathways more efficacious and repairing the injured SC.

Title: Extensive recovery of respiratory motor function at chronic and super-chronic time points following cervical spinal cord injury

Authors: *P. M. WARREN[1], P. M. MACFARLANE[2], J. SILVER[3], W. J. ALILAIN[1]
[1]Dept. of Neurosci., Metrohealth Med. Centre, Case Western Reserve Univ. Sch. of Med., Cleveland, OH; [2]Dept. of Paediatrics, [3]Dept. of Neurosci., Case Western Reserve Univ., Cleveland, OH

Abstract: Treatments to restore respiratory function following chronic cervical spinal cord injury (SCI) have not been extensively studied. We provide evidence that a pharmacological agent and rehabilitative training may provide the key for recovery of diaphragm activity following chronic trauma. The ablation of respiratory function is caused by disruption of motoneuron pathways, formation of the chondroitin sulphate proteoglycan (CSPG) rich astroglial scar, and a reduction in interneuron, motoneuron and synaptic density. Following acute cervical SCI, CSPG breakdown by application of chrondroitiase ABC (ChABC) can restore functional diaphragm activity while intermittent hypoxia (IH) training increases respiratory drive and synaptic strength. We now provide evidence for the recovery of robust functional respiratory motor activity at both chronic (3 month) and super-chronic (1.5 year) time points following LC2H through a combination of IH training and ChABC. We used diaphragmatic electromyography (diaEMG) and phrenic nerve recordings to demonstrate that a single

application of ChABC (0.005U) can recover extensive respiratory motor function following chronic and super-chronic SCI. Control treated animals showed no endogenous recovery of diaphragm function. While having limited effect upon diaEMG patterns, IH training alone was shown to enhance maximal phrenic nerve activity. However, the combined treatment of IH and ChABC was shown to substantially enhance diaEMG and maximal phrenic nerve activity beyond that demonstrated by either group alone. Interestingly, in a subpopulation of animals the muscle activity in this combination group can become unstructured, degrading patterned activity on the lesioned side. This tonic/chaotic activity is governed by a serotonergic (5-HT) mechanism and suggests considerable remodeling of spinal cord circuitry below the level of the lesion at chronic stages. Indeed, ChABC and IH treated animals which recover normal breathing patterns following treatment can be made chaotic by giving exogenous 5-HT, while those that are already chaotic can be normalized by blocking certain 5-HT receptors. These data demonstrate the significant restoration of diaphragm function and nerve activity at chronic and super-chronic time points following cervical SCI due to matrix modification, induction of plasticity and facilitation of drive. Yet, the potential emergence of chaos is indicative of the complications inherent in repairing the chronically injured spinal cord and suggest the need for tight mechanistic and environmental control.

Title: The neuroprotective effects of co-ultraPEALut in a mouse model of spinal cord injury

Authors: I. PATERNITI[1], D. IMPELLIZZERI[1], R. CRUPI[1], G. BRUSCHETTA[1], E. ESPOSITO[1], S. CUZZOCREA[1], *J. V. PRIESTLEY[2]
[1]Dept. of Biol. and Envrn. Sci., Univ. of Messina, Messina, Italy; [2]Neurosci Ctr., Queen Mary Univ. of London, London, United Kingdom

Abstract: Traumatic injuries to the spinal cord frequently cause permanent neurological disabilities and yet there is no effective therapeutic option to improve functional recovery. Spinal cord injury (SCI) is well-known to induce the formation of reactive astrocytes and the infiltration

of immune cells in the area of the lesion site, but whether SCI also induces the production of new neurons *in vivo* remains controversial. Neurogenesis has been described in various regions of the central nervous system. Significant spontaneous neuroplasticity occurs over the weeks and months following brain or spinal cord trauma leading to some functional recovery. Moreover, studies have shown that spinal neurogenesis occurs to a limited extent after SCI, but that it could be stimulated by experimental intervention. In that regard, in a recent study, we have demonstrated that treatment with a new composite, a formulation including palmitoylethanolamide (PEA) and the antioxidant compound luteolin (Lut), subjected to an ultramicronization process, co-ultraPEALut, significantly reduced inflammatory secondary damage associated with SCI. Thus, the aim of this study was to investigate the neuroprotective effect of co-ultraPEALut in the injury-induced neurogenesis in a mouse model of SCI. Materials and Methods: SCI was induced in mice through spinal cord compression by the application of vascular clips (force of 24 g) to the dura via a four-level T5 to T8 laminectomy. The animals were sacrificed and the spinal cord were collected. Results: Chronic exogenous administration of co-ultraPEALut increased bromodeoxyuridine (BrdU) and doublecortin immunoreactive cells in the spinal cord of SCI subjected mice. This neuronal development was correlated with synaptic plasticity, identified using the Golgi impregnation method to quantify dendritic spines in spinal cord. In addition, co-ultraPEALut treatment also increased the expression of different neurotrophic factors such as brain-derived neurotrophic factor (BDNF), glial cell-derived neurotrophic factor (GDNF), nerve growth factor (NGF) and neurotrophin-3 (NT-3). Conclusions: The results indicate that co-ultraPEALut could have a role on birth, survival, and differentiation of new neurons and maturation of spines in the spinal cord and could be a therapeutic target in traumatic diseases.

