Title: Local environment shapes phenotypic variations of hippocampal and neocortical chandelier cells

Authors: *H. TANIGUCHI, Y. ISHINO, M. J. YETMAN, S. M. SOSSI, A. STEINECKE, Y. HAYANO

Max Planck Florida Inst., Jupiter, FL

Abstract: Different cortical regions processing distinct information, such as the hippocampus and the neocortex, share common cellular components and circuit motifs but form unique networks by modifying these cardinal units. Cortical circuits include diverse types of GABAergic interneurons (INs) that shape activity of excitatory principal neurons (PNs). Canonical IN types conserved across distinct cortical regions have been defined by their morphological, electrophysiological, and neurochemical properties. However, it remains largely unknown whether canonical IN types undergo specific modifications in distinct cortical regions and display "regional variants". It is also poorly understood whether such phenotypic variations are shaped by early specification or regional cellular environment. The chandelier cell (ChC) is a highly stereotyped IN type, which innervates axon initial segments of PNs, and thus serves as a good model to address this issue. Here we show that Cadherin-6 (Cdh6), a homophilic cell adhesion molecule, is a reliable marker of ChCs and Cdh6-CreER mice provide genetic access to hippocampal ChCs (h-ChCs). We demonstrate that compared to neocortical ChCs (nc-ChCs), h-ChCs cover twice as much area and innervate twice as many PNs. Interestingly, a subclass of h-ChCs exhibits calretinin (CR) expression, which is not found in nc-ChCs. Furthermore, we find that h-ChCs appear to be born earlier than nc-ChCs. Surprisingly, despite the difference in temporal origins, ChCs display host region-dependent axonal/synaptic organization and CR expression when heterotopically transplanted. These results suggest that local cellular environment plays a critical role in shaping terminal phenotypes of regional IN variants in the hippocampus and the neocortex.

Title: Cell lineage progression in the adult hippocampus revisited: Evidence of progenitor transdifferentiation

Authors: *D. S. MOURA¹, C. M. QUEIROZ², M. R. COSTA²

¹Brain Institute-Ufrn, Natal, Brazil; ²Brain Inst., Univ. Federal do Rio Grande do Norte, Natal, Brazil

Abstract: Cell lineage in the adult hippocampus comprises multipotent (Type 1 and 2a) and neuron-determined (Type 2b and 3) progenitors. The current model assumes that multipotent stem cells generate neuron-determined intermediate progenitors that become post-mitotic neurons in a unidirectional way. In the present work, we fate-mapped neuronal progenitors using Dcx-CreERT2 and CAG-CAT-EGFP double-transgenic mice, hereafter referred to as cDCX/EGFP. We show that three days after tamoxifen-mediated recombination in cDCX/EGFP adult mice, virtually all GFP+ cells in the dentate gyrus co-expresses DCX. However, within 30 days, about 15% of GFP+ cells become GFAP+ astrocytes. These data suggest that Type 2b/3 DCX+ progenitors either retain the capacity to generate astrocytes or can regress to more primitive stages (Type 2a or 1). To evaluate these possibilities, we boosted neurogenesis in the dentate gyrus by local administration of epileptogenic drugs. Intrahippocampal injection of kainic acid (KA) led to a significant increase in the number of GFP+ cells in both ipsi and contralateral dentate gyrus. Remarkably, in the ipsilateral dentate gyrus, most GFP+ cells adopted glial morphologies and expressed the astrocytic protein GFAP. Conversely, on the contralateral side, GFP+ cells differentiated mainly into granular neurons. Intriguingly, at early time-points after recombination, we observed a small number of unexpected labeled cells displaying radial-glia morphology, a hallmark of Type 1 multipotent progenitors, suggesting that some type2b progenitors transdifferentiated. Intrahippocampal injection of pilocarpine also leads to an important increase in the number of GFP+ cells in both ipsi and contralateral dentate gyrus, but the vast majority of cells differentiate into neurons. Importantly, both drugs were able to bilaterally elicit paroxysms, high-amplitude discharges and seizures. Altogether, these results indicate that Type 2b/3 progenitors are not restricted to the generation of neurons, but rather retain bi-potency and/or the ability to return to more primitive stages in the lineage and generate astrocytes. Under basal conditions, generation of astrocytes represents a small fraction of newly generated cells in the adult hippocampus, but under pathological conditions, this proportion can

be massively altered. Finally, these observations also suggest that the drug used to model temporal lobe epilepsy differentially affects cell lineage progression in the adult hippocampus.

Title: Role of mitochondrial fusion dynamics in adult hippocampal NSCs lineage progression and new neuron development

Authors: *S. WENDLER¹, G. WANI¹, J. GÖBEL¹, M. BERGAMI^{1,2} ¹Univ. Hosp. of Cologne, CECAD Inst., Koeln, Germany; ²Ctr. for Mol. Med., Koeln, Germany

Abstract: The dentate gyrus (DG) of the hippocampus is one of the very few restricted regions in the adult mammalian brain, where neurogenesis persists lifelong. Here, radial glia-like neural stem cells (NSCs) can enter cell division and give rise to fast-dividing progenitor cells, which in turn generate new neurons. Once born, the new neurons undergo a step-wise maturation process that lasts several weeks and during which they integrate into the pre-existing DG network. Recent work suggests that along this lineage, and in particular from the moment NSCs become activated, substantial changes in their energy metabolism take place, with genes involved in mitochondrial function becoming increasingly up-regulated, once the cell divides and progresses towards a post-mitotic (neuronal) stage. On the contrary, little is known on the physiological relevance of mitochondrial dynamics during this lineage progression, and in particular, whether changes in fusion and fission events (known to dynamically shape and maintain the mitochondrial network in cells) may alter the fate of NSCs or development of new neurons. Here, we utilized a set of Cre-inducible mouse lines to conditionally manipulate the proteins Mfn1 or Mfn2, which are the main drivers of mitochondrial outer membrane fusion, specifically in adult NSCs and their neuronal progeny in vivo. Genetic deletion of Mfn1 or Mfn2 disrupted the structure of the mitochondrial network in adult NSCs, as revealed by crossings with a mitoYFP reporter line. Analysis of proliferation in neural stem and progenitor cells revealed that these genetic manipulations did not affect the early steps along the lineage, as similar numbers of new neurons were generated in presence or absence of Mfn1 and 2. To assess the maturation process and survival of newly-born neurons upon loss of mitochondrial fusion, we used a mouse line expressing the cytosolic marker tdTomato, allowing for a detailed analysis of cellular morphology in labeled cells. In Mfn2 conditional knock-out mice we found a selective depletion of new neurons, which became manifest from the moment they started to incorporate into the hippocampal network, that is, when they switched from a DCX+ to a NeuN+ stage. This

indicates, that mitochondrial fusion is dispensable for earlier stages along the neurogenic lineage, while it becomes essential for the survival of new DG neurons during a period critical for their integration into the pre-existing circuit.

Title: Uncovering floor plate descendants in the ependyma of adult mouse CNS by mapping of Nato3-expressing cells

Authors: *N. BEN-ARIE

Hebrew Univ. Jerusalem, Jerusalem, Israel

Abstract: During embryonic development of the central nervous system (CNS), the expression of the bHLH transcription factor Nato3 (Ferd3l) is unique and restricted to the floor plate of the neural tube. In mice lacking Nato3 the floor plate cells of the spinal cord do not fully maturate, whereas in the midbrain floor plate, progenitors lose some neurogenic activity, giving rise to a reduced population of dopaminergic neurons. Since the floor plate is considered to be disintegrated at the time of birth, Nato3 expression was never tested postnatally and in adult mice. Here, we utilized a Nato3 knockout mouse model in which a LacZ reporter precisely replaced the coding region under the endogenous regulatory elements, such as its expression recapitulates the spatiotemporal pattern of Nato3 expression. Nato3 was found to be expressed in the CNS throughout life in a highly-restricted manner along the medial cavities: in subpopulations of cells in the third ventricle, the cerebral aqueduct, the fourth ventricle, the central canal of the spinal cord, and the subcommissural organ, a gland located in the midbrain. A few unifying themes are shared among all Nato3-positive cells: all are positioned in the midline, are of an ependymal type, and contact the cerebrospinal fluid (CSF) similarly to the embryonic position of the floor plate bordering the lumen of the neural tube. Taken together, Nato3 defines an unrecognized subpopulation of medial cells positioned at only one side of circular ependymal structures, and it may affect their regulatory activities and neuronal stem cell function.

Title: Capture Hi-C reveals the chromatin interactome and long-range gene regulatory landscape of cerebellar granule neuron progenitors

Authors: *M. BASSON¹, K. RIEGMAN^{1,2}, C. GEORGE², C. MOHAN¹, D. WHITTAKER^{3,4}, B. HUNTLY⁴, D. SIMS², C. OSBORNE¹

Abstract: Cellular differentiation and cell type-specific gene expression are under the control of distal regulatory elements in the genome. These elements, which include elements with enhancer or repressor activities, can be located at some distance from the gene being regulated. Chromatin conformation capture techniques provide information on genome organization by capturing regions in the genome that are in close proximity to each other. Here we applied such an approach to define the chromatin interactome of mouse cerebellar granule neuron progenitors (GNPs). GNPs are transit amplifying, lineage committed neural progenitors that are responsible for the postnatal growth and the formation of the characteristic foliated structure of the cerebellum. Using a Capture Hi-C approach, we identified over 75,000 possible interactions with over 20,000 gene promoters throughout the genome. The promoter-interacting regions were characterized further by a combination of ATACseq and ChIP-seq analysis to identify putative enhancer elements. The chromatin remodeling factor CHD7 (chromodomain helicase DNA binding factor 7) that controls GNP proliferation and differentiation has been shown to primarily localize to distal regulatory regions where it affects DNA accessibility. A comparison of DNA accessibility at these putative distal regulatory elements in control and CHD7-deficient GNPs defined the CHD7-regulated enhanceosome of GNps. These findings provide fundamental insights into the long-range gene regulatory landscape of cerebellar GNPs and will form the basis of future studies aimed at elucidating chromatin reorganization during GNP differentiation and the regulation of cerebellar growth and development by factors that coordinate these interactions.

Title: Autophagy sustains hyper-activation of mTORC1 in TSC1-deficient neural stem cells to promote tuberous sclerosis complex-associated defects

Authors: *C. WANG, M. HAAS, S. YEO, S. CHEN, J. WEN, J.-L. GUAN Univ. of Cincinnati Dept. of Cancer Biol, Cincinnati, OH

Abstract: Tuberous Sclerosis Complex (TSC) is a neurodevelopmental disorder characterized by hyperactivation of mechanistic target of rapamycin (mTOR) complex 1, causing abnormal cell growth, proliferation, and differentiation in affected brains. We found that conditional knock out of Tsc1 with hGFAP-Cre in mouse (designated as TSC1 cKO mice) resulted in hyperactivation of mTORC1 in postnatal neural stem cells (NSCs), which impaired self-renewal and neurogenesis in the subventricular zone. Moreover, TSC1 cKO mice developed subependymal nodules (SEN) with a mixed neuronal and glial lineage as found in human subependymal giant astrocytoma. The mTORC1 inhibitor rapamycin suppressed mTORC1 hyperactivation and rescued the maintenance and differentiation defects in TSC1-null NSCs. The tumorigenesis of SEN was also suppressed by rapamycin in mutant mice. Interestingly, although mTORC1 hyperactivation is known to inhibit autophagy through phosphorylating ULK1 in many cells, the autophagy activity is not completely diminished in TSC1-deficient NSCs. To study the functions and mechanisms of autophagy in regulating mTORC1 activation, we generated a double conditional knockout mouse (designated as 2cKO) with deletion of TSC1 and FIP200 in postnatal NSCs. We found that high mTORC1 activity in NSCs of TSC1 cKO mice was restored in 2cKO mice to comparable level as in wild type mice. Moreover, the impaired self-renewal, neurogenesis, and tumorigenesis of TSC1-null NSCs were also rescued in 2cKO mice. Metabolic analysis of NSCs in various mice showed an increased glycolysis and mitochondrial oxidative phosphorylation in TSC1-null NSCs. The rewired metabolism was driven by hyperactivated mTORC1 and required intact autophagy in TSC1-deficient NSCs. Lastly, we found that the combination of a glycolysis inhibitor 2-Deoxy-D-glucose and an autophagy inhibitor chloroquine, but not either compound alone, significantly reduced high mTORC1 activity and

pathological defects in TSC1-deficient NSCs. Together, these results suggest a novel metabolic mechanism for autophagy to regulate mTORC1 activity in a neurodevelopmental disease model.

Title: Hox genes are essential for the diversification and connectivity of spinocerebellar tract neurons

Authors: *M. BAEK¹, A. W. HANTMAN², T. M. JESSELL³, J. S. DASEN⁴ ¹Neurosci., NYU Sch. of Med., New York, NY; ²Janelia Res. Campus, Howard Hughes Med. Inst., Ashburn, VA; ³Departments of Neurosci. and Biochem. and Mol. Biophysics, HHMI, Columbia Univ., New York, NY; ⁴Neurosci., NYU school of medicine, New York, NY

Abstract: Motor control relies on the relay of muscle-derived sensory information to the central nervous system. Proprioceptive sensory information is processed locally within spinal circuits and is delivered to higher brain centers through spinal projection neurons. Spinocerebellar tract neurons (SCTNs) relay proprioceptive sensory information to the cerebellum; the central cervical nucleus (CCN), caudal cervical SCTNs, and Clarke's column neurons (CC) relay sensory information from the neck, forelimb, and hindlimb muscles, respectively. Although the anatomical organization of diverse SCTN populations has been well characterized, their specification is poorly understood. To define the molecular profile of SCTNs, we performed transcriptional profiling of retrogradely labeled SCTNs. RNA sequencing analysis identified novel molecular markers for CC and CCN. We also found that during embryonic development, expression of specific Hox transcription factors distinguish these and additional subsets of SCTNs. By combining immunostaining with retrograde tracing from the cerebellum, we determined the expression pattern of Hox genes in the SCTNs; Hox4-8 paralogous define subtypes of cervical SCTNs, while Hox9 and Hox10 genes are specifically expressed in the thoracic SCTNs. We tested whether Hox genes establish SCTNs identity and connectivity through genetic manipulation of their activities. We found that Hoxc9 is required for the development of thoracic SCTNs, including CC neurons. In Hoxc9 mutants, markers of CC neurons were absent in thoracic segments of the spinal cord. Strikingly, in Hoxc9 mutants CC neurons appear to be transformed to the identity of SCTN populations normally present at cervical levels of the spinal cord; in Hoxc9 mutants thoracic SCTNs show caudal cervical SCTNs characteristic cell body positions, Hox gene expression, and sensory input sources. In

contrast to caudal cervical SCTNs, CCN neurons in the rostral cervical region are not expanded in Hoxc9 mutants, which is reminiscent of the Hoxc9 mutant phenotype in motor neurons. Collectively these studies indicate that, similar to spinal motor neurons, the subtype diversity and connectivity of spinal interneurons relies on Hox-dependent genetic programs.

Title: Identification of active enhancers during cerebellum development through co-regulation temporal analysis of enhancer RNAs

Authors: *M. RAMIREZ¹, R. ROBERT², P. ZHANG¹, F. CONSORTIUM³, J. SONG⁴, D. GOLDOWITZ¹

¹Genome Sci. and Technol., Univ. of British Columbia, Vancouver, BC, Canada; ²Univ. of Rennes 1, Rennes, France; ³RIKEN, 2-1 Hirosawa, Wako, Saitama 351-0198, Japan; ⁴New Mexico State Univ., Las Cruces, NM

Abstract: The developing cerebellum requires intricately controlled expression of specific gene regulatory networks across time. Due to advancement in genomic technology, the known mechanisms responsible for the regulation of gene expression during development have expanded to incorporate non-coding cis- and trans-acting elements. Among these elements are enhancers, which are distal regions to transcript start sites (TSSs) that have previously been known to selectively activate genes in a tissue-specific and temporal-specific manner under various conditions. Recently, bi-directional transcription of non-coding RNAs at enhancer domains, known as enhancer RNAs (eRNAs), has been positively correlated with the expression of both nearby genes and their regulatory target genes. eRNA transcription has been defined as a signal of active enhancers during various biological processes.

The identification of active enhancers during brain development, specifically for the cerebellum, has yet to be elucidated. The goal of our work is to use eRNA expression to identify active enhancers contributing to the fine control of gene expression throughout cerebellar development. Transcriptomic data produced by the FANTOM5 consortium through Cap Analysis Gene Expression (CAGE) followed by high throughput sequencing were utilized to quantify eRNA

expression for a catalogue of predicted enhancers. This was performed for embryonic and early postnatal stages of murine cerebellum development (from embryonic day 11 to postnatal day 9). Previously defined enhancers were curated based on dynamic eRNA expression throughout the time course. The analytical pipeline defined 238 eRNA-enhancers that are active during cerebellum development. Comparison with other developing murine tissues was performed and revealed that these eRNA-expressing enhancers are highly specific to cerebellar development. Finally, co-expression networks including 10,316 expressed TSSs were defined to identify predicted regulatory target genes. The identified co-expression modules revealed enhancer elements activated at different stages in development. Validation by ChIP-seq for enhancer associated chromatin modifications and other experimental approaches will be conducted to produce a set of robust active enhancers.

Title: Lin28-mediated mRNA translation promotion is critical for neural progenitor cell fate and brain development

Authors: *S. A. HERRLINGER

Univ. of Georgia, Athens, GA

Abstract: The development of the brain is a dynamic and complex process that requires precise timing of neural precursor cell (NPC) behaviors. While many transcriptional and epigenetic regulators of neurodevelopment are known, the roles that translational regulators play are poorly understood. Lin28 is an RNA-binding protein that is highly expressed in NPCs at the early stage of brain development. Two homologs for Lin28 exist in mammals (Lin28a/b). Our previously published work showed that Lin28a single-knockout leads to reduced NPC self-renewal and microcephaly (smaller brains) in mice (Yang et al., Development, 2015). Using Nestin-Cre, we found that NPC-specific overexpression of Lin28a causes macrocephaly (enlarged brains) by promoting NPC self-renewal. These studies show that Lin28a promotes NPC expansion and

brain development. Because there exists 76% homology between both homologs of Lin28, it is likely that redundant function is shared between them. We found that double knockout mutants of Lin28a/b exhibit an open neural tube defect (NTD) predominantly in the hindbrain. In vivo NPC behavior analyses confirm a decrease in proliferation of hindbrain NPCs in Lin28a/b double mutant mice both prior to neural tube closure and sustained after neural tube closure failure. Precocious differentiation can also be observed immediately after neural tube closure failure in the double mutant hindbrain region, while there is no notable change in apoptosis. These results suggest that Lin28a/b are required for NPC fate and brain development. Lin28a has been reported to promote or inhibit mRNA translation in a cell type dependent manner. To address the mechanism of action of Lin28 in the developing brain, we used the Rpl24 (encoding a ribosomal subunit) hypomorphic allele mouse, a well-established genetic tool to reduce mRNA translation. Whereas Lin28a depletion alone results in smaller brains, Lin28a knockout in the background of Rpl24 hypomorphic allele results in NTDs, which recapitulate the NTDs in Lin28a/b double knockouts. Furthermore, Rpl24^{Bst/}-mediated decrease of mRNA translation completely rescued the macrocephaly defect from NPC-specific Lin28a overexpression. Together, these results suggest that reduced mRNA translation in NPCs is sufficient to cause microcephaly, Lin28 promotes mRNA translation in the developing brain, and Lin28-mediated translation promotion is required for NPC cell fate control and brain development.

Title: Deep homology of the genetic program controlling dopaminergic neuron differentiation in nematodes & mammals

Authors: *L. R. GOMEZ¹, M. MAICAS¹, A. ESCRICHE¹, C. CUCARELLA¹, R. RUIZ¹, Á. JIMENO¹, L. CHIRIVELLA¹, A. PEREZ², I. FARIÑAS², N. FLAMES¹ ¹Neurobiologia del Desarrollo, Insituto De Biomedicina De Valencia CSIC, Valencia, Spain; ²Biología celular, Univ. de Valencia, Valencia, Spain **Abstract:** Dopamine (DA) is one of the main neurotransmitters in the brain and regulates a variety of complex behaviors. Understanding the regulatory logic of DA terminal differentiation is important for both basic as well as translational research. Using the model organism *C. elegans* we found that a combination of three transcription factors (TFs) from three different families (ETS, DLL and PBX) directly regulate terminal differentiation of DA cells (Doistsidou et al. 2013).

The most ancestral mammalian dopaminergic population are the olfactory bulb (OB) dopaminergic neurons. Interestingly mouse orthologs for both ETS (Etv1/Er81) and DLL (Dlx2) TFs are already known to be required for mouse OB DA differentiation. Pbx1 and Pbx2 have been recently shown to control OB neurogenesis, however a specific role on dopaminergic terminal differentiation has not been assessed.

Here we show that PBX1 and PBX2 are expressed in the adult OB DA neurons, however, only specific DA lineage conditional *Pbx1* mutant mice exhibit a dramatic decrease in the number of DA neurons of the OB suggesting that PBX1 but not PBX2 is required for the correct DA specification. Moreover, lineage tracing experiments indicate that *Pbx1* mutant cells remain in the OB but they are unable to properly differentiate. We find that *Pbx1* is required for the expression of other transcription factors that are known to be important for the DA differentiation such as COUP-TF1 and MEIS2. In addition, overexpression of *Pbx1* in the mouse SVZ progenitors is sufficient to induce DA differentiation in the OB. Considering the evolutionary conservation of PBX, ETS and DLX TF on dopaminergic neuron differentiation we further analyzed to what extent the regulatory programs are homologous. Surprisingly, we find that worm orthologs of COUP-TF1, MEIS2 and PAX6 are also required in nematode DA specification. Our findings demonstrate a remarkable extent of homology in the specification of a critically important neuronal cell type, conserved over a billion years of

evolution.

Title: Mechanisms of fate specification in Cux2-expressing neural progenitors

Authors: *S. P. FREGOSO¹, B. DWYER¹, S. J. FRANCO²

¹Univ. of Colorado, Aurora, CO; ²Pediatrics, Univ. of Colorado Sch. of Med., Aurora, CO

Abstract: During neocortical development, neurons are produced by a diverse pool of neural progenitors. A subset of these progenitors express the Cux2 gene and predominantly produce late-born excitatory neurons, but the upstream pathways that specify this subset of progenitors remain unknown. Elucidating how Cux2 expression is activated in forebrain progenitors could provide insights into mechanisms of fate specification. To uncover the transcriptional network that regulates Cux2 expression, we are characterizing an ultraconserved Cux2 enhancer that we find recapitulates endogenous Cux2 expression in the developing forebrain. Using bioinformatic analysis of this enhancer to identify putative transcription factor binding sites, we found several potential binding sites for well-known forebrain patterning genes, including Emx1/2, Lhx2/6/8, and Dlx1/2. We are currently testing the role of these candidate transcription factors in regulating expression from the Cux2 enhancer using a combination of in vitro cell culture and in vivo studies. Additionally, as many putative *Cux2* regulators identified in our analysis are directly downstream of BMP signaling, we reasoned that BMPs could regulate Cux2 expression in the developing forebrain, as has been reported in other embryonic tissues. We demonstrate that BMP4 can upregulate Cux2 expression from both the Cux2 enhancer and the endogenous Cux2 locus in cell culture and in neocortical explants, respectively. While BMP signaling is known to be important for patterning forebrain progenitor domains, our results suggest that BMPs may also be an important contributing factor for activating the transcriptional network that directs $Cux2^+$ progenitor fate.

Title: Overturning the role of Math5 (Atoh7) in retinal ganglion cell specification

Authors: *J. BRODIE-KOMMIT¹, H. SHI², F. WU³, T. GLASER⁴, T. M. SCHMIDT⁵, X. MU³, J. H. SINGER², S. HATTAR^{6,7}

¹Biol., John Hopkins Univ., Baltimore, MD; ²Biol., Univ. of Maryland, College Park, MD; ³Univ. at Buffalo - Downtown Campus, Buffalo, NY; ⁴Dept. of Cell Biol. and Human Anat., Univ. of California Davis, David, CA; ⁵Neurobio., Northwestern Univ., Evanston, IL; ⁶Biol. and Neurosci, Johns Hopkins Univ., Baltimore, MD; ⁷Section on Light and Circadian Rhythms (SLCR), Natl. Inst. of Mental Hlth., Bethesda, MD

Abstract: Retinal ganglion cells (RGCs) are the sole conduits of light information to the brain for both image and non-image forming functions. RGC differentiation occurs by retinal progenitor cells expressing transcription factors in a developmentally temporal fashion, including Math5 (Atoh7). Math5, a bHLH transcription factor, is thought to be necessary for RGC specification; since Math5 null mice lack 95% of RGCs, lack an optic nerve, lack adult retinal vasculature, yet contain an overgrown version of the developmental hyaloid vasculature. A recent publication used lineage tracing to show that a subset of RGCs do not express Math5. Therefore, we re-examined the Math5 null mouse line on a background that prevents RGC death by knocking out the proapoptotic gene, Bax. Surprisingly, we found that even in the absence of Math5, substantial numbers of retinal progenitor cells differentiate into RGCs. These rescued RGCs predominantly phenocopy wildtype RGCs gene expression (including Brn3a, Brn3b, & Isl1). However, despite restoring a large numbers of RGCs, the optic nerve still failed to develop in these animals, similar to the Math5 null mice. Since RGCs are classically defined as output neurons, we wanted to investigate whether these rescued RGCs receive rod/cone light input. Indeed, using multielectrode array recordings, RGCs from Math5/Bax double knockout animals displayed ON, OFF and ON/OFF rod/cone light responses. These data show there are two populations of RGCs, those that require Math5 for specification and those that do not, however all RGCs require Math5 for survival. Surprisingly, even though RGCs are rescued, in the double null retina, the hyaloid vasculature fails to regress, suggesting that communication between the Math5 dependent RGCs and the hyaloid vasculature is required for regression. Overall, these data suggest that Math5 is not required for proper specification of all RGCs, but that the RGCs that require Math5 for specification, or downstream Math5 effectors, are required for the survival of all RGCs, proper optic nerve development, and hyaloid vasculature regression.

Title: Non-canonical Wnt signaling through Ryk drives SST cortical interneuron fate

Authors: *M. MCKENZIE¹, L. COBBS², G. J. FISHELL³, E. AU⁴ ¹Pathology and Cell Biol., Columbia Univ. Med. Ctr., New York, NY; ²NYULMC, New York, NY; ³Harvard Univ., Cambridge, MA; ⁴Columbia Univ., New York, NY

Abstract: Cortical GABAergic interneurons exhibit remarkable diversity in their intrinsic firing properties, subtype marker expression, layer organization, synaptic connectivity and morphology. The mechanisms underlying the generation of this diversity are largely unknown. We have identified a rostral-caudal Wnt gradient within the medial ganglionic eminence (MGE) that delineates the specification of the two main interneuron subtype classes. Caudally-situated MGE progenitors receive high levels of Wnt signaling and give rise to somatostatin (SST)expressing cortical interneurons. Parvalbumin-expressing basket cells, by contrast, originate mostly from the rostral MGE where Wnt signaling is attenuated. Interestingly, canonical Wnt signaling through b-catenin is not required for this process. Wnt signals transmitted via nuclear translocation of the intracellular domain of the non-canonical receptor Ryk, however, are sufficient to drive interneuron progenitors to a SST fate. Inhibition of Ryk signaling by a function blocking antibody conversely decreases the production of SST positive interneurons. Graded Ryk gain of function experiments performed in mouse ES-derived cortical interneurons reveal a dose-dependent effect, suggesting Ryk signaling acts in a gradient. These data, in combination with in vivo genetic loss of Ryk signaling in MGE derived lineages reveal a complex and important role for non-canonical Wnt signaling in establishing the correct ratios of mature cortical interneuron subtypes.

Title: Heterotypic transplantations reveal how the environment directs interneuron diversity and maturation

Authors: *T. J. PETROS¹, G. QUATTROCOLO², G. FISHELL² ¹Developmental Neurosci. Br., NIH/NICHD, Bethesda, MD; ²Neurosci., NYU, New York, NY

Abstract: Neural progenitors in the ganglionic eminences give rise to diverse GABAergic interneuron subtypes that populate all forebrain regions. Medial ganglionic eminence-derived progenitors are initially fated towards parvalbumin- or somatostatin-expressing classes during embryogenesis, a process that is guided by spatial and temporal gradients, and the mode of neurogenic division. The extent to which these cells are genetically predefined into specific interneuron subtypes, or rather their mature characteristics are obtained upon interaction with environmental cues, remains unknown. To address this question, we performed homo- and heterotopic transplantation of early postnatal MGE-derived cortical and hippocampal interneurons. Grafted cells migrated and displayed neurochemical, electrophysiological and morphological profiles similar to endogenous interneurons. Our findings indicate that the proportion of interneuron classes was largely determined by the host region. However, some transplanted cells retained characteristics indicative of their donor region, indicating that they may be more 'hard-wired' and not influenced by environmental signals. Our approach enables us to study how the environment regulates interneuron differentiation and maturation, which is critical for understanding normal interneuron development and the burgeoning therapeutic application of this transplantation approach.

Title: Role of de novo DNA methyltransferases in the development and function of human motor neurons

Authors: *J. ORTEGA¹, M. ZILLER², D. SANTOS³, A. MEISSNER⁴, E. KISKINIS³ ¹Dept. of Neurol., Northwestern University, Feinberg Sch. of Medici, Chicago, IL; ²Max Planck Inst. of Psychiatry, Munich, Germany; ³Northwestern Univ., Chicago, IL; ⁴Broad Inst. of MIT and Harvard, Cambridge, MA

Abstract: DNA methylation is an epigenetic modification that is essential for gene regulation and development in mammals. DNA methylation patterns are exerted by three distinct DNA methyltransferase (DNMT) enzymes; DNMT1 is mainly responsible for genome wide maintenance of methylation patterns during replication, while DNMT3A and DNMT3B establish de novo DNA methylation. DNMT3A is known to be widely expressed in neural progenitors along the central nervous system (CNS) and to be critical for cell fate choice. However, the targets for *de novo* methylation mediated by DNMT3A, as well as the functional redundancy with DNMT3B during CNS development, remain unclear. Here, we utilized a powerful human embryonic stem cell (ESC) differentiation model for the generation of spinal motor neurons (MNs) in combination with genetic mutations in the *de novo* DNA methyltransferase machinery to assess the specific role of DNMT3A and 3B on: (1) neural lineage fate decisions and, (2) the physiological properties of postmitotic neurons. Over the MN differentiation, the two de novo DNMTs displayed opposite expression patterns. While the expression levels of DNMT3B rapidly decreased in the initial stages of differentiation, DNMT3A exhibited a dynamic expression pattern with sustained high levels at later stages. Systematic characterization of DNMT3A and DNMT3B KO and wild type cell lines over the MN differentiation protocol by different immunolabeling techniques showed that DNMT3A KO ESCs exhibited a reduced capacity to generate neurons and MNs, compared to isogenic control cells. RNA-sequencing and whole-genome bisulfite sequencing (WGBS) analysis demonstrated that this effect is in part due to a modification in the expression pattern of an important group of transcription factors. During MN differentiation, DNMT3A KO cultures displayed silenced expression of pro-neuronal transcription factors and up-regulation of neural floor plate transcription factors compared to the isogenic control cell line, while DNMT3B KO cultures remained unaffected. Strikingly, we also discovered that DNMT3A KO MNs displayed abnormal morphological, biochemical and electrophysiological properties. Our study underscores the importance of *de novo* DNA methylation during human neurogenesis, dissecting the regulatory link between DNA methylation dynamics and MN specification and functional maturation.

Title: A role for Tlx3 and Hipk2 in Prrx11 phosphorylation during the development of nociceptive neurons

Authors: *C. M. REGUENGA^{1,3}, A. F. DIAS^{3,2}, F. MONTEIRO^{3,2}, D. LIMA^{3,2} ¹Biomedicine - Exptl. Biol. Unit, ²IBMC- Inst. De Biologia Mol. E Celular, Porto, Portugal; ³Faculdade de Medicina da Univ. do Porto, Porto, Portugal

Abstract: Proper balance in the number of excitatory glutamatergic and inhibitory GABAergic neurons in dorsal spinal cord is essential for the correct functioning of the neuronal circuitry integrating sensory information from the periphery to the brain. It is known that the homeodomain transcription factors Tlx3 and Prrx11 are essential for the determination of the excitatory phenotype. Noteworthy, Prrx11 phosphorylation appears to play an important role in the spinal cord glutamatergic population development, changing from very high levels at early stages, where neural fate commitment takes place, to progressively low levels from E15.5 onwards. Multiple phosphorylation sites were mapped in the Prrx11 primary structure and four correspond to conserved phospho-S/T-P sites, which suggest a role for the prolyl isomerase Pin1 in regulating Prrxl1 function. These S/T-P sites give rise to distinct phosphorylation profiles, which are key determinants of Prrx11 conformation and thereby protein functioning. The phosphorylation states acquired by Prrxl1 during different developmental phases promote the association of Prrx11 with distinct molecular partners. We showed, by 2D electrophoresis and reporter assays, that both Tlx3 and Hipk2 (homeodomain-interacting protein kinase 2) modulate Prrxl1 activity by controlling its phosphorylation status. In addition, Hipk2 is not transcriptionally regulated by Tlx3, as revealed by qPCR, which suggests that Tlx3 promotes Prrx11 phosphorylation via Hipk2 recruitment to the transcriptional protein complex. Finally, we also implicated the Hipk2/Pin1 protein complex in the positive modulation of Tlx3 transcriptional activity, further implicating phosphorylation events in the molecular interplay between Tlx3 and Prrx11. The role of post-translational mechanisms in embryonic development is now beginning to be explored, and ours are the first data pointing to their importance in the differentiation of the nociceptive neurons.

Abstract: Corticospinal motor neurons (CSMN), residing in layer V of the neocortex, are the brain component of the multi-neuron circuitry controlling voluntary movement in mammals. CSMN are closely related to deep layer callosal projection neurons (CPN) and have the same birthdates, however very different projection targets and functions. CPN are similarly glutamatergic cortical projection neurons, but are involved in associative cognitive function and project to the contralateral cortex. While several transcription factors important for both CSMN and CPN have been identified, much of the molecular regulation of this process remains incompletely understood. MicroRNAs (miRNAs) are post-transcriptional gene regulators that act by promoting degradation or repressing translation of target mRNAs, including those encoding transcription factors. miRNAs are ideally suited to control developmental programs, as multiple miRNAs can converge on multiple targets to repress translation. While miRNAs have been shown to play a role in the earliest stages of cortical development, their role in cortical projection neuron development and diversity is unknown. A differential miRNA expression analysis of CSMN vs. CPN revealed 20 miRNAs that are more highly expressed by CSMN vs. CPN at postnatal day 1 (P1) mouse. Several of these miRNAs are encoded on a single genomic miRNA cluster. One cluster-encoded miRNA, miR-CSMN1, is enriched in CSMN compared to CPN at P1 but not at P4. Predicted gene targets of miR-CSMN1 include CITED2 and LMO4, two transcription factors important for CPN and associative projection neuron development. Gainand loss-of function studies demonstrate that miR-CSMN1 can control cortical projection neuron fate in embryonic cortical cultures. Similar functional studies on other cluster-encoded miRNAs are ongoing. Characterizing cluster-encoded miRNA controls on CSMN development may

inform stem cell-based regenerative therapies for paralysis in clinically relevant conditions, including spinal cord injury and ALS.

Abstract: GABAergic cortical interneurons (CINs), primarily generated by medial and caudal ganglionic eminences (MGE & CGE), control circuit excitability by acting as a breaking system in the brain. CIN malfunctions are implicated in neuropsychiatric diseases including autism spectrum disorder, schizophrenia and epilepsy. Understanding CIN generation and maturation are crucial in order to better understand interneuronopathy-related brain diseases. MGE-derived CINs are composed of two broad subgroups: parvalbumin- (PV; late-born) and somatostatin- (SST; early-born) expressing. While MGE interneuron progenitor fate is initially determined by the Nkx2.1 and Lhx6 transcription factors (TFs), factors regulating the control over CIN fate and generation are still being uncovered. Here, we characterized two TFs, Mafb and c-Maf, which are genetically downstream of Nkx2.1, Lhx6 and Dlx, as critical for generating the correct balance of early and late born MGE CIN progenitors.

Combined deletion of Mafb and c-Maf from MGE progenitors resulted in ~70% reduction of MGE-derived CINs at P35, with preferential loss of the PV subgroup. Surviving CINs reside in deeper cortical layers and are more likely to be early-born SST interneurons. At embryonic ages, EdU birthdating experiments showed no change of MGE CIN progenitor numbers with deletion of Mafb and c-Maf but an increase of precocious neurogenesis. Notably, we also found a robust increase of SST CINs in the neocortex of these mutants. Together, these results suggest Mafb and c-Maf control the balance of neurogenesis in late progenitors of the MGE, and these early disruptions cause a shift in the balance of PV^+ and SST^+ CINs.

Abstract: For neuronal circuits in the spinal cord that control locomotion, developmentally expressed transcription factors have served as entry points for functional assignment of left-right and flexor-extensor coordination circuits, as well as for rhythm-generation circuits. It is clear though that functions within each of these circuits most often are represented by molecularly heterogeneous groups of neurons, where further specification by molecular markers is needed to dissect the circuitries. In other cases, known groups of neurons already specified by distinct markers may not completely capture the functionality of the circuits and alternative or supplementary markers will be needed. For rhythm-generation several glutamatergic molecularly

defined groups of cells are thought to be involved without any of them being responsible alone.creating the function alone. In order to capture new markers for this important groups of neurons in the spinal cord we have performed FAC-sorting, RNA-sequencing and differential expression analyses on glutamatergic neurons from the mouse ventral spinal cord. We compared the postnatal transcriptional expression profile of all glutamatergic neurons in the SC, the Vglut2-expressing neurons, to that of non-glutamatergic neurons as well as to one of the glutamatergic subgroups so far linked to rhythm-generation, the Shox2 interneurons (Dougherty et al. 2013). Amongst the transcripts up-regulated in the Vglut2-expressing neurons are wellknown glutamatergic developmental-markers such as *Sim1*, *Evx2*, *Lhx3*, *Chx10*, *Shox2* and *Lbx1*. The analysis also identified more then 200 receptors, transcription factors, ion-channels and other neurotransmitters specifically

expressed in the entire population of Vglut2-positive neurons as compared to non-glutamatergic neurons and Shox2-positive neurons. Our findings identify novel glutamatergic subgroups in the spinal cord and provide tools for further specification of spinal cord functions. In addition, since Vglut2 positive neurons are found in many regions of the nervous system, this work provide new molecular entry points to reveal the diverse function of this group of transmitter-defined neurons.

Title: Preferential expression of Foxp2 in striatonigral projection neurons in the striatum of adult mouse brain

Authors: L. FONG, *F.-C. LIU Natl. Yang-Ming Univ., Taipei, Taiwan

Abstract: The striatum comprises GABAergic projection neurons which accounts for ~90% of striatal neurons. There are two populations of striatal projection neurons (SPNs), striatonigral SPNs of the direct pathway and striatopallidal SPNs of the indirect pathway. Striatonigral SPNs express dopamine D1-class receptor, whereas striatopallidal SPNs express dopamine D2-class receptor. It has been proposed that activation of striatonigral pathway facilitates movement,

whereas activation of striatopallidal pathway inhibits movement. The antagonistic but balanced activity of these two pathways is important for motor control. Foxp2, a language-associated gene, is expressed at high levels in the striatum. Our recent study suggests that Foxp2 plays an important role in synaptogeneis of corticostriatal circuits and vocal communication (Chen et al., 2016). It is of interest to characterize striatal cell types that express Foxp2. Here, we analyzed the expression pattern of Foxp2 with respect to specific cell types of SPNs and interneurons in the adult mouse striatum. Based on double in situ hybridization and immunostaining, we found that Foxp2 was expressed in SPNs, but not in striatal interneurons. Moreover, Foxp2 was preferentially expressed in striatonigral SPNs. This result is consistent with the previous BAC transgenic mouse study showing that Foxp2 expression is primarily associated with Drd1-EGFPpositive neurons in the striatum (Vernes et al., 2011). We also analyzed the expression pattern of Foxp1, a member in Foxp family. In contrast to the preferential expression of Foxp2 in striatonigral SPNs, Foxp1 was expressed in both populations of striatonigral and striatopallidal SPNs. Foxp1 was not expressed by striatal interneurons, either. In summary, the cell-type preference of Foxp2 expression in the striatum implicates a unique role of Foxp2 in regulation of striatonigral SPNs in striatal circuits.

Title: Distribution, morphology, and function of serotonergic neurons in the larval zebrafish spinal cord

Authors: *J. E. MONTGOMERY¹, T. D. WIGGIN¹, B. CORWIN¹, C. LILLESAAR², L. BALLY-CUIF³, M. A. MASINO¹

¹Dept. of Neurosci., Univ. of Minnesota, Minneapolis, MN; ²Dept. of Physiological Chem., Würzburg, Germany; ³Inst. of Neurobio. Alfred Fessard, Gif-sur-Yvette, France

Abstract: Vertebrates possess two distinct cellular sources of spinal serotonin. The first source is the raphe nuclei, from which supraspinal projections descend to innervate the spinal cord. The second source is a population of intraspinal serotonergic neurons (ISNs) that are intrinsic to the

spinal cord. ISNs in fish and amphibians are almost exclusively localized to the ventromedial spinal cord, in close proximity to motor neurons and premotor interneurons. Thus, it is hypothesized that the ISNs are involved in modulating locomotor output. Here, we use a combination of *in vivo* optical imaging strategies to investigate the morphology and activity of the ISNs. The tryptophan hydroxylase 2 and pet1 Ets-domain transcription factor promoters were used to drive expression of fluorescent reporters in the ISNs. First, examination of EGFP expression revealed that ISNs somas were ventrally-located and evenly distributed along the rostrocaudal axis of the spinal cord. Next, we photoconverted Kaede in single ISNs between 3 and 10 days post fertilization to quantify and track cell morphology, such as projection distances, neurite lengths, and arborization. Morphological characteristics exhibited the greatest changes between 3 and 4 days post fertilization, which corresponds to the onset of mature beat-and-glide swimming behavior. Finally, genetically-encoded calcium indicators were used to study the relationship of ISN activity to fictive locomotor output. ISNs displayed a variety of activity states: quiescence, tonic activity, and phasic with motor activity. All three of these activity states were observed during both fictive swimming episodes and periods of rest. ISN activity not being phasically coupled with locomotor activity is consistent with the ISNs having a modulatory influence on locomotor output, rather than being an integral part of the pattern generating network.

Title: KAT3 proteins are crucial for the maintenance of neuronal identity

Authors: *M. LIPINSKI, J. M. CARAMES, N. CASCALES-PICÓ, M. T. LÓPEZ-CASCALES, J. FERNÁNDEZ-ALBERT, J. MEDRANO-RELINQUE, A. MEDRANO-FERNÁNDEZ, B. DEL BLANCO, S. CANALS, J. P. LOPEZ-ATALAYA, A. BARCO Inst. De Neurociencias De Alicante UMH-CSIC, San Juan De Alicante, Spain

Abstract: Studies in different organisms have demonstrated that neuronal identity needs to be actively maintained throughout life by the combined action of transcription factors and chromatin modifiers. The paralogue lysine acetyltransferases 3 (KAT3) CBP/KAT3A and p300/KAT3B play an important role in the regulation of transcription and chromatin threedimensional structure. Although both proteins are essential for the normal development of the nervous system, their specific functions in post-mitotic neurons remain unclear. In order to investigate this matter, we produced inducible forebrain-specific knockout (ifKO) mice for either one or for both KAT3 proteins. Interestingly, we observe that only when both proteins are knocked out simultaneously, mice show severe neurological phenotypes and an increased mortality. These deficits are accompanied by a rapid and progressive reduction in the dendritic complexity of forebrain neurons and loss of normal electrophysiological properties. Remarkably, these dramatic changes correlate with a strong and specific downregulation of neuron-specific gene expression whereas housekeeping genes were mostly unaffected. We also observed that the lack of KAT3 caused a robust decrease in histone acetylation at specific residues, such as H2B panacetylation and H3K27ac. Overall, our experiments demonstrate that KAT3 proteins are necessary for maintaining neuronal identity and function during adulthood, most probably through the regulation of acetylation levels at neuronal enhancers and gene bodies.

Title: Neural patterns underlying the development of planning tool use

Authors: *O. OSSMY, B. KAPLAN, M. XU, K. E. ADOLPH Dept. of Psychology and Ctr. of Neural Sci., New York Univ., New York, NY

Abstract: Flexible, purposeful tool use requires action planning. Adults' action plans keep both the initial contact with the tool and the end goal in mind, even when the end goal stretches far into the future. Children, however, show dramatic deficits in planning when the end goal is not immediately accessible to perception. For example, participants of all ages normally reach for the handle of a hammer using an overhand radial grip. But when the handle points away from the

dominant hand, an initially uncomfortable underhand grip is required to ensure the desired final position of the tool. This phenomenon of sacrificing comfort in the initial grip to allow for a comfortable end position is called "end-state comfort." In contrast to adults, young children frequently select a comfortable initial grip, as if planning for *start-state comfort*. As a consequence, their hand is in an awkward end-state position when they use the tool. Indeed, children do not show consistent planning for end-state comfort until 10 or 12 years of age. Here, we examined the possible sources of differences in action planning between young children and adults. We innovated a novel method for obtaining electroencephalography (EEG), headmounted eye tracking, motion tracking, and video simultaneously in an end-state comfort hammering task. First, we replicated previous work showing deficits in 4-year-old children's action planning. Then we compared EEG and visual attention for each age group for trials requiring planning for end-state comfort (handle pointing away from dominant hand) and trials that required planning only for start-state comfort (handle pointing toward dominant hand). At the neural level, we found differences in readiness potential over sensory-motor sites preceding initial end-state comfort grips in adults compared with the readiness potential preceding similar grips in young children. We used support vector machine (SVM) and random forest (RF) algorithms to describe preparatory neural patterns underlying differences in planning between the age groups. We also show that participants' fixation location and motion kinematics are correlated with their grip. These results indicate that young children's deficits in planning for end-state comfort stem from differences in neural activity and visual attention prior to moving the hand.

Title: Abnormal prostaglandin E_2 signalling results in autism-associated behaviours in novel mouse models

Authors: *C. T. WONG^{1,2}, I. BESTARD LORIGADOS^{2,3}, R. RAI-BHOGAL^{2,3}, D. A. CRAWFORD^{1,2,3} ¹Kinesiology and Hlth. Sci., ²Neurosci. Grad. Diploma Program, ³Dept. of Biol., York Univ., North York, ON, Canada **Abstract: Background**: Prostaglandin E2 (PGE₂) is an endogenous lipid-derived signalling molecule produced by Cyclooxygenase-2 (COX2). PGE₂ is important in brain development and function. We have previously shown that PGE₂ affects calcium regulation in growth cones, migration, proliferation, and differentiation in neural stem cells *in vitro*. Moreover, PGE₂/COX2 signalling can be disrupted through genetic changes along the pathway or exogenous factors, such as diet and exposure to infections, inflammation, and chemicals; all which have been associated with autism. Behavioural outcomes that manifest from abnormal PGE₂/COX2 signalling during prenatal development *in vivo* remain unknown.

Objective: The major goal of this study is to determine if mice exposed to PGE_2 during the critical time in prenatal development or mice lacking the PGE_2 producing enzyme (COX2) exhibit behaviours typically seen in autism. We also aim to determine whether there are age or sex differences in these animal models.

Methods: In this study, we examined offspring from a minimum of three independent litters for PGE₂-exposed and homozygous COX2^{-/-} groups. In the PGE₂-exposed model, a single subcutaneous injection of 16,16-dimethyl-PGE₂ ($0.2\mu g/g$) was administered to pregnant C57bl/6 wildtype mice on embryonic day 11, corresponding to neurogenesis. 129S6 wildtype mice served as the controls for the COX2^{-/-} mice. Subjects were split into young (4-6 weeks old) and adult (8-12 weeks old) groups, and underwent the following behavioural tests on separate days: marble test, 3-chamber test, open field test, and inverted screen test.

Results: We showed that PGE₂-exposed and COX2^{-/-} mice buried more marbles than control mice, indicating both models display greater repetitive and anxiety-related behaviour compared to respective controls. In the 3-chamber test, PGE₂-exposed and COX2^{-/-} mice spent less time in the novel mouse chamber and more time in the novel object chamber compared to controls, demonstrating lower sociability in both groups. In the open field test, PGE₂-exposed and COX2^{-/-} mice travelled a greater pathlength than controls, suggesting increased hyperactivity in both groups. In the inverted screen test, no differences in fall percentage were seen in PGE₂-exposed mice, while COX2^{-/-} mice fell more than their controls. Age and sex differences were also observed in both models for all behavioural tests.

Conclusions: Our findings determined that disruption in PGE₂/COX2 signalling during prenatal development can result in autism-like behaviours. We provide new evidence supporting the usage of these novel model systems for studying neurodevelopmental disorders such as autism.

Title: Relationship between cadherin 11 and autism traits

Authors: *Y. WANG¹, *Y. WANG¹, C. WANG², X. YUAN² ¹Hussman Inst. For Autism, Baltimore, MD; ²Hussman Inst. for Autism, Baltimore, MD

Abstract: Genome-wide association studies and whole exome sequencing have suggested that genetic variants of type II cadherins, including Cdh8, Cdh9, Cdh10, Cdh11, Cdh12, Cdh13, are associated with autism. However, whether there is a causal relationship between cadherin alterations and autism traits remains to be clarified. Based on genome-wide gene co-expression analysis, we found that in the developing human brain, a group of well-established autism risk genes exhibits convergent expression profiles. Interestingly, the expression of one type II cadherin family member Cdh11, but not Cdh9, is highly correlated with the expression of several well-established autism risk genes, suggesting greater relevance of Cdh11 than Cdh9 in the development and function of autism-related brain circuits. The functional linkage of Cdh11 and Cdh9 with autism was further evaluated by behavioral analysis of Cdh11 and Cdh9 gene knockout (KO) mice. Cdh11 KO mice exhibited behavioral abnormalities that are very similar to core behavioral traits and comorbidities of people with autism, including higher explorative activity, reduced anxiety level, increased repetitive behavior, reduced social interactions, and impaired motor coordination. In contrast, Cdh9 KO mice only exhibited very mild abnormalities in the same behavioral tests. In cerebellar tissues from Cdh9 and Cdh11 KO mice, activities of the PI3K signaling pathway, a pathway implicated into autism pathology, were also affected differently. These findings establish a potential relationship between Cdh11 rather that Cdh9 and autism traits, and identified Cdh11 KO mice as an important animal model for autism. Our findings also highlight the effectiveness of the genome-wide gene co-expression analysis in the prediction of the functional impact of novel gene variants in autism studies.

Title: An altered neurodevelopmental profile in mice deficient for autism associated Neurexin1 gene communicative and motor aspects at an early stage

Authors: *M. L. SCATTONI¹, A. CARUSO¹, S. DELLA NOTTE¹, C. FERNANDES² ¹Inst. Superiore di Sanita, Roma, Italy; ²King's Col. London, London, United Kingdom

Abstract: Autism Spectrum Disorders (ASD) are a group of neurodevelopmental disorders with early onset of symptoms, characterized by socio-communicative deficits and patterns of stereotyped behaviours. Although the causes of ASD remain unclear, evidence strongly supports the role of genetic factors in their aetiology, including mutations in Neurexin (NRXN) family genes. Our study aimed the behavioural phenotyping of mice with deletion of Nrxn1 α gene encoding for a neuronal presynaptic cell-adhesion molecule in order to identify autistic-like features, as soon as possible during the early developmental period. We evaluated the ontogentic profile of the vocal response during the first weeks of life through a detailed analysis of the ultrasonic vocalizations. Ultrasonic vocalizations are emitted by mouse pups in response to isolation from the mother and littermates and considered a suitable tool for the identification of early communication deficits in autism mouse models. Moreover, since motor dysfunctions can predict the onset of the other symptoms in ASD, we performed a fine-grain characterization of spontaneous motor behaviours, recorded simultaneously with the ultrasonic vocalizations. This is the first vocal and motor evaluation of Nrxn1a mutant pups that allows identification of autisticlike phenotypes at an early developmental stage. Our results indicate that an altered profile is detectable in the emission of ultrasonic vocalizations and acquisition of specific motor patterns in $Nrxn1\alpha$ mutant pups, in line with behavioural phenotypes of ASD children. Our findings suggest that the $Nrxn1\alpha$ gene has an important neurodevelopmental function and its deletion causes specific early behavioural abnormalities.

Title: NRF2 deficient mice exhibit regression following P14 exposure to valproic acid

Authors: *J. GIFFORD, S. A. NORTON, A. W. KUSNECOV, G. C. WAGNER Psychology, Rutgers Univ., Piscataway, NJ

Abstract: Autism is associated with high levels of oxidative stress biomarkers, increased body burdens of environmental toxicants that induce oxidative stress, and decreased levels of antioxidants. The objective of the present study was to advance our model of autistic regression using mice with a deletion of the NRF2 gene (nuclear factor E2-related factor 2), a master regulator for downstream enzymes associated with management of toxicant-generated reactive oxygen species. On postnatal day 14 KO and WT animals were exposed to sodium valproate (VPA; 400 mg/kg; s.c.) or saline and evaluated on a behavioral battery assessing maturation of

normal social and motor skills to classify toxicant-induced deficits along a developmental timeline. Prior studies revealed this treatment induces functional and pathological changes akin to autistic regression. Results of mid air righting testing provide evidence of regression of normal motor development in that saline-treated animals show similar development across genotypes but animals exposed to VPA exhibited a loss of the recently acquired ability to mid-air right with the NRF2 KO mice more affected than WT mice. We operationally define this loss of an acquired skill as *regression*. Additionally, in the rotarod test, KO-treated animals spent significantly less time than WT and saline-treated counterparts on the rotarod. These results indicate a critical importance of NRF2 during development as it might relate to autism and, more generally, the deleterious effects of oxidative stress during early development.

Abstract: It is known that males have greater risk of developing neurodevelopmental disorders, such as autism spectrum disorders (ASD), than females. Our previous proteomics study identified collapsin response mediator protein (CRMP) 4 as a protein exhibiting sex-different expression during sexual differentiation of the sexually dimorphic nucleus of the hypothalamus (Iwakura et al., 2013). Recently, we found a *de novo* mutation of *CRMP4* in a male patient with ASD from whole exome sequencing. ASD is characterized by impaired social interaction, verbal and non-verbal communication, restricted range of interest, and abnormal sensory perception. The aim of the present study is to investigate the relationship between Crmp4-deficiency in mice and ASD-like behaviors as well as sex different effects of Crmp4-deficiency by comparing social interaction behaviors and sensory perception abilities between Crmp4-KO and wild type (WT) mice of both sexes. Furthermore, in order to obtain the information for mechanisms underlying Crmp4-deficiency-induced ASD-like behaviors, altered gene expressions in brain areas including the cortex, hippocampus, and olfactory bulb were examined in Crmp4-KO and WT mice of both sexes. In addition, we examined the effect of Crmp4-deficiency or de novo mutation of Crmp4 on dendritic morphology of cultured hippocampal neurons. First, eight types of behavioral tests including social interaction test and three-chambered social approach task were performed in young adult (4-11 weeks old) WT and Crmp4-KO mice of both sexes. Crmp4-KO mice exhibited decreased social interaction activity, compared to WTs. It was more severely changed in male Crmp4-KO mice than in females. Furthermore, altered thermal perception was observed only in male Crmp4-KO mice, compared to male WTs. The expression levels of some genes including AMPA receptors (GluR1 and 2) and a dopamine receptor (D1R) were changed mostly in a gender-dependent manner in the brain of Crmp4-KO mice, compared to WTs. Furthermore, Crmp4-deficiency enhanced dendritic branching of cultured hippocampal neurons, compared to WTs. Expression of mutated mouse Crmp4, which is homologous to human mutated CRMP4 found in ASD patient, in cultured hippocampal neurons derived from Crmp4-KO mice also increased their dendritic branching, compared to those derived from Crmp4-KO mice and transfected with WT Crmp4. These studies indicate the functional relevance of a case-specific rare-variant of one molecule, Crmp4, to some symptoms of ASD and suggest its possible mechanisms.

Title: Loss of CDKL5 impairs hippocampus-dependent memory and hippocampal LTP in a mouse model of CDKL5 disorder

Authors: *S. HAO^{1,2}, Z. WU^{1,2}, B. TANG^{1,2}, Y. HUANG^{1,2}, H. Y. ZOGHBI^{1,2,3,4,5}, J. TANG^{1,2} ¹Dept. of Pediatrics, Baylor Col. of Medici, Houston, TX; ²Jan and Dan Duncan Neurolog. Institute, Baylor Col. of Medici, Houston, TX

Abstract: Mutations in the X-linked gene cyclin-dependent kinase-like 5 (CDKL5) have been identified to induce CDKL5 disorder, a neurodevelopmental disease characterized by early-onset seizures, severe intellectual disability, motor impairment, and autistic features. A few studies showed that CDKL5 animal models recapitulate some of the CDKL5 symptoms including cognitive deficits. Although long-term potentiation (LTP) serves as a neural substrate of learning and memory, the synaptic plasticity in CDKL5 mutant mice has not been investigated. Here, we assessed the hippocampus-dependent learning and memory function in a unique CDKL5 knockout mouse model with exon 6 deletion (B6.129(FVB)-Cdkl5^{tm1.1Joez}/J). In fear conditioning task, the male CDKL5 knockout mice ($Cdkl5^{-/y}$) froze significantly less than wide type (WT, $Cdkl5^{+/y}$) littermates in both contextual and cued fear memory test, consistent with the previous report. Importantly, we uncovered that the female heterozygous $Cdkl5^{+/-}$ mice were impaired in contextual fear memory as well, compared to WT controls. In another hippocampus-dependent task, passive avoidance, both male and female CDKL5 mutant mice had shorter latencies to enter the dark compartment during memory retention test in comparison with WT littermates. Guided by these behavioral data, we examined hippocampal LTP in awake, free moving $Cdkl5^{-/y}$ mice vs. WT controls. Field recordings from the hilar region of the dentate were measured in response to electrical stimulation in the medial part of the perforant path. The recording and stimulating electrodes were implanted 2-3 weeks before the tests. Theta burst stimulation induced 174% potentiation in mutant mice compared to 239% in WT controls 1 h after induction, indicating the impairment of synaptic plasticity in Cdkl5^{-/y} mice. These results demonstrate that CDKL5 mediates hippocampal learning and memory likely through the regulation of hippocampal synaptic plasticity.

Title: Zinc as a therapy in an experimental model of autism prenatally induced by valproic acid

Authors: *L. C. CEZAR¹, T. B. KIRSTEN², C. C. N. FONSECA³, A. P. N. LIMA¹, M. M. BERNARDI², L. F. FELICIO¹

Abstract: Autism is a complex developmental disorder characterized by numerous behavioral impairments, such as communication, socialization and cognitive inflexibility. Valproic acid (VPA) is an anti-epileptic drug with teratogenic activity that has been related to autism. In rodents, exposure to VPA during the pregnancy induced symptoms similar to those found in the human condition of that disorder. However, there are no effective treatments for autism. Particularly, exposure to VPA may alter zinc metabolism resulting in a transient deficiency of zinc. Therefore, we selected zinc as prenatal treatment to prevent VPA-induced deficiencies. In a rat model of VPA-induced autism, we tested the treatment with zinc supplementation. Wistar female rats received either saline solution or VPA (400 mg/kg, i.p) on gestation day (GD) 12.5. In order to test the zinc supplementation effect, after 1 h of treatment with saline or VPA, a dose of zinc (2 mg / kg) was injected. The offspring was tested for abnormal communication behavior by ultrasound vocalization task on post-natal day 11 (PND), repetitive behavior and cognitive ability was tested by T-maze task on 29 PND and social interaction was tested by play behavior task on 30 PND. We also evaluated tyrosine hydroxylase protein (TH) expression, in the striatum. VPA treatment induced alterations in various behavioral parameters. VPA group showed decreased ultrasonic vocalization, repetitive/restricted behavior, cognitive inflexibility, impairment of socialization, characterized by decreased play behavior and reduction in striatal TH levels as compared with saline control group. The zinc treatment reduced VPA-induced autism-like behavioral changes. Zinc supplementation generated behavioral improvement in the cognitive inflexibility, attenuated the VPA-induced deficit on social play behavior, and restored the vocalization pattern. However, we found no evidence of zinc effect on the VPA-induced reduction in the TH striatum levels. The persistence of low TH expression in VPA-Zn group suggests that Zn-induced behavioral improvement in autistic rats may not depend on TH activity.

Title: Analysis of empathic neural circuits regulated by oxytocin

Authors: *S. YADA, K. HORIE, K. NISHIMORI

Tohoku Univ., Sendai-Shi, Japan

Abstract: Human has highly sociality. Social behavior is essential in human society, in particular, compassionate and cooperative behaviors which help others without expecting external compensation are important, It is said that motivation for causing such social behaviors is "empathy" [Decety et al. 2016]. Empathy is impaired in many neuropsychiatric disorders including autism spectrum disorder (ASD). Although ASD has a high prevalence rate (~1%), its etiology and treatment are still unknown. ASD is a congenital neurodevelopmental disorder that is impaired in sociality and communication skill. Patients show perseveration and avoid interpersonal relationships. It is thought that neuroscientific analysis of empathy broadly lead to the treatment of social disorders of many psychiatric disorders including ASD. In recent years, Oxytocin (Oxt) and its receptor (Oxtr) are focused on ASD study because it has been reported that administration of Oxt to ASD patients and model mice has restored social disorders [Brian et al. 2015, Watanabe et al. 2015]. Oxt is a peptide synthesized in the paraventricular nucleus and supraoptic nucleus in the brain and is known to be involved in social behaviors such as maternal behavior and affinity. There are few reports on the association between empathy and Oxt / Oxtr and it has not been comprehensively understood yet. In this study, we aim to clarify how the Oxt / Oxtr system controls empathy. We performed empathic behavioral tests using Oxt / Oxtr knockout mice and prairie vole (Microtus ochrogaster) to identify brain regions involved in empathy. Prairie voles are known to show strong monogamous system and used as a model animal in social behavior research, since there is a report that wild-type prairie voles show empathetic behavior between monogamous pair [Burkett et al. 2016]. In the behavioral test, after pair bonding, we provide a fear stimulus to female mouse or prairie vole. We measured empathy as allogrooming behavior from paired male to female which showed fear response. It resulted that wild-type mice and prairie voles showed empathic behavior. However, empathic behaviors

were reduced in Oxt / Oxtr knockout mice compared with wild type ones. In addition, immediately early gene activations were detected in anterior cingulate cortex and olfactory nucleus during empathic behavior.

Title: Transient early gestational antithyroid treatment in mice results in behavioral deficits in adult offspring

Authors: M. PITSIANI¹, L. J. WILSON¹, A. RAJIC⁴, D. BELL⁴, C. FERNANDES², *R. J. WINGATE³

¹MRC Neurodev Disorders, ²MRC SGDP, ³King's Col. London, London, United Kingdom; ⁴Fac. of Health, Sci. and Technol., Univ. of Suffolk, Ipswich, United Kingdom

Abstract: Hypothyroidism within a critical window of brain development leads to severe mental retardation later in life associated with maldevelopment of the cortex and cerebellum. However, a variety of sources of evidence suggest that transient hypothyroidism in early gestation, prior to the critical window for "cretinism", is associated with cognitive deficits in offspring in later life including Autistic Spectrum Disorder. We have previously examined the affects of transient depletion of thyroid hormone levels on the early development of the avian cerebellum. In chick, early hypothyroidism disrupts the formation of the nuclei that comprise the output of the cerebellum well before the thyroid hormone- dependent events in cortical and cerebellar development. We therefore hypothesised that thyroid-dependent cerebellar disconnection may underlie cognitive deficits in late life. Hence, transient early gestational hypothyroidism might result in discrete cerebellar functional and anatomical consequences that are distinct from cortical phenotypes associated with late embryonic and early postnatal hypothyroidism. To test this, we used a mouse model and treated pregnant dams with either Methimazole (0.1%)in the drinking water) or control treatment from 0 to 14 days gestation. ELISA analysis showed that Methimazole (MMI) treatment results in a significant drop in T3 and T4 levels at 14 days gestation. Litters (n = 16) were then raised through to P64 and challenged with a battery of behavioural and motor tests (juvenile social play, adult social investigation, three chamber test, olfactory habituation/dishabituation test, open field, light/dark, elevated plus maze, grooming, marble burying, Y maze spatial discrimination, rotarod, muscle grip).

The brains of adult offspring in experimental and control groups were analysed by X-ray micro-CT scan following immersion in Iohexol (150-200 mg/mL) for 14 days. Gross morphology of both groups was broadly similar, suggesting that the behavioural phenotype result from relatively subtle changes in cell number, physiology or connectivity.

The only significant differences in behaviour were detected in open-field test of anxiety and a three-chamber test for sociability. These phenotypes are sex-specific. Male offspring show heightened anxiety (open-field). Female mice show reduced social interaction (three-chamber test). Both results are consistent with features of mouse models of human autistic spectrum disorder. This suggests that the findings in clinical and epidemiological studies of human cohorts can be simulated in a simple model of transient gestational hypothyroidism in mice.

Abstract: N-methyl-D-aspartate receptors (NMDARs) are important for brain development, synaptic plasticity, and learning and memory. NMDAR dysfunction has been linked to a number of neurodevelopmental disorders including autism and schizophrenia. While loss of NMDAR has been previously associated with social deficits, age and sex specificity has been understudied. We used the Cre-Lox system to ablate the the NMDAR subunit GluN1 (NR1) specifically in either excitatory or a subset of inhibitory neurons with a CaMKII or parvalbumin (PV) promoter, respectively, and measured social approach behavior of 30-day-old and 70-day-old male and female mice in a three-chambered apparatus. We found that deletion of GluN1 in either cell type had no effect on distance traveled in the arena. Mice lacking GluN1 in PV neurons showed no change in time spent sniffing the cylinder containing the social target compared to PV-Cre littermate controls, regardless of age or sex. However, both male and female mice lacking GluN1
in forebrain excitatory neurons showed a significant increase in time spent sniffing the cylinder containing the social target mouse compared to CaMKII-Cre littermate controls, at both 30d and 70d of age. These findings may shed light upon cell types and brain areas involved in autism, schizophrenia, and other disorders of sociability.

Title: Characterizing ultrasonic vocalizations in NS-Pten knockout pups: Implications for autism

Authors: *M. BINDER, J. LUGO

Psychology & Neurosci., Baylor Univ., Waco, TX

Abstract: A signaling cascade that plays a crucial role in the development of an autistic-like phenotype is the PI3K/AKT/mTOR pathway. Mouse models that illustrate this connection include Fmr1, Tsc1, and Neuron-subset specific (NS)-Pten knockout mice. While numerous studies have investigated ultrasonic vocalizations (USVs) in Fmr1 and Tsc1 knockout mice, none have investigated USVs in NS-Pten knockout mice using the Avisoft recording system. In light of this, the present study utilized a maternal separation paradigm to characterize neonatal vocalizations in NS-Pten knockout male and females on postnatal days 8 and 11. We found that knockout pups emitted fewer vocalizations for both sexes (p < .05). Knockout males had calls of a shorter duration and lower peak amplitude on day 8, while showing a shorter duration, lower peak amplitude, and higher peak and fundamental frequency on day 11 (p < .001). Knockout females vocalized at a lower peak amplitude and fundamental frequency, and a higher peak frequency on day 8, while showing a shorter duration and higher peak and fundamental frequency on day 11 (p < .001). Spectrographic analyses also revealed significant differences in call type for both genotypes and sexes (p < .05). These findings demonstrate that deletion of NS-Pten results in significant decreases in vocalizations across both sexes. Additionally, our findings indicate that the aberrant vocalizations and increased call duration seen in other mTOR models are also present in NS-Pten knockout mice. Our study provides evidence of a connection between hyperactive mTOR signaling and ultrasonic vocalizations. The results may provide new insights into the impact of mTOR signaling and an autistic-like phenotype.

Title: Pathogenic role for kynurenine pathway in maternal immune activation-induced autismlike behavior in mice

Authors: *D. S. COELHO¹, A. M. GARRISON², K. KIMENEZ², L. REDUS², J. VALDERAS², J. C. O'CONNOR³

¹Pharmacol., Univ. of Texas Hlth. Sci. Ctr. At San A, San Antonio, TX; ²Univ. of Texas Hlth. Sci. Ctr. at San Antonio, San Antonio, TX; ³Pharmacol., UTHSCSA, San Antonio, TX

Abstract: Prenatal inflammation is a risk factor for neurodevelopmental disorders. In rodent models, maternal immune activation (MIA) causes phenotypes in offspring that resemble many of the features of these human disorders, but the pathogenic mechanisms remain unclear. Immune activation upregulates the tryptophan metabolizing enzyme indoleamine 2,3dioxygenase (IDO) which mediates many of the behavioral consequences of inflammation in adults, and experimentally increasing kynurenine levels of pregnant dams causes developmental consequences in the offspring. Therefore, we hypothesized that MIA-induced upregulation of IDO during gestation is a pathogenic mechanism by which fetal neurodevelopment is disrupted and autism-like phenotypes develop. Pregnant female IDO-/- mice or control C57BL/6J mice were administered 20 kg/mg polyinosinic:polycytidylic acid (poly I:C) or saline i.p. on gestational day 12.5. At various ages, autism-like behaviors were measured. Repetitive selfgrooming behavior was significantly increased in WT-MIA male offspring compared to WTsaline controls. Self-grooming behavior in IDO-/- mice was not affected by MIA. MIA reduced preference for social novelty, measured in the 3-chamber test, in male offspring independent of IDO, while it increased social novelty preference in WT female mice. In mice with targeted deletion of kynurenine monooxygensase (KMO), endogenous kynurenine levels are markedly increased, and offspring of KMO KO dams exhibit several autism-like behaviors. Our data suggest that IDO may play an important pathogenic role in the development of specific autismlike behaviors caused by MIA.

Title: Preadolescent oxytocin ameliorate effects of maternal corticosterone and SSRI exposure on male and female offspring

Abstract: Postpartum depression can affect up to 15% of women. Fluoxetine is a common antidepressant prescribed to treat postpartum depression. Although the data are conflicting, perhaps to do timing and nature of exposure, developmental exposure to selective serotonin reuptake inhibitors (SSRIs), like fluoxetine, during the peri-partum and postpartum period may increase the risk of Autism Spectrum Disorder in children. Oxytocin can enhance social interactions in rodents, and intranasal oxytocin is currently being investigated in clinical trials as a treatment for children with Autism Spectrum Disorder. The aim of this study is to investigate the effects of maternal postpartum corticosterone (to induce depressive-like behavior in the dam) and maternal fluoxetine administration on male and female offspring. Oxytocin is a peptide hormone that does not readily cross the blood-brain barrier. Here we used a nanoparticle drug delivery system TriozanTM to facilitate oxytocin entering the central nervous system in preadolescent offspring. We hypothesized that the use of Fluoxetine during the postpartum period to dams will decrease social behaviour in both male and female offspring. Administration of high corticosterone to the dam increases maternal depressive-like behavior, reduces maternal care and increases anxiety-like behavior in male, but not female, offspring. We expect that oxytocin, given to preadolescent offspring, will reverse the adverse effect of maternal fluoxetine and normalize social behaviour, microbiome composition, proinflammatory cytokines, and adult neurogenesis compared to controls. Dams will be given corticosterone (40mg/kg) to simulate postpartum depression and fluoxetine (10mg/kg) for 23 days. Administration of oxytocin (0.5mg/kg) and TriozanTM (0.25mg/mL) in offspring will occur for 10 days from postnatal day 25 to day 34. Offspring will be tested for social, anxiety and locomotor behaviour during adolescence (postnatal day 35-37) and again in adulthood (postnatal day 70-73). Preliminary

results indicated in adult rats showed that in both males and females, 0.5mg/kg of oxytocin increased social investigation. The results of the current study will determine whether preadolescent exposure to oxytocin mitigates any adverse effects of maternal corticosterone and concurrently fluoxetine on offspring behavior, microbiome, and neuroinflammatory profile. Funding from CIHR to LAMG (MOP-142308).

Title: Sensory processing deficits in a prenatal immune activation model of altered neurodevelopment

Authors: F. HADDAD, L. LU, C. DEOLIVEIRA, *S. SCHMID Univ. of Western Ontario, London, ON, Canada

Abstract: Altered brain development is associated with neuropsychiatric disorders like autism spectrum disorder (ASD) and schizophrenia. Maternal infection during pregnancy has been linked with an increased risk of offspring developing these disorders, implicating maternal infection in abnormal neurodevelopment. Further epidemiological and preclinical research identified the immune response as a major mediator of these detrimental effects on neurodevelopment. To isolate effects of the innate maternal immune response on fetal brain growth, the viral marker polyinosinic:polycytidylic acid (poly I:C) is commonly used to elicit a pathogen-free immune response. Maternal injection of poly I:C during gestation produces offspring with structural and behavioral changes relevant to core symptoms of ASD and schizophrenia. We investigated the effect of early and mid-gestation (Gestation Days 9 and 14) poly I:C treatment in rats on offspring social behaviour, spontaneous open field activity and sensory processing. Sensory processing was measured through habituation and multisensory prepulse inhibition of the acoustic startle response, while social behavior was investigated using a 3-chamber apparatus measuring sociability and social recognition. All tests were done in adolescence (6 weeks) and adulthood (4 months) to investigate the change in phenotype across age in the offspring. Our results show that mid-gestation immune activation impaired visual but not auditory prepulse inhibition (PPI) in both adolescence and adulthood, and this effect was sexdependent in adolescence. In contrast, spontaneous short and long-term habituation of startle as

well as spontaneous open field activity were unaffected. Additionally, adolescent GD-14 poly I:C offspring showed decreased sociability with familiar animals but normal social recognition. Social behaviour in adulthood was unaffected. Preliminary results from GD-9 immune activation show similar deficits in multisensory PPI with a decrease in visual PPI compared to the controls. However, no effects of early immune activation were found in social behavior or spontaneous open field activity. The observed visual PPI and sociability impairments can be linked to neurodevelopmental disease phenotypes, particularly those involving sensory processing and multisensory integration deficits. Future studies will attempt to study the association of these phenotypes with anatomical and molecular findings, as well as whether they correlate with higher order cognitive function.

Abstract: SYNGAP1 haploinsufficiency is one of the most common causes of nonsyndromic intellectual disability and autism. De novo mutations in the SYNGAP1 gene lead to the loss of the encoded protein SynGAP, one of the most abundant of postsynaptic proteins. SynGAP acts as a regulator of signaling pathways linked to AMPA- and NMDA-receptor plasticity at the post synaptic density. The *Syngap* heterozygous mouse model has been widely used to understand the pathophysiology underlying abnormal SynGAP-mediated signaling. Recent advances in techniques for genome manipulation allow for the generation of rat models of neurodevelopmental disorders; enabling phenotypes to be validated across species and addressing cognitive and social dysfunction, using paradigms that are more difficult to assess in mice. In this study, we examine the pathophysiology associated with a heterozygous deletion of the C2 and catalytic GAP domain of the protein, in rats (HET). Importantly, this smaller form of SynGAP is produced and localises to synapses at the same levels as wild type SynGAP. As was found with a homozygous null deletion of SynGAP in mice, homozygous loss of the C2 and GAP domains results in perinatal death in rats. However, in contrast with HET mice, HET rats do not present with hyperactivity and can be habituated to an open field environment. To examine associative recognition memory, we tested the rats in five spontaneous exploration tasks for short-term memory, object-recognition (OR), object-location (OL), object-place (OP), objectcontext (OC) and object-place-context (OPC). We also tested long-term memory in OR and OL. Both groups were able to perform short-term memory tasks, but only wild type rats performed above chance in OL with a 24h delay, suggesting deficits in long-term spatial memory. We then tested if partial loss of the GAP domain in SynGAP affects social behaviour in rats and we found that HET rats exhibited impaired short-term social memory, with no signs of social isolation. One consistent observation through all the tasks was decreased exploratory activity of the HET rats which was due to increased immobility. To examine this further we tested rats in a cued-fear conditioning paradigm, where we found that HET rats had generalised fear and abnormal fear extinction. These findings do not fully recapitulate abnormalities reported in the mouse model of Syngap haploinsufficiency, suggesting that some key behavioural phenotypes may be speciesspecific. We are currently examining the effect of the full protein deletion in rats, to complement existing data and provide greater insight into cognitive dysfunction associated with dysregulation in SynGAP-mediated signaling.

Title: Assessing the differential integration of reward benefits and costs in neurexin1a mutant mice

Authors: *O. O. ALABI, M. FORTUNATO, M. FUCCILLO Neurosci., Univ. of Pennsylvania, Philadelphia, PA

Abstract: Abnormalities in how reward shapes behavior are present in a number of neuropsychiatric disorders including autism spectrum disorders and schizophrenia. While there are extensive genetic resources available to study these disorders in mice, few goal-directed tasks have been designed that reliably characterize how mice weigh differential reward benefits and cost in their selection of actions. In this study, we designed a forced-choice two-alternative serial reversal task in which each lever was associated with specific reward outcomes and required operant contingencies. Furthermore, to simultaneously probe flexibility of choice, we used instantaneous performance measures to trigger contingency switches over the course of a session. We developed global and trial-by-trial measures to assess the choice patterns and behavioral flexibility of mice in response to differing "choice benefits" (modeled as reward magnitude ratios) and different types of "choice cost" (modeled as either increasing repetitive motor effort or increased delay to reward delivery). We have made the following observations: (1) mouse choice is highly sensitive to both relative reward ratio and the density of feedback information; (2) choice costs are heavily discounted in environments with large disparities in reward volume; (3) mice differentially altered their response pattern in response to the introduction of delay and effort costs on the higher reward lever. Delay decreased the likelihood that mice would choose the same alternative on subsequent trials (effectively decreasing the positive reinforcing effects of that alternative), while increasing effort thresholds on high-reward alternatives paradoxically increased the reinforcing effects of the non-modified alternative. We are currently employing this behavioral paradigm in Neurexin1 α mutants, a mouse genetic model of neuropsychiatric disease, where preliminary data suggests deficits in both value-based reinforcement and flexible adaptation of choice.

Title: Prenatal minocycline treatment alters synaptic protein expression, in oxytocin receptorknockout mice

Authors: *S. MIYAZAKI, S. HIDEMA, K. NISHIMORI

Tohoku Univ., Sendai-Shi, Japan

Abstract: Autism spectrum disorder (ASD) is a neurodevelopmental disorder characterized by impaired communication, difficulty in companionship, repetitive behaviors and restricted interests. Recent studies have shown amelioration of ASD symptoms by intranasal administration of oxytocin and demonstrated the association of polymorphisms in the oxytocin receptor (Oxtr) gene with ASD patients. Deficient pruning of synapses by microglial cells in the brain has been proposed as potential mechanism of ASD. Other researchers have shown specific activation of microglial cells in brain regions related to sociality in patients with ASD. Although the roles of Oxtr and microglia in ASD are in the spotlight, the relationship between them remains to be elucidated. In this study, we found abnormal activation of microglial cells and a reduction of postsynaptic density protein PSD95 expression in the Oxtr-deficient brain. Moreover, pharmacological inhibition of microglia during development can alter the expression of PSD95 and improve abnormal mother-infant communication in Oxtr-deficient mice. Our results suggest that microglial abnormality is a potential mechanism of the development of ASD-like phenotypes.

Title: Novel paradigms to analyze digging motivation and social interaction in mouse models of neuropsychiatric disease

Authors: *H. POND¹, O. MCKISSICK¹, M. WILKINSON¹, P. PARLANTI³, M. MANZINI² ²Pharmacol. and Physiol., ¹The George Washington Univ., Washington, DC; ³NEST - Natl. Enterprise for nanoScience and nanoTechnology, Scuola Normale Superiore, Pisa, Italy

Abstract: Digging behavior is often used to test anxiety and repetitive behaviors in mice. However, digging is also a normal mouse behavior, that can be focused toward different goals, i.e. foraging for food, burrowing for shelter, removing noxious stimulus, or even for recreation as has been seen in animals like dogs and ferrets. The marble burying test, where digging is measured as related to the number of marbles buried in deep bedding has become a popular assay for anxiety, obsessive compulsive disorder and repetitive behaviors in autism spectrum disorder (ASD) in mouse models. However, this test can have ambiguous results and does not discriminate between anxiety due to presence of the novel objects, the marbles, and compulsivity using intensity of digging.

We developed the Discriminatory Digging Behavior test a test to make clear determinations between different types of digging behavior in mice based on the driving motivation, distinguishing between foraging (food-seeking) and burrowing (shelter-seeking). Mice are given a choice between emptying a tube filled with paper bedding (the burrow) and digging in deep corncob bedding. By testing mice which were fed ad libitum and then food-deprived, we showed that mice will increase foraging outside the burrow when hungry. To show that this difference was not due to acclimatization to the new environment, we performed the test again on the food deprived mice two weeks after their food intake returned to ad libitum showing that they revert to the previous behavior. When comparing male and female mice, we also found that females do not switch between burrowing and foraging when food deprived as males do. Females have shown different physiological response to food-deprivation than males and they greatly reduce energy expenditure. This sex difference appears to be captured by our test. This novel test can be used to probe brain circuits involved in food seeking, shelter/safety seeking and anxiety and to test animal models of neuropsychiatric disorders. We started by using a mouse model of intellectual disability (ID) and ASD with reduced marble burying performance, mice deficient for the ASD/ID gene Cc2d1a. We found that in fact their burrowing index and burrowing behavior in general was reduced in males, and not altered in females. Because burrowing improves with experience and is also socially facilitated we are now developing variants on this test for assessing learning and social deficits. This cooperative burrowing test can provide a novel social test that is not focused on olfaction as a measure, using mice that are already part of the subject's social structure.

Title: Development of an operant task to quantify social motivation in autism mouse models

Authors: *C. T. WEICHSELBAUM¹, K. PARKER², K. KNIEPKAMP³, M. R. BRUCHAS⁴, J. D. DOUGHERTY⁵

²Anesthesiol., ³Genet., ¹Washington Univ. In St. Louis, Saint Louis, MO; ⁴Departments of Anesthesiol. and Anatomy-Neurobiology, Washington Univ., Saint Louis, MO; ⁵Genet. and Psychiatry, Washington Univ. Sch. of Med., Saint Louis, MO

Abstract: The social motivation theory of autism posits that social interaction may be less rewarding for individuals with autism spectrum disorders (ASD) than typically-developing individuals. However, it has also been suggested that reward processing may be affected more globally in ASD. Mouse models present a promising opportunity to explore these competing hypotheses across a variety of ASD etiologies, such as ASD-associated genetic mutations; however, standard sociality tasks do not directly quantify social motivation. Thus we developed an operant conditioning task to measure the rewarding value of a social stimulus, which may be compared with non-social stimuli to assess whether deficits in reward processing are global or specific to the social domain. We modified a standard mouse operant chamber (Med Associates Inc.) to house a stimulus animal accessible to the test mouse via a guillotine-style door. Bars in the doorway prevent the test mouse from exiting the operant chamber, but allow visual, auditory, olfactory, and tactile contact between mice when the door is raised. Thus the test mouse may be rewarded with social interaction rather than the typical food or drug reward. A progressive ratio (PR) schedule of reinforcement determines the breakpoint for the social reward, that is, how much effort the mouse is willing to exert to obtain that social contact. When rewarded with access to a novel age- and sex-matched conspecific, the majority of wildtype C57Bl/6j mice successfully condition within 5 days on a fixed ratio (FR)-1 schedule, and demonstrate a PR breakpoint comparable to that of non-social rewards (i.e. sucrose pellets). Testing of several ASD genetic mouse models is ongoing. This social operant task represents a valuable addition to the repertoire of sociality tasks used to assess mouse models of ASD, and will help to elucidate the role of social-specific vs. global reward processing deficits in this disorder.

Title: An autism mouse model exhibits enhanced stress responses associated with increased norepinephrine system activity

Authors: *J. W. LUNDEN¹, C. PENG¹, M. GENESTINE SCHMITT¹, M. DURENS¹, S. PREM¹, V. R. MIRABELLA², A. MARKOV¹, J. H. MILLONIG³, E. M. DICICCO-BLOOM⁴ ¹Neurosci. and Cell Biol., Rutgers - Robert Wood Johnson Med. Sch., Piscataway, NJ; ²Neurosci. and Cell Biol., Rutgers - Robert Wood Johnson Med. Sch., New Brunswick, NJ; ³Neurosci. and Cell Biol., Rutgers Univ., Piscataway, NJ; ⁴Dept Neurosci & Cell Biol/ Pediatrics (Child Neurol. & Neurodevelopmental Disa, Rutgers-Robert Wood Johnson Med. Sch., Piscataway, NJ

Abstract: Autism spectrum disorder (ASD) is a pervasive neurodevelopmental disorder with prevalent psychiatric comorbidities including anxiety and depression. Monoamine neurotransmitters, including norepinephrine (NE) and serotonin, play important roles in modulating anxiety and mood. Significantly, the neural patterning transcription factor Engrailed-2 (En2) is involved in the development of the embryonic mid-hindbrain region, where monoamine neurons emerge, and our studies, as well as others, suggest EN2 is associated with ASD. The present study tested the hypothesis that En2 knockout mice (En2-KO) would have defects in regulating the hypothalamic-pituitary-adrenal (HPA) axis stress system, which is controlled in part by innervating NE fibers and activity. The amygdala and ventral hippocampus (vHipp) exert stimulatory and inhibitory inputs to the paraventricular nucleus of the hypothalamus (PVN) to regulate glucocorticoid release. Multiple regions were characterized structurally (NE fibers) and functionally (c-fos) before and after swim stress. The En2-KO amygdala exhibited increased NE innervation, including increased TH (1.7-fold; p<0.02) and NET (1.5-fold; p<0.0017) proteins and NET fibers (2.3-fold; p<0.0007) though CRF mRNA levels were reduced by 85% (p<0.0019). Similarly, the PVN had increased NET fibers (1.7-fold; p<0.016) yet reduced CRF (50%; p<0.004). Based on these results we speculated that altered NE innervation may produce parallel changes in neural activity, which we assessed by defining nuclear c-fos immunostaining. Swim stress is known to produce increased brain regional c-fos+ cells 2h later. Indeed, in amygdala swim stress induced 30% (p=0.03) greater increase in BLA cfos+ neurons in En2-KO vs WT, and 2-fold greater c-fos+ cells in PVN (p=0.001) suggesting correlations between innervation and activation. As one source of NE neurons we examined

locus coeruleus and found swim stress induced a 6-fold increase in c-fos+ neurons in En2-KO (p<0.0001) compared to only 2-fold increase in WT (p<0.0001), potentially identifying a mechanism for increased NE fiber activity. On other hand, the En2-KO vHipp exhibited 30% lower c-fos response to swim stress compared WT (p=0.0074). Our observations indicate that NE fiber innervation in the *En2*-KO mice is markedly increased in the PVN and BLA, whereas it is reduced in the hippocampus. These results support a model of NE fiber innervation regulating neural activity. Moreover, this pattern of enhanced excitatory signaling (amygdala, PVN) accompanied by reduced inhibitory activity (vHipp) will likely lead to excessive activation of the HPA axis, an outcome under current investigation.

Title: The role of STEP in a prenatal valproic acid exposure model of autism

Authors: *M. CHATTERJEE, J. XU, P. SINGH, P. J. LOMBROSO, P. K. KURUP Child Study Ctr., Yale Univ., New Haven, CT

Abstract: Autism Spectrum Disorder (ASD) is characterized by social communication deficits, repetitive and restrictive behaviors. Genetic and environmental factors which interfere with the early stages of neuronal development contribute to an increased risk for ASD. Valproic acid (VPA) is a commonly used antiepileptic drug and mood stabilizer. Maternal exposure of VPA is associated with a significant increase in the occurrence of ASD in humans as well as in rodent models. Prenatal exposure of VPA interferes with the normal synaptic signaling pathways during brain development which eventually contributes to behavioral abnormalities seen in ASD. STEP (STriatal-Enriched Protein tyrosine phosphatase) is a CNS-specific enzyme, which opposes the development of synaptic plasticity. STEP downregulates the surface expression of glutamate receptors as well as several kinases involved in synaptic strengthening. High levels of STEP activity is implicated in several neurological disorders where it contributes to synaptic and cognitive deficits. In this context, reducing STEP activity by genetic ablation or pharmacologic inhibition significantly attenuates the biochemical, behavioral and cognitive deficits in these disorders.

Here, we investigated the role of STEP in a prenatal VPA model of autism. We have found that STEP protein levels are upregulated in the prefrontal cortex of prenatal VPA-exposed mice, which show characteristic autistic symptoms. The increase in STEP level is correlated with a decrease in the phosphorylation status of its substrates (ERK, GluN2B) suggesting a relationship between STEP activity and behavioral abnormalities in these models. We hypothesize that abnormal STEP expression and downregulation of its substrates during critical stages of development contributes to synaptic and behavioral deficits, which could be attenuated by pharmacological reduction of STEP activity. STEP Inhibitor, TC-2153 rescues the behavioral abnormalities like hyperactivity, stereotypy and social deficits in the VPA exposed wildtype offsprings. These pre-clinical experiments will serve as a proof of concept to understand the role of STEP in an environmental model of autism.

Title: Modification of GABA receptors in the cerebellum of autistic rats subjected to an enriched environment

Authors: *J. A. PEREZ¹, O. E. CRUZ¹, M. R. TOLEDO-CARDENAS², L. I. GARCIA², G. CORIA-AVILA², M. E. HERNÁNDEZ², J. MANZO² ¹Doctorado En Investigaciones Cerebrales ,UV, Xalapa, Mexico; ²Ctr. en Investigaciones Cerebrales, UV, Xalapa, Mexico

Abstract: Autism is a neurodevelopmental disorder that causes a spectrum of heterogeneous behaviors, having as common denominator problems in social interaction and alterations in both communication and movement. Also, another common denominator is the alteration of the cerebellum, which presents a reduction in size and a significant decrease in the GABAergic

neurotransmission. Considering the central role of GABA in the functioning of the cerebellum, in this project we were interested in analyzing the density of its receptors in an autistic rat model, and the impact of the stimulation of the subjects by an enriched environment. Thus, we did an immunohistochemical analysis of GABA receptors (rGABA) as a basis for the study of this neurotransmitter in the spectrum. We used an autistic Wistar rat model obtained after postnatal injection of a daily dose of 150 mg/kg of valproic acid to pups from day P6 to P12. Four groups of males were used, Controls (Ct) in standard (SE) and enriched (EE) environment, and Autistic (At) in SE and EE. Then, rGABA in the vermis of the cerebellum was quantified. The results showed that At subjects presented a significant reduction of rGABA, whose density increased to level Ct after being exposed to an enriched environment. The results show that no matter the reduction of rGABA in autistic subjects, the enriched environment has an optimal impact in its density. Therefore, data shows non-pharmacological benefits that can be applied to subjects within the spectrum, possibly prompting appropriate modifications in their behavioral displays, which will be analyzed in future studies.

Abstract: Human chromosome 16p11.2 microdeletion (16p11.2 del), a genetic alteration associated with impaired development and mild intellectual disability, is one of the most

common gene copy number variation in autism, accounting for approximately 0.5-1% of all autism spectrum disorder (ASD) cases. Recent studies suggest that ASD symptoms may be partly mediated by deficiencies in brain synchronization and connectivity arising during development. This study tests the hypothesis that genetic vulnerability to ASD conferred by 16p11.2 might involve dysfunctional communication amongst brain regions. To this purpose, we first analysed resting-state fMRI (rsfMRI) scans in 16p11.2 del and control subjects from the Simons VIP repository. By using motion-related volume scrubbing we were able to retain a sufficient number of control and 16p11.2 del subjects for inter-group statistical mapping (n=28 and n=19, respectively). Inter-group rsfMRI connectivity mapping revealed reduced global connectivity in lateral temporal regions of 16p11.2 del carriers, plus a focal involvement of medial prefrontal areas. To corroborate these findings, we probed prefrontal rsfMRI connectivity in a mouse model of 16p11.2 deletion and found that 16p11.2^{+/-} mice exhibit reduced prefrontal connectivity within the default and salience networks. Importantly, retrograde axonal labelling in 16p11.2^{+/-} mutants revealed altered neuronal density in prefrontal-projecting thalamic-nuclei, suggesting a contribution of thalamo-frontal miswiring to the observed connectivity impairment. We also probed microstructural white matter integrity in $16p1.2^{+/-}$ mice using diffusion tensor imaging and show that 16p11.2 mutants exhibit widespread increase in fractional anisotropy, a finding recapitulating previous observation in children with 16p11.2 deletion. By using electron microscopy, we identified increased axonal diameter in callosal fibers as a possible cellular correlate of these alterations. Taken together, our findings highlight convergent connectivity aberrancies in human 16p11.2 del carriers and in a mouse model of human 16p11.2 deletion, and suggest that ASD-associated 16p11.2 copy number variations can predispose to neurodevelopmental disorders and cognitive disability through a dysregulation of prefrontal functional connectivity.

Title: Medial prefrontal cortex microcircuit dysfunction in NL3 R451C knock-in mice

Authors: *S. LIN

Zhejiang Univ., Zhejiang, China

Abstract: Neuroligins (NLs) are postsynaptic cell adhesion molecules that are related with autism spectrum disorders (ASDs). The neuroligin-3 (NL3) amino acid substitution (R451C) mutation was found in two brothers with ASDs in a Swedish family, and caused social novelty deficits in the specific mutation knock-in mice. The medial prefrontal cortex (mPFC), a brain region that is closely associated with neuropsychiatric disorders including autism. However, little is known about the roles of NL3 during the development of glutamatergic and GABAergic circuitry in mPFC, particularly the roles of NL3 that associated with fast-spiking (FS) interneurons. And gamma oscillation regulated by FS interneurons dysfunction exists in some ASD mouse models. Thus, we hypothesized the gamma oscillation in the mPFC is involved in autism. We found that gamma oscillation dysfunction, decreased Glutamate N-methyl-D-aspartate receptors (NMDARs) function of pyramidal neurons and declined excitability of fast-spiking (FS) interneurons. Together, our findings suggest that the mPFC microcircuit dysfunction may contribute to the ASD-like phenotypes in NL3 R451C KI mice.

Abstract: Copy number variation (CNV) is one of the most prevalent genomic abnormalities in ASD. We previously generated a 15q11-13 duplication model mouse corresponding to the most cytogenetically frequent CNV in ASD and showed that paternal duplication (15q dup) mice displayed ASD-like behaviors including poor social communication and interaction, behavioral inflexibility and abnormalities of cortical spines and cerebellar functions. We also found a reduction in the level of serotonin (5-HT) and in the volume of the dorsal raphe nucleus (DRN), which contains a large proportion of 5-HT neurons providing serotonergic projections to cortical forebrain regions. In the central nervous system of ASD patients, a decreased rate of 5-HT synthesis in developmental stages was reported, suggesting a hyposerotonergic state. The 5-HT system also has abnormal modulatory effects on cognitive function in ASD, and behavioral abnormalities are thought to result from 5-HT-impaired neural networks although direct evidence is lacking. Excitation/inhibition (E/I) balance is suggested to be disrupted in ASD and enhancement of the GABAergic system rescues physiological and behavioral deficits in ASD model mice. However, the hyposerotonergic state and its physiological and behavioral consequences, particularly for cortical E/I balance and social behavior, remain unexamined in ASD model mice. Here, we show that normal 5-HT levels are essential for the proper maintenance of neocortical E/I balance, correct sensory stimulus tuning, and social behavior. Conversely, low 5-HT levels in 15q dup mice result in impairment of the same phenotypes. Restoration of normal 5-HT levels by early 5-HT intervention with selective serotonin reuptake inhibitor (SSRI) revealed the reversibility of the ASD-related symptoms of 15q dup mice. These findings suggest that 5-HT enhancement may have therapeutic potential for discrete symptoms in ASD.

Title: Dysregulation of brain serotonergic systems in BALB/c mice: Relevance for autism and anxiety-like behavior

Authors: *M. W. HALE¹, A. M. RUSSO¹, A. J. LAWTHER¹, B. M. PRIOR¹, L. ISBEL¹, G. SOMERS¹, J. A. LESKU¹, A. RICHDALE², C. DISSANAYAKE², S. KENT¹, C. A. LOWRY³ ¹La Trobe Univ., Melbourne (Bundoora), Australia; ²Olga Tennison Autism Res. Ctr., La Trobe Univ., Melbourne, Australia; ³Dept. of Integrative Physiol. and Ctr. for Neurosci., Univ. of Colorado Boulder, Boulder, CO

Abstract: Although the biological mechanisms underlying autism spectrum disorder (ASD) are not fully understood, evidence suggests that dysregulation of serotonergic systems may play a role in ASD psychopathology. Preclinical models using mice with altered serotonergic neurotransmission may provide insight into the role of serotonin in behaviors relevant to clinical features of ASD. For example, BALB/c mice carry a loss-of-function single nucleotide polymorphism (SNP; C1473G) in *Tph2*, which encodes the rate-limiting enzyme for serotonin synthesis, and frequently have been used to model symptoms of ASD. In this study, juvenile male BALB/c and C57BL/6J mice, which carry the wild type variant of the C1473G SNP, were exposed to two behavioral tests: first, the three chamber sociability test, and one week later to the elevated plus-maze (EPM). Immediately following testing in the EPM, all mice received injections of the aromatic amino acid decarboxylase (AADC)-inhibitor, NSD-1015. One hour later, tissue was collected for quantification of concentrations of 5-hydroxytryptophan (5-HTP) in subregions of the dorsal raphe nucleus (DR) as a measure of Tph2 activity. BALB/c mice showed reduced social behavior and increased anxiety-like behavior, as well as decreased Tph2 activity in the rostral and mid-rostrocaudal DR. Tryptophan hydroxylase 2 activity in the midrostrocaudal DR was correlated with anxiety-like behavior in the EPM. In a subsequent experiment, supplementation of brain serotonin synthesis in BALB/c mice using peripheral administration of 5-HTP combined with the AADC-inhibitor, carbidopa, increased the time spent in the social chamber of the three-chamber sociability test compared with mice treated with carbidopa alone. Finally, an experiment using acute or chronic administration of the selective serotonin reuptake inhibitor fluoxetine in BALB/c mice demonstrated that acute administration of fluoxetine decreased social behavior, while chronic administration of fluoxetine increased

social behavior compared with vehicle-treated controls. Taken together, these data are consistent with the hypothesis that dysregulation of serotonergic systems is associated with mouse behaviors that resemble some of the clinical features of ASD.

Title: Perinatal hyperserotonemia influences dopamine expression in the midbrain

Authors: Z. ZEISLER, S. SMITH, *K. NORTHCUTT Biol. Dept., Mercer Univ., Macon, GA

Abstract: Prenatal and neonatal hyperserotonemia has been the most consistently documented neurochemical finding in children with autism spectrum disorders. Furthermore, pregnant women taking SSRIs prescribed for depression are more likely to give birth to children with autism. A perinatal hyperserotonemia rat model has been developed using the serotonin agonist 5-methoxytryptamine (5-MT). Daily injections of 5-MT to pregnant dams beginning on embryonic day 12 and then into pups upon birth until postnatal day 20 can induce autism-like symptoms, such as social deficits, sensory hyper-responsiveness, and coordination deficits. Corresponding changes in neural development have also been consistently found in this model. Because alterations in dopaminergic networks can produce symptoms similar to those described above, we examined the effects of perinatal hyperserotonemia on the number of dopamine neurons in the midbrain of juvenile male and female rats. We injected 5-MT (1 mg/kg) or a vehicle solution daily to dams (days 12-21 of gestation) and subsequently to their pups (first 20 postnatal days). On postnatal day 30-32, subjects were perfused and their brains were collected. We processed their brains immunohistochemically for tyrosine hydroxylase, the rate-limiting enzyme in dopamine synthesis. The number of tyrosine hydroxylase-immunoreactive neurons in the substantia nigra and ventral tegmental area were quantified. We have focused on these midbrain areas because of their importance in movement regulation and motivation. Our results indicate that perinatal hyperserotonemia increases the number of dopaminergic neurons in the substantia nigra, but only in males. In contrast, treatment has no effect on dopamine expression in the ventral tegmental area. Increases in dopamine expression in the substantia nigra of juvenile males could relate to the coordination and impulsivity deficits that are commonly observed with this model and with children with autism. Similar sex differences have been reported in other studies examining the effects of perinatal 5-MT on neurochemistry, such as alterations in oxytocin and serotonin receptor expression. Furthermore, these sex differences in juvenile dopamine expression could contribute to sex differences in behaviors, such as juvenile play behavior, that have been observed in this model.

Title: Altered maturation of auditory system processing and sensory filtering deficits in the CNTNAP2 knockout rat model of autism: Electrophysiology and behaviour

Authors: *K. SCOTT, B. L. ALLMAN, S. SCHMID

Anat. and Cell Biol., Univ. of Western Ontario, London, ON, Canada

Abstract: The mammalian auditory system undergoes considerable development and experience-dependent plasticity in early life. However, this normal maturation is perturbed in individuals with developmental disorders, such as autism spectrum disorder (ASD). These maturational differences may lead to impairments in auditory processing, and ultimately underlie the communication deficits and altered reactivity to sensory stimuli associated with ASD. For example, individuals with mutations in the autism-linked gene, contactin-associated protein-like 2 (CNTNAP2), are known to experience language processing deficits, yet the contribution of CNTNAP2 to the maturation of auditory processing and sensory filtering remains unknown. We addressed this question with a recently-developed rat model, by comparing the developmental timeline of hearing thresholds and temporal processing using the auditory brainstem response (ABR) and assessing sensory filtering via the acoustic startle response (ASR) in male and female juvenile, adolescent, and adult CNTNAP2 homozygous knockout (cntnap2^{-/-}), heterozygous knockout (cntnap2^{+/-}), and wildtype Sprague Dawley rats. The ABR in response to click stimuli (90 to 10 dB SPL in 5dB steps) was recorded at postnatal day 28, 42, and 70, and the hearing threshold as well as the latency and magnitude of waves I-IV in response to the 90 dB click stimulus were compared between genotypes and across age groups. Auditory sensitivity and sensory filtering (habituation and sensorimotor gating) were assessed behaviourally at P44 and P72 using the magnitude and latency of the ASR. Specifically, the level of startle reactivity to 65 dB - 105 dB noise pulses was used as an index of auditory sensitivity, and habituation of the ASR was measured in response to the repeated presentation of a 105 dB noise pulse. Finally, to

assess sensorimotor gating, the level of prepulse inhibition was determined under a variety of stimuli conditions (i.e., prepulses at 75 or 85 dB; 30ms or 100ms inter-stimulus interval). Ultimately, we found that sound-induced neural activity was transmitted slower throughout the early stages of the auditory pathway in juvenile *cntnap2*^{-/-} rats compared to age-matched wildtype controls; however, this CNTNAP2-related delay was no longer present in adulthood. In contrast, although differences in auditory sensitivity and sensory filtering were also observed, the significant sensorimotor gating deficit found in juvenile *cntnap2*^{-/-} rats did not improve with age. Overall, these results provide insight into the altered maturation of the auditory system in a preclinical model of ASD and how it may lead to altered reactivity to acoustic stimuli.

Title: Bioinformatics study of non-genetic rodent models with ASD-consistent phenotypes

Authors: *M. A. ESTEVEZ, I. DAS, W. PEREANU, A. A. SARKAR, S. BANERJEE-BASU Mindspec, Inc., McLean, VA

Abstract: There is consensus in the autism research community that autism spectrum disorder (ASD) has a complex etiology, combining both genetic and environmental factors. The Animal Model module of AutDB catalogues rodent ASD models, which can be models of genetic or non-genetic factors. Although it is recognized that the environment plays an important role in ASD etiology, most ASD research has focused on genetic factors. Here we want to focus on animal models of non-genetic factors. In AutDB, we have annotated both mouse and rat models of ASD from peer-reviewed publications. Our recent addition of rat data to the Animal Model module of AutDB has highlighted ASD research focused on environmental factors. Together, our animal model data compiles 185 ASD models from 70 non-genetic factors. The objective of our analysis is to assess non-genetic rodent models with ASD-consistent phenotypes. Because ASD is a neurodevelopmental disorder, we want to analyze the developmental time points that are used in the induction of the environmental models. Our hypothesis is there is a correlation between the development of ASD-consistent phenotypes with the trajectory of brain development. Our data show that two developmental time points have an effect in the emergence of ASD-consistent phenotypes: one is mid-gestational and the other early postnatal. We have also classified the non-genetic factors based on environmental etiological models. This

classification allows us to compare different etiological models, which are based on human studies, to the emergence of ASD-consistent phenotypes in rodents. By comparing the non-genetic factors, based on both etiology and phenotypic data, we can score the importance of the underlying pathways. Overall, our study demonstrates that ASD-consistent phenotypes in rodent models are linked to specific neurodevelopmental time points and etiological pathways.

Title: Placental allopregnanolone loss alters fetal brain development in a novel mouse model

Authors: *J. O'REILLY¹, D. BAKALAR², A. A. PENN³

¹The Inst. for Biomed. Sci., The George Washington Univ., Washington, DC; ²Ctr. for Neurosci., ³Fetal Med. Institute, Dept. Neonatology, Children's Natl. Hlth. Syst., Washington, DC

Abstract: A major consequence of preterm birth is premature loss of the placenta and the support it provides. The placenta is a critical neuroendocrine organ that supplies the developing fetus with essential hormones, including neurosteroids such as allopregnanolone (ALLO). ALLO is a metabolite of progesterone that is produced via a two-step enzymatic conversion process that depends specifically on 3α -hydroxysteroid dehydrogenase (3α HSD; in mouse encoded by the AKR1c14 gene). ALLO is a potent, positive allosteric modulator of GABAA receptors. High levels of ALLO are provided by the placenta, at a time when synapses are predominantly GABAergic and GABA is excitatory, rather than inhibitory. GABA excitation is critical for maturation and integration of neurons into developing circuits. ALLO is implicated in regulation of neurogenesis, neural outgrowth and survival, migration and synapse stabilization. To directly test placental ALLO's role in fetal cortical and hippocampal development, AKR1c14 floxed mice designed by our laboratory were bred with CYP19-CRE mice to create a placental-specific knockout of 3aHSD, confirmed by qPCR and *in situ* hybridization. Here, the long-term consequences of placental AKR1c14 loss are described. Immunohistochemistry, gene expression assays and progenitor labeling techniques were used to assess anatomical changes. Alterations in GABAergic interneurons (somatostatin and parvalbumin subtypes) were detected in hippocampus and cortex. Adult mice underwent a behavioral test battery (open field, Y maze, 3chamber sociability, and novel object recognition). Adult mice not exposed to placental ALLO

exhibited higher anxiety, decreased sociability, and impaired cognitive function compared to litter-mate controls. The behavioral deficits mirror those seen in human preterm survivors; GABA loss has been implicated in these deficits. Placental ALLO may regulate GABAergic interneuron development in key regions, including hippocampus and cortex. Our results suggest that loss of placental ALLO can dysregulate early GABAergic signaling, resulting in long-lasting neurological deficits. Our novel placental knockout model is now allowing direct testing of this mechanism and will allow testing of neurological rescue based on ALLO and other placental hormones.

Title: Long-term alteration of cerebellar white matter following prenatal allopregnanolone loss

Authors: J. SALZBANK¹, C. VACHER¹, *A. A. PENN^{2,1} ¹Ctr. for Neurosci. Res., ²CRI, Fetal Med., Children's Natl. Med. Ctr., Washington, DC

Abstract: Prematurity is a risk factor for a wide array of neurodevelopmental disorders and CP is no exception; nearly 50% of children who develop CP are born before 37 weeks gestation. While CP is classically associated with cortical white matter injury (WMI), recent studies suggest that cerebellar WMI may also contribute to the disease pathology. Peak growth and maturation of the cerebellum, accelerating rapidly from 24 weeks gestation through postnatal life leaves this region vulnerable to developmental abnormalities. Prematurity deprives the fetus of high levels of placental neuroactive steroids, specifically the progesterone derivative, allopregnanolone (ALLO), widely investigated for its neuroprotective properties, notably by promoting myelination. This study focuses on the impact of early loss of placental ALLO on cerebellar development and long-term function. To examine the cerebellum following loss of placental ALLO, we bred a Cyp19-Cre driven transgenic mouse model to specifically knock out AKR1C14, the gene encoding ALLO's synthetic enzyme, in trophoblast cells, providing a targeted decrease of placental ALLO. Pups received EdU at E15.5 to analyze late-term cell proliferation in the cerebellum. Immunohistochemical staining with Olig2/Ki67/NogoA and Myelin Binding Protein was used to track oligodendrogenesis. Preliminary data indicated that

early loss of ALLO is associated with a decrease in cerebellar oligodendrocyte density. In addition, RNA-seq analysis performed in P30 cerebella showed differential expression of genes specific to myelination processes and axonal outgrowth. In parallel, a battery of cerebellar-specific behavioral tests, including the Erasmus ladder, was used to characterize long-term motor abnormalities. These results suggest long-term cerebellar WM and motor function deficits that persist long after prenatal ALLO loss. Understanding the mechanisms underlying cerebellar growth suppression and injury that follows preterm birth will allow for the development of new interventions to protect this vulnerable region.

Anokhin Inst. of Normal Physiology, Russia, Moscow, Russian Federation; ⁵Cold Spring Harbor Lab., Stony Brook, NY; ⁶Stony Brook Univ., Stony Brook, NY

Abstract: Allopregnanolone (ALLO), along with its precursor progesterone, is a neuroactive steroid primarily synthesized prenatally by the placenta and postnatally by the brain. ALLO exerts neurodevelopmental and neuroprotective actions through allosteric activation of GABA-A receptor. In fetal brain, ALLO notably promotes neurogenesis and myelination, and protects developing neurons and glial cells from damage. Preterm delivery is associated with premature loss of placental ALLO, potentially contributing to the long-term consequences of prematurity, including learning impairment, attention deficits and cerebral palsy. To test this hypothesis, we generated a transgenic mouse model in which the gene encoding the synthetic enzyme for ALLO (AKR1C14) is deleted in trophoblastic cells expressing Cyp19-Cre transgene to suppress placental ALLO production specifically. We combined two unbiased approaches to assess this prenatal ALLO loss on brain development: (1) 3D analysis of cell proliferation in the whole

brain (whole mount-CLICK) after EdU injection at late gestation, and (2) RNA sequencing in adult brain to characterize the transcriptome of cerebral cortex, hippocampus, hypothalamus and cerebellum, with our without prenatal placental ALLO exposure. RNA sequencing analysis revealed long-term, sex-specific gene expression changes. Differentially expressed genes include those involved in cell proliferation (in agreement with our cell proliferation analysis), survival apoptosis, neurite outgrowth, neurotransmission, myelination and epigenetics, as well as region-specific functions such as energy homeostasis and somatic growth. By providing new evidence on the importance of placental hormones on shaping and programing the developing brain, our data paves the way for further investigation in the emerging neuroplacentology field that can lead to novel therapeutic approaches to prevent adverse neurological outcomes from preterm birth.

Title: Correlation study of prolonged sedation and incidental MRI findings in full-term infants

Authors: H. W. KILCOYNE¹, C. R. L. MONGERSON¹, D. B. PIER², S. L. WILCOX³, R. W. JENNINGS⁴, P. E. GRANT⁶, *D. BAJIC⁵

²Neurol., ³Dept. of Anesthesiol., ⁴Surgery, ⁵Dept Anesthesiol., ¹Boston Children's Hosp., Boston, MA; ⁶Div. of Newborn Med., Boston Childrens Hosp., Boston, MA

Abstract: Prolonged administration of opioids and benzodiazepines used for pain and sedation management in the youngest of patients is associated with a high incidence of drug tolerance and dependence. The clinical impact of such treatment on the full-term infants is largely unknown. We hypothesized that prolonged sedation with opioids and benzodiazepines in full-term infants younger than 1 year is associated with (1) increased incidence of brain abnormalities as per brain MRI scan, (2) increased CSF volumes, and (3) decreased brain volumes in comparison to healthy controls. Subjects were compared between two groups as per IRB approval at the Boston Children's Hospital. Subjects underwent research scan at 3T MRI scanner for 3D T-1 and T2-weighted anatomical images, while charts were reviewed for quantification of sedation. Endpoint analyzes included: (1) length of sedation and weaning (days), (2) total treatment doses per

patient (mg/kg/day), (3) average daily doses during sedation and weaning (mg/kg/day \pm SD), (4) number of anesthesia events, (5) number of incidental findings on brain MRI reports, and (6) estimated normalized cerebrospinal and brain volumes using MANTiS segmentation. Pearson's correlation coefficient was used to measure the linear relations between the different variables analyzed. Morphine and midazolam were the two drugs used the most frequently for prolonged sedation and were administered at the highest doses. We report significant positive linear relationships for the average daily dose of received morphine and midazolam with the number of neuroradiological findings (e.g. abnormalities in extra-axial space, ventricular system, parenchyma, and/or white matter structures) that were not present in any of the controls. There was no significant relationship between the average daily dose of morphine or midazolam despite the apparent positive trend with cerebrospinal fluid volume, and negative trend with estimated brain volume. Given the current standard of care using these drugs for prolonged sedation, future investigations of gray and white matter organization in at-risk full-term infants can provide crucial information of how prolonged sedation can affect brain development and potentially lead to long-term neurobehavioral sequelae.

Title: Brain tissue oxygen regulation in neonates under anesthesia

Authors: *D. P. AKSENOV¹, A. DMITRIEV², M. MILLER¹, A. WYRWICZ¹, R. A. LINSENMEIER² ¹NorthShore Univ. HealthSystem, Evanston, IL; ²Northwestern Univ., Evanston, IL

Abstract: Normal brain function depends on keeping the level of oxygen within a relatively narrow range that is sufficiently high to prevent hypoxia and low enough to minimize generation of toxic oxygen species. Stable blood flow is maintained throughout the brain by cerebrovascular autoregulation, which regulates the response of cerebral arteries to fluctuations in arterial pressure, ensuring sufficient oxygen for basal neuronal activity. It is known that anesthesia has a significant effect on neuronal function and cerebral metabolism which can be different in adults and children. The goal of this study was to compare brain tissue oxygen regulation in neonates in the awake state and during anesthesia. Partial oxygen pressure (PO₂) and single unit (SU)

recordings were performed in the somatosensory cortex of neonatal rabbits (9-12 days postnatal) before, during and after anesthesia with 1 MAC of either isoflurane or sevoflurane delivered both in air and in 80% oxygen. Each animal served as its own control. The same electrodes were used for SU and PO₂ recording. The PO₂ electrodes were polarized at -0.7 volts, and connected to an ammeter (Keithley 614) to record a current that was typically 3 to 10 nA before anesthesia. The current was converted to voltage, notch and low-pass filtered (30 or 50 Hz), and amplified. After completion of PO₂ experiments SU recordings were obtained from the same rabbits before, during and after anesthesia. The multiple SU signals from the microwires were fed through a miniature preamplifier to a multichannel differential amplifier system (Neuralynx Inc, Bozeman, Montana, USA). The signals were amplified, band-pass-filtered (300Hz to 3 kHz), and digitized (32 kHz/channel) using a Neuralynx data acquisition system. Unit discrimination was performed offline using threshold detection followed by a cluster analysis of individual action potential wave shapes using Neuralynx analysis software. Our results showed that when delivered in air, only isoflurane increased brain PO₂. Sevoflurane did not significantly change brain PO₂ likely due to severe respiratory depression. During inspiration of 80% O₂, brain PO₂ increased more when the animals were anesthetized with isoflurane or sevoflurane than when they were awake. This increase was large and varied considerably among the subjects. Single unit activity was greatly suppressed by both isoflurane and sevoflurane, indicating lower consumption of tissue oxygen.

Title: The African Zika virus is more virulent and causes more severe brain damage compared to the Asian lineage and Dengue virus

Authors: *J.-F. CHEN¹, Q. SHAO¹, S. A. HERRLINGER², M. YANG², M. BRINDLEY² ¹Ctr. for Craniofacial Mol. Biol., Univ. of Southern California (USC), Los Angeles, CA; ²Univ. of Georgia, Athens, GA Abstract: Our group is interested in understanding mechanisms underlying neural tube defects (NTDs) and microcephaly. Focusing on a microcephaly disease gene WDR62, we discovered a novel disease mechanism, in which mitotic delay and cell death of neural progenitor cells (NPCs) lead to microcephaly (Nat. Communication, 2014). Zika virus (ZIKV) infection has been linked with fetal brain abnormalities. By developing the first postnatal mouse model associated with ZIKV, we recently established the causative link between ZIKV and microcephaly. Specifically we discovered that Zika virus infection disrupts neurovascular development and results in postnatal microcephaly with brain damage (Development, 2016). The Zika virus (ZIKV) has two lineages: the ZIKV-Asia and ZIKV-Africa isolates. There is no scientific documentation of ZIKV-Africa related brain defects. Dengue virus (DENV), a close family member of ZIKV, is also not linked with brain disorders. Here we performed the intracerebral inoculation of embryonic mouse brains and found that DENV2 is sufficient to cause microcephaly due to increased cell death in neural progenitor cells (NPCs) and neurons. Compared to ZIKV-Asia, DENV2 grows slower, causes less neuronal death, and fails to cause postnatal animal death. Surprisingly, our side-by-side comparison uncovers that ZIKV-Africa is more potent in causing brain damage and postnatal lethality than ZIKV-Asia. In comparison to ZIKV-Asia, ZIKV-Africa grows faster in NPCs and in the developing brain, causes more pronounced cell death in NPCs and neurons, resulting in more severe neuronal loss. Together, these results reveal that DENV2 is sufficient to cause microcephaly but in a less severe manner than ZIKV-Asia. ZIKV-Africa is more virulent and causes more severe brain damage than ZIKV-Asia, highlighting the need to better understand the neurological complications associated with ZIKV-Africa.

Title: Folic acid supplementation during prgnancy partially recovers memory deficits caused by neonatal hypoxia-ischemia in rats

Authors: ***B. FERRARY DENIZ**¹, H. DEOLA CONFORTIM¹, P. M. MIGUEL², L. BRONAUTH¹, B. DE OLIVEIRA¹, L. R. CECHINEL³, I. R. SIQUEIRA³, L. O. PEREIRA¹

¹Federal Univ. of Rio Grande Do Sul, Porto Alegre, Brazil; ²Ciências Morfológicas, ³Univ. Federal Do Rio Grande Do Sul, Porto Alegre, Brazil

Abstract: Folic acid (FA) supplementation during the first trimester of pregnancy is recommended to prevent neural tube closure defects. Our previous studies have demonstrated that treatment with FA after a hypoxic-ischemic (HI) event has a dual effect. Considering this, the aim of this study was to investigate the effect of different doses of FA supplementation during pregnancy on the rat's offspring submitted to neonatal HI. Male and Female Wistar rats were obtained from a local breeding colony by Federal University of Rio Grande do Sul (Approval n° 28136). After mating confirmation, female rats were divided into 3 groups, according to FA supplementation: standard diet (SD), supplemented with 2 mg/kg of FA (FA2) and supplemented with 20 mg/kg of FA (FA20). After birth, all animals returned to receive the SD diet. At the 7° post-natal day (PND), puppies were submitted to Levine-Vanucci model of HI (permanent occlusion of the right carotid and hypoxia during 90 min), generating 6 groups: 1) control with SD diet (CTSD), 2) HI with SD diet, 3) CT with FA2 (CTFA2), 4) HIFA2, 5) CT with FA20 (CTFA20) and 6) HIFA20. Starting at 60° PND, it was performed the novel object recognition (NOR) and the inhibitory avoidance tasks (n=9-13/group). Another group of animals were euthanized at 60° PND and had their hippocampi dissected to evaluate the BDNF concentration (n=5-7/group). In NOR, no differences were observed in the exploration time of the two similar objects in the first session. In the second session, HIPD group had lower novelobject preference index than all control groups, indicating a memory deficit by the lesion. HIPD was also different from HIFA20 and HIFA2 was similar to HIPD and control groups. Deficits caused by HI injury were partially prevented by the lower dose of FA and completely prevented by the higher dose of FA. In the second day of inhibitory avoidance task, HIPD had lower latency to step down the platform when compared to CTPD. HI supplemented with FA groups had no differences with CT and HIPD groups, showing that there was an aversive memory deficit caused by the HI lesion and a partially recovery by FA supplementation. Considering the BDNF concentration, no differences were found in the contralateral hippocampus (left hemisphere). All HI groups had higher BDNF concentration in the ipsilateral side, indicating no effect of FA supplementation. In conclusion, FA supplementation during pregnancy was able, at least, to partially recovery memory deficits caused by HI lesion, indicating a fetal programming effect. This recovery is not due to BDNF concentration.

Title: Developmental effects of the pyrethroid insecticide deltamethrin on medium spiny neurons of the nucleus accumbens

Authors: *C. M. TAPIA¹, K. WINTERS², M. NENOV¹, L. HALLBERG³, B. AMEREDES³, T. GREEN¹, F. LAEZZA¹

¹Pharmacol. and Toxicology, ²Neurosci. and Cell Biol., ³Inhalation Toxicology Core Facility, Univ. of Texas Med. Br. Galveston, Galveston, TX

Abstract: Deltamethrin (DM) is a commonly used pyrethroid insecticide that exerts its effect on insect voltage-gated sodium (Nav) channels by delaying onset of Nav channel inactivation, which is important for the initiation and propagation of action potentials mediating neuronal excitability. Due to high evolutionary conservation of Nav channels and cross reactivity among species, it is imperative to investigate the possible effects of DM in humans. New findings from epidemiological studies correlate the presence of pyrethroid metabolites in urine to an increased risk of attention deficit hyperactivity disorder (ADHD) diagnosis in children. Furthermore, supporting evidence show that rats exposed to DM exhibited ADHD-like behavioral phenotypes, which was attributed to the dopaminergic (DA) reward pathway in the nucleus accumbens (NAc). Similar dysregulation of DA medium spiny neurons (MSNs) has been implicated in multiple neuropsychiatric disorders such as anxiety and depression. In the DA MSN, there is a prevalence of Nav 1.6 channel isoform that is important in synaptic transmission. Nav1.6 heterologous cell studies have shown that prolonged DM exposure significantly potentiated Nav 1.6 mediated persistent and tail currents. Here, we investigate the mechanism of MSN dysfunction due to developmental DM exposure. Pregnant female B6 mice were exposed to 3.0 mg/kg of DM throughout pregnancy and lactation. Then, male mice littermates from post-natal day ~30 were used for subsequent experiments. We employed whole-cell patch-clamp electrophysiology in coronal brain slices to monitor changes in NAc MSNs firing due to developmental DM exposure. At 110 pA of injected current, DM exposure significantly decreased the mean number of action potentials when compared to control (DM 6.8 \pm 2, C 15 \pm 2.4, n= 7-12, p<0.05 with Student t-test). At 190 pA of injected current, DM exposure significantly lowered the instantaneous firing frequency when compared to control (DM 18.4 \pm 4.2 Hz, C 34.7 \pm 5.3 Hz, n= 7-12, p<0.05 with Student t-test). These effects were observed over a series of several current steps. No changes were observed in other active and passive electrical

properties. These studies will advance our knowledge of the toxic activity of DM in the developing brain and help assess risk exposure in the human population.

Title: The effect of vincristine on the developing brain: A longitudinal MRI study in a mouse model

Authors: *L. SPENCER NOAKES¹, C. NICHOLLS², B. J. NIEMAN^{3,4}

¹Mouse Imaging Ctr., The Hosp. For Sick Children, Toronto, ON, Canada; ²Univ. of Waterloo, Waterloo, ON, Canada; ³Hosp. For Sick Children, Toronto, ON, Canada; ⁴Ontario Inst. for Cancer Res., Toronto, ON, Canada

Abstract: Introduction

Acute lymphocytic leukemia (ALL) is the most common form of childhood cancer. Advances in modern medicine have allowed a survival rate of up to 90%. However, children are often left with late effects, which impair cognitive ability, cause cardiac dysfunction, and ultimately limit the quality of life of leukemia survivors. It is widely believed that the combination chemotherapy used in treatment for ALL is responsible for late effects. However, because many chemotherapy agents are administered together in a complex, multi-phase treatment, it is not possible to determine which agents are most toxic. In recent work, we have studied a mouse model of chemotherapy treatment in which we systematically characterized the effects of the most common chemotherapy agents individually. We found that when mice were treated with vincristine at an infant equivalent age, they exhibited significant volume deficits in the brain at early adulthood. In this work, we measured brain development in mice longitudinally to establish how vincristine-induced changes in brain development emerge.

Description of Project

At an infant equivalent age, male and female mice were treated with vincristine intravenously. Mice were imaged using *in vivo* MRI once before treatment, and three times after until they reached nine weeks of age. Treated mice were compared to saline-treated littermates to assess differences in volume across the brain as a function of age.

Results and Conclusion

Changes due to vincristine treatment were widespread, with prominent changes in white matter regions, some areas in the cortex and the cerebellum. Changes began after treatment and emerged progressively over time, with the deficit becoming most significant at the final imaging time point. This work provides an important indication of the progressive—as opposed to acute—impact of vincristine on brain development and implicates vincristine as a toxic component of ALL treatment.

Title: Long-term effects of perinatal bisphenol A exposure on the number of microglia and synapses in the medial prefrontal cortex of rats

Authors: *L. M. WISE, S. RHOADS, S. WANG, J. M. JURASKA Dept. of Psychology, Univ. of Illinois Dept. of Psychology, Champaign, IL

Abstract: Bisphenol A (BPA) is an environmental endocrine disruptor that has been detected in the vast majority of the United States population. Previous research from our lab has found an increase in the number of neurons and glia in the medial prefrontal cortex (mPFC) of male rats following perinatal exposure. The current study explores the effects of environmentally relevant doses of BPA on the number of microglia and synapses in the mPFC. Pregnant dams consumed doses of 0, 40, or 400 ug/kg/day of BPA from gestational day 2 through parturition. After birth, the pups individually consumed the same dose of BPA from postnatal day 1 through 10. Brain tissue was collected in adulthood (~P90) and, using immunohistochemistry, adjacent sections were stained for IBA-1 (microglia) or synaptophysin (synapses). The density of microglia and synapses in the mPFC was calculated using the optical disector in StereoInvestigator. Preliminary results do not show a long-term effect of BPA on the density of microglia or synapses in the mPFC. However, the density may not indicate the actual number of cells or synapses. The density will be multiplied by the volume of the mPFC in order to determine the actual number of microglia and synapses. In addition, the morphology of microglia in the mPFC was assessed. There is a trend towards a decrease in the percent of microglia in the ameboid stage with perinatal BPA exposure. No differences were found in the other morphological stages. Disclosures: L.M. Title: Perinatal exposure to either bisphenol A or phthalates and a high-fat diet minimally affect oxidative stress within the medial prefrontal cortex of both male and female pups

Authors: *D. G. KOUGIAS¹, L. M. WISE², A. P. BELAGODU¹, J. M. JURASKA³ ¹Neurosci. Program, Univ. of Illinois at Urbana-Champaign, Champaign, IL; ²Dept. of Psychology, Univ. of Illinois Dept. of Psychology, Champaign, IL; ³Psychology, Univ. of Illinois, Champaign, IL

Abstract: Since endocrine-disrupting chemicals (EDCs), like phthalates and bisphenol A (BPA), are extensively used as plasticizers and chemical agents in a variety of consumer products, humans are ubiquitously exposed. However, due to environmental contamination, diet is presumed to be the main source of exposure to most of these EDCs, with fatty foods containing the highest concentrations. Given this correspondence and that high-fat diets and these EDCs can separately increase oxidative stress and inflammation systemically, it is important to study them together to examine the potential for interactive effects. Furthermore, since these EDCs can readily cross the placenta and disrupt the actions of hormones that drive the organizational circuitry of the developing brain, the gestational period appears to be a particularly vulnerable window to the effects of EDCs. Unsurprisingly, prenatal EDC exposure in humans is associated with adverse neurodevelopmental and behavioral outcomes. Likewise in rodents, there are perinatal EDC exposure studies corroborating the adverse effects on cognitive behavior; however, these studies have not investigated whether these adverse effects are related to local inflammation. Previously, we have shown that EDC exposure and a high-fat diet perinatally in rats can lead to sex-specific behavioral and cognitive effects in adolescence and adulthood that rely on the medial prefrontal cortex (mPFC).

Here, we examined the effects of perinatal high-fat diet and EDC exposure on oxidative stress markers in the mPFC. Throughout gestation to postnatal day (P) 10, dams were provided a control or high-fat diet. Dams were also orally dosed with either a phthalate mixture or BPA

throughout gestation, but only phthalates can be passed to pups through lactation, so that BPA was directly administered to pups until P10, whereas phthalate consumption continued in dams. Pups were sacrificed on P10 within hours of the last oral EDC administration and their brains were harvested and processed for ELISA. Our results indicate that males may be more vulnerable to brain-specific oxidative stress from perinatal environmental factors, but neither treatment nor diet had consistent or systematic effects on oxidative stress markers within the mPFC.

Title: The effect of perinatal phthalate exposure on the number of synapses in the medial prefrontal cortex

Authors: *E. SELLINGER¹, D. G. KOUGIAS², J. M. JURASKA³ ¹UIUC, Champaign, IL; ²Neurosci. Program, Univ. of Illinois at Urbana-Champaign, Champaign, IL; ³Psychology and Neurosci. Program, Univ. of Illinois, Champaign, IL

Abstract: The perinatal period is crucial for brain development while at the same time, a period where the brain is particularly prone to environmental insult. One such environmental concern is exposure to phthalates, a class of endocrine-disrupting chemicals used as plasticizers, solvents, and emulsifiers in a variety of products that are known to readily cross the placenta and can be passed to offspring though lactation. Previously, we have shown perinatal phthalate exposure in rats can lead to sex-specific behavioral and cognitive changes in adolescence and adulthood that rely on the medial prefrontal cortex (mPFC). Due to these behavioral findings, in this study we examine the effect of perinatal phthalate exposure on the number of synapses in the adult mPFC. Dams were dosed orally with an environmentally relevant phthalate mixture composed of 35.35% DEP, 21.12% DEHP, 15.12% DiNP, 15.10% DBP, 8.16% DiBP, and 5.15% BBP at 0, 200, or 1000 µg/kg/day. Pups were sacrificed in adulthood and their brains harvested. Immunohistochemistry was performed on coronal slices of the mPFC for synaptophysin, a

presynaptic vesicle marker, and then stereologically analyzed. Our preliminary results indicate that increasing phthalate exposure generally decreases synaptic density, particularly in layer V/VI, in both sexes. However, the addition of mPFC volume measurements will allow for the calculation of total synapse number in the mPFC, which will provide a more complete picture of the lasting impact of perinatal phthalate exposure on mPFC synaptic development.

Title: Effects of a phthalate combination during perinatal development on apoptosis in the mPFC of male and female rats

Authors: *J. M. JURASKA¹, J. WILLING¹, D. G. KOUGIAS²

¹Psychology, Univ. of Illinois, Champaign, IL; ²Neurosci. Program, Univ. of Illinois at Urbana-Champaign, Champaign, IL

Abstract: Phthalates are endocrine disrupting compounds that can affect androgenic and estrogenic systems, and are found ubiquitously throughout the environment in a variety of consumer products. The developing fetus can exposed to phthalates through placental transfer and lactation during critical periods of neural development. Previous work indicates that exposure to the phthalate DEHP during prenatal development can decrease cell number and increase apoptosis in the rodent neocortex. Here we examine the effects of exposure to a combination of phthalates found in pregnant human females on the development of the medial prefrontal cortex (mPFC) in male and female rats. Pregnant and lactating rats were fed a cookie with a dose of 0mg/kg, 1mg/kg or 5mg/kg phthalate solution containing six different phthalates (including DEHP and DBP, which have previously been shown to induce apoptosis) at environmentally relevant levels. Dosing occurred from embryonic day 2 through postnatal day (P)10. Brain and body weights were collected from male and female pups at P10 and P25. We additionally examined markers for apoptosis in the medial mPFC at P10, and total mPFC volume

at P25. Both male and female pups dosed with 5mg/kg phthalates had a higher density of TUNEL positive cells in the mPFC, indicating higher levels of cell death, while the 1mg/kg dose caused a reduction in mPFC volume at P25 in both sexes. Additionally, there was a sex difference in the amount of apoptosis in the 1mg/kg group at P10 with effects in males, but not females. Collectively, these results imply that combinations of common phthalates found in the environment can affect the development of the mPFC in a dose and a sex-dependent manner in a brain region critical for executive function.

Title: Chronic exposure to Bisphenol F, a substitute for Bisphenol A, and anxiety in male mice

Authors: *A. TALAROVICOVA, J. W. IRVIN, H. E. SCHRADER, E. F. RISSMAN North Carolina State Univ., Raleigh, NC

Abstract: In many products, Bisphenol F (BPF) is being used as a substitute for Bisphenol A (BPA). Traces have already been found in canned foods as well as in river sediments. Emerging in vitro data show that BPF may not be a safe alternative to BPA, pointing to similar, or even more potent endocrine disruptive abilities. BPF increases progesterone and upregulates the expression of Cyp2d4 in the brain, the enzyme that converts progesterone to allopregnanolone, a potent GABAa modulator. Given the potential of BPF to affect inhibitory signaling in the brain, we used chronic BPF exposure and examined anxiety in adult CD1 male mice. We selected an oral route of administration and doses that reflect likely human exposure to BPF (0mg, 0.5mg 5mg and 50mg BPF/kg food). After 7 weeks of exposure animals were tested in the Open field and the Elevated plus maze test. Based on toxicity studies with much higher doses of BPF we hypothesized that the chronic exposure to all 3 of the low doses of BPF would decrease activity and increase anxiety-like behavior in male mice. Our initial data from the Open field test so far show no differences in activity between the groups. Additionally, contrary to our expectations the animals exposed to BPF are less anxious as reflected by a tendency to spend more time in the center of the Open field and lower amount of defecation. We will discuss the results further in relation to direct versus parental exposure to BPF.

Title: Nature versus nurture: Small additions to one carbon metabolism in pregnant mice alter behavior in offspring as adults

Authors: *R. F. YOSHIMURA, A. ALACHKAR, A. LO, E. MURADYAN, H. SHAHARUDDIN, Y. TU, Y. YI, O. CIVELLI Pharmacol., Univ. of California, Irvine, Irvine, CA

Abstract: One-carbon metabolism regulates the availability of methyl groups for the methylation of DNA and histone proteins. Methionine can be taken exogenously from the diet and is converted in the one-carbon metabolism cycle to the universal methyl donor responsible for biological methylation. We have previously demonstrated that subchronic treatment with a low dose of L-methionine (L-MET) in adult mice caused a number of behavioral changes (Wang et al., 2015). We subsequently saw similar effects in the offspring of females given the same L-MET treatment during pregnancy (manuscript in preparation). We wanted to determine the contribution from the maternal environment to these behaviors, so we cross-fostered the treatment groups (saline pups with L-MET mothers and L-MET pups with saline mothers) and tested them alongside of control groups in adulthood. We examined locomotor activity, T-maze performance, social interaction, prepulse inhibition and fear conditioning. The results suggest a stronger correlation between direct or epigenetic factors and aberrant behavior, in comparison to the maternal environment. This suggests that changes in dietary levels of methionine during pregnancy may have profound behavioral results that are independent of the maternal environment.

Title: Prenatal one-carbon dysregulation impairs memory

Authors: *A. ALACHKAR, R. YOSHIMURA, L. WANG, G. ABBOTT, X. XU, O. CIVELLI Pharmacol., Univ. of California Irvine, Irvine, CA

Abstract: The one-carbon metabolism, which relies on the methionine-folate cycles, has been implicated in the pathophysiology of a number of psychiatric disorders such as autism, Alzheimer's, and schizophrenia. Here we examined the effects on mouse development and behavior of perturbation of one-carbon metabolism evoked by daily methionine administration to dams in the last week of gestation. The dose of methionine is equivalent to double their normal daily dietary intake. The resulting pups (MET mice) exhibited deficits in cognitive functions and memory as shown in T-maze, social recognition, novel object recognition, novel location recognition, and fear conditioning. MET mouse brains also exhibited decreased neurogenesis and synaptic plasticity, increased gliogenesis, and abnormally reduced local excitatory synaptic connections in CA1 neurons. Strikingly, neural transcript expression of only one gene, encoding the Npas4 transcription factor, was >2-fold altered (downregulated) by prenatal methionine administration. Our data support a role for prenatal one-carbon pathway in memory, and suggest methionine metabolism as a potential therapeutic target for psychiatric disorders associated with cognitive deficits

Abstract: The formation of the blood brain barrier (BBB) is key to brain development. Recently it has been demonstrated that radial glial (RG) neural progenitor cells have a strong impact on brain vessel development and BBB formation in the embryonic cortex through modulating endothelial wnt signaling. Maternal brain reactive antibodies (Abs) can penetrate the fetal brain before the embryonic BBB is established. Abs to the brain water channel protein Aquaporin-4 (AQP4) have been associated with fetal loss and may contribute to neurodevelopmental impairment in the offspring of patients with Neuromyelitis optica (NMO), a neurological autoimmune disease characterized by AQP4-IgG in the vast majority of patients. In NMO patients, AQP4 Abs bind to AQP4 on astrocytic endfeet surrounding blood vessels. AQP4 is expressed at the BBB interface and has probably an important role in BBB formation. In order to study the effect of maternal AQP4 Abs we injected intravenously human monoclonal AQP4-IgG or an isotype matched control antibody to pregnant mice at embryonic day E14.5. Western blot and qPCR results show that AQP4 is expressed at a significantly higher level in the fetal brain compared to the placenta throughout all gestational stages. Immunohistochemistry staining shows that a single exposure to AQP4-IgG during embryogenesis alters the vasculature and the number of GFAP positive astrocytes in the hippocampus and cortex of AQP4-IgG in utero exposed male mice throughout adulthood, but did not affect the vasculature of the kidney, where AQP4 is also expressed. We performed a PET study in these mice, which revealed BBB impairment in the entorhinal cortex, which was accompanied by an increased blood flow. QPCR analysis demonstrated differential expression of wnt signaling molecules and LEF1, a transcription factor regulated by wnt signaling pathway, in the cortex of AQP4-IgG exposed mice at postnatal day P0.

Currently we are studying if the altered vasculature and BBB impairment are caused by binding of AQP4-IgG to RG cells. Our findings add to the understanding of BBB formation during embryogenesis and include NMO to the list of potential conditions in which maternal Abs lead to neurodevelopmental problems in the offspring.

Title: Evolution of the HIV-1 transgenic rat: Utility in assessing the progression of HIV-1 associated neurocognitive disorders

Authors: *K. A. MCLAURIN, R. M. BOOZE, C. F. MACTUTUS Dept. of Psychology, Univ. of South Carolina, Columbia, SC

Abstract: Due to the marked increase in life expectancy following the advent of combination antiretroviral therapy (cART), there is a critical need to examine the progression of HIV-1 associated neurocognitive disorders (HAND). Longitudinal experimental designs, in comparison to cross-sectional studies, provide an opportunity to establish age-related disease progression in HAND. The HIV-1 transgenic (Tg) rat, which has been promoted for investigating the effect of long-term HIV-1 viral protein exposure in neurocognitive deficits, was used to examine two interrelated goals. First, to establish the integrity of sensory and motor systems through the majority of the animal's functional lifespan. Strong evidence for intact sensory and motor system function through advancing age in HIV-1 Tg and control animals, was observed in cross-modal prepulse inhibition (PPI) and locomotor activity. The integrity of sensory and motor system function suggests the utility of the HIV-1 Tg rat in investigating the progression of HAND. Second, to assess the progression of neurocognitive impairment, including temporal processing and long-term episodic memory, in the HIV-1 Tg rat; the factor of biological sex was integral to the experimental design. Cross-modal PPI revealed significant alterations in the development of temporal processing in HIV-1 Tg animals relative to controls. Female HIV-1 Tg rats exhibited more pronounced alterations in the progression of temporal processing relative to male HIV-1 Tg animals. Locomotor activity revealed deficits in intrasession habituation, suggestive of a disruption in long-term episodic memory, in HIV-1 Tg animals. Understanding the progression of HAND heralds an opportunity for the development of an advantageous model of progressive neurocognitive deficits in HIV-1 and establishes fundamental groundwork for the development of neurorestorative treatments. Title: Neurodevelopmental and behavioural consequences of maternal immune activation in male and female Wistar rats

Authors: *J. OLADIPO¹, V. FASOLINO¹, M. E. EDYE³, N. DOOSTDAR¹, G. PODDA¹, M. MANCA¹, J. MIYAN², J. C. NEILL¹

Abstract: Background: Viral infection in pregnancy is suggested a risk for the development of autistic spectrum disorder (ASD). Maternal immune activation (mIA), using the viral mimetic poly (I:C), produces phenotypes relevant to ASD in mice when administered at gestational day (GD)12.5. However, no studies have explored mIA at GD12.5 in rats. Our aim is to characterise effects of mIA at GD12.5 on offspring neurobiology and behaviour in Wistar rats. Methods: Pregnant female Wistar rats were injected (i.p.) with poly (I:C) (10mg/kg, n=15 dams) or saline (n=18 dams) at GD12.5. All offspring were monitored for changes in morphometric parameters at GD21 (n=36-51 pups/treatment), (body weight (BW), brain weight (BrW) and placental weight (PW). BW was measured regularly until postnatal day (PD)21 alongside BrW (n=22-30 pups/treatment). The open field test (OFT) was used to measure anxiety-like and repetitive behaviour in adolescence (n=12-16 pups/treatment). Gene expression in frontal cortex (FC) of GD and PD21 offspring was measured using qPCR for genes related to synaptic development and stability alongside blood brain barrier (BBB) integrity. For data analysis between treatment groups, a nested-ANOVA was used with litter as a random variable. Results: At GD21, no effect of mIA was observed on BW or BrW. In male offspring a significant down regulation of Snap25 expression was found (p < 0.05). A significant reduction was found in female PW (p < 0.01) and at PD1 in BW for both sexes from poly (I:C) dams vs. saline (p < 0.001). Reduced BW was maintained at PD12-21 (p<0.001). BrW from offspring at PD21 was decreased in male offspring from poly (I:C) dams vs. saline (p < 0.01). A significant increase in gene expression of structural protein Shank3 was found in FC of male offspring only (p < 0.05). In females, a significant reduction in expression of BBB marker Mfsd2a was shown in the FC (p < 0.05). Similarly, only male offspring showed a significant increase in anxiety-like behaviour in the OFT (p < 0.05). Both male and female offspring from poly (I:C) dams showed increased grooming in the OFT that failed to reach statistical significance. Conclusion: To our knowledge this is the first mIA study investigating the effects of 10mg/kg poly (I:C) in Wistar rats at GD12.5. We provide an in depth developmental analysis of both male and female offspring in this model. mIA resulted in sex

specific alterations in morphometric parameters and gene expression in the FC at GD and PD21. A subtle behavioural phenotype relevant to ASD was shown in male offspring. We suggest that this one-hit exposure to poly (I:C) provides a priming model, relevant for investigating neurodevelopmental disorders at the preclinical level.

Title: End-gestational group B Streptococcus-induced inflammation and attention deficit/hyperactivity disorder in the female rat offspring

Authors: *M.-J. ALLARD¹, M.-E. BROCHU², J. BERGERON², G. SEBIRE^{1,2} ¹McGill Univ., Montreal, QC, Canada; ²Univ. de Sherbrooke, Sherbrooke, QC, Canada

Abstract: <u>Introduction</u>: We previously reported autistic-like behaviors in male - but not female - offspring exposed to group B *Streptococcus* (GBS) placental infection and/or inflammation (live and formaldehyde-killed GBS rat models). Female offspring exposed *in utero* to killed GBS displayed increased social interaction time and forebrain injuries in the periventricular external capsule were detected at postnatal day (P) 40, corresponding to young adulthood. Sex differences have been reported in neurodevelopmental disorders including autism spectrum disorder and attention deficit hyperactivity disorder (ADHD), which might affect differently male and female subjects. We hypothesized that female rats exposed *in utero* to GBS may present neurobehavioral impairments detectable only after the juvenile period, *i.e.* during adulthood. <u>Methods</u>: Lewis dams were injected intraperitoneally on gestational day (G) 19 with either saline (controls) or formaldehyde-killed serotype Ia GBS (10⁹ CFU). Maternal weight gain from G19 to G22, litter size and mean weight of pups following natural birth were measured. Spontaneous

motor activity, anxiety, grooming and rearing behaviors were assessed at P15, P20 and P25 using the open field apparatus. Motor learning was investigated using the Rotarod test performed at P30, P35 and P40. Anxiety and anxiety-related impulsivity behaviors were assessed using the Elevated-plus-maze test on adult rats (P104-P110). Results: GBS had a negative impact on maternal weight gain, but did not affect litter size. GBS-exposed males - but not females weighted less than male controls at P1, but no difference was observed from P2. Reduced time and number of rearing episodes were detected at P20 and P25 in GBS-exposed vs control rats. Increased average time of grooming episodes was observed in GBS-exposed vs control males but not females - at P15. At P40, the latency to fall in the Rotarod test was reduced in GBSexposed females - but not males - as compared to controls. Anxiety-related impulsive behavior associated with open-arm exploration - was observed in GBS-exposed versus control females but not males - during adulthood. Discussion: End-gestational GBS-induced inflammation resulted in ADHD-like behaviors in female - but not male - offspring, which were noticed only from the late juvenile/young adulthood period. Neurobehavioral impairments might be subtler in female subjects before adulthood. Therefore, further neurobehavioral assessments during adulthood would be of interest to better understand these sex differences.

Title: Behavioural & molecular consequences of perinatal infection throughout development

Authors: *R. V. WHEELER, S. ALAM, I. C. G. WEAVER, T. B. FRANKLIN Psychology and Neurosci., Dalhousie Univ., Halifax, NS, Canada

Abstract: Human studies have indicated a link between perinatal infection (PI) and the development of autism-spectrum disorder (ASD) suggesting an epigenetic etiology. Previous research has shown that mice exposed to PI have an ASD-like phenotype, behaviourally and molecularly. However, to date, the literature has primarily focused on the effects of PI on adult male mice; there are few reports describing the behavioural and molecular effects of PI on females, or mice in early development. In the current study, we injected pregnant C57BL/6 mice with lipopolysaccharide (LPS) or polyinosinic:polycytidylic (PolyIC) acid to induce a bacterial or viral response, respectively. Male and female offspring were tested during development and at adulthood for the three core symptoms of ASD: social communication, social interaction, and

repetitive behaviours. Ultrasonic vocalizations to maternal separation, repetitive grooming, and juvenile play between unfamiliar mice were measured during early development. Olfactory habituation/dishabituation to social stimuli, marble burying, 3-chamber social preference, and free-social interaction was measured during adulthood. Additionally, the expression of several synaptic (*Nlgn2/3, Shank3, Mdga2, Mtor*) and regulatory epigenetic (*Hdac2*) genes was analyzed in the hippocampus, cerebellum and frontal cortex of offspring at postnatal day zero (P0) and at 3 months of age to discriminate prenatal from postnatal effects. Changes in gene expression were related to DNA methylation in the promotor regions of these genes. Ultimately, the PI mice displayed abnormal social behaviours, repetitive behaviours and gene expression compared to control sham-injected mice. Moreover, exposure to bacterial infection had differing effects than exposure to viral infection. Distinct sex effects which have not been previously reported were also observed. Overall, this study identified novel mechanistic insights on PI-induced ASD.

Title: Porcine fetal microglial cells are transiently activated by maternal viral infection

Authors: *A. M. ANTONSON, R. W. JOHNSON

Univ. of Illinois Urbana-Champaign, Urbana, IL

Abstract: Epidemiological studies have revealed that prenatal exposure to maternal infection increases the risk of psychiatric disorders like autism and schizophrenia, though the mechanisms remain to be elucidated. We have previously established a maternal immune activation (MIA) swine model, which results in altered piglet social behaviors postnatally, in the absence of microglia activation. Thus, we sought to identify microglia activity prenatally, immediately following maternal infection. We hypothesized that MIA would elicit transient fetal microglia activation concomitant to maternal symptoms of infection. Pregnant gilts were inoculated with porcine reproductive and respiratory syndrome virus (PRRSV; 5 x 10⁵ TCID₅₀ of live virus) on gestational day (GD) 76 and cesarean sections were performed 7 and 21 days post-inoculation (dpi). Primary microglia were isolated from fetal brains and assessed for activation status through flow cytometry, phagocytosis and chemotaxis assays, and LPS and Poly I:C stimulation in culture. Maternal PRRSV treatment did not affect fetal body weights at 7 or 21 dpi; however,

fetal brain weights were reduced (p < 0.0001) at 21 dpi, but not 7 dpi, due to maternal infection. At 7 dpi, primary fetal microglia from PRRSV-infected litters expressed more MHCII (p < 0.0001), and tended to express more CD68 (p = 0.0534), compared to control litters. Additionally, these fetal microglia displayed reduced phagocytic (p < 0.0001) and chemotactic (p < 0.0001) activity compared to controls at 7 dpi. At 21 dpi, expression of MHCII was still elevated (p < 0.05) in microglia from PRRSV-infected litters, though to a lesser extent, and CD68 expression no longer differed. Interestingly, though chemotaxis remained reduced (p < 0.05), phagocytic activity returned to control levels. Intriguingly, TNF α production by primary microglia stimulated with LPS and Poly I:C was not impacted by maternal infection, though production of this pro-inflammatory cytokine was greatly reduced at GD 97 compared to GD 83 (p < 0.0001). Overall, these data suggest that the activity of fetal microglia are transiently altered by maternal viral infection, indicating a potential mechanism through which MIA could negatively impact prenatal neurodevelopment and cause altered behaviors postnatally.

Title: Autism-relevant behavioral outcomes in an antigen-driven rat model of maternal autoantibody related autism

Authors: *M. D. BAUMAN¹, A. MELTZER³, K. L. JONES⁴, R. F. BERMAN², J. VAN DE WATER³

¹Univ. California, Davis, Sacramento, CA; ²Neurolog. Surgery and Neurotherapeutic Res. Inst., Univ. California, Davis, Davis, CA; ³UC Davis, Davis, CA; ⁴Div. of Rheumatology/Allergy and Clinical Immunology, Univ. of California Davis, Davis, CA

Abstract: Maternal autoantibodies reactive to fetal brain proteins have been described by numerous researchers in a subset of mothers of children with autism spectrum disorder (ASD), but not in mothers of typically developing children. While previous passive transfer animal models in mice and nonhuman primates have yielded promising results, they did not reflect a constant exposure to the salient autoantibodies throughout gestation, as would be the case in the

clinical setting. Our research group has recently developed a novel non-passive transfer mouse model of maternal autoantibody related (MAR) ASD to directly assess the pathologic significance of prenatal exposure to epitope-specific autoantibodies in generating ASD-relevant behaviors in offspring. Here we expand this program of research from the mouse and into the laboratory rat in order to evaluate the impact of maternal autoantibody exposure in a species that exhibits complex, reciprocal play behavior. In order to generate epitope-specific autoantibodies that mimic those found in the mothers of children with ASD, female Sprague Dawley rats randomly assigned to MAR-ASD treatment received a series of immunizations containing the immunodominant peptide epitope sequences of the four primary target proteins of MAR ASD (lactate dehydrogenase A and B, collapsin response mediator protein 1, and stress-induced phosphoprotein 1). Control females were injected with saline only. Following confirmation of autoantibody production, females were paired with male breeders to produce the experimental offspring of interest. Subsequent male and female offspring were tested in a sequence of autismrelevant behaviors and developmental milestones from an early postnatal period through adulthood. Our results indicate offspring prenatally exposed to ASD-specific maternal antibodies emit fewer ultrasonic vocalizations as pups, display robust deficits in social interactions at juvenile and young adult time points, and exhibit increased self-grooming behaviors as adults. The developmental trajectory of social impairments and repetitive behaviors observed parallels features of human autism. These findings contribute to the ongoing efforts towards identification of biomarkers specific to subphenotypes of ASD and the establishment of a highly translatable rat model of ASD.

Title: Biodistribution of autism-specific maternal autoantibodies in both maternal and fetal tissues throughout gestation and early postnatal life

Authors: *K. L. JONES^{1,2}, J. FUNG³, D. ROWLAND³, C. SMITH³, D. KUKIS³, J. L. SUTCLIFFE^{3,4}, J. VAN DE WATER^{1,2}

¹Div. of Rheumatology/Allergy and Clinical Immunology, ²MIND Inst., ³Ctr. for Mol. Genomic Imaging, ⁴Dept. of Biomed. Engin., Univ. of California Davis, Davis, CA

Abstract: While the etiology of autism spectrum disorders (ASD) is currently unknown, immune dysregulation has been noted consistently in individuals with ASD and their families, including the presence of immunoglobulin G (IgG) autoantibodies reactive to fetal brain proteins in 23% of mothers of children with ASD versus less than 1% in mothers of typically developing (TD) children. However, the mechanisms through which these maternal autoantibodies act to influence neurodevelopment and subsequent behaviors in the offspring have yet to be elucidated. Further, although maternal IgG is known to cross the placenta during gestation, it is important to determine the extent to which the autoantibodies access the fetal brain. Therefore the objective of this study was to establish the biodistribution of the circulating maternal autoantibodies during gestation and early postnatal life, as well as the extent to which they enter the fetal compartment. To accomplish this, maternal IgG from either autoantibody positive mothers of children with ASD or autoantibody negative TD mothers were conjugated with desferrioxamine for radiolabeling with 89Zr (half-life 78.4 hours), using established methods. The radiolabeled maternal IgG (approximately 200 uCi) in isotonic solution was then injected intravenously of timed-pregnant C57BL/6J female mice on gestational day 15. Pregnant dams were then imaged under anesthesia 2, 24, and 96 hours after injection using microPET emission scans to capture biodistribution during gestation. Additionally, resulting male and female offspring were scanned on postnatal days 0.5, 3.5, and 4.5. Each emission scan was immediately followed by a cobalt-57 transmission scan (400 s) for attenuation correction, and a magnetic resonance (MR) scan for anatomical reference. Zirconium-89 filled capillaries attached to the animal bed were used for alignment of the PET and MR scans during image co-registration. For image analysis, 3D-binned listmode data from the emission scans was reconstructed using a MAP3D algorithm, attenuation corrected and co-registered with the MR data. Regions of interest were drawn for selected organs, as well as the fetal compartment and standardized uptake values calculated. Preliminary results suggest that radiolabeled IgG from mothers of children with ASD and from TD mothers readily enters the fetal compartment beginning 24 hours post-injection. Further, radioactivity was readily detected in the brains of offspring during gestation and persisting into the first week of postnatal life.