Title: Development of combinatorial, biomaterial-mediated gene therapies for spinal cord tissue regeneration

Authors: *S. SEIDLITS[1,2], R. BOEHLER[2], A. THOMAS[2], D. SMITH[2], D. MARGUL[2], T. KUKUSHLIEV[2], T. HE[2], D. MCCREEDY[2], A. GOODMAN[2], D. HASSANI[2], B. CUMMINGS[3], A. ANDERSON[3], L. SHEA[2]

Abstract: The local environment after spinal cord injury (SCI) lacks cues support axon growth, cell survival, and remyelination and exhibits an abundance of cues that inhibit these processes. Development of clinically effective strategies to restore tissue function after SCI will require consideration of multiple aspects of this inhibitory environment. The goal of this research is to develop a multifaceted gene therapy for spinal cord injury repair that delivers vectors encoding for growth factor cues that enhance cell survival, reduce inflammation, prevent glial scar formation and promote axonal growth and remyelination. For these studies, porous biomaterials fabricated from poly(lactide-co-glycolide) (PLG) were used as a platform for tandem, localized delivery of lentiviral vectors encoding for multiple regenerative factors, including sonic hedgehog (SHH), neurotrophin-3 (NT-3), chondroitinase and interleukin-10. Previously, we have reported that porous bridges with a defined channel architecture that significantly encourage axons to regenerate across the injury site and can be used to deliver lentiviral vectors. This research builds upon the success of these bridges by adding a gene delivery component to enable localized, sustained expression of multiple factors designed to simultaneously address different barriers to spinal cord regeneration. Moreover, these factors were selected to target various barriers to spinal cord regeneration. First, we report that delivery of lentivirus encoding for interleukin-10 (IL10) significantly reduces the presence of specific inflammatory cells thought to be detrimental to repair. In addition, we demonstrate that tandem delivery of sonic hedgehog (SHH) and neurotrophin-3 (NT-3) resulted in significant increases in the number of regenerated axons through the bridge platforms and myelination of these axons by oligodendrocytes. Although PLG biomaterials are useful as an investigational platform for identifying clinically relevant gene therapy targets *in vivo*, they require that sections of spinal cord be removed prior to implantation and do not adequately resemble the native tissue. As a clinically viable alternative, we are also investigating the use of hydrogel biomaterials based on hyaluronic acid, which is abundant in the extracellular matrix of the uninjured spinal cord and down-regulates the inflammatory response after injury for their ability to mediate SCI repair.

Title: Agmatine modulates the phenotype of macrophage after spinal cord injury

Authors: *J. KIM[1], J. PARK[1,2], K. PARK[1], W. LEE[1], J. LEE[1,2]
[1]Dept. of Anat., [2]BK21 Plus Project for Med. Sci. and Brain Res. Inst., Yonsei Univ. Col. of Med., Seoul, Korea, Republic of

Abstract: Agmatine is a decarboxylated arginine by arginine decarboxylase (ADC). Agmatine has been known as a neuroprotective agent. It has been reported that agmatine work in many kinds of CNS injuries as a NMDA receptor blocker or a competitive nitric oxide synthase (NOS) inhibitor. In spinal cord injury, agmatine showed reduction of neuropathic pain, improvement of locomotor function, and neuroprotection. Macrophage is a key cellular component in neuroinflammation, a major cause of impairment after spinal cord injury. Macrophage has subtypes, M1 and M2 macrophages. M1 macrophage induces pro-inflammatory response but M2 inspires anti-inflammatory response. In this study, it is clarified whether neuroprotective effect of agmatine is related with the modulation of macrophage subdivision after spinal cord injury. Spinal cord injury was induced in SD rats with 25.0 gCm contusion by MASCIS. Animals received agmatine (100mg/kg/day, IP) for 1 week after spinal cord injury. The proportion of M1 and M2 macrophages in the epicenter of injury are confirmed with immunohistochemistry. iNOS +/CD68+ cells were counted as M1 macrophages and CD206+/CD68+ cells as M2 macrophages. The treatment of agmatine increased CD206 expression. These results suggested that agmatine reduce impairment after spinal cord injury through modulating the phenotype of macrophage from M1 to M2 macrophage.

Title: Promoting human induced pluripotent stem cell-derived oligodendrocyte precursor cell survival after transplantation into the injured spinal cord with hydrogels

Authors: T. FUEHRMANN[1], B. BALLARIN[1], I. E. DONAGHUE[1], R. TAM[1], B. COLES[1], D. VAN DER KOOY[1], C. MORSHEAD[1], A. NAGY[3], C. TATOR[4], *M. S. SHOICHET[2]
[1]Donnelly Ctr. for Cell. and Biomolecular Res., [2]Chem. Engin. and Applied Chem., Univ. of Toronto, Toronto, ON, Canada; [3]Samuel Lunenfeld Res. Inst., Mount Sinai Hosp., Toronto, ON, Canada; [4]Krembil Neurosci. Ctr., Toronto Western Hosp., Toronto, ON, Canada

Abstract: Introduction: Traumatic spinal cord injury (SCI) is a devastating condition, leading to severe, and often permanent, motor, sensory and autonomic disturbances, associated with a poor prognosis. The lack of functional improvements is not primarily due to an inherent lack of capacity for regeneration, but rather to the overall balance of growth promoting and growth inhibitory molecules. Since remyelination of spared, demyelinated axons after spinal cord injury has the potential to preserve functional pathways and improve function we are investigating the hypothesis that implanted human induced pluripotent stem cell-derived oligodendrocyte precursor cells (hOPCs), a potentially autologous source, will promote functional tissue repair in an experimental animal model of SCI. However, cell replacement strategies rely on the long term

survival and integration of the cells upon transplantation, which is limited with current methods. Therefore, we designed a minimally invasive injectable cell-delivery system comprised of hyaluronan and methylcellulose (HAMC) aimed to enhance the survival and integration of grafted cells, which may lead to greater beneficial effects. **Methods:** Human iPS cells were differentiated into oligodendrocyte precursor cells using purmorphamine, T3, NT-3 and PDGF. T2 vertebra of adult female rats was exposed and compressed with a modified aneurism clip (24g) for 1 minute. One week post operation, animals received transplants of hOPCs with and without HAMC at 4 sites rostral and caudal to the lesion (total volume 8 µl; 10.000 cells / µl). **Results:** Human induced pluripotent stem cells were differentiated into oligodendrocyte precursor cells (hOPCs) as shown by their expression of OLIG2, NKX2.2, SOX10, and PDGF-receptor alpha using RT-PCR, flow cytometry and immunocytochemistry. Surviving cells were found at the injury/injection site 7 days after transplantation (14 days after injury), but only when transplanted in HAMC. The surviving hOPCs expressed SOX10, a marker for oligodendrocytes and oligodendrocyte precursor cells. No surviving cells were found in animals receiving hOPCs in media. **Conclusion:** These data indicate the feasibility of our approach to promote graft cell survival with hydrogels. Cell survival is being correlated with functional repair in ongoing studies using a modified hydrogel and greater cell numbers.

Title: The effects of the combination treatment of keratan sulfate digestion and rehabilitation in rat spinal cord injury

Authors: *Y. ISHIKAWA[1], S. IMAGAMA[1], Z. ITO[1], K. ANDO[1], N. ISHIGURO[1], K. KADOMATSU[2]
[1]Dept. of Orthopedic Surgery,, [2]Dept. of Biochem, Nagoya Univ. Sch. of Med., Nagoya / Aichi, Japan