Title: Host cell binding mechanism of the zika virus envelope protein

Authors: M. MAY¹, C. A. PEARSON¹, D. GOODE¹, R. GEGUCHADZE¹, D. C. MOLLIVER¹, R. F. RELICH², J. M. VAUGHN¹, *T. E. KING¹ ¹Biomed. Sci., Univ. of New England, Biddeford, ME; ²Indiana Univ., Indianapolis, IN

Abstract: Zika virus (ZIKV) is responsible for an ongoing and intensifying epidemic in the Western Hemisphere. We previously reported a systems biology analysis of ZIKV utilizing diverse strains (representing temporally diverse members of the African lineage, the Asian lineage, and the current outbreak in the Americas) to explore the natural history of this previously little-known virus. Our analysis highlighted a persistent change in the N-linked glycome of all Asian and American strains examined: glycosylation of the envelope (E) protein residue ASN₁₅₄, a modification proposed to mediate neurotropism in related flaviviruses. This modification was absent from examined African strains. Structural analysis indicates that this residue is modified by addition of N-acetylglucosamine (NAG) and falls within a disordered region of the E protein, suggesting that it is part of a linear epitope in vivo. We synthesized short (20-mer) peptides representing this region from strain HPF2013, which is conserved in all sequenced Western Hemisphere isolates, the Nigerian strain IbH30656, and the type strain MR 766(Uganda). A NAG-linked version of the HPF2013 peptide and an unglycosylated version were generated to explore the contribution of this modification to interaction with neuronal cells and fibroblasts, expecting interactions to be representative of ZIKV E protein/cell interactions. Non-glycosylated peptides from HPF2013, IbH30656, and MR 766 bound MDCK cells and primary dorsal root ganglia neurons significantly above a scrambled HPF2013 control peptide at equivalent levels, implicating this motif in ZIKV-cell interactions. These peptides significantly inhibited the ability of ZIKV strain MR 766 to adsorb to host cells, as measured by TCID[50], indicating that we have positively identified the binding mechanism of ancestral African ZIKV strains. Surprisingly, binding of the NAG-glycosylated (i.e., native) HPF2013 peptide to MDCK cells and DRG neurons was abolished, potentially indicating that HPF2013 and related strains target host cells with an alternative binding mechanism. Studies exploring a.) alternative HPF2013 binding motifs and b.) trafficking of NAG-glycosylated and unglycosylated peptides to the central nervous system and the placenta in vivo are ongoing.

Title: Rat model of prenatal Zika virus infection

Authors: *M. L. SHERER¹, P. KHANAL², M. PARCELLS², J. M. SCHWARZ³ ¹Psychology, ³Psychological and Brain Sci., ²Univ. of Delaware, Newark, DE

Abstract: Zika virus (ZIKV), a mosquito-borne flavivirus, has been associated with microcephaly and other neurological disorders in infants born to infected mothers. Despite being declared an international emergency by the World Health Organization, comparatively very little is known about the pathogenesis, mechanisms, or behavioral consequences of maternal ZIKV infection in the offspring. Our lab is interested in developing a working animal model to answer some of these questions. Here, we use a rat model of prenatal ZIKV infection to measure the level of infectivity, as well as the rate of viral clearance in both the mother and her pups. We use quantitative PCR to measure the effect of ZIKV on inflammatory gene expression, and examine various aspects of brain development in pups, including cortical thickness, microglia morphology, and apoptosis. Given that pregnancy is also associated with significant immunomodulation, we are also interested in the role that pregnancy has on the impact of ZIKV infection, therefore we compare viral infectivity between both pregnant and non-pregnant female rats. This model will allow us to 1) better understand the mechanisms underlying ZIKV infection and transmission to the fetus, 2) determine the impact of ZIKV infection on the developing fetal brain, and 3) in the future, measure potential behavioral deficits associated with fetal ZIKV infection later in life.

Title: An investigation into the microglial response to neonatal ZIKV infection

Authors: *J. H. LAWRENCE¹, A. TURANO¹, M. S. PARCELLS², J. M. SCHWARZ¹ ¹Psychological and Brain Sci., ²Animal and Food Sci., Univ. of Delaware, Newark, DE

Abstract: Zika Virus (ZIKV), unlike other *Flaviviruses*, has an apparent selective tropism for developing neural stem cells. As a result, the fetal brain is acutely more vulnerable to ZIKV infection than the adult brain. ZIKV can cross the placental barrier to directly enter the fetal brain. In the fetal brain, ZIKV appears to specifically target developing radial glia. In embryonic mice, ZIKV infection of neural progenitor cells (NPCs) arrests the cell cycle and hinders

apoptotic cell death by 24 hours post-infection. However, by 3 days post-infection, ZIKV induces apoptosis in NPCs and stimulates pro-inflammatory cytokine expression from microglial cells - the resident immune cells of the brain. It is unclear whether neural progenitor cells are the only cells targeted by ZIKV. It is also unclear what role microglia have in the mitigation or exacerbation of cell death associated with ZIKV infection. We hypothesize that ZIKV infection of NPCs will induce microglia to express high levels of pro-inflammatory cytokines (IL-1ß and IL-6), either mitigating or contributing to the resultant cell death of developing neural cells. To test this hypothesis using a rat model, we collected hippocampal and cortical tissue from male and female Sprague Dawley rat pups and generated three distinct cell populations for culture: isolated neonatal microglia, all other developing neural cells, and a population of unsorted cells containing both microglia and all other neural cells. The cells were infected with ZIKV at 0, 0.1, 1, or 10 MOI and collected for qPCR analysis of pro-inflammatory cytokine expression, markers of microglial activation, and apoptotic cell death. A separate set of similarly-treated cell cultures were fixed for analysis of cell type-specific ZIKV infection and apoptosis. This experimental design is unique in its use of a rat animal model as well as its use of a primary cell culture model over a complex in-vivo model. These infection studies will allow us to better characterize Zika virus-host interactions in the developing brain, including how the developing neural immune system responds to this emergent virus. Our preliminary data indicate that ZIKV replication can be detected in rat neural cells following a 16-hour incubation at 1 MOI, an unprecedented result in a rat animal model. Still, the infected cell type remains to be determined. We are currently examining these samples for pro-inflammatory cytokine (IL-1 β , IL-6, and TNF- α) and type I interferon (IFN- α) expression. Ultimately, we predict that the microglial response to infection will be exacerbated by the presence of other developing neural cells, infected and dying from the infection.

Title: Late stage spontaneous waves and their role in downstream visual areas In vivo

Authors: *A. GRIBIZIS^{1,1}, X. GE¹, J. B. ACKMAN², D. LEE¹, M. C. CRAIR¹ ¹Dept. of Neurosci., Yale Univ., New Haven, CT; ²Molecular, Cell & Developmental Biol., Univ. of California, Santa Cruz, Santa Cruz, CA

Abstract: In the developing mammalian visual system, neighboring retinal ganglion cells (RGCs) fire in correlated bursts of action potentials that are observed as propagating waves across the retina. These spontaneous waves of activity, which in mice begin around the time of birth and last until eye opening, are thought to be crucial for normal formation of visual system circuitry. The features of retinal waves have been described in detail in a number of species in vitro, but little is known about their properties in the epoch just prior to eye opening ('Stage III' or P9-P13 in mice) in vivo. Using optical imaging techniques with genetically encoded Ca2+ indicators, we report here on experiments examining the spatiotemporal and pharmacological properties of Stage III retinal waves in RGCs, the superior colliculus, lateral geniculate nucleus and visual cortex in mice in vivo. In comparison to Stage II waves, Stage III waves are smaller, faster, and of shorter duration, which is simultaneously observed in their downstream targets. We also describe the results of novel dual wavelength and fluorophore (RCaMP, GCaMP) experiments to simultaneously image presynaptic axons and postsynaptic neuronal activity. Both Stage II and Stage III waves show faithful transfer to postsynaptic targets in the SC, however Stage III wave transfer is less predictable, likely due to increased post-synaptic activity at older ages. Our data also suggest that Stage III retinal waves propagate in a wave like fashion in both the colliculus and thalamic afferents, but cortical activity is less tightly correlated to retinal activity in Stage III waves than during Stage II. We also examined the effects of pharmacological manipulations in the eye on the propagation of retinal waves to the superior colliculus and higher order visual circuits. These results demonstrate that Stage III waves have unique properties and trans-synaptic propagation compared to earlier (Stage II) spontaneous activity, which may be essential in the patterning of circuits throughout the visual system in vivo.

Title: Origin and function of directionality in spontaneous retinal waves

Authors: *X. GE, A. GRIBIZIS, M. C. CRAIR Neurosci., Yale Univ., New Haven, CT

Abstract: Before the onset of visual experience, spontaneous retinal waves are the main source of activity in the developing superior colliculus (SC), thalamus and primary visual cortex in the mammalian visual system. Genetic and pharmacological manipulations of this spontaneous retinal activity suggest a causal link between retinal waves and circuit refinement. Previous studies found that Stage II (around the first week after birth in mice) spontaneous waves exhibit a strong directional bias. However, it remains unclear how this bias emerges, whether it changes over development and whether this spatiotemporal feature of spontaneous waves is critical for circuit refinement and the development of functional circuit properties. Here, we describe experiments that investigate the role and origin of spontaneous wave directionality during visual system development. We used wide-field Ca²⁺ imaging of retinal ganglion cell (RGC) projections in the SC in vivo and optogenetic or light stimulation of the retina to examine spontaneous and stimulus induced wave direction bias. We observe that the directional bias emerges at the end of Stage II (~P8) waves and vanishes around the time of eye opening (~P13). The biased direction (temporal to nasal) is consistent between P8 and P13. The averaged wave propagation direction distributes inhomogenously across the retina, suggesting a difference in wave initiation and propagation in different parts of the retina. To understand the origin of wave directional bias in vivo, we used selective optogenetic stimulation of starburst amacrine cells (SACs), or light stimulation after the onset of light response (~P10), to initiate waves at various locations in the retina. Our preliminary data suggests that starting from around P10, stimulated retinal waves propagate in a direction consistent with intrinsic waves, regardless of their nucleating sites. This suggests a biased retinal circuit that favors the propagation of waves in a specific direction on the retina. These results suggest a specific developmental stage in which spontaneous retinal waves exhibit a strong bias, which could potentially affect visual circuit refinement in the retina and other parts of the developing visual system.

Title: Ontogenetic course of the establishment of the thalamo-palio-intra pallial connectivity in birds. The chick visual DVR as a study case

Authors: R. REYES-PINTO, G. MARIN, *J. MPODOZIS

Univ. of Chile, Santiago, Chile

Abstract: In spite its evident cytoarchitectonic differences, avian and mammalian pallial territories are comparable in terms of the complexity of its neural processing capabilities. This operational similarity has been attributed to a similar organization of the thalamic inputs to the pallium, and also to a seemingly common pattern of organization of the intrapallial circuits. The avian pallium contains a dorsal intraventricular protrusion known as dorsal ventricular ridge (DVR), which is formed by a dorsal neuronal stratum, known as the mesopallium and a more ventral stratum, the nidopallium. Of particular concern to us is the visual DVR, which can be regarded as a complex composed of three main layers: an internal nidopallial one, the entopallium (E), in receipt of afferents from the dorso-thalamic stage of the tecto-fugal visual system, the nucleus rotundus (Rt); an overlaying nidopallial region, the intermediate nidopallium (NI), lacking sensory inputs; and a more external mesopallial one, the ventral mesopallium (MV). Interconnections between these layers follow a "columnar/ recurrent" arrangement that features a striking resemblance with that of the interlaminar circuitry of the mammalian sensory cortex. We prompted to ask whether the structural similarities between avian and mammalian pallia arise from comparable ontogenetic trajectories. To that end, we study the ontogenetic development of the Rt-E projection, along with that of the E-M reciprocal connectivity in chicks. Minute deposits of biocytin crystals were placed in selected locations of vital slices of the brain of chick embryos. These slices were then reacted with DAB/Ni and counterstained with giemsa. Neurotracing experiments revealed the existence of a prospective Rt as early as E8. At this stage, the visual DVR appear cytoarchitectonically composed by the three main layers described in adults; axons from the prospective Rt were found reaching the nidopallium and delineating in it a prospective entopallial region. Furthermore, columnarly organized axonal processes running reciprocally and homotopically between the E and the MV were found from, at least, E12 onwards. These results suggest that the "cortical like" arrangement proper of the adult visual DVR is established in early embryonic stages, in conjunction with the arrival of the rotundal axons to E, and prior to the (previously documented) date of arrival of the tecto-visual afferents to the dorsal thalamus. This situation may be comparable to that of mammals, where the early ingrowth of thalamic fibres and the maturation of the cortex take place in conjunction, and before the arrival of sensory afferents to the dorsal thalamus.

Title: Hedgehog interacting protein is a candidate regulator of visual circuit formation in the superior colliculus

Authors: *U. JAVED¹, A. MONAVARFESHANI³, M. A. FOX³, J. TRIPLETT² ²Ctr. for Neurosci. Res., ¹Children's Natl. Med. Ctr., Washington, DC; ³Virginia Tech. Carilion Res. Inst., Roanoke, VA

Abstract: We are able experience and navigate through the world through the use of our highly elaborate visual system. In this system, parallel circuits process information about various aspects of the visual scene. For instance, there are multiple subtypes of retinal ganglion cells (RGCs) that respond to specific stimuli, such as contrast or motion. The molecular components that are essential in the formation of these sub-circuits have not been clearly elucidated. In this study, we focus specifically on the sub-circuits of the retina's projection to the superior colliculus (SC). In Isl2-EphA3 knock-in mice (EA3ki/ki), the projections of different RGCs are segregated into the rostral and caudal regions of the SC. Interestingly, the sublaminar targeting of class-specific projections was unaffected, suggesting that the molecules that regulate this process may also be differential expressed in the SC of EphA3^{ki/ki} mice. We performed RNAseq analysis of microdissected regions of the developing SC and identified the hedgehog-interacting protein (*hhip*) was as a potential candidate regulator of class-specific circuit formation. Using a combination of RNA in situ hybridization and immunohistochemistry, we found that *hhip* is expressed specifically in neurons located in the retino-recipient layer of the SC. Additionally, we found that expression of *hhip* was temporally regulated during development, peaking at postnatal day 4 (P4), a time point that overlaps with the period of laminar targeting by RGCs in the SC. Interestingly, we found that *hhip* was expressed in retinal neurons; however, the specific subset of RGCs has not been clearly identified. Taken together these data suggest that *hhip* is ideally positioned to mediate class-specific targeting of RGCs in the SC and raise the possibility that *hhip* may be involved in trans-synaptic signaling between both RGCs and neurons in the SC.

Title: Investigating the mechanisms of parallel circuit formation by converging visual inputs in the superior colliculus

Authors: *N. GABRESKI, J. TRIPLETT

Ctr. for Neurosci. Res., Children's Natl. Med. Ctr., Washington, DC

Abstract: Integrating sensory information is a central task of the nervous system, which is necessary to create a unified percept of the outside world. In the mammalian visual system, distinct neuronal subtypes monitor different aspects of the visual scene, such as contrast or motion, and this information needs to correctly converge in integrative centers to successfully relay both qualitative and spatial information about stimuli. One such integrative center, the superior colliculus (SC), receives converging input from retinal ganglion cells (RGCs) of the eye through the retinocollicular pathway, and also from Layer 5 (L5) of the primary visual cortex (V1) through the corticocollicular pathway. We previously demonstrated that retinal input instructs the spatial alignment of V1 neurons in a process requiring the normal pattern of spontaneous waves of activity. Based on this, we hypothesized that subtypes of RGCs instruct both the spatial and functional alignment of matched L5-V1 inputs in the SC. Utilizing the Islet2^{EphA3/EphA3} knock-in mouse model in which distinct morphological and functional types of RGC inputs are segregated into two independent subdomains of the SC, we are able to separate neuronal projections from L5-V1 that align with these distinct retinal projections. To retrogradely label corticocollicular neurons making monosynaptic connections in the SC of adult mice, a Cre-based pseudotyped rabies viral tracing strategy is being used. Consistent with previous data, we have found that corticocollicular L5-V1 neurons are pyramidal cells that have complex apical and basal dendritic tufts. Current and future experiments using a combination of anatomical tracing, in vivo electrophysiology, and optogenetics will determine the morphological and functional differences of L5-V1 corticocollicular neurons aligning with distinct retinal inputs in the SC.

Abstract: Visual system, part of the central nervous system, receives external visual cues and transforms it into visual and non-visual signals, which enables organisms to react to environment. However, the development of the visual system is influenced by light experience, which implicates the involvement of epigenetic regulations. We focused on the role of one of the epigenomic phenomenon, genomic imprinting, which is expressed in parent-of-origin-specific manner, during critical periods of visual system development. By manipulating light experience during critical periods of visual system development in the mice, we identified experience-regulated, isoform-specific, and brain region-specific imprinted genes. We also found imprinted microRNAs occurring in the clusters. Our results provide the first comprehensive profiling of light-experience regulation of the transcriptome and imprintome during critical periods of visual system development and potential therapeutic strategy for visual impairments and circadian rhythm disorders.

Abstract: In higher mammals, the primary visual cortex (V1) is organized into various functional maps such as an orientation map. The topographies of these maps in the same cortical area are geometrically correlated with each other, but it remains unclear as to how such systematic organization may have developed. Recent studies have reported that the structure of each functional map is strongly correlated with the local organization of ON and OFF thalamic inputs (Kremkow et al., 2016; Lee et al., 2016). It was also proposed that a quasi-periodic orientation map can be seeded by the moiré interference of hexagonal lattices of ON and OFF retinal ganglion cells (RGC) (Paik and Ringach, 2011). Here, expanding upon the previous model, we propose that such a regular distribution of RGCs can also seed the spatial frequency, direction and ocular dominance maps in a way that their topographies are systematically correlated, as observed in experiments. First, we simulated multiple functional maps on a moiré interference of RGC by estimating the individual selectivities of model V1 neurons. As the preferred orientation is determined by the alignment of neighboring ON and OFF cells, the preferred frequency depends on the spatial distribution of neighboring ON and OFF cells in the moiré interference. Because the alignment and the local distribution changes in relation to the other property in the orthogonal direction, we successfully reproduced the orthogonal organization of the orientation map and the spatial frequency map (Nauhaus et al., 2012). Given that this periodic change in the spatial distribution causes the preferred direction to flip at the center of an iso-orientation domain, the iso-orientation domain was divided into two isodirection domains with opposite directions (Weliky et al., 1996). Next, we simulated the ocular dominance while assuming that a V1 neuron receives input from two sets of moiré interference, mimicking the contra- and ipsilateral retina. Because the early orientation map is dominated by

the contralateral eye (Crair et al., 1998), the contralateral input was assumed to be projected from the retina to V1 by local wiring that can seed a clear orientation map (Paik and Ringach, 2011), whereas more extensive wiring was assumed for the ipsilateral projection. In our simulation, the ocular dominance peaks were located where the local density of the contra-RGC is relatively high or low. This reproduced the previous observation of singularities in the orientation map which are located at the center of an ocular dominance domain (Crair et al., 1997). Our results suggest the retinal origin of multiple functional maps and their structural correlation.

Abstract: Thyroid hormones are crucial for the development and proper maturation of the CNS. Severe changes in thyroid hormones levels during perinatal period can result in impaired brain development since they regulate neurogenesis, neuronal growth and synaptogenesis (Zoeller, Dowling et al. 2002; Plateroti Bernal et al. 2011). During the post natal development, the sensory experience plays a key role in the refinament and maturation of of neural circuits, since it regulates the development of intrinsic programs to modulate gene expression as both the anatomical and functional properties of neuronal circuits through patterns of neuronal activity. The objective of this study is to evaluate the role of thyroid hormones in the development of neural circuits modeled the visual system that has topographical organization characteristics and formation of eye-specific layers, properties that point to the formation of organized neuronal circuits.

Title: Targeted expression of GCaMP6 to map functional retinotopy in the optic tectum of Xenopus tadpoles

Authors: *V. J. LI, A. SCHOHL, E. S. RUTHAZER Montreal Neurolog. Inst., McGill Univ., Montreal, QC, Canada

Abstract: The wiring of the developing *Xenopus laevis* retinotectal system has been well described anatomically, but the functional organization of the retinotopic map has not been thoroughly characterized. Here we report on the development of an optical approach to visualize retinotopy in the tectal neuropil of albino Xenopus larvae, based on in vivo two-photon imaging of calcium fluorescence changes in response to visual stimulation. By microinjecting messenger RNA for the genetically-encoded calcium indicator GCaMP6 into one blastomer of two-cell stage Xenopus embryos, expression of calcium indicator can be restricted to half of the developing tadpole. Because the projection from the eye to the brain crosses the midline, this approach permits the presynaptic terminals of retinal ganglion cell inputs and the postsynaptic dendritic fields of tectal neurons to be observed independently. Drifting bar stimuli were presented on a LED monitor placed adjacent to the animal under the microscope. Threedimensional stacks of calcium fluorescence images of the neuropil and tectal cell somata were collected using resonance-scanning 2-photon excitation with piezo focus control, at acquisition rates of up to 30 Hz. Correlation of fluorescence intensity changes to visual stimulus location revealed smooth maps for both azimuth and elevation. This method can uncover continuous retinotopic maps in most of the volume of the tectal neuropil, and can serve as a tool to examine the influences of various developmental factors on map organization.

Title: Characterization of Brn3c RGCs

Authors: *T. C. BADEA¹, N. PARMHANS², E. NGUYEN², K. CHUANG², S. SAJGO², W. LUO³, J. NIU³

¹Retinal Circuits Develop. and Genetics/N-NRL/DIR/NEI/NIH, ²Retinal Circuits Develop. and Genet. Unit, Natl. Eye Inst., Bethesda, MD; ³Neurosci., Univ. of Pennsylvania, Philadelphia, PA

Abstract: We have previously described a transcriptional combinatorial code of Pou domain transcription factors regulating Retinal Ganglion Cell (RGC) diversity in the mouse. RGCs expressing the Brn3c transcription factor constitute a small fraction of all mouse RGCs, and, depending on the particular subtype, they can also express the transcription factors Brn3a and/or Brn3b, as well as neurotrophin receptors such as cRet. We have recently described a sequential Dre to Cre recombination strategy involving a Dre-dependent conditional Cre knock-in allele at the Brn3c locus. In addition, we have described a unique cell type identified by the intersection of the cRet and Brn3c expression domains. We are taking advantage of these unique tools to characterize the dendritic arbor lamination, molecular profile and brain projections for RGCs expressing Brn3c, hopefully leading to the characterization of the physiological and circuit function of individual RGCs expressing Brn3c.

Title: Thalamic contributions to the developmental acquisition of state-dependent cortical activity

Authors: *Y. MURATA¹, M. T. COLONNESE²

¹Pharmacol. and Physiol., George Washington Univ., Washington, DC; ²Pharmacol. and Physiol., The George Washington Univ. Sch. of Med., Washington, DC

Abstract: Two major checkpoints of cortical development are the acquisition of continuous background (spontaneous) activity and the state-dependent modulation of this activity. In both humans and rodents, cortical activity during early development is discontinuous, meaning it contains long (>1 second) silent periods, and oscillatory activities are poorly modulated by arousal state. Continuous background activity that is reliably modulated by state develops around the term age in humans and at the end of second postnatal week in rodents. Abnormal development of continuity is often a result of brain damage due to epileptic seizures or hypoxic-ischemic encephalopathy. However, the underlying circuit changes that instruct continuity are unknown. Thalamic lesions in adults can result in discontinuous activity and disrupt state-dependent modulation in cortex, but the changing behavior and function of thalamus around the time of continuous activity development has not been examined.

Here we use the rodent visual system as a model to examine the role of thalamus in cortical activity development. We conducted simultaneous recordings in the lateral geniculate nucleus (LGN) and visual cortex (VC) of awake head-fixed rats using linear multi-electrode arrays throughout development. We find that between P5 and P11 spontaneous LGN activity is discontinuous and not modulated by movement. By P13 activity in both VC and LGN becomes continuous and movement causes increased multi-unit firing in both structures. To determine the role of thalamus in this change, we pharmacologically silenced LGN. This treatment reduces firing and continuity in VC at all ages. Furthermore silencing LGN causes movement to suppress, rather than increase, VC activity. Thalamic single-units isolated with spike sorting showed that the developmental acquisition of continuity and movement dependence occur at the neuron level. Thalamic bursting only emerged on P16, a few days after thalamic acquisition of movement modulation, suggesting that the mechanisms initiating the development of movement modulation and bursting are different.

Together our results demonstrate that maturation of LGN circuitry, not intra-cortical or thalamocortical connections, plays a determinative role in the developmental acquisition of continuity and state-dependence observed in cortex. Our study has implications for understanding the circuit basis of human EEG development, which could improve diagnosis and treatment of preterm and neonatal infants.

Title: The profile of the critical period for darkness-induced recovery of vision in monocularly deprived kittens

Authors: *D. E. MITCHELL¹, N. A. CROWDER², K. R. DUFFY³

¹Dept of Psychology and Neurosci., ²Psychology & Neurosci., Dalhousie Univ., Halifax, NS, Canada; ³Psychology & Neurosci., Dalhousie, Halifax, NS, Canada

Abstract: In Long-Evans rats (He et al., *Nat Neurosci* 10:1134, 2007) and 3 month-old kittens (Duffy & Mitchell *Curr Biol* 23:382, 2013), a 10 day period of total darkness has been shown to precipitate fast improvement of the visual acuity of the deprived eye induced by a short early period of monocular deprivation (MD). For rats, the period of darkness was imposed when the animals were considered adult (at P70 – 100 days) and beyond the upper limit of the age (~7weeks) of vulnerability of neural connections with the deprived eye in the rat visual cortex to the effects of MD. On the other hand, 10 days of darkness when imposed on adult cats at 1 yr of age promoted no recovery of vision in the deprived (amblyopic) eye (Holman et al., *Soc Neurosci* 780.02, 2014), a result that implied that the benefits of darkness in felines were confined to an early critical period.

To document the profile of the critical period for the benefits of darkness, the same 10 day period of darkness was imposed on 15 kittens of progressively older ages each having received an identical early one week period of MD from P30-37 days. Longitudinal measurements were made by use of a jumping stand to assess the recovery of grating acuity of the two eyes at regular intervals, as well as the extent and time course of any recovery that occurred in the period following the period of darkness. Total darkness over 10 days was ensured by use of a custom-built darkroom facility (Mitchell *Clin Exp Optom* 96: 363, 2013).

In terms of the grating acuity of the derived eye, the effects of 10 days of darkness appeared quite uniform with respect to both the speed and the extent of the recovery of acuity when darkness was applied at any age prior to P180. However, thereafter there was a precipitous decline in the benefits of darkness such that no darkness-induced improvement in the acuity of the deprived eye was evident at all after P195 days. It is known that darkness can influence the levels of many putative molecules that serve to either facilitate or inhibit neural plasticity in the visual system. The protracted period during which darkness is efficacious may represent a period

during which at least a subset of such molecules retain sufficient susceptibility to environmental manipulation to promote significant recovery. The abrupt termination of the critical period for darkness-induced recovery may reflect the age at which alteration of the slowest developing plasticity mechanisms is no longer possible with darkness. From a clinical perspective, the results imply that for darkness to be effective for treatment of human amblyopia it should be applied only in childhood.

Title: Cell architecture alterations and loss of retinal ganglion cells followed by pupillary light reflex alteration in prenatal hypoxia ischemia rats

Authors: *G. D. TAVEIRA¹, L. S. FONSECA², M. N. OLIVEIRA³, F. TENORIO², P. C. BARRADAS², T. KRAHE³

¹Farmacologia e Psicobiologia, Univ. Do Estado Do Rio De Janeiro, Rio de Janeiro, Brazil; ²Farmacologia e Psicobiologia, Univ. Do Estado Do Rio De Janeiro, Rio DE Janeiro, Brazil; ³Fisiologia, Univ. do Estado do Rio de Janeiro, Rio de Janeiro, Brazil

Abstract: Prenatal hypoxia-ischemia (HI) is one of the main causes of neurodevelopmental impairment in the newborn and is associated with cerebral palsy, attention problems, hyperactivity, epilepsy, and sensory alterations, including visual processing problems. The retina is widely recognized as a neural circuit model used in the study of the development and plasticity of neuronal circuits. Thus, the investigation of the effects of prenatal HI on retinal development offers great potential to elucidate mechanisms related to the effects of HI during pregnancy. Here we studied the effects of prenatal HI on retinal morphology and function. Specifically, we evaluated the number of retinal ganglion cells (RGCs) and the pupillary light reflex (PLR) after prenatal HI of Wistar rats. Prenatal HI was induced by occlusion of uterine arteries for 45 minutes on the eighteenth gestational day (HI group, n = 23 rats from 6 litters). Control animals were obtained from pregnant females submitted to the same surgical procedures except for the occlusion of the uterine arteries (SH group, n = 24 rats from 6 litters). Histological procedures were made at postnatal (P) day 2, 9, 23 and 30. Hematoxylin and eosin staining revealed a

significant reduction in retinal layer thickness of HI animals compared to controls for all ages except P30. Immunohistochemical labeling of RGCs with Brn3- α showed a significant reduction in the number of RGCs in the HI group compared to control. PLR was evaluated in a separate group of animals at P30 (HI, n = 7; SH, n = 8) after two hours of dark adaptation. Both groups showed equal pupil constriction times and sizes, but HI animals were not able to sustain pupillary constriction under continuous illumination. Sustainability of the PLR is attributed to the activation of intrinsically photosensitive RGCs (ipRGCs). Therefore, our results suggest that prenatal HI could be preferentially eliminating ipRGCs.

Title: Developmental refinement of interhemispheric connections in ferret visual cortex

Authors: *R. KHALIL^{1,2,3}, C. GONZALEZ¹, J. B. LEVITT^{1,2}

¹Dept. Biol., City Col. of the City Univ. of New York, New York, NY; ²Grad. Ctr. of the City Univ. of New York, New York, NY; ³Dept. Biology, Chemistry, and Envrn. Sci., American Univ. of Sharjah, Sharjah, United Arab Emirates

Abstract: Visual corticocortical connections in adult animals link cortical areas in the same hemisphere (intrahemispheric) as well as in the opposite hemisphere (Interhemispheric or callosal). The adult pattern of callosal connections between visual areas in both hemispheres in a number of species is thought to emerge from an immature state during development through refinement of some aspects of this circuit. We studied the postnatal refinement of callosal connections projecting from multiple cortical areas to ferret (*Mustela putorius furo*) primary visual cortex (area 17) during the period from just before eye opening (4 weeks) to 10 weeks of age. Our goal was to determine (a) whether callosal projections from multiple visual cortical

areas to area 17 refine with a similar rate and (b) whether the developmental refinement of callosal projections parallels that of intrahemispheric cortical circuits. To follow the development of callosal connections we injected the bidirectional tracer CTb into area 17 of juvenile ferrets, and visualized the distribution and pattern of callosal projecting cells in area 17, 18, 19, 21, and Ssy of the contralateral hemisphere. We analyzed the refinement of retrogradely labeled callosal cells in each source area by quantifying their areal and laminar distribution. Throughout development, the greatest proportion of callosal projections arises from the infragranular layers in most visual areas. At 4 weeks of age we find the greatest proportion of callosal inputs to area 17 arising from Ssy, with a lesser and comparable proportion arising from areas 17, 18, 19, and 21. From 5 to 6 weeks of age the proportion of callosal projections from Ssy to contralateral area 17 declines significantly, while the proportion from contralateral area 18 increases. From 6 weeks to 10 weeks of age there is minimal change in the proportion of callosal input to area 17 arising from areas 18 and Ssy. In contrast, we find no significant change in the proportion of total callosal inputs to area 17 arising from contralateral areas 17, 19, and 21 during this postnatal period. We observe the same trends in the postnatal refinement of intrahemispheric feedback to area17; around the time of eye opening the major ipsi- and contralateral corticocortical input is provided by area Ssy, but within a week or two thereafter area 18 supplants Ssy as the major corticocortical input. This suggests that the refinement of both interand intrahemispheric connections follows a broadly similar developmental trajectory during the period just after eye opening.

Title: Binocular integration of orientation selectivity in the developing ferret visual cortex

Authors: *D. E. WHITNEY¹, G. B. SMITH³, B. HEIN⁴, M. KASCHUBE⁵, D. FITZPATRICK²

¹Neurosci., ²Max Planck Florida Inst., Jupiter, FL; ³Max Planck Florida Inst. For Neurosci., Jupiter, FL; ⁴Frankfurt Inst. For Advanced Studies, Frankfurt, Germany; ⁵Frankfurt Inst. For Advanced Studies, Frankfurt Am Main, Germany

Abstract: Selectivity for stimulus orientation is a fundamental property of primary visual cortex in primates and carnivores, where it is exquisitely organized into a smoothly varying columnar map that emerges in an activity-dependent manner during early postnatal life. Recently, we reported that the initial absence of orientation selectivity can be accounted by high trial-to-trial

variability at a columnar scale. Thus, response variability appears to be a limiting feature of the developing cortex, and its reduction crucial for the emergence of feature-specific representations. However, variability may also beneficially provide a flexible and dynamic mechanism for the developing cortex to explore and select relevant feature-specific input.

To test whether response variability might be associated with a constructive role in forming coherent cortical representations, we chose to investigate how binocular inputs for orientation tuning become matched in ferret visual cortex. In rodents, this is an activity-dependent process that begins around eye-opening as orientation selectivity emerges (Wang et al., Neuron, 2010), but it is unclear if a similar process occurs in a species with cortical columns. Using functional imaging of GCAMP6s at both the columnar and cellular level, we show that the monocular presentation of drifting gratings to either eye evokes robust and modular responses. Furthermore, as in rodents, orientation-tuning is initially mismatched through the eyes, resulting in dissimilar orientation maps. The initial mismatch in orientation preference is gradually eroded, and within 5-7 days of visual experience monocular orientation maps match at near adult-levels. We next tested the idea whether a gradual reduction in trial-to-trial variability to responses evoked by monocular stimuli precisely coincides with a developmental matching of orientation tuning through the two eyes. Indeed, we find both processes occur simultaneously. Moreover, because of the higher trial-to-trial variability, we observe with dimension reduction techniques that stimuli presented to each eye evoke activity in overlapping neural populations. In principle, Hebbian-based learning rules could then associate orientation-selective responses through the two eyes to a common neural population. In summary, while early trial-to-trial variability is a limiting factor for the emergence of orientation-selectivity in visual cortex, variability might also serve as an important framework to align binocular inputs for forming a coherent percept of the visual scene through both eyes.

Abstract: The calyx of Held (CH) is a giant nerve terminal that monoinnervates the medial nucleus of the trapezoid body (MNTB) within the brainstem and is critical for relaying interaural timing information for sound localization. This synapse exhibits hallmark developmental features of strengthening and pruning necessary to sculpt a precise neural circuit. Using serial block-face scanning electron microscopy (SBEM) on tissue collected from neonatal littermate mice (24-48 sampling), we previously found that around birth most principal cells host many small competing inputs (20+). Then, largely between postnatal (P) days 2 and 4, most inputs are pruned and selected terminals (2-3) grow at rates of 200 μ m² per day. Finally, a single input is strengthened into a calyx by P6. Importantly, this allows for the establishment of a large yet precise circuit ahead of the onset of hearing (P10). To date, imaging techniques have likely underestimated the actual growth dynamics of a developing neural circuit, owing to poor temporal resolution. Here, we examine the temporal dynamics of synaptic organization in the MNTB as it relates to the ultrastructure revealed with SBEM. We employed the lattice lightsheet (LLS) microscopy that offers fast acquisition with minimal bleaching. Acute coronal brainstem slices (300-600 µm thickness) were collected daily in neonates ranging from P0-14. Following 4D image acquisition, data was imported into syGlass, a custom software package designed in-house, for immersive virtual reality aided-analysis. Points were manually placed through time to track growth dynamics of calyces and their emanating processes including filopodia and growth cone tipped collateral branches extending as far as 75 µm. We found an age-dependent relationship with motility of these calyceal collaterals that form a fluid field around the host calyx. Growth cones, perhaps the most dynamic feature of this system, extend fastest during the growth of the calyx yet tend to slow as monoinnervation is established (P2: 65±11 μm/hr; P3: 288±20 μm/hr; P4: 176±33 μm/hr; P5: 90±7 μm/hr). Instantaneous velocities are unprecedented however for growth cones in any system (P2: 270±18 µm/hr; P3: 1318±101 μm/hr; P4: 1037±79 μm/hr; P5: 713±54 μm/hr). This is because movement of calyceal collaterals are stochastic where as much time is spent extending and retracting as pausing. These data are effective in monitoring the navigation patterns of assembling neural circuits in an intact system. Moreover, these observations reveal the dynamic nature of growth and retraction of developing neurites that may otherwise be missed without sufficient temporal resolution.

Title: Influence of thyroid hormone deficiency on mouse auditory cortex

Authors: *M. CHANG¹, H. D. KAWAI²

¹Dept. of Bioinformatics, ²Dept. of Sci. and Engin. for Sustainable Innovation, Soka Univ., Tokyo, Japan

Abstract: Auditory system requires thyroid hormone for normal development and function. Lack of thyroid hormone during development causes such symptoms of psychiatric disorders as auditory hallucination. Since auditory hallucination is thought to involve abnormal cortical connectivity, we suspected that hypothyroidism affected the distribution of neurons and laminar formation in the auditory cortex. Previous studies had suggested that the retrogradely labeled callosal projection neurons were mis-distributed within auditory cortex in the adult hypothyroid rats. Whether hypothyroidism affects the distribution of corticothalamic and subcortical projection neurons in primary auditory cortex (A1) is a remaining question. In this study, we investigated this using mice treated with methimazole, an antithyroid drug, starting at embryonic day 10 until the day of experiments up to postnatal day 60.

To identify corticothalamic and subcortical projection neurons using the immunofluorescence technique, antibodies against transcription factors Forkhead-box protein 2 (Foxp2) and COUP-TF interacting protein 2 (Ctip2) were used, respectively. Dendrites and dendritic spines of layer 5 neurons were also analyzed by the Golgi staining. We found that Foxp2-immunopositive cell density and distribution were not affected, whereas Ctip2-immunopositive cells were misdistributed without changing their cell density in layer 5 of hypothyroid mice. Further, we also found abnormal spine morphology in layer 5 pyramidal neurons in hypothyroid mice. In summary, hypothyroidism in mice induces misdistribution of subcortical projection neurons and abnormal spine morphology of pyramidal neurons in layer 5 of A1 during development and in the adult. These changes may underlie the symptoms of psychiatric disorders such as auditory hallucination.

Title: Transcriptional profiling of the tonotopic critical period in mouse primary auditory cortex

Authors: B. KALISH¹, E. E. DIEL², M. E. GREENBERG¹, *T. K. HENSCH² ¹Dept. of Neurobio., Harvard Med. Sch., Boston, MA; ²Harvard Univ., Cambridge, MA

Abstract: Sensory experience drives neural circuit refinement during critical periods of heightened plasticity, but little is known about the genetic regulation of these developmental windows. The primary auditory cortex (A1) exhibits a critical period for thalamocortical connectivity between postnatal days P12-P15, during which continuous tone exposure alters the tonotopic topography of A1. We hypothesized that a coordinated, multicellular transcriptional program governs this window for patterning of the auditory cortex. To generate a robust multicellular map of gene expression, we performed droplet-based, nuclear single cell RNAsequencing (scRNA-seq) of A1 homogenates across three developmental time points spanning the tonotopic critical period (P10, P15, P20). We also tone-reared mice (7kHz pips) during the 3day critical period and collected A1 at P15 and P20. Using semi-supervised clustering and marker genes, we identified and profiled neuronal (glutamatergic and GABAergic) and nonneuronal (oligodendrocytes, microglia, astrocytes, and endothelial) cell types. This yielded cell type-specific and shared developmental gene programs. Next, we clustered genes based on their temporal expression kinetics and described ontological categories for these clusters. We were able to subgroup glutamatergic neurons into cortical layer-specific populations and GABAergic interneurons into known subtypes. This data is a rich resource for the identification of potential new tools for cell type-specific studies of A1. Furthermore, we sought to identify novel candidate genes that may execute auditory critical period plasticity. By comparing normally-reared and tone-reared mice, we found hundreds of genes in both glutamatergic and GABAergic cells with altered expression as a result of sensory manipulation in the critical period. Based on expression patterns, we identified genes as potentially positive or negative regulators of plasticity, and further validated cell-type specific expression of select genes using *in situ* hybridization. This paves the way for assessing therapeutic reopening of critical periods in A1 following removal of molecular 'brakes' on plasticity. To our knowledge, our study represents the first single cell transcriptomic analysis of the developing auditory cortex and is a powerful discovery platform with which to identify mediators of tonotopic plasticity.

Title: Cochlear purinergic receptors contribute to *In vivo* spontaneous activity in the developing auditory system

Authors: *T. A. BABOLA^{1,3}, A. GRIBIZIS⁴, A. P. LOMBROSO⁵, J. ISSA², S. LI³, B. LEE³, M. C. CRAIR⁴, D. E. BERGLES³

²Dept. of Biomed. Engin., ¹Johns Hopkins Sch. of Med., Baltimore, MD; ³The Solomon H. Snyder Dept. of Neurosci., Johns Hopkins Univ. Sch. of Med., Baltimore, MD; ⁴Dept. of Neurosci., ⁵Dept. of Neurobio., Yale Univ., New Haven, CT

Abstract: Spontaneous electrical activity is a prevalent feature of the developing nervous system and has been shown to influence the maturation and survival of neurons, as well as refinement of circuits in the brain. In the developing auditory system, bursts of activity originate in the cochlea and propagate through the brainstem and midbrain to the auditory cortex before hearing onset. Although spontaneous activity is initiated in the cochlea, the sequence of events that lead to burst firing of spiral ganglion neurons remains uncertain, in part, because there have been few mechanistic studies performed in vivo. To define the patterns of activity that occur in auditory circuits in the brain and determine the mechanisms responsible, we developed an in vivo method for imaging synchronized neuronal activity in unanesthetized mice before hearing onset. In neonatal prehearing mice, spontaneous activity in the inferior colliculus (IC) was imaged using the genetically encoded calcium indicator, GCaMP6s, expressed in neurons under the SNAP25 promoter. Widefield epifluorescence imaging revealed that groups of neurons located along the tonotopic axis exhibit periodic spontaneous increases in calcium at this age (P7-9). These events were bilateral, spatially restricted and oriented along the tonotopic axis, consistent with the excitation of adjacent hair cells in the cochlea by supporting cells. Bilateral cochlear ablation eliminated these bursts of activity, demonstrating that that they originate within the developing cochlea. Unilateral cochlear ablation revealed that although activity from one cochlea is bilaterally represented, there is a strong contralateral bias, consistent with previous in vivo

electrophysiological studies of sound evoked activity. When NBQX, an AMPA receptor antagonist, was applied to the round window membrane, activity in the contralateral IC was suppressed, mimicking unilateral cochlear ablation, indicating that permeation through the round window membrane is sufficient to enable pharmacological manipulation of the cochlea. To test the involvement of the metabotropic ATP receptor, P2ry1, which is highly expressed by inner supporting cells in the cochlea, in generating spontaneous activity, a selective P2ry1 antagonist (MRS2500) was applied to the round window membrane. Activity in the IC was dramatically reduced following acute P2ry1 antagonism, an effect that was mimicked in high frequency zones in P2ry1 knockout mice. These studies provide the first in vivo evidence that ATP release within the cochlea promotes burst firing in central auditory circuits.

Title: Investigating the perinatal expression of tyrosine hydroxylase in the mouse spiral ganglion

Authors: *T. SANDERS, M. W. KELLEY NIDCD, NIH, Bethesda, MD

Abstract: The afferent innervation to the cochlea is composed of the spiral ganglion neurons (SGNs), which transmit mechanosensory input from the hair cells centrally to the cochlear nucleus as an electrochemical signal. There are two populations of SGNs in the mammalian cochlea: Type 1 SGNs which constitute 90-95% of the total population, and form contacts with inner hair cells (IHCs); and Type 2 SGNS which constitute the remaining 5-10% of the total population and form contacts with outer hair cells (OHCs). Recently, Tyrosine Hydroxylase (TH), an enzyme involved in the synthesis of catecholamines, has been shown to be expressed exclusively by Type 2 SGNs predominantly in the apical region of the adult mouse cochlea. To further understand the development of this TH expressing population in the mouse we undertook an immunohistochemical study analyzing the proportion of TH+ SGNs in the basal,

mid and apical turns of the cochlea across a range of prenatal and early postnatal time points. TH protein expression was first detected in the spiral ganglion at embryonic day 16 (E16). At post natal day 0 (P0) an average of 3.9% of SGNs were TH+ in the basal turn, 8.9% in the mid turn and 7.2% in the apical turn (n=5). Interestingly, while the proportion of TH+ SGNs remained relatively stable until P5 in both the basal and apical turn, in the mid turn the proportion significantly decreased to 2% at P5 (P<0.05, one way ANOVA with posthoc Tukey's test, n=5). In all three turns the proportion of TH+ SGNs appears to decrease further at P7 (n=5). Consistent with this data we observed strong TH staining in the terminals surrounding the OHCs in the apical and mid turns of the cochlea beginning at P0. The amount of staining below hair cells in the mid turn appears to decrease at P5, whereas the apical staining remains consistent. However, at least some of this staining may be due to dopaminergic efferent terminals in the same region which also express TH. No staining was observed in the terminals surrounding the IHCs at any age.

Overall this work shows that TH, a newly described Type II SGN marker, is expressed more widely in the early postnatal cochlea than in the mature cochlea. Future studies will focus on determining the phenotype of the population which turn off TH expression, and the role TH may be playing in the development of these neurons.

Title: Pharmacological reprogramming of lateral line progenitors to a multipotent state

Authors: M. KHALIL¹, *J. R. MEYERS²

¹Neurosci., ²Biol., Colgate Univ., Hamilton, NY

Abstract: The zebrafish lateral line is a series of mechanosensory organs termed neuromasts that detect the flow of water along the body; the homology between the cells and genes in the lateral line and those in the inner ear have made this an attractive system for studying development and regeneration of mechanosensory cells and organs. The neuromasts are deposited along the head and trunk by a migratory clusters of cells termed primordia comprised of mesenchymal, multipotent progenitors that organize into epithelial rosettes which are deposited from the back end of the primordium where they differentiate to form the sensory hair cells, non-sensory supporting cells, and the surrounding mantle cells. The migration of the primordium and deposition of neuromasts have been well studied and is known to be coordinated by Wnt at the leading, migratory edge, and FGF and Notch signaling in the trailing region where the
neuromasts organize and are deposited. We have utilized pharmacological alterations in these signaling cascades to alter the fates of the progenitor cells during migration and deposition and to attempt to revert the differentiating cells back to a progenitor-like state. Mimicking the signaling environment of the leading edge of the primordium by simultaneously activating Wnt signaling with the GSK3 β inhibitor 1-azakenpaullone and inhibiting FGF signaling with the FGFRTK inhibitor PD166866 after all of the neuromasts have been deposited leads to the supporting cells reverting to a migratory mesenchymal-like state. These cells retain progenitor-like properties as following washout of the drug cocktail, they re-epithelialize into neuromasts, though with improper positioning and numbers, and produce physiologically active and innervated hair cells within each neuromast. We also show that inhibition of MEK with PD0325901 is sufficient to induce a similar reprogramming of the supporting cells to a migratory mesenchymal state that can reform new neuromasts upon washout of the drug. Together these data demonstrate that lateral line supporting cells can be reverted to a migratory progenitor-like state that are capable of producing new sensory organs including new mechanosensory hair cells.

Title: Developmental features of primary sensory cortex and subcortical areas in the prosimian galago (Otolemur garnettii)

Authors: *E. C. TURNER, J. H. KAAS

Psychology, Vanderbilt Univ., Nashville, TN

Abstract: The primate cerebral cortex undergoes striking changes during its development, but much is still unknown regarding how the primary sensory systems develop to reach their mature organization. We used a combination of immunohistochemical markers in the prosimian galago (Otolemur garnettii, n=8), aged P0 to P72, to follow the cortical and subcortical development of areas connected to primary sensory cortex (visual, somatosensory, and auditory). In addition to standard Nissl and cytochrome oxidase staining, we used vesicular glutamate transporter 2 (VGluT2) protein, which is primarily expressed in glutamatergic feedforward thalamocortical connections, and neuronal nuclei (NeuN) protein, which identifies all neurons, to characterize architectonic features. We also used calcium-binding proteins (CBPs) parvalbumin (PV) and calbindin (CB), as while the function of CBPs remains debated, they are known to be observed in

well-defined subpopulations of neurons. We find that all sensory thalamic nuclei, including the lateral geniculate nucleus (LGN), medial geniculate nucleus (MGN), and ventroposterior nucleus (VPN), show distinct subdivisions, related to the representation of their respective sensory inputs, that differ from expressions in the adult galago. For example, there is evidence for developmental changes in the connections of the magnocellular (M), parvocellular (P), and koniocellular (K) pathways to visual cortex; the P layers of the LGN are the only layers to express PV at P0, in contrast to full expression throughout the LGN layers in the adult. Similarly, VGluT2 expression at P0 in the LGN is evenly distributed across the M, P, and K layers, in contrast to the adult galago which has the strongest reactivity in the M layers, followed by the P layers, and most weakly in the K layers. In all primary sensory areas, layer IV is easily identifiable with PV reactivity, in contrast to the surrounding non-primary areas which show minimal reactivity across cortex. One exception to this is middle temporal visual area (MT), which contains strong neuropil and cell immunoreactivity for PV in layer IV at P0. These results, similar to those reported for MT in marmosets (Warner et al., 2012), suggest that area MT may serve as a primary-like area early during development. These architectonic maps of galago cortex can reveal more about the hierarchical developmental of cortical areas and the functional roles of these areas in early postnatal development.

Fac. Mannheim, Heidelberg Univ., Mannheim, Germany; ⁵Georg-August-Univ, Göttingen, Germany; ⁶Univ. Heidelberg, Med. Fac. Mannheim, Germany

Abstract: The axon initial segment (AIS) is an electrogenic microdomain with potential impact on neuronal excitability in the context of activity-dependent cortical plasticity in adult networks. Its length and location (25-40µm in most cortical pyramidal neurons, usually at the proximal axon) and molecular infrastructure (clustering of voltage-gated ion channels) as well as its unique innervation pattern by axo-axonic GABAergic synapses make it a prime candidate for modulating neuronal input-output properties. Recent studies have highlighted its role in cellular mechanisms reminiscent of homeostatic plasticity, both under physiological and pathophysiological conditions. Structural AIS plasticity (changes in length or position) has been observed both *in vitro* and *in vivo* and is thought to fine-tune neuronal activity when networks are either activity-deprived or hyperexcited.

In a previous study we showed that in the rodent somatosensory cortex (barrel field), the AIS undergoes partially activity-dependent structural plasticity during development and also retains a level of plasticity in adult circuits after bilateral whisker-trimming in adult mice (postnatal day (P) 180). AIS length changes were observed within time frames of days to weeks. However, the question whether AIS plasticity also occurs rapidly after hours, e.g. as a response to sudden changes in network state, has yet to be addressed in vivo. Therefore, we set out to investigate whether rapid AIS plasticity, so far only described in vitro, also occurs in the mouse barrel cortex (S1BF). We employed confocal analysis of immunofluorescent AIS stainings as well as electrophysiological recordings in acute slices prepared from mice that were subjected to either sensory deprivation or stimulation (exposure to enriched environment, EE). Our data show that sensory deprivation via whisker trimming from birth until P15 results in slow, significant AIS lengthening in layer II/III of S1BF. Additionally the previously described shortening of AIS length after the onset of active whisking (P12) is delayed, but not completely abolished, by deprivation. Accordingly, our preliminary electrophysiological data indicate that the shift in firing patterns during normal S1BF development correlates with AIS shortening after P15 and that sensory deprivation causes increased excitability. Strikingly, stimulation of the barrel network via EE results in significant rapid shortening of the AIS within 3 hours by 10%. This effect could no longer be observed 6 hours after EE, suggesting that rapid AIS plasticity could serve as a fast modulator of neuronal activity in excited networks until a homeostatic balance is achieved.

Title: Embryonic thalamic calcium waves predate cortical map formation

Authors: *N. ANTÓN-BOLAÑOS¹, H. GEZELIUS², L. PÉREZ-SAIZ¹, F. J. MARTINI¹, A. FILIPCHUK¹, A. ESPINOSA¹, A. SEMPERE-FERRÀNDEZ¹, J. P. LÓPEZ-ATALAYA¹, M. VALDEOLMILLOS¹, G. LÓPEZ-BENDITO¹

Abstract: Sensory systems are represented in the primary sensory areas of the brain organized in anatomical and functional maps. For instance, the whisker pad representation in the barrel field of S1 in rodents. Many intrinsic and extrinsic factors have been proposed to shape sensory maps during early development. Thalamic spontaneous calcium waves propagate from the thalamus to the cortex perinatally, before sensory maps are formed. Recently, we have shown their role in controlling sensory area size (Moreno-Juan et al., 2017), being a good candidate to influence cortical map formation as an extrinsic factor. Despite these recent evidences, the role of prenatal spontaneous subcortical activity in cortical map formation remains to be elucidated. To this end, we developed a mouse model in which thalamic neurons are hyperpolarized due to the overexpression of the inward rectifier potassium channel Kir2.1 (Th^{kir}). Th^{kir} mice show a disruption of prenatal thalamic spontaneous calcium waves and lack the somatosensory map representation in the cortex. Remarkably, although thalamocortical axons (TCAs) reach their cortical target in S1, they do not segregate into cortical barrels, thus losing their characteristic point-to-point refined organization. To unfold whether these topographical defects are controlled by gene expression changes, we performed genome-wide transcriptomic analysis in the somatosensory thalamus at different embryonic stages. We also tested to what extent the lack of a somatotopic map alter the function of the somatosensory system. In vivo extracellular recordings upon whisker stimulation in Th^{kir} mice show a clear reduction of the cortical responses in S1, which is in agreement with a decrease of whisker-specific cFos induction after novelty exposure in these mice. Hence, by generating a mouse model in which prenatal spontaneous calcium waves are suppressed in the somatosensory thalamus, we disrupt the formation and function of the barrel-field map in the somatosensory cortex. Our results suggest that cortical somatosensory map formation relies on the spontaneous calcium waves of the thalamus, giving a main role to the prenatal thalamic activity in cortical acquisition of sensory map representations.

Title: Differences in state-dependent responses to sensory feedback between somatosensory and motor cortex in developing rats

Authors: *J. C. DOOLEY, M. S. BLUMBERG

Dept. of Psychological and Brain Sci., Univ. of Iowa, Iowa City, IA

Abstract: In the developing rat, myoclonic twitches occur in skeletal muscles across the entire body during active sleep (AS, or REM sleep). The sensory feedback from these twitches strongly drive neural activity throughout the sensorimotor system. Further, early in development, the motor function of primary motor cortex (M1) has not yet developed, and thus neural activity in M1 is primarily related to sensory input. We have recently shown that in the region within M1 that represents the forelimb, reafference from forelimb twitches results in substantially more neural activity than reafference from wake movements. This raised the following question: Is this state-dependent difference in the magnitude of reafferent responses unique to M1, or is it a more general feature across sensorimotor cortex. To answer this question, using 9- to 11-day-old rats, we recorded from neurons in the regions of M1 and primary somatosensory cortex (S1) that are responsive to forelimb movements. We then examined the neural activity in the period immediately after forelimb twitches and wake movements. Consistent with previous findings, we found that both S1 and M1 show strong responses to forelimb twitches. However, unlike M1, S1 shows equally strong responses to wake movements. This finding indicates that M1 and S1 process wake-related movements differently and highlights the unique ability of AS-related twitches to activate the entire somatomotor neuraxis. Combined with our previous work showing state-dependent gating of reafference in the medullary external cuneate nucleus, this result suggests a segregation of the sensory pathways providing reafference to S1 and M1 in the developing rat. Determining the mechanisms and pathways involved in this segregation is one focus of current work.

Title: Distribution of P2X2 and P2X3 purinergic receptors in newborn and developing opossums, Monodelphis domestica

Authors: *A. BEAUVAIS, E. CORRIVEAU-PARENTEAU, J.-F. PFLIEGER Sci. biologiques, Univ. De Montréal, Montreal, QC, Canada

Abstract: We use the opossum Monodelphis domestica as a model of sensorimotor development given its immaturity at birth, comparable to a rat embryo of 13-14 days, allowing easier access to early developmental stages. Previous experiments using in vitro preparations of newborn opossums have shown that motor responses to mechanical stimulation of the face are affected by application of the non-specific purinergic receptor antagonists PPADS. Purinergic receptors are involved in a large number of functions in adult mammals and are expressed early in the central nervous system of rodents. Firstly, to identify if P2X2R and P2X3R purinergic receptors may be involved in sensorimotor responses in neonatal opossums, we have used immunofluorescence on fixed tissues to examine their distribution in the neuraxis and spinal ganglia from the day of birth (P0) to P13. P2X2R labeling was observed from P1 onwards and solely in some fibers at the periphery of the spinal cord, in the presumptive white matter under the pial surface and mostly in the dorsomedial part of the cord. Some of these fibers seemed to end by a growth cone. At older ages, labeled fibers increased in number and were observed more laterally and ventrally in the cord, still predominantly located at the periphery of the cord but an increasing proportion of them adopt a radiating orientation. In the head tissues, P2X2R labeling was not observed at P0 but was present at P5, P9 and P13 in the trigeminal ganglion and the brainstem. In the latter, labeled fibers were seen mostly at the periphery, but also centrally in the presumptive pons. No neuronal cell bodies appeared to be labeled anywhere in the central nervous system. P2X3R immunolabeling was noticed only from P5 to P13, being restricted to the skin covering the back of the lids and the cornea. These results suggest that both P2XR subtypes are expressed in neonatal opossums, particularly P2X2R. Pharmacological experiments should allow us to determine if they are involved in the control of the precocious sensorimotor behaviors in opossums.

Title: Use of optogenetics to trigger and characterize somatodendritic dopamine release in the mouse mesencephalon

Authors: *B. DELIGNAT-LAVAUD, L.-E. TRUDEAU

Pharmacol. and Physiol. and Neurosciences GRSNC, Univ. De Montreal, Montréal, QC, Canada

Abstract: Most dopamine (DA) release in the brain occurs from axon terminals through a classical exocytotic mechanism. However, DA can also be released from the somatodendritic (STD) compartment of DA neurons. The molecular mechanisms of STD DA release are unclear. STD DA release has been previously studied in mouse brain sections by combining extracellular field stimulation with cyclic voltammetry or with patch-clamp recordings of D2-mediated currents. An important limitation of these approaches is that extracellular stimulation nonselectively depolarizes DA neurons as well as local terminals and cell bodies of GABA and glutamate neurons, in addition to axon terminals containing 5-HT, which can complicate analysis of cyclic voltammetry recordings. Here we further explored this unconventional form of transmitter release in mouse brain slices by combining optogenetics to selectively activate DA neuron cell bodies and cyclic voltammetry. For this purpose, a mouse line expressing the lightactivated channelrhodopsin (ChR2) was crossed with a DA-specific Cre driver mouse line (Ires-Dat-Cre) to selectively express ChR2 in DA neurons. We find that train pulses of blue light can effectively trigger an electrochemical response of small amplitude, which can be increased in magnitude by blocking the membrane DA transporter (DAT) and the D2 autoreceptor. The capacity of this releasable DA pool appears to be small, as repeated train pulses with an interval of 5-10 min lead to a large decrement of the response. We are presently exploring strategies to increase the size of the releasable STD DA pools.

Title: Input-specific, dopaminergic modulation of synaptic gain in medial prefrontal cortex

Authors: *K. BURKE, K. J. BENDER UCSF, San Francisco, CA

Abstract: The prefrontal cortex (PFC) supports working memory and decision-making tasks by integrating excitatory and neuromodulatory inputs from across the brain. Performance on these tasks is dependent on the neuromodulator dopamine, as well as long-range excitatory input from several limbic, thalamic, and cortical regions. The dopamine D1 receptor family, including D1 and D5 receptors, has been previously shown to suppress glutamatergic transmission in PFC, but whether D1/D5 receptors differentially regulate these PFC inputs remains unclear. Here, we show that D1/D5 receptors preferentially suppress action potential-evoked calcium influx in a subset of excitatory long-range inputs to PFC. By analyzing trial-to-trial fluctuations in presynaptic calcium influx in axonal boutons, we show that dopamine likely alters voltagedependent recruitment of calcium channels, in turn lowering vesicular release probability. Interestingly, dopamine alters release probability at these synapses without altering short-term facilitation or depression. This allows dopamine to modulate synaptic gain, a process more commonly associated with changes in postsynaptic efficacy. Moreover, because dopamine acts presynaptically, this mechanism can alter the relative input strength of modulated and unmodulated inputs. Taken together, these findings suggest that D1/D5 receptors can bias information transfer in PFC through previously unidentified cellular mechanisms.

Title: Localization and trafficking of dopamine D2 autoreceptors

Authors: *B. G. ROBINSON, J. R. BUNZOW, J. T. WILLIAMS Vollum Inst., Oregon Hlth. and Sci. Univ., Portland, OR

Abstract: Dopamine D2 autoreceptors are G protein-coupled receptors (GPCRs) that regulate the excitability of dopamine neurons. In the midbrain, D2 receptors are activated by the somatodendritic release of dopamine from neighboring neurons. D2 receptor signaling and distribution was investigated in this study by combining electrophysiology with the imaging of tagged receptors. Surprisingly, upon agonist exposure, GFP-tagged D2 receptors on dopamine neurons in the substantia nigra pars compacta (SNc) were not internalized. D2 receptors were seen to internalize in other neuron types indicating a specific interaction within dopamine neurons. Additionally, tagged D2 receptors were found to be clustered on the somata and dendrites of dopamine neurons. Furthermore, specific dopamine release areas corresponding to individual D2 receptor clusters were identified using localized theta stimulation. These results are at odds with structural data that show the majority of D2 receptors reside at extrasynaptic locations. In this study, the distribution, lack of trafficking, and localized activation of receptor clusters indicate a purposeful placement within dopamine synapses of a subset of midbrain D2 autoreceptors.

Title: Subcellular D2-receptor localization in the substantia nigra pars compacta of an EGFP transgenic mouse line

Authors: *S. R. SESACK¹, S. HETELEKIDES¹, M. TRINKLE¹, J. BALCITA-PEDICINO¹, B. G. ROBINSON², J. R. BUNZOW³, S. A. AICHER³, J. T. WILLIAMS² ¹Neurosci., Univ. of Pittsburgh, Pittsburgh, PA; ²Vollum Inst., ³Physiol. & Pharmacol., Oregon Hlth. & Sci. Univ., Portland, OR

Abstract: Dopamine (DA) neurons in the substantia nigra pars compacta (SNc) project to forebrain areas involved in goal-directed behavior and are subject to plasticity induced by psychostimulant addiction. SNc DA cells are extensively autoregulated by somatodendritic DA release acting on D2-receptors (D2Rs), although neither the exact mechanism for DA release nor the precise subcellular distribution of D2Rs have been fully characterized. Our electrophysiological evidence suggests that a vesicular-type DA release mechanism produces spontaneous inhibitory postsynaptic currents in SNc DA neurons in a manner that resembles classical synaptic transmission. We therefore hypothesized that D2Rs are distributed in clusters along restricted regions of the somatodendritic membrane. To investigate this, we utilized transgenic mice with an EGFP tag incorporated into the N-terminus of the D2R and light microscopic immunofluorescence labeling for EGFP, which provided further evidence for clustered D2Rs. We next sought to verify our observations by electron microscopic examination of silver-enhanced immunogold labeling for EGFP. In the SNc of the transgenic mice, EGFP-D2R labeling was found predominately in dendrites and less frequently in axon varicosities and glia. While most immunolabeling was observed in the cytoplasm, roughly 29% of EGFP-D2R gold particles contacted the plasma membrane. Gold particles were relatively uniformly distributed along mainly extrasynaptic regions, although the proportion of total labeling found on the membrane increased as dendritic diameter decreased (i.e. in a distal direction). Enrichment of EGFP-D2R gold to dendrodendritic synapses and dendritic spines was found only rarely. Axon varicosities expressing EGFP-D2R typically formed symmetric synapses likely to mediate inhibition. Surprisingly, a few putative axon initial segments with marked EGFP-D2R along the plasma membrane were also found. As most SNc neurons are dopaminergic, these axon initial segments likely derive from DA cells, marking the first observation of autoreceptors at this compartment in a monoamine cell population. The relatively uniform ultrastructural distribution of D2Rs along dendritic membranes is inconsistent with observations from light microscopy and electrophysiology, indicating that further experiments are needed to determine the precise distribution of functional D2Rs in the SNc. These findings have important implications for understanding the modulation of DA cell activity in health and addiction.

Title: Understanding the selective vulnerability of neurons in Parkinson's disease: An *In vitro* study of the relationship between axonal growth, bioenergetics, and survival of noradrenergic neurons of the locus coeruleus

Authors: *S. BURKE NANNI, M.-J. BOURQUE, L.-E. TRUDEAU Departments of Pharmacol. and Physiology, and Neuroscience, GRSNC, Univ. de Montréal, Montreal, QC, Canada

Abstract: In Parkinson's disease (PD) several restricted neuronal populations, including those of the substantia nigra pars compacta (SNc) and locus ceruleus (LC), gradually degenerate. It has emerged that mitochondrial dysfunction is likely central to the disease mechanism, and this has led to a hypothesis that one important common characteristic of vulnerable neurons is that they are particularly active from a bioenergetic point of view and thus more susceptible to any mitochondrial impairment. This high basal activity of mitochondria would in turn be associated with elevated production of reactive oxygen species and chronic oxidative stress. We have recently examined different dopaminergic neuronal sub-groups including those of the SNc, ventral tegmental area and olfactory bulb and provided evidence for a tight link between neuronal vulnerability, basal bioenergetics and the size of the axonal arbor of neurons, raising the hypothesis that elevated basal mitochondrial function in vulnerable neurons is in part secondary to the development and maintenance of a particularly large axonal arbor. In the objective of further testing the generality of this hypothesis, we have begun to examine noradrenergic neurons of the LC. We first isolated primary mouse LC neurons from neonatal TH-GFP transgenic mice. After 7 days in vitro and immunostaining for TH and MAP2, confocal image capture coupled with semi-automated tracing confirmed that LC noradrenergic neurons also develop a very large axonal arbor in vitro, with a size even larger than that of SNc dopamine neurons. Measurements of basal and maximal oxygen consumption rate performed with a Seahorse bioanalyzer revealed that the rate of oxidative phosphorylation in LC neurons is comparable to that of SNc neurons. We are now extending these experiments to examine the relationship between basal bioenergetics and firing. These data contribute to validating the hypothesis that the bioenergetic phenotype of neurons plays an important role in determining their vulnerability in PD.

Title: Comparison of transitional vs surgical menopause on monoamine and amino acid levels in the brain

Authors: *T. LONG^{1,2}, J. K. YAO^{1,2}, J. LI¹, Z. KIRSHNER¹, D. NELSON¹, G. G. DOUGHERTY², R. B. GIBBS¹

¹Pharmaceut. Sci., Univ. of Pittsburgh, Pittsburgh, PA; ²Med. Res. Service, Veterans Affairs Pittsburgh Healthcare Syst., Pittsburgh, PA

Abstract: Loss of ovarian function has important effects on neurotransmitter production and release. To date, there has been little direct comparison of the effects between surgical and transitional menopause on neurotransmitter pathways in the brain. In this study, effects on monoamine and amino acid levels were evaluated in adult ovariectomized (OVX) rats and in rats that underwent selective and gradual ovarian follicle depletion by daily injection of 4vinylcyclohexene-diepoxide (VCD). Tissues from the hippocampus (HPC), frontal cortex (FCX), and striatum (STR) were dissected and analyzed at 1- and 6-week (w) following OVX or VCD treatments (n=6-8). Tissues from gonadally intact rats were collected at proestrus (n=8) and diestrus (n=8) periods to represent neurochemical levels during natural states of high and low estrogens. Seven different monoamines and their metabolites were quantified along with eight different amino acids. In the FCX of gonadally intact rats, higher levels of serotonin (5-HT) were detected at proestrus than at diestrus, and the ratio of 5-hydroxyindoleacetic acid (5-HIAA)/5HT in the FCX and HPC was lower at proestrus than at diestrus, suggesting an effect on 5-HT turnover in these regions. No other significant differences between proestrus and diestrus were observed. In OVX- and VCD-treated rats, substantial changes were observed in the HPC at 1-w following treatment. Specifically, levels of norepinephrine (NE), 5-HIAA and eight tested amino acids were significantly reduced in both menopausal models compared to proestrus and diestrus. The largest effects were the decreases (up to 80%) in the levels of the amino acids. By six weeks the levels of NE, 5-HIAA and all tested amino acids had returned to normal. In the FCX, dopamine (DA) levels were elevated at 6-w after OVX relative to diestrus rats. A similar trend was observed at 1-w (but not 6-w) following VCD treatment. In the STR, NE levels were elevated at 1-w following OVX, and HVA levels were elevated at 1-w following VCD treatment, relative to proestrus and diestrus. These effects were not observed at 6 weeks. Collectively, our results demonstrate that surgical and transitional loss of ovarian function have significant neurochemical effects on the brain, which are region-specific and time-dependent. In many instances OVX and VCD treatments produced similar effects. Most notable changes are the substantial decreases in amino acid levels in the HPC with corresponding effects on NE and 5-HT pathways. The effects likely contribute to the surgical and transitional menopause on hippocampal function and cognitive performance.

Abstract: All drugs of abuse increase the concentration of dopamine in the nucleus accumbens. Benzodiazepines are anxyolitic drugs that are also susceptible to abuse. Benzodiazepines are allosteric modulators of the GABA_AR, and are known to alter dopamine transmission. Previous studies have demonstrated that benzodiazepines disinhibit dopamine neurons but also decrease the concentration of dopamine released in the nucleus accumbens. Here we sought to characterize how benzodiazepines alter dopamine transient release events in the awake and behaving rat. Using fast scan cyclic voltammetry we demonstrated that the benzodiazepines diazepam (trade name valium) and zolpidem (trade name ambien) dose-dependently increase the frequency and decrease the amplitude of dopamine transient release events in the nucleus accumbens core and shell in a dose dependent manner. These effects were occluded by the administration of flumazenil, a benzodiazepine antagonist. This study implies that an increase in frequency, indifferent of amplitude, may be adequate to provide abuse liability to a drug. Further research shows that ethanol administration interrupted by a benzodiazepine augments the frequency of dopamine transient release events yet drastically decreases the amplitude.

Title: Noradrenaline in the monkey thalamus: Axonal innervation and adrenoceptors

Authors: I. PÉREZ-SANTOS^{1,2}, N. PALOMERO-GALLAGHER^{2,3}, *C. CAVADA¹, K. ZILLES^{2,3}

¹Univ. Autonoma Madrid, Fac Medicina, Madrid, Spain; ²Inst. of Neurosci. and Med. (INM-1), Res. Ctr. Jülich, Jülich, Germany; ³Psychiatry, Psychotherapy, and Psychosomatics, Med. Faculty, RWTH Aachen, and JARA - Translational Brain Med., Aachen, Germany

Abstract: The role of noradrenaline (NA) in the thalamus is relevant because of its key position in cortico-thalamo-cortical pathways and in relaying information from subcortical structures to the cortex. We have mapped the thalamic NA innervation in adult macaque monkey brains using immunohistochemistry against the NA synthesizing enzyme, and the NA transporter. We also analyzed the distributions of Alpha1 and Alpha2 adrenoceptors using quantitative *in vitro* receptor autoradiography.

The maps of the two different NA markers are highly coincident. NA axons are present in all thalamic nuclei, albeit highly heterogeneously distributed. The most innervated ones are the midline nuclei. High NA axon densities are also present in some intralaminar nuclei (paracentral -Pcn- and parafascicular), and in the medial sector of the mediodorsal nucleus (MDm). The ventral motor nuclei receive a moderate NA innervation, with the ventromedial subdivision of the ventral anterior nucleus (VAvm) and area X holding the highest innervation among these nuclei. The lateral geniculate nucleus (GL) holds the lowest NA innervation. Densities and distribution of Alpha1 and Alpha2 receptors are also considerably heterogeneous throughout the thalamic nuclei, with Alpha1 densities being higher than Alpha2 densities. The nuclei with the highest Alpha1 densities are the MDm, the parvocellular part of the ventral posterior medial nucleus, medial pulvinal (PulM), and midline nuclei. The nucleus with the lowest Alpha1 consultion of alpha2 receptor densities are highest in the lateral dorsal, centromedian, PulM, inferior pulvinar, and midline nuclei.

Thus, location and densities of NA axons and Alpha receptors match only partially. Matching

distributions of NA axons and Alpha1 receptors are present in MDm, VAvm, area X and midline nuclei. However, PulM exhibits moderate NA innervation but comparatively high Alpha receptor densities. A reverse relationship is present in other nuclei; for instance, in Pcn there is dense NA innervation while Alpha receptors are scarce. These differences between NA axonal distribution and Alpha receptor densities suggest interesting local modulations of NA-based signal transmission caused by the receptors. The high NA axon innervation in nuclei with low Alpha receptor densities could point out to a more prominent role of Beta family receptors on noradrenergic signalling within these nuclei. And the presence of conspicuously high receptor densities in poorly/moderately innervated regions may reveal nuclei in which Alpha receptors considerably modulate NA-driven signal transmission.

Title: A role for norepinephrine in modulating glutamatergic synaptic transmission during and following intermittent hypoxia

Authors: *M. A. KHUU, J. E. BARNARD, A. J. GARCIA, III Univ. of Chicago, Chicago, IL

Abstract: Several recent studies have proposed that the efficacy for neuromodulation may be state dependent. This ongoing study seeks to examine the interaction between adrenergic neuromodulation and acute intermittent hypoxia (AIH) on glutamatergic synaptic transmission and synaptic plasticity in area CA1 of the hippocampus. Electrophysiological recordings of the evoked field excitatory postsynaptic potential (fEPSP) were made in the CA1 neuronal population of adult mouse hippocampal brain slices. AIH was achieved by exposing preparations to three hypoxic intervals (95% N2, 5% CO2 duration=180 sec) separated by periods of recovery (95% O2, 5% CO2 duration=180 sec). Enhanced adrenergic tone (10 microM norepinephrine, NE) augmented the suppressive action of AIH on the evoked fEPSP. Interestingly, NE also suppressed paired pulse facilitation only after AIH. Yohimbine, an α 2 adrenergic receptor antagonist, mimicked the effects of NE following AIH, which implicates α 2 adrenergic receptor involvement. Our findings suggest that that increased adrenergic tone may play a protective role by reducing excessive glutamatergic synaptic transmission during and following intermittent hypoxia. These findings may ultimately be important to understanding the neurological aspects

associated in conditions, like sleep apnea, where oscillations in blood gases are accompanied with enhanced adrenergic tone.

Abstract: Deficits in neurotrophic and neuroprotective processes are believed to contribute to the detrimental effects of chronic stress and chronic elevations of glucocorticoids, and to the pathophysiology underlying major depressive disorder. Recent studies demonstrated that astrocytes respond to norepinephrine with increases in the synthesis and release of brain-derived neurotrophic factor (BDNF). Treatment of cultured astrocytes with the glucocorticoid corticosterone has the opposite effect on BDNF expression. We are examining potential cellular mechanisms by which glucocorticoids and norepinephrine may interact to regulate astrocyte BDNF expression. We have recently demonstrated that organic cation transporter 3 (OCT3), a corticosterone-sensitive monoamine transporter, is densely expressed in the outer nuclear membranes of astrocytes, and that beta1-adrenergic receptors are also localized to the nuclear envelope of these cells, suggesting that NE may activate G-protein-mediated signaling cascades in the nucleus, and that OCT3 gates the access of norepinephrine to nuclear membrane adrenergic receptors. We hypothesized that nuclear beta-1ARs are functionally coupled to stimulatory G-proteins in the nuclear compartment, and that norepinephrine-induced increases in BDNF expression are mediated by activation of nuclear cAMP signaling. To test this hypothesis, we examined A) the localization of Gs-related signal transduction machinery to the nuclear compartment, using immunofluorescence; and B) the effects of norepinephrine treatment on BDNF protein expression in astrocytes cultured from wild-type or OCT3-deficient mice. Gsalpha-like immunostaining was observed in both cytosolic and nuclear compartments in triton X-100-permeabilized cells, but only in the cytosolic compartment in cells permeabilized with digitonin. Phosphodiesterase 4B-like immunoreactivity was observed primarily in the nuclear

compartment in triton-100-permeabilized astrocytes, and nuclear PDE4B-like immunoreactivity was not observed in digitonin-permeabilized cells. Treatment of wild-type mouse astrocytes with norepinephrine resulted in dose-dependent increases in BDNF as measured by western blot. The same treatment had no effect on BDNF expression in OCT3-deficient astrocytes. Together, these data indicate that nuclear membrane beta-1 ARs couple to intranuclear signal transduction machinery; that access of norepinephrine to nuclear membrane receptors is mediated by OCT3, and that nuclear membrane beta-1 ARs mediate norepinephrine effects on BDNF expression.

Title: Disruption of the axonal trafficking of tyrosine hydroxylase mRNA impairs catecholamine biosynthesis in the axons of sympathetic neurons

Authors: A. ASCHRAFI¹, *A. E. GIOIO², L. DONG³, B. B. KAPLAN⁴ ¹NIH/NIMH, Bethesda, MD; ²Lab. of Mol. Biol., NIH, NIMH-, Bethesda, MD; ³Genet. Engin. Core, Natl. Inst. of Health, Natl. Eye Inst., Bethesda, MD; ⁴NIMH, Bethesda, MD

Abstract: Tyrosine hydroxylase (TH) is the enzyme that catalyzes the rate-limiting step in the biosynthesis of the catecholamine neurotransmitters. In a previous communication, we provided evidence that TH mRNA is trafficked to the axon and that the mRNA is locally translated. In addition, we identified a 50bp sequence element in the 3'untranslated region (3'UTR) of TH mRNA that directs TH mRNA localization to distal axons. In the present study, the hypothesis was tested that local translation of TH plays a key role in the biosynthesis of the catecholamine neurotransmitters in the axon and/or presynaptic nerve terminal. Toward this end, a targeted deletion of the axonal transport sequence element was developed, using the lentiviral delivery of the CRISPR/Cas9 system, and two guide RNA sequences flanking the 50bp *cis-* regulatory element in rat superior cervical ganglion (SCG) sympathetic neurons. Deletion of the axonal transport element present in the 3'UTR of TH mRNA reduced TH mRNA levels in the distal axons and reduced the axonal proteins levels of TH and TH phosphorylation at SER40 in SCG neurons, as well as diminished the axonal levels and release of dopamine and norepinephrine. Conversely, the local translation of exogenous TH mRNA in the distal axon enhanced TH levels

and activity, as measured by Ser40 phosphorylation, and enhanced axonal norepinephrine levels. Taken together, our results provide evidence to support the hypothesis that TH mRNA trafficking and local synthesis of TH plays a key role in the synthesis of catecholamines, allowing for a rapid response to alterations in the need for neurotransmitter synthesis and release.

Title: Absence of translin/trax, a microRNA degrading RNase complex, blocks cocaine's ability to increase dopamine tone

Authors: X. FU¹, A. SHAH¹, M. NIWA¹, D. FUKUDOME¹, A. SAWA¹, J.-L. CADET², J. KEIGHRON², G. TANDA², *J. M. BARABAN¹ ¹Johns Hopkins Univ., Baltimore, MD; ²NIDA, Baltimore, MD

Abstract: Recent studies indicate that the microRNA system plays a key role in regulating behavioral responses to drugs of abuse. However, its role in reward pathways is poorly understood. Accordingly, we have initiated studies aimed at understanding the role of the microRNA system in regulating dopamine (DA) signaling. While synthesis of nearly all microRNAs is mediated by a single enzyme, Dicer, multiple enzymes are involved in degrading microRNAs. Hence, selective deletion of individual microRNA degrading enzymes, such as the translin/trax RNase complex, leads to restricted increases in a subset of microRNAs and can be used to define the function of this subpopulation.

As the translin/trax (TN/TX) RNase complex is expressed by midbrain DA neurons, as well as D1R+ and D2R+ striatal neurons, we tested whether translin KO mice, display abnormal dopamine signaling. We found that these KO mice exhibit marked impairment in the ability of cocaine to enhance locomotor activity in an open field arena. This deficit does not reflect degeneration of DA neurons as TH immunostaining and striatal DA levels are normal in these mice. In addition, we confirmed that cocaine levels in forebrain and serum samples from WT and translin KO mice are not significantly different. Microdialysis studies demonstrated that the ability of cocaine to increase extracellular DA in the nucleus accumbens is blunted in translin KO mice in parallel with their reduced locomotor response to cocaine. In contrast, the ability of

amphetamine to elevate DA levels in the accumbens is unaffected. Preliminary fast scan voltammetry studies to monitor evoked DA release in the nucleus accumbens have not revealed any difference in DA max or clearance rates between translin KO mice and age-matched WT mice. However, the ability of cocaine to increase evoked release of DA in the nucleus accumbens is impaired in translin KO mice. Although this effect of cocaine is thought to underlie its rewarding properties and is mediated by its interaction with the dopamine transporter, how it enhances evoked DA release is poorly understood. Accordingly, further studies aimed at defining how translin deletion blocks this response may provide valuable clues to understanding the biological basis of cocaine's reinforcing properties.

Title: Glutamate counteracts dopamine/PKA signaling via dephosphorylation of DARPP-32 Ser97 and alteration of its cytonuclear distribution

Authors: *A. NISHI¹, M. MATAMALES², V. MUSANTE³, E. VALJENT⁴, M. KUROIWA¹, Y. KITAHARA¹, H. REBHOLZ⁵, P. GREENGARD⁵, J.-A. GIRAULT², A. C. NAIRN³ ¹Dept. of Pharmacol., Kurume Univ. Neurosci., The Rockefeller Univ., New York, NY

Abstract: The interaction of glutamate and dopamine in the striatum is heavily dependent on signaling pathways that converge on the regulatory protein DARPP-32. The efficacy of dopamine/D1 receptor/PKA signaling is regulated by DARPP-32 phosphorylated at Thr34 (the PKA-site), a process that inhibits protein phosphatase 1 (PP1), and potentiates PKA action. Activation of dopamine/D1 receptor/PKA signaling also leads to dephosphorylation of DARPP-32 at Ser97 (the CK2-site), leading to localization of phospho-Thr34 DARPP-32 in the nucleus where it also inhibits PP1. In this study, the role of glutamate in the regulation of DARPP-32 phosphorylation at 4 major sites was further investigated. Experiments using striatal slices revealed that glutamate decreased the phosphorylation states of DARPP-32 at Ser97 as well as Thr34, Thr75 and Ser130 by activating NMDA or AMPA receptors in both direct and indirect pathway striatal neurons. The effect of glutamate to decrease Ser97 phosphorylation was mediated by activation of PP2A. In vitro phosphatase assays indicated that the PP2A/PR72 heterotrimer complex was likely responsible for glutamate/Ca²⁺-regulated dephosphorylation of DARPP-32 at Ser97. As a consequence of Ser97 dephosphorylation, glutamate induced the nuclear localization in cultured striatal neurons of dephospho-Thr34/dephospho-Ser97 DARPP-32. It also reduced PKA-dependent DARPP-32 signaling in slices and in vivo. Taken together, the results suggest that by inducing dephosphorylation of DARPP-32 at Ser97 and altering its cytonuclear distribution, glutamate may counteract dopamine/D1 receptor/PKA signaling at multiple cellular levels.

Abstract: Methamphetamine (METH) is a powerful psychostimulant drug with neurotoxic properties. METH increases dopamine (DA) signaling by inhibiting DA reuptake, resulting in increased oxidative stress and eventual degeneration of DAergic terminals. Selenium (Se) is an antioxidant trace element that is incorporated into selenoproteins, a family of proteins with multiple functions that include protection from oxidative stress. Se protects against METH toxicity and may also play a role in the DA system. Selenoprotein P (Sepp1) is vital for proper brain function as it is responsible for supplying neurons with Se, and may also play a role in DAergic transmission. Fast-scan cyclic voltammetry (FSCV) is an electrophysiological technique that can be used to measure DA release and reuptake kinetics. We used FSCV to measure DA release in nucleus accumbens (NAc) slices in order to investigate the role of Sepp1 in DAergic transmission and modulation by METH. Sepp1-KO mice had reduced basal DA reuptake rates compared to wild-type controls, suggesting reduced dopamine transporter (DAT) activity. Sepp1-KOs also had decreased levels of basal stimulated DA release. However, KOs displayed a dramatic increase in stimulated DA release in response to METH compared to wildtype mice. The DA receptor 2 (D2R) agonist quinpirole prevented the large METH-induced increase in stimulated DA release in Sepp1-KOs, while the D2R antagonist sulpiride dramatically increased METH response in wild-type slices but not in Sepp1-KO slices. These results suggest that D2R dysfunction in Sepp1-KO mice potentiates METH-induced DA release.

Title: Activity of local inhibitory neurons gates locus coeruleus noradrenergic activity

Authors: *V. BRETON-PROVENCHER, M. SUR Picower Inst. for Learning and Memory, MIT, Cambridge, MA

Abstract: Locus coeruleus noradrenergic (LC-NE) neurons send broad neuromodulatory projections to the central nervous system. While these neurons are thought to be involved in a variety of functions, including arousal, attention, and cognitive shifts, the behavioral contexts and the underlying mechanisms that drive LC-NE neurons remain largely unknown. Here, we examined the microcircuit mechanism of LC-NE activity by investigating a population of local GABAergic neurons located in the ventromedial region of the LC (LC-GABA). We monitored pupil size as a behavioral marker of LC-NE activity, and performed cell type-specific optogenetic manipulations and electrophysiological recordings within the LC of awake headfixed mice. We found that activating LC-GABA neurons resulted in constriction of the pupil, similar to direct inactivation of LC-NE activity, suggesting a functional coupling between these cell types. In support of this hypothesis, simultaneous recordings using multi-channel extracellular probes revealed an ongoing interaction between putative LC-GABA and LC-NE activity, in which GABAergic activity followed the increase in NE associated with pupil dilation. Importantly, LC-GABA neurons may critically gate LC-NE function, as increasing their activity impaired responses of LC-NE neurons to novel sensory stimuli. We are currently investigating brain-wide inputs to LC-NE and LC-GABA neurons using monosynaptic rabies virus tracing to identify upstream brain regions that regulate this gating mechanism. Overall, these results demonstrate the existence of a local population of interneurons in the LC capable of rapidly controlling overall NE activity by modulating LC responses to unexpected sensory stimuli.

Title: PEDOT nanocomposites based electrodes for high sensitivity detection of tonic and phasic dopamine *In vivo*

Authors: *I. M. TAYLOR¹, X. CUI² ¹Bioengineering, ²Dept. of Bioengineering, Univ. of Pittsburgh, Pittsburgh, PA

Abstract: Dopamine (DA) signaling over multiple time courses is responsible for the regulation of a variety of vital life functions. Furthermore, dysfunction in dopaminergic signaling pathways has been implicated in the onset of various neurological disorders. When studying DA signaling pathways, it is absolutely necessary to monitor extracellular DA, as changes in the concentration and kinetics of DA release and uptake are highly correlated to physiological functionality. Fast

scan cyclic voltammetry (FSCV) has been performed at carbon fiber microelectrodes (CFEs) for in vivo DA detection for decades, but the technique is limited by issues resulting from moderate sensitivity, poor sensor longevity and the inability to measure resting DA concentrations. We have developed poly(3,4-ethylene dioxythiophene) (PEDOT) nanocomposites based electrode coatings capable of electrochemically measuring both sub second DA fluctuations as well as resting DA concentrations with high sensitivity and selectivity. PEDOT/graphene oxide coated CFEs exhibit an 880% increase in sub second, transient DA detection sensitivity using FSCV, decreased the lower limit of detection for DA by 50% and minimally altered electron transfer kinetics compared to bare CFEs. PEDOT/carbon nanotube coated CFEs exhibit a 4700% increase in sensitivity for the detection of resting DA levels using pulse voltammetric methods compared to bare CFEs, exhibited a sub-50 nM lower limit of detection for DA and are capable of stable continuous recording over multiple hours. Both PEDOT coated CFEs are capable of in vivo DA recording in the rat dorsal striatum. PEDOT/graphene oxide coated CFEs electrodes exhibit a 5.5X increase in measured current resulting from electrically stimulated in vivo DA release. PEDOT/carbon nanotube coated CFEs are capable of measuring the resting DA concentration in the rat dorsal striatum as well as pharmacologically induced tonic DA changes. Overall, PEDOT-based coatings significantly improve DA detection capabilities both in vitro and in vivo and is expected to considerably improve our understanding of the DA function signaling over multiple time courses.

Title: High sensitivity electrochemical probes for detection of glutamate and dopamine in brain tissue

Authors: *T. A. MURRAY¹, C. TAN², M. HOSSAIN², P. DOUGHTY¹, C. PERNICI¹, J. SCOGGIN¹, S. SIDDIQUI¹, P. ARUMUGAM¹ ¹Biomed. Engin., ²IFM, Louisiana Tech. Univ., Ruston, LA

Abstract: Enhanced neurochemical microsensors were developed for brain slice recordings where higher sensitivity is required to detect small, dynamic changes in glutamate and dopamine levels. Dopamine sensors were created by electrophoretically depositing <100-nm thick multiwall carbon nanotubes (MWCNT) onto platinum microelectrode arrays and then drop

casting 0.2 µL of 5% wt. nafion solution. Glutamate sensors were created by drop casting a mixture of 0.1 U/µL glutamate oxidase, 1% bovine serum albumin and 0.125% glutaraldehyde followed by curing at room temperature for 72 h. A size-exclusion polymer, mphenylenediamine, was electrochemically deposited to the enzyme coated MEA to prevent ascorbic acid, an interferent, from reaching the electrode surface. Coronal slices from adult murine brain were maintained in artificial cerebral spinal fluid. Caudate putamen was used to test dopamine sensors and parietal cortex was used to test glutamate sensors. Current responses to biphasic stimulation, were recorded on a F.A.S.T. 16mkIII system (Quanteon, Kentucky). Responses (Fig. 1) were compared to previously acquired standard curves from 1-40 µM of glutamate and dopamine concentrations. The high randomness and open pores present in the three dimensional MWCNT film contributed to a significant increase in the electroactive area and adsorption sites for dopamine. In vitro calibration studies showed that with nafion coating, the MWCNT modified microelectrode had a 100-fold increase in DA sensitivity (20 nA/ μ M). The glutamate microsensor showed a sensitivity of 25 pA/ μ M, which is much higher than similar commercial probes (< 15 pA/ μ M) reported in the literature. Future work includes combining these microsensors into a single probe and further refinement of the coatings for chronic, in vivo recordings.

Figure 1. Responses to biphasic stimulation (platinum wires, 300 mA, 2Hz) of dopamine (left) and glutamate (right). Stimulation artifact is denoted by blue arrows. Black and blue traces are recorded from electrode 1 and 8, respectively, on modified CenMeT 8-TRK microelectrode arrays.

Title: Enhancing fast-scan cyclic voltammetry detection of dopamine with tryptophan derivatives

Authors: *S. E. THOMPSON¹, E. RAMSSON²

¹Cell and Mol. Biol., ²Biomed. Sci., Grand Valley State Univ., Allendale, MI

Abstract: Fast-Scan Cyclic Voltammetry (FSCV) is an analytical tool which is used to detect sub-second changes in dopamine (DA) concentration in the striatum. In FSCV, repeated adsorption and oxidation of DA occurs on the carbon fiber microelectrode surface. Using background subtraction, the current produced can be used to create a calibration curve for [DA] that allows correlation with in vivo measures. We are exploring the electrodeposition of various coatings as a method for improving the detection limit for this technique. The goal of these coatings is to increase the amount of DA adsorbed onto the electrode surface, thus increasing the oxidation current, which is proportional to the concentration of DA. The goal of this project is to investigate different tryptophan derivatives plated onto the surface of the electrodes for their ability to improve FSCV sensitivity for DA. The coated electrodes must not only be investigated for their ability to improve the detection limit of DA, but their selectivity and durability must be investigated. Coated electrodes will be tested in vitro in the presence of other neurotransmitters which are present in the striatum. The durability of the coatings on the electrodes will be tested through extended FSCV cycling and collection periods. Improving the limit of detection of FSCV for DA will help with monitoring low levels of DA which are present in patients with Parkinson's and Alzheimer's. We hope with this project, to provide a simpler, a cost-effective and time-efficient means of increasing the FSCV sensitivity for DA to aid in the research of these diseases.

Title: Investigation of the basal dopamine levels in the zebrafish telencephalon using fast-scan controlled adsorptive voltammetry

Authors: K. BAUSTERT¹, *E. RAMSSON²

¹Dept. of Chem., ²Biomed. Sci., Grand Valley State Univ., Allendale, MI

Abstract: Zebrafish are widely used organisms for a variety of different studies in neuroscience. The neurotransmitter dopamine (DA) is a molecule important in learning and memory, motivation, and movement in higher vertebrates. Quantification of DA in the zebrafish brain has recently taken place via amperommetry and fast scan cyclic voltammetry (FSCV). FSCV is a technique that uses a triangle waveform with background subtraction to measure DA oxidation current as a proportional measure to DA concentration. This can be used to quantify small changes in neurotransmitter concentration but is limited to acquiring only concentration changes, and not basal DA levels, due to this subtraction. Fast scan controlled-absorptive voltammetry (FSCAV) allows for inquiries into basal DA levels and changes to those levels. Since little is known about the basal DA concentrations present within the zebrafish telencephalon, we used FSCAV to investigate these levels.

Abstract: We investigated the character of chemotherapy-evoked neuropathic pain using rats treated with paclitaxel. The novel method of in vivo voltammetry was utilized to determine if changes in extracellular seratonin levels and release in rats occur after chronic paclitaxel therapy. Peripheral neuropathy is the dose-limiting side effect of paclitaxel. The cause of the pain is not known. This study investigated whether changes in seratonin homeostasis occur after paclitaxel treatment in specific brain areas.

Materials:

Analgesiometer (Randal- Selitto) was used to measure the mechanical allodynia. 2 milimolar seratonin was given to the areas and uptake activities were recorded with in vivo voltammetry. 270-310 g rats are important for in vivo voltammetry studies for true brain stereotaxic coordinates.

Coordinates	X	Y	Z
CA3 (Cornus Ammonis)	3,4	-4	-3,8

Results:

Paclitaxel-evoked pain was detected by analgesiometer test on 7th day and it continued to 50th day. Pain tests were done on 0, 8, 15, 21, 30, 50 th days.

n Control Mean±SD Paclitaxel Mean±SD Paclitaxel+Escitalopram Mean±SD

0.day	5 125,00±0,00	124,00±2,24	116,00±12,45*
8. day	5 114,00±11,40	63,00±40,40*	59,00±12,94*

Title: Isoflurane anesthesia alters monoamine levels in prefrontal cortex (PFC) of C57BL/6J (B6) mouse

Authors: *X. ZHANG¹, A. BAER¹, N. R. HARP¹, H. A. BAGHDOYAN², R. LYDIC² ¹Anesthesiol., Univ. of Tennessee Med. Ctr., Knoxville, TN; ²Anesthesiol. & Psychology, Univ. of Tennessee, Knoxville, TN

Abstract: Previous studies quantifying isoflurane-induced changes in brain chemistry typically have been limited to measures of a single neurotransmitter (*J Neurochem* 119: 419, 2011).

During anesthesia, however, levels of multiple, interacting neurotransmitters change simultaneously (Sleep 35: 1325, 2012). This ongoing study is quantifying several neurotransmitters in brain samples obtained by in vivo microdialysis. Dialysis probes were aimed for the PFC (histology pending) and samples (25 microliters) were collected during wakefulness (n=9 mice) and isoflurane (1.3%) anesthesia (n=12 mice). Dialysis samples were derivatized, separated with LC/MS and quantified using the AnalystTM data system (Applied Biosystem, version 1.4.2). A between-groups design enabled evaluation of state-dependent increases (+) and decreases (-) in levels of histamine (HA), dopamine (DA), serotonin (5-HT), and norepinephrine (NE). Compared to levels measured during wakefulness, percent change values during anesthesia were: HA = -30.8%, DA = +39.6%, 5-HT = +7.4%, and NE = +41.6%. Independent t-test comparisons revealed that these isoflurane-induced changes were statistically significant for HA (t=2.2, df=16, p=0.03), DA (t=1.91, df=12, p=0.04), and NE (t=1.95, df=17; p=0.03). We are unaware of previously reported measures of monoamines from PFC of B6 mice during isoflurane anesthesia. Many studies have shown that monoamines promote cortical activation and behavioral arousal. Microdialysis data indicate that stimulants increase levels of HA (Eur J Pharm 558:96, 2007), and 5-HT, NE, and DA (Neuropsychopharmacology 27:699, 2002) in PFC of rat. The present results encourage efforts to determine the extent to which increased levels of monoamines resulted from isoflurane-induced changes in monoamine synthesis, degradation, and/or reuptake. Combining metabolomic data (http://www.abstractsonline.com/pp8/index.html#!/4071/presentation/6411) with measures of neurotransmitters offers unique opportunities to increase understanding of the mechanisms through which volatile anesthetics alter brain chemistry. Together, these analytic approaches may provide new insights into mechanisms of anesthetic action.

Title: Structure-activity relationships of N,N-diallyltryptamine hallucinogens

Authors: *L. M. KLEIN¹, M. A. GEYER², S. D. BRANDT³, A. L. HALBERSTADT² ¹Neurosciences, UCSD, San Diego, CA; ²Psychiatry, UCSD, La Jolla, CA; ³Pharm. and Biomolecular Sci., Liverpool John Moores Univ., Liverpool, United Kingdom

Abstract: N,N-Dialkyltryptamines such as psilocybin and N,N-dimethyltryptamine (DMT) are a potent class of serotonergic hallucinogens. Recently, designer hallucinogens derived from N,Ndiallyltryptamine (DALT) have been marketed online as New Psychoactive Substances, resulting in numerous cases of acute toxicity. Tryptamine hallucinogens act primarily as 5-HT_{1A} and 5-HT_{2A} receptor agonists, but it is not clear whether DALT derivatives have a similar mechanismof-action. To investigate the pharmacology and structure-activity relationships of these compounds, we assessed the binding affinities of DALT and 11 ring-substituted derivatives at 44 receptor and transporter sites. A subset of the compounds were also assessed for induction of the head twitch response, a 5-HT_{2A} receptor-mediated behavioral response in rodents that is often used as a proxy for human hallucinogen effects. Binding assays confirmed that DALT and its ring-substituted derivatives bound non-selectively to most 5-HT receptors, including 5-HT_{1A} and 5-HT_{2A}. DALT significantly increased HTR counts in male C57BL/6J mice relative to vehicle $(ED_{50} = 3.42 \text{ mg/kg IP})$. The 4-hydroxy and 5-methoxy derivatives induced the HTR with almost twice the potency of DALT; 4-acetoxy- or 5-fluoro-substitution produced even greater increases in potency. By contrast, 5-bromo substitution did not significantly alter HTR potency relative to DALT. 2-Methyl or 2-phenyl substitution abolished HTR activity, as did 7-ethyl substitution. An ordinary least-squares (OLS) regression revealed that 5-HT_{1A} and 5-HT_{2A} binding affinities significantly predicted HTR potency (R^2 =0.904, $R^2_{adjusted}$ =0.840). These results confirmed that 5-HT_{2A} and 5-HT_{1A} receptors made positive and negative contributions, respectively, to HTR potency. To our knowledge, this is the first quantification of the relative contributions of 5-HT_{2A} and 5-HT_{1A} receptors to the behavioral effects of tryptamine hallucinogens. These findings improve our understanding of how tryptamine hallucinogens produce their effects, and allow for better prediction of the abuse potential of novel derivatives of DALT.

Title: Serotonin restricts synaptic plasticity and decreases excitability of vestibular circuits via distinct receptors

Authors: *Y.-S. CHAN¹, L. HAN¹, Y. H. LI², K. L. K. WU¹, D. K.-Y. SHUM¹ ¹Sch. of Biomedic. Sci., Fac. Med., Univ. Hong Kong, Hong Kong, China; ²Sch. of Life Sci. and Technology, Xi'an Jiaotong Univ., Xi'an, China

Abstract: The medial vestibular nucleus (MVN) is a major relay station for postural coordination, eye movement control and spatial cognition. Microinjection of 5-HT to the MVN impaired performance of vestibular-mediated motor balance and negative geotaxis in both adult and juvenile (P13-16) rats. We hypothesize that serotonergic neurotransmission modulates the activity of neurons in the MVN circuitry for vestibular-related behaviors. Specific activation of 5-HT₇ receptors in the MVN restricted circuit plasticity by abolishing NMDAR-mediated LTD via a protein kinase A (PKA)-dependent postsynaptic mechanism. Activation of 5-HT_{1A} receptor attenuated the excitability of vestibular circuits, as evidenced by reduction of both evoked excitatory and inhibitory transmission (eEPSC and eIPSC), through a presynaptic mechanism. These results reveal that 5-HT_{1A} and 5-HT₇ receptors within the MVN exhibit differential modulatory mechanisms but these in concert accomplish synergistic influence on motor coordination.

Title: Electrophysiological properties of target-specific populations of rat dorsal raphe projection neurons

Authors: *E. W. PROUTY¹, W.-J. GAO¹, B. D. WATERHOUSE²

¹Neurobio. and Anat., Drexel Univ. Col. of Med., Philadelphia, PA; ²Cell Biol. and Neurosci., Rowan Univ. Sch. of Osteo. Med., Stratford, NJ

Abstract: Serotonin (5-HT)-containing neurons in the dorsal raphe (DR) nucleus project throughout the mammalian forebrain and are implicated in a host of physiological processes and neuropsychiatric disorders. These neurons have been characterized in terms of their electrophysiology and show differences in presynaptic drive, passive membrane properties, and excitability, but studies to determine if these attributes align with specific brain functions or specific forebrain terminal fields have only recently begun. The goal of this study was to link DR neurons to a specific functional role in sensory versus cognitive circuit operations by characterizing cells according to both their efferent connectivity and electrophysiological properties; specifically, comparing cells projecting to the medial prefrontal cortex (mPFC), a region implicated in decision-making and emotion with cells projecting to the lateral geniculate nucleus (LGN) of the thalamus, a subcortical relay for visual information. We have previously shown that over 90% of the DR neurons projecting to these regions are serotonergic. After injecting the retrograde tracer FluoroGold (FG) into the mPFC or LGN of Sprague-Dawley rats, brainstem sections from these animals were collected and whole-cell patch clamp recordings were made from FG-labeled neurons within the DR. Initial results show that these two populations of projection neurons have similar passive membrane properties; however, cells targeting the mPFC respond to depolarizing current steps with a higher firing frequency than LGN-projecting cells. This greater excitability of mPFC vs LGN-projecting cells may suggest that greater stimulus-driven 5-HT release is required to optimize the function of cognitive and limbic circuits within the mPFC than for early stage visual processing in the LGN. Interestingly, LGN-projecting neurons display a greater frequency of putative AMPA-mediated spontaneous postsynaptic currents (t = 3.05, p = 0.0081), an indication that these cells receive greater presynaptic excitatory drive than those projecting to mPFC. Such target-specific differences in the synaptic regulation and excitability of DR projection neurons provide insight into the functional organization of the DR 5-HT system and indicate that this type of characterization may be a valuable strategy for untangling the diverse psychological and behavioral roles of 5-HT in the forebrain. Ongoing studies will determine if the electrophysiological profile of these DR projection neurons changes from late adolescence to adulthood. (NIMH MH101178 to BDW)

Title: Neurochemical profile in mice genetically depleted of brain serotonin: A proton magnetic resonance spectroscopy study

Authors: *F. GHODDOUSSI¹, D. I. BRIGGS², D. M. KUHN^{3,4}, M. P. GALLOWAY³, J. A. STANLEY³

¹Anesthesiol. & Magnetic Resonance Core, Wayne State University, Sch. of Med., Detroit, MI; ²Behavioral and Functional Neurosci. Lab., Stanford University-School of Med., Paolo Alto, CA; ³Psychiatry & Behavioral Neurosciences, Wayne State University-School of Med., Detroit, MI; ⁴Res. & Develop. Service, John Dingell VA Med. Ctr., Detroit, MI

Abstract: Introduction: Serotonin (5HT) neurons originating in the dorsal raphe innervate nearly all areas of the brain. 5HT is involved in mediating neuronal development as well as behavioral and physiological processes including, sleep, aggression, aging, control of food intake and body weight. In addition, the dysfunction in the 5HT neuronal system has been linked to neuropsychiatric conditions such as depression, anxiety, obsessive compulsive disorder and suicide. Serotonin selective reuptake inhibitors (SSRIs) are the most common treatment for depression and their therapeutic effect is generally attributed to their ability to increase the synaptic levels of 5HT. Tryptophan hydroxylase-2 (TPH2), expressed selectively in 5HT neurons, is the initial and rate limiting enzyme in the biosynthesis of 5HT. Genetic ablation of the TPH2 gene provides a hypo-serotonergic animal model to examine the influence of 5HT innervation on development and behavior. TPH2^{-/-} mice show intense compulsivity and impulsivity, social communication deficits, exaggerated aggression and decreased levels of anxiety like behavior. 5HT neurons in these mice, although lacking 5HT, retain their characteristic electrophysiological properties as well as relatively normal brain development and elaboration of the 5HT neuronal system. This suggests that behavioral phenotypes of the TPH2^{-/-} may be mediated via the absence of a modulatory effect of 5HT on other neurotransmitter systems such as Glutamate (GLU) and GABA. Methods: TPH2^{-/-} mice were generated by deleting exon1 of the Tph2 gene and were on a mixed C57BL/6-Sv129 background. High resolution magic angle spinning (HR-MAS) proton magnetic resonance spectroscopy (¹H-MRS) ex vivo (translation potential to clinical MRS) was used to assess unbiased neurochemical profiles in 12 different brain regions of 8 week-old WT (n=8) and KO (n=12) mice. Results: MRS analysis showed significant decrease in GLU and GABA levels in Hippocampus (dentate gyrus, HP), significant increase in Glu and GABA levels in Cerebellum (CB), no change in GLU and GABA levels in Anterior Striatum (AST). Discussion: Animal and clinical studies suggested, although with conflicting findings, that a deficit in GABAergic activity may be crucial in the pathophysiology of mood disorders. The 5HT innervation in ACC, CB and HC is substantial and 5HT release has modulatory effects on the release of the GLU and GABA neurotransmitters. Changed concentrations of GLU and GABA may reflect a developmental

insult related to 5HT deficits in the critical period or a compensatory effect both associated with the unique behavioral phenotypes of the TPH^{-/-}mouse.

Title: Serotonin-7 receptors in the hippocampus vary with time of day but not aging

Authors: *M. J. DUNCAN, K. M. FRANKLIN, J. T. SMITH Dept Anat/Neurobiol, Univ. of Kentucky Dept. Neurosci., Lexington, KY

Abstract: Activation of serotonin-7 (5-HT₇) receptors modulates circadian rhythms, memory, REM sleep, and depression, processes which are deleteriously affected by aging. Endogenous regulation of these receptors is not well understood, although pharmacological regulation has been reported. Chronic treatment with selective serotonin re-uptake inhibitors known to increase extracellular serotonin levels leads to down-regulation of 5-HT7 receptors. Because endogenous serotonin release exhibits a daily rhythm with higher levels at night, we hypothesized that 5-HT₇ receptors exhibit 24-h variations characterized by lower nighttime expression. Our previous studies of Syrian hamsters showed that aging decreases 5-HT₇ receptors in the dorsal raphe nucleus, a brain region in which these receptors affect circadian rhythms and REM sleep, but not in the several other circadian substrates, such as the suprachiasmatic nucleus. Here we tested whether aging reduces 5-HT7 receptors in the hippocampus, a likely substrate for the effects of 5-HT₇ receptor drugs on memory and depression. Male Syrian hamsters (young, 3-5 months; old, 17-21 months) exposed to a daily alternating cycle of 14 h light:10 h dark were euthanized at 4 times of day (zeitgeber times [ZT]1, 6, 13, & 19; ZT12 = time of lights:off; N=8-13/tim/age). Coronal sections through the hippocampus were processed for 5-HT₇ receptor autoradiography using [³H]8-OH-DPAT [2 nM] as the radioligand and SB-269970 [1 µM] to define nonspecific binding. Tissue sections and radioactive standards were apposed to X-ray films to generate autoradiograms that were assessed by computer-assisted microdensitometry. Robust specific 5-HT7 receptor binding was observed in the hippocampal dentate gyrus (DG), CA1, and CA2 but not in CA3. In the DG and CA1, specific 5-HT7 receptor binding sites exhibited 24-h rhythms with troughs at night (P<0.005; P<0.05, respectively), in support of the hypothesis. Specific 5-HT₇ receptor binding in the CA1 and DG were not significantly affected by age or by

interactions between time and age. In conclusion, these data indicate that 5-HT7 receptors in the hippocampus are influenced by time of day but not by aging. Furthermore, these findings suggest that the therapeutic effectiveness of 5-HT₇ drugs may persist in old age but will depend on the daily time of administration.

Title: Towards a zebrafish serotonin receptor pharmacology

Authors: *H. SCHNEIDER¹, P. SURESH², S. GERONGAY², D. HUYNH² ¹Dept. of Biol., Depauw Univ., Greencastle, IN; ²DePauw Univ., Greencastle, IN

Abstract: Serotonin (5-hydroxytryptamine; 5-HT) is a neurotransmitter in the brain of vertebrate animals and humans. 5-HT is involved in the regulation neurological states such as mood, pain, and anxiety and has been linked to drug dependency. Zebrafish (*Danio rerio*) could represent a tool for the pre-clinical development of pharmacotherapies of human disorders with a link to the serotonin system. We identified 23 serotonin receptor (htr) genes in the zebrafish genome. Every human htr gene appears to have an ortholog in zebrafish, except for three htr3 receptor types. Because of a teleost genome duplication event several but not all human serotonin receptor genes have duplicates in the zebrafish genome. For a pharmacological characterization of zebrafish serotonin receptors, we have cloned and sequenced htr2cl1, htr2aa, htr2ab and htr7c entire coding regions. At the protein level, zebrafish amino acid sequences are about 70% identical to human serotonin receptors. Expression of serotonin receptors in HEK293 cells enables the isolation of htr proteins for binding assays which are being carried out to determine the degree of similarity between zebrafish and human serotonin receptor pharmacology.

Abstract: Tryptophan hydroxylase 2 (TPH2) is the key enzyme in the synthesis of neuronal serotonin. Although previous studies suggest the NRSF-mediated negative regulation of the human TPH2 (hTPH2) gene, the mechanisms by which the hTPH2 gene expression is activated remains unresolved. An in silico analysis, 5'-flanking region revealed the presence of two consecutive GC-rich motifs (GCB1, -207/-199 and GCB2, -182/-174), within which the putative transcription factor binding sites, including early growth response proteins (EGRs) and specificity proteins (Sps), were found. A 2-kb region of the hTPH2 gene (-1850/+141) was cloned into pGL4-Basic and its 5'-untranslated region (+10/+121; a region containing repression elements including NRSE) was deleted to yield TPH2-100. Furthermore, the 48-bp segment (-124/-77) adjacent to GCBs was deleted from TPH2-100 to prepare TPH2-131. Quantitative realtime RT-PCR analysis revealed the expression of Egr-1, Egr-2, Egr-3, Egr-4, Sp1, Sp3, Sp4, Nab1 and Nab2 genes in rat raphe RN46A cells. Reporter assays showed that the promoter activity of hTPH2-131 was about 2-times that of hTPH2-100, suggesting that the 48-bp downstream segment contains a not-yet-identified inhibitory element. Interestingly, this 48-bp segment is well conserved between humans and rodents. Overexpression of EGRs (EGR1, 2, 3 and 4) and/or Sps (Sp1, Sp3 and Sp4), either alone or in combination, only caused marginal effects on the hTPH2-100 promoter activity. Whereas overexpression of EGRs or Sps alone exhibited only a marginal effect on the hTPH2-131 promoter activity, when both were coexpressed, the joint effect was additive. These results indicate that EGRs and Sps apparently bind to the GCBs in a noncompetitive manner and act together to increase the hTPH2-131 promoter activity. Moreover, these results suggest that the 48-bp segment has an inhibitory effect on the joint function of EGRs and Sps via the GCBs. To analyze these GCBs further, mutant reporters were prepared and co-expression studies were performed using EGR4 and Sp3 expression vectors. Although mutation of either the GCB1 or the GCB2 reduced the hTPH2-131 promoter activation by EGR4 and Sp3, the GCB2 mutation produced a greater reduction compared to that of the GCB1 mutation. Double mutations of the GCB1 and GCB2 brought a further reduction. These results indicate that the GCB2 is critical for the hTPH2-131 promoter activation by EGR4 and Sp3, and the GCB1 might play an accessary role. Collectively, these results imply that the hTPH2 promoter activation by EGRs and Sps is dependent on the GCBs and is subjected to the inhibitory modulation mediated by the unique downstream 48-bp segment.

Title: Regulation of tetrahydrobiopterin (BH4), a required cofactor for serotonin & dopamine synthesis, in the nematode *C. elegans*

Authors: *C. M. LOER

Univ. of San Diego, San Diego, CA

Abstract: The rate-limiting synthetic enzymes for serotonin and dopamine synthesis, for phenylalanine catabolism, for ether lipid metabolism, and the nitric oxide synthases (NOSs) all require the cofactor 5,6,7,8-tetrahydrobiopterin (BH4) for catalytic function. We have recently described the function and expression of genes required for BH4 synthesis and regeneration in the nematode C. elegans (Loer et al., 2015, Genetics 200: 237). Worms that can't synthesize BH4 are serotonin- and dopamine-deficient, and have leaky, fragile cuticles caused by aberrant lipid metabolism in the epidermis; BH4-deficiency also alters susceptibility to bacterial pathogens. In humans, regulation of BH4 levels is important for many physiological functions. BH4 is synthesized in four steps starting with GTP; the first step is performed by GTP Cyclohydrolase I (GTPCH1, C. elegans gene cat-4). Like in many biochemical synthesis pathways, the first enzyme in the pathway is regulated by 'end product feedback inhibition.' This typically occurs by the end product itself binding to another site on the enzyme – allosteric regulation. For BH4, it is more complicated - in mammals, GTPCH1 inhibition by BH4 requires an additional small protein called GTPCH1 feedback regulatory protein (GFRP). Crystal structures show that the analog BH2 binds at the interface between pentamers of GTPCH1 & GFRP to inhibit GTPCH1 function, mainly interacting with GTPCH1 (Maita et al., 2004, J Biol Chem 279: 51534). Phe, which stimulates GTPCH1, also binds at the interface between the two proteins, mainly interacting with GFRP. C. elegans also encodes a likely ortholog of GFRP (gene *gfrp-1*); sequence analysis and structural predictions suggest the worm GFRP will function like the mammalian protein, binding both BH4 and Phe. In mammals, GTPCH1 and GFRP can also bind the selective inhibitor 2,4-Diamino-6-hydroxypyrimidine (DAHP), which is structurally similar to both GTP (substrate) and BH4 (pathway end product). At low concentrations, DAHP apparently inhibits GTPCH1 like BH4 by binding with GFRP; this inhibition is GFRP-dependent. At higher concentrations, DAHP acts as a competitive inhibitor, binding at the GTPCH1 active site like GTP; this inhibition is GFRP-independent (Xie et al., 1998, J Biol Chem 273: 21091). Although DAHP treatment has no obvious effect on wildtype C.

elegans, serotonin levels (a proxy for BH4 levels) are reduced by DAHP in worms with a reduction-of-function mutation [*cat-4(e3015)*] that already have less BH4. We plan to test whether this presumed inhibition of worm GTPCH1 is GFRP-dependent by knocking down *gfrp-1* gene function in DAHP-treated *cat-4(e3015)* worms.

Title: Therapeutic potential of mGlu1 PAMs in the treatment of schizophrenia via regulation of striatal dopamine release through an endocannabinoid-dependent mechanism

Authors: *S. E. YOHN¹, D. J. FOSTER¹, D. P. COVEY², P. M. GARCIA-BARRANTES¹, J. F. CHEER², C. W. LINDSLEY¹, P. J. CONN¹ ¹Vanderbilt Univ., Nashville, TN; ²Univ. of Maryland, Baltimore, MD

Abstract: Given the shortcomings of current antipsychotics, novel therapeutic approaches are needed that exhibit clinical efficacy with reduced adverse effect liability. Activation of the muscarinic M₄ receptor has previously been demonstrated to have antipsychotic-like efficacy in several preclinical models. Recently our laboratory reported that these antipsychotic effects are mediated through a novel mechanism wherein activation of M4 receptors reduces dopamine release through a CB₂ cannabinoid-dependent mechanism. Herein, we present new data suggesting that metabotropic glutamate 1 receptor (mGlu₁) plays a critical role in mediating these M₄-dependent dopaminergic effects. Bath application of an mGlu₁ negative allosteric modulator (NAM) VU0458650 blocks M₄-induced reductions in striatal dopamine and M₄mediated antipsychotic-like effects. A key role for mGlu₁ in regulating DA release could provide important new insights into mechanisms by which loss of mGlu1 signaling could contribute to symptoms observed in schizophrenia patients. Our laboratory has recently developed a novel highly-selective mGlu₁ positive allosteric modulator (PAM) VU6004909, which has an excellent pharmacokinetic (PK) profile for use in in vivo studies. Through use of both ex vivo and in vivo fast-scan cyclic voltammetry (FSCV), we report that application of VU6004909 reduces striatal DA release. Moreover, administration of VU6004909 possesses antipsychotic-like efficacy in

rodent models of schizophrenia, suggesting that $mGlu_1$ selective compounds may alleviate the positive symptoms of schizophrenia. Taken together, these results indicate that **i**) $mGlu_1$ activation plays a regulatory role in the antipsychotic-like effect of M₄ PAMs and **ii**) highlight the potential of a novel intervention strategy utilizing selective $mGlu_1$ compounds.

Title: Hindbrain cholinergic projections to the substantia nigra pars reticulata regulate direct pathway dopamine signaling

Authors: *M. S. MOEHLE¹, T. PANCANI¹, S. YOHN¹, N. BYUN¹, J. DICKERSON¹, D. REMKE¹, C. JONES¹, Z. XIANG¹, C. NISWENDER¹, J. WESS², G. WILSON¹, C. LINDSLEY¹, J. ROOK¹, J. CONN¹ ¹VCNDD, Vanderbilt Univ., Nashville, TN; ²NIH, NIDDK, Bethesda, MD

Abstract: Dysregulation of dopamine (DA) release within the basal ganglia from midbrain dopaminergic neurons of the substantia nigra pars compacta (SNpc) underlies pathological states in several psychiatric and movement disorders. Within the basal ganglia, DA acts on two separate non-overlapping pathways, the direct and indirect pathway. Because of the critical modulatory role of DA, great effort has been placed on understanding both how DA modulates the basal ganglia direct and indirect pathways and how other neurotransmitter systems regulate DA signaling. One such regulator of DA is the muscarinic acetylcholine receptor subtype 4 (M4). Recently, our lab has shown that M4 activation on direct pathway spiny projection neurons (SPNs) can inhibit DA release from SNpc terminals in the striatum through an endocannabinoid dependent mechanism. However, we now report that M4 activation can block D1 DA signaling

in addition to blockading DA release. Using a wide range of behavioral, electrophysiological, optogenetic, pharmacological, and imaging techniques, we directly tested how M4 signaling opposes D1 activation. Interestingly, we have found that cholinergic projections from the hindbrain regulate D1 DA signaling at the level of the substantia nigra pars reticulata (SNr) through M4. Additionally, these data suggest that M4 activity may tonically inhibit direct pathway SPNs and D1 DA signaling. We additionally present data that suggests that elimination of cholinergic projections from the hindbrain has widespread effects on basal ganglia dependent behaviors. Taken together, our data demonstrate a new role for M4 in modulating DA signaling, extend the current model of basal ganglia processing, and suggest an important role of hindbrain cholinergic projections in regulating the basal ganglia.

Abstract: Huntington's Disease (HD) is a genetic and neurodegenerative disease characterized by multiple symptom stages resulting in motor and cognitive deficits. Currently, the treatments for HD only address late-stage symptom management, indicating the need for further understanding of the disease, and development of treatments for early-stage symptoms. While the exact causes behind the neurodegeneration observed in HD are not clear, there are several circuit level changes that precede motor symptoms including hyperactive neurotransmission in

the striatum. We theorize that modulation of this imbalanced basal ganglia circuitry through activation of the M₄ subtype of the muscarinic acetylcholine receptor can provide a novel therapeutic strategy for treating HD. Through studies utilizing fast-scan cyclic voltammetry, we have confirmed that two animal models of HD, BACHD and YAC128 HD, are hyperdopaminergic compared to wild-type littermates at young ages prior to the onset of motor phenotypes. Both electrical stimulation, as well as optical stimulation in mice expressing channel rhodopsin 2 in dopamine neurons, induced larger dopamine transients in ex vivo brain slices of HD mice. In addition, in vivo voltammetry recordings made from anesthetized HD mice demonstrated larger electrically evoked dopamine transients than littermate controls. The increased striatal dopamine release in HD mice did not correlate with changes in motor function when tested in an open field paradigm. However, the BACHD model did show increased social aggression behavior compared to littermates as assessed using a tube dominance test. Through voltammetry, we have also found that the nonselective muscarinic acetylcholine receptor agonist oxotremorine-M, induced sustained reductions of dopamine release more potently in BACHD mice than in their littermates. This sustained inhibition of DA release could be potentiated by the selective M₄ positive allosteric modulator (PAM), VU0467154, demonstrating that increased M₄ signaling can normalize excessive striatal dopamine release in HD mice. Previous studies have demonstrated that chronic administration of M4 PAMs can delay the onset of motor deficits in these mouse models. Collectively, these data suggest that these mice display excessive dopamine transmission in the striatum that correlates with increased social aggression. Furthermore, we found that activation of the M4 receptor could normalize this excessive dopamine transmission suggesting that this receptor may be a novel therapeutic target with which to normalize neurotransmission in early disease stages.

Title: M₁ Allosteric modulators without agonist activity in the medial prefrontal cortex may provide the optimal profile for cognition enhancement

Authors: *S. P. MORAN, C. A. DOYLE, Z. XIANG, H. C. PLUMLEY, J. W. DICKERSON, D. H. REMKE, C. M. NISWENDER, D. W. ENGERS, C. W. LINDSLEY, J. M. ROOK, P. J. CONN

Abstract: The M₁ subtype muscarinic acetylcholine (ACh) receptor (mAChRs) has emerged as an exciting potential target for novel therapeutic agents for the treatment of schizophrenia. Recently, highly-selective M₁ positive allosteric modulators (PAMs) have provided compelling evidence that M₁ PAMs have cognition-enhancing effects and actions that predict reduction in negative symptoms in rodent models of schizophrenia. Specifically, M₁ PAMs can enhance a novel form of mAChR-induced long-term depression, termed mLTD, at the hippocampoprefrontal cortex (PFC) synapse. mLTD at this synapse is disrupted in rodent models of schizophrenia and is thought to contribute to hippocampo-PFC communication deficits observed in schizophrenia patients. To better understand the pharmacological properties necessary for in vivo efficacy, our lab and others have developed M1 allosteric modulators with diverse pharmacological properties. One such property is intrinsic agonist activity, in addition to PAM activity, in an in vitro system used for compound characterization, such as a calcium mobilization assay. While application of M₁ PAMs with no intrinsic agonist activity, such as VU0550164 and VU0453595, do not induce mLTD by themselves at this hippocampo-PFC synapse, interestingly, M1 PAMs with agonist activity (ago-PAMs) such as MK-7622 and PF-06764427 robustly induce mLTD. Furthermore, in contrast to a VU0453595, a PAM with no observable agonist activity in vitro, these M1 ago-PAMs failed to improve novel object recognition, an assay of cognition in rodents. Thus, it is possible that structurally distinct M₁ PAMs could have fundamentally different effects on important aspects of CNS function, depending on the presence of observable agonist activity in vitro. These findings suggest that ago-PAM activity is not required for cognition enhancement and may, in fact, be detrimental.

Title: Mechanisms underlying persistent cholinergic excitation of corticofugal neurons

Authors: *A. L. BAKER, A. T. GULLEDGE

Dept. of Mol. & Systems Biol., Geisel Sch. of Med. at Dartmouth, Lebanon, NH

Abstract: In the rodent medial prefrontal cortex (mPFC), pyramidal neurons in layer 5 broadly express G_a-coupled M1-type muscarinic ACh receptors, but the ionic mechanisms underlying cholinergic excitation of pyramidal neurons are not well understood. Recent work in our lab has characterized a long-lasting cholinergic excitation of corticofugal neurons in layer 5 of the mouse mPFC. Here we explore the mechanisms underlying cholinergic excitation in retrogradely-labeled corticopontine neurons in the mPFC of wild-type mice or mice expressing channelrhodopsin-2 in cholinergic neurons. Persistent cholinergic excitation did not depend on network activity, as it remained robust in the presence of glutamate (kynurenate, 3 mM) and GABA (gabazine, 10μ M) receptor blockers (n = 11). Cholinergic excitation was not contingent on intracellular calcium signaling, as it was not diminished in magnitude or duration following chelation of intracellular calcium with BAPTA (10 or 30 mM; n = 12 and n = 15, respectively), despite elimination of calcium-dependent cholinergic afterdepolarizations. However, blockade of the M-current with bath application of XE991 (10 μ M; n = 11) reduced the magnitude and duration of cholinergic excitation by $19 \pm 11\%$ and $29 \pm 24\%$, respectively, suggesting that Kv7 channels play a role in generating and maintaining this excitation. To test the role of calcium conductances, we combined intracellular BAPTA with removal of extracellular calcium (replaced with equimolar MgCl₂). Removal of calcium decreased both the magnitude and duration of cholinergic excitation, by $42 \pm 8\%$ and $49 \pm 20\%$, respectively, and was reversible upon reintroduction of extracellular calcium (n = 13). Moreover, combining intracellular BAPTA with the nonselective calcium conductance blocker cadmium (200 µM) similarly reduced the magnitude (by $47 \pm 8\%$) and duration (by $59 \pm 10\%$) of cholinergic excitation. The effects of blocking the M-current and eliminating calcium conductances were additive, such that removal of calcium in the presence of XE991 generated a $65 \pm 8\%$ decrease in peak cholinergic excitation, and a 76 \pm 13% reduction in response duration (n = 7). Together, these results indicate that cholinergic excitation of cortical brainstem-projecting neurons involves suppression of the M-current and activation of a calcium-permeable cation conductance.

Title: Allosteric modulators enhance responses evoked at muscarinic receptors following alkylation by acetylcholine mustard or acetylethylcholine mustard

Authors: *J. ELLIS, G. ELMSLIE

Psychiatry and Pharmacol., Penn State Univ., Hershey, PA

Abstract: Mustard analogs of many receptor ligands have been used to irreversibly label or inactivate receptors. In aqueous solution, mustard groups cyclize to form aziridinium ions that closely mimic quaternary amines. Such a reactive intermediate may therefore bind in the same orientation within the same binding pocket of the receptor that accommodates the related reversible ligand. Once oriented, it is capable of alkylating any of a number of nearby amino acid side chains. In principle, a mustard analog of an agonist might yield irreversible activation of the receptor. However, acetylcholine mustard has been widely reported to possess agonist activity at muscarinic receptors only until alkylation is achieved, at which point the receptor becomes inactivated. Therefore, we were surprised to find that agonist activity persisted after irreversible binding of acetylcholine mustard and its analog, acetylethylcholine mustard, at Gq-linked muscarinic receptors (M₁, M₃, and M₅) expressed in CHO cells. The most interesting results were obtained when measuring the receptor-stimulated release of labeled arachidonic acid (AA) from intact cells. After cells were preincubated with cyclized agonist mustards and thoroughly washed, the basal AA release was found to be elevated to a small but significant degree. This elevation could be prevented if atropine was include in the preincubation phase, but was not inhibited by the presence of atropine in the assay phase. By contrast, inclusion of amiodarone in the assay phase dramatically increased the response of cells that were preincubated with the agonist mustards. We have previously shown amiodarone to be a positive allosteric modulator (PAM) at these receptors. Once again, atropine in the assay itself did not prevent the effect of amiodarone, but atropine in the preincubation phase prevented it completely. At the M₁ subtype, the well-known M₁-specific PAM BQCA enhanced the mustard-induced activity in a manner similar to that observed for amiodarone. The agonist mustards were also found to irreversibly stimulate the metabolism of inositol phosphates (IP), by a similar paradigm. The IP response to the irreversible agonists was more robust than the AA response, and the effects of the PAMs were therefore typically smaller in the IP response. These studies demonstrate that the allosteric sites for amiodarone, BQCA, and other ligands that were investigated are still available following the mustard treatment, and that receptors that have been alkylated by acetylcholine

mustard and acetylethylcholine mustard do adopt active conformations that can be further enhanced by appropriate allosteric ligands.

Abstract: Group II metabotropic glutamate (mGlu) receptors (mGlu2 and mGlu3) are implicated in the pathophysiology of schizophrenia and are considered as potential targets for new antipsychotic drugs. Changes in the expression of mGlu2 and mGlu3 receptors have been found in the prefrontal cortex of mice exposed to prenatal stress. These mice show epigenetic abnormalities in biochemical markers of GABAergic interneurons and show a psychotic-like phenotype in the adult life (Matrisciano et al., Neuropharmacology, 2013). Moving from these findings, we decided to examine whether the lack of mGlu2 or mGlu3 receptors affects the expression profile of biochemical markers of GABAergic interneurons in the prefrontal cortex and hippocampus at postnatal day (PND)1, PND9, and PND30. The following markers were examined: parvalbumin, somatostatin, reelin, glutamic acid decarboxylase 1 and 2 (GAD67/65), cannabinoid receptor 1 (CB1), neuropeptide Y (NPY), GABA transporter 1 (GAT1), aristaless related homeobox (ARX), distal-less homeobox 2 (DLX2) and the α_2 and δ subunits of GABA_A receptors. The most prominent finding was a marked reduction of parvalbumin mRNA and protein levels in the prefrontal cortex of mice with genetic deletion of mGlu3 receptors. This finding suggests that mGlu3 receptors play a prominent role in the development of fast-spiking parvalbumin-positive GABAergic interneurons, which are known to be defective in schizophrenia. Of note, polymorphic variants of the gene encoding for the mGlu3 receptor (the GRM3 gene) have been repeatedly associated with schizophrenia. Perhaps, these variants influence the development of specific populations of GABAergic interneurons in the cerebral

cortex and hippocampus, causing abnormalities in cognitive functions that lie at the core of the pathophysiology of schizophrenia.

Title: Activation of mGlu1 metabotropic glutamate receptors plays a key role in excitotoxic neurodegeneration in the mouse retina

Authors: M. ROMANO¹, F. LIBERATORE², D. BUCCI¹, G. MASCIO¹, A. PULITI^{3,4}, M. MADONNA¹, *R. GRADINI^{2,1}, G. BATTAGLIA¹, V. BRUNO^{2,1}, F. NICOLETTI^{2,1} ¹IRCCS Neuromed, Pozzilli, Italy; ²Univ. Sapienza, Roma, Italy; ³Univ. of Genoa, Genoa, Italy; ⁴Inst. Giannina Gaslini, Genoa, Italy

Abstract: Several lines of evidence demonstrate a role for excitotoxicity in retinal ganglion cell (RGC) death and most studies focus on activation of the N-methyl-d-aspartate (NMDA) receptors. To our knowledge, no studies have addressed the role of metabotropic glutamate (mGlu) receptors in mechanisms of retinal degeneration. We have recently found that only mGlu1, but not mGlu5, receptors are coupled to polyphosphoinositide hydrolysis in the mouse retina (Romano et al., 2016), even if both subtypes are expressed in the retina. Here we have studied the role of the mGlu1 receptors on retinal degeneration using the monosodium glutamate (MSG) model. A single systemic injection of MSG to C57BL/6J mouse pups at postnatal day 9 induced a severe retinal degeneration as assessed by immunohistochemistry and stereological counts of the RGCs using the specific marker, brain-specific homeobox/POU domain protein 3A (Brn3a). The selective mGlu1 receptor negative allosteric modulator, JNJ16259685 (2.5 mg/kg, s.c.), was highly protective against MSG-induced retinal degeneration, suggesting that activation of mGlu1 receptors contributes to excitotoxic neuronal death in the mouse retina. Accordingly, MSG-induced RGC death was attenuated in crv4 mice lacking mGlu1 receptors because of a spontaneous recessive mutation of the *Grm1* gene. These findings suggest that mGlu1 receptor is a key player in mechanisms of excitotoxic retinal degeneration and that it might represent a candidate drug target for the treatment of degenerative ocular diseases.

Title: Comparative subcellular expression patterns of metabotropic glutamate receptor 3 in the prefrontal cortex of the adult rat and monkey

Authors: *J. L. CRIMINS, A. F. T. ARNSTEN, C. D. PASPALAS Neurosci., Yale Univ. Sch. of Med., New Haven, CT

Abstract: Layer III pyramidal neuron networks of the dorsolateral prefrontal cortex (dlPFC) that subserve working memory are vulnerable to the effects of schizophrenia, aging, and Alzheimer's disease. These networks interconnect on dendritic spines with glutamatergic N-Methyl-Daspartate receptor synapses, which are crucial for delay-related firing during a working memory task. On the basis of data from rodents, group II metabotropic glutamate receptors are generally thought to weaken excitatory glutamatergic signaling through Gi/Go-dependent inhibition of glutamate release from presynaptic axons (mGluR2), and/or increased glutamate uptake through excitatory amino acid transporters on astroglia (mGluR3). In monkey layer III dlPFC, we discovered that mGluR3 are also expressed within spine synapses. From this postsynaptic site, mGluR3 strengthen network connectivity and enhance working memory-related neuronal firing via inhibition of cAMP-PKA opening of potassium channels. Yet, rodent literature remain at odds with these data, suggesting that mGluR3 stimulation would primarily increase astroglial glutamate removal from the synaptic cleft, ultimately leading to reduced postsynaptic excitation. To test whether this discrepancy might reflect true species differences, we used immunoelectron microscopy to map mGluR3 in the layer III neuropil of rat medial PFC, the region underlying working memory. We have found that, in addition to classical astroglial expression, mGluR3 are concentrated within preterminal axons where they are positioned to modulate extrasynaptic glutamate release (volume transmission). A postsynaptic component similar to that of nonhuman primates, albeit less extensive, was also identified within the spine synapse. Shared postsynaptic localization in PFC of both species introduces the possibility that mGluR3-mediated enhancement of working memory circuits is phylogenetically conserved.

Title: Allosteric modulation and thermodynamic constraints in occupancy models of oligomeric G protein-coupled receptors

Authors: *G. D. SMITH¹, R. HAMMACK²

¹The Col. of William & Mary, Williamsburg, VA; ²Virginia Commonwealth Univ., Richmond, VA

Abstract: Terrell Leslie Hill diagrammatic method of quantifying free energy transduction in biochemical cycle kinetics (e.g., the sliding filament model of muscle contraction) is readily applied to stochastic models of ligand-receptor binding. Hill's method uses the Markov Chain Tree Theorem to express the steady-state probability distribution of a receptor occupancy model in terms of the unimolecular rate constants associated to its state-transition graph G, with each spanning tree of G rooted in a given state contributing to that state's occupancy measure. To facilitate application of Hill's diagrammatic method to G protein-coupled receptor oligomers, we have characterized the structural properties of "reduced graph powers" - denoted $G^{(N)}$ - that are the transition graphs for the master Markov chain for N identical (but not independent) M-state receptor models with transition graph G of size |G|=M. Most significantly, we provide a construction of minimum cycle bases of $G^{(N)}$ that elucidates the combinatorics of allosteric modulation and thermodynamic constraints on equilibrium association constants in occupancy models of oligomeric G protein-coupled receptors.

Title: Role of metabotropic glutamate receptors in low Mg²⁺-induced Ca²⁺-spikes in cultured rat hippocampal neurons

Authors: S. JEON, J. YANG, *S. YOON

Dept. of Physiology, Col. of Med., Catholic Univ. of Korea, Seoul, Korea, Republic of

Abstract: Reducing $[Mg^{2+}]_0$ to 0.1 mM has elicited repetitive $[Ca^{2+}]_i$ spikes in cultured rat hippocampal neurons, driven by glutamatergic synaptic transmission. Group 1 metabotropic glutamate receptors (mGluRs), positively affect postsynaptic neuronal excitability. Present study was investigated to determine whether group 1 mGluRs are involved in the synapticallyinducced [Ca²⁺]_i spikes induced by HEPES-buffered Hank's salt solution containing 0.1 mM MgCl₂ and 10 µM glycine in cultured rat hippocampal neurons from embryonic day 17 fetal Sprague-Dawley rats using digital imaging methods for Ca². Reduction of [Mg²⁺]₀ to 0.1 mM induced synchronized and repetitive $[Ca^{2+}]_i$ spikes within 30 s at day 11.5. The group 1 mGluR agonist, DHPG (1 μ M), significantly increased the frequency and the area under the curve of the 0.1 mM $[Mg^{2+}]_{0}$ -induced $[Ca^{2+}]_{i}$ spikes. The mGluR5 antagonist MPEP (25 μ M) antagonist significantly inhibited the frequency and the area under the curve of the $[Ca^{2+}]_i$ spikes, but the mGluR1 antagonist LY367385 (100 μ M) did not affect the [Ca²⁺]_i spikes. The phospholipase C inhibitor U73122 (1 μ M) significantly inhibited the [Ca²⁺]_i spikes. The IP₃ receptor antagonist 2-APB (30 μ M) or the ryanodine receptor antagonist TMB-8 (10 μ M) also inhibited the [Ca²⁺]_i spikes. All these results suggest that mGluR 5 is involved in the 0.1 mM $[Mg^{2+}]_0$ -induced $[Ca^{2+}]_1$ spikes in cultured rat hippocampal neurons through release of Ca²⁺ from IP₃ and ryanodinesensitive stores. This work was supported by the Basic Science Research Program through the National Research Foundation of Korea funded by the Ministry of Education (NRF-2016R1D1A1B03934176).

Title: Synaptic ERK2 phosphorylates and regulates metabotropic glutamate receptor 1 *In vitro* and in neurons

Authors: *J. YANG¹, L. MAO², J. Q. WANG^{2,3}, E. CHOE¹

¹Pusan Natl. Univ., Pusan-City, Korea, Republic of; ²Dept. of Anesthesiol., Sch. of Medicine, Univ. of Missouri-Kansas City, Kansas City, KS; ³Beijing Inst. of Brain Disorders, Capital Med. Univ., Beijing, China

Abstract: A synaptic pool of extracellular signal-regulated kinases (ERK) controls synaptic transmission, although little is known about its underlying signaling mechanisms. Here, we found that synaptic ERK2 directly binds to postsynaptic metabotropic glutamate receptor 1a (mGluR1a). This binding is direct and the ERK-binding site is located in the intracellular C-terminus (CT) of mGluR1a. Parallel with this binding, ERK2 phosphorylates mGluR1a at a cluster of serine residues in the distal part of mGluR1a-CT. In rat cerebellar neurons, ERK2 interacts with mGluR1a at synaptic sites, and active ERK constitutively phosphorylates mGluR1a under normal conditions. This basal phosphorylation is critical for maintaining adequate surface expression of mGluR1a. ERK is also essential for controlling mGluR1a signaling in triggering distinct postreceptor signaling transduction pathways. In summary, we have demonstrated that mGluR1a is a sufficient substrate of ERK2. ERK that interacts with and phosphorylates mGluR1a is involved in the regulation of the trafficking and signaling of mGluR1.

Title: Role of ubiquitination in glutamate receptors trafficking

Authors: *R. GULIA¹, R. SHARMA², S. BHATTACHARYYA¹ ¹Biol. Sci., Indian Inst. of Sci. Educ. and Res., Mohali, India; ²Biol. Sci., Indian Inst. of Sci. Educ. and Res., Mohali, SAS Nagar, Knowlwdge city, Sec-81, India

Abstract: Glutamate is a major excitatory neurotransmitter in the central nervous system (CNS). Glutamate receptors which bind to glutamate are categorized into two groups: ionotropic glutamate receptors (ion channels) and metabotropic glutamate receptors (GPCRs). Group I metabotropic glutamate receptors (mGluRs) consists of two members viz., mGluR1 and mGluR5. They are predominantly localized at the post-synaptic side are key players in the process of neuronal development as well as in synaptic plasticity in the CNS. These receptors are positively coupled to Gq pathway. Accurate temporal and spatial localization of these receptors at postsynaptic surface is crucial for normal signaling, and their spatiotemporal localization is maintained by trafficking of the receptor. Trafficking also play crucial role(s) in the regulation of these receptors. Thus, studies of the trafficking of these receptors are of utmost importance. Furthermore, these receptors upon activation result in the endocytosis of AMPA receptors, leading to mGluR-dependent Long-term depression (mGluR-LTD). We are interested in investigating the cellular and molecular mechanisms that govern the group I mGluR trafficking and it effect on mGluR-mediated AMPAR endocytosis. Our data suggest that ubiquitination plays critical role in the trafficking of these receptors. We have found that these receptors get ubiquitinated upon binding with the ligand and subsequently get endocytosed. We further demonstrated that lysine residue present at the C-terminus of mGluR1 plays critical role in the endocytosis of mGluR1. In addition, E3 ligase, Siah-1A was found to be involved the ubiquitination of mGluR1. Acute knockdown of Siah-1A also enhanced group1 mGluR mediated AMPAR endocytosis in primary neurons.

Abstract: Pharmacological activation of mGlu5 metabotropic glutamate receptors reduces the frequency of spike-and-wave discharges (SWDs) in the WAG/Rij rat model of absence epilepsy. Recent evidence suggests a protective role for group I metabotropic glutamate receptors as potential candidates for the treatment of absence epilepsy. The evidence that the anti-absence activity of the mGlu5 positive allosteric modulator (PAM), VU0360172, was reversed by intrathalamic infusion of the GABA transporter inhibitor, tiagabine, raised the possibility that mGlu5 receptors regulate the expression/activity of the high affinity GABA transporter, GAT-1, in the ventrobasal thalamus. Accordingly, systemic treatments with VU0360172 was able to upregulate GAT-1 expression in the thalamus after 1 hour. The drug was also able to up-regulate GAT-1 expression in the somatosensory cortex, but this effect required three days of repeated administrations. Here, we provide new evidence in support to this hypothesis by demonstrating that systemic treatment with VU0360172 could enhance GABA uptake in the thalamus. Symptomatic WAG/Rij rats were treated with VU0360172 (3 mg/kg, s.c.) or its vehicle either acutely (single injection) or repeatedly (twice a day for three days). All animals were killed one hour after the last injection. [³H]-GABA uptake was measured in superfused isolated synaptosomes prepared from the thalamus and somatosensory cortex. Both single and repeated administrations of VU0360172 significantly enhanced GABA uptake in thalamic synaptosomal preparations, but not in cortical synaptosomes, where acute treatment with VU0360172 unexpectedly reduced GABA uptake. These findings demonstrate that mGlu5 receptors regulate GABA uptake in the thalamus and support the view that mGlu5 PAMs can be developed as antiabsence drugs. We are currently exploring the mechanisms responsible for the short-onset enhancement of GABA uptake caused by mGlu5 receptor activation focusing on changes in GAT-1 intracellular trafficking.

Title: Coincident activation of adenosine A1 receptors and metabotropic glutamate receptor 5 modulates neuronal signalling

Authors: *K. J. GREGORY¹, S. HELLYER¹, S. ALBOLD¹, A. CHRISTOPOULOS², T. WANG¹, L. T. MAY¹

¹Monash Univ., Parkville, Australia; ²M.I.P.S., Monash Univ., Parkville, Australia

Abstract: G protein-coupled receptors (GPCRs) are highly 'druggable' proteins and represent the largest class of targets for current therapeutics. Two distinct neuromodulatory GPCRs, the adenosine A_1 receptor (A_1AR) and the metabotropic glutamate receptor subtype 5 (mGlu₅), have been implicated in Alzheimer's disease (AD) pathology and as potential targets to treat cognitive impairments and disease progression. Both receptors are found on the same CNS-resident cell types, in particular neurons and astrocytes, and are expressed within key regions of the brain implicated in AD pathology. GPCR discovery programs generally only consider GPCR activity in isolation, without factoring in the influence of other GPCRs or stimuli present. Importantly, both glutamate and adenosine are often present within culture medium and/or released from cultured cells. GPCR cross-talk and/or heteromerisation can introduce pharmacological heterogeneity and offer new avenues for targeted drug development. We sought to test the hypothesis that coincident activation of co-located GPCRs modulates signalling in primary neurons. Primary cultures were derived from striatum and cortices of E16 mice. After 6-8 days in culture, high-throughput signalling assays were performed (iCa^{2+} mobilisation, inositol phosphate (IP1) and cAMP accumulation). We first confirmed the presence of functional mGlu₅ and A₁AR in both cultures by assessing the ability of: 1) A₁AR selective agonist (MeCCPA) to inhibit forskolin stimulation of cAMP accumulation; and 2) mGlu₅ selective allosteric agonist (VU0424465) to stimulate iCa²⁺ and IP1 accumulation. Coincident activation of A₁AR enhanced mGlu₅-mediated iCa²⁺ mobilisation in response to both orthosteric and allosteric agonists in striatal and cortical neurons. The maximal response and potency (~3 fold) of both DHPG (mGlu5 orthosteric agonist) and VU0424465 were significantly increased. In contrast, A1AR activation had no effect on mGlu5-mediated IP1 accumulation in cortical neurons. Conversely, coincident activation of mGlu₅ had little influence on A₁AR-mediated inhibition of cAMP accumulation. Collectively, our data demonstrate that coincident activation of mGlu₅ and A₁AR differentially modulates intracellular signalling pathways in primary neurons. Future work exploring the underlying mechanisms may reveal new strategies for targeting these GPCRs to treat AD and cognitive disorders.

Title: Involvement of mGluR I in EphB/ephrinB reverse signaling induced retinal ganglion cell apoptosis in a rat chronic ocular hypertension model

Authors: *Y. ZHAO¹, Q. LI², X.-Y. LI¹, F. GAO², P. CUI¹, X.-H. SUN³, Z. WANG³ ¹Inst. of Brain Sci., Shanghai City, China; ²Dept. of Ophthalmology at Eye & ENT Hosp., Shanghai City, China; ³Inst. of Brain Science, Dept. of Ophthalmology at Eye & ENT Hospital, State Key Lab. of Med. Neurobiology, Shanghai Key Lab. of Visual Impairment and Restoration, Collaborative Innovation Ctr. for Brain Science, Fudan Univ., Shanghai City, China

Abstract: Our previous study has demonstrated that EphB/ephrinB reverse signaling was activated in a chronic ocular hypertension (COH) rat model, which contributed to retinal ganglion cell (RGC) apoptosis by modulating GluA2 subunit of AMPA receptors. Here, we explored whether and how mGluR I is involved in RGC apoptosis by activated EphB/ephrinB reverse signaling in COH rats using whole-cell patch-clamp techniques in retinal slices. We found that the frequency of spontaneous firing of RGCs was increased in both EphB2-Fc intravitreally injected retinas and COH retinas, which was blocked by pre-injection of either the tyrosine kinase inhibitor PP2 or the selective mGluR1/mGluR5 antagonists LY367385/MPEP. Co-immunoprecipitation experiments showed an interaction between ephrinB2 and mGluR1 in both normal and EphB2-Fc-injected retinas. These results suggest that activation of EphB/ephrinB reverse signaling increased RGC excitability through affecting mGluR I in COH retinas. In addition, numerous TUNEL-positive signals were observed in the COH and the EphB2-Fc-injected retinas, which were significantly reduced by intravitreally pre-injecting LY367385 or MPEP. Together, our results suggest that activation of EphB/ephrinB reverse signaling increase RGC excitability and apoptosis through interacting with mGluR I in COH retinas, in addition to the GluA2-containing AMPA receptors.

Title: Tonic and phasic activation of GIRKs contribute to low dentate granule cell excitability

Authors: *J. GONZALEZ, S. A. EPPS, S. J. MARKWARDT, J. I. WADICHE, L. OVERSTREET-WADICHE

Neurobio., Univ. of Alabama At Birmingham, Birmingham, AL

Abstract: The dentate gyrus (DG) is a main entry point for neural activity into the hippocampal formation, integrating sensory and spatial information from the cortex in a manner that generates a neural representation ("engram") of a context. This role within the trisynaptic circuit requires that only a small fraction of the principal granule cells (GCs) are active at any given time. This sparse neural activity is enforced by powerful networks of inhibitory GABAergic interneurons in combination with low intrinsic excitability of GCs. Although the cellular and circuit properties that dictate synaptic inhibition are well studied, less is known about mechanisms that confer low GC intrinsic excitability. Using an electrophysiological approach here we demonstrate that intact G-protein mediated signaling is required to maintain the characteristic low resting membrane potential that differentiates dentate granule cells from CA1 pyramidal cells and immature adult born GCs. We show that intact G-protein signaling enables constitutive G-protein gated inwardly rectifying potassium channels (GIRK) activity, resulting in part from tonic GABA_B receptormediated stimulation of GIRKs. Perforant path electric stimulation evokes a phasic activation of GIRKs by synaptic GABA_B receptors on mature GCs, but adult born new GCs completely lack functional GIRK activity, with both tonic and phasic GABA_B-receptor mediated GIRK signaling developing only after 3-4 weeks of maturation. Using transgenic mice and optogenetic tools we show that GABA_B evoked phasic GIRK activation is interneuron specific, arising primarily from neuronal nitric oxide synthase (nNOS)-expressing interneurons rather than parvalbumin or somatostatin-expressing interneurons, and requires expression of GIRK2 subunits. Together these results demonstrate that G-protein mediated signaling robustly contributes to the low intrinsic excitability that differentiates mature and developing dentate GCs, and suggests that nNOS-expressing interneurons are principal gate-keepers of GABA_B-receptor synaptic inhibition.

Title: The unorthodox kynurenine metabolite, cinnabarinic acid, potently inhibits MK-801induced hyperactivity by interacting with mGlu4 metabotropic glutamate receptors

Authors: F. FAZIO¹, M. ULIVIERI², L. LIONETTO³, M. CURTO², G. MASCIO¹, A. TRAFICANTE¹, G. GIANNINO², V. BRUNO^{2,1}, *G. BATTAGLIA¹, M. SIMMACO⁴, F. NICOLETTI^{2,1} ¹I.R.C.C.S. Neuromed, Pozzilli, Italy; ²Univ. Sapienza, Roma, Italy; ³Advanced Mol. Diagnostic, IDI-IRCCS, Roma, Italy; ⁴S. Andrea Hospital, Univ. Sapienza, Roma, Italy

Abstract: The kynurenine pathway is the quantitatively main branch of L-tryptophan degradation in the mammalian body and gives rise to a plethora of metabolites, collectively known as "kynurenines". Some of these metabolites, such as kynurenic acid, quinolinic acid, xanthurenic acid and cinnabarinic acid interact with glutamate receptors thus influencing excitatory transmission in the central nervous system (CNS). Kynurenic acid, an antagonist of NMDA receptors at the glycine co-activation site, has been implicated in the pathophysiology of schizophrenia, and its levels are reduced in prefrontal cortex tissues and in the cerebrospinal fluid of schizophrenic patients. The higher levels of kynurenic acid in patients affected by schizophrenia are in line with the glutamatergic hypothesis of schizophrenia, which postulates that a reduced activity of NMDA receptors causes a hypofunction of GABAergic interneurons resulting into a hyperactivity of pyramidal neurons. Recently, metabotropic glutamate (mGlu) receptors have also been included in the glutamatergic theory, because drugs that activate mGlu2 and mGlu4 receptors show efficacy in experimental animal models of psychosis. Because cinnabarinic acid acts as an orthosteric agonist of mGlu4 receptors (Fazio et al., Mol. Phamacol., 2012), we decided to examine whether systemic administration of cinnabarinic acid could affect MK-801-induced hyperactivity in mice, which models positive symptoms of schizophrenia. We were surprised to find that very low systemic doses of cinnabarinic acid (0.125 mg/kg) were able to reduced MK-80-induced hyperactivity without affecting basal motor activity. Cinnabarinic acid was less potent and efficacious in mGlu4 receptor knockout mice, suggesting that, at least, part of the antipsychotic-like activity of the compound was mediated by the activation of mGlu4 receptors. These findings suggest that the expected reduction in cinnabarinic acid synthesis in schizophrenia (which might be a downstream consequence of the reduced kynurenine monooxygenase activity) might contribute to the pathophysiology of the disease, and raise the attracting possibility that cinnabarinic acid may display therapeutic activity against positive symptoms of schizophrenia.