Abstract: Various treatments have been used to overcome the neurological dysfunctions and inhibitory mechanisms resulting from spinal cord injury (SCI). Single-agent treatments used in previous studies did not result in recovery after SCI in most cases. Recently, a number of reports have suggested that combination therapies are more effective. The combination of Chondroitinase ABC (ChABC) and rehabilitation is an effective therapy that promotes plasticity and functional recovery. Our previous study showed that Keratanase II (K-II), a keratan sulfate (KS) digestion enzyme, and ChABC exert comparable effects on SCI. No studies have examined the combination treatment of K-II and rehabilitation. The purpose of this study was to evaluate the effects of this combination treatment on SCI. First, we examined the localization of KS in adult Sprague Dawley (SD) rats. BCD4-positive KS surrounded neurons and colocalized with components of the perineuronal nets (PNN). Second, to establish how K-II affects the PNN, we examined sections treated with K-II and confirmed the disappearance of KS that was colocalized with the PNN. Next, SD rats received a SCI at C3/4 and treatment with K-II, C-ABC, or saline with or without forearm training. Their recovery from SCI was evaluated by behavioral and histological assessments. In each of the treated groups, animals receiving training had a significantly improved recovery rate from SCI compared to those without training (K-II + training: 66.5%, K-II + no training: 38.9%, chABC + training: 65.2%, chABC + no training: 36.5%, saline + training: 53.4%, saline + no training: 26.0%). However, the combination of K-II or chABC with training did not result in significantly better recovery rates for fine motor skills compared to combination of saline and training. Histologically, 5-HT/GAP43 positive fibers rostral to the lesion site were counted as 5HT/GAP43-positive pixels. In each treatment group, rats that received training had significantly larger positive pixel areas than those with no training. For both 5HT and GAP43, rats receiving K-II or ChABC with training showed pixel areas that were twice that of rats receiving saline with training. These results suggest that combination of K-II or ChABC with training promotes more axon sprouting/regeneration compared to training only. These results suggest that combination of K-II or ChABC with training promotes more axon sprouting/regeneration compared to training only. These robust regrown axons did not contribute to the behavioral changes. Hence, other experimental conditions such as the timing of K-II treatment or evaluation needs consideration.

Title: Enhanced axon regeneration with combined exercise and peripheral nerve grafts after acute and chronic spinal cord injury

Authors: *C. C. THEISEN, V. NINAN, C. SZE, S. AUSTIN, J. D. HOULE
Neurobio. & Anat., Drexel Univ. Col. of Med., Philadelphia, PA

Abstract: Exercise (Ex) of rats after spinal cord injury (SCI) leads to increased levels of intraspinal neurotrophic factors and increased levels of cFos and phospho-S6 in interneurons of thoracic and lumbar spinal cord. Intraspinal peripheral nerve grafts (PNGs) provide a hospitable environment for axon regeneration through or around a lesion site. Here we provide evidence that Ex increases the number and distribution of propriospinal neurons that regenerate their ascending or descending axon into a graft. Adult female Sprague Dawley rats received a thoracic level 12 complete transection injury and either acute PNGs at the time of injury or delayed PNGs 6 weeks after SCI. Groups of rats received 4-5 weeks of cycling exercise, which began 5 days after SCI for the acute PNG group and either 5 days or 5 weeks after SCI for the chronic PNG groups. Control rats received PNGs but no exercise. Five weeks after grafting, the distal ends of PNGs were exposed to True Blue (TB) to retrogradely label neurons that regenerated their axon into the graft. One week later, Ex and control rats were perfused and the brain, spinal cord and lumbar dorsal root ganglia (DRGs) were harvested and sectioned in serial order. In rats receiving acute PNGs, the number and location of TB+ neurons relative to the lesion site was recorded. In acute PNG Ex rats there were significantly more (> 2 fold increase) TB+ neurons close to (within 5mm of) the injury/graft sites, a 3-fold increase in TB+ neurons in the thoracic cord, and a 9-fold increase in TB+ neurons in the lumbar cord caudal to the injury. There was no significant effect of Ex on regeneration by peripheral sensory neurons (DRGs). The effect of Ex on regeneration by chronically injured neurons is under study. This demonstration of exercise-dependent plasticity and regeneration by propriospinal or interneurons provides evidence of a reproducible, non-invasive therapeutic treatment that may be useful in promoting structural and functional recovery after SCI. Whether Ex leads to enhanced axonal outgrowth beyond the PNGs remains to be demonstrated.