Abstract: In all current models of L-DOPA-induced dyskinesias (LIDs), the occurrence of abnormal involuntary movements (AIMs) is accompanied by the activation of extracellular signal-regulated kinase 1 and 2 (ERK1/2) signaling in striatal neurons. This activation is a consequence of the supersensitivity of D1 receptor (D1R) signaling caused by dopamine (DA) denervation. Antagonists of mGlu5 metabotropic glutamate receptor ameliorate L-DOPA-induced dyskinesias, and blunt D1R agonist-induced ERK1/2 posphorylation (pERK1/2). In DA-denervated striatal slices, D1R-mediated pERK1/2 can be inhibited by antagonizing mGlu5 receptor or its downstream signaling mediator, phospholipase C (PLC) (Fieblinger et al., 2014). In the present study, we set out to (i) examine the effects of PLC inhibition *in vivo*, and to (ii) investigate its role in the DA-denervated striatum.

Rats sustained unilateral 6-OHDA lesions of the nigrostriatal DA pathway, followed by chronic treatment with the D1/D5 receptor agonist SKF38393 to induce AIMs. Dyskinetic rats receiving challenge injections of the PLC inhibitor U73122 (30 mg/kg) had significantly lower AIM scores compared to vehicle-treated animals. Moreover, in vivo administration of U73122 blunted SKF38393-induced striatal activation of ERK1/2. These results prompted the question whether the activation of D1R in the DA-denervated striatum could lead to PLC activation. To answer this question, we used an assay of PLC activity in striatal slices estimating the production of [³H]-inositolmonophosphate (InsP) following SKF38393 incubation. Compared to baseline conditions, D1R stimulation induced a significant increase in [³H]-InsP in the DA-denervated striatum, but not in the intact striatum. In addition, the coapplication of SKF38393 and the mGlu5 receptor agonist DHPG induced a marked increase in inositol phospholipid hydrolysis that was (i) higher than the levels obtained when either agonist was applied alone, and (ii)

specific to the DA-denervated striatum. In conclusion, these results are the first to indicate that the stimulation of D1R and mGlu5 receptor in the DA-denervated striatum converge on PLC activation. This signalling cascade is causally linked with the occurrence of dyskinesia.

Title: Metabotropic glutamate receptors 4 and 7 modulate thalamus - lateral amygdala synaptic transmission and plasticity

Authors: ***A. C. CIOBANU**¹, C. FLORES NAKANDAKARE², E. VAN DEN BURG², R. LUTJENS³, R. STOOP²

¹Ctr. de Neurosciences Psychiatriques, CHUV, Prilly, Switzerland; ²Ctr. de Neurosciences Psychiatriques, CHUV, Lausanne, Switzerland; ³Addex Therapeut., Geneva, Switzerland

Abstract: Thalamic nuclei project to the lateral amygdala (LA) and these connections are important for fear and anxiety. The group III metabotropic glutamate receptors 4 (mGluR4) and 7 (mGluR7) are expressed in the LA and they are involved in acquisition and extinction of fear. Here, we aimed to investigate the role of these receptors in thalamo-LA synaptic transmission and plasticity using two new specific compounds displaying anxiolytic effects in rodents: ADX88178 (positive allosteric modulator for mGluR4) and ADX71743 (negative allosteric modulator for mGluR7).

Whole-cell patch-clamp recordings were performed on pyramidal neurons in the LA to assess the roles of mGluR4 and mGluR7 on spontaneous activity, evoked thalamic synaptic transmission and long term potentiation (LTP). ADX88178 decreased and ADX71743 increased the frequency of spontaneous EPSCs. When thalamic inputs were electrically stimulated, ADX88178 decreased and ADX71743 increased the amplitude of the evoked responses. Moreover, both the positive allosteric modulator for mGluR4 and the negative allosteric modulator for mGluR7 decreased the LTP seen in the control group, at the thalamus to LA synapses.

Thus, mGluR4 and mGluR7 are functionally expressed in the LA and they control both spontaneous neuronal activity and synaptic transmission from the thalamus. Also, the two receptors have the potential to modulate long term synaptic plasticity which likely impacts learning in the lateral amygdala. This may explain the previously described anxiolytic effects of

ADX88178 and ADX71743 in systemically treated animals. The opposite effects of the compounds at cellular level, suggest that their activity is mediated by different neurons, likely part of parallel networks. Our data suggest a mechanism trough which mGluR4 and mGluR7 modulate pyramidal neurons in the LA with implications for fear and anxiety disorders.

Title: Activity-dependent mGluR7 ubiquitination regulates receptor stability and trafficking

Authors: S. LEE, H. LEE, J. SONG, *Y. SUH Dept. of Biomed. Sci., Seoul Natl. Univ. Col. of Med., Seoul, Korea, Republic of

Abstract: The metabotropic glutamate receptor 7 (mGluR7) is a predominant group III mGluR in the presynaptic active zone, where it regulates the excitatory neurotransmitter release via G-protein signaling cascade. Although it has been reported that many different GPCRs are regulated by post-translational ubiquitination that dynamically regulates protein turnover and trafficking, it remains elusive that mGluR7 undergoes ubiquitination in response to synaptic activity. In this study, using biochemical approaches coupled with confocal imaging, we have explored whether mGluR7 is a target of ubiquitination. We found that mGluR7 is ubiquitinated at the cytoplasmic loop 2 region and the C-terminal tail by the treatment of agonist in HEK 293T cells and primary cortical neurons. In addition, we found the ubiquitination of mGluR7 increases the endocytosis and degradation of mGluR7. Given the importance of the ubiquitin-proteasome system in neurodegenerative and neuropsychiatric disorders, mechanisms underlying mGluR7 ubiquitination will provide insights into the fundamental role of mGluR7 in neurological diseases as well as in physiological processes.

Title: Phosphorylation of $GABA_{B1}$ by CaMKII β triggers lysosomal degradation of $GABA_B$ receptors by regulating MIB2-mediated Lys63-linked ubiquitination

Authors: *K. BALAKRISHNAN¹, K. ZEMOURA^{1,2}, T. GRAMPP¹, D. BENKE¹ ¹Univ. of Zurich, Zurich, Switzerland; ²Picower Inst. for Learning and Memory, MIT, Cambridge, MA

Abstract: G protein-coupled GABA_B receptors consist of GABA_{B1} and GABA_{B2} subunits and control neuronal excitability by mediating slow and prolonged inhibitory neurotransmission. An important factor governing the signaling strength of GABA_B receptors is their availability at the plasma membrane, which is tightly regulated by lysosomal degradation of constitutively internalized receptors. Sorting the receptors to the lysosomal degradation pathway requires Lys63-linked ubiquitination of GABA_{B1} by the E3 ubiquitin ligase Mind bomb-2 (MIB2). How MIB2-mediated Lys63-linked ubiquitination of GABA_{B1} is regulated remained unknown. Here we show that Ca²⁺/calmodulin-dependent protein kinase II (CaMKII) promotes MIB2-mediated Lys63-linked ubiquitination of GABA_B receptors under physiological and pathological conditions. We observed an increased expression of cell surface GABA_B receptors after shortterm inhibition of CaMKII and decreased receptor levels upon overexpression of CaMKIIB, but not CaMKIIa. We found that CaMKII-dependent phosphorylation of GABA_{B1} at Ser-867 promoted the Lys63-linked ubiquitination of GABA_{B1} at multiple sites that was mediated by the E3 ligase MIB2. Mutational inactivation of the CaMKII phosphorylation site in GABA_{B1}(GABA_{B1}(S867A)) prevented the Lys63-linked ubiquitination of GABA_{B1} and increased the cell surface expression of GABA_B receptors. Conversely, the phospho-mimetic mutant GABA_{B1}(S867D) strongly increased Lys63-linked ubiquitination of GABA_{B1} and decreased cell surface receptor levels. Finally, sustained activation of glutamate receptors, a hallmark of cerebral ischemia that downregulates GABA_B receptors via lysosomal degradation, was accompanied with strongly increased GABA_{B1}(Ser-867) phosphorylation-dependent Lys63linked ubiquitination of GABA_B receptors. These findings indicate that CaMKIIB regulates Lys63-linked ubiquitination of GABA_{B1} and thereby controls sorting of internalized GABA_B receptors to lysosomal degradation. This mechanism regulates the amount of cell surface GABA_B receptors under physiological as well as pathological conditions.

Title: New advances in the knowledge of the 5HT2A / mGlu2/3 receptor-receptor functional cross talk in mammal central nervous system

Authors: A. PITTALUGA¹, G. OLIVERO¹, M. VERGASSOLA¹, T. BONFIGLIO¹, B. GARRONE², F. DI GIORGIO², S. TONGIANI², C. USAI³, *M. GRILLI¹, M. MARCHI¹ ¹Univ. of Genoa, Genova, Italy; ²Angelini S.p.A. R&D Res. Ctr., Roma, Italy; ³Natl. Rese Council, Genova, Italy

Abstract: Data in literature clearly demonstrated the existence of presynaptic-release-regulating mGlu2/3 autoreceptors in selected regions of central nervous system (CNS). Recent evidence showed that mGlu2/3 receptors can form intergroup dimers with co-localized mGluRs belonging to the third group as well as heteromeric complexes with non-glutamatergic metabotropic receptors, increasing the complexity of the scenario. It is the case of the 5HT_{2A} receptors. Studies to elucidate the 5HT_{2A}-mGlu2/3 interaction were carried out in the cortex, where they were mainly dedicated to describe the mGlu2/3-mediated control of serotonergic signalling. We recently provided evidence that spinal cord glutamatergic nerve endings are endowed with both presynaptic $5HT_{2A}$ heteroreceptors and mGlu2/3 autoreceptors, the activation of which inhibits glutamate exocytosis. The two receptors co-localize on the same terminals, where they functionally couple in an antagonist-like manner to control glutamate exocytosis. Actually, when concomitantly activated, the two receptors became unexpectedly inactive. This observation together with the findings that i) mGlu2/3 and 5HT_{2A} receptor immunoreactivities is largely colocalized and ii) mGlu2/3 immunoprecipitates from spinal cord synaptosomes are also 5HT_{2A} immunopositive seem best interpreted by assuming that, in spinal cord synaptosomes, the two receptors co-localize and functionally cross-talk in an antagonist-like manner. Consistently, exposure of synaptosomes to the 5HT_{2A} antagonists (MDL11939, MDL10007, ketanserin and trazodone) reinforced the release-regulating activity of mGlu2/3 autoreceptors, while antagonists acting at presynaptic release-regulating 5HT receptors other than the 5HT_{2A} ones (namely the

5HT1A, 1B and 1D receptors) were inactive. The gain of function of mGu2/3autoreceptors elicited by 5HT_{2A} antagonists was paralleled by an increased expression of mGlu2/3 receptor proteins in synaptosomal plasmamembranes. To the best of our knowledge, these findings provide the first demonstration of the existence of a presynaptic, heterodimeric control of glutamate exocytosis in spinal cord nerve endings involving mGLu2/3 and 5HT_{2A} receptors. On the basis of our observations, we propose that 5HT_{2A} antagonists could act as *"indirect positive allosteric modulator"* (*IPAM*) of mGlu2/3 receptors. Our results envisage a therapeutic alternative to the use of mGlu2/3 *direct* modulators for the cure of spinal diseases typified by hyperglutamatergicity.

Title: Murine genetic variance in muscarinic cholinergic receptor antagonism of sucrose and saccharin solution intakes in three inbred mouse strains

Authors: K. OLSSON¹, F. BOURIE¹, B. ISKHAKOV¹, A. BURAS¹, G. FAZILOV¹, M. SHENOUDA¹, J. ZHEZHERYA¹, *R. J. BODNAR² ¹Psychology, Queens College, CUNY, Flushing, NY; ²Psychology- Neuropsychology, Queens Col., Flushing, NY

Abstract: Solutions containing nutritive (sucrose) and non-nutritive (saccharin) sweeteners stimulate intake in inbred mouse strains. Marked genetic variance has been observed for sucrose and saccharin intake in pharmacological analyses of inbred mouse strains with BALB/c, SWR

and C57BL/6 mice differing in their response to dopamine (DA) and opioid receptor antagonism of different forms of sweet intake. Whereas DA D1 receptor antagonism (SCH23390) reduced sucrose (16%) intake in all three strains, opioid receptor antagonism (naltrexone) reduced sucrose intake maximally in C57/BL/6 mice, in intermediate fashion in BALB/c mice, but not in SWR mice. Saccharin (0.2%) intake was potently reduced by DA D1 receptor antagonism in all three strains, but was more potently reduced by opioid receptor antagonism in SWR and BALB/c relative to C57BL/6 mice. Scopolamine (SCOP), a muscarinic cholinergic receptor antagonist, reduced sweet intake and sugar-conditioned flavor preferences in outbred rats. The present study examined the systemic dose-dependent effects of SCOP (0.1-10 mg/kg) on saccharin and sucrose intakes over a 2 h time course in BALB/c, SWR and C57BL/6 mice. Sucrose intake was significantly reduced following all five doses across the entire time course in C57BL/6 mice, and following the 2.5, 5 and 10 mg/kg doses across the time course in BALB/c mice. In contrast, SWR mice displayed only transient (15 min) reductions in sucrose intake following the three higher SCOP doses. Saccharin intake was significantly reduced following all five doses across the entire time course in C57BL/6 mice, and following the 2.5, 5 and 10 mg/kg doses across the time course in BALB/c mice. In contrast, SWR mice displayed significant though smaller reductions in saccharin intake following the two higher SCOP doses. These data indicate that although both nutritive and non-nutritive sweet intakes are governed by muscarinic cholinergic receptor signaling, this process is subject to murine genetic variance with rank-order sensitivity observed in C57BL/6 > BALB/c > SWR inbred mouse strains.

Title: Murine genetic variance in muscarinic receptor antagonism of sucrose conditioned flavor preferences in three inbred mouse strains

Authors: *F. R. BOURIE¹, B. ISKHAKOV³, G. FAZILOV³, M. SHENOUDA³, J. ZHEZHERYA³, A. BURAS³, R. J. BODNAR² ²Psychology- Neuropsychology, ¹Queens Col., Flushing, NY; ³Psychology, Queens College, CUNY, Flushing, NY

Abstract: In addition to innate factors, learning modulates sugar intake by producing conditioned flavor preferences (CFP) in rodents. Genetic variance has been observed in the pharmacological substrates controlling the magnitude and persistence of sucrose-CFP; BALB/c and SWR mice exhibited stronger CFP responses than C57BL/6 mice. Systemic dopamine (DA) D1 and opioid, but not NMDA receptor antagonists attenuated the expression (maintenance) of an already-learned sucrose-CFP in BALB/c and SWR mice. DA D1 and NMDA receptor antagonism also impaired acquisition (learning) of sucrose-CFP in both strains, whereas opioid receptor antagonism impaired sucrose-CFP acquisition only in BALB/c mice, indicating dissociable genetic variance. Muscarinic (scopolamine: SCOP), but not nicotinic cholinergic receptor antagonism eliminated acquisition of sugar-CFP in rats. The present study examined whether SCOP blocked acquisition or expression of sucrose-CFP in BALB/c, C57BL/6 and SWR inbred mouse strains. In expression studies, food-restricted mice were trained in 10 onebottle-trials (1 h) to drink a sucrose (16%) solution mixed with one flavor (CS+, e.g., cherry) on odd-numbered days, and a less-preferred saccharin (0.05%) solution mixed with another flavor (CS-, e.g., grape) on even-numbered days. Two-bottle tests (CS+, CS-, 1 h) with the two flavors mixed in 0.2% saccharin were assessed over three subsequent pairs of tests in which the three strains received SCOP (0, 1, 5 mg/kg). Magnitude differences in sucrose-CFP were observed for BALB/c (77%), C57BL/6 (68%) and SWR (84%) mice. Whereas SCOP dose-dependently reduced expression of sucrose-CFP in BALB/c and C57BL/6 mice, it minimally altered expression of sucrose-CFP in SWR mice. In acquisition studies, separate groups of foodrestricted mice of the three strains received 10 one-bottle training trials (1 h) with CS+ and CSsolutions following vehicle, and SCOP at doses of 1, 2.5 and 5 mg/kg in daily treatment. Six 2bottle tests (CS+, CS-, 1 h) with the two flavors mixed in 0.2% saccharin were assessed over three subsequent pairs of tests without injections. SCOP dose-dependently reduced acquisition of sucrose-CFP in BALB/c mice with the highest dose producing indifference. SCOP's inhibitory effects on acquisition of sucrose-CFP were less pronounced in C57BL/6 and SWR strains. These data implicate muscarinic cholinergic receptor signaling in the maintenance of sucrose-CFP in BALB/c and C57BL/6, but not SWR mice, and in acquisition (learning) of sucrose-CFP in the three strains, but especially BALB/c mice, thereby indicating strong genetic variance in sweetdriven learning.

Title: Symbiotic bacteria underlie neurotoxin production and evolution of toxin resistance in voltage-gated sodium channels of rough-skinned newts (Taricha granulosa)

Authors: *P. VAELLI^{1,2,3}, K. R. THEIS^{4,3}, J. A. FOSTER^{5,3}, H. L. EISTHEN^{1,2,3} ¹Integrative Biol., Michigan State Univ., East Lansing, MI; ²Ecology, Evolutionary Biology, and Behavior Grad. Program, East Lansing, MI; ³BEACON Ctr. for the Study of Evolution in Action, East Lansing, MI; ⁴Dept. of Microbiology, Immunol. and Biochem., Wayne State Univ., Detroit, MI; ⁵Dept. of Biol., Univ. of Idaho, Moscow, ID

Abstract: Rough-skinned newts (Taricha granulosa) are poisonous salamanders that can possess high concentrations of tetrodotoxin (TTX), a potent neurotoxin that blocks voltage-gated sodium channel (VGSC) conductance in neurons and muscle cells. TTX is present in all species of the genus Taricha, but some populations of T. granulosa (hereafter "newts") possess extreme quantities not seen in any other TTX-bearing species, including puffer fishes, blue-ringed octopuses, and many diverse marine invertebrates. Geographic variation in TTX toxicity across different newt populations is thought to be driven by ecological interactions with predators. Despite the central role of TTX in the physiology and evolution of newts, the mechanisms of TTX production and neurophysiological resistance are unknown. Because of the polyphyletic distribution of TTX among animals, we explored the hypothesis that TTX is produced by symbiotic skin bacteria in newts. We conducted 16S rRNA gene-based sequencing surveys to characterize skin-associated bacterial communities of newts from toxic and non-toxic populations. From here, we employed ecologically-guided cultivation strategies to target skinassociated symbionts and produce pure cultures. We screened cultures for TTX production using a customized HILIC-MS/MS method and confirmed TTX production in multiple isolated bacterial strains. Furthermore, we investigated the molecular adaptations underlying apparent TTX resistance in the VGSCs of newts. We cloned and sequenced the TTX binding site, the S5-S6 pore loop regions, of all six VGSC genes present in this species and compared sequences from toxic and non-toxic populations, as well as from other vertebrates. As a result, we identified several mutations present in the S5-S6 pore loops of all six genes, indicating a remarkable parallel evolution of TTX resistance across the VGSC gene family. Taken together, our results indicate that TTX is derived from the skin microbiome in the extremely toxic rough-skinned newt and that multiple adaptations in VGSCs were required for the newt nervous system to adapt to TTX toxicity. Overall, this research contributes to a growing understanding that symbiotic microbes can affect the physiology of nervous systems, and that evolution by natural selection may target genetic variation across both host and symbiont genomes, collectively termed the 'hologenome'.

Title: Role of CaMKIIy in Associative Conditioning and GLR-1 expression in C. elegans

Authors: *A. H. BLACK¹, S. LIN², M. R. PRIBIC³, N. D. JOHNSON², A. R. LOFTUS², L. K. ALFILER², J. K. ROSE² ²Behavioral Neurosci. Program, ³Biol., ¹Western Washington Univ., Bellingham, WA

Abstract: Recent work has shown that the calcium/calmodulin-kinase II (CaMKII) y-isoform plays a role in neuronal mechanisms associated with learning and memory. In C. elegans, the unc-43 gene codes for an ortholog of CaMKII and previous studies report that UNC-43 regulates glutamate receptor expression (specifically GLR-1) in neurons. The current study examined the *unc-43*(gk452) strain (ortholog to CaMKII_{γ}) in associative conditioning and glutamate receptor expression to begin to elucidate the role of this particular isoform in learning. A previous report indicates *unc-43*(gk452) worms show a memory deficit for an associative appetitive chemotaxis assay. Research from our lab has shown unc-43(gk452) worms exhibit a learning deficit for an associative avoidance chemotaxis assay; a procedure that requires prolonged stimulus pairing (>1 hour). An associative conditioning assay whereby increased responsiveness to a discrete stimulus following brief paired presentations with another stimulus has been shown in C. elegans. Our lab has reported that pairing delivery of two distinct stimuli (blue light ~480 nm and a mild mechanosensory vibration; Vib) results in increased responsiveness to either the blue light or Vib stimulus alone. The unc-43(gk452) strain was also found to show a deficit in this light-vibration associative conditioning. The effects of the unc-43(gk452) mutation on glr-1 expression levels were examined with qRT-PCR following light-vibration associative conditioning and in vivo GLR-1::GFP expression patterns were assessed. By observing both behavior and receptor expression in intact animals, these results begin to elucidate the role of this unique CaMKII isoform in associative forms of learning and memory.

Title: Calcium regulation of voltage-gated sodium channels in serotonergic raphe neurons

Authors: *M. A. NAVARRO, M. MILESCU, L. S. MILESCU Biol. Sci., Univ. of Missouri, Columbia, MO

Abstract: We have previously shown that voltage-gated sodium (Nav) channels in spontaneously firing medullary raphé neurons inactivate with a slow component. This long term inactivation (LTI) modulates neuronal firing and is potentially due to an interaction with fibroblast growth factor - homologous factors (FHF). There is some evidence that the Nav-FHF interaction may also include calmodulin, and thus it may depend on $[Ca^{2+}]$. Here, we test whether intracellular calcium concentration has any effect on LTI in these neurons. We used whole-cell patch-clamp to record Na⁺ currents in neonatal (P0-P3) rat brainstem slices, under two $[Ca^{2+}]_i$: 60 nM and 6 μ M. Under voltage-clamp, we found that the Nav steady-state activation and inactivation curves did not shift significantly with $[Ca^{2+}]_i$. However, the kinetics of recovery from inactivation to perturb the Nav-FHF interaction, and observed a change in the recovery from inactivation, but only at low $[Ca^{2+}]_i$. Under current clamp, neurons loaded with high $[Ca^{2+}]_i$ fired action potentials with greater amplitude and lower threshold than neurons with low $[Ca^{2+}]_i$.

Title: NaV subtypes in itch versus pain C-fibers in mouse skin

Authors: D. JURCAKOVA, M. KOLLARIK, F. RU, *B. J. UNDEM Dept Med., Johns Hopkins Asthma Ctr., Baltimore, MD

Abstract: Sodium channels represent a promising drug target to relieve pain and itch. We have evaluated the sodium channel subtypes in C-fibers in the skin using a unique, recently developed innervated isolated dorsal skin preparation in which action potential discharge in single afferent C-fibers (CV <1 m/s) nerve terminating in the skin is evaluated with extracellular electrode positioned in the dorsal root ganglia. The dissected section of skin also includes the main arterial supply through which chemical stimuli is delivered directly to the receptive field (see J. Physiol, 2017). We have evaluated the pharmacology of the NaVs most responsible for action potential discharge in three C-fiber subtypes that innervate the skin, namely itch fibers (chloroquine (CQ) and capsaicin sensitive, high mechanical thresholds), pain fibers (CQ-insensitive, capsaicinsensitive, high mechanical thresholds); and low threshold mechanosensitive C-fibers (LTMCs) (CQ and capsaicin-insensitive, very low mechanical thresholds).We evaluated the effect of NaV blocking drugs added directly to the receptive field on AP discharge in response to mechanical stimulation. In 100% of the pain fibers (n=65) and 100% of the LTMCs (n= 8) blocking TTXsensitive NaVs abolished AP discharge. In contrast, 20% of itch fibers still responded normally when TTX-sensitive channels were blocked (n=19). In these fibers adding a NaV1.8 blocker (A803467) abolished the responses. We evaluated two selective NaV1.7 blockers (PF05089771 and Cmpd 13), the results were similar so we pooled the data. Blocking NaV 1.7 abolished AP discharge in 63% of pain C-fibers, 40% of itch C-fibers, but only 20% of LTCMs. The selective NaV1.1, 1.2, 1.3 blocker ICA121431 alone did not inhibit responses in any of the three C-fiber phenotypes. In the presence of NaV1.7 blockade ICA abolished the response in 3 of 7 pain fibers and 2 of 2 LTCMs, but had no effect on itch fibers (0/4). Using single cell RT-PCR we evaluated the expression in individual pain (MRGPRA3-negative, TRPV1-positive) vs itch fiber neurons (MRGPRA3 and TRPV1 positive) retrogradely labeled from the region of the dorsal skin that corresponded to our functional studies. The % of pain neurons that expressed NaV 1.1, 1.2,1.3. 1.6. 1.7, 1.8, and 1.9 was 15%, 5%, 5%, 29%, 86%, 95% and 100% (n=21), respectively. In the itch fibers the corresponding % of each NaV was 0%, 0% 8%, 8%, 85%, 100%, 100% (n=13). We conclude that NaV1.7 blockers can inhibit about 40-60% of pain and itch fibers in mouse skin, but is less effective in inhibiting LTCMs. Those C- fibers that respond in the presence of NaV1.7 blockade it is likely due to the activity of 1.8 in itch fibers, 1.6, 1.1 in pain fibers.

Title: The scaffold protein Magi-1 regulates voltage-dependent sodium channels in dorsal rott ganglion neurons

Authors: *K. D. PRYCE¹, R. POWELL², A. BHATTACHARJEE¹

¹Pharmacol., State Univ. of New York At Buffalo, Buffalo, NY; ²Pharmacol. and Toxicology, SUNY at Buffalo, Buffalo, NY

Abstract: The voltage-gated sodium channel Nav1.8 is preferentially expressed in small- and medium- sized DRG neurons specialized for the detection of noxious stimuli. The underlying molecular machinery responsible for the trafficking and membrane expression of Nav1.8 in dorsal root ganglion (DRG) remains to be fully elucidated. In this study, we have identified the Membrane-associated Guanylate Kinase with Inverted Orientation -1 (Magi-1), a widely expressed multi-PDZ (PSD-95/Dlg-A/ZO-1) and WW domain containing protein as a channel partner that binds directly to NaV 1.8 and plays an essential role in the functional expression of Nav1.8. Here, we used immunohistochemistry, electrophysiology, and membrane biotinylation assays to characterize the physiological significance of the Magi-1/Nav1.8 interaction in DRG neurons. We find that like Nav1.8, Magi-1 was preferentially expressed in small- and mediumsized DRG neurons. We used small interfering RNAs to knockdown Magi-1 in DRG neuronal cultures and observed a profound decrease in the ability for DRG neurons to fire action potentials and a concomitant decrease in the total sodium current as compared to a negative control siRNA. To further elucidate the contribution of Nav1.8 after Magi-1 knockdown, we use tetrodotoxin (TTX) to block all TTX-sensitive sodium currents and verified that Magi-1 knockdown caused a significant and substantial decrease in both TTX-sensitive and TTXresistant sodium currents. To further determine how Magi-1 regulates Nav1.8, we conducted membrane biotinylation assays and demonstrated that after Magi-1 knockdown there was a 50% reduction in the surface expression of Nav1.8. Heterologous expression of Nav1.8 is notoriously difficult requiring accessory proteins, however, co-expression of Nav1.8 with Magi-1 lead to observable currents in heterologous cells. These findings demonstrate that Magi-1 controls the membrane expression of Nav1.8 in DRG neurons and that a downregulation of Magi-1 results in neuronal hypo-excitability. These data suggest that Magi-1 plays a central role in the functional expression of Nav1.8 and that Magi-1 is essential in regulating neuronal excitability through their interaction with sodium channels.

Title: Dual action of CBZ as a blocker and modulator of activation of mutant $Na_v 1.7$ channels that cause inherited erythromelalgia

Authors: *T. ADI^{1,2}, M. ESTACION^{1,2}, Y. YANG^{1,2}, S. D. DIB-HAJJ^{1,2}, S. G. WAXMAN^{1,2} ¹Dept. of Neurol., Yale Univ. Sch. of Med., New Haven, CT; ²Ctr. for Neurosci. and Regeneration Research, Rehabil. Res. Ctr., VA Connecticut Healthcare Syst., West Haven, CT

Abstract: Inherited erythromelalgia (IEM), a severe pain disorder characterized by intense burning pain and redness of the extremities, is caused by gain-of-function dominant mutations to voltage-gated sodium channel Na_v1.7. In the past, pharmacotherapy for IEM has generally been reported to be ineffective. We have previously shown that carbamazepine (CBZ) is effective for two IEM mutants (S241T and V400M) *in vitro* as well as *in vivo*. In principle, CBZ might act via either of two mechanisms: 1) the classical mechanism of use-dependent block, and/or 2) by correcting hyperpolarized shifts in activation, returning activation voltage-dependence towards more wild-type Na_v1.7 values. We have shown that CBZ restores wild-type-like activation in the S241T and V400M Na_v1.7 IEM mutations.

Here we report another IEM mutant, Nav1.7-I234T (I234T), that responds to CBZ pretreatment with a depolarization of activation. As with V400M and S241T, CBZ normalizes the hyperpolarized voltage-dependence of activation and reduces hyperexcitability of DRG neurons expressing I234T. Use-dependent current reduction of I234T is not enhanced by CBZ, suggesting that the classical mechanism of use-dependent block is not a large contributing factor to this reduction in firing. We then implemented a moderate throughput automated patch-clamp system (Nanion Patchliner) to perform voltage-clamp on HEK293 cell lines. We successfully recapitulated the CBZ effect on activation of the S241T and V400M mutant channels as observed using manual patch-clamp, and went on to investigate the effects of additional drugs (CBZ derivatives oxcarbazepine and licarbazepine, and other local anesthetic and antiepileptic drugs). A principal concern was to utilize clinically relevant concentrations of clinically-used drugs equivalent to achievable therapeutic ranges *in vivo*. We assessed drug effects on multiple modes of channel gating (activation, fast-inactivation, and slow-inactivation) as well as effects on use-dependent block and dose-response, thereby providing a more detailed insight into both mechanism of drug action as well as inherent biophysical properties of the mutants. We predict

that this *in vitro* pharmacology approach may mitigate the trial-and-error treatment of IEM patients and promote a more personalized approach to pain pharmacotherapy.

Abstract: Sodium channel Nav1.9 is preferentially expressed in peripheral nociceptive somatosensory neurons and visceral afferents, and myenteric neurons. Gain-of-function mutations of Nav1.9 have been linked to human painful disorders, including painful peripheral neuropathy and familial episodic pain, and painless channelopathies. Identification and functional assessment of new Nav1.9 mutations will help to elucidate the phenotypic spectrum of Nav1.9 channelopathies. Here we report a novel Nav1.9 mutation, isoleucine 807 substitution by valine (I807V) in the domain II S6 segment, which was identified from two 59 year old unrelated patients. Both patients displayed painful symptoms including tingling in their hands and feet. One patient experienced dysautonomic symptoms including hyperhidrosis, palpitations, diarrhea and constipation. They both were diagnosed with small fiber neuropathy based on their clinical

symptoms and abnormal quantitative sensory testing results. Our initial attempts to characterize this mutation after incubation of transfected neurons at 37°C were hampered because of the small amplitude of the Nav1.9 current. The mutant channel current was rescued by incubating transfected neurons at 30°C. Voltage-clamp analysis shows a 5.3 mV hyperpolarizing shift of activation albeit with a reduced current density compared with wild-type channels. There was no effect on channel steady-state fast inactivation. The hyperpolarized activation combined with unaffected fast inactivation indicate an increased window current within the physiological voltage domain close to the resting membrane potential of neurons. Since Nav1.9 channel plays an important role in regulating resting potential and prolonging the depolarizing response to subthreshold stimuli, the increased window current predicts that the expression of Nav1.9 mutant channels would render DRG neurons hyperexctiable, consistent with pain symptoms observed from the two patients carrying this Nav1.9-I807V mutation. The fact that lowering temperature rescues the current amplitude suggests that this mutant channel may play a more important role in peripheral terminals, close to a skin temperature of 32-33°C, rather than at the soma or central terminals which are exposed to a physiological temperature of 37°C.

Title: From Nav1.7 to Nav1.8: A case for precision medicine

Authors: *C. HAN^{1,2,3}, A. THEMISTOCLEOUS⁴, L. MACALA^{1,2,3}, I. BLESNEAC⁴, C. FRATTER⁵, D. L. BENNETT⁴, S. D. DIB-HAJJ^{1,2,3}, S. G. WAXMAN^{1,2,3} ¹Dept. of Neurology, Yale Uni. Sch. of Med., New Haven, CT; ²Ctr. for Neurosci. & Regeneration Research, Yale Univ. Sch. of Med., New Haven, CT; ³Rehabil. Res. Center, VA Connecticut Healthcare Syst., West Haven, CT; ⁴Nuffield Dept. of Clin. Neurosci., Oxford, United Kingdom; ⁵Oxford Med. Genet. Laboratories, Oxford Univ. Hosp. NHS Fndn. Trust, Oxford, United Kingdom
Abstract: Voltage-gated sodium channel Nav1.7 and Nav1.8 are preferentially expressed in peripheral sensory neurons and are important contributors to pain signaling. Gain-of-function mutations in Nav1.7 and Nav1.8 have also been identified in patients with painful peripheral neuropathies. Using atomic structure modeling, mutant cycle analysis and pharmacological testing, we predicted the responsiveness of the Nav1.7 mutation S241T mutation to carbamazepine (CBZ), based on a similar behavior of a "seed" mutation V400M that was known to confirm responsiveness to CBZ. With pre-treatment of cells expressing either the S241T or the V400M with clinically-relevant concentrations of CBZ (30 uM), the mutation-induced hyperpolarizing shift of activation of Nav1.7 channels was corrected. Based on these in vitro data, a double-blind placebo-controlled clinical trial on two patients carrying the S241T mutation demonstrated clinical efficacy of CBZ treatment. Here we present a study on a novel Nav1.8 mutation which suggests that this precision medicine approach can be extended to another channel. A 67-year old male patient with type 2 diabetes and neuropathic pain showed a total loss of intra epidermal nerve fiber density in a skin biopsy (0.0 fibers/mm), and profoundly and bilaterally reduced thermal and mechanical thresholds in QST testing. Genetic analysis identified a missense mutation in Nav1.8, S242T, which corresponds to the Nav1.7-S241T mutation. Voltage-clamp analysis of Nav1.8-S242T mutation demonstrated a hyperpolarized and accelerated activation, slowed deactivation as well as enhanced slow-inactivation, gain-offunction features that are shared with the Nav1.7-S241T channels. However, unlike the Nav1.7-S241T mutation, Nav1.8-S242T channels show enhanced fast-inactivation. Current-clamp analysis showed that like the Nav1.7-S241T mutation, Nav1.8-S242T mutant channels render DRG neurons hyperexcitable, manifested as reduced current threshold, hyperpolarized voltage threshold and increased evoked firing. The increased excitability of DRG neurons is consistent with pain symptoms reported by the patient carrying this Nav1.8-S242T mutation. Based on the location of this mutation, we hypothesized that Nav1.8-S242T channels should respond to preincubation with CBZ. Voltage-clamp recordings confirmed that 30 µM carbamazepine depolarizes activation of Nav1.8-S242T, similar to the CBZ effect on the Nav1.7-S241T mutant channels. Our data show that the DI/S4-S5 linker plays an important role in the gating of Nav1.8, and suggest that treatment of patients carrying this mutation may be effective to treat pain.

Unit, IRCCS Fndn., Milan, Italy; ⁵Dept of Clin. Genomics, Univ. Med. Ctr. Maastricht, Maastricht, Netherlands; ⁶Neurol., Spaarne Hosp., Hoofddorp, Netherlands

Abstract: Small nerve fiber neuropathy (SFN) often occurs without identifiable causes, but recent targeted genetic studies have been performed in patients with idiopathic SFN (I-SFN). We sought to identify a genetic basis for I-SFN by screening patients with idiopathic SFN for novel mutations in the sodium channel genes which are preferentially and abundantly expressed in peripheral axons.

A patient referred with possible I-SFN who met criteria of ≥ 2 SFN-related symptoms, normal strength, tendon reflexes, vibration sense and nerve conduction studies, and reduced intraepidermal nerve-fiber density (IENFD) plus abnormal quantitative sensory testing (QST) and no underlying etiology for SFN, was assessed clinically, and screened for mutations in SCN9A, SCN10A, SCN11A but no mutations were found in those genes. Further analysis of sodium channel beta subunit genes revealed a mutation upon which we have performed functional analyses. Functional analysis using current-clamp revealed that heterologous expression of the mutant beta2 subunit rendered dorsal root ganglion neurons hyperexcitable compared wild-type beta2 subunit.

Sodium channel beta subunits have been reported to modulate the properties of voltage-gated sodium channels in a number of ways. Beta subunits can act to increase current density, alter inactivation kinetics, and modulate subcellular localization. In our recordings from small DRG neurons transfected with either WT or mutant beta2 subunits, an increase of stimulated excitability to expression of the mutant beta2 subunit suggests that the mutant beta2 subunit has altered regulation of one or more voltage-gated sodium channels. Since the difference in firing was largest at the stronger current injections that cause higher firing rates, we evaluated the relative fractions of fast (TTX-sensitive) vs the kinetically slower (TTX-resistant) sodium currents. In addition, we compared whether cumulative inactivation of either component was altered by the presence of the mutant bata2 subunit. Results of this analysis will be presented.

Title: Atypical changes in DRG neuron excitability and complex pain phenotype associated with a Nav1.7 mutation that massively hyperpolarizes activation

Authors: ***J. HUANG**¹, B. TANAKA¹, M. ESTACION¹, S. LIU¹, S. M. WALKER², S. D. DIB-HAJJ¹, S. G. WAXMAN¹

Abstract: Sodium channel Na_v1.7 is known to play a central role in human pain signaling, with dominant gain-of-function mutations causing severe pain syndromes including inherited erythromelagia (IEM) and recessive loss-of-function mutations of Na_v1.7 producing congenital insensitivity to pain. IEM is caused by mutations of Na_v1.7 that hyperpolarize activation, with most of them shifting activation of by 5-12 mV. When expressed within dorsal root ganglion (DRG) neurons, these mutant channels depolarize resting membrane potential (RMP) by 4-6 mV and produce DRG neuron hyperexcitability that underlies a relatively stereotyped clinical phenotype of severe distal limb pain triggered by mild warmth. The I234T Na_v1.7 mutation hyperpolarizes activation by 18 mV and is associated with a more complex clinical phenotype that can include IEM-like distal pain, proximal pain, corneal anesthesia, and absence of pain in response to some injuries. How a mutation that produces a gain-of-function in Na_v1.7 causes loss of pain sensibility has remained enigmatic. Here we document additional painless injuries (painless fractures, painless venipuncture and injections) associated with the I234T mutation, and elucidate a possible mechanism by which expression of I234T mutant channels result in loss of excitability in a subpopulation of DRG neurons.

Title: Myosins interact with voltage gated sodium channels, sodium calcium exchangers and sodium potassium ATPases

Authors: *B. DASH, C. HAN, E. J. AKIN, S. DIB-HAJJ, S. G. WAXMAN Neurol., Yale Univ. Dept. of Neurol., West Haven, CT

Abstract: The distinct electrical properties of axonal and dendritic membranes, and the ionic properties of other cellular membranes are largely a result of the ionic balance maintained by a multitude of transmembrane (TM) proteins such as ion channels (e.g., voltage gated sodium channels/Na_v), ion exchangers (e.g., sodium calcium exchangers/NCX), ion pumps (sodium potassium ATPase/NKA); etc. The synthesis, transport, sorting to different cellular compartments, and insertion of these TM proteins into neuronal or other cellular membranes is highly regulated. The mechanisms by which these TM proteins reach their destinations are not well understood. We hypothesized that the actin based motor proteins, myosins known to transport various cellular cargoes, might play an important role in the trafficking of Nav, NCX, and NKA to the cellular membranes. To this end we used co-immunoprecipitation (Co-IP) and western blot (WB) assays, patch clamp electrophysiological recording and total internal reflection fluorescence (TIRF) microscopy using multiple substrates such as young or adult animal (mouse or rat) brain samples, rat dorsal root ganglion (DRG) or hippocampal neurons, ND7/23 cells and/or transiently or stably transfected HEK cells. Our results indicate that one or more isoforms of the class II non-muscle myosins such as myosin heavy chain 9 (myh9), myosin heavy chain 10 (myh10) or myosin heavy chain 14 (myh14) interact with Nav, NCX2 and NKA al. Additionally, we found that other myosins such as Myo5a, Myo6 or Myo19 also interact with NKA a1. Voltage clamp recordings from transfected ND7/23 cells show that myh10 regulates current density and gating properties of Nav1.8. Overexpression of myh10 in rat DRGs also led to broadening of action potentials. Based on these findings we hypothesize that these novel interactions of myosins with TM proteins (Na_v, NCX2 and NKA α 1) may play an important role in maintaining cellular sodium, calcium and/or potassium homeostasis which might be exploited for developing therapeutics for pain or other neuronal or non-neuronal diseases.

Title: Targeting pain pathways by inhibition of voltage-gated sodium channels

Authors: *J. L. COSTANTIN¹, A. OBERGRUSSBERGER², S. STÖLZLE-FEIX², N. BECKER², C. HAARMANN², M. RAPEDIUS², T. GOETZE², I. RINKE-WEIß², E. DRAGICEVIC², C. BOT¹, R. HAEDO¹, M. GEORGE², A. BRÜGGEMANN², N. FERTIG² ¹Nanion Technologies, Livingston, NJ; ²Nanion Technologies, Munich, Germany

Abstract: Chronic and neuropathic pain is a significant health problem affecting millions of people worldwide each year, with 1 in 5 individuals experiencing moderate to severe chronic or persistent pain. Neuropathic pain serves no protective or healing purpose and appears to arise due to an increase in intrinsic nerve excitability. Voltage-gated Na channels (NaV) are attractive targets for the treatment of these conditions due to their physiological role in action potential generation and propagation and, thus, neuronal excitability. Most of the clinically available pain therapeutics targeting NaV channels are rather non-selective and are associated with cardiotoxic and CNS side effects. Nav1.7 is found primarily in the peripheral nervous system and is thought to play a role in nociception and pain sensing. Recently, venom isolated from different species including spider and centipede have been shown to selectively block Nav1.7 and are powerful analgesics in animal models of pain. Similarly, mutations in the SCN9A gene have been shown to result in loss of function of the Nav1.7 channel in patients with congenital indifference to pain (CIP). The Nav1.8 gene (originally named PN3 or SNS; gene symbol SCN10A) encodes a NaV channel, and is selectively expressed in dorsal root ganglion (DRG) neurons. In contrast to the fast and rapidly inactivating TTX-sensitive channels, Nav1.8 is TTX-resistant, with slower kinetics, and a depolarized voltage-dependence of activation and inactivation. We present data of Nav1.7 and Nav1.8 on a novel high throughput screening patch clamp platform. Nav1.7 was expressed in CHO cells and the current voltage relationship recorded was consistent with Nav1.7 obtained using other methods. Vhalf of activation was -24 mV (n = 275). Using a double step voltage protocol we were able to investigate whether compounds, such as tetracaine, exhibit state dependence. We show that tetracaine exhibited a lower IC₅₀ on the second pulse, i.e. the inactivated state of the receptor, compared with the resting state. Nav1.8 expressed in CHO cells started to activate at approximately -40 mV, peaking at between 10 mV and 20 mV with a Vhalf of activation of -2.7 mV (n = 380). In order to study NaV channels involved in pain pathways in a more physiological environment, we used stem cell-derived neurons, more specifically with an overexpression of Nav1.8. In these cells, endogenous NaV-mediated currents were recorded with activation parameters consistent with Nav1.7 (i.e. blocked by TTX in the nM range). Moreover,

information about the role of NaV channels in neuronal signalling in intact neuronal networks was gleaned using microelectrode array (MEA) technology.

Title: A small molecule activator of $Na_v 1.1$ channels increases fast-spiking interneuron excitability and GABAergic transmission *In vitro* and has an anti-convulsive effect *In vivo*

Authors: *C. HOUGAARD¹, K. FREDERIKSEN², D. LU³, J. YANG³, H. S. JENSEN², J. F. BASTLUND², C. YANG³, M. GRUNNET² ¹Synaptic Transmission In Vitro, ²H Lundbeck A/S, Valby, Denmark; ³Shanghai ChemPartner Co, Shanghai, China

Abstract: Fast-spiking parvalbumin-positive GABAergic interneurons mediate the fast rhythmic synaptic inhibition of pyramidal cells associated with gamma oscillations - a mechanism for neuronal processing of information related to memory and cognitive performance. Inappropriate function of fast-spiking interneurons is associated to decreased cognitive capabilities. Nav1.1 (SCN1A) channels, located in GABAergic fast-spiking interneurons are pivotal for action potential generation and propagation in these neurons. Impaired Nav1.1 channel function is linked to various diseases in the central nervous system, including seizure disorders, autistic behavior and intellectual disability.In the present study we have identified a small molecule activator of Nav1.1 channels (3-Amino-5-(4-methoxyphenyl)thiophene-2-carboxamide, AA43279). In whole-cell voltage-clamp recordings using HEK-293 cells expressing human

Na_v1.1 channels, AA43279 induced a concentration-dependent increase in the Na_v1.1 current mainly by impairing the fast inactivation kinetics of the channels. In hippocampal brain slices from Sprague Dawley rats, AA43279 augmented action potential firing recorded from fast-spiking interneurons and increased the frequency of spontaneous inhibitory post-synaptic currents (sIPSCs) recorded in pyramidal neurons. On the other hand, AA43279 had no effect on action potential firing in pyramidal neurons. When tested *in vivo*, AA43279 had anti-convulsive properties in the maximal electroshock seizure threshold test. AA43279 was tested for off-target effects on 72 different proteins, including other Na_v1.X channels and exhibited reasonable selectivity towards Na_v1.1 channels.Taken together, AA43279 could constitute a valuable tool for revealing physiological and pathophysiological functions of Na_v1.1 channels.

Title: Hyperexcitability of GABAergic neurons triggers cortical spreading depression: New mechanism of migraine?

Authors: O. CHEVER¹, S. ZERIMECH¹, M. AYRAULT¹, F. DUPRAT¹, *M. A. MANTEGAZZA^{2,1} ¹CNRS, Inst. of Mol. and Cell. Pharmacol., Valbonne, France; ²Inst. of Mol. and Cell. Pharmacol., Valbonne, France

Abstract: Migraine is a common episodic brain disorder; 30% of patients have transient neurological disturbances before the headache, called aura. A mendelian form of migraine with aura, Familial Hemiplegic Migraine (FHM), has allowed to disclose some molecular/cellular pathological mechanisms. In FHM1 and 2 (Ca_V2.1 Ca²⁺ channel and Na⁺K⁺ATPase mutations, respectively), different dysfunctions lead to excessive glutamatergic transmission that facilitates CSD. FHM3 is caused by mutations of Na_V1.1 (*SCN1A*) Na⁺ channel, which is particularly important for GABAergic neurons' excitability. Epileptogenic loss-of-function Na_V1.1 mutations lead to hypoexcitability of GABAergic neurons, reduced inhibition and network hyperexcitability. Conversely, we have shown that FHM3 mutations can cause Na_V1.1 gain-of-

function and GABAergic neurons' hyperexcitability in transfected cells, suggesting a novel migraine mechanism. However, it is not clear how this could lead to CSD/migraine and there is no causal link yet between GABAergic neurons' hyperexcitability and CSD.

We addressed this issue performing selective optogenetic stimulation of GABAergic neurons in cre/lox mice and studying the neurophysiological correlate of aura: cortical spreading depression (CSD): a wave of transient intense neuronal firing followed by a long lasting depolarization that could lead to headache. We found that increased activity of GABAergic neurons can by itself trigger CSD. The use of selective pharmacological blockers showed that activation of GABAergic or glutamatergic ionotropic receptors is not necessary for CSD initiation, whereas efflux of K⁺ ions caused by interneurons' firing can induce $[K^+]_{out}$ build-up, leading to initiation of CSD. Notably, the optogenetic stimulation of GABAergic neurons was able to ignite CSD also in vivo.

Thus, we have provided a causal relationship between initial hyperactivity of GABAergic neurons, progressive increase of $[K^+]_{out}$ at the site of CSD initiation, and CSD ignition. Neuronal firing-induced K^+ build-up is the key factor for CSD ignition in this optogenetic model of FHM-3, differently than in models of FHM-1/-2. This is a novel mechanism that may be at play in FHM-3 and possibly also in other types of migraine.

Title: Akt regulates neuronal excitability by modulating Nav1.6 sodium channel

Authors: *M. N. NENOV¹, W. C. HSU¹, M. A. ALSHAMMARI^{1,2}, O. FOLORUNSO¹, N. I. PANOVA¹, F. LAEZZA¹

Abstract: Protein kinase B, also known as Akt, is a serine/threonine kinase that receives converging signals from multiple transmembrane receptors. Activation of Akt is critical in providing protection against neuronal hyperexcitability and synaptic dysfunction. Yet, the molecular mechanisms underlying this pathway are still poorly understood. Phosphorylation plays an essential role in regulating function of voltage-gated sodium (Nav) channels with profound effects on intrinsic excitability and activity-dependent plasticity. Here, we hypothesized that some of the known modulatory effects of Akt on excitability could arise from direct regulation of the Nav1.6 channel isoform that is enriched at the axonal initial segment (AIS) and mediates repetitive firing in neurons throughout the cortico-limbic circuit. To test this hypothesis, we determined the effect of triciribine, a pan Akt inhibitor, on Na⁺ currents in HEK293 cells stably expressing the Nav1.6 channel isoform using whole-cell patch-clamp. We found that 1 hour exposure to triciribine significantly potentiates Nav1.6 peak current density (at voltage step of -10 mV was -47.8±9.4 pA/pF in control, n=11 versus -99.4±14.6 pA/pF in triciribine group, n=11; p<0.01 with Student *t*-test) with no changes in voltage-dependence of activation and steady-state inactivation. To provide correlative evidence for this effect, we performed patch-clamp recordings in hippocampal slices and found that triciribine increases repetitive firing of CA1 pyramidal neurons (number of spikes was 15.1±3.3 in control, n=10 versus 22.9 \pm 2.4 in the triciribine group, n=10; p<0.05 with Mann-Whitney test), and decreased action potential current threshold (124±17.1 pA in control, n=10 versus 75±13.4 in triciribine group, n=10; p<0.05 with Student *t*-test). To determine whether inhibition of Akt resulted in changes in Nav1.6 expression and pattern distribution that might explain increase in excitability, we studied the effect of triciribine on Nav1.6 expression level at the AIS in primary hippocampal cultures. Akt inhibition over a prolonged period of time (12 hour) resulted in upregulation of Nav1.6 channel expression at the AIS (ratio of Nav1.6 to PanNav was 0.5±0.2 in control, n=12 versus 1.1±0.2, n=13 in triciribine group; p<0.05 with Student *t*-test) along with a shift in Nav immunoreactivity toward the distal, more excitable segment of the AIS (4.1±0.5 µm in control, n=15 versus 5.8±0.5 µm in triciribine group, n=14; p<0.05 with Student *t*-test). In summary, we provide a novel mechanism by which Akt might regulate neuronal excitability through a direct effect on Nav1.6 channel function and sub-cellular distribution.

Title: Disease-specific mechanism of action of voltage-gated sodium channel allosteric modulators in a mood disorder mouse model

Authors: *K. E. WINTERS

Neurosci., Univ. of Texas Med. Br., Galveston, TX

Abstract: Protein: protein interactions (PPI) offer unexploited opportunities for probe development in the CNS. The voltage-gated Na+ (Nav) channel complex comprises of a matrix of interacting proteins including fibroblast growth factor 14 (FGF14), a regulator of neuronal excitability in the cortico-mesolimbic circuit. The FGF14:Nav1.6 complex is also known to be part of the glycogen synthase kinase 3 (GSK3) pathway, which is implicated in various neuropsychiatric disorders, including mood disorder such as anxiety and depression. However, little is known about how the interaction between the FGF14, Nav1.6 and GSK3 might contribute to changes in excitability underlying any of these disorders. Here, we present evidence for a disease-specific mechanism of action of a novel peptidomimetic probe, ZL181, which targets the PPI interface of the FGF14:Nav1.6 channel complex. Using whole-cell patch clamp electrophysiology in the acute brain slice preparation, we show that 1 hour incubation with 50 µM of ZL181 increases intrinsic excitability in medium spiny neurons (MSN) of the nucleus accumbens (NAc) in the GSK3 knock-in mouse model of mood disorder. Specifically, compared to DMSO controls, ZL181 treated MSNs exhibited significantly increased number of spikes $(6.3\pm3.5 \text{ spikes in control}, n=3 \text{ versus } 22\pm4.4 \text{ spikes in the ZL181 group}, n=5, \text{ values taken at}$ current step of 120 pA; p<0.05 with Student *t*-test), increased instantaneous firing (9.6±5.2 Hz in control, n=3 versus 30.9±5.8 Hz in the Zl181 group, n=3, values taken at current step of 120 pA; p<0.05 with Student *t*-test), and lower action potential current threshold (116.7±23.3 pA in control, n=3 versus 44±5.1 pA in the Zl181 group, n=5; p<0.01 with Student *t*-test) These data can be contrasted with supporting ongoing studies which demonstrate that ZL181 decreases excitability in MSNs of wild-type mice. Overall, these results suggest disease-specific remodeling of the Nav channel complex that might be of interest for mood disorder therapeutic development.

Title: Mechanism of chemical induced peripheral neuropathy (cipn) by vincristine

Authors: *H. LEE¹, M. JOUNG², Y. CHOI², H. SUH⁴, S. JUNG³ ¹Physiol., Hanyang Univ. Col. of Med., Seoul, Korea, Republic of; ³Physiol., ²Hanyang Univ., Seoul, Korea, Republic of; ⁴Phamacology, Hallym Univ., Chooncheon, Korea, Republic of

Abstract: The possible roles of NaV1.8 channels located in the dorsal root ganglia (DRG) and the spinal cord in the regulation of chemotherapy-induced peripheral neuropathy were studied in ICR mice. We found in the present study that repeated intraperitoneal (i.p.) injections with vincristine (0.1 mg/kg per day for 7 consecutive days), caused an elevation of the hargreaves latency and reduction of pain threshold in von-frey test. The NaV 1.8 channel expression was increased in DRG vincristine-induced peripheral neuropathy animal model. Next, the NaV1.8 channels activities in DRG cells were magnified in vincristine-induced peripheral neuropathy animal models. Moreover, The electrical activities of NaV1.8 channels of nerves were far sensitive in all vincristine-induced peripheral neuropathy animal models. In addition, A803467, a selective NaV1.8 channel blocker, inhibited NaV1.8 channel activity in DRG, revealing IC50 value of A803467 is 150±20 nmole.

Furthermore, the i.p. administration with A803467 (from 20 to 80 mg/kg) attenuated vincristineinduced neuropathy as manifested in both hargreaves and Von-frey tests in a dose-dependent manner. Our results suggest that NaV1.8 channels located in DRG and the spinal cord play important roles for the production of vincristine-induced peripheral neuropathy.

Title: Strong G-protein-mediated voltage-dependent inhibition of voltage-gated sodium channels

Authors: *G. B. MATTHEISEN¹, T. TSINTSADZE², S. M. SMITH³ ¹PCCM, OHSU, Portland, OR; ³PCCM, ²VAPORHCS/OHSU, Portland, OR

Abstract: Voltage-gated sodium channels (VGSCs) are strategically positioned to mediate cellular plasticity due to their influence on action potential waveform. VGSC function may be strongly inhibited by local anesthetic and antiepileptic drugs and modestly modulated via second messenger pathways. Here we report that allosteric modulators of the calcium-sensing receptor (CaSR), cinacalcet, calindol, calhex, and NPS 2143, completely inhibit VGSC current in cultured and acutely isolated mouse neocortical neurons. This inhibition of VGSC current persisted in CaSR deficient neurons, indicating a CaSR-independent mechanism. Cinacalcet-mediated blockade of VGSCs was prevented by the GDP analog GDP β s, indicating G-proteins mediated this effect. However, unlike other reports of VGSC modulation, cinacalcet-mediated inhibition was independent of protein kinase A or C activation. Cinacalcet negatively shifted steady-state inactivation of VGCs and inhibition was reversed by prolonged hyperpolarization. These data identify a dynamic signaling pathway by which G-proteins regulate VGSC current to indirectly modulate neuronal excitability.

Title: Loperamide inhibits sodium channels to alleviate inflammatory hyperalgesia

Authors: *H. YU, Y. WU, M. LI, X. WANG Pharmacol., Inst. of Materia Medica, Chinese Acad. of M, Beijing City, China

Abstract: Previous studies demonstrated that Loperamide, originally known as an anti-diarrheal drug, is a promising analgesic agent primarily targeting mu-opioid receptors. However some evidences suggested that non-opioid mechanisms may be contributing to its analgesic effect. In the present study, Loperamide was identified as a Nav1.7 blocker in a pilot screen. In HEK293 cells expressing Nav1.7 sodium channels, Loperamide blocked the resting state of Nav1.7 channels (IC50=1.86±0.11 µM) dose-dependently and reversibly. Loperamide produced a 10.4 mV of hyperpolarizing shift for the steady-state inactivation of Nav1.7 channels without apparent effect on the voltage-dependent activation. And the drug displayed a mild use- and state-dependent inhibition on Nav1.7 channels, which was removed by the local anestheticinsensitive construct Nav1.7-F1737A. But inhibition of Nav1.7 at resting state was not altered significantly by the F1737A mutation. Compared to its effects on Nav1.7, Loperamide exhibited higher potency on recombinant Nav1.8 channels in ND7/23 cells (IC50=0.60±0.10 µM) and weaker potency on Nav1.9 channels (3.48±0.33µM). Notably more pronounced inhibition was observed in the native Nav1.8 channels (0.11±0.08 µM) in DRG neurons. Once mu-opioid receptor was antagonized by Naloxone in DRG neurons, potency of Loperamide on Nav1.8 was identical to that of recombinant Nav1.8 channels. The inhibition on Nav channels might be the possible mechanism of Loperamide for pain relief beyond mu-opioid receptor. In the meanwhile, the opioid receptor pathway may also influence the blocking effect of Loperamide on sodium channels, implying a cross-talk between sodium channels and opioid receptors in pain processing.

Title: Site-directed mRNA editing of sodium channels has potential to alter neuronal firing and network dynamics: Computer models

Authors: *W. W. LYTTON¹, ***W. W. LYTTON**¹, ***W.** W. LYTTON², A. KNOX³, J. J. C. ROSENTHAL⁴ ¹SUNY Downstate, Brooklyn, NY; ²Neurol., Kings County Hosp., Brooklyn, NY; ³Neurol., Univ. of Wisconsin, Madison, Madison, WI; ⁴Marine Biol. Lab., Woods Hole, MA

Abstract: mRNA editing offers the potential for targeting transcripts in the living animal or patient, providing the possibility of treatment of underlying genetic diseases. Adenosine deamination in mRNA has was used to alter the conductance of mammalian fast sodiums (Naf) channels (NaV1.4), changing a lysine to an arginine residue in the region of the peptide that determines selectivity -- the aspartate-glutamate-lysine-alanine motif DEKA is altered to DERA. The removal of channel selectivity allowed passage of both potassium and sodium through the channel, altering the effective reversal potential of a proportion of these channels. The proportion of wild type (WT) versus edited channels (EC) can be controlled experimentally and will be controllable in vivo. We therefore looked at the effects of changes in the EC/WT proportion in a set of single cell models and in a cortical network model. In the Hodgkin-Huxley model, we demonstrated the expected reduction in action potential amplitude, with increase in EC/WT. At a point related to the size of the modeled axon (input impedance), and to the density of potassium channel, the action potential failed as the sodium channels could no longer source sufficient current to oppose the outward currents. Speed of conduction was also affected by the proportion of mutated channel. This was primarily noticeable at locations far from the axon terminal where a baseline velocity of 2 m/s was reduced by 20% before conduction failure occurred. By contrast, conductance speed near the axon terminal was faster, 10 m/s, and was preserved with increased EC/WT, as current build-up near the high-impedence boundary allowed charge to build up fast enough to compensate for the reduced drive. After compensating for the faster kinetics by reducing overall channel density, similar models could be run at mammalian temperatures as were run in the origianl models at 6.3 C. Modification of sodium channels has the potential for future clinical use for the epilepsies and for pain syndromes.

Title: Specific interaction of amphiphiles with sodium channels

Authors: Z. WANG¹, S. R. LEVINSON², *T. HEINBOCKEL¹ ¹Dept. of Anat., Howard Univ. Col. of Med., Washington, DC; ²Dept. of Physiol. and Biophysics, Univ. of Colorado Denver Sch. of Med., Denver, CO

Abstract: Amphiphiles are chemical compounds possessing both hydrophilic and lipophilic properties. They are widely used in pharmaceuticals, food, cosmetics and for drug delivery. Their effects include ameliorating symptoms of neurological pain, increasing blood brain barrier, enhancing transdermal drug delivery, and prolonging sensory-selective nerve blockade of local anesthetics. Their effects are thought to result from non-specific lipid-protein interactions, namely, a bilayer-protein hydrophobic coupling mechanism. Little is known about the molecular interaction between amphiphiles and target proteins. Here, we hypothesize that some amphiphiles specifically interact with sodium channels to exert their pharmacological action. Two groups of chemical analogues, Polysorbates and Spans, were selected to test the direct action on sodium channels using whole-cell patch-clamp recordings from transfected CHO cells that stably expressed the Nav1.2 sodium channel isoform. Polysorbate 20 and Polysorbate 80 display tonic inhibition of sodium currents, modulation of voltage-dependent availability and larger use-dependent block. However, Spans, which are chemically analogous to Polysorbates but lack the poly(-O-CH2Ch3) group in their hydrophilic head, fail to modulate the function of sodium channels. The results indicate that 1) not all amphiphiles modulate sodium channel function through a bilayer-protein hydrophobic coupling mechanism; 2) Polysorbates specifically interact with sodium channels to inhibit sodium channel function. The specific interaction with sodium channels provides direct evidence that the prolonged sensory-selective nerve blockade of anesthetics by amphiphiles is pharmacodynamic rather than pharmacokinetic, and will lead to the development of novel prolonged-duration local anesthetics and a novel therapeutic strategy for treatment of neuropathic pain.

Abstract: Dravet syndrome (DS) is a severe epileptic encephalopathy with infantile onset, characterized by refractory seizures, increased risk of sudden death, as well as mental, behavioral and motor comorbidities. In most cases, the genetic basis is a haploinsufficiency caused by mutations in SCN1A, which encodes the alpha subunit of a voltage-dependent Na⁺ channel (Nav1.1). Due to the complex physiopathology of DS, etiological approaches such as gene therapy have unique chances to obtain a global improvement in the life of these patients. We aim to deliver a functional copy of the SCN1A gene to the brain using High-Capacity adenoviral vectors (HC-Ad). To provide proof of concept about the feasibility of this approach we generated a preliminary vector prototype carrying a codon-optimized SCN1A cDNA under the control of a ubiquitous promoter sequence (CAG). The expression cassette inserted into the vector genome was stable in E. Coli and gave rise to viable HC-Ad particles following a standard rescue and amplification protocol. The resulting HCA-CAG-SCN1A vector was able to infect neurons and increase the amount of Nav1.1 in a dose-dependent manner. Biodistribution analysis using HC-Ad vectors encoding GFP demonstrated efficient transduction of neurons upon intracerebral administration. Finally, in vitro luciferase reporter assays were performed to select a regulatory sequence with preferential activity in GABAergic/paravalbumin-expressing inhibitory neurons. In summary, the results obtained so far indicate that gene therapy based on HC-Ad vectors is a viable option for the treatment of DS.

Title: The mechanism of propofol action on voltage-gated sodium channels

Authors: ***E. YANG**¹, D. GRANATA², Y. WANG³, R. G. ECKENHOFF⁵, P. TANG⁴, Y. XU⁶, V. CARNEVALE², M. COVARRUBIAS¹

Pittsburgh Sch. Med., Pittsburgh, PA

Abstract: Voltage-gated Na⁺ channels (Navs), which play a pivotal role in the electrical excitability of the central nervous system, are inhibited by clinically relevant concentrations of many general anesthetics and are thus highly relevant anesthetic targets. The molecular mechanisms of this inhibition, however, remain unclear. Here, we investigated the electrophysiological response of NaChBac and NaVMs, two anesthetic-sensitive bacterial homologs of eukaryotic Navs, to the intravenous anesthetic propofol at 2, 5, and 10 µM. In both NaChBac and NaVMs, propofol induced hyperpolarizing shifts of the pre-pulse inactivation and conductance-voltage (G-V) relationships, reduced the time constant of inactivation, and increased the time constant of deactivation in a dose dependent manner without significant effects on recovery from inactivation. Previous investigations suggested that general anesthetics might inhibit NaChBac by open channel block in a manner resembling local anesthetics. Contrary to predictions based on this mechanism, however, propofol induced hyperpolarizing shifts in the G-V curve with minimal effects on current amplitude and the rate of current decay in a non-inactivating NaChBac mutant at both 2 and 5 µM. Propofol may bind to the channel to stabilize the open state, ultimately facilitating activation-coupled inactivation, a mechanism that is supported by kinetic modeling. Guided by molecular dynamics simulations and ¹⁹F-NMR, we have evaluated putative propofol binding sites in the pore and voltage-sensing domains with electrophysiology and mutational analysis to identify structural determinants of Nav gating involved in modulation by propofol. With the photoactive propofol analog *m*-Azipropofol, we will use photoaffinity labeling and mass spectrometry to identify propofol binding sites in these Navs.

Title: Peptides mapping of the FGF14:Nav1.6 complex interface

Authors: *A. K. SINGH¹, P. A. WADSWORTH², O. O. FOLORUNSO³, S. R. ALI⁴, F. LAEZZA⁵

¹Pharmacol. & Toxicology (MRB Build.), Univ. of Texas Med. Br. (UTMB), Galveston, TX; ²UTMB, Galveston, TX; ³Univ. of Texas Med. Br., Galveston, TX; ⁴Dept. of Pharmacol., Yale Univ., New Haven, CT; ⁵Dept. of Pharmacol. & Toxicology, Univ. of Texas Med. Br. at Galveston, Galveston, TX

Abstract: Voltage-gated sodium (Nav) channels provide the basis for electrical excitability in the brain. Nav channels are comprised of nine isoforms (Nav1.1-1.9), which are specifically regulated by accessory proteins such as intracellular fibroblast growth factor 14 (FGF14). FGF14 binds directly to the cytosolic domain of the Nav1.6 channel, and regulates its biophysical properties and expression, leading to significant effects on intrinsic excitability in neurons. In pursuit of probes that could modulate the FGF14:Nav1.6 complex, we designed and synthesized three peptides (FLPK, PLEV, EYYV) based on homology modeling studies of the FGF14:FGF14 homodimer and the FGF14:Nav1.6 channel complex. To evaluate the potency and mechanism of action of each peptide against the FGF14:Nav1.6 channel complex, we combined computational modeling, molecular dynamics, split-luciferase complementation assay (LCA), surface plasmon resonance (SPR) and whole cell patch-clamp electrophysiology. First, in silico peptide docking revealed that FLPK likely interacts with residues (V160 and Y158) at the interface of the FGF14:Nav1.6 homology model, and subsequent LCA validation supported this hypothesis. Our LCA results show that FLPK disrupts the FGF14:Nav1.6 channel complex interaction and the effect is abolished in the presence FGF14^{Y158N/V160N} mutations. Furthermore, SPR showed that FLPK has a high binding affinity for FGF14 (K_D=6.4µM) and no measurable affinity for Nav1.6 C-tail. Lastly, using whole-cell patch clamp electrophysiology, we show that FLPK prevents FGF14-dependent regulation of Nav1.6 currents, voltage-dependent activation and steady-state inactivation of Nav1.6 channels. In summary, these results show the FLPK disrupts the FGF14:Nav1.6 complex which could be important for therapeutic development against Nav channel dysfunctions.

Title: Functional modulation of voltage-gated sodium channel Nav1.6 by peptidomimetics

Authors: *O. FOLORUNSO¹, L. BOURNER², P. A. WADSWORTH³, S. R. ALI², Z. LIU², H. CEHN², J. ZHOU², F. LAEZZA²

Abstract: Voltage-gated sodium (Nav) channels interact with auxiliary proteins, including intracellular fibroblast growth factor 13 (FGF13), which modulate their biophysical properties in different regions within the CNS and PNS. These protein-protein interactions (PPI) are necessary to maintain neuronal excitability, and FGF13 dysfunction is associated with epilepsy and neuropathic pain. The physiologically relevant Nav1.6 C-terminal tail binds to FGF13, and the functional specificity of this interaction provides an opportunity for the development of novel Nav isoform-specific probes. Here, we combined the split-luciferase complementation assay (LCA) with molecular modeling to screen various peptidomimetics to target intracellular FGF:Nav channel interfaces. We identified ZL192 as a potential regulator of the FGF13:Nav1.6 complex. We show that ZL192 is specific to the FGF13:Nav1.6 complex, and has no effect on other Nav1.6 interactors such as FGF14. Furthermore, our dose response experiments show that ZL192 action is specific to the FGF13-1b ($IC_{50} = 24.4 \mu M$) and not the FGF13-1a isoform. Next, we investigated the functional impact of ZL192 on HEK293 cells stably expressing Nav1.6 and transiently transfected with FGF13-1b-GFP using whole-cell patch clamp recordings. Our initial studies show that there is a significant decrease in the peak current density at multiple voltage steps (at -25mV, p= 0.022, ANOVA, Fisher's LSD) in FGF13-1b-GFP plus ZL192 compared to GFP-Nav1.6 cells, and a hyperpolarizing shift in voltage dependence of steady-state inactivation of the Nav1.6 channel in FGF13-1b-GFP plus ZL192, (p= 0.038, ANOVA post-hoc Bonferroni) which was not observed with FGF13-1b-GFP alone. Therefore, ZL192 might selectively modulate a pool of Nav1.6 channels associated with FGF13-1b leading to a directed effect on neuronal excitability, and a potential applicability for drug discovery in the epilepsy and pain fields.

Title: GSK3 β is a new molecular determinant of neuronal excitability

Authors: *P. A. WADSWORTH¹, A. K. SINGH², K. M. SEPURU¹, K. RAJARATHNAM¹, F. LAEZZA²

¹Biochem. and Mol. Biol., ²Pharmacol. and Toxicology, UTMB, Galveston, TX

Abstract: Glycogen synthase kinase 3 (GSK3) is a multifaceted enzyme with ubiquitous expression in the central nervous system (CNS). Increased levels of GSK3 trigger a cascade of serine/threonine (S/T) phosphorylation events that correlates with maladaptive plasticity of neuronal circuitries in neuropsychiatric disorders spurring an interest in identifying new molecular targets within this pathway for drug discovery purposes. In previous studies we have shown that changes in GSK3 levels modify neuronal excitability by regulating protein:protein interactions (PPI) between fibroblast growth factor 14 (FGF14) and the voltage-gated Na+ channel. Suppression of GSK3 leads to loss in neuronal excitability in hippocampal neurons with dispersion of the FGF14:Nav channel complex from the axonal initial segment. Based on in vitro phosphorylation studies showing that GSK3β phosphorylates both FGF14 and the Nav1.6 channel, we hypothesized that GSK3ß may form a stable complex with either FGF14 and Nav1.6. To test this hypothesis, we first applied the split-luciferase complementation assay (LCA) to screen the interactions between each of these proteins, as well as to show how complex formation is dependent upon regulation by cellular signaling pathways. Furthermore, Surface Plasmon Resonance (SPR) on E.coli purified proteins was used to assess putative binding affinity of GSK3^β to either FGF14 or Nav1.6, as well as to map respective interaction sites. SPR studies revealed strong binding affinity (K_D=0.159 μM) between FGF14 and GSK3β pointing for the C-tail of FGF14 as a necessary structural element mediating PPI. NMR studies using 15Nlabeled FGF14 further confirmed FGF14 binding to Nav1.6. Altogether, these results reveal

FGF14, Nav1.6 and GSK3 β as potential new structural determinants of neuronal excitability in the brain circuit.

Title: Sodium channel beta2 subunits prevent action potential propagation failures at axonal branch points

Authors: *M. B. HOPPA¹, I. CHO², L. PANZERA³, M. CHIN¹ ¹Biol. Sci., ³Biol., ²Dartmouth Col., Hanover, NH

Abstract: The arrival of an action potential (AP) at a presynaptic terminal dictates both calcium channel opening and the driving force for calcium entry, which are powerful levers modulating synaptic strength. Excitatory hippocampal neurons contain highly ramified axons (~200 branch points) that form a large number of en passant boutons (~8,000). Unmyelinated sections of axon are very diverse structures encompassing branch points and numerous presynaptic terminals with undefined molecular partners of sodium channels. At present, we have little idea about how cells regulate the density and subcellular distribution of ion channels to ensure AP delivery and sculpt the propagating waveform. This question has been particularly difficult to study in hippocampal neurons due to the fine structures of distal axonal branches that preclude detailed electrophysiological analysis. Here we have used a combination of optogenetic indicators to make subcellular measurements of both membrane potential and calcium influx at nerve terminals to study sodium channel distribution across the axon of cultured hippocampal neurons. Using these probes, we demonstrate that large variations in AP shape exist between branches of a single axonal arborization as well as disparate sensitivity to propagation blockade by TTX. We go on to show that these properties are independent of morphology and likely related to local molecular repertoires. We go on to demonstrate that Na^+ channel $\beta 2$ subunits ($Na_y\beta 2$) are required to prevent AP propagation failures across the axonal arborization of cultured rat hippocampal neurons. In the absence of Na_v β 2s, we identify two specific phenotypes: (1) membrane excitability and AP-evoked Ca^{2+} entry are reduced at synapses, and (2) AP

propagation is severely compromised with over 40% of axonal branches no longer responding to AP-stimulation. Thus, $Na_v\beta 2$ is a critical regulator of axonal excitability and synaptic function in unmyelinated axons. Given the fact that synaptic transmission is highly sensitive to changes Ca^{2+} influx controlled by the biophysical properties of the AP, this finding reveals a new important role for $Na_v\beta 2$ subunits to control the spread of excitability in the nervous system.

Title: Neurofascin-186 modulates axon initial segment morphpology and function

Authors: *S. ALPIZAR, M. B. HOPPA Biol. Sci., Dartmouth Col., Hanover, NH

Abstract: Voltage gated sodium channel (VGSC) types 1.2 and 1.6 are recruited to the axon initial segment (AIS) following the enrichment of the scaffolding protein AnkyrinG during development. The location and distribution of these VGSCs has a strong impact on neuronal excitability. Also uniquely localized at the AIS are cellular adhesion molecules (CAMs) such as Neuronal Cellular Adhesion Molecule and Neurofascin-186 (NF-186). While these molecules are known for their functions in neurite extension, axon formation, and neuron-glial interactions, they have recently been implicated in modulating AnkyrinG stability at the AIS, although mechanisms in which this occurs remain elusive. Our aim is to identify a potential role of NF-186 in stabilizing critical AIS components and therefore influencing structural parameters of the AIS. We also aim to elucidate the functional consequences of NF-186 loss on action potential (AP) firing. Here, using primary rat hippocampal cultures, we combined localization measurements of fluorescently tagged VGSCs with genetic ablation of Neurofascin-186 using CRISPR. These localization experiments were combined with optical AP measurements that allow for waveform analysis using QuasAr, a genetically encoded voltage indicator that provides accurate detection of single action potentials as well as high-frequency trains. Additionally, the ability to measure voltage changes at both the soma and distal axon allowed us to observe NF-186's influence on both VGSC types enriched at the AIS. The loss of NF-186 altered the localization of AnkyrinG within the axon. Here we show the impact of NF-186 ablation on VGSC location and dynamics at the AIS. NF-186 may play a direct role in AnkyrinG localization which influences VGSC distribution and dynamics at the AIS.

Title: Allosteric modulatory effects of SRI-30827 on HIV-1 Tat protein-induced inhibition of human dopamine transporter function and cocaine condition place preference in inducible Tat transgenic mice

Authors: *J. ZHU

Drug Discovery and Biomed. Sci., Col. of Pharmacy, Univ. of South Carolina, Columbia, SC

Abstract: The inducible HIV-1 Tat transgenic (iTat) mouse model recapitulates many aspects of neurocognitive impairments observed in HIV infected individuals. Tat and cocaine synergistically increase synaptic dopamine (DA) levels by directly inhibiting DA transporter (DAT) activity, ultimately leading to dopaminergic neuron damage. This study determined allosteric modulatory effects of SRI-30827 on HIV-1 Tat protein-mediated regulation of human DAT and cocaine condition place preference (CPP) in iTat mice. Results show that SRI-30827 attenuated Tat-induced inhibition of [³H]DA uptake and [³H]WIN35,428 binding in PC12 cells expressing human DAT. After a 7-d doxycycline (Dox) treatment, HPLC analysis revealed that DA content in the prefrontal cortex (PFC) and nucleus accumbens (NAc) of iTat-Tg mice were increased by 92% and 37%, respectively, compared to control mice. Consistently, DA/DOPAC in the PFC and NAc of iTat-Tg mice was increased by 44% and 26%, respectively. We performed the patch clamp recording to measure medium spine neurons (MSN) firing in brain NAc slices of iTat mice in the presence of DA and cocaine. Results show that that action potential frequency of NAc shell MSN was significantly increased in iTat mice compared to control mice. Further, action potential frequency of NAc shell neurons was decreased in response to 5 μ M cocaine, and further decreased when cocaine and 5 μ M were applied together, which were completely attenuated in iTat mice. Finally, we found that ICV infusion of SRI-30827, a novel allosteric modulator, partially attenuated the potentiated cocaine-CPP in iTat mice. These findings suggest the hypothesis that Tat potentiates cocaine rewarding effect and allosteric modulator has potential for treatment of Tat-induced drug reward

Ctr., Copenhagen Univ. Hosp., Copenhagen, Denmark; ⁷Dept of Molec Physio & Biophys, Vanderbilt Univ., Nashville, TN

Abstract: The dopamine transporter (DAT) exerts a critical function in dopamine homeostasis by mediating reuptake of dopamine. An increasing number of missense mutations in the dopamine transporter (DAT) have been identified in patients suffering from psychiatric disorders. Moreover, complete 'loss of function' mutations in DAT have been identified a rare cause of hereditable infantile/childhood onset parkinsonism-dystonia. We recently described the first patient, carrying DAT missense mutations, who suffered from both early-onset parkinsonism and ADHD. Here, we further expand the clinical spectrum of DAT associated disease by presenting an additional patient that present with the unique combination of earlyonset parkinsonism and concurrent psychiatric disorder. This patient is heterozygote for a missense mutation in the C-terminal PDZ binding domain of DAT. Two SPECT scans of the patient performed seven years apart, uncovered reduced DAT binding along with a mild progressive worsening. A characterization of the mutant in heterologous cells revealed reduced dopamine uptake capacity (60% of WT DAT), attenuated amphetamine induced efflux, and reduced expression of DAT-K619N. Importantly, the K619N mutation has a pronounced effect in vivo. Drosophila Melanogaster that express the hDAT-K619N mutant show reduced dopamine uptake and 90% reduction in amphetamine induced dopamine efflux, compared to flies expressing WT hDAT. Moreover, we demonstrate that DAT-K619N has dominant negative actions on endogenous DAT, as viral expression of DAT-K619N in mice significantly reduces striatal dopamine uptake. Our identification of yet another patient with DAT associated

parkinsonism and neuropsychiatric disorder further supports that abnormal DAT function may constitute a risk factor for both psychiatric disorders and parkinsonism.

Title: Cholesterol- and neuronal activity-dependent dopamine transporter nanodomains revealed by super-resolution microscopy

Authors: *M. D. LYCAS¹, T. RAHBEK-CLEMMENSEN¹, S. ERLENDSSON¹, J. ERIKSEN¹, M. APUSCHKIN¹, F. VILHARDT², T. N. JØRGENSEN¹, F. H. HANSEN¹, U. GETHER¹ ¹Dept. of Neurosci. and Pharmacol., ²Dept. of Cell. and Mol. Med., Univ. of Copenhagen, Kobenhavn N, Denmark

Abstract: Dopamine regulates reward, cognition and locomotor functions. By mediating rapid reuptake of extracellular dopamine, the dopamine transporter (DAT) is critical for spatiotemporal control of dopaminergic neurotransmission. Here, we show with super-resolution imaging that DAT is regulated by dynamic sequestration into cholesterol-dependent nanodomains in the plasma membrane of presynaptic varicosities and neuronal projections of dopaminergic neurons. Stochastic optical reconstruction microscopy (STORM) revealed irregular DAT nanodomains (~70 nm mean diameter) that were virtually dissolved by cholesterol-depletion. A similar DAT nanodomain localization was demonstrated in heterologous cells by live, photoactivated localization microscopy (PALM). In the neurons, dual-color dSTORM showed that tyrosine hydroxylase and vesicular monoamine transporter-2 are distinctively localized adjacent to, but

not overlapping with, the DAT nanodomains. In addition, dual-color dSTORM images of DAT and syntaxin-1 indicate a functional role of the clustered expression of DAT. The molecular organization of DAT in nanodomains was reversibly reduced by short-term activation of NMDA-type ionotropic glutamate receptors, implicating DAT nanodomain distribution as a potential mechanism to modulate dopaminergic neurotransmission in response to excitatory input. Through super resolution microscopy, the functional characteristics of DAT clusters are elucidated in the context of the dopaminergic presynapse.

Title: Phenotypic characterization of aging dopamine transporter DAT-AAA knock-in mice

Authors: A. B. KØNIG¹, C. FITZPATRICK¹, M. RICKHAG¹, *U. GETHER² ¹Ctr. for Neurosci., ²Univ. Copenhagen, Koebenhavn N, Denmark

Abstract: Being part of a multi-protein complex situated in the presynaptic compartment, the dopamine transporter (DAT) re-uptakes released dopamine from the extracellular space, thus maintaining synaptic dopamine homeostasis. We have developed a novel knock-in (KI) mouse strain with a disrupted DAT C-terminal PSD-95/Dlg1/ZO-1 homology (PDZ)-domain by substituting the C-terminal PDZ-target sequence (-LLV) with three alanines (-AAA) (DAT-AAA mice). This resulted in abolished PDZ-domain interaction and dramatic loss of functional DAT in striatal synaptic terminals. Interestingly, DAT mutations have recently been identified in patients with neuropsychiatric disorder, such as ADHD and autism, as well as in patients with juvenile and early-onset neurodegenerative parkinsonism. Some of these mutations display functional impairment similar to that observed for DAT in DAT-AAA mice. We therefore set out to phenotypically characterize aging DAT-AAA mice to assess their validity as a possible model for dopamine pathologies. Applying an extensive battery of motor tests at ages 9, 12, 15, 18 and 21 months, we found that DAT-AAA mice showed a steady and substantial hyperactive locomotive behavior in the open field test when compared to wild type (WT) mice. DAT-AAA mice furthermore showed increased amounts of rearings at 21 months consistent with a preserved hyperdopaminergic motor phenotype. We found no differences in fine motor skills, motor coordination and balance when testing the mice in the pole test, the adhesive removal test, the hanging wire test and on the rotarod, nor were there signs of pathological clasping behavior or kyphosis. There were no differences in anxiety/exploratory behavior in the elevated plus maze at 12 months. Our findings in the DAT-AAA mice describe a hyperactive locomotive phenotype that persists with age and displays no apparent dysfunctions of fine motor skills, motor coordination and balance. A further exploration of this dopaminergic phenotype should be relevant for understanding the physiological consequences of disrupting C-terminal PDZ interactions in vivo and for evaluating the mice as models for dopaminergic dysfunction and dopamine related diseases.

Title: The trace amine receptor 1 (TAAR1) is coupled to G_s and G_{13} G-protein subunits in distinct subcellular compartments

Authors: *S. M. UNDERHILL¹, S. H. MILLAN³, P. D. HULLIHEN⁴, J. CHEN³, S. G. AMARA²

Abstract: Amphetamine (AMPH) and its derivatives are useful therapeutic agents, but can also have a negative impact as a consequence of their addictive properties. Acute AMPH exposure elevates extracellular dopamine and glutamate by a variety of mechanisms including an increase in the rate of internalization of the plasma membrane dopamine transporter (DAT) and of the excitatory amino acid transporter 3 (EAAT3). AMPH-mediated trafficking of these carriers requires activation of the small GTPase RhoA that is negatively regulated by direct phosphorylation by protein kinase A (PKA). The trace amine receptor 1 (TAAR1) is a G-protein coupled receptor (GPCR) known to couple through $G_{s\alpha}$ and activate PKA signaling. TAAR1 also has been shown previously to contribute to the actions of psychostimulants in dopamine neurons and thus these observations led us to examine the potential role of TAAR1 in RhoA and PKA activation as well as in transporter trafficking. We used CRISPR-Cas9 gene editing technology to disrupt the TAAR1 gene in HEK293 cells and then measured AMPH-stimulated trafficking of DAT and EAAT3, as well as activation of Rho and PKA. In cells lacking TAAR1, AMPH did not induce internalization of DAT or EAAT3. We could not detect Rho or PKA activation in the knockout cells despite robust responses in the parallel wildtype TAAR1(+) cultures. AMPH-induced internalization of DAT and EAAT3 could be restored in the knockout cell line by transfecting with a modified, nuclease-resistant TAAR1. We hypothesized that TAAR1 was coupled to more than one subtype of G-protein alpha-subunit that mediated these diverse actions. To test this, we used mini-genes that interfere with various alpha-subunits and we determined that TAAR1 also couples to a $G_{13}\alpha$, an activator of RhoA signaling. By using short targeting domains to direct FRET sensors to various intracellular compartments, we found that the TAAR1 receptors that couple to $G_{13\alpha}$ subunits display signaling that is restricted to regions around the ER. In contrast, TAAR1- activated PKA signaling was detected in non-raft membranes. These observations show that TAAR1 serves as the intracellular target that mediates the effects of AMPH on RhoA and cAMP signaling and suggest new pathways to consider in order to better understand the mechanisms of action of AMPH.

Title: Biogenic amine transporter activity of cathinone analogues

Authors: *A. M. DECKER¹, A. LANDAVAZO¹, J. S. PARTILLA², B. E. BLOUGH¹, M. H. BAUMANN², R. B. ROTHMAN² ¹RTI Intl., Rtp, NC; ²IRP, NIDA, NIH, Baltimore, MD

Abstract: Psychostimulants are highly addictive drugs that stimulate central and peripheral nervous system function and cause a variety of harmful physiological effects in humans. "Bath salts" or "legal highs" are synthetic stimulants that have recently become a serious abuse problem. The major components of many of these "bath salts" are synthetic cathinones, such as mephedrone, methylone, and methcathinone, which produce powerful stimulant, hallucinogenic, and addictive effects, all of which are similar to the effects experienced by cocaine, MDMA (ecstasy), and amphetamine users. Like many psychostimulants, synthetic cathinones are biogenic amine transporter (BAT) ligands and act as either transporter reuptake inhibitors or substrate type releasers. Given the detrimental effects of synthetic cathinones, it is becoming increasingly important to understand the pharmacology of these drugs so that new treatments for their abuse can be developed.

The current study set out to synthesize a series of methcathinone analogues with altered phenyl ring substitutions. All analogs were evaluated for BAT reuptake inhibition and release activity in freshly prepared rat brain synaptosomes. Our results show that several analogues are more potent dopamine and serotonin transporter releasers compared to methcathinone.

Abstract: Dopamine (DA) plays an important role in the central nervous system by regulating a variety of functions, including cognition and motivation. While DA dysfunction is known to be involved in several neuropsychiatric disorders, its role in autism spectrum disorder (ASD) is largely unknown. We have recently identified several single nucleotide variants in the *SLC6A3* gene in individuals with ASD. The *SLC6A3* gene encodes the DA transporter (DAT), a presynaptic membrane protein critical to DA neurotransmission. Specifically, DAT mediates the active high affinity re-uptake of DA from the synapse into the synaptic bouton, maintaining DA

homeostasis. We report a novel SLC6A3 variant identified in an ASD proband from whole exome sequencing. This variant encodes an in-frame deletion of three nucleotides, resulting in the deletion of an asparagine at position 336 ($\Delta N336$). In vitro experiments demonstrate that $\Delta N336$ results in nearly absent DAT-dependent DA uptake despite normal surface expression. We utilize Drosophila melanogaster as an animal model to determine functionally and behaviorally whether expression of hDATAN336 in DA neurons results in DA dysfunction. Drosophila has enabled rapid progress in neuroscience research due to its cost-effectiveness, genetic tractability, rapid life cycle and conserved mechanisms of neurotransmission. Notably, mechanisms mediating DA neurotransmission including transport, synthesis, and secretion are largely conserved. Expression of $\Delta N336$ in *Drosophila* leads to impaired brain DA uptake and reverse transport of DA. Moreover, flies expressing hDAT Δ N336 display increased basal locomotion and grooming. This data is consistent with increased levels of extracellular DA. We evaluated further whether impairments in DA clearance affect defensive responses (i.e. freezing or fleeing) and/or social interactions, behaviors which are altered in individuals with ASD. Flies expressing $\Delta N336$ display aberrant freezing, fleeing, as well as, social behaviors. These results add to the growing body of literature associating altered regulation of DA homeostasis to complications in ASD.

Title: Conformational changes induced by $G\beta \gamma$ subunits regulate dopamine transporter function

Authors: *J. GARCIA-OLIVARES¹, ***J. GARCIA-OLIVARES**¹, S. A. WASSERMAN¹, D. TORRES-SALAZAR¹, W. C. HONG², S. G. AMARA¹ ¹Natl. Inst. of Mental Hlth., Bethesda, MD; ²Buttler Univ., Indianapolis, IN

Abstract: The dopamine transporter (DAT) is regulated by cellular mechanisms such as phosphorylation, ubiquitination, and interactions with other proteins. We have reported a mechanism for regulation of the DAT by $G\beta\gamma$ subunits of heterotrimeric G-proteins. We found that after G-protein activation the $G\beta\gamma$ subunit binds directly to the C-terminus of the DAT and

decreases dopamine (DA) accumulation. We later found that this decrease in DA accumulation does not involve a change in uptake, but instead results from an increase in DA efflux through DAT. To further understand the mechanism of $G\beta\gamma$ regulation of DAT function, we examined whether the functional effects were linked to conformational changes in the DAT that facilitate efflux in HEK293 cells. An extracellularly-oriented cysteine residue (C306) in the DAT was used to probe conformational changes induced by the G_β activator peptide, mSIRK, and by ligands such as cocaine and other modulators of DAT function. The accessibility of C306 to an impermeant thiol-reactive biotin reagent was significantly reduced in cells treated with mSIRK. It has previously been shown that cocaine increases the accessibility of C306 by stabilizing an outward facing conformation of the DAT. However, pretreatment of cells with mSIRK reduced the cocaine-induced increase in C306 reactivity, suggesting that G_β activation limits the available binding sites for cocaine, perhaps by stabilizing an inward conformation. We also use a set of Cys-substitution mutants (I159C; K264C; S262C) in combination with permeant and impermeant thiol-reactive reagents to examine the DAT induced conformational changes that facilitate a shift in DAT conformation towards an inwardly-oriented efflux mode. Finally, we wanted to test if the observed conformational changes were result of the GBy binding or if the binding of $G\beta\gamma$ is conformation-dependent. For that we used the proximity-ligation assay to study how the interaction DAT-GBy is modified in the presence of different conformationspecific DAT-ligands. Our results provide a basis for further studies to establish the structural determinants for dopamine efflux and the relevance of GBy modulation for the actions of psychostimulants such as cocaine and amphetamines

Title: Regulation of amphetamine actions by the dopamine transporter and G protein beta gamma subunits interaction

Authors: *S. S. HARRIS¹, J. A. PINO¹, J. C. MAUNA², E. THIELS², G. E. TORRES¹ ¹Pharmacol. and Therapeut., Univ. of Florida, Gainesville, FL; ²Univ. of Pittsburgh, Pittsburgh, PA

Abstract: The dopamine transporter (DAT) plays an important role in regulating dopamine (DA) neurotransmission by transporting extracellularly released dopamine back into dopaminergic neurons, thereby limiting the duration and intensity of dopamine signaling. In addition, DAT can also function to release DA, a process known as reverse transport or efflux. This reverse transport of DA through DAT is the mechanism by which amphetamine and methamphetamine produce their effects. Amphetamine is used clinically in the treatment of conditions such as attention deficit hyperactivity disorder (ADHD) and narcolepsy, but is also abused due to its rewarding and addictive properties. However, the molecular details associated with the actions of amphetamine are not well understood. Our lab reported a novel interaction between G protein $\beta\gamma$ subunits and DAT, whereby $G\beta\gamma$ subunits bind directly to the C-terminus of DAT. Our previous findings showed that activation of GBy subunits by mSIRK down-regulate DAT-induced DA uptake. We recently provided additional evidence using heterologous systems and primary DA neurons in culture that mSIRK also increases DA efflux through DAT and this effect is blocked by inhibition of G_β subunit activation by gallein or a peptide that binds within the C-terminal region where GBy binds to DAT. Moreover, we also show, *in vivo*, that inhibition of GBy activation by gallein reduces amphetamine-induced increases in locomotor activity and extracellular DA levels in the nucleus accumbens in rats. Findings from these studies suggest that GBy subunits interact directly with DAT to regulate DA efflux and this interaction is involved in amphetamine's actions. Therefore, the present study sought to further characterized the role of G_β subunits in the actions of amphetamine using *ex vivo* and *in vivo* approaches. Rat striatal tissue was used to determine the effects of activation of GBy subunits by mSIRK on amphetamine-induced DA release using a superfusion assay. We also determined the effects of mSIRK on amphetamine-induced extracellular DA levels in the nucleus accumbens using in vivo microdialysis. Our preliminary results provide further support for the role of GBy subunits in modulating the actions of amphetamine in the brain.

Abstract: The dopamine transporter (DAT) is a neurotransmitter transporter that regulates the extra-cellular concentrations of dopamine (DA) by re-uptaking DA into dopaminergic neurons. Psychostimulants disrupt DA homeostasis by competitively blocking DAT (cocaine) or inhibiting DA reuptake and reverse transport activity, resulting in increased synaptic DA levels and efflux of DA via DAT (methamphetamine). We investigated the proteomic differences between these psychostimulants by tandem mass spectrometry to examine the interacting proteome of DAT when exposed to methamphetamine (Meth), a DAT substrate and cocaine (Coc), a DAT blocker. We used Perseus software platform to interpret our proteomics data. Analysis of the data revealed distinct protein repertoires for Coc and Meth treated cells. We confirmed some known DAT interacting proteins at various time points. Post spectroscopy analysis revealed novel protein interactions including redox, actin-binding, calcium binding/regulating, and voltage-dependent proteins based on drug treatment. Here we provide a comprehensive, qualitative analysis of proteins detected in response to psychostimulant treatment. Co-immunoprecipitation and confocal microscopy experiments confirm novel protein interactions with DAT when exposed to Meth or Coc. Lastly, comparative analyses of the Meth and Coc interactome have brought to light several interesting molecular pathways, offering the possibility to explore psychostimulant-specific protein interactions in the cell.

Title: Behavioral impact of Rin GTPase and dopamine transporter trafficking: AAV studies using novel conditional and inducible shRNA

Authors: *C. G. SWEENEY¹, J. XIE², G. GAO², H. E. MELIKIAN¹ ¹Brudnick Neuropsychiatric Res. Inst., ²Gene Therapy Ctr., Univ. of Massachusetts Med. Sch., Worcester, MA

Abstract: Dopamine (DA) signaling is critical for movement, motivation, and addictive behavior. Following synaptic release, DA is rapidly taken up into the presynaptic neurons by the DA transporter (DAT), thereby spatiotemporally restricting downstream DA signaling. DAT plasma membrane presentation is requisite to regulate extracellular dopamine levels. Neuronal DAT surface expression is acutely regulated via PKC activation, which drives rapid DAT loss from the cell surface via endocytic trafficking. We previously reported that this mechanism requires the small, neuronal GTPase, Rin (Rit2). Although PKC-stimulated DAT downregulation has been well described for over a decade, the physiological importance of regulated DAT trafficking, and Rin's role in DAT downregulation in vivo, are poorly defined. Here, we tested whether Rin-dependent, PKC-stimulated DAT trafficking is required for DA-related behaviors. To accomplish this objective, we developed an rAAV (TET-OFF/ON) vector that uses a tetracycline responsive element (TRE) to drive Rin-targeted shRNA expression selectively in cells expressing the Tet transactivator (tTA). When injected into Pitx3^{IRES-tTA/+} mouse midbrain, we observed selective reporter expression and Rin knockdown in midbrain DAergic neurons, which was suppressed when mice were maintained on a doxycycline diet. Rin knockdown in DAergic neurons resulted in an anxiolytic phenotype, as determined by elevated plus maze and open field behavioral assays. Ongoing experiments are testing whether Rin expression in DA neurons plays a role in psychostimulant reward, and whether Rin is required for PKC-stimulated DAT trafficking in ex vivo striatal slices. These studies are among the first to achieve both conditional and inducible gene knockdown in vivo and, importantly, provide evidence that regulated DAT trafficking may exert a robust influence on DA-dependent behaviors.

Title: The impact of regulated dopamine transporter endocytosis on dopamine-dependent behaviors: *In vivo Drosophila melanogaster* studies

Authors: *R. R. FAGAN^{1,3}, C. G. SWEENEY^{1,3}, P. EMERY², H. E. MELIKIAN^{1,3} ²Dept. of Neurobio., ¹Univ. of Massachusetts Med. Sch., Worcester, MA; ³Brudnick Neuropsychiatric Res. Inst., Worcester, MA

Abstract: The neurotransmitter dopamine (DA) critically controls movement, sleep, learning, and reward. The plasma membrane dopamine transporter (DAT) clears extracellular DA following release, thereby spatially and temporally limiting synaptic DA availability. Recent reports have identified multiple DAT coding variants in attention-deficit/hyperactivity disorder, infantile parkinsonism-dystonia, and autism spectrum disorder probands, illustrating DAT's critical role in DA homeostasis and DA-related behaviors. Both DAT activity and surface expression are acutely regulated by endocytic trafficking. PKC activation leads to diminished DAT surface levels, and studies from our lab have demonstrated that the small, neuronal GTPase, Rin (RIT2) and the non-receptor tyrosine kinase, Ack1, are critical factors in controlling DAT surface stability and endocytic response to PKC stimulation. However, it is unknown whether regulated DAT endocytosis impacts DA-related behaviors such as locomotion, sleep, or reward. Moreover, it is not known whether trafficking-dysregulated DAT coding variants influence DA homeostasis. For example, the DATR615C mutation, found in an autism spectrum proband, exhibits significantly enhanced basal endocytosis, however whether this mutation deleteriously affects DA-dependent behavior is unknown. The Drosophila melanogaster model system has provided novel insights into the impact of DAT dysfunction on DA-dependent behaviors. In the current study, we capitalized on the tractability of *Drosophila* to test whether perturbing DAT trafficking impacts DA-related behaviors. Overexpressing constitutively active Ric, the Drosophila Rin homolog, or knocking down Ric via RNAi inhibited PKC-mediated DAT downregulation in *Drosophila* cell lines, suggesting that dDAT and hDAT are similarly subject to Rin (or Ric)-dependent downregulation. In vivo Drosophila studies revealed decreased locomotion and decreased daytime, but not nighttime, sleep in response to either overexpressing constitutively active Ric or knocking down Ric in DAergic neurons using the TH-Gal4 driver. Ongoing and future experiments will test whether dDAT is subject to PKC-dependent surface loss, and whether this process requires Ric and/or Ric activity, in both cultured cells and ex vivo, intact Drosophila brains. Furthermore, we will investigate whether DAT trafficking dysfunction affects DA-dependent behaviors by expressing trafficking-dysregulated hDATs in a dDAT null background. Taken together, these studies comprise one of the first *in vivo* investigations testing the physiological impact of regulated DAT trafficking on DA-related behaviors.

Title: Roles for cholesterol and the isoprenylation pathway in serotonin transporter regulation

Authors: *C. MITCHELL¹, A. SCHROERING², B. K. YAMAMOTO³

¹Dept. of Pharmacol. and Toxicology, Indiana Univ., Indianapolis, IN; ²Univ. of Toledo, Toledo, OH; ³Neurosciences, Indiana Univ. Sch. of Med., Indianapolis, IN

Abstract: The serotonin transporter (SERT) localizes in cholesterol-rich microdomains within the plasma membrane. Although the role of these microdomains serves as a scaffold for phosphorylating kinases and protein-protein interactions, the role of cholesterol within these microdomains on serotonin transporter (SERT) function remains to be understood. To investigate the general role of cholesterol on SERT function, serotonergic RN46A-B14 cells were stably overexpressed with myc-tagged SERT. Cholesterol within lipid rafts were disrupted by simvastatin, an inhibitor of the rate-limiting enzyme in cholesterol synthesis, 3-hydroxy-3methyl-glutaryl-coenzyme A (HMGCoA) reductase. Serotonin (5-HT) transport activity was assayed by measurement of intracellular 5-HT content after incubation of cells with 5-HT. Simvastatin significantly increased 5-HT uptake in a dose and time-dependent manner at 24hr, 48hr, and 72hr of simvastatin exposure. The SERT inhibitor, fluoxetine blocked the enhanced uptake at each time point, indicating that simvastatin enhances 5-HT uptake in a SERTdependent manner. Cholesterol precursors downstream of HMGCoA reductase were added back into the media to determine the pathway necessary for the enhanced 5-HT uptake. Mevalonate completely blocked the enhanced uptake, and geranylgeranyl pyrophosphate partially blocked the enhanced uptake. However, the more immediate precursor to cholesterol, squalene, did not block the enhanced uptake. Results indicate that simvastatin enhances 5-HT uptake via SERT in a manner *independent* of cholesterol. The involvement of the isoprenylation pathway downstream of HMGCoA reductase is currently under investigation.

Title: Dopamine transporter activation regulates Kv2.1 cluster size and activation potential

Authors: *J. J. LEBOWITZ¹, J. A. PINO², D. O. SAMBO¹, S. STREIT¹, K. DIVITA¹, C. HENCKEL¹, M. LIN¹, G. E. TORRES², H. KHOSHBOUEI¹ ¹Dept. of Neurosci., ²Dept. of Pharmacol. and Therapeut., Univ. of Florida, Gainesville, FL

Abstract: Selective neuronal vulnerability is a pervasive phenomenon in which distinct neuronal subtypes are differently affected by a pathological burden. In the case of Parkinson's disease, the vast axonal field and high level of tonic firing activity intrinsic to dopaminergic (DAergic) neurons are thought to contribute to their degeneration. Interestingly, within the ventral midbrain, substantia nigra (SNc) DAergic neurons degenerate in the presence of Lewy bodies, while the neighboring DAergic neurons of the ventral tegmental area (VTA) are relatively spared. Because many of the data that corroborate this are from postmortem human studies, however, it is difficult to know which subtle differences between the two DAergic populations lead to the difference in vulnerability. Previous work has focused on intracellular Ca²⁺ flux and oxidative stress as important differences between the two regions, but many additional therapeutic targets remain unexplored. Altered dopamine transporter (DAT) activity is implicated in Parkinson's disease, where missense DAT mutations are directly associated with adult early-onset Parkinsonism and progressive dopaminergic neurodegeneration. Kv2.1 is a voltage gated potassium channel that has also been shown to be dysregulated in a mouse model of neurodegeneration. Both modulators of neuronal excitability, Kv2.1 and DAT were shown to co-immunoprecipitate and the association was confirmed via FRET microscopy. Importantly, we found that the degree of colocalization is cell region specific in the SNc, but not the VTA. Functional analysis found that methamphetamine-induced DAT activation reduced the interaction between the two proteins and decreased Kv2.1 cluster size which is directly coupled to activation potential changes and thus neuronal excitability. Recent data from our lab and the literature suggest the sigma-1 receptor (SIG-1R), which is a chaperone protein that reduces oxidative stress, not only decreases DAT activity, but also interacts with Kv2.1 and DAT. Ongoing experiments are exploring the nature and mechanism of DAT regulation of Kv2.1

activation potential changes in the SNc vs.VTA and SIG-1R as a novel therapeutic target to confer protection from degeneration in the SNc.

Title: Dopamine transporter interactome reveals differential interaction with DJ-1 when exposed to METH

Authors: *N. BERRYMAN¹, S. INGRAM², S. ELUHU², B. OGHIDE¹, T. RANA², H. KHOSHBOUEI³, J. S. GOODWIN²

Abstract: Extracellular dopamine (DA) concentrations are tightly regulated by reuptake through the dopamine transporter (DAT). Methamphetamine (METH) - a widely abused psychostimulant - is a substrate for DAT, disrupting dopamine homeostasis by inhibiting DA reuptake and by triggering the reverse transport of DA into the synaptic cleft. DA dysregulation can be detrimental to proper brain function and has been implicated in several disease states. We postulated that DAT-interacting proteins are altered in the presence of METH, compared to control conditions, leading to the dysregulation of DAT. A proteomic-based study that employed liquid chromatography-tandem mass spectrometry (LC-MS/MS), immunoprecipitation, immunostaining and other complementary techniques, examined the interactome of DAT and

revealed an association between DJ-1 and DAT in control conditions, but a dissociation of DJ-1 and DAT in METH conditions. DJ-1, a multifunctional protein also known as PARK7, inhibits the aggregation of α -synuclein and is widely studied for its involvement in Parkinson's Disease. Recently, it was reported that DJ-1 interacts with DAT to increase DA uptake; overexpression led to enhanced uptake of DA and knockdown lead to decreased uptake. Based on this evidence, we examined how DJ-1 affects DAT function in the presence of METH, contributing to the dysregulation of the transporter. We found that METH decreased DJ-1 interaction with DAT and altered DAT function.

Title: Differential site-specific serotonin transporter phosphorylation governs kappa-opioid receptor mediated biphasic serotonin clearance

Authors: *S. RAMAMOORTHY, S. SUNDARAMURTHY, L. D. JAYANTHI Pharmacol. and Toxicology, Virginia Commonwealth Univ., Richmond, VA

Abstract: Upregulation of dynorphin/kappa-opioid receptor (KOR) systems has been implicated in the pathogenesis of depression and the mood dysregulation that charactizes withdrawal from cocaine and other drugs of abuse. Serotonin (5-HT) plays an important role in regulating the KOR systems impotantly, KOR proteins are expressed on serotonergic neurons and terminals. Presynaptic 5-HT transporter (SERT) activity controls serotonergic neurotransmission by rapid reuptake of released 5-HT, thus playing an important role in several behavioral and physiological functions. We previously demonstrated that KOR activation down-regulates SERT activity through decreasing active surface SERT, enhanced SERT internalization, decreased SERT delivery, and increased SERT phosphorylation via Akt and CaMKII dependent siganling pathways (PMC5148672). Our current studies showed that depending on Thr276-Ser277-SERT phosphorylation, KOR activaton differentially affects SERT function and trafficking. KOR-Akt induced decreased SERT function via Thr276 phosphorylation, while KOR-CaMKII signaling increased SERT function via Ser277 phosphorylation. Collectively, our studies revealed a novel mechanism of KOR-mediated biphasic regulation of SERT functions associated with differential SERT phosphorylation of Thr276 and Ser277- sites via Akt and CaMKII respectively. Moreover, these findings identify a novel mechanism by which KOR regulates 5-HT neurotransmission via phosphorylation dependent SERT regulation, and suggesting that SERT dysregulation/phosphorylation may be one mechanism underlying dynorphin/KOR-mediated alterations in mood and affect. Findings from these studies will enhance our understanding of the neural substrates upon which dynorphin/KOR act to regulate behaviors, aid in the development of effective pharmacological agents for the treatment of addiction, depression and provide new insights into the role of SERT phosphorylation in regulating synaptic 5-HT clearance and behavior.

Title: Interaction of neurokinin signaling and norepinephrine transport in amphetamine behavior

Authors: *L. D. JAYANTHI, P. MANNANGATTI, S. RAMAMOORTHY Pharmacol. & Toxicology, Virginia Commonwealth Univ., Richmond, VA

Abstract: A close anatomical and physiological association exists between neurokinin and noradrenergic systems in the brain. The neurokinin 1 receptor (NK1R) and its endogenous ligand substance P have been linked to stress and drug-abuse. Animal studies indicate therapeutic benefits of NK1R antagonists in treating stimulant abuse and thus, the utility of NK1 directed therapeutics is an area of interest. Substance P is released in the rat ventral striatum following amphetamine (AMPH) and is known to enhance acute stimulatory effects of AMPH. On the other hand, NK1R antagonists decrease psychostimulant-induced locomotor activation. Our recent studies have shown that aprepitant, a clinically used NK1R antagonist, attenuates conditioned place preference (CPP) and locomotor activation induced by AMPH and cocaine (PMC5266628). The psychostimulants cocaine and AMPH target all three monoamine transporters and AMPH has nearly equal affinity for the norepinephrine and dopamine transporters (NET & DAT). We and other investigators have shown that AMPH as well as NK1R activation downregulate both NET and DAT. Here we examined whether NK1R-mediated NET or DAT regulation is involved in AMPH-induced behaviors. Our results show that while aprepitant attenuated AMPH-induced CPP in the wild type and DAT knockout (KO)

mice, it failed to affect AMPH-CPP in the NET KO mice. Our previous work demonstrated that substance P and AMPH mediated NET downregulation is dependent on the transporter T258/S259 trafficking motif (PMID16740633; PMC2939970) and that NET regulation by NK1R is facilitated by NET-NK1R protein-protein interactions (PMC3789959). A single bilateral intraaccumbal microinjection of TAT-T258/S259-WT peptide but not the T258A/S259A-mutant peptide prior to post-conditioned test significantly attenuated AMPH-induced CPP expression and CPP reinstatement in rats. Collectively, our data indicate a role for NK1R-mediated T258/S259-dependent NET regulation in AMPH-induced behaviors. Since the sequence surrounding T258/S259 motif is identical in NET and DAT, ongoing studies using NET and DAT KO mice are exploring the utility of TAT-T258/S259 peptide strategy to delineate the role of T258/S259-dependent NET regulation in AMPH mediated behaviors.

Title: Regulation of the sigma-1 receptor multimerization

Authors: *W. C. HONG

Dept. of Pharmaceut. Sci., Butler Univ., Indianapolis, IN

Abstract: Following the initial proposal of sigma receptors in 1976 and subsequent molecular cloning of the sigmal receptor ($\sigma_1 R$) in 1996, extensive studies have shown that $\sigma_1 R$ is a unique membrane protein that may serve as a molecular chaperone. In 2016 a breakthrough on the crystal structure of $\sigma_1 R$ revealed a homotrimer, with each protomer containing a single transmembrane domain, a cytoplasmic ligand-binding domain and trimerization interface. Because oligomerization of membrane proteins may regulate their function, we devised a novel biochemical method to examine $\sigma_1 R$ multimerization. Epitope-tagged $\sigma_1 R$ from transfected cells was solubilized using mild detergents, separated in non-denaturing gels, and detected by immunoblotting. Immuno-reactive signals were displayed as three bands, likely corresponding to $\sigma_1 R$ monomer, dimer, and multimer based on their apparent electrophoretic mobility. Multimerization was abolished in a splice variant of $\sigma_1 R$ lacking amino acid residues 119 - 149. Further, pH values in the lysis buffer substantially affected $\sigma_1 R$ multimerization, suggesting that

side chain protonation of certain amino acid residues may impact on $\sigma_1 R$ protomer interaction. Importantly, $\sigma_1 R$ multimers were significantly decreased by treatment with (+)-pentazocine (agonist) but increased by BD1063 (antagonist), suggesting that oligomerization of $\sigma_1 R$ is regulated by binding of agonists or antagonists in a distinct manner. Ligand binding also appeared to alter multimerization of $\sigma_1 R$ on the cell surface, as detected by surface biotinylation assays. Since $\sigma_1 R$ has been shown to modulate the function of various membrane proteins, we hypothesize that $\sigma_1 R$ ligands differentially regulate the formation of $\sigma_1 R$ monomers and affect their dynamic interactions with client proteins.

Title: Slc22a3, a potential second presynaptic serotonin transporter

Authors: *M. ARNOLD¹, A. O. WILLIAMS², A. AGRAWAL², H. E. DAY², J. TALBOOM⁴, M. ORCHINIK⁵, C. A. LOWRY³

¹Integrative Physiol., ³Dept. of Integrative Physiol. and Ctr. for Neurosci., ²Univ. of Colorado Boulder, Boulder, CO; ⁵Sch. Life Sci., ⁴Arizona State Univ., Tempe, AZ

Abstract: Brain serotonergic systems play a role in cognitive and affective function and have been implicated in the pathophysiology of trauma-related, anxiety, and affective disorders. Drugs that block serotonin reuptake into presynaptic terminals are used widely in the treatment of these disorders, and therefore understanding mechanisms underlying presynaptic clearance of serotonin is of major clinical interest. The neurotransmitter serotonin is cleared from brain synapses by the presynaptic sodium-dependent, high-affinity, low-capacity serotonin transporter, solute carrier family 6 (neurotransmitter transporter) member 4 (Slc6a4). However, evidence suggests possible expression of a second serotonin transporter, the sodium-independent, lowaffinity, high-capacity serotonin transporter, organic cation transporter 3 (Oct3; Slc22a3), in serotonergic neurons. However, it is unclear if Slc22a3 localizes to the presynaptic serotonergic terminal, or to other cellular compartments within these cells, and, furthermore, if it co-localizes to the same presynaptic terminals as Slc6a4. For example, recent studies at the electron microscope level have identified Slc22a3 expression on neuronal and glial endomembranes, including Golgi, mitochondrial and nuclear membranes. Using a dual label fluorescence in situ hybridization histochemistry approach we demonstrated overlapping expression patterns of tryptophan hydroxylase 2 (Tph2), the rate-limiting enzyme in the biosynthesis of brain serotonin, and Slc22a3 mRNA expression within the rat dorsal raphe nucleus. To understand Slc22a3

protein location on the presynaptic terminals we used a quadruple label immunofluorescence for Slc6a4, Slc22a3, postsynaptic density protein 95 (Psd-95) and DAPI (4',6-diamidino-2-phenylindole), using n-super-resolution microscope (n-SIM) imaging. We were able to demonstrate that Slc22a3 and Slc6a4 co-localize in the same presynaptic terminals within the rat dorsal raphe nucleus, the main source of serotonergic projections to forebrain limbic structures. These findings highlight the need to understand the dynamic interactions between Slc6a4 and Slc22a3 in controlling serotonin reuptake and serotonergic signaling, physiology, and behavior in health and disease.

Title: Investigation of IL-1 β activation of serotonin transporter-mediated serotonin clearance *In vivo*

Authors: *N. L. BAGANZ¹, M. J. ROBSON¹, W. A. OWENS², L. C. DAWS², R. D. BLAKELY¹

¹Biomed. Science, Charles E. Schmidt Col. of Med. and Brain Inst., Florida Atlantic Univ., Jupiter, FL; ²Cell. and Integrative Physiol., Univ. of Texas Hlth. Sci. Ctr. at San Antonio, San Antonio, TX

Abstract: Central serotonin (5-HT) neurotransmission and immune system activation have been linked to the etiology of multiple psychiatric disorders, including depression and autism. Previously, we showed that peripheral immune system activation in mice using the endotoxin lipopolysaccharide (LPS) rapidly (30-60 min) increases 5-HT clearance, and produces depressive-like effects on behavior. These effects are lost in constitutive IL-1R1 knockout mice and in wild-type mice pre-treated with systemic injections of the p38 MAPK inhibitor SB203580. Moreover, we found that *in vitro* incubations of synaptosomes with IL-1β rapidly increases activity of the antidepressant-sensitive 5-HT transporter (SERT), effects absent in

synaptosomes of IL-1R1 KO mice or synaptosomes pre-treated with SB203580. These findings suggest that IL-1 β , via p38 MAPK signaling to SERT, mediates the ability of peripheral LPS to enhance rates of CNS 5-HT clearance. To validate this hypothesis, we performed *in vivo* chronoamperometry in the dorsal hippocampus (CA3) of mice, evaluating the impact of locally applied p38 MAPK activator anisomycin, as well as IL-1 β , to enhance clearance of 5-HT. As predicted, anisomycin rapidly (2 minutes) enhanced 5-HT clearance, with effects blocked by prior application of SB203580. Similarly, local IL-1 β rapidly (10 minutes) enhanced 5-HT clearance. Ongoing studies seek to test the actions of both systemic LPS and local IL-1 β to modulate 5-HT clearance in mice generated that allow for 5-HT neuron-specific elimination of IL-1R1. Together, these experiments will further specify pathways by which peripheral and CNS inflammatory signaling can rapidly alter brain extracellular 5-HT homeostasis.

Title: Structural, biochemical and functional evidence of a biased conformation of serotonin transporters imposed by an autism-associated mutation

Authors: *M. A. QUINLAN^{1,2}, D. KROUT³, M. J. ROBSON², L. K. HENRY³, R. D. BLAKELY²

¹Vanderbilt, Nashville, TN; ²Charles E. Schmidt Col. of Med. and Brain Inst., Florida Atlantic Univ., Jupiter, FL; ³Biomed. Sci., Univ. of North Dakota Sch. of Med. and Hlth. Sci., Grand Forks, ND

Abstract: The serotonin (5-HT) transporter (*Slc6a4*, SERT) plays a crucial role in regulating the extracellular availability of 5-HT. Current models suggest that SERT, like other solute carriers (SLC), translocate substrate across the membrane through a multi-state process that results in alternating exposure of the 5-HT binding site to the extracellular and cytoplasmic spaces. We hypothesize that population of these states can be biased by natural regulatory stimuli as well as disease-associate mutations, leading to a change in 5-HT affinity, 5-HT uptake velocity and/or

efflux capacity, independent of SERT surface trafficking. Here we report our efforts to determine if these hypotheses can explain the change in transport function associated with the autismassociated SERT coding variant Gly56Ala, using both transfected cells and the SERT Ala56 mouse model. In one effort we are using the substituted cysteine accessibility method to compare Cys109 and Cys277 accessibility in WT hSERT and hSERT Ala56, expressed in HEK-MSR cells. Our data reveal that the $t_{1/2}$ of methanethiosulfonate reagent inactivation of hSERT Ala56 is increased for Cys109 and decreased for Cys277 compared to WT hSERT, consistent with stabilization of hSERT Ala56 in an outward facing conformation. We are also examining the sensitivity of the N-terminus to digestion by trypsin. Previous studies show that when SERT is stabilized in an outward facing conformation, the N-terminus of the transporter is less sensitive to trypsin digestion, compared to inward facing conformations. Our findings indicate that the Nterminus of hSERT Ala56 is less sensitive to tryptic cleavage compared to WT hSERT. These findings are consistent with hSERT Ala56 as biased in an outward facing conformation. To examine conformational bias with native SERT Ala56, we are assessing fenfluramine-induced 5-HT efflux from [³H]5-HT preloaded brain slices, prepared from mice expressing WT SERT or SERT Ala56. Our findings indicate that slices from SERT Ala56 mice demonstrate a dosedependent sensitivity for fenfluramine-mediated [³H]5-HT efflux. Since 5-HT efflux is believed to be favored by an inward facing conformation, a decreased efflux sensitivity to fenfluramine adds further support or the hypothesis that SERT Ala56 is stabilized in an outward facing conformation. These studies are being complemented by candidate and proteomic analyses of SIPs to evaluate the contribution of altered protein associations in stabilizing SERT Ala56 conformations, as well as by studies of IL-1R1/p38A MAPK signaling, which like SERT Ala56, enhances SERT 5-HT affinity and increases transport function at low substrate concentrations.

Title: Transgenic mice carrying a serine to alanine mutation at residue 1928 of the voltage-gated calcium channel $Ca_V 1.2$ display strong, sex-dependent differences in behavior related to learning, memory, and stress

Authors: *K. E. IRETON¹, J. W. HELL² ¹Neurosci., ²Dept. of Pharmacol., UC Davis, Davis, CA

Abstract: The voltage-gated calcium channel (VGCC) Cav1.2 is the most abundant VGCC in the brain as well as the heart, and influences cellular excitability, gene expression, and synaptic plasticity in neurons. Manipulations of its activity and expression affect learning-, stress-, and reward-seeking-related behaviors in rodents, and genome wide association studies in humans have identified mutations in its gene CACNA1C as risk factors for bipolar disease and schizophrenia, besides the known role of a specific mutation in Timothy syndrome, a fatal condition causing severe mental and cardiac dysfunction. Cav1.2 channel activity is known to be upregulated by norepinephrine via β -adrenergic receptors (β -AR). A mutant mouse line with a mutation at serine 1928 to alanine (S1928A), the most important site of phosphorylation by PKA downstream of β-AR signaling, was previously found to display no apparent cardiac or obvious neurological deficits, indicating S1928 phosphorylation was not needed to regulate CaV1.2 activity in the heart. However, our lab has recently published that strong differences exist in channel activity regulation and induction of theta tetanus LTP in mutant hippocampal neurons, in culture and brain slice, highlighting a surprising dichotomy between regulation of Cav1.2 between brain and heart. We hypothesized that due to the mutant deficit in LTP induction, they ought to display at least a mild deficit in some long-term memory-dependent behaviors compared to wildtypes. Much to our surprise, we found strong, but sex-dependent, enhancements in mutant short- and long-term learning behavior, compared to litter-matched controls. The magnitude of the changes in behavior roughly correlated with the stress of the behavioral assay, indicating enhanced stress resilience in mice lacking the S1928 phosphorylation site for β-AR regulation. We continue to test the mice in further behavioral assays, including fear conditioning for a direct test of stress-related learning. Our initial results indicate a profound physiological role of CaV1.2 in regulating rodent learning, memory, and stress-response behaviors, and may add to the growing body of evidence that CaV1.2 could be a promising target for pharmaceutical intervention in certain human neurological disorders.

Title: Theta-burst firing of a single dentate granule cell induces presynaptic LTP at mossy celldentate granule cell synapse

Authors: *K. NASRALLAH¹, P. E. CASTILLO²

¹Rose F. Kennedy Ctr., Albert Einstein Col. of Med., Bronx, NY; ²Albert Einstein Coll Med., Bronx, NY

Abstract: The dentate gyrus, a major input area of the hippocampus, contains two types of excitatory neurons: dentate granule cells (GCs) and hilar mossy cells (MCs). MCs receive inputs from GCs and project back to GCs locally (intralamellar), contralaterally, and along the longitudinal (dorsoventral) axis of the hippocampus, thereby establishing an associative positivefeedback loop (GC-MC-GC). Such projections may be important to connect the dorsal hippocampus, primarily involved in spatial memory, with the ventral hippocampus, primarily involved in emotional memory. However, how MCs contribute to dentate gyrus function remains poorly understood. Here, we studied the dynamic properties of MC-GC synapses using rodent hippocampal slices. We found that theta-burst firing (TBF) of a single GC by direct depolarization is sufficient to induce LTP at MC-GC synapses (TBF-LTP), but not at medial perforant path excitatory inputs onto GCs. While the induction of TBF-LTP requires postsynaptic calcium rise in an NMDA receptor-independent manner, this plasticity is expressed presynaptically as indicated by a decrease in paired-pulse ratio, coefficient of variation and failure rate. Taken together, these observations strongly suggest the involvement of retrograde signaling in TBF-LTP. Moreover, TBF-LTP was abolished by the TrkB antagonist ANA-12 (15 µM) and conditional TrkB deletion from GCs, as well as by bath application of the PKA inhibitors H89 (10 μ M) and myristoylated PKI₁₄₋₂₂ amide (1 μ M), but not by intracellularly loading GCs with PKI₆₋₂₂ amide (2.5 µM). Thus, TBF-LTP requires postsynaptic BDNF/TrkB and presynaptic cAMP/PKA signaling. By increasing the strength of MC inputs onto GCs, TBF-LTP could facilitate information transfer between dorsal and ventral hippocampus, and contribute to memory formation and epilepsy.

Title: The effect of extracellular glutamate on synaptic plasticity and its relevance to neurodegenerative disease

Authors: J. R. BARNES, *M. P. PARSONS

Biomed. Sci., Mem. Univ., St John's, NL, Canada

Abstract: Recent literature on the mechanisms of synaptic plasticity has highlighted a dichotomous role of synaptic and extrasynaptic NMDA receptor (exNMDAR) activation, with the former promoting long-term potentiation (LTP) and the latter inhibiting it. Glutamate transporters rapidly clear glutamate from the extracellular space, thereby preventing exNMDAR overactivation, and many lines of evidence suggest a dysfunction of the glutamate transporter proteins in various neurodegenerative diseases associated with cognitive decline. Thus, an attractive and well-cited hypothesis states that glutamate transporter dysfunction underlies the LTP and cognitive impairments in disease states including Alzheimer Disease (AD). However, the precise relationship between the spatiotemporal dynamics of extracellular glutamate and synaptic plasticity has yet to be investigated. Here, we use a novel optogenetic sensor of glutamate, termed iGluSnFR, to monitor extracellular glutamate dynamics in real-time (200 Hz) in the mouse hippocampus during standard LTP-inducing protocols. A range of concentrations of various glutamate transporter blockers were used to impair glutamate clearance during LTP induction, allowing us to characterize the relationship between glutamate uptake and LTP magnitude; these results were compared to those obtained for amyloid beta, a toxic protein in the AD brain that is thought to impair LTP in part by reducing glutamate transporter function. Interestingly, we found concentrations of the GLT-1 glutamate transporter inhibitor DHK that dramatically impaired glutamate clearance rates yet had no effect whatsoever on LTP magnitude. Surprisingly, LTP was not impaired until glutamate clearance rates were slowed well over twofold with TBOA, a nonselective glutamate transporter blocker. Lastly, Aβ had no significant effect on glutamate clearance rates, yet potently suppressed LTP. Overall, these data indicate that synaptic plasticity is not as sensitive to glutamate spillover as previously thought, and that the degree of transporter impairment required to inhibit LTP is likely not reached in physiological or even pathological conditions.

De Recherche Univ. Laval Robert-Giffard, Quebec, QC, Canada; ⁵Cell. Neurobio., Univ. Laval, Quebec, QC, Canada

Abstract: Hippocampal neurons in the adult brain express the secreted chemotropic guidance cue netrin-1. We show that membrane depolarization and long-term potentiation (LTP) induction triggers dendritic post-synaptic secretion of netrin-1. Using selective genetic deletion, we demonstrate that neuronal expression of netrin-1 is required for activity-dependent LTP and hippocampal-dependent spatial memory. We show that application of exogenous netrin-1, in the absence of high frequency stimulation, is sufficient to potentiate excitatory glutamatergic transmission at hippocampal Schaffer collateral synapses. Netrin-1 functions downstream of NMDAR activation to engage DCC-dependent synaptic recruitment of GluA1 receptors via activation of CaMKII. Further, netrin-1 increases the volume of thin-type dendritic spines and the frequency of miniature AMPAR-mediated excitatory postsynaptic currents with no change in presynaptic function. Using minimal-intensity stimulation, we demonstrate that netrin-1 unmasks silent glutamatergic synapses. These findings indicate that activity-dependent netrin-1 release recruits GluA1 AMPA receptors to unmask silent synapses in the adult brain.

Title: Ketamine induces lasting alterations of AMPA receptors and synaptic plasticity in the mesolimbic circuit

Authors: *O. SKITEVA¹, N. YAO¹, X. ZHANG², P. SVENNINGSSON², K. CHERGUI¹ ¹Physiol. and Pharmacol., ²Clin. Neuroscience, Section of Translational Neuropharmacology, and Ctr. for Mol. Med., Karolinska Institutet, Stockholm, Sweden

Abstract: Low doses of ketamine trigger rapid and lasting antidepressant effects after one injection in treatment-resistant patients with major depressive disorder. Modulation of AMPA receptors (AMPARs) in the hippocampus and prefrontal cortex is suggested to mediate the antidepressant action of ketamine and one of its metabolites (2R, 6R)-hydroxynorketamine ((2R,6R)-HNK). We have examined if ketamine and (2R,6R)-HNK affect glutamatergic transmission and plasticity in the mesolimbic system, brain regions known to play key roles in reward-motivated behaviors, mood and hedonic drive. We found that one day after the injection of a low dose of ketamine, long-term potentiation (LTP) in the nucleus accumbens was impaired. Loss of LTP was maintained for 7 days and was not associated with an altered basal synaptic transmission mediated by AMPARs and N-methyl-D-aspartate receptors (NMDARs). Inhibition of mTOR signaling with rapamycin did not prevent the ketamine-induced loss of LTP but inhibited LTP in saline-treated mice. However, ketamine blunted the increased phosphorylation of the GluA1 subunit of AMPARs at a CaMKII/PKC site induced by an LTP induction protocol. Moreover, ketamine caused a persistent increase in the phosphorylation of GluA1 at a PKA site. (2R,6R)-HNK also impaired LTP in the NAc. In dopaminergic neurons of the ventral tegmental area from ketamine- and (2R,6R)-HNK-treated mice, AMPAR-mediated responses were depressed while those mediated by NMDARs were unaltered, which resulted in a reduced AMPA/NMDA ratio, a measure of long-term synaptic depression. These results demonstrate that a single injection of ketamine or (2R, 6R)-HNK induces enduring alterations in the function of AMPARs and synaptic plasticity in brain regions involved in reward-related behaviors.

Title: NMDA receptors are specifically involved in LTP induction in late-spiking neurons of the rat visual cortex

Authors: K. JOO¹, K.-H. CHO², H.-J. JANG³, *D.-J. RHIE⁴ ¹The Catholic Univ. of Korea, Seoul, Korea, Republic of; ²The Catholic university of Korea, Seoul, Korea, Republic of; ³Catholic Univ. Korea, Seoul, Korea, Republic of; ⁴Coll Med. Catholic Univ. Korea, Seoul, Korea, Republic of

Abstract: Cortical inhibitory interneurons play important roles in development, information processing, circuit dynamics and plasticity. These inhibitory interneurons are also driven by excitatory connections and thus plasticity of the excitatory synaptic transmission on interneurons is critical to understand the cortical functions. However, subtype-specific long-term synaptic plasticity remains largely unknown. Therefore, using intracellular recordings and confocal reconstruction, we investigated the mechanism of long-term synaptic plasticity in each subtypes of inhibitory interneurons, especially in late-spiking (LS) neurons of layer 2/3 of the primary visual cortex in rats. Inhibitory interneurons were classified into four subtypes according to the electrophysiological and morphological characteristics: fast-spiking (FS), LS, burst-spiking (BS) and regular-spiking non-pyramidal (RSNP) neurons. Excitatory postsynaptic potentials were recorded by stimulation of underlying layer 4. We used different conditioning stimulation to induce long-term depression (LTD) and potentiation (LTP). All the inhibitory neurons showed LTD with low-frequency stimulation (1 Hz, 15 min) except FS neurons. LTD induced in LS neurons was blocked by intracellular application of BAPTA (10 mM) and bath application of nimodipine (10 µM), but not by bath application of D-AP5 (50 µM). Theta-burst stimulation (5 shocks at 100 Hz, 5 times at 5 Hz) did not change the synaptic efficacy in LS neurons. Tetanic stimulation (5 x 20 Hz trains for 1s at 0.5 Hz, 5 times at 2 min interval) reliably induced LTP in LS neurons as well as pyramidal neurons. LTP in LS neurons was blocked by intracellular application BAPTA and bath application of D-AP5 or nimodipine. These results suggest that LS neurons in layer 2/3 of the visual cortex exhibit bidirectional long-term changes in synaptic strength, which are dependent on the increase of intracellular calcium. NMDA receptors are specifically involved in the induction of LTP, while L-type calcium channels are involved in both types of plasticity. The bidirectional modification of synaptic transmission in LS neurons may be important in visual information processing and postnatal development. Title: PKA and Ube3a synergistically regulate SK2 synaptic expression and LTP

Authors: *J. SUN, G. ZHU, Y. LIU, R. ADHIKARI, X. HAO, C. CATO, L. HERRERA, M. BAUDRY, X. BI Western Univ. of Hlth. Sci., Pomona, CA

Abstract: The ubiquitin ligase, UBE3A, plays important roles in both brain development and function, since its deficiency results in Angelman Syndrome (AS) while its over-expression increases the risk for autism. We previously showed that Ube3a ubiquitinates SK2, a Ca^{2+} activated small conductance potassium channel, and facilitates its removal from excitatory synapses. Ube3a deficiency results in increased postsynaptic SK2 levels, thereby effectively inhibiting NMDAR activation and LTP induction. SK2 levels in cell membranes are also regulated by protein kinase A (PKA); PKA phosphorylates SK2 in its C-terminal domain, facilitating its endocytosis. Here, we report that activation of PKA by forskolin (FSK) in hippocampal slices from AS mice significantly improves theta burst stimulation (TBS)-induced LTP by removing synaptic SK2 from synaptic membranes. FSK treatment also prevented the LTP enhancement of apamin, a SK2 blocker, in AS mice. Western blot analyses indicated that PKA activation reduced SK2 levels in hippocampal membrane fractions from AS mice. While TBS was unable to induce LTP in hippocampal slices from AS mice, a second TBS (TBS2) applied 15 min after the first TBS (TBS1) successfully induced LTP; immunofluorescence staining results showed that TBS1 induced a significant reduction in the percentage of SK2immunopositive synapses in both WT and AS mice 15 min later. Furthermore, incubation of hippocampal slices with KT5720, a cell-permeable specific PKA inhibitor, blocked TBS2induced LTP in AS mice, indicating that PKA-mediated SK2 removal could compensate for the lack of Ube3a-mediated SK2 removal. Subsequent experiments showed that FSK treatment not only increased SK2 phosphorylation but also its ubiquitination, suggesting that PKA and Ube3a interact to regulate SK2. Mutation of the PKA sites Ser568-570 to alanine (non-phosphorylatable 3S/A-SK2) abolished the effect of FSK on SK2 ubiquitination in COS-1 cells, while mutation of Ser568-570 to aspartate (phosphomimetic 3S/D-SK2) enhanced SK2 ubiquitination. Finally, in *vitro* ubiquitination experiments with GST-3S/D-SK2 showed that phosphomimetic mutations significantly increased SK2 ubiquitination. Our results indicate that both Ube3a-mediated ubiquitination and PKA-induced phosphorylation stimulate SK2 endocytosis, and that PKA and Ube3a synergistically regulate synaptic SK2 levels. The complex interactions between PKA and Ube3a in the regulation of SK2 synaptic levels might provide new tools to for developing new treatments for AS patients as well as various forms of autism.

Title: The Octopus vulgaris LTP expression and maintenance is mediated by activity dependent long-term elevation in NO concentration

Authors: *B. HOCHNER¹, N. STERN-MENTCH^{1,2}, N. NESHER², T. SHOMRAT², A. L. TURCHETTI-MAIA¹

¹Dept of Neurobiology, Hebrew Univ., Jerusalem, Israel; ²The Ruppin Academic Center, Sch. of Marine Sci., Michmoret, Israel

Abstract: The Octopus vulgaris vertical lobe (VL) is organized as a fan-out fan-in network. The fan-out glutamatergic synaptic connection possess a robust presynaptic, NMDA-independent, activity-dependent LTP. The VL LTP is important for the acquisition of long-term memory outside the VL (Shomrat T. et al 2008). We have previously shown that the presynaptic expression of LTP involves activation of nitric oxide synthase (NOS), and that a nitric oxide (NO)-dependent 'molecular switch' is responsible for the very long LTP maintenance (>10h) (Turchetti-Maia et al SFN 2016). This molecular switch seems to replace the common protein synthesis dependent LTP maintenance as 20µM anisomycin, which effectively blocks protein synthesis in octopus brain, neither blocked LTP induction nor its long-term expression, while NOS inhibitors reversibly blocked LTP expression. The presence of NOS in the VL is further supported by the intense positive NADPH-d labeling in the VL neuropil. Unexpectedly, our current results do not support the involvement of the common NO dependent cGMP cascade in the VL LTP, as none of the treatments that aim at intervening with this cascade, like inhibitors of guanylyl cyclase, cGMP analogs and phosphodiesterase inhibitors, had an effect on LTP expression. Moreover, NO-donors and NO-scavengers that can modulate low concentration ranges of NO (<nM), and thus are effective in the regulation of the cGMP cascade, had no effect on LTP expression. These negative results suggest that NO might function at higher concentrations, similar to those needed for the direct non-enzymatic proteins s-nitrosylation. To test the feasibility of such mechanism we adapted Dias C. et al (2016) electrochemical method to measure NO amperometrically in the VL neuropil. The results showed that induction of LTP either by tetanization or by phorbol ester are accompanied by an increase in the amperometric

signals that correspond with the oxidation peak potential of NO (750 mV), an increase which is indeed at the μ M range. These findings support our previous conclusion that LTP expression is mediated by a constitutive elevation in NO concentration and further suggest that this elevation is to a relatively higher μ M range. In summary, our amperometric results, together with the abundant NADPH-d staining of the VL neuropil, suggest that LTP is mediated by a higher concentration range of NO that takes place at synaptic regions of the VL. We therefore hypothesize that a process such as s-nitrosylation, which is activated by a relatively high NO concentration, mechanistically could serve as an effective local retrograde message for ensuring specificity in presynaptic Hebbian plasticity.

Title: Activity-dependent plasticity of synaptic zinc signaling in the dorsal cochlear nucleus - A novel synaptic plasticity mechanism

Authors: *N. W. VOGLER, T. TZOUNOPOULOS

Dept. of Otolaryngology, Univ. of Pittsburgh, Pittsburgh, PA

Abstract: In many brain areas, such as the neocortex, limbic structures, and the auditory brainstem, glutamatergic nerve terminals also contain zinc in their synaptic vesicles (synaptic zinc). In the dorsal cochlear nucleus (DCN), an auditory brainstem nucleus, synaptic zinc is released from glutamatergic parallel fiber synapses. Synaptically released zinc inhibits presynaptic glutamate release by recruiting endocannabinoid signaling, and it also inhibits postsynaptic NMDA and AMPA receptors (NMDARs/AMPARs), thus functioning as a major inhibitory modulator of excitatory synaptic strength (Perez-Rosello et al., 2013; Anderson et al., 2015; Kalappa et al., 2015). This inhibition is activity-dependent, because vesicular zinc levels are reduced following sound exposure (Kalappa et al., 2015). However, the signaling mechanisms underlying this plasticity remain unknown. To study these mechanisms, we employed *in vitro* electrophysiological recordings in DCN brain slices. Application of the extracellular zinc chelator ZX1 (100μM) potentiates AMPAR and NMDAR EPSCs evoked by

stimulation of zinc-rich parallel fibers, demonstrating AMPAR/NMDAR inhibition by synaptic zinc. High-frequency stimulation (HFS, 3 x 100 Hz) of parallel fibers eliminates potentiation by ZX1, indicating activity-dependent plasticity of zinc-mediated inhibition (zinc plasticity). Zinc plasticity is NMDAR-independent, because it is unaffected by the NMDAR antagonist APV (50μ M). However, zinc plasticity is blocked by the metabotropic glutamate receptor (mGluR) antagonist MCPG (500μ M), and the Type 1-specific mGluR antaonists MPEP (4μ M) and LY367385 (100μ M). Additionally, it is blocked by the intracellular calcium buffer BAPTA (10mM). Therefore, zinc plasticity requires activation of Type 1 mGluRs and increases in postsynaptic calcium. Furthermore, the application of CPA (20μ M), an inhibitor of SERCA ATPase which depletes calcium from intracellular stores, is sufficient to induce zinc plasticity. Our results demonstrate activity-dependent plasticity of zinc-mediated inhibition at DCN parallel fiber synapses. Zinc plasticity is NMDAR-independent, but involves activation of Type 1 mGluRs and release of calcium from intracellular stores. Together, these results reveal a novel synaptic plasticity mechanism that modulates zinc-mediated inhibition of glutamatergic neurotransmission.

Title: Projection-specific bias in CB₁R signaling and function in hippocampus: Implications for memory encoding

Authors: *C. D. COX¹, W. WANG², Y. JIA⁴, L. C. PALMER⁴, K.-M. JUNG³, D. PIOMELLI⁵, C. M. GALL⁴, G. LYNCH⁴

¹Anat. and Neurobio., UCI, Irvine, CA; ²Dept. of Anat. and Neurobio., ³Anat. & Neurobio., Univ. of California Irvine Dept. of Anat. and Neurobio., Irvine, CA; ⁴Anat. and Neurobio., Univ. of California, Irvine, CA; ⁵Fondazione Inst. Italiano Di Tecnologia, Genova, Italy

Abstract: Recent studies have shown that the lateral perforant path (LPP) afferents to hippocampus exhibit an unusual form of LTP: in contrast to potentiation in hippocampal field CA1, LPP LTP is dependent upon postsynaptic generation of the endocannabinoid 2-

archadonolglycerol (2-AG), presynaptic CB_1 receptor (CB_1R) signaling to actin, and increased neurotransmitter release. These findings raise questions as to the mechanisms through which 2-AG and CB1 predominantly suppress excitatory transmission in the CA1 Schaffer-commissural (S-C) system but increase neurotransmitter release in LPP innervation of the dentate gyrus. As recent work has shown that CB₁R signaling to the synaptic vesicle protein Munc18-1 is critical for CB₁-mediated release suppression, we tested effects of CB₁R agonist WIN55212-1 (WIN) in the two hippocampal subfields. WIN infusion (in the presence of picrotoxin) depressed S-C synaptic responses, blocked LTP and increased presynaptic phospho (p) Munc18-1 levels in field CA1. In contrast, WIN infusion increased the amplitude of *lpp*LTP without effect on LPP baseline responses or presynaptic pMunc18-1 levels in the LPP field. CB₁ has been reported to work cooperatively with integrins to signal through focal adhesion kinase (FAK) and RhoA kinase (ROCK) and influence the actin cytoskeleton. In line with this, we found WIN infusion increased presynaptic pFAK and pROCK levels in the LPP field. Similarly, high frequency stimulation used to induce *lpp*LTP caused a CB₁R-dependent increase in pFAK and pROCK in LPP terminals. These findings indicate that there is projection-specific bias in CB₁R signaling and function in hippocampus with predominant signaling (i) through the ERK1/2 - Munc18-1 pathway, leading to direct suppression of excitatory synaptic transmission, in field CA1 and (ii) through a FAK - ROCK cascade leading to enhanced neurotransmitter release in the LPP. These results further suggest that forms of learning that depend upon the LPP (cue identity, semantic information) may engage and depend upon the FAK/ROCK cascade. This was tested in rats trained in a two-odor discrimination paradigm known to depend on the LPP. We found that odor discrimination learning caused a CB₁R-dependent increase in presynaptic pROCK in the LPP field. Together these findings show sharp differences in the bias of CB₁R signaling at two major excitatory relays in hippocampal circuitry and suggest a neurobiological basis for discrete cannabinoid effects on learning.

Title: Facilitating endocannabinoid signaling restores a component of episodic memory in Fmr1-KO mice

Authors: *C. M. GALL, W. WANG, B. M. COX, Y. JIA, A. A. LE, C. D. COX, K. M. JUNG, D. PIOMELLI, G. LYNCH Anat. and Neurobio., Univ. of California, Irvine, CA

Abstract: Autism spectrum disorders frequently entail disturbances in episodic memory but the neurobiological basis of this intellectual disability is not understood. The hippocampus is critical for the formation and use of episodic memory, with cue identity ('what') information relayed to hippocampus via the lateral perforant path (LPP). We have shown that in normal rats and mice the LPP afferents of the dentate gyrus exhibit an unusual form of long-term potentiation (*lpp*LTP) that depends on the CB₁ receptor and signaling by the endocannabinoid 2archadonolglycerol (2-AG) at excitatory synapses (Wang et al., 2016). The present electrophysiological analyses of acute hippocampal slices show that *lpp*LTP is profoundly impaired in Fmr1-KOs relative to wild type mice. The plasticity impairment was substantially greater than for other major afferents to the dentate gyrus granule cells or in hippocampal field CA1. Behavioral studies demonstrated that learning to recognize odors presented in a series depends on the LPP and that such serial odor learning is severely impaired in the KOs. Acquisition of odor identity outside of the sequence was not affected by the mutation. Finally, we show that multiple strategies for enhancing 2-AG signaling in Fmr1-KO mice, rescues both *lpp*LTP and serial odor learning. Thus, manipulations that target endocannabinoid transmission in hippocampus restore plasticity in a pathway critical to the encoding of the semantic element of an episode and thereby rescue an important component of cognition in Fragile X model mice.

Title: Long-term potentiation of inhibitory inputs onto VTA GABA neurons

Authors: *T. M. NUFER¹, J. G. EDWARDS² ¹Physiol. and Developmental Biol., ²Brigham Young Univ., Provo, UT

Abstract: The mesolimbic dopamine circuit, and in particular the ventral tegmental area (VTA), processes reward and motivational behaviors. The VTA contains dopaminergic cells thought to mediate reward as well as GABAergic inhibitory cells that regulate dopamine cell activity. In response to drug exposure, synaptic connections of this circuit can be rewired via synaptic plasticity—a phenomenon thought be responsible for the pathology of addiction. Therefore, an understanding of normal and pathologic synaptic plasticity in VTA neural circuitry is critical if we are to better understand and treat addiction. While much is known about dopamine neuron plasticity, less is known regarding the potential for and type of plasticity exhibited by VTA GABA cells. VTA GABAs receive inhibitory input from outside the VTA, however we know little about these inputs and their synaptic plasticity. A recent study demonstrated a novel form of GABAergic long-term potentiation (LTP) onto VTA GABA cells, which was presynaptic and dependent on voltage-gated calcium channels and D1 dopamine receptors (Bocklisch et al., 2013, Science). We have confirmed this GABA LTP in VTA GABA cells from GAD67/GFPpositive mice using whole cell electrophysiology. Paired pulse ratios suggest a presynaptic mechanism, as noted previously (baseline, 1.20 ± 0.19 ; after stimulation, 0.79 ± 0.14 ; n=9, p=0.068). Therefore, we examined several presynaptic mediators of plasticity, including cannabinoid receptor 1 (CB1) and nitric oxide. In CB1 knock-out animals (n=6) or in the presence of the CB1 antagonist AM251 (n=4), significant LTP was still exhibited (p < 0.05). The nitric oxide synthase antagonist L-NAME also failed to block the observed LTP (n=4, p < 0.05), and the nitric oxide donor SNAP failed to induce plasticity (n=5, p > 0.05). This LTP was also independent of D2 dopamine receptors, as the D2 antagonist eticlopride did not block LTP (n=5). However, surprisingly this LTP appears to be NMDA-dependent, as it was blocked by the NMDA receptor antagonist APV (n=4; p > 0.05). Collectively, our data suggest a presynaptic mechanism of LTP that is yet to be fully determined, but production of a retrograde factor produced from excitatory synaptic activation is likely involved.

Title: Synaptic plasticity of interlamellar ca1 network of hippocampus

Authors: *H. TETTEH¹, D. SUN², J. SU¹, S. YANG¹, S. YANG² ¹Dept. of Biomed. Sci., City Univ. of Hong Kong, Kowloon, Hong Kong; ²Nano-bioengineering, Incheon Natl. Univ., Incheon, Korea, Democratic People's Republic of **Abstract:** The connection along the longitudinal axis of the CA1 hippocampal cells has not received attention while most studies have looked at the transverse orientations of the CA3 and/or CA1 regions. Recently, our group has shown that the CA1-CA1 pyramidal neurons are well-organized and have a longitudinally projecting synaptic network. This triggered an interest in synaptic plasticity of long-term potentiation (LTP) and long-term depression (LTD) within the longitudinal CA1 hippocampal region. Here we studied long-term synaptic plasticity in CA1 longitudinal plane using *in vitro* and *in vivo* recordings. Animals used were C57BL6 mice. We found that the longitudinal network has N-methyl-D-aspartate receptor (NMDAR)-dependent LTP. Meanwhile, there is no apparent long-term depression (LTD) under the frequently used LTD induction protocols. These results implicate a unique functional property in the longitudinal projection, stimulating a further research regarding how the longitudinal network contributes to information processing.

Title: Highly irregularly patterned 10 Hz stimulation, but not regularly patterned 10 Hz stimulation, activates a disinhibition mechanism that induces long-term potentiation following mild traumatic brain injury

Authors: *Q. S. FISCHER, D. KALIKULOV, M. J. FRIEDLANDER Virginia Tech. Carilion Res. Inst., Roanoke, VA

Abstract: Previously, using whole cell (WC) recordings in acute slices of visual cortex, we found that 10 Hz discontinuous highly irregular stimulation patterns (interstimulus intervals with a coefficient of variation = 1, or CV = 1) but not regular stimulation patterns (CV = 0), led to a significant net long-term potentiation (LTP) of postsynaptic responses in rats with mild traumatic brain injury (mTBI rats) but not in control rats. Here we used field potential (FP) recordings and pharmacological manipulations (gama-aminobutyric acid receptor blockade, or GABAblk) to investigate the potential underlying mechanisms for these phenomena. Acute slices of visual cortex were taken from 10 - 13 week old normal rats and rats who had received an mTBI 2 - 3 weeks prior. We applied a defined pattern of stimulation to layer 4 and made FP recordings in layer 2/3. Conditioning stimulation consisted of 900 pulses at 10 Hz (9 epochs x 100 stimuli spaced equally over 900 sec) with a CV of 0 or 1. Recording of evoked FPs were made in

response to 0.1 Hz test stimulation before and after conditioning in artificial cerebral spinal fluid alone or with the addition of GABA receptor blockers (GABAblk). The post- to pre-conditioning ratio of the peak amplitudes of the 0.1 Hz evoked FPs was used to assess plasticity. We defined long-term depression (LTD) as a significant (P < 0.05, t-test) decrease ($\geq 10\%$) in post/pre ratios, LTP as a significant increase in post/pre ratios, or no change (NC) as post/pre ratios that changed < 10% and/or were not significantly different (P > 0.05, t-test). For regular (CV = 0) stimulation, control rats exhibited a net LTD while mTBI rats exhibited a net NC, and this was comparable in WC (0.81 \pm 0.08, N = 17 vs. 0.90 \pm 0.07, N = 17; P = 0.40, t-test) and FP (0.89 \pm 0.04, N = 16 vs. 0.95 ± 0.05 , N = 12; P = 0.44, t-test) recordings. Moreover, GABAblk did not significantly change FP values in controls $(0.89 \pm 0.04, N = 16 \text{ vs. } 0.92 \pm 0.04, N = 5, P = 0.79 \text{ t-test})$ or mTBI rats $(0.95 \pm 0.05, N = 12 \text{ vs. } 0.89 \pm 0.09, N = 8$: P = 0.57 t-test). For highly irregular (CV = 1) stimulation, control rats showed a net LTD or net NC while mTBI rats showed a net LTP which was similar in WC (0.63 ± 0.07 , N = 19 vs. 1.17 ± 0.12 , N = 18; P = 0.001, t-test) and FP $(0.94 \pm 0.05, N = 24 \text{ vs. } 1.15 \pm 0.10, N = 17; P < 0.05, t-test)$ recordings. Finally, GABAblk reduced FP values in mTBI rats (1.15 ± 0.10 , N = 17 vs. 0.99 ± 0.05 , N = 18; albeit not quite significantly P = 0.12, t-test), but not control rats (0.94 \pm 0.05, N = 24 vs. 0.95 \pm 0.06, N = 18; P = 0.90, t-test). These results indicate that highly irregular (CV = 1) 10 Hz stimulation, but not regular (CV = 0) 10 Hz stimulation, activates a disinhibition mechanism that induces LTP following mTBI.

Abstract: Long-term potentiation (LTP) and depression (LTD) are the mechanisms by which neurons modulate their inherent synaptic plasticity and support the storage and recovery of memories in the mammalian brain. The ability to potentiate a synapse long term declines

significantly in neurodegenerative disorders. In addition to deficiencies in synaptic plasticity, degenerating neurons display acute and chronic mitochondrial dysfunction, suggesting that dysregulated mitochondria play a hand in synaptic dysfunction in addition to their known role in apoptotic death. Our previous work shows that the anti-apoptotic protein Bcl-xL not only prevents somatic cell death, but it also potentiates long-term synaptic responses. Here, we show that Bcl-xL is responsible for dramatic changes of ATP levels at synapse-specific sites in hippocampal neurons during LTP. Using fluorescent imaging of an ATP-FRET (ATeam) construct in living cells, we find that LTP induction in cultured neurons causes a short decrease in ATP levels followed by a persistent long term increase in ATP production. This suggests that after high frequency or intense synaptic stimulation, neurons may become metabolically more efficient; oxygen consumption rates during LTP are now being performed to confirm or refute the proposed change in efficiency. The long-term increase in ATP levels of LTP-stimulated synapses is blocked when we inhibit Bcl-xL and when ATP synthase activity is blocked with oligomycin. Bcl-xL inhibition also prevents a long-term increase in surface glutamate receptor insertion. We are completing studies to see what effect blocking ATP synthase activity has on glutamate receptor insertion. In hippocampal slice recordings, inhibition of Bcl-xL greatly impairs early stage LTP and prevents late stage LTP. We suggest that long term changes in mitochondrial efficiency brought on by activity-dependent translocation of Bcl-xL to mitochondria are required for LTP. These results shed light upon the role of changes in mitochondrial metabolic efficiency in the acute induction and long-term maintenance of learning and memory storage. If such mitochondrial changes fail to occur, synaptic dysfunction associated with neurodegeneration may ensue. Our study places mitochondria and Bcl-xL at the center of synaptic metabolism and synaptic plasticity.

Title: Effects of non-selective activation of dopaminergic receptors by apomorphine in the hippocampus

Authors: *L. ARROYO GARCÍA, SR¹, R. A. VAZQUEZ-ROQUE¹, A. DIAZ¹, A. RODRIGUEZ-MORENO², F. DE LA CRUZ³, G. FLORES¹

Abstract: Apomorphine is a dopaminergic agonist used in the treatment of Parkinson's disease (PD), which activates D1-like and D2-like dopaminergic receptors. Currently, the role of apomorphine in non-motor activity is poorly studied, and the effects of dopaminergic activation in brain areas that do not have motor functions are unknown. The aim of this study is to determinate the effect of dopaminergic receptor activation in plasticity and behavior in the hippocampus. Adult mice were chronically administrated with 1 mg/kg apomorphine during 15 days. Memory and learning, synaptic plasticity, oxidative stress response and morphological changes were evaluated. For plasticity experiments, electrophysiological recordings (fEPSPS) were obtained in the CA1 region of hippocampal slices prepared from adult mice and the effect on LTP of apomorphine (20 µM) studied. In this experimental condition LTP was prevented. Also in the presence of apopmorphine, by using the Morris water maze test, a decrease in the learning and the long-term memory capabilities of mice were observed. Additionally, a decrease in the total dendritic length of CA1 neurons, and an increase in the number of astrocytes were observed in the presence of apomorphine by using the Golgi-Cox stain and GFAP immunohistochemistry, respectively. These results suggest that, in the hippocampus, the nonselective activation of dopaminergic receptors by apomorphine prevents LTP, causes neuronal damage and triggers deficiencies in learning and memory.

Title: The role of postsynaptic cell-adhesion molecules in the trafficking of AMPA-type glutamate receptors

Authors: *A. RILEY, X. WU, R. C. MALENKA, T. C. SUDHOF Stanford Univ., Stanford, CA

Abstract: Long-term potentiation (LTP), an activity dependent, long-lasting change in synaptic strength, is a critical form of synaptic plasticity underlying learning and memory and has been implicated in various neuropsychiatric disorders. The expression of NMDA receptor-dependent

LTP is dependent on the trafficking of AMPA receptors (AMPARs) to the postsynaptic membrane. The present project is guided by the unexpected role of cell adhesion proteins, which mediate trans-synaptic signaling, in LTP. Specifically, the project focuses on the role of postsynaptic neuroligin 1 and its binding to presynaptic neurexins. This heterophilic interaction is present in mature and developing synapses and its absence has been shown to impair LTP. Here, we generate various neuroligin constructs in which different functional domains of neuroligin 1 are mutated. We used these constructs to determine which specific neuroligin domains are necessary for the AMPAR exocytosis that occurs during LTP. Specifically, we prepared primary dissociated mouse hippocampal cultures from neuroligin 1 (NL1) and neuroligin 1, 2, 3, and 4 (NL1234) conditional knockout mice (cKO) and infected these cultures at DIV7-9 with lentiviruses containing Cre recombinase and either wildtype (WT) NL1 or mutant forms of NL1. At DIV18-20, we induced a form of chemical LTP by bath applying glycine and measured the resultant increases in surface expression of endogenous AMPARs using immunocytochemistry. Our results suggest that the exocytosis of AMPARs during chemical LTP is impaired upon deletion of neuroligin 1; can be rescued solely by the extracellular domain of neuroligin 1; does not require neuroligin dimerization, and is impaired when NL1 binding to neurexin is inhibited. Thus, the trans-synaptic interaction between NL1 and presynaptic neurexins appears to be necessary for the increase in surface expression of endogenous AMPARs following the induction of chemical LTP in dissociated cultures prepared from NL cKO mice. This hypothesis is also being tested using acute hippocampal slices prepared from NL cKO mice (see abstract from Wu et al....).

Title: Extrasynaptic NMDA receptor dependent long-term potentiation of hippocampal CA1 pyramidal neurons

Authors: *S.-T. LI¹, Q. YANG¹, J. WANG², J. LUO² ¹Bio-X Institutes, Shanghai Jiao Tong Univ., Shanghai, China; ²Zhejiang Univ. Sch. of Med., Zhejiang, China

Abstract: In the adult mouse hippocampus, NMDA receptors (NMDARs) of CA1 neurons play an important role in the synaptic plasticity. The location of NMDARs can determine their roles in the induction of long-term potentiation (LTP). However, the extrasynaptic NMDARs (ES-NMDARs) dependent LTP haven't been reported. Here, through the use of a 5-Hz stimulation and MK-801 (an irreversible antagonist of NMDARs) in the CA1 neurons of adult mice hippocampal slices, synaptic NMDARs were selectively inhibited and NMDAR-mediated excitatory postsynaptic currents were not recovered. We found that a robust LTP was induced by 3-train 100-Hz stimulation when the synaptic NMDARs and extrasynaptic NR2B containing NMDARs were blocked, but not in the any of the following conditions: blocking of all NMDARs (synaptic and extrasynaptic), blocking of the synaptic NMDARs, and blocking of the synaptic NMDARs and extrasynaptic NR2A-containing NMDARs. The results indicate that this LTP is ES-NMDARs dependent, and NR2B-containing ES-NMDARs modulates the threshold of LTP induction.

Title: Utilization of a newly synthesized degradable biocomposite: Copper-high aspect ratio structure (CuHARS) for dynamic signaling to brain cells

Authors: *K. C. ST MARTHE, A. KARAN, Z. NORCROSS, M. A. DECOSTER Biomed. Engin., Louisiana Tech. Univ., Ruston, LA

Abstract: New materials at the nano- and micro-scale are being engineered for a host of potential neuroscience applications. This includes desired outcomes of drug delivery, cellular guidance, and sensing, for example. Here we have applied a newly synthesized, copper-

containing high aspect ratio structure (CuHARS), for dynamic signalling delivery to brain cells in vitro. CuHARS is a biocomposite discovered by our group, containing the amino acid dimer cystine and the metal copper. CuHARS scales from nanometer to micrometer in diameter, and micrometer in length. Upon synthesis termination, CuHARS is stable in water, but degraded up to 95% as determined by image analysis when incubated for 18 days in microglial brain cell culture media under physiological conditions. Degradation is accelerated by use of metal chelators such as ethylenediaminetetraacetic acid (EDTA), with similar near-complete degradation occurring in 4 days; the effect was concentration dependent (10 mM- 50mM). We applied these findings to the question of whether discrete, biodegradable biocomposites could be used in dynamic signalling networks of brain cells. We engineered two types of brain cell environments: 1) glial depleted, and 2) glial enriched, and then carried out intracellular calcium imaging on both systems. All experiments were carried out on identical platings of cells, with glial depleted cultures developed over time using the anti-mitotic cytosine arabinoside (1mM final concentration). The two cell environments once developed were stimulated with successive, increasing concentrations of glutamate (Glu) and with ionomycin at the end of the scan to cause calcium influx in all cells. Responses to Glu were detected as low as 250 nM in some cells. In contrast, control cultures of pure astrocytes responded consistently at 1,000x greater Glu (high micromolar to millimolar stimulus or to control stimuli such as KCl and ATP). The dynamics of intracellular calcium changes were very different in environments 1 and 2, with glial enriched cultures demonstrating more oscillatory dynamics post Glu compared to glial depleted cultures. The randomness of oscillations in stimulated cells was compared to a discrete logistic model that could be tuned for chaotic behavior. Using this model, it was found that glial enriched cultures were more chaotic. In this same imaging system, CuHARS were fluorescently labeled such that they could be observed simultaneously with cells. This system along with a novel degradable biocomposite (CuHARS) could provide new tools for dynamically stimulating brain cells over longer periods than when using traditional, immediately soluble chemical applications.

Title: Enhanced responsiveness in asynchronous irregular network states as a mechanism for modulating sensory awareness

Authors: *A. DESTEXHE^{1,2}, Z. GIRONES¹, Y. ZERLAUT^{1,3} ¹CNRS, Gif-sur-Yvette, France; ²European Inst. for Theoretical Neurosci., Paris, France; ³Inst. Italiano di Tecnologia, Rovereto, Italy

Abstract: Desynchronized brain states are known to be associated with arousal and increased awareness, but the underlying cellular and network mechanisms are unknown. Here, we explore networks of excitatory and inhibitory neurons displaying asynchronous irregular (AI) states, where the activities of the two populations are balanced. At the single-cell level, it was previously shown that neurons subject to balanced and noisy synaptic inputs can display enhanced responsiveness. We show here that this enhanced responsiveness is also present at the network level, but only when single neurons are in a regime where their conductance state and fluctuation level are consistent with experimental measurements. By scanning a large number of AI states, we show that the network responsiveness can be explained based on the mean conductance state, the mean membrane potential (Vm), and the amplitude of Vm fluctuations in individual neurons. Optimal responsiveness is obtained when these parameters are all consistent with experimental measurements. Multi-layer networks endowed with such "realistic" AI states are capable of transmitting information reliably across layers (Fig. 1). We conclude that when displaying "realistic" AI states, networks can be exquisitely sensitive to afferent inputs, transmit information reliably, and make the information available to the entire network. We propose that these features define a low-level form of sensory awareness, which can be modulated at the millisecond scale.

Figure 1: A. Scheme of successive layers each consisting of a network of excitatory and inhibitory neurons. A Gaussian-distributed pulse packet is given as input to a subset of neurons. B. Propagation of the pulse packet across layers is state dependent. Blue (Active): all layers displayed AI states consistent with intracellular measurements. Brown: quiescent networks (at equivalent Vm) for comparison. The pulse packet was reliably transmitted only in AI states, and the interlayer propagation speed was also faster (modified from Zerlaut and Destexhe, Neuron, 2017; Girones and Destexhe, arXiv 2016).

Title: A study of single-pulse cortical stimulation effects across cortical micro-domains

Authors: *P. KUDELA¹, R. OH³, G. MILSAP², N. E. CRONE⁴, W. S. ANDERSON¹ ¹Neurosurg., Johns Hopkins Univ., Baltimore, MD; ²Johns Hopkins Univ., Biomedical Engineering, MD; ³Johns Hopkins, Whiting School of Engineering, MD; ⁴Neurol., Johns Hopkins Hosp., Baltimore, MD

Abstract: Introduction: Direct cortical stimulation is widely used for functional mapping of eloquent cortex and for interrupting seizures using closed-loop brain stimulators. The neurophysiological effects of cortical stimulation in a volume of cortical tissue are complex and difficult to predict as they may depend on the context of ongoing neural activity and may be affected by many factors including tissue heterogeneity, morphology, and cortical connectivity. To investigate how direct cortical stimulation induces neuronal activity spatially and temporally we combined micro-intracranial electrocorticographic (mECoG) recordings from human subjects with a large scale computational model of neocortex. Using single-pulse electrical stimulation we investigated the dynamics and evolution of stimulus-evoked cortical activity across micro-domains sampled by micro-electrode arrays. Methods: Two adult patients (male and female) were implanted with a subdural grid embedded with 4x4 micro-electrode arrays (superior temporal or precentral/postcentral gyri). Center-to-center distances between the macro and micro electrodes were between 4 and 8 mm. Monopolar stimulation with biphasic pulses were delivered to the macroelectrode elements (pulse width 0.3 ms, stim. current 1-10 mA, 50 trials, 5

s intervals between pulses). Data from the micro-electrodes were sampled at 30 kHz. The cortical model was designed in pGENESIS 2.3 to simulate the effects of monopolar stimulation on cortical neurons modeled as multi-compartmental cells. Stimulus-evoked responses for both recorded and simulated data were derived by trial-averaging. Result: Early (<10ms) and late cortical responses resembling sharp-and-slow waves were observed in mECoG from micro-domains after stimulation. Early responses were difficult to analyze due to stimulation artifacts. Peak latency analyses of the late responses from different micro-electrodes revealed statistically significant differences in the measured latencies, suggesting a consistent pattern of activity propagation across micro-domains. This propagation was not uniform and had saltatory characteristics across micro-domains. Conclusions: Early cortical responses reflect direct neuronal recruitment by the stimulating electrode and possibly early activity propagation through the superficial cortical layers that follows stimulation. The late responses likely reflect interactions with subcortical structures, and the different latencies among late responses across micro-domains may partially result from initial propagation after stimulation. We have also observed similar effect in cortical model simulations.

Title: Balancing excitation and inhibition shapes the dynamics of a neuronal network for movement and reward

Authors: A. R. RADULESCU, 12561¹, *A. SCIMEMI²

¹Mathematics, SUNY New Paltz, New Paltz, NY; ²Univ. at Albany State Univ. of New York, Albany, NY

Abstract: The cortico-striatal-thalamo-cortical (CSTC) pathway is a brain circuit that controls movement execution, habit formation and reward. The striatum shapes the activity of the CSTC pathway through the coordinated activation of two classes of medium spiny neurons (MSNs) that express D1 or D2 dopamine receptors. It is unknown exactly how the balanced

excitation/inhibition in the entire CSTC pathway or in D1- and D2-MSNs shapes the network dynamics of the entire circuit. Here we answer this question using non-linear modeling of neuronal activity and bifurcation theory. Our findings indicate that a global and proportionate increase in excitation/inhibition pushes the system to states of generalized hyper-activity throughout the entire CSTC pathway. Certain disproportionate changes in global excitation/inhibition trigger network oscillations. Local changes in the excitation/inhibition of MSNs generate specific oscillatory behaviors inMSNs as well as in the CSTC pathway. These findings indicate that subtle changes in the relative strength of excitation/inhibition of MSNs powerfully control the network dynamics of the CSTC pathway, in ways that are not easily predicted by its own synaptic connections.

Title: Activation of hilar mossy cells and dentate granule cells during sharp wave ripples In vitro

Authors: *A. OUCHI, N. MATSUMOTO, Y. IKEGAYA

The Univ. of Tokyo, Tokyo, Japan

Abstract: Various hippocampal oscillations may differently control memory and learning. Hippocampal sharp waves (SWs)/ ripples are high-frequency oscillations emitted mainly during slow-wave sleep or quiet rest states and play a role in memory consolidation. While it is known that SWs are initiated in the CA3 subregion and propagate to the downstream CA1 subregion, we observed that they also propagate back to the dentate gyrus. However, neither the role of CA3-to-DG SW backpropagation nor its propagation mechanism has been fully understood. We reasoned that mossy cells mediate the backpropagation, because these neurons receive direct synaptic inputs from CA3 neurons and made synaptic connection with granule cells in the dentate gyrus. In this study, we simultaneously recorded the membrane potentials from mossy cells or granule cells and the local field potentials from the CA3 stratum pyramidale. The recorded cells were morphologically confirmed based on *post-hoc* intracellular biocytin labelling. Compared with granule cells, mossy cells more reliably depolarized immediately after the generation of SWs. Therefore, mossy cells precisely reflect the activity of SWs from the CA3 subregion. Our findings shed light on a novel mechanism underlying the SW backpropagation will provide a new perspective to memory consolidation.

Title: The characterization of hippocampal theta-driving neurons --- a time-delayed mutual information approach

Authors: *S. LI¹, J. XU², G. CHEN², L. LIN², D. ZHOU³, D. CAI¹ ¹New York Univ., New York, NY; ²East China Normal Univ., Shanghai, China; ³Shanghai Jiao Tong Univ., Shanghai, China

Abstract: Interneurons are important for computation in the brain, in particular, in the information processing involving the generation of theta oscillations in the hippocampus. Yet the functional role of interneurons in the theta generation remains to be elucidated. Here we use time-delayed mutual information to investigate information flow related to a special class of interneurons --- theta-driving neurons in the hippocampal CA1 region of the mouse --- to characterize the interactions between theta-driving neurons and theta oscillations. For freely behaving mice, our results show that information flows from the activity of theta-driving neurons to the theta wave, and the firing activity of theta-driving neurons shares a substantial amount of information with the theta wave regardless of behavioral states. Via realistic simulations of a CA1 pyramidal neuron, we further examine to which interneuron type these theta-driving neurons belong. We apply time-delayed mutual information to analyze information flow between

the experimentally recorded theta wave and the computationally obtained membrane potential trace induced by each of five candidate interneurons --- the basket cell, the axo-axonic cell, the bistratified cell, the oriensalveus/lacunosummoleculare cell, and the cholecystokinin-expressing basket cell. Based on the consistency of information flow from the activity of the pyramidal neuron to the theta wave, our analysis demonstrates that theta-driving neurons fit the characteristics of the cholecystokinin-expressing basket neurons. Our results suggest that it is important to take into account the role of cholecystokinin-expressing basket neurons in the generation and information processing of theta oscillations.

Title: Can neural activity propagation be mediated by ephaptic coupling?

Authors: *R. SHIVACHARAN, C.-C. CHIANG, D. M. DURAND Dept. of Biomed. Engin., Case Western Reserve Univ., Cleveland, OH

Abstract: It is well documented that synapses play a significant role in transmission of information between neurons. However, in the absence of synaptic transmission, neural activity has been observed to continue to propagate. Previous experiments conducted in our laboratory have shown epileptiform spikes in rodent hippocampi propagate at a consistent speed of 0.1 m/s and can take place in the absence of synaptic transmission. Computer simulations and osmolarity experiments indicate that electric fields could be responsible for this phenomenon. These data suggest that electric fields can activate neighboring neurons (ephaptic coupling), thereby generating a self-propagating wave. Here, we test the hypothesis that electric fields are directly responsible for the propagation by 1) determining if an applied field with amplitude similar to the endogenous fields can trigger a propagating wave and 2) applying an uniform electric field (1-5 mV/mm) can generate a wave that travels at similar speeds to that of 4-AP activity (~0.1 m/s). We also observed that applying a uniform field (1-5 mV/mm) can speed up or slow down
propagation of the spontaneous activity depending on the polarity. In addition, short-circuiting the field resulted in a decrease in propagating speed. These results strongly support the hypothesis that ephaptic coupling can be responsible for volume conduction of neural activity and point to a novel mechanism of neural activity propagation in the brain. Title: Layer-dependent inter-areal effective connectivity among anterior cingulate and prefrontal cortex in monkeys revealed by electrical microstimulation

Authors: *V. NACHER¹, T. WOMELSDORF^{1,2}

¹Ctr. for Vision Res., York Univ., Toronto, ON, Canada; ²Dept. of Psychology, Vanderbilt Univ., Nashville, TN

Abstract: The anterior cingulate cortex (ACC) and prefrontal cortex (PFC) functionally coactivate during the monitoring and shifting of attention. This co-activation is evident in spiketrain correlations, burst-to-LFP synchronization, and inter-areal phase-amplitude coupling. This diverse functional connectivity pattern is paralleled by a diverse pattern of anatomical connectivity with a large proportion long-range synapses made to inhibitory interneurons. One approach to elucidate the possible link between functional and anatomical connectivity is to characterize the efficacy and temporal patterning of anatomical connections using electrical microstimulation. Here, we set out to map this so-called "effective connectivity" across layers between the ACC (areas 32, 24c) and the PFC (areas 9/46d, 46d, 46v) in two awake monkeys using electrical microstimulation consisting of single, 2, 4 or 8 biphasic square pulses (200 µs duration each, 40-500 µA current amplitude), with an inter-pulse delay of 2 ms. These protocols reliably triggered long-range evoked responses in both directions with evoked field amplitudes increasing from 1 to 8 pulses and 140 to 500 µA. We found three main results. Firstly, ACC-to-PFC stimulation resulted in shorter-latency evoked fields than PFC-to-ACC stimulation. This asymmetry could indicate differential synaptic connectivity profiles in both directions. Secondly, the majority of evoked responses showed a multiphasic pattern with 2-4 points of inflection. This indicates resonance or ringing phenomena that could help understanding the underlying mechanisms of synaptic integration. Thirdly, amplitudes of the evoked responses varied

systematically with the laminar location of either recording or stimulation electrode. This layer specific amplitude modulation likely relates to the density of synaptic contacts made between ACC and PFC circuits. In summary, we characterized the diversity of effective connectivity patterns between those two brain areas whose interactions is believed to be critical for goal directed behavior. We believe that the effective connectivity maps we report will serve as the critical link to bridge the gap between anatomical connections and the possible functional co-activations that ride on top of them during different functional states.

Title: Peak reduction of axonal spikes in the hippocamal mossy fibers during the high frequency stimulation

Authors: *S. OHURA, H. KAMIYA

Hokkaido Univ. Grad. Sch. of Med., Sapporo, Japan

Abstract: Axons are considered as the reliable digital cable which enable the secure propagation of neuronal information from the cell body to the nerve terminal. However, axons in the central nervous system (CNS) have the "en passant" structures with multiple varicosities, which can be the risk factors of conduction block of axonal spikes. In addition, axonal voltage-gated sodium channels play critical roles in spike propagation, and thus accumulating inactivation of sodium channels might result in the frequency-dependent propagation failure. In this study, we examined the reliability of spike propagation and activity-dependent waveform changes in the hippocampal mossy fibers at different stimulation frequency. We performed the loose-patch clamp recordings from single mossy fiber boutons, which are the exceptionally large presynaptic terminals. In the mouse hippocampal slice, large mossy fiber boutons were visually identified under the IR-DIC optics. Extracellular stimulation at the granule cell layer of dentate gyrus evoked axonal spikes in all-or-none fashion. In response to supra-threshold stimulation at 0.1 Hz, axonal spikes were evoked in response to the most of stimuli and propagated without failure during repetitive stimuli. In high frequency stimulation experiments, bi-phasic stimuli were used to minimize the stimulation failure. Even at 50 or 100 Hz stimuli for 1 s, spike failure was also rarely observed. In addition, the peak amplitude of the latter spikes during the high frequency stimulation was significantly decreased compared to the first response, in contrast to the digital signal processing

in the axon. Also, the width of the last axonal spikes during 1 s stimuli at 100 Hz was significantly increased compared to the first spike, which reflected the activity-dependent broadening of axonal spikes that previous study demonstrated. Mossy fibers reported to be expressed the higher density of sodium channels compared to the somatodendritic compartments, which might secure the high-fidelity propagation of axonal spikes, even in the structures causing impedance mismatch of thin axon shafts and large axon terminals. Furthermore, the small reduction of axonal spikes might result from the accumulation of sodium channel inactivation, which implied that the abundance of sodium channels was not sufficient to propagate the full-size action potentials. Both peak reduction and broadening of action potentials in response to the repetitive-stimuli might reflect the ability of activity-dependent tuning of axonal spikes in the hippocampal mossy fibers.

Title: Scale-free correlations in neuronal activity of behaving animals

Authors: *T. L. RIBEIRO¹, S. YU², D. WINKOWSKI³, P. O. KANOLD³, D. CHIALVO⁴, D. PLENZ¹

¹Section on Critical Brain Dynamics LSN/NIMH, NIH, Bethesda, MD; ²Brainnetome Ctr., Inst. of Automation, Chinese Acad. of Sci., Beijing, China; ³Biol., Univ. of Maryland, College Park, MD; ⁴Ctr. for Complex Systems & Brain Sci., Univ. Nacional de San Martin, San Martin, Argentina

Abstract: It has recently been shown that resting state networks, computed from fluctuations of the blood oxygenated level dependent signal, exhibit divergent correlation length (CL): the average distance where the correlation of the fluctuations around the mean crosses zero increases with the system size (Fraiman & Chialvo, 2012; Haimovici et al, 2013). The existence of a divergent CL implies critical phenomena, in which the dynamics at all spatial scales are explained, after rescaling, by the same law. Examples range from spins of a magnet (Stanley, 1987) to bird flocks (Cavagna et al, 2010). In the brain, evidence of critical dynamics, which has been shown to provide numerous advantages for information processing, was found mostly in the context of neuronal avalanches, spatiotemporal clusters of scale-free activity that propagate in cortical layers whose size and duration are well-described by power laws (Beggs & Plenz, 2003).

On the other hand, CL provides an important alternative to neuronal avalanches to assess the dynamical state of neuronal networks, being especially useful in situations where power-law distributed activity cascades may be hard to obtain, such as in recordings with low temporal resolution, recordings affected by subsampling and/or in the case of non-stationary activity increases due to sensory stimulation or motor command execution. Here we investigate this issue in two experimental conditions: (a) multi-electrode array recordings (10x10 array, ~400 µm between electrodes) in premotor and prefrontal cortex of behaving nonhuman primates and (b) 2photon imaging (~500 µm x 500 µm field of view) in primary visual and auditory cortex of awake mice during sensory stimulation. Our experimental findings are complemented with computer simulations to explore the origins of the divergence in CL. We identify for the first time in behaving nonhuman primates and in the awake mouse the presence of scale-free CLs during stimuli or motor command processing epochs. Numerical simulations confirm a linear relation between network size and the CL that is indeed unique to critical dynamics. In contrast, deviations from critical dynamics lead to deviations from this scaling relation. Our results demonstrate that scale-free sensory-evoked activity in awake animals is in line with predictions from a neural network exhibiting critical dynamics. We therefore conclude that the brain could take advantage of optimization principles proposed for information processing in critical systems such as optimized stimulus sensitivity, information transmission, computational capability and mnemonic repertoires size.

Title: Analytical studies of activity propagation in neural networks

Authors: *R. J. ERAZO¹, C. T. THURMAN², R. M. OSAN^{1,3} ¹Neurosci. Inst., ²Physics and Astronomy, ³Mathematics and Statistics, Georgia State Univ., Atlanta, GA

Abstract: We examine mathematical and computational models of traveling waves that describe the evolution of activity propagation in networks of integrate-and-fire neurons with excitatory connections. The network dynamics are heavily influenced by the coupling function, which assumes that strength of synaptic connections depend only in the distance between neurons. The finite support function assumes that the amount of excitation produced by the spike of one neuron is equal to all neuron neighbors within a discrete synaptic footprint. We determine how wave velocity depends on the global excitability as well as on other neuron and network parameters. We take an analytical approach to compute a delayed differential equation that accurately describes the transient activity in the neuronal network, which can ultimately give rise to propagation failure or constant-speed wave solutions. We conclude that our analytical predictions are in perfect agreement with the numerical simulations. We determine that after the wave initialization, done by inducing spiking at a set region, wave speed shows transient large amplitude oscillations before converging to a constant speed solution or quiescence, i.e. activity propagation and propagation failure, respectively. We are currently examining the mechanism that supports stability and the basins of attraction to small perturbations.

Title: Investigating the mechanisms of claustrum-cortical connectivity

Authors: *J. C. JACKSON¹, M. M. KARNANI², D. BURDAKOV², A. K. LEE³ ¹Janelia Res. Campus, Ashburn, VA; ²The Francis Crick Inst., London, United Kingdom; ³HHMI Janelia Res. Campus, Ashburn, VA

Abstract: The claustrum is a small subcortical brain region known to be highly connected with all areas of the neocortex. Claustrum inputs and outputs are topographically organized, whereby spatially segregated claustrum cells receive inputs and send outputs to different cortical regions. Despite the wealth of anatomical knowledge regarding the interactions between the claustrum and cortex, there is very little information regarding the mechanisms by which claustrum neurons influence cortical activity and the strength of inputs to different cell types in the cortex. One major reason for this shortcoming arises from the fact that the claustrum is difficult to target anatomically or genetically. To target claustrum -> cortical circuits, we used newly developed retrograde AAVs (Tervo et al., Neuron 92: 372-82, 2016) to insert ChR2 specifically into claustrum neurons projecting to different regions of the cortex. With this technique we optically activated claustrum cells projecting to specific cortical regions and assessed the influence on different cell types and network activity patterns. These studies will provide a foundation for future studies seeking to understand the mechanism and function of claustrum-cortical signaling.

Title: Network dynamics of GABAergic neurons

Authors: *D. POZZI¹, Q. SONG^{1,2}, V. TORRE^{1,2}

¹Intl. Sch. For Advanced Studies, Trieste, Italy; ²Ningbo Inst. of Materials Technol. and Engineering, Chinese Acad. of Sci., Zhejiang 315201, China

Abstract: We analyzed properties of *in vitro* dissociated cortical cultures and organotypic cortical slices in which GABAergic neurons were transgenically labeled with a green fluorescent protein (GFP). We stained these neuronal cultures with the membrane permeable calcium dye Fura-red, so that we identified GABAergic neurons by green light illumination and simultaneously followed calcium transients ($\Delta F/F_0$) in GABAergic and non GABAergic neurons using a red light. Fluorescence images (512x512 pixels) were acquired with an Electron Multiplier CCD camera at acquisition rates ranging from 5 to 50 Hz. We calculated the cross-correlation index (ρ) of the occurrence of the peaks of calcium transients in a time window of 10 seconds, and we found that GABAergic neurons. This difference was statistically significant (p < 0.001 One-way ANOVA, Tukey post - hoc test). Specifically, calcium transients larger than 30% ($\Delta F/F_0$) had a higher value of ρ , whereas smaller calcium transient were less correlated (0.619 ± 0.007 vs 0.298 ± 0.011 for GABAergic neurons; 0.487 ± 0.008 vs 0.233 ± 0.011 for non GABAergic neurons).

After blockage of GABA-A receptors with gabazine, the synchronization of calcium transients increased in both populations, maintaining higher values for GABAergic neurons (0.865 ± 0.004 vs 0.828 ± 0.007). The mean amplitude of $\Delta F/F_0$ was similar in GABAergic and non GABAergic neurons, whereas the time interval between bursts was significantly lower in the GABAergic population (26.07 ± 2.13 seconds vs 34.62 ± 2.62 seconds; p < 0.05). The dynamics of large synchronous calcium transients was analyzed when fluorescence images were acquired at 50 Hz, in order to determine the relative timing of calcium transients in GABAergic and non GABAergic neurons, but no consistent delay was detected at the available temporal resolution of 20 msec.

Our results suggest that GABAergic neurons have more synchronized and frequent spontaneous

activity compared to other neuronal types, and preliminary experiments in organotypic cell cultures seem consistent with these conclusions. Additional properties of the GABAergic neuronal network will be investigated.

Title: Standard LFP reconstruction does not explain neuronal avalanches with power law scaling

Authors: *D. PLENZ, T. LINS-RIBEIRO, Y. KARIMIPANAH Sect Critical Brain Dynamics, Natl. Inst. of Mental Health, NIH, Bethesda, MD

Abstract: The local field potential (LFP) infers population dynamics from the local population of neurons. Based on LFP measures in vitro, in rodents and non-human primates using multielectrode arrays, it has been shown that ongoing neuronal activity in superficial cortical layer 2/3 organizes as neuronal avalanches characterized by power law scaling. Recently, it was suggested that even uncorrelated neuronal activity reveals LFP measures with power law scaling (Touboul & Destexhe, 2017). In this latter approach the LFP was simulated from local current sources in a 2-dimensional network using the monopolar source model. Here, we examined this approach both numerically and analytically, and show that such scale-invariance is solely contingent on the assumption of a certain spatial dependency, namely the monopole current source. Furthermore, we show that such an assumption would have serious unrealistic consequences and that it does not compare to real LFP measures. In our simulations, layer 2/3 neurons were randomly distributed in 3-dimensions (3D) and their synaptic currents were modeled by independent Poisson processes convolved with an alpha-function. An embedded electrode matrix allowed the calculation of the LFP as a spatially weighted sum of all synaptic currents. Spatial distance r dependencies of potentials including 1/r^alpha, with alpha being a constant were explored. We found that in 3D, alpha=1 constitutes a phase transition between two phases of decorrelated and extremely correlated regimes: for alpha<1, both the LFP amplitude and fluctuations are mostly determined by distant neurons, whereas alpha>1 (which includes dipole reconstructions) results in de-correlated activity with a finite spatial reach for LFP's. Furthermore, we show that contrary to what was reported by Touboul & Destexhe (2017), for a large system it would be impossible to have power law distributed LFP avalanches for alpha=1, as each electrode would be almost identical. On the other hand, for alpha<1 or finite size systems (with any alpha), we show that it is only possible to have spurious power laws for a fine-tuned set of the parameters (depending on the density and the size of the array). Finally, when compared to real LFP data from spontaneous cortical activity in nonhuman primates, power law distributed avalanches compare with significantly lower pair-wise correlations than those suggested from a monopolar source approach. Our results demonstrate the implausibility of deriving neuronal avalanches measured in the LFP from the simple integration of uncorrelated sources.

Abstract: In the human neocortex, solitary spikes in a subset of layer 2-3 pyramidal cells (PCs) trigger brief episodes of network activity known as complex events through strong excitatory synapses that specifically innervate GABAergic interneurons. Yet, how these layer 2-3 "master PCs" configure the local network activity is not well understood. We report that single spikes in the PCs elicit firing of fast-spiking basket cells (FSBCs) with a short delay (average 2.7 ms) and high temporal precision with small jitter. The FSBC firing is triggered by >13 mV monosynaptic EPSP from single PC. The discharge of FSBCs is observed in the first wave of the complex event interneuron activity triggered by the master PCs. The FSBCs generate fast-kinetic inhibitory postsynaptic current (IPSCs) in layer 2-3 PCs, and similar IPSCs occur phase-locked to the master PC spike in the beginning of the complex events with high probability and 4.3 ms average delay with small jitter. In comparison, IPSCs with slow kinetics from non-fast spiking

interneurons appear more incosistently in the complex events with variable delay and low probability. The high-precision discharge of FSBCs characterizes the early phase of the complex event interneuron activity in the human neocortex.

Title: Characterization of the inhibitory effects of bumetanide and several other loop diuretics on the sodium-potassium-chloride-cotransporter splice variants hNKCC1A and hNKCC1B

Authors: *P. HAMPEL^{1,2}, K. RÖMERMANN¹, N. MACAULAY³, W. LÖSCHER^{1,2} ¹Dept. of Pharmacology, Toxicology and Pharm., Univ. of Vet. Med. Hannover, Hannover, Germany; ²Ctr. for Systems Neurosci. Hannover, Hannover, Germany; ³Dept. of Neurosci. and Pharmacol., Univ. of Copenhagen, Copenhagen, Denmark

Abstract: Bumetanide is a loop diuretic that acts via inhibition of NKCC2 in the kidney. The NKCC isoform NKCC1, which is also blocked by bumetanide, is of interest in the pathology of neurological diseases such as epilepsy or neonatal seizures, which leads to new potential therapeutic indications for bumetanide. Epilepsy-associated upregulation of NKCC1 leads to a GABA shift from hyperpolarizing to depolarizing. Bumetanide has been proposed to restore GABA function in neonates with difficult-to-treat seizures as an add-on therapy to a GABA-potentiating anti-seizure drug, such as phenobarbital (PB). A European multicentral clinical trial by Pressler et al. (2015) examining PB and bumetanide in neonates with PB-resistant seizures, however, was stopped early due to low efficacy and ototoxic adverse effects. Vibat et al. (2001) described two human splice-variants, hNKCC1A and hNKCC1B, of which NKCC1B is predominantly expressed in the brain. Thus, a substance that acts more selectively on hNKCC1B than hNKCC1A and penetrates better into the brain tissue than bumetanide is expected to be an effective anti-seizure treatment while having reduced peripheral effects.

Rubidium-86-transport-assays using Xenopus laevis oocytes that expressed either the human transporter hNKCC1A or hNKCC1B were performed with several known loop diuretics, hence NKCC2-inhibitors, which to our knowledge mostly have not been tested previously towards their effects on NKCC1. The examined compounds can roughly be divided into 5-sulfamoylbenzoic acid derivatives, the azosemide-like group lacking an acidic group, and a group of non-

sulfonamide derivatives. For negative control, we included the thiazide diuretic xipamide and the antidiabetic glybenclamide.

Bumetanide was used as a reference substance. IC_{50} values for bumetanide did not show significant differences for hNKCC1A and hNKCC1B and ranged from 0.5 to 1.1 μ M in-between experiments. Similarly, furosemide and torasemide inhibited hNKCC1A and hNKCC1B at about the same potencies. In contrast, neither xipamide nor glybenclamide inhibited transport in concentrations up to 200 μ M. Experiments with various other loop diuretics are under way. To our knowledge, we are first to compare the inhibitory potencies of various clinically approved loop diuretics towards the two major human splice-variants hNKCC1A and hNKCC1B. Though yet none of the tested compounds was selective for hNKCC1B, further experiments with chemically more diverse substances will be performed.

Title: Spontaneous activity and increase in seizure susceptibility in the YCaMKII KO mice

Authors: *A. SALAH¹, H. MA², O. DEVINSKY³, R. W. TSIEN¹ ¹NYU Neurosci. Inst., New York Univ. Sch. Med., New York, NY; ²Neurosci. Inst., Zhejiang Univ., Hangzhou, China; ³Comprehensive Epilepsy Ctr., NYU Univ. Sch. Med., New York, NY

Abstract: <u>Objective</u>: Activity-dependent gene expression is central for sculpting neuronal connectivity and neuronal plasticity in the brain. Recently, we identified the γ CaMKII as a shuttle protein for synapto-nuclear signaling that operates by carrying Ca⁺⁺/CaM into the nucleus to activate CaMKIV, CREB phosphorylation and gene expression in cultured neurons. However, the functional importance of this signaling pathway in vivo remains unclear. Knowing that CaMKII's are involved in neurological diseases like epilepsy and autism, we used a γ CaMKII KO mouse model to investigate their spontaneous activity and seizure susceptibility under Kainic acid (KA) by performing long-term (6 h to 2 weeks) video-electroencephalography (V-EEG). <u>Methods:</u> 3-6 month old mice under isoflurane anesthesia were implanted with 6 epidural electrodes. In search of spontaneous activity, each animal was subjected to recordings for 60 h at

3 different points (20 h per session). For seizure susceptibility, animals were recorded for 2 h at baseline before KA administration (25 mg/kg; i.p); after the injection mice were recorded for an additional 4 h to determine seizure latency (n=6 for each phenotype). Behavioral scoring for seizure intensity after KA injections was performed with a modified Racine Scale. Seizure latency was determined along with the time spent to reach the first stage (S1) and the first tonicclonic seizure (S4). **Results:** Spontaneous activity was increased in the *γ*CaMKII KO mice compared to controls as seen in the mean number of single spikes (p<0.0001), repetitive spikes (p<0.0035), and runs of spikes (p<0.07) over a 30 min period. Over 90 min, highly significant differences were found for all three conditions (p<0.0001) (n=6 for each phenotype). After KA injections, seizure susceptibility was greater in YCaMKII KO mice compared to controls (p<0.0001). Also, yCaMKII KO mice required less time to reach the first stage (S1) (p<0.0001) or the first tonic-clonic seizure (S4) (p<0.006). Conclusions: Taken together, our results indicate γ CaMKII, a little-studied member of the CaMKII family, may play a critical role in maintaining normal neuronal activity. Multiple genetic studies have suggested that γ CaMKII is a risk gene for autism. Importantly, our data show that γ CaMKII levels in autistic patients is only ~50% of the healthy group. Considering that about 30% ASD patients show epilepsy, our data support the idea that *y*CaMKII and, by extension, the synapto-nuclear signaling it mediates, may be involved in both epilepsy and autism.

Title: The γ -aminobutyric acid receptor modulates the mean duration of absence seizures on the myelin mutant taiep rat

Authors: *J. M. IBARRA-HERNÁNDEZ¹, C. CORTES², J. EGUIBAR³

¹Lab. de Neurofisiología de la Conducta y Control Motor, Inst. De Fisiología. Benemérita Univ. Au, Puebla, Mexico; ²Physiol., Benemerita Univ. Autonoma de Puebla, Puebla, Mexico; ³Benemerita Univ. Autonoma de Puebla, Puebla, Pue., Mexico **Abstract:** The absence seizures are one type of epilepsy which is characterized by a sudden loss of consciousness and characteristic spike-wave discharges in the electroencephalogram. Absence seizures are due to a decrease in the activity of the γ -aminobutyric acid receptor type A (GABAa) in the somatosensory cortex and an increase of the inhibition mediated by GABAa in the thalamo-cortical circuit. The aim of this study was to determine the effects of two GABAergic agonists gabapentin and gaboxadol in the absence seizures in myelin mutant taiep rats.

We used 9 months old taiep rats which were implanted and fixed to a stereotactic Kopft frame there we implanted electrodes in the hippocampus, cerebral cortex, neck muscles and in the right orbit of the eye to recorded there. Gabapentin (50, 100 and 400 mg/Kg) and gaboxadol (5, 10 and 20 mg/Kg) were given intragastrically at 0800 h. We made four 24-hour video-EEG recordings, the first one is control, and three additional recordings using an increasing doses scheme every 72 hours. Off-line we analyzed the frequency and mean duration of each absence seizure and the latency of the first crisis. We followed the NIH rules for the care of experimental animals and the protocol was approved by BUAP-IACUC with the number COSM-SAL-17-I.

The mean duration of absence seizures decreased by 2 hours after gabapentin administration from to 2.72 ± 0.13 s with 100 mg/Kg, 2.94 ± 0.16 s with 200 mg/Kg to a maximum reduction to 2.84 ± 0.12 s with 400 mg/Kg, being significant (*P*<0.05). On the other hand, gaboxadol produced a maximum effect during at 7 hours after administration with mean duration from 4.10 ± 0.12 s in control conditions to 6.33 ± 0.26 s with 10 mg/Kg, 4.90 ± 0.27 s with 20 mg/Kg being significant between all doses respect to control (*P*<0.05). Importantly, frequency and the latency for the first absence seizure did not change under both treatments.

The decrease in duration of absence seizures due to gabapentin and the increase induce by gaboxadol strongly suggest that different types of GABAa receptors participate in the modulation of thalamo-cortical circuit because gabapentin act preferentially in extrasynaptic sites and gaboxadol in the postsynaptic ones.

Title: Deconstruction of thalamic circuits in a mouse model of post-traumatic epilepsy

Authors: *S. HOLDEN¹, J. PAZ²

¹UCSF, San Francisco, CA; ²Neurol., Gladstone Inst. of Neurolog. Dis., San Francisco, CA

Abstract: Post-traumatic epilepsy (PTE) accounts for 20% of symptomatic epilepsy cases and 5% of all epilepsy cases. The mechanisms underlying how traumatic brain injury (TBI) leads to PTE remain unknown, which has limited the development of interventions for preventing or curing epilepsy after injury. The cortex is typically the most affected brain area at the onset of a TBI, but the thalamus is also an important site of dysfunction after injury because of its reciprocal connections with the cortex. One of the prominent characteristics of the thalamus is its ability to produce reverberating bursting activity, which is important for sensory processing, attention, and the maintenance of sleep. Abnormal thalamic bursting is associated with cognitive dysfunction after TBI and is also pathological in some types of epilepsies. However, it remains unknown whether cortical TBI can alter thalamic function, and whether these alterations may be involved in the development of PTE. Furthermore, there is currently no cure for PTE. Here we use electrophysiological approaches to identify how cortical TBI may lead to hyperexcitability and aberrant synaptic plasticity in the thalamus, and to test whether the thalamus could be a potential therapeutic target for preventing or curing PTE. We hypothesized that TBI causes a shift in the brain's excitation/inhibition balance by altering the excitability of thalamic neurons and rewiring connections in the intra-thalamic circuit. We used the controlled cortical impact PTE model in mice and performed electrophysiological recordings in brain slices and in vivo to determine if TBI in the somatosensory cortex leads to altered function of thalamic cells. Using whole-cell patch-clamp recordings in thalamic slices, we showed that cortical TBI reduces the intrinsic excitability of inhibitory neurons and enhances the intrinsic excitability of excitatory relay thalamocortical neurons, but that glutamatergic and phasic GABAergic synaptic function are unaltered in the thalamus. Using EEG/video and thalamic depth recordings during free behavior, we showed that post-traumatic seizures are characterized by robust high-frequency bursts in the somatosensory thalamus. Our study shows that TBI alters the inhibitory/excitatory balance in the thalamus, mainly through changes in intrinsic membrane properties of thalamic cells, and that the thalamus is involved in PTE seizure expression. These results reveal how neural circuits adapt after TBI and may provide new therapeutic strategies for enhancing functional recovery while preventing seizures and/or epileptogenesis after injury.

Title: Impaired homeostatic potentiation of inhibitory GABAergic currents induced by slowwave oscillation in an idiopathic generalized epilepsy model with GABAR A322D mutation

Authors: *C. ZHOU¹, L. DING¹, M. J. GALLAGHER², R. L. MACDONALD³ ¹Neurol., Vanderbilt Univ. Med. Ctr., Nashville, TN; ²Neurol., Vanderbilt Univ. Sch. of Med., Nashville, TN; ³Professor & Chair, Dept Neurol, Vanderbilt Univ., Nashville, TN

Abstract: Seizures affect almost 3 million peoples in US and cause cognitive and other clinical comorbidities and in two thirds of patients, the causes are not known (possible genetic origins, idiopathic generalized epilepsy). Particularly epileptic activity onset is mostly present during sleep-wake transition or quiet wake period, suggesting that slow-wave oscillations during sleep period may have important roles on seizure onset/initiation. Here we used an idiopathic generalized epilepsy mouse model with GABAR A322D mutation to examine the homeostatic potentiation of both spontaneous excitatory and inhibitory synaptic currents in layer V pyramidal neurons of somatosensory cortex, with whole-cell recordings in ex vivo brain slice preparation. Spontaneous(s) EPSCs were recorded at Cl⁻ reversal potentials, and spontaneous(s) IPSCs recorded at -60mV with AMPARs being blocked. After 10 minutes slow-wave oscillation induction, sEPSCs or sIPSCs at 25~30 min were measured and averaged for 5 min recordings, in comparison to sEPSCs or sIPSCs before slow-wave oscillation induction. We found that 0.5 Hz cosine slow-wave oscillation (10 min) could potentiate sEPSCs (from -9.9 \pm 0.81 to -14.4 \pm 0.76 pA, n=7, percentage increase 47.8 \pm 6.46%, pair t-test p=0.001) and sIPSCs (from -19.9 \pm 2.29 to -32.9 ± 3.46 pA, n=9; percentage increase 70.6 $\pm 15.96\%$, paired t-test p=0.002) in WT littermates, suggesting that the dynamic balance of potentiated synaptic E-I in pyramidal neurons induced by slow-wave oscillation is maintained. In heterozygous mice with A322D mutation, slow-wave oscillation still potentiated sEPSCs (from -19.58 ± 5.81 to -23.16 ± 4.05 pA, n=4, percentage increase $32.36 \pm 16.50\%$, not significant different from WT increase, t-test p=0.433). However, slow-wave oscillation could not potentiate sIPSCs (from -17.09 \pm 2.54 to -18.86 \pm 3.24 pA, n=6, percentage increase 9.40 \pm 6.70%, significant from WT sIPSCs increase, t-test 0.005), suggesting that the dynamic balance of potentiated synaptic E-I in pyramidal neurons might be impaired in het mice. In conclusion, slow-wave oscillation during sleep or quiet wake period could create the dynamic imbalance between potentiated sEPSCs and sIPSCs in het mice, which would exacerbate the synaptic E-I imbalance in layer V cortical pyramidal neurons and

very likely initiate seizures in this idiopathic generalized seizures model during sleep-wake transition or quiet wake period.

Title: Enhydrazinones have anticonvulsant activity in rat In vitro seizure models

Authors: *S. B. KOMBIAN¹, F. KHALIFOUH², I. O. EDAFIOGHO³, C. I. EZEAMUZIE² ²Fac. of Med., ¹Kuwait Univ., Safat, Kuwait; ³Pharmaceut. Sci., Univ. of St. Joseph, Hartford, CT

Abstract: Enaminones are a novel class of compounds with reported anticonvulsant activity. Enhydrazinones are similar to enaminones but have a hydrazino moiety (NHNH) joined to a keto group through a carbon-carbon double bond. We tested if this chemical modification also yielded compounds with synaptic depressant and anticonvulsant activity. 350 µM thick coronal slices of the forebrain containing the hippocampus were generated from male Sprague-Dawley rats. Evoked, population spikes (PS) were recorded in the cell body layer of area CA1 of the hippocampus using bipolar electrodes to activate Schaeffer collateral/commissural fibers. In vitro seizures were generated either chemically or electrically. The effects of 3 enhydrazinones were tested on the PS and seizure models. All the tested enhydrazinones, EMP6, EMP8 and EMP10 caused dose-dependent reduction in PS amplitude with estimated EC₅₀ values of 1.7, 0.83 and 6.62 μ M respectively. 1 μ M EMP8 consistently depressed the PS by -23.3 \pm 2.3% (n=6). This effect was blocked by 50 μ M bicuculline (-8.2 \pm 2.2%, n=4) and by 1 μ M CGP54626 (-2.4 \pm 9.3%, n=5). When *in vitro* seizure-like activity was induced by removing Mg^{2+} from the perfusion solution, (zero Mg²⁺ model) the slice developed multiple spikes(mPS) (1 vs 3.3 ± 0.3). Subsequent treatment with 1 μ M EMP8, reduced the spike number to 2.0 \pm 0.3 (36.3 \pm 2.7% reduction, n=10). A similar result was observed when picrotoxin was used to generate mPS (3.2 \pm 0.6 in picrotoxin alone vs 2.2 \pm 0.6 in EMP8, n=7). The effect of EMP8 on zero-Mg²⁺-induced mPS was blocked by 1 μ M CGP54626 (3.3 ± .4 in CGP vs 2.7± 0.4 in CGP+EMP8; n=4). EMP8 (1 μ M) also inhibited spontaneous bursting (SB) induced by zero-Mg²⁺ (8.3 ± 2.5 vs 0.3 ± 0.4, n=3), nearly 100% abolition. This effect EMP8 on SB frequency was blocked by CGP54626 (3.4 \pm 1.5 vs 3.0 \pm 0.5; n=4). Finally, SB induced by high frequency afferent stimulation (stimulus train induced bursts-STIBs) were also suppressed by EMP8 (9.0 ± 0.9 /min vs 2.8 ± 0.9 /min, n=4) yielding an average of $67.3 \pm 9.9\%$ depression. Taken together, our data indicate that enhydrazinones, like enaminones, suppress PS and chemically- and electrically-induced seizure-like activity in the rat hippocampus via a GABAergic mechanism.

Title: Opposite control by 5-HT_{2C} receptors on generalized and focal seizures

Authors: *G. DI GIOVANNI^{1,2}, G. DEIDDA^{1,2}, R. COLANGELI¹, A. CAVACCINI², M. VENZI², G. ORBAN^{1,2}, M. PIERUCCI¹, V. CRUNELLI^{1,2} ¹Physiol. and Biochem., Univ. of Malta, Msida, Malta; ²Cardiff Univ., Cardiff, United Kingdom

Abstract: The 5-HT_{2C} receptor (5-HT_{2C}R) is thought to be involved in neuronal excitability and seizure generation. 5-HT_{2C}R knockout mice display spontaneous generalized convulsive seizures which cause a high mortality rate and a reduced threshold for various convulsant stimuli. Conversely, 5-HT_{2C}R activation increased the threshold of generalized convulsive seizures induced by pentylenetetrazole and electroshock in mice. Here we show the 5-HT_{2C}R also negatively controls non-convulsive generalized seizures, in the polygenic animal model of absence epilepsy, the Genetic Absence Epilepsy Rat from Strasbourg. RO60-0175, lorcaserin and CP809101 were capable of blocking absence seizures. Interestingly, as expected, SB242084 blocked the effect of lorcaserin and CP809101, but also showed some anti-absence effects. One possible mechanism by which 5-HT_{2C}R activation exerts antiepileptic effects is via the normalization of the aberrant GABAA receptor tonic inhibition in the ventrobasal thalamus seen in different animal models of absence epilepsy. The 5-HT_{2C}R system seems devoid of any modulatory role in partial seizures, or paradoxically, have a pro-epileptic role in this type of epilepsy. Indeed, we observed that mCPP and lorcaserin, but not RO60-0175, were able to halt hippocampal afterdischarges in a rat model of temporal lobe epilepsy, an effect potentiated and insensitive to SB242084 pretreatment. We confirmed this evidence in the pilocarpine-model of status epilepticus in rats, where the RO60-0175 was devoid of any anti-seizures effect, while SB242084 increased the antiepileptic activity of cannabinoids agonists. In summary, 5-HT_{2C}R agonists may have new therapeutic utility in generalized epilepsy. Moreover, activation of the 5HT_{2C}R may also be useful for treating comorbid neuropsychiatric disorders commonly seen in people with epilepsy.

Title: An investigation into the cell-type specific effects of a dominant negative mutation in Kv3.1 underlying cases of progressive myoclonic epilepsy

Authors: *J. C. CARPENTER, G. LIGNANI, S. SCHORGE Clin. and Exptl. Epilepsy, UCL Inst. of Neurol., London, United Kingdom

Abstract: Unverricht-Lundborg disease (ULD) is the most common form of Progressive Myoclonic Epilepsy (PME); a highly heterogeneous group of rare neurological disorders characterised by action myoclonus, tonic-clonic seizures and ataxia, with largely preserved cognition. The genetic causes of ULD are diverse, occurring in genes of apparently unrelated function with no direct effects on neuronal excitability. Recently, however, a de novo, dominant negative mutation in KCNC1 has been identified as a novel cause of ULD-like PME. KCNC1 encodes Kv3.1, a member of the Kv3 family of voltage-gated potassium channels, which contribute to the rapid repolarisation of action potentials and high frequency firing. Kv3.1 channels are highly expressed in fast-spiking, parvalbumin-positive interneurons, leading some to suggest that KCNC1-based PME represents a selective dysfunction of these cell types. Here we combine optogenetic and classical electrophysiological approaches with the Cre-lox genetic system to determine how the c.959G>A mutation in KCNC1 alters the activity of fast spiking parvalbumin interneurons. Our method allows for the presynaptic effects of this mutation to be isolated and restricted to specific excitatory or inhibitory cell types and we will focus initially, on how overexpression of mutant Kv3.1 channels alters the intrinsic properties of different types of neuron.

Title: Optokindling: Catastrophic reorganization of cortical circuits by repeated optogenetic stimulation

Authors: *K. M. FRANKS¹, P. LEE², B. RYU² ¹Neurobio., ²Duke Univ., Durham, NC

Abstract: Different odors activate specific, distributed and overlapping ensembles of ~10% of principal cells in piriform cortex (PCx). These cells are also interconnected via long-range recurrent collateral connections. The formation of odor memories is thought to result by selective strengthening of recurrent synaptic connections between repeatedly co-active neurons. We sought to examine this process by directly activating random subsets of PCx neurons. To do this, we first used viral vectors to express channelrhodopsin-2 (ChR2) in random subsets of ~10% of PCx principal cells and then repeatedly co-activated these ensembles directly. We stimulated these cells several times per day with brief light trains delivered via an optical fiber implanted above PCx (20 Hz trains for 5 s. 6x/day). Optical stimulation initially had little effect, with animals pausing briefly during the light train. However, within 4 days, the same stimulation reliably triggered a cascade of activity that culminated in massive, stage 6 running-jumping seizures. Continuous local field potential (LFPs) recordings revealed that cortical activity becomes increasingly entrained to the 20 Hz light trains never produced seizures in kindled mice.

To reveal the neural circuit consequences of this process, which we call "optokindling", we isolated acute brain slices from injected mice and used whole-cell patch-clamp recordings to examine changes in synaptic connectivity. We found a large change in the balance of recurrent excitation/feedback inhibition in kindled mice. However, surprisingly, this was not due to robust increases in recurrent excitation, but rather, was due to a large decrease in feedback inhibition. These changes were synapse-specific, as both afferent excitatory inputs from olfactory bulb and the feedforward inhibitory inputs they recruit were unaffected. Consistent with this result, we found a dramatic decrease in GABA expression in PCx inhibitory interneurons in kindled

mice.Next, we examined the role of endogenous and exogenous cannabinoids in seizure expression. Low systemic doses of the CB1 agonist, Win55,255, completely suppressed light-evoked seizures in kindled mice. By contrast, low doses of the CB1 antagonist, AM251, exacerbated seizures that often killed the mice (4/7 mice, vs. 2/58 control mice). In slice experiments, we reveal a CB1-dependent DSE PCx that could support this on-demand neuroprotective effect.

Optokindling can therefore be used to probe the consequences of pathological activity in a recurrent cortical circuit.

Title: Measurement of effects and administration of carbenoxolone in real time on high frequency oscillations involved in hippocampal epileptogenesis

Authors: *C. VENTURA, J. R. BELTRAN-RAMIREZ, M. A. CERPA-GALLEGOS, E. ARCINIEGA-VÁZQUEZ, S. A. CASILLAS-ROMERO, E. A. PADILLA-ZEPEDA, J. A. JÍMENEZ-OLVERA, G. ZARATE-RODRÍGUEZ, J. A. CHÁVEZ-GARCÍA Ctr. De Enseñanza Técnica Industrial, Guadalajara, Jalisco, Mexico

Abstract: Epilepsy is a neurological disorder that affects the world population and presents a prevalence of 2 to 5%. Animal models are a key tool for the study of the basic mechanisms of crisis generation and the Pilocarpine-induced Temporal Lobe Epilepsy (ELT) model simulates the main features of this pathology. In this model the presence of high frequency activity (250 to 600Hz) denominated Fast Ripples (FRs) has been observed, as well as in ELT patients. FRs reflect the activity of a group of pathologically interconnected neurons that play an important role in epileptogenesis of the hippocampus. Likewise, there is experimental evidence of the participation of the communicating unions (UC) in epilepsy. Until now they have related to the modulation of gap junctions but has not worked with measuring equipment in real time without the intervention of human labor, as well as the administration of drugs without human intervention so the registration and administration can be performed without interruption, which allows us to analyze the data obtained with an algorithm which does not throw errors by the manipulation periods and gives us periods of time without real analysis or with errors of detection of activity. In this work we will analyze the effect of carbenoxolone on the hippocampus of spontaneous recurrent seizures induced by pilocarpine in order to determine the possible modulation of FRs by electrical synapses by a system without errors and in real time.

Until now we have a 80% diminution of epileptiform activity in the hippocampus in only two wistar rats.

Title: GluA1 subunit plasticity is necessary to sustain prolonged seizures

Authors: *S. JOSHI, E. LEWCZUK, J. WILLIAMSON, M. PENMETSA, J. KAPUR Dept of Neurol., Univ. of Virginia, Charlottesville, VA

Abstract: Prolonged seizures enhance AMPAR-mediated neurotransmission and increase surface membrane trafficking of GluA1 subunits. Whether this GluA1 subunit plasticity contributes to sustaining prolonged seizures is not known.

Adult mice lacking GluA1 subunit of AMPA receptors (GluA1^{-/-}, KO) or GluA1 subunitexpressing littermates (GluA1^{+/+}, WT) were used. Electrical pulse trains (50 Hz, 0.1sec, 50-200 uA, 10 sec duration were delivered to the left hippocampus to determine afterdischarge threshold (ADT). Animals received pulse trains (2X ADT) every 15 sec (5 sec off period) for 30 or 60 min. Animals were monitored by continuous video-EEG for 24 hr. Seizure spread was determined in terms of expression of Fos protein using standard immunohistochemical techniques. ADT in the KO mice was similar to WT mice ($130 \pm 12 vA$). The electrically-evoked seizure lasted for 10-15 sec in both the strains of mice. Hippocampal stimulation for 30 min caused self-sustaining seizures in 64% of WT mice (n=12), but not in the KO mice (n=7, p<0.05, Chi-square test). Stimulation for 60 min triggered self-sustaining seizures in 77% of WT mice, n=13) as compared to 50% of KO mice (n=11, p<0.05). Although 50% of the KO animals experienced prolonged seizures, the total seizure duration in these animals was shorter than that in the WT mice (91 ± 14 min vs 342 ± 64 min, p<0.05).

Seizure spread to extrahippocampal areas could sustain prolonged seizures. In the WT animals intense Fos immunoreactivity (IR) was present in the DGCs, CA3 and CA1 pyramidal neurons, neurons in the subiculum, entorhinal cortex, lateral septum, cingulate and motor cortex, and

olfactory bulbs and olfactory cortex. In contrast, Fos IR was primarily restricted to the hippocampi in the KO mice. The number of Fos-positive neurons was also reduced in CA1 and subiculum.

WT animals in self-sustaining seizures evoked by continuous hippocampal stimulation for 60 min were treated with calcium-permeable AMPAR blocker IEM 1460 or saline. The seizures lasted for 206 ± 15 min (n=17) in saline-treated animals. In contrast, seizures terminated after 106 ± 21 min (n=5) in the mice treated with IEM 1460 30 min after the end of stimulation. Treatment of IEM 1460 at 15 min following stimulation led to a further shortening of seizure duration (51 ± 21 min, n=9, p<0.05).

In KO mice seizure were less likely to become self-sustaining (status epilepticus). When selfsustaining seizure were initiated in KO mice they were of shorter duration with limited spread. These studies combined with drug treatment study suggested a critical role for GluA1 plasticity in sustaining prolonged seizures.

Title: Potentiation of AMPA receptor-mediated synaptic transmission in hippocampal CA1 pyramidal activated by a single seizure

Authors: *H. SUN, J. WILLIAMSON, J. KAPUR Neurol., Univ. of Virginia, Charlottesville, VA

Abstract: <u>Rationale:</u> Seizures consist of sustained repetitive firing of a group of neurons. Seizures can enhance susceptibility to further seizures but the mechanisms remain uncertain. We tested whether single seizure potentiates AMPA receptor (AMPAR) mediated synaptic transmission on seizure-activated CA1 pyramidal neurons.

<u>Methods</u>: Transgenic mice that express EGFP under the control of tetracycline repressor and early immediate gene, cfos (Mayford) were maintained on high doxycycline diet until 48 hours prior to a single seizure, induced by pentyleneterazol (40 mg/kg, i.p.). Hippocampal slices appropriate for patch clamp electrophysiology were prepared 30 minutes after the seizure.

Whole-cell patch clamp recordings of AMPAR-mediated EPSCs, passive and active membrane properties were made from GFP^{+ve} and neighboring GFP^{-ve} cells in the same slice. Results: A small number of GFP^{+ve}CA1 pyramidal neurons dispersed among GFP^{-ve} neurons were visualized from hippocampal slices under fluorescent/DIC microscope. Passive membrane properties (resting membrane potential, membrane time constant and membrane resistance) of GFP^{+ve} and neighboring GFP^{-ve} were similar (16 pairs, from 16 animals). Although action potential threshold, amplitude, and width were similar, 11/20 GFP ^{+ve} cells fired >1 action potential in response to depolarizing current steps, only 3/20 GFP ^{-ve} (p < 0.05 c² test)did so. Miniature EPSCS were recorded after blocking GABA-A receptors (picrotoxin) and action potentials (TTX) under voltage clamp. The amplitude of mEPSCs from GFP ^{+ve} neurons (19.37 mV + 1.88, mean + 2 SD) was larger than that recorded from neighboring GFP –ve neurons (16.85 mV + 2.12) from the same slice and animal (P = 0.0002, paired t-test for 15 pairs). To investigate whether AMPAR properties were altered during seizure-induced enhancement of transmission, we investigated rectification of evoked EPSCs. There was inward rectification of eEPSCs recorded from GFP^{+ve} neurons, which was not observed in GFP^{-ve} neurons. Morphological study of the neurons performed by 3D reconstruction of biocytin filled neurons is in progress.

<u>Significance</u>: These studies suggest that a single seizure potentiates AMPAR-mediated transmission in a small number of CA1 neurons, identifiable by the activation of cfos gene. Seizures cause calcium entry into neurons, which entry could also trigger potentiation of glutamatergic transmission, through insertion of GluA1 subunit into glutamatergic synapse and activation of cfos gene.

Abstract: The link between inhibitory GABAergic neurotransmission and genetic generalized epilepsy (GGE) is a well-supported paradigm generated from molecular genetics of GABA receptor subunits, transgenic model systems, pharmacology, neuropathology, and electrophysiology. The focus on postsynaptic GABA channelopathies has historically attracted much attention, however, the research focus is evolving towards a proteomic synaptopathy approach. Consequently, we investigated the genetic variation within GABAergic transporters (GAT1 & GAT3) and biosynthetic proteins (GAD65 & GAD67) in 708 GGE cases from Australia, UK and New Zealand using a combination of light-scanner heteroduplex screening and direct Sanger sequencing. Eighteen novel or rare GABAergic variants were discovered in 34 GGE cases with a strong preference for absence seizure syndromes. All 18 GABAergic missense variants had deleterious outcomes in mutation-prediction software and protein-structure molecular modelling. Wild-type and mutation expression-constructs were prepared for all 18 GABAergic gene-variants in addition to a further 7 published de novo GAT1 mutations linked to myotonic-atonic seizures but without functional validation. GAT1 and GAT3 variants were analysed using various in vitro functional assays including a bespoke GABA-activity assay based on isotopically-labelled GABA with Mass Spectrometry, essential splice-site assays and cellsurface trafficking status. Reduced GABA activity was observed for the majority of GAT1 and GAT3 gene-variants. GAD65 and GAD67 mutation constructs were tested in a highly-sensitive florescence-based GAD enzymatic assay using a resazurin-linked GABase microplate format. This revealed altered GAD activity and reduced binding properties to co-factor, pyridoxal 5'phosphate (PLP). This study confirms the association between GABA transport / biosynthesis and absence seizures in GGE syndromes, which is supported by extensive in vitro evidence with important patient-specific outcomes.

Title: Short-term depression of sprouted mossy fiber synapses from adult-born granule cells

Authors: *W. HENDRICKS¹, Y. CHEN¹, G. L. WESTBROOK¹, E. SCHNELL² ¹Vollum Inst., Portland, OR; ²Portland VA Med. Ctr., Portland, OR

Abstract: Epileptic seizures potently modulate hippocampal adult neurogenesis, and adult-born dentate granule cells contribute to the pathologic retrograde sprouting of mossy fiber axons, both hallmarks of temporal lobe epilepsy. The characteristics of these sprouted synapses, however, have been largely unexplored, and the specific contribution of adult-born granule cells to functional mossy fiber sprouting is entirely unknown. To overcome previous technical limitations, we use DcxCreER^{T2} transgenic mice to permanently pulse-label and optogenetically activate neurons born either before or after pilocarpine-induced status epilepticus (SE). We demonstrate that adult-born granule cells born prior to SE form functional recurrent monosynaptic excitatory connections with other granule cells by two months following SE. Surprisingly, although healthy mossy fiber synapses in CA3 are well characterized "detonator" synapses that potently drive post-synaptic cell firing through their profound frequency-dependent facilitation, sprouted mossy fiber synapses from adult-born cells exhibited profound frequencydependent depression, despite possessing some of the morphological hallmarks of mossy fiber terminals. Neonatally-born, mature granule cells also contributed to functional mossy fiber sprouting, but exhibited less synaptic depression. Interestingly, granule cells born shortly after SE did not form functional excitatory synapses, despite robust sprouting. Considering that adultborn granule cells are the most likely to sprout recurrent mossy fiber axons, our results suggest that although they form recurrent excitatory circuits with some of the morphological characteristics of typical mossy fiber terminals, the functional characteristics of these sprouted

synapses would limit the contribution of adult-born granule cells to hyperexcitability in the epileptic hippocampus.

Title: The role of Neuroligin 2 and inhibitory transmission in the function of thalamic circuitry during epilepsy

Authors: *F. CAO, J. LIU, Z. JIA

Neurosci. and Mealth Hlth., The Hosp. For Sick Children, Toronto, ON, Canada

Abstract: Epilepsy is one of the most common neurological disorders. At the cellular level, epileptic seizures are caused by abnormal, excessive or synchronous neuronal electrical activity in the brain. However, the exact mechanisms of epilepsy remain largely unknown. Neuroligin 2 is a postsynaptic cell adhesion protein, which is exclusively located at inhibitory synapses and serves a role in regulating the balance between brain excitation and inhibition. Importantly, the imbalance between excitation and inhibition tends to cause the disruption of neuronal activities, which may lead to epileptic seizures. By using electroencephalogram and electrophysiological recordings, we found that mice lacking Neuroligin 2 display abnormal seizure-like brain activities and an impaired inhibitory neuronal function in an epilepsy-related thalamic circuitry. Importantly, the abnormal brain activity can be rescued by the administration of a drug directed at enhancing the inhibitory synaptic transmission. These results suggest that Neuroligin 2 regulates normal brain function through modulating inhibition. Our findings provide crucial insight into the mechanisms underlying epilepsy generation and to facilitate the understanding and treatment of related brain disorders.

Title: Effects of BDNF and trk receptors on models of seizure activity in hippocampal slices

Authors: J. J. BOTTERILL, *H. E. SCHARFMAN

Dementia Res., The Nathan Kline Inst. For Psych. Res., Orangeburg, NY

Abstract: It has been shown that brain-derived neurotrophic factor (BDNF) acting at trkB receptors may promote seizure activity in hippocampus under some conditions. Interestingly, few studies have examined the effects of BDNF and trk in models of seizures in hippocampal slices of control animals, where many investigators have examined effects of antiseizure drugs in the past. Therefore we used hippocampal slices from naïve rats and mice to test the effects of trk antagonism on seizure-like activity produced in three ways that have been commonly used in the past: reduced $[Mg^{2+}]_0$, elevated $[K^+]_0$, or disinhibition. Hippocampal slices from adult male Sprague-Dawley rats or C57BL6 mice were prepared with standard procedures. In brief, 400 µm-thick horizontal slices were cut in artificial cerebrospinal fluid (ACSF) containing sucrose substituted for NaCl and immediately placed in an interface-style recording chamber at 32°C. After 30 min a NaCl-based ACSF was used containing (in mM: 126 NaCl, 3.5 KCl, 2 mM MgSO₄, 1.25 NaH₂PO₄, 2.4 CaCl₂, 26 NaHCO₃, 10 d-glucose; pH 7.3-7.4). Recording electrodes containing this ACSF were positioned in area CA3. Three methods were used to induce seizurelike activity: 1) [Mg²⁺]₀ was decreased (to nominally 0 mM), 2) [K⁺]₀ was elevated (to 7.5 mM), or 3) GABAA receptors were blocked with 10 µM bicuculline methiodide. The types of epileptiform activity that were measured were 1) epileptiform bursts (each burst composed of a cluster of population spikes, >50 ms duration, recurring at 0.1-0.25 Hz) and 2) spontaneous episodes of spreading depolarization (SD). SD was characterized by a >10 mV DC negative shift that lasted >5 min. The trk antagonist K252a (500 nM) reduced SD in all three seizure models but there was no detectable effect on epileptiform bursts (n=2 animals per seizure model where 2-3 slices were sampled per animal). Vehicle (DMSO) had no detectable effect. If SD is considered analogous to a seizure, and epileptiform bursts in area CA3 are considered analogous to interictal spikes, the data would suggest that trk is involved in seizures but possibly not interictal spikes. Collectively, our findings suggest that trk antagonism could be an effective way

to inhibit seizures that involve area CA3. The data may also be relevant to migraine, because SD is often considered to contribute mechanistically.

Abstract: Epilepsy, characterized by unprovoked recurrent seizures, is linked to behavioral changes such as loss of memory, difficulty learning, and decreased cognition in the postictal period. Status epilepticus (SE), or an uninterrupted seizure of extended length has been seen to not only increase the risk for the development of epilepsy later in life, but also has been linked to changes in structural morphology in the neuronal network. After the occurrence of SE, dendrites undergo a morphological change which reduces the number of dendritic spines as well as the dendritic branching (Swann et al, 2000). In addition to changes in dendritic morphology, previous studies have shown that there is a significant change in the morphology and accumulation of microglia in the hippocampus after an episode of SE (Schartz et al, 2016). Although the post-SE anatomical changes in the hippocampus have been demonstrated in CA1 neurons up to 35 days after the event, the physiological changes that are predicted to accompany these changes have not been measured. In this study, we investigate the changes in hippocampal CA1 network responses using local field potential (LFP) recordings in slice to measure the synaptic efficacy at different time points following an induced episode of SE as well as induction of long term potentiation (LTP) to measure the synaptic plasticity retained. Preliminary results suggest that synaptic efficacy is diminished at and beyond 14 days post induced SE. Furthermore, we hypothesize that the plasticity of the remaining synapses is not affected at these time points. Understanding these properties in relation to microglial-mediated changes in synaptic density after a prolonged seizure will help with the understanding of the behavioral side effects that are commonly associated with epilepsy and provide information for modulation of neuronal mechanisms to reduce or prevent the accumulation of these effects.

Title: Contrasting properties of active and inactive hippocampal dentate granule cells

Authors: *S. A. PARK¹, F.-C. HSU¹, H. TAKANO¹, I. PETROF¹, D. A. COULTER^{1,2,3} ¹Neurol., ²Pediatrics, Children's Hosp. of Philadelphia, Philadelphia, PA; ³Neurosci., Univ. of Pennsylvania, Philadelphia, PA

Abstract: The hippocampus is a critical mediator of spatial learning and navigation. The dentate gyrus contributes to this function through its sparse activation properties, which aids in distinguishing between similar cortical inputs (pattern separation). Using 2-photon imaging in awake, behaving animals navigating a virtual environment, we found that a smaller number of dentate granule cells (DGCs) activate at lower frequencies than neighboring CA1 pyramidal neurons. We explored the intrinsic and local circuit mechanisms mediating this characteristic sparse DGC activation. We used fos-TRAP (targeted recombination in active populations) transgenic mice, crossed to a tdTomato reporter mouse to label active DGCs in vivo following exposure of mice to an enriched environment and 4-hydroxytamoxifen injection, and then recorded from hippocampal slices prepared from these same mice. In fosTRAP mice, in active neurons, the fos promoter drives expression of CreERT, which, in the presence of tamoxifen, drives tdTomato reporter expression. As expected, fosTRAP labeled DGCs were sparse: on average, 7.2 cells were labeled with tdTomato per dentate blade in a given slice. To understand the intrinsic and synaptic properties that differentiate active (tdTomato+) from inactive (unlabeled) DGCs, we used whole-cell patch-clamp to record intrinsic properties as well as synaptic potentials elicited by perforant path stimulation. Active DGCs had a larger IPSC amplitude, shorter IPSC time-to-peak, and a longer EPSC time-to-peak compared to neighboring inactive DGCs. These data, where larger, faster IPSCs associate with active DGCs, are counterintuitive. We further tested whether intrinsic neuronal properties might contribute to differential activation, and found that active DGCs had a lower input resistance, and a higher action potential threshold, both also inconsistent with elevated excitability. These results suggest that DGCs activate in vivo primarily due to a difference in the afferent input, and not to local circuit processing. Continued investigation of the synaptic connections and microcircuit properties may further clarify how active and inactive DGCs process their synaptic inputs to generate their characteristic behavior.

Title: Optogenetic dissection of developing synaptic activity during evolving epileptiform activity

Authors: *R. T. GRAHAM¹, E. JOHNSON¹, N. CODADU², R. R. PARRISH⁴, A. J. TREVELYAN³

¹Inst. of Neurosci., Newcastle Univ., Newcastle-upon-Tyne, United Kingdom; ²Inst. of Neurosci., Newcastle Univ., Newcastle Upon Tyne, United Kingdom; ³Inst. of Neurosci., Newcastle Univ., Newcastle upon Tyne, United Kingdom; ⁴Inst. of Neurosci., Univ. of Newcastle, Newcastle Upon Tyne, United Kingdom

Abstract: Bathing brain slices in 0 Mg^{2+} artificial cerebro-spinal fluid (ACSF) induces an evolving pattern of epileptiform activity, including short interictal bursts of activity, and sustained discharges that replicate many features of tonic-clonic seizures in vivo. The most important, initial effect of removing Mg²⁺ ions is considered to be the removal of the voltage-dependent blockade of NMDA receptors, thereby greatly enhancing the excitatory synaptic effects mediated by glutamate. This though occurs rapidly, and the evolving epileptiform activity continues over a time course of many minutes and even hours. The epileptiform discharges therefore, cannot be ascribed simply to the NMDA effect, but rather, will involve dynamic reorganisation of the network. Changes in synaptic strength are likely to contribute to this process. We asked therefore whether the key network transitions seen in these preparations were associated with changes in synaptic function. We used an optogenetic approach to selectively stimulate three different subclasses of neurons (pyramidal cells, and two classes of interneurons: parvalbumin-positive (PV+) and somatostatin-positive (SOM+) that selectively expressed Channelrhodopsin, while monitoring the postsynaptic effect.

Brief optogenetic activation was achieved by 50ms flashes, delivered at 0.1Hz, close to the recording location through an optic fibre connected to an LED. The postsynaptic effects of

pyramidal activation was monitored using extracellular electrodes located in layers 1 and 5. Interneuronal activation was monitored by whole cell patch clamp recordings of pyramidal cells. We found clear changes in all three synaptic pathways associated with the evolving activity, and acutely with local seizure activity. Interestingly, regular "open-loop" optogenetic stimulation of the pyramidal cells appears to alter the time course of epileptic evolution in this simple model, consistent with other recent studies of open loop electrical stimulation in animal epilepsy models.

Title: Constitutive phosphomimetic inhibition of KCC2 at Thr906/Thr1007 causes GABAdependent network excitability, seizure, and early postnatal death

Authors: *M. WATANABE¹, J. DUAN², M. MANSURI², J. ZHANG², A. FUKUDA¹, K. T. KAHLE³

¹Dept Neurophysiol, Hamamatsu Univ. Sch. Med., Hamamatsu, Japan; ²Departments of Neurosurgery, Yale Sch. of Med., New Haven, CT; ³Departments of Pediatrics and Cell. and Mol. Physiology; Centers for Mendelian Genomics, Yale Sch. of Med., New Haven, CT

Abstract: A post-natal decrease in intraneuronal Cl⁻ concentration [Cl⁻]_i dependent on the Cl⁻ extruding KCC2 cotransporter establishes fast synaptic GABA inhibition. Inhibitory phosphorylation of KCC2 at two threonines (Thr⁹⁰⁶ and Thr¹⁰⁰⁷), a powerful switch of KCC2 activity, decreases in parallel with an increase in KCC2 activity and the lowering of neuronal [Clli, but the significance of this *in vivo* is unknown. Here, using unbiased LC-MS/MS phosphoproteomics, we demonstrate that KCC2 exhibits precise developmental regulation at only several phosphorylation sites, and most significantly at Thr⁹⁰⁶. We engineered mice to express two KCC2 alleles with the missense mutations Glu^{906} and Glu^{1007} "($KCC2^{e/e}$)" to mimic constitutive phosphorylation at these sites. $KCC2^{e/e}$ mice showed body weight reduction but exhibited normal gross and histological organogenesis and the characteristic developmental up-regulation of KCC2 protein. However, all KCC2^{e/e} mice exhibited status epilepticus provoked by mild physiological stimulation such as brushing and tail pinch, and died within the first post-natal day. *KCC2^{e/e}* mice showed spontaneous seizure and the frequency of seizure gradually increased before death. Patch-clamp measurements of E18.5 ventral spinal cord neurons in WT and KCC2^{e/e} mice demonstrated that the resting Cl⁻ level was not changed in KCC2^{e/e} mice but Cl⁻ extrusion capacity was significantly impaired after Cl⁻loading. In contrast to WT mice, KCC2^{e/e}

mice a lack of spontaneous respiratory discharge recordings from cervical ventral roots (C4) and altered locomotor rhythm recordings from lumbar ventral roots (L2). *KCC2^{e/e}* mice exhibited significant abnormalities in neuronal distribution in the septum, hypothalamus, hippocampus, and cortex, but normal dendritic spine formation. These data demonstrate precisely regulated KCC2 Thr906/Thr1007 phosphorylation during brain development is essential for activity-dependent Cl⁻ extrusion, neuronal development, and post-natal survival.

Title: Role of somatostatin and parvalbumin interneurons in 4-aminopyridine-induced epileptiform discharges in mouse cortex

Authors: *W. E. LADO, J. J. HABLITZ

Dept. of Neurobio., Univ. of Alabama in Birmingham, Birmingham, AL

Abstract: 4-Aminopyridine (4-AP) induces epileptiform discharges in a variety of brain regions. These events are associated with enhanced inhibitory as well as excitatory synaptic transmission. The relative contribution of specific subclasses of GABAergic interneurons to epileptiform activity in 4-AP model has not been well characterized. We have used genetically-encoded archaerhodopsin to investigate the role of somatostatin (SST) and parvalbumin (PV) interneurons in the regulation of evoked epileptiform discharges. Whole cell patch clamp recordings were obtained from L5 pyramidal cells in somatosensory cortex of 30 to 70 day old mice. In the presence of 100 µM 4-AP, local stimulation was used to evoke epileptiform activity. Archaerhodopsin activation in SST interneurons during (Light Off: 6385.98 ± 562.1 mV*ms vs Light On: $2873.44 \pm 165.2 \text{ mV*ms}$; p < 0.05, paired t-test) and after local stimulation (Light Off: 6601.67 ± 642.82 vs Light On: 4339.20 ± 431.6 mV*ms; p < 0.05, paired t-test) reduced the area under the curve (AUC) of epileptiform discharges. Similarly, archaerhodopsin activation in PV interneurons was effective in reducing the evoked responses when electrical stimulation occurred during (Light Off: 11029.35 ± 732.7 mV*ms vs Light On: 2234.16 ± 203.8 mV*ms; p < 0.05, paired t-test) or after (Light Off: 10610.44 ± 715.1 vs Light On: 3719.62 ± 288 ; p < 0.05, paired t-test) light onset. Light activation of the PV interneurons reduced responses to a significantly greater extent than that of SST interneurons both during $(24.49 \pm 1.2 \% \text{ vs } 55.19 \pm 2.3 \%; \text{ p} < 1.2 \% \text{ vs } 55.19 \pm 2.3 \%; \text{ p} < 1.2 \% \text{ vs } 55.19 \pm 2.3 \%; \text{ p} < 1.2 \% \text{ vs } 55.19 \pm 2.3 \%; \text{ p} < 1.2 \% \text{ vs } 55.19 \pm 2.3 \%; \text{ p} < 1.2 \% \text{ vs } 55.19 \pm 2.3 \%; \text{ p} < 1.2 \% \text{ vs } 55.19 \pm 2.3 \%; \text{ p} < 1.2 \% \text{ vs } 55.19 \pm 2.3 \%; \text{ p} < 1.2 \% \text{ vs } 55.19 \pm 2.3 \%; \text{ p} < 1.2 \% \text{ vs } 55.19 \pm 2.3 \%; \text{ p} < 1.2 \% \text{ vs } 55.19 \pm 2.3 \%; \text{ p} < 1.2 \% \text{ vs } 55.19 \pm 2.3 \%; \text{ p} < 1.2 \% \text{ vs } 55.19 \pm 2.3 \%; \text{ p} < 1.2 \% \text{ vs } 55.19 \pm 2.3 \%; \text{ p} < 1.2 \% \text{ vs } 55.19 \pm 2.3 \%; \text{ p} < 1.2 \% \text{ vs } 55.19 \pm 2.3 \%; \text{ p} < 1.2 \% \text{ vs } 55.19 \pm 2.3 \%; \text{ p} < 1.2 \% \text{ vs } 55.19 \pm 2.3 \%; \text{ p} < 1.2 \% \text{ vs } 55.19 \pm 2.3 \%; \text{ p} < 1.2 \% \text{ vs } 55.19 \pm 2.3 \%; \text{ p} < 1.2 \% \text{ vs } 55.19 \pm 2.3 \%; \text{ p} < 1.2 \% \text{ vs } 55.19 \pm 2.3 \%; \text{ p} < 1.2 \% \text{ vs } 55.19 \pm 2.3 \%; \text{ p} < 1.2 \% \text{ vs } 55.19 \pm 2.3 \%; \text{ p} < 1.2 \% \text{ vs } 55.19 \pm 2.3 \%; \text{ p} < 1.2 \% \text{ vs } 55.19 \pm 2.3 \%; \text{ p} < 1.2 \% \text{ vs } 55.19 \pm 2.3 \%; \text{ p} < 1.2 \% \text{ vs } 55.19 \pm 2.3 \%; \text{ p} < 1.2 \% \text{ vs } 55.19 \pm 2.3 \%; \text{ p} < 1.2 \% \text{ vs } 55.19 \pm 2.3 \%; \text{ p} < 1.2 \% \text{ vs } 55.19 \pm 2.3 \%; \text{ p} < 1.2 \% \text{ vs } 55.19 \pm 2.3 \%; \text{ p} < 1.2 \% \text{ vs } 55.19 \pm 2.3 \%; \text{ p} < 1.2 \% \text{ vs } 55.19 \pm 2.3 \%; \text{ p} < 1.2 \% \text{ vs } 55.19 \pm 2.3 \%; \text{ p} < 1.2 \% \text{ vs } 55.19 \pm 2.3 \%; \text{ p} < 1.2 \% \text{ vs } 55.19 \pm 2.3 \%; \text{ p} < 1.2 \% \text{ vs } 55.19 \pm 2.3 \%; \text{ p} < 1.2 \%; \text{ p} < 1.$

0.05, paired t-test) and after $(44.3 \pm 1.9\% \text{ vs } 65.26 \pm 0.8\%; \text{ p} < 0.05, \text{ paired t-test})$ electrical stimulation. This suggests that PV neurons may be more effective in reducing excitability in the 4-AP model. Since both types of cells were effective in reducing epileptiform activity, it raises the possibility that non-selective activation of interneurons could be more efficacious.

Title: Co-morbid epilepsy in a mouse model of autism

Authors: *M. L. LEWIS¹, J. M. RHO², Q. J. PITTMAN¹

¹Neurosci., Univ. of Calgary, Calgary, AB, Canada; ²Paediatrics, Alberta Children's Hosp. Res. Inst., Calgary, AB, Canada

Abstract: Autism Spectrum Disorder (ASD) and epilepsy co-occur at a high rate of 30%, suggesting that they may be linked by a common mechanism. To investigate mechanisms involved in the development of co-morbid ASD and epilepsy, a novel mouse model with a robust phenotype for both disorders was developed and validated.

BTBR T+tf/J (BTBR) mice are a well-validated model of ASD due to the ASD-like behavioural phenotype. This mouse model of ASD however, has not yet been shown to have co-morbid epilepsy. To this end, BTBR mice exposed to an immune challenge at postnatal day 7 (lipopolysaccharide, LPS; 100 μ g/kg i.p.) exhibited as adults a significant decrease in seizure thresholds (1% pentylenetetrazol; 2.5 ml/min i.v.; p<0.05), a significant increase in hippocampal electrographic seizure activity (p<0.05), and importantly, a preservation of the ASD behavioural phenotype when compared to saline treated controls.

Patients affected with co-morbid ASD and epilepsy often have a high rate of intractability with common pharmaceutical options. A limited neurobiological understanding of these disorders has precluded development of effective and personalized therapeutics. The ketogenic diet (KD) consists of a consumed ratio of 4:1 fat to combined protein and carbohydrate by weight resulting in conversion of fats into fatty acids and ketone bodies, which are used as an energy source. The KD has been shown to be an effective treatment for medically intractable epilepsy and may reduce the severity of ASD behaviours in animal models. Due to a major knowledge gap in how

the KD elicits neuroprotective and possibly disease-modifying effects, this treatment modality is not routinely used as a complementary alternative to pharmaceuticals. We asked if it would be effective in reducing the increased excitability and behavioral features in our model. We found that adult P7 LPS treated BTBR mice that were subsequently treated with the KD from P46 to P60 had a significant increase in seizure threshold compared to P7 LPS treated BTBR mice that remained on a standard chow diet (p<0.05). Lastly, BTBR mice treated with the KD had a significant reduction in a few behavioural measures of the ASD phenotype (e.g. frequency of self-grooming and communication) compared to BTBR mice on a standard diet (p<0.05). These results indicate that the KD may be effective in targeting mechanisms that are responsible for the epilepsy and ASD phenotype in this novel co-morbid mouse model. Our future directions will continue to investigate the mechanisms that lead to the development of co-morbid epilepsy in a mouse model of ASD with exposure to a postnatal immune challenge.

Title: Establishment of Tsc1^{flox/flox}-GFAP-Cre (Tsc1^{GFAP}CKO) mice for evaluating potential new antiepileptic therapies for tuberous sclerosis complex

Authors: *S. C. LEISER¹, A. GHAVAMI², M. KWAN², J. BELTRAN², D. SONG¹, D. M. DEVILBISS¹, M. WONG³, N. RENSING³, S. L. ROBERDS⁴, D. BRUNNER⁴ ¹Translational EEG, PsychoGenics, Tarrytown, NY; ²PsychoGenics, Montvale, NJ; ³Dept. of Neurol., Washington Univ. Sch. of Med., St. Louis, MO; ⁴Tuberous Sclerosis Alliance, Silver Spring, MD

Abstract: In this two-part study, we evaluated incidence of seizures using EEG and changes in mRNA biomarkers using quantitative PCR (qPCR) in *Tsc1*^{GFAP}CKO mice. First, we evaluated effects of rapamycin on incidence of seizures and mortality given that previous reports indicated these mice develop spontaneous postnatal epilepsy rescued by treatment with the mTOR inhibitor. EEG from mice were continuously recorded (using Pinnacle Technology's data acquisition platform) from P35-P49. The vehicle-treated group (n=10) exhibited on week 5 and 6 an average of 3.5 ± 1.1 and 2.33 ± 1.1 seizures, respectively. In contrast, the rapamycin-treated group that started at P35 (n=8) exhibited a reduction in seizures for weeks 5 (1.75 ± 0.65) and 6 (0.38 ± 0.26) nearly reaching significance at week 6 (p=0.06, Tukey-Kramer). Moreover, the rapamycin-treated group that started at P21 (n=10) showed no seizures during week 5 and 6 (p<0.05, Tukey-Kramer). In summary, whereas *Tsc1*^{GFAP}CKO mice treated with vehicle from

P21-48 suffered robust electrographic seizures and a significant mortality over this period, mice treated with 3 mg/kg rapamycin from P21-48 showed zero seizures and zero mortality over the same period. The group receiving rapamycin 3 mg/kg from P35-48 showed reduced seizure frequency and zero mortality. Thus, we confirm the protective effects of mTOR inhibition against seizures and premature death in these mice. Secondly, in a separate cohort, we used qPCR to evaluate changes in mRNA levels of transcripts involved in axon formation, synapse function, glutamate transport, mTOR activation, cell adhesion, angiogenesis, cell regulation, inflammation and unfolded protein response activation in brain at 5 weeks of age. Expression levels between control (Cre⁻; $Tsc1^{+/flox}$) and Cre⁺; $Tsc1^{+/flox}$ mice were similar for all transcripts reported in this study. In contrast, Tsc1^{GFAP}CKO mice (Cre⁺; Tsc1^{flox/flox}) showed genotypedependent changes in some transcripts analyzed. Of particular note were decreased mGluR5 and Tyrosine Kinase c-kit and increased IBA1, CD68, ICAM1, VEGF-D, and TLR4 mRNA expression in *Tsc1*^{GFAP}CKO mice. In some cases affected transcripts in Cre⁺; *Tsc1*^{flox/flox} mice showed significant variation among individuals that cannot simply be explained by differential effectiveness of CRE-mediated knockout since, except one animal, all Cre⁺; Tsc1^{flox/flox} mice showed similarly reduced expression levels of *Tsc1* mRNA. Further, mRNA levels might covary with seizure frequency or age of seizure onset which needs to be assessed in future studies. Overall, our findings suggest a clear utility of using these mice to screen potential anti-epileptic therapeutics.

Title: A spontaneous deletion in Eml1 underlies the bilateral cortical malformation in the tish rat model of subcortical heterotopia

Authors: *D. K. GROSENBAUGH¹, S. JOSHI², K. S. LEE⁵, M. P. FITZGERALD⁶, M. J. ANZIVINO³, M. J. MCCONNELL⁷, H. P. GOODKIN⁴ ¹Dept. of Neurol., ²Dept of Neurol., ³Univ. of Virginia, Charlottesville, VA; ⁴Univ. of Virginia, Charlottesvle, VA; ⁵Univ. Virginia Hlth. Systems, Charlottesvle, VA; ⁶Children's Hosp. of Philadelphia, Philadelphia, PA; ⁷Biochem. and Mol. Genet., Univ. of Virginia Sch. of Med., Charlottesville, VA

Abstract: Malformations of cortical development (MCD) are common in children with pharmacoresistance epilepsy. Although surgery can be successful for some, not all forms of MCD are operable. The tish (telencephalic internal structural heterotopia) rat, which arose spontaneously in a colony of Sprague-Dawley (SD) rats, is a model of severe, non-operable MCD. The tish rat is characterized by a large bilateral heterotopic cortex separated from the overlying normotopic neocortex. Prior studies reported an aberrant proliferative zone composed of misplaced neuronal progenitors with altered cell cycle kinetics. These misplaced cells result in alterations in neuronal migration which lead to the heterotopic cortex and a neuronal network capable of generating spontaneous seizures. However, the genetic mutation underlying this MCD and the earliest age of identifiable electrographic (EEG) abnormalities have not been identified. In EEG recordings spanning from postnatal day (P) 8 - P45, spontaneous spike wave discharge (SWD) bursts were determined to begin at P18 - P20 in all tish rats examined, while no spontaneous discharges were observed in any of the age-matched control SD rats. The presence of paroxysmal discharges is consistent with altered network connectivity and hyperexcitability in these animals beginning at a young age. We performed 30X whole genome sequencing of tish and SD rats, and identified a tish-specific deletion ~50kb upstream of the *Eml1* locus (Rnor 6.0). Using RNAseq and RT-PCR, we confirmed that this deletion spans an unannotated exon 1 leading to a 4-fold down-regulation of Eml1 transcript abundance in embryonic day (E) 18 tish cortex. Rescue experiments (i.e., F2 cross) demonstrated that the deletion in *Eml1* segregates with both the observed heterotopic phenotype and the occurrence of spontaneous SWD bursts. These data link a mutation in *Eml1* to the development of a bilateral heterotopic cortex and a resultant hyperexcitable network of the tish rat. Mutations in *Eml1* have been identified in patients with subcortical heterotopia and epilepsy. These findings further strengthen the tish rat as a translational model of human non-operable MCD-associated epilepsy.

Title: Seizure-like activity in Bang-sensitive *Drosophila* is increased by GABA_A receptor antagonists and decreased by ellagic acid

Authors: ***A. A. SMITH, JR**¹, J. PAULDURAI², A. JAEGER², A. TROFIMOVA², C. BARCENAS², W. HARDEMAN², L. VILLALPANDO², A. BRISENO², N. KALYNOVSKA²,

R. E. HARTMAN²

¹Psychology, Loma Linda Univ., Colton, CA; ²Loma Linda Univ., Loma Linda, CA

Abstract: Introduction: Epilepsy is a worldwide public health concern associated with debilitating neurological, cognitive, and psychosocial consequences. Current anti-seizure drugs can have debilitating side effects and new treatments are needed for individuals with drugresistant seizures. Ellagic acid, a polyphenol present in several fruits and nuts, has shown beneficial effects in rodent models of epilepsy and anxiety, possibly mediated through GABAergic pathways. "Bang-sensitive" Drosophila experience mechanically induced seizurelike activity (SLA), possibly providing a high-throughput alternative to costly and lengthy rodent studies. The objectives of this study were to examine the anticonvulsant effects of ellagic acid in a fruit fly model of epilepsy and to explore the mechanism of action through the addition of two GABA_A receptor antagonists: flumazenil (a benzodiazepine site antagonist) and picrotoxin (a GABA site antagonist or channel blocker). Method: Adult males from two Bang-sensitive strains (bang senseless [Bss] and easily shocked [Eas]) were fed ellagic acid, flumazenil, and/or picrotoxin in their food media. Following treatment, flies received mechanical stimuli (vibration) to induce SLA, which was recorded with a digital video camera. Results: Approximately 93% of flies from each strain exhibited vibration-induced SLA. Vibration induced shorter SLA in Eas flies than in Bss flies (~4 s vs. 6 s), and ellagic acid decreased SLA duration slightly in Eas flies (to ~3 s), but not in Bss flies. Flumazenil and picrotoxin each increased SLA duration in both strains, but more so in *Eas* flies (to ~6.5 s and 8.5 s, respectively). Conclusions: Vibration reliably induced SLA in both Bss and Eas strains of Bang-sensitive Drosophila. SLA duration in Bss flies was slightly longer than in Eas flies, not affected by ellagic acid, and slightly increased by GABA_A receptor antagonists. SLA duration in Eas flies was slightly reduced by ellagic acid and significantly increased by GABAA receptor antagonists. These data show that seizure modeling with Bang-sensitive Drosophila can serve as an effective drug-screening tool for refractory epilepsy in humans and suggest that compounds found in plants may provide prophylactic benefits with regard to seizure severity.

Abstract: Purpose: Prolonged video-EEG monitoring in chronic epilepsy rodent models has become an important tool in pre-clinical drug development of new therapies, in particular for anti-epileptogenesis, disease modification and drug resistant epilepsy. We have developed an easy to use, reliable, computational tool for detection of electrographic seizures from prolonged EEG recordings in rodent models of epilepsy.

Methods: We applied a novel method based on advanced time-frequency analysis which detects the episodes of EEG with excessive activity in certain frequency bands. The method uses an advanced technique of short term spectral analysis - the Similar Basis Function algorithm. The method was applied for off-line seizure detection from chronic EEG recordings from four spontaneously seizing, chronic epilepsy rat models: post-status epilepticus model of temporal lobe epilepsy (n=39 rats, n=124 seizures); the fluid percussion injury model of post-traumatic epilepsy (n=5 rats, n=49 seizures); and two genetic models of absence epilepsy - GAERS and WAG/Rij (n=41 and 14 rats, n=8733 and 825 seizures respectively).

Results: High values of power spectrum in frequency band 17-25 Hz were found to specifically indicate seizures in all four animal models. This peculiarity comes from the frequency composition of single discharges within the seizures in these animals. Focusing on this band, our computer program detected 100% of seizures in all 99 rats. Electrode artefacts, which are usually present in long-term EEG recordings, may also significantly contribute to this frequency band, so they were also selected by the program. This selection, however, generated a very low rate of false positives. For their elimination, a quick user inspection was needed. The overall processing time for 12 day-long recordings varied from few minutes (5-10) to an hour, depending on the number of artefacts.

Conclusion: Our seizure detection tool provides high sensitivity, with acceptable specificity, for chronic EEG recordings from chronic rat epilepsy models. This has the potential to improve the efficiency and rigor of pre-clinical research and therapy development using these models.

Title: Variable phenotype in a Dravet syndrome model in Charles river versus Jackson C57BL/6 mice

Authors: J. L. WHITE¹, K. LEE², B. TARHAN¹, J. QI³, *S. KOH¹ ¹Pediatrics, Emory Univ., Atlanta, GA; ²Pediatrics, Daegu Catholic Univ., Daegu, Korea, Republic of; ³Northwestern Univ., Chicago, IL

Abstract: Rationale: The majority (~80%) of Dravet syndrome (DS) is associated with a neuronal sodium channel alpha 1 subunit (SCN1A) mutation causing epilepsy onset in infancy, intractable seizures, sudden unexpected death, and various neurobehavioral comorbidities. The variable phenotypes in this disease are, at least in part, a result of modifier genes. Many Dravet syndrome mouse models have demonstrated the hallmark features of DS; yet none characterized the wide array of phenotypes. We present the developmental disease characteristics in three distinct C57BL/6 mice sub-strain as breeders.

Methods: We used the F1 generations of Scn1a (*129S-Scn1a^{tm1Kea}/Mmjax*) mice bred to C57BL/6 mice from (1) The Jackson Laboratory (DS-Jax) and (2) Charles River (DS-Crl). Then we bred Jackson Laboratory to Charles River C57BL/6 mice for 3 generations to establish a hybrid sub-strain (JC) as breeders for F1 DS mice. The 3 groups of F1 DS mice, DS-Jax, DS-Crl and DS-JC underwent prolonged (30 minutes) febrile (LPS +hyperthermia) seizures at P30. At P50, select mice were implanted with EEG electrodes and recorded for 24-hours, once per week, for three weeks to detect electroclinical seizures.

Results: Hyperthermia induced seizures in all (100%) 3 groups of DS mice with similar mean threshold temperatures as follows: DS-Jax, $39.7\pm0.5^{\circ}$ C (*n*=8); DS-JC, $40.3\pm0.3^{\circ}$ C (*n*=7); DS-Crl, $39.8\pm0.1^{\circ}$ C (*n*=16). Sudden unexpected and unexplained death occurred from weaning age until P49, mortality occurred in each of the DS mice groups: 5 deaths were noted (5/21, 24%) in DS-Jax while only one death each occurred in DS-JC and DS-Crl mice (1/7, 14% and 1/18, 6%, respectively). EEG recording showed abnormal EEG and spontaneous electroclinical seizures in 100% (*n*=2/2) of DS-Jax mice, 80% (*n*=4/5) of DS-J-C mice, and 60% (*n*=3/5) of DS-Crl mice. **Conclusion:** Susceptibility to hyperthermia-induced seizures was noted in all 3 sub-strains of F1 generation *129S-Scn1a* -C57BL/6 mice. There was a dose response-like trend in both mortality and electrographic seizures. DS mice from the Jackson lab C57BL/6J background appear to be more affected, while the Charles River C57BL/6NCrl bred DS mice had the milder response to

the SCN1A gene mutation. Our observation suggests that genetic modifiers may exist, even within C57BL/6 mice that originated from the same gene pool that led to variable effects on Dravet syndrome phenotype.

Title: Toll-like receptor and cytokine expression changes in a rodent model of epilepsy

Authors: *C. SADANGI¹, F. ROSENOW², B. NORWOOD^{3,2} ¹Philips University, Marburg, Marburg, Germany; ²Goethe Univ., Frankfurt, Germany; ³Philipps Univ., Marburg, Germany

Abstract: Rationale: Toll-like receptors (TLRs) are innate immune receptors that are important in early host defense against pathogens. TLRs recognize pathogen- or damage-associated molecular patterns (PAMPs/DAMPs), and are either expressed on the cell surface or in the endosomes. TLRs 1, 2, and 6 are expressed on the cell surface, whereas TLR8 is expressed intracellularly. TLRs 1 and 2 have been implicated in experimental epilepsy; however, the other TLRs have yet to be studied. IL-2, a cytokine, regulates immune response through T-cell activation and it has been shown to be upregulated in epilepsy. IL-6 is both a pro- and antiinflammatory cytokine regulating inflammatory and immune response, and it has also been shown to be expressed during seizure. The chemokine RANTES (CCL5) is involved in leading leukocytes to the site of injury and has been shown to be upregulated in epilepsy. Here we investigated the gene expression changes of TLRs, cytokines, and a chemokine during epileptogenesis in rodent models of acquired epilepsy and chronic epilepsy. Methods: Freely moving male Sprague-Dawley rats (n=4 per group) received systemic administration of kainate and Lorazepam (KaL) and were sacrificed after 4 d, 14 d, or 20 weeks, and whole hippocampi were removed post treatment. The mRNA level was analyzed for the TLRs, IL-2, IL-6, and RANTES with custom-designed primers. Relative gene expression changes were calculated using the REST software (Pfaffl method). IL-2, IL-6, and RANTES

protein expressions were analyzed using ELISA.

<u>Results</u>: During epileptogenesis, except TLR1, all the other TLRs expressions were enhanced after 4 d, and all TLRs were further enhanced after 14 d. However, all the TLRs exhibited downregulation during chronic epilepsy. The mRNA expression of IL-2 was upregulated at 4 d

but declined during 14 d epileptogenesis and chronic epilepsy. The IL-6 protein expression diminished at 4 d, but elevated at 14 d epileptogenesis, however, in the chronic epilepsy phase it remained was downregulated again. RANTES was downregulated during 4 d but was upregulated during 14 d epileptogenesis, and had a slight decrease in expression during chronic epilepsy but remained upregulated.

<u>Conclusion</u>: TLRs expressions are enhanced and prolonged during epileptogenesis. Evoked seizures also upregulate expressions of these TLRs, but transiently and not to the same extent. Cytokines and chemokine expressions change during epileptogenesis and chronic epilepsy. These data warrant the further investigation on the role of these TLRs, cytokines, and chemokine in epilepto- and ictogenesis.

Title: A proposed role for the nucleus of pontis oralis of the brainstem (NPO) in sudden unexpected death in epilepsy

Authors: R. P. VERTES¹, M. GIL², R. STCLAIR², R. LEMOS², K. KOROMA², *C. ISGOR² ¹Ctr. for Complex Systems & Brain Sci., Florida Atlantic Univ., Boca Raton, FL; ²Charles E. Schmidt Biomed Ctrr, Florida Atlantic Univ. Charles E Schmidt Col. of Med., Boca Raton, FL

Abstract: A network inhibition hypothesis of seizure-related vulnerability to death postulates that seizures excite the hypothalamus and lateral septum which in turn send inhibitory projections to subcortical arousal centers, one of the most prominent being the **nucleus pontis oralis** (**NPO**) of the brainstem. A marked suppression (or total inhibition) of NPO activity would generally manifest as postictal generalized electroencephalography suppression (PGES) - or the cortical EEG "flattening" that accompanies seizures and presents a major risk for fatality. PGES is reportedly one of the few predictors of susceptibility to sudden unexpected death in epilepsy (SUDEP) in human patients. We postulate that repeated seizures will result in the progressive damage to NPO cells - with further deleterious effects on arousal/consciousness in epilepsy. We will use a novel transgenic mouse model of epilepsy (brain-derived neurotrophic factor overexpressing mice under the Cam/KIIa promoter) that exhibits progressive lengthening of PGES episodes with successive seizures (as a critical marker of severity of seizures) that does not require any invasive procedures to generate epileptic activity. Spontaneous seizures are

produced in a controlled fashion by simply to tail suspension or cage shaking stimulation and which become more severe with time. Using this model, we will test whether repeated seizures cause progressive neuronal injury/death of NPO cells, which are responsible for the increased severity of PGES. Our preliminary data show that mice become more seizure prone with age and the duration of postictal generalized EEG suppression (PGES) progressively increases with each seizure episode. In addition, epileptic mice spend more time in non-REM sleep as a function of seizure frequency in inactive phase, and the average length of REM bouts decrease accordingly implicating deficits in normal NPO sleep function. In order to establish that the increased duration of PGES over repeated seizures is associated with progressive deterioration (or cell loss) in NPO and reflects subsequent alterations in sleep architecture, we crossed a commercially available live mouse strain, Thy1-eYFP (JAX 003782), with our epileptic mice and noted significant loss of neurons in the gigantocellular field of the NPO as a function of PGES severity. These findings implicate seizure-induced cellular injury in the NPO for the emerging risk for SUDEP.

Title: Correlation of seizure-associated central apneic episode durations with their frequency of occurrence in a rat model

Authors: *M. G. STEWART¹, S. VILLIERE⁴, K. NAKASE¹, R. KOLLMAR², R. ORMAN³ ¹Physiol. & Pharmacol., ²Dept. of Cell Biol., ³Physiology&Pharmacology, SUNY Downstate Med. Ctr., Brooklyn, NY; ⁴Res. Initiative for Scientific Enhancement (RISE) Program, CUNY Medgar Evers Col., Brooklyn, NY

Abstract: Respiratory derangements, including irregular, tachypnic breathing and central or obstructive apnea can be consequences of seizure activity. Periods of seizure-associated central apnea suggest that seizures spread to brainstem respiratory regions to disrupt breathing. Recently, we showed that seizure-associated central apnea episodes are associated with 1) a reset of the respiratory rhythm, and 2) activation of brainstem regions serving the diving reflex to suppress respiratory behavior (Villiere et al., Neurobiol. Dis. 2017; 101:8-15). Using a rat model, we demonstrated a sequence of events ending in death that begins with

obstructive apnea caused by seizure-induced laryngospasm (Nakase et al., Epilepsy Res. 2016; 128:126-139). We sought to determine if patterns of central apnea behavior (duration and/or frequency of occurrence) correlated with the tendency for obstructive apnea to occur. There were not statistically significant differences in central apneic episode duration or number of recorded episodes in animals that eventually showed obstructive apnea compared with animals that never showed obstructive apnea. There was, however, a clear positive correlation of the average apneic episode duration with the number of apneic episodes recorded (R^2 =0.54) and their crude frequency of occurrence (events/min of recording; R^2 =0.58). Whereas the frequency or duration of central apneic episode duration with frequency suggests that these episodes may reflect an attempt by brainstem networks to protect core physiology. A deeper understanding of seizure spread into brainstem regions may permit additional biomarkers (see e.g. Stewart et. al., Epilepsia 2017 in press doi:10.1111/epi.13765) to be established for identifying risk of severe systemic consequences of epileptic seizures.

Title: A continuous hippocampal stimulation model of status epilepticus and temporal lobe epilepsy in C57bl/6 mice

Authors: *J. KAPUR, E. LEWCZUK, S. JOSHI, J. WILLIAMSON Dept Neurol., Univ. Virginai Hlth. Sci. Ctr., Charlottesvle, VA

Abstract: Transgenic mice can provide insights into molecular pathophysiological processes. Available murine models of status epilepticus (SE) and temporal lobe epilepsy (TLE) include seizures induced by pilocarpine or kainic acid. However, pilocarpine causes high mortality and extensive neuronal loss occurs following infusion of kainic acid. Electrical stimulation models of status epilepticus and TLE are well characterized in rats, but not in mice. Adult (22-25 g, 10-12 week old) male and female C57bl/6 were implanted with bipolar electrodes in the left hippocampi (3 mm AP, 3 mm ML, 3 mm DV), bilateral supra-dural cortical electrodes, and a cerebellar reference. The mice were stimulated with a 1 msec biphasic square wave pulse for 10 s to determine after discharge threshold (ADT). The initial stimulation was set at 20 vA and the intensity was increased by 20 μ A until a seizure was triggered, maximum 200 vA. The current intensity was set to twice ADT, with minimum at 100 vA, and continuous stimulation was performed by cyclic application of 10 sec stimulation followed by 5 sec off period for 60 min. SE consisted of rhythmic and evolving spike-wave discharges sustained for 30 min or more. Mice were monitored continuously for 24 hr following the end of stimulation; the monitoring to determine spontaneous seizures was started 2 weeks later. Mice that developed at least 2 spontaneous seizures were classified as having TLE. Cell death was determined 3 days following SE using fluorojade labeling. Animals were perfused with PFA and horizontal brain sections (40 μ m thick) were labeled with fluorojade-C and neuronal marker protein NeuN. Images were acquired on a confocal microscope.

The ADT was $70 \pm 36 \ \mu\text{A}$ and seizures (SE) lasted $181 \pm 90 \ \text{min}$. CHS caused SE in 82% of animals (28/34). 50% of the mice survived SE (n=14) and were monitored for onset of TLE. In the first week of monitoring none of the animals experienced spontaneous seizures, during the 2^{nd} week 1 out of 5 animals monitored had spontaneous seizures and the number of epileptic animals increased to 7 out of 14 (50%) by 7 weeks.

Extensive fluorojade labeling was observed in CA3 and CA1 pyramidal neurons, and in dentate hilar neurons.

We have developed and characterized a mouse model of SE induced by CHS. More mice survived SE as compared to the pilocarpine model. The pattern of neurodegeneration in the hippocampus was similar to that described in other models. Half of the surviving animals also developed epilepsy. Thus, CHS provides an alternate model of SE and TLE in mice.

Abstract: Absence seizures, the most common type of generalized epilepsy, consist of behavioral impairment and a distinctive spike-and-wave electrographic signature. These seizures, and associated attentional deficits and developmental difficulties, have a major impact on quality of life and are frequently insufficiently redressed by pharmacological treatments. Recent evidence shows that the degree of behavioral impairment associated with seizures is variable, and correlates with hemodynamic and electrographic changes. The neural mechanisms underlying this impairment can be investigated in a genetic model of absence seizures in the rat. We studied hemodynamics, electrophysiology and behavioral components of absence seizures in undrugged Genetic Absence Epilepsy Rats from Strasbourg (GAERS), a well-characterized and valid model of absence epilepsy. Incremental habituation was employed to accustom rats to head fixation and the environment of a high-field magnet (9.4T), allowing the acquisition of BOLD fMRI dynamics, cerebral blood flow, and local electrophysiology during absence seizures. Separate animals were used to investigate the behavioral impact of seizures in a task-free, unguided licking paradigm and in sensory detection and discrimination tasks. Cortical BOLD fMRI dynamics during seizure qualitatively match those of human absence seizures, reconciling previously-noted discrepancies with anesthetized rodent spike-and-wave discharges. Specifically, somatosensory cortex BOLD signal initially increased around seizure start, but then displayed a prolonged decrease as seizures continued. These dynamics were matched by those of both cerebral blood flow and cortical multi-unit activity. The initial increase in the latter was associated with increased spike-and-wave frequency rather than intensity of neuronal firing at each cycle, and its amplitude correlated with eventual duration of seizure (p<0.01). Impairment of the task-free licking behavior was observed during seizure as compared to matched control periods (p<0.001).

These data suggest that mechanisms of absence seizures must be investigated in undrugged models, as anesthesia appears to substantively alter neuronal activity and hemodynamics as well as arousal and seizure-associated behavior. With further investigation we hope that greater understanding of the physiological mechanisms of behavioral impairment in absence epilepsy can guide improved treatment.

Title: Mechanism of decreased subcortical cholinergic arousal in focal limbic seizures: wholecell recordings *In vivo*

Authors: *J. P. ANDREWS¹, Z. YUE³, G. T. NESKE⁴, D. A. MCCORMICK⁵, H. BLUMENFELD²

²Dept. of Neurol., ¹Yale Univ. Sch. of Med., New Haven, CT; ⁴Neurosci., ³Yale Univ., New Haven, CT; ⁵Dept. Neurobiol, Yale Univ. Sch. Med., New Haven, CT

Abstract: The mechanism of how seizures impair consciousness is not fully understood, but recent evidence suggests that ictal suppression of subcortical cholinergic arousal circuits, such as the nucleus basalis (NB) and pedunculopontine tegmental nucleus (PPTg), may play a role. Functional imaging and extracellular recordings show ictal suppression of activity in the NB and PPTg in a rat model of limbic seizures, but the synaptic mechanisms of this depressed firing rate are not known. The purpose of this investigation is to elucidate whether reduced neuronal firing in the subcortical cholinergic arousal system during seizures is associated with reduced excitatory input or with increased inhibitory input to cholinergic neurons. Whole cell recording is commonly used to access cortical neurons in vivo, but has not been previously reported from deep brain structures such as PPTg. In this study, whole-cell recordings were obtained in neurons of the PPTg, accessed 5.4 - 6.2 mm deep measured from the cortical surface, in the brain of head-fixed, anesthetized rats during focal limbic seizures. Micropipettes were fabricated with a ~10-mm taper and 4-6 M Ω resistance. The first pipette in each recording session was lowered to the target region and left in place for 30-60 minutes to allow the brain to form a narrow, lowresistance canal through which subsequent pipettes may pass. Intrapipette positive pressure was maintained at 500 mbar throughout the descent, and dropped to <30 mbar at the target region. A K-gluconate-based internal solution was used for all recordings. Seizures were triggered using a 2 second stimulation of the hippocampus through a twisted bipolar electrode with current titrated to seizure threshold. Continuous recordings were made using Spike2, with signal digitized using a Micro1401 (CED). Whole cell current clamp recordings of histologically identified cholinergic PPTg neurons during seizures showed hyperpolarization of membrane potential associated with decreased action potential firing. In addition, moment-to-moment input-resistance was measured using 5-10Hz 30pA hyperpolarizing current pulses. Input resistance showed an increase during seizures concomitant with hyperpolarization. Non-cholinergic neurons from the same region generally did not show these changes during seizures. These data suggest that cholinergic PPTg neurons show decreased firing during hippocampal seizures through a mechanism of reduced excitatory input. The identification of the synaptic mechanisms of depressed subcortical arousal during seizures may ultimately lead to new treatments aimed at preventing these changes and improving ictal and postictal cognition.

Title: Behavioral assessment of intralaminar thalamic neurostimulation to improve consciousness during the postictal period of seizures

Authors: ***J. XU**¹, M. M. GALARDI¹, J. Y. POK¹, C. P. MCCAFFERTY¹, L. FENG¹, A. GUMMADAVELLI², A. J. KUNDISHORA², J. L. GERRARD², M. LAUBACH⁴, N. D. SCHIFF⁵, H. BLUMENFELD^{1,3,2}

¹Neurol., ²Neurosurg., ³Neurosci., Yale Univ. Sch. of Med., New Haven, CT; ⁴American Univ., Washington, DC; ⁵Weill Cornell Med. Col., New York, NY

Abstract: The postictal period is an impaired state of consciousness characterized by electrophysiological cortical depression, decreased cortical blood flow and neurocognitive disturbance immediately following seizures. Using deep brain stimulation (DBS) to improve consciousness during the postictal period may have a major benefit on life quality for patients suffering from medically refractory epilepsy. Previous work has shown that bilateral stimulation of the thalamic central lateral nucleus (CL) during the postictal period of seizures restored normal-appearing cortical electrophysiology and markedly improved spontaneous behavioral arousal in the rodent model. Here, we focused on further investigating the effect of this stimulation on purposeful behavior.

We implemented a lever-press escape/avoidance (E/A) task to evaluate task performance during the postictal period to assess for cognitive improvements provided by the DBS. During successive E/A task training sessions, animals showed an increased avoidance percentage and decreased response times. Post-training, bilateral CL and unilateral hippocampal and lateral cortex electrodes were implanted. Following recovery, animals were retrained in the task until they achieved >90% avoidance. In trials within a session, seizures were induced by 2 second hippocampal stimulation at 60 Hz. In postictal period, following the appearance of slow-wave activity, the CL was stimulated at 100 Hz while recording electrophysiology and behavior. As a natural control for behavior during an inattentive state, we compared behavior elicited during briefs arousal induced by conditioned tones during sleep to that measured during the post-ictal period.

We found that task performance was normal during the natural sleep slow-wave period (response time: 12.77 ± 3.796 , avoidance percentage: 79.18 ± 20.83 , n=17 from 3 rats), but impaired

during the postictal period with cortical slow wave activity (response time: 63.05 ± 3.377 , avoidance percentage: 16.66 ± 9.617 , n=8 from 3

rats). Moreover, CL stimulation improved task performance (response time: 40.58 ± 5.988 , avoidance percentage: 53.34 ± 10.19 , n=14 from 3 rats) when compared with sham groups (response time: 62.69 ± 1.107 , avoidance percentage: 11.11 ± 11.11 , n=11 from 3 rats). To conclude, this is the first instance in which we identified a difference in task performance ability when comparing normal sleep and the postictal slow-wave period in rats. The DBS in bilateral CL increased the ability to perform the E/A task in the postictal period. These findings further support the potential role of targeted DBS to improve cognitive function in patients following seizures.

Title: Uncovering limbic seizure networks using optogenetic and neuroanatomical tracing approaches *In vivo*

Authors: L.-A. SIEU¹, *L. FENG¹, C. MA¹, C. W. ZHAO¹, J. CARDIN¹, H. BLUMENFELD^{1,2,3} ¹Dept. of Neurol., ²Neurosciences, ³Neurosurg., Yale Sch. of Med., New Haven, CT

Abstract: Limbic seizures are known to impair consciousness but the neural circuit responsible for this alteration of brain function is still poorly understood. During temporal lobe seizures, intracranial EEG recordings show sleep-like slow wave activity in the cortex, accompanied by reduced cholinergic neurotransmission. Considering that the nucleus basalis (NB) provides the most cholinergic input to cortex, we propose that partial seizures originated from limbic system structures (eg. hippocampus) cause depressed cholinergic neuronal activity in NB via subcortical pathways. Our previous work demonstrated that the lateral septum (LS), a putative inhibitory region strongly connected to hippocampus, could induce cortical slow waves together with a decrease of choline release during electrostimulation in absence of seizure. Here, we examined a

possible pathway that includes the LS and NB to explain how focal seizures originating from hippocampus can result in cortical depression. We applied an optogenetic approach to selectively stimulate cholinergic neurons in the NB during focal limbic seizures induced in a lightly anesthesized rat model. We found that slow oscillations in the cortex dramatically convert to fast waves in response to cholinergic stimulation, which support the hypothesis that cholinergic output from NB plays a critical role in maintaining cortical arousal. By using a combination of retrograde and anterograde tracing to identify LS and NB interconnections, our histology results did not reveal any direct anatomical connection between those two regions. However, the paratenial thalamic nuclei (PT), located among the midline thalamic nuclei known to participate in arousal, receive strong output from LS and have direct input to NB. Multiunit activity (MUA) recordings in PT showed a decrease of neuronal firing during seizures, which support an inhibitory effect from LS output and a reduced excitatory effect on NB. These results show that limbic partial seizures can exert an impact on a polysynaptic subcortical network including LS, PT and NB to facilitate the occurrence of cortical depression. Further investigation of this network may lead to novel therapeutic interventions aimed at improving cortical function and consciousness during and following seizures.

Title: Rapid development of structural abnormalities following PTEN deletion from newborn dentate granule cells in a mouse model of epilepsy

Authors: S. R. ARAFA¹, *C. L. LASARGE², S. C. DANZER²

¹Drug Develop., Univ. of Cincinnati JLW Col. of Pharm., Cincinnati, OH; ²Dept. of Anesthesia, Cincinnati Children's Hosp. Med. Ctr., Cincinnati, OH

Abstract: Postnatal deletion of the mTOR negative regulator phosphatase and tensin homolog (PTEN) from a subset of hippocampal dentate granule cells is sufficient to cause epilepsy in mice. PTEN deletion leads to somatic hypertrophy, increased dendritic branching and aberrant basal dendrite formation. Whether these abnormalities appear quickly and plateau, or become

progressively more severe over time has not been fully elucidated. To answer this question, *Gli1-CreER*^{T2} hemizygous; PTEN ^{flox/flox}; Brainbow^{+/+} were treated with tamoxifen 3 weeks after birth, and mice were sacrificed at 7, 9, 14 and 18 weeks of age. The morphology of PTEN knockout cells expressing brainbow fluorochromes was compared to age-matched wildtype granule cells. The appearance of neuronal hypertrophy was rapid - evident in cells lacking PTEN for only four weeks - and showed little progression between 7 and 18 weeks. Assessment of other changes is ongoing. Additionally, we queried whether inflammatory changes occur at any of the time points examined by immunostaining for the microglial marking Iba1 and the glial marker GFAP. Iba1 immunoreactivity was similar among time points between control and PTEN knockout mice, while GFAP staining was elevated at 14 and 18 weeks. Together, these data reveal the rapid onset of morphological changes in PTEN knockout granule cells, and the delayed onset of inflammatory changes. The findings support the conclusion that disease progression following PTEN deletion is driven by the appearance of both primary and secondary changes.

Abstract: Deletion of the mTOR pathway inhibitor PTEN from postnatally-generated hippocampal dentate granule cells causes epilepsy. Here, we conducted field potential, whole cell recording and single cell morphology studies to begin to elucidate the mechanisms by which granule cell- specific PTEN-loss produces disease. Cells from both male and female mice were recorded to identify sex-specific effects. PTEN knockout granule cells showed altered intrinsic excitability, evident as a tendency to fire in bursts. PTEN knockout granule cells also exhibited

increased frequency of spontaneous excitatory synaptic currents (sEPSC's) and decreased frequency of inhibitory currents (sIPSC's), further indicative of a shift towards hyperexcitability. Morphological studies of PTEN knockout granule cells revealed larger dendritic trees, more dendritic branches and an impairment of dendrite self-avoidance. Finally, analysis of cells from male and female animals demonstrated that both female control and female knockout cells receive more sEPSC's than corresponding male cells -- but also receive more sIPSC's - resulting in statistically equivalent EPSC/IPSC ratios. Consistent with this latter observation, extracellularly evoked responses in hippocampal slices were similar between male and female knockouts; albeit both groups of knockouts were abnormal relative to controls. Together, these studies reveal a host of physiological and morphological changes among PTEN knockout cells likely to underlie epileptogenic activity.

Title: Cellular heterogeneity in the anti-sezire effect of ontogenetic activation of the pedunculopontine nucleus

Authors: *V. R. SANTOS¹, R. HAMMACK³, P. A. FORCELLI²

¹Dept. of Pharmacol. and Physiol., ²Dept of Pharmacol., Georgetown Univ., Washington, DC; ³Gerogetown Univ., Washington, DC

Abstract: Epilepsy is the second most prevalent neurological disorder. One form of epilepsy, absence epilepsy, is characterized by typical absence seizures (ASs). ASs are brief (3-30 second) nonconvulsive epileptic events that consist of sudden impairment of consciousness accompanied by a generalized synchronous, bilateral, 2.5-4 Hz spike and slow-wave dischargers (SWDs) in the electroencephalogram (EEG). Various subcortical structures play a critical role in modulating seizures, including substantia nigra (SN) and superior colliculus (SC). These structures display anti- seizure effects, however, the mechanism by which they produce changes in brain-wide excitability are poorly understood. Both structures provide input to pedunculopontine nucleus (PPN), a brainstem nucleus part of the ascending reticular activating system. Activation of the PPN can trigger potent desynchronization of the cerebral cortex. Thus, the PPN is both anatomically and functionally positioned to mediate the anticonvulsant effects of SNpr and SC. The PPN contains a variety of cell types, including cholinergic, GABAergic and glutamatergic

neurons. Here, we evaluated the anti-absence seizure effects of optogenetic activation in different neuron populations of PPN. We used ChAT::Cre and GAD::Cre Long-Evans (LE) rats transfected with AAV-hSyn-FLEX-Chronos-GFP or AAV-hSyn-FLEX-ArchT-GFP to activate or inhibit cholinergic and GABAergic neurons of PPN. To study the role of glutamatergic neurons, we injected AAV-CamKII-Chr2-mCheery or AAV-CamKII-ArchT-mCherry in wildtype LE. Absence seizures were evoked by systemic administration of y-butyrolactone - GBL (SWD- thalamocortical/absence seizures model) and electrographic seizures were recorded on a within- subject basis (i.e., with and without optogenetic activation/silencing). Optogenetic activation (5 Hz) of ChAT+ neurons suppressed cortical SWD absence seizures. However, inhibition of cholinergic neurons had no effect on number of absence seizures. Meanwhile, optogenetic activation of GABAergic neurons of PPN increased absence seizures, whereas optogenetic silencing of GABAergic neurons was without effect on seizures. Finally, activation or inhibition of glutamatergic neurons from the PPN have no effect of the number of seizures. Parallel studies are underway using DREADD-mediated modulation of PPN effect on other seizure types. These data indicate that different populations of neurons in the PPN exert diverse effects in the modulation of seizures. Using optogenetic neuronal activation in cholinergic neurons from PPN is a promising target for seizures control of epilepsy.

Title: Wistar Audiogenic Rat (WAR) strain: contributions for epilepsy and associated comorbidities

Authors: *L. D. GODOY¹, I. B. BACCHIEGA¹, J. MARQUES GUZZI¹, J. CORTES DE OLIVEIRA¹, E. H. UMEOKA², N. GARCIA CAIRASCO¹ ¹Physiol. Department, Univ. of Sao Paulo, Ribeirao Preto, Brazil; ²Mental Hlth., Ribeirão Preto Sch. of Med. - Univ. of São Paulo, Ribeirao Preto, Brazil

Abstract: Epilepsy is characterized by an enduring predisposition to generate seizures, which is usually followed by metabolic and neurobiological alterations. Wistar Audiogenic Rat (WAR) is

a strain selected from the inbreeding of Wistar rats that exhibit seizures when exposed to acoustic stimuli. Accordingly, physiological and behavioral abnormalities make WAR an interesting strain for the study of epilepsy comorbidities. Based on this, the current study aims to evaluate in the WAR strain: 1. Maternal care under undisturbed and stressful conditions 2. depressive-like behaviors basally and after audiogenic kindling (Auk) 3. metabolic function. 1. Maternal behavior was daily monitored during lactating period for 1h in undisturbed condition (30 events/block). On lactating day 2 (LD2), dams (n=6) were submitted to pup retrieval test (PRT) and maternal defense test (MDT) was performed on LD7. There was no difference for arched back nursing posture, licking/grooming or time of dam in nest. There is no difference for number of attacks, and aggressive behaviors on maternal defense test. Although WAR latency to retrieve first pup, half of the litter and last pup in PRT also were not different, 100% of Wistar dams grouped the entire litter, whereas in WAR only 40%.2. To evaluate depressive-like behaviors, rats were submitted to 20 acoustic stimuli twice a day (AuK) (Wistar-AuK;WAR-Auk), while respective controls remained undisturbed (Wistar; WAR). Animals (n=10) were subjected also to sucrose preference (SPT) and forced swim (FST) tests. WARs did not differ from Wistar in SPT, and WAR AuK group presented hedonic behavior compared to control groups [F(3,52)=7.11;p<0.001]. In FST, using a neuroethological analysis, WARs displayed a poorly connected behavioral repertoire compared to Wistar, in both pre-test and test sessions. WAR and WAR-AuK presented significant reduction of climbing in test session when compared to Wistar [F(2,16)=5.39;p=0.0162]. 3. Wistar and WARs were placed in metabolic cages (n=8). WARs presented significant reduction in body weight (t=14.07; p<0.001), water (t=5.14;p<0.001) and food intake (t=7.57;p<0.001), compared to Wistar rats. There was no difference in urine volume between strains but WARs show significant reduction in urine osmolarity (t=2.21;p<0.05). Although the WAR strain does not present differences in maternal behaviors in basal conditions, it seems to display alterations under stress. Also, based on the current findings, we suggest that inbreeding selection for seizure susceptibility is linked to altered stress-coping behavioral strategies and metabolic function. In addition, chronic seizures may alter reward systems.

Abstract: Spreading Depolarization (SD) is a neurophysiological phenomenon of large-scale depolarization of brain cells followed by a period of long-lasting neuronal inactivity. SD propagates through the brain at approximately 3-5 mm per minute causing an underlying swelling in the brain tissue invaded. This swelling alters the diffusion properties of cerebral spinal fluid at the cellular level, which we have utilized to visualize SD across the entire brain with Diffusion-Weighted Magnetic Resonance Imaging (DW-MRI). We hypothesized that SD invades brainstem tissue using fatal seizures, following district propagation pathways that are spared during non-fatal seizures.

Combining DW-MRI with EEG monitoring we examined the propagation of SD during fatal and non-fatal seizures elicited by electrical brain stimulation in a mouse model of Sudden Unexpected Death in Epilepsy (SUDEP). In addition, we utilized optogenetic stimulation to induce SD in specific brain regions to examine the propagation path from targeted subcortical foci. This was further correlated with in vitro analyses of neuronal and synaptic activity at the cellular level.

DW-MRI identified two brain regions associated with SD during seizures in the mouse SUDEP model. Targeted optogenetic stimulation in these regions revealed that they are specifically-sensitive to SD only in the SUDEP model. Further, electrophysiological analyses of intrinsic neuronal and synaptic activity in these brain regions reveals distinct gain-of-function properties related to SD susceptibility. These findings highlight that distinct brain regions are involved in the propagation of SD to the brainstem during seizures and provide support to the theory that brainstem depolarization is directly linked to SUDEP.

Title: Datamining to quantify and characterize dynamics of In vitro mouse seizures

Authors: D. N. CRISP¹, R. PARENT², G. G. MURPHY³, *W. C. STACEY⁴ ¹Biomed. Engin., ²Mol. and Behavioral Neurosciences Inst., ³MBNI/Physiology, ⁴Neurol., Univ. of Michigan, Ann Arbor, MI

Abstract: Our recent work demonstrated that despite epilepsy's inherent heterogeneity, seizures exhibit a set of conserved dynamical features that allow them to be characterized based upon scientific principles. The types of onset and offset patterns, known as bifurcations, establish a dynamical taxonomy of seizure dynamics. We used this taxonomy to characterize seizures in in vitro models of seizure activity, using inter-spike intervals and spike amplitude trends to categorize a limited number of specific bifurcations, coupled with several traditional quantitative signal processing measurements. However, the physiological meaning and relevance behind these bifurcation types are currently unknown. We used these measurements for two purposes: to elicit the underlying physiological properties and to quantify and compare seizures across different experiments. Mouse brain slices containing hippocampus, amygdala, and entorhinal cortex regions with a variety of pro- and anti-epileptic conditions (low magnesium, epileptic mutations, anti-epileptic drugs (AEDs), ketogenic diet, and pre-ictal therapeutic electrical stimulation) were used to generate an array of different seizure types. Each seizure was quantified with our algorithm, which allowed scientifically-based measures of seizure dynamics and direct comparison of their dynamical features.

Title: The role of K_v beta2 in modulating *In vitro* seizure activity in mice treated with the ketogenic diet

Authors: *R. PARENT¹, G. L. FISHER¹, D. N. CRISP², H. BURNS¹, W. C. STACEY³, G. G. MURPHY⁴

Abstract: The ketogenic diet (KD) has been an effective antiepileptic treatment dating back to the mid-1920s. While a number of hypotheses have been advanced, the exact cellular mechanism that underlies the antiepileptic action of the KD remains unclear. Evidence has been accumulating that ketones can directly enhance voltage-gated potassium currents gated by potassium channel complexes that contain Kvβ2 auxiliary sub-units which themselves possess an aldo-keto reductase enzymatic core domain. Therefore, we advance the novel hypothesis that ketones generated under ketogenic conditions directly interact with Kvß auxiliary sub-units to increase voltage-gated potassium currents which in turn reduces neuronal excitability. At 8 weeks of age, wild-type (WT) and $Kv\beta2^{-/-}$ (KO) mice were separated into two groups, one of which was fed standard chow, and the other which was fed a KD for a minimum of 6 weeks. Ex vivo coronal and modified horizontal slices were prepared from each group. In virto extracellular field potential recordings were made from either the dorsal hippocampus (HP) of coronal slices, or the ventral HP, entorhinal cortex (EC) and lateral amygdala (LA) simultaneously in modified horizontal slices in standard aCSF, with or without the addition of ketones. Epileptiform bursts were induced by removing Mg²⁺ and increasing K⁺ concentrations in the aCSF ($[Mg^{2+}]_0$ aCSF). The percentage of slices that exhibited bursting, latency to continuous bursting, and inter-burst interval, were measured for at least one hour after perfusion with the $[Mg^{2+}]_0$ aCSF.

In WT mice, acute application of ketones to slices from animals that were not maintained on a KD significantly reduced the induction of ictal events in the ventral HP. This effect is ventral HP specific and was not seen in the dorsal HP, KO mice or animals maintained on a KD. In the ventral HP, ketogenic conditions caused a significant reduction in the latency to ictal events regardless of genotype, however, in the dorsal HP, this reduction not observed in KO slices. In both the ventral HP and the LA, maintenance of WT animals on the KD causes a reduction in the inter-burst interval, which is not seen in slices made from KO animals. This effect is not seen in the EC or the dorsal HP. Additionally, treatment with the KD appears to alter the functional connectivity in the brain, regardless of genotype, as measured by the order in which the three areas (HP, EC, & LA) begin bursting after induction with ($[Mg^{2+}]_0$ aCSF. Although it is not clear exactly how K_vB2 is modulating the effects of the ketogenic diet, it is clear that these effects differ across brain regions, indicating that the ketogenic diet affects separate regions of the brain in different ways.

Title: Genetic background influences in "fast" kindling-susceptible PPKS and "slow" kindling-resistant PPKR rats transfer to kindling of the olfactory bulb

Authors: S. DUNN, C. LEVENICK, *T. P. SUTULA Dept of Neurol., Univ. of Wisconsin, Madison, WI

Abstract: Kindling is a neurobiological phenomenon of progressive seizure-induced plasticity that permanently increases susceptibility to recurring seizures, development of epilepsy, and progressive adverse effects of repeated seizures. The molecular, cellular, structural, and functional alterations induced in neural circuits by kindling are influenced by genetic background, as demonstrated by the recent development of distinct strains of "fast" and "slow" kindling rats selected and bred for "fast" or "slow" rates of kindling in response to stimulation of the perforant path. The "fast" and "slow" strains are referred to, respectively, as perforant path kindling-susceptible (PPKS) or perforant path kindling-resistant (PPKR). Compared to outbred Sprague Dawley (SD) rats which developed secondary generalized (Class V) seizures after 16.8 ± 2.5 afterdischarges (ADs), the PPKS and PPKR strains demonstrated Class V seizures after 10.0 ± 1.2 and 27.3 ± 4.4 ADs, respectively, and also demonstrated distinct behavioral phenotypes (Langberg et al., Neurobiol Dis 85:122-129, 2015). It was of interest to determine if the genetic background of these strains selected by stimulation of the perforant path also influences seizures and neural circuit plasticity evoked by stimulation of other pathways. To address this question, rates of kindling development in seizure-naïve PPKS, PPKR, and outbred SD rats were compared in response to repeated stimulation of the olfactory bulb (OB) with 1 sec trains of 60 hz biphasic constant current pulses that evoked ADs. Outbred SD rats developed Class V seizures evoked by OB stimulation after 8.6 ± 1.4 ADs, while "fast" PPKS rats required 6.8 ± 0.7 ADs and "slow" PPKR rats required 12.1 ± 1.4 ADs (p < 0.01, ANOVA). The rate of OB kindling was faster in PPKS vs. PPKR rats (p < 0.01, post-hoc t test). The results demonstrate that susceptibility or resistance to kindling development in the PPKS and PPKR strains transfers to kindling of other pathways in addition to the PP, and imply that genetic background conferring susceptibility or resistance to seizure-induced plasticity in the PPKS and PPKR strains influences multiple pathways of the central nervous system.

Title: Optimization of a human stem cell derived neuron/astrocyte co-culture system for seizure liability assessment using microelectrode arrays

Authors: *G. C. LUERMAN¹, C. FLEMING¹, D. HESS², T. PALM², A. EHLICH², H. BOHLEN²

¹Axiogenesis Inc, Plymouth Meeting, PA; ²Axiogenesis AG, Köln, Germany

Abstract: Historically, animal EEG studies have been the standard for preclinical assessment of drug induced seizures. Furthermore, in a typical ex vivo study, cortical neurons derived from rat forebrain must be extracted and cultured on microelectrode arrays (MEA) for roughly 4 weeks before mature functional network activity can be utilized for seizure assessment. With recent advances in human stem cell technologies, iPS-derived neurons can provide spontaneous electrical activity closely resembling that of murine ex vivo preparations. Here, using Axion Maestro MEAs, the electrophysiological function was compared amongst three different iPSderived neuronal subtypes in the presence and absence of astrocytes. As with ex vivo preparations, we found that astrocytes are indeed necessary to provide iPS neurons with the physiological co-culture environment required for mature network level activity. Once network level activity was achieved (typically 2-3 weeks), co-cultures were exposed to 12 different compounds having a variety of seizure-related, anti-seizure, or neurotoxic activity (e.g. GABA A, K+ channel, Na+ channel, muscarinic ACh, glycine, D2 receptor, & MAO block). Though "time to assay readiness" was different, sensitivity to these compounds were similar for the three neuronal populations. Importantly, these co-culture models all demonstrated good predictivity within the 12 drug set and allowed for significantly faster "assay ready" culture times than typical murine ex vivo preparations. In conclusion, human iPS neurons + astrocytes provide a number of advantages over current models for seizure liability and anti-epileptic drug screening efforts and should be further explored to develop a more comprehensive library to better understand their predictivity for drug induced seizures.

Title: Estrous cycle stage-dependent and sex-specific alterations of GnRH neuron firing activity in a mouse model of temporal lobe epilepsy

Authors: ***J.** LI¹, J. ROBARE², M. A. GHANE², M. E. NELSON^{1,2,3}, C. A. CHRISTIAN^{1,2,3} ¹Neurosci. Program, ²Mol. and Integrative Physiol., ³Beckman Inst., Univ. of Illinois at Urbana-Champaign, Urbana, IL

Abstract: Both women and men with temporal lobe epilepsy (TLE) are at greater risk for reproductive endocrine disorders, but the neural mechanisms underlying these co-morbidities have not been elucidated. Hypothalamic gonadotropin-releasing hormone (GnRH) neurons, the neural output for controlling reproduction, likely play key roles in driving these co-morbidities. We recently demonstrated robust estrous cycle disruption in female mice in the intrahippocampal kainic acid (KA) model of TLE. Here, we made targeted extracellular recordings of GnRH neuron firing in acute coronal brain slices at 2 mo after KA/saline injection. In females, GnRH neurons showed distinct responses to KA-induced epilepsy depending on estrous cycle stage on the day of recording. On diestrus, GnRH neuron mean firing rate was increased in the KAtreated female mice that developed prolonged (≥ 7 d) estrous cycles (saline, n=16 cells, 0.30+0.04 Hz, KA/prolonged n=20 cells, 1.03+0.25 Hz, p<0.01), but KA-treated female mice that maintained regular 4-6 d cycles did not show this change (KA/normal, n=20 cells, 0.39+0.08 Hz). On estrus, however, GnRH neurons from KA-treated female mice displayed lower firing rate than control mice, and this change was not correlated with estrous cycle period (saline, n=18 cells, 0.64+0.12 Hz; KA/prolonged, n=13 cells, 0.13+0.04 Hz, p<0.01 vs. saline; KA/normal, n=6 cells, 0.21+0.14 Hz, p<0.05 vs. saline). Cells located in the medial septum and preoptic area were most strongly affected. GnRH neurons also showed a sex-specific response to epilepsy, as cells from KA-treated males did not show a change in mean firing rate (saline, n=14 cells, 0.47+0.13 Hz, KA, n=22 cells, 0.61+0.13 Hz). To examine if GnRH neuron firing pattern was also affected by KA treatment, we performed spike pattern analysis for burst detection in the recorded cells from males and diestrous females. Interspike interval joint scatter plots and kmeans clustering methods were used for burst identification and analysis. The burst duration and the number of spikes per burst were both increased (p<0.001) in all KA-treated mice, regardless of estrous cycle period or sex. Among KA-treated females, however, the intraburst firing rate increased significantly in those with prolonged estrous cycles but decreased in those with normal estrous cycles (p<0.01). In KA-treated males, by contrast, the intraburst firing rate was not changed. Together, these findings are the first direct demonstrations of aberrant GnRH neuron function in an animal model of epilepsy, and indicate dynamic and sex-specific effects of epilepsy on the neural control of reproduction in different reproductive physiological states.

Title: Non-periodic electrical stimulation to the amygdala delays the kindling-induced epileptogenesis in rats

Authors: *D. MARTÍNEZ-VARGAS, F. SANTOS-VALENCIA, S. ALMAZÁN-ALVARADO, A. RUBIO-LUVIANO, V. MAGDALENO-MADRIGAL, A. VALDÉS-CRUZ Inst. Nacional De Psiquiatría, Ciudad DE Mexico, Mexico

Abstract: Deep brain stimulation has been used as a treatment for epilepsy, however, the mechanisms targets and optimal stimulation parameters are undeterminated. A novel protocol of stimulation is the non-periodic electrical stimulation pattern (NPS) which consists of changes in the temporal pattern of pulse firing, instead of periodic interpulse intervals an unstructured nonperiodic electrical stimulation is applied, with randomized interpulse interval. The delivering NPS at four pulses per second to the amygdala (AM) reduce the severity and number of seizures induced by pentylenetetrazole and pilocarpine in rats, nevertheless, the effects on epileptogenesis are unknown. The aim of this work was to analyze the effects of NPS applied to the AM on the acquisition of kindling-induced epileptogenesis in adult rats. Twenty-one adult male rats were implanted in the right basolateral AM. The implanted electrodes were used for daily kindling stimulation (AK) and NPS. Rats were divided in 3 groups: control, preemptive NPS and NPS/AK. Control animals were stimulated once a day with AK stimulus (1s, 60 Hz, 1ms/pulse). Animals in preemptive NPS group were stimulated for 10 days with NPS (20 min, four pulses per second, 0.1ms/pulse with non-periodic pattern) before the start of the AK. Rats in NPS/AK group received NPS during the development of kindling, the NPS was applied five minutes after of AK stimulus. The EEG of the AM was recorded. Seizure severity was classified according to

the Racine scale, in addition to seizure stage, the afterdischarge duration (AD) and the generalized seizure duration (GSD) were analyzed. All animals were stimulated until exhibited three consecutive stage 5 seizures. Significant differences were found between NPS during AK animals versus control group: The number of stimulations required to reach the first stage V seizures, (p < 0.02) and the number of days on stage I (p < 0.004) and II (p < 0.02) seizures increased in NPS/AK animals compared to the control ones. The daily AD (p < 0.01), the cumulative AD of the 3 stages V seizures (p < 0.02) and the GSD (p < 0.02) decreased in the NPS/AK animals compared to the control ones. The preemptive NPS did not show differences in the acquisition of AK. Our data suggest an anti epileptogenic effect by NPS when the stimulation was applied during the development of AK. On the other hand, the NPS may be an alternative treatment against the progress and the pathophysiology of epilepsy, however, a better understanding of the role of NPS in the modulation of neural networks will help us to find the physiological mechanisms to achieve a better therapeutic effect with NPS.

Title: Neuropathological assessment of hippocampal damage in C57BL/6J mice following convulsive motor seizures induced by repeated low-dose kainate administration

Authors: *D. L. NGUYEN, P. H. BESKE, M. R. EISEN, M. J. STENSLIK, D. M. KNIFFIN, C. L. HONNOLD, P. M. MCNUTT USAMRICD, Aberdeen Proving Ground, MD

Abstract: *Status epilepticus* (SE) is a medical emergency resulting from continuous epileptic seizures that persist for longer than 5 minutes. If left untreated, SE can result in devastating damage to the brain. While chemoconvulsants such as pilocarpine and kainate (KA) are commonly used to induce SE in rats, efforts to transition these models to inbred mouse strains have been met with numerous challenges (high mortality, inconsistent SE behavior, resistance to pathology). Recent studies have suggested that repeated low-dose (RLD) administration of KA to adult mice may provide a reliable and survivable approach for SE induction. To evaluate this model, KA was repeatedly administered to male C57BL/6J mice (7-8 wk; 9-10 wk; 11-12 wk) until onset of Racine scale 4-5 convulsive motor seizures (CMS). The effects of seizure

induction on neuronal damage and GFAP immunoreactivity were then evaluated in medial temporal lobe brain regions and correlated to age. While CMS onset consistent with SE induction was observed in all age groups, survival and neuropathology were found to be age-dependent, as survival rates and resistance to neuronal damage increased with age. Most survivors of severe KA-induced CMS exhibited frank neuronal loss of *cornus ammonis* (CA) area 1 and 3 neurons and increased GFAP staining in the hippocampal formation. The spatial distribution of hippocampal damage was assessed across 3 bregmas (-1.4, -2.0, and -2.6), with neuropathology found to be largely consistent along the ventral-dorsal axis. Interestingly, KA-induced damage was restricted to the hippocampus, with minimal evidence of neurotoxicity observed in other brain regions. Collectively, while RLD administration of KA to C57BL/6J mice represents a reliable CMS induction method, further optimization of this model is necessary to reduce variability in survival rates and neuropathological outcomes.

Title: Dorsal versus ventral hippocampus: Does target location matter in the kainic acid mouse model of temporal lobe epilepsy?

Authors: *Z. ZEIDLER¹, C. LEINTZ², M. BRANDT-FONTAINE², E. I. KROOK-MAGNUSON² ¹Dept. of Neurosci., ²Univ. of Minnesota, Minneapolis, MN

Abstract: Temporal lobe epilepsy is a highly prevalent form of adult epilepsy and commonly modeled in mice using an intrahippocampal injection of kainic acid into the dorsal hippocampus. However, the hippocampus in mice is heterogeneous; targeting different aspects of the hippocampus may produce distinct phenotypes in an intrahippocampal kainic acid model of temporal lobe epilepsy. The ventral hippocampus is known to have differences in connectivity and function compared to the dorsal hippocampus, including greater connectivity with the amygdala. Furthermore, acute seizures induced via manipulation of the ventral hippocampus are

more likely than dorsal hippocampal seizures to generalize into overt behavioral seizures. Therefore, mice were subjected to a unilateral injection of kainic acid in either the dorsal (n=17) or ventral (n=17) hippocampus to induce an initial epileptogenic insult in order to monitor chronic, spontaneous overt behavioral seizures as well as behavioral and anatomical phenotypes. These mice were compared to saline controls (n=19). The dorsally and ventrally injected kainic acid groups exhibited similar deficits on a spatial memory task compared to saline injected mice (p<0.01). Ventrally injected kainic acid mice additionally displayed a hypohedonic phenotype (p<0.05). Surprisingly, both dorsally and ventrally injected kainic acid groups had similar levels of spontaneous overt behavioral seizures (3 or greater on the Racine scale). Hippocampal pathology will also be compared - examining the extent and focality of several anatomical phenotypes of temporal lobe epilepsy including cell loss, granule cell dispersion, and mossy fiber sprouting. Correlations between seizures, behavior, and pathology will also be tested. These results inform how different aspects of the hippocampus may contribute to distinct or common pathologies and comorbidities observed in temporal lobe epilepsy.

Title: Increased expression of proinflammatory cytokines IL-1 α , IL-6 and TNF- α by a kainic acid-induced status epilepticus model in the neonatal rat brain

Authors: *M. J. T. HERRERA¹, C. R. DE LA CRUZ-NEGRETE¹, S. OROZCO-SUÁREZ¹, M. A. DELI², A. HARAZIN², F. WALTER³, L. ROCHA⁴, P. CAMPOS-BEDOLLA¹ ¹Unidad de Investigación Médica en Enfermedades Neurológicas, Inst. Mexicano Del Seguro Social, Ciudad de México, Mexico; ²Lab. of Mol. Biol., Hungarian Acad. of Sci., Szeged, Hungary; ³Dept. of Pathology and Lab. Med., Univ. of Wisconsin, Madison, WI; ⁴Dept. de Farmacología, CINVESTAV, Ciudad de México, Mexico

Abstract: Introduction. Status epilepticus (SE) is an important neurological condition that requires immediate clinical attention. Neonatal seizures constitute one of the most common neurologic disorders in the newborn with the highest incidence in the first year of life. Neonatal status epilepticus has been extensively studied and it's been reported it can lead to neuronal death by apoptosis, morphological alterations in neural networks, among others, mediated by

excitatory amino acids and inflammatory cytokines. Neuroinflammation promotes the activation of microglia, astrocytes and brain endothelial cells, causing the release of glutamate, interleukin- 1α (IL- 1α), interleukin-6 (IL-6) and Tumoral Necrosis Factor- α (TNF- α), which provoke neuronal damage. Until now, the expression of proinflammatory cytokines IL-1 α , IL-6 and TNFα by kainic acid-induced status epilepticus in the neonatal rat brain (P2) is not known. For this reason, we have proposed to evaluate it. Material and methods. It was standardized a model of SE induced by KA in newborn rats (P2). The behavioral assessment to determine SE was performed using the modified Racine scale. Control and kainic acid treated rats (1.5 mg/kg, KA) were sacrificed 30 minutes and 24 hours after the treatment. The brains were obtained to determine the histological damage and expression of IL-1 α , IL-6 and TNF- α in hippocampus and cortex by immunological techniques. We used monoclonal antibodies against the NeuN protein to evaluate the functional status of the neurons. The immunological staining was performed using previously published methods. Results. The SE model was established in newborn rats (P2) at a dose of 1.5 mg/kg AK, with 80% survival. The SE model caused morphological damage in the hippocampus and cortex regions, quantified by densitometry. We observed a decrease in the neuronal integration of AK-treated rats. On the other hand, there was a significant increase in expression of IL-1 α , IL-6 and TNF- α proinflammatory cytokines in the neonatal rat brain by kainic acid-induced SE. A greater expression of these cytokines was observed at 30 min compared to 24 h later. Conclusions. We obtained an appropriate SE model with a high survival rate and an extraordinary reproducibility. We also defined that KA produces morphological damage in the hippocampus and cortex regions, both in rats sacrificed 30 minutes later and 24 hours after the stimulus. The immunohistochemical expression of proinflammatory cytokines (IL-1 α , IL-6 and TNF- α) is higher in the group of animals sacrificed at 30 minutes compared to the 24-hour group.

Title: Cyclooxygenase-2 inhibitors differentially attenuate pentylenetetrazol-induced seizures and increase of pro- and anti-inflammatory cytokine levels in the cerebral cortex and hippocampus of mice

Authors: *C. F. MELLO¹, F. R. TEMP², T. DUARTE², J. R. MARAFIGA², M. M. PILLAT² ¹Fed Univ. S. Maria (UFSM), Santa Maria, Brazil; ²Univ. Federal de Santa Maria, Santa Maria, Brazil

Abstract: Seizures increase prostaglandin and cytokine levels in the brain. However, it remains to be determined whether cyclooxygenase-2 (COX-2) derived metabolites play a role in seizureinduced cytokine increase in the brain and whether anticonvulsant activity is shared by all COX-2 inhibitors. In this study we investigated whether three different COX-2 inhibitors alter pentylenetetrazol (PTZ)-induced seizures and increase of interleukin-1ß (IL-1ß), interleukin-6 (IL-6), interferon- γ (INF- γ), tumor necrosis factor- α (TNF- α) and interleukin-10 (IL-10) levels in the hippocampus and cerebral cortex of mice. Adult male albino Swiss mice received nimesulide, celecoxib or etoricoxib (0.2, 2 or 20 mg/kg in 0.1% carboxymethylcellulose (CMC) in 5% Tween 80, p.o.). Sixty minutes thereafter the animals were injected with PTZ (50 mg/kg, i.p.) and the latency to myoclonic jerks and to generalized tonic-clonic seizures were recorded. Twenty minutes after PTZ injection animals were killed and cytokine levels were measured by ELISA. Behavioral data were analyzed by Kruskal-Wallis followed by nonparametric Dunn's test. Cytokine data were analyzed by three-way ANOVA, considering the brain structure as within-subject-factor followed by Bonferroni test. PTZ increased cytokine levels in the cerebral cortex and hippocampus. While celecoxib and nimesulide attenuated PTZ -induced increase of proinflammatory cytokines in the cerebral cortex, etoricoxib did not. Nimesulide was the only COX-2 inhibitor that attenuated PTZ-induced seizures. This effect coincided with an increase of IL-10 levels in the cerebral cortex and hippocampus, constituting circumstantial evidence that IL-10 increase may be involved in the anticonvulsant effect of nimesulide.

Abstract: <u>Purpose.</u> Mild traumatic brain injury (mTBI) is a risk factor for neurodegenerative diseases, Post-Traumatic Stress Disorder (PTSD), major depression and epileptic seizures. It is generated by explosions, traffic accidents, falls or impact sport events. The resulting closed-head injuries can be identified with Diffusion Tensor Imaging (DTI) by axonal reduction of Fractional Anisotropy (FA). The clinical severity is correlated with the concussion duration. mTBI produces Chronic Traumatic Encephalopathy (CTE), biomarked by hyperphosphorylated tau protein (pTau). mTBI also serves as a tool in animal models to investigate the cell biological mechanisms of the induced pathological states.