Abstract: Cavity formation after spinal cord injury (SCI) is one of the major obstacles for axonal regeneration since injured axons fail to reach caudal tissue in the absence of physical and mechanical support from extracellular matrix (ECM). Implanting artificial scaffolds has been considered as a promising approach, but successful bridging with scaffolding biomaterials has not been convincingly demonstrated in contusive SCI model, which closely mimics human SCI. Unpredictable and irregular geometry of lesion cavities formed in this model would necessitate the use of injectable hydrogel for this purpose. In the present study, we injected temperature sensitive poly(phosphazene) hydrogel, with a sol-gel transition behavior at 37°C, into the lesion epicenter in contusive rat SCI model at 2 week after injury. The hydrogel injection almost completely prevented cavity formation. In animals with the hydrogel injection, the lesion epicenter was replaced by fibronectin-enriched ECM by 4 weeks after the injection. The fibronectin positive ECM was surrounded by GFAP positive glial scars with an interface laden with chondroitin sulfate proteoglycans. Injection of hydrogel mixed with Taxol, which was previously reported to selectively suppress fibrotic scars, resulted in the failure of bridging cavities, suggesting a role of ECM produced by fibroblasts in the hydrogel effects. Interestingly, zymography showed upregulation of MMP-9 activity in animals with the hydrogel injection, and MMP-9 was highly expressed at the center of the fibronectin enriched ECM. The cellular source for the MMP-9 immunoreactivity was CD11b positive macrophages. Our study convincingly demonstrates that the poly(phosphazene) hydrogel successfully bridges lesion cavities in contusive SCI model. Modulation of the molecular environment in the newly generated ECM may lead to successful axonal regeneration through the hydrogel-induced bridge.

Title: Enbrel treatment promotes transplanted donor human mesenchymal precursor cell survival following spinal cord injury

Authors: S. J. LOVETT[1], A. R. HARVEY[1], G. W. PLANT[2], *S. I. HODGETTS[1]

Abstract: Immediately following spinal cord injury (SCI), pro-inflammatory cytokines such as tumour necrosis factor alpha (TNFα) and interleukins 1β and 6 are released from damaged cells and resident cells of the spinal cord. This cytokine release initiates the inflammatory response to injury and is responsible for the extensive and persistent spread of secondary damage following SCI. The activation and infiltration of immune cells into the spinal cord contributes to secondary degeneration with an increase in apoptosis of neurons and glia, demyelination of intact axons and cyst formation at the injury site. We have previously shown marked improvements in functional (locomotor) and morphological (tissue sparing, cyst size) outcomes in host tissue following transplantation of adult human mesenchymal precursor cells (hMPCs) into the contused spinal cord. However, donor hMPCs do not survive beyond 4 weeks post transplantation, most likely due to the host immune response. Improving donor hMPC survival (past 4 weeks) may promote further beneficial morphological and functional (locomotor) effects of hMPC therapy. Modulating pro-inflammatory cytokine levels immediately following SCI may attenuate the immune response, reduce immune cell activation and promote neuroprotective effects following injury. By combining the TNFα antagonist Enbrel with hMPC transplantation our aim is to reduce the activity of TNFα immediately following SCI thereby reducing the amount of secondary degeneration and promoting prolonged survival of transplanted hMPCs. Initial data analysis shows that Enbrel treatment improved donor cell survival in all Enbrel + hMPC treated animals, with hMPCs present in the spinal cord at 4 weeks post-transplantation (c.f. two thirds of hMPC only treated animals). Although transplanted hMPC survival was increased, there were no statistically significant improvements in functional recovery at 5 weeks post-injury for any treatment groups. Also, combined Enbrel + hMPC treatment did not further reduce cyst size compared to hMPC transplantation alone. Extended time points are currently being evaluated to assess the effects of Enbrel treatment on long-term donor hMPC survival. Enbrel may have a

moderate impact on SCI repair alone, but may be useful in combinatorial clinical applications to enhance donor stem cell survival in transplantation based therapies.

Title: Treatment with ketone bodies preserves mitochondrial function and reduces oxidative stress following contusion spinal cord injury

Authors: *S. P. PATEL[1], J. L. VANROOYEN[2], N. P. VISAVADIYA[1], T. L. SMITH[1], P. G. SULLIVAN[3], A. G. RABCHEVSKY[2]