Experimental. In most experiments, we used male C57BL/6N mice (7-8 weeks old) anesthetized with isoflurane. Their lungs and ears were protected with nylon ballistic coats and plastic plugs, respectively. The anesthetized mice were exposed for 0.2 msec to a supersonic helium wave produced by an aluminum 6 feet long and 2 inches wide shock tube. In some experiments, the animals were repetitively (twice or four times on subsequent days) exposed at 70 or 36 psi. Controls were treated similarly except for the missing helium wave. Subsequently, all mice were cardioperfused 2, 5, or 12 days after the last blast. The isolated brains were subjected to DTI and pTau histology. For absence seizure detection, three stainless steel screw electrodes were inserted into the skull over the hippocampus and the cerebellum. Two wire electrodes were additionally inserted into the neck musculature to record electromyography (EMG) activity. After recovery for one week, EEG and EMG signals were amplified in a range of 0.3 to 70 Hz. Absence seizures were identified by i.p. injection of pentylenetetrazole (PTZ). Thereafter, the mice were subjected to forced swim and sucrose preference tests to check on depression-like behavior.

<u>Results</u>. No mortality was observed. The mice required 5-7 minutes to recover from one blast. After repetitive blast (2 x 70 psi), the recovery process needed significantly less time. Four hours after one exposure to 70 psi, the blood brain barrier was found to be open. By PTZ injection, a significant discharge at 2-4 Hz in mTBI-induced mice indicated absence seizures. No evidence for depression-like behavior was observed, possibly because of the antagonism between epileptic and depressive actions. The role of the mTBI-induced increase of pTau will be discussed.

<u>Conclusion</u>. The hypothetical inverse relationship between epileptic and depressive processes will be further investigated by antiepileptic intervention.

Title: A novel fluorescamine-based imaging approach to investigate the diffusion of 4aminopyridine in rat neocortex

Authors: *M. ZHAO^{1,2}, R. E. RADWANSKI^{1,3}, E. BAIRD-DANIEL¹, H. MA^{1,2}, N. NISHIMURA³, C. B. SCHAFFER³, T. H. SCHWARTZ^{1,2,4} ¹Dept Neurolog Surg, ²Brain and Mind Res. Inst., Weill Cornell Med. of Cornell Univ., New York, NY; ³Dept. of Biomed. Engin., Cornell Univ., Ithaca, NY; ⁴New York Presbyterian Hosp., New York, NY

Abstract: Epilepsy is a neurological disorder that affects roughly 1% of the population worldwide. Although effective treatments with antiepileptic drugs are available, more than 20% of patients have seizures that are refractory to medical therapy and many patients experience adverse effects. Animal models of epilepsy are very important not only for understanding the fundamental neuronal mechanism of epilepsy but also for testing the efficacy of new antiepileptic drugs or other therapeutic interventions. 4-Aminopyridine (4-AP) is a potent convulsant when applied to the neocortex. Microinjection of 4-AP in vivo can induce focal seizures, but the volume of tissue in which the 4-AP is released over time is poorly understand. Here, we combined the 4-AP with fluorescamine, a fluorescent agent that reacts with primary amines to form a highly fluorescent compound, to characterize the radial diffusion pattern of 4-AP. 0.5 µl fresh fluorescamine/4-AP solution was injected into rat neocortex (25mM 4-AP and 270mM fluorescamine). We excited fluorescamine/4AP with a 395 nm LED light passed through a 395 ± 2 nm bandpass filter. The excitation light was diverted onto the neocortex via an extended reflectance dichroic mirror. The emitted fluorescence was passed through a band-pass 474±13.5 nm emission filter and collected by an Adimec 1000M/D camera. Serial imaging of the fluorescence of the mixture of fluorescamine and 4-AP can be used to trace the diffusion of 4-AP over time. The mixture of fluorescamine/4-AP showed strong fluorescence signals compared to

the background autofluorescence of cortex. On average, injection of 4-AP leads to an early rapid increase in the area of fluorescence with a second slower increase from diffusion. The delay of 4-AP starting diffusion is $210\pm105.9 \text{ sec}$ (n=5 rats). The averaged diffusion distances at 1800, 2400, 3000, 3600, 5400, and 7200 sec were $372.77 \pm 54.30 \mu m$, $466.48 \pm 54.62 \mu m$, $526.67 \pm 48.33 \mu m$, $589.60 \pm 42.86 \mu m$, $497.94 \pm 78.35 \mu m$, and $428.17 \pm 54.15 \mu m$, respectively. The average maximum distance of diffusion of $589.60 \pm 85.72 \mu m$ was reached at 3600 seconds. Taken together, these results demonstrate that the fluorescamine-based bioassay could be used as a novel method to investigate the distribution of 4-aminopyridine or other compounds with primary amines in the brain.

Title: The effect of time of day on respiratory outcomes and survival following maximal electroshock seizures in mice

Authors: *B. S. PURNELL^{1,2}, M. A. HAJEK³, G. F. BUCHANAN^{1,3,2} ¹Neurol., ²Interdisciplinary Grad. Program in Neurosci., Univ. of Iowa, Iowa City, IA; ³Neurol., Yale Sch. of Med., New Haven, CT

Abstract: One in twenty-six Americans are diagnosed with epilepsy at some point during their lifetime. While the majority of these patients achieve seizure control with medications, approximately one-third of epilepsy patients are refractory to therapy with antiepileptic drugs. Patients with refractory epilepsy are at high risk for sudden unexpected death in epilepsy (SUDEP). The preponderance of evidence suggests that SUDEP occurs due to seizure-induced

respiratory and/or cardiac dysfunction. In addition, the majority of SUDEP cases occur during the night. Since humans tend to sleep during the night, this has been attributed to SUDEP occurring during sleep. Sleep state certainly affects seizures, and there is evidence that sleep state influences SUDEP; however, the observation that SUDEP tends to occur during the night might also implicate circadian influences on SUDEP that are independent of the influences of sleep state. We investigated this possibility here. Adult male wild-type mice were implanted with EEG, EMG, and EKG recording electrodes. After recovery from surgery and acclimation to the recording chamber, seizures were induced via maximal electroshock (50 mA, 200 msec, 60 Hz, biphasic sine wave) during wakefulness, non-rapid eye movement (NREM) sleep and rapid eye movement (REM) sleep during the daytime and the nighttime (n = 12 per condition). EEG, EMG, EKG, and breathing plethysmography data were collected during each seizure induction. Seizure severity and duration, and the effects of seizures on breathing, cardiac function, EEG power, and survival were assessed. Seizures induced during the daytime, the inactive phase of rodents, were longer in duration, more severe, and more likely to be fatal than seizures induced during the nighttime. Seizures induced during the daytime were also associated with more profound respiratory dysregulation and post-ictal EEG suppression compared to those induced during the nighttime. There were no statistically significant differences in the effects of seizures induced during different vigilance states and times of day on cardiac function. Seizures induced during REM sleep during either the daytime or the nighttime were fatal. Taken together these data suggest that time of day influences the physiological consequences of seizures that may lead to seizure-induced death. Additional work is needed to determine the mechanisms by which time of day affects seizure outcomes. Understanding these mechanisms may inform strategies to prevent SUDEP.

Title: Ketogenic diet-induced extension of longevity in epileptic Kcna1-null mice is influenced by gender and age at treatment onset

Authors: K.-C. CHUN^{1,2}, S.-C. MA², *H.-J. CHOI³, J. M. RHO⁴, D. KIM² ¹Dept of Ob&Gyn, Inje university, ilsan paik hospital, Goyang-si, Korea, Republic of; ²Barrow Neurolog. Institute, St. Joseph's Hosp. & Med. Ctr., Phoenix, AZ; ³Harvard Med. Sch. (SERI/MEEI), Somerville, MA; ⁴Alberta Children's Hospital, Univ. of Calgary, Calgary, AB, Canada

Abstract: Sudden unexpected death in epilepsy (SUDEP) is a leading cause of premature mortality in patients with medically intractable epilepsy. While the pathophysiology of SUDEP remains unclear, multiple risk factors have been identified, including generalized tonic-clonic seizure (GTC) frequency, gender, early age at seizure onset and polytherapy with anti-seizure drugs. The spontaneously epileptic Kcnal-null (KO) mouse, lacking the delayed rectifier potassium channel protein Kv1.1, has been validated as a model of SUDEP, and a recent study has shown that a high-fat, anti-seizure ketogenic diet (KD) significantly extends longevity relative to KO mice fed normal rodent chow (PMID: 27346881). Here, we investigated whether the KD-induced extension of lifespan in KO animals is dependent upon gender and/or age of onset of KD administration. As mice aged, we found that KO animals had a steadily increasing daily seizure frequency (6.5 \pm 4.7 at postnatal days [PD] 33-38 vs. 10 \pm 2.2 at PD40-45, p < 0.01) and early demise by PD 46.9 \pm 0.8 (n=112). In standard diet (SD)-fed KO mice, there was no difference in lifespan between male and female animals. By contrast, following KD initiation at PD30, KD-fed mice exhibited significantly extended longevity (PD 69.8 \pm 1.7; n=36; p <0.01), and concomitantly had a decreased frequency of daily seizures (4.1 ± 0.9 ; n=36; p < 0.01). Seizure control on the KD was similar between male and female mice, but KD-fed female KO mice survived longer than their male counterparts. The average ages of mortality were PD 73.1 ± 2.5 (n=21) and PD 65.1 ± 1.4 (n=15) for females and males, respectively (p < 0.05). Comparing KO mice with KD onset at two different ages, we found that diet initiation at PD25 led to longer lifespans compared to those who were placed on the KD starting at PD35. Collectively, these data further support the notion that the KD can retard disease progression and sudden death in the Kcna1-null mouse model of early developmental epilepsy, but that these effects are dependent on sex and age at initiation of therapy. The profound alterations in cellular metabolism and mitochondrial bioenergetics elicited by the high-fat diet are likely to be influenced by other factors as well, and future studies are necessary to clarify the specific mechanisms underlying the disease-modifying effects of the KD.

Title: Validating a nerve agent-induced seizure model by evaluating the anticonvulsant and neuroprotective effects of scopolamine, memantine, phenobarbital, and ganaxolone

Authors: C. JACKSON, C. ARDINGER, D. BALLOUGH, H. CRAIG, J. H. MCDONOUGH, *H. S. MCCARREN US Army Med. Res. Inst. of Chem. Def, Aberdeen Proving Ground, MD

Abstract: Nerve agents are organophosphorus (OP) compounds which have been used by terrorist organizations and militant governments in civilian attacks. Nerve agents irreversibly block acetylcholinesterase activity, resulting in an accumulation of excess acetylcholine at neural synapses. This leads to a state of prolonged seizures known as status epilepticus, which is associated with significant morbidity and mortality. Benzodiazepines, the current anticonvulsant standard of care, become less effective as the time to treatment increases. In a mass civilian nerve agent exposure, concurrent trauma and limited resources would likely cause a delay in first response time. We have developed a rat model to test the anticonvulsant and neuroprotective efficacy of novel therapeutics at delayed time points. Adult, male rats with cortical EEG electrodes are exposed to the nerve agent soman and administered test treatments along with midazolam 20 minutes after seizure onset. FluoroJade B (FJB) staining is used to assess the neuroprotective effects of the treatments. We have validated our model using four drugs with established efficacy, or lack thereof, in other seizure models. Scopolamine, an anticholinergic, stopped seizures within one hour of treatment, in 5/9 rats treated with 5.6 mg/kg, 7/11 rats treated with 10 mg/kg, and 6/10 rats treated with 30 mg/kg, while saline + midazolam was ineffective (n = 11). Scopolamine also reduced the number of FJB+ neurons compared to controls in the five brain regions considered (amygdala, thalamus, piriform cortex, hippocampus, and parietal cortex). Memantine, an NMDA antagonist, had no anticonvulsant or neuroprotective effect and led to significant mortality (4/10 survivors) when tested at 56 mg/kg. Phenobarbital, a barbiturate, stopped seizures in rats 51.98 minutes (SEM = 14.23) after treatment in 8/8 rats treated with 100 mg/kg. In 4/10 rats treated with 56 mg/kg, seizures terminated, but returned an average of 19.63 minutes (SEM = 3.06) later and lasted throughout the day. Phenobarbital dosedependently reduced the number of dying cells in the amygdala only. Ganaxolone, a neuroactive steroid, also demonstrated dose-dependent anticonvulsant efficacy with seizures terminating in 2/13 rats at 3 mg/kg, 3/9 rats at 6 mg/kg, and 5/9 rats at 10 mg/kg. Our results align with previous findings, thus validating our model as a way to successfully test the anticonvulsant and neuroprotective effects of novel drugs that may stop nerve agent-induced seizures.

Abstract: Understanding how seizures propagate across the brain is important to elucidating seizure dynamics and improving treatment strategies in pharmacoresistant focal epilepsy. While it has long been recognised that sensory stimuli can facilitate or inhibit epileptic seizures, very little is known about the cortical mechanisms that underpin such behaviour. Since it is thought that seizure propagation is restrained by feed-forward inhibition, and sensory adaptation during repetitive stimulation alters the balance between cortical excitation and inhibition, we sought to perturb focal seizure propagation dynamics through activation of sensory regions adjacent to the seizure focus. To this end, we exploited our established multi-modal methodology to examine neural and hemodynamic responses in cortex during physiological stimulation and recurrent focal acute seizures, and our mathematical model that allows decomposition of evoked LFPs into excitatory and inhibitory components. Two multi-channel depth electrodes were implanted into visual and adjacent vibrissal cortex of the urethane-anesthetized rat, the latter loaded with 4aminopyridine (4-AP, 15mM) for induction of recurrent focal seizures. 4-AP was infused into layer 6 visual cortex after a pre-infusion baseline recording. High-resolution spatial measures of total haemoglobin concentration were obtained using optical imaging spectroscopy. Whisker stimulation (16s, 5Hz, 1.2mA) was delivered at specific time-points following 4AP infusion and responses compared to controls to determine the effect of nearby epileptic activity on sensory processing and assess the manner in which ictal propagation is modulated by nearby sensory stimulation. Laterolaminar properties of epileptiform activity and resultant neurovascular coupling processes during the horizontal spread of epileptic activity were concurrently assessed using a suite of analysis techniques. Somatosensory activation in the ictal surround during ongoing recurrent seizures was associated with: 1) an increase in synchronisation between electrodes in the seizure onset zone and neighbouring S1 cortex within the gamma-frequency range of the LFP; and 2) a profound decrease in multi-unit activity in deep cortical layers.

Notably, the reverse of the latter was observed in an isolated case where sensory responses and background cortical activity were consistent with a lighter anesthetic state. Our findings provide new insights into the complex effects of sensory stimulation on the propagation of adjacent acute focal seizures that may have important implications for our understanding of seizure dynamics.

Title: Optogenetically induced population discharge threshold (oPDT) as a sensitive measure of excitability

Authors: *D. C. KLORIG¹, G. ALBERTO², D. W. GODWIN³

¹Neurosci. Program, Wake Forest Hlth. Sci., Winston Salem, NC; ³Neurobiology/Anatomy, ²Wake Forest Sch. of Med., Winston Salem, NC

Abstract: Current pre-clinical methods for characterizing the efficacy of anti-epileptic drugs and/or surgical interventions rely on the ability to prevent, delay, or lessen the severity of artificially induced seizures, either as a result of electric shock or the administration of proconvulsant drugs. These measures exhibit a large degree of baseline variability, requiring large numbers of replicates to achieve the statistical power required to demonstrate efficacy. We have developed a new method to detect small shifts in network excitability (e.g. seizure susceptibility) using optogenetically induced population discharge thresholds (oPDT), in mice, as a surrogate for seizure. By combining optogenetic stimulation of the hippocampus with chronic multi-site recording in peri-hippocampal structures of awake behaving animals, we can induce and detect abnormal network wide population discharges that mirror spontaneous interictal spikes in terms of waveform shape and latency. By varying the intensity of light we can compare the magnitude of the optogenetically mediated current to the probability of population discharge. This probability curve is well fit by a Boltzmann curve, allowing calculation of a V50. Here we demonstrate that the V50 is a sensitive and reliable metric of network excitability. Manipulations known to increase excitability such as chronic EtOH withdrawal, or sub-convulsive doses (20 mg/kg) of pentylenetetrazol (PTZ) produce a leftward shift in the curve compared to baseline.
Anti-epileptic drugs, in combination with pro-convulsive manipulations, produce a rightward shift to baseline. oPDT baselines are remarkably stable over time, allowing for within-subject experimental design with multiple pharmacological manipulations, reducing the total number of animals needed. Furthermore we have fully characterized the close relationship between the oPDT and optogenetically induced seizure thresholds, thus demonstrating that the oPDT is a useful surrogate. The oPDT is the first example of a sensitive measure of subconvulsive network excitability, with broad applicability to a number of areas of investigation.

Title: Forebrain neuron-specific deletion of Sod2 results in epilepsy, mitochondrial oxidative stress, and altered bioenergetics and gene expression

Authors: R. FULTON¹, J. N. PEARSON², S. AIVAZIDIS¹, T. SHIMIZU³, *M. N. PATEL⁴ ¹Pharmaceut. Sci., Univ. of Colorado Anschutz Med. Campus, Aurora, CO; ²Univ. of Colorado, Aurora, CO; ³Advanced Aging Med., Chiba Univ., Chiba, Japan; ⁴Dept Pharmaceut. Sci., Univ. Colorado, Anschutz Med. Ctr., Aurora, CO

Abstract: Superoxide dismutase-2 (Sod2) is a critical mitochondrial antioxidant enzyme that catalyzes the detoxification of superoxide radicals in the mitochondrial matrix. Global deletion of Sod2 causes neonatal lethality. The goal of this study was to determine the consequences of mitochondrial oxidative stress in forebrain neurons during adulthood. A brain specific knock out (KO) mouse was generated by crossing an Sod2 p lox mouse strain with a neuronal basic helix-loop-helix (NEX) cre-recombinase mouse. The homozygous lox/lox offspring (Sod2-/-) were compared to their wild type littermates (Sod2+/+) for redox and metabolic parameters, behavioral deficits and cell death. Compared to Sod2+/+ mice, Sod2-/- mice displayed lower body weights at 1 month (p=0.03) and 2 months (p=0.006) of age with average age of death of approximately 2 months. Sod2-/- mice exhibited progressive age-dependent ataxia, kyphosis, and eventual hind limb paralysis. A rotarod test at 6 weeks revealed a deficit in balance, grip strength, and/or motor coordination (p=0.001). Mitochondrial aconitase, but not fumarase activity, a measure of oxidative stress, was decreased in 1 month (p<0.0007) and 2 month (p<0.0001) old Sod2-/- mice compared to Sod2+/+ mice. Spontaneous seizure activity was detected in 6 week old Sod2-/- mice. Cell death, identified by Fluoro Jade B stain, was

progressive and specific to the prefrontal cortex ($p \le 0.01$) and somatosensory/motor cortex ($p \le 0.05$) in Sod2-/- mice. Primary cortical cultures isolated from 5 day-old Sod2-/- and Sod2+/+ littermates revealed increased glycolytic rates in Sod2-/- cultures. Correspondingly, blood glucose levels were decreased in 6 week old Sod2-/- mice (p=0.0101). Finally, using a PCR array, we identified nine genes with increased expression in the prefrontal cortex of Sod2-/- mice. These results suggest that mitochondrial oxidative stress in forebrain neurons results in seizures and behavioral deficits, selective neuronal death and increased glycolysis.

Title: Are microglia replaceable?

Authors: *A. J. FILIANO, J. C. CRONK, D. GOLDMAN, J. KNOPP, A. LOUVEAU, I. MARIN, R. MARSH, E. JI, I. SMIRNOV, C. C. OVERALL, J. KIPNIS Neurosci., Univ. of Virginia, Charlottesville, VA

Abstract: Ontogeny and function have been the major foci of microglia research in recent years. However, numerous questions remain unanswered regarding their role in pathology and whether monocyte-derived macrophages can assume microglia function in the adult brain. Whether or not monocyte-derived macrophages can engraft the brain and whether engrafted cells become microglia or instead retain unique functions remain major points of contention in the field. Here, we demonstrate that adult microglia, despite prevailing dogma, can be replaced spatially by peripheral monocytes without brain irradiation or blood-brain barrier disruption. However, these monocyte-derived engrafted macrophages do not differentiate to microglia, but acquire a unique transcriptomic profile. Using a bioinformatics approach, we defined signatures that detect the presence and unique function of engrafted macrophages among putative myeloid transcriptomes. Further, we developed a technique to replace microglia with hematopoietic-derived macrophages and compared their responses to the response of microglia under numerous physiological and pathological conditions. Under baseline conditions brain-engrafting macrophages cause no overt deficits in behavior, yet have aberrant response to peripheral or local challenges. These aberrant responses may be relevant for many neurological conditions and may impact neural function over the life of an individual.

Title: cAMP modulates microglial phagocytosis

Authors: *M. ANDOH, R. KOYAMA, Y. IKEGAYA Grad Sch. Pharma Sci, Univ. Tokyo, Tokyo, Japan

Abstract: Phagocytosis is one of the crucial functions of microglia. Recently, cAMP signaling in microglia is suggested to regulate their phagocytic capacity. However, it remains unclear whether cAMP signaling enhances or attenuates microglial phagocytosis. We investigated how changes in the intracellular cAMP levels in microglia modulate their phagocytic capacity. For this purpose, we developed a coculture system of microglia with astrocytes and neurons, in which the in vivo-like ramified shape of microglia is maintained. We found that pharmacological activation of cAMP slightly facilitated microglial phagocytosis of E.coli particles. In addition, we investigated the role of cAMP in microglial phagocytosis by optogenetically stimulating photoactivated adenylyl cyclase (PAC) in cultured microglia. We also applied this system for the live imaging of synaptic pruning by microglia. To image microglia-synapse interactions in real time, hippocampal neurons were transfected with synaptophysin-mCherry and were cocultured with GFP-expressing microglia prepared from CX3CR1^{GFP/+} mice. Using this system, we observed a translocation of mCherry-labeled synaptophysin from axons of living neurons to GFP-labeled microglial processes. Thus, our experimental system is useful to examine the mechanisms that regulate the phagocytic capacity of microglia.

Title: Epigenetic regulation of microglial phosphatidylinositol 3-kinase (PI3K) pathway involved in synaptic plasticity

Authors: *G. SAW¹, M. KARTHIK², T. DHEEN¹ ¹Anat., ²Physiol., Natl. Univ. of Singapore, Singapore, Singapore

Abstract: Microglial cells are the immune-competent macrophages present in the central nervous system (CNS). Microglia-mediated neuroinflammation has been shown in various neurological disorders such as Alzheimer's disease, Parkinson's disease, brain injury and infection. Phosphatidylinositol 3-kinase (PI3K) is known to play a significant role in synaptic plasticity in neurons. It is also expressed in microglia and its role in microglia has been mainly studied in the context of inflammation and phagocytosis. Studies have also shown that PI3K can bring about a phenotypical switch in microglia from pro-inflammatory (M1) to antiinflammatory (M2) which may prevent neurotoxicity. Downstream effectors of microglial PI3K such as protein kinase B (Akt), cAMP response element binding protein (CREB) and brainderived neurotrophic factor (BDNF) have been found to influence synaptic plasticity. We therefore hypothesise that the PI3K/Akt pathway in microglia regulates the production of BDNF which in turn alters synaptic plasticity. In this study, we investigated the regulation of microglial PI3K epigenetically through histone modification and post-translationally through sumoylation. Western blot and immunohistochemistry (ICC) analysis showed that sodium butyrate, a histone deacetylase inhibitor (HDACi) upregulated PI3K expression and the phosphorylation of Akt and CREB in microglia, suggesting that BDNF secretion from microglia may be altered via epigenetic regulation of PI3K. Knockdown of SUMO1 in stable BV2 microglia decreased the phosphorylation of Akt and CREB as well as the expression of BDNF. These results suggest that microglial PI3K is epigenetically regulated by histone modifications and post-translationally modified by sumoylation. We will next explore the role of microglial PI3K in long-term potentiation (LTP) in hippocampal slice cultures. Understanding the mechanisms by which microglial PI3K influences synapses may give us an insight into the ways by which it can modulate synaptic transmission and subsequently synaptic plasticity in learning and memory.

Title: CRISPR/Cas9-mediated disruption of SGK1 enhances potential inflammatory activity of microglial BV-2 cells

Authors: H. ASAI, *K. INOUE, E. SAKUMA, T. UEKI Nagoya City Univ. Sch. Med., Nagoya, Japan

Abstract: Distinct from other type of cells in brain, microglia are derived from myelogenous cells and responsible for immunological and inflammatory events in central nervous system. While they play a major role in acute inflammation on a variety of disorders, recent studies have revealed that chronic inflammation caused by active microglia leads to neurodegenerative diseases such as Alzheimer's disease and psychiatric diseases such as schizophrenia. Thus, the comprehensive understanding of brain inflammation elicited by microglial activation would refine therapeutic strategies of multiple neurological disorders. We have recently shown that two subunits of serum- and glucocorticoid-inducible kinases (SGKs), SGK1 and SGK3, are expressed in multiple microglial cell lines. Application of an SGK inhibitor gsk650394 results in enhanced lipopolysaccharide (LPS)-induced expression of iNOS and TNFα and nitric oxide (NO) production. These results imply the involvement of SGKs in cellular inflammatory responses (Inoue et al, 2016 BBRC). Here, to explore further the mechanism by which SGKs participate in microglial function, we focus on the roles of SGK1 in microglial BV-2 cells. We first employed the CRISPR/Cas9 system to introduce mutations in SGK1 gene, and successfully obtained heterozygous and homozygous knockout cell lines. Disruption of SGK1 gene leads to deramification of BV-2 cells; proportion of relatively round amoeboid cells is increased while that of ramified cells having long process(es) is decreased, suggesting the likelihood of microglial activation in SGK1^{-/-} cells. In support of this, deleting SGK1 accelerates proliferation rate, another potential parameter of activation. NO is generated by an administration of LPS, and it is enhanced in SGK1^{-/-} cells. In addition, those cells are treated with ATP to induce activation and injury, and SGK1^{-/-} cells turn out to be more susceptible to ATP-induced cell death, suggesting an increase in sensitivity to apoptotic signals. Taken together, these findings

demonstrate that SGK1 contributes to fundamental cellular function in regard with microglial activation. Further experiments will be performed.

Title: Aif1-iCre knock-in mouse line: A tool for conditional gene manipulation in microglia

Authors: *M. ABE, F. PENG, K. SAKIMURA

Cell. Neurobiol, Brain Res. Inst, Niigata Univ., Niigata, Japan

Abstract: Microglia, the resident immune cells of the brain, are known to play important roles in pathological and physiological conditions. Their main function, as immune cells, is to detect the signs of pathogenic invasion or tissue damage, and moderate the potential damage to the CNS and support tissue repair. In addition, recent findings have revealed that microglia are also involved in maintaining the neurodevelopment process and synaptic plasticity and controlling other neural functions. In order to investigate detailed functions of microglia, we have undertaken development of a conditional gene manipulation system in microglia using Cre/loxP recombination. We generated a new knock-in mouse line expressing codon-improved Cre recombinase (iCre) under the control of the Aif1 (Allograft inflammatory factor 1, also known as Iba1) promotor. This Aif1-iCre line was established by insertion of iCre gene into the translation initiation site of the Aif1 in frame using C57BL/6N ES cells via homologous recombination. Resulting Aif1-iCre mice were viable, grew normally, and were fertile. By crossing the Aif1iCre line with the tdTomato reporter mouse line, we investigated its recombination pattern in the brain. We found that tdTomato fluorescence was detected in the almost cells expressing Iba1 protein, indicating that conditional recombination was performed in a very large population of microglia. Although the recombination seemed to be highly microglia-selective, we also detected fluorescence in a minor population of excitatory neurons, which express a neuronal marker NeuN but contain no inhibitory transmitter GABA, in the forebrain and cells that comprise a part of capillary vessel throughout the brain. It seems that the recombination in these cells was due to transient expression of Cre recombinase at an early stage of development because no immunoreactivity for Iba1 was detected in the adult brain. However, no tdTomato fluorescence was not overlapped with the immunofluorescence for astrocyte marker GFAP, glial fibrillary acidic protein, or oligodendrocyte marker APC, adenamatous polyposis coli. Thus, the Aif1-iCre line on the C57BL/6N background will be a useful genetic tool to manipulate gene expression in microglia without affecting the functions of other glial cells.

Title: TSPO interacts with NOX2: a novel function in murine primary microglia

Authors: *M. K. LOTH^{1,2}, T. R. GUILARTE²

¹Envrn. Hlth. Sci., Columbia Mailman Sch. of Publ. Hlth., New York, NY; ²Envrn. & Occup. Hlth., Florida Intl. Univ., Miami, FL

Abstract: Translocator protein 18 kDa (TSPO) is a glial stress-response protein used in preclinical and clinical neuroimaging studies as a biomarker of neuroinflammation. Recent studies using TSPO knockout mice have questioned the long-held view that TSPO functions to transport cholesterol into the mitochondria for steroid synthesis. Further, the understanding of TSPO function in microglia is lacking. We have previously shown that TSPO ligands (TSPO-L) induce microglia functions consistent with an activated state, suggesting a role of TSPO in the inflammatory response to brain injury. Primary microglia exposed to TSPO-L (1-100 nM) induces ROS production which is abrogated by NADPH oxidase (NOX2) inhibitors, suggesting an association between TSPO and NOX2. NOX2 is a multi-subunit enzyme highly enriched in microglia and a major source of ROS in the CNS. To further elucidate the TSPO-NOX2 association in microglia, we used different molecular approaches to assess protein-protein interaction under unstimulated or stimulated conditions (100 ng/mL lipopolysaccharide (LPS) for 18 hours). 1) Co-immunoprecipitation (co-IP) revealed that the NOX2 subunits, gp91phox (gp91) and p22phox (p22), co-IP with TSPO supporting a protein-protein interaction. TSPO's association with gp91 and p22 decreased with LPS stimulation, whereas TSPO's association with VDAC, a mitochondrial protein, remained constant. These findings suggest that microglia activation changes the dynamics of the TSPO-NOX2 interaction. 2) Confocal imaging and colocalization analysis of TSPO/gp91/VDAC or TSPO/p22/VDAC immunofluorescence in microglia confirmed that TSPO colocalizes with both NOX subunits, as well as VDAC. Under LPS-stimulated conditions, TSPO associated with gp91 and TSPO associated with p22, exhibit decreased colocalization with VDAC. 3) Duolink Proximity Ligation Assay confirmed that TSPO interacts with p22, gp91 and VDAC in murine primary microglia. TSPO interaction with these proteins mirrored our co-IP data in that TSPO's association with NOX2 subunits decreased with LPS activation, whereas TSPO's association with VDAC did not change. Our findings suggest a novel TSPO-gp91-p22 interaction with VDAC in primary microglia that

is disrupted by microglia activation with LPS. This TSPO-NOX2-VDAC putative complex may be disrupted by LPS-induced changes in membrane lipid composition, and promote the trafficking of TSPO, gp91, and p22 away from VDAC. We propose that the TSPO-gp91-p22-VDAC interaction modulates the subcellular localization of gp91 and p22 proteins, thereby altering NOX2 activity and mitochondrial function.

Title: Dark microglia: A follow-up study across the lifespan

Authors: *K. BISHT¹, K. PICARD¹, N. VERNOUX¹, K. SHARMA¹, Y. Y. GRINBERG², J. FAUSTINO⁴, M. J. CARSON³, Z. S. VEXLER⁵, M.-E. TREMBLAY⁶ ¹Dept. of Mol. Medicine, CHUL, Laval Univ., Quebec, QC, Canada; ³Div. of Biomed. Sci., ²Univ. of California Riverside, Riverside, CA; ⁴Univ. California, San Francisco, CA; ⁵Dept Of Neurol., UCSF, San Francisco, CA; ⁶Dept. of Mol. Med., Univ. Laval, Quebec, QC, Canada

Abstract: Previously, we reported the existence of dark microglia, a newly defined microglial phenotype found during chronic stress, aging, fractalkine signaling deficiency, and Alzheimer's disease pathology (APP-PS1 mice), but rarely present under steady state conditions (Bisht *et al.*, Glia, 2016). Ultrastructurally, the dark microglia exhibited characteristic features of oxidative damage, and also expressed TREM2 (triggering receptor expressed on myeloid cells 2), a cell surface receptor that mediates phagocytosis, when found in association with the plaques of amyloid β . These cells appeared to be phagocytically more active than normal microglia, with their highly ramified and extremely thin processes extensively encircling axon terminals, dendritic spines, and even entire synapses, suggesting their implication in the pathological remodelling of neuronal circuits. Since brain development is also characterized by massive synaptic remodelling, including synaptic pruning, that requires microglial activity, it is important to look at the contribution of these highly phagocytic cells in development mechanisms to better understand their implication in diseases. In continuation with the previous study, we have attempted to characterize further these cells across stages of the lifespan, employing immunohistochemistry followed by transmission electron microscopy analyses. Previously, we

found these cells to be associated with pathological states. Nevertheless, surprisingly, they are also abundant in the normal developing brain, as early as postnatal day 5 (P5). Detection of dark microglia in the early developing brain could be associated with the clearance of cellular debris and synaptic connections overproduced during early postnatal development, however, direct evidence for the involvement of dark microglia in early brain development is lacking. Recent studies have shown the expression of TREM2 mRNA in embryonic and postnatal brain, primarily in microglia. Inducing TREM2 expression in microglial cells results in an increased phagocytosis, whereas its knockdown causes a reduced phagocytic ability. Given the importance of TREM2 in mediating microglial survival and phagocytic response, we attempted to detect dark microglia could not be detected in brain sections prepared from TREM2 knockout animal brains in comparison to their wildtype controls. Our focus is on the identification of specific markers that could selectively label these cells, in order to characterize their implication across brain development, plasticity, and disease.

Title: Donepezil suppresses intracellular Ca^{2+} mobilization through the PI3K pathway in rodent microglia

Authors: *Y. MIZOGUCHI, Y. HARAGUCHI, T. MURAKAWA-HIRACHI, Y. IMAMURA, A. MONJI

Dept. Psychiatry, Fac. Medicine, Saga Univ., Saga, Japan

Abstract: Microglia are resident innate immune cells which release many factors including proinflammatory cytokines or nitric oxide (NO) when they are activated in response to immunological stimuli. Pathophysiology of Alzheimer's disease (AD) is related to the inflammatory responses mediated by microglia. Intracellular Ca^{2+} signaling is important for microglial functions such as release of NO and cytokines. In addition, alteration of intracellular

Ca²⁺ signaling underlies the pathophysiology of AD, while it remains unclear how donepezil, an acetylcholinesterase inhibitor, affects intracellular Ca²⁺ mobilization in microglial cells. In this study, we observed that pretreatment with donepezil suppressed the TNFα-induced sustained intracellular Ca^{2+} elevation in rodent microglial cells. On the other hand, pretreatment with donepezil did not suppress the mRNA expression of both TNFR1 and TNFR2 in rodent microglia we used. Pretreatment with acetylcholine but not donepezil suppressed the TNFainduced intracellular Ca^{2+} elevation through the nicotinic α 7 receptors. In addition, sigma 1 receptors were not involved in the donepezil-induced suppression of the TNFα-mediated intracellular Ca²⁺ elevation. Pretreatment with donepezil suppressed the TNFα-induced intracellular Ca²⁺ elevation through the PI3K pathway in rodent microglial cells. Using DAF-2 imaging, we also found that pretreatment with donepezil suppressed the production of NO induced by TNFα treatment and the PI3K pathway could be important for the donepezil-induced suppression of NO production in rodent microglial cells. Finally, phagocytosis assay showed that pretreatment with donepezil promoted phagocytic activity of rodent microglial cells through the PI3K but not MAPK/ERK pathway. These suggest that donepezil could directly modulate the microglial function in vitro through the PI3K pathway.

Title: Exosomes regulate microglia responses to inflammation and aging

Authors: *J. C. UDEOCHU^{1,2}, A. CAI², A. JOVICIC³, C. SANCHEZ DIAZ⁴, P. VENTURA², S. VILLEDA²

¹San Francisco, CA; ²Univ. of California, San Francisco, San Francisco, CA; ³Stanford Univ., Palo Alto, CA; ⁴Univ. of California, San Francisco, San Francisco, CA

Abstract: Microglia are important cellular sentinels in the brain, however mechanisms of communication directing homeostatic responses are poorly understood. Brain aging represents a unique model for studying such mechanisms given prominent alterations in microglia homeostasis driven by aging-associated inflammation and loss of proteostasis. Here, we focus our study on exosomes, a subtype of extracellular vesicles containing bioactive proteins, RNA molecules and lipids, based on their endosomal origin and previously reported involvement of exosomes in regulating peripheral immune cell activation. We hypothesized that aging alters microglia exosome production and that these changes serve to regulate microglia inflammatory activation. Our initial characterizations revealed increased exosome abundance in the interstitial space of aged compared to young brains. Additionally, aged microglia expressed significantly higher levels of exosome release gene, rab27a, and showed enhanced abundance of exosomeassociated proteins compared to young microglia. Utilizing in vitro approaches, we investigated the signaling capability of microglia exosomes by analyzing exosome content. Microglia exosomes contained heterogeneous mixtures of proteins and microRNAs, enriched with molecules involved in the regulation of inflammatory processes including cytoskeletal rearrangement and cytokine signaling. To directly test the signaling capability of these exosomeassociated molecules, we performed stimulation assays using exosomes from activated microglia. RNA sequencing identified differential induction of numerous genes involved in immune activation, cytokine production and phagocytosis in exosome- relative to vehicle-treated microglia. Functional in vitro assays corroborated these gene expression changes confirming exosome-mediated inflammatory propagation in microglia. To determine if exosomes regulate such responses during microglia aging, we performed unilateral stereotaxic injection of exosome inhibitor, GW4869, or vehicle into aged brains. Subsequently analysis of microglia activation revealed significantly higher expression of CD68 in response to exosome inhibition. Together, we identify a novel form of cell-cell communication in microglia with important implication in regulating homeostatic and inflammatory responses during aging.

Title: Spatial and temporal activation of microglia and astrocytes following transcranial focused ultrasound

Authors: *J. SILBURT^{1,2}, S. HEINEN², K. MARKHAM-COULTES², M. A. O'REILLY², K. HYNYNEN⁴, I. AUBERT³

¹Lab. Med. and Pathobiology, Univ. of Toronto, Toronto, ON, Canada; ³Biol. Sci., ²Sunnybrook Res. Inst., Toronto, ON, Canada; ⁴Med. Biophysics / Physical Sci., Univ. of Toronto / Sunnybrook Res. Inst., Toronto, ON, Canada

Abstract: Transcranial focused ultrasound (FUS) enables non-invasive and controlled drug delivery across the blood-brain barrier (BBB) in a temporal (6- to 12-hours) and localized manner. Previous work reported varying degrees of microglial and astrocytic activation triggered by FUS over time. For example, Jordão et al (2013) showed that microglia were activated by 4 hours, and astrocytes by 4 days, both returning to baseline levels by 14 days post-FUS. This work did not use a feedback controller, which can better control opening. Depending on the type and severity of brain challenge, microglia can display a gradient of activation, and can contribute to inflammation and pathology, or reduce pathology (e.g. clear amyloid-beta) and promote regenerative processes. Mild challenges result in earlier resolution of microglia and astrocyte activation, and are not associated with the detrimental characteristics of glial scars. Here, we investigated a time-course of glial activation following FUS coupled with a feedback controller. We hypothesized that FUS treatment would transiently activate microglia and astrocytes near permeabilized, but not ruptured, blood vessels. We developed a machine learning protocol to analyze, in an unbiased manner, the spatio-temporal activation of microglia and astrocytes as determined by changes in morphology and the intensity of established glial markers. We show that microglia activation occurs by 1 day post-FUS and is significantly reduced by 10 days post-FUS. Astrocytes show activation beginning by 1 day post-FUS and remain activated at 10 days post-FUS. Furthermore, we quantified microglia and astrocyte proliferation, and the levels of stress proteins, including heat shock proteins. Microglia showed an increase in proliferation consistent with activation, while astrocytes did not proliferate. We observed no changes in heat shock proteins 70 and 90. Finally, neuronal cell death following FUS was not observed and erythrocyte extravasation was minimal. We conclude that following FUS, microglia and astrocytes are activated for at least 10 days, with progressive reductions in microglia activation. This activation was not associated with cell death, significant red blood cell entry in the brain, or changes in common heat shock proteins.

Abstract: Microglia play critical roles in CNS injury responses, tissue homeostasis, and can also modulate neuronal function and synaptic connectivity. In contrast to astrocytes and oligodendrocytes, which arise from multiple progenitor pools, microglia arise from yolk sac progenitors and are widely considered to be equivalent throughout the CNS. However, little is known about the basic properties of deep brain microglia, such as those residing within the basal ganglia (BG). Here, we show that microglial anatomical features, lysosome content, and membrane properties differ significantly across BG nuclei. In addition, transcriptome sequencing revealed significant differences in gene expression between midbrain and cortical microglia. Region-specific phenotypes of BG microglia emerged during the second postnatal week and were re-established following genetic or pharmacological microglial ablation and repopulation, indicating that local cues play an ongoing role in shaping microglial diversity. Together, these observations demonstrate that microglia in the healthy brain exist along a spectrum of distinct functional states and these data provide a critical foundation for defining microglial contributions to BG circuit function.

Title: Effect of microglia depletion on cerebral kynurenine pathway metabolism in control and R6/2 mice

Authors: *K. V. SATHYASAIKUMAR¹, D. W. DONLEY², M. A. R. THOMAS¹, F. M. NOTARANGELO¹, P. SEVERSON³, B. L. WEST³, J. H. FOX², R. SCHWARCZ¹ ¹Univ. of Maryland Sch. of Med., Baltimore, MD; ²Vet. Sci., Univ. of Wyoming, Laramie, WY; ³Translational Pharmacol., Plexxikon Inc, Berkeley, CA

Abstract: Kynurenine 3-monooxygenase (KMO) plays a key regulatory role in the kynurenine pathway (KP) of tryptophan degradation, which contains several neuroactive metabolites. In vitro studies suggested that KMO in the mammalian brain is predominantly localized in microglial cells (Alberati-Giani et al., 1996; Heyes et al., 1996, Guillemin et al., 2001), but verification in vivo has not been provided so far. We showed recently that KMO activity is unchanged in adult wild-type (WT) mouse brain after depletion of microglia (Sathyasaikumar et al., SfN Abstr., 37.19, 2016). As KMO activity is substantially increased in the brain of R6/2 mice, an established animal model of Huntington's disease (HD) (Sathyasaikumar et al., 2010), we now examined possible impairments in KMO and other elements of cerebral KP metabolism in R6/2 mice after pharmacological depletion of microglial cells. To this end, we treated animals with the colony stimulating factor 1 receptor inhibitor PLX5622, which depletes microglia in normal mice by 80% after 1 week of treatment (Dagher et al., 2015). WT and R6/2 mice were fed either PLX5622 (1,200 ppm in chow) or normal chow for 28 days starting at 7.5 weeks of age (N=10-12 per group). Animals were euthanized on the last day of treatment, and KMO, kynureninase and 3-hydroxyanthranilic acid dioxygenase (3-HAO) activities, as well as 3hydroxykynurenine (3-HK), kynurenic acid (KYNA) and quinolinic acid (QUIN) levels were determined in the forebrain. In addition, we analyzed brain weight, body weight and rotarod behavior in all animals. Compared to WT animals, R6/2 mice showed increased KMO (+214%) and decreased kynureninase (-42 %) activity. Neither of these changes was affected in PLX5622treated animals. In contrast, brain 3-HAO activity was essentially identical in WT and R6/2 mice, and PLX5622 treatment caused dramatic reductions in enzyme activity in both genotypes (WT: -65%; R6/2: -77%), indicating microglial localization of the majority of 3-HAO in the brain of both WT and HD mice. PLX5622 treatment had no significant effects on body weight, or on the brain levels of 3-HK, KYNA and QUIN in either genotype. Brain weight was significantly reduced in R6/2 mice, but PLX5622 treatment had no effect. The latency to fall measured by rotarod task worsened with age in R6/2 mice, but was unaffected by PLX 5622 in either genotype. Taken together, our data suggest that microglial cells do not harbor the majority of KMO and kynureninase in either physiological or pathological conditions. Possible compensatory events following PLX5622 treatment are currently under investigation.

Title: The role of microglia/macrophages in the response to olfactory bulb damage in adult zebrafish

Authors: *S. R. VAR, C. A. BYRD-JACOBS

Biol. Sci., Western Michigan Univ., Kalamazoo, MI

Abstract: The inherent plasticity of the zebrafish olfactory system serves as a useful model for examining immune cell response after injury. Microglia are the resident immune cells of the central nervous system that respond to damage by migrating to the site of injury and phagocytizing neuronal debris. We have shown a microglial response to olfactory deafferentation and direct injury; however, the timing and pattern of microglial migration remains unclear. We hypothesize that the microglial response to deafferentation or direct bulb injury facilitate regeneration and that liposome-encapsulated clodronate treatment will induce specific and localized macrophage depletion after damage and inhibit regeneration efficiency. Peripheral deafferentation and direct injury to the olfactory bulb in the whole fish was performed and compared to results in the isolated brain removed of all afferent input and peripheral influence. Comparisons of whole fish treatment groups to controls showed a significant increase in activated microglia in the damaged bulb following peripheral deafferentation at 4, 12, 24, 48, and 72h. Amoeboid profiles significantly increased between 1-4h, decreased between 4-12h, increased again at 12-24h, and decreased again at 24-48h. Following direct injury to the bulb, there was a significant increase in activated microglia in the ipsilateral and contralateral bulbs at 1 and 4h after injury. At 4h after injury, there was a significant decrease in amoeboid profiles, which remained low until 72h. Comparisons of isolated brain treatment groups to controls showed significantly more activated microglia in the olfactory bulbs after 4 and 12h in culture. Isolated brains that received a direct injury showed a significant increase in activated microglia after 1, 4, and 12h in culture; however, isolated brains that received this injury showed significantly fewer responsive microglia in the damaged bulb when compared to direct injury to the bulb in the whole fish at 12h, suggesting that microglia can respond to damage without afferent input or peripheral influence, but only up to a certain time after injury. When liposomeencapsulated clodronate was injected into the telencephalic ventricle 24h before insult in whole fish, there appeared to be a significant reduction in microglia 4h after injury but only a small reduction in microglia 24h after injury, perhaps suggesting a temporal significance and selective

phagocytosis during the resolution of inflammation, particularly between the hours of 4 and 24h. Additional work is required to explore further the timing of the response and the potential role of these immune cells in recovery and regeneration after injury.

Title: Improved culturing conditions for the generation of In vivo-like primary microglia

Authors: *H. CYNIS¹, S. BARENDRECHT¹, B. HIETEL¹, R. EICHENTOPF¹, S. SCHILLING¹, H. U. DEMUTH¹, D. C. WAGNER² ¹Fraunhofer IZI-MWT, Halle, Germany; ²Johannes-Gutenberg Univ., Mainz, Germany

Abstract: Microglia cells are phagocytic immune cells in the CNS. They make up 8-13% of the total cell population in the brain and derive from primitive yolk-sac macrophages. Microglia cells have many different functions in the brain, both in normal brain development and in pathological conditions such as Alzheimer's disease (AD). The exact role of microglia in AD remains unknown: while some studies show a positive contribution of microglia through clearance of amyloid-beta plaques, other studies report a negative effect of inflammatory cytokines released by microglia during pathology. Primary murine microglia are often used to model the functioning of microglial cells in vitro. However, these experiments suffer from a rapid loss of the *in vivo* microglial phenotype, due to the lack of input from other CNS cells, which is necessary for microglial development and homeostasis. Our primary goal was to retain the microglial phenotype in cultured primary microglia, by mimicking the input normally present in the CNS. For this purpose we have tested and developed specific culturing conditions, which are able to restore the *in vivo* phenotype in primary microglia. We used qPCR and microarray analysis to compare the gene expression in our cultured primary microglia to the expression levels seen in freshly isolated microglia. Furthermore we were interested in the functioning of microglia in relation to neurodegenerative disease, specifically AD. Microglial-specific activity such as phagocytosis (of amyloid-beta) and responses to inflammatory stimuli were tested in freshly isolated microglia and cultured primary microglia. Firstly, we found that the native microglial phenotype is indeed restored by culturing primary microglia with a specific mix of factors important for microglial development and functioning. We also show that this effect is time-dependent. Regarding the functioning of the newly generated in vivo-like primary microglia, we expect these cells to function in a similar fashion as freshly isolated microglia and thus to better resemble microglia cells inside the brain. The culturing conditions developed in our lab make it possible to better analyze and understand the functioning of microglia in neurodegenerative disease. Our main focus is on the role of microglia in antibody-mediated clearance of amyloid-beta plaques, to improve the development and *in vitro* testing of possible new therapeutic antibodies for AD.

Title: Microglial-specific gene expression in adult prefrontal cortex following perinatal exposure to high fat diet

Authors: *B. L. SMITH¹, S. E. MCKEE², E. S. WOHLEB¹, T. M. REYES¹ ¹Dept. of Psychiatry and Behavioral Neurosci., Univ. of Cincinnati, Cincinnati, OH; ²Dept. of Pharmacol., Univ. of Pennsylvania, Philadelphia, PA

Abstract: Impulsivity is a key behavioral feature of many mental health disorders, such as substance abuse, attention-deficit/hyperactivity disorder, autism, and bipolar disorder. The prefrontal cortex (PFC) is critical for impulse control. Maternal malnutrition in the form of high fat diet (HF) increases impulsivity in the adult offspring and changes PFC gene expression of targets involved in reward, inflammation, and epigenetics. Using this maternal malnutrition model for impulsivity in mice, we sought to identify cell type specific molecular mediators that could contribute to this behavioral phenotype. Maternal HF diet increases markers of neuroinflammation in the offspring, but more work is needed to understand the exact consequences of this proinflammatory effect for the offspring into adulthood. To this end, we isolated microglia from the PFC of the adult male (M) and female (F) offspring that were either exposed to maternal HF or control diet (CD) throughout gestation and lactation. Because stress exposure can enhance neuroimmune responses and alter PFC-mediated behaviors, we included an acute restraint challenge prior to tissue collection (8 groups total, n = 6/group: M CD unstressed, F CD restraint, F HF unstressed, F HF restraint). Finally, we performed high throughput RT-qPCR to measure

microglial gene expression of 32 targets, including various cytokines, chemokines, epigenetic markers, and receptors expressed on microglia that are putatively involved in stress and PFC-mediated behaviors.

Abstract: Studies found new-born microglia replenished the whole brain after selective elimination of microglia (>99%) in adult mice. Immunohistochemical evidences suggested that repopulated microglia were differentiated from *de novo* progenitors expressing Nestin in the brain, which raised the possibility that the cross-lineage differentiation occurs in the mature brain. However, the origin of repopulating microglia has been hotly debated. In the present study, we investigated the origin of repopulating microglia by fate mapping. We first excluded that repopulated microglia were from blood cells. We then identified that repopulated microglia were not differentiated from Nestin-positive cells. Next we demonstrated all new-born microglia were derived from the proliferation of surviving microglia (<0.90%). Moreover, we confirmed that the whole brain transcriptome were not largely altered among stages of microglial progenitor cells were not existed in the adult brain.

Title: Translational profiling of microglia reveals artifacts of cell sorting

Authors: *J. D. FRYER¹, S. KANG²

¹Neurosci., Mayo Clin. FL, Jacksonville, FL; ²Neurosci., Mayo Clin., Jacksonville, FL

Abstract: Microglia are the resident innate immune population of the central nervous system that constantly survey and influence their local environment. Transcriptomic profiling has led to significant advances in our understanding of microglia in several disease states, but tissue dissociation and purification of microglia is known to lead to cellular activation. Here we use RiboTag translational RNAseq profiling to demonstrate that commonly used cell sorting methods lead to a fundamental alteration of the microglial transcriptome, with several transcripts that can be used to mark artifacts of isolation. Microglial RiboTag RNAseq profiling after peripheral immune challenge with lipopolysaccharide demonstrates unique transcriptional targets that are not evident using cell sorting methodology. Finally, we applied our technique to reveal novel shared and distinct pathways when comparing microglial transcriptomes after peripheral challenge with bacterial or viral mimetics. This study has broad implications for approaches that examine microglial transcriptomes in normal and pathological states.

Title: Noradrenergic modulation of microglial dynamics and synaptic plasticity

Authors: *R. STOWELL, A. MAJEWSKA

Univ. of Rochester, Rochester, NY

Abstract: Microglia, the innate immune cells of the central nervous system (CNS), respond rapidly and dynamically to homeostatic perturbations of the CNS milieu. In the healthy unperturbed brain, microglial processes make frequent contacts with neurons at synapses, impacting synaptic remodeling and turnover of dendritic spines. However, it remains unclear what receptors and signaling pathways govern microglial surveillance and synapse monitoring. Noradrenaline is a powerful signal that can affect many aspects of synaptic function and plasticity. Because microglia express high levels of β_2 adrenergic receptors (AR) compared to other cell types in the brain, we asked whether noradrenergic tone could alter microglial behavior with respect to synapses through β_2 AR signaling. To test this hypothesis we have manipulated β_2 AR signaling pharmacologically using the following agents: Nadolol (blood brain barrier (BBB) impermeant β AR antagonist), Clenbuterol (BBB permeant β_2 AR agonist), and ICI 118-551 (BBB permeant β_2 AR antagonist). We paired nadolol with clenbuterol to stimulate β_2 ARs centrally without concomitant peripheral stimulation. We then evaluated changes in basic microglial physiology through a combination of *in vivo* two-photon microscopy and immunohistochemical staining for Iba-1, a microglia-specific protein. We have found that stimulation of β_2 AR signaling *in vivo* reduces microglial motility and pseudopodia formation and causes microglia to assume a less ramified morphology. We also found that stimulation of β_2 ARs leads to impaired microglial responsiveness to focal tissue injury. These experiments show that β_2 AR signaling can affect microglial physiology and immune responses. Our next question was if these changes in basic microglial function could impact microglial interactions with neurons and functional experience-dependent plasticity. Using intrinsic optical signal imaging we have shown that pharmacological manipulation of β_2 AR signaling impairs ocular dominance plasticity in the visual cortex during the visual critical period in mice. We have shown that microglia are directly involved in this impairment through cre-mediated excision of β_2 AR

specifically in microglia. Based on our results we believe that β_2 AR signaling serves important roles in modulating microglial physiology and our future experiments will begin to address how the endogenous ligand, norepinephrine, is involved in mediating the effects observed. These results and future findings will improve our understanding of the signaling mechanisms that govern microglial interactions with synapses and how they impact activity-dependent synaptic modifications.

Title: Alcohol, exercise, and sex differences in microglial activation

Authors: *E. A. BARTON¹, C. BAKER¹, J. L. LEASURE²

¹Dept. of Psychology, ²Psychology, Univ. of Houston, Houston, TX

Abstract: Alcohol use disorders (AUDs) are associated with damage to corticolimbic brain regions. As the prevalence AUDs increases, it is necessary to find effective treatments. Exercise is a low-cost adjunctive treatment option that has been investigated. While it provides numerous health and cognitive benefits, the interactive effects of alcohol and exercise on the brain remain largely unexplored. Additionally, our current data suggest sex differences in basal microglia activation states as well as the microglial response to binge alcohol and exercise, as well as the potential sex differences in neural immune function.

Our lab utilizes a short-term (4-day) animal model of binge alcohol exposure that results in coroticolimbic damage consistent with damage seen in the clinical population of chronic alcohol user. In this model, rats are gavaged with ethanol (25% w/v) every 8 hours for 4 days. Control animals receive an isocaloric control diet also by gavage. Using this model we have demonstrated a loss of granule cells in the dentate gyrus of the hippocampus that persisted 35 days following the last dose of alcohol in female rats that is not seen in males. Voluntary wheel running, however, recovered the observed cell loss. This exciting finding supports the idea of using exercise as an adjunctive treatment for AUDs. However, when we examined microglia in the medial prefrontal cortex (mPFC) of the same animals, we found a drastically altered microglial response following binge and exercise that resulted in a staggering decrease in microglia cell number. Emerging evidence suggests alcohol exposure may be a priming stimulus

for microglia, meaning it potentiates microglia to launch an exaggerated response to a second stimulus. Indeed, a morphological analysis of microglia revealed a subpopulation of larger, thicker cells consistent with morphological descriptions of priming. These primed microglia were found in all female animals regardless of experimental condition, however, the binge exercise group had the most. Additionally, all females (regardless of binge or exercise) show marked OX-42 and MHCII (both markers of early microglia activation and priming), which is comparably limited in males, suggesting a basal sex difference in microglia expression profiles. Furthermore, the female binge exercise group shows the highest expression of both markers. This sex difference in microglia expression profiles and morphology may contribute to female vulnerability to alcohol-induced neural damage.

Title: Microglial-specific myd88 signaling impacts extinction of morphine cpp and adult hippocampal neurogenesis

Authors: *P. D. RIVERA^{1,2}, R. HANAMSAGAR^{1,2}, M. KAN³, P. TRAN¹, D. STEWART⁴, M. GUNN³, S. BILBO^{1,2,4}

¹Dept. of Pediatrics, Massachusetts Gen. Hosp. for Children, Charlestown, MA; ²Dept. of Pediatrics, Harvard Med. Sch., Boston, MA; ³Dept. of Immunol., Duke Univ. Med. Ctr., Durham, NC; ⁴Dept. of Psychology & Neurosci., Duke Univ., Durham, MA

Abstract: It is now appreciated that drugs of abuse - such as morphine - promote a neuroimmune response from glia, primarily microglia, which may play an important role in mediating addiction-like behaviors. For example, opiate administration in rodents increases the microglial surface marker CD11b and neuro-immune signaling molecules such as IL-1B and TNFa within discrete regions of the CNS involved in reward. Additionally, addiction-like behaviors such as conditioned place preference (CPP) can be prevented using pharmacological blockades and genetic knock-outs of signaling molecules responsible for pro-inflammation from microglia (i.e. Toll-like receptor 4 and MyD88). However, the specific role of microglial pro-inflammatory signaling on morphine CPP has yet to be determined. We therefore developed a novel transgenic mouse in which pro-inflammatory signaling (i.e. MyD88-dependent pathway) specifically in microglia (i.e. CX3CR1-Cretg/0 x MyD88f/f, Cretg/0) is ablated within the CNS. Microglial isolations from Cretg/0 verified diminished MyD88 gene expression in the CD11b+ cells while CD11b- cells, Cre0/0 x MyD88f/f, and WT controls maintain MyD88. A battery of behavioral tests on young and aged Cretg/0 mice revealed similar levels of anxiety and social interaction relative to Cre0/0, indicating normal mouse behavior. Next, 4-month-old Cretg/0 and Cre0/0 mice were trained under the morphine (3 mg/kg) CPP paradigm to assess the role of microglial-specific pro-inflammatory signaling. Both Cretg/0 and Cre0/0 groups acquired morphine CPP, however the Cretg/0 group had prolonged extinction and enhanced reinstatement compared to Cre0/0 controls. Given that adult hippocampal neurogenesis is involved in extinction learning, dentate gyrus doublecortin (DCX) was then examined. Interestingly, Cretg/0 mice had decreased DCX relative to Cre0/0 mice after morphine CPP. To determine if microglia are involved in the morphine CPP induced decrease in adult neurogenesis, CD68+, a lysosomal marker found in microglia, DCX+ cells were also assessed. Taken together, our results suggest that microglial-MyD88 signaling impacts extinction learning and adult neurogenesis and may have a protective role in addiction-like behaviors.

Abstract: Recent studies have suggested that microglia play critical roles in maturation and refinement of neural networks during postnatal brain development. Although it is known that microglia arise from the yolk sac and colonize the CNS during early embryogenesis and undergo a second wave of expansion during the first two weeks of postnatal life in rodents, it is less clear what intrinsic signals regulate the postnatal microglia development and how disrupted microglial

function at this developmental stage impacts on normal brain development. Here we report that signal transducer and activator of transcription 3 (Stat3) signaling plays a key role in microglial survival and activation in postnatal developing brain. $CX_3CR1^{CreER/+}$: Stat3^{flox/flox}: R26-tdTomato conditional mice were generated to achieve inducible and selective ablation of the phosphorylation site containing exon 22 of the *Stat3* gene in microglia after birth (P2-P4). Expression of tdTomato was used to evaluate the efficacy of tamoxifen-induced Crerecombination and to visualize Stat3 mutant microglia. Immunohistochemistry was used to analyze brain tissues collected from mice at different postnatal developmental stages. Our data showed clear morphological differences between activated microglia at P7-P10 and ramified microglia at P28-30. Cell counting analysis revealed significant decrease of microglial cell population in the Stat3 mutant mice (P7 and P10) in comparison to littermate controls. Interestingly, this loss of microglia during the first 1-2 weeks was largely recovered by P30. However, the transient decrease of microglia at P7-P10 was associated with increased innate immune responses including interferon signaling, complement pathways and cytokine/chemokine production as determined by RNA-sequencing analysis of acutely isolated microglia at P7. Dystrophic dendrites of cortical pyramidal neurons were found in the mutant mice when analyzed at P30. The functional consequence of microglial Stat3 inactivation is being examined in adult mice and our preliminary data suggest behavioral alterations in the conditional Stat3 mice as compared with littermate controls. Together, our data demonstrate that Stat3 signaling plays an essential role in microglial survival and activation in the postnatal developing brain and suggest that disruption of Stat3 signaling may elicit long-term neurological effects.

Title: Lifelong myelin plasticity along single cortical axons

Authors: *R. A. HILL, A. LI, J. GRUTZENDLER Neurol., Yale Univ. Sch. of Med., New Haven, CT Abstract: Unlike any other cell in the cerebral cortex, myelinating oligodendrocytes are continuously generated in the adult. Little is known about how new cells integrate into the preexisting neural architecture and whether the structure and distribution of myelin internodes along single axons is fixed throughout life. Using high resolution label-free and fluorescence in vivo optical imaging with transgenic fate mapping we discovered distinct patterns of lifelong oligodendrocyte generation occurring in parallel with changes in myelin internode deposition, length, and distribution along single axons. Myelin formation was largely a result of oligodendrocyte generation and occurred on both previously partially myelinated and unmyelinated axons. The distribution of internodes and total myelin coverage of single axons progressed up to two years of age demonstrating that these processes continue to evolve into late adulthood in the mouse neocortex. These findings reveal novel forms of lifelong myelin-dependent plasticity with broad implications for flexibility within adult cortical circuits.

Title: Nanoscale alignment of the periodic subcortical cytoskeleton of axon and glia at nodes of Ranvier

Authors: *E. D'ESTE, D. KAMIN, F. BALZAROTTI, S. W. HELL Max Planck Inst. For Biophysical Chem., Goettingen, Germany

Abstract: The ultrastructural organization of nodes of Ranvier has been investigated mainly by electron microscopy due to their small size (~1 μ m). This technique, however, provides limited molecular specificity. On the other hand, the resolution power of conventional light microscopy impedes the identification of substructures formed by antibody labelled proteins. Here, we exploit Stimulated Emission Depletion (STED) super-resolution microscopy to analyze the nanoscale organization of axonal and glial markers at the nodes of Ranvier of teased sciatic nerve fibers from mice. STED nanoscopy permits to achieve resolutions of few tens of nanometers without compromising on the molecular specificity. We found that the ~190 nm periodic subcortical actin/spectrin lattice that has been previously described in cultured neurons is present all along myelinated axons. Indeed, this lattice is continuous at the transition between paranodes and nodal gaps, where betaII spectrin and betaIV spectrin are present, respectively. In the latter compartment, sodium and potassium channels (Kv7.2) alternate and also follow the

~190 nm periodicity, which, however, appears less regular for adhesion molecules such as neurofascin-186 and nrCAM.

Paranodes are characterized by a tight interaction between the axon and glial cells. In these regions, both axonal (Caspr) and glial (neurofascin-155) adhesion molecules exhibit the same quasi-one-dimensional order, and the axonal subcortical cytoskeleton has a periodic arrangement. In the paranodal loops, the glial cytoskeletal protein Ankryin B features this same periodic organization. Notably, we observed a high degree of interdependence between the position of the axonal and glial proteins, hence suggesting the presence of mechanisms that finely align the cytoskeleton of the axon with the one of the glial cells.

Taken together, our observations suggest a master role for the periodic subcortical cytoskeleton in the organization of nodes of Ranvier and pave the way for a deeper investigation of these structures.

Title: Oligodendrocyte myelination: Axon size may be all that matters

Authors: *S. R. MAYORAL¹, A. ETXEBERRIA², C. J. SHIN³, C. S. YIAN³, J. R. CHAN² ¹Neurol., Univ. of California San Francisco Dept. of Neurol., San Francisco, CA; ²Neurol., UCSF, San Francisco, CA; ³Chem. and Biomed. Engin., Nanyang Technological Univ., Singapore, Singapore

Abstract: Myelination in the CNS is thought to occur via two distinct, but coupled processes. First, highly proliferative and migratory oligodendrocyte precursor cells (OPCs) differentiate

into mature, post-mitotic oligodendrocytes (OLs). Second, OL membrane extensions concentrically wrap around selected axons forming myelin. OL differentiation and myelination occur in a spatially and temporally stereotyped manner throughout development, which implies that environmental cues are at play in their regulation. There is increasing evidence that dynamic neuronal signaling involving neuronal activity and transcriptional control plays a role in regulating these processes, but it is unclear whether this is the case in regions where there is synchronous and robust differentiation and myelination within a short timeframe as in the early development of white matter tracts like the optic nerve. By eliminating dynamic neuronal signaling in the optic nerve our findings indicate that (1) OL differentiation and myelination are indeed coupled processes where myelination will occur upon differentiation if provided with a permissive substrate, and (2) dynamic neuronal signaling is not required for the majority of OL differentiation during early white matter development. We propose a model in which OL differentiation is largely regulated by extrinsic, non-neuronal factors during development, but myelination is sensitive to the biophysical properties of axonal diameter.

Title: Selection of CNS axons for myelination is negatively regulated by EphA4 and RhoA signaling

Authors: *L. S. LAURSEN¹, M. HARBOE¹, J. TORVUND-JENSEN², K. KJAER-SORENSEN³

²Dept. of Biomedicin, ³Dept. of Mol. Biologi and Genet., ¹Aarhus Univ., Aarhus, Denmark

Abstract: During development of the central nervous system not all axon are myelinated, and each axon may have a distinct myelination pattern, combined with the oligodendrocytes ability to myelinate up to 50 different axons this suggest that local signals between the oligodendrocyte process and the axon determine whether a myelin sheath can be formed. However, our current knowledge about the axonal signals involved in regulating this process is very limited. We here identify EphA4 as the receptor responsible for ephrinA-1 induced inhibition of process

extension in oligodendrocytes, and show that Ephrin-A1-EphA4 interaction activates a RhoA-Rock-myosin-II signaling cascade. Inhibition of signaling at different levels of this pathway regulates myelination by increasing the number of myelin sheaths formed by each oligodendrocyte. In contrast, activation of EphA4 reduces the number of internodes formed per oligodendrocyte. Combined this suggest that activation of the EphA4-RhoA pathway by axonal ephrin-A1 negatively regulate the formation of the stable axo-glia interaction required for formation of a myelin sheath.

Title: Pentose pathway activation in M leprae-infected Schwann cells leads to reduced lactate generation and nerve damage

Authors: *B. S. MIETTO¹, K. G. C. VASCONCELLOS¹, B. JUNQUEIRA¹, R. C. A. MEDEIROS¹, S. L. G. ANTUNES¹, M. C. V. PESSOLANI¹, E. N. SARNO², F. A. LARA² ¹Leprosy Dept., Fiocruz, Rio De Janeiro, Brazil; ²Leprosy Dept., Fiocruz, Rio de Janeiro, Brazil

Abstract: Leprosy is a chronic infectious disease caused by the intracellular pathogen *Mycobacterium leprae (M. leprae)*, which disturbs peripheral nerve integrity, impairing axonal and myelin function. There is growing evidence supporting that the molecular basis of Leprosy neuropathy could be located in infected Schwann cells. Of importance, Schwann cells are deeply involved in a wide range of axonal behavior including the maintenance of axonal and myelin integrity. Our group recently demonstrated that *M. leprae* was able to modulate Schwann cells glucose metabolism for its own benefit (Medeiros et al., 2016). Our results indicated that infected human Schwann cells increased glucose uptake with a concomitant upregulation in glucose-6-phosphate dehydrogenase (G6PDH) activity, the key enzyme of the oxidative pentose pathway. We also observed a two-fold reduction in lactate release from infected cells when compared to control ones. We also observed mitochondria shutdown in infected Shwann cells *in vitro* and mitochondrial swelling in myelinated and unmyelinated axons from Leprosy patients.

Here, we advance these findings by showing that neurons treated with M. leprae-infected Schwann cell-derived supernatant had a marked impairment in neurites outgrowth and complexity. In addition, ML was able to enhance the degradation of myelin contents in infected Schwann cells *in vitro*, and nerve biopsies harvested from patients with Leprosy neuropathy have augmented expression of mRNA for several autophagy genes (*ATG5, ATG7, BECLIN1 and LC3B*) as compared with control non-Leprosy nerves. In short, our results points to the notion that low levels of lactate content along with the presence of toxic mediators in ML-infected Schwann cells-derived supernatant are able to disturb neuronal integrity and growth responses. In addition, ML infection accelerated myelin degradation by up-regulating autophagy pathways *in vitro* and *in vivo*. Collectively, these data indicates that the pentose phosphate pathway is paramount for *M. leprae* infection success in Schwann cells, leading to a reduction in lactate generation, and that infected Schwann cells are detrimental to nerve function.

Title: Nectin-like 2 (Necl-2) cell adhesion molecule is a negative regulator of Schwann cell myelination

Authors: *P. MAUREL, M.-S. CHEN, C. HEFFERNAN, M. RODRIGUEZ Dept. of Biol. Sci., Rutgers - The State Univ. of New Jersey, Newark, NJ

Abstract: Axo-glial interactions are critical for Schwann cell genesis, myelination and domain organization of myelinated fibers. We previously characterized three members of the Nectin-like (Necl) cell adhesion molecules family as mediators of the axo-glial interaction along the internode, in the Peripheral Nervous System (PNS). Necl-4 is expressed by the myelinating Schwann cells whereas its ligand Necl-1 is expressed by the axon to be myelinated. Necl-2 expressed by both cell types, is also a ligand for Necl-1, although at a lower affinity than the Necl-1/Necl-4 pair. As we and others have shown that Necl-4 is needed for PNS myelination, it was assumed that Necl-1 would also be pro-myelinating. Our work has now shown that Necl-1 is

in fact inhibitory to myelination. We therefore extended our analysis to Schwann cell-expressed Necl-2, the other ligand for Necl-1. Using loss and gain of function approaches and the *in vitro* model of PNS myelinating, we demonstrate that Necl-2 is also inhibitory to the formation of myelin segments by Schwann cells. Our findings suggest that Necl-2 employs at least two mechanisms to prevent myelination. One is the down-regulation by Necl-2 of the promyelinating Akt signaling molecule. This is most dramatically observed upon axonal contact. The second mechanism is a dysregulation of small GTPases Rac1 and RhoA in Schwann cells, leading to dramatic changes in Schwann cell morphology and stress fibers organization. The stress fibers are almost completely absent in Schwann cells that do not express Necl-2, whereas the over-expression of Necl-2 induces a 3-fold increase in the number of lamellipodia formed by a single Schwann cell. We are currently evaluating how Schwann cell- axon interaction is perturbed by the absence or over-expression of Necl-2 in Schwann cells. Both Necl-1 and Necl-2 are expressed at birth, onward. However their developmental pattern of expression is in opposition. Necl-2 is strongly expressed during the first week post-nataly (onset of myelination) then its levels dramatically drop down, whereas the expression of Necl-1 increases over time. Our data suggests a new concept that Necl-1 and Necl-2 put a "negative clamp" on the promyelinating properties of Necl-4, at different time points of the myelination process.

Title: Reversing polycomb repression in schwann cells after nerve injury

Authors: *P. T. DUONG^{1,2}, K. H. MA^{2,2}, J. P. SVAREN^{3,2} ²Waisman Ctr., ³Dept. of Comparative Biosci., ¹Univ. of Wisconsin-Madison, Madison, WI

Abstract: The peripheral nervous system relies on Schwann cells to provide metabolic support, and insulating myelin that wraps the axons. Schwann cells also play a role in coordinating the regenerative response when peripheral nerves sustain injury. Schwann cells are a potential

therapeutic target as they have an ability to stimulate the functional recovery and restoration of damaged nerves. Underlying this regeneration potential, Schwann acquire a new state by transdifferentiating into repair cells. In this mode of reprogramming, a number of previously unexpressed genes become expressed after injury and are vital for axon regeneration. Our preliminary data have pinpointed epigenomic pathways that are responsible for the reprogramming of Schwann cells to their repair state after nerve injury. We found many regeneration genes are dually associated with repressive histone H3K27 methylation (H3K27me3) and H2A ubiquitination (H2AmUb) in mature nerve prior to injury. These histone modifications are formed by Polycomb Repressive Complex 2 (PRC2) and PRC1 respectively, which either independently or in conjunction repress transcription. ChIP profiling revealed significant loss of H3K27me3 and H2AmUb modifications on several genes that become activated upon nerve injury, such as sonic hedgehog and glial-derived neurotrophic factor (Shh and Gdnf). Furthermore, we have investigated H3K27 demethylases JMJD3/KDM6B and UTX/KDM6A as the putative mechanisms that facilitate the reversal of histone methylation on H3K27. Previous studies have shown JMJD3 induction at 4 days post injury (Gomez-Sanchez et al, 2013), and we find also that UTX appears to be upregulated in 1 and 5 post injury. These data support the hypothesis that reversal of polycomb repression by removal of H3K27 methylation is required for Schwann cell reprogramming after nerve injury. Analysis of Schwann cell-specific knockouts of these demethylases will decipher this early step of the regeneration timeline and test whether reversal of Polycomb repression is a requirement in initiating the injury response.

Abstract: The energetic requirement of the nervous system is extremely high in proportion to its size. In addition, some axons of peripheral neurons extend over 1m in humans, raising the question of how their metabolic needs are attained at regions distant from the neuronal cell body. A natural candidate to perform metabolic support functions is Schwann cells (SCs), the glia of the peripheral nervous system. As they ensheath both myelinated and non-myelinated axons along their length, SCs could provide metabolites to fuel mitochondrial activity in axons. Furthermore, partial oxidation of substrates might be favored in SCs to fulfill the need of carbons for lipid biosynthesis to produce and maintain myelin. However, the metabolic properties of SCs are poorly understood. In order to investigate the metabolic needs of SCs, we first bred mice expressing floxed Pdha1 gene and CNPase-Cre to generate Pdha1f/f; CnpCre/+ mice and Pdha1f/f littermate controls. The Pdha1f/f; CnpCre/+ animals lack pyruvate dehydrogenase complex (PDC) activity in SCs. PDC is responsible for connecting the glycolysis with the TCA cycle trough the conversion of pyruvate to acetyl-CoA. Surprisingly, there was no significant change in myelination, nerve conduction velocity or motor performance in Pdha1f/f; CnpCre/+ mice at 1 month. In addition, results were corroborated and extended with Pdha1f/f; P0-Cre mice, which did not show any morphological, behavioural or functional alteration up to 10 months. Taken together, these results indicate that PDC function might be dispensable in SCs. A particularly intriguing hypothesis is that SCs satisfy their energetic requirement via glycolysis and secrete partially oxidised metabolites, such as lactate, to be used by axonal mitochondria. We are currently investigating the SC intermediary metabolism using the Seahorse Xp Flux Analyzer. Moreover, we are characterizing mitochondrial location and morphology in Schwann cells throughout development using the photo-activatable mitochondria (PhAM) mouse, which allows fluorescent labeling of mitochondria in SCs upon recombination mediated by P0-Cre. Understanding the energetic adaptations of SCs could reveal new targets for drug development and medical strategies aiming to restore nerve function or prevent axon damage in demyelinating diseases.

Title: AMPA receptor signaling regulates the fate of oligodendrocyte progenitors

Authors: *A. AGARWAL¹, L. CHAKRAVARTI², K. SPARKS², A. MENON², D. E. BERGLES³

¹Dept. of Neurosci., ²Neurosci., Johns Hopkins Univ., Baltimore, MD; ³Johns Hopkins Univ. Sch. Med., Baltimore, MD

Abstract: Oligodendrocyte precursor cells (OPCs) express Ca²⁺ permeable AMPA receptors and form synapses with unmyelinated axons throughout the CNS, but the role of this signaling in vivo remains undefined. The primary obstacle to defining the role of this neuron-glial cell signaling is that OPCs express the same complement of receptors as neurons, precluding pharmacological manipulations. To overcome this limitation, we developed a conditional knockin mouse line in which the formation of functional AMPA receptors can be prevented cell autonomously by expressing a dominant-negative GluA2 subunit (EGFP-dnGluA2), in which a glutamine to arginine substitution was made in the pore region. EGFP-dnGluA2 was targeted to the ROSA26 locus with a conditional allele to enable cell-type specific expression. To evaluate whether dnGluA2 subunits are expressed at levels sufficient to modulate AMPA receptor function in OPCs, we bred these mice to NG2-CreER/+ mice. Double transgenic offspring were injected with 4-hydroxytamoxifen (4HT) at various developmental stages and analyzed 2-20 weeks later. Tetrameric AMPA receptors containing this subunit are non-conducting and OPCs expressing dnGluA2 lack AMPA receptor-mediated EPSCs. Fate tracing revealed that blocking AMPA receptor function in OPCs in vivo enhanced their survival and rate of proliferation during development, and reduced their differentiation into oligodendrocytes (OLs). OPCs lacking functional AMPA receptors were also morphologically less complex and extended shorter processes. To investigate the role of this signaling in controlling the behavior of OPCs following demyelination, mutant and control mice were either fed with 0.2% cuprizone or subjected to unilateral focal demyelination by injecting 1.0% lysolecithin into the corpus callosum. The number of OPCs expressing dnGluA2 was significantly enhanced in demyelinated lesions in both conditions, indicating that recruitment of OPCs is normally reduced by AMPA receptor signaling. However, fate tracing revealed that the effect of AMPA receptor blockade on OPC differentiation was distinct in the two contexts - OL generation was reduced following cuprizone-induced demyelination, which lacks an adaptive immune response, and enhanced following lysolecithin-induced demyelination, which is associated with infiltration of peripheral immune cells. These results indicate that the effect of AMPA receptor signaling in OPCs is highly context dependent, either promoting or inhibiting lineage progression depending on the environment and perhaps the pattern of activity exhibited by the axons they form synapses with.

Title: Optogenetic, electrical and electromagentic stimulation for subcellular induction of neuron activity in myelination studies *In vitro*

Authors: *A. BLASIAK, D. WONG, N. V. THAKOR, J. YOO, I. YANG Singapore Inst. for Neurotechnology, NUS, Singapore, Singapore

Abstract: Objective: Neuron activity modulates myelination and is considered a therapeutic target for treating demyelination diseases. Neuron activity induction can be applied to a whole cell *in vitro*, but is cumbersome *in vivo*. Alternatively, the stimulation can be applied focally, i.e. to the distal axons or to the somata only. Our objective was to develop a platform to study the mechanisms of activity-dependent myelination after focal neuron stimulation. Materials and Methods: Primary neurons were cultured in a two-chamber (somatic and axonal) device such, that the primary oligodendrocyte precursor cells (OPCs) plated in the axonal chamber could interact exclusively with the distal axons. This device was integrated with novel stimulators electrical, optogenetic, and electromagnetic (ESTIM, OSTIM and MSTIM, respectively) - for inducing neuron activity via the stimulation in the somatic (SomaSTIM), axonal (AxonSTIM) or both chambers (WholeSTIM). The effects on neuron activity and myelination were assessed by calcium imaging, cAMP level measurements, and through quantification of OPCs differentiation markers and morphology. **Results:** We integrated the culture device with platinum electrodes to apply ESTIM. Calcium firing and increased cAMP level showed that the stimulation successfully induced neuron activity. Interestingly, an indirect stimulation of axons (SomaSTIM), direct stimulation of axons and OPCs (AxonSTIM), and direct stimulation of the whole system (WholeSTIM) had the same effects on myelination. To achieve subcellular OSTIM we: (i) successfully induced neuronal expression of channelrhodopsin; (ii) modified the device material so it blocked the light, but remained biocompatible; (iii) integrated the device with custom build programmable LED array. In contrast to ESTIM, OSTIM exclusively stimulated neurons and not OPCs. Nevertheless, the effects of SomaSTIM, AxonSTIM and WholeSTIM on myelination were the same. Subcellular MSTIM does not require modification of neuronal expression or the culture device but it requires generation of pulsatile magnetic field spatially restricted to the size of one chamber. The stimulator and its effects on myelination are being characterized. Conclusions: The cellular mechanisms of ESTIM and OSTIM are not the

same. However, the consistency in their results strongly suggests that focal stimulation is sufficient to increase axon myelination. SomaESTIM and OSTIM results further imply that the activity-dependent myelination does not require direct stimulation of OPCs. MSTIM platform has the biggest translational potential as it is the least invasive out of the three presented neuron stimulation methods.

Title: Diverse patterns of myelination along individual axons in the adult cerebral cortex

Authors: *C. CALL, D. E. BERGLES

Neurosci., Johns Hopkins Univ., Baltimore, MD

Abstract: Axons in the cerebral cortex exhibit diverse patterns of myelination, with some axons devoid of myelin, some exhibiting discontinuous patches of myelin, and others continuous myelin that is interrupted only by nodes of Ranvier. It is unclear when these distinct patterns are established, whether different classes of neurons exhibit consistent myelination and if these patterns are stable over time or modified by experience. To define the distinctive characteristics of cortical axon myelination in the adult brain, we examined the distribution of myelin along single axons in layer I of somatosensory cortex. In this region, a wide array of axons from different cell types comingle within the same microenvironment, such that resident oligodendrocytes are provided a diverse set of myelination targets. Thus, differences in myelination are likely to reflect axonal differences in oligodendrocyte preference and myelin stability. Using confocal laser scanning microscopy in horizontal sections of flattened cerebral cortex, we measured the distribution of myelin internodes along individual corticocortical, thalamocortical, and interneuron axons for up to 2-3 mm in adult (5 months old) mice. For the cell types that were myelinated (parvalbumin+ interneurons, neurexophilin-4+ layer 6b/7 neurons, and neurons from ventromedial and posterior thalamic nuclei), the distribution of myelin was highly variable between different axons of the same cell type, as well as across different branches of a single axon. These results suggest that although cell identity can bias myelination of a given axon, other factors (e.g. activity or local environment) appear to influence the pattern of myelination that is established.

¹New York Univ. Neurosci. Inst., New York, NY; ²Dept. of Neurosci. and Physiol., NYU Sch. of Med., New York, NY

Abstract: The trafficking and targeting of proteins to distinct sites underlies the exquisite, polarized organization of neurons. Myelinated axons are further organized into a series of functionally and biochemically distinct domains, i.e. the nodes, paranodes, juxtaparanodes, and internodes. This organization provides a striking example of the differential targeting of proteins to subdomains of the axon and is essential for effective saltatory conduction. Of particular interest are the nodes of Ranvier, which are enriched in a multimeric complex of voltage gated Na⁺ channels form and their associated beta subunits, the neuronal cell adhesion molecules (CAMs) neurofascin (NF) 186 and NrCAM, and the cytoskeletal protein ankyrin G.We previously reported that NF186 and other axonal CAMs redistribute to the node and to other domains from pre-existing pools of diffusely distributed proteins on the axon surface (Zhang et al., Neuron 2012). In contrast, ion channels and ankyrin G require transport to the node during myelination. The slow replenishment of all nodal components in mature myelinated fibers also depends on transport. We have now directly investigated how these proteins are transported within the axon prior to and after myelination. To this end, we live-imaged neurons engineered to express combinations of proteins labeled with distinct fluorescent tags. In general, each nodal protein is anterogradely transported in separate vesicles except for NrCAM and NF186, which are co-transported in the same vesicles. Likewise, CAMs destined for other axonal domains are independently transported in distinct vesicles. In contrast, there is significant co-transport of retrogradely transported proteins presumably during recruitment into a common endocytic vesicle. These patterns of transport did not change with myelination. Taken together with our earlier study, these results support a model in which nodal component are sorted to separate
vesicles and transported independently to the axon rather than as a preformed complex; upon myelination, they assemble at the node via a combination of local recruitment (CAMs) and de novo transport (channels and cytoskeletal proteins).

Title: Abeta oligomers in synaptic lipid rafts induce phosphorylated tau and impair signal transduction

Authors: *T. KAWARABAYASHI, S. NARITA, K. SATO, T. NAKAMURA, Y. SEINO, M. HIROHATA, N. NAKAHATA, M. SHOJI Hirosaki Univ. Grad. Sch. of Med., Hirosaki, Japan

Abstract: Lipid rafts are crucial platform in $A\beta$ production and aggregation, leading to the formation of neurotoxic $A\beta$ oligomers in the brain. Recent findings suggest that lipid rafts are pathological signaling platforms where $A\beta$ oligomers exert synaptic failure and neurotoxicity. We examined whether $A\beta$ oligomers induce phosphorylated tau and impair signal transduction in

lipid rafts from synaptosome of Tg2576 mice. Tg2576 mice and nontransgenic littermates (4, 6, 12, and 22 month old, Tg n=18, NonTg n=18) were used. Synaptosome fraction was separated by Ficoll gradient fractionation. Lipid rafts fraction was separated from synaptosome by sucrose gradient fractionation. In Tg2576 mice, the amount of phosphorylated tau and Fyn increased in synaptosome, and also in lipid rafts of synaptosome with accumulation of A β oligomers. Accumulation of phosphorylated tau in lipid rafts of synaptosome began at 6 month when the behavioral disturbance appears in Tg2576 mice. A β oligomers may induce phosphorylated tau and Fyn-NMDA receptor signal transduction pathways in lipid rafts of synapse.

Abstract: The microtubule-associated cytoskeletal protein tau has been considered primarily axonal in healthy brains, while in Alzheimer's (AD) the tau gradient shifts toward somatodendritic compartments where it accumulates as intracellular aggregates. Tau is now generally thought to be released into the extracellular space from synaptic terminals, facilitating transynaptic spreading across neural circuits, but this process is poorly understood. Our previous work has shown that C-terminal truncated tau is abundant in synaptic terminals, and that tau and exosomes are released by depolarization from Alzheimer's disease synaptosomes. In the present work, synaptosomes were prepared from cryopreserved cortical (A7) samples from AD cases, from A β -independent tauopathy cases, and from cognitively normal aged control cases. The Tau RD P301S FRET biosensor system was used to evaluate the capability of human synaptosome-derived extracts for seeding tau aggregation. P-2 (crude synaptosome) extracts were added to the

biosensor cell media, and after 48 hours, cells were analyzed for FRET fluorescence using an ImageStream flow cytometer. Extracts from normal (n=2) and tauopathy cases (n=3) generated little FRET signal (<5% positive); in contrast, samples from two AD cases propagated tau aggregation, generating FRET signal in 43% and 28% of the populations examined (10,000 cells/sample). These results are consistent with the hypothesis that oA β localized to AD synapses accelerates tau propagation in this *in vitro* system. Using this system, clarification of synaptic tau release mechanisms in human samples can provide important insights with respect to disease progression and tau immunotherapies.

Title: Characterization of a novel APP/tau transgenic mouse model of Alzheimer's disease

Authors: *S. L. LIPPI, M. L. SMITH, T. T. DIMOPOULOS, J. M. WOOD, A. BOOTH, J. M. FLINN

George Mason Univ., Fairfax, VA

Abstract: Alzheimer's disease (AD) is a neurodegenerative disorder that consists of the accumulation of amyloid and tau proteins in the brain, causing deficits in learning, memory, and behavior. Mouse models of AD highlight the role of amyloid, but tau is often less studied. Dyshomeostasis of trace metals in the brain, including Zinc (Zn) plays important roles in the progression of AD-pathology and remediation may serve as an area of future therapeutics. The current study utilizes a novel double transgenic mouse bred to express mutated human amyloid precursor protein (hAPP) and mutated human tau (P301L). Offspring are the result of a J20 x rTg4510 cross (Jackson Lab); this is the first mouse to be made from these parent mice. Half of the mice were given 10 parts per million (ppm) Zn in their drinking water and behavior was assessed at 3.5 months. Previous research shows that Zn supplementation can impact behavior in Tg mouse models of AD. Three and a half months represents an early time point in disease

progression, when we can assess Zn supplementation on behavior early in the disease. Behaviors were assessed through the following tests: open field (OF), elevated zero maze (EZM) and Barnes Maze. Preliminary data show significant differences of genotype in time spent in the center of the OF and the percent time in the open arms of the EZM. Mice carrying mutations in both hAPP/tau (double) and only tau spent more time in the open arms of the EZM and spent less time in the center of the OF compared to those animals with no mutations (wildtypes). A significant genotype x water interaction was also seen with number of head dips in the EZM. Significant differences in spatial memory were seen in the Barnes Maze; animals carrying mutations in only tau and both hAPP/tau showed increased latencies to escape and find the target hole compared to wildtype animals and those with only the presence of the CaMKIIa promoter. Behavior will also be assessed at 7 months to examine changes as a result of increased cellular pathology and long-term Zn supplementation.

Title: Impairments in activities of daily living and wheel running behavior in a novel APP/tau mouse model of Alzheimer's disease

Authors: *M. L. SMITH, *M. L. SMITH, S. L. P. LIPPI, J. M. WOOD, T. T. DIMOPOULOS, C. M. HERNANDEZ, J. M. FLINN George Mason Univ., Fairfax, VA

Abstract: Alzheimer's Disease (AD) is characterized by the formation of beta-amyloid plaques and hyperphosphorylated tau tangles which slowly damage the brain. Zinc (Zn) is a biometal that can alter progression and remediation of AD. This novel mouse model includes both amyloid and tau pathology, and examines how they impact disease progression. J20 (hAPP) and rTg4510 (tau) mice were obtained from Jackson Laboratory and bred to produce APP/tau offspring. Mice were split into groups and received either 10 parts per million Zn in their drinking water, or standard laboratory water. Animals were tested at 3.5 months of age in activities of daily living including nesting, burrowing, and circadian wheel running behavior. Preliminary data show animals having both hAPP/tau perform significantly worse in both nesting and burrowing, as early as 3.5 months of age. The animals' wheel running activity was assessed for one week. Differences were seen in activity between genotypes. These non-cognitive tasks are important to study because the brain accumulates amyloid plaques and tau tangles, which may be impacting these behaviors years before diagnosis of AD. This study attempts to allow early detection of AD by measuring innate behaviors, which may offer insight into early detection, diagnosis, and treatment. No metal differences were seen at 3.5 months, in contrast to results in EZM (see linked poster, Lippi et. al). Behavior will also be assessed at 7 months of age to examine the effects of long term zinc exposure.

Title: A common upstream target? Novel small drug-like molecules decreasing toxic Abeta species and tau phosphorylation simultaneously

Authors: *V. R. LINGAPPA¹, A. MÜLLER-SCHIFFMANN², D. DEY¹, S. SELVARAJAH¹, V. ASUNDI¹, C. KORTH²

¹Prosetta Biosciences, Inc, San Francisco, CA; ²Univ. of Düsseldorf, Düsseldorf, Germany

Abstract: Background

Alzheimer's Disease (AD) is characterized by senile plaques consisting of the A β peptide and neurofibrillary tangles formed by hyperphosphorylated tau. Aggregation of Abeta and tau play key roles in progression of AD, but, so far, a compelling molecular scenarios connecting both proteins has not been established.

We hypothesize that many enzymes involved in biochemical pathways don't just work together, but are physically associated, and their association does not come about spontaneously, but rather is catalyzed, by transient multi-protein complexes (MPCs) we term assembly machines. In our view, A β aggregates and tau hyperphosphorulation are both downstream consequences of aberrant assembly machine action and should be correctable by targeting the previously unappreciated assembly machines.

Over the last decade, we have established a library of 300 small molecules targeting the assembly machines that catalyse viral capsid formation, termed the Hit-finder collection. By virtue of the diversity of viral structure, the Hit-finder collection is a promising starting point for discovery of assembly machine modulators able to alter events in the pathogenesis of AD.

Objectives

To screen the Hit-finder collection for compounds interfering with both oligomerization of $A\beta$

and phosphorylation of tau, simultaneously.

Methods

We generated cell models that secrete either monomeric or toxic oligomeric and N-terminal elongated monomeric A β forms, and cell lines that express mutant tau. For drug target identification we used drug resin affinity chromatography (DRAC) followed by mass spectrometry.

Results

We identified a subset of chemotypes that, after structure-activity relationship optimization, reduced the secretion of toxic $A\beta$ species at low nanomolar concentrations. DRAC revealed at least 8 proteins, some of which had already been described in the context of AD thus supporting the validity of our working hypothesis and screening approach. The most potent molecules also reduced total monomeric $A\beta$ load without affecting gamma-secretase activity, or APP expression. Interestingly, some of the most active compounds against $A\beta$ also reduced the phosphorylation of tau at specific sites in a dose dependent manner.

Conclusion

Novel compounds act against MPC assembly machines upstream of $A\beta$ and tau aggregation and counter their misassembly into aggregates and tangles. The exact nature of these upstream MPC assembly machines is beginning to be revealed and will advance our understanding of AD cellular pathology.

Title: Exogenous tau produces sectorial degeneration in the murine retinal projection

Authors: *M. A. SMITH¹, E. S. PLYLER¹, G. N. WILSON³, C. M. DENGLER-CRISH², S. D. CRISH⁴

²Pharmaceut. Sci., ¹Northeast Ohio Med. Univ., Rootstown, OH; ³Kent State Univ., Akron, OH; ⁴Pharmaceut. Sci., NEOMED, Rootstown, OH

Abstract: Retinal pathologies are suggested to be some of the earliest changes in chronic neurodegenerations such as Alzheimer's disease (AD). Glaucoma, a group of chronic optic neuropathies that make up the leading cause of blindness worldwide, has recently been shown to have epidemiological and mechanistic similarities to AD. Along these lines, several lab groups have reported somatodendritic accumulation of the microtubule associated protein tau with advancing pathology in common mouse models of glaucoma. Axonal and trans-synaptic transport of tau is postulated to play a large role in the onset and progression of several neurodegenerations, yet the mechanisms remain unknown. We investigated whether application of tau to the retina would produce glaucomatous pathologies in normal mice. We injected fibrillized Alexa Fluor-tagged recombinant human tau (FITau) into the vitreal chamber of C57BL/6J mouse eyes. After two weeks we found extensive astrogliosis, microglial activation, and loss of the retinal ganglion cell synaptic markers in subcortical visual structures corresponding to the injected eyes. Furthermore, these projections exhibited distinct sectorial patterns of pathology in the superficial superior colliculus (SC). Retinotopic sectors of SC exhibiting normal distribution of neural and glial markers were adjacent to areas with extreme gliosis and reduced synaptic marker immunoreactivity—mimicking the sectorial axonopathy seen in glaucoma and diabetic retinopathy. These pathological changes in SC were accompanied by increased levels of the FlTau, indicating that it was taken up and transported by retinal ganglion cells. Additionally, we saw increased gliosis and reduced synaptic markers in the primary visual cortex contralateral to injected eyes. Fluorescence-tagged tau label was also present in this region, a finding that suggests trans-synaptic transport occurred and produced pathology. We conclude that intraocular administration of tau induces neurodegeneration that mimics sectorial pathologies in other diseases affecting the retina and its projection. Furthermore, given its accessibility, simplicity, and straightforward connectivity, we believe that the primary visual system may be a useful and accessible model for studying tau-related mechanisms of neurodegeneration.

Title: Ocular amyloid-beta induces sectorial gliosis in the distal retinal projection

Authors: *E. S. PLYLER¹, M. A. SMITH¹, C. M. DENGLER-CRISH², S. D. CRISH³ ²Pharmaceut. Sci., ¹Northeast Ohio Med. Univ., Rootstown, OH; ³Pharmaceut. Sci., NEOMED, Rootstown, OH

Abstract: The anterior visual system (AVS; retina, optic nerve, and optic tract) is a common site of neurodegeneration in blinding disorders and in more widespread degenerative conditions of the central nervous system (CNS) such as multiple sclerosis. Intriguingly, amyloid-beta (A β), a neurotoxic protein relevant to Alzheimer's disease (AD), was recently identified in post-mortem retinal tissue of AD patients as well as in the visual system of certain animal models of AD. Moreover, the retina and other parts of the AVS has been implicated as some of the earliest sites of pathology in AD, with amyloidosis occurring before the degeneration of hippocampus and entorhinal cortex that characterizes this disorder. Amyloid-β aggregation and tau accumulation were recently reported to occur in age-related macular degeneration, diabetic retinopathy, and glaucoma. Given that the AVS is accessible, simple, and topographically mapped, it is an ideal system for studying mechanisms of, and interventions targeting, neurodegeneration. We exploited the accessibility of this system to study the effects of AB on axonopathy and neuroinflammation, two processes heavily implicated in CNS degenerations. To conduct these studies, we injected fluorophore-tagged, fibrillized Aß into the vitreal chamber of C57BL/6J mice and used immunofluorescent techniques to stain brain, nerve, and retinal tissue after a 2week survival period. Within two weeks, amyloid fibrils were evident throughout the retina along with hypertrophied astrocytes in the nerve fiber layer. We also found pronounced astrogliosis and microglial activation in major retinal targets in the brain, including the lateral geniculate nucleus and superior colliculus. Even though our injection procedure exposed the entire retina to Aβ oligomers, gliosis was sectorial, i.e. occurring in discrete retinotopic regions, with surrounding areas appearing normal. This parallels the pattern of gliosis and degeneration in glaucoma and diabetic retinopathy, two blinding disorders where abnormal Aß aggregation has been implicated. In contrast with our previous findings in mouse models of glaucoma, Aβinduced collicular gliosis preceded axonal transport deficits and overt axon or cell body loss. Overall, our findings suggest a direct role for retinal amyloidosis in AD and other chronic neurodegenerations, emphasizing the importance of studying the AVS as it relates to a widerange of neurodegenerative disorders.

Title: Retinofugal degeneration in Alzheimer's disease: Evidence of axonal transport deficits in aged 3xtg mice

Authors: *C. M. DENGLER-CRISH¹, M. A. SMITH², A. J. SCHULLER³, E. S. PLYLER², S. D. CRISH⁴

¹Pharmaceut. Sci., ²Northeast Ohio Med. Univ., Rootstown, OH; ³The Univ. of Akron, Akron, OH; ⁴Pharmaceut. Sci., NEOMED, Rootstown, OH

Abstract: The scope of structures damaged in Alzheimer's disease (AD) is rapidly expanding beyond the classic cortical and hippocampal associated with the hallmark cognitive and memory deficits of this disorder. Of these expansions, none may show more promise in helping us understand the pathogenesis and progression of degeneration, as well as develop much needed biomarkers and interventions, than the visual system. In other disorders affecting retinal ganglion cells (RGCs), such as glaucoma and diabetic retinopathy, axonal transport deficits and axonopathy precede cell body loss. Using neuronal tract tracing, immunofluorescence, and capillary-based western blotting techniques on a Wes Simple Western platform, we examined the integrity of the retinofugal projection in 3xtg mice, a widely-used model that develops agerelated, progressive AD-like neuropathology. Aged 3xtg mice (10+ months) showed loss of CTB transport from the retina to the superior colliculus (SC) and this was not seen in young (3 mo.) 3xtg or age-matched background-specific (B6129SJ) and C57BL6J controls. This transport loss occurred in "sectors" of the retinotopic SC similar to the pattern of degeneration seen in mouse glaucoma models. RGC counts did not differ between young and old 3xtg mice or from controls and nearly 100% of RGCs in 3xtg retina took up and packaged CTB for transport. Intraocular pressure (a major risk factor for glaucoma) was not elevated in 3xtg mice as a function of age or as compared to controls. Quantification of phosphorylated tau (ptau) load in retina, optic nerve (ON) and retinorecipient SC using capillary electrophoresis showed significantly increased ptau-231 burden in ON and SC, but not retina, at 10 mo. Overall, these findings are indicative of axonal transport deficits and tauopathy in the retinal projection of a progressive, pathological model of Alzheimer's disease. This underscores the utility of the anterior visual system in expanding our approach to studying and understanding neurodegenerative disease.

Title: Mechanism of toxicity mediated by the interplay of tau, amyloid- β and α -synuclein

Authors: K. S. INGRAM¹, E. WIAFE², B. FORBES², T. LEWTER², S. TATE², M. GUERRERO-MUNOZ³, *D. L. CASTILLO-CARRANZA²

¹Minority Men's Hlth. Initiative / Hampton Univers, Hampton, VA; ²Minority Men's Hlth., ³Dept. of Chem. Engineering, Sch. of Engin. and Technol., Hampton Univ., Hampton, VA

Abstract: Alzheimer's disease (AD) is the most common type of dementia caused by a mechanistic relationship between misfolded protein tau and amyloid- β . Previous literature has disclosed evidence that acknowledges the role of α -synuclein as a third key toxic component involved in the disease. Although a crosstalk between these abnormal proteins have been suggested, the mechanism of toxicity remain unclear. Dysfunctional tau is key in most types of dementia. However, while amyloid- β promotes tau missorting from the axon to the cell body and dendrites, tau mediates the detrimental effects of amyloid- β . This suggests amyloid- β and tau act synergistically to promote neurodegeneration. Interestingly, recent studies in mice have suggested that an increase in α -synuclein levels depend upon synergy between amyloid- β and tau. However, amyloid-beta aggregates alone do not promote cognitive decline; and neither dysfunctional tau nor α -synuclein reproduce the full effects of AD. Thus, dissecting the relationship between abnormal proteins tau and amyloid- β is pivotal in understanding the initial events that may drive α -synuclein dysfunction and the subsequent neurodegenerative process that characterizes AD. Errant proteins tau, amyloid- β , and α -synuclein are known to form pre-fibrillar aggregates called oligomers (multiples of monomeric proteins). These are considered the toxic entity of the disease and have been found within synaptic compartments in AD brains. We previously showed that oligomers of tau and α -synuclein exist in the same aggregates, forming hybrid oligomers in Parkinson's disease cases, providing evidence of co-occurrence of asynuclein and tau into their most toxic forms. Herein, we investigated the synergistic relationship of these oligomeric species that is essential in identifying the mechanisms of toxicity in AD. Using stable cells lines, we found that both, amyloid- β and α -synuclein oligomers potentiate tau oligomers toxicity and accelerates neuronal death. Our findings provide evidence of the mechanism by which amyloid- β enhances the harmful effects of tau, thus, contributing to disease progression.

Title: Amyloid beta and Tau neuropathology increases with aging in a natural model of Alzheimers Disease (Octodon degus)

Authors: *C. B. LINDSAY¹, D. S. RIVERA², P. CISTERNAS³, N. C. INESTROSA⁴ ¹Pontificia Univ. Catolica De Chile, Santiago, Chile; ²Pontificia Univ. Católica de Chile, Santiago, Chile; ³CARE-UC, Pontificia Univ. Católica de Chile, Santiago, Chile; ⁴Ctr. For Aging and Regeneration (CARE), P. Catholic Univ. of Chile, Santiago, Chile

Abstract: Alzheimer's disease (AD), one of the most disabling syndromes in the adult population and the most common form of dementia in the world, has not cure or even an effective treatment. AD is characterized the presence of senile plaques of amyloid beta $(A\beta)$ peptide and neurofibrillary tangles of phosphorylated *tau* protein in the brain that trigger neuronal loss and consequently a severe cognitive deficit which then precludes the entire life. In the present work, we explore the hippocampus of different groups of young and old Octodon degus (O. degus), an animal model for the study of non-genetic AD maintained in a clear acrylic aquarium (50x35x23 cm) under standard conditions; with food and water ad libitum, without exercise or environmental enrichment. AD hallmarks were observed by biochemical and histological approaches finding almost 3-fold higher A β_{1-42} and A β_{1-40} peptide levels (≈ 20 pg/ml in young animals and ≈ 60 pg/ml in old animals), at least 2 times increased levels of Aβoligomers and the presence of A β aggregates called senile plaques in different areas of the hippocampus and cortex of old O. degus compared to young ones (up to 6 plaques per 300µm² of hippocampus in old animals and no plaques in young animals). Furthermore, up to 3-fold increased levels of phosphorylated *tau* protein at different epitopes related to AB and microtubule dissemble (Thr231, Ser235, Ser202 and Thr205) were observed in the old animals. In agreement, the presence of *tau* protein aggregates were found in the old O. degus group compared to the

young group (from 0 to 1 in young *O.degus* and up to 8 positive cells per field in old *O. degus*). Our data support the idea that *O. degus* present the main neuropathology of AD, and therefore is an optimal study model for this disease.

Abstract: The C9*orf*72 hexanucleotide repeat expansion is one of the most common causes of amyotrophic lateral sclerosis (ALS) and frontotemporal dementia (FTD); two disorders which display different protein aggregates. The C9*orf*72 hexanucleotide expansion is a structural polymorphism formed by a GGGGCC repeat region that impedes traditional transcription, and leads to several abortive transcripts. These transcripts can then undergo non-AUG dependent translation, leading to the production of several dipeptide repeat-containing proteins (DPRs) including GP, GA, GR, PA or PR. These DPRs form neuronal inclusions in patients with ALS and FTD, and several studies indicate that these inclusions are neurotoxic. Among the different dipeptides produced by the non-AUG translation, there are some such as GA, which have aggregative properties, as well as the tendency to sequester other proteins in the cell. Furthermore, with the increasing evidence that oligomeric species are the main cause of neurotoxicity in disorders such as Alzheimer's disease and Parkinson's disease, and with the ability of these DPRs to aggregate, we decided to investigate the formation of DPR oligomers. We demonstrate that some of these DPRs not only form oligomers, but also cross-seed with other

proteins, causing their gain in neuronal toxicity, and perhaps the loss of function of important molecular pathways. Using immunohistochemical, immunofluorescent, and immunoblot techniques, we show the formation of these oligomeric species, and their cross seeding *in vitro*. These results show that the aggregation of DPR is harmful to the cells, and may be acting via several mechanisms including direct toxicity by DPR oligomers alone and in combination with other oligomeric proteins. Thus, the ability to detect oligomeric DPR using specific antibodies has great potential to further our understanding of these diseases and aid in the development of targeted therapeutics.

Title: Genetic modification of proteasome expression in Drosophila

Authors: *T. SCHMIDT-GLENEWINKEL¹, C.-H. YEH¹, M. E. FIGUEIREDO-PEREIRA² ¹Biol. Sci., Hunter Col. of CUNY, New York, NY; ²Hunter Col., New York, NY

Abstract: Unfolded, misfolded, mutant, and oxidatively damaged proteins are a severe and never ending threat to cell survival. The ubiquitin proteasome system (UPS) degrades these abnormal proteins to prevent protein aggregation and avoid disrupting cellular homeostasis. To investigate the proteotoxic effects induced by impaired UPS *in vivo*, we developed a Drosophila model with "tunable" proteasome dysfunction by regulating the expression of its d β 5 catalytic subunit through double-stranded RNA interference (RNAi). The duration and expression level of the d β 5 RNAi were controlled by an RU486 inducible act5C promoter. We first assessed the effects of long term downregulating d β 5 in adult male and female flies. D β 5 downregulation induced shorter lifespan, proteasome impairment, accumulation and aggregation of ubiquitinated (Ub)-proteins, locomotor dysfunction, and low resistance to oxidative stress in both fly genders. In females only, a potentially new 20S proteasome form exhibiting chymotrypsin-like activity was detected upon d β 5 downregulation. We next investigated the effects of short term (5 days) proteasome dysfunction. We controlled the duration and level of d β 5 downregulation via the conditional Gene-Switch binary system, by altering the length of RU486 administration. Our

results demonstrate that transient proteasome impairment negatively and irreversibly affects lifespan and locomotor activity. Moreover, short term proteasome impairment was sufficient to induce long lasting Ub-protein accumulation and aggregation that was not reversed upon proteasome recovery. In conclusion, we clearly show that transient proteasome impairment is critical to the formation of irreversible Ub-protein aggregates. Moreover, short term proteasome impairment in adult flies can have long term negative and irreversible consequences.

Title: TDP-43 oligomers in AD pathogenesis

Authors: *S. A. MCALLEN^{1,2}, M. CARRETERO MURILLO^{1,2}, U. SENGUPTA^{1,2}, R. KAYED¹

¹Neurol., ²Mitchell Ctr. for Neurodegenerative Dis., Univ. of Texas Med. Br., Galveston, TX

Abstract: TDP-43 is a protein that binds to both DNA and RNA and is present mostly in the nucleus of the cell. This protein is required in many cell functions such as microRNA biogenesis, RNA splicing, and in neurons, TDP-43 has a much more critical role in synaptic plasticity and axonal transport. The essential role of TDP-43 was demonstrated in rodents when knockouts were embryonic lethal. The diseases frontotemporal dementia (FTD) and amyotrophic lateral sclerosis (ALS) are characterized by inclusion bodies that are formed when TDP-43 has been ubiquitinated and hyperphosphorylated into aggregates that are mislocalized into the cytoplasm. The role of TDP-43 in these diseases suggested that the protein is also involved in Alzheimer's Disease (AD). The primary pathology of AD is $A\beta$ senile plaques and Tau neurofibrillary tangles (NFT), though more recently TDP-43 aggregates have been shown in AD as well. A large amount of evidence suggests that Tau, a protein that is important to axonal transport and microtubule stability, forms oligomers that are the toxic entity in AD and other neurodegenerative diseases. Immunohistochemistry and biochemical analyses have shown that TDP-43 oligomers are present and interact with Tau and Aβ in AD cases and we utilize these techniques to further investigate these interactions. By using both generic and newly generated antibodies against TDP-43 oligomers in immunoblot and immunohistochemistry techniques, we

aim to establish the incidence of these oligomers in Alzheimer's Disease. We will investigate the relationship between TDP-43 aggregates and Tau in the oligomerization process and determine if TDP-43 and Tau form hybrid oligomers within the AD brain. Investigating the formation and interactors of TDP-43 oligomers in AD could lead to a better understanding of the role of cross-seeding in the formation, stability and toxicity of the different protein aggregates in AD and may lead to the development of disease therapies.

Title: Restoration of progranulin to progranulin-deficient mice corrects lysosomal abnormalities

Authors: *A. E. ARRANT¹, D. E. UNGER¹, V. C. ONYILO¹, E. D. ROBERSON² ¹Neurol., Univ. of Alabama At Birmingham, Birmingham, AL; ²Neurol & Neurobio, UAB, Birmingham, AL

Abstract: Loss of function mutations in progranulin (*GRN*) are a major autosomal dominant cause of frontotemporal dementia (FTD), and likely cause disease through progranulin haploinsufficiency. Homozygous *GRN* mutations that produce complete progranulin deficiency cause the lysosomal storage disorder neuronal ceroid lipofuscinosis (NCL), revealing that progranulin is critical for proper lysosomal function. Impaired lysosomal function may also play a role in FTD due to *GRN* mutations (FTD-*GRN*), as brains from FTD-*GRN* patients exhibit elevated levels of lysosomal proteins. As in humans, progranulin-deficient mice (*Grn*^{+/-} and *Grn*^{-/-}) exhibit lysosomal abnormalities throughout the brain, with elevated levels of lysosomal proteins.

granules. In this study, we investigated whether brains from progranulin-deficient mice and FTD patients with *GRN* mutations exhibit similar lysosomal abnormalities, and tested whether restoration of progranulin to progranulin-deficient mice would reverse these abnormalities. $Grn^{+/-}$ and $Grn^{-/-}$ mice, as well as FTD-*GRN* patients, exhibited increased activity of β -Hexosaminidase A (HEXA), which was associated with increased protein and RNA levels of the enzyme. Brains from FTD-*GRN* patients and $Grn^{-/-}$ mice had reduced activity of β -glucocerebrosidase (GBA), an enzyme with previously reported abnormal trafficking in $Grn^{-/-}$ macrophages. $Grn^{-/-}$ mice also exhibited additional enzymatic changes not present in FTD-*GRN* samples. Restoration of progranulin to $Grn^{-/-}$ mice by intracranial injection of an adeno-associated viral (AAV)-progranulin vector normalized activity of lysosomal enzymes and reduced lipofuscin levels throughout the brain. These data indicate that lysosomal dysfunction due to progranulin deficiency is reversible, which supports use of progranulin-boosting therapies for FTD-*GRN* patients, particularly in the early stages of disease.

Title: Disruption of ion channel gradients in aged cognitively-impaired rats

Authors: *L. A. BEAN¹, T. F. MUSIAL¹, M. L. RUSSO¹, R. BORENSTEIN¹, S. A. MULLEN¹, G. D. AYALA¹, M. M. OH², J. F. DISTERHOFT³, D. NICHOLSON¹ ¹Neurolog. Sci., Rush Univ. Med. Ctr., Chicago, IL; ²Dept Physiol., Northwestern Univ. Med. Sch., Chicago, IL; ³Northwestern Univ. - Chicago, Chicago, IL

Abstract: Age-related memory changes are not homogenous within similar aged-groups. A few older people will not experience problems with cognitive function and retain a "youth-like" brain phenotype. However, most people will notice an increase in forgetfulness and take longer to learn and recall information, tasks that rely heavily on the hippocampus. Fortunately, symptoms of normal cognitive aging are not necessarily a harbinger of dementia; nevertheless if memory problems worsen, it may signal advancement into mild cognitive impairment, which is an intermediate stage between normal age-related memory changes and the more serious disabling

dementia. Therefore it is necessary to fully understand the neurobiology of aging to preclude the advancement of cognitive malfunction. The substrates involved in age-related cognitive decline are unknown. There is no major neuron or synapse loss in the hippocampus with this non-disease associated type of cognitive impairment. However, it has been proposed that voltage-signaling and/or Ca²⁺-signaling networks or interactomes within the neuron are disrupted leading to impairments in memory. We previously showed that single-dendrite gradients in synapse number and ion channels /receptors exist in young rats. For example, the number of synapses on an oblique dendrite decreased with distance from the main apical dendrite, and AMPAR expression increased while NMDAR expression decreased with distance from the soma. While immunolocalization of many ion channels and /or receptors is known within the young and aged hippocampus, little is known about the relative expression of these channels to one another. In this study, we employ multiple antibodies and high-resolution Array Tomography to visualize differences in ion channel gradients in electrophysiologically-characterized dendrites within the dorsal CA1 region of rats identified as being young (Y), aged-unimpaired (AU) or aged-impaired (AI) by two hippocampal-dependent memory tasks. We find disruption of ion channel interactomes involved in voltage and Ca^{2+} regulation in aged impaired animals. These experiments are necessary to identify targets for pharmacological approaches in preventing cognitive decline with age.

Title: Alzheimer's disease-linked HCN channelopathy rescued via intrahippocampal infusion of carvedilol

Authors: *T. F. MUSIAL, L. A. BEAN, M. L. RUSSO, S. A. MULLEN, G. AYALA, D. A. NICHOLSON Neurolog. Sci., Rush Univ. Med. Ctr., Chicago, IL **Abstract:** In various transgenic mouse models of AD, we find that both supra- and sub-threshold voltage signaling, both of which are heavily influenced by passive and active dendritic properties, progressively deteriorate with age in hippocampal CA1pyramidal neurons. Utilizing functional, molecular, and ultrastructural imaging techniques, we identify the hyperpolarization-activated, cyclic nucleotide-gated (HCN) channel as a primary suspect responsible for this disrupted voltage signaling.

Calcium signaling abnormalities are thought to be a major agent involved in cellular dysfunction associated with AD. We sought to manipulate internal calcium signaling via the endoplasmic reticulum, and in doing so, elicit store depletion induced h-channel plasticity (SD-h plasticity) to re-establish HCN function in these altered neurons.

Delivering intrahippocampal infusions of carvedilol (a non-specific beta-adrenergic blocker with affinity to antagonize ryanodine receptors) in anaesthetized transgenic mice, we find that HCN channel function is indeed re-established using patch-clamp recordings of hippocampal slices post-infusion. In addition, some hippocampal sections were processed for pre-embedding immunogold electron microscopy to determine channel distribution after induction of SD-*h* plasticity. These results confirm the treatment increased insertion of the channel into plasma membranes as well as appearing to increase protein trafficking to the distal dendrites where these channels are critical for proper CA1 neuron dendritic computations.

Title: Alterations in the failure rate of antidromic action potential generation in mouse models of Alzheimer's disease

Authors: *M. L. RUSSO, G. D. AYALA, S. A. MULLEN, D. NICHOLSON Neurolog. Sci., Rush Univ. Med. Ctr., Chicago, IL

Abstract: The substantial cognitive deficits experienced by patients with Alzheimer's disease (AD) have long been thought to be the product grey matter changes. However, recent work has indicated that disruptions in neural network connectivity may be attributable to changes in white matter (WM) integrity during AD progression. Diffusion tensor imaging (DTI) has revealed significant volume changes in the white matter of patients with early AD and mild cognitive

impairment (MCI). These changes are particularly robust in the parahippocampal gyrus and hippocampus, which are both highly susceptible to AD pathology. In addition, oligodendrocytes have exhibited sensitivity to the cytotoxic effects of amyloid beta (Aβ), the principle component of the characteristic AD plaques. Therefore, cognitive decline during MCI and AD may be, at least in part, due to disrupted connectivity that results from decreased integrity of WM. Given the primary function of myelin in facilitating rapid action potential (AP) propagation along axons via saltatory conduction, it is possible to examine physiological properties that depend on myelination of axons. In the present study, we employed whole cell patch clamp physiology to monitor AP generation in the axons of CA1 pyramidal neurons of wild-type and AD transgenic mice. Specifically, antidromic APs were generated by a stimulating electrode placed in the alveus, and successful AP generation and propagation was monitored using a somatic recording electrode. Two types of protocols were used to assess each neuron's ability to generate antidromic APs. The first consisted of two pulses spaced at varying frequencies from 2 Hz to 500 Hz, while the second consisted of a train of ten stimuli at frequencies between 10 Hz and 100 Hz. Our results have shown that failure rate is increased in the CA1 pyramidal neurons of aged AD mice, consistent with observed changes in the WM of AD patients and animal models. Interestingly, the increased failure rate appears to be more pronounced at specific stimulus frequencies, regardless of the number of pulses used. Overall, our findings support previously reported WM changes in AD, as well as provide physiological characterization of the consequences of these WM alterations in a specific portion of the hippocampal circuit.

Title: JZ101 is required for mitochondrial quality control

Authors: *L. CHAO, J. ZHANG Peking Union Med. Col., Beijing City, China

Abstract: Mitochondrial dysfunction is a prominent feature in many neurodegenerative diseases, such as Parkinson's disease (PD). Many tail-anchored (TA) proteins are located to the endoplasmic reticulum (ER) membrane. However, TA proteins may misplace on mitochondria rarely and affect mitochondrial normal function. Here, we identified a new mitochondrial out membrane protein named JZ101 which mediates the clearance of the TA protein on mitochondria. And, JZ101 overexpression enhanced the fusion of mitochondria, whereas JZ101 deficiency results in more fragmented mitochondria and impaired energy metabolism of

mitochondria, which could be rescued by restoring the expression of JZ101. Our study may provide a potential target for neurodegenerative diseases.

Biol., Univ. of Pittsburgh, Pittsburgh, PA; ⁴Univ. of Pittsburgh Brain Inst., Pittsburgh, PA; ⁵Pittsburgh Inst. for Neurodegenerative Dis., Pittsburgh, PA; ⁶KU Leuven Ctr. for Human Genet. and Leuven Inst. for Neurodegenerative Dis. (LIND), Leuven, Belgium

Abstract: Alzheimer's disease (AD) is the most common type of dementia and is characterized by the insidious degeneration of brain networks involved in memory and cognition. Accumulation and aggregation of the amyloid β (A β) peptide in the brain are pathological hallmarks of AD. Sequential cleavage of the amyloid precursor protein (APP) by the β - and γ secretases leads to generation of the AB peptide. We have shown that the orphan G proteincoupled receptor 3 (GPR3) plays an important role in regulation of the γ -secretase complex and Aβ generation in AD. However, investigation of the *in vivo* functions of GPR3 is challenging due to the lack of availability of suitable antibodies that recognize endogenous mouse GPR3. To circumvent this issue with other GPCRs, fluorescently and hemagglutinin (HA) labeled GPCR knockin (KI) mice have been generated to study the physiological and pathophysiological function of several GPCRs. Several genome editing systems, including transcription activatorlike effector nucleases (TALEN), clustered regularly interspaced short palindromic repeats (CRISPR)/CRISPR-associated protein-9 nuclease (Cas9), and zinc finger nucleases (ZFNs) have been used to insert fluorescent proteins and HA tags to study receptor function. Among the three genome editing technologies, CRISPR/Cas9 is efficient, highly specific, and easier to design than TALEN and ZFNs. In the current study, we utilized a CRISPR/Cas9-mediated genome editing strategy to insert two HA tags into the murine Gpr3 gene. By co-injection of guide RNAs (gRNAs), Cas9 mRNA, and single-stranded DNAs (ssDNA) containing the HA tag sequence into the one-cell mouse embryos, we successfully introduced two HA tags into the N-terminus of the Gpr3 gene in the first generation founder mice. One founder has been bred and successful

germline transmission has been confirmed. The HA-GPR3 KI mice are currently being used to investigate the expression, localization, and binding partners of GPR3 *in vivo*. The protein expression pattern and localization of GPR3 in different cell types will be essential to understand the physiological roles of endogenous GPR3 and to evaluate potential therapeutic approaches targeting GPR3 in AD.

Title: In silico simulation of LRRK2 and rab3 vesicle cycle interactions in Parkinson's disease

Authors: *L. E. VINCENT¹, J. W. RYAN², D. A. DODDS², A. D. LEE², B. BEHROUZ² ¹Neuropsychology, ²Neurosci., Neuroinitiative, Jacksonville, FL

Abstract: In 2004, two articles were published which suggested mutations in the leucine-rich repeat kinase 2 (LRRK2) gene cause autosomal dominant Parkinson's disease (PD). This gene encodes for the protein of the same name, which impacts vesicular trafficking within the cell through phosphorylation of a subset of rab GTPases. Effector proteins, in addition to guanine nucleotide exchange factors (GEFs) and GTPase activating proteins (GAPs) activate and deactivate rabs for their various tasks. Rab activation occurs when a GEF exchanges the GTPase's GDP for GTP, while inactivation occurs when a GAP initiates hydrolysis of GTP to GDP. A great number of GEFs and GAPs exist in the cell, which provides both specificity, and some redundancy, to this highly specialized system. At present, LRRK2 has been shown to phosphorylate 14 of these rabs: rab3A, rab3B, rab3C, rab3D, rab5A, rab5B, rab5C, rab8A, rab8B, rab10, rab12, rab29, rab35, and rab43. While phosphorylation of these rabs decreases their affinity for GEFs and GDIs, it is unclear how this may impact the downstream effects of the rab proteins. In this study, NeuroInitiative's, Simulation Environment for Experimental Design (SEED), was used to run in silico pathway models of rab3A, rab3B, rab3C, and rab3D, which play a role in vesicle trafficking and exocytosis. Data from baseline LRRK2 models was compared with mutated LRRK2 (G2019S) and knockout models.

Title: Inhibition of LRRK2 kinase activity results in abnormal protein dynamics and reduces protein stability

Authors: *B. J. SANSTRUM, B. M. S. S. GOO, D. Z. Y. HOLDEN, D. D. DELGADO, N. G. JAMES

Cell and Mol. Biol., Univ. of Hawaii at Manoa, Honolulu, HI

Abstract: Mutations in the LRRK2 (Leucine Rich Repeat Kinase 2) gene have been linked to both sporadic and familial forms of Parkinson's disease (PD). Our lab has performed many fluorescence-based microscopy experiments to study the protein-protein interactions of LRRK2-EGFP in live cells. We have demonstrated that the active, membrane bound form of LRRK2-EGFP is predominantly a dimer due to self-association on the membrane. However, lack of knowledge about the mutations that alter the kinase function of this protein has resulted in limited targeted treatment options. The most common PD-linked LRRK2 mutation, G2019S, has been shown to increase the kinase activity of LRRK2 resulting in major deficits in endocytosis and vesicle trafficking. Because of this finding, current drug discovery efforts have been geared toward the optimization of LRRK2 kinase inhibitors as a potential disease modifying therapy. Controversially, previous studies have shown adverse side effects of LRRK2 kinase inhibitors in peripheral tissues and decreased LRRK2 protein concentration in mouse brain lysates treated at therapeutic doses. Since these studies were performed postmortem, little data have been shown in functional living systems. This project expanded past experiments by adding LRRK2 kinase inhibitors (100nM) to quantify their effects on LRRK2-EGFP function in a live dopaminergiclike neuronal system. We utilized 2-photon confocal microscopy and total internal reflection fluorescence microscopy (TIRF) to monitor protein dynamics and self-association of LRRK2-EGFP in the cytosol and at the membrane. Raster image correlation spectroscopy (RICS), photon counting histogram (PCH), and number and brightness (N&B) replicated the decreases in LRRK2 protein concentration but also indicated a novel increase in dimer and higher-order oligomers and a decreased diffusion rate in both wild type (WT) LRRK2-EGFP and G2019S LRRK2-EGFP expressing cells. This suggests an alteration in protein dynamics that is

contradictory to the intended function of kinase inhibitors. In order to characterize this functional abnormality in more therapeutically relevant models, we lowered the drug doses to IC50 concentration and conducted spatial intensity distribution analysis (SpIDA) on endogenously expressed protein. These methods noted similar alterations in oligomerization and concentration when compared to vehicle treated controls. Overall, these studies show striking results about the effects of LRRK2 kinase inhibitors on protein dynamics. Follow up studies are needed to determine the extent of these notable abnormalities and the efficacy of LRRK2 kinase inhibitors for novel PD therapy.

Abstract: Mutations in LRRK2 are a common genetic cause of Parkinson's disease (PD). LRRK2 interacts with and phosphorylates a subset of Rab proteins including Rab8a, a protein which has been implicated in various centrosome-related events. However, the cellular consequences of such phosphorylation remain elusive. Here, we show that pathogenic LRRK2 causes deficits in centrosomal positioning with effects on neurite outgrowth, cell polarization and directed migration. Pathogenic LRRK2 also causes deficits in centrosome cohesion which can be detected in peripheral cells derived from LRRK2-PD patients as compared to healthy controls, and which are reversed upon LRRK2 kinase inhibition. The centrosomal cohesion and polarity deficits can be mimicked when co-expressing wildtype LRRK2 with wildtype but not phosphodeficient Rab8a. The centrosomal defects induced by pathogenic LRRK2 are associated with a kinase activity-dependent increase in the centrosomal localization of phosphorylated Rab8a, and are prominently reduced upon RNAi of Rab8a. Our findings reveal a new function of LRRK2 mediated by Rab8a phosphorylation and related to various centrosomal defects.

Title: Rats carrying human LRRK2 G2019S mutation show dopaminergic vulnerability and gait abnormalities after peripheral LPS induced inflammation

Authors: *S. SUBRAMANIAM¹, E. HINGCO¹, N. NECKEL², J. WANG², R. MALHAS¹, R. MIRAMONTES¹, X. SU², M. S. FIANDACA¹, H. J. FEDEROFF¹ ¹Neurol., Univ. of California Irvine, Irvine, CA; ²Neurosci., Georgetown Univ. Med. Ctr., Washington DC, DC Abstract: Abstract: Leucine-rich repeat kinase (LRRK2) mutations are associated with autosomal dominantly inherited Parkinson's disease (PD). Genome-wide-association-studies (GWAS) indicate that the genetic locus containing the LRRK2 gene also presents a risk factor for sporadic PD. A mutation in the LRRK2 kinase domain, G2019S, is most common in familial and apparently sporadic forms of PD. Such a mutation increases the kinase activity by ~two-fold, with toxic effects confirmed in vitro and in vivo. Whether LRRK2 kinase activity is essential for its role in PD is still hotly debated. Despite involvement of LRRK2 in several neuronal pathways, including cytoskeletal dynamics, vesicular trafficking, mitochondrial function, and autophagy, its physiological function and role in PD pathology remains unclear. In the current rodent study, we induced peripheral inflammation via single intraperitoneal (ip) injection of lipopolysaccharide (LPS) to transgenic rats expressing the human G2019S mutation featuring the bacterial artificial chromosome (BAC) form of the entire human LRRK2 genome locus (BAChLRRK2-G2019S). BAC-hLRRK2-G2019S rats showed elevated levels of the pro-inflammatory cytokine IL-1ß in nigral tissue 90 days after a single LPS ip injection. In addition, 90 days after LPS administration there was loss of dopaminergic neurons in the substantia nigra and striatal dopaminergic neurites in BAC-hLRRK2-G2019S rats. Moreover, LPS treated BAC-hLRRK2-G2019S rats also exhibited gait abnormalities as early as 4 days after ip injection, which progressively worsened until day 60. Non-transgenic animals showed no pathobiology following LPS administration. In conclusion, these results suggest that LRRK2-G2019S carriers may be predisposed to excessive focal brain responses to a peripheral inflammatory stimulus, resulting in PD-like neurotoxicity and motoric deficits. To advance our investigations, we have generated novel rat BAC transgenic lines that express either hLRRK2-G2019S or hLRRK2-WT but lack endogenous rat LRRK2 (rLRRK2-/-) (BAC-hLRRK2-G2019S::rLRRK2-/-, BAC-hLRRK2-WT::rLRRK2-/-). These new transgenic lines will allow us to remove the contributory effect of endogenous LRRK2 thus yielding a precise model for future experiments. Using these animal models, we intend to more fully characterize mutant LRRK2 function as it relates to systemic and central neuroinflammation, nigrostriatal vulnerability and the potential to evaluate therapeutic options.

Title: Parkinson's disease-linked LRRK2 positively regulates type 1 Interferon-induced inflammatory signaling and cytokine production through selective DSCR1 phosphorylation

Authors: H. PARK¹, K. HAN¹, *H. RHIM², K. CHUNG¹ ¹Yonsei Univ., Seoul, Korea, Republic of; ²Korea Inst. Sci. Tech. (KIST), Seoul, Korea, Republic of

Abstract: LRRK2 is a Ser/Thr kinase with mixed lineage kinase-like and GTPase domains, and controls neurite outgrowth and cell death. Mutations in *LRRK2* gene is known to cause autosomal dominant late-onset Parkinsonism. Several studies have also suggested that LRRK2 is involved in innate immune response signaling, but the underlying mechanism is unknown yet. Down syndrome candidate region 1 (DSCR1, also known as regulator of calcineurin 1 or RCAN1) protein was shown to upregulate type 1 interferon-induced inflammatory signaling by modulating several intracellular targets of interleukins in immune cells. Moreover, DCSR1 negatively affects neuronal cell death and survival through increased susceptibility to oxidative stress. In this study, we investigated any biochemical and functional link between LRRK2 and DSCR1, and their roles in type 1 interferon-mediated inflammatory signaling. At the meeting, our recent data concerning the action of LRRK2 on DCSR1 and DSCR1-mediated downstream inflammatory signaling will be presented, In conclusion, our data demonstrate that LRRK2 directly phosphorylates DSCR1 and consequently acts as a positive regulator of inflammatory signaling though DCSR1 modulation under type 1 interferon stimulation. This study further imply that LRRK2 positively regulates inflammatory responses in Parkinson's disease.

Title: Age-dependent dopaminergic neurodegeneration and impairment of the autophagylysosomal pathway in LRRK-deficient mice

Authors: *Y. YUAN¹, E. GIAIME¹, Y. TONG¹, L. WAGNER¹, J. SHEN^{1,2} ¹Dept. of Neurol., Brigham and Women's Hosp., Boston, MA; ²Program in neuroscience, Harvard Med. Sch., Boston, MA

Abstract: LRRK2 mutations are the most common genetic cause of Parkinson's disease, but its normal physiological role in the brain is unclear. We previously generated LRRK2-/- mice and found no detectable phenotypes in the brain, but the kidney develops striking age-dependent PDlike change. To determine whether the absence of the phenotypes in the LRRK2-/- brain is due to the relative high expression of its functional homologue LRRK1 in the brain, we developed double knockout mice lacking both LRRK1 and LRRK2. Here we show that inactivation of LRRK2 and LRRK1 results in earlier mortality and age-dependent, selective neurodegeneration. Loss of dopaminergic neurons in the substantia nigra pars compacta (SNpc) and noradrenergic neurons in the locus coeruleus is accompanied with increases in apoptosis, whereas the cerebral cortex and cerebellum are unaffected. Furthermore, selective age-dependent neurodegeneration is only present in LRRK-/- but not LRRK1-/- or LRRK2-/- brains, and is accompanied with increases of α -synuclein and impairment of the autophagy-lysosomal pathway. Quantitative electron microscopy analysis revealed age-dependent increases of autophagic vacuoles in the SNpc of *LRRK*-/- mice before the onset of dopaminergic neuron loss. These findings revealed an essential role of LRRK in the survival of dopaminergic neurons and the regulation of the autophagy-lysosomal pathway in the aging brain.

Title: Altered slow-wave sleep in the LRRK2 G2019S mouse model of Parkinson's disease

Authors: *J.-P. WIEGAND¹, K. GIES², M. J. BARTLETT³, T. FALK⁴, S. L. COWEN² ¹Evelyn F. McKnight Brain Inst., ²Dept. of Psychology, Univ. of Arizona, Tucson, AZ; ³Dept. of Neurol., ⁴Dept. Of Neurol., Univ. of Arizona Col. of Med., Tucson, AZ

Abstract: The leucine-rich repeat kinase 2 (LRRK2) mutation represents a common genetic cause of Parkinson's disease (PD). Although REM sleep behavior disorder is associated with sporadic PD and the development of synucleinopathies, REM disorders are less common in LRRK2 PD (Kestenbaum and Alcalay, 2017). Furthermore, the LRRK2 mutation is associated with altered cortical synaptic excitability, which could alter sleep-associated oscillatory activity. Consequently, we sought to determine if transgenic mice with the LRRK2 G2019S mutation expressed changes in behavioral and physiological markers of sleep and sleep depth. To investigate this question, we measured cortical electroencephalography (EEG) and cortical and subcortical local-field activity in 15 LRRK2 G2019S and 10 wild-type (WT) C57bl/6 male mice. Physiological and behavioral data (EMG and inertia measurement data) were acquired during periods of rest and active foraging behavior. Surface electrodes were implanted above somatosensory (S1) and visual cortex (V1). We observed that LRRK2 G2019S mice showed an increase in EMG activity during sleep and behavioral epochs when compared to WT mice (p < p0.0005, Kruskal-Wallis with Tukey post-hoc). Analysis of inertial and EMG activity also revealed that LRRK2 G2019S mice had shorter sleep bouts during post-foraging sleep (p < 0.005), shorter inter-sleep bout intervals in the pre-foraging sleep epoch (p < 0.05), and spent proportionally more time sleeping in the pre-sleep epoch (p < 0.001). Physiological measurements indicated that LRRK2 mice had higher power in high gamma band frequencies (80-120Hz) in their cortical EEG LFP (p < 0.001) and also expressed a significant increase in the power of sleep spindles relative to WT controls (p < 0.05, Student's t-test) in the S1 trunk region. In contrast, no difference in the distributions of peak spindle frequencies and durations was observed between LRRK2 G2019S and WT mice. Our results suggest that the LRRK2 G2019S mutation alters behavioral and physiological markers of the depth of slow-wave sleep.

Abstract: The gene encoding for Leucine Rich Repeat Kinase 2 (LRRK2) has been linked to familial and sporadic/idiopathic forms of Parkinson's disease (iPD), as well as cancer, leprosy and Crohn's disease, making this gene a target for discovery therapeutics. Since it's discovery as a PD gene in 2004, LRRK2 has been associated with a wide range of cellular functions but the physiological roles of LRRK2 remain unclear. The most prevalent and pathogenic LRRK2 mutations in PD have been shown to affect cellular macroauthophagy in a variety of cellular models^{1,2}. Furthermore, recent *in vivo* studies have recapitulated an effect of LRRK2 in autophagy signalling^{3,4}. This raises the question whether differential autophagic activity is relevant to disease progression in PD patients harbouring LRRK2 mutations. To test this, we examined the levels of autophagic markers in the basal ganglia of G2019S LRRK2 PD postmortem tissue, in comparison to pathology-matched iPD. An increase in LC3-II levels was observed in iPD compared to controls but this was not the case for G2019S PD cases that showed similar levels to control cases. Furthermore, significantly lower levels of ULK1, a downstream effector of mTOR and AMPK involved in autophagosome generation, were observed in G2019S compared to iPD cases. An increase in p62 was observed in iPD but not reflected in G2019S cases while Lamp1 levels were found to be divergent in these cases compared to iPD and controls. Immunohistochemistry of p62 on brain tissue recapitulated a distinct signature for G2019S PD. Our data highlight a divergence of G2019S PD carriers in terms of autophagic response in affected brain regions compared to iPD, similar to what we have reported for alpha-synuclein solubility in these cases⁵. It is possible that the deregulation of autophagy and altered alpha-synuclein solubility in the LRRK2 G2019S cases are inter-linked. References:

Title: Phosphorylation of p53 by LRRK2 induces microglial TNFα-mediated neurotoxicity

Authors: *D.-H. HO¹, J. EUN², W. SEOL¹, I.-H. SON³

¹Inam Neurosci. Res. Ctr., Gunpo-City, Gyeonggi-Do, Korea, Republic of; ²Dept. of Biomed. Sciences, Neurosci. Grad. Program, Ajou Univ. Sch. of Med., Suwonshi, Korea, Republic of; ³Dept. of Neurology, Sanbon Med. Center, Collage of Medicine, Wonkwang Univ., Gunpo, Korea, Republic of

Abstract: Leucine-rich repeat kinase (LRRK2), a major causal gene of Parkinson's disease (PD), functions as a kinase. The most prevalent mutation of LRRK2 is G2019S. It exhibits increased kinase activity compared to the wildtype LRRK2. Previous studies have shown that LRRK2 can phosphorylate p53 at T304 and T377 of threonine-X-arginine (TXR) motif in neurons. Reduction of LRRK2 expression or inhibition of LRRK2 kinase activity has been shown to be able to alleviate LPS-induced neuroinflammation in microglia cells. In this study, we found that LRRK2 could also phosphorylate p53 in microglia model BV2 cells. Transfection of BV2 with phosphomimetic p53 T304/377D significantly increased the secretion of pro-inflammatory cytokine TNFα compared to BV2 transfected with p53 wild type after LPS treatment. In addition, conditioned media from these transfected cells increased the death of dopaminergic neuronal SN4741 cells. Moreover, such neurotoxic effect was rescued by co-treatment with the conditioned media and etanercept, a TNFa blocking antibody. Furthermore, TNFa secretion was significantly increased in primary microglia derived from G2019S transgenic mice treated with LPS compared to that in cells derived from their littermates. These results suggest that LRRK2 kinase activity in microglia can contribute to neuroinflammation in PD via phosphorylating p53 at T304 and T377 site.

Title: LRRK1 and LRRK2 function in the kidney

Authors: *G. HUANG¹, L. WANGER¹, J. SHEN^{1,2}

¹Dept. of Neurol., Brigham and Women's Hosp., Boston, MA; ²Program in Neurosci., Harvard Med. Sch., Boston, MA

Abstract: Dominantly inherited missense mutations in leucine-rich repeat kinase 2 (LRRK2) are the most common genetic cause of Parkinson's disease. LRRK1 and LRRK2 belong to the Roco family and share a high degree of sequence similarity. Our previous findings showed that LRRK2-deficient mice display an age-dependent dysregulation of protein degradation pathways in the kidney, including striking α -synuclein accumulation and aggregation and increases of apoptotic cell death and oxidative damage. To investigate the normal physiological role of LRRK and the relative contribution of LRRK1 and LRRK2 in carrying out LRRK function, we generated LRRK-/-, LRRK1-/- and LRRK2-/- mice. Analysis of these mutant mice and wild-type controls at the ages of 6, 10 and 15 months ages showed age-dependent reduction of body weight in LRRK-/- mice beginning at 6 months. LRRK1-/- mice also showed significant reduction of body weight at 15 months but not at 6 and 10 months, whereas LRRK2-/- mice are unaffected. In the kidney of LRRK-/- mice, significant increases of apoptotic cell death were detected at 6 months and were further increased at 10 and 15 months of age, and apoptosis was also increased in the kidney of LRRK2-/- mice beginning at 10 months, whereas apoptosis in the LRRK1-/kidney was unaffected. We also observed age- and genotype-dependent accumulation and aggregation of α -synuclein, ubiquitinated proteins and p62 in the kidney of these mutant mice. The detailed results of these analyses in all four genotypic groups will be presented.

Title: Decreased Lamp2 CSF concentrations in female Parkinson's disease patients with LRRK2 mutations

Authors: *D. A. LOEFFLER¹, A. C. KLAVER¹, M. P. COFFEY¹, J. O. AASLY², P. A. LEWITT³

¹Beaumont Hlth., Royal Oak, MI; ²St. Olav's Hosp., Trondheim, Norway; ³Henry Ford West Bloomfield Hosp., West Bloomfield Township, MI

Abstract: Chaperone-mediated autophagy (CMA) is the principal pathway for clearing alpha synuclein, the main component of Lewy bodies in Parkinson's disease (PD). Lysosomeassociated membrane glycoprotein 2a (Lamp2a), the rate-limiting protein in CMA, is thought to be decreased in the PD substantia nigra. The effect of LRRK2 gene mutations, the most frequent cause of inherited PD, on Lamp2a levels is unknown. We used ELISA to measure total Lamp2 (isoforms Lamp2a, Lamp2b and Lamp2c) in CSF from patients with sporadic PD (sPD, n = 31), PD patients with LRRK2 gene mutations (LRRK2 PD, n = 20), and healthy similar-aged control subjects with or without LRRK2 mutations (LRRK2 CTL = 30, CTL = 27). The lowest median Lamp2 value was in the LRRK2 PD group; median values (pg/mL) were sPD = 333, LRRK2 PD = 127, CTL = 436, and LRRK2 CTL = 412. The difference between Lamp2 concentrations in LRRK2 PD and LRRK2 CTL subjects was statistically significant (p = 0.02). Gender effects may have influenced this result, because the LRRK2 PD group had a larger proportion of females (80%) than the other three groups (52% - 63%) and Lamp2 levels in the 67 females in this study (median = 247 pg/mL) were lower than the levels of this protein in the 41 males (median = 778 pg/mL) (p = 0.0002). An ANOVA was therefore performed on log-transformed Lamp2 concentrations which simultaneously modeled gender, diagnosis, and interaction effects. Evidence was found for differences between the eight "gender*diagnosis" groups (p < 0.0001); Tukey-Kramer multiple comparison testing revealed that the log-transformed Lamp2 levels in LRRK2 PD females were statistically different (lower) than those in each of the other gender*diagnosis groups except for sPD females. These results suggest that CSF concentrations of Lamp2 may be lower in females than in males, and may also be decreased in female PD patients with LRRK2 mutations. Further studies are required to determine the correlation between CSF and substantia nigra Lamp2 levels.

Boston., Boston, MA; ³Dept. of Cell Biol. and Anat., Rosalind Franklin Univ. of Med. and Sci., North Chicago, IL

Abstract: The Leucine-Rich Repeat Kinase (LRRK2) G2019S gain of function gene mutation is one of the most prevalent mutations contributing to Parkinson's disease (PD) pathogenesis. Using human induced pluripotent stem cell (iPSC)-derived neurons carrying the LRRK2 G2019S mutation, we and others have shown that the LRRK2 mutation, which increases LRRK2 kinase activity, alters axon outgrowth, intracellular trafficking, mitochondrial health and autophagy. We have also shown that this mutation contributes to an increased vulnerability of iPSC-derived neurons to PD-associated cell stressors and can be rescued by treatment with LRRK2 inhibitors (Cooper et al., 2012, Sci Transl Med. 2012, 4;4(141):141ra90.). Previously we described that human iPSC-derived neurons carrying the LRRK2 G2019S mutation challenged with the sarco/endoplasmic reticulum Ca²⁺ -ATPase (SERCA) uptake blocker thapsigargin (THP), exhibit an increase in depolarization-induced calcium influx and a modified calcium decay (interpreted as buffering capacity), when compared to neurons derived from healthy subject controls. Here, we show that endoplasmic reticulum (ER) Ca²⁺ levels, measured using an ER specific calciummeasuring organelle-entrapped protein indicator (Cepia-ER), are lower in iPSC-derived forebrain and midbrain dopamine neurons carrying the LRRK2 G2019S mutation compared to healthy subject controls. The lower level of ER calcium in LRRK2 G2019S neurons is still present even after THP-induced SERCA block. This phenotype was ameliorated by treatment with an antisense oligonucleotide that partially decreases LRRK2 levels. qPCR analysis of key ER Ca²⁺ channels and regulators, and membrane Ca^{2+} channels, known to regulate store operated calcium entry (SOCE), indicates altered expression in LRRK2 G2019S neurons. In summary, these data suggest that the LRRK2 G2019S mutation alters intracellular calcium homeostasis, which could contribute to PD-specific neuronal dysfunction. Further studies will identify specific targets of the ER homeostasis pathway affected by the LRRK2 G2019S mutation.

Title: Parkinson's disease-linked LRRK2 regulates epigenetic histone tail acetylation and neuronal apoptosis through HDAC3 phosphorylation and modulation of its activity and localization

Authors: W. SHIN¹, K. HAN¹, H. RHIM², *K. C. CHUNG¹ ¹Dept Systems Biol., Yonsei Univ., Seoul, Korea, Republic of; ²Korea Inst. Sci. Tech. (KIST), Seoul, Korea, Republic of

Abstract: Parkinson's disease (PD) is characterized by slow, progressive degeneration of dopaminergic neurons in the substantia nigra. The cause of neuronal death in PD is largely unknown, but several genetic loci, including LRRK2, have been identified. LRRK2 has GTPase and kinase activities, and mutations in LRRK2 are the major cause of autosomal-dominant familial PD. Histone deacetylases (HDACs) remove acetyl groups from lysine residues on histone tails, promoting transcriptional repression via condensation of chromatin. Here, we demonstrate that LRRK2 binds to and directly phosphorylates HDAC3 at Ser-424, thereby stimulating HDAC activity. Specifically, LRRK2 promoted the deacetylation of Lys-5 and Lys-12 on histone H4, causing repression of gene transcription. Moreover, LRRK2 stimulated nuclear translocation of HDAC3 via the phoshorylation of karyopherin subunit $\alpha 2$ and $\alpha 6$. HDAC3 phosphorylation and its nuclear translocation were increased in response to 6-OHDA treatment. LRRK2 also inhibited myocyte-specific enhancer factor 2D activity, which is required for neuronal survival. LRRK2 ultimately promoted 6-OHDA-induced cell death via positive modulation of HDAC3. These findings suggest that LRRK2 affects epigenetic histone modification and neuronal survival by facilitating HDAC3 activity and regulating its localization.

Abstract: LRRK2 G2019S is the most common mutation associated with familial Parkinson's disease (PD). Located in the kinase domain of LRRK2, G2019S facilitates substrate access to the kinase thus increasing the catalytic rate of the enzyme. Patient-derived induced pluripotent stem cells present increased activated caspase-3, simplification of neurites and cell body accumulation of α -synuclein after dopaminergic differentiation of the A9 subtype. Although some transgenic rodent species overexpressing human LRRK2 G2019S exist, there have not yet been similar modeling strategies applied to nonhuman primates. Moreover, utilization of clustered regularly interspaced short palindromic repeat (CRISPR)/Cas9 for precision editing, models that more closely mimic natural disease progression are now more achievable. In an effort to validate the common marmoset as a candidate species for a genomic model of PD, we first chose to investigate in vitro cell modeling strategies. The p.G2019S mutation derives from a g.G6055A mutation within exon 41. Here we report utilization of CRISPR/Cas9 that recognizes the G6055 region of the marmoset LRRK2 genome. We have successfully isolated a marmoset embryonic stem cell clone that contains bi-allelic nucleotide deletions that lead to a truncated form of LRRK2 (tLRRK2). After the clone was expanded, we administered a dual-SMAD inhibition protocol that our group previously validated for differentiating marmoset stem cells to neurons. The wild type (WT) parental cell line was differentiated in parallel as a control for phenotypic comparison. On day 28 of differentiation, the cells were incubated in a maturation medium for two weeks. The cells were then lifted, quantified, and replated to cover slips at an equal density

for morphological analysis and fixed one week later. After immunostaining for βIII-tubulin, 30 different fields for parental and edited cell lines were imaged. The ImageJ plugin NeuriteQuant was used for objective quantification of neurite complexity. Preliminary results suggest that tLRRK2 in neurons leads to a significant increase in average neurite length, number of branches per cell and overall neurite length per cell when compared to WT controls. There was no significant difference in the number of cells evaluated, number of neurites per cell, branches per neurite length and branches per neurite. Our results demonstrate that LRRK2 may play a critical role in the level of neurite complexity in marmoset neurons, and that disrupting functional LRRK2 expression may have a reverse effect of the gain-of-function G2019S mutation phenotype observed in human neurons. We are currently evaluating LRRK2 G2019S marmoset cells.

Title: Pharmacodynamic profiles of LRRK2 kinase inhibitors in transgenic rats

Authors: *K. J. KELLY

Univ. of Alabama At Birmingham, Birmingham, AL

Abstract: Parkinson disease (PD) is the most common movement disorder and is pathologically characterized by the presence of Lewy bodies and the loss of dopaminergic neurons in the substantia nigra. In 2004, the genetic link between mutations in *leucine rich repeat kinase 2* (LRRK2) and PD were identified in familial PD cases. The G2019S mutation in the LRRK2 kinase domain is the most common pathogenic mutation and leads to a gain-of-function that increases LRRK2 kinase activity. Small molecule LRRK2 kinase inhibitors are sought that might block or return LRRK2 activity to normal. Although several LRRK2 kinase inhibitors have been developed, few successful chronic dosing regimens in rats have been reported. Outbred rats are the standard rodent model in most pre-clinical campaigns to identify clinical candidate molecules. Here, we evaluated several chronic dosing strategies for two LRRK2 kinase inhibitors, PF-360 and MLi2, in wild-type and hBAC G2019S-LRRK2 transgenic rats, both on
the Taconic Sprague Dawley outbred background. Our goal is to relate drug concentrations in the brain and plasma in reducing the abundance of autophosphorylated LRRK2, pS935-LRRK2, and total LRRK2 protein, in both the context of over-expressed mutant LRRK2 enzyme as well as wild-type LRRK2 protein in the rats. We developed a scalable and ultra-sensitive assay using protein capillary electrophoresis to assess these proteins from tissues and cerebral spinal fluid. Our data suggest that MLi2 and PF-360, despite both compounds binding to the LRRK2 ATP pocket, differentially affect total protein stability and show different sensitivities towards inhibition of the autophosphorylation pS1292 residue and the constitutively phosphorylated pS935 residue. We can demonstrate that successful long-term chronic dosing regimens are possible in the rat, tuned to different potencies with respect to LRRK2 inhibition.

Title: Biochemical and behavioral outcome in AMN mice after intrathecal delivery of AAV9-hABCD1

Authors: *Y. GONG¹, F. LAHEJI¹, A. BERENSON¹, A. VOLAK¹, G. GAO³, X. O. BREAKEFIELD², C. MAGUIRE¹, F. EICHLER¹ ¹Massachusetts Gen. Hosp., Boston, MA; ²Molec Neurogenetics Unit, Massachusetts Gen.

Hosp., Charlestown, MA; ³Gene Therapy Ctr. of Univ. of Massachusetts, Boston, MA

Abstract: Adrenomyeloneuropathy (AMN) is the most common phenotype of X-linked adrenoleukodystrophy, a debilitating neurological disorder caused by mutations in the ABCD1 gene that encodes a peroxisomal ATP binding cassette transporter (ABCD1) responsible for transport of CoA-activated very long-chain fatty acids into the peroxisome for degradation. Close examination of the known Abcd1-/- mouse model of AMN reveals a 4-fold increase of C26:0 levels in spinal cord. Further we discovered that mechanical hypersensitivity of Abcd1-/- mice begins around 9 month of age, half a year prior to motor symptoms. In previous work we demonstrated that rAAV9-mediated ABCD1 gene transfer via intrathecal osmotic pump (IT pump) led to more uniform and widespread gene delivery to CNS with reduced leakage into the systemic circulation compared to either intravenous injection or intrathecal bolus (IT bolus)

injection. Here we report the biochemical and behavioral impact of intrathecal rAAV9-ABCD1 delivery. rAAV9 encoding ABCD1 (rAAV9-ABCD1) were delivered to Abcd1-/- mice intrathecally (IT) at spine region L4-L5 using either a gas-tight Hamilton syringe attached to a 33-gauge steel needle over 2mins or an osmotic pump over 24h, with PBS injections serving as sham control. Two weeks after injection, mice were sacrificed and tissue was collected for lipid analysis (C26:0 measurements). For behavioral testing another cohort of mice was similarly injected with rAAV9-ABCD1 at 5 months of age. Lipid analysis showed a 27% and 32% reduction in C26:0 of the spinal cord after rAAV9-ABCD1 IT pump and IT bolus injection (1X10¹¹gc/mouse) respectively. Importantly, after AAV9-ABCD1 delivery via IT pump we found a 2-fold improvement in the nominal force threshold compared to the PBS injected group. Behavioral testing after AAV9-ABCD1 IT bolus delivery is still pending. Meanwhile, no significant weight loss was detected after 1X10¹¹gc rAAV9-ABCD1 IT pump delivery compared to the PBS group. Even a 3-fold higher dose $(3X10^{11}gc/mouse)$ did not impact bodyweight, suggesting that intrathecal rAAV9-ABCD1 delivery is well tolerated. We conclude that rAAV9mediated ABCD1 gene transfer via intrathecal osmotic pump leads to biochemical correction and sensory improvements without associated toxicity. These findings may encourage further dose escalation and bode well for future clinical translation.