Abstract: The prophylactic ketogenic diet (KD) has been shown to be a neuroprotective strategy clinically, as well as experimentally, for several neurological disorders and traumatic brain injuries, which all show that mitochondrial dysfunction is a pivotal therapeutic target. The KD is comprised of high fat and low carbohydrates to mimic the effects of fasting which increases serum levels of ketone bodies, notably β-hydroxybutyrate (BHB), acetoacetate, and acetone due to the breakdown of fatty acids in mitochondria. Accordingly, we hypothesized that administration of BHB will maintain mitochondrial function, increase tissue sparing and improve hindlimb functional recovery after contusion spinal cord injury (SCI). The current study assessed the effects of BHB treatment on mitochondrial bioenergetics and markers of oxidative stress following contusion SCI. Injured rats (250 kdyn at L1/L2 spinal level) were administered Vehicle (saline) or BHB (0.415 or 0.83 or 1.66 mmols/kg body weight, i.p.) 15 min post-injury followed by immediate insertion of an osmotic mini-pump (s.c.) to deliver Vehicle or BHB (0.415 or 0.83 or 1.66 mmols/kg body weight/day.) for 24hrs. A Sham group received only a T12

laminectomy. At 24hr post-injury, Ficoll purified mitochondria were isolated from spinal cord tissue (1.5cm centered on injury site) and assessed for mitochondrial oxygen consumption rate (OCR) using Seahorse Bioscience XFe24 extracellular flux analyzer. Levels of oxidative stress markers including Protein Carbonyls (PC), 4-Hydroxynonenal (4-HNE), and 3-nitrotyrosine (3-NT) were assessed using slot blot. Results showed significantly decreased OCR in Vehicle-treated injured group compared to Sham. Treatment with 0.83mmol BHB significantly preserved mitochondria OCR near Sham levels, whereas 0.415 and 1.66 mmol BHB dosages were not effective. Levels of PC, 4-HNE and 3-NT were significantly increased after SCI. Treatment with BHB reduced PC levels but not 4-HNE or 3-NT. On-going experiments are assessing the effects of BHB treatment on activity of key mitochondrial enzyme complexes and glutathione levels at 24 hr post-injury, as well as long-term tissue sparing and recovery of hindlimb function following SCI.

Title: Intravenous multipotent adult progenitor cell treatment for acute spinal cord injury: promoting recovery through immune modulation

Authors: *M. A. DEPAUL[1], S. A. BUSCH[2], M. PALMER[2], J. A. HAMILTON[2], R. CUTRONE2[2], B. LANG[1], A. E. TING[2], R. J. DEANS[2], R. W. MAYS[2], J. SILVER[1]

Abstract: Adult bone marrow derived stem cells are known to have immunomodulatory capabilities, but their potential to alter inflammatory processes and promote regeneration after spinal cord injury (SCI) has not been thoroughly studied. In this study, we sought to determine

the optimal window of administration, dosing, and the biodistribution of human multipotent adult progenitor cells (MAPCs) in a contusion model (250 kdyn Infinite Horizon impactor injury at T8). MAPCs are the research grade variant of the clinical grade MultiStem® product currently in clinical evaluation for treatment of ischemic stroke. Rats received saline or $4x10^6$ cells via iv injection immediately following or 1 day post injury (DPI). We performed locomotor testing through 10 weeks post injury (WPI) and found significant and sustained improvements in BBB scores, subscores, and the Catwalk regularity index. We monitored urination every two weeks using metabolic cages and found the void volume significantly reduced 10 WPI in cell treated animals. At the study endpoint, rats underwent urodynamic assessment. Bursting activity of the external urethral sphincter was seen in correlation with a void in several treated animals, whereas in untreated animals bursting was rare, sporadic, and uncoordinated. Treated animals urinated at a smaller bladder volume, had less residual volume, showed improved return to baseline pressure following a void, and had a decrease in bladder weight. Increasing the dose to $8x10^6$ cells showed no increase in locomotor recovery, but did improve bladder function. Cell distribution was determined using CryoViz technology by iv infusing Qdot-labeled MAPCs into either SCI or laminectomy control animals 1 DPI. Lungs, liver, spleen, and spine were collected 24 or 48 hours after treatment. MAPCs were found in the lungs, liver, and spleen at 24 hours, amounting to <5% of administered cells, and cell numbers decreased at 48 hours. Normalizing cell counts to tissue weight showed a preferential homing to the spleen, while few cells were found in the spinal column. Microarray analysis of the lesion, blood, and spleen suggests MAPCs alter many injury-induced pathways including those involved in recruitment, activation and migration of immune cells. In support of this data, we found a decrease of $ED1^+$ macrophages at the lesion site 4 DPI in treated animals. These data suggest that MAPCs, when administered iv in an acute model of SCI, are more likely to exert benefit through peripheral organ systems than via homing and direct interaction with the site of injury.