Title: The DNA repair histone H2AX controls motor learning and balance

Authors: *U. WEYEMI¹, B. D. PAUL², S. H. SNYDER³

¹Neurosci., Johns Hopkins Univ., Baltimore, MD; ²The Solomon H. Snyder Dept. of Neurosci., Johns Hopkins Univ. Sch. of Med., Baltimore, MD; ³Johns Hopkins Univ. Sch. Med., Baltimore, MD

Abstract: Ataxia telangiectasia (A-T) is an autosomal recessive disorder caused by a mutated ATM gene, which is characterized by genomic instability and progressive cerebellar degeneration leading to loss of motor control. A crucial aspect of A-T disease progression may be the elevated level of reactive oxygen species (ROS). Interestingly, while ATM is best known for its function in DNA repair, it has recently been shown to have an important role in cellular ROS homeostasis. Our previous study revealed that oxidative stress mitigation reduces some of the A-T phenotypes. ATM drives efficient DNA repair through rapid phosphorylation of the

histone variant H2AX. H2AX was recently described to elicit several functions beyond DNA repair, including the sensing of oxidative stress. H2AX mice recapitulate several features of Atm knockout mouse including defective DNA repair, immunodeficiency and increased risk of lymphoma. However, little is known about a role for H2AX in oxidative stress and the deficits in motor balance observed in Atm knockout mouse. Moreover, the neurobehavioral deficits in the Atm knockout mice are not robust, and the mutants do not display cerebellar degeneration. Therefore, there is an urgent need for a surrogate model that more faithfully recapitulates the A-T phenotype. We have preliminary observations that mouse embryonic fibroblasts deficient for the histone H2AX exhibit substantial ROS. Of interest, expression of several genes involved in the physiologic response to oxidative stress is impaired in H2AX knockout cells. Our observations are consistent with evidence that H2AX-deficient cells exhibit enhanced cytotoxicity in response to exogenous and endogenous oxidants like hydrogen peroxide (H₂O₂) and L-buthionine-S,R- sulfoximine (BSO). Many studies have suggested a crucial role for oxidative stress in the key phenotypes observed in A-T. We explored the functional consequences of H2AX deficiency in relation to behavioral defects. Our preliminary observations indicate that H2AX knockout mice exhibit impaired motor performance. Our data provide the first evidence that deficiency of H2AX, one of the major ATM targets, results in increased oxidative stress and impaired motor coordination. Additional lines of investigation will include whether mitigation of the oxidative stress in vivo rescues mice for the observed deficits. Analyses of cerebellum as well as other motor balance-associated regions in the brain including the cortex and the striatum will help to substantiate whether the H2AX mouse is a heuristic model for A-T disease.

Title: How extracellular α -synuclein affects the function of oligodendrocytes and the pathology of multiple system atrophy?

Authors: *S. KAJI, T. MAKI, N. UEMURA, R. TAKAHASHI Neurol., Kyoto Univ. Grad. Sch. of Med., Kyoto-Shi, Japan

Abstract: <u>Background</u> Multiple system atrophy (MSA) is one of the most refractory neurodegenerative diseases with no disease-modifying treatment. Since α -synuclein (α -syn), known as a neuronal protein, accumulates within oligodendrocytes (OLGs) even in the early stage of MSA, the interaction between α -syn and OLGs is believed to play a pivotal role in MSA pathogenesis. As oligodendroglial α -syn pathology eventually leads to neurodegeneration in MSA brains, the interpretation of how extracellular α -syn affects OLGs would aid the development of treatment for MSA. Our research aims to elucidate the oligodendrocyte condition in MSA and the influence of exogenous α -syn on OLG function.

<u>Method</u> To investigate the mRNA expressions of *SNCA* and genes for glial cell markers in MSA human brains, we performed quantitative PCR analysis. The frontal cortices of four MSA cases were examined, along with those of four control cases. For *in vitro* understanding of α -syn-induced OLG dysfunction, we prepared primary OLG culture. Mixed glial cells were obtained from postnatal day 1-2 rat, followed by isolation of oligodendrocyte precursor cells by overnight shaking. Seven days after maturation induction, OLGs were used for experiments. Bacterially expressed recombinant human α -syn was purified by ion exchange chromatography, followed by 3-7 days incubation with agitation at 37°C for the preparation of α -syn pre-formed fibrils (PFFs). OLGs were incubated with α -syn PFFs for 24 hours (for immunoblotting), or 72 hours (for qPCR).

<u>*Results*</u> Patient analysis revealed no significant difference of mRNA expressions of α -syn in MSA cases compared with controls. *MBP* and *NG2* mRNA expressions showed tendency to be higher in MSA cases than controls. Exogenous α -syn PFFs application caused remarkable decrease in the protein expressions of myelin basic protein (MBP). On the other hand, the *MBP* mRNA expression was significantly increased after α -syn PFFs application. *Discussion MBP* mRNA expressions were increased both in MSA cases and in α -syn-PFFs-

Discussion MBP InRNA expressions were increased both in MSA cases and in a-syn-PPPstreated primary OLG culture. Given that a previous study has shown the decrease of normal MBP and the emergence of degraded MBP in MSA human brains, the extracellular α -syn PFFs may trigger the degeneration of normal MBP and the compensatory increase of *MBP* mRNA expressions, which leads to the OLG dysfunction and neurodegeneration in MSA patients.

Title: Preclinical assessment of an FTY720-derivative, FTY720-Mitoxy, as a potential novel therapy for multiple system atrophy (MSA)

Authors: G. VIDAL-MARTINEZ¹, B. YANG¹, I. SEGURA¹, J. VARGAS-MEDRANO¹, S. CHAPPARO¹, J. B. ARTERBURN², *H. SANDOVAL³, R. G. PEREZ¹ ¹Texas Tech. Univ. Hlth. Sci. Center- El Paso Campus, El Paso, TX; ²New Mexico State Univ., Las Cruces, NM; ³Texas Tech., El Paso, TX

Abstract: In the demyelinating neurodegenerative disorder, multiple system atrophy (MSA), α synuclein (α Syn) protein accumulates inside myelinating oligodendroglia (OLG), forming glial cytoplasmic inclusions (GCIs). In MSA patients, this causes OLG glial and neuron cell death, demyelination, and related parkinsonian, autonomic, and cerebellar dysfunction. MSA patients also develop constipation. MSA mice overexpressing a Syn in OLG cells also develop GCIs and MSA-like symptoms. We have shown that the FDA-approved drug FTY720, is protective in parkinsonian mice. Our novel FTY720-analogue, FTY720-Mitoxy, crosses the blood brain barrier and can protect OLGs and neurons in cell culture, in part by turning up trophic factor expression. We propose that FTY720-Mitoxy protects MSA mice against progressive α Syn pathology and associated behavioral loss. MSA mice and wild type littermates received placebo or FTY720-Mitoxy from 8.5-11 mo by Alzet osmotic pumps. We used rotarod to assess balance and coordination, fecal water content to measure constipation, and carmine red gavage to measure total gut motility from 5-11 mo. Tissues were collected to evaluate aSyn pathology in brain and gut. At 4-6 mo, control and MSA mice were similar on all tests. MSA mice developed motor deficits that worsened by 10-11 mo in placebo treated MSA mice. After 2.5 mo of FTY720-Mitoxy treatment, preliminary data suggest MSA mice had better movement performance, reduced constipation, and improved gastrointestinal transit time. aSyn evaluation is underway. Evidence that FTY720-Mitoxy can slow MSA dysfunction and a Syn pathology in MSA mice encourages Phase I safety trials of the drug.

Title: TDP-43 is a key factor in regulating oligodendroglial lineage biogenesis and myelination

Authors: *J. WANG, W. HO, S.-C. LING Natl. Univ. of Singapore, Singapore, Singapore **Abstract:** TDP-43 aggregates are pathological hallmarks for amyotrophic lateral sclerosis (ALS) and frontotemporal demenia (FTD). Intriguingly, TDP-43 proteinopathies are characterized by loss of its nuclear staining with concomitant cytoplasmic accumulation. Furthermore, TDP-43 aggregates are present in neurons, astrocytes and oligodendrocytes. Together the evidence suggests that TDP-43 mediated neurodegeneration may be caused by both loss- and gain-of-TDP-43 functions and the damages from non-neuronal cells. To address how glial TDP-43 dysfunctions contributes to ALS, we selectively deleted TDP-43 in mature oligodendrocytes in mice. Although mice with TDP-43 deleted in oligodendrocytes are born in Mendelian ratio and develop normally, they develop progressive neurological phenotypes leading to early lethality by 90-days of age accompanied by age-dependent reduced myelination, altered oligodendrocyte biogenesis, loss of motor neurons, astrogliosis and microgliosis in the spinal cords. Our data showed that TDP-43 is indispensable for the functions of mature oligodendrocyte and loss of oligodendroglial TDP-43 may be an integral part in ALS pathogenesis.

Title: Non-immunosuppressive FTY720 analogues increase brain derived neurotrophic factor (BDNF) in oligodendroglia

Authors: I. SEGURA-ULATE¹, T. BELCHER¹, G. VIDAL-MARTINEZ¹, *R. G. PEREZ² ¹Texas Tech. Hlth. Sci. Ctr., El Paso, TX; ²Biomed. Sci., Texas Tech. Univ. Hlth. Sci. Ctr. - El Paso Campus, El Paso, TX

Abstract: Multiple system atrophy (MSA) is a demyelinating disorder with α-synuclein (aSyn) protein buildup inside myelinating oligodendroglia (OLG) and brain neurons. MSA dysfunction includes loss of brain-derived neurotrophic factor (BDNF) in OLGs. Loss of BDNF in brain cells is reversed by FTY720, an FDA-approved multiple sclerosis drug. Phosphorylated FTY720 also causes immunosuppression by reducing blood lymphocytes, which may be undesirable for MSA patients. New FTY720-analogues, FTY720-C2 and FTY720-Mitoxy, are not phosphorylated but still increase BDNF in neurons. Thus, we hypothesize that novel FTY720-analogues increase BDNF in OLG cells without producing immunosuppressive effects. BDNF expression in OLN-93, an OLG cell line, was assessed at 12 and 24 hr by qPCR after FTY720-C2 and FTY720-Mitoxy, or

equimolar FTY720-C2/FTY720-Mitoxy or 10X higher doses. Blood lymphocytes were counted by microscopy of Wright's stained blood smears at 24 hr after treatments. FTY720, as a positive control, caused immunosuppressive loss of blood lymphocytes to 80% of baseline at 24 hr in mice. Equimolar FTY720-C2 and FTY720-Mitoxy did not alter lymphocyte counts; though 10X FTY720-Mitoxy caused a 10% non-immunosuppressive loss of blood lymphocytes. Moreover, FTY720-Mitoxy increased BDNF expression in OLN-93 cells at 12 and 24 hr, with less effect noted for FTY720-C2.Cumulative evidence suggests that FTY720-Mitoxy increases BDNF in neuronal and OLG cells, similar to FTY720, while reducing the risk of immunosuppression. This supports further evaluation of FTY720-Mitoxy as a potential therapy for MSA.

Abstract: Ubiquitin carboxy-terminal hydrolase L1 (UCHL1) is a deubiquitinase that plays a critical role in maintaining free ubiquitin levels in neurons. Mice that lack all UCHL1 function (UCHL1^{nm3419}, UCHL1-/-) display motor neuron defects and profound corticospinal motor neuron (CSMN) degeneration characterized by increased ER-stress, vacuolated apical dendrites, and spine loss. These findings show the importance of UCHL1 for CSMN health. We hypothesize that in the absence of UCHL1, UCHL1 interacting partners could lose appropriate modulation leading to improper protein recycling or mislocalization in the neuron, and this in turn could reveal in underlying mechanism of CSMN vulnerability and degeneration in motor neuron diseases including amyotrophic lateral sclerosis. Here, we used a UCHL1- immunoprecipitation coupled with bottom-up proteomics approach to reveal the proteins that interact with UCHL1 in the motor cortex. Our findings have shown that UCHL1 indeed interacts with numerous proteins in the motor cortex including collapsing response mediator protein-2 (CRMP2). CRMP2 is a CRMP family member responsible for neurite outgrowth, spine

maintenance and axon guidance. Our data demonstrates a novel interaction between UCHL1 and CRMP2 that could explain the pathology observed in CSMN devoid of UCHL1.

Title: Prolonged striatal cholinergic activation and nicotine treatment similarly reduce L-dopainduced dyskinesias

Authors: ***T. BORDIA**, M. QUIK, X. PEREZ Ctr. for Hlth. Sci., SRI Intl., Menlo Park, CA

Abstract: L-dopa treatment in Parkinson's disease leads to involuntary hyperkinetic movements called L-dopa-induced dyskinesias (LIDs). We recently showed that selective activation of striatal cholinergic interneurons reduces LIDs via nicotinic (nAChR) and muscarinic (mAChR) acetylcholine receptors. Notably, the extent of reduction was similar to that observed previously with nicotine treatment. We therefore probed the cholinergic mechanisms leading to LIDs reduction with nicotine treatment. Choline acetyltransferase (ChAT)-Cre mice were unilaterally lesioned with 6-hydroxydopamine to induce parkinsonism, injected with AAV5-ChR2-eYFP in the dorsal striatum and implanted with optical cannulas. After stable virus expression, mice were rendered dyskinetic using L-dopa and stimulated. As previously, short optical cholinergic interneuron stimulation (0.005 s ON/ 0.5 s OFF) applied for 2 h after L-dopa injection enhanced LIDs, while longer pulse stimulation (1 s laser on/ 0.5 s laser off) reduced LIDs. The mice were then divided into two groups, with one receiving saccharin and the other saccharin-containing nicotine (300 µg/ml, ramped over a two-week period) with L-dopa treatment continued. As expected, there was a reduction in LIDs in the nicotine-treated group. In addition, the nAChR antagonist mecamylamine decreased LIDs in saccharin-treated but not nicotine-treated mice. By contrast, the mAChR antagonist atropine increased LIDs expression in nicotine but not saccharin-treated mice. Short pulse stimulation increased LIDs in both saccharin and nicotine treated mice. While this effect was not blocked by mecamylamine in either treatment groups, atropine prevented the increase in LIDs in saccharin-treated mice and further augmented LIDs in nicotine-treated mice. These data suggest a pro-dyskinetic role for mAChRs, which is further potentiated with nicotine-treatment. We next investigated whether longer cholinergic interneuron stimulation still decreases LIDs after nicotine treatment. No change in LIDs was observed in the nicotine-treated mice with longer cholinergic activation. These data together with the lack of effect of mecamylamine in nicotine-treated mice suggest that nAChR desensitization is a common cohesive mechanism for LIDs reduction. The atropine-mediated increase in LIDs expression regardless of stimulation durations in nicotine-treated mice may indicate a regulatory relationship between desensitized nAChRs and mAChRs to exacerbate LIDs. Overall, these results highlight a critical role for decreased striatal cholinergic signaling arising from nAChR desensitization in reducing LIDs.

Title: Targeting hypersensitive corticostriatal terminals and the dopamine D₄ receptor in restless leg syndrome

Authors: *C. R. QUIROZ¹, G. YEPES¹, M. SANCHEZ-SOTO¹, H. YANO¹, X. GUITART¹, W. REA¹, N. S. CAI¹, V. CASADÓ-ANGUERA², V. CASADÓ², R. P. ALLEN³, C. J. EARLEY³, S. FERRÉ¹

¹Medications Discovery Br., Natl. Inst. on Drug Abuse Intramural Res. Program, Baltimore, MD; ²Univ. of Barcelona, Barcelona, Spain; ³Neurol., Johns Hopkins Univ. Dept. of Neurol. and Neurosurg., Baltimore, MD

Abstract: The objective of the study was to demonstrate alterations in the sensitivity of corticostriatal glutamatergic terminals in the rodent with brain iron deficiency (BID), a pathogenetic model of Restless Legs Syndrome (RLS), and to determine if these terminals constitute a significant target for drugs effective in RLS, including dopamine receptor agonists (pramipexole and ropinirole) and $\alpha 2\delta$ ligands (gabapentin). The methods included an in vivo optogenetic-microdialysis approach in the rat and in vitro dynamic Bioluminescence-Resonance-Energy-Transfer techniques in transfected cells, to determine the biochemical profile of the putative dopamine D2-like receptor subtypes present in corticostriatal glutamatergic terminals. The results demonstrate hypersensitivity of corticostriatal glutamatergic terminals (lower frequency of optogenetic stimulation to induce glutamate release) in rats with BID as compared

with those with normal brain iron levels. Both hypersensitive and control glutamatergic terminals were significant targets for pramipexole, ropinirole and gabapentin, which significantly counteracted optogenetically induced glutamate release. Using selective antagonists, a significant involvement of D4 and D2 receptor subtypes on the effects of the dopamine receptor agonists was determined with the in vivo and in vitro approaches. Specifically, the results suggest the involvement of D4-D2S receptor heteromers. Significant differences on the efficacy of pramipexole and ropinirole, that depended on receptor heteromerization, were observed between D4.4 and D4.7, the products of polymorphic variants of the human D4 receptor gene. The interpretation of these results is that: i) hypersensitivity of corticostriatal glutamatergic terminals can be a main mechanism involved in the pathogenesis of RLS symptoms; ii) these terminals are already constituting targets for drugs effective in RLS; iii) selective D4 receptor agonists should provide a more efficient treatment with less secondary effects.

Title: Assessment of haloperidol-induced tremulous jaw movement in rats using loose restraint and a video recording system

Authors: R. HODGSON, *E. LATONUMMI, A. J. NURMI, L. KOISTINEN Charles River Discovery, Kuopio, Finland

Abstract: Chronic administration of haloperidol to rats induces a tremulous jaw movement, also referred to as vacuous chewing, characterized by involuntary rapid downward deflections of the lower jaw. These jaw movement have been widely used as a model of the motor complications associated with Parkinson's disease; anti-parkinsonian drugs reliably reverse the jaw movements. More recently, haloperidol-induced jaw movements have been used as a model of antipsyhotic-induced extrapyrimadal syndrome (EPS); promising treatments for EPS, such as adenosine A2A receptor antagonists reliably reverse haloperidol-induced tremulous jaw movements. The model has a significant value for the advancement of novel chemical entities both to help derisk putative antipsychotics in development, or to assess the efficacy of novel candidates designed to reverse antipsychotic-induced extrapyramidal syndrome. While the rat model has much higher throughput than the Cebus monkey model, which is the gold standard animal model of EPS, a high-throughput execution of the model has not yet been developed. The most challenging

barrier to increasing the throughput of the model is that it requires a live human observer to score the moments and it is difficult to video the behavior because the observer must "bob and weave" with the rats in order to maintain a line of sight to the jaw. Here we developed a system to loosely restrain the rats during video recording forcing the animals to face the camera. Because the animals are treated with haloperidol, their movement is already pharmacologically limited and we find that the loose restraint is sufficient to maintain the directionality of the animals allowing for video recording and post-hoc recording of the jaw movements. Moreover, using post hoc video recording allows for scoring by more than a single observer to allow for confirmation of the findings by an independent observer. Here we show that, using this video recording system, we achieve reliable recordings and measurement of the haloperidol-induced jaw movements, and their reversal with the selective A2A receptor antagonist istradefylline. This system provides a novel way to execute the haloperidol jaw movement assay much higher throughput, and reliability way than has been previously reported.

Abstract: Multiple system atrophy (MSA) is a rare, progressive neurodegenerative disorder with an uncertain pathophysiology, in which α -synuclein preferentially accumulates in oligodendrocytes rather than neurons. Aggregated α -synuclein is thought to elicit changes in oligodendrocyte function, such as reduced neurotrophic support and demyelination. To date, only transgenic murine models of MSA exist, which lead us to develop a novel viral vector-based model of MSA by over expressing α -synuclein in oligodendrocytes using a novel oligotrophic adeno-associated virus (AAV) vector, Olig001. As proof-of-concept, rats received unilateral injections of the Olig001 vector expressing GFP stereotaxically in the striatum. After 4-weeks,

rodents were sacrificed and histological methods were used to assess the specificity of the viral vector. Using unbiased stereology, our data showed $126,574 \pm 11,304$ GFP-positive cells in the striatum, and a volume of GFP transduction to cover 3.87 ± 0.609 mm³ throughout the rostral-caudal extend of the striatum. Immunofluorescence double labeling showed 94-97% of the GFP-positive cells co-localizing with oligodendroglial marker Olig2. There was little or no co-expression in NeuN (2.9-4.7%) or GFAP (0.18-0.49%)-positive cells.

Additional cohorts of rats were injected with either Olig001-GFP or Olig001- α -syn in the striatum. 5-months following injection, histological analysis revealed widespread transgene expression throughout the striatum in both GFP and α -syn injected animals. α -syn expression, indicated by LB509 and phosphorylated Serine-129 immunoreactivity, revealed widespread inclusions in the corpus callosum and striatum, which were shown to be resistant to proteinase K digestion. These pathological inclusions were found to be localized in oligodendroglia, and seem to elicit pathological changes similar to early MSA. Marked demyelination was observed throughout the white matter of α -syn- but not GFP-injected animals. Within the timeframe of this study, no overt neurodegeneration or depletion of striatal dopamine or its metabolites were observed. Taken together, our data indicate that viral vector-mediated overexpression of human α -synuclein in oligodendroglia recapitulates pathology observed in early MSA. Longer time points are needed to fully evaluate the potential of this model to recapitulate neurodegeneration and behavioral deficits seen in MSA.

Title: Combined therapy with tempol (4-Hidroxy-TEMPO) and human mesenchymal stem cells from adipose tissue: Neuroprotection, glial reactivity attenuation, and immunomodulation in SOD1-G93A transgenic mice

Authors: *G. CHIAROTTO, M. V. DE CASTRO, A. S. S. DUARTE, Â. C. M. LUZO, A. L. OLIVEIRA

Univ. of Campinas, Campinas, Brazil

Abstract: Amyotrophic lateral sclerosis (ALS) is a neurodegenerative disease characterized by the selective loss of the upper motoneurons in the cerebral cortex, and the lower motor neurons in the brainstem and spinal cord. Among the hypotheses to explain the neurotoxic mechanism that triggers neuronal death are the oxidative stress, inflammation, and glutamate excitotoxicity. However, the precise mechanisms which lead to such scenario remain unknown. Stem cell therapy is a promising alternative for treating ALS based on the fact that such cells target active areas of degeneration, promoting immunomodulation and local release of various neurotrophic factors. Thus, the present work aimed to evaluate the success of combined therapy with the antioxidant tempol (4-hidroxy-TEMPO) and human mesenchymal stem cells (hMSC) obtained from adult adipose tissue. Such treatment was performed in SOD1-G93A transgenic mice, used as a model for ALS. Treatment with tempol (50mg/kg) and hMSC was initiated in 70 days old mice (pre-symptomatic stage). Tempol was given orally (gavage) on alternate days up to 100 days of life when the animals were sacrificed for spinal cord analysis. Cell therapy was carried out in 70 days old subjects through the tail vein, at the concentration of 1×10^5 cells. Data evaluation encompassed Nissl staining, for evaluation of neuronal survival and immunohistochemistry to evaluate astrogliosis, microglial reaction, and preservation of synapses. qRT-PCR was used for evaluation of pro-inflammatory cytokines, neurotrophic factors, and iNOS gene expression. The combined treatment of tempol and hMSC decreased astrocyte activation by 30% and microglial reaction by 40%. These results were paralleled with downregulation, by 50%, of IL1B and TNFa mRNA levels. Also, hMSC treatment led to downregulation of iNOS gene expression at lumbar spinal cord ventral horn. Overall, spinal cord microenvironment immunomodulation, by the combined therapy described herein, prevented motoneuron loss by 90% in 100 days old mice, which was coupled with a trend of preservation of synaptic circuits at the motor nucleus (lamina IX of Rexed). In turn, the association of hMSC and tempol administration may be considered as a promising therapy for attenuating the progression of ALS.

Title: Optimizing patient-specific cellular neurodegenerative disease model based on human iPSc derived neuronal differentiation

Authors: *M. FANG¹, Z. HU², Y. YANG³

¹Zhejiang Univ., Zhejiang, China; ²Dept. of Obstetrics and Gynecology, Hangzhou Red Cross Hosp., Hangzhou, China; ³Inst. of Neurosciences, Zhejiang Univ. Sch. of Med., Hangzhou, China

Abstract: Researches concerning human brain disease are hampered by the difficulties of obtaining live specimens. The induced pluripotent stem (iPS)-derived and differentiated cells allow researchers to examine disease onset and progression directly in a human culture model. Creating isogenic iPS cell lines conquer problems of variability in human genomes; also it is much easier to employ genome-editing technique, thus performing therapeutic drug screens on a specific human genetic background. Shinya Yamanaka played his magic using 4 genes to do reprogramming and generate embryonic-like iPS cells, which were supposed to herald a medical revolution while they are transforming biological research instead. Our previous collaborative study have identified a dominantly inherited heterozygous variant c.1064G>A (p.G355D) in ATAD3A by using whole-exome sequencing in a mother presenting with hereditary spastic paraplegia (HSP) and axonal neuropathy and her son with dyskinetic cerebral palsy. Results show that overexpression of the mutant ATAD3A fragments the mitochondrial network and induces lysosome mass. Furthermore, altered dynamics of the mitochondrial network and increased lysosomes in patient fibroblasts and neurons derived through differentiation of patientspecific induced pluripotent stem cells were observed. These alterations were verified in patient fibroblasts to associate with upregulated basal autophagy through mTOR inactivation, which resembling starvation. Similarly, iPSC generated from patient carrying Usher syndrome causing mutation MYO7A were first differentiated to neurons, mitochondrial dynamic status were checked. And a bipolar disorder family has been identified, whole exome sequencing approached, fibroblasts and reprogramming iPSC were generated from the affected members, mitochondrial balance has been explored in patient neuronal differentiated cell model. The patient-specific iPSCs would provide disease pathogenesis as well as enable the evaluation of drug and patient classification of different types of neurodegenerative diseases.

Title: Neurological manifestation of Wilson disease as a distinct disease subgroup

Authors: *B. LEE¹, G. SEO², Y.-M. KIM², G.-H. KIM¹, H.-W. YOO² ¹Asan Med. Ctr., Seoul, Korea, Republic of; ²Asan Med. Ctr. Children's Hosp., Seoul, Korea, Republic of

Abstract: Wilson disease (WD) is an inborn error of copper metabolism (OMIM #277900) caused by the recessive genetic defects in the P-type copper-transporting ATPase. WD is one of the most common inherited metabolic disorders with the frequency of 1 in 30,000 in the Korean population. WD manifests as hepatic dysfunction or neurological manifestations that include tremor, dysarthria, ataxia, rigidity, dyskinesia, cognitive impairment and mood disturbances. In a previous study of a large Korean WD cohort, we found that the clinical courses of WD patients with neurological manifestations are more indolent and less favorable than those with hepatic dysfunction and without neurological manifestations. In the current study, we investigated the biochemical and molecular genetic features of WD with neurological manifestations to identify more evidences that these WD patients' group is a distinct phenotypic or genetic group among WD patients. We evaluated the detailed biochemical profiles and genotypic characteristics between WD patients with neurological manifestations and without neurological manifestations in 384 Korean WD patients. Of note, all the biochemical profiles including the levels of platelet, liver enzymes, serum copper and ceruloplasmin were different among these two groups, and these differences were still significant even among the patients with liver cirrhosis. Regarding the correlation with genotypes, the mutation types or common mutations including p.Arg778Leu, p.Ala874Val, p.Asn1270Ser, p.Lys838SerfsX35 and p.Leu1083Phe, were not differentially distributed between the two groups. However, the low frequency of mutations in the transduction or ATP-hinge domain, were significantly noted in patients with neurological manifestations. The results of the current study provide more evidence that WD patients with neurological manifestations hold a distinct phenotypic and or genotypic subgroup of WD.

Title: PRRT2 function and mutations in the pathogenesis of Paroxysmal Kinesigenic Dyskinesia

Authors: *Y. PAN^{1,2}, Y. YANG^{1,2}, Q. LIU^{1,2}, Y. TIAN², W. CHEN², K. YANG², X.-J. LI¹, S. LI^{1,2}, B. TANG² ¹Human Genet., Emory Univ. Sch. of Med., ATLANTA, GA; ²Dept. of Neurol., Xiangya Hospital, Central South Univ., Changsha, China

Abstract: PKD (Paroxysmal Kinesigenic Dyskinesia) is a rare autosomal dominant inherited paroxysmal movement disorder, which is characterized by recurrent, brief attacks of abnormal involuntary movements induced by sudden voluntary movements. Our previously study had identified that mutations in the *PRRT2* (proline-rich transmembrane protein 2) gene are associated with PKD and that the 'c.649dupC' missense mutation is the major causative mutation. However the underlying pathophysiological mechanism of PRRT2 mutations is still unclear. We found that PRRT2 started to express from embryonic day 18 and showed a markedly increased expression after postnatal stage till adulthood. In situ hybridization and immunoblotting results showed that PRRT2 is widely distributed in the whole brain, with high levels in the hippocampus, cortex, cerebellum, and thalamus. Immunofluorescence of brain slices revealed that PRRT2 was specifically expressed in neuron, but not in astrocytes. Consistent with the synaptic distribution of PRRT2, co-immunoprecipitation and GST pull-down assay demonstrated the interaction between PRRT2 and SNAP25 (synaptosomal-associated protein 25). We also found that the interaction sites in PRRT2 and SNAP25 are the cytoplasmic domain of PRRT2 and linkage domain of SNAP25, respectively. In addition, we have generated a Prrt2 knockout mouse model and the mutation (c.649DupC) knock-in mouse model to compare their motor related behaviors, neural plasticity, and epilepsy susceptibility in order to investigate the role of *PRRT2* mutations in the pathology of PKD.

Title: Functional activity within the visuomotor system predicts severity of essential tremor

Authors: *D. B. ARCHER¹, W. T. CHU¹, J. W. CHUNG¹, R. G. BURCIU², S. A. COOMBES¹, A. WAGLE SHUKLA¹, D. E. VAILLANCOURT³ ²Dept. of Applied Physiol. and Kinesiology, ³Applied Physiol. and Kinesiology, ¹Univ. of Florida, Gainesville, FL

Abstract: Abstract

Essential tremor (ET) is a neurological disease with dysfunction in the cerebello-thalamo-motor cortical pathway. It is unclear if other pathways in the brain also contribute to tremor in ET. ET patients demonstrate visuomotor control deficits, which suggests that the visuomotor pathways could play a significant role in tremor amplitude in ET. Here, we directly manipulated the visual feedback error signal during an fMRI grip force task in 19 ET patients and 19 controls, and hypothesized that an increase in visual feedback magnification would exacerbate tremor in the 4-12 Hz range in ET. We also hypothesized that this increase in tremor would be accompanied with dysfunction within the cerebello-thalamo-motor cortical and visuomotor pathways. Magnifying visual feedback led to reductions in force error in ET and a control group, whereas only ET tremor was exacerbated by increases in visual feedback. ET had hyperactivity within primary motor cortex, and hypoactivity within cerebellar lobules I-IV. Further, ET patients had a reduced blood oxygenation level dependent (BOLD) response in several cerebello-thalamomotor cortical and visuomotor regions including inferior and superior parietal lobules, primary motor cortex, middle temporal gyrus, and cerebellar lobule VI. Approximate entropy of the BOLD signal showed the ET patients had irregular approximate entropy in the left superior parietal lobule, supplemental motor area, extrastriate area, and right somatosensory cortex. Multiple regression models identified that two regions in the visuomotor pathway, in addition to cerebellar lobules I-IV, were predictive of the clinical severity of tremor irrespective of visual feedback level, including the extrastriate visual areas and inferior parietal lobule. These findings point to novel evidence that in addition to the cerebellar-thalamo-cortical pathway, the visuomotor pathway is a significant predictor of tremor amplitude in ET.

Title: Creating volitional movement in cerebral palsy

Authors: *K. N. HUGGINS¹, M. TURNER²

¹Physiol. and Pharamcology, Movement Lesson, LLC, Kingsport, TN; ²Movement Lesson, LLC, Peoria, AZ

Abstract: Development of complex movement patterns (e.g. walking) requires the coordination of momentum and acceleration in space with no fixed points of reference. Functional movement builds upon experiences of moving in space from the neonatal period forward. An infant, having no experience with movement in a gravitational field, creates unique system mechanics in relation to gravity while lacking the cognitive ability to willfully transfer might against mass. An infant with a medical condition at birth or during the early stages of development will miss opportunities to lay the foundation for complex movement. Cerebral palsy results from a brain insult during the time of life between birth and age 5. Current therapies and standard of care are aimed at symptom management with no concerted effort to organize the nervous system and enable habilitation through neuroplasticity. Constraints during this developmental period either internal or external lead to system shut down or long-term restrictions. Here, the authors describe a method to improve the efficiency and frequency of volitional movement in children with movement disorders. Utilizing specific types of movement, the authors replicate early developmental period experience to organize the nervous system and facilitate movement following developmental delays. Changes in movement patterns and system mechanics are outward expressions of underlying changes in the brain and are followed by changes in vision, sensory processing and other concomitant delays.

Title: Human superoxide dismutase 1 (SOD1) enters the nucleus and binds chromatin in neurons of G93A-SOD1 transgenic mice

Authors: *B. KIM, L. J. MARTIN Pathology, Div. of Neuropathology, John Hopkins Univ. Sch. of Med., Baltimore, MD

Abstract: Amyotrophic lateral sclerosis (ALS) is a fatal neurodegenerative disorder that causes gradual degeneration and elimination of neurons that control voluntary muscles. Some familial ALS is linked to mutations in copper, zinc superoxide dismutase 1 (SOD1). This enzyme

destroys free superoxide radicals in the cytosol but mutant forms are believed to acquire an adverse property. However, underlying therapeutically relevant mechanisms on how the mutations in SOD1 cause neurodegeneration are unknown. Here, we used transgenic mice expressing human G93A-SOD1 to test the hypothesis that SOD1 has a nuclear presence that becomes abnormal during disease. By subcellular fractionation and immunoblotting, human SOD1 (hSOD1) in mouse brain and spinal cord was detected in cytoplasmic and nuclear fractions, hSOD1 was found chromatin bound. Immunofluorescence demonstrated that the nuclear localization of hSOD1 was exclusive to motor neurons and interneurons, not to glia such as astrocytes and oligodendrocytes. This hSOD1 in neurons showed three different localization patterns: higher level of hSOD1 in the nucleus, in the cytoplasm, or the protein being equally distributed in both compartments. Furthermore, compared to pre-symptomatic G93A-SOD1 transgenic mice, symptomatic mice showed overall decreased numbers of motor neurons and interneurons in the spinal cord but the expression patterns of hSOD1 and the relative percentages of neurons in each pattern remained comparable. Our findings suggest that degeneration of the vulnerable neurons in ALS is cell autonomous and nuclear hSOD1 and chromatin interactions could be important in the pathogenesis of the disease.

Title: Increasing urate levels may delay disease onset in the SOD1 G93A mouse model of amyotrophic lateral sclerosis

Authors: *E. GRANUCCI¹, K. E. GLAJCH¹, K. TSIORAS², K. A. MUELLER¹, A. M. DIOS¹, Y. XU¹, R. BAKSHI¹, X. CHEN¹, S. PAGANONI¹, M. A. SCHWARZSCHILD¹, E. KISKINIS², G. SADRI-VAKILI¹ ¹Massachusetts Gen. Hosp., Charlestown, MA; ²Northwestern Univ., Chicago, IL

Abstract: Amyotrophic lateral sclerosis (ALS) is a neurodegenerative disease characterized by progressive loss of upper and lower motor neurons resulting in impaired motor function, paralysis, and eventually death by respiratory failure. Currently there are no therapies for the treatment of ALS, indicating a clear need for the development of novel treatment options. Although the exact mechanisms involved in the onset and progression of the disease remain unknown an increase in oxidative stress has been implicated. Thus, an improved understanding

of oxidative stress-induced motor neuron death may lead to mechanism-based therapies. One of our major endogenous defenses against oxidative stress is urate, an antioxidant and byproduct of purine metabolism. Recent findings have highlighted the neuroprotective potential of urate in neurodegenerative diseases such as Parkinson's disease (PD), Huntington's disease, Alzheimer's disease (AD) and ALS. Specifically, urate was shown to be a strong molecular predictor for both reduced risk (PD, AD) and favorable progression (PD, ALS, HD). Furthermore, urate elevation was found to be neuroprotective in pre-clinical PD models. However, little is known about the neuroprotective effects of urate in ALS. Here we assessed the neuroprotective effects of increasing urate levels in the SOD1 G93A mouse model of ALS. To increase CNS urate levels, mice with a mutation in the gene (UOx) encoding urate oxidase, enzyme responsible for urate metabolism, were crossed with transgenic (Tg) SOD1 G93A mice to generate Tg SOD1/UOx^{-/-} mice and littermate controls. We assessed body weight, neurological score, motor function, disease onset and progression. Our results demonstrate that elevated urate levels are associated with a twenty-day delay in the onset of hind limb paresis in the Tg SOD1/UOx^{-/-} mutant mice compared to Tg SOD1/UOx+/+ or wild-type littermates. Ongoing studies are assessing the effects of increased urate on motor neuron counts and neuromuscular junction integrity. In addition, in order to validate the potentially beneficial effects of urate in the context of human patient motor neurons we assessed its ability to protect mutant SOD1 and isogenic control motor neurons in vitro. We found that pretreatment of patient motor neurons with urate significantly protected against glutamate and oxidative stress-induced toxicity. Together these findings demonstrate that, similar to PD, increasing urate levels may provide therapeutic benefits in ALS and support ongoing translational studies of urate elevation in patients with ALS.

Title: Behavioral and histological evaluation of SOD1 (G93A) and Profilin 1(PFN1 G118V) mouse models of motor neuron disease

Authors: *I. MORGANSTERN¹, N. ROBERTS¹, E. SABATH¹, D. HAVAS¹, L. THIEDE¹, M. KIAEI², T. HANANIA¹

¹Behavioral Pharmacol., Psychogenics, Tarrytown, NY; ²Pharmacol. and Toxicology, Dept. of Neurology, Dept. of Geriatrics, Univ. of Arkansas for Med. Sci., Little Rock, AR

Abstract: The present study was aimed at identifying behavioral tests that are most sensitive to the emergence of behavioral/neurological deficits in SOD1-G93A (SOD1) mice in a cross comparison with the newly proposed hPFN1G118V (PFN1) (Fil et al., 2016) mouse model of motor neuron disorder. The test battery consisted of commonly used metrics such as rotarod, open field and more complex proprietary algorithm-based behavioral platforms such as NeuroCube ® and SmartCube ®. In addition to behavioral assessment, histological evaluation of neuroinflammation in the spinal cord will also be presented. The behavioral findings demonstrate similarities in progressive muscle weakness and a decline in motor coordination in both models of motor neuron disease with a later onset and slower progression noted with PFN1 animals. Additionally, sophisticated algorithm-based systems determined a strong phenotype effect in both the PFN1 and SOD1 mice at very early ages. Our NeuroCube ® analyses identified early changes (8-12 weeks) related to gait geometry/ dynamics in both SOD1 and PFN1 mice, which progressed over time. Similarly, using SmartCube® technology we identified distinct behavioral changes as early as 6-7 weeks of age in SOD1 mice and 12-14 weeks for PFN1 mice. Histological assessment demonstrated reactive gliosis of both astro- and microglia in the spinal cord of end-stage disease SOD1 and PFN1 mice. Quantification of GFAP and Iba1 immunoreactivity revealed parallels in both mouse models in addition to distinct patterns of microglial activation. In summary, we demonstrate similar neurological/motor function deficits as well as glial cell activation in SOD1 and PFN1 mice, both exhibiting clinically-relevant attributes of Amyotrophic Lateral Sclerosis (ALS), with more advanced computer vision systems identifying distinctive behavioral patterns and discriminating the phenotype at very early disease stages in both models. This earlier period of disease identification presents a valuable model for early intervention and improved assessment of potential therapeutic approaches for ALS.

Title: Longitudinal measurements of neurofilament light in the SOD1^{G93A} mouse model of amyotrophic lateral sclerosis

Authors: *B. L. BURGESS¹, D. L. BAKER², S. L. DOMINGUEZ³, A. DATWANI², F. L. YEH¹

¹Biomarker Develop., ²Bioanalytical Sci., ³Neurosci., Genentech, South San Francisco, CA

Abstract: Introduction: Neurofilaments have emerged as an important biomarker for neurodegenerative disorders, especially for diseases, such as amyotrophic lateral sclerosis (ALS) and multiple sclerosis. Neurofilament light (NF-L), medium (NF-M) and neurofilament heavy (NF-H) expression is largely restricted to neurons where they serve as intermediate filaments to lend structural support for the cell. NF-L levels in cerebrospinal fluid (CSF) and blood have been demonstrated to have diagnostic and prognostic value in ALS; however, additional studies are required to help guide interpretation of NF-L biomarker data in an interventional trial. To gain a greater understanding of the factors that govern peripheral levels of this biomarker we sought a suitable preclinical model of neurodegeneration that also exhibited elevated NF-L in blood. Transgenic mice carrying the ALS-associated mutant form of human superoxide dismutase 1 ^{G93A} (SOD1^{G93A}) recapitulate several aspects of ALS pathology and were therefore evaluated as a possible preclinical model to investigate the biology of NF-L in blood. Methods/Materials: Plasma was collected from SOD1^{G93A} transgenic (26-31 copies) mice and non-transgenic littermates (n=4 per group) at early (9 wks), mid (11 & 14 wks) and late stages (16 wks) of the disease. NF-L was measured using the Quanterix Simoa NF-L immunoassay with a bovine NF-L calibrator. **Results:** Plasma NF-L was elevated 15-fold in the SOD1^{G93A} positive animals over SOD1^{G93A} negative littermates at 9 weeks of age. NF-L continued to rise sharply in SOD1 ^{G93A} transgenic animals to 23-fold over controls at 11 weeks and 28-fold by 14 weeks, but appeared to plateau by 16 weeks at 30-fold over control. **Discussion** We observed that NF-L progressively increases in the plasma of SOD1^{G93A} mouse model of ALS. Previous characterization of this strain has shown that denervation of neuromuscular junctions in the gastrocnemius muscle occurs prior to 9 weeks without significant loss motor neurons in the spinal cord. These results demonstrate that *SOD1*^{G93A} mice can be used as a model system to investigate the mechanistic origins of peripheral levels of NF-L in ALS and the relationship between plasma NF-L and the development of motor neuron pathology.

Title: Altered regulation of upper motor neuron synaptic hyper-excitability by TrkB receptor signaling in the SOD1G93A mouse model of amyotrophic lateral sclerosis

Authors: J. PRADHAN¹, P. G. NOAKES^{1,2}, *M. C. BELLINGHAM³ ¹Sch. of Biomed. Sci., ²Queensland Brain Inst., ³Univ. of Queensland, Brisbane, Australia

Abstract: Brain Derived Neurotrophic Factor (BDNF) is well recognized for its neuroprotective functions, via activation of its high affinity receptor, tropomysin related kinase B (TrkB). However, BDNF/TrkB signalling has also been shown to cause detrimental effects on motor neurons in amyotrophic lateral sclerosis (ALS), via enhancement of glutamate excitotoxicity, causing hyper-excitation and ultimately motor neuron death. Furthermore, direct inhibition of TrkB receptors has been shown to protect motor neurons from these toxic insults. However, the effects of TrkB receptor modulation on neurotransmission and synaptic hyper-excitability in cortical pyramidal neurons that are vulnerable in ALS remain to be determined. We have investigated the effects of TrkB receptor modulation on excitatory synaptic activity in presymptomatic mice over-expressing a human superoxide dismutase 1 G93A mutation (SOD1G93A) and their wild type (WT) littermates (P21-P27). Whole cell patch clamp recordings of spontaneous excitatory postsynaptic currents (sEPSCs) were made from layer V pyramidal neurons (LVPNs) of the motor cortex in acute cortical brain slices. The TrkB receptor agonist, 7,8 dihydroxyflavone (10µM), significantly enhanced sEPSC frequency by 131% (pvalue 0.046, n=8) in WT LVPNs; however, 7,8 dihydroxyflavone did not evoke a significant change in sEPSC frequency in SOD1G93A LVPNs (n=4). The TrkB receptor antagonist ANA-12 (10nM) significantly reduced sEPSC frequency by 40% (p-value 0.011, n=4) in SOD1G93A LVPNs, but did not significantly reduce sEPSC frequency in WT LVPNs (n=6). There was no change in sEPSC amplitude after application of the TrkB agonist or antagonist for LVPNs of either genotype. These results clearly demonstrate that there is an up-regulation in TrkB receptor-mediated enhancement of sEPSC frequency in LVPNs of the motor cortex of presymptomatic SOD1G93A mice, presumably by

enhanced endogenous BDNF. Our results suggest that modulation of TrkB receptor signalling may be important in early disease pathogenesis in ALS.

Abstract: Amyotrophic lateral sclerosis (ALS) is a neurodegenerative disorder defined by axonal retraction accompanied by selective upper and lower motor neuron degeneration. Patients suffer from progressive muscle atrophy and will typically die within 2 to 5 years after disease onset as no effective treatment is currently available. In 90% of ALS cases the etiology is unknown, the remaining 10% of ALS patients have a family history of disease. Dominant mutations in C9orf72, SOD1, TDP43 and FUS are the most frequent causes of this inherited form. Although traditionally viewed as a motor neuron disease, damage developed within nonneuronal supporting cells, such as oligodendrocytes, is crucial to motor neuron dysfunction in ALS. A cycle of oligodendrocyte death and replacement precedes the onset of motor neuron death and symptoms in ALS mice. Newly formed oligodendrocytes appear to be immature and dysfunctional in ALS, consistent with impaired oligodendrocyte differentiation. Motor neurons consequently loose an important source of both structural and trophic support, potentially contributing to axonal injury and motor neuron loss. In order to improve this differentiation process, we selectively removed Inhibitor of differentiation 2 (ID2) from oligodendrocyte progenitor cells (OPCs) of pre-symptomatic SOD1^{G93A} ALS mice using a conditional, tamoxifen-inducible mouse model. ID2 is a basic helix-loop-helix (bHLH) transcription factor that impairs differentiation of oligodendrocytes in vitro and was identified as a disease modifier in the ALS zebrafish model established in our lab. Our results showed that oligodendrocytic ID2 deletion was not able to delay disease onset of ALS mice, nor did it prolong survival. At disease end-stage, no significant improvement of oligodendrocyte function could be observed, possibly explaining the negative outcome on disease progression. It remains to be clarified whether ID2 ablation confers a transient effect on oligodendrocyte differentiation or function *in vivo* at earlier stages of disease.

Title: Assessing skeletal muscle bioenergetics *In situ* in amyotrophic lateral sclerosis: Characterizing metabolic perturbations in a SOD1 mouse model

Authors: *R. LI¹, S. T. NGO^{1,2,3,4}

¹The Univ. of Queensland, SBMS, Brisbane, Australia; ²Queensland Brain Inst., ³Ctr. for Clin. Res., The Univ. of Queensland, Brisbane, Australia; ⁴Dept. of Neurol., Royal Brisbane & Women's Hosp., Brisbane, Australia

Abstract: Amyotrophic lateral sclerosis (ALS) is a fatal neurodegenerative disease that primarily affects upper and lower motor neurons, causing progressive muscle wasting and paralysis. Systemic metabolic changes including rapid weight loss and impaired glucose and lipid handing have been observed in ALS patients and mouse models of ALS. While less is known about the mechanisms that contribute to metabolic abnormalities in ALS, recent evidence suggests that impairments in skeletal muscle metabolism may contribute to disease progression. In order to characterize alterations in skeletal muscle bioenergetics in ALS, we developed a novel method to assess real-time mitochondrial fuel utilization in intact extensor digitorum longus (EDL) muscle fibre bundles from the SOD1^{G93A} (SOD1) mouse model of ALS and littermatched wild type (WT) mice. In the presence of carbonyl cyanide-ptrifluoromethoxyphenylhydrazone (FCCP), EDL fibre bundles of mid-stage and end-stage SOD1 mice showed increased maximal capacity when utilizing pyruvate as a substrate, indicating that the mitochondrial oxidation capacity increased with the disease progression. Next, we determined the metabolic flexibility of muscle by assessing the ability of muscle fibres to oxidize a particular substrate (e.g. fatty acid) with or without the presence of alternative substrates (e.g. glucose or glutamine). By inhibiting pyruvate, long-chain fatty acid or glutamate transporters, we showed decreased glucose oxidation dependence and concomitant increased fatty acid oxidation dependence in EDL fibres of mid-stage SOD1 mice. Although we found increased intramuscular lipid accumulation in EDL muscle sections of mid-stage and end-stage SOD1 mice, the intact EDL fibres of end-stage SOD1 mice failed to oxidize stored intracellular lipids for energy after

the inhibition of pyruvate and glutamine utilization. Altogether, our study is the first to use realtime assessment of cellular bioenergetics to demonstrate a transition of fuel preference towards fatty acid oxidation in intact skeletal muscle of SOD1 mice. In line with the previous evidence of higher energy demands in muscle of SOD1 mice, our data suggest that enhanced mitochondrial oxidation, especially fat oxidation, may occur as a positive adaptive response to maintain the energy balance of skeletal muscle in ALS.

Abstract: Amyotrophic lateral sclerosis (ALS) is a fatal neurodegenerative disorder due to loss of upper and lower motor neurons (MNs). The mechanisms of neuronal death are largely unknown, thus prejudicing the successful pharmacological treatment. ASL is a multifactorial disease and one major cause for MN degeneration in ALS is represented by glutamate(Glu)-mediated excitotoxicity, sustained by glial uptake reduction (1), abnormal Glu release (2), and altered Glu receptor function (3). We reported that activation of Group I metabotropic Glu receptors (mGluR1, mGluR5) at glutamatergic spinal cord nerve terminals produces abnormal Glu release in the widely studied SOD1^{G93A} mouse model of ALS (4). We also reported that halving mGluR1 expression in the SOD1^{G93A} mouse had a positive impact on survival, disease onset and a number of cellular and biochemical clinical features of ALS (5). We generated here SOD1^{G93A} mice with reduced expression of mGluR5 (SOD1^{G93A}mGluR5^{-/+}) by crossing the SOD1^{G93A} mutant mouse with the mGluR5 heterozigous Grm5^{-/+} mouse. SOD1^{G93A}mGluR5^{-/+}

mice, and delayed pathology onset. These effects were associated to enhanced number of preserved MNs in the lumbar spinal cord; decreased expression of GFAP and CD11, as markers of astrocyte and microglia activation, respectively; reduced cytosolic free Ca²⁺ concentration and normalized Glu release in SOD1^{G93A}mGluR5^{-/+} mouse spinal cord synaptosomes. Unexpectedly, when studying disease progression by measuring the RotaRod task, the hind limbs extension reflex and gait impairment scores, only male SOD1^{G93A}mGluR5^{-/+} mice showed improved motor skills vs. SOD1^{G93A}mice, while SOD1^{G93A}mGluR5^{-/+} females did not. These results demonstrate that a lower constitutive level of mGluR5 has a significant positive impact in mice with ALS and support the idea that blocking Group I mGluRs may represent a potentially effective pharmacological approach to the disease. Title: Symptom severity in the acute phase following repeat mild TBI predicts early disease onset in the SOD1^{G93A} ALS rat model

Authors: *G. M. THOMSEN, N. CHO, N. DHILLON, M. ALKASLASI, P. HARO-LOPEZ, O. SHELEST, G. BARMPARAS, E. LEY Cedars-Sinai Med. Ctr., West Hollywood, CA

Abstract: Objectives: Populations prone to sustaining traumatic brain injury (TBI), including veterans and professional contact-sport athletes, might be at a higher risk of developing such neurodegenerative disorders as chronic traumatic encephalopathy (CTE) and amyotrophic lateral sclerosis (ALS). Currently, there is only a loose correlation between trauma and ALS, however, genetically predisposed animal models, such as the SOD1^{G93A} ALS rat that recapitulates the human condition, allow us to closely study this link.

We recently developed a novel model of repeat TBI associated with sustained motor deficits. Rats administered multiple TBI exhibit brain atrophy and tauopathy consistent with the TBIlinked neurological disease CTE. These sustained deficits and pathology have not been observed in other rodent TBI models that deliver one-time, or repeat, *unilateral* insults. Using this model to more accurately represent injuries sustained by populations such as professional athletes and veterans, we further explored the link between repeat TBI and the initiation of premature onset of ALS in SOD1^{G93A} rats.

Methods: SOD1^{G93A} rats were administered repeat TBI starting at (pre-symptomatic) postnatal day 60, whereby a closed-skull, bilateral controlled cortical impact (CCI) injury was delivered once weekly for 5 weeks. Uninjured SOD1^{G93A} sham controls were exposed to anesthesia only. TBI rats were classified as having "mild" or "severe" symptoms based on rotorod performance following the last injury. Rats were assessed weekly for motor function and followed to disease endpoint.

Results: SOD1^{G93A} rats administered repeat TBI that were observed to have initial severe rotorod deficits following their final TBI, exhibited forelimb paralysis significantly earlier than their SOD1^{G93A} sham counterparts (median onset: 150 vs 169 days, respectively p<.0001). Earlier disease onset translated into shortened survival in SOD1^{G93A} TBI rats relative to SOD1^{G93A} sham controls (median survival: 168 vs 179 days, p=.038), with no observed gender differences. Interestingly, rats exhibiting only mild initial rotorod deficits did not show exacerbation of disease.

Conclusions: We demonstrate using a SOD1^{G93A} rat model of ALS that recurrent TBI can lead to earlier disease onset. Our findings have important implications for those who are genetically predisposed to neurodegenerative diseases and suggest that for these individuals, exposure to austere environments or participation in sporting teams that have a high incidence for repeat concussions should be carefully considered.

Title: Studying neuroprotective mechanisms in the SOD1-G93A mouse model of Amyotrophic lateral sclerosis

Authors: *S. FIGUEROLA SANTAMONICA¹, F. DE LORENZO¹, M. SENDTNER², M. H. VOUTILAINEN¹, M. SAARMA¹ ¹Inst. of Biotech., Univ. of Helsinki, Helsinki, Finland; ²Univ. Wurzburg, Wuerzburg, Germany

Abstract: Amyotrophic lateral sclerosis (ALS) is a fatal neurodegenerative disease characterized by the progressive degeneration of motor neurons (MN) leading to muscle atrophy, paralysis and

eventually death of the patients within 1-3 years from onset of symptoms. To date, there is no curative treatment for ALS.

Motoneuron degeneration in ALS is caused by a complex interplay between multiple pathogenic processes. Molecular processes such as mitochondrial dysfunction, accumulation of SOD1 and TDP-43 protein aggregates, oxidative stress and Endoplasmic reticulum (ER) stress have been shown to contribute to dysfunction and death of MNs in ALS.

The aim of this study was to characterize the SOD1-G93A mouse model of ALS and study pathological mechanisms associated in the SOD1-G93A mouse model. The progression of the disease in SOD1-G93A mice was evaluated by body weight changes, signs of disease and behavioral tests such as rotarod, grip strength and multirod system. At the disease endpoint, mice were sacrificed and samples from spinal cord, gastrocnemius muscle and motor cortex were collected for the molecular analyses of unfolded protein response (UPR) pathways. SOD1 mice showed reduced body weight, survival and motor deficits as compared to wild type

littermates. In addition, MN number was reduced and UPR pathways activated in spinal cord of these mice.

In the poster, we will report the effects of new molecule in SOD1-G93A mouse model.

Title: SOD1^{G93A} astrocytes induce toxicity in motor neurons via a DR6-mediated pathway in ALS model

Authors: *V. MISHRA¹, V. LE VERCHE¹, D. B. RE², K. POLITI¹, P. RINCHETTI¹, M. J. ALVAREZ³, A. CALIFANO³, F. LOTTI¹, S. PRZEDBORSKI^{1,4} ¹Motor Neuron Ctr., ²Dept. of Envrn. Hlth. Sci., ³Dept. of Systems Biol., Columbia Univ., NY, NY; ⁴Dept. of Neurology, Pathology and Cell Biol., Columbia Univ., New York, NY

Abstract: Amyotrophic Lateral Sclerosis (ALS) is a progressive neurodegenerative disease caused by loss of motor neurons in the brain and spinal cord. Among the 10% familial cases of ALS, substitution in superoxide dismutase-1 (SOD1) gene at position G93 is one of the most

common mutations found in ALS. Previous results in the lab have shown that conditioned media from SOD1^{G93A}, but not SOD1^{WT} expressing astrocytes were able to induce toxicity specifically in primary and embryonic stem cell-derived motor neurons (ES-MNs). We combined proteomics and genomics approaches to understand how astrocyte conditioned media (ACM) exposure induces motor neuron death and to identify pivotal players driving the death phenotype. Death Receptor 6 (DR6) is one of the candidate genes, whose activity is upregulated in motor neurons treated with SOD1^{G93A} ACM. DR6 is a member of Tumor Necrosis Factor receptor superfamily (TNFRSF) family of receptors that has been shown to be involved in cell death signaling pathway and immunomodulation in various in vitro cancer cell models. Additionally, the role of DR6 in neurite growth is well established but its role in neuronal cell death pathway is still unclear. We hypothesize that DR6 might be one of the upstream signaling molecules involved in initiation of motor neuron cell death. Indeed, cell culture-based experiments showed that DR6 KO motor neurons show protection against toxicity induced by SOD1^{G93A} expressing astrocytes compared to WT motor neurons. To further verify these results in animal models, we used DR6 knockout mice and viral transduction of motor neurons to assess the consequences of reduced DR6 levels on the disease phenotype of ALS mice. We performed a panel of morphological assays to determine the effect of reduced DR6 signaling on motor neuron survival and neuromuscular junction (NMJ) innervation. SOD1^{G93A} mice with DR6 knock-down exhibited improvement in motor neuron survival (P120) compared to SOD1^{G93A} alone but, no difference was detected in NMJ denervation at this time. In-spite of modest improvement in motor neuron counts, there was minimal effect on disease onset and survival in SOD1^{G93A} mice with reduced DR6 levels. Functional recovery evaluated by behavioral testing showed transient improvement in grip strength. Current efforts are focused on establishing an inducible ES-derived model to study the molecular pathways that lead to motor neuron-specific cell death by DR6 activation. This study will provide an insight into the possible mechanisms involved in the signaling cascade leading to motor neuron death, and in combination with NMJ preserving compounds, might lead to new therapies for preventing or delaying ALS.

Title: Towards syncing polytherapy to the multi-factorial dynamics of the SOD1 G93A ALS pathology

Authors: A. LEE¹, S. TRAVAGLINO¹, T. KITTEL¹, *C. S. MITCHELL² ¹Biomed. Engin., Georgia Inst. Technol., Atlanta, GA; ²Biomed. Engin., Georgia Inst. of Technol., Atlanta, GA

Abstract: An expansive range of preclinical ALS treatments have been evaluated in SOD1 G93A mice with limited success. Given temporal dynamics are crucial to homeostasis, we hypothesize that the perceived failure of previous preclinical and clinical treatments may be due to the fact they targeted only one factor or were not optimally timed to the corresponding ALS disease stages, where the pathophysiology is dynamically ever-changing and has been found to be mathematically unstable. That is, ALS may require combination treatments or "polytherapy" initiated in sync with the corresponding target dynamics associated with each pathophysiologically distinct disease stage; such therapies may not necessarily target the initiating mechanistic perturbation, but rather, compensatory regulatory system dynamics capable of restoring homeostasis to halt the spread of motoneuron death. The long-term goal of the present work is to devise a multi-faceted polytherapy strategy that considers ALS dynamics at each disease stage and is clinically translatable. To this end, we first assess the efficacy of individual preclinical treatments targeting specific categories of ALS pathophysiology as a function of time, disease stage, and assessment modality (e.g. survival, general health, muscle function, time of onset). The approach consists of performing a multi-treatment meta-analysis of data transcribed from over 3,800 peer-reviewed studies to compare the individual effects of all 9 ALS ontological pathophysiology treatment targets (e.g. apoptosis, axonal transport, cellular chemistry, energetics, excitability, inflammation, oxidative stress, proteomics, and systemic) over 7 temporal stages throughout the in vivo SOD1 G93A mouse lifespan (on average, about 150 days). A sub-set of data, which experimentally examined the simultaneous or serial usage of two or more pathophysiological treatment categories is compared to the at-large traditional individual categorical treatments. Our presented results illustrate the best treatment targets at each temporal disease stage and their quantified efficacy as a function of assessment modality. Secondly, we present updated computational models to continuously assess inter-relationships and regulatory compensation needed to maintain motoneuron homeostasis in the physiological wild type system and re-establish post-onset homeostasis in the pathological ALS system. The latter models provide a foundation for in silico identification and testing of promising ALS polytherapy strategies precisely timed to maximally target pathology dynamics.

Title: Point mutations within Tardbp differentially affect TDP-43 functions

Authors: *A. ACEVEDO AROZENA^{1,2}, T. RICKETTS², P. SIVAKUMAR³, H. OLIVEIRA², V. PLAGNOL³, K. LO³, J. HUMPHREY³, E. M. C. FISHER³, P. FRATTA³ ¹Unidad de Investigación, Hosp. Universitario De Canarias, La Laguna, Spain; ²MRC Mammalian Genet. Unit, Harwell, Oxfordshire, United Kingdom; ³UCL, London, United Kingdom

Abstract: We generated and fully characterised two novel mouse models of TDP-43 proteinopathies, developed using *N*-ethyl-*N*-nitrosurea (ENU) mutagenesis, each containing a single substitution within the coding region of the mouse endogenous *Tardbp* gene. The first mutation (**F210I**) lies within the second RNA recognition motif (RRM2). The second mutation (**M323K**) occur within the C-terminal glycine rich domain where the majority of ALS/FTD causing mutations are found. However, none of the mutations have been reported in human patients. Both models have been extensively studied through behavioural and histopathology analysis. At the molecular level, RNA sequencing was used to examine alternative splicing events and differential gene expression from different systems, while individual nucleotide resolution crosslinking and immunoprecipitation (iCLIP) highlighted changes in RNA-binding patterns of the TDP-43 mutants. Severe molecular dysregulation was identified in both mouse mutants, alongside opposite changes in TDP-43 splicing activity.

The F210I mutation leads to a dose dependent loss of TDP43 function via diminishing RNA binding capacity. Homozygous animals ($Tardbp^{F210I/F210I}$) are not viable, but depending on genetic background can survive up to E18.5. Heterozygous ($Tardbp^{F210/+}$) mice do not develop neurodegeneration but display extensive genome-wide molecular changes at the splicing and expression levels. Although the total TDP-43 protein levels are not changed by the F210I mutation, we detected changes in the processing of the *Tardbp* transcript potentially impacting on TDP-43 autoregulation mechanism.

The M323K mutation leads to opposite effects to the F210I mutation in TDP-43 mediated splicing activity. The mutation does not affect RNA binding or TDP-43 protein levels. Homozygous mice (*Tardbp*^{M323K/M323K}) survive to adulthood on a mixed genetic background, and we are currently finishing their behavioural and histopathological analysis. Overall, here we show that point mutations within the *Tardbp* gene can differentially affect TDP43 known functions. The array of RNA binding and processing features disrupted by each mutation

provides novel insights into how TDP-43 regulates RNA processing *in vivo*, revealing potential early molecular mechanisms in the development of ALS.

Title: Muscle fiber atrophy in tibialis posterior of a TDP-43 over-expressing mouse

Authors: *L. HEYBURN¹, M. HEBRON², C. E. MOUSSA², B. T. HARRIS² ²Neurol., ¹Georgetown Univ., Washington, DC

Abstract: TAR DNA binding protein (TDP-43) is a DNA/RNA binding protein whose expression is altered in diseases of TDP-43 pathology including amyotrophic lateral sclerosis (ALS) and frontotemporal lobar degeneration (FTLD). Amyotrophic lateral sclerosis (ALS) is a progressive neurodegenerative disease affecting both upper and lower motor neurons in the brain and spinal cord, respectively. ALS affects neurons that innervate skeletal muscles and control voluntary movement. Some forms of FTLD also involve motor neuron degeneration (FTLD-MND). Loss of motor neuron input into the skeletal muscles leads to muscle weakness and atrophy, eventually leading to respiratory failure. Roughly 70% of ALS patients present with limb onset weakness, with symptoms eventually spreading to other areas. Patients with mostly lower motor neuron forms of ALS have a slower disease progression and have single muscle fibers with a larger cross-sectional area than patients with a quicker disease progression. There is currently no cure for TDP-43 pathologies, however, our group has been investigating the use of tyrosine kinase inhibitors (TKIs) for the treatment of neurodegenerative diseases. Nilotinib is a TKI that is FDA-approved for the treatment of chronic myelogenous leukemia. We have previously shown that it can induce autophagy and reduce levels of the ALS-associated protein TDP-43 in vitro and in vivo. In this study, we use a hemizygous transgenic mouse model that overexpresses human wild-type TDP-43 in neurons to examine spinal cord and skeletal muscles for signs of changes like those seen in TDP-43 pathology. This model uses a Thy1 promoter, which restricts transgene expression to neurons, allowing us to understand how changes to TDP-43 in motor neurons may affect muscles. Homozygous TDP-43 overexpressors do show signs of an ALS-like phenotype, but the hemizygous mice used in this study do not have an overt

phenotype of muscle weakness or motor deficits. We treated these hemizygous transgenic mice (n=4 per group) with nilotinib for 4 weeks and examined spinal cord motor neurons and muscle fibers in the tibialis posterior and compared with untreated transgenic and wild-type mice. We found that overexpression of TDP-43 in this mouse does not lead to a significant reduction in spinal cord motor neuron count, but does lead to a significant reduction in average muscle fiber area, indicating that these hemizygous mice exhibit low level muscle atrophy. In addition, treatment with nilotinib did not significantly increases muscle fiber size or spinal cord motor neuron count compared to control-treated transgenic mice.

Title: Regulation of CDC7 kinase activity controls pathological TDP-43 phosphorylation

Authors: *N. LIACHKO, H. CURREY, B. C. KRAEMER GRECC, VA Puget Sound Hlth. Care Syst., Seattle, WA

Abstract: Amyotrophic lateral sclerosis (ALS) and frontotemporal lobar degeneration (FTLD) are two devastating fatal neurodegenerative diseases. Over 90% of ALS cases and approximately 50% of FTLD cases are characterized by pathological inclusions containing the protein TDP-43. Mutations in TARDBP, the gene coding for TDP-43, cause some cases of familial ALS and have been identified in patients with sporadic ALS and FTLD, indicating that TDP-43 functions are critical for neuronal health. While numerous post-translational modifications of TDP-43 have been identified in disease, phosphorylation events at TDP-43 serines 409 and 410 are consistently present and used diagnostically to identify pathological TDP-43-positive inclusions. Phosphorylation of TDP-43 (pTDP) reduces its turnover, increases its aggregation, and promotes neurotoxicity and neurodegeneration. We found that the kinase CDC7 is a key regulator of pTDP accumulation in C. elegans and cell culture models of ALS and FTLD [1]. By phosphorylating TDP-43, CDC7 increases levels of neurotoxic pTDP and worsens disease phenotypes, including neurodegeneration. We have identified post-translational modifications of CDC7 that coincide with a shift in its cellular localization. This shift precedes TDP-43 phosphorylation, and may represent a cellular response to genotoxic stress. Understanding the regulation of TDP-43 phosphorylation will provide insight into the causes of TDP-43 proteinopathies, and may lead to additional targets for therapeutic intervention.

Title: Activation of PI3K/mTOR pathway alleviates TDP-43-induced axonopathy in the spinal motor neuron in a zebrafish ALS model

Authors: *K. ASAKAWA^{1,2}, K. KAWAKAMI^{1,2}

¹Natl. Inst. of Genet., Mishima / Shizuoka, Japan; ²SOKENDAI, MIshima / Shizuoka, Japan

Abstract: TAR DNA-binding protein 43 (TDP-43, *TARDBP*) is a major component of the cytoplasmic inclusions that are a pathological hallmark of amyotrophic lateral sclerosis (ALS). While the spinal motor neuron is a primary target for degeneration in ALS, how TDP-43 leads to dysfunction and degeneration of the spinal motor neuron has not been fully understood. In order to understand early pathological changes caused by TDP-43 toxicity, an animal model that allows for monitoring an identified single spinal motor neuron *in vivo* should prove effective. Exploiting the optical and genetic accessibility of zebrafish, we focus on the spinal motor neuron CaP, which is uniquely present in each spinal hemisegment and innervates a defined territory within the ventral myotome. We find that both systemic knockout and targeted overexpression of TDP-43 result in axonal outgrowth defects in CaPs, suggesting that dysregulation of TDP-43 at the protein level causes a reduction in motor unit size. Furthermore, *in vivo* two-photon calcium imaging reveals that the CaPs overexpressing TDP-43 display attenuated calcium transients in both the cell body and axon terminals during fictive swimming, indicating a reduced neuronal excitability. Consistent with this observation, pan-neuronal overexpression of TDP-43 results in

an impaired swimming activity. By using this transgenic zebrafish ALS model, we explore biological pathways that rescue the toxicity associated with an elevated TDP-43 level. We discover that the targeted activation of PI3K α effectively restores the axonal outgrowth of CaPs overexpressing TDP-43. The defects in neuromuscular synapse formation and neuronal excitability are also rescued, albeit partially, by the PI3K α activation. The bath application of rapamycin, an inhibitor of the mTOR protein kinase, blocks the PI3K α -mediated restoration of the axonal outgrowth, suggesting that mTOR is a downstream effector the rescue effect. Intriguingly, while rapamycin treatment inhibits the axonal outgrowth of CaPs in the wild type fish, it does not exacerbate the axonal outgrowth defect caused by TDP-43 overexpression, implying that TDP-43 causes the axonal outgrowth defect through inhibiting the mTOR pathway. These observations suggest that an elevated TDP-43 level hampers axonal outgrowth through attenuating the PI3K α /mTOR pathway that promotes axonal outgrowth in the spinal motor neuron. Therefore, activation of the PI3K α /mTOR pathway might serve as a potential strategy to maintain or restore motor unit size in ALS.

Title: *In vivo* characterisation of neurodegeneration and TDP-43 redistribution following UV induced stress in the Zebrafish spinal cord

Authors: *A. J. SVAHN, R. RADFORD, E. K. DON, N. J. COLE, R. CHUNG, M. MORSCH MND Res. Centre, Dept. of Biomed. Sci., Macquarie Univ., Sydney, Australia

Abstract: The clinical progression of motor neuron disease (MND) suggests a pathological spread of neurodegeneration through the nervous system. The mechanisms that are responsible for the spread of neurodegeneration are not known. *In vitro* evidence has emerged for a 'prion-like' spread of aggregates from cell to cell.

To follow the time-course of neurodegeneration and examine the potential for transfer of proteins following cell stress *in vivo*, we took a live imaging approach in the Zebrafish spinal cord. We tracked fluorescently labelled cell membranes and the RNA binding protein TDP-43, which has been identified as the main protein of pathological inclusions that characterise MND and frontotemporal lobar dementia (FTLD).

Live imaging following selective UV pulse targeting of a single motor neuron in the zebrafish
spinal cord induced cell stress and an apoptotic or necrotic process. Ablated and dying neurons showed characteristic morphological changes, including the shrinkage of the cell soma, and progressive anterograde degeneration (blebbing) commencing at the target site and continuing along the axon over time. In the healthy, developing spinal cord this resulted in rapid attraction of local microglia and take-up of the cell body containing TDP-43. In the absence of microglia following PU.1 (spi1b) knockdown, stressed motoneurons underwent a stereotyped process of neurodegeneration including redistribution of TDP-43 from the nucleus, exosome shedding and eventual cell breakdown.

This real-time representation of TDP-43 redistribution and microglial phagocytosis in the living zebrafish spinal cord provides novel opportunities to study the mechanisms of the spread of neurodegeneration.

Title: Impaired mitophagy in ALS mice results in degeneration of neuromuscular junctions

Authors: *R. S. ROGERS¹, S. TUNGTUR¹, T. TANAKA¹, Y. BADAWI¹, L. L. NADEAU¹, H. WANG², H.-M. NI², W.-X. DING², H. NISHIMUNE¹ ¹Anat. & Cell Biol., ²Pharmacology, Toxicology and Therapeut., Univ. of Kansas Med. Ctr., Kansas City, KS

Abstract: Amyotrophic lateral sclerosis (ALS) is a motor neuron disease starting from degeneration of pre-synaptic nerve terminals, known as a dying back neuropathy. Defects in autophagy play an important role in the progression of nerve terminal degradation in ALS.

Importantly, some familial ALS patients have a mutation in an important autophagic gene, SQSTM1. Using an animal model of ALS, SOD1^{G93A} mice, we examined whether defects in mitophagy, the autophagic process of degrading depolarized and degenerating mitochondria, play a role in motor neuron degeneration. Neuromuscular junctions (NMJs) of SOD1^{G93A} mice have a greater number of autophagosomes and degenerated mitochondria compared to wild-type mice. These changes precede similar changes that occur in motor neuron cell bodies. Importantly, we detected mitophagosomes at NMJs of SOD1^{G93A} and wild-type mice, but the number of mitophagosomes in NMJs did not increase in parallel with the accumulation of degenerated mitochondria – indicating a potential defect in mitophagy in SOD1^{G93A} mice. In addition, content of mitophagic proteins were lower in motor neuron cell bodies of SOD1^{G93A} mice compared to wild-type mice. To establish a causal role for defective mitophagy in the progression of motor neuron degeneration, we examined double knockout mice of PTENinduced putative kinase 1 (Pink1) and Parkin. Pink1 and Parkin are essential for sensing depolarized, degenerating mitochondria and recruiting autophagosomes to these mitochondria. Pink1/Parkin double knockout mice at 4 months of age exhibited degeneration and denervation of NMJs and accumulation of mitochondria in NMJ presynaptic terminals. Together these data support that defective mitophagy plays a role in motor neuron degeneration in ALS.

Title: A resource for research on peripheral neuropathy using mouse models at The Jackson Laboratory

Authors: *K. L. SEBURN, R. W. BURGESS, C. M. LUTZ Jackson Lab., Bar Harbor, ME

Abstract: Inherited peripheral neuropathy, or Charcot-Marie-Tooth disease (CMT), constitutes an important area of research given its cumulative frequency of greater than 1 in 2500 people and the lack of any curative treatments. Mouse models of inherited peripheral neuropathy contribute to this research effort, but also present challenges in terms of accessibility, varying degrees of face validity, and poorly defined genetic backgrounds. To improve the usefulness of mouse

models of inherited peripheral neuropathy, and to facilitate rigor and reproducibility between investigators, we have created the Resource for Research on Peripheral Neuropathy at The Jackson Laboratory (www.jax.org/rrpn, email: peripheral.neuropathy@jax.org), funded by NINDS (R24 NS098523). The goal of this resource is to import existing models of CMT, and to create new models using genetic engineering when suitable models do not already exist. We anticipate adding five to ten models per year to this resource, with advice on prioritization coming from our external steering committee. These mice are then placed on a defined genetic background and made available to the research community through The Jackson Laboratory's Mouse Repository under standard terms of use. In addition to these models being available through the highly visible and accessible JAX Catalog, the resource will also perform baseline phenotyping using a battery of clinically relevant tests. This data, and the phenotyping protocols, will also be publicly available. In this way, the models are validated for their disease relevance, and interested investigators can use public data concerning sex differences, age of disease onset, and severity of disease for planning experiments, performing power analyses, etc. Thus, the Resource for Research on Peripheral Neuropathy serves as an example of how animal models can be generated and made available for research with optimal rigor and reproducibility of both the mice and the data.

Title: Animal model indicating an interaction between MS and exercise's impact on adult hippocampal neurogenesis

Authors: *J. KLEINER¹, B. M. SCHILDER¹, C. SHERWOOD², K. A. PHILLIPS³ ²Anthrop., ¹George Washington Univ., Washington, DC; ³Psychology, Trinity Univ., San Antonio, TX

Abstract: While multiple sclerosis (MS) is typically understood as an autoimmune disease that degrades motor functioning, it can also have significant impacts on cognition. Previous studies suggest that MS affects the hippocampus, damaging patients' cognitive spatial and memory

abilities.Dysregulation of adult hippocampal neurogenesis (AHN), the birth of new granule cells (neuroblasts) which are necessary for proper memory formation, may be a mechanism by which MS disrupts hippocampal functioning. Some research suggests that exercise may lessen some neuropathological effects of MS. The present study utilized marmoset monkeys (Callithrix *jacchus*) to model the neurobiological impacts of MS and exercise therapy on AHN. Eight adult male marmosets were sensitized to myelin oligodendrocyte (MOG) glycoprotein (MOG 34-56) in incomplete Freund adjuvant. This was injected into eight adult male marmosets, inducing autoimmune encephalomyelitis (EAE) which models the neurobiological effects of MS in humans with relapse-remitting MS. An additional four control subjects were injected with incomplete Freund adjuvant alonesaline. Half of the EAE and control subjects engaged in aerobic exercised for 30 minutes, three days/week for 10 weeks. Sections across the anteroposterior length of the hippocampus were immunohistochemically stained for doublecortin (DCX) as a marker for neuroblasts. Stereologic counts of the absolute number, proportion (relative to granule cells) and density of DCX cells were quantified in the dentate gyrus of the hippocampus, divided into the Granule Cell Layer (GCL) and the Subgranular Zone (SGZ), where neuroblasts proliferate. Our findings showed that although neither EAE nor exercise statuses had a significant main effect on any of the DCX cell measures alone (p><0.05), there was a significant interaction between these two variables (ANOVA, Fdf=7.103, p=0.029). Exercise increased absolute DCX cell numbers in the EAE group but decreased it in the control group. Similarly, non-significant trends were observed for %DCX cells and DCX cell density. These results suggest a relationship between exercise and EAE's impact on AHN. This supports the hypothesis that exercise mitigates the impacts of MS on AHN. Thus, this interaction may be a physiological explanation of the benefit human patients see with exercise therapy, regarding spatial and memory cognition.

Title: Environmental and genetic contributions in an ALS rat model: Failed recovery and enhanced ventral horn inflammation after peripheral nerve injury

Authors: *S. SCHRAM¹, D. CHUANG², H. PIPONOV², C. HELDER², G. SCHMIDT², R. MICHAEL², F. SONG¹, J. KERNS², M. GONZALEZ², J. LOEB¹ ¹Neurosci., Univ. of Illinois - Chicago, Chicago, IL; ²Univ. of Illinois at Chicago, Chicago, IL

Abstract: Background: ALS is poorly understood and no effective therapeutics exist to stop its insidious progression. For some it starts in a hand or a foot, and in others with trouble swallowing. Once it starts, the disease progresses along the spinal cord, ultimately resulting in respiratory failure. Clinicopathologic human studies have shown a clear relationship between disease onset and lower motor neuron loss, with the most severe lower motor neuron loss at the site of disease onset. One long entertained observation is that ALS may be precipitated by nerve or brain injury. In fact, many patients with ALS are veterans or athletes (Lou Gehrig) and may have suffered minor nerve injuries in the limb where ALS first presents. However, it is unclear whether and how nerve injury plays a role in ALS development. A growing number animal models for ALS are based on human genetic forms of the disorder, but a large number of therapeutic interventions that showed efficacy in these models have failed in human clinical trials. Our lab and others have previously shown an increase in spinal cord microglial activation in post-mortem ALS patient tissue, as well as at early stage in animal models of ALS, suggesting microglial activation contributes to early stages of neurodegeneration. Objectives: Our current study seeks to link an environmental factor (nerve injury) with a genetic factor (SOD1 mutation) to induce symptom onset and disease progression. Methods: We performed sciatic nerve crush injuries in SOD1 G93A rats and littermate wild type controls in early disease stage, prior to any known symptoms. Functional recovery using the Extensor Postural Thrust (EPT) test was tracked weekly. Spinal cord tissue was collected at different stages of disease for staining and quantitative analysis. Results: Significantly enhanced and sustained microglial activation was seen in the ventral horns of SOD1 rats at 1 and 2 weeks after injury that spread to nearby, uninjured motor neuron pools. This microglial activation in the SOD1 animals subsided by 7 weeks. While wild type animals showed full functional recovery by 4 weeks, the SOD1 animals never fully recover. Long term effects of this early injury on survival and the underlying mechanism by which enhanced inflammatory mechanisms lead to failed recovery are currently being investigated. Discussion: These studies take a unique approach to understand the effects of early environmental contributions (nerve injury) in a genetic model of ALS. The system developed could be an important new model for drug development that focuses on disease onset and progression rather than traditional models of survival and may therefore translate better to the human condition.

Abstract: DiGeorge/22q11 Deletion Syndrome (22q11DS), a micro-deletion of 30 to 50 genes on human chr.22, is associated with neurodevelopmental disorders. Cardiovascular and craniofacial abnormalities as well as intellectual disability, schizophrenia, autistic spectrum or attention deficit/hyperactivity disorders define the 22q11DS clinical phenotypic spectrum. 22q11DS craniofacial anomalies are also linked to common perinatal feeding and swallowing disorders (dysphagia) whose origins remain poorly understood. We have shown that the LgDel mouse model of 22q11DS recapitulates the human phenotypic spectrum including perinatal dysphagia, prefigured by disruption of hindbrain patterning and cranial nerve differentiation in LgDel embryos. We also found that changes in neuronal excitability in hypoglossal nucleus (nXII) motoneurons recorded in brainstem slices from one week old LgDel mouse pups accompany LgDel perinatal dysphagia. We therefore asked whether nXII cytological abnormalities are also associated with LgDel feeding/swallowing difficulties. We used a ChAT:GFP reporter to identify and visualize nXII motorneurons. Motorneuron morphology and perikaryal volumes are altered in LgDel nXII. Confocal 3D reconstructions of single biocytininjected nXII motorneurons demonstrate dendritic and axonal abnormalities, including degenerating dendrites. Finally, block-face scanning electron microscopy allowed integrated analysis of nXII location, neuronal identity and ultrastructural characteristics in individual mouse pups. We confidently identified dilated mitochondrial cristae, pale mitochondrial matrix, and swollen Golgi and endoplasmic reticulum in nXII motoneurons of one week old LgDel but not wild type pups. At later ages, we found that LgDel nXII motorneurons and interneurons have cytoskeletally sparse, organelle depleted, pale cytoplasm, as well as reduced synaptic frequency. In addition, there is pronounced hypertrophy of perineuronal as well as perivascular astrocytic processes, especially around capillaries. In these *LgDel* mice there is limited evidence of dark degeneration; however we find no evidence of condensed chromatin and nuclear envelope changes associated with neuronal apoptosis. These results suggest that non-apoptotic neuronal degeneration in LgDel nXII may contribute to perinatal dysphagia. The developmental and degenerative changes in cranial nerve circuits for feeding and swallowing may reflect diminished dosage of several 22q11 genes that regulate neuronal mitochondrial metabolism.

Title: Branch-specific assembly and disassembly precedes global motor-unit degeneration in a model of amyotrophic lateral sclerosis

Authors: *E. MARTINEAU¹, A. DI POLO^{1,2}, C. VANDE VELDE^{1,2}, R. ROBITAILLE¹ ¹Dept. de neurosciences, Univ. de Montréal, Montreal, QC, Canada; ²Ctr. de recherche du Ctr. Hospitalier de l'Université de Montréal, Montréal, QC, Canada

Abstract: Amyotrophic lateral sclerosis (ALS) is a late-onset neurodegenerative disease affecting motor neurons. Although loss of neuromuscular junction (NMJ) is an early event, it remains unclear whether it is a consequence of local pathological signals or the expression of a degenerating neuron. Single time point observations show that a subgroup of degenerating motor neurons retract from their NMJs while a distinct population compensates via collateral sprouting. This strongly suggests that NMJ denervation is mainly dependent on the state of the neuron which innervates it. However, the rescue of motor neuron death does not necessarily rescues NMJ loss, suggesting that the local neuromuscular environment may play a key role. If that is the case, the initial loss of NMJs should be branch-specific and asynchronous within a single axonal arborization (motor-unit). Thus, we sought to directly assess the time course of structural changes within single motor-units using repeated in vivo imaging over a 3 month period in a slow progressing model of inherited ALS (SOD1^{G37R} mice). Here we show in symptomatic mice that individual terminal axon branches and synapses are dismantled asynchronously for weeks before the whole motor axon degenerates. Denervation events tend to propagate from the first lost NMJ in an axonal arbor, with distal branches being more susceptible. This precise spatiotemporal pattern implies that local micro-environment factors are involved. Surprisingly, we observed that dismantling of individual axonal branches is accompanied by simultaneous axonal

sprouting and synapse formation onto nearby NMJs. Axonal arborizations sprouted almost exclusively onto NMJs that they did not initially innervate, thus increasing motor-unit size. Paradoxically, motor-units failed to re-innervate their dismantled NMJs which further suggest that local signals dictate the pattern of neuromuscular remodeling in ALS. This motor-unit dynamism was phenotypically silent as indicated by grip strength and body weight measurements. Our results support a model in which NMJ denervation in ALS is a dynamic, initially slow, process of continuous denervation and new innervation. This raises stabilization of NMJs or enhancement of re-innervation as attractive therapeutic targets for ALS.

Title: Novel mouse model of an amyotrophic lateral sclerosis-associated profilin 1 mutation

Authors: *M. E. BRETTLE, H. STEFEN, A. DJORDJEVIC, J. W. CHAN, S. FOK, F. DELERUE, Y. D. KE, L. M. ITTNER, T. FATH Sch. of Med. Sci., UNSW Australia, Randwick, Australia

Abstract: Amyotrophic lateral sclerosis (ALS) is the most common form of motor neuron disease. Sporadic and familial forms of disease present with similar clinical symptoms and histopathology. Understanding the underlying pathogenesis of the disease is essential for the development of treatments. Mutations in the actin-associated protein, profilin 1, have been identified as a rare cause of familial ALS. We have developed a novel mouse model to elucidate the role that PFN1^{C71G} plays in ALS. Expression of V5-tagged PFN1^{C71G} is targeted to α -motor neurons in the spinal cord. Initial data shows V5-PFN1^{C71G} expression in the anterior horn of the neural tube starting from embryonic stages in transgenic mice. Motor testing shows that transgenic mice have motor deficits on RotaRod commencing at 1 months of age. This novel mouse model of PFN1^{C71G} will provide a potential tool to understand the role that PFN1 plays in the pathogenesis of ALS and could be used for testing future ALS therapeutics.

Title: Exosome-derived from bone marrow mesenchymal stem cells promote retinal ganglion cell survival

Authors: B. MEAD¹, *S. I. TOMAREV²

¹Section of Retinal Ganglion Cell Biol., Natl. Eye Institute, NIH, Bethesda, MD; ²SRGCB, LRCMB, NEI, NIH, Bethesda, MD

Abstract: The loss of retinal ganglion cells (RGC) and their axons is a leading cause of blindness and includes traumatic (optic neuropathy) and degenerative (glaucoma) eye diseases. Mesenchymal stem cells (MSC) have demonstrated significant neuroprotective and axogenic effects on RGC in both of the aforementioned models. The present study aimed to test neuroprotective properties of exosomes isolated from bone marrow-derived MSC (BMSC) in a rat optic nerve crush (ONC) and microbeads or laser photocoagulation glaucoma models. Exosomes were isolated from human BMSC and characterized by NanoSight, flow cytometry and CD63 ExoELISA. Using an *in vitro* axotomized rat RGC model and *in vivo* rat models of ONC and glaucoma, $3x10^9$ exosomes were treated/injected into the cell culture well/vitreous. To measure their neuroprotective and axogenic capacity immunochemistry, optical computerized tomography (OCT) and electroretinography (ERG) were used. The composition of miRNA in exosomes from human BMSC and control human fibroblasts was investigated by RNA sequencing and used to identify candidate target mRNA in RGC.

Both BMSC and fibroblasts secrete similar numbers of exosome as detected and analysed by ExoELISA, electron microscopy, flow cytometry and NanoSight. Treatment of RGC cultures with exosomes led to significant RGC survival (299 ± 24.1 RGC/well) compared to both fibroblast exosome treated (72.3 ± 6.4 RGC/well) and untreated (121.3 ± 6.2) cultures. Following intravitreal transplantation, exosomes successfully integrated into the inner retinal layers, including RGC layer. After ONC (21d), BMSC exosomes provided significant therapeutic effects as compared with fibroblast exosomes or uninjected eyes. For the three measured outputs, the thickness of the retinal neve fibre layer was $33.8 \pm 4.8 \mu m$, $21.6 \pm 1.5 \mu m$, and $18.0 \pm 2.1 \mu m$, respectively; RGC density was $73.3 \pm 7.8/mm$ of retina, $20 \pm 2.2/mm$ of retina, and $23.6 \pm 7.7/mm$ of retina, respectively; and positive scotopic threshold response was $28.6 \pm 8.1 \mu v$, $13.2 \pm 3.4 \mu v$, and $13.7 \pm 1.1 \mu v$, respectively. The significant therapeutic benefits

were also seen in the treatment of glaucoma models. The therapeutic benefit of BMSC exosomes was reduced significantly if isolated from BMSC following knockdown of Argonaute 2, a protein that complexes with miRNA and is integral to their function. RNAseq analysis of miRNA from BMSC and fibroblasts exosomes identified over 20 candidate miRNA that were expressed exclusively or significantly higher in BMSC exosomes.

We demonstrate for the first time that BMSC-derived exosomes offer significant therapeutic benefit to the protection of RGC, an effect mediated at least partially by their miRNA.

Services, Bethesda, MD; ³BioSEaD, LLC, Rockville, MD; ⁴Walter Reed Army Inst. of Res., Silver Spring, MD

Abstract: The exposure to organophosphorous (OP) compounds such as the chemical warfare nerve agent soman (GD) can induce *status epilepticus* (*SE*) and brain damage through inhibition of acetylcholinesterase followed by glutamate excitotoxicity. Studies were conducted to investigate the long-term neurological and cardiovascular changes that occur after subcutaneous exposure to 1.0 LD₅₀ GD. Adult male Sprague-Dawley rats implanted with telemetry devices to continuously record EEG, ECG, EMG, body temperature and activity received 1.0 LD₅₀ GD (s.c.) followed by an admix (i.m.) of atropine sulfate (ATS; 2 mg/kg) and the oxime HI-6 (93.6 mg/kg) at 1 min after exposure to increase survival, and diazepam (DZP; 10 mg/kg; s.c.) at 30 min after onset of *SE*. Rats were continuously monitored for up to 10 months after GD exposure for physiological changes. Rats exposed to GD that developed *SE* displayed an increase in the EEG power in the delta and theta band. The power in delta, theta and alpha band remained chronically increased following GD exposure until the end of the study, while the power in the beta band decreased. GD-exposed rats that had *SE* developed spontaneous recurrent seizures (SRS; latency 5-120 days) with increased incidence over time. By 10 days post-SE, ~30% of rats

developed SRS; by 60 days post-SE, ~70% of rats developed SRS, and by 120 days post-SE, 100% of rats had developed SRS. Rats also presented hyperactivity, prolonged QTc intervals and transient increase of heart rate and ECG-derived respiration (EDR). The EMG power spectra increased during behavioral seizure activity and decreased after treatment with DZP. Transient drop in body temperature occurred in all GD-exposed rats but was faster in rats that did not seize. GD-exposed rats that developed *SE* and SRS had significant neuronal loss 10 months after exposure. This natural history study demonstrates that with time, epileptogenesis occurs in the majority of GD-exposed rats that display *SE*.

DSI supplied HD-S02 telemetry implants

Title: Evaluation of an improved telemetry transmitter (HD-S02) in experimental pharmacology studies to assess seizure activity in rats

Authors: *M. D. FURTADO^{1,2}, C. SCHULTZ³, T. HAAS⁴, F. ROSSETTI⁵, M. STONE³, B. MARRERO-ROSADO³, L. A. LUMLEY³

¹Anatomy, Physiol. and Genet., USUHS, Bethesda, MD; ²BioSEaD, LLC, Rockville, MD; ³US Army Med. Res. Inst. of Chem. Def., Aberdeen Proving Ground, MD; ⁴Data Sci. Intl., St. Paul, MN; ⁵Walter Reed Army Inst. of Res., Silver Spring, MD

Abstract: The use of telemetry for EEG recording is the most reliable option in experimental pharmacology and physiology because it reduces animal stress, which leads to an increase in data quality. Despite some disadvantages, such as a reduced number of channels when compared to tethered EEG systems, it better identifies oscillatory brain patterns that are pathological as a result of neurological injury. The development of small wireless telemetry systems with good

signal to noise ratio and spectral resolution enables an in-depth inspection of EEG activity in small animals during events such prolonged seizures (status epilepticus - SE). Also, EEG recordings allow us to detect more epileptic abnormalities than does observation of behavioral seizures alone. We present here a telemetry transmitter (HD-S02) capable of signal acquisition at a higher sampling rate (375 Hz) when compared to our previous iterations (240 Hz). Additionally, an automatic calibration of each channel is implemented with no need to manually input the specific frequencies for each device. The battery can last for up to 5 months of continuous use, which is crucial in experimental epilepsy studies when spontaneous recurrent seizures (SRS) can be delayed in development and brief compared to the initial status epilepticus. Also, the longer battery life of the HD-SO2 reduces need for multiple surgeries to replace battery packs as is needed with some other transmitter types. The battery run-time is conveniently monitored and cross-talk is detected when multiple animals are placed closer than the recommended distance. Each transmitter broadcasts its own signal identification, and as a result, the recording stops when an animal is placed on the wrong receiver or too close to the receiver, thus avoiding the recording of invalid data. To test the efficacy of the new transmitters, male rats implanted with HD-S02 to continuously record the EEG, body temperature and activity received 1.2 LD₅₀ GD (s.c.) followed by an admix (i.m.) of atropine sulfate (ATS; 2 mg/kg) and the oxime HI-6 (93.6 mg/kg) at 1 min after exposure to increase survival, and midazolam (MDZ; 3 mg/kg; i.p.) with or without an experimental antiepileptic drug (lacosamide, rufinamide) at 40 min after onset of SE. Rats were continuously monitored for up to 14 days after GD exposure for physiological changes. EEG seizures were successfully recorded after exposure, and SRS were detected during the sub-chronic period. These findings validate the use of HD-S02 in experimental pharmacology studies. In addition, the higher sampling rate can potentially permit the detection of more features in the EEG signal, ranging from 0.5-100 Hz.

Title: Evaluation of cannabinoids for anticonvulsant and neuroprotective efficacy in a rat model of soman-induced status epilepticus

Authors: *B. MARRERO-ROSADO¹, C. R. SCHULTZ¹, E. KUNDRICK¹, M. F. STONE¹, S. O'BRIEN¹, K. WALKER¹, F. ROSSETTI², L. A. LUMLEY¹ ¹US Army Med. Res. Inst. of Chem. Def., Aberdeen Proving Ground, MD; ²Blast Induced Neurotrauma Br., Walter Reed Army Inst. of Res., Silver Spring, MD

Abstract: Cannabidiol (CBD), the non-psychoactive component of cannabis, has received increased attention as a potential therapy for treatment-resistant epilepsy. Cannabinoids have beneficial effects in multiple animal models of seizure, ischemia, and traumatic brain injury. Exposure to soman (GD), a chemical warfare nerve agent, induces status epilepticus (SE) and spontaneous recurrent seizures (SRS), leading to extensive neuronal damage and cognitive impairment. When treatment of SE is delayed, the standard anticonvulsant midazolam is ineffective at preventing the development of epilepsy. In the present study, we evaluated the potential benefits of CBD and of JZL195, a drug that increases endogenous cannabinoids through inhibition of degradative enzymes, against GD-induced seizure activity and neuropathology. Adult male Sprague-Dawley rats were surgically implanted with transmitters to continuously record electroencephalographic (EEG) activity. Rats received a lethal dose of GD (sc) followed by an admix (im) of atropine sulfate (ATS; 2 mg/kg) and the oxime HI-6 (93.6 mg/kg) at 1 minute after GD exposure to increase survival. Rats received JZL195 (5, 10 or 20 mg/kg, ip) 1 min after exposure or 40 minutes after SE onset. JZL195 (20 mg/kg) significantly decreased cell death in the basolateral amygdala and reduced the loss of inhibitory interneurons (GAD67+) in the piriform cortex at 72 hours after GD exposure. At 2 weeks after exposure, JZL195 significantly reduced the loss of mature neurons (NeuN+) in the basolateral amygdala and medial thalamus. In a second experiment, rats received 150 mg/kg (ip) of CBD either at 60 or 30 minutes before GD exposure or at 1 minute after GD exposure and MDZ (3 mg/kg; sc) at 30 minutes after SE onset. CBD administered as pretreatment reduced the risk of developing SRS and the number of SRS events in a time-dependent manner with the 60-minute pretreatment being the most beneficial. Preliminary data suggest a decrease in mature neuronal cell loss in CBD pretreatment groups at 2 weeks following GD exposure. Altogether, data from these studies suggest that cannabinoids reduce the toxic effects of GD poisoning. This research was supported by an NIH Interagency Agreement with the USAMRICD.

Title: Neuroprotective effects of active fraction of flavonoids from Saperavi on kainic acidinduced epilepsy in rats

Authors: M. QURASBEDIANI¹, N. DOREULEE¹, *M. ALANIA¹, B. CHKHARTISHVILI¹, B. PARTSVANIA², M. CHIKOVANI¹, R. BUKIA¹

¹I.Javakhishvili Tbilisi State Univ., Tbilisi, Georgia; ²Georgian Tech. University, Inst. of Cybernetics, Tbilisi, Georgia

Abstract: Temporal lobe epilepsy (TLE) is one of the common human seizure disorders characterized by seizures poorly controlled with anticonvulsant medications. Earlier reduction of the total antioxidant status and increase of production of nitric oxide (NO) in epileptogenesis were demonstrated. In new approaches of TLE treatment plant flavonoids are very important, because of their abilities to scavenge reactive oxide species and to inhibit pathological NO. In our previous experiments antioxidant potency of flavonoids from saperavi (SF) was revealed. The aim of the first series of current experiments was to define a role of supplementation of rats during the early stages of epileptogenesis with SF (8 days, 25mg/kg per day, after single i.p. injection of kainic acid (15mg/kg)) on a number and duration of the behavioral seizure attacks. The effects of SF were compared with the effects of flavonoid quercetin and L-NAME (a nonselective inhibitor of NO synthase) (8 days of administration, 25mg/kg and 40mg/kg per days, respectively). Behavioral seizures were monitored during open field and T-maze laboratory tests. It was revealed that behavioral alterations in Kainic Acid-Status Epilepticus (KA-SE) animals were abolished by administration of SF. The frequency and duration of behavioral seizures in KA-SE rats statistically decreased and correction in learning/memory ability were detected. The efficiency of quercetin on epilepsy induced cognitive impairment compared to the SF was less pronounced. L-NAME effectively blocked the KA-SE-induced seizure frequency and duration, but exacerbate memory deficit induced by epilepsy. The aim of the next series of experiments was to determine the influence of early postnatal feeding of rats with SF on electrophysiological characteristics of neurons in the CA1 field of the hippocampus. The specific objectives were to investigate the effects of SF on background spiking activity and frequency/amplitude characteristics of epileptiform discharges induced by high frequency electrical stimulation. Early postnatal feeding of rats with SF raised the network desynchronization: in the background activity the number of discharges was increased and the amplitude was decreased. High frequency electrical stimulation induced epileptiform discharges with lower amplitude and frequency in SF fed animals compared to the control group. It was suggested that SF has protective effects on the early stages of epileptogenesis.

Abstract: Selective estrogen receptor modulators have been used as a part of therapeutic schedules to prevent cognitive decline associated with aging, in which estrogenic deficiency and possible chronic cerebral hypoperfusion (CCH) may occur in pre- and post-menopausal women. The present study was aimed to evaluate the neuroprotective effect of Raloxifene in an experimental model of CCH (occlusion of both common carotid arteries, one-week apart), under absence of estrogenic cerebral influence mainly dependent on ovarian secretion. Twenty-five Sprague-Dawley female rats (250-300 g bw) were ovariectomized and randomly allotted, two weeks later, to the following groups: Sham (surgical procedures for CCH, without interrupting cerebral blood flow, n=10); CCH+Veh (CCH+vehicle, 10% dimethylsulfoxide in water, 0.3 ml/day, sc, n=7); CCH+Raloxifene (CCH+Raloxifene, 3.0 mg/Kg/day, sc, n=8). After 60 days of vehicle or Raloxifene treatment, spatial learning and memory were evaluated in the Morris water maze, and brains were processed to evaluate hippocampal CA1 pyramidal neuron population. Parameters of spatial learning and memory (escape latencies, swimming path lengths) did not significantly differ along the seven successive testing days in the three experimental groups. However, during the probe trial (day 8) swimming through the target quadrant, as well as number of crossings over the precise former escape platform location, were similar in the CCH+Raloxifene and the Sham groups, and significantly higher (p<0.05) than in the CCH+Veh group. Hippocampal CA1 pyramidal neuron population was significantly reduced (p<0.05) to a 75%, as compared to the Sham group (100%). Raloxifene treatment prevented this neuronal loss, and resulted in a slight non-significant increase in the pyramidal neuron population (115%). These results support the neuroprotective effects of Raloxifene on the brain structures being a

part of the neural substrate for cognitive functions, affected by estrogenic deprivation and chronic cerebral hypoperfusion.

Title: Neuroprotective effects of Aristotelia chilensis (Maqui berry) extract and dapsone on neonatal status epilepticus model induced by kainic acid

Authors: *L. A. BAUTISTA OROZCO¹, S. A. OROZCO-SUAREZ² ¹Inst. Mexicano Del Seguro Social, Ciudad DE Mexico, Mexico; ²Inst. Mexicano del Seguro Social, México, Mexico

Abstract: The neuroprotection after an initial insult as seizure activity is considered essential in order to avoid the establishment of epilepsy. The aim of this study was to evaluate the neuroprotective effects of Aristotelia chilensis (Maqui berry, MB) extract and Dapsone (D) on the epileptogenesis associated to the damage produced by status epilepticus induced with kainic acid (KA) in neonate rats. Male Sprague Dawley rats (96, 12 days old) were divided into 5 groups: Control group (C), AK group, AKMB group, AKD group and AKMBD group with 3 evaluation time (24 h, 5 and 20 days). The kainic acid was administered once with a 3 mg/kg dose to induce status epilepticus. Seizure activity was assessed daily, The brains were obtained by craniotomy which were processed for immunofluorescence techniques to identify proinflammatory proteins (NFkB, IL-1 ß and COX2 and immunoperoxidase for GFAP) and assess the damage by Fluorojade-stain, and other brains were processed for western blot to quantify NFkB, IL-1 β and COX2. The *Maqui berry* extract reduced the number of seizures at 17 and 32 PN days, as well as the number of cells on degeneration process and the expression of pro-inflammatory proteins at 24 h after kainic acid injection, as compared with AK (P<0.05), however Dapsone had a greater effect in reducing the number of seizures at 17 and 32 PN days, the number of cells on degeneration process and also reduced the relative expression of proinflammatory proteins at 24 h after seizures. Maqui berry extract has neuroprotective and antiinflamatory effects, these effects were greater with Dapsone. This study suggests that early intervention on the inflammation and antioxidant pathways reduces the risk of developing epilepsy.

Title: Ferulic acid enhances the neuroprotective properties of calorie restriction against acrylamide model in *Drosophila melanogaster*: Neurobehavioral and biochemical evidences

Authors: *G. CHANDRAN¹, K. SUGUR², J. CHAUHAN²

¹biochemistry, ²Biotechnology, Microbiology and Biochem., Pooja Bhagavat Mem. Mahajana PG centre, Mysuru, India

Abstract: Protein malnutrition is associated with neurochemical implications, and behavioural deficits in experimental animals. Oxidative stress is a pivotal denominator underlying the protein malnutrition physiology. However, limited dietary restriction is implicated with reduced redox markers among different neuron types in vivo. Accordingly it was inquisitive to assess possible therapeutic property for dietary protein in a neurodegenerative model. Casein (the complete protein) was selected as a dietary modulant against acrylamide induced neurotoxicity in Drosophila melanogaster, which is an extensively used in vivo system to assess the relation between dietary intervention and neuronal oxidative stress. In our study, adult (8-10d) males were maintained on varying concentrations of dietary casein (0.1-2%; n=20 flies/vial, 3vials/group) for 2 weeks were coexposed to acrylamide (Acr 2mM). Motor function and mortality were noted at regular intervals. Terminally, the fly homogenates were subjected to biochemical analysis for redox markers, mitochondrial function and neuronal function markers. Acr induced significant mortality in a time dependent manner (25%) and locomotor phenotype among survivors (35%) which was markedly reduced among casein groups. Casein also reduced the oxidative markers (hydroperoxides, protein carbonyls, GSH, SOD) and neurotoxicity parameters (AChE, BChE) among fly homogenates. Interestingly, coexposure with ferulic acid (FA, 100µM) among casein flies further protected the flies against Acr-neurotoxicity. In addition, modifications in the dietary carbohydrate resulted in obvious fatigue among the flies and therefore was not pursued in this study. From our study, dietary casein proved to be a significant modulator of neuronal health in vivo along with FA. Our data suggests a therapeutic role for dietary protein and ferulic acid-like polyphenols for neurodegenerative diseases.

Title: Shining a light on glaucoma: Optogenetic brain stimulation confers retinal neuroprotection

Authors: *E. GEERAERTS, M. CLAES, E. DEKEYSTER, C. VAN DEN HAUTE, M. SALINAS-NAVARRO, L. H. ARCKENS, L. MOONS KU Leuven, Leuven, Belgium

Abstract: Glaucoma is a neurodegenerative disease characterized by a progressive loss of the retinal ganglion cells (RGCs). The central brain targets of the RGCs are well-known to be important for the survival and activity of their retinal connections. To investigate this two-way connection between the brain and the RGCs as a neuroprotective strategy in glaucoma, a series of experiments was performed in which the major retinal projection in the mouse, the superior colliculus (SC), was optogenetically activated in an established experimental mouse glaucoma model.

Optogenetic activation of the SC was performed via injection of an adeno-associated viral vector coding for the stable step-function opsin (SSFO). The SSFO is a channelrhodopsin 2 mutant with slow closing kinetics, thus facilitating prolonged neuronal activation. Transgene expression was shown to cover a large area of the SC. After optic fiber implantation, animals were subjected to the previously reported laser-induced ocular hypertension model (OHT), which induces glaucoma-like RGC loss. Starting one day before OHT induction, the experimental group received light stimulation twice daily until the animals were sacrificed at 14 dpi. Neuronal activation of the SC was validated via immunostaining for the immediate-early gene c-Fos and behavioral analysis. Activation of the SC is known to induce specific behavioral changes, such as turning, freezing and running, which were all observed upon repeated optogenetic stimulation. Behavioral changes lasted for 20 - 30 minutes, coinciding with the SSFO kinetics. Together, these data show that repeated optogenetic stimulation of the SC is possible. Furthermore, following semi-automated quantification of RGCs on Brn3a-stained retinal flatmounts, the optogentically stimulated group showed an significant increase in RGC survival, with 91% (± 4% SEM, N=21) survival versus 75% (± 6% SEM, N=16) in the non-stimulated group, compared to untreated eyes. Our data clearly reveal that repeated stimulation of central brain targets can contribute to neuroprotection of RGCs. Ongoing work includes elucidation of a

possible mechanism, with a focus on involvement of neurotrophins. In conclusion, these results unveil exciting new possible treatment paradigms for glaucoma and other optic neuropathies.

Abstract: Introduction: Oligodendrocytes loss and myelin sheet destruction are one of the main events that characterize Multiple Sclerosis, a chronic neurodegenerative disease. Endogenous neural precursors in the adult brain may be good candidates to help restore the oligodendroglial population. Phenytoin promotes cell proliferation of neural precursor cells (NPCs) in the postnatal brain. Hence, the pharmacological stimulation of NPCs with phenytoin may represent a viable alternative to promote white matter regeneration. **Purpose:** To evaluate whether phenytoin promotes remyelination in the corpus callosum of adult mice intoxicated with cuprizone. **Methods:** 24 CD1 male mice were exposed to 0.2% cuprizone mixed with food chow for 8 weeks; then we assembled two groups: phenytoin-treated group and the untreated control group. The treated group received oral phenytoin (10 mg/kg) for 4 weeks upon cuprizone removal. The control group only received vehicle solution (0.1ml of 25% ethanol v/v solution). To evaluate remyelination, we quantified the number of oligodendrocyte precursor cells (**OPC**) and mature oligodendrocytes that expressed Olig2/Brdu, NG2/Brdu, RIP/Brdu cell markers, and the expression level of myelin basic protein (**MBP**), as well as and the muscle strength and

motor coordination. **Results:** The number of OPC and oligodendrocytes significantly increases after the phenytoin administration as compared to untreated group. Densitometric analysis also show an increase in the expression of MBP in the corpus callosum. Functional test show a significant improvement in the score rates obtained with horizontal bars test in the phenytoin group. **Conclusions:** Phenytoin stimulates OPC proliferation that contributes to reestablish the oligodendroglial population and promotes remyelination of the corpus callosum. These cellular effects are associated with functional recovery in motor coordination and strength.

Title: Alpha7 nAChR activation or inhibition can mediate neuroprotective activity in hippocampal slices and in isolated mitochondria

Authors: V. A. ETEROVIC¹, H. R. ARIAS³, M. SKOK⁴, D. PEREZ², *P. A. FERCHMIN² ¹Neurosci., ²Biochem., Univ. Central del Caribe; Sch. of Med., Bayamon, PR; ³Dept. of Basic Sci., California Northstate Univ. Col. of Med., Elk Grove, CA; ⁴Dept. of Mol. Immunol., Palladin Inst. of Biochem., Kyiv, Ukraine

Abstract: 4R-cembranoid (4R), methyllycaconitine (MLA) and 3-furan-2-yl-N-p-tolylacrylamide (PAM-2) are neuroprotective drugs that target the alpha-7 nicotinic acetylcholine receptor (α 7). However, while 4R and MLA neuroprotective activities are mediated by inhibition of α 7, PAM-2 is a positive allosteric modulator of α 7. The objective of this work is to compare the neuroprotective activity of PAM-2 with those of 4R and MLA, in rat hippocampal slice and in isolated mice mitochondria expressing α 7 receptors. Recording of population spikes (PSs) in rat area CA1 of acute hippocampal slices was used to assess the injury caused by NMDA excitotoxicity and the neuroprotection by 4R, MLA, and PAM-2. The PS is the sum of axon potentials of functionally active pyramidal neurons synaptically elicited by stimulation of the Schaffer collaterals. Excitotoxicity was produced by a 10 min application of 0.5 mM NMDA which decreased the PS recovery to 40% of ACSF controls. The neuroprotective drugs were

applied for one hour 30 min after NMDA. In each experiment, the initial PS was measured before NMDA and the final PS, one and a half hour after NMDA. Data were analyzed by Kruskal-Wallis ANOVA, followed by Dunn's test. The recovery of PS was significantly increased when NMDA was followed by the application of 10 µM PAM-2 (68%), 10 µM 4R (82%), or 10 nM MLA (54%). Upon simultaneous application of 10 µM PAM-2 and 10 µM 4R, the PS recovery was 60%, while the application of 10 µM PAM-2 plus 10 nM MLA caused a recovery to 61%. All differences shown were significant (p<0.05). In conclusion, significant PS recovery after NMDA was observed when applying PAM-2, a positive α 7 modulator, and two selective inhibitors of a7 nAChR, MLA and 4R. This finding could be explained by the involvement of different synaptic circuits. On the other hand, the fact that the positive effects of PAM-2 and 4R were not additive could be explained by direct competition of a positive modulator and an inhibitor at the a7 receptor. The activity of PAM-2 and 4R was determined in liver mitochondria obtained from WT and mutant mice. The results indicated that PAM-2 efficiently attenuated Cyt c release in WT, but not α 7-/- or α 7/ β 2-/- mice mitochondria exposed to high Ca^{2+} , but not to H_2O_2 or wortmannin, whereas 4R activity was effective against Ca^{2+} and H₂O₂, but less against wortmannin. These results suggest that PAM-2 and 4R inhibit Cyt c release by distinct intracellular pathways, where PAM-2 activity is mediated by α 7-containing AChRs triggering CaKMII-dependent, but not Src- or PI3K-dependent, intracellular pathways.

Title: Palmitate-enriched diet mitigates BDNF expression in the brain

Authors: *G. A. MARWARHA¹, J. LILEK², J. SCHOMMER², O. GHRIBI¹ ¹Biomed. Sci., Univ. of North Dakota Sch. of Med., Grand Forks, ND; ²Biomed. Sci., Univ. of North Dakota, Grand Forks, ND

Abstract: A multitude of epidemiological, clinical, and laboratory studies have suggested that diets rich in saturated fat precipitate cognitive impairment and exacerbate cognitive decline in the elderly leading to an increase in the risk for dementia and neurodegenerative disorders. Palmitic acid (palmitate) is the most abundant saturated free fatty acid (sFFA) present in the saturated fat higher palmitate levels in the plasma inversely correlate with cognitive function.

However, the molecular mechanisms underlying the effects of a palmitate-enriched diet in the derangement of cognitive function and evoking learning and memory deficits has not been characterized. Herein, we determined the effects of a palmitate-enriched diet and exogenous treatment on Brain-derived Neurotrophic Factor (BDNF) expression, in the mouse brain and SH-SY5Y human neuroblastoma cells, respectively. We fed a cohort of nine-month old wild-type C57BL/6J mice (n=15), a palmitate-enriched diet or a control-chow diet for three months and determined the effects on BDNF expression in cortex and hippocampus and elucidated the role of changes in cAMP/PKA/CREB signaling pathways that results in changes in CREB-binding to the BDNF promoter by ChIP-qPCR. We further determined the extent to which exogenous palmitate treatment of human neuroblastoma SH-SY5Y cells evokes changes in cAMP/PKA signaling pathway that results in altered CREB activation and CREB-mediated BDNF expression and delineated the signaling cascades by selective knock-down of kinases and ectopic expression of transcriptionally-inert mutant forms CREB. We demonstrate, in palmitate-treated human neuroblastoma cells and in the brains of palmitate-enriched diet-fed mice, that palmitate evokes a reduction in cAMP levels leading to a mitigation in PKA-mediated CREB activation that culminates in attenuated BDNF expression. We further show that the mitigation of CREB transcriptional activity is essential for the palmitate-induced decrease in BDNF expression, as constitutively active CREB precludes the deleterious effects of palmitate on BDNF expression. Our study highlights the derangements in cAMP/PKA/CREB signaling pathway as the conduit for palmitate-induced down-regulation of BDNF, the most abundant neurotrophin and growth factor in the brain that is indispensable for neuronal survival and synaptogenesis, and other facets of neuronal physiology integral in learning and memory.

Title: Knockdown of heat shock proteins HSPA6 (Hsp70B[`]) and HSPA1A (Hsp70-1) affects the viability of differentiated human neuronal cells following thermal stress

Authors: *C. A. DEANE, I. R. BROWN

Ctr. for the Neurobio. of Stress, Dept. of Biol. Sci., Univ. of Toronto Scarborough, Toronto, ON, Canada

Abstract: Heat shock proteins (Hsps) are highly conserved proteins that play important roles in cellular repair and protective mechanisms that counteract protein misfolding and aggregation that are features of neurodegenerative diseases. HSPA6 (Hsp70B') is an inducible member of the HSPA (Hsp70) multigene family that has received little attention compared to the more widely studied HSPA1A (Hsp70-1). Interestingly, the HSPA6 gene is found in the human genome but is not present in mouse and rat. Hence it is absent in current animals models of neurodegenerative diseases which have been characterized as protein misfolding disorders. To advance knowledge of this little studied HSPA member, the effect of selective knockdown of HSPA6 and HSPA1A was examined in relation to the ability of differentiated human SH-SY5Y neuronal cells to survive thermal stress. Induction of Hsps by low dosage co-application of celastrol and arimoclomol was observed to enhance the ability of differentiated neuronal cells to tolerate heat shock. Small interfering RNA (siRNA) knockdown of HSPA6, or HSPA1A, resulted in loss of the protective effects of co-application of celastrol/arimoclomol. More pronounced effects were observed at 44°C heat shock compared to 43°C. These results suggest that induction of both HSPA6 and HSPA1A is required for the protection of differentiated human neuronal cells from cellular stress.

Title: Neuroprotective and anti-inflammatory effects of the microneurotrophin BNN27 in the STZ-model of diabetic retinopathy

Authors: *R. IBÁN-ARIAS¹, S. LISA², N. MASTRODIMOU¹, I. CHARALAMPOPOULOS¹, A. GRAVANIS³, K. THERMOS¹

¹Pharmacol. Lab, Med. Sch., Heraklion, Greece; ²Dept. of Cell Biol. and Pathology, Inst. de Neurociencias de Castilla y León (INCyL), Univ. of Salamanca & Inst. of Biomed. Res., Salamanca, Spain; ³Inst. of Mol. Biol. & Biotechnology, Fndn. of research & Technology-Hellas (FORTH), Heraklion, Greece

Abstract: Diabetic retinopathy (DR) is the most common ocular disease of people under diabetes, which gradually leads to visual impairment and blindness. Three major pathogenic

components define DR, namely neovascularization, neurodegeneration and inflammation. Available therapeutics target only the formation of new blood vessels. Recent findings propose that the imbalance between prosurvival neurotrophic factors and inflammatory components lead to apoptosis and pro-inflammatory responses. We have shown that BNN27, a novel synthetic DHEA derivative that interacts with neurotrophin receptors -thus called *microneurotrophin*-, reverses the diabetes-induced retinal damage (on amacrine retinal cells and ganglion cell axons). More specific, it activates the NGF TrkA receptor and its downstream prosurvival signaling in the Streptozotocin (STZ)-model of DR. The main aim of the present study was to examine the effect of BNN27 on the diabetes-induced changes a) in the immature isoform of NGF, proNGF, which binds with high affinity to the p75 ^{NTR} neurotrophin receptor, b) on gliosis, and c) on the pro- and anti-inflammatory mediators in the STZ-model of DR. BNN27 attenuated the diabetesinduced increase in proNGF, p75^{NTR}, glial fibrillary acidic protein (GFAP) and Iba-1 (microglia marker) expression. The levels of the transcription factor NFkB, known to be implicated in the production of pro- inflammatory cytokines, were increased in the diabetic retina. BNN27 attenuated the diabetes-induced increase in the pro-inflammatory cytokines TNF α and IL-1 β . In addition, it up-regulated the levels of the anti-inflammatory cytokines IL-10 and IL-4. The PI3K/Akt signaling pathway is also implicated in survival by regulating the production of proinflammatory cytokines. In the diabetic retina, Akt kinase phosphorylation was amplified, while BNN27 attenuated the phosphorylation of Akt kinase in a dose-dependent manner. In conclusion, these results provide important findings regarding the effects of the microneurotrophin BNN27 on the expression of proNGF and p75^{NTR}, gliosis and inflammation in the diabetic retina. However, further studies are necessary in order to support its beneficial use as therapeutic for the treatment of diabetic retinopathy.

Title: Genetic deletion of Sarm1 prevents axon degeneration in chemotherapy induced peripheral neuropathy

Authors: *A. CETINKAYA-FISGIN¹, X. LUAN¹, N. REED¹, A. HOKE² ²Neurol., ¹Johns Hopkins Sch. of Med., Baltimore, MD

Abstract: Although increasing numbers of cancer patients are experiencing excellent outcomes with prolonged survival with chemotherapy, many chemotherapeutic agents often cause Chemotherapy Induced Peripheral Neuropathy (CIPN), a serious, painful, and dose-limiting complication. There are currently no effective therapies that prevent CIPN. In order to examine the mechanisms that lead to axon degeneration in CIPN and identify new therapeutic pathways for the treatment, we asked if genetic deletion of Sarm1 (sterile α-motif-containing and armadillo-motif containing protein) which has a pivotal role in activating axonal degeneration following injury, is protective against axonal degeneration in mouse CIPN models. Paclitaxel (25 mg/kg three times for one week), Cisplatin (4 mg/kg once a week for 4 weeks) and Bortezomib (0.8 mg/kg twice a week for 4 weeks) are administered by tailvein injections to wild-type mice and Sarm1 knockout mice. The key manifestations of mouse peripheral neuropathy models, including loss of intra epidermal nerve fibers (IENF), thermal hyperalgesia, and reduction in sensory evoked responses were observed in wild-type mice, but Sarm1 knockout mice did not show loss of IENF, thermal hyperalgesia or reduction in sensory evoked responses. As genetic deletion of Sarm1 blocks the development of peripheral neuropathies induced by these three different chemotherapy drugs that cause peripheral neuropathy via different mechanisms of actions, our findings suggest that axonal degeneration in CIPN has a final common pathway mediated by Sarm1. Therapeutic strategies aimed at reducing or inhibiting SARM1 activity may offer a new therapeutic target for CIPN.

Title: Intestinal dysbiosis affects motorsensory function after intracerebral hemorrhage

Authors: *G. KONE, C. IADECOLA, J. ANRATHER Feil Family Brain and Mind Res. Inst., Weill Cornell Med., New York, NY

Abstract: While intracerebral hemorrhage (ICH) accounts for only 15-20% of all strokes, it is the most deadly of stroke subtypes with a 40-50% mortality within 1 month. The brain damage that occurs following ICH is in part determined by inflammation, mediated by both innate and

adaptive immune cells. In particular, regulatory T-cells and $\gamma\delta T$ cells have both been shown to infiltrate the brain following ICH (Mracsko et al., Stroke, 2014). Furthermore, regulatory T-cell implants have been shown to limit neuroinflammation and improve functional outcomes following ICH (Yang et al., International Immunopharmacology, 2014). We have previously shown that intestinal dysbiosis, induced by antibiotic-produced alterations of the intestinal microbiota, can alter T-cell trafficking to the brain and reduce brain injury following ischemic stroke (Benakis, et al., Nature Medicine, 2016). In the present study we explored whether intestinal dysbiosis can similarly provide neuroprotection in ICH. C57BL/6 mice treated with amoxicillin and clavulanic (AC) acid in tap water were housed alone (AC sensitive) or co-housed with seeder mice that had AC resistant gut flora which were then transferred to their cage mates (AC resistant). ICH was induced via stereotaxic injection of 0.075U bacterial collagenase into the striatum. Sensorimotor function was assessed using the tape test 1 day prior and on days 1, 3, and 7 following ICH and measuring the time to contact and removal of tape on the forepaws. On day 7, brains were sectioned to measure swelling by comparing the volumes of the hemisphere ipsilateral and contralateral to the lesion. AC sensitive mice made earlier contact with tape on their contralesional forepaw on day 1 ($42\pm 29s$) and day 3 ($13\pm 7s$) than AC resistant mice made on day 1 (91 \pm 36s, p = 0.0049; Mann-Whitney U test) and day 3 (55 \pm 33s, p=0.0007, n=15). Similarly, AC sensitive mice more quickly removed tape from their contralesional forepaw on day 1 ($86\pm 37s$) and day 3($65\pm 30s$) than AC resistant mice did on day 1($150\pm 24s$, p=0.0120) and day 3 (147 ± 21 s, p= 0.0001, n=13). Brains from AC sensitive mice showed a trend for less swelling of the injured hemisphere, but this change did not reach statistical significance in this small group (p>0.05; Mann-Whitney U test). These results suggest that the gut-brain axis may play a role in the evolution of functional decline following ICH, and suggest a novel therapeutic avenue for attenuating the inflammatory response following ICH.

Title: Photoregulin3 prevents retinal degeneration in mice

Authors: *P. A. NAKAMURA¹, A. SHIMCHUK¹, S. TANG², S. DING², T. REH¹ ¹Biol. Structure, Univ. of Washington, Seattle, WA; ²Gladstone Inst., San Francisco, CA

Abstract: Nr2e3 is a retina-specific nuclear receptor and a master regulator of photoreceptor gene expression. Chemical modulation of this receptor has great potential as a therapeutic strategy to treat retinal degenerative diseases like Retinitis Pigmentosa (RP) and macular

degeneration. Toward this end, we have identified several series of small molecule modulators of Nr2e3 that regulate the expression of photoreceptor-specific genes. Thus far, we have focused on two series of chemically distinct compounds, the Photoregulin1 (PR1) series and the Photoregulin2 (PR2) series. Manipulation of photoreceptor expression with either PR1 or PR2 slows the progression of retinal degeneration in vitro in the Rho^{P23H} and $Pde6b^{Rd1}$ models of RP (Nakamura et al., 2016). However, in vivo analyses with these series, especially the PR1 series, were limited by the compounds' potency, solubility, and stability in vivo. We have also identified a third series, Photoregulin3 (PR3), which is more potent than the first two series. After systemic delivery, PR3 has large effects on rod photoreceptor gene expression (e.g. Nrl, *Rhodopsin*, *Gnat1*) by RNAseq analysis. In *Rho^{P23H}* mice, a model of autosomal dominant RP, most rod photoreceptors undergo cell death by the end of the third postnatal week, and we hypothesized that decreasing Rhodopsin expression with PR3 treatment would prevent retinal degeneration in this model. We treated Rho^{P23H} mice with PR3 or vehicle from postnatal day 12-14 (P12-14) until P20 and assessed retinal structure and function at P21. PR3-treated Rho^{P23H} mice had larger scotopic and photopic ERG responses than littermate controls, in addition to significantly decreased degeneration of photoreceptors. Together, our data suggest that pharmacological disruption of Nr2e3 signaling may be a therapeutically advantageous strategy for the treatment of RP and other degenerative diseases of the retina.

Title: Intrathecally injected bone marrow stromal cells produce sustained neuropathic pain reduction via neuro-immune regulation

Authors: *Y. D. HUH, G. CHEN, R.-R. JI Dept. of Anesthesiol., Duke Univ. Med. Ctr., Durham, NC

Abstract: Chemotherapy-induced peripheral neuropathy is the *de facto* toxic effect that limits the administration of anti-neoplastic agents such as paclitaxel in the treatment of cancer. This

toxic effect limits the utilization of aggressive chemotherapeutic regimens associated with an increase in patient survival from cancer. Understanding the mechanisms of chemotherapyinduced peripheral neuropathy may enable the development of treatments to curtail the neurotoxicity of chemotherapeutic agents and allow for increased usage of aggressive treatment regimens in oncology. Chen et al. discovered that intrathecal injection of bone marrow stromal cells (BMSCs) reduced peripheral neuropathy for more than two months in murine chronic constriction injury and spared nerve injury models. The study found that TGF- β 1 was the factor secreted by BMSCs responsible for the reduction in neuropathic pain, and furthermore the injected BMSCs migrated specifically to injured dorsal root ganglia through an interaction between CXCR4 and CXCL12. In this study, we examined the effects of BMSC intrathecal injections on peripheral neuropathy in the murine paclitaxel model (four intraperitoneal injections on alternate days at a concentration of 2.0mg/kg). We discovered that at a single injection of a similar dosage (3.0 x 10⁵ cells) of BMSCs into the intrathecal space of paclitaxeltreated mice produced a significant reduction in mechanical allodynia that lasted for more than six weeks. The analgesic effect of intrathecally injected bone marrow stromal cells in paclitaxelinduced peripheral neuropathic mice was reversed by an intrathecal injection of anti-TGF-B1 antibody, suggesting TGF-B1 as the specific factor secreted by BMSCs that inhibits neuropathic pain. We also confirmed that TGF-β1 injected intrathecally at a dosage of 100ng produced an immediate but transient reduction in mechanical allodynia in paclitaxel-treated mice. These findings suggest that bone marrow stromal cells injected into the intrathecal space secreting factors including TGF-B1 can produce significant and sustained analgesia for pain associated with chemotherapy-induced peripheral neuropathy.

Title: Efficacy of novel acetylcholinesterase reactivators against organophosphate poisoning: In silico and *In vitro* studies

Authors: *M. ARSHAD¹, M. Q. FATMI¹, K. MUSILEK², K. KUCA³, S. M. NURULAIN¹ ¹Biosci., Comsats Inst. Of Information Technol. Islama, Islamabad Gpo, Pakistan; ²Biomed. Res. Ctr., Univ. Hosp. Hradec Kralove, Hradec Kralove,, Czech Republic., Czech Republic; ³Univ. of Defense, Hradec Kralove, Czech Republic, Czech Republic

Abstract: Organophosphate (OP) poisoning is a global issue. The organophosphorus compounds manifest toxicity by inhibiting neurochemical, acetylcholinesterase (AChE).Oxime is used to

reactivate the inhibited AChE. First oxime was developed in 1956, named pralidoxime. However, its efficacy is controversial. Hence, there is pressing need to develop a new efficacious oxime. Present study was aimed and designed to introduce a novel efficacious oxime and compared with another experimental oxime, K27. *In silico* and *in vitro* methods were employed to assess the potency and compare the efficacy of novel oximes against paraoxon (POX) inhibited AChE.

Molecular docking of the oximes revealed that novel oximes K378 and K727 binds at peripheral anionic site (PAS) with low binding affinity and high binding energy. Other tested oximes were having high binding affinity and low binding energy for the active catalytic site at the bottom of the gorge. LogP determination showed that novel oxime K727 possess low permeability to blood brain barrier. Intrinsic toxicity of K727 and K378 (in term of IC₅₀) were 0.99 μ M and 0.94 μ M respectively. Percent reactivation (R₅₀) for PAM-Cl, K27, K727 and K378 were found to be 135.45 μ M, 2.68 μ M, 1.7109X10¹⁴ μ M and 2.67X10¹⁷ μ M respectively. Apparent rate constant of the oximes revealed slow apparent rate constant for K727 (≈0.002 moles/minute) and K378 (≈0.005 moles/minute) in comparison K27 (≈0.06 moles/minute), and PAM-Cl (≈0.02 moles/minute). The delayed time point application of oximes showed that K27 is effective even, when applied after 20 minutes of intoxication by POX. Other oximes decreased the efficacy with increase in time point of oxime application

It is concluded that K378 and K727 are not efficacious than pralidoxime. However, pralidoxime is inferior in efficacy than K27. Further work with structurally different organophosphates is suggested.

Title: Mechanism of action of retinal pigment epithelial (RPE) grafts reducing drug seeking in high-dose cocaine taking rats after a period of abstinence

Authors: *K. VENKITESWARAN¹, T. CAYTON¹, S. SINGH¹, A. PATEL¹, T. SUBRAMANIAN¹, P. SUE GRIGSON² ¹Neurol & Neural & Behav Sci., Penn State Milton S Hershey Med. Ctr., Hershey, PA; ²Neural & Behavioral Sci., Penn State Col. of Med., Hershey, PA

Abstract: Prolonged exposure to cocaine affects VTA-NAc dopaminergic neurons resulting in imbalance to mesolimbic pathway in vivo, contributing to relapse seen in chronic cocaine addiction. Our previous study in rat model of cocaine addiction demonstrated that retinal pigment epithelial (RPE) cells grafted into NAc, helped to reduce drug seeking in high-dose cocaine-self-administering animals after a period of abstinence (Venkiteswaran et al. 2016). To verify this and to understand the underlying mechanisms, we investigated if cocaine induced neuronal death and RPEC-mediated rescue could occur in primary cultures of mouse fetal ventral mesencephalic (mFVM) neurons. mFVM tissue dissected from E13.5 mouse embryos was made to single cell preparation and was cultured in vitro. These cultures were exposed to increasing doses of cocaine (3 µM to 1300 µM) in vitro for 24 hours. After this, the cultures were fixed and stained for tyrosine hydroxylase (TH) and quantified the TH positive neurons by stereology. The study showed in vitro dose responsive neuronal degradation and also upregulation of glial cell proliferation in the mFVM cultures when exposed to increasing doses of cocaine. Cocaine treated mFVM cultures were treated with RPEC conditioned medium (RPE-CM) 1) 24 hours prior to cocaine administration (pretreatment), 2) with cocaine administration (simultaneous treatment), and 3) 24 hours after cocaine administration (post treatment) in vitro. As controls, Glial Derived Neurotropic Factor (GDNF, 1µg/ml) and Pigment epithelial derived factor (100ng/ml) were used to treat separately on the mFVM, cultured in vitro. The cultures were fixed on day 6 and the dopaminergic neurons were analyzed by TH immunocytochemistry, stereology and neuron tracing techniques. TH positive neurons were quantified by petrimetrics and neuronal characteristics were measured using Neurolucida. GDNF and PEDF treatments showed better survival of dopaminergic neurons in the cocaine treated mFVM cultures. However the neuronal characteristics were different for the two growth factors. Treatment with RPE-CM showed better survival of TH positive neurons with healthier neuronal characteristics.

Title: Using Trichostatin A to rescue Trka+ neurons in a mouse model of familial dysautonomia

Authors: *R. G. BUKSCH, III, J. WALTERS, J. GOFFENA, L. GEORGE Biol. and Physical Sci., Montana State Univ. Billings, Billings, MT

Abstract: Familial Dysautonomia (FD) is a severe neurodevelopmental and neurodegenerative disease that devastates the peripheral nervous system, culminating in death of most patients by age 40. FD results from a single base mutation in the gene Ikbkap/Elp1 that encodes the scaffolding unit for the Elongator complex. A hallmark feature of FD, present at birth, is a severely reduced number of TrkA+ pain and temperature sensing nociceptors in the dorsal root ganglia. Previous studies in a mouse model for FD have shown that impaired neurogenesis during embryonic development contributes to this decreased number of nociceptors. Multiple studies in both familial dysautonomia patients and mouse models of FD have also documented reduced levels of acetylated histone H3. To examine whether depleted histone acetylation may play a causal role in the failed production of TrkA+ neurons during embryogenesis, we evaluated the ability of the histone deacetylase inhibitor, Trichostatin A (TSA), to rescue TrkA+ neuron number in Wnt1-Cre; Ikbkap^{LoxP/LoxP} conditional knockout (CKO) mice where Ikbkap/Elp1 is selectively ablated in the peripheral nervous system. Although CKO pups die within 24 hours of birth, their survival through development allowed us to ask whether hyper-acetylation of histones during embryogenesis could rescue TrkA+ neuron number. Pregnant dams were treated with either 1mg/kg of Trichostatin A (experimental) or vehicle alone (control), at E8.5, E10.5, and E12.5, a time frame corresponding to neurogenesis in the mouse dorsal root ganglia. Quantification of TrkA+ neuron number at E17.5 shows a significant increase in TSA-treated embryos over vehicle controls (132.9% increase; p<.00001). We are currently exploring the molecular and cellular mechanisms via which histone deacetylase inhibition rescues TrkA+ neuron number during embryogenesis.

The post-natal death of *Wnt1-Cre; Ikbkap^{LoxP/LoxP}* pups has been attributed to complications of a cleft palate. Interestingly, TSA treated CKO embryos show significant changes in head morphology at E17.5. We are currently investigating whether this altered head development includes correction of cleft palate such that CKO pups survive beyond their first 24 hours. Further studies will also evaluate the ability of Trichostatin A to protect cultured mature neurons *in vitro*, as well as to prevent neurodegeneration *in vivo*, in adult mice.

Title: Rescuing synaptic activity in prion-disease mice

Authors: *J.-M. BOURGOGNON, J. R. STEINERT

MRC Toxicology unit, MRC Toxicology Unit, Leicester, United Kingdom

Abstract: It has been suggested that nitric oxide and S-nitrosylation are involved in the pathogenesis of various neurodegenerative disorders including Parkinson's disease (PD), and Alzheimer's disease (AD). Elevated neuroinflammation levels that characterize these pathologies are largely associated with an increased production of nitric oxide (NO) leading to abnormal protein S-nitrosylation. We use a mouse model of neurodegeneration to investigate the role of nitric oxide mediated pathways at the synapse and its contribution to neuronal decline. We show that in prion-infected mice synaptic activity is dramatically decreased. Indeed the amplitude and frequency of miniature EPSCs are lowered together with potassium currents. However chronic injection of a NOS inhibitor L-NAME totally rescues presynaptic release probability / the number of functional synaptic sites and the density/conductance of postsynaptic receptors at individual synapses. We evaluate the impact of blocking nitric oxide synthase on memory and survival of the prion mice. We further examine the expression of synaptic proteins like synapsin and complexin1/2 in prion-infected mice as the disease progresses using Western blotting and immunohistochemistry. Future work will study the effect of chronic L-NAME treatment on synaptic protein expression and nitrosylation status of synaptic proteins.

Title: GDPGP1 is a novel and conserved stress-responsive gene in neurons

Authors: *A. SCHULZ¹, M. HAMMARLUND²

¹Program in Cell. Neuroscience, Neurodegeneration and Repair, ²Yale Univ. Sch. of Med., New Haven, CT

Abstract: Our mechanistic understanding of how neurons respond to stress and injury is incomplete, and this lack of fundamental knowledge impedes the development of urgently needed therapies for neurological diseases. We used an RNA-Seq screen against multiple stress conditions to unravel the common transcriptional signature of acutely stressed cortical mouse

neurons. Our expression screen and subsequent retests identified GDPGP1 as a novel stressresponsive gene. GDPGP1 expression is down-regulated in primary cortical mouse neurons following hypoxic and oxidative stress. Further, knockdown of GDPGP1 in primary cortical mouse neurons leads to widespread neuronal cell death. To characterize the *in vivo* function of GDPGP1 in the neuronal response to stress and injury, we used a genetic approach in *C. elegans*. GDPGP1 has a single homologue in *C. elegans*, *mcp-1*. *mcp-1* shows neuron-specific expression and, consistent with our results in cultured mouse cortical neurons, is transcriptionally downregulated in response to a range of stresses. Loss-of-function mutations of *mcp-1* improve axon regeneration after axotomy, but lead to increased degeneration of GABA neurons as well as reduced survival of worms following environmental stress. Taken together, our data identifies GDPGP1/*mcp-1* as a novel stress-responsive gene in nematode and mammalian neurons, and suggest that GDPGP1 has an important *in vivo* function in mediating neuronal responses to multiple stresses. The downregulation of GDPGP1 in injured or stressed neurons might contribute to loss of cell survival.

Title: Neuroprotection and neurodegenerative response by CB1 and CB2 cannabinoid receptor inactivation after neonatal peripheral nerve lesion

Authors: *M. PEREZ¹, L. P. CARTAROZZI¹, G. B. CHIAROTTO¹, F. S. GUIMARÃES², A. L. R. OLIVEIRA¹ ¹Unicamp, Campinas, Brazil; ²Univ. of São Paulo, Ribeirão Preto, Brazil

Abstract: Neonatal peripheral nerve lesion results in degeneration of spinal motoneurons and dorsal root ganglia (DRG) already at the acute phase post-axotomy. Neurotrophic substances may prevent such cell loss, allowing axonal regeneration and rehabilitation. We have previously shown that cannabidiol (CBD), a non-psychotropic component of cannabis leaves, is neuroprotective for both motoneurons and DRG neurons, when administrated during the five subsequent days post nerve lesion. CBD can activate the endocannabinoid system, via

cannabinoid receptors, namely CB1 and CB2. However, the relative importance of each receptor is elusive regarding neuronal response to axonal transection. Therefore, the aim of present work was to investigate the neuroprotective effects of CBD by selectively inactivating CB1 and CB2 receptors following neonatal sciatic nerve lesion. For this purpose, Wistar neonatal rats (P2) were subjected to unilateral sciatic nerve injury and treated with CBD (15mg/Kg) or vehicle solution for five consecutive days. CB1 and CB2 were blocked alone or simultaneously by the use of AM251 (CB1 antagonist) and AM630 (CB2 antagonist). Neuronal survival was assessed by direct counting in Nissl stained sections. RT-qPCR was used to measure gene expression of CB1, CB2, BDNF, and GDNF both in the lumbar intumescence and DRGs. Similarly, immunohistochemistry was used to evaluate protein expression in situ. Unexpectedly, the spinal motoneuron survival was 40% greater than vehicle when CBD alone or the combination of AM251 and AM630 were used. Also, qRT-PCR analysis demonstrated that AM251 and AM630 alone or together generated 40% decrease of CB1 receptor and 20% of BDNF gene expression. Importantly, the use of CB1 and CB2 antagonists result in a significant increase of CB2 and GDNF gene expression in the DRGs (60% upregulation), suggesting that cannabinoid receptors blockade also impacts the primary afferents response to injury. Taking together, the results herein show that the cannabinoid receptors can play a role in the neuroprotective and regenerative response after peripheral nerve lesion during the neonatal phase.

Abstract: Maintaining motoneuron (MN) survival is critical for successful neuroregeneration after peripheral nerve injury. Elucidating the cellular mechanisms that determine whether a MN

survives or perishes after a peripheral nerve injury will be necessary for the development of therapies for the treatment of nerve injury and may yield important clues about the pathogenesis of amyotrophic lateral sclerosis (ALS), a disease which is also thought to be initiated by a distal insult to the MN axon. Of particular interest to our laboratory is interleukin-10 (IL-10), an antiinflammatory cytokine. We have previously found that a central source of IL-10 is required for CD4+ T cells to mediate MN survival after facial nerve axotomy (FNA) and that axotomy induces astrocytes to upregulate IL-10 receptors. The objective of this study is to investigate the cellular source and role of IL-10 in mediating neuroprotection after FNA. Immunohistochemistry and utilization of an IL-10/GFP reporter mouse revealed that astrocytes were positive for IL-10 after FNA, whereas microglial production of IL-10 was undetectable. Unexpectedly, MN themselves appeared to be constitutive producers of IL-10. To determine whether a glial source of IL-10 is critical for MN survival, we generated Cre/lox mouse strains to selectively knock down IL-10 in microglia and astrocytes. In accordance with our previous findings, knockdown of IL-10 in microglia had no effect on MN survival after axotomy. To our surprise, knocking down IL-10 in astrocytes also did not affect MN survival. These results have led to the hypothesis that a neuronal source of IL-10 is necessary for MN survival after FNA, potentially by modulating glial reactivity. Experiments to address this neuronal source of IL-10 are underway. The pattern of IL-10 expression in the mSOD1^{G93A} mouse model of ALS after FNA is also under investigation. These studies pave the way for future application of immune-modulating therapies after nerve injury.

Title: Activating transcription factor 3 protects retinal ganglion cells and promotes regeneration after optic nerve crush

Authors: C. KOLE¹, T. ZHAO², L. BONET-PONCE¹, *N. NAKAYA¹, B. MEAD¹, S. I. TOMAREV¹ ¹SRGCB/LRCMB, ²RNPS, Natl. Eye Inst., Bethesda, MD

Abstract: Injured mature CNS axons do not regenerate in mammals. Activating transcription factor 3 (ATF3) is a member of a family of ATF/cyclic AMP responsive element binding

transcription factors and was identified as a protein whose activity is regulated by stressful stimuli. In the peripheral nervous system, upregulation of ATF3 expression is closely linked to the survival of neurons and the regeneration of their axons following axotomy. Here, we sought to determine whether ATF3 promotes the survival of CNS neurons and the regeneration of their axons using an optic nerve crush model. In zebrafish which are able to regenerate the optic nerve after transection, a 19.2 fold upregulation of atf3 expression was demonstrated in the retina 48h after optic nerve crush compared with uninjured retina. In order to elucidate whether overexpression of ATF3 may stimulate regeneration of the optic nerve in mammals, we performed intravitreal injections of recombinant AAV2.9/2yF vector encoding mouse ATF3 2.3E+10 viral particles into adult mouse eyes one week before the optic nerve crush, AAV2.9/2yF encoding for mCherry was used as negative control. Survival of retinal ganglion cells (RGCs) and regeneration of their axons were analyzed one week after crush. RGC were identified by positive RBPMS staining whereas axons were labeled with the anterograde fluorescent tracer cholera toxin beta. Intravitreal injection of AAV encoding ATF3 increased survival of RGCs by 23% relative to eyes injected with control AAV encoding cherry protein or non-injected eyes. ATF3 overexpression induced significant regeneration of RGC axons with an approximate 3-fold higher number of axons 1mm distal to the laminin⁺ crush site compared with controls. At 40d post-crush, some axons were identified within the optic chiasm after ATF3 overexpression. . The optomotor test was done using the OptoMotry system and was used to record head movements (optomotor reflex; OMR) in an animal in response to a rotating visual stimulus. ATF3 overexpression led to a partial restoration of OMR compared to control animals 35 days after the crush. Altogether, these results indicate that ATF3 has a neuroprotective and axogenic effect on injured RGCs, promoting the restoration of some visual-dependant behaviours.

Title: Cromolyn sodium administration after pilocarpine-induced Status epilepticus reduces the subsequent neuronal damage in hippocampus of rats
Authors: *M. G. VALLE DORADO¹, S. A. OROZCO², L. ROCHA¹

¹Pharmacobiology, CINVESTAV, Ciudad de Mexico, Mexico; ²Unit for Med. Res. in Neurolog. Dis., Netional Med. Ctr., Mexico City, Mexico

Abstract: Pretreatment with Cromolyn sodium (CGS) produces neuroprotector effects in experimental hypoxia-ischemia and Status epilepticus (SE). However, at present it is unknown if its administration after SE is able to prevent the subsequent neuronal damage. This study was focused to investigate if a single administration of CGS applied 1 h after pilocarpine-induced SE can reduce the neuronal damage in hippocampus. Rats (n=20) received one saline solution administration (1 ml/kg, i.p.) per day for 5 consecutive days for habituation to manipulation. Twenty-four hours after the last saline injection, animals received the administration of lithium chloride (3 mEq/kg i.p.), and 18 h later, methylscopolamine (1 mg/kg, s.c.) was applied. Pilocarpine (30 mg/kg, i.p.) was injected 30 min after methylscopolamine to induces SE. Two hours after the establishment of SE, rats were injected with diazepam (2.5 and 1.25 mg/kg, i.m, 1 h and 8 h after SE, respectively) to reduce the convulsive seizures. A group of animals (CG-SE n=6) was injected with CGS (50 mg/kg s.c.) 1 h after the first administration of diazepam. The SE control group (SS-SE n=8) was manipulated as described above except that vehicle was applied instead of CGS. A control group (SS, n=6) received vehicle instead of pilocarpine. Animals were sacrificed 24 h after SE and the brain was used to evaluate neurons in process of death using Fluoro-Jade B. We found that the control group presented scarce cell in process of death. In contrast, SS-SE group showed neuronal damage 24 h after SE in dorsal hippocampus (dentate gyrus, 363.4±128 mm³; hilus, 186.7±28 mm³; CA1, 233.3±155 mm³ and CA3, 260.3±48 mm³), lateral-dorsal thalamic nucleus (260.3±24 mm³) and layers V and VI of cortex (213.3±49 mm³). When compared with SS-SE group, CGS-SE group presented less neuronal damage induced in the dorsal hippocampus (dentate gyrus, 86% p=0.0158; hilus, 42% p=0.0122; CA1, 80% p=0.0377 and CA3, 68% p=0.0093). This situation was not evident in the lateraldorsal nucleus of thalamus and neocortex. In conclusion, our data indicate that CGS applied after SE can be used as a therapeutic strategy to reduce the subsequent neuronal damage.

Title: Analysis of Recurrent Seizures after soman-induced status epilepticus: Comparison between Tezampanel versus Diazepam when treatment is delayed

Authors: *T. H. FIGUEIREDO¹, J. P. APLAND², M. D. FURTADO³, V. ARONIADOU-ANDERJASKA⁴, M. M. F. BRAGA⁴

¹Anatomy, Physiol. & Genet., Uniformed Services Univ., Bethesda, MD; ²Neurobehavioral Toxicol, USAMRICD, Gunpowder, MD; ³Anatomy, Physiol. and Genet., USUHS, Bethesda, MD; ⁴Anatomy, Physiol. and Genet., Uniformed Services Univ. of the Hlth. Sci., Bethesda, MD

Abstract: The use of nerve agents (NA) in recent years, even against civilians, bring again to the forefront the question of readiness and whether the existing medical countermeasures can save lives and protect against the long-term health consequences of exposure. The primary action of NA is the inhibition of acetylcholinesterase, which, in addition to the peripheral cholinergic crisis, induces status epilepticus (SE); if SE is not adequately controlled, death may ensue, or brain damage, with long-lasting neurological and behavioral consequences. The total duration of SE after exposure determines to a significant degree the extent of brain damage. In previous research from our group, antagonists of GluK1-containing kainate receptors (GluK1Rs) were found to be effective against soman-induced seizures even when administration is delayed 1 hour or later. On the other hand, diazepam (DZP), the only FDA-approved anticonvulsant for the treatment of NA-induced seizures, has been demonstrated in animal models to lose efficacy with delayed administration; furthermore, we have observed significant recurrence of convulsive seizures after the initial SE is terminated by DZP, making the total duration of SE with 24 hours post-exposure no different from that in animals who do not receive anticonvulsant treatment. In the present study, we compared the occurrence of recurrent seizures after treatment of somanexposed rats with tezampanel (LY293558) or DZP. We have analyzed video-EEG of animals exposed to 1.4X LD50 soman (pretreated 30 min earlier with 125 mg/kg HI-6 and administered 2 mg/kg Atropine Sulfate at 1 min after exposure) and treated with DZP (10 mg/kg) or LY293558 (50 mg/kg) at 1 to 2 hours after exposure. The latency to the appearance of recurrent convulsive seizures was significantly longer in animals treated with LY293558 (1020 ± 78 min) versus DZP $(330 \pm 28 \text{ min})$. We also used power spectrum analysis to study the progression of recurrent electrographic seizures during the 24-hour period post-exposure. Although seizures recurred after either LY293558 or DZP treatment, LY293558 was significantly more efficacious in suppressing them, thus reducing the total duration of SE in the 24-hour post-exposure period significantly more than DZP. The data suggest that targeting the glutamatergic system to suppress seizures after NA exposure will not only terminate the initial SE but also reduce significantly the total duration of post-exposure seizures, which predicts significant protection against brain damage; suppression of the total duration of seizures in the 24-hour post-exposure period cannot be achieved by drugs targeting the GABAergic system, such as DZP.

Title: Steroid hormone receptors control neuronal inositol 1,4,5-trisphosphate receptor activity in the nucleus

Authors: *P. KOULEN

Basic Med. Sci. & Ophthalmology, Univ. of Missouri Kansas City, Kansas City, MO

Abstract: Controlling the nucleoplasmic concentration of free calcium ions (Ca²⁺) is essential for the physiological activity of neurons, such as gene expression and neuronal survival under disease conditions. At the same time, the steroid hormones progesterone and the estrogen 17βestradiol have been identified as neuroprotective and critical for proper neuronal viability as transcription factors directly controlled by extracellular hormone signaling. The present study determined novel mechanisms of action how signaling mediated by the interaction of inositol 1,4,5-trisphosphate receptors with steroid hormone receptors in the nuclear envelope control the Ca^{2+} concentration of the nucleoplasm in neurons. Specifically, it was identified how direct binding of estrogen receptors to inositol 1,4,5-trisphosphate receptors on the nucleoplasmic face of the nuclear envelope affects release of Ca^{2+} from the nuclear envelope by controlling the activity of this major type of ligand-gated intracellular Ca²⁺ release channels in the nuclear envelope of neurons. Using immunochemistry, optical imaging and electrophysiology, as well as immunochemical assays for determining protein-protein binding, changes in the activity of inositol 1,4,5-trisphosphate receptors in the nucleus after binding of steroid hormone receptors were determined. Binding of steroid hormone receptors to the intracellular Ca²⁺ release channel resulted in distinct changes in both channel open frequency as well as the number of channel openings at the single channel level and preservation of key biophysical parameters of the channels such as single channel conductance. These molecular changes in channel open probability were mirrored at the cellular level by altered release of Ca²⁺ from the nuclear envelope and in the nucleoplasm as well as altered susceptibility of neurons to stimuli selectively elevating nucleoplasmic Ca^{2+} levels. The work indicates that Ca^{2+} signaling in the nucleus of neurons mediated by inositol 1,4,5-trisphosphate receptors as Ca^{2+} dependent intracellular Ca^{2+} release channels is critically controlled by steroid hormone receptor binding. Such nucleoplasmic Ca^{2+} signaling controlled by protein-protein interactions in neurons of the central nervous system potentially provides a novel mechanism for both genomic as well as non-genomic actions of steroid hormone receptors as a new target for drug development in the area of neurodegeneration.

Title: EphB2 controls depression & cognitive impairment by regulating neurogenesis in hippocampus

Authors: *Y. XIAOKAITI¹, V. LURIA², H. ZHANG³, J. O'DONNELL¹, Y. XU¹ ¹Dept. of Pharmaceut. Sci., State Univ. of New York at Buffalo, Buffalo, NY; ²Dept. of Systems Biol., Harvard Med. Sch., Boston, MA; ³Depts Behav Med. & Psych, Pharm, West Virginia Univ. Hlth. Sci. Ctr., Morgantown, WV

Abstract: EphB2 activates signaling transduction in central nervous system by interacting with membrane-anchored ligands ephrins. EphB2 (receptor tyrosine kinase) is considered to mediate development of the neurogenic niche of excitatory neurons, implicating its role in neuropsychiatric disorders. However, how EphB2 controls depression and memory and cognitive processes remain partially understood. The present study examined depression-like behaviors and cognitive impairment induced by EphB2 knockout (KO) in series behavioral tests and the correlation with hippocampal neurogenesis. The EphB2 KO mice produced depression-like behaviors and deficits in spatial memory and cognition in comparison with matched wild-type littermates in tail suspension, forced swimming, Morris water maze, novel object recognition and novel object location tests. Further study suggested that depletion of EphB2 significantly reduced expression of neural stem cells (NSCs)/progenitor cells (NPCs), and also affected differentiation of neural progenitors in the hippocampus. These alterations were accompanied by the findings that increased N-methyl-D-aspartate (NMDA) receptor 2B, decreased phosphorylation of cAMPresponse element binding protein (pCREB) and brain derived neurotrophic factor (BDNF) levels were significant in EphB2 KO mice. These alterations exhibited by knockout of EphB2 highlight that EphB2 receptor controls the progression of depression and cognitive impairment by increased hippocampal neurogenesis, which implicate that EphB2 is one of candidate molecules

for modulating the production and integration of new neurons for treatment of emotional and cognitive disorders.

Key Words: EphB2; depression; cognition; neurogenesis; NMDA-2B receptor

Title: Time-dependent changes in cholesterol 24-hydroxylase expression in the spinal cords during experimental autoimmune encephalomyelitis

Authors: *I. LAVRNJA, K. SMILJANIC, D. SAVIC, A. MLADENOVIC-DJORDJEVIC, K. TESOVIC, S. KANAZIR, S. PEKOVIC Inst. For Biol. Res. Sinisa Stankovic, Belgrade, Serbia

Abstract: The dysfunction of cholesterol metabolism may be a crucial event that leads to the progression of multiple sclerosis (MS). Using a rat experimental autoimmune encephalomyelitis (EAE) model of MS, the specific changes of main molecule involved in the retaining of cholesterol homeostasis in the spinal cord: cholesterol 24-hydroxylase (CYP46A1) expression was monitored on gene and protein level during the course of disease. The present study is aimed to explore the molecular pattern of CYP46A1 expression over the course of EAE and cell type(s) accountable for its expression. EAE was induced in Dark Agouti rats by immunization with the spinal cord tissue homogenate and Complete Freund's adjuvant. Animals were sacrificed 9, 13, and 22 days after immunization. First signs of the disease appeared at 9 days after immunization and the disease reached a peak at day 13. Clinical signs of EAE decreased afterwards during the period of recovery, and all rats completely recovered by day 22 (end of the disease). Development of EAE signs was accompanied with body weight loss; maximal loss coincided with paralysis at the peak of disease. Myelin lipid debris was seen only at the peak of EAE and was efficiently removed until the end of disease. Since CYP46A1 is a crucial molecule for elimination of cholesterol excess, a detailed cellular profiling of CYP46A1 expression was

undertaken, and revealed regional and temporal specificities in its distribution. Double immunofluorescence staining showed presence of CYP46A1 protein in neurons, infiltrated macrophages, microglia and astrocytes in the areas of demyelination, implying that these cells have a role in cholesterol turnover during EAE. Summarizing, the observed changes in the regulation of cholesterol metabolism EAE may enhance symptoms at the onset and peak of the disease, but during the recovery period could contribute to the regeneration of myelin sheath. The fact that cholesterol is a crucial, rate-limiting factor for myelin growth and that its metabolites may have a role in promoting autoimmunity as inflammatory mediators, warrants further investigation of cholesterol metabolism in autoimmune diseases like MS.

Title: Baicalein neutralizes inflammation and nerve growth factor in cerebral cortex in diabetic rat model

Authors: S. S. AL-REJAIE¹, *M. N. ASHRAF²

¹King Saud Univ., Riyadh, Saudi Arabia; ²Pharmacol., The Islamia Univ. of Bahawalpur, Bahawalpur, Pakistan

Abstract: Diabetes-induced encephalopathy is a well-reported consequence among diabetic subjects. Alteration includes cellular, molecular and functional complications. Nevertheless, the mechanisms responsible for the pathogenesis and the therapeutic strategies are not fully reported. In the present investigation, baicalein as a flavonoid was examined as a protective agent against the experimental diabetic neurodegenerative diseases based on its potent free radical-scavenger activity. Baicalein was orally administered in two different doses (25 and 50 mg kg¹⁻ day¹⁻) to diabetic rats for five consecutive weeks. Following the end of the treatment, cerebral cortex tissues were harvested and directly frozen in liquid nitrogen till analysis. Baicalein markedly lowered the expressions of inflammatory cytokines including interleukin (IL)-1 β , tumor necrosis factor (TNF)- α and IL-6 and corrected the altered levels of neurotrophic factors such as brain derived neurotrophic factor (BDNF), nerve growth factor (NGF) and insulin growth factor (IGF)-1 in the diabetic cerebral cortex tissues compared to untreated diabetic group. Taken together, these finding indicate the beneficial role of baicalein in alleviating the provoked inflammation and enhancing the neurotrophic support in the diabetic cerebral cortex.

Title: Role of neuroinflammation in the regulation of the cytochromes P450 2C11 and 2J3 in the brain

Authors: *M. M. LOAIZA ZULUAGA, C. NAVARRO-MABARAK, S. L. HERNÁNDEZ-OJEDA, R. CAMACHO-CARRANZA, J. J. ESPINOSA-AGUIRRE Inst. de Investigaciones Biomédicas, Univ. Nacional Autónoma De México, CDMX, Mexico

Abstract: The cytochromes P450 (CYP) are membrane proteins that are expressed in the endoplasmic reticulum of plants, fungi and animal cells. They contribute to the degradation of endogenous and exogenous compounds including drugs and carcinogens. CYP presents a variety of isoforms, 2C and 2J isoforms have epoxygenase activity. CYP epoxygenases have been considered the major producers of short chain fatty acids, such as epoxyeicosatrienoic acids (EETs) from the oxidation of arachidonic acid (AA). EETs have diverse biological properties including anti-inflammatory activities, inhibiting NF- κ B as a transcriptional factor, thus avoiding its participation in the production of pro-inflammatory cytokines.

It has been seen that phenomena such as inflammation and infection can affect the regulation of epoxygenases during the metabolism of AA to EETs, inhibiting their transcriptional expression in tissues like heart, liver and kidney. It has also been shown that these enzymes are expressed in brain, but its regulation by inflammation has not been studied yet in this important organ. Based on previous studies and in the relevance that the EETs have acquired, we seek to determine if there are changes in the expression and protein levels of CYP2J3 and CYP2C11 in the cortex and hippocampus of animals exposed to LPS as a result of the presence of pro-inflammatory cytokines such as IL-6, IL-1 β and TNF- α in the brain. We performed an in vivo model of neuroinflammation by the intraperitoneal administration of LPS (1mg/kg) to male Wistar rats, and as a vehicle, commercial saline solution. The sacrifice was by decapitation at 6, 12, and 24 hours, obtaining the hippocampus and the cerebral cortex of the control and treated rats. We evaluated the transcriptional expression of CY P2J3 and 2C11 in these tissues by RT-PCR, considering GAPDH as the housekeeping gene. Our results show for the first time that LPS treatment in the periphery (i.p. administration) is able to downregulate CYP 2J3 and 2C11 expression in the brain. Pro-inflammatory cytokine levels in the cerebral cortex will be

determined by specific ELISA kits and CYP protein levels will be determined by Western Blot in the hippocampus and cerebral cortex to further confirm our hypothesis.

Title: Neuromodulators of inflammation in mouse administered with exogenous soluble gp130

Authors: *A. M. SALAZAR, A. S. MURTISHAW, M. M. BOLTON, J. W. KINNEY PSYCHOLOGY, Univ. of Nevada Las Vegas, Las Vegas, NV

Abstract: Neuroinflammation is a multifaceted biological response of the nervous tissue to harmful stimuli, cell damages, and some metabolic diseases. It is a vital component of the immune response to promote healing and restoration. However, prolonged inflammation can be harmful. Emerging evidences suggest that it plays a significant role in the pathogenesis and exacerbation of neurodegenerative diseases such as Alzheimer's Disease, Parkinson's Disease and Multiple Sclerosis. Neuroinflammation is commonly characterized by activated microglia and abnormal levels of cytokines, such as IL-6 that has both pro- and anti-inflammatory effects. IL-6 is needed for the activation of the immune system. IL-6 binds IL-6 receptor and the complex associates with gp130, a signal transducer, to initiate signaling via JAK/STAT pathway. This process contributes to the regenerative and protective effect of IL-6 signaling during inflammation. IL-6 is also found to bind to the soluble form of IL-6 receptor (sIL-6R) and this complex instead induces IL-6 trans-signaling in cells with gp130 only in their membrane. This condition is reported to stimulate inflammation. However, a soluble form of gp130 (sgp130) is described to bind the IL-6/sIL-6R complex that suppresses the IL-6 trans-signaling and regulates inflammation. This effect is characterized by several studies on animal models of human diseases such as intestinal and acute inflammation, rheumatoid arthritis, sepsis, arteriosclerosis, asthma, and various cancers. In a high fat diet-induced obesity model, the increased level of sgp130 in the plasma suggests an antagonistic response to systemic inflammation. While the position of sgp130 in IL-6 signaling is well-established and proofs of its role in regulating inflammation are growing, less information on its effect in neuroinflammation is available. In addition, investigations on the effects of sgp130 in the expression of other inflammation modulators are limited. Thus, we investigated the influence of sgp130 in neuroinflammation. We examined the

effects of exogenous sgp130 in TLR3-mediated inflammation. This study is aimed at describing the effects of a three-consecutive day intraperitoneal administrations of exogenous sgp130 in healthy and immunocompromised wildtype mice to specifically evaluate the expression profiles of cytokines with or without poly I:C. Hippocampal tissues were analyzed for cytokine levels. The results showed that sgp130 alone evoked an immune response and demonstrated significant effects on the expression of several cytokines. We also found that sgp130 altered several cytokines in the poly I:C inflammation model.

Title: Changes in neuroinflammation markers across brain regions of interest in alcohol-related brain damage

Authors: *P. TOLEDO NUNES¹, L. C. VEDDER², T. DEAK³, M. M. DEAK², L. M. SAVAGE, Ph.D.⁴

¹Psychology, Binghamton Univ. - SUNY, Vestal, NY; ²Psychology, Binghamton Univ., Binghamton, NY; ³Behavioral Neurosci. Program, Dept. of Psychology, Binghamton University-SUNY, Binghamton, NY; ⁴Psychology-Behavioral Neurosci., Binghamton Univ. Dept. of Psychology, Binghamton, NY

Abstract: Neuroinflamation has been suggested to play a significant role alcohol-related brain dysfunction. Thiamine deficiency (TD) is a key contributor to alcohol-related brain damage. The goal of this study was to determine the long-term impact of Chronic Ethanol Treatment (CET; 20% ethanol in drinking water for 6 months) and thiamine deficiency (induced by pyrithiamine-induced thiamine deficiency and thiamine free diet; PTD) on the expression of several key neuroimmune genes (IL-1 β , IL-6, TNF α , IkB α) in brain regions with established vulnerabilities to alcohol-related brain damage (thalamus, hippocampus, frontal cortex). Using real time RT-PCR assessments, we observed only minor fluctuations in these neuroimmune genes as a result of CET, regardless of the structure being examined. In contrast, PTD treatment led to a profound increase in all four neuroimmune genes within the thalamus, a structure that demonstrates severe pathology as a result of TD. Cytokine changes in the thalamus ranged in magnitude from moderate (3-4 fold increase for IL-1 β and IkB α) to severe (10-40 fold increase in TNF α and IL-

6, respectively). Though a similar pattern was observed in the hippocampus and frontal cortex, overall fold-increases were comparatively small relative to the thalamus. Importantly, neuroimmune gene induction varied significantly as a function of severity of TD, and displayed a gradual decline across recovery (24-hr, and 3 weeks post-treatment). Overall, these data suggest that rapid induction of neuroimmune genes may contribute to the severity of thalamic lesions induced by TD. Furthermore, TD, rather than a life-long history of alcohol consumption per se, appears to contribute greater vulnerability toward neuroinflammation. Finally, the temporal aspects of neuroimmune gene induction suggests the degree of TD may be a key driver of neuroimmune gene expression and subsequent neuroinflammation.

Title: Dynamics of blood-brain barrier repair in a neonatal rabbit model of cerebral palsy and its implications in nanoparticle-based drug delivery

Authors: *J. E. PORTERFIELD¹, E. S. SMITH², K. LIAW¹, Z. ZHANG², R. M. KANNAN³, S. KANNAN²

Abstract: Two of the key physiological hallmarks of cerebral palsy (CP) are an impaired bloodbrain barrier (BBB) and neuroinflammation. Recent nanotechnology efforts have taken advantage of the impaired BBB, for targeted attenuation of neuroinflammation. It has previously been shown in a neonatal model of CP induced by maternal-fetal inflammation that motor function, BBB integrity, and survival can all be increased dramatically by targeted delivery of Nacetyl cysteine, a potent anti-oxidant/anti-inflammatory agent, to activated microglia and astrocytes via dendrimers. We have recently discovered that the restoration of the BBB could be time-dependent, which may have major implications on the development of a dosing regimen for dendrimer-based therapies in preclinical models, due to the fact that neuroinflammation persists, but becomes less accessible over time.

To study BBB repair dynamics after neonatal exposure to maternal inflammation, pregnant New Zealand white rabbits are given an intrauterine dose of LPS endotoxin on gestation day 27, then

labor is induced on day 29 and kits are obtained. To investigate whether the BBB was becoming less penetrable over time, kits were injected i.v. with Evan's Blue Dye (EBD) at varying time points after birth. After sacrifice the brain was perfused with saline, flash frozen, microdissected, and homogenized in 50% trichloroacetic acid for spectroscopic quantification. The quantity of EBD in the brain tissue decreased incrementally over a 24-hour period, indicating a decrease in permeability of the BBB. Additionally, occludin expression is currently undergoing analysis through western blot, which is expected to further confirm the time-dependent repair of the BBB in the absence of therapeutics.

For analysis of the impact on dendrimer therapy, dendrimer-cyanide 5 dye conjugate (D-Cy5) was administered to the kits i.v. at varying time points after birth. 24 hours after D-Cy5 administration, kits were sacrificed and perfused, and D-Cy5 quantification was performed similarly to EBD. The results show significantly decreased uptake of D-Cy5 at later time points, suggesting that the ability of the dendrimer to cross the BBB is diminished over time. This data indicates that BBB repair may function independently of neuroinflammation within this model of CP, and that for effective treatment of CP with dendrimer nanotechnologies, administration may have to occur in the early stages of the disease, or may require higher dosing to achieve the same effective concentration of drug in the brain. These results are integral to understanding mechanisms of CP as well as other neonatal conditions marked by maternal inflammation.

Title: Intranasal IGF-1 protects against neonatal lipopolysaccharide-induced neuroal inflammation in the brain of juvenile rats

Authors: *L.-T. TIEN¹, Y.-J. LEE¹, C.-C. CHIEN^{1,2}, S. LU³, L.-W. FAN³ ¹Fu Jen Catholic Univ., Taipei, Taiwan; ²Anesthesiol., Cathay Gen. Hosp., Taipei, Taiwan; ³Univ. of Mississippi Med. Ctr., Jackson, MS

Abstract: Neonatal lipopolysaccharide (LPS) exposure-induced brain inflammation resulted in motor dysfunction and brain dopaminergic neuronal injury, and increased the risks of neurodegenerative disorders in adult rats. Our previous studies showed that intranasal administration of insulin-like growth factor-1 (IGF-1) protects against LPS-induced white matter injury in the developing rat brain. To further examine whether IGF-1 protects against LPSinduced brain neuronal injury and neurobehavioral dysfunction, recombinant human IGF-1 (rhIGF-1) at a dose of 50 µg/pup was administered intranasally 1 hour following intracerebral injection of LPS (1 mg/kg) in postnatal day 5 (P5) Sprague-Dawley rat pups. Neurobehavioral tests were carried out from P7 to P21, and brain neuronal injury was examined at P21. Our results showed that LPS exposure resulted in disturbances of motor behaviors in juvenile rats. Moreover, LPS exposure caused injury to central catecholaminergic neurons, as indicated by reduction of tyrosine hydroxylase (TH) immunoreactivity in the substantia nigra (SN) and ventral tegmental area (VTA), and brain noradrenergic neurons, as indicated by reduction of TH immunoreactivity in the locus coeruleus (LC) of the P21 rat brain. The LPS-induced reduction of TH+ cells were observed at a greater degree in the SN and LC of the P21 rat brain. Intranasal rhIGF-1 treatment attenuated LPS-induced central catecholaminergic neuronal injury and motor behavioral disturbances, including locomotion, beam walking test and gait analysis. Intranasal rhIGF-1 administration also attenuated LPS-induced elevation of IL-1ß levels and numbers of activated microglia, and cyclooxygenase-2+ cells, which were double labeled with TH+ cells in the SN, VTA, and LC of the P21 rat brain. These results suggest that IGF-1 may provide protection against neonatal LPS exposure-induced central catecholaminergic neuronal injury and motor behavioral disturbances, and that the protective effects are associated with the inhibition of microglia activation and the reduction of neuronal oxidative stress by the suppression of the neuronal cyclooxygenase-2 expression.

Title: Mammary tumors induce neuroinflammation, but not behavioral deficits in Balb/C mice

Authors: *W. H. WALKER, J. C. BORNIGER, A. A. ZALENSKI, S. GAHOLT, N. ZHANG, A. C. DEVRIES

Neurosci., The Ohio State Univ., Columbus, OH

Abstract: Women diagnosed with breast cancer are considerably more likely to develop a mood disorder and to report cognitive deficits than women in the general population. Previous studies suggest that peripheral tumors, such as mammary tumors, may create an immune response that can drive neuroinflammation, in turn leading to depression and cognitive deficits. In the present study, two cohorts of female Balb/C mice received bilateral orthotopic injections of syngeneic 67NR, 4T07, or 4T1cells (1x10⁵ cells per injection) to induce mammary tumors. Approximately three weeks later, cognitive function (via fear conditioning) or depressive-like behavior (via tail suspension and forced swim test) was assessed. Tissues were collected following the completion of behavioral testing. Proinflammatory cytokine levels were increased in the serum (IL-1 β , TNF α , IFN γ) and livers (IL-1 β , IL-6, TNF α) of mice injected with 4T07 or 4T1 cell lines compared to the 67NR cell line and vehicle control. IL-1ß was increased in both the hippocampus and cortex of mice injected with 4T07 or 4T1 cell lines relative to the vehicle and 67NR treatment groups. However, mammary tumors had no effect on hippocampal neurogenesis (DCX+ cells) and did not alter depressive-like behavior or induce cognitive deficits. Collectively, these data demonstrate that similarly sized tumors can produce differential immune responses both peripherally and centrally and that tumor-induced neuroinflammation can exist without resulting in the development of depressive-like behavior or cognitive deficits.

Title: Application of retinoic acid after optic nerve injury affects optic nerve glia and macrophages in adult frog Rana pipiens

Authors: V. DE LA ROSA-REYES¹, M. V. DUPREY-DIAZ², J. M. BLAGBURN³, *R. E. BLANCO⁴

¹Univ. of Puerto Rico- Med. Sci. Campus, San Juan, PR; ²Inst. of Neurobio., San Juan, PR; ³Inst. Neurobiol, Univ. Puerto Rico, San Juan, PR; ⁴Inst. Neurobiol Univ. Puerto Rico, San Juan, PR

Abstract: Retinoic acid (RA) is a vitamin A-derived lipophilic molecule that plays major roles during development of the nervous system. The RA signaling pathway is also present in parts of the adult nervous system, and components of it are upregulated after injury. Recently we have shown that the components of RA signaling are present at low to moderate levels in frog retinas and tecta of control, unoperated animals. After optic nerve injury, there is a large increase in the synthetic enzyme RALDH and the retinoic acid receptors (RARs) in the frog retina. It is not known whether similar changes take place in the glia of the injured optic nerve. The objective of the present study is to characterize the RA signaling system in the frog optic nerve and to determine the changes that occur after axotomy and application of RA. We performed optic nerve crush and applied into the nerve either saline solution or retinoic acid. We examined the optic nerves at 48h, one week, and two weeks after axotomy with immunocytochemistry and electron microscopy. Our results indicate that RARs are present in the optic nerve glia at very low levels, and that one week after axotomy there is a significant increase in staining intensity in those glial cells. Electron microscopy studies of the proximal, injury, and distal sites of the optic nerves show macrophages filled with secondary lysosomes and residual bodies. Application of RA to the optic nerve causes a significant increase in the number of macrophages present one week after optic nerve injury. Immunocytochemistry of various macrophage subtypes was carried out followed by confocal microscopy. The vast majority of cells were F4/80-positive in saline- and RA-treated nerves. We also identified a sub-population of anti-inflammatory M2 macrophages (arginase-positive) at the injury and distal sites. We are currently studying the changes in time and location of these populations. In conclusion, axotomy increases RARs in optic nerve cells. The application of RA affects the number and the distribution of macrophages after optic nerve injury and it may play a role in the success of optic nerve regeneration.

Title: Effects of Humanin on cognitive deficit and neuroinflammation by short-term exposure to cuprizone in mice

Authors: M. MURAKAMI¹, *Y. ABE², T. NIIKURA¹

¹Sophia Univ., Tokyo, Japan; ²Dept. of Pharmacol., Sch. of Medicine, Keio Univ., Tokyo, Japan

Abstract: Humanin (HN) is a 24-residue neuroprotective peptide. HN with a substitution of glycine for serine 14 (HNG) is a highly potent HN derivative and shows neuroprotective activity at nano M levels in vitro. HNG reduced amyloid burden and suppressed cognitive impairment in a mouse model of Alzheimer's disease. HNG also ameliorated amnesia induced by a muscarinic receptor antagonist and a GABA_A receptor agonist in mice. In addition, HN is noted to suppress LPS-induced cytokine production and activation of primary astrocytes in vitro. This indicates that HN has anti-inflammatory function to glial cells. However, the effects of HN on neuroinflammation in vivo remain unclear. Cuprizone (CPZ), a cupper chelator, induces demyelination in the central nervous system when mice are exposed to it for four to eight weeks (long-term exposure). A short-term (one week) exposure to CPZ triggers schizophrenia-like behavior in mice. In these mice, neuroinflammatory responses, up-regulation of a proinflammatory cytokine and glial activation, but not demyelination were observed, indicating that inflammatory responses occur prior to demyelinateion. Here, we tested the effect of HNG on these responses induced by short-term CPZ exposure in mice. Intraperitoneal injection of HNG for one week reversed the CPZ-induced deficit in object recognition memory but not in working memory. We detected activation of microglia and astrocytes in these mice by immunohistchemistry. Quantitative analysis showed no significant changes by HNG in CPZinduced glial activation. We then analyzed levels of transcripts for glial markers in hippocampi by quantitative PCR. Though the effect was limited, HNG significantly suppressed CPZ-induced activation of microglia and astrocytes. On the other hand, HNG did not alter the reduced level of myelin-specific transcript as a result of CPZ treatment. These results imply cell-type-specific action of HN. These findings suggest that HN can suppress neuroinflammation and associated cognitive deficit in a wide range of neurological disorders.

Abstract: Huntington's disease (HD) is a hereditary neurodegenerative disorder caused by a mutation in exon 1 of the huntingtin gene. HD courses with neuronal loss and neuroinflammatory processes, among other pathological processes. Mast cells (MCs) participate in inflammatory processes, where histamine (Hist) is the principal mediator. In different neuroinflammation models, His potentiates NMDA receptor-mediated cytotoxic effects. Intrastriatal (i.e.) administration of quinolinic acid (QUIN; NMDA agonist) in rodents mimics the most representative neurochemical characteristics of HD. In this study, we set to investigate the participation of MCs in the neurological and oxidant damage observed in a neurochemical model of HD. For this purpose, were used MCs-deficient Kit w-sh / w-sh mice (Wsh) and C57BL6 / J mice administered with QUIN (30nmol/µL, i.e.) as a reference for damage. To verify the participation of MCs in the QUIN-induced damage, Wsh mice were reconstituted with MCs precursors derived from mouse bone marrow (BMMCs). Reconstitution with BMMCs was performed by two routes: intracerebroventricular (ICV) (5x105 cells) and intraperitoneal (IP) (2x106 cells). In parallel, a group of animals was administered with Hist ICV (5 µg). Ipsilateral turns, striatal GABA content, lipid peroxidation (LP) and reactive oxygen species (ROS) were measured. Wsh mice presented a lower number of ipsilateral turns, GABA, LP and ROS levels in response to QUIN, in comparison to the control. I.p. reconstituted mice showed no significant difference from un-reconstituted Wsh mice. In contrast, Wsh mice ICV reconstituted with BMMCs or administered ICV with Hist increased the number of ipsilateral turns and GABA levels similar to control. Our results demonstrate that, at central level, His secreted by MCs potentiates the neurological and oxidative damage in this neurochemical model of Huntington disease.

Title: Fibroblasts infiltrate the spinal cord in experimental autoimmune encephalomyelitis

Authors: *S. L. YAHN, J. LI, R. BRAMBILLA, J. K. LEE Neurolog. Surgery, Univ. of Miami, Miami, FL

Abstract: Remyelination failure is a crucial component of disease progression in the autoimmune demyelinating disease Multiple Sclerosis (MS). The regenerative capacity of oligodendrocyte progenitor cells to differentiate into myelinating oligodendrocytes is likely influenced by many aspects of the lesion environment including inflammatory signaling and extracellular matrix deposition. These features of MS lesions are typically ascribed to infiltrating leukocytes and reactive astrocytes. Here we demonstrate that fibroblasts also infiltrate the spinal cord parenchyma in the animal model of MS, experimental autoimmune encephalomyelitis (EAE). Using Col1 α 1-GFP transgenic mice, we show that perivascular/meningeal fibroblasts are activated in the spinal cord at EAE onset and infiltrate the parenchyma by the peak of behavioral deficits. Furthermore, infiltrating fibroblasts are associated with areas of macrophage accumulation, demyelination, and fibronectin deposition. These results implicate fibroblasts in EAE pathology and suggest that fibrotic mechanisms may serve as novel therapeutic targets.

Title: Low dose of Diphenyleneiodonium (DPI), specific NADPH oxidase 2 (NOX2) inhibitor, targets NOX2 & ameliorates experimental autoimmune encephalomyelitis (EAE) severity in mouse model

Authors: *C.-F. HU¹, S.-J. CHEN¹, J.-S. HONG² ¹Pediatric Dept., Tri-Service Gen. Hosp., Taipei, Taiwan; ²NIEHS, Rtp, NC

Abstract: Nicotinamide adenine dinucleotide phosphate oxidase, type 2, (NADPH oxidase 2, NOX2), a key superoxide-producing enzyme which forms reactive oxygen species (ROS), plays a critical role in microglia-mediated chronic neuroinflammation & subsequent progressive

dopaminergic neurodegeneration in Parkinson's disease in mouse model. However, seldom articles discuss about the values & effects on different diseases, like experimental autoimmune encephalomyelitis (EAE) in mouse model. The aim of this study was to evaluate the characteristics & effects of low dose of NOX2 inhibitor, diphenyleneiodonium (DPI) in moderate severity of EAE mouse model. Furthermore, we want to ask whether NOX2 knockout mice show disease protection through reducing superoxide production & subsequent inflammatory process.

Our preliminary data reveal that pre-treatment strategy with DPI (both intravenous injection & drinking water formula) significantly attenuates progressive encephalomyelitis & reduces the severity of limbs paralysis of mice after disease induction. Meanwhile, NOX2 knockout mice show EAE protection through the inhibition of microglia activation, less peripheral macrophages infiltration in the central nervous system (CNS), & also a reduction in the expression of proinflammatory factors.

Title: Intestinal microbiota modulates depressive-like behavior in a mouse model of multiple sclerosis

Authors: *J. E. GOERTZ, I. A. MARIN, A. GAULTIER Univ. of Virginia, Charlottesville, VA

Abstract: In addition to the traditional motor impairments that are hallmark symptoms, depression has been found to be one of the most common symptoms in multiple sclerosis (MS) patients. While the immune system was previously thought to be the main link between this autoimmune disease and depression, new evidence points to the microbiome, the collection of organisms that live in and on the body, as an active player in depression etiology. The microbiome has recently been implicated in autoimmunity, as data has shown that autoimmune disease cannot be induced in germ-free mice and also that the microbiota composition may be responsible for the gender bias observed in the prevalence of autoimmune diseases. Previous

studies from our lab have shown that the microbiome, and in particular *Lactobacillus*, are involved the development of stress-induced depression in mice. Therefore, we hypothesize that changes in the gut microbiota in response to autoimmune disease induce depressive behavior. In order to tackle this problem, we induced experimental autoimmune encephalomyelitis (EAE), the mouse model of MS to examine the effect of disease on behavior and microbiota composition. We utilized the sucrose preference test and the social preference test to measure depressive behavior as the disease progressed. 16S sequencing showed robust changes in the composition of intestinal microbiota. These data suggest the microbiota in the gut, specifically *Lactobacillus*, is altered in mice affected by CNS autoimmune disease in correlation with their depressive behavior. Further research in this area may suggest new leads in developing novel therapies that could be used to treat depression in MS patients.

Title: Dose-dependent effects of systemic inflammation on murine cortical activity

Authors: *E. R. JAECKEL¹, M. I. BANKS¹, C. N. MURPHY², S. M. GRADY¹, P. A. BARNARD³, S. KAUR³, E. A. TOWNSEND⁴, R. D. SANDERS¹ ¹Anesthesiol., ²Physiol. Grad. Training Program, ³Col. of Letters and Sci., ⁴Sch. of Med. and Publ. Hlth., Univ. of Wisconsin, Madison, WI

Abstract: Introduction: Neuroinflammation is associated with cognitive and behavioral anomalies, but the mechanisms are unclear. At its extreme, during delirium, profound changes in cognitive function are accompanied by increased slow wave activity, and decreased 8-14Hz phase lag index (PLI) connectivity, in the EEG. We sought to model the changes in the behavioral and EEG responses to systemic inflammation by administering Lipopolysaccharide (LPS). Methods: All procedures were approved by the UW-Madison Animal Care and Use Committee. 14 mice (male; BL6 background; 12-20 wks old) were instrumented with bilateral parietal and frontal skull screw EEG electrodes. After 5-7 days recovery, mice were given intraperitoneal (IP) saline injections, and 1-2 days later IP injections of LPS (12.5, 25 or 125 ug/kg). Animals were tethered to a lightweight headstage during the experiment allowing movement to signify wakefulness. Data were collected for 1 hr prior and at 2-3 hrs post-injection. Average power was computed in the EEG δ (1-4 Hz), θ (4-10Hz), α (10-20 Hz), β (20-

30 Hz) and γ (30-100Hz) bands during movement defined via video recording. Comparisons were between the post-injection:control ratios of normalized band power (to total power) for saline versus LPS. Additionally, 8-14Hz PLI was calculated between frontal and parietal electrodes. Results: LPS increased average delta power across frontal and parietal electrodes at 12.5 ug/kg (p=0.0079), 25 ug/kg (p=0.0016) and 125 ug/kg (p=0.0022) during wakefulness. At 125 ug/kg (p=0.06) or 25 ug/kg (p=0.11). Multi-way ANOVA showed a trend to effect for LPS dose (p=0.06) but not electrode (p=0.39). LPS also decreased alpha and gamma power at each dose tested (p<0.05) but with no effect of dose in multi-way ANOVA (alpha LPS dose effect p=0.15; gamma LPS dose effect p=0.24). 125 ug/kg LPS also decreased frontoparietal 8-14Hz band PLI (p=0.0057) with no effect at the other doses (p>0.05). Conclusions: Ongoing studies will resolve the dose-dependence, and electrode site-dependence of inflammation. LPS injection is a promising model for neuroinflammatory effects on brain activity in wakefulness confirmed by spontaneous movement.

Title: Correlation analysis of [¹⁸F]ROStrace *Ex vivo* autoradiography and dihydroethidium fluorescent images in lipopolysaccharides treated animals

Authors: *C.-C. WENG, C. HOU, C. ZENG, C.-J. HSIEH, S. LI, H. LEE, R. H. MACH Radiology, Univ. of Pennsylvania, Philadelphia, PA

Abstract: Reactive oxygen species (ROS) play a critical role in the "neurotoxic" form of inflammation occurring in several neurodegenerative disorders. However, there is little data regarding the relationship between the in vivo ROS and neuroinflammation. For a better understanding, herein we performed the distribution correlation analysis between [¹⁸F]ROStrace and some common inflammation markers in a lipopolysaccharides (LPS) treated animal model. The LPS-treated mice (female Balb/c, body weight 20-25 g) received a 5 mg/kg i.p. injection of LPS 24 hr before study. Firstly, a 60-min dynamic PET scan was performed after an i.v. injection of [¹⁸F]ROStrace (~11MBq in 0.1 mL saline solution). To verify the ROS distribution, a dose of 15 mg/kg dihydroethidium (DHE) was also i.v. injected to the same animal after imaging, and it

was sacrificed 30 min after DHE injection. The brain was sectioned and acquired for ex vivo [¹⁸F]ROStrace autoradiography and DHE fluorescence. For further information on the inflammation, the sections were also stained for GFAP and Iba-1 and fused with the DHE images.

From the in vivo PET images of LPS-treated animals, we found a high uptake of the [¹⁸F]ROStrace in the brain, and a steady-state was reached roughly 30 min after tracer injection. Examination of the ex vivo autoradiography showed that the uptake ratio of the whole brain is about 3-fold higher in the LPS-treated group compared to the control one, and the tracer uptake was mainly distributed in the subregions of cortex, thalamus, hippocampus, and cerebellum. This showed a good correlation with the DHE fluorescent images and the antibody staining results. The [¹⁸F]ROStrace PET images can clearly delineate the ROS generation in the LPS-treated animal, and the ex vivo autoradiography further shows the tracer uptake regions were colocalized with the ROS markers, DHE and inflammation antibodies. This study provides evidence that [¹⁸F]ROStrace is useful for further in vivo ROS research.

Title: Persistence of cognitive deficits in the absence of systemic inflammation following acute LPS administration in immune-competent and immunodeficient mice

Authors: *S. REGE, H. HACKBART, A. TEICHERT, J. MASUMI, S. P. BRAITHWAITE, S. MINAMI

Alkahest, Inc., San Carlos, CA

Abstract: Peripheral inflammation has been linked to cognitive dysfunction in both animal models and in humans. Elevated levels of peripheral cytokines, classical hallmarks of inflammation, have been associated with lower cognitive performance, and there exists a well-established relationship between peripheral inflammation and cognitive dysfunction in patients experiencing acute infection and recent surgical procedures. However, there is little known about the long-lasting effects of transient systemic inflammation on cognitive function. Here we demonstrate that an acute dose of LPS peripherally can result in persistent cognitive dysfunction in the absence of elevated systemic inflammation. We administered a high (5mg/kg) and low (1mg/kg) dose of LPS to 2-month-old C57Bl/6 mice and assessed cognitive performance one week and one month later. The high dose group demonstrated diminished cognitive performance

in hippocampus dependent tests, like novel object recognition and y-maze, both one week and one month after administration of LPS. The low dose group was less affected after one month, with the only deficiency observed in the novel object recognition test. There were no effects on locomotor function or general physical health of the mice at either one week or one month after treatment. Immunocompromised mice are often used as a model to test human protein-containing therapies; in order to test the utility of these mice in an acute peripheral inflammation-induced cognitive dysfunction model, we treated NOD.Cg-*Prkdc^{scid}Il2rg^{tm1Wjl}*/SzJ (NSG) mice and found that their performance in hippocampus-dependent tests was slightly impaired. Additionally, we measured levels of circulating inflammatory cytokines immediately after LPS induction and terminally, at which point we assessed brain tissue by histological methods and performed protein analysis of neuronal and inflammatory cell markers. These results indicate that LPS can be utilized to establish a model of cognitive dysfunction induced by acute systemic inflammation in both immune-competent and immunodeficient mice, thus enabling future studies to better understand the relationship between inflammation and cognition.

Title: Baicalein neutralizes brain oxidative stress in diabetic rat model

Authors: *S. ALSHARARI¹, S. AL-REJAIE²

¹Dept Pharmacol & Toxicol, 1217 E. Marshall St, Richmond, VA; ²Dept Pharmacol & Toxicol, King Saud Univ., Riyadh, Saudi Arabia

Abstract: Diabetic-induced encephalopathy is a well-documented complication in diabetic patients, which is characterized by cellular, molecular and functional alterations. Nevertheless, the mechanisms responsible for the pathogenesis and the therapeutic strategies are not fully reported. In the present investigation, a flavonoid baicalein was examined as a protective agent against the experimental diabetic neurodegenerative diseases based on its potent free radical-scavenger activity. Baicalein was orally administered in two different doses (25 and 50 mg kg1-day1-) to diabetic rats for five consecutive weeks. At the end of the treatment period, the cerebral cortex tissues were harvested and directly frozen in liquid nitrogen till analysis. Baicalein,

especially the higher dose, improved insulin and blood glucose levels. In addition, diabetic associated oxidative injury in the diabetic cerebral cortex tissues was ameliorated by baicalein, which was manifested by enhanced glutathione, superoxide dismutase and catalase activities and decreased lipid peroxidation products compared to untreated diabetic rats. Taken together, these finding indicate the beneficial role of baicalein in alleviating the provoked oxidative stress in the diabetic cerebral cortex.

Title: CCL2 increases neuronal excitability during the early stage of systemic inflammation

Authors: *L.-H. DUAN^{1,2}, X.-D. ZHANG^{1,2}, W.-Y. MIAO¹, H.-M.-Z. LI¹, X. YU^{1,2} ¹Inst. of Neurosci., ShangHai, China; ²Univ. of Chinese Acad. of Sci., Beijing, China

Abstract: Acute infection by bacteria and viruses, if not kept in check, can quickly become systemic, leading to inflammatory responses in the brain. Young children are particularly vulnerable, with inflammation-induced cephalomeningitis being a leading cause of death among newborns, especially premature babies. The long-term effects of neuroinflammation on the brain function and behavior have been studied extensively, while its acute effects (within the first few hours) are relatively unknown. Here, using different systemic inflammation models, including Lipopolysaccharides (LPS), Poly(I:C) and ODN 1668, to respectively mimic infections mediated by bacteria, RNA virus and DNA viruses, we demonstrated that during the early stage of infection (within 2 hours), mice exhibited increased neuronal excitability and increased susceptibility to kainic acid induced seizure. High level expression of the chemokine (C-C motif) ligand 2 (CCL2) was observed in all three models, with the effects of LPS being highest. Overproduction of CCL2 may interfere with normal brain development and neuronal function, which may in turn, result in inflammation-induced neuronal hyperexcitability. Consist with this hypothesis, bath application of CCL2 in acute brain slices increased the frequency of miniature excitatory postsynaptic currents (mEPSCs) in hippocampal and cortical pyramidal neurons, as well as their neuronal firing. Further investigations demonstrated that the effects of LPS induced increase in mEPSC frequency and neuronal excitability were blocked in CCL2 knockout mice. Together, these results demonstrate that CCL2 plays a key role in regulating excitatory synaptic transmission and neuronal excitability, during the early stage of systemic inflammation.

Title: Establishment of minimal positive conditions to ensure brain safety for rapid development of emergency vaccines

Authors: ***H. BAEK**¹, G. KIM¹, M. PARK¹, B. KO¹, K. KIM¹, H. SEO², S. YI¹ ¹Soonchunhyang Univ., Asan, Korea, Republic of; ²Konyang Univ., Nonsan, Korea, Republic of

Abstract: With the increase in international human and material exchanges, contagious and infectious epidemics are being discovered. One of the effective methods of inhibition is the rapid development and supply of vaccines. Considering the safety of the brain during vaccine development is very important. However, manuals for brain safety assays for new vaccines are not uniform and efficient globally. Therefore, the aim of this study is to establish positive control protocol for effective brain safety test to help rapid vaccine development. Using the characteristics of tight junction of blood-brain barrier with the selective defense of the brain, it is possible to destroy this important micro-structure by administering lipopolysaccharides (LPSs), thereby artificially increasing the permeability of the parenchyma. The conditions are established so that the degree of brain penetration or brain destruction of a newly developed vaccine can be quantitatively identified. The most effective conditions were suggested by measuring the time-dependent expression of two types of mice (C57BL/6 and ICR), two types of LPSs (*Salmonella* and *Escherichia*), and tight junction biomarkers (ZO-1 and Occludin) after exposure to LPSs. In the future, we hope the positive-protocol will be able to speed up the determination of brain safety of various vaccines through this condition.

Title: Deficits in touchscreen-based operant tasks and fear conditioning memory in the cuprizone model of multiple sclerosis

Authors: A. J. NURMI¹, M. KOPANITSA¹, K. LEHTIMÄKI¹, M. FORSMAN¹, A. SUHONEN¹, J. KOPONEN¹, *A.-M. KÄRKKÄINEN¹, A. MERENLENDER-WAGNER², J. KAYE², A. ORBACH²

Abstract: Cognitive problems frequently accompany neurological manifestations of multiple sclerosis (MS). Therefore, evaluation of cognitive performance in mouse models of MS is needed to determine learning and memory parameters that change with the emergence of MSrelated symptoms and can be used as benchmark phenotypes for testing of drug candidates. We assessed cognitive behavior of female 9-10-week-old C57Bl/6J mice subjected to continuous cuprizone exposure by oral gavage (400 mg/kg daily) for two or four weeks and compared their performance to that of vehicle-treated mice. Cuprizone causes death of mature oligodendrocytes leading to demyelination, mostly, in the corpus callosum, that resembles pathology seen in MS patients. Cuprizone-treated mice demonstrated multiple deficits in a sequence of touchscreenbased operant tasks of gradually increasing difficulty. In particular, in comparison to vehicletreated animals, cuprizone-treated mice completed fewer trials, responded more slowly to visual stimuli, and were also slower to collect food reward after correct responses. Furthermore, cuprizone-treated mice exhibited significantly lower accuracy of responses during "Punish incorrect" stage of operant training. In contextual/cued fear conditioning experiments, in the 2week cohort, cuprizone-treated mice demonstrated significantly lower levels of both contextual and cued freezing than vehicle-treated mice. In the 4-week treatment cohort, a significant effect of treatment was observed only on contextual freezing level. Mild demyelination was observed in the 2-week cuprizone-treated cohort as reflected by significantly lower fractional anisotropy values in forceps minor of the corpus callosum and external capsule of cuprizone-treated animals. Stronger demyelination was induced by the longer, 4-week treatment, as indicated by larger and more widespread decreases of fractional anisotropy values in the brain of cuprizonetreated mice (forceps minor of the corpus callosum, genu of corpus callosum, body of corpus callosum, splenium of corpus callosum, external capsule, internal capsule) compared to myelination levels in the brain of animals that received vehicle. Our results suggest that touchscreen operant tests and fear conditioning paradigms sensitively detect cognitive consequences of MS-like anatomical brain abnormalities caused by relatively short exposures to cuprizone. Therefore, novel drug candidates for MS-treatment could be screened for their ability to reverse those cognitive deficits and to improve brain structural parameters in longitudinal experiments in the same animals.

Title: Immunophenotyping and characterization of PLP and MOG induced relapsing/remitting and chronic mouse models of experimental autoimmune encephalomyelitis

Authors: J. KURKIPURO, *M. VIHMA, L. KOISTINEN, *M. VIHMA, A. OKSMAN, L. TAHTIVAARA, A. J. NURMI Charles River Discovery, Kuopio, Finland

Abstract: The experimental autoimmune encephalomyelitis (EAE) is an inflammatory demyelinating disease of the central nervous system characterized by infiltration of immune cells into the CNS and subsequent demyelination by activated myelin-specific T-cells. We have characterized two models of EAE; the chronic myelin oligodendrocyte glycoprotein (MOG) induced model in C57BL/6J mice and the relapsing/remitting proteolipid protein (PLP) induced model in SJL mice. Altogether 20 female C57BL/6J and SJL/J between 9-10 weeks of age were inoculated with MOG₃₅₋₅₅/CFA or PLP₁₃₉₋₁₅₁/CFA, respectively, without PTX for the induction of the chronic and relapsing/remitting EAE models. Mice were then monitored for clinical signs of disease development and changes in body weight for three weeks before sacrificing the cohorts for harvesting of draining lymph nodes (DLN), brain and spinal cord samples for immunophenotyping and characterization by flow cytometry and immunohistochemistry. The EAE development in both models showed first clinical signs roughly 10 days after the inoculations. The chronic C57BL/6J model reached higher clinical score and showed no relapse of the disease development whereas this was observed in the SJL model. In the relapsing/remitting SJL model, the clinical signs were also less severe in comparison to chronic model. Flow cytometry analysis of the brain tissue showed elevated T-cell populations, significant invasion of CNS-associated monocytes from periphery as well as upregulation of the microglial population in both models. Finally, the analysis of the DLN tissues showed that the levels of NK-cells seem to be more elevated in the MOG model than in the PLP model.

Title: Treatment of brain injury due to extreme prematurity: Effect of melatonin on ADHD-like hyperactivity and midbrain dopaminergic neurons

Authors: *O. OKPE, ***O. OKPE**, L. GODDARD, D. E. OORSCHOT Dept. of Anat., Univ. of Otago, Dunedin, New Zealand

Abstract: The birth of an extremely premature baby (≤28 weeks of gestation) is costly to health systems. Children born extremely prematurely can experience repeated hypoxic injury to the brain and can develop attention deficit hyperactivity disorder (ADHD). In a new Sprague-Dawley rat model of repeated hypoxic brain injury during the equivalent of extreme prematurity, ADHD-like hyperactivity and a lower absolute number of midbrain dopaminergic neurons in the ventral tegmental area was observed. Yet, treatment with melatonin, which is safe in clinical neonatology and a known antagonist of the proposed biological mechanisms that generate a lower number of midbrain dopaminergic neurons in the ventral tegmental area, has not been investigated. Nor has the effect of melatonin on ADHD-like hyperactivity been investigated. Hence, the aim of this study was to investigate whether treatment with melatonin rescues ADHD-like hyperactivity and midbrain dopaminergic neurons in the ventral tegmental area. Postnatal day 1-3 Sprague-Dawley male rats were exposed to repeated hypoxia and divided into treatment groups of repeated hypoxia diluent-treated (n = 9 pups) and repeated hypoxia melatonin-treated (n = 10). At 9 months-of-age, each rat was tested for ADHD-like hyperactivity using a well characterised fixed interval test. At 10 months-of-age, each rat was perfuse-fixed, and its right cerebral hemisphere was serially sectioned and then immunohistochemically stained with an antibody to the catecholaminergic enzyme, tyrosine hydroxylase, to label dopaminergic neurons. The absolute number of dopaminergic neurons in the ventral tegemental area was then measured using the Cavalieri and disector methods. There was no significant difference between the repeated hypoxia melatonin-treated and the repeated hypoxia diluent-treated animals for the extent of ADHD-like hyperactivity (repeated measures ANOVA, p = 0.35) and the absolute number of midbrain dopaminergic neurons in the ventral tegmental area (Student's *t*-test, p =0.15, two-tailed test, n = 7/group and 6/group, respectively). The results of this study suggest that melatonin does not rescue ADHD-like hyperactivity and dopaminergic neurons in the ventral tegmental area after repeated hypoxic brain injury during the equivalent of extreme prematurity.

Abstract: Transendothelial trafficking of immune cells into the central nervous system (CNS) and disruption of the blood brain barrier (BBB) are pathophysiological hallmarks of neuroinflammatory disorders like multiple sclerosis (MS). Accumulating evidence suggest that oxidative stress plays a major role in the pathogenesis of MS, whereas a specific influence of oxidative stress on BBB dysfunction in MS was unclear so far. Here, we identify NADPH oxidase type 4 (NOX4) as a specific and direct modulator of BBB integrity. Deficiency of NOX4, but not NOX1 or NOX2, rendered mice more susceptible to experimental autoimmune encephalomyelitis (an animal model of MS) and was accompanied by a remarkable enhancement of BBB disruption and CNS inflammation. Murine and human *in vitro* analysis revealed that lack

of NOX4 amplifies leukocyte trafficking by modified endothelial cells. Further, reduced endothelial NOX4 expression was found in CNS tissue of individuals suffering from MS indicating an important role of NOX4 also in humans. Our study demonstrates, for the first time, that NOX4 is an important and direct regulator of BBB integrity.

NOX4 activation can decrease BBB damage and cell invasion during neuroinflammation and may offer a novel strategy for the treatment of MS.

Mississippi Med. Ctr., Jackson, MS

Abstract: Chronic brain neuronal inflammation has been proposed to play an important role in the development of neurodegenerative disorders in adult life. Our previous study showed that perinatal lipopolysaccharide (LPS) exposure induced a chronic neuronal inflammation, as indicated by increases in cytokines and pro-inflammatory molecules-induced cyclooxygenase-2 (COX-2)+ cells, and enhanced adult susceptibility to develop neurodegenerative disorders triggered by rotenone, a commonly used pesticide. The objective of the current study was to examine whether celecoxib, a selective COX-2 inhibitor, has long-lasting protective effects and attenuates LPS-induced motor behavioral dysfunction and LPS-enhanced susceptibility to

rotenone toxicity in later life of these rats. Intraperitoneal (i.p.) injection of LPS (2 mg/kg) or saline was performed on postnatal day 5 (P5) Sprague-Dawley male rat pups, and celecoxib (20 mg/kg) or vehicle was administered (i.p.) 5 min after LPS injection. On P70, rats were challenged with rotenone through subcutaneous mini-pump infusion at a dose of 1.25 mg/kg per day for 14 days. Motor behavioral tests were carried out from P70 to P98. Rats were sacrificed and LPS-induced injury to the dopaminergic system was assessed by losses of tyrosine hydroxylase immunoreactive neurons in the substantia nigra. Our results showed that neonatal administration of celecoxib provided protection against rotenone-induced neurobehavioral impairments including bradykinesia, akinesia, and rigidity in rats with the neonatal exposure to LPS. Celecoxib treatment also provided protection against LPS-enhanced rotenone-induced brain injury in adult rats, including loss of tyrosine hydroxylase positive neurons, a decrease in mitochondrial complex I activity, and an increase in the number of activated microglia in the substantia nigra of P98 rats. Results from the current study suggest that treatment with celecoxib has long-lasting protective effects against perinatal brain inflammation-enhanced adult susceptibility to environmental toxin-induced neurodegenerative disorders. Our results are useful for studying mechanisms involved in the pathogenesis of dopaminergic neuronal injury induced by infection/inflammation and the development of potential therapeutics.

Title: The role of inflammation in healthy and natural neruodegenerative states of a sensorimotor pathway responsible for song production

Authors: *T. LARSON¹, Y. TOKAREVA², M. MERRITT-COLE1², E. A. BRENOWITZ³ ¹Dept. of Biol., Univ. of Virginia, Charlottesville, VA; ²Psychology, ³Psychology and Biol., Univ. of Washington, Seattle, WA

Abstract: Neuroinflammation is typically considered a negative response following neuronal injury and damage. For example, inflammatory microglia become polarized from the "inactive" surveying (or ramified) state following neuronal loss and promote a classic cytokine-mediated inflammatory response. Neuroinflammation can, however, play a beneficial role in the healthy adult brain. Ramified microglia elicit positive effects through neuronal and synapse pruning to maintain proper neuronal number and connections. To identify the role of inflammation in both healthy and natural degenerative states, we employed the natural seasonal regression of the motor pathway responsible for song production in Gambel's white crowned sparrow (Zonotrichia leucophrys gambelii). Neuronal number in the song control nucleus HVC (proper name) changes seasonally such that as male sparrows transition between breeding and nonbreeding conditions, HVC neuronal number increases and decreases by about 68,000 neurons, respectively. As a result of the seasonal apoptosis of HVC neurons, neural stem cell proliferation increases - a process termed natural reactive neurogenesis. With this unique model of natural and rapid neurodegeneration, we show that inflammation is both necessary and sufficient for increases in reactive neurogenesis using pro- and anti-inflammatory agents during health and degenerative states, respectively. Quantification of the number of ramified and activated microglia in HVC using immunohistochemistry further suggests that local inflammatory status is conferred to the neural stem cells via microglia.

Title: Differential anticonvulsant responses of the basolateral amygdala and area tempestas to muscarinic receptor subtype antagonists following soman-induced seizures

Authors: *K. LAITIPAYA¹, J. K. CHANDLER², E. A. JOHNSON³, J. W. SKOVIRA⁴ ¹USAMRICD, Gunpowder, MD; ²US Army Med. Res. Inst. of Chem. Def, Aberdeen Proving Ground, MD; ³Pharmacol., US Army Med. Res. Inst. of Chem. Def., Aberdeen Proving Ground, MD; ⁴US Army Med. Res. Inst. of Chem. Def., Aber Prov Grd, MD

Abstract: Excessive cholinergic neurotransmission, particularly that involving the muscarinic receptor (MR), initiates seizure activity following exposure to the organophosphorus nerve agent soman. The MR antagonist scopolamine has been shown to prevent the onset of soman-induced seizures when given as a pretreatment or shortly after soman exposure. Scopolamine, however, is a non-specific MR subtype antagonist. The purpose of this study was to determine if antagonism

of specific MR subtypes is necessary to prevent soman-induced seizures. Using an up-down dosing procedure over successive animals we evaluated the microinjection of MR subtype specific antagonists into the basolateral amygdala or area tempestas (structures implicated as possible foci for soman-induced seizures) for their ability to pharmacologically modulate seizure activity. Rats were surgically prepared one week prior to the experiment with electrodes to record brain electroencephalographic (EEG) activity and with guide cannula bilaterally directed toward a designated brain structure. On the day of the experiment, animals were pretreated by microinjection (1 µl/cannula) with a MR subtype specific antagonist and intraperitoneal HI-6 (150 mg/kg). Thirty minutes later, animals were injected subcutaneously with 180 µg/kg soman (1.6 x LD₅₀) followed one minute later by 2.0 mg/kg atropine methyl nitrate intramuscularly. Animals were then returned to a cage where EEG was monitored for seizure activity. The MR subtype specific antagonists telenzepine (M_1) and 4-DAMP (M_3) provided an anticonvulsant effect when injected into the basolateral amygdala (anticonvulsant $ED_{50} = 30.06$ and 40.79 $\mu g/\mu l/cannula$, respectively). Rats injected with telenzepine into the basolateral amygdala also had the highest survival rate, followed by those injected with 4-DAMP. In the area tempestas only the M_2 antagonist methodramine produced an anticonvulsant effect (anticonvulsant $ED_{50} =$ 107.90 μ g/ μ l/cannula) while also having the highest survival rate. The results show that different MR subtypes within the basolateral amygdala and area tempestas respond to produce an anticonvulsant effect against soman-induced seizures while also increasing survivability of the specimens. More MR subtypes provided an anticonvulsant response in the basolateral amygdala than in the area tempestas. These results suggest that the response of multiple MR receptor subtypes within a brain structure may thus contribute to a greater anticonvulsant effect by nonspecific MR subtype antagonists such as scopolamine.

Title: Ppary Agonism in alzheimer's disease and irradiated mouse models

Authors: *D. CORTEZ¹, L. A. DENNER², K. T. DINELEY, 77550³ ¹UTMB, Galveston, TX; ²Intrnl. Med., Univ. Texas Med. Br., Galveston, TX; ³Neurol., The Univ. of Texas Med. Br., Galveston, TX

Abstract: Converging evidence from animal and human studies suggest that an early target of Alzheimer's disease (AD) amyloid pathology is synaptic activity within the entorhinal cortex

(EC), dentate gyrus, and Cornu Ammonis 3 (EC/DG/CA3) network. A major function of this hippocampal network is to perform pattern separation; the ability to process overlapping environmental cues into unique representations and distinguish similar, yet non-identical contexts. We have previously shown that aged Tg2576 mice (a model for early AD that recapitulates amyloid pathology, hippocampal cognitive deficits and disrupted EC/DG/CA3 circuitry) exhibit improved circuit and cognitive performance with peroxisome proliferator activated receptor gamma (PPAR γ) agonism. PPAR γ is a nuclear receptor and transcription factor that can be activated with FDA-approved drugs. Since we have found that the PPAR γ transcriptome and proteome contains mediators and markers for neurogenesis, we postulated that cognitive tests that require continued adult neurogenesis (e.g., context discrimination) would be altered in Tg2576 AD mice compared to littermate controls and that RSG treatment would normalize this behavior. Consistent with enhanced acute BrdU uptake, a mitotic marker, Tg2576 performed superiorly to littermate controls in context discrimination and cranial irradiation significantly impaired both groups' ability to distinguish between similar contexts. Further, PPARy agonism improved wild type performance. Conversely, Tg2576 groups exhibited delayed context discrimination with rosiglitazone treatment suggesting an effect of PPARy agonism on subgranular zone mitosis as measured with BrdU incorporation. Interestingly, doublecortin quantitation of neuronal precursor cells and immature neurons incorporated into the granule cell layer of the hippocampus revealed no significant difference between untreated and rosiglitazone treated wild type and Tg2576 groups.

Thus, superior context discrimination in Tg2576 appears to be due to enhanced mitosis in the subgranular zone; however, the extent to which subsequent adult-born neuronal precursors and immature neurons contribute to the dentate gyrus circuit is still open. PPAR γ agonism appears to reduce BrdU incorporation with no net effect on doublecortin-positive neuronal precursors and immature neurons leaving it open still as to the mechanism underlying improved context discrimination in wildtype mice with rosiglitazone treatment.

Title: Imaging the 18-kda translocator protein (a marker for neuroinflammation) in alcoholism

Authors: *R. E. TYLER¹, S. KIM¹, Y. JANG¹, C. WIERS¹, L. VENDRUSCOLO², G. KOOB², G.-J. WANG¹, J.-S. LIOW³, M. GUO¹, R. DAMADZIC¹, N. VOLKOW¹ ¹NIAAA, NIH, Bethesda, MD; ²NIDA, NIH, Baltimore, MD; ³NIMH, NIH, Bethesda, MD **Abstract:** Chronic alcohol consumption is associated with neurotoxicity and cognitive impairment. However, the neurobiological mechanism underlying alcohol's neurotoxic effects is poorly understood. We postulate that alcohol-induced neuroinflammation plays a role in alcohol's neurotoxic effects. Here, we determine if chronic alcohol use is associated with neuroinflammation. Towards this aim, we used [¹¹C]PBR28 positron emission tomography (PET) to measure the expression of the 18-kDa Translocator Protein (TSPO) in a rat model of alcoholism *in vivo*. TSPO is predominantly expressed in activated microglia and astrocytes in the brain, and therefore considered a biomarker of neuroinflammation.

10 rats (Wistar, male, mean weight= 547 ± 3) became alcohol dependent (AD) by passively inhaling alcohol sprayed in their cage for 14hrs/day during a 1.5-2.5 month period (blood alcohol levels averaged 196 mg/dL). [¹¹C]PBR28 brain PET scans were performed for each rat along with a control (n=10, mean weight= $568\pm6g$). After scanning, rats were sacrificed and brains harvested for [³H]PK-11195 autoradiography.

In vivo results show consistently lower whole brain uptake of [¹¹C]PBR28 in AD rats compared to controls. Autoradiography confirms these results, showing lower specific binding of [³H]PK-11195 in brains from AD rats. These results are consistent with our findings that human subjects with alcohol use disorder (AUD) express lower levels of TSPO in their brains. This may reflect alterations in the innate immune response of rats and humans exposed to chronic alcohol. Experiments to determine whether this alteration can recover after 1 month of abstinence are underway.

Title: Axonal conduction is a useful measurement to assess demyelination and remyelination in preclinical models and correlates with histology

Authors: *P. PANG, B. GIACOMOZZI, N. PANDE, W. M. SIDERS, C. E. PEDRAZA Sanofi, Framingham, MA

Abstract: The corpus callosum (CC) is the largest fiber bundle in the CNS connecting left and right cerebral hemispheres and mediating interhemispheric communication. In multiple sclerosis (MS) patients, the CC exhibits focal demyelinating lesions and axonal damage from early disease stages. CC damage may contribute to cognitive dysfunction in MS. Although several

immunomodulating therapies have been approved for MS patients, no therapies exist that target remyelination. **Objective:** Using systemic cuprizone and focal lysolecithin induced damage models of demyelination/remyelination, we assessed neuronal functional decline and recovery using axonal conductance and histological analysis of myelin. Methods: For the cuprizone model, mice were fed with cuprizone for 5 weeks to induce demyelination and then returned to normal diet for 8 weeks to allow remyelination to occur. The CC was dissected at several time points over the 13 week period for electrophysiological and histological analyses. One cohort of cuprizone fed animals was treated with Triiodothyronine (T3), a pro-myelinating agent, to determine whether enhancing remyelination affects axonal conductance. For the focal demyelination model, lysolecithin was injected directly into the CC, tissue was collected at various time points and myelin was analyzed. Results: In the cuprizone model, CC axonal conductance was correlated with histological analysis of demyelination during the 5 weeks of the cuprizone diet. Upon removal of cuprizone, CC axonal conductance slowly recovered as did axon remyelination. However, axonal conductance did not reach control values within the 13 week period examined. As expected, T3 treatment enhanced myelination and preserved neuronal function as reflected by axonal conductance. In the lysolecithin model, demyelination peaked at one week post-injection and was followed by spontaneous remyelination over 2-3 weeks. Axonal conductance is being assessed in this model following treatment with compounds known to enhance remyelination. Conclusions: Axonal conductance provides a direct measurement of neuronal function in vivo, reflecting changes in myelin integrity during demyelination and remyelination. This functional readout can be used in combination with histology to assess remyelination enhancing therapeutics for MS.

Title: Cognitive impairment induced by systemic inflammation in mice

Authors: *E. ANDRIAMBELOSON, B. HUYARD, E. POIRAUD, F. LAUGA, C. NEVEU, S. WAGNER NEUROFIT, ILLKIRCH, France

Abstract: Systemic inflammation is believed to play a role in ageing as well as in various dementia-related neurological disorders. Indeed, several lines of evidence indicate positive association between systemic inflammation and cognition and other aspects of behaviour in the

elderly and demented.

The present study was conducted to investigate the impact of systemic inflammation on cognitive function in mice. To this end, a single intraperitoneal administration of a non-septic dose of lipopolysaccharide (LPS) (0.25 mg/kg) was undertaken and the time course of cognitive decline was assessed. Reduced spontaneous alternation of mice in a T-maze was used as a measure of cognitive deficit.

Results showed that 1 week after the injection of LPS, a dramatic reduction in the alternation of mice in the T-maze was observed which suggests a cognitive deficit in LPS-treated mice. Although the cognitive deficit persisted for up to 3 weeks following LPS injection there was no change of the general health of mice. Furthermore, the locomotor behavior of LPS-mice as assessed by spontaneous free exploration in the open-field was comparable to that of naive mice. The treatment of LPS- treated mice with Memantine, a drug approved for cognitive enhancement in the elderly, fully restored their cognitive performance. Similar pattern of result was obtained with donepezil, another approved cognitive enhancer drug. Moreover, LPS-induced cognitive deficit was fully prevented by treatment of mice with anti-inflammatory drugs such as dexamethasone or ibuprofen, which confirmed the inflammatory-driven mechanism of LPS-induced cognitive relapse was observed after discontinuation of the anti-inflammatory therapy, which indicates the presence of an underlying chronic and persistent inflammation process.

Taken together, these above results suggest that low grade systemic inflammation is capable of mediating sustained cognitive impairment in mice.

Title: Prior exposure to repeated LPS injections prevents further accumulation of hippocampal beta-amyloid

Authors: *J. L. PETERMAN, J. D. WHITE, A. HARDY, M. J. EIMBERBRINK, K. PAULHUS, M. THOMPSON, G. W. BOEHM, M. J. CHUMLEY Psychology, Texas Christian Univ., Fort Worth, TX

Abstract: Alzheimer's disease (AD) is characterized by the accumulation of beta-amyloid plaques and neurofibrillary tangles. Our laboratory has previously demonstrated that repeated
bouts of inflammation increase beta-amyloid within the hippocampus of C57BL6/J mice. Given the relationship between inflammation and AD pathology onset and progression, we sought to explore how a second series of lipopolysaccharide (LPS) injections will impact beta-amyloid levels. Male C57BL6/J mice were given daily injections of LPS (250µg/kg) or sterile saline for seven days. Fourteen days following the last injection, animals were administered another series of daily injections of LPS or sterile saline. Hippocampal tissue was collected and assayed to quantify total beta-amyloid levels. Results demonstrated that animals given one round of LPS injections had significantly more beta-amyloid than saline injected controls, whereas animals administered two rounds of LPS had intermediary levels of beta-amyloid. This effect appears to be driven by the reduced inflammatory response to the secondary exposure to LPS, following a fourteen-day recovery. Specifically, four hours following the first LPS injection of the second series, animals previously exposed to LPS had significantly less central and peripheral inflammation than animals exposed to LPS for the first time. The mechanism behind this diminished inflammatory response may not be due to endotoxin tolerance but, rather, result from antibody production against LPS or beta-amyloid, as IgM levels were increased in animals exposed to LPS in the first injection series. The specificity of these antibodies is currently being explored.

Bluefield Project to Cure FTD

Title: Progranulin loss dysregulates splenic and peripheral blood immune cells populations and may contribute to neuroinflammation and neurodegeneration in early-onset frontotemporal dementia

Authors: *T. L. KUKAR¹, G. T. KANNARKAT², K. P. MACPHERSON², E. M. KLINE³, C. J. HOLLER¹, M. A. JOHNSON¹, M. G. TANSEY⁴ ¹Pharmacol., ²Physiol., ³Emory Univ., Atlanta, GA; ⁴Physiol., Emory Univ. Sch. of Med., Atlanta, GA

Abstract: Autosomal dominant mutations in the progranulin gene (GRN) cause a drastic reduction in progranulin (PGRN) and granulin levels contributing to the pathogenesis of familial frontotemporal degeneration (FTD), the most common form of early-onset dementia. Rare homozygous GRN mutations in humans cause neuronal ceroid lipofuscinosis (NCL), which shares neuropathological features with FTD-GRN patients, suggesting shared disruption of lysosomal pathways. Multiple studies have implicated PGRN as a key regulator of neuroinflammation and neurodegeneration. Genetic ablation of the GRN gene is associated with aberrant increases in phagocytosis and pro-inflammatory cytokine production in microglia. Further, global Grn KO and microglia-specific Grn KO mice have increased sensitivity to the neurotoxin MPTP. Most recently Grn deficiency was shown to promote circuit-specific synaptic pruning by microglia via complement activation. While intense focus has been placed on investigating the effect of GRN deficiency in microglia, we have focused our efforts on investigating the effects of GRN loss in all major subsets of peripheral immune cells based on the rationale that peripheral-central immune cross-talk is key for brain health and disruptions in these pathways may promote degeneration. We performed deep-immunophenotyping using flow cytometry of brain, spleen, and peripheral blood of *Grn* KO and WT mice ages 18-22 months. We found a generalized increase in cell numbers in the blood with an increased frequency of NK cells and Ly6C+ monocytes in blood as well as increased MHC-II expression on B cells and monocytes in blood; and a decreased proportion of non-CD4/CD8 T-cells made up CD3+ T cell populations. In addition, Grn KO mice displayed decreased NK cells, B cells, and macrophages in the spleen with decreased expression of MHC-II; and non-CD4/CD8 T-cells make up a larger proportion of CD3+ T cells in their spleen. These novel findings support a model for PGRN in regulation of peripheral immune cell populations and raise the interesting possibility that analysis of peripheral immune cells could shed light on the role of central-peripheral immune cross-talk in the pathogenesis of FTD patients with GRN mutations. Immunophenotyping analyses of immune populations in the brain of *Grn* KO vs WT mice is underway and will be compared with changes observed in the periphery [Funding provided by NIH/NINDS 5R01NS092122 and 5R01NS093362, and The Bluefield Project to Cure FTD].

Title: The TRAIL DR5 receptor substantially contributes to amyloid beta-related neurotoxicity in the mouse

Authors: *R. BERNARDINI¹, G. DI BENEDETTO², L. LEMPEREUR³, F. SERAPIDE², H. WALKZAC⁴, G. CANTARELLA²

¹Dept. Biomed. & Biotechnological Sci., Univ. Catania Med. Sch., Catania, Italy; ²Dept. Biomed. & Biotechnological Sci., Univ. of Catania, Catania, Italy; ³Eli-Lilly/Policlinico lab Catania, Eli-Lilly, Catania, Italy; ⁴4Dept of Cancer Biology, CRUK-UCL Cancer Ctr., UCL, London, United Kingdom

Abstract: TRAIL, a proapoptotic cytokine belonging to the TNF superfamily, is a potent inducer of neuronal death in animal models of Alzheimer's disease (AD). TRAIL effects appear mediated by its death receptor 5 (DR5). Immunoneutralization of TRAIL results in restored cognition, as well as in blunted expression of inflammatory molecules in the AD 3x transgenic mouse brain. To better understand the role of TRAIL in neurodegeneration, in-vitro experiments were run to analyse the impact of treatment with amyloid-beta (AB), as compared to TRAIL, on survival of dispersed Trail- r-deficient mouse embryonal hippocampal cells. Next, the expression of TRAIL, TRAIL-R, as well as microglia and astrocytes markers were studied in the hippocampi of animals undergone treatment with fragment 1-42 of AB. Hippocampal cells from Trail-rdeficient mice showed significant resistance to death induction by both AB 1-42 or TRAIL, as compared to cells Trail-r-proficient mice. Immunofluorescence showed decreased activation of microglia (Iba-1) and astrocytes (GFAP) after stereotactical treatment of Trail-r-deficient mice with AB 1-42. Finally, western blot analysis of hippocampi from Trail-r-deficient mice treated with AB 1-42, showed decreased expression of either IL-1, iNOS and phosphorylated tau protein. The bulk of these results demonstrate that lack of TRAIL-R is associated with substantial decline of noxious effects of AB 1-42, providing genetic evidence that, during ABrelated neuroinflammation, TRAIL supplies a pivotal contribute to subsequent neurodegenerative processes. In conclusion, according to these results, it is plausible to hypothesize that the TRAIL system may be regarded as a potential target for innovative AD therapy.

Abstract: Zika virus (ZIKV) infection during pregnancy has been largely associated with microcephaly and neurodevelopmental disorders. The epidemic of ZIKV which started in 2015 was considered a public health emergency of international concern by the World Health Organization. However, how ZIKV affects the developing brain is poorly understood and most of the studies performed so far are based on infection performed in immunodeficient mice. This study aims to investigate whether early neonatal ZIKV infection leads to histological or behavioral changes related to brain function in immunocompetent, wild type mice throughout their lifespan. For such, both male and female Swiss mice were infected subcutaneously with ZIKV (strain isolated from a Brazilian patient) at post-natal day 3 (PND3) and early neonatal reflexes were assessed. ZIKV-infected group showed no impairment in reflex development compared to Mock mice. Viral replication in the brain and cytokine expression were assessed by qPCR. ZIKV successfully replicated in the brains of immunocompetent mice. Motor dysfunction were found in pre-weaning pups infected with ZIKV compared to Mock animals. ZIKV-infected group showed persistent decrease in body weight gain and by PND70 mortality rates were approximately 60% in ZIKV-infected group (0% in Mock group). Finally, histological and immunohistochemical analysis will be made in the animals to evaluate the organization of cortical structure and brain inflammation. We believe our study will help guide public health policies for ZIKV-exposed babies and children around the world, positively contributing to the field. Ethical approval: CEUA/CCS/UFRJ protocol no. 075/15.

Title: Zika virus replicates in adult human and mouse brains, leading to brain inflammation, synapse loss and memory impairment in mice

Authors: *F. G. BARROS-ARAGÃO¹, C. P. FIGUEIREDO², R. L. S. NERIS², P. S. FROST², D. C. ZAMBERLAN³, L. M. S. ANTONIO², C. S. P. S. MELO², A. S. SOUZA², A. L. A. GUIMARÃES², J. M. SOUZA², S. ALVES-LEON², F. G. DE FELICE², J. R. CLARKE², I. B. ASSUNÇÃO-MIRANDA², A. DA POIAN², S. FERREIRA² ¹Biomed. Sci. Inst., Federal Univ. of Rio De Janeiro, Rio De Janeiro, Brazil; ²Federal Univ. of Rio de Janeiro, Rio de Janeiro, Brazil; ³Federal Univ. of Santa Maria, Santa Maria, Brazil

Abstract: Zika virus (ZIKV) infection during pregnancy is associated to severe neurological complications in newborns, including microcephaly and cortical calcifications. Initially considered a self-limited illness in adults, ZIKV infection was recently linked to various neurological manifestations, including acute myelitis, encephalitis and meningoencephalitis. Whereas several lines of evidence indicate that human neural precursor cells are affected by this infection, whether human adult neuronal tissue is susceptible to it remained to be determined. We aimed to determine the ability of ZIKV to replicate in human and mice adult brain tissue and its possible effects on memory and cognition. Initially, ex-vivo human adult cortical tissue was infected with 10⁷ plaque-forming units (PFU) of a ZIKV strain isolated from a Brazilian patient, or the corresponding volume of virus-free C6/36 cells conditioned medium (mock). Culture media were collected for determination of the number of infectious viral particles by plaque assay and levels of cytokines by ELISA, and slices were processed for quantification of viral RNA by qPCR. ZIKV RNA in tissue, infectious particles and interleukin-6 (IL-6) released to the medium increased in a time-dependent manner, demonstrating that ZIKV successfully replicates in adult human mature neural tissue. To study the consequences of ZIKV infection in the adult brain, we performed intracerebroventricular injections of ZIKV (10⁵ PFU) in young adult male Swiss mice. Brain infusion of ZIKV was not associated with increased mortality of mice, but caused a persistent reduction in body weight when compared to mock-infused mice. Brains of ZIKV-injected mice were collected at different time points for determination of viral RNA by qPCR. Increasing viral RNA levels were found, peaking at 6 days post-infection (dpi). Viral mRNA was higher in the hippocampus and frontal cortex when compared with others brain regions. No fluorojade-positive cells were found in the brain of ZIKV-infected mice, but we found an increase in Iba-1 (microglial) positive cells and a decrease in synaptophysin (synaptic marker) levels in their hippocampus. Brain IL-6 and tumor necrosis factor-α mRNA levels were markedly increased at 6 dpi. Using the novel object recognition task, memory impairment was detected as early as 1 dpi, persisting for up to 30 dpi. Our findings indicate that ZIKV replicates in human and mice adult brain in sites unrelated to neurogenesis, and that viral infection induces brain inflammation, synapse loss and memory impairment.

Title: Intraventricular administration of TH2 cells into the CNS ameliorates the inhibitory effects of IFNg on remyelination

Authors: *M. J. ALEXIS, L. R. HERBST, H. STRAUSBURGER, K. MARTIN, L. KIRBY, P. CALABRESI

Johns Hopkins Sch. of Med., Baltimore, MD

Abstract: Multiple sclerosis is an immune mediated demyelinating disease of the CNS. One potential cause of remyelination failure is chronic inflammation, therefore understanding the molecular mechanisms by which CNS inflammation inhibits the oligodendrocyte precursor cells (OPC) is important. While effector T-cells of the TH1 and TH17 phenotype are understood to be critical for the pathogenesis of MS, effector T-cells of the TH2 phenotype may have an opposing role by promoting remyelination and repair especially in an inflammatory setting. To investigate the role of TH2 cells we utilized the GFAP/tTA; TRE/IFNg transgenic mouse line in which CNS expression of IFNg from GFAP positive astrocytes is achieved upon doxycycline withdrawal. In order to determine whether TH2 cells promote remyelination after cuprizone induced demyelination we first directly administered TH2 cells into the CNS via intraventricular microinjection. In three separate experiments remyelination was significantly improved in TH2 injected mice compared to PBS injected control animals (mean percent difference = 18.91; pvalue = 0.0107) as determined by black gold staining in corpora callosa tissue. Interestingly, the TH2 effect of improved remyelination was only detected in cuprizone fed mice induced to express IFNg in the CNS and there was no significant difference between TH2 and control mice in which IFNg expression was suppressed two weeks TH2 injection. After thorough examination at the one week time point we did observe a significant increase in remyelination from TH2 cells compared to control. The fact that TH2 cells can reproducibly overcome the strong and potent

inhibitory effect of IFNg and promote remyelination is notable. In addition, it was found that arginase 1, a marker for anti-inflammatory microglia, in corpora callosa tissue was elevated in the presence of TH2 cells. To investigate by what mechanism the TH2 cells produce this effect, we directly treated OPCs with TH2 cells, but observed no significant response. Due to the fact that TH2 cells do not seem to promote OPC differentiation directly but have an effect on microglia activation, we hypothesize the at effect on remyelination may be mediated indirectly through microglia. In order to further probe the question of how TH2 cells are mediating their effect, further work will involve an OPC differentiation assay to examine microglial secreted factors in response to TH2 supernatants on OPC differentiation.

Title: Interleukin-4 induced protein 1 as a biomarker & treatment option in multiple sclerosis

Authors: *S. DAVIS¹, H. OFT¹, E. VIETSCH³, F. AMJAD⁴, A. WELLSTEIN³, J. HUANG² ²Dept. of Biol., ¹Georgetown Univ., Washington, DC; ³Lombardi Comprehensive Cancer Ctr., ⁴Dept. of Neurol., MedStar Georgetown Univ. Hosp., Washington, DC

Abstract: Analysis of interleukin-4 induced protein 1 in human peripheral blood mononuclear cells

Multiple sclerosis (MS) is a chronic inflammatory neurodegenerative disease of the central nervous system that, with an average age of onset of 34, afflicts over 2.3 million individuals worldwide during many of the most productive years of their lives. The pathogenesis of MS, though known to involve unresolved inflammation and autoimmune destruction of myelin, is poorly understood. Accurate biomarkers, which could predict disease progression, are yet to be identified and would provide valuable information to patients and their treating clinicians. Likewise, while disease modified drugs have been developed to combat the symptoms of relapsing remitting MS, none prevent progression to, or symptoms of, the progressive phase of MS.

Interkeukin-4 induced protein 1 (IL4I1), an endogenously secreted L-amino acid oxidase

expressed by immune cells is a promising candidate for both roles. Recently demonstrated by our lab, IL4I1 is upregulated during CNS remyelination, and functions to reduce inflammation to enable CNS remyelination in mice after experimental demyelinating injury. The goal of the present study is to evaluate the effect of IL4I1 on inflammatory cytokines in human peripheral blood mononuclear cells (PBMCs).

Our preliminary data show that addition of recombinant human IL4I1 to CD3/CD28-activated PBMCs modulates MS-related inflammatory cytokines expression, including *IFNg* and *IL17*. Moreover, we found that recombinant IL4I1 altered the expression of *TOB1*, an anti-proliferative protein whose levels are known to correlate with progression from clinically isolated syndrome (CIS) to clinically definitive MS. These results suggest that the immunomodulatory effects of IL4I1 in mouse-models of MS are also found in human populations, and that the mechanism of this effect may involve a previously identified correlate of MS development. These findings from healthy control PBMCs justifies our next steps to further explore IL4I1 in the clinical patient population.

Title: The development of inflammatory responses in degenerative thalamic injury after stroke

Authors: *Z. CAO, M. CHENG, A. FOLTZ, G. STEINBERG Neurosurg., Stanford Univ., Stanford, CA

Abstract: Background: After stroke, the primary infarct site can cause secondary degeneration in neighboring and connected regions. In particular, a secondary degenerative injury has been observed in the connected thalamus. This progressive secondary injury causes neurological dysfunction and impedes stroke recovery. Inflammation in the injured thalamus is considered to be a hallmark of thalamic injury. However, the dynamics of inflammatory activation during the development of thalamic injury is unclear. We aim to investigate the development of microglial/astrocyte activation in secondary thalamic injury after stroke. **Material and Methods**: Cortical ischemic stroke was generated by permanent occlusion of left middle cerebral artery in male C57BL6J mice (12-15 weeks). Time course analysis of Inflammatory responses were assessed by immunostaining in brain sections collected on day 1, 3, 7, 14 and 28 after stroke.

Immunostaining was performed with antibodies specific for activated microglia/macrophage (CD68) and astrocytes (GFAP). Images were captured by confocal imaging with z-stack and activated microglial/astrocytes at different time points were analyzed. Results: Primary infarction was observed mainly in the somatosensory cortex after stroke. Time course analysis of microglial/astrocyte activation revealed differential patterns after stroke. At the primary infarct site, activated microglia were initially detected on post-stroke day 1 surrounding the infarct, and gradually appeared in the infarct core after day 14. Activated astrocytes were detected at poststroke day 3, surrounding the infarct with a stellate morphology. Interestingly, astrocytes became densely packed and elongated after day 7. At the secondary thalamic injury site, activated microglia were sparsely detected as early as post-stroke day 1, while activated astrocytes were not observed until day 3. Clustered activated microglia/astrocytes with clear boundary were observed starting day 7, and gradually accumulated and became denser at later time points (day 14 and 28). Conclusion: Our study suggests that microglial and astrocyte activation exhibit differential patterns after stroke, in both timing of activation and morphology. Microglial activation occurs earlier than astrocyte activation in both the primary cortical infarct and the degenerative ipsilesional thalamus. Current studies investigate the subtypes of activated microglia and astrocytes in the thalamus after stroke. Identifying specific subtypes of astrocyte/microglia and their involvement in thalamic injury will provide potential targets for stroke recovery.

Title: Determination of endogenous antioxidant capacity and profile of proinflammatory cytokines in patients with metabolic syndrome: Risk for neurodegenerative diseases

Authors: *R. G. RESENDIZ GUTIERREZ, I. IBARRA VALVODINOS, B. UGALDE VILLANUEVA, M. SALGADO SALGADO, M. RAMOS GÓMEZ, N. HERNÁNDEZ CHAN, H. L. HERNÁNDEZ MONTIEL

Abstract: Introduction: Metabolic Syndrome (MS) has become a public health problem because of its association with increased risk of cardiovascular disease. The International Diabetes Federation (IDF) has reported that it least 25% of the world's population suffers from it.

Several studies have shown that a basis of its pathophysiological is insulin resistance (IR) the common with neurodegenerative diseases such as Alzheimer's and Parkinson's, sharing more risk factors than previously thought. The body has endogenous antioxidant systems that can be altered by the presence of MS. This pathophysiological connection suggests that the increase in the prevalence of MS will also increase the prevalence of neurodegenerative disorders, and metabolic problems are associated with oxidative stress and inflammatory status. **Objective**: To determine the profile of inflammatory markers (TNF α , IL-6, IL-1 β) and the endogenous antioxidant system (CAT, SOD and GSH) in patients with MS, which are common in neurodegenerative diseases. **Results**: It will show it share profile of endogenous antioxidant enzymes and proinflammatory cytokines in patients with MS, analyzing the similarity of this behavior with that of neurodegenerative disorders.

Title: Up-regulation of the neurotrophin receptor p75NTR by valproic acid in human neuroblastoma cells

Authors: *S. DEDONI, M. C. OLIANAS, P. ONALI Univ. of Cagliari, Dept Biomed. Sci., Cagliari, Italy

Abstract: The anticonvulsant and mood-stabilizer drug valproic acid (VPA) has been shown to adversely affect neuronal differentiation, growth and survival through mechanisms still not completely understood. We have previously reported that exposure to VPA down-regulates the expression and signalling of the brain-derived neurotrophic factor (BDNF) receptor TrkB in neuronal cells, suggesting that VPA may impair central BDNF activity. In the present study we show that in human neuroblastoma cells VPA causes a marked up-regulation of p75NTR, a common neurotrophin receptor that belongs to the tumor necrosis factor receptor superfamily. Prolonged treatment with VPA (1.0 mM) and other histone deacetylase (HDAC) inhibitors, such as trichostatin A (TSA), sodium butyrate (NaBut), MS-275 and MC 1568, enhanced the protein levels of p75NTR in either undifferentiated or retinoic acid (RA)-differentiated SH-SY5Y neuroblastoma cells. VPA also significantly increased the expression of sortilin, a member of the

Vps 10p-domain receptor family which complexes with p75NTR to mediate neuronal cell death. Under similar experimental conditions, the levels of TrkA, the receptor of nerve growth factor (NGF), were not significantly affected by VPA in RA-differentiated SH-SY5Y cells. A marked increase of the cellular levels of p75NTR was also detected in LAN-1 human neuroblastoma cells following treatment with VPA. In these cells the enhanced p75NTR expression was associated with stimulation of apoptotic cell death induced by either VPA, NaBut and MS-275. Collectively, our data demonstrate that VPA and other HDAC inhibitors alter the balance between neurotrophin receptors by down-regulating TrkB and up-regulating the p75NTR/sortilin complex and suggest that this action may contribute to the deleterious effects of these agents on neuronal survival.

Title: Changes in the blood-brain barrier under toxic demyelination

Authors: *J. SHELESTAK¹, R. CUKELJ¹, N. K. SINGHAL², J. MCDONOUGH¹, R. CLEMENTS³

¹Biomed. Sci., ²Dept. of Biol. Sci. and Sch. of Biomed. Sci., ³Kent State Univ., Kent, OH

Abstract: The cuprizone animal model is widely used to study toxic demyelination and subsequent remyelination in the central nervous system. A copper chelator, cuprizone affects oligodendrocytes, leading to their degeneration and the loss of myelin sheathing. Studies suggest the cuprizone model appears to maintain an intact blood-brain barrier throughout the treatment. In the present study, we aim to assess the integrity of the blood brain barrier after 6 weeks of cuprizone administration followed by 2 weeks without to allow for remyelination. Mice were imaged using MRI every two weeks starting on week 0 of administration. Measurements of demyelination and ventricle enlargement were taken with T1, T2, and diffusion weighted protocols. A portion of mice were intraperitoneally injected with Evans Blue 3 days prior to sacrifice in order to stain the vasculature as well as investigate any potential areas of integrity breakdown in the BBB. Immunohistochemistry was utilized to stain brain sections after sacrifice. The tissue sections were stained for neurons, myelin, astrocytes, microvessels, oligodendrocytes, immune cells, as well as aspects of the extracellular matrix to assess the integrity of the bloodbrain barrier. Cuprizone treatment caused significant weight loss, as well as a measurable change in ventricle size seen after 6 weeks of treatment. There was a significant increase in gliosis, as well as morphological changes indicative of activation. BBB integrity was assessed using

computational image analysis to measure changes in vessel size, astrocyte ensheathment, and degeneration.

Title: Evaluation of the electrophysiological effect in patients with diabetic polyneuropathy treated with thiamine pyrophosphate

Authors: *I. IBARRA VALDOVINOS, B. UGALDE VILLANUEVA, R. G. RESENDIZ GUTIERREZ, M. SALGADO SALGADO, M. RAMOS GÓMEZ, N. G. HERNANDEZ CHAN, H. L. HERNANDEZ MONTIEL

Abstract: Introduction: Diabetes mellitus type 2 (DM2) is one of the diseases of high prevalence in the Mexican population. Included in the microvascular complications associated with this pathology are diabetic polyneuropathy (DPN), which affects the quality of life of diabetic patients. Currently, treatment for DM2 focuses on optimizing adequate glycemic control with oral hypoglycemic agents and insulin to prevent or delay the development of DPN. When the patient develops DPN, the treatment focuses on providing relief of symptoms; however, there is little evidence that any of the drugs used modifies the underlying pathophysiology of DPN. **Objective**. Analyze the effect of thiamine pyrophosphate (TPP) on the nerve conduction velocity of lower limbs of patients with DPN. Material and methods. We studied 26 patients with DPN, organized into 2 study groups: Group I (n=14) patients with 1 to 10 years of evolution of diabetes mellitus type 2 (DM2) and Group II (n=12), with 10 to 20 years of DM2. Both groups were treated with TPP (10 mgrs/kg body weight) for intramuscular injection once a week for three months. The effect of the therapy was evaluated by the Michigan Neuropathy Screening Instrument (MNSI), biochemical analysis and nerve conduction tests, before and after treatment. Results: After 3 months of treatment, the patients of Group I showed improvement in the speed of conduction of the lower limbs while Group II patients had a lower response of improvement with treatment. For both groups, prolonged latencies, reduction in amplitude of the potential and increase of its duration were determined. Conclusions. The results show a marked improvement

in the nerve conduction velocity of the lower limbs in Group I, with a shorter evolution time of the disease.

Title: Knockout mice with inhibited IL-1 and TNF signaling pathways have significantly reduced seizure activity, morbidity and mortality following exposure to soman

Authors: ***E. A. JOHNSON**¹, J. F. IRWIN¹, K. LAITIPAYA¹, J. K. CHANDLER¹, D. D. PALMER¹, T. M. FERRARA-BOWENS¹, C. L. HONNOLD², M. D. WEGNER³ ¹Pharmacol., ²Comparative Pathology, US Army Med. Res. Inst. of Chem. Def., Aberdeen Proving Ground, MD; ³Armed Forces Res. Inst. of Med. Sci., Bangkok, Thailand

Abstract: Exposure to acetylcholinesterase inhibitors such as soman (GD) can initiate status epilepticus (SE) that can lead to progressive brain damage and behavioral impairment. Current treatments targeting the GABA system can ameliorate GD-induced SE, though treatment effectiveness diminishes rapidly following exposure. Therefore, new treatment strategies that do not rely on the GABA system are needed to reduce seizure activity, tissue loss and cognitive deficits. One strategy involves modulation of the pro-neuroinflammatory response, a prominent feature in GD-induced brain injury, which can exacerbate seizure susceptibility, generation and frequency. We have previously shown that reducing interleukin -1 receptor 1 (IL-1R1) or tumor necrosis factor receptor 1A (TNFR1A) signaling can moderately reduce many deleterious physiological effects after SE. This study focused on inhibition of both IL-1 and TNFα signaling as an anticonvulsant and neuroprotective strategy. Using an IL-1R1/ TNFR1A double knockout (KO) mouse, seizure profiles, neuropathology, mortality, cognitive performance and other relevant physiological responses were compared to a wild type background mouse strain. Inhibiting both IL-1 and TNF α signaling pathways had a synergistic effect on reducing deleterious physiological effects of GD-induced SE such as neuropathology, seizure activity and mortality. These results show that IL-1R1/TNFR1A double KO mice are remarkably resilient to the effects of GD exposure to include reduced seizure incidence, morbidity, mortality and cognitive deficit. These data suggest that inhibition of specific pro-inflammatory pathways may

be a viable addition to standard therapies to treat GD-induced SE.

Title: Exosomally secreted miR-146a dysregulates brain energy metabolism during neuroinflammation

Authors: *S. JUN¹, A. E. RUSSELL¹, W. WANG², S. N. SARKAR¹, J. W. SIMPKINS¹, C. M. BROWN²

¹Physiol. and Pharmacol., ²Microbiology and Immunol., West Virginia Univ. Hlth. Sci. Ctr., Morgantown, WV

Abstract: Mitochondrial dysfunction is associated with the aging process and with the pathogenesis of a variety of disorders such as metabolic syndrome and neurodegenerative diseases including Alzheimer's disease (AD). Interestingly, miRNAs can modulate mitochondrial activity, and a discrete miR set has recently been identified in mitochondria of different species and cell types (mitomiRs). Among them, miR-146a is involved in important cell

functions including inflammation, immune responses, invasion, metastasis and cell death. The impact of miR-146a on mitochondrial function and glucose metabolism has not been previously analyzed. Since a single microRNA (miRNA) is capable of deregulating many genes' function, we hypothesized that increased miR-146a by inflammatory stimuli including LPS, TNF- α and Aβ may influence mitochondrial function and glucose metabolism, especially glycolysis through regulating multiple target proteins involved in these processes in AD. We found that the level of miR-146a was significantly associated with Braak and Braak (B&B) stage not only in temporal cortex but also in frontal cortex and cerebellum of AD patients. We also found that increased miR-146a levels by inflammatory signaling may not be limited to the cellular level but also secreted exosomes in multiple brain cell types, including neurons, glial cells, and brain endothelial cells. Through an *in silico* bioinformatics analysis study, we identified four putative target genes related to mitochondrial electron transport chain as well as two glycolysis related genes. Furthermore, overexpression of miR-146a significantly decreased ATP production, spare capacity, and maximum respiration as measured in rat primary mixed glial cells as measured by an XF^e96 extracellular flux analyzer. MiR-146a also significantly decreased glycolysis and glycolytic reserve. The overexpression of miR-146a in HT22 and C8B4 also reduced level of proteins involved in electron transport chain complex II (SDHC) and glycolysis (PGK1). Our results indicate that the increased level of miR-146a in brain cells may play a direct role in controlling mitochondrial function and energy metabolism by regulating mitochondrial protein expression as well as proteins regulating glycolysis. The modulation of miR-146a could thus mediate the loss of mitochondrial integrity and function in various brain cells, inducing or contributing to the brain's inflammatory response in diseases such as AD and other neuroinflammatory disorders.

Title: Efficacy of subcutaneous route of administration of gm1 ganglioside in the r62 mouse model of huntington disease

Authors: *N. MUNRO, D. SIMON, N. GHENA, G. DUNBAR, J. ROSSIGNOL Neurosci., Central Michigan Univ., Mount Pleasant, MI

Abstract: Huntington's Disease (HD) affects nearly 30,000 people in the United States. This disease is an inherited disease characterized by the progressive degeneration of nerve cells within

the nervous system. The disease was first documented in 1872 by George Huntington. Since then, we have come to learn that the symptoms of HD usually appear between the ages of 30 and 50. These symptoms include chorea (involuntary movements), impared cognitive function, personality changes, progressive weight loss and eventually death. There is no current cure for HD, just palliative treatment. In the later stages of the disease, the patient will be unable to walk, talk or care for themselves.

One possible treatment that has been looked at as of recently is the use of the substance GM1. GM1 is a ganglioside and resides within the outer leaflet of our cells. It has been shown to have neuroprotective effects and is important in the development of our neurons In neurodegenerative diseases like HD, Parkinson's Disease, and Alzheimer's Disease, GM1 is significantly reduced within the cells. Recent studies have used GM1 as a treatment for HD and have seen positive results. In this study, we have looked at the efficacy of subcutaneous administration of GM1 in the R6/2 mouse model of HD. Previous studies have only looked at intraventricular administration of GM1. We have chosen subcutaneous administration due to the fact that it is much more practical. We hypothesize that the administration of GM1 will help to reverse the effects the disease has on behavior and cognition.

Title: Dimethyl fumarate accelerates axonal regeneration following peripheral nerve axotomy by modifying macrophage response post-injury

Authors: *A. L. BOMBEIRO¹, B. T. N. PEREIRA², A. L. OLIVEIRA³ ¹Depto. Biologia Estrutural e Funcional, Univ. Estadual De Campinas, Campinas, Brazil; ²Univ. of Campinas, Campinas, Brazil; ³Univ. of Campinas - Lab. of Nerve Regeneration, Campinas, Brazil

Abstract: Following peripheral nerve injury, distal stump degeneration takes place, allowing tissue clearance, and remodeling, mostly driven by Schwann cells and macrophages. Dimethyl fumarate (DMF) is a fumaric acid ester that presents antioxidant properties, anti-inflammatory, and mmunomodulatory activity, shifting the overall response towards an anti-inflammatory (Th2) profile. However, DMF activity on peripheral nerve regeneration is poorly studied. Thus, unilateral sciatic nerve crushing in C57BL/6J mice was followed by DMF (100mg/Kg, orally) or vehicle (methylcellulose) daily treatment, 3 days after lesion (3 dal, when there is a high influx of macrophages in the nerve) up to 28 dal (when regeneration is established). Motor recovery was recorded daily (3 - 28 dal), using a computerized walking track test system (CatWalk system). Animals were euthanized at 7, 14 and 28 dal (n=5/group/time point) and nerves were analyzed regarding the expression of neurofilaments (axonal marker), growth associated protein 43 (GAP-43, regrowing axons) and Iba1 (macrophage marker). Intact nerves were used as the baseline control. Under DMF treatment, macrophage immunolabeling peaked at 7 dal (2,420%, p<0.001), being kept constant up to 14 dal and then decreasing, while in the control group it peaked at 14 dal (2,400%, p<0.001) and then dropped. In both groups, axon labeling rose at 7 dal (134%, p<0.05, DMF; 122%, ns, control), possibly as the sum of degenerating and growing axons. However, while axon labeling progressively decreased in the DMF group, it abruptly diminished in the control at 14 dal (67%, p<0.05), possibly due to a massive macrophage infiltration. Neurofilament baseline levels were restored at 28 dal in both groups. GAP-43 kinetics in the control group resembled that of neurofilament, with smaller expression at 14 dal (59%), however, peaking at 28 dal (384%, p<0.001). On the contrary, in DMF group it rose at 14 dal (477%, p<0.001), decreasing at 28 dal. Motor recovery was fully reestablished in both groups at 28 dal, with no significant difference between then. Overall, the present data indicates that DMF accelerates axon regeneration, besides extending macrophage permanence in the regenerating nerve microenvironment, possibly in a Th2, anti-inflammatory fashion.

Title: Neurotoxic reactive astrocytes in neurodegenerative disease

Authors: *S. A. LIDDELOW¹, T. PETERSON², R. N. ELDANAF¹, A. M. MÜNCH¹, K. A. GUTTENPLAN¹, A. D. HUBERMAN³, M. S. BUCKWALTER⁴, B. A. BARRES¹ ¹Neurobio., ²Neurol. and Neurolog. Sci., ³Dept. of Neurobio., ⁴Neurol., Stanford Univ., Stanford, CA

Abstract: Although reactive astrocytes are rapidly generated following brain injuries and neurodegenerative and neuroinflammatory diseases, their role in trauma and disease states is not well understood. Previously we distinguished two reactive astrocyte subclasses based on the kind of inducing injury. We named these classes "A1" and "A2". Based on their gene profiles we hypothesized that they were harmful and helpful respectively. We have shown that the harmful A1 reactive astrocytes are induced by classically-activated neuroinflammatory microglia. Specifically, we found that activated microglia induce A1s by secreting II-1 α , TNF α , and C1q, and that these factors together are necessary and sufficient to induce A1s both in vitro and in vivo. A1s have little ability to promote neuronal survival, outgrowth, synaptogenesis or phagocytosis and instead are powerfully toxic to neurons and oligodendrocytes. We further showed that A1s are present in human Alzheimer's disease, Huntington Disease, Amyotrophic Lateral Sclerosis, and Multiple Sclerosis, and that death of axotomized CNS neurons is prevented when A1 formation is blocked with neutralizing antibodies to Il-1a, TNFa, and C1q. We now show the role of A1 neurotoxic reactive astrocytes in the context of neurodegeneration in both acute (ischemia) and chronic (glaucoma) mouse models. Taken together our findings strongly suggest that A1s drive death of neurons in neurodegenerative disorders, and point the way forward for developing new treatments for these diseases.

Title: Effect of intra-nigral injection of endotoxin on neuronal homeostasis in the hippocampus

Authors: B. DARWISH¹, F. CHAMAA², J. ISMAIL², E. AL-CHAER², N. SAADE², *W. ABOU-KHEIR²

¹Fac. of Med., American Univ. Of Beirut, Beirut, Lebanon; ²American Univ. of Beirut, Beirut, Lebanon

Abstract: Background Neurogenesis in the hippocampus has been shown to be prone to alterations in response to a variety of physiological and pathological factors, one of which is neural inflammation. Inflammation has been implicated in changes observed in neurodegenerative diseases such as Parkinson's and Alzheimer's. Previous studies are in favor of the hypothesis that overt or discrete brain inflammation can result in reduced neurogenesis and/or neuronal death associated with cognitive decline and other functional disorders. We aim to show that mild inflammation induced by unilateral Endotoxin injection in the substantia nigra (SN) and ventral tegmental area (VTA) can alter neurogenesis in the Dentate Gyrus (DG) of the hippocampus. Methods Adult Sprague Dawley female rats (250-300g) received stereotaxic unilateral injection of Endotoxin (2ug/2ul saline) or sterile saline (2ul) in the right SN. Rats then received 3 consecutive intraperitoneal injections of 5'-Bromo-2'-deoxyuridine (BrdU) (66mg/kg/injection) separated by 2 hour intervals on the day of the surgery. The rats were perfused on day 3, 6, or 9. Behavioral observations included cylinder test, y-maze and Rotarod tests. The fractionator method was used together with confocal immunofluorescent analysis to probe for BrdU and NeuN positive cells in the left and right DG. In addition, Tyrosine hydroxylase (TH) immunostaining was performed and TH cells were quantified in the right and left SN. Results The cylinder test showed significant ipsilateral bias (right side) in the rats that received ET injection compared to the sham and Naïve rats at days 2, 3 and 6, with the most prominent effect at day 3 (p<0.0049). The Rotarod test showed significant decrease in the latency to fall for ET injected rats at day 2 (p<0.0059), which was partially reversed on day 3 and back to normal by day 6. ET injection in the SN led to a significant decrease of BrdU positive cells (p<0.05) in the DG at day 3 compared to sham and there was no significant difference between sham and naïve rats. This was followed by a trend decrease in neurogenesis on days 6 and 9 post injection. Interestingly, there was no prominent difference between left and right DG and the decrease appears to be a bilateral decrease. Moreover, at day3 post injection, SN showed a 35% decrease of TH in the right side compared to the left and this decrease was no longer present at day 9. Conclusion This study shows that neurogenesis is altered following localized inflammation and represents one process that can be further investigated in neurodegenerative diseases.

Title: In vivo analysis of calcium-initiated axon degeneration in an animal model of MS

Authors: *M. M. WESOLOWSKI¹, M. A. SCHUMACHER¹, K. KNELLES¹, I. KLEIN¹, M. KERSCHENSTEINER^{1,2}

¹Inst. of Clin. Neuroimmunology, Muenchen, Germany; ²Munich Cluster of Systems Neurol. (SyNergy), Munich, Germany

Abstract: Multiple sclerosis (MS) is a chronic inflammatory disease of the central nervous system and a major cause of neurological disability in young adults. There is robust evidence showing that immune-mediated axon damage is the major cause for progression of permanent neurological deficits. Using in vivo imaging in a mouse model of MS we identified focal axonal degeneration as a correlate of inflammatory axon loss. It is characterized as a sequential process, beginning with focal swellings and progressing to multi-focal axon fragmentation. This process is observed in axons with intact myelin sheaths and its early stages can recover spontaneously. We were able to show that elevated calcium levels influence the axonal fate to degenerate in EAE lesions, however the degenerative process triggered via elevated calcium is not understood. In this work, we investigated which mechanism is involved in the neurodegeneration in experimental autoimmune encephalomyelitis (EAE), an animal model of MS. We assessed the effect of delayed Wallerian degeneration genotypes (Δ NLS-Wlds and Sarm1 knock-out), which did not result in a reduction of clinical disability or reduction of axonal fragmentation in acute or chronic lesions in vivo. The inhibition of Calpain, a calcium-activated protease, reduces axonal fragmentation in acute lesions in vivo. These results suggest a mechanism of axonal destruction which appears to be distinct from Wallerian degeneration and opens possibilities for neuroprotective therapies targeting the calcium-calpain axis.

Abstract: Phenylketonuria (PKU) is an autosomal recessive inborn error of amino acid Lphenylalanine (Phe) metabolism caused by deficiency of phenylalanine hydroxylase (PAH) activity. Biochemically, it is characterized by hyperphenylalaninemia (HPA). Clinically, patients present with psychomotor impairment and severe intellectual disability. The pathogenesis of brain alterations related to PKU is based on HPA neurotoxicity, which is not completely understood. In this context, the aim of this study was to evaluate neurochemical, inflammatory and behavioral parameters in rats submitted to an experimental HPA model. For this, five-dayold female Wistar rats received 2 daily subcutaneous injections of Phe (5.2 µmol/g; 12 hours interval between administrations) and daily subcutaneous administration of pchlorophenylalanine (0.9 µmol/g), a PAH inhibitor, from the 5th to the 30th day of life. Control group received saline solution under the same conditions. Twenty-four hours after the last administration, behavioral tasks (open field and radial maze) were evaluated. Immediately after, animals were euthanized and cerebral cortex, hippocampus and striatum were dissected and used for the determination of synaptophysin immunocontent and brain derived neurotrophic factor (BDNF), interleukin (IL)-1beta (IL-1 β), IL-6, IL-10 and tumoral necrosis factor alpha (TNF α) levels. HPA caused cognitive deficit in animals, as seen in the open field test, without any alteration in the radial maze. HPA also decreased synaptophysin immunocontent, a marker of synaptic integrity, and increased levels of the IL-6 (proinflammatory interleukin) and IL-10

(anti-inflammatory interleukin) only in cerebral cortex of hyperphenylalaninemic animals. On the other hand, IL-1 β , TNF α and BDNF levels were not altered in HPA animals. The present study demonstrated that chronic HPA causes cognitive damage, which could be subsequent to synaptic changes and neuroinflammation. These results may contribute to the understanding of the pathological mechanisms of cognitive damage observed in phenylketonuric patients.

Title: Dynamics of spinal cord axonal degeneration and innate immune cell phenotypes in multiple sclerosis

Authors: *C. CARAVAGNA¹, A. JAOUËN¹, K. K. FENRICH², S. JEGO-DESPLAT³, M. MALISSEN⁴, G. ROUGON¹, F. DEBARBIEUX¹

Abstract: Multiple sclerosis (MS) is dependent on an interplay between the adaptive and innate immune cell subsets. Activation of resident microglia together with infiltrating leucocytes are key elements in the myelin and axons' degradation during disease initiation and progression, responsible for clinical symptoms. However, the precise interdependence between these elements remains unknown. We developed a mouse preclinical model of MS in order to dynamically analyze the relationships between inflammation, neurodegeneration and disease progression. We induced experimental autoimmune encephalomyelitis (EAE) in Thy1-CFP//LysM-EGFP//CD11c-EYFP transgenic reporter mice¹. Animals carrying a spinal glass window² were subjected to recurrent two photon imaging and the *in vivo* spatio-temporal distribution as well as the morphology of LysM- and CD11c-expressing cells were correlated to the observed axonal

degeneration, weight losses and clinical scores. We validated a 19 parameters flow cytometry panel³ compatible with the simultaneous detection of the two EGFP and EYFP fluorescent reporter proteins. LysM-expressing cells were identified as infiltrating monocytes and neutrophils and CD11c-expressing cells as microglia. Our data define a precise pathology timeline, with primary infiltration of neutrophils and monocytes through the meningeal compartment, secondary *in situ* differentiation of monocytes into monocyte-derived dendritic cells, and finally recruitment of microglial cells in the entire spinal cord followed by migration to plaques. The occurrence of monocyte-derived dendritic cell subset and the diminution of EGFP-expressing cells characterized a stabilization of axon degradation and clinical signs and the predominance of microglia to process axon debris in plaques. Our technical set up and animal model should help identifying targets for efficient anti-inflammatory drugs as well as the opportunity windows for their administration.¹ Fenrich et al., 2013, J Vis Exp, (82):e50826² Fenrich et al., 2012, J Physiol, 590(16):3665-75³ Tamoutounour et al., 2013, Immunity, 39(5):925-38

Title: Modification of gut microbiota through Brassicaceae and Asteraceae plants (Kale, Arugula, Dandelion) modulate neurodegeneration and memory in diet-induced obese prediabetic C57BL/6 mice

Authors: *B. TENG¹, D. FOSTER², D. G. HICKS¹, A. A. OYETUNDE¹, N. OCFEMIAA¹, G. E. FLORES¹, L. R. BANNER¹ ¹Biol., ²California State Univ. Northridge, Northridge, CA

Abstract: World obesity rates have increased in the last few decades. An increase in high fat consumption along with a decrease in physical activity is the primary driver leading the obesity epidemic. Diet-induced obesity predisposes individuals to type-2 diabetes and contributes to complications including those of the nervous system and the immune system. Diabetes is associated with an elevated risk for neurodegeneration and dementia and changes in hippocampal plasticity. Studies have shown that neurodegeneration caused by diabetes is related in part, to elevated levels of inflammatory cytokines involved in brains of animals fed a high fat diet

(HFD). In addition, it is well documented that a high fat diet causes changes in gut microbiota. The dysbiosis of gut microbiota triggers a pro-inflammatory response and may also disrupt neuronal signaling. While diabetes caused by diet-induced obesity is largely preventable by reducing high fat intake, individuals often find it difficult to radically change unhealthy aspects of their diet. Instead, we are proposing to alter the imbalance of gut microbiota through supplementation of kale, arugula (f. Brassicaceae) and dandelion (f. Asteraceae) plants to mediate the inflammatory response, potentially taper neurodegeneration, and thus stymie cognitive decline.

To address this issue, C57BL/6 mice were fed either a control or high-fat diet (HFD)(60% fat) for 18 weeks until the high-fat group reached a pre-diabetic stage. After 18 weeks, mice on a HFD weighed significantly more than the control mice, displayed elevated blood glucose levels, and showed deficits in spatial learning. During weeks 18 to 40, the diets of all the mice were supplemented daily with 1.0 gram of kale, arugula, or dandelion. Consumption of the greens had no effect on the weights of either groups. During the 22-weeks when the mice were fed their supplemental kale, arugula, or dandelion diets, the mice were subjected to multiple repetitions of the Morris Water Maze, Barnes Maze, and Nonconditioned Social Discrimination Procedure, to probe for changes in their memory. Fecal samples before and after supplementation of Brassicaceae and Asteraceae plants were collected and changes in gut microflora were characterized by 16S rRNA gene sequencing for bacterial identification using the Illumina MiSeq platform. Analyses are ongoing; the brains of the subject animals will also be analyzed for inflammatory, neuronal markers and changes in dendritic spine morphology.

Title: Chronic inhibition of HDACs for the treatment of neurodegenerative diseases

Authors: M. S. ALAM¹, *K. HALDAR²

¹Boler-Parseghian Ctr. for Rare and Neglected Diseases, Dept. of Biol. Sci., ²Biol. Sci., Univ. of Notre Dame, Notre Dame, IN

Abstract: Histone deacetylase inhibitors (HDACi) are approved for treating rare cancers and are of great interest as potential therapies for both mono- and polygenetic neurological disorders.

However, the toxicity and poor permeability of HDACi across the blood-brain barrier (BBB) have been major barriers for their use in neurological disorders. We developed a triple combination formulation (TCF) comprising the FDA-approved HDACi vorinostat, the caging agent 2-hydroxypropyl-beta-cyclodextrin (HPBCD), and polyethylene glycol (PEG) for treating a mouse model of Niemann-Pick type C (NPC) disease a difficult-to-treat, neurodegenerative disorder. Vorinostat alone showed activity in cultured primary cells derived from Npc1^{nmf164} mice but did not improve animal survival. However, low-dose, once-weekly intraperitoneal injections of the TCF containing vorinostat increased histone acetylation in the mouse brain, preserved neurites and Purkinje cells, delayed symptoms of neurodegeneration, and increased mouse life span by over 100%. We demonstrate that the TCF boosted the ability of HDACi to cross the blood-brain barrier with no metabolic toxicity or neuroinflammation in the brain, even when used long term. TCF enable dose reduction, an additional challenge in HDACi therapy. Mechanistically, TCF enables epigenetic resetting and rescue the function of the misfolded NPC1 protein in the brain. Data will also be presented on adapting TCF therapy for multiple neurological disorders.

Title: Blood vitronectin robustly induces LIF and pro-inflammatory IL-6 expression *In vitro* and in the mouse brain through integrin-FAK signaling

Authors: *M. P. KEASEY¹, C. JIA², L. PIMENTEL², R. SANTE², C. LOVINS², T. HAGG³ ¹East Tennessee State Univ., Johnson City, TN; ²Dept. of Biomed. Sci., East Tennessee State Univ., Mountain Home, TN; ³Dept. of Biomed. Sci., East Tennessee State Univ., Johnson City, TN Abstract: We have identified a novel function for vitronectin (VTN), an abundant blood protein, as a rapid and potent inducer of leukemia inhibitory factor (LIF) and pro-inflammatory interleukin-6 (IL-6) both in vivo and in vitro. In contrast to VTN, laminin-111, fibrinogen, fibronectin or collagen-1 had no effect on either cytokine after 4 hours in cultured C6 astroglioma cells. Also in vitro, plasma from VTN -/- mice was a less effective inducer of LIF and IL-6 relative to wild type plasma. In adult mice, intra-striatal injection of VTN but not heatdenatured VTN significantly increased LIF and IL-6. Conversely, VTN -/- mice had reduced LIF and IL-6 in response to intracerebral haemorrhage relative to wild type mice. In vitro, VTN induction of LIF and IL-6 were suppressed by RGD-integrin blocking peptides, including one specific for $\alpha v\beta 3$ integrin. Pharmacological blockade of the urokinase plasminogen activator receptor (uPAR), which can bind VTN, also reduced LIF and IL-6 induction by VTN. Further, pharmacological blockade of focal adhesion kinase (FAK) activation and siRNA against FAK, but not the related PYK2, suppressed both LIF and IL-6 in endothelial cells. Overexpression of mutated FAK (Y397F) in cultured cells reduced mechanical injury-mediated LIF and IL-6 induction. We propose that VTN leakage from the blood is an important mediator of cytokine and inflammatory signalling. Integrin-FAK activation may represent a novel target for the regulation of both LIF and IL-6 with implications for the stem cell and inflammation fields.

Title: Ethanol activates 'death receptor' signaling to cause neurodegeneration

Authors: *L. G. COLEMAN, JR¹, J. Y. ZOU², F. T. CREWS³

¹Univ. of North Carolina at Chapel Hill, Chapel Hill, NC; ²Univ. North Carolina, Chapel Hill, Chapel Hill, NC; ³Prof Pharmacol & Psychiat, Skipper Bowles Ctr. Alcohol, Chapel Hill, NC

Abstract: Alcohol addiction is associated with neurodegeneration in the hippocampus and cortex, which is associated with functional deficits. We investigated the role of TNF receptor family, i.e. the Death Receptor Family, in the pathology of alcohol-induced neurodegeneration. Ethanol, both in vivo and in vitro caused activation of the death receptor pathway. The TNFrelated apoptosis-inducing ligand (TRAIL), in particular was activated by ethanol. TRAIL binds two receptors, DR4 and DR5, resulting in caspase-dependent cell death. TRAIL was increased in brain by nearly two-fold 24 hours after acute ethanol in vivo (6g/kg, **p<0.01). TRAIL was also increased in the mouse plasma by 4-fold 12 hours after ethanol. In BV2 microglia, TRAIL was also increased 2.3-fold (**p<0.01) and SH-SY5Y neurons (1.5-fold, *p<0.05) at 24 hours after ethanol (100mM). Ethanol caused a 140% increase in DR5 expression in BV2 microglia at 12 hours after ethanol. Immunofluorescent co-labeling found the majority of TRAIL was present in neurons in vivo. In SH-SY5Y neuronal cultures, DR4 and DR5 were increased by 125% and 155% respectively 12 hours after ethanol treatment. Interestingly, neurons secreted TRAIL into the media in response to ethanol, suggesting autocrine-paracrine signaling. In order to assess the effect of ethanol on TRAIL-mediated neurodegeneration, hippocampal-entorrhinal cortex (HEC) slice culture was employed. Ethanol (100mM) caused increased TRAIL in HEC at 48 hours (1.5fold, p<0.05). DR4 and DR5 were also increased after 48 hours of ethanol exposure (150%). Pre-treatment of slices with ethanol (48h) followed by addition of TRAIL resulted in a robust enhancement of neurodegeneration, evidenced by a near 3-fold increase in propidium iodine uptake greater than either TRAIL or ethanol alone (*p<0.05). Thus, ethanol increases TRAIL signaling and enhances TRAIL mediated neurodegeneration. TRAIL mediated neurodegeneration represents a novel mechanism of ethanol-induced neurodegeneration. This may represent a novel target for the developmental degeneration associated with alcohol abuse.

Ethanol Enhances TRAIL Neurotoxicity (Propidium Iodine)

Title: Intracellular calcium channel expression in autoimmune encephalomyelitis

Authors: *R. GUMMI, S. L. GRILLO, H. JOHNSON, C. L. MONTGOMERY, P. KOULEN Basic Med. Sci. & Ophthalmology, Univ. of Missouri Kansas City, Kansas City, MO

Abstract: Multiple sclerosis (MS) is a common cause of autoimmune demyelination of the central nervous system (CNS) leading to motor and vision deficits. The exact mechanism of MS remains unknown, though disruption in calcium homeostasis is thought to play a role. MS can be modeled in experimental animals through generation of experimental autoimmune encephalomyelitis (EAE) by inducing an autoimmune response against the myelin sheath, an insulating layer covering the nerve fibers. This causes perivascular inflammatory infiltrates and lesions of demyelination in the spinal cord. We hypothesize that intracellular calcium channels (ICCs) are altered during MS development, resulting in abnormal calcium signaling, resulting in neuronal dysfunction, and therefore contributing to loss of axons. This study measured the expression levels of inositol 1,4,5-trisphosphate receptors (IP₃Rs) in EAE-induced animals to determine if calcium channel complexes contribute to neurodegeneration in EAE and might ultimately represent a target for the development of novel pharmaceutical treatments of MS. EAE was induced in female Dark Agouti rats through immunization with myelin oligodendrocyte glycoprotein (MOG) protein. Immunoblotting was used to quantify ICCs in the CNS. Immunohistochemistry was used to visualize and quantify expression of ICCs, as well as of markers for cell types and structures affected by EAE, including oligodendrocytes, somata and axons of neurons, as well as astrocytes. Image analysis software was used to quantify levels of protein immunoreactivity. Six out of eight rats immunized with MOG protein exhibited signs of EAE and presented with increased cell infiltration and demyelination in CNS lesions. Increased expression of some, but not all ICCs was found. Expression of neuronal ICCs was increased in CNS neurons after EAE-induction. Increase in ICC expression could lead to apoptosis of neurons and axon damage during autoimmune encephalomyelitis disease progression due to calcium toxicity. Our findings of altered ICC calcium expression in a model of MS provides a strong rationale for further investigations determining the role of calcium regulation in MS as the basis for novel therapy development to prevent impairment of motor function and vision.

Title: Nasal Associated Lymphoid Tissue ablation does not affect infarct volume or immune cell infiltration after stroke

Authors: *D. BREA¹, C. POON², M. MURPHY³, C. IADECOLA³, J. ANRATHER⁴ ¹Weill Cornell Med. Col., Joan and Sanford I Weill Med. Col. of Cornell Univ., New York, NY; ²BMRI, Weill Cornell Med. Col., New York, NY; ³Weill Cornell Med., New York, NY; ⁴Weill Cornell Med., NEW YORK, NY

Abstract: Stroke is a devastating disease with a strong inflammatory component partially mediated by meningeal IL17⁺ $\gamma \delta T$ cells^{1,2}. $\gamma \delta T$ cells constitute a lymphocyte population with innate features that populate epithelial surfaces, such as the nasal-associated lymphoid tissue (NALT). We have shown that, in the context of stroke, T cells migrate from the small intestine to the meninges but whether $\gamma\delta T$ cells can migrate from other epithelial surfaces is still unknown. Because of its close proximity, one possible source of stroke-associated IL17⁺ $\gamma\delta T$ cells could be the NALT from which T cells could migrate along olfactory nerve sheaths into the brain or the meninges. Indeed, it has been shown that Th17 cells are able to do it after intranasal infection with group A Streptococcus³. The role of NALT as a source for immune cells participating in the inflammatory response and in stroke outcome are still unknown. In order to study this, 25 C57bl/6 mice (male, 8-10 weeks old) were randomized to NALT ablation or sham surgery. 14 days later mice were subjected to transient middle cerebral artery occlusion (tMCAO). Infarct volumes were determined on Nissl stained coronal sections 3 days after reperfusion. Infarct volume analysis did not show any significant difference between sham $(39.99 \pm 6.46, n=12)$ and NALT-ablated mice (47.85 ± 7.13 , n=13, p>0.05). Although NALT ablation does not affect infarct volume, we sought to investigate its effect on immune cell infiltration, and specifically IL17⁺ T cells, in the brain or meninges after stroke. For this purpose, 14 IL17-eGFP mice were randomized to NALT ablation or sham surgery, and subjected to tMCAO. At 16 hours after reperfusion, at a time when IL17+ $\gamma\delta T$ cells are increased in the meninges after stroke¹, immune cells were isolated from brain and meninges and analyzed by flow cytometry. No significant differences were found in total infiltrated CD45⁺ cells (3318 ± 892 vs 3095 ± 933 ; p=0.87, n=7 per group), CD11b⁺ cells (2389 \pm 739 vs 2122 \pm 865; p=0.82), TCR β^+ cells (234 \pm 51 vs 203 \pm 35; p=0.62), TCR $\gamma\delta^+$ cells (27 ± 6 vs 31 ± 6; p=0.67), Th17 cells (16 ± 6 vs 10 ± 3; p=0.32) or IL17- $\gamma\delta$ T cells (13 ± 3 vs 15 ± 4; p=0.78) in the brain. No significant differences were found in total CD45⁺ cells (4485 \pm 1599 vs 2303 \pm 741; p=0.24), CD11b⁺ cells (2625 \pm 1119 vs 1245 \pm 422; p=0.27), TCR β^+ cells (376 ± 114 vs 260 ± 99; p=0.46), TCR $\gamma\delta^+$ cells (57 ± 16 vs 40 ± 11;

p=0.36), Th17 cells (16 ± 6 vs 11 ± 4 ; p=0.46) or IL17- $\gamma\delta$ T cells (57 ± 16 vs 40 ± 11 ; p=0.36) in the meninges of sham surgery and NALT-ablated animals. We conclude that NALT ablation does not affect ischemic brain damage or immune cells infiltration of the meninges or brain after stroke. ¹ Nat Med 22: 516 ² Blood 120: 3793 ³ J Clin Invest 126: 303

Title: Natural product balasubramide derivative ameliorates brain inflammation and brain ischemic stroke via AMPK-mediated microglia polarization

Authors: *T. PANG¹, Y. WANG¹, W. RUAN¹, H. WANG¹, H. LIN² ¹China Pharmaceut. Univ., Jiangsu, China; ²Col. of Pharm., Guangzhou, China

Abstract: Brain inflammation plays an important role in the pathophysiology of brain ischemic stroke, psychiatric and neurological diseases. During brain inflammation, microglia cells are activated and show pro-inflammatory M1 and anti-inflammatory M2 phenotypes, producing neurotoxic molecules and neurotrophic factors, respectively. We discovered a natural product balasubramide derivative 3C exhibiting anti-inflammatory effects in microglia cells, but the underlying mechanisms and its beneficial effects on brain inflammation and brain ischemia are unknown. We found that 3C inhibited M1 polarization and promoted M2 polarization in LPS-stimulated BV2 and primary microglia cells, and these effects are mediated by CaMKKβ/AMPK/JNK signaling pathway. Furthermore, 3C prevented M1 gene expression and enhanced M2 gene expression in a mouse model of LPS-induced neuroinflammation, and reduced the LPS-induced sickness behavior. In addition, 3C significantly reduced infarct volume, improved the neurological deficit, and reduced neuroinflammation in rats with acute focal cerebral ischemia. Our results indicate that the natural product balasubramide derivative 3C suppresses microglia activation by promoting M2 polarization and may provide a novel therapeutic approach to treat brain ischemic stroke associated with enhanced brain inflammation.

Title: Mafb prevents excess inflammation after ischemic stroke by accelerating clearance of danger signals through MSR1

Authors: *T. SHICHITA¹, H. OOBOSHI², A. YOSHIMURA³

¹Stroke Renaissance Project, Tokyo Metropolitan Inst. of Med. Sci., Tokyo, Japan; ²Dept. of Intrnl. Medicine,, Fukuoka Dent. Col. Med. and Dent. Hosp., Fukuoka, Japan; ³Dept. of Microbiology and Immunol., Keio University, Sch. of Med., Tokyo, Japan

Abstract: Inflammation is an essential step for the pathology of ischemic stroke. Since no pathogen exists within brain, post-ischemic inflammation will be triggered by some endogenous molecules (DAMPs: danger associated molecular patterns), which were released from dying brain cells. High mobility group box 1 (HMGB1) and peroxiredoxin (PRX) have been recently identified as DAMPs in the ischemic brain. HMGB1 exaggerates the disruption of blood brain barrier; on the other hand, PRX directly activates macrophage/neutrophil and induces the inflammatory cytokine production through the stimulation of Toll-like receptor (TLR2/4). Both the extracellular release of PRX and the infiltration of immune cells reach the peak within 1 to 3 days after the onset of ischemic stroke, and thereafter they decrease. This will lead to the resolution of post-ischemic inflammation.

We clarified the molecular meshanisms for the clearance of DAMPs from ischemic brain. Using random mutagenesis method, MSR1 (scavenger receptor) and *Mafb* (transcription factor) were idetified as key factors for DAMP clearance. MSR1 expression levels in infiltrating mononuclear phagocytes increased from day 1 to day 3 after stroke onset, which was dependent on *Mafb*. These MSR1-high cells removed DAMPs efficiently and produced IGF-1, a neurotrophic factor, and therefore revealed pro-resolving phenotype. The deficiency of *Msr1* or *Mafb* in infiltrating immune cells resulted in the exacerbation of inflammation and neuronal damages. Thus, *Mafb*-MSR1 pathway is important for the resolution of cerebral post-ischemic inflammation. We also found that Am80, a retinoic acid receptor agonist, enhanced MSR1 expression in infiltrating immune cells through *Mafb* and revealed neuroprotective effects against ischemic brain injury. Our results indicate that DAMPs regulate not only the induction but also the resolution of post-ischemic inflammation (Nat Med 2017 DOI: 10.1038/nm.4312). The novel neuroprotective strategy for ischemic stroke can be developed by accelerating the endogenous pro-resolving mechanisms to prevent the excess inflammatory responses.

Title: Infiltrated peripheral macrophages expresses elevated phagocytic markers in the stroked brain during recovery

Authors: *K. PARK¹, M.-S. WOO², S. CHO³

¹Burke-Cornell Med. Res. Inst., White Plains, NY; ²Burke/Cornell Med. Res. Inst., white plains, NY; ³Burke/Cornell Med. Res. Insitute, White Plains, NY

Abstract: Infiltrating monocyte-derived macrophages (MMs) have been implicated in strokeinduced inflammation and injury. Although the inflammatory nature of MMs in acute stroke has been well documented, their role during the resolution phase of stroke is less clear. The present study investigates the changes of infiltrated MMs subsets and phagocytic markers at sub-acute (7 days (d)) and chronic recovery periods (2 month (m)). C57 male mice (12 weeks old) were subjected to transient focal ischemia. Brain immune cells were collected and CD11b+ cells were further distinguished by CD45^{Hi} and CD45^{Low} subset. Stroke caused the appearance of CD45^{Hi} subset at 7d and 2m after stroke. CD45^{Low} populations were presented both hemispheres with significantly more in the stroked hemisphere. Adoptive transfer of GFP+ splenocytes 24 hour before sacrifice showed the presence of GFP+ cells in CD45^{Hi} and CD45^{Low} subsets at 7d and 2m, Protein expression of CD36 and lysosomal acid lipase (LAL), M2 and phagocytic markers, were increased at 7d and 2m with a greater extent at 2 m. Immunohistochemical analyses showed CD36 expression in infiltrated GFP+ MMs in the ipsilateral hemisphere. The present study showed persistent infiltration of MMs during sub-acute and long-term stroke recovery phase. The accumulation of CD45^{Low} MMs in the stroked hemisphere suggests a potential conversion of infiltrated CD45^{Hi} subset to CD45^{Low} subset. Additionally, elevated CD36 and LAL in MMs at 7d and 2m indicate an involvement of infiltrating MMs in injury repair through phagocytosis.

Abstract: A particularly important technique for neuroprotection in complex cardiac surgery is hypothermic circulatory arrest (HCA). However, HCA leads to multifocal brain injury and neurobehavioral alterations. Inflammatory cytokines are increased in response to brain injury and targeting neuroinflammation is neuroprotective in some brain injury models. We characterized the inflammatory response in a large animal model at different time points after HCA. Twentyfour dogs underwent 2-hour HCA at 18 degrees and were sacrificed 2, 8 or 24 h later (n=8 per group). 8 normal dogs were used as gene expression controls. The hippocampus is highly vulnerable to injury after HCA, and therefore changes in mRNA expression were evaluated in the hippocampus using cDNA microarrays. Gene ontology (GO) analysis was completed using Spotfire Decision Site® and Ingenuity® Pathway Analysis was used to examine regulated

pathways. Selected proteins were further analyzed in hippocampal homogenates using ELISA. Gene ontology analysis indicated that the expression of inflammatory response genes was altered after HCA, with 91 of 430 genes regulated at 2h, 152 at 8h, and 67 at 24h (p<10⁻⁵ at each time point). Several pro-inflammatory cytokines (IL-6, IL-8, CCL2, IL-1b) were upregulated at all three time points, with peak expression at 8h post HCA. The signaling pathways iNOS Signaling, Nf-kb Signaling and Dendritic Cell Maturation signaling pathways were upregulated at 2 and 8h post HCA. Trem-1 Signaling, Granulocyte Adhesion and Diapedesis, and Glucocorticoid Receptor Signaling were upregulated at all time points. IL6 and IL8 were examined at the protein level and expression peaked at 8h, consistent with the temporal pattern of mRNA expression (85 and 115 pg/mg of protein respectively: significantly greater than normal 2 h and 8 h after HCA. Brain inflammation occurs rapidly in response to HCA, with detectable increases in mRNA for multiple inflammatory cytokines and chemokines at 2 h, strikingly elevated expression at 8 h and with some inflammatory mediators remaining elevated 24 h after HCA. This pattern was confirmed at the protein level for selected cytokines. These results support the hypothesis that inflammation contributes to brain injury after HCA, and suggest that therapeutic approaches modulating this response may be beneficial.

Title: Interferon-gamma as a double-edged sword: Its roles on neural stem cells therapy for ischemic stroke model

Authors: *G. ZHANG, *G. ZHANG, B. LI, L. CHEN Dept. of Neurosurgery, Zhongda Hosp., Sch. of Medicine, Southeast Univ., Jiangsu, China

Abstract: The inflammatory and immune responses induced by ischemic stroke commonly affect the functional or structural recovery of nerve system. The pro-inflammatory cytokine interferon gamma (IFN- γ) plays a vital role on both inflammatory and immune responses, and IFN- γ also influences on the role of neural stem cells (NSCs). The aim of this study was to

examine the effects of IFN- γ on NSCs in vitro and ischemic stroke model in vivo. Here it showed that low concentration IFN- γ (10 or 20 ng/ml) superior to other cytokines (BDNF, VEGF, TGF-β1 and IGF-1) could increase the proliferation and differentiation of NSCs in vitro. After treated by NSCs with IFN- γ , it significantly increased the level of inflammatory oxidative stress of NSCs cultured, but it did not induce NSCs abnormality. At in vivo experiment, we built cerebral ischemic model of Sprague Dawley (SD) rats by transient middle cerebral artery occlusion. Two hundred and ten rats were randomized into seven groups as PBS group, high concentration IFN- γ (500ng/rat) group, low concentration IFN- γ (50ng/rat) group, NSCs group, NSCs combined with high concentration IFN-y (500ng/rat) group, NSCs combined with low concentration IFN-y (50ng/rat) group and sham group. It was observed that IFN-y groups did not improve the mNSS scores of ischemic rats, but the repairing function of NSCs group or NSCs combined with IFN- γ groups had been improved compared to PBS group, and the repairing ability of NSCs combined with low concentration IFN-y group was better than NSCs group. TTC staining showed the same results with mNSS, and rats in NSCs combined with low concentration IFN- γ group had smaller infarct volume than rats in other groups. And more brdu/nestin, brdu/DCX positive cells were found in NSCs combined with low concentration IFN- γ group. However, CD4 and CD8 T cells significantly infiltrated into the ischemia sites of rats in high IFN- γ combination group, and the expression of SOD and IFN- γ were significantly increased in high concentration IFN- γ and PBS groups. ELISA showed that the levels of anti-inflammatory cytokines IL-10 and TGF-B1 in cerebrospinal fluid (CSF) and proteins in different time of ischemic rats were increased in NSCs or combined treatment groups compared to IFN-y and PBS groups, but the expressions of pro-inflammatory cytokines (IL-1 β , IL-6, IFN- γ , and TNF- α) were decreased. Thus, transplantation of NSCs combined with low concentration IFN-y can promote the recovery of ischemic stroke rats and reduce the inflammatory response. In conclusion, low concentration IFN-y can promote the functions of transplanted NSCs and change the ischemic microenvironment, so as to facilitate neurological recovery.

Title: Sexual dimorphism in inflammasome activation: Possible cause of exacerbated ischemic brain damage in reproductively senescent female rats

Authors: *A. P. RAVAL¹, J. DE RIVERO VACCARI²

¹Neurol., ²Dept. of Neurolog. Surgery and The Miami Project to Cure Paralysis, Univ. of Miami, Miami, FL

Abstract: A woman's risk of a stroke increases exponentially following the onset of menopause, and underlying mechanisms remains unknown. The current study tests the hypotheses that: (1) inflammasome activation is significantly higher in the brain of RS females as compared to their young counterparts and senescent male rats, (2) RS triggers an innate immune inflammatory response in the ovaries that spreads to the brain, making the brain more susceptible to ischemic damage. We tested our hypotheses using Sprague-Dawley rats of both sexes (6-7 and 9-12 months). The estrous cycles of female rats were monitored for 14-20 days prior to experimentation by daily examination of vaginal smears. Rats that remain in constant diestrus were considered RS. Rats (n = 4-7) of both sexes and ages were sacrificed and hippocampus, gonads, serum and cerebrospinal fluid (CSF) were collected. Additionally, cerebrospinal fluid (CSF) of women (<40 and >50 age) was obtained. Extracellular vesicles (EV) were isolated from serum and CSF using an Invitrogen kit. Inflammasome proteins caspase-1, apoptosis-associated speck-like protein containing a caspase recruitment domain (ASC) and IL-1ß significantly increased in the hippocampus, serum, and ovaries of RSF as compared to YF (p<0.05). This was not observed in the hippocampus or gonads of age-matched males. Importantly, EV obtained from RSF contains significantly higher levels of the inflammasome proteins as compared to YF (p<0.05). EV containing inflammasome proteins originates in the ovaries of RSF and then are carried to the brain via blood. The observed increase in ovary-derived EV containing inflammasome proteins in the brain contributes to the inflammation present in the brain of RSF, and it might exacerbate ischemic brain damage. Future studies investigating the role of ovarian EV in post-ischemic inflammation are underway to understand how modulating EV trafficking can reduce the incidence and impact of cerebral ischemia in post-menopausal women.

Title: Neuroprotective effect of a single injection of losartan in male and female rats subjected to ischemic stroke
Authors: *S. MARTINEZ¹, M. N. GONZALEZ VEGA², A. H. MARTINS³ ¹Neurosci., Univ. Central Del Caribe, Bayamon, Puerto Rico; ²Univ. Central del Caribe, Bayamon, PR; ³Univ. of Puerto Rico Med. Sci. Campus, San Juan, PR

Abstract: Stroke is the fifth leading cause of death in the US, affecting 80,000 people with new or recurring stroke every year. Ischemic stroke, which accounts for 87% of all types of strokes, is caused by a blockade of blood vessels in the brain by a blood clot. Hence loss of oxygen causes apoptosis and necrosis, giving rise to inflammatory conditions. This inflammation affects neurons, astrocytes and consequently the blood brain barrier (BBB). The BBB then becomes more permeable and allows inflammatory molecules into the brain, which exacerbates ischemic brain damage in a positive feedback fashion. Losartan is an angiotensin type 1 receptor blocker commonly used to decrease blood pressure but also has anti-inflammatory properties. In recent studies, losartan has been observed to help maintain BBB integrity. But these studies have been performed with chronic administration of losartan in male rodents for several days to weeks. The efficacy of a single acute injection of losartan in stroke has yet to be quantified. We propose that a single dose of losartan will decrease the neuronal damage and at least partially restore BBB integrity in male and female rats subjected to ischemic stroke. In order to verify this hypothesis we performed middle cerebral artery occlusion (MCAO) to induce an ischemic stroke in male and female Sprague Dawley rats weighing 250-300g. Losartan 1mg/Kg or sterile saline injection was given intravenously. For BBB integrity analysis, Evans Blue (EB) 2% was injected intraperitoneal 1hr after stroke onset. Rats were perfused with sterile saline 24hrs after stroke induction and brain was removed for analysis. For infarct damage analysis, rats were decapitated 24hrs after stroke induction and brain was submerged in tetrazolium chloride (TTC) solution. Both EB dye infiltration and infarct damage was quantified using ImageJ software. Results showed that losartan reduces infarct damage and BBB permeability in losartan-treated male and female Sprague Dawley when the angiotensin receptor 1 blocker was injected 5 min before stroke (p<0.05). These results are reproduced in our preliminary data using rats injected with losartan 2hrs after the stroke onset. Therefore, these results suggest that even a single injection conserves the neuroprotective effects of losartan against stroke and could prove to be a useful alternative therapeutic approach in stroke therapy.

Title: The apolipoprotein E4 allele induces neurovascular dysfunction mediated by perivascular macrophages

Authors: *Y. HATTORI¹, K. UEKAWA¹, K. KOIZUMI¹, L. ZHAO³, S. M. PAUL⁵, C. IADECOLA², L. PARK⁴

¹Feil Family Brain and Mind Res. Inst., ²Weill Cornell Med., New York, NY; ³Appel Alzheimer's Dis. Res. Institute, Brain and Mind Res. Inst., ⁴Feil Family Brain and Mind Res. Inst., Weill Cornell Med. Col., New York, NY; ⁵Director, Appel Alzheimer's Dis. Res. Inst., New York, NY

Abstract: The apolipoprotein E4 (ApoE-ε4, ApoE4) allele is a major risk factor for Alzheimer's disease and white matter ischemic lesions (Neurology 81:292, 2013). However, the mechanisms underlying the increased risk for cerebrovascular diseases and neurodegeneration associated with ApoE4 remain unclear. We sought to determine if the ApoE4 genotype is associated with alterations in the regulation of the cerebral microcirculation that may render the brain more susceptible to ischemic brain injury and neurodegeneration. Cerebral blood flow (CBF) was recorded by laser-Doppler flowmetry in the somatosensory cortex of urethane-chloralose anesthetized human ApoE targeted replacement mice (ApoE4-TR) (Sullivan et al., JBC, 272:17972, 1997) and wild-type (WT) mice (males; age 3-4 months; n=5/group). Blood pressure and blood gases were monitored and controlled. In ApoE4-TR mice, the increase in CBF produced by whisker stimulation (WS) or by topical application of the endothelium-dependent vasodilator acetylcholine (ACh, 10 µM) was attenuated (WS, -49±3%; ACh, -38±3%; p<0.05; mean±SE) compared WT mice, while the CBF increase evoked by the smooth muscle relaxant adenosine (400 μ M) was not affected (p>0.05). The neurovascular dysfunction is mediated by oxidative stress because neocortical superfusion of the reactive oxygen species (ROS) scavenger MnTBAP (100 µM) reversed the suppression of WS and ACh responses in ApoE4-TR mice (p>0.05 form WT). Next, we sought to determine if Nox2 is the enzymatic source of the ROS responsible for the dysfunction. Neocortical superfusion of the Nox2 peptide inhibitor gp91ds-tat (1µM), but not its control peptide, counteracted the neurovascular dysfunction in ApoE4-TR mice (p<0.05 from control peptide). Perivascular macrophages (PVM) are closely associated with cerebral resistance vessels, are enriched with Nox2, and mediate neurovascular dysfunction in models of hypertension (JCI, 126:4674, 2017). Therefore, we tested if ApoE4 in PVM is required for the neurovascular dysfunction in ApoE-TR mice. To this end, after lethal irradiation, we transplanted ApoE4 BM in WT mice to repopulate their perivascular space with ApoE4 PVM. In WT mice transplanted with ApoE4 BM, the increase in CBF induced by WS or by ACh was attenuated compared to WT mice receiving WT BM (WS, -45%; ACh, -35%; p<0.05 from WTOWT). These data indicate that the ApoE4 genotype is associated with profound alterations in neurovascular regulation mediated by oxidative stress and dependent on ApoE4 expression in PVM. Such alterations are likely to play a role in the increased susceptibility to ischemic brain injury and neurodegeneration conferred by the ApoE4 genotype.

Title: Suppression of nitric oxide level from microglia by co-culturing with human mesenchymal stem/progenitor cells

Authors: *H. OHTAKI¹, J. WATANABE⁴, K. YAGURA¹, K. MIYAMOTO², Y. HIRAIZUMI³, K. HONDA¹, K. DOHI²

Abstract: We have reported that transplant of human mesenchymal stem/progenitor cells (hMSCs) decreased ischemic neuronal cell death after ischemia. We also have determined that hMSCs modified several transcriptomes which related to immune and inflammatory responses. In particular, hMSCs modified microglial activating phenotype in the ischemic brain. However, it is still unclear that how hMSCs regulate microglial activation in detail. In present study, we determined that mixed cultured hMSCs reduced nitric oxide production from mice microglial cell line, BV-2. Several number of passage 3 hMSCs $(1.25 - 20 \times 10^4)$ were plated on six-well plate and were cultured with 20% FBS in α-MEM (20% completed cultured medium (CCM)). The next day, the media were replaced to 1% CCM and added $1x10^{6}$ BV-2 and then added vehicle, 10ng/mL IFNy or 10ng/mL IL-4. At 24 and 48 hours after cultivation, the media were collected and measured nitric oxide (NO) level by Griess method. The cells were measured inducible nitric oxide synthase (iNOS) level by western blotting. Moreover, the BV-2 were cultured with inviable hMSCs and human dermatomal fibroblast (HDF) to determine the contribution of cell-cell communication and of xenoreaction. BV-2 increased NO in the media and iNOS in the cells with IFNy application. The BV-2 also increased medial TNFa and cellular gp91^{phox}. These are the IFNy applied BV-2 activated to classical cytotoxic phenotype. On the other hands, IL-4 applied BV-2 decreased medial TNFα and increased cellular Ym1 and arginase activity, suggesting anti-inflammatory phenotype. The phenotypic BV-2 did not produced NO in media. Cultured BV-2 with hMSCs decreased NO in media and iNOS in cells with hMSCsnumber dependent fashion. Four different kinds of inviable hMSCs did not show any NO reduction, suggesting a cell-cell communication required to the response. Moreover, although cultured BV-2 with HDF (20 x 10⁴) slightly decreased NO, the reduction was obviously weaker than that with hMSCs. These results suggested that hMSCs suppressed microglial inflammatory responses with direct cell-cell communication.

Title: Transplantation of mesenchymal stem cells which overexpress interleukin 10 as treatment for stroke-induced behavioral deficits in rats

Authors: *M. M.-M. ANDREWS¹, S. PERUZZARO², J. ROSSIGNOL⁴, G. L. DUNBAR³ ¹Neurosci., ²Central Michigan Univ., Mount Pleasant, MI; ³Dept Psychol, Central Michigan Univ., Mt Pleasant, MI; ⁴Field Neurosciences Inst. Lab., Mount Pleasant, MI

Abstract: Stroke is a leading cause of death and long-term disability worldwide. There is currently only one FDA approved pharmacological treatment and due to strict exclusion criteria, it is administered to only a few stroke patients. Initial damage from stroke occurs from loss of oxygen and nutrients while damage continues even after blood flow is restored, due to the inflammation that ensues. Interleukin 10 is an anti-inflammatory cytokine that may help to improve functional recovery following stroke. Rats underwent the middle cerebral artery occlusion procedure to produce a 75-min stroke. Two days after stroke, rats were given two intracerebral injections as follows: Group 1 received mesenchymal stem cells that were engineered to over-express interleukin 10; Group 2 received unaltered mesenchymal stem cells; Group 3 received Hanks balanced salt solution (HBSS); and Group 4 received sham surgery and HBSS. Following intracerebral injections, rats were given a battery of behavioral tests. For the first five weeks, rats underwent cylinder testing and rotorod testing weekly. Open field testing and ladder testing occurred bi-weekly during the same period. Following these tests rats were then trained to lever press for sucrose pellets in an operant chamber. After training, a behavioral flexibility operant task was put into place and five consecutive lever presses on the active lever were required to earn a pellet. The active lever was assigned at random at the beginning of the session and each time a pellet was earned the active lever would alternate between the two levers, although no signal identified this switch. The behavioral flexibility task was administered for 7 days. At the conclusion of operant testing, rats were euthanized (day 45 post-stroke). Brain tissue was collected for Hematoxylin and Eosin staining to quantify infarct size and levels of inflammation and interleukin 10 was also examined. Preliminary results indicate stroke-induced deficits, but no significant treatment effect has been observed thus far.

Title: The role of GPR37 in microglia/macrophage activation and proinflammatory responses after focal ischemic stroke

Authors: X. HUANG^{1,4}, M. R. MCCRARY¹, M. Q. JIANG¹, X. H. GU¹, R. A. HALL², M. FAN⁴, L. WEI^{1,3}, *S. YU¹ ¹Anesthesiol., ²Pharmacol., ³Neurol., Emory Univ. Sch. of Med., Atlanta, GA; ⁴Dept. of Cognitive Sci., Inst. of Basic Med. Sci., Beijing, China

Abstract: Post-ischemic inflammation and uncontrolled glial responses could contribute to longterm damage of the brain. GPR37, an orphan G protein-coupled receptor, is highly expressed in the mammalian central nervous system, but its function remains obscure. We observed previously that the GPR37 KO mouse shows deficient reactive astrocyte and significantly reduced glia scar formation after cerebral ischemia, evidenced by reduced number of GFAP+ astrocytes in the peri-infarct region as well as the mean GFAP fluorescence intensity across the ischemic boundary regions (Jiang et al., 2016). Compared to WT controls, elevated autophagic cell death and apoptosis were observed in the peri-infarct region of GPR37 KO animals at early time points of 6 to 48 hrs after stroke (McCrary et al, 2016). The current investigation hypothesized that GPR37 KO elevated microglia/macrophage activation that contributes to enforced inflammatory responses. Adult WT and GPR37KO mice were subjected to a focal cerebral ischemia affecting the right sensorimotor cortex. Immunohistochemical staining was performed to identify Iba-1+ microglia/macrophage in the post-stroke brain of WT and GPR37 KO mice. qPCR identified M1 and M2 microglia/macrophage phenotypes by quantifying the expression levels of related genes. Our data showed that there were more Iba-1+ cells in the periinfract region of GPR37 KO animals compared to WT at all inspected time points. iNOS, an M1type gene, was significantly upregulated in the GPR37 KO brain whereas Ym1 and Fizzl, M2type genes, remained unchanged. The expression of interleukin (IL)-1 β , IL-6, monocyte chemoattractant protein (MCP)-1 and macrophage inflammatory protein (MIP)-1 α significantly increased in GPR37 KO mice compared to WT mice. These results indicate that deletion of GPR37 would increase microglia/macrophage activation and augment injurious inflammatory responses after stroke. This study may further suggest GPR37 as a potential regulator of microglia/macrophage activation and long-term inflammation after ischemic stroke.

Title: TREM1 signaling in peripheral infiltrating myeloid cells increases stroke severity

Authors: *Q. LIU, J. WANG, Q. WANG, H. YE, K. ANDREASSON Stanford Univ., Stanford, CA

Abstract: TREM1 is an amplifier of maladaptive innate immune responses in peripheral models of inflammatory disease and is exclusively expressed in myeloid cells, including macrophages, monocytes, neutrophils, and microglia. Cerebral ischemia causes a significant and well characterized immune response in the days and weeks following stroke, beginning with infiltration of myeloid cells from the periphery, including macrophages and neutrophils. This post-stroke immune response contributes to stroke injury, however cellular mechanisms underlying this effect are not fully understood. We tested the hypothesis that TREM1, which signals through DAP12 to amplify pro-inflammatory responses in peripheral models of inflammation, may drive injury elicited by the post-stroke inflammatory response in the murine middle cerebral artery-reperfusion (MCAo-RP) model. Following MCAo-RP, TREM1 surface expression was highly induced in infiltrating CD11b/CD45hi macrophages at 48h and subsequently declined by 6d. Systemic administration of a decoy peptide that inhibits TREM1 ligand binding reduced infarct volume, improved neurological scores and was associated with reduced TREM1 expression in infiltrating myeloid cells. Consistent with this, genetic ablation of

TREM1 reduced stroke injury and improved neurological scores. In previous studies, we determined that TREM1 expression was highly induced by inflammatory PGE₂ EP2 signaling, a major suppressor of beneficial microglial functions. In Cd11bCre; EP2 ^{lox/lox} mice lacking myeloid EP2 receptor, as well as in Rosa26CreERT2; EP2 ^{lox/lox} mice, TREM1 surface expression and numbers of infiltrating myeloid cells were significantly decreased. Taken together, these studies suggest that modulating the innate immune response after stroke, via inhibition of TREM1 activity, improves stroke outcome, and peripheral targeting of TREM1 may be effective in reducing injury and accelerating recovery in a model of transient focal cerebral ischemia.

Title: Alcohol-induced inflammatory priming worsens outcome after ischemic stroke

Authors: ***A. DRIEU**¹, M. NAVEAU², A. QUENAULT¹, D. VIVIEN¹, M. RUBIO¹ ¹INSERM U1237, ²UMS 3408, GIP Cyceron, Caen, France

Abstract: Alcohol consumption is as risk factor for stroke. Furthermore, recent clinical and fundamental studies have shown that chronic alcohol consumption aggravates ischemic stroke outcome (Ducroquet et al., 2013; Lemarchand et al., 2015). Our hypothesis is that long-term alcohol consumption provokes a silent inflammatory status (i.e., inflammatory priming) that could be responsible of exacerbated inflammatory responses in the brain after ischemic stroke. In this study, we used adult male Swiss mice exposed to water (control group) or to 10% ethanol *ad libitum* (alcohol group) for 6 weeks. Inflammatory status was evaluated by original techniques such as the *in vivo* measurement of microglial phagocytosis, *in vivo* vascular adhesion molecular MRI and intravital two-photon microscopy as well as immunohistochemistry. Alcohol exposure provoked a silent inflammatory status (i.e., inflammatory priming) in the brain characterized by a

significant increase in (i) microglial phagocytosis, (ii) the number of perivascular macrophages, (iii) the vascular adhesion molecule P-selectin and (iv) leukocyte rolling and adhesion to blood vessel walls. These results suggest an alcohol-induced inflammatory priming that was confirmed by the exacerbated inflammatory brain reaction after the systemic injection of lipopolysaccharide (LPS). The consequence of this alcohol-induced inflammatory priming is the worsening of ischemic stroke outcome (induced by thrombin injection directly into the middle cerebral artery). Our results demonstrate that alcohol-induced inflammatory priming markedly worsens the outcome after ischemic stroke. Inflammatory priming could thus be an essential target to avoid worsening in the outcome of stroke patients.

Title: The role of the left inferior frontal cortex in cognitive challenge

Authors: *D. NARDO¹, K. PAPPA¹, J. DUNCAN³, P. ZEIDMAN⁴, M. CALLAGHAN², A. P. LEFF², J. CRINION⁵

¹Inst. of Cognitive Neurosci., ²Univ. Col. London, London, United Kingdom; ³Med. Res. Council, Cambridge, United Kingdom; ⁴UCL Inst. of Neurology, London, United Kingdom, London, United Kingdom; ⁵UCL, London, United Kingdom

Abstract: Background. The left inferior frontal cortex (including Broca's area) is traditionally regarded as a core hub for spoken language processing. However, whether its role is domain-specific (i.e., linguistic), or domain-general (i.e., involved in multiple challenging cognitive functions) is a matter of debate [Fedorenko & Thompson-Schill, Trends Cogn Sci 2014]. **Method.** In an fMRI study we investigated how the left inferior frontal cortex is modulated by task and task challenge using a $2 \times 2 \times 2$ (*Task x Challenge x Modality*) factorial design. 11 healthy right-handed native English speakers performed both a linguistic (picture naming) and a non-linguistic (size judgment) task. Stimuli were 480 black and white pictures of monosyllabic objects. Task challenge (low vs. high ambiguity) was manipulated by varying: 1) visually, the amount of visual noise superimposed to a picture (5 vs. 15 black squiggly lines); 2) aurally, the cue delivered concurrently with the picture (initial phoneme vs. noise control). Subjects' overt spoken responses (object names, yes/no replies for size judgment) were recorded online, and

reaction times (RT) were computed. **Results.** RT data showed no significant main effect of *Task* (i.e., tasks were behaviourally matched overall), significant *Challenge x Modality* interactions (visual, p<.001; auditory, p<.001), and significant Task x Challenge x Modality interactions (visual, p=.038; auditory, p<.001). Higher ambiguity resulted in slower RT across both tasks. fMRI data (p<.05 FWE-corrected) revealed that both tasks recruited a common widespread network including the left inferior frontal cortex and supplementary motor area, as well as bilateral visual, auditory and premotor cortices. There was a main effect of Task with the naming task activating bilateral superior temporal cortices more than the non-naming task. The Challenge x Modality interactions showed significant effects in bilateral visual cortices for the visual modality, and in bilateral temporal cortices and in the left precuneus for the auditory modality. The Task x Challenge x Modality interaction showed no significant activation for the visual modality, but significant activations in the left inferior frontal cortex, supplementary motor area, and premotor cortex for the auditory modality. Conclusions. Our data suggest that the left inferior frontal cortex is domain-general (i.e., involved in both cognitive tasks), yet modulated by complex interactions between task, cognitive challenge and sensory modality. Connectivity analyses will enable further characterisation of the neural mechanisms underlying its dynamic role within these task-engaged networks.

Title: Dynamic rat MCA stroke evolution in relation to reperfusion and spreading depolarizations

Authors: U. HOFFMANN¹, *D. A. TURNER² ¹Anesthesia, ²Neurosurg., Duke Univ. Med. Ctr., Durham, NC

Abstract: MCA stroke evolution centers on the evolution of the dynamic relationship between penumbra and ischemic core over time, with infarct size determined by collaterals, reperfusion and spreading depolarizations (SDs). Our hypothesis is that MCA infarcts can be dynamically tracked using imaging and physiological markers, and that infarct consolidation occurs over several days, ameliorated by increasing collateral blood flow, reperfusion and avoidance of SDs. Our methods include filament occlusion of MCA in adult rats, direct infarct monitoring via craniotomy in isoflurane and propofol anesthetized animals, and reperfusion using filament removal at specific times post occlusion. We performed intrinsic optical imaging (IOS), blood flow, DC recordings, tissue pO2, direct fluorescent angiograms, and KCl-induced SD spread to assess collateral flow and infarct size. For long term observations over several days we also measured spontaneous SDs and cortical activity in vivo using high density cortical µECoG arrays in awake animals, before and after MCA infarct.

KCl-induced SD propagation was reliable (from anterior to posterior) in exposed rat cortex with clear IOS wavefront propagation and physiological SD measurement (n = 36 SD episodes). After MCA infarct (n = 7) the blood flow was reduced with decreased angiographic vessel filling, both improved with reperfusion at 2 hr. KCl-induced SDs did not propagate into the core infarct region, instead deviating through the penumbra, and spontaneous SDs showed circuitous cortical paths around the highlighted core infarct region. Reperfusion significantly enhanced collateral flow and reduced infarct size. Isofluorane suppressed most spontaneous SD occurrences whereas propofol did not; KCl-induced SD episodes occurred equally in both anesthesia conditions. Ongoing longer-term recordings in awake rats using implanted high resolution arrays to define SD occurrence and infarct size will substantially enlarge our observation time window and avoid the confounding effects of anesthesia.