Title: Promoting neuroplasticity after spinal cord injury by over-expressing polysialic acid

Authors: *L. ADAMS, Y. ZHANG, P. K. YIP, A. T. MICHAEL-TITUS, J. V. PRIESTLEY, X. BO
Barts and The London Sch. of Med. and Dent., Ctr. For Neurosci. and Trauma, London, United Kingdom

Abstract: Some neuronal populations are surrounded by a dense extracellular matrix structure known as the perineuronal net (PNN). Formed during the late stages of postnatal development, the PNN contains a high proportion of chondroitin sulphate proteoglycans (CSPGs), molecules that exert a strong inhibitory effect on neuroplasticity. CSPGs are up-regulated following spinal cord injury and the PNN is believed to be partly responsible for the poor behavioural recovery observed in this condition. Unpublished data from our laboratory suggests there is an inverse relationship between the PNN and polysialic acid (PSA), a sugar molecule found almost exclusively bound to the neural cell adhesion molecule. We have noted that the development of the PNN coincides with the down-regulation of PSA, from which we propose that PSA may restrict the formation of the PNN *in vivo*. The aim of the present study is to further examine the relationship between PSA and the PNN and to investigate the use of PSA as a plasticity-promoting therapy for spinal cord injury. Adult rats were injected with a lentiviral vector carrying the cDNA for the polysialyltransferase gene (LV/PST) into the sensorimotor cortex. In a separate experiment, adult rats received an injection of LV/PST into the cervical spinal cord. Strong PSA immunolabelling could be detected surrounding the injection site 2, 4 and 6 weeks post-injection in animals injected with LV/PST. Preliminary histological analysis shows that Wisteria floribunda agglutinin lectin (WFA)-PNN immunolabelling is reduced or absent around neurons transduced by LV/PST. We believe this is due to a reduction in WFA binding to its site within the PNN. To see whether this treatment can cause any behavioural improvements following spinal cord injury, adult rats were given a C5 hemisection lesion. Rats received two injections of LV/PST or the control virus LV/GFP rostral and caudal to the lesion between C4 and C7 and forelimb function was monitored for six weeks. Sprouting of corticospinal axons to or across the lesion site and the formation of new neural circuits with the surviving interneurons or spinal motor neurons, along with improved functional recovery, will be examined.

Title: Local and sustained delivery of growth factor mediates spinal learning after injury

Authors: *Z. Z. KHAING[1], J. H. PARK[2], J. W. GRAU[3], K. H. LEE[3], A. NIEMERSKI[3], C. E. SCHMIDT[1]

Abstract: Damaged axons in the adult mammalian central nervous system (CNS), including those of the spinal cord, do not regenerate spontaneously. This is the result of both intrinsic and extrinsic inhibitory factors that limit the regeneration of adult neurons. Even after the removal of extrinsic inhibitory components, regeneration of adult neurons is still limited. Therefore, additional factors that can further enhance the intrinsic plasticity of the adult neurons are need. To this end, we developed a highly versatile biomaterial platform for sustained, localized delivery of brain-derived neurotrophic factor (BDNF). Using injectable hydrogel in combination with microparticles, we intend to deliver BDNF in order to improve neuronal regeneration. We hypothesize that BDNF from the hydrogels will release first, followed by BDNF release from microparticles. A physical blend of hyaluronic acid (HA) and methylcellulose (MC) was used to produce a thermally gelling hydrogel. We determined that HAMC hydrogels (1.5% HA, 7% MC) degraded by 7 days (n=5 gels at each time points) and their compressive modulus is within the range to that of adult rodent spinal cord tissue (~800 Pa). We loaded HAMC hydrogels with BDNF and determined the therapeutic dose released using ELISAs and found that over 70% of the encapsulated BDNF was by 12 hrs *ex vivo*. Currently, these hydrogels are being further refined using rheological analyses, degradation and BDNF release studies. For our secondary release mechanism, a FDA approved, degradable synthetic polymer poly-lactic-co-glycolic acid (PLGA) was used. To promote sustained delivery, microparticles with a range of sizes (5 - 40 μm) have been produced. Moreover, we applied BDNF, a growth factor with known beneficial effects following spinal cord injury (SCI), locally to the injured spinal cord using HAMC hydrogels. We found spinal mediated learning in HAMC loaded with BDNF while the learning