These novel experiments reveal the ongoing, dynamic nature of stroke boundaries as well as the role of reperfusion and SD occurrences in secondary stroke expansion. Thus, MCA infarct size may be tracked dynamically with IOS, blood flow and tissue pO2, SD propagation and angiographic vessel filling complemented by chronic recordings in awake freely moving rats after stroke. This dynamic MCA infarct assessment will assist in identifying additional treatment mechanisms.

Title: Relative and absolute reliabilities of the MScanFit MUNE

Authors: *X. LI¹, Y. ZONG², P. ZHOU³

¹Univ. of Texas, Houston, TX; ²UTHealth, Houston, TX; ³PM&R, Univ. of Texas Hlth. Sci. Ctr. At Houst, Houston, TX

Abstract: This study examined the reliability of a novel motor unit number estimation (MUNE) technique based on the compound muscle action potential (CMAP) scan. Six healthy subjects (28-45 y) without any known neurological disorders participated in the same experiments at two different days. CMAP scans were recorded from extensor digitorum bevis (EDB) and abductor hallucis (AH) muscles by stimulating the peroneal nerve and tibial nerve respectively. Motor unit population from two test sessions was quantified using the MScanFIT MUNE technique. Relative and absolute reliability of the technique was assessed by calculation of the intraclass correlation coefficient (ICC), standard error of measurement (SEM), smallest real difference (SRD) and Bland-Altman's 95% limits of agreement (LOA). MUNE of EDB and AH muscles were averaged on different sessions and the estimations were 110±12 and 44±11 respectively. MUNEs of the two muscles were pooled and the ICC, SEM% and SRD% were calculated as0.967, 0.099%, and 0.049%, respectively. The Bland-Altman test indicated no systematic bias between most of the repeated measurements. These findings suggest that MScanFit is a reliable technique in assessment of motor unit counts.

Title: Understanding neurovascular mechanisms during cortical spreading depression in ischemic stroke rats

Authors: *L.-D. LIAO, H.-C. PAN, S.-P. SUN Inst. of Biomed. Engin. and Nanomedicine, Natl. Hlth. Res. Inst., Miaoli County, Taiwan

Abstract: Brain functions, such as motor and sensory functions, are based on neuronal activities and also highly associated with the hemodynamic supporting for energy and metabolic homeostasis. Therefore, the corresponding neurovascular mechanism plays an important role in the complex brain activities. To elucidate the neurovascular mechanisms underlying physiological or pathological conditions, we develop a novel multimodality imaging system for simultaneously recording the electrocorticography (ECoG) signals for brain activities and hemodynamics responses by laser speckle contrast imaging (LSCI), so-called ECoG-LSCI system, to collecting the sufficient information of neurovascular functions with high

spatiotemporal resolution. The photothrombotic ischemia (PTI) rat model is used and induced the stroke over the motor cortex of right hemisphere at the coordinate of anterior-posterior: 0 mm and medial-lateral: +1.5 mm to the bregma. Interestingly, the PTI stroke leaded to contralateral somatosensory evoked potential (SSEP) attenuations of primary motor cortex (M1) and primary sensory cortex forlimb (S1FL), resting-state evoked potential (RS-EP) decline, cortical spreading depression (CSD)-like surge induction and ischemic infarct damages in motor cortex which confirmed by 2,3,5-triphenyltetrazolium chloride (TTC) staining. Taken together, the ECoG-LSCI system provides *in vivo*, full-field, real-time, multi-functional and useful detection for the neurovascular mechanism of ischemia-induced CSD study.

Title: Sequential restoration patterns of cerebral autoregulation in different ischemic rat models

Authors: *E. CHOI, G. PARK, Y. KWON, K.-E. LEE, M. CHOI, J. LEE, J. HONG Dept. of Neurology, Ajou Univ. Sch. of Med., Suwon, Korea, Republic of

Abstract: BACKGROUND: Cerebral autoregulation (CA) is the ability to maintain sufficient and stable cerebral blood flow (CBF) despite changes in cerebral perfusion pressure (CPP). Theoretically, CA has been known as an initiative surrogate for cerebrovascular dysfunction and subsequent brain damage. Early prognostication ways with various CA measurements for accurate prediction of the brain injury would be a useful screening tool to triage a candidate for numerous neurovascular protectives. For this reason, we are to assess the feasibility of various CA measurements for early prognostication in ischemic rat models according to the different mode of brain damage. **METHODS:** Cerebral ischemia were assessed in male Sprague-Dawley rats (250-280g). The temporary focal ischemia was performed by transient middle cerebral artery occlusion (tMCAO) for 90 minutes. The transient global ischemia with four-vessel occlusion (4-VO) was performed by an electrocauterization of two vertebral arteries and temporary clamping of two common carotid arteries (CCA) for 10 minutes. Sequential changes of cerebral blood flow (CBF) by intravenous acetazolamide (50mg/kg) administration was measured using PeriScan PIM 3 System at baseline (T0) and 1 (T1), 3 (T3), 5 (T5) and 7 (T7) days after surgery and expressed as cerebrovascular reserve capacity (CVRC). We analyzed infarction volume, neuronal death, and glial activation with immunohistochemistry. We assessed the neurological behavior with modified neurological severity score (18 points). RESULTS: The focal tMCAO had an immediate ipsilateral CBF reduction to 41±17% from baseline (100%), representing with

post-stroke neurological deficits (8.4 ± 0.6 point) and infarct volume (321 ± 20 mm³) at 7days. As compared with CVRC on contralateral hemisphere (T1: $18\pm3\%$, T2: $18\pm5\%$, T5: $10\pm7\%$, T7: $4\pm4\%$), CVRC on ipsilateral hemisphere was initially decreased (T1: $-4\pm4\%$, T3: $-3\pm6\%$) and restored after 5 days (T5: $3\pm6\%$, T7: $11\pm4\%$). The global 4-VO model showed a marked decrease in CBF to $12\pm2\%$ from baseline after temporary clapping of CCAs. An immediate overflow ($139\pm16\%$ of baseline) after recirculation was shown and its flow maintained below baseline until 7 days (T1: $87\pm7\%$, T7: $85\pm5\%$). The global 4-VO model also showed a selective neuronal death at CA1 region of the hippocampus. CVRC on bilateral hemispheres remained above baseline. **CONCLUSIONS:** Our data shows that CVRC has a temporary reduction and restoration in focal tMCAO, and it also increases above baseline in global 4-VO models. Such findings can be feasible as biological surrogates to mitigate subsequent brain damage for new drug development in post-cardiac arrest care.

Title: Using diffusion kurtosis magnetic resonance imaging to monitor iPS-MSCs treatment response in stroke

Authors: *C.-W. CHIANG¹, K.-J. WU², S.-Y. LIN^{1,4}, K.-H. CHO¹, B. YEN³, Y. WANG², L.-W. KUO^{1,5}

¹Inst. of Biomed. Engin. and Nanomedicine, ²Ctr. for Neuropsychiatric Res., ³Inst. of Cell. and Syst. Med., Natl. Hlth. Res. Inst., Miaoli, Taiwan; ⁴Dept. of Computer Sci., Natl. Chiao Tung Univ., Hsinchu, Taiwan; ⁵Inst. of Med. Device and Imaging, Natl. Taiwan Univ. Col. of Med., Taipei, Taiwan

Abstract: After stroke onset, the degenerative reactions were activated leading to cell death and affecting neural repair. Stem cell administration shows an attractive therapeutic approach that reduces inflammation and enhances brain reorganization. Diffusion kurtosis imaging (DKI), an extension of diffusion tensor imaging (DTI), not only computes diffusion tensors but also allows to evaluate the non-Gaussianity of water diffusion. DKI has also been demonstrated to provide

complementary and sensitive imaging biomarkers in many neurological diseases. For example, an increase of mean kurtosis (MK) may be represented as an increase of cell infiltration. Recently, many therapies were focused on pre-treatment study which limits the application of many stroke patients. Therefore, it is important to expend the therapeutic window as well as to apply appropriate neuroimaging to monitor the ischemic damage and recovery. In this study, we aimed to apply DKI to evaluate the stem cell treatment response at different time points and further investigate the underneath pathology. Adult Sprague-Dawley rats were underwent right middle cerebral artery occlusion (MCAo) for 60 minutes. Our recently-developed induced pluripotent stem cells from human mesenchymal stromal cells (iPS-MSCs) was administrated. Cyclosporine was employed as anti-inflammation agent. A total of 12 stroke rats was underwent iPS-MSCs (n=4), iPS-MSCs with cyclosporine (n=5), or vehicle (n=3) grafting on contralateral corpus callosum of rat brain on day 2 post-stroke. T₂-weighted imaging (T2WI) and diffusion weighted imaging (DWI) were acquired on day 3, 10 and 16, using a 7T/30cm animal scanner (Bruker Biospec, Germany). T2WI was acquired for examination of infarct volume. Diffusion tensors and diffusion kurtosis tensors were reconstructed with DKI model analysis. Regions-ofinterest (ROIs) of cortex and external capsule on both lesioned and contralateral sites of rat brain around bregma were selected. ROI analysis was performed on DKI-computed MD and MK maps for cortex as well as on FA maps for white matter. Two sample t-test was performed for statistical analysis. Our preliminary results suggest, by DKI, transplantation of iPS-MSCs poststoke shows the efficacy to resolve inflammation and potentially enhance neural repair at chronic. DKI shows the ability to provide sensitive imaging biomarkers for neuronal pathologies in stroke non-invasively. Histology will be further examined for pathological validation.

Title: Determination of stroke volume using multi-parametric analysis based on *In vivo* MRI measurements in rats

Authors: *K. J. PATZWALDT¹, P. KATIYAR¹, Y. WANG², X. YANG², R. K. LERCH¹, J. A. DISSELHORST¹, S. POLI³, S. CASTANEDA VEGA¹, B. J. PICHLER¹ ¹Werner Siemens Imaging Center, Dept. of Preclinical Imaging & Radiopharmacy, ²Herti Inst. for Clin. Brain Res., Eberhard Karls Univ. of Tuebingen, Tuebingen, Germany; ³Dept. of Neurol. & Stroke, Univ. Hosp. Tuebingen, Tuebingen, Germany

Abstract: Ischemic Stroke (IS) is the third most common cause of death affecting 15 million people each year worldwide. Magnetic resonance imaging (MRI) allows non-invasive in vivo evaluations of stroke volume (SV), edema and perfusion. However, reliable computational methods for measuring SV are still warranted since subjective analysis of multi-parametric MRI data often leads to an overestimation of SV, which is partly due to the lack of specificity (edema vs stroke) in T2 weighted images (T2WI). In order to develop personalized therapies, it is essential to accurately assess the extent of ischemic injury using automated algorithms analyzing multi-parametric data. Therefore, in this work we aimed to determine the spatial distribution of ischemic lesions and other biological compartments using a Gaussian mixture model (GMM) and the following MRI features: apparent diffusion coefficient (ADC) maps, perfusion weighted images (PWI) and T2WI. We induced IS on rats using the middle cerebral artery temporary occlusion stroke model (MCAO). MRI was measured longitudinally at multiple time points until 2 weeks post-stroke using ADC, PWI and T2WI and behavioral tests (BT) were performed per time point. ADC maps and PWI were co-registered to the T2WIs and volumes of interest (VOIs) were drawn around the brain. The 24 h time point MRI data of 16 rats were divided into training (n=12) and testing (n=4) group. A GMM was applied on the training set to identify different biological compartments, including stroke and non-stroke areas. Testing was performed using random forest and classification maps were corroborated using histology. A strong spatial correspondence was present between the stroke areas identified using the proposed approach and the corresponding histology. The BTs also indicated the severity of the symptoms correlating to the clustering results. Stroke compartment was characterized in the training step with an average ADC value of $[401.82 \pm 64.11] \times 10^6 \text{ mm}^2/\text{s}$, a perfusion value of $[38.0 \pm 17.93] \text{ ml}/100\text{g/min}$. Likewise, the average ADC and perfusion values for the stroke cluster in the test phase were $[369.32 \pm 70.44] \times 10^6$ mm²/s and $[31.9 \pm 15.16]$ ml/100g/min, respectively. The proposed algorithm identified clusters with radiological characteristics classical of IS, which we were able to corroborate with histology at 24 h. Using this machine learning approach on multi-parametric MRI data, we aim to model the behavior of the stroke region over the remaining time points and subsequently, to objectively characterize and evaluate the efficacy of treatments at different time points.

Title: An introduction to 'F2': A quantitative MRI classifier for treatment stratification of acute ischaemic stroke patients with unknown onset time

Authors: *B. L. MCGARRY¹, M. J. KNIGHT¹, P. CLATWORTHY², R. BOSNELL², D. CARONE³, G. HARSTON³, J. KENNEDY³, P. JEZZARD⁴, R. A. KAUPPINEN¹ ¹Sch. of Exptl. Psychology and Bristol Clin. Res. and Imaging Cent, Univ. of Bristol, Clifton, United Kingdom; ²North Bristol NHS Trust, Bristol, United Kingdom; ³Radcliffe Dept. of Med., Acute Vascular Imaging Ctr., University of Oxford, United Kingdom; ⁴Nuffield Dept. of Clin. Neurosci., Oxford Ctr. for Functional MRI of the Brain, University of Oxford, United Kingdom

Abstract: Unknown onset time is a major contraindication to hyper acute ischaemic stroke treatment. If MRI could identify patients within the therapeutic time window or with enough salvageable tissue, many more patients would receive IV thrombolysis. Weighted MR images are unreliable due to shading effects from strong brain surface signals and bias field problems resulting from multi-element receiver systems. Quantitative T_2 (qT_2) relaxation time images avoid these problems. Elevated qT_2 is a potential proxy for stroke timing and tissue status ^{1,2,3}, however the increase is small (1-2 ms/hr) and cerebral qT₂ distributions are broad, reflecting heterogeneity of ischaemic lesions^{3,4}. We propose a classifier 'F2' to identify potentially treatable strokes^{3,4}. F2 is the proportion of voxels with elevated qT_2 within regions of decreased apparent diffusion coefficient (ADC); F2 increases with time in a rat stroke model⁴. **Objectives:** We determine qT_2 and F2 time dependencies in ischaemic stroke patients. **Methods:** In this ongoing study, ischaemic stroke patients (onset < 9hrs) are scanned at 3T at 2 hospitals. Protocol includes ADC, multi-echo T_2 and $3D-T_1$. Ischaemic tissue = ADC voxels 1MAD < whole-brain ADC distribution. Elevated $qT_2 = qT_2$ voxels > modal non-ischaemic qT_2 by HWHM. F2 =100*(high qT₂ voxels/low ADC voxels). Potential issues considered include lesion size and location, and natural regional variability in qT_2 including low qT_2 in iron rich

regions.

Results (Figure 1): Initial observations of the first 7 patients with ADC lesions > 2cm³ are consistent with rat stroke³ as elevated qT₂ is heterogeneous within low ADC volumes and larger F2s occur in later onsets.

Conclusions: F2 may identify patients within the therapeutic window and reveal the extent of potentially salvageable tissue. Thus, F2 is a potential classifier for treatment stratification of stroke patients with unknown onset.

Title: A theranostic approach in stroke imaging: The benefit of using an intranasal erythropoietin-tracer for multiparametric imaging

Authors: *R. K. LERCH, K. J. PATZWALDT, P. KATIYAR, R. STUMM, N. ALTMEYER, A. MAURER, S. CASTANEDA VEGA, B. J. PICHLER Dept. of Preclinical Imaging and Radiopharmacy, Werner Siemens Imaging Ctr., Tübingen, Germany

Abstract: Erythropoietin (EPO) is a glycoprotein that mediates neuroprotective effects through various pathways. It was shown, that there is an upregulation of the EPO-receptor in the brain under hypoxic conditions, which makes it a specific target for brain imaging and neuroprotection in stroke research. However, EPO administered intravenously can lead to

increased systemic side effects due to altered blood parameters. Therefore, an alternative administration route which reduces systemic delivery and simultaneously increased brain delivery is warranted. In this project, we investigated the therapeutic potential of Cu-64 radiolabelled EPO, as well as its applicability for imaging when administered intranasally. Sprague Dawley rats were induced a stroke using the middle cerebral artery occlusion stroke model. The rats were randomly divided into groups, with each rat receiving a dose of radiolabelled EPO intranasally three hours after stroke on-set at different dosages. Stroke progression was examined repeatedly up to three months after on-set of the stroke using behavioural tasks and brain imaging consisting of T2-weighted magnetic resonance imaging (MRI), diffusion weighted MRI, perfusion weighted MRI and positron emission tomography (PET). Furthermore, we performed autoradiography and biodistribution after 24 hours. The biodistribution of intranasal EPO showed a remarkably different biodistribution pattern when compared with intravenous administration, specially in the kidney. Results of the autoradiography showed, that an increased uptake in the brain and the stroke area, is achievable but rather inconsistent. PET-images showed inhomogeneous brain uptake which we attribute to a not long enough half-life of Cu-64 to demonstrate brain penetration. However, the behavioural and the stroke volume data showed a tendency for a dose dependent effect of the EPO-tracer on stroke-outcome.

Our work shows that EPO presented a promising reduction of stroke volume in a dose-dependent manner without increasing the biodistribution in non-target organs, hence potentially decreasing systemic side effects. The findings are consistent with literature, where it has been shown small amounts of EPO mediate an effect when administered intranasally . Ongoing work using a longer half-life tracer will likely allow a better visualization of the distribution of EPO in the stroke area and present neuroprotection without systemic side effects.

Title: A novel infarct-avid agent ¹⁸F-fluorodeoxyglucaric acid (FGA) for imaging brain stroke by positron emission tomography (PET)

Authors: *V. AWASTHI¹, H. HOUSON¹, A. MDZINARISHVILI² ¹Univ. of Oklahoma Hlth. Sci. Ctr., Oklahoma City, OK; ²Dept. of Rehabil. Sci., Univ. of Oklahoma, Col. of Allied Hlth., Oklahoma City, OK

Abstract: Background: Stroke is a common cause of death worldwide and leads to considerable disability among survivors. Current management of stroke patients is aimed at preventing the progression of at-risk tissue towards infarction by restoring blood supply to ischemic penumbra. Diffusion-perfusion mismatch in magnetic resonance or computed tomography images is routinely employed for discerning non-viable and viable tissue and optimize treatment in brain stroke patients. However, diffusion-perfusion mismatch is not always a reliable indicator of salvageable tissue; some lesions may show acute reversal, whereas others may fail to infarct. The objective of this study was to synthesize ¹⁸F-FGA and demonstrate its potential for PET imaging of infarct in the brain stroke. Methods: Radiopharmaceutical ¹⁸F-FGA was synthesized in onepot by 3 min controlled oxidation of commercially available ¹⁸F-fluorodeoxyglucose (FDG). Quality control of radiopharmaceutical was performed by ion-exchange HPLC and thin-layer chromatography. Brain stroke was induced in the left cerebral hemisphere of male CD-1 mice (20-25 g) by occluding middle cerebral artery and allowing reperfusion after 1 h of occlusion (transient MCAO model). Post-stroke PET imaging was performed on the day of occlusion as well as 24 h after occlusion. Approximately 100-500 µCi of ¹⁸F-FGA was injected intravenously and PET data was acquired for 20 min after 1 and 2 h of injection. In some instances, right and left cerebral hemispheres were separated upon necropsy and radioactivity counting was performed in a well counter to compare ipsilateral versus contralateral accumulation of ¹⁸F-FGA. Results: Synthesis of ¹⁸F-FGA was accomplished in a quantitative manner from rapid oxidation of ¹⁸F-FDG. The synthesized ¹⁸F-FGA was well tolerated by mice when injected intravenously. Ex vivo counting of the brain hemispheres showed that ipsilateral tissue accumulated more than 2.5 times ¹⁸F-FGA as compared to the contralateral tissue (p < 0.05, Student's t-test). However, in vivo images were difficult to interpret because of the small volume of injury surrounded by non-specific accumulation of ¹⁸F-FGA in nasal secretions. To circumvent this, we isolated the intact brain together with skull for imaging; these ex vivo images clearly showed higher ipsilateral accumulation of ¹⁸F-FGA as compared to the contralateral hemisphere. Conclusions: Results show that infarct-avid agent ¹⁸F-FGA can be synthesized from ubiquitously available ¹⁸F-FDG in a simple reaction. As the first infarct-avid PET agent, ¹⁸F-FGA has a potential to enable extremely sensitive and high resolution neuroimaging of the brain infarct pathologies.

Title: Genomic analysis revealed changes of inflammation-related genes in a mice model of focal cerebral ischemia

Authors: *Z. CHENGJIE^{1,2,3}, Y. B. ZHU³, S. WANG², Z. Z. WEI², M. Q. JIANG², Y. B. ZHANG¹, Y. H. L. PAN³, S. X. TAO³, J. M. LI¹, L. WEI² ¹Neurol. Beijing Friendship Hosp.Capital Med. Univ., Beijing City, China; ²Anesthesiol., Sch. Med., Emory Univ., Atlanta, GA; ³Labs. Stem Cell Biol. Regen. Med., Exp. Res. Ctr., Beijing Friendship Hosp., Beijing, China

Abstract: Ischemic stroke remains one of the leading causes of human death and disability in the world, caused by a cascade of pathological processes including increased inflammation involving inflammatory cell activation and filtration in and around ischemic lesion areas. However, our understanding of these complicated cellular and molecular events following ischemic stroke are still incomplete. In this investigation, we used RNA sequencing to analyze the whole genomic gene expression profiles at different days (D1, D3, D7, D14, D21, D60, D90) in a mice model of focal cerebral ischemia. The result showed that the number of differentially expressed genes (DEGs) increased over time after ischemia. There were 1967 DEGs at D1, 2280 DEGs at D3, 2631 DEGs at D7, 5516 DEGs at D14, 7093 DEGs at D21, 3971 DEGs at D60, and 4471 DEGs at D90. By performing gene ontology enrichment and network analyses, 87 DEGs significantly related to inflammation were identified. Among them, pro-inflammatory genes CD86, tumour necrosis factor (TNF)- α , and interleukin (IL)-1 β were all upregulated and peaked at D14; antiinflammatory genes arginase 1 (Arg1) and Chitinase-like 3 (Ym1) peaked at D1 while IL-10, transforming growth factor (TGF)-β and CD206 peaked by D7 to D14. Our study provided new insights and detailed information on the molecular pathology of experimental ischemic stroke. The genomic data analysis-revealed regulatory mechanisms would be useful in developing therapeutic interventions targeting inflammation of ischemic stroke in humans.

Title: Regional diffusion differences in people with severe upper limb impairment post-stroke: A multi centre study

Authors: *K. S. HAYWARD^{1,3}, M. R. BORICH⁴, S. C. CRAMER⁵, A. BORSTAD^{6,7}, J. C. STEWART⁸, J. L. NEVA², J. K. FERRIS², J. M. CASSIDY⁹, L. A. BOYD² ¹Physical Therapy, ²Univ. of British Columbia, Vancouver, BC, Canada; ³Florey Inst. of Neurosci. and Mental Hlth., Melbourne, Australia; ⁴Emory Univ., Atlanta, GA; ⁵Univ. of California Irvine, Irvine, CA; ⁶Col. of St. Scholastica, Duluth, MN; ⁷Ohio State Univ., Columbus, OH; ⁸Univ. of South Carolina, Columbia, SC; ⁹Neurol., Univ. of California Irvine Dept. of Neurol., Irvine, CA

Abstract: Background: Severe upper limb (UL) impairment post-stroke often results from significant structural damage to the corticospinal tract (CST), the primary motor output pathway. In individuals with severe impairment with movement limited to proximal musculature, structural integrity of supporting motor pathways may be important. Aim: To determine the unique contribution of CST, alternate motor (corticorubrospinal and corticoreticulospinal), and corpus callosum (CC) tracts to motor outcome in individuals with severe as compared to mild-moderate impairment post-stroke and non-stroke older adults. We hypothesise: 1) tract order of importance for motor outcome in the severe group will be CST followed by alternate motor and CC tract integrity; 2) time post-stroke may alter the pattern of importance in the severe group; and 3) an overall effect of group by pathway, such that people with severe have the poorest tract integrity. Methods: Data was pooled from four centres across three participant groups defined

apriori: individuals with 1) severe impairment (Fugl-Meyer Upper Limb, [FM-UL] score: \leq 30/66); 2) mild-moderate impairment (FM-UL score: >30/66); 3) no history of stroke. All individuals underwent diffusion weighted imaging (DWI). Participants with stroke completed a motor impairment (FM-UL) and/or function (Wolf Motor Function Test [WMFT] WMFT-rate) assessment. Hand-drawn regions of interest were delineated to reconstruct the CST, alternate motor, and CC tracts, and extract mean fractional anisotropy (FA). Planned analysis are: 1) stepwise linear regression model for each dependent motor outcome (FM-UL, WMFT-rate) for each stroke group (severe, mild-moderate), with mean FA of reconstructed tracts entered as independent variables; 2) one-way ANOVA with between-subject factor of TIME (subacute, chronic) in severe group only; and 3) two-way mixed model ANOVA of GROUP (severe, mildmoderate, healthy) x MOTOR PATHWAY (FA of CST, alternate motor, CC). Results: We have DWI data from 65 individuals with severe UL impairment (30 subacute, 35 chronic), 30 with chronic mild-moderate impairment and 30 non-stroke adults. Preliminary analysis of 10 chronic individuals from one centre indicated that CC was more strongly correlated with impairment than CST or alternate motor tracts. Conclusions: This pooled analysis of DWI in people with severe UL impairment after stroke will advance our understanding of the regional importance of white matter status to motor outcome across severity levels; inform studies of stroke recovery; and contribute to more precise targeting of treatments to individual patients based on white matter status.

Title: Quantification of corticospinal tract using DTI in chronic stroke survivors

Authors: *B. KIM¹, S. CHOI², D. B. KAY², N. SCHWEIGHOFER¹, J. P. HALDAR³, R. M. LEAHY³, B. E. FISHER¹, C. J. WINSTEIN¹ ¹Div. of Biokinesiology and Physical Therapy, ²Neurosci. Grad. Program, ³Ming Hsieh Dept. of Electrical Engin., USC, Los Angeles, CA **Abstract:** There are a number of different DTI-based methods that have been used to quantify corticospinal tract (CST) structure in the context of stroke rehabilitation research. However, there is no gold standard method that has been shown to provide the most accurate estimate of CST structure in chronic stroke survivors. This study aims to compare different DTI-based approaches to quantify CST structural characteristics in chronic stroke survivors, and to determine which, if any, reveals the strongest brain-behavior relationship. We used DTI and clinical motor behavior data from a phase-I clinical trial. Participants were chronic stroke survivors with mild-tomoderate arm and hand motor impairment (N=37, average chronicity=3 years). We processed the Imaging data using BrainSuite16a (http://brainsuite.org/), and used the Wolf Motor Function Test log mean time score for distal control items (WMFT-distal) as the primary motor behavior measure. We calculated mean Fractional Anisotropy (FA) for CST of each tract (L, R) with 7 different approaches: 1) manually drawn 2-D posterior limb of the internal capsule (PLIC) region, 2) manually drawn 2-D cerebral peduncle (CP) region, 3) 3-D PLIC template volume from a JHU white matter atlas, 4) 3-D CP template volume from a JHU white matter atlas, 5) 3-D CST individual volume from each participant's tractography, 6) 3-D CST template volume from a standard white matter atlas, and 7) 3-D CST template volume generated from participants' contra-lesional CST. We compared CST FA between the two tracts for each method using a paired *t*-test; calculated a CST FA asymmetry index between the two hemispheres from each approach, and performed partial correlation analyses between each CST FA asymmetry index and WMFT-distal time score, controlled for age, chronicity, and severity. The mean ipsilesional CST FA was significantly lower than the mean contralesional CST FA for all 7 methods. Only CST FA asymmetry from the 3-D CST individual volume from each participant's tractography significantly correlated with WMFT-distal (r=0.46, p=0.005). Further only range of CST FA asymmetry from individual tractography met the criterion of CST FA asymmetry for those who have mild-to-moderate arm motor impairment. These findings suggest that compared to the six other methods, CST FA asymmetry based on the individual's CST tractography is the most accurate estimate of CST structural characteristics in chronic stroke survivors with mild-tomoderate motor impairment. We recommend this method for future studies in chronic stroke that aims to investigate the relationship between CST structural characteristics and motor behavior.

Abstract: Functional imaging as a prognostic biomarker for post-stroke motor recovery would help understanding of neural mechanisms in post-stroke recovery. Among various types of imaging modalities, resting-state fMRI (rs-fMRI) is one of the emerging methods yielding biomarkers of brain conditions. In this research, we tested association between rs-fMRI and clinical motor impairment scale using least absolute and selection operator (LASSO) analysis.Fifty-three post-stroke hemiplegic patients in the subacute stage participated in this study after giving written informed consent. Clinical motor impairment scale, Fugl-Meyer Assessment (FMA) motor score, and rs-MRI scans were obtained at the admission, 8 weeks after admission, and the discharge. In total, 96 rs-fMRI scans were used for the analysis. MRI data were acquired using a 3-T scanner (GE Discovery MR750w). T1 weighted image was acquired for the localization of the lesions and for adjunct data for rs-fMRI analysis.rs-fMRI data were pre-processed with slice timing correction, motion correction, spatial normalization to the standard brain space and smoothing, with functional connectivity toolbox and SPM12. rs-fMRI was flipped between right and left when a patient had impairment in the left-side impairment. Functional connectivity matrix was estimated as a correlation coefficient of MRI signals for each pair of anatomical volumes of interest (AAL). Features of the functional connectivity matrix that statistically correlates with FMA were selected by LASSO model.Figure 1 shows functional connectivity selected by LASSO for the estimation of FMA in all the patients. Functional connection including the ipsilateral cerebellum and fronto-parieto-temporal opercular areas contralateral to the impaired hemibody are positively associated with FMA. The present study suggests that rs-fMRI can be used as a biomarker of motor impairment in post-stroke hemiplegia.

Title: Ascending cerebello-cortical projection viewed by manganese-enhanced MRI

Authors: *L. COVOLAN¹, A. MARTIN², C. WATHEN⁴, C. ANDROJNA³, H. BATTAPADY³, K. B. BAKER⁵, A. G. MACHADO⁶ ¹Physilogy, ²Neurosciences, ³Lerner Res. Inst. - Cleveland Clin., Cleveland, OH; ⁴Lerner Col. of Med., ⁵Dept. of Neurosci., ⁶Ctr. Neurolog. Restoration, Cleveland Clin., Cleveland, OH

Abstract: Pre-clinical studies in rodent models of stroke suggest that deep brain stimulation (DBS) of the lateral cerebellar nucleus (LCN) may be a promising treatment to enhance recovery after stroke.Our aim here was to map, both anatomically and functionally, the cerebellar-cortical

projection in vivo using manganese-enhanced MRI (MEMRI). In the first part of the study the cerebellar-cortical projections were mapped by tracking manganese chloride (MnCl₂) transport over a 48-h period. For this, male Long-Evans rats a single injection of MnCl₂ into LCN (500 mM, 1 uL). MRI scans were performed at 2-, 8-, 24- and 48-h post injection utilizing a 3D T1-FLASH protocol with the following parameters: TE=6.37 ms, TR=50 ms, SA=3, Flip angle = 20, bandwidth = 20,000 Hz, and FOV = $200 \times 200 \times 200$ (Bruker Biospec Avance 70/20 (Bruker Biospin) system with a 72 mm volume coil setup). MRI processing and quantification were performed using FSL and AFNI toolkits. To visualize the LCN-cortical projections at 8h, 24H and 48H after injection, a whole brain statistical map (z map) was quantified for each time point by comparisons with the 2h scan. The voxel that survived FDR correction at a threshold of p<0.05 on the z map were included in the final visualization map. Our results indicate that MEMRI is a suitable and accurate way to study cerebello-cortical projections in vivo; 8H after LCN manganese chloride injection the contrast can be visualized in cortical areas, mainly contralateral. The peak of contrast was obtained 24H post-injection with bilateral distribution and faded by 48H. In the second part of the study, we tested the functionality of this projection via DBS activation. Animals underwent surgical implant of MRI-compatible electrode into the LCN. One week later, these animals received a systemic injection of MnCl₂ (60 mg/kg). Twelve hours post injection, the animals were scanned using the same MRI protocol as above. Immediately after the first scan, the animals received one hour of DBS with the following parameters: 100- 200 uA, 30 Hz, 90 us. LCN-DBS was then followed by a second MRI scan. Similar manganese-induced enhancement in contrast was observed in animals that underwent LCN DBS after systemic manganese chloride injection. Differences between pre and post-DBS MRI are higher than 20% for most studied brain areas. In contrast, animals who did not receive DBS showed no increase the in the MEMRI contrast. Overall our data suggest that the LCN-DBS can be functionally evaluated by means MEMRI in longitudinal in vivo studies.

Title: Monomethyl fumarate confers neuroprotective effect against experimental model of ischemic stroke in rat by inhibiting TNF- α and IL-1 β

Authors: *D. SINGH¹, R. KH², U. SHARMA³, J. NR³, Y. K. GUPTA² ²Pharmacol., ³NMR &MRI Facility, ¹All India Inst. of Med. Sci. (AIIMS) Ne, New Delhi, India

Abstract: Despite advances in the understanding the pathophysiology of cerebral ischemia, no drug is available to protect the brain from stroke-induced neuronal injury. Increasing evidences suggest that inflammatory cytokines plays an important role in progression of stroke. The objective of this study was to evaluate the effect of an ester of fumaric acid, monomethy fumarate (MMF) on cerebral infarct and levels of inflammatory cytokines TNF- α and IL-1 β . Middle cerebral artery was occluded using a 3.0 monofilament in male Sprague Dawley rats (260-290 g) for 90 min followed by 24 h of reperfusion. Laser Doppler flow meter was used to confirm middle cerebral artery occlusion (MCAo). MMF (10 mg/kg) was administered at two time points, 30 min post ischemia and 5 min post reperfusion. Twenty four hours later, neurological deficits score and time spent on rota rod were evaluated. Cerebral infarct was estimated by MRI-T2 imaging using 7.0T animals MRI. After MRI, rats were sacrificed; cortex and striatum were separated and homogenized. The levels of TNF- α and IL-1 β were estimated using ELISA kits. Post occlusion, cerebral blood flow reduced by $82.8 \pm 1.8\%$ of baseline and post reperfusion 71.1 \pm 2.7% of blood flow was found to be restored. Treatment with MMF improved neurological deficit score and the time spent on rota rod significantly (p<0.01) when compared to MCAo group. Further, in MMF group, cerebral infarct $(23.5 \pm 4.3 \%)$ was significantly (p<0.01) reduced when compared to MCAo group (36.6 ± 2.0 % of ipsilateral area). The levels of inflammatory cytokines were increased significantly in MCAo group when compared to sham group. MMF treatment significantly (p<0.05) reduced the levels of both TNF- α (115 ± 25 to 83 ± 6.5 pg/mg of protein) and IL-1 β (130 ± 10 to 99 ± 6.1 pg/mg of protein) in cortex when compared to MCAo group. However, in striatum, there was no significant decrease in the levels of cytokines when compared to MCAo group. Our results indicate that MMF limits the progression of brain infarct from striatum to cortex by regulating the levels of inflammatory cytokines.

Title: CXCR4 antagonist CX549 induces neuroprotection in stroke brain

Authors: *Y. WANG, K.-J. WU, S.-J. YU, E. BAE, K.-S. SHIA Natl. Hlth. Res. Inst., Zhunan, Taiwan

Abstract: C-X-C chemokine receptor type 4 (CXCR4) is a receptor for a pleiotropic chemokine CXCL12. The purpose of this study was to characterize the neuroprotective and neurotrophic effect of a novel CXCR4 antagonist CX549. We demonstrated that CX549 had a higher affinity for CXCR4 and was potent to inhibit CXCL12 -mediated chemotaxis in culture. CX549 effectively reduced the activation of microglia and improved neuronal survival after injury in primary rat cortical neuron and BV2 microglia co-cultures. The protective effect of CX549 was further examined in an animal model of stroke. Adult male rats were subjected to a transient (60 min) distal middle cerebral artery occlusion. CX549 or vehicle was administered to the animals at 10 min after the onset of reperfusion and then daily for 4 days. Early post-stroke treatment with CX549 significantly improved behavioral function, reduced brain infarction, and suppressed the expression of inflammatory markers TNFa and IL6. Our data support that CX549 is a potent anti-inflammatory and neuroprotective agent against ischemic brain injury and may have clinical implications for the treatment of stroke.

Title: Therapeutic antibody targeting of Notch 3 signaling prevents mural cell loss in CADASIL

Authors: *J. ARBOLEDA-VELASQUEZ, A. I. MACHUCA-PARRA, A. A. BIGGER-ALLEN, A. V. SANCHEZ

Schepens Eye Res. Inst., Boston, MA

Abstract: Cerebral autosomal dominant arteriopathy with subcortical infarcts and leukoencephalopathy (CADASIL) is a neurological syndrome characterized by small vessel disease (SVD), stroke, and vascular cognitive impairment and dementia caused by mutations in NOTCH 3. No therapies are available for this condition. The prevalence of CADASIL mutations in NOTCH 3 is estimated at 3.4/1,000. Loss of mural cells, which encompass pericytes and

vascular smooth muscle cells, is a hallmark of CADASIL and other small vessel diseases including diabetic retinopathy, resulting in vascular instability. We report the characterization of a mouse model of CADASIL in which mural cell coverage in arteries depends upon human Notch 3 function. Here we showed that Notch 3 signaling is both necessary and sufficient to support mural cell coverage in arteries using genetic rescue in Notch 3 knockout mice. Furthermore, we show that systemic administration of an agonist Notch 3 antibody prevents mural cell loss and modifies plasma proteins associated with Notch 3 activity including endostatin/collagen 18a1, and Notch 3 ectodomain in mice with the C455R mutation, a CADASIL variant associated with Notch 3 loss-of-function. These findings open opportunities for the treatment of CADASIL by modulating Notch 3 signaling and establish that the levels of Notch 3 ectodomain and endostatin/collagen 18a1 in liquid biopsies could be used as surrogate markers of Notch 3 activity in vivo. Figure shows (A) Timeline of A13 antibody injections in N3KO (light gray) and CADASIL mutant mice (black). (B) Immunofluorescence images of retinal whole mounts showing SMA staining in green and collagen IV (ColIV) in white for N3KO and C455R mutant mice treated with IgG or A13 antibodies (scale bar=1mm). Right panels show merged images of green and white signals (scale bar = 100μ m). (C) Quantification of the effect of antibody injection on SMA coverage in retinal vasculatures. *p<0.05, data were analyzed via ANOVA. (D) Images of brain tissue from C455R injected with A13 or IgG antibody stained with V1662 antibody. Scale bar = $100 \,\mu m$.

Title: Green tea polyphenols and cAMP induce internalization of the Nogo-A receptor NgR1 and desensitize neuronal cells to axonal growth inhibitor Nogo-A

Authors: *R. GOPALAKRISHNA¹, U. GUNDIMEDA², S. ZHOU², H. BUI², C. LE², A. DAVIS², T. MCNEILL², W. MACK² ¹Cell and Neurobio., ²USC Keck Sch. of Med., Los Angeles, CA

Abstract: Recovery from injury to the mammalian CNS requires axonal regeneration from the remaining neurons. However, conditions in the CNS are impermissive to this regeneration because of the presence of axonal growth inhibitors such as Nogo-A. NgR1, a cell-surface protein, serves as a receptor for Nogo-A and other axonal growth inhibitors. Currently, various pharmacological agents are being evaluated for the ability to block NgR1 or its downstream signaling to enhance axonal sprouting and functional recovery. Inexpensive and safe natural products such as green tea polyphenols (GTPP) are well suited for this purpose and elucidating their mechanism of action will help optimize their use and develop drugs with greater efficacy. In the current study, we found that GTPP, especially epigallocatechin-3-gallate, induced the internalization of NgR1 in Neuroscreen-1 neuronal-like cells and mouse primary cortical neurons. This NgR1 internalization was mediated by cAMP, which was generated in response to GTPP binding to a high affinity 67kDa laminin receptor. Consistent with this finding, exogenous dibutyryl-cAMP and agents that elevate intracellular cAMP such as forskolin, an adenylyl cyclase activator, and rolipram, a cyclic nucleotide phosphodiesterase inhibitor, induced substantial internalization of NgR1. This GTPP- and cAMP-induced internalization also occurred in protein kinase A(PKA)-deficient cells. Furthermore, N⁶-benzoyl-cAMP, which selectively activates PKA, did not induce NgR1 internalization. In addition, KT 5720, a specific PKA inhibitor, failed to block the GTPP- and cAMP-induced internalization of NgR1. Conversely, 8-pCPT-2'-O-methyl-cAMP, which selectively activates another effector of cAMP, EPAC (exchange protein directly activated by cAMP), induced internalization of NgR1. Moreover, ESI-09, an EPAC-specific inhibitor, blocked GTPP- and cAMP-induced internalization of NgR1. These results suggest that EPAC may play a greater role than PKA in

this process. This internalization was mediated by both clathrin- and lipid raft-mediated mechanisms. Internalization of NgR1 by GTPP and cAMP, correlated with their ability to prevent Nogo-A from causing growth cone collapse and inhibiting neurite outgrowth. Desensitization of neurons through the internalization of NgR1 may be one of the intracellular mechanisms to influence axonal growth and may be exploited for drug development to enhance functional recovery after stroke and other neuronal injuries.

Title: Palmitic acid methylation provides neuroprotection against cerebral ischemia

Authors: *A. DO COUTO E SILVA¹, R. H.-C. LEE², C. Y.-C. WU², H. POSSOIT², R. AZIZBAYEVA³, J. NEUMANN³, H. LIN² ¹Cell. Biol. and Anat., ²Neurol., LSU Hlth. Sci. Ctr. Shreveport, Shreveport, LA; ³West Virginia Sch. of Osteo. Med., Lewisburg, VA

Abstract: Cardiopulmonary arrest (CA) remains one of the leading causes of death and disability in the USA. Whole body ischemia disrupts cerebral blood flow (CBF) that results in severe and selective brain damage. CA-induced hypoperfusion (decrease in CBF) contributes to neuronal cell death leading to cognitive impairment. Our goal is to identify novel neuroprotective therapies that will modulate CBF and provide neuroprotection with beneficial functional outcomes after ischemia. We previously discovered that palmitic acid methyl ester (PAME) is a novel vasodilator/neuroprotective agent derived from the superior cervical ganglion (sympathetic) innervating major cerebral arteries enhanced in the presence of arginine derivatives. Arginine is a substrate to activate protein arginine methyltransferases (PRMTs), which can act as a "switch" to turn "on or off" pre or post-transcriptional/translational modifications. Thus, our hypothesis is that methylation of palmitic acid (PA) via PRMT to form PAME, enables PAME's therapeutic actions against ischemia, providing enhancements in CBF, neuroprotection, and functional recovery. Methylation of PA to form PAME but not PA alone, is

necessary to enhance CBF, neuroprotection, and cognitive function after asphyxial CA (ACA, 6 min). To investigate the neuroprotective properties of PA v. PAME, hippocampal slices were subjected to oxygen glucose deprivation (OGD), and visualized using propidium iodide staining for cell death. Our results indicate that PAME, but not PA, provides neuroprotection in the CA1 region of the hippocampus after OGD [vehicle OGD (0.538 ± 0.022) and PAME OGD (0.232 ± 0.055)]. Furthermore, we utilized a rodent model of global cerebral ischemia (ACA, 6 min) to investigate if the methylation is crucial for the enhancement of CBF after ACA. Rats received PA/PAME treatment (0.02mg/kg, IV) 30 min before ACA. The rat skull was thinned to visualize red blood cell speed (an indicative measure of CBF) in microvessels of the neocortex via intravital two-photon laser scanning microscopy. PAME enhanced cortical CBF while maintaining systemic blood pressure in vivo. Functional cognitive/memory outcomes were tested post-ACA via spontaneous alternation test (T-maze). Posttreatment of PAME improved functional outcomes after ACA [improvements in both alternation ratio ACA (0.261±0.049), ACA+PAME (0.487±0.039) and side-bias preference, ACA (0.821±0.046), ACA+PAME (0.641 ±0.025)]. Overall, our data suggest that methylation of PA to form PAME, rendered PAME's biological activity under normal and pathological conditions to enhance CBF, provide neuroprotection, and improve functional outcomes after CA.

Title: Role of prostaglandin D₂ DP1 receptor on post-stroke sleep disturbance and stroke outcomes

Authors: *A. S. AHMAD^{1,2}, P. KAMAT^{1,2}, D. HERNANDEZ^{1,2}, S. DORE^{1,2,3} ¹Dept. of Anesthesiol., Univ. of Florida, GAINESVILLE, FL; ²Ctr. for Translational Res. in Neurodegenerative Dis., ³Departments of Neurology, Psychiatry, Pharmaceutics, Psychology, and Neurosci., Univ. of Florida, Gainesville, FL

Abstract: Post-stroke sleep disturbance is reported to be an indicator of poor stroke outcomes. The strategic location of the PGD₂ DP1 receptor in specific brain regions regulating cerebrospinal fluid and sleep led us to hypothesize that the DP1 receptor may attenuate the deleterious effects associated with post-stroke sleep disturbance. First, to test the effect of sleep deprivation on locomotor activity, wildtype mice were individually housed and their activity was monitored 20h/d for 3d. Day zero was used to obtain baseline, while for the next two days, mice were subjected to sleep disturbance for 10h during the sleep phase followed by 10h of no sleep. Second, to test whether a selective DP1 receptor agonist decreases locomotor activity, mice were given an intraperitoneal injection of the agonist and locomotor activity was monitored. Third, to test the effect of post-stroke sleep disturbance on stroke outcomes, wildtype and DP1-/- mice were subjected to 45min of MCAO and 7d of reperfusion. After MCAO, mice were subjected to post-stroke sleep disturbance for 12h/d for 3d during the mouse sleep phase. Sleep disturbance resulted in higher activity (awake like) during the sleep phase and lower activity during the awake phase. The distance travelled during the awake phase after sleep deprivation was significantly lower (P<0.001). These data suggest that sleep deprivation attenuated locomotor activity. The total ambulatory distance covered by DP1 agonist-treated group 4h post-treatment was 2161.2±846.4cm compared with the vehicle group activity of 7093.5±1953cm (P<0.01), suggesting that the selective pharmacological agent induced sleep. Analysis of the Cresyl violetstained sections revealed a significantly larger (P<0.05) infarction volume and neurologic deficit in post-stroke, sleep-disturbed DP1^{-/-} mice compared to similarly treated WT mice. These data show that the PGD₂ DP1 receptor plays a vital role in attenuating the deleterious effects of sleep disturbance on stroke outcomes. Additional studies are underway to further investigate mechanisms and optimal therapeutic conditions.

Title: Microrna-9 inhibition upregulates glutamate oxaloacetate transaminase attenuating stroke injury

Authors: S. KHANNA¹, R. STEWART², S. GNYAWALI², C. K. SEN², *C. L. RINK² ¹Surgery, Ohio State Univ., Columbus, OH; ²Surgery, The Ohio State Univ. Wexner Med. Ctr., Columbus, OH

Abstract: Elevated extracellular glutamate causes ischemic brain injury. The current study stems from our key observation demonstrating that induction of glutamate oxaloacetate transaminase (GOT), an oxygen-sensitive glutamate-metabolizing enzyme in the brain, can attenuate strokeinduced injury. GOT metabolizes glutamate to generate energy in the ischemic neural tissue. Here, we report that inducible GOT expression in the brain is regulated by miR-9. This work demonstrates that GOT is subject to post-transcriptional gene silencing by miR-9. Computational prediction, target reporter luciferase assay, and Western blot analysis provided first evidence demonstrating that miR-9 targets and silences GOT. Delivery of miR-9 inhibitor to HT4 neural cells upregulated GOT protein expression. Consistently, delivery of miR-9 mimic lowered the abundance of GOT protein. To validate whether miR-9 dependent binding exerts translational repression, GOT 3'UTR reporter assay was performed using HT4 neural cells. Delivery of miR-9 mimic suppressed GOT 3'UTR reporter luciferase activity. To test the role of miR-9 in glutamate neural toxicity, miR-9 mimic was delivered to the cells followed by glutamate challenge. Delivery of miR-9 mimic significantly exacerbated the toxic effects of glutamate as measured by loss of cell viability. To evaluate the role of miR-9 in stroke in vivo, miR-9 inhibitor lentiviral transduction particles or non-targeting scrambled control were delivered to S1 cortex of C57/BL6 mice by stereotaxic injection. After 72h of delivery, mice were subjected to middle cerebral artery occlusion (MCAO) for 90 minutes followed by reperfusion. At 48h post-stroke, brain was collected to measure miR-9 and GOT levels. Mice that received the miR-9 inhibitor exhibited increased GOT protein expression at the stroke site and reduced stroke lesion volume when compared to control mice. Thus, inhibition of miR-9 at the stroke site de-silenced GOT and attenuated brain injury.

Title: Xenon improves hemorrhagic stroke outcome in spontaneous hypertensive rats

Authors: *H. SHENG¹, H. SUN², B. YAN³, D. S. WARNER⁴

¹Duke Univ. Med. Ctr., Durham, NC; ²Kunming Med. Univ., Kunming, China; ³Xian Jiaotong Univ., Xian, China; ⁴Anesthesiol., Duke Univ. Dept. of Anesthesiol., Durham, NC

Abstract: Introduction: Xenon, as a glutamate NMDA receptor antagonist, has neuroprotective effects in several types of brain injury including ischemic stroke. We hypothesized that xenon would also serve to improve intracerebral hemorrhage (ICH) outcome. If xenon either has no adverse effect on ICH or is found to improve ICH outcome, this may allow early therapy onset, prior to neuroimaging diagnostics.

Methods: Male SHR rats (8-10 weeks old) were anesthetized with isoflurane, ventilated and mounted on a stereotaxic frame. Pericranial temperature was controlled at 37 °C. Via a midline scalp incision, a small burr hole was made at the coordinates of 0 mm anterior to bregma and 3 mm left lateral to midline. A 5 µl Hamilton syringe needle was inserted 6 mm below the cortical surface and 2.5 µl collagenase solution (0.1875 units/µl) was slowly injected into the left striatum area. Rats then were randomly assigned to groups and transferred into a gas exposure system where they were treated with either 30% O₂ or 30% Xe in 30% O₂ for 20 hours beginning 2 hours after injection (n=10). Sham rats received underwent procedures except collagenase injection and were treated with 30% O₂ (n=6). Oxygen and xenon concentrations were monitored and automatically regulated by computer software. Pericranial temperature was controlled at 37 °C Normal saline was infused IV at 1 ml/h during the treatment period. Body weight, blood pressure and rotarod performance were measured prior to surgery and 3, 7 and 28 days after surgery. Neurological score was evaluated at 7 and 28 days. Morris water maze was tested at 29 to 33 days post-ICH. Brain histology was examined after completing the water maze. Results: Male SHR rats subjected to ICH had a transient body weight loss. Hypertension was persistent at all time points. No intra-group (30% xenon versus 0% Xe) difference was found for either body weight or blood pressure. Latency to fall from the was decreased in both groups on days 3, 7 and 28 post-ICH. However, this latency was improved in the rats receiving 20 hours 30% xenon (p < 0.05). Hemorrhage also resulted in a significant neurological deficit that was improved by xenon treatment (p < 0.05). In Morris water maze test, hemorrhage induced a decline of latency to find the escape platform. Xenon treatment did not significantly prevent this decline. Brain histology still is in progress.

Conclusions: This long-term study demonstrated that xenon improves functional outcome in hemorrhagic stroke when 20 hours of 30% xenon exposure is given beginning at 2 hours poststroke. Brain histopathology will be evaluated to further verify this effect. Xenon has the potential to serve as a stroke therapeutic in near future.

Title: The endozepine ODN improves functional recovery after experimental stroke

Authors: *J. CHUQUET¹, R. LAMTAHRI¹, M. HAZIME¹, P. P. QUILICHINI², B. LEFRANC¹, D. VAUDRY¹, J. LEPRINCE¹ ¹Normandy University, UNIROUEN, INSERM U1239, Rouen, France; ²Neurosciences Systems Inst., INSERM U1106 INS, Marseille, France

Abstract: In stroke, the survival of neurons and their ability to re-establish connections to recover lost functions are strongly influenced by the balance between neuronal excitation and inhibition. In the acute phase of stroke, lethal hyperexcitability can be attenuated by positive allosteric modulators (PAM) of the GABAA receptor (GABAAR). In contrast, in the chronic phase, negative allosteric modulators (NAM) of the GABAAR can correct the sub-optimal excitability and improve cellular plasticity (Clarkson et al. 2010). Endozepines, known as the endogenous ligands of benzodiazepine-binding sites include the diazepam binding inhibitor (DBI) and its processing products, the triakontatetraneuropeptide (TTN, DBI₁₇₋₅₀) and the octadecaneuropeptide (ODN, DBI₃₃₋₅₀). Here, we hypothesized that ODN, an allosteric modulator of the GABA_AR synthetized by astrocytes, influences the outcome of ischemic brain tissue and its functional recovery. Local field potential analysis and calcium imaging confirmed that ODN acts like a NAM of the GABA_AR in the intact cortex. As expected, during the acute phase of brain ischemia, ODN dramatically exacerbated brain lesions, and enhanced hyperexcitation processes involved in the development of stroke damage (excitotoxicity and spreading depression waves). However, a daily ODN treatment starting 3 days after the onset of stroke safely enhanced the functional recovery over the following 4 weeks. To conclude, our results show that endozepines may have a significant role to tune the excitatory and inhibitory synaptic balance and reinforce the idea that an appropriate correction of GABAergic tone at the right time, can promote neuroprotection and improve functional recovery after stroke.

Title: Neuroprotective effects diphenyldihaloketone EF24 in brain stroke model

Authors: *A. MDZINARISHVILI¹, H. HOUSON², V. AWASTHI² ¹Dept. of Rehabil. Sci., Univ. of Oklahoma, Col. of Allied Hlth., Oklahoma City, OK; ²Pharmaceut. Sci., Univ. of Oklahoma, Col. of Pharm., Oklahoma City, OK

Abstract: <u>Background:</u> Brain stroke is the second most common cause of death worldwide. It is caused by an interruption of the blood supply to the brain which leads to the loss of neurologic function and death of the brain tissue. Current management of stroke patients is aimed at preventing the progression of at-risk cerebral tissue towards infarction by restoring blood supply to ischemic penumbra in a timely manner. Surgical removal of clot and thrombolytic therapy are the most common approaches to this effect, however they do not address local and systemic inflammation associated with stroke pathology. Our objective was to investigate a diphenyldihaloketone EF24 - an NF- κ B inhibitor, as a therapeutic agent in a mouse model of the brain stroke.

<u>Methods</u>: Stroke was induced in male CD-1 mice (20-25 g) by occluding middle cerebral artery and removing the occlusion after 1 h to allow reperfusion (transient MCAO model). EF24 treatment was given either 10-15min after reperfusion (Post-treatment) or 10-15min before occlusion (Pre-treatment). Control/stroke group received vehicle. Sham mice underwent the surgical procedure without artery occlusion. The surviving mice were euthanized 24 h after stroke to collect the brain and blood. The brain was sectioned for TTC-staining to determine histologic stroke volume. Inflammatory markers, IL-6 and TNF- α , and stress marker, corticosterone, were estimated in plasma samples.

<u>Results:</u> The 24 h survival was increased in both the EF24-treated groups compared to the untreated stroke group. Plasma corticosterone increased >10 fold in stroke; EF24-Post treatment prevented this increase in plasma corticosterone. Plasma IL-6 and TNF- α were not significantly altered by occlusion surgery or EF24 treatment. Compared to the untreated stroke group, the infarct size, as assessed by TTC-staining, was reduced by 41% and 52% in the Pre-treatment and Post-treatment groups, respectively. Additionally, the stroke-associated edema was significantly reduced in the both EF24-treated groups.

<u>Conclusion</u>: The results indicate therapeutic efficacy of anti-inflammatory molecule EF24 in controlling stroke pathology and improving survival. Especially notable was the reduction in stroke size even when EF24 was given after reperfusion. Although the biochemical basis of

EF24 action is still under investigation, its remarkable effects in the t-MCAO brain stroke model engender new therapeutic class of neuroprotective agents for brain ischemia and edema.

Title: Thrombolysis and antihypertensive agents in the functional and clinical outcome of acute ischemic stroke

Authors: *T. I. NATHANIEL¹, N. PATIL², C. UBAH³, B. BAILES³, T. FLEMING³, Z. CONN³, L. BRECHTEL³, M. SCALISE³, J. SULIVAN³, A. FRAZIER³, A. SHIPLEY³, L. WORMACK³, A. VENKATESH³, B. AVERKAMP³, S. STERNBERG², D. BLACKHURST² ¹Biomed. Sci., Univ. of South Carolina, Greenville, SC; ²Greenville Hlth. Syst., Greenville, SC; ³Univ. of South Carolina Sch. of Med. Greenville, Greenville, SC

Abstract: Background.

In general, antihypertensive treatment is generally known to reduce the risk of first and recurrent stroke, and poor adherence to antihypertensive treatment is directly linked to increased incidence of cerebrovascular events. However, no previous study has developed a tool to measure the functional outcome following treatment of stroke patients with prior treatment with antihypertensive agent. The objective of this study is to determine whether the functional ambulatory status of the patient can be used to assess functional outcome in stroke patients' treated with rt-PA with a prior history of anti-hypertensive medication.

Method.

We examined 1446 stroke patients that received antihypertensive agents prior to treatment with rt-PA for acute ischemic stroke, and analyzed functional ambulatory status as measurement of out outcome following treatment with rt-PA. Multiple logistic regression analysis was used to obtain adjusted odds ratios for functional ambulation at discharge for patients with history of taking antihypertensive agents vs the control group of patients with no history of taking antihypertensive agents. Adjustment was made for known risk factors and group differences. The backward selection method was used to exclude non-significant risk factors. Significance level was set at the probability level of 0.05.

Results.

Multiple logistic regression analysis for functional ambulation at discharge with adjustments for multiple confounding clinical factors showed significant association (OR, 0.63; P = .04) of improved ambulation at discharge compared to ambulation at discharge.

Conclusions

Functional ambulation can be used as the functional outcome tool to determine improved acutephase therapy outcomes for the use of rt-PA. Keywords: rt-PA, stroke, antihypertensive agents

Title: Role of caspase-9 in blood brain barrier integrity in a mouse model of stroke

Authors: *E. CANEPA, K. JOHNSON, M. AVRUTSKY, B. CHRISTOPHE, E. CONNOLLY, C. TROY

Pathology and Cell Biol., Columbia Univ., New York, NY

Abstract: The caspase family of death proteases has been implicated during ischemic stroke and neurodegeneration. Data from our laboratory demonstrate that specifically inhibiting caspase-9 (Casp9) abrogates edema and provides cellular and functional neuroprotection. Reperfusion injury after stroke can exacerbate damage to the blood brain barrier and lead to edema, an abnormal accumulation of fluids in the brain parenchyma. Cerebral edema, caused by a loss of vascular integrity, is the primary cause of mortality within the first three days following ischemia. Specifically targeting the molecular mechanisms underlying the development of edema is required for optimal therapeutic intervention. Preliminary data show that inhibition of Casp9 abrogates its own activation in blood vessels (BVs) and reduces Evans Blue (EB) extravasation at 4 hours post reperfusion (hpr), supporting a role for active Casp9 in early disruption of the BVs. It has been shown by others that matrix metalloproteinase-9 (MMP-9) null animals develop less edema and show less extravasation of EB during ischemia. It had been proposed that MMPs regulate edema and that activation of MMP-9 occur upstream of caspase activation. Our preliminary data show transient middle cerebral artery occlusion (tMCAo) induces Casp9 activation in wild-type and MMP-9 null mice and that the specific inhibition of Casp9 increases MMP-9 expression. This supports the hypothesis that Casp9 acts upstream of MMP-9 in the vasogenic pathway. Moreover, analysis of junctional proteins in BV fractions at 4 hpr from

ipsilateral cortices shows a significant reduction of vascular endothelial cadherin (VECad) and claudin-5 (Clau5) expression, and this loss is abrogated by Casp9 inhibition. These data suggest a novel Casp9-dependent process that regulates BBB dysfunction and vasogenic edema during cerebral ischemia. To assess endothelial function of Casp9 in ischemia- induced cerebral edema, we have generated inducible endothelial cell Casp9 null mice. Thus, targeting caspase-9 in stroke might improve vascular health and provide neuroprotection which could aid functional recovery.

Title: Evaluation of systemic and cerebral safety profile of pro-hemostatic red blood cell microparticles

Authors: *K. DAVE¹, A. K. REHNI¹, C. BIDOT, Jr.², H. NAVARRO², Y. S. AHN², W. JY² ¹Neurol., Univ. Miami Sch. Med., Miami, FL; ²The Wallace H Coulter Platelet Laboratory, Div. of Hematology/Oncology, Dept. of Med., Univ. of Miami Sch. of Med., Miami, FL

Abstract: Red blood cells microparticles (RMPs) possess potent hemostatic activity. Procoagulant activity of RMPs has shown beneficial effect in a study on blood drawn from patients with coagulation disorders. Before efficacy of RMPs can be tested clinically, rigorous preclinical studies are warranted. The goal of this study was to test for any potential complications following RMPs administration. We specifically tested the effects of RMPs on physiological parameters and thrombosis following RMP injection as is relevant for a hemostatic agent. RMPs were prepared from Type O+ human RBCs using high pressure extrusion method. RMPs were characterized and quantified using flow cytometry. In vitro coagulant activity was confirmed using thromboelastogram. Male rats were treated with: I) $1 \times \text{bolus}$ (6.07 $\times 10^{10}$ particles / kg b.w.), II) $1/3 \times$ three bolus 7.5 minutes apart (6.07 $\times 10^{10}$ particles / kg b.w.), III) 1 \times over 30 min $(6.07 \times 10^{10} \text{ particles / kg b.w.})$, IV) 4 × over 60 min (2.43 × 10¹¹ particles / kg b.w.), V) 20 × over 60 min $(1.21 \times 10^{12} \text{ particles / kg b.w.})$, and (VI) vehicle (saline). We monitored physiological parameters viz. blood pressure; blood pH, pCO2, and pO2; body and head temperature; and hematocrit before and after RMPs injection. In a separate set of experiments, rats in groups IV and VI were perfused at 4 h post-RMPs injection using formaldehyde: acetic acid: methanol mixture. Brains were histologically assessed by an investigator blinded to

treatments for any thrombosed blood vessels or indications of toxicity. We did not observe any adverse effects of RMPs injection. Comparisons were made against baseline values. However, a minor but significant drop in blood pH (Δ pH=0.04 at 45 min of treatment, p<0.05), body temperature (0.35°C at 45 min of treatment, p<0.01), and increase in blood pO2 (21%, p<0.05 at 45 min of treatment) was observed for 1 × over 30 min regimen. We observed significant increase in blood pO2 for 20 × over 60 min regimen (24% at 75 min of treatment, p<0.05). Besides, we observed a significant drop in hematocrit values for 1/3 × three bolus (8, 12 and16% at 15, 30 and 45 min of treatment respectively, p<0.001), 1 × over 30 min regimen (11, 14, 16 and 20% at 30, 45, 60 and 75 min of treatment respectively, p<0.001). In general, we did not observe any side-effects of RMPs in rats. Moreover, RMP treatment did not produce any thrombosed blood vessels or indications of cerebral toxicity. Thus, we conclude that RMPs do not show systemic toxicity and thromboembolism in brain. Confirming safety profile of RMPs is critical in establishing their therapeutic potential.

Title: Huo-Luo-Xiao-Ling-Dan plays a protective role in ischemic brain in rats via inhibiting inflammatory responses after stroke

Authors: Z. JIN¹, W. SHEN², *H. ZHANG³

¹Sch. of Basic Medicine, Zhejiang Chinese Med. Univ., Hangzhou, China; ²The First Affiliated Hospita of Zhejiang Chinese Med. Univ., Hangzhou, China; ³Dept Psychiatry, Univ. of Illinois at Chicago, Chicago, IL

Abstract: Huo-Luo-Xiao-Ling dan (HLXL), a traditional Chinese herbal mixture, can play an important role of anti- inflammation in the treatment of cerebral ischemia. In this study, we examined the effects of HLXL on brain injury of ischemic stroke in rats. Focal cerebral ischemia was induced by middle cerebral artery occlusion (MCAO) for 2 hours followed by 24 or 48 hours reperfusion in male rats. We treated ischemic stroke rats with HLXL (0.5, 2.0 and 6.0g/kg) by daily gavages beginning at the onset of stroke. The control group received the vehicle. HLXLD 2.0, 6.0/kg treatment significantly attenuated the infarct volume, neurological deficits,

upregulation of proinflammatory cytokines in the brain of rats after stroke compared with that of non-HLXLD group. HLXLD can induce the expression of MCPIP1 in brain tissue. Furthermore, the activation of NF- κ B signaling was significantly reduced in HLXLD treated rats after stroke compared to that of non-HLXLD group. Because MCPIP1 not only plays an important role in early cortical neurogenesis but also reveal an unexpected link between neocortical development, immune regulators, and epigenetic modification. Our data demonstrated that HLXLD can play an important protective role in brain injury after ischemic stroke via inhibiting inflammatory responses in the brain. We need further investigate the molecular mechanism of the HLXLD which via modulate the MCPIP1 expression.

Title: Multimodal tocotrienol vitamin e protection against ischemic stroke

Authors: C. RINK¹, S. KHANNA¹, H. HARRIS¹, S. GNYAWALI¹, *C. K. SEN² ¹Surgery, The Ohio State Univ. Wexner Med. Ctr., Columbus, OH; ²Ohio State Univ. Med. Ctr., Columbus, OH

Abstract: At nanomolar concentration, lesser-characterized natural vitamin E tocotrienol (TCT), but not α-tocopherol, potently protects neural cells from glutamate induced neurotoxicity *in vitro* and attenuates ischemic stroke injury in a pre-clinical setting *in vivo*. While *neuro*protective mechanisms of TCT have been elucidated, neuroprotection alone is unlikely to explain the robust protection against stroke observed *in vivo*. Indeed, neuroprotective agents have largely failed in clinical trials where multimodal mechanisms (*i.e.* neuro and vascular) are recognized as necessary for protection against ischemic stroke. In the current work, we sought to test for and identify mechanisms of vascular protection in a pre-clinical setting of ischemic stroke. C57/BL6 mice (male, 5 wks) were orally gavaged daily with 50mg/kg body weight of TCT or volume matched placebo (n=12) for 10 wks prior to induction of ischemic stroke using the intraluminal thread method of middle cerebral artery occlusion (MCAO). While stroke-induced ischemia persisted, cerebrovascular perfusion was measured using laser speckle flowmetry. After imaging,

mice were euthanized and perfused with FITC-conjugated lectin to characterized cerebrovascular perfusion in the MCA territory of the stroke-affected hemisphere. Anastomotic connections (diameter and number) were quantified as CD31+/FITC-lectin+ arterioles in stroke-affected S1 cortex and collected by laser capture microdissection. Pro-arteriogenic mediators of vascular remodeling were queried by real-time PCR and histology. Compared to placebo, TCT treatment significantly increased perfusion (38.7%, p<0.05), collateral size (21.2%, p<0.05), and collateral number (5.7-fold, p<0.05) during MCAO. Furthermore, prophylactic TCT supplementation significantly induced TIMP1 expression 9.6-fold (p<0.05) in laser-captured collaterals as compared to placebo controls. In a separate experimental cohort, we observed TCT protection against ischemic stroke was lost in TIMP1 knockout mice. Taken together with known neuroprotective properties, the current work supports additional (multimodal) vascular-protective properties of TCT against stroke by inducing arteriogenesis in a TIMP1-dependent manner for functional collateral growth.

Title: Impact of immune receptor CD36 on post-stroke cognitive impairments

Authors: *M. BALKAYA, J. YANG, S. CHO Burke-Cornell Med. Res. Inst., White Plains, NY

Abstract: Post-stroke cognitive neuropsychological impairments (CNI) are common, affecting more than a half of stroke survivors. Despite the high prevalence and clinical significance, our knowledge on post-stroke cognitive deficits is limited. Using WT and CD36 KO mice (N= 7-11/group) subjected to transient focal ischemia, this study investigates long-term CNI and the impact of CD36 deficiency on CNI. A battery of tests for motor (rotarod, open field), depression (sucrose preference, forced swim test), anxiety and memory tests (Y maze) were performed before stroke, and 2 and 7 weeks after stroke. To evaluate spatial learning and memory, water maze tests were performed at 9W for hippocampal based learning: training (hidden platform) and probe trials (remove platform) and for hippocampal-striatal based trial (visible platform). At baseline CD36 KO animals displayed reduced exploration in open field and reduced motor performance on rotarod. Following stroke, WT mice showed impaired motor function in rotarod

and displayed increased activity in open field at 2W and 7W. Sucrose preference was markedly reduced at 2W, but returned to baseline at 7W. CD36 KO animals did not display any significant post-stroke behavioral difference from pre-stroke baseline. Water maze tests revealed that stroke caused impaired learning during the training phase and CD36 KO mice performed better although probe trial did not show a genotype difference. CD36 KO mice showed better performance in visible platform trials compared to WT mice (Fig 1). Our result showed that stroke induces a transient hedonic deficit, a persistent hyperactivity and memory impairments that hinders the striatal-based new rule learning and strategy switching. The detection of better cognition in CD36 KO mice further suggests a sensitive preclinical platform that can assess stroke-induced CNI in different genotype mice during recovery phase.

Title: Pinocembrin protects hemorrhagic brain primarily by inhibiting toll-like receptor 4 and reducing M1 phenotype microglia in mice

Authors: *X. LAN, X. HAN, Q. LI, J. WANG Johns Hopkins Med., Baltimore, MD

Abstract: Neuroinflammation is a major contributor to intracerebral hemorrhage (ICH) progression, but no drug is currently available to reduce this response and protect against ICHinduced injury. Recently, the natural product pinocembrin has been shown to ameliorate neuroinflammation and is undergoing a phase II clinical trial for ischemic stroke treatment. In this study, we examined the efficacy of pinocembrin in an ICH model, and further examined its effect on microglial activation and polarization. In vivo, pinocembrin dose-dependently reduced lesion volume by ~47.5% and reduced neurologic deficits of mice at 72 h after collagenaseinduced ICH. The optimal dose of pinocembrin (5 mg/kg) suppressed microglial activation as evidenced by decreases in CD68-positive microglia and reduced proinflammatory cytokines tumor necrosis factor (TNF)- α , interleukin (IL)-1 β , and IL-6. Pinocembrin also reduced the number of classically activated M1-like microglia without affecting M2-like microglia in the perilesional region. Additionally, pinocembrin decreased the expression of toll-like receptor (TLR)4 and its downstream target proteins TRIF and MyD88. The protection by pinocembrin was lost in microglia-depleted mice and in TLR4^{lps-del} mice, and pinocembrin failed to decrease the number of M1-like microglia in TLR4^{lps-del} mice. Inhibition of the TLR4 signaling pathway and reduction in M1-like microglial polarization might be the major mechanism by which pinocembrin protects hemorrhagic brain. With anti-inflammatory properties, pinocembrin could be a promising new drug candidate for treating ICH and other acute brain injuries

Title: Inhibition of neuronal ferroptosis protects hemorrhagic brain in mice

Authors: *Q. LI, X. HAN, X. LAN, J. WANG Anesthesiol. & Critical Care Med., Johns Hopkins Univ., Baltimore, MD

Abstract: Background and Purpose: Intracerebral hemorrhage (ICH) causes high mortality and morbidity, but our knowledge of post-ICH neuronal death and related mechanisms is limited. In this study, we aimed to investigate whether ferroptosis contributes to neuronal death post-ICH and whether inhibition of ferroptosis protects hemorrhagic brain in vivo. Methods: We injected collagenase to left striatum of mice and quantified mitochondrial area in neurons at perihematoma region. In addition, we injected ferrostatin-1 (a specific inhibitor of ferroptosis) 2h delay (intraventricular) post-ICH, and accessed the protection effects of ferrostatin-1 with Fluoro-Jade B staining, CV/Fast blue staining, neurologic deficit scoring, etc. Furthermore, we detected lipid ROS accumulation and cyclooxygenase-2 (COX-2) expression by MDA assay and Western blotting using 4-HNE and COX-2 antibodies. Results: We first demonstrated that ferroptosis, a newly identified form of cell death, occurs in the collagenase-induced ICH model in mice with evidence of shrunken mitochondria in neurons. We found that mice treated with ferrostatin-1 after ICH exhibited marked brain protection and improved neurologic function. Additionally, we found that ferrostatin-1 reduced lipid reactive oxygen species production and attenuated the increased expression level of COX-2 in vivo. Conclusion: These results indicate that ferroptosis contributes to neuronal death after ICH, that administration of ferrostatin-1 protects hemorrhagic brain, and that cyclooxygenase-2 could be a biomarker of ferroptosis. The insights gained from this study will advance our knowledge of the post-ICH cell death cascade and be essential for future preclinical studies.

Title: Neuropeptide Y plays a detrimental role in cardiac arrest-induced brain injury

Authors: ***R. H.-C. LEE**¹, A. COUTO E SILVA², H. POSSOIT¹, C. Y.-C. WU¹, H. LIN¹ ¹Neurol., ²Cell. Biol. and Anat., LSU Hlth. Sci. Ctr. Shreveport, Shreveport, LA

Abstract: Cardiopulmonary arrest (CA, a form of global cerebral ischemia) is the leading cause of death and disability in the US. More than 350,000 victims/year suffer CA with only a 12% survival rate. The whole body ischemia following CA leads to brain damage causing severe neurological deficits such as learning/memory deficits. We previously showed that enhanced sympathetic nervous system (SNS) activity is one of the major contributors to CA-induced hypoperfusion (a decrease in cerebral blood flow, CBF), which plays a critical role in the progression of CA-induced neuronal cell death and learning/memory deficits. However, mechanisms underlying SNS-induced hypoperfusion and ischemic brain injury is unclear. It is important to note that neuropeptide Y (NPY, a 36-amino acid neuropeptide) is released upon SNS activation. The release of NPY induces a long-lasting and potent vasoconstriction (100-fold more potent than other sympathetic neurotransmitters, such as norepinephrine), which reduces the blood supply to the brain. We sought to attenuate NPY release from pre-synaptic sympathetic nerves via peptide YY (PYY)₃₋₃₆ (a pre-synaptic NPY2 receptor agonist) to investigate the impact of NPY inhibition on CA-induced hypoperfusion. A rat model of global cerebral ischemia (6 mins asphyxial cardiac arrest, ACA) was used in the present study. Results from intra-vital two-photon laser scanning microscopy suggest post-treatment with PYY₃₋₃₆ (56.87±4.48%; p<0.05 evaluated by Student's t test) attenuated cortical hypoperfusion (-33.20±2.65%) 24 hrs after ACA. Interestingly, post-treatment with PYY₃₋₃₆ inhibited neuronal cell death (via hematoxylin and eosin stain) in the CA1 region of the hippocampus. We further assessed cognitive/behavioral function (T-maze) to evaluate the rats' functional learning/memory after ACA. Rats post-treated with PYY₃₋₃₆ (0.5 ± 0.17) presented with better neurological outcomes than the control rats (0.26±0.05) after ACA. Here, we show that NPY plays a detrimental role in CA-induced brain injury. Inhibition of NPY release via PYY₃₋₃₆ provides neuroprotection against CA-induced hypoperfusion, neuronal cell death, and neurological deficits.

Title: The role of nitric oxide and dimethyl sulfoxide in formation of penumbra characteristics

Authors: *M. DEVDARIANI, L. DAVLIANIDZE, M. NEBIERIDZE, L. GUMBERIDZE, I. KVACHAKIDZE, N. SIKHARULIDZE, N. MITAGVARIA I.Beritashvili Ctr. of Exptl. Biomedicine, Tbilisi, Georgia

Abstract: Under the conditions of focal cerebral stroke the critical value, from the patient's output point of view has an optimal use of so called «therapeutic window". In particular this applies to preservation of Penumbra zone from the involvement in the ischemic processes as well as slowing of the processes taking place in the focus of stroke. The aim of this study was to obtain the specific data that will clarify the processes having place in development of focal stroke (and after its completion) in both ischemic focus and a zone of penumbra). From this point of view we tried to clarify: 1. The dynamics of local blood flow and oxygen tension changes in cerebral tissue as well as the level of Nitric Oxide in different time intervals. 2. The role of changes in the properties of blood rheology and presence of free radicals in defining of both geometric sizes of Penumbra and the levels of blood flow and oxygen tension in it. 3. To evaluate the results of the morphological changes taking place in the focus of ischemic Stroke and in the zone of Penumbra. 4. Analysis of the results obtained in our experiments with taking into account the data available in the literature and getting the generalized conclusions. Studies were conducted on groups of white rats by means of two experimental models: a non-invasive induction of focal ischemic stroke by photochemical method and local hyperthermia, therapeutic method that is used in the treatment of tumors. It was found that in both experimental models: 1. In the process of formation of ischemic stroke greatest complication causes the thrombosis of cerebral vessels due to changes in blood rheological properties. 2. Reduction of the scale and severity of damages in brain tissue (according to the received morphological changes in it) is possible by using antioxidants and free radical scavenger (dimethyl sulfoxide - DMSO) and / or a change in the relationship between the concentrations of Nitric Oxide and Oxygen Radicals (for favors of the first). We believe that these results at least will clarify the general principles of hyperthermic therapy, and its use in cancer clinic, both in terms of tolerance of brain tissue to hyperthermia and incorporating the role of free radicals, nitric oxide, and rheological properties of blood in the process of development and/or prevention of further damages having place especially in penumbra zone.

Title: Xueshuantong Injection effectively relieves inflammatory reaction induced by ischemic stroke through regulating NF-kappa B signaling pathway

Authors: *X. LIANG

UCSF, San Francisco, CA

Abstract: Inflammatory reaction plays a key role in progression of ischemic stroke. Xueshuantong Injection(XST) is a traditional Chinese medicine which used to treat ischemic stroke widely in China. Objectives: XST can improve the degree of the ischemic stroke patient's neurological impairment through regulating the expression of IκB α, nuclear factor (NF)-κB p65 and some related inflammatory cytokines. Method: In clinic research, we measured the serum levels of hsCRP,MMP-9,TIMP-1,IL-6,IL-18,ICAM-1,IP-10,MIP-1,GFAP and S100B in patients with acute stroke (patients should be admitted into observation within the first 72 h after stroke onset) using the method of enzyme-linked immuno sorbent assay (ELISA). Neurological impairment was scored with National Institute of Health Stroke Scale(NIHSS) at the days of the 1st day, 3rd day, 5th day and 14th day after be admitted into hospital.62 patients were divided into two groups randomly, one group was treated with basic treatment (IS+Vehicle group) and another group was treated with basic treatment and was injected with Xueshuantong Injection additionally(IS+XST group). In vivo, we established middle cerebral artery occlusion(MCAO) model in rats. Western blot analysis was performed to analyze expression levels of IkBa and NFκB p65. Results: In clinical research: XST group can improve the NIHSS significantly at the 14th day after stroke onset compared with basic treatment group in the respect of facial paralysis improvement (P<0.05). Xueshuantong Injection can decrease the serum level of TIMP-1, IL-18,ICAM-1 at 3 days after stroke onset significantly compared with basic treatment (t=1.973,-2.685 and 3.167 respectively, P<0.05). Xueshuantong Injection can decrease the serum level of hsCRP, TIMP-1, ICAM-1 and S100B at 5 days after stroke onset significantly compared with basic treatment (t=-2.241, 2.410, 2.397 and 2.102 respectively,P<0.05). Xueshuantong Injection can decrease the serum level of MMP9, TIMP-1, IL-6, ICAM-1 and GFAP at 14 days after stroke onset significantly compared with basic treatment (t=-2.404,4.260,3.475,5.561 and 1.992 respectively,P<0.05). In vivo research: Xueshuantong Injection can decrease the protein

expression of IkBa and NF-k B p65 compared with model

group(P<0.05).Conclusions:Xueshuantong Injection can improve the neurological impairment through regulating the NF-κB p65 signaling pathway and some related inflammatory cytokines.

Title: Role of the haptoglobin-CD163 scavenging system in intracerebral hemorrhage

Authors: *C. M. LI¹, J. L. LECLERC¹, S. DORÉ²

¹Anesthesiol., ²Dept. of Anesthesiology, Neurology, Psychiatry, Neurosci., Univ. of Florida, Gainesville, FL

Abstract: Hemoglobin (Hb) released by red blood cell lysis following intracerebral hemorrhage (ICH) causes neuroinflammation and cell death, inflicting irreversible brain damage. Haptoglobin (Hp) and CD163 form a primary scavenging system for Hb and protect tissues from its cytotoxic effects. Hp directly binds to Hb, and this complex is endocytosed by macrophages/microglia expressing the membrane receptor CD163. Currently, there is no effective treatment against ICH, and limited research exists on the respective functions of Hp and CD163 after ICH. This study aims to investigate the individual effects that Hp and CD163 have on outcomes after ICH and, furthermore, we also investigate how these individual effects change when both proteins are affected simultaneously in transgenic animals. ICH was induced in wildtype (WT) control, CD163 knockout (CD163-/-), Hp knockout (Hp-/-), and Hp plus CD163 double knockout (Hp-/-xCD163-/-) mice. Various functional and anatomical outcomes were assessed at 3d post-ICH. Lesion volume, hematoma volume and tissue injury in CD163-/- mice was 27.5+/-5.8% (p<0.0001), 30.6+/-6.4% and 23.0+/-4.1% (p=0.0041) smaller compared to WT mice, respectively. Lesion volume and tissue injury in Hp-/- mice was 28.2+/-7.2% (p=0.0006) and 29.5+/-2.5% (p=0.0011) smaller compared to WT mice, respectively. No significant differences in these measurements were detected between the double Hp-/-xCD163-/- and WT mice; thus, CD163-/- and Hp-/- mice had significantly smaller lesion volumes and tissue injuries compared to this double knockout group as well. Preliminary data for additional measures are as follow: Hp-/- mice had smaller hemispheric enlargement (an indicator of brain swelling/edema)

and blood-brain barrier breakdown compared to WT mice, less iron and astrogliosis compared to WT and CD163-/- mice, and less induction of heme oxygenase compared to all other groups. The CD163-/- mice had less total Hb in brain tissue and less blood-brain barrier breakdown compared to WT mice. The Hp-/-xCD163-/- mice had less blood-brain barrier breakdown compared to WT mice. These initial findings demonstrate the differences in recovery following ICH. The outcomes of this preclinical study help in the design of future clinical trials to limit devastating brain damage following ICH.

Title: Parawixin2, a gaba uptake inhibitor molecule isolated from parawixia bistriata spider venom is neuroprotective against experimental ischemic stroke damage in wistar rats

Authors: *T. BRONHARA¹, J. L. LIBERATO², W. F. SANTOS² ²Biol., ¹Faculdade De Filosofia Ciências E Letras RP FFCLRP, Ribeirao Preto, Brazil

Abstract: Acute ischemic stroke (AIS) is a major cause of adult disability with very few therapeutic options. GABA receptor agonists (GABAr) present neuroprotective effects (NP), which save the brain of AIS damage. However, the undesired effects of GABAr have limited their wider application in patients. So compounds that block GABA uptake represent potential tools for providing an efficient protection against AIS injury. Parawixin2 (Pwx2) presents a potent activity in decrease GABA uptake *in vitro* essays. This study evaluated the NP effect of Pwx2 on striatum (S), motor (M) and somatosensorial (C) cortices, as well as the neurological deficits (ND) after treatment in a model of AIS. Wistar rats under anesthesia were injected with endothelin1 (Et1; 600 pmol, in 6 uL) near to Middle Cerebral Artery (MCA) to induce AIS. Pwx2 (2 ug/uL; 1 uL) or Saline 0.9% (1 uL) were delivered into lateral ventricle and carry out 30 min before from AIS. ND were evaluated 24 hs before and after AIS by Open Field Test (OF) and forepaw touch test (FT). Cell death in S, C, and M infarcted areas was evaluated by Fluoro-Jade C (FJC) methods. Treatment with Pwx2 improved neurological function in all parameters tested (OF and FT). More remarkable, Pwx2 reduced FJC+ cells in all areas analyzed (S =81.6%; M=91.7%; C=82.8%). Considering that Pwx2 is one of very few compounds that block GABA

transporters, our findings suggest that their neuroprotective potential might represent a promissory drug to stroke therapies. Financial Support: CAPES and FAPESP

Title: Advances in vasospasm research: Vasoactive impact of heme degradation products (HDPs) on mouse cerebral arterioles *In vivo* and *In vitro*

Authors: A. JOERK¹, N. LANGGUTH¹, M. RITTER², R. A. SEIDEL³, M. GUENTHER¹, G. POHNERT², M. WESTERHAUSEN², K. HOLTHOFF⁴, *O. W. WITTE⁵ ¹Hans Berger Dept. of Neurol., ²Inst. of Inorganic and Analytical Chem., ³Dept. of Anaesthesiology and Intensive Care Medicine, Ctr. of Sepsis Control and Care, Friedrich Schiller Univ. Jena, Jena, Germany; ⁴Friedrich-Schiller-University Jena, Jena, Germany; ⁵Hans Berger Dept. of Neurol., Friedrich Schiller Univ. Jena, Jena, Germany

Abstract: BACKGROUND: Delayed vasospasm of cerebral arteries is alleged to be the most common determinant of mortality and unfavorable prognosis in patients who suffer from subarachnoid hemorrhage (SAH). Recent guidelines concerning vasospasm treatment recommend the application of the calcium channel antagonist nimodipine, hemodynamic interventions like induced hypertension or cerebral angioplasty. All therapeutic options may associate with serious side effects and fail to improve the clinical outcome. Previous studies have demonstrated that heme degradation products (HDPs) like bilirubin oxidation end products (BOXes), originating from the intracranial hematoma surrounding the ruptured aneurysm, are involved in inhibiting large conductance BK_{Ca} potassium channels in vascular smooth muscle cells. It is commonly accepted knowledge that blocked BK_{Ca} channels fail to hyperpolarize cell membrane and increase the myogenic tone. METHODS: Using two-photon laser scanning microscopy we analyzed changes in diameter and perfusion of pial and intraparenchymal arterioles in adult wildtype and BK channel deficient mice *in vivo*. DIC video microscopy was the preferred optical technique to study diameter changes of intracortical arterioles in acute brain slices of mice. RESULTS: We demonstrated that the subarachnoid applications of the

propentdyopents (PDPs) or synthetic Z-BOX isomers cause a long-lasting and sustainable diameter decrease of pial arterioles in living mice. This vasoconstrictive effect depends on BK_{Ca} channel activity, because it was absent in mice, expressing dysfunctional BK_{Ca} channels through a conventional knockout of the Slo1 gene. These data are consistent with our investigations on acute brain slices suggesting that isolated intermediates and end products of oxidative bilirubin breakdown are able to induce arteriolar vasoconstriction in mice with functional BK_{Ca} channels. CONCLUSION: Our findings confirm the contribution of heme degradation products in developing diameter dysregulation of cerebral vasculature after SAH and highlight the involvement of microvessels in arterial vasospasm.

Title: Biodistribution study of human red blood cell microparticles (RMPs) in rat

Authors: *V. SHUKLA¹, A. K. REHNI¹, C. BIDOT, Jr², H. NAVARRO², Y. S. AHN², W. JY², K. R. DAVE¹ ¹NEUROLOGY, ²The Wallace H. Coulter Platelet Laboratory, Div. of Hematology/Oncology, Dept. of Med., MILLER SCHOOL OF MEDICINE, UNIVERSITY OF MIAMI, Miami, FL

Abstract: Spontaneous intracerebral hemorrhage (sICH) is the severe form of stroke and remains a significant cause of morbidity and mortality throughout the world. No proven treatment is available so far. Limiting hematoma expansion in sICH has been attractive therapeutic target. RMPs have hemostatic properties. Thus, RMP can be used as potential therapeutics for preventing hematoma growth. The goal of this experiment was to determine the biodistribution of RMPs in blood and organ/tissues to predict any potential side-effects when injected to rats. RMPs were labeled with Alexa Fluor-488 TFP ester (ThermoFisher Scientific), unconjugated dye was removed using microdialysis membrane (Spectra/Por) and dialyzed against saline overnight with frequent saline changes. Dialyzed labeled RMPs were collected and filtered before use. Labeled RMPs were injected by single bolus injection of the total dosage $(6.07 \times 10^{10} \text{ particles/kg})$ delivered over 20 seconds. Rats were perfused at 15 min or 24 h post-RMPs injection. Blood was collected before perfusing rats. Brain, lung, heart, liver, spleen,

kidney, bone marrow (BM), lymph node (LN), and muscles were harvested and frozen at -80°C until further use. Tissues homogenates were made on ice in RIPA buffer, sonicated and fluorescence was measured in resultant tissue homogenates as an indicator of presence of RMPs in the tissue by measuring fluorescence at Ex: 490/EM: 520. Results are expressed as mean fluorescence (MF)/g tissue or MF/ml blood. MF for RMPs injected was $926,432 \pm 72,643$ AFU/kg body weight and $800,310 \pm 25,554$ AFU/kg body weight for 15 min and 24 h groups, respectively. Major fluorescence was detected in liver (71,360 \pm 6,791, n = 6), spleen (24,518 \pm 2,344, n = 6); moderate fluorescence in heart $(2,395 \pm 455, n = 6)$, kidney $(5,268 \pm 781, n = 5)$, lung $(6,160 \pm 2,088, n = 6)$, and LN $(8,468 \pm 2,700, n = 5)$ while minor fluorescence in brain $(661 \pm 229, n = 6)$, muscle $(670 \pm 157, n = 6)$, and BM $(529 \pm 70, BM$ harvested from femur bone obtained from both the hind limbs, n = 6) at 15 min post-RMP injection. Fluorescence in 24 h post-RMP injection group was significantly lower for liver $(31,515 \pm 1,018, n = 6, p < 0.001)$, spleen (16,943 \pm 1,176, n = 6, p<0.05), and BM (218 \pm 51, n = 5, p<0.01); while non-significant increase was observed in kidney $(74,326 \pm 53,257 \text{ AFU} / \text{g}, n = 6)$, muscle $(1,010 \pm 391, n = 6)$ and LN (9,595 \pm 2,721, n = 5) compared to 15 min time point . We observed MF of 37 \pm 23 and 287 ± 105 for blood at 15 min and 24 h post-RMP injection, respectively. Our results indicate that very small fraction of injected RMPs is retained in the body at both 15 min and 24 h post-RMP injection. Thus, RMP can be safely used for treatment following sICH.

Title: Transplanted modificed bone marrow-derived mesenchymal stem cells, SB623, ameliorate chronic behavioral and pathological deficits in stroke rats

Authors: *E. MORADI¹, ***E. MORADI**¹, Z. WARRAICH¹, A. SATO¹, M. RAZAVIAN¹, M. PERNETT^{1,2}, M. POLEWSKI^{2,3}, K. RAVINA³, M. DUGICH-DJORDJEVIC², M. SHAMLOO³, D. BATES¹, Y. ANDREWS-ZWILLING¹ ¹Sanbio, Inc., Mountain View, CA; ²Wester Univ. of Hlth. Sci., Pomona, CA; ³Stanford Univ. Sch. of Med., Stanford, CA **Abstract:** Stroke is the leading cause of long-term disability in adults. We recently completed a Phase 1/2a clinical trial with intracranial implantation of SB623, which appear to be safe and were associated with improvements in a majority of the clinical outcome end points. In this nonclinical study, we investigated the mechanism of action of SB623, which leads to amelioration of chronic behavioral deficits in rats. The present study assessed the efficacy of SB623 cells implanted intracranially into rats at day 28 following transient Middle Cerebral Artery occlusion. Treatment efficacy was assessed by sensorimotor behavioral tests: Cylinder and Paw Whisker Test. If untreated, the ischemic injury showed stable behavioral deficits for at least 72 days following lesion. Histopathological end-points were correlated with functional endpoints to determine the mechanism of action of SB623. Compared to post-stroke/pretransplantation levels, significant improvements in sensorimotor function were detected in stroke rats that received SB623 vs. vehicle. At 72 days post-transplantation, histopathological analysis indicated no difference in infarct size in both experimental groups, but significantly reduced levels of reactive GFAP-positive astrocytes, activated immune cells and type III collagen in the striatal peri-infarct area of SB623-treated rats. Furthermore, there was a strong negative correlation between improvement of neurological sensorimotor function and GFAP and type III collagen levels. These data demonstrate that SB623 cells ameliorate chronic inflammation, reduce levels of collagen deposits and reactive astrocytes, and this reduction is strongly associated with improvement in recovery in a rodent model of chronic stroke

Abstract: Stroke is currently the 5th leading cause of death in adults in the United States, and has accounted for approximately 14% of total health care spending in recent years¹. Despite thousands of ongoing clinical trials for potential stroke therapies, currently only one FDA approved small molecule therapy, tPA, exists to date. We proposed to use neural stem cell extracellular vesicles, a type of cell derived nanovesicle, and their potential neuroprotective properties as a novel therapeutic to combat behavioral and motor impairments following middle cerebral artery occlusion (MCAO) in a porcine model of stroke. For this study, we used 16 land raised male castrated pigs which were divided into either an extracellular vesicle treatment group or a control saline group. First, we isolated the extracellular vesicles from neural stem cell spent media using ultracentrifugation and filtration, and then characterized their size, morphology, and concentration using nanoparticle tracking analysis. We then IV administered the extracellular vesicles, or a control sham saline solution, at 2, 14, and 24 hours post MCAO. We then performed open field and novel object recognition behavioral tests at 24 hours post, 3 days post, 1 week post, 3 weeks post and 12 weeks post MCAO, and used behavior tracking software to quantify differences between pigs in the extracellular vesicle treated and saline treated groups. During open field testing, we found that by 1 week post MCAO, control pigs had statistically significant decreases in velocity and distance traveled in the testing arena, while the extracellular vesicle treatment group did not. We also saw during open field testing, the total distance traveled by extracellular vesicle treated pigs at 12 weeks was significantly greater than the distance traveled by sham pigs. We did not find any statistically significant differences in the novel object recognition test between the sham and extracellular vesicle treated pigs at any of the 5 tested time points. Overall, we found that neural stem cell derived extracellular vesicle therapy following a right sided MCAO in pigs aided in preventing a significant decrease in velocity and total distance traveled during open field testing as well as had a significant positive influence on these parameters 12 weeks post MCAO compared to control. 1. Title: Sex differences in stroke neuroprotection via stimulation of FAO

Authors: *M. M. SIFUENTES¹, J. LECHLEITER²

¹Univ. of Texas Hlth. Sci. Ctr. At San A, San Antonio, TX; ²Cell. & Structural Anat., Univ. of Texas Hlth. San Antonio, San Antonio, TX

Abstract: Stroke is a leading cause of death and disability in the United States, yet few options exist for afflicted patients. Our previous research demonstrated that thyroid hormone stimulation of astrocyte fatty acid oxidation (FAO) reduced lesion volume after stroke. However, the mechanism for this neuroprotection is not yet known. Here we show that thyroid hormone increases astrocyte spare respiratory capacity under nutrient deprivation, increasing survival under mitochondrial stress. Accordingly, thyroid hormone rescues the decreased maximal respiration of starved astrocytes in a dose-dependent manner. In vivo experiments using a photothrombotic model of stroke found that thyroid hormone neuroprotection differs based on sex, with males being responsive at lower doses. We show that a 25 ug/kg dose of thyroid hormone is protective up to three hours after stroke, although higher concentrations at longer timepoints have yet to be tested. Overall, our research suggest that thyroid hormone treatment presents as a possible therapeutic approach to reduce injury after stroke.

Title: In vitro stroke model for evaluating SPION translation and clot lysis

Authors: *H. H. ENGELHARD¹, A. LEVIN¹, S. PERNAL¹, Z. GAERTNER¹, M. SABO², F. CREIGHTON²

¹Univ. of Illinois, Chicago, IL; ²Pulse Therapeutics, Inc., St. Louis, MO

Abstract: <u>Background</u>: Stroke continues to be a leading cause of death and disability, worldwide. Superparamagnetic iron oxide nanoparticles (SPIONs) hold great promise as vehicles for enhancing drug delivery for stroke, and other CNS diseases. Magnetically-induced rotary

traction (MIRT) offers a means to improve SPION targeting at clinically-relevant distances. Here, we describe a novel, inexpensive in vitro system for evaluating the potential of SPIONdrug combinations which are intended for use in intracranial clot lysis. Methods: Our model system includes three components: 1) a patented rotating magnet (mini-MED), 2) standardized magnetic microbeads (the SPIONs), and 3) a novel tissue culture tray (MIRT tray). The mini-MED contains a neodymium-boron-iron permanent magnet, which is rapidly rotated (3 Hz), causing SPIONs to counter-rotate (like meshed gears) in the MIRT tray, moving by means of surface traction. Rabbit endothelial cells were seeded into the lanes of the tray (1/8th inch wide), to which pre-formed blood clots were added. Movement of SPIONs in the MIRT tray was measured at various distances (and relative positions) using video photography. Results: SPIONs moved readily in the MIRT tray through even 100% serum, at distances 7.5 - 30 cm from the magnet. SPION velocity varied according to position with speeds of 0.26 +/- 0.05 cm/sec maintaining the integrity of the endothelial cell monolayer. SPIONS combined with t-PA showed the greatest potential for clot lysis. Conclusions: SPIONs are easily rotated and translated at physiologic distances, even through 100% serum, by means of surface traction generated by the Pulse mini-MED system. The MIRT tray is a convenient device which allows SPION translation over live cells to be studied. Clot lysis was demonstrated with SPION - enhanced delivery of t-PA. A larger version of the Pulse system is currently being evaluated in clinical trials for stroke.

Title: Mitochondria in cerebral vascular endothelial cells play a key role in blood-brain barrier opening

Authors: *H. HU, I. FAROOQI, K. GRASMICK, S. RELLICK, X. REN Physiolgoy & Pharmacol., West Virginia University, Ctr. For Basic and Translational Stroke Res., Morgantown, WV

Abstract: The blood-brain barrier (BBB) is a dynamic and specialized vascular endothelial cell (VEC) interface that maintains cerebral homeostasis from peripheral attacks. The BBB is disrupted in acute ischemic stroke, and inflammatory components penetrate into the brain causing cerebral edema. Our previous studies have revealed that compromised mitochondria in VECs opens BBB *in vitro* and *in vivo*. To further elucidate the role of mitochondria in BBB opening, we performed transient middle cerebral artery occlusion (tMCAO) in rats, purified cerebral VECs derived from ischemic and non-ischemic hemispheres, and evaluated mitochondrial function in VECs. Interestingly, we observed that oxidative phosphorylation was

significantly inhibited in VEC mitochondria from the ischemic hemispheres compared to the contralateral hemispheres while simultaneously opening the BBB. Further, using a murine tMCAO model, we demonstrated that rotenone (an inhibitor for mitochondrial respiratory chain complex I) exacerbated stroke infarction, worsened neurological deficits, and increased post-stroke mortality. Consistently, rotenone significantly increased BBB permeability in post-stroke mice demonstrated by Evan's blue extravasation assay. These novel findings provide primary evidence that mitochondria in VECs play a key role in BBB opening and suggest a potential new therapeutic approach for neurological disorders by manipulating VEC mitochondria.

Title: PTP σ knockdown promotes Akt phosphorylation after spinal cord transection in the lamprey

Authors: *W. RODEMER¹, K. G. ZHANG¹, J. HU¹, M. SELZER^{1,2} ¹Shriners Hosp. Pediatric Res. Ctr., ²Dept. of Neurol., Lewis Katz Sch. of Med. at Temple Univ., Philadelphia, PA

Abstract: Traumatic spinal cord injury (SCI) results in long lasting functional deficits due to the lack of axon regeneration within the mammalian CNS. After SCI, chondroitin sulfate proteoglycans (CSPGs) contribute to a growth non-permissive extracellular environment by interacting with the receptor protein tyrosine phosphatases, PTP σ and LAR, on axons to activate the small GTPase, RhoA, and antagonize the Akt/mTOR pathway. Unlike mammals, lampreys experience robust functional recovery after complete SCI, despite the presence of CSPGs and other inhibitory molecules. After injury, axons of the lamprey's large identifiable reticulospinal

(RS) neurons regenerate with heterogeneous but predictable probabilities. RS neurons that fail to regenerate undergo a delayed form of apoptotic cell death. Previously, this lab reported that lamprey PTPo and LAR mRNAs are preferentially expressed in "bad regenerator" RS neurons before SCI-induced caspase activation. The present study examines the effect of $PTP\sigma$ knockdown (KD) on caspase activation, axon regeneration, and downstream signaling in the larval lamprey following complete spinal cord transection (TX). PTPo KD was induced using antisense morpholino oligomers (MOs) that targeted the splice junctions flanking exon 3 of lamprey PTP_o pre-mRNA to create a reading frame shift and premature stop codon, leading to nonsense-mediated decay of the mis-spliced mRNA. In subsequent experiments, fluoresceinconjugated control or PTPo-targeting MOs were applied *in vivo* to the proximal spinal cord stump immediately following TX. At 2 weeks post-TX, lampreys administered PTPσ MOs showed a 62% reduction in the number of RS cells positive for PTP σ mRNA compared to controls, as assessed by *in situ* hybridization with a riboprobe specific for the normal transcript. At 2, 4, 7, and 10 weeks post-TX, no difference was observed between $PTP\sigma$ and control MO groups in the percentage of morphant cells that were positive for activated caspases using FLICA. At 10 weeks post-TX, PTPo KD did not increase axon regeneration as assessed by retrograde labeling. Nevertheless, PTPo KD significantly increased Akt phosphorylation (T308) in combined brain/spinal cord homogenates at 2 weeks post-TX. This suggests the PTP σ downstream pathway is conserved between mammals and lampreys. It is possible that compensation from other CSPG receptors attenuates the pro-regenerative effects of PTPo KD alone. Ongoing efforts will assess the effects of LAR KD by itself and in combination with PTPσ.

Title: The effect of axon resealing time on retrograde neuronal death after spinal cord injury

Authors: *K. G. ZHANG¹, W. RODEMER¹, T. LEE¹, J. HU¹, M. E. SELZER^{1,2} ¹Shriners Hosp. Pediatric Res. Ctr., Lewis Katz Sch. of Medicine, Temple Univ., Philadelphia, PA; ²Dept. of Neurol., Lewis Katz Sch. of Med. at Temple Univ., Philadelphia, PA

Abstract: Spinal cord injury (SCI) leads to permanent disability in mammals because injured axons do not regenerate across the lesion to reconnect their previous targets. The failure of axon regeneration is due to both extrinsic inhibitory factors, e.g., the chondroitin sulfate proteoglycans (CSPGs) or the myelin-associated growth inhibitors (MAIs), and to neuron-intrinsic factors, such as the expression of receptors for the extrinsic inhibitory factors. Evidence for the importance of neuron-intrinsic factors is illustrated by the heterogeneity in the regenerative abilities of the axons belonging to the 18 pairs of individually identified reticulospinal neurons (RNs) in the lamprey, some being very good regenerators and others bad. After transection (TX), the bad regenerators tend to upregulate several chemorepulsive receptors (UNC5, DCC, Neogenin, PlexinA and EphB), as well as α-synuclein. These same neurons undergo very delayed apoptosis post-TX, and we have noticed that most (but not all) of them are among the largest RNs. One possible reason for this is that large neurons have large-diameter axons, and these reseal more slowly than small axons. Thus we tested the hypothesis that delayed axon sealing contributes to retrograde neuronal death by introducing retrograde tracers at different times post-TX. In lamprey, axons belonging to the small neurons of the medial inferior reticulospinal nucleus resealed within 15 min post-transection, whereas axons of the larger neurons, e.g., the Mauthner neuron (Mth), I1, M3, and B1 could take more that 20 hours to reseal. We found a significant inverse correlation between an RN's volume and the probability that its axon would regenerate (r = -0.81), or that the neuron would undergo delayed apoptosis, as indicated by fluorescentlylabeled activator of caspases (FLICA; r = 0.73). Next we determined the effect of polyethylene glycol (PEG), which is commonly used to fuse cell membranes and seal damaged axon membranes, on resealing of lamprey RN axons, retrograde neuronal death and axon regeneration. Compared to normal Ringer-treated controls, applying 40% PEG in lamprey Ringer to the cut axon tips for 5 min. speeded axon resealing, reduced initial axon retraction during the first 2 weeks post-TX, enhanced axon regeneration investigated at 4 weeks, and reduced retrograde neuronal death by 57.8%. Since the relationship between neuron size and retrograde death was not absolute, other factors must play a role in determining regenerative ability and long-term survival post-TX.

Title: Correlation of diffusion tensor indices and axonal injury in rat spinal cord distal from injury

Authors: *O. MOTOVYLYAK¹, M. D. BUDDE², S. N. KURPAD², B. D. SCHMIT^{4,3} ¹Biomed. Engin., Marquette Univ., Milwaukee, WI; ²Dept. of Neurosurg., ³Med. Col. of Wisconsin, Milwaukee, WI; ⁴Dept. of Biomed. Engin., Marquette Univ. Dept. of Biomed. Engin., Milwaukee, WI

Abstract: Introduction: The overall objective of this study was to correlate MRI diffusion measures with histological changes in the cervical cord after a contusion injury to the thoracic region in rats. Diffusion Tensor Imaging (DTI) is a non-invasive method of studying central nervous system structure. Despite its widespread use in research, DTI has not been clinically relevant in spinal cord injury, in part due to stabilization hardware at the site of injury which causes imaging artifacts. Furthermore, secondary injury factors such as inflammation, edema, and hemorrhage make prognostication based on imaging biomarkers more difficult. Previous research has documented diffusion changes in the spinal cord both caudal and cranial to the injury epicenter; however, pathological underpinnings of those changes are not clear. Methods and Materials: Female Sprague-Dawley rats (n=40) underwent a controlled T8 contusion injury at one of four severities (mild, moderate, severe, or sham) determined by the drop height of a weight. The rats underwent *in vivo* DTI scans at 2, 30, and 90 days post injury using a 9.4T Bruker horizontal bore scanner and were assessed on the Basso, Beattie, and Bresnahan (BBB) scale to determine their functional recovery and locomotion. Diffusion weighted images were acquired with a 4-shot echo-planar spin-echo sequence (TE=27 ms; TR>1800 ms) and custom routines were used to reconstruct and register DTI maps. Animals were euthanized and C5 segment was excised and fixed in formalin. Sections were stained with primary antibodies for non-phosphorylated neurofilaments (SMI32), which is a marker of injured axons. Digital images were acquired using a confocal microscope (Leica Microsystems), thresholded, and the number of stained objects was counted using a custom-developed script. Two-way ANOVA and linear regression were used to determine significant differences between time points and injury severities for imaging and histological measures.

Results and Discussion: The group averages of stained axons were correlated with BBB scores at early time points. At 2 and 30 days many of the axons in white matter are injured, thus SMI32 staining was abundant. By 90 days, however, most axons were removed by inflammatory cells. Additionally, axial diffusivity (AD) was well correlated with BBB chronically. This suggests that while AD is a good predictor of axonal injury, secondary injury, such as edema and inflammation, also have a strong influence on diffusion at early time points.

Conclusion: Chronically, AD correlates well with injury severity, but the influence of secondary injury factors acutely needs to be explored further.

Title: Synapse formation of NG2 glia prevents re-entry of sensory axons at the CNS-PNS border

Authors: ***H. KIM**¹, S. HAN¹, J. XIA², H. HU², S. H. KANG¹, Y.-J. SON¹ ¹Dept. of Anat. and Cell Biology, Lewis Katz Sch. of Medicine, Temple Univ., SHPRC and Ctr. for Neural Repair and Rehabilitat, Philadelphia, PA; ²Dept. of Pharmacol. & Physiol., Drexel Univ. Col. of Med., Philadelphia, PA

Abstract: In the first *in vivo* imaging analysis (Di Maio et al., J. Neurosci, 2011), we previously found that dorsal root (DR) axons rapidly terminate regeneration at the dorsal root entry zone (DREZ), where they form numerous axon swellings with the features of presynaptic boutons. These observations suggested that the regeneration failure might be due to aberrant synaptogenesis with incorrect targets, which causes growth to cease prematurely at the DREZ. Here, we report that the unknown postsynaptic cells in contact with presynaptic boutons are NG2 glia (i.e., oligodendrocyte precursor cells (OPCs)). We found that NG2 glia are abundant in the CNS territory of the DREZ, that they rapidly proliferate in response to distant DR injury, and that they form an intense 'cellular net' where DR axons usually terminate regeneration. Almost all of the axon tips and shafts intensely labeled with synapse markers are either co-localized or in close apposition with processes of NG2 glia. ImmunoEM analysis revealed that the gold particlelabeled processes and cell bodies of NG2 glia contact pre-synaptic terminals of DRG neurons. We have also cultured purified NG2 glia from adult mice and co-cultured them with adult DRG neurons. Electrophysiological analysis revealed functional synapses between NG2 glia and DRG neurons. Lastly, we investigated if NG2 glia ablation affects axon regeneration across the DREZ. We used an inducible line, Rosa26-iDTa;PDGFRα-CreERTM, and obtained successful ablation of >90% NG2 glia in spinal cord following DR crush. At 2 weeks after crushing DR axons, we observed modest but significantly enhanced penetration of DR axons across the DREZ. These findings show that DR axons fail to regenerate into the spinal cord, at least in part, because they

form aberrant synapses with NG2 glia at the DREZ. These results support the notion that NG2 glia are a previously unappreciated barrier to CNS axon regeneration.

Title: The effect of duraplasty after a traumatic spinal cord injury on behavioural recovery, spinal cord morphology, and tissue sparing, in a porcine model of SCI

Authors: M. STRAWFORD¹, *K. SO¹, F. STREIJGER¹, K. SHORTT¹, N. MANOUCHEHRI¹, E. B. OKON¹, B. K. KWON^{1,2}

¹ICORD (International Collaboration On Repair Discoveries), Univ. of British Columbia, Vancouver, BC, Canada; ²Dept. of Orthopaedics, UBC, Vancouver Spine Surgery Inst., Vancouver, BC, Canada

Abstract: Severe swelling of the human spinal cord is typically observed after a traumatic spinal cord injury (SCI). Intrinsic cord swelling within the pia mater, along with the swollen cord filling the subarachnoid space and pushing against the relatively stiff dura mater, may result in increased intraspinal pressure. Such cord constriction can lead to reduced blood flow, hypoxia and ischemia, leading to secondary damage. Using our porcine model of SCI, we examine the effects of an expansile duraplasty surgery on behaviour, spinal cord morphology, and tissue sparing following an acute SCI.

Female Yucatan mini-pigs received a T10 contusion SCI followed by 5-minutes of compression and were randomized into two groups: 1) SCI without dural expansion surgery (control group) or 2) SCI with dural expansion duraplasty with an artificial graft (Durepair, Medtronic; 1-cm width, 10-cm length) centered around the impact site (duraplasty group). Behavioural recovery was monitored weekly for 12 weeks and animals were scored using the Porcine Thoracic Injury Behaviour Scale (PTIBS). Ultrasound imaging at 7 days post-SCI was used to compare spinal cord morphology (dorsal-ventral height of the spinal cord and subarachnoid space) at various level of the spine between the two groups. At 12 weeks post-SCI, animals were euthanized and histological analysis was done on their spinal cords to quantify both grey and white matter sparing.

At 7 days post-SCI, ultrasound analysis showed an enlargement of the subarachnoid space at the T9-T11 for the duraplasty group (T9-T11: 2.0 ± 0.4 mm; 2.1 ± 0.3 mm; 2.4 ± 0.2 mm) compared to the controls (T9-T11: 1.1 ± 0.4 mm; 0.5 ± 0.3 mm; 0.5 ± 0.2 mm) with an increased spinal cord height (duraplasty: 7.4 ± 0.2 mm; controls: 6.2 ± 0.2 mm). Throughout the 12-week recovery period, most control animals were only capable of hind limb dragging (PTIBS score of 1-3) after SCI, while most duraplasty animals showed weight-supported stepping (PTIBS ≥ 4). Histological analysis of the spinal cords demonstrated more spared white matter at the epicenter in the duraplasty group compared to the controls. No difference in the spare grey matter was demonstrated.

In summary, our results demonstrated that, 7 days after SCI the swollen cord almost fills the subarachnoid space. Expansive duraplasty surgery in a porcine model of SCI, enlarged the subarachnoid space for days after SCI, and allowed for non-restrictive swelling of the spinal cord. This might have lead to improved hind limb function and increased spared tissue at the site of injury as observed at 12 weeks post-SCI. This data supports the potential of improving neurologic outcome with expansile duraplasty.

Biol., ⁴ICORD (International Collaboration On Repair Discoveries), ⁵ICORD (International Collaboration on Repair Discoveries), The Univ. of British Columbia, Vancouver, BC, Canada; ⁶ICORD, Vancouver, BC, Canada

Abstract: Introduction: Development and translation of effective therapies for acute traumatic spinal cord injury (SCI) are hindered by both the paucity of information regarding the biology of human SCI, as well as reliance on functional tests of motor function and sensation to grade injury severity. In the acute SCI setting, comorbid substance use and severe injuries often prevent valid baseline examination of SCI severity. In turn, individuals become ineligible for clinical trial enrollment, because they cannot be appropriately stratified into studies within required timelines; this enrollment challenge contributes to the high cost and difficulty of clinical trials for potential therapies, and scarcity of information regarding human SCI biology. Beyond offering the promise of more objective diagnostics, exploratory investigations seeking to identify biomarkers of SCI severity present the opportunity to increase our understanding of the biology of human SCI.

Objective: This study seeks to quantify the abundance of 496 peptides within the cerebrospinal fluid (CSF) of human SCI patients and characterize the changes in related protein loads during the five days immediately following SCI, in order to enhance understanding of human SCI, as well as to broaden the scope of potential protein biomarkers of acute SCI severity.

Methods: Parallel reaction monitoring (PRM), a mass spectrometry approach for targeted protein identification and quantification, is used to analyze the presence of 496 peptides in CSF from AIS A (n = 55), AIS B (n = 12), and AIS C (n = 12) SCI patients obtained through indwelling intrathecal catheters at 24, 48, 72, 96, and 120 hours post-injury, as well as in CSF from non-SCI patients (n = 19). The 496 target panel represents 396 unique proteins and includes a number of CSF contents known to be readily detectable via mass spectrometry, as well as peptides which the literature links to processes of SCI and other neurological conditions, such as: Alzheimer's, Parkinson's disease, stroke, and traumatic brain injury, the literature suggests them to be potential CSF biomarkers.

Results: This project establishes a targeted experimental workflow which defines m/z ranges and retention time windows at which each peptide can optimally be detected. We are in the process of preparing the CSF samples for PRM evaluation.

Abstract: Rapid, accurate assessment of the severity of spinal cord injury (SCI) is critical in determining a course of treatment. Currently the 'gold standard' is the American Spinal Injury Association Impairment Scale (AIS), which uses a functional assessment to determine injury severity. However, it has its drawbacks: it requires verbal information from patients who may not be able to respond, and relies on potentially subjective self-reporting. Biological markers that objectively classify injury severity and predict outcome would circumvent these drawbacks and greatly facilitate efforts to evaluate acute SCI therapies.

In an attempt to identify blood protein biomarkers we previously analyzed serum samples of a small set of AISA A, B, and C patients (n=9) collected 17-23 hours post-injury. Here, we extend our findings by reporting on the analysis of serum from 115 acute SCI patients. Specifically, the purpose of this study is to analyze serum biomarkers over a 5 day period post-SCI to determine if they are able to distinguish between baseline AIS grades, and predict AIS conversion. Patients classified as AIS A, B, or C were recruited as part of an ongoing, prospective multicenter study (Canadian Multicenter CSF Pressure and Biomarker Study, CAMPER). Blood samples were collected every 8h for 5 days in order to determine serum profiles following injury. Additionally, non-SCI control serum samples were collected from patients undergoing hip or knee surgery during their spinal anaesthetics. Blood samples were kept at room temperature for 20 min and then centrifuged at 10,000 rcf for 5 min to obtain serum. Serum concentrations of IL-6, IL-8, TNF-R1, MCP-1, IP-10, S100B, GFAP, and NSE were evaluated using custom multiplex kits. Serum levels of TAU were determined using commercially available kits. Plates were read on the Meso Scale Discovery electrochemiluminescent system.

Initial data confirms that the concentrations of serum proteins such as IL-6, IL-8, MCP-1, Tau, S100b, GFAP and NSE are many orders of magnitude lower in the blood than cerebrospinal fluid (CSF). While our data show clear differences in CSF levels of IL-6, Tau, S100b, and GFAP between the different baseline AIS grades, with the exception of Tau such a clear distinction between baseline AIS grades is not observed in the serum samples. Further analysis is currently being conducted.

By characterizing the acute pathophysiologic responses to traumatic SCI in humans and

establishing serum biomarkers for better injury stratification and improved prognostication of neurologic recovery, we hope to provide the field with tools that can be utilized in clinical trials to facilitate the evaluation of novel therapies.

Abstract: Purpose: 1) To develop a large animal model of SCI that exhibits cardiovascular dysregulation resembling that which is observed in individuals with high lesion SCI, and 2) to examine the acute cardiac and hemodynamic response to SCI. **Methods:** Ten Yorkshire pigs (25Kg, approx. 6 months of age) were instrumented with a triple lumen central venous catheter, femoral artery catheter, and left-ventricular pressure-volume conductance catheter. The left-ventricular catheter was placed via a right carotid artery approach under fluoroscopic guidance. Pigs were subjected to a 20cm weight drop (50g) contusion SCI at T2 or T10 followed by 5 min of compression. Beat-by-beat systolic blood pressure (SBP), mean arterial pressure (MAP), heart rate (HR), left-ventricular pressure (LVP), and rates of contraction (dP/dt_{max}) were continuously monitored until 4 hours post-SCI. **Results:** In response to T2 SCI, there was an immediate pressor response that peaked at 3 min post-SCI, whereby MAP increased by 35mmHg (± 5.5 mmHg), and dP/dt_{max} (1100 ± 342 mmHg/s). For T10 SCI, there was no significant increase in any cardiac or hemodynamic indices (p>0.122). Following decompression at 5min, MAP, LVP, dP/dt_{max} and dP/dt_{min} were significantly reduced relative to baseline in both T2 and

T10 SCI (all p<0.025). Between 30 and 60 minutes following decompression, there was a gradual (albeit insignificant) increase in all hemodynamic indices in both T2 and T10 SCI. From 1 hour post-SCI onwards, MAP and LVP_{max} gradually declined and were consistently lower than pre-SCI at 3hr post-SCI in both T2 and T10 SCI (all p<0.06). Only T2 SCI exhibited a significant reduction in dP/dt_{max} from 3 hours post-SCI onwards (p=0.017). **Conclusions:** High-thoracic SCI is characterized by an immediate pressor response, followed by a rapid and sustained impairment in cardiac and hemodynamic function. Low-thoracic SCI is characterized by a rapid and sustained reduction in blood pressure but not cardiac function.

Abstract: INTRODUCTION

With limited treatment options currently available to clinicians, there is an urgent need for noninvasive biomarkers to aid in the scientific development and clinical validation of novel therapies for acute spinal cord injury (SCI). MicroRNAs are small regulatory noncoding RNA molecules that mediate gene expression. The current body of literature suggests that miRNAs orchestrate a wide range of biological processes such as inflammation, synaptic plasticity and apoptosis. Many miRNAs are highly enriched in the nervous system and are also directly implicated in the pathogenesis of various neurodegenerative diseases including traumatic TBI and SCI. In addition to miRNA, Cell-Free DNA is released from tissues following cell death and is emerging as a diagnostic tool for monitoring pathology. Specific tissues contain DNA fragments with altered methylation, therefore when they are detected in fluids, it is possible to determine their tissue origin and quantify the magnitude of damage in the affected tissue.

METHODS

In this study, we compared the cell-free expression profiles of microRNA (miRNA) and cell-free DNA (cfDNA) in serum and cerebrospinal fluid (CSF) collected from human patients with SCI. Patients classified as AIS A, B, or C were recruited as part of an ongoing, multi-center study called CAMPER. CSF and blood samples were collected every 8h for 5 days in order to compare CSF and serum miRNA profiles following injury. Additionally, control "non-injury" CSF samples were collected via a single lumbar puncture from patients undergoing hip or knee surgery during their spinal anesthetics.

Next-generation sequencing was used to compare effects of injury severity on miRNA and cfDNA levels. Extracellular miRNA and cfDNA were isolated and sequenced using the Illumina HiSeq 2500 system. Generated data was processed using the Mayo Clinic's Comprehensive Analysis Pipeline for miRNA Sequencing Data (CAP-miRSeq), and aligned reads were used to compare differential expression.

RESULTS AND CONCLUSIONS

Here, we present miRNA and cfDNA profiles in CSF and serum clinical samples during acute stages after SCI. This analysis was done in parallel to the investigation of miRNA in the serum of pigs following SCI. This characterization is important to establish whether biomarkers of SCI found in pigs can be transferred to humans and vice-versa.

Abstract: Effective restraint of secondary injury plays a fundamental role in minimizing neurodegeneration and significantly improves functional recovery after spinal cord injury (SCI). Although the complex mechanisms underlying secondary damage after SCI are still not fully defined, the local immune response to SCI has been identified as an important mediator of secondary damage. Following injury, marked changes in cellular inflammation have been observed in spinal cord lesion. Different innate (neutrophils, monocytes, dendritic cells, etc.) and adaptive (T and B lymphocytes) immune cells are activated and recruited to the injured area. Dendritic cells (DCs) are professional antigen presenting cells (APC), with a key role in promoting and modulating immune responses. When these cells mature, they link innate and adaptive immunity by presenting processed antigens and providing costimulatory signals to activate specific T cells. While the presence of different DC subsets in the CSF of patients with some inflammatory neurological diseases, such as lupus erythematosus (SLE), multiple sclerosis (MS), experimental autoimmune encephalomyelitis (EAE), has been reported, despite their recognized importance in regulating immune responses, very little is known about DC subsets and their role in SCI and many fundamental questions, such as the onset and duration of infiltrated DC subsets in acute SCI is remain unanswered. DCs comprise two major classes: plasmacytoid DCs (pDCs) and conventional or classical DCs (cDCs). pDCs rapidly produce type 1 interferon (IFN) following activation through nucleic acid-sensing TLRs, such as TLR7 and TLR9. cDCs are dedicated APCs that have a characteristic dendritic morphology and express high levels of MHC class II molecules. In this study, we have evaluated the frequency and cytokine production profile of infiltrating DC subsets in blood, CSF and spinal cord lesion of rat and porcine models of SCI during acute and chronic phase of spinal cord injury. Pigs and rats were undergone the contusive SCI using a weight-drop apparatus. CSF and blood samples were drawn pre-injury, 4, 8, 12, & 24 hours and then daily until day 7 post-injury. The percentages of pDC and cDC in blood and CSF were evaluated in vitro by flow cytometry. Preliminary data from our rat and pig models of SCI have revealed that there are differences in the pre- and post-SCI pDCs and cDCs frequency in CSF and blood. The data generated from this study, will improve our knowledge of local and systemic immune response mechanisms triggered after SCI. Moreover, it may pave the way for novel cell therapies in SCI, aiming at modulating specific pathogenic cell type.

Title: The acute effects of vasopressor administration timing on perfusion, oxygenation and metabolic responses in a porcine model of traumatic spinal cord injury

Authors: *E. B. OKON¹, K. SO¹, F. STREIJGER¹, N. MANOUCHEHRI¹, K. SHORTT¹, M. STRAWFORD¹, D. E. GRIESDALE², M. SEKHON³, B. K. Hospital, Div. of Critical Care Med., Vancouver, BC, Canada; ⁴Dept. of Orthopaedics, UBC, Vancouver Spine Surgery Inst., Vancouver, BC, Canada

Abstract: Traumatic Spinal cord injury (SCI) can lead to severe irreversible consequences, having a devastating impact on patients, families and society. A decrease in mean arterial pressure (MAP) is often observed after SCI, resulting in decreased cord perfusion and subsequent ischemia, both of which contributes to secondary damage. Early intervention strategies remain limited, with vasopressor support of MAP to improve spinal cord perfusion being one of the few treatment options available. Previous work from our lab has shown that norepinephrine, over phenylephrine, was the more effective vasopressor for restoring blood flow and oxygenation. However, the effect of intervention timing, particularly in the acute setting, on perfusion, oxygenation, and metabolic responses warrants consideration. Indiscriminate augmentation of MAP in the traumatically injured spinal cord with impaired vascular autoregulation could do more harm than good. In this study, we sought to determine the effects of MAP support intervention on the acute hemodynamic and metabolic responses during the compressed and decompressed states of injury.

Using our porcine model of SCI, female Yucatan miniature pigs received a T10 contusion injury followed by 2-hours of sustained compression. After SCI, norepinephrine was used to elevate MAP by 20 mmHg for a period of 1.5 to 3.0 hours while the cord was compressed, after the cord was decompressed, or during both injury states. A control group, which received an SCI,

received no vasopressor treatment. Laser Doppler flowmetry/oxygenation, fibre optic pressure, and microdialysis probes were inserted into the cord at 2mm and 22mm caudal from injury to measure spinal cord blood flow (SCBF), oxygenation (PO2), spinal cord pressure (SCP), and from which microdialysis samples were collected to analyze for lactate, pyruvate, glucose, glutamate and glycerol. Preliminary data show that MAP support during cord compression only mildly improved SCBF and PO2 and did not reduce L/P ratios back to baseline levels. However, MAP support after decompression improved SCBF and PO2 more effectively, restoring both parameters to pre-injury levels and decreased L/P ratio back to baseline levels. Combined, our preliminary results suggest that MAP support is more effective at improving cord perfusion and preventing ischemia after decompression than during the compression state of injury. Histological analysis for haemorrhagic damage resulting from vasopressor treatment will be examined and further work to consolidate our current findings is being carried out.

Abstract: Controlling inflammatory responses is important for functional recovery after spinal cord injury (SCI). Infiltrating inflammatory cells such as neutrophils and monocyte/macrophages are suggested to deteriorate the tissue damage, and to support for tissue recovery. Although the cell migration into the injury site is regulated by several chemokines, expression patterns and distributions of the chemokines and the receptors have not been determined in detail. Male young adult C57/BL6 mice were subjected to spinal cord transection by razor at level between

T9 and T10 intervertebral spinal cord. The spinal cord from T8 to T11 was collected on shamoperated control mice (day 0), and on post-operative day 1, 3, 7 and 14. The tissues were quantified gene expressions of monocyte/macrophage-related CC- and CXC-chemokines, and the receptors by SYBR-Green based qPCR. Moreover, the frozen sagittal sections of spinal cord were immunostained against CCL2, CCL5 and the receptor antibodies on day 0, 1 and 14. There were two patterns of increases the chemokines. Increases of the gene expression within 3 days after SCI were including such as CCL2 and CXCL1. The increase gene expressions of the receptors also consisted with the chemokines. The gene expressions of these chemokines and receptors were gradually decreased at day 7. On the other hand, the CCL5 gene expression gradually increased after SCI and reached a peak on day 14. A receptor of CCL5, CCR5 increased and reached a peak on day3 and remained elevated until day 14. Immunoreactivities of CCL2, and CCL5 on spinal cord were merged with NeuN-positive cells in the peri-injury sites at day 1. Although immunoreactivity of CCL2 was diminished, CCL5 immunoreactivity was recognized in Iba1-positive and GFAP-positive cells, suggesting microglia/macrophage and astroglia in peri-injury site at day 14. These results were suggested diverse chemokines were increased in spinal cord after injury and could regulate an increase of inflammation and the resolution communicated with glial cells. (No COI)

Title: The spinal transcriptome after large unilateral cortical stroke and its impact on sprouting and 'side-switch' of contralateral corticospinal fibers

Authors: *J. KAISER¹, I. SALPETER¹, V. BARBOSA C. DE SOUZA², M. D. ROBINSON², M. E. SCHWAB¹ ¹Brain Res. Inst., Zürich, Switzerland; ²Inst. of Mol. Life Sci., Zürich, Switzerland

Abstract: Functional recovery of skilled forelimb movements after a large insult to the primary motor and premotor cortex involves activation of the contralateral hemisphere with the contralesional cortex growing new collaterals crossing the midline into the denervated hemi-cord on cervical levels of the spinal cord. The underlying molecular mechanisms of growth induction in these adult, intact, fully wired and functional corticospinal tract (CST) fibers, midline crossing and target innervation are yet unclear. Such mechanisms could be of high importance for future therapies. Cervical sprouting following a large photothrombotic insult to the motor cortex in adult C57bl/6 mice induced pronounced sprouting of fibers of the intact CST across the spinal cord midline into the denervated hemi-cord. These sprouts were most numerous at cervical levels C5-C6 and targeted mostly the intermediate laminae (Lam 5-7). Total RNA of this target area was prepared at different time points after stroke corresponding to previously identified key plastic events: initiation phase of fiber growth (7dpi), maintenance phase (14dpi), period of highest density of sprouts (28d) and anatomical rearrangement and pruning phase (42dpi). RNA-Seq (Illumina Hi-Seq) reads were mapped to the mouse transcriptome and quantified for differential expression analysis. Genes were ranked by their fold change to controls, and top differentially regulated genes for each time point were identified. This unbiased approach allows for evaluation of the spinal transcriptome in response to de- and re-innervation and the defined key steps of this process. Further analyses include gene ontology (GO) analysis as well as Kyoto Encyclopedia of Genes and Genomes (KEGG) analysis to establish functional relevant processes at all time points.

Title: Transcriptional screen in the target region of sprouting hindlimb corticospinal fibers after thoracic spinal cord injury in rats

Authors: *N. RUSSI, A.-S. HOFER, A. K. ENGMANN, S. IMOBERSTEG, J. M. HELDNER, M. E. SCHWAB

Brain Res. Inst., Univ. and ETH Zurich, Zurich, Switzerland

Abstract: Depending on the severity of a CNS injury, in humans as well as in experimental animal models certain degrees of functional recovery are observed. Rodent studies have provided much evidence for underlying anatomical changes involving neurite outgrowth of both spared and axotomized fiber tracts, also referred to as sprouting.

Following a thoracic spinal cord injury in adult rats, axotomized fibers of the hindlimb corticospinal tract (CST) were found to sprout into the cervical spinal cord at different rostrocaudal levels. Anterograde tracings showed that these new collaterals of motor cortical hindlimb fibers project into the intermediate laminae of the cervical grey matter, particularly pronounced at the level of cervical segment five (C5). The molecular cues which induce the growth and guide these sprouts of hindlimb CST fibers are unknown. We hypothesize that sectreted factors and guidance and adhesion molecules are specifically expressed in the intermediate laminae of the cervical spinal cord to direct and target the ingrowth of the sprouting hindlimb CST fibers.

To test our hypothesis a transcriptional screen in adult rats with a thoracic dorsal hemisection injury is currently being performed. At different time points post injury the intermediate laminae of C5 were dissected. Total RNA was extracted and subjected to deep sequencing. Data are being analysed, and differentially expressed genes will be presented. The results will allow us to determine the role of the cervical spinal cord (target region) for sprouting of hindlimb CST fibers.

Title: Emergence of epigenetic mechanisms by metalloproteinases and purinergic receptors modulation in the maladaptive plasticity in the rat spinal cord

Authors: A. VIRTUOSO¹, C. DE LUCA¹, G. CIRILLO¹, L. ALBERGHINA², A. COLANGELO², *M. PAPA¹

¹Dept. di Salute Mentale e Fisica e Medicina Preventiva, Anatomia Umana Univ. Degli Studi Della Campan, Napoli, Italy; ²Univ. of Milano-Bicocca, Milano, Italy

Abstract: A significant reshaping of the spinal neuroglial circuitry follows peripheral nerve injury (PNI), it perturbs spinal homeostasis and induces a condition defined maladaptive synaptic plasticity. Metalloproteinases (MMPs) activity and the purinergic system "in vivo" both, play a key role in determining maladaptive changes in the central nervous system (CNS) following nerve injury. The maladaptive plasticity is an enduring process, producing long-lasting changes; therefore it claims a genomic remodeling. The aim of this study was to investigate the mechanism through which, MMPs inhibition and/or purinergic receptors (P2X) blockage may produce transcriptional and post-transcriptional regulation, having a neuroprotective role. We study inflammatory and epigenetic markers in the spared nerve injury (SNI) of the sciatic nerve rat model. Rats were divided into 5 groups: 1) sham, 2) SNI, 3) SNI-treated with MMP inhibitor (GM6001), 4) purinergic receptors inhibitor [oxidized ATP (oxATP)], or 5) both GM6001 and oxATP. Inflammatory and epigenetic factors were evaluated by western blot and immunocytochemical analysis at day 3 and 8 after surgery. Histone deacetylase (HDAC)1, HDAC2 and the Recombination signal Binding Protein for immunoglobulin kappa J region (RBPJ) expression were analyzed in the lumbar spinal cord. The inhibition of MMPs activity and the P2Xrs were effective to reduce reactive gliosis and neuroinflammation markers, chiefly 8 days after the injury. Moreover, investigating the neurotrophic pathways, both treatments decreased TrkA receptor expression; the oxATP modified pro-Nerve Growth Factor (pro-NGF) and p75 expression. MMPs inhibition modulates HDAC1 protein expression while combined therapy affected HDAC2 levels, thus suggesting a key role in epigenetic modifications. Taken together, these data suggest that MMPs and P2Xrs play a dual role as transcriptional and posttranscriptional regulators, moreover confirmed the therapeutic potential of GM6001 and/or oxATP in reducing the maladaptive plasticity changes in the CNS, in response to injury.

Title: Abnormal posture and muscle spasms after spinal cord injury: different neuronal circuits but a common neural mechanism

Authors: *C. BELLARDITA¹, O. KIEHN²

¹Karolinska Institutet, Stockholm, Sweden; ²Dept. of Neuroscience, Karolinska, Stockholm, Sweden

Abstract: Spinal cord injury (SCI) results in sustained involuntary muscle contractions that may generate abnormal and chronic posture or sudden and temporally-limited muscle spasms. The neuronal mechanisms for these aberrant motor responses are not well understood. Here we used a mouse model of chronic SCI with a sacral lesion that exhibits an abnormal posture of the tail, characterized by sustained activity in small sized motor units (MUs), and spontaneous muscle spasms, characterized by a sudden activation of large sized MUs. After SCI optogenetic activation of excitatory spinal interneurons triggered and maintained spasms with temporallydefined recruitment of large MUs. Further in vitro calcium imaging in lesioned mice revealed a persistent neural activity in excitatory spinal interneurons during spasms. On the contrary, stimulation of excitatory neurons did not evoke a chronic tail posture and the concurrent sustained change in activity of the small MUs, indicating different circuits generating the two responses. However complete silencing of the calcium channels Ca_V 1.3 in all spinal neurons reduced both spasms and the abnormal posture. However when the Cav 1.3 channels were silenced in excitatory spinal neurons the mice exhibited a decrease in spasms even though they developed dystonia, similar to the wild-type, but a. In conclusion abnormal posture and spasms may emerge from small and large MUs whose activity is driven by different pre-motor neuronal circuits. However the two motor dysfunctions are characterized by sustained activity of the MUs thus the Cav 1.3 channels may represent a shared neural mechanism, allowing output amplification.

Title: Identification of a novel binding domain for heparin in RPTP σ , but not LAR or RPTP δ : Implications for proteoglycan signaling Authors: H. KATAGIRI¹, S. HIGASHI¹, A. A. MORGAN^{3,1}, N. J. BANGAYAN¹, R. JUNKA¹, *P. YU⁴, H. M. GELLER² ²Office of Educ., ¹NIH, Bethesda, MD; ³Columbia Univ., New York, NY; ⁴GHMICR, Jinan Univ., Guangzhou, China

Abstract: Type IIa Receptor protein tyrosine phosphatases (RPTPs) have been shown to modulate neural regeneration and development. All members of this family (RPTP σ , RPTP δ , and LAR) have a cell adhesion molecule-like extracellular domain that includes three N-terminal Ig domains and four to nine fibronectin type III (FNIII) domains, as well as tandem intracellular tyrosine phosphatase domains. Compelling evidence suggests that both heparan sulfate (HS) and chondroitin sulfate (CS) are ligands for RPTPo and LAR with similar nanomolar dissociation constants, and the Lys-loop located in the first Ig domain is responsible for ligand binding. However, the reason for the different functional outputs of HS and CS binding to RPTPo (respectively, promotion and inhibition of axonal growth) remains a mystery. Although attributed to the differential oligomeric state of RPTP σ upon binding to HS, but not to CS, our data indicate that both HS and CS can cause RPTP_o clustering. Furthermore, we demonstrate a differential contribution of FNIII domains required for high affinity binding to glycosaminoglycans (GAGs). In particular, binding of $PTP\sigma$ to heparin was not completely abolished by disruption of the Lys-loop. This, along with a decrease in binding with deletion of the fourth FNIII-containing domain, leads us to hypothesize that there is a greater contribution of the FNIII domain in binding to GAGs than previously believed. To support this notion, we found the fourth FNIII-containing domain alone binds to heparin independently of the three Ig domains and does not bind to CS-E or DS. Intriguingly, while addition of heparin to 293 cells expressing wild-type RPTP σ (full length) altered tyrosine phosphorylation transiently, disruption of the Lysloop in RPTPo (full length) did not affect this transient response induced by heparin. Thus, our findings clearly indicate that this novel HS-specific binding domain on RPTPo plays an important role in controlling the different biological actions of HS and CS.

Title: Impact of spinal cord injury on synaptic transmission in neurons of mouse major pelvic ganglia

Authors: *C. W. KYI¹, V. B. GARCIA², D. J. SCHULZ³

¹Biol. Sci., ²Div. of Biol. Sci., Univ. of Missouri, Columbia, MO; ³Div. of Biol. Sci., Univ. of Missouri-Columbia, Columbia, MO

Abstract: Lower urinary tract function is one of the autonomic functions impaired after spinal cord injury (SCI). Acute SCI results in areflexic bladder and complete urinary retention while patients with chronic SCI suffer from hyperreflexic bladder, incontinence and inefficient voiding. The major pelvic ganglia (MPG) of the mouse contain neurons that innervate the urinary bladder, genitals and distal colon. MPG is a mixed ganglion that primarily receives parasympathetic input from the preganglionic neurons located in the sacral cord through pelvic nerve and sympathetic input from those in the lumbosacral cord through hypogastric nerve. Nicotinic cholinergic transmission is the major neurotransmitter system involved in pre-to postganglionic communication at the MPG. The goal of this project is to understand the effects of spinal cord injury on synaptic transmission at the MPG neurons involved in micturition function. The spinal cord was completely transected at thoracic 8 (T8) vertebral level of transgenic mice (B6.Cg-Tg (RP23-268L19-EGFP) 2Mik/J) containing cholinergic neurons labelled with green florescent protein. We used both male and female mice that were 8 to 12 weeks old. We had four experimental groups- acute SCI (3days post-surgery), chronic SCI (28 days post-injury), and sham-surgical control groups for each time point. We quantified mRNA abundance of receptor genes using quantitative PCR as well as measured functional properties of the neurons via intracellular recording. We measured the excitability, passive properties, and firing patterns of the neurons in response to current injection, and also measured excitatory postsynaptic potentials (EPSPs) and excitatory postsynaptic currents (EPSCs) in response to pelvic nerve stimulation, and pressure ejection of 1mM acetylcholine (ACh). We further characterized the major subunits involved in the neurotransmission by measuring current responses before and after application of subtype-specific blockers. We measured the mRNA abundance of $\alpha 2$, $\alpha 3$, $\alpha 4$, $\alpha 5$, $\alpha 6$, $\alpha 7$, $\beta 2$ and β4 nicotinic receptor subunits in whole MPGs. Our preliminary data indicate that after 3 days post-injury, the mRNA for a3 subunit was significantly decreased compared to those of sham controls. However, after 28 days, the mRNA levels were no longer significantly different from those of sham controls. These results suggest that acute SCI results in downregulation of one of the major receptor subunits involved in synaptic transmission at the MPG, and this may contribute to impairment of target organ function following SCI.

Title: Reciprocal interaction between mesenchymal stem cells and macrophages support the formation and maturation of blood vessels. An *In vitro* study

Authors: *I. MALDONADO-LASUNCION^{1,2}, M. OUDEGA³, J. VERHAAGEN⁴ ¹The Miami Project to Cure Paralysis, Univ. of Miami, Miami, FL; ²Vrije Univ. Amsterdam, Amsterdam, Netherlands; ³Dept. of Neurolog. Surgery, The Miami Project to Cure Paralysis, Univ. of Miami Dept. of Neurolog. Surgery, Miami, FL; ⁴Netherlands Inst. for Neurosci., Amsterdam, Netherlands

Abstract: Mesenchymal stem cell (MSC) transplants support spinal cord nervous tissue repair, in part, by mediating the formation of new blood vessels (angiogenesis) resulting in tissue sparing associated with improved functional outcome. Usually, at the time of transplantation, the injury site is populated by inflammatory cells, including many macrophages presenting the inflammatory phenotype (M1). From previous studies using different types of tissues we know that MSCs and macrophages engage in a molecular cross communication supporting the establishment of a reparative environment. At present, the interactions between transplanted MSCs and endogenous inflammatory macrophages in the injured spinal cord are poorly understood. We have employed an *in vitro* system to start understanding the presence and molecular mechanisms of the crosstalk between transplanted MSCs and endogenous macrophages, with special emphasis on angiogenesis and immunomodulation. We showed that the secretion of vascular endothelial growth factor (VEGF) by MSCs was dramatically increased after exposure to inflammatory macrophage-conditioned medium. VEGF plays an important role in the formation of new blood vessels. Interestingly, when MSCs were exposed to the conditioned medium of reparative macrophage (M2)-conditioned medium, they significantly increased the secretion of platelet-derived growth factor (PDGF) as well as that of brain-derived neurotrophic factor (BDNF) and insulin growth factor-1 (IGF-1). Within angiogenesis, PDGF is known for its role in stabilizing newly formed blood vessels. We hypothesized that VEGF in an autocrine loop enhances the production and secretion of anti-inflammatory cytokines by MSCs, which in turn mediate the shift in macrophage phenotype from M1 to M2. Such reciprocal crosstalk would orchestrate the creation of a reparative milieu in the injury site. Revealing MSCmacrophage interactions may help identifying molecular targets for enhancing MSC-mediated nervous tissue repair.

Title: Role of local neurogenesis in functional recovery following spinal cord injury in larval zebrafish

Authors: *D. VASUDEVAN

Neurobio. and Anat., Univ. of Utah, Salt Lake City, UT

Abstract: Successful treatment for human spinal cord injury (SCI) is currently an insurmountable goal. The biggest obstacle is the inability of severed axons and neurons to regenerate. Adult mammals have a conspicuous inability to regenerate post SCI, but zebrafish show full functional recovery throughout life due to axon regrowth, rewiring of existing circuits and/ or local neurogenesis. Our aim is to understand the role of local neurogenesis in functional recovery. Studies from our lab have shown that resident radial glia undergo a change in morphology, and actively make neurons post injury. We have generated a unique combinatorial approach to genetically label newly-born neurons from a radial glial lineage after injury, using the Cre-lox recombination system. To test the hypothesis that neurons born after SCI integrate into existing circuits and are required for recovery of sensorimotor behavior, we are using two approaches. In the first approach, we are genetically ablating neurons that arise from a radial glial lineage post injury to evaluate their specific requirement in swimming behavior. The second approach is to express a calcium reporter specifically in neurons arising from radial glia after injury, to determine whether they exhibit physiological activity during a defined escape behavior. We are also tracing the lineage of radial glia to test whether specific neuronal identities with known physiological properties are restored. Testing swim and escape behaviors following recovery will tell us about the relative contributions of axon regrowth and neurogenesis to the reestablishment of local circuitry. These studies will establish the significance of neuronal regeneration as a potential therapeutic response to SCI.

Title: Acute immune response to spinal cord injury in the dorsal root ganglia as a predictor of pain development

Authors: *S. J. CHHAYA, A. ONG, J. D. HOULE, M. R. DETLOFF Neurobio. and Anat., Drexel Univ. Col. of Med., Philadelphia, PA

Abstract: Spinal cord injury (SCI) damages sensory systems and causes chronic, intractable neuropathic pain. Selective upregulation of pro-inflammatory mediators such as the chemokine CCL2 by specific phenotypes of myeloid cells causes secondary tissue damage, influences neuronal plasticity, alters nociceptive processing by nociceptors in the dorsal root ganglia (DRG) and may contribute to the development of chronic pain. There is a gap in our understanding of chemokine signaling events that transpire in the DRG after SCI that could induce pathological changes in the nociceptor and drive pain. This study aimed to determine whether myeloid cell recruitment after SCI is essential to pain development and explore whether the phenotype and cytokine release profile of macrophages in the DRG dictates pain development. We used a previously established C5 unilateral contusion model of spinal cord injury-induced neuropathic pain in female Sprague-Dawley rats, where 40% of rats develop pain. Rats were sacrificed early after SCI (12, 24, 72 hours and 5 days) as well as at 14 days post-injury (dpi) when pain was assessed using von Frey, Hargreaves' and mechanical conflict avoidance tests. qPCR was used to measure pro-inflammatory cytokine expression and expression of myeloid cell phenotype markers in whole C7-8 ipsilesional DRG lysates. Preliminary analysis revealed that rats are distributed into two distinct clusters based on cytokine gene expression-those with a large foldchange in cytokine mRNA expression and those with near-normal expression (n=6/timepoint). ED-1 immunohistochemistry was used to identify infiltrating myeloid cells in the DRGs at these time points. Infiltration began as early as 12 hours post-injury, and rats with pain at 14 dpi had an increased number of ED1+ myeloid cells than rats without pain. We are conducting experiments to block myeloid cell infiltration using a CCR2 inhibitor (INCB3344) early (0-72h) post-SCI to prevent CCL2-mediated recruitment, and will assess the necessity of myeloid cell recruitment in the development of pain, as well as correlations between pain development and macrophage phenotype and inflammatory environment in the DRG. Studying the acute immune response after SCI in the DRG could reveal key mechanisms that initiate maladaptive processes that lead to nociceptor dysfunction and prolonged pain.

Title: AAV9-driven neuron-specific transgene expression: A tool to study the role of IMP2 in axon regeneration

Authors: *S. BLIZARD, D. PARK, N. O'TOOLE, S. NOOROZ, M. DELA TORRE, S. AUSTIN, J. HARMAN, S. HARASZTI, M. XU Philadelphia Col. of Osteo. Med., Philadelphia, PA

Abstract: Insulin-like growth factor-II (IGF-II) mRNA-binding protein-2 (IMP2) is one of the three homologues (IMP1-3) that play an important role in the post-transcriptional regulation of gene expression during development. Its alternative splice product aberrantly expresses in human hepatocellular carcinoma, and is therefore identified as HCC. Several lines of studies have demonstrated that IMP1/ZBP1 (zipcode binding protein) is critical in axon guidance and regeneration by regulating localization and translation of specific mRNAs. However, the role of IMP2 in the nervous system is largely unknown. Previously, we used transfection to overexpress IMP2 and HCC in the cultured dorsal root ganglion (DRG) neurons to study their roles during axon regeneration in vitro. We noted significant toxicity. We also tried to overexpress IMP2 and HCC by rabies-G pseudotyped lentiviral vector in the severed sciatic nerve, and found the expressions predominantly in neurons and but occasionally in non-neuronal cells as well. In this study, we used the synapsin promoter-driven adeno-associated viral (AAV) 9 constructs to specifically express YFP-IMP2 and -HCC in neurons both in vitro and in vivo. We applied AAV9.hSyn.YFP, AAV9.hSyn.YFP-hIMP2 and AAV9.hSyn.YFP-hHCC in the DRG neuron culture. We also injected the viral vectors into the crushed sciatic nerve. These viral vectors have proven to be effective to introduce neuron-specific transgene expression of IMP2 and HCC. In addition, our data shows that overexpression of HCC promotes axon outgrowth of the cultured DRG neurons. Ongoing experiments are aimed at studying the role of IMP2 and HCC in the nerve crush model and understanding the underlying mechanisms.

Abstract: Spinal cord injury in humans generates devastating conditions leading to the permanent loss of sensory-motor and autonomic functions. This is because the injured cord is unable to self-repair as in some non-mammalian vertebrates. Remarkably, freshwater turtles are able to heal the injured spinal cord and partially regain lost functions even during adulthood. The importance of this relies on the fact that they are the only amniotes exhibiting this feature. Gene expression analysis at the sub-acute phase of the response (4 days after injury) shows that several genes involved in diverse functions are activated : reaction to ischemic insult, extracellular matrix re-organization, immune response, and inflammation and axonal growth. Interestingly we found that almost all of these genes are present in mammals too. Additionally, we failed to find genes exclusively belonging to regenerating taxa. Indeed, the comparison of expression patterns among species shows that the response to spinal cord injury in the turtle is more similar to that of mice and non-regenerative Xenopus than to Xenopus during its regenerative stage. This observation, along with current accepted phylogenetic placement of turtles (sister group of crocodilians and birds), indicates that that turtles developed this capability from a nonregenerative ancestor, that was achieved by re-organizing gene expression patterns. In this work we extend our previous studies by characterizing the gene expression profile using RNASeq analysis during the whole process of regeneration after injury from the acute phase (1 day after injury) till the moment in which functional recovery is observed (at least 30 days after injury). We speculate our findings may provide useful clues to develop new therapies for the treatment of spinal lesions.

Title: Macrophages promote axonal regeneration after spinal cord injury in zebrafish larvae

Authors: *T. TSAROUCHAS, D. WEHNER, T. BARRETT, T. CARR, L. CAVONE, T. BECKER, C. G. BECKER

The Univ. of Edinburgh, Edinburgh, United Kingdom

Abstract: Zebrafish, in contrast to mammals, regenerate lost neurons and functional axonal connections after spinal cord lesion. We find that the immune response, occurring after injury, is essential for neuronal regeneration in larvae (Ohnmacht et al., 2016, Development 143, 1464-74), but its contribution to axonal regrowth across a non-neural lesion site is less clear. Here we characterize the role of the innate immune response for axonal regeneration by assessing axonal regrowth, debris clearance and cytokine levels in wildtype larvae and macrophage-deficient irf8 mutants. We find that at 2 days after a lesion of 3-day-old larvae, 81% of wildtype larvae showed axonal continuity between rostral and caudal spinal cord, whereas in irf8 mutants only 37% showed axonal bridging. Recovery of swimming function was also impaired in the mutants compared to wildtype fish, which regain their swimming capacity within 48 hours post-injury. Debris clearance was strongly inhibited in the irf8 mutants compared to lesioned age-matched wildtype larvae. Cytokine levels were increased in wildtype animals after injury and higher than in irf8 mutants. A notable exception was the pro-inflammatory cytokine *il1-beta*, which was increased in expression in the mutant at 2 days post-lesion. At that time point, *il1-beta* was already down-regulated to basal levels in wildtypes. Currently, we are testing the relevance of *ill-beta* upregulation in the mutant. These results suggest important functions of macrophages for debris clearance and resolution of inflammation in the spinal lesion environment, which in turn promotes axonal regrowth in successful spinal cord regeneration in zebrafish.

Abstract: MicroRNAs (miRs) are known to regulate the development and maintenance of the CNS. Specifically, miR-21 is among the most robustly upregulated genes following spinal cord injury (SCI). However, the impact of miR-21 on SCI pathobiology is not fully understood. Predictive algorithms suggest that miR-21 targets multiple genes in the Interleukin-6 pathway (IL6ST, IL6RA, and STAT3). The IL-6/STAT3 pathway is known to influence CNS inflammation and has been implicated in SCI; therefore, we hypothesized that knockout of miR-21 will alter the activation of microglia, the primary inflammatory cells of the CNS, in a model of non-traumatic SCI. Wild-type and miR-21 Knockout mice were randomly assigned to either sham or injury groups (n=7/group). For injury groups, a biomaterial that facilitates bone deposition was inserted under the C5-C6 laminae, causing progressive compression of the cervical spinal cord. Injured mice were assessed for motor deficits using the rotarod test. Standard immunohistochemistry for Iba1+ microglia was performed followed by cell counting using unbiased stereology. To determine effects of miR-21 on target genes during inflammation, primary microglia were isolated from Day 2 pups and stimulated with E.coli Lipopolysaccharide (LPS). RNA was isolated and analyzed by RT-qPCR. Deletion of miR-21 improved locomotor performance on the rotarod by 70% compared to wild type injured mice (p<0.01). Active Iba1+ microglia were reduced by 45% in the compressed region of miR-21 knockout mice compared to wild-type spinal cords (p<0.001). Isolated miR-21 knockout microglia also expressed 4-10 times more IL6 signal transducer (IL6ST) RNA than wild-type after stimulation with LPS (p<0.01). In summary, knockout of miR-21 reduced inflammation at the injury site and resulted in significant motor preservation relative to wild-type animals. These effects on microglia activation were

associated with differential expression of predicted miR-21 target genes in miR-21 knockout mice. Given these relationships, miR-21 and its downstream genes may provide interesting therapeutic targets for future SCI research.

Title: Stimulation of cervical excitatory cells restores breathing after cervical SCI

Authors: *K. SATKUNENDRARAJAH¹, S. K. KARADIMAS², A. M. LALIBERTE³, S. SIVAKUMARAN⁴, M. G. FEHLINGS⁵

¹Genet. and Develop., Toronto Western Res. Inst., Toronto, ON, Canada; ²Krembil Discovery Tower, Toronto, ON, Canada; ³Genet. and Develop., Univ. Hlth. Network, Toronto, ON, Canada; ⁴Genet. and Develop., Univ. of Toronto, Toronto, ON, Canada; ⁵Div. Neurosurg., Toronto Western Hosp., Toronto, ON, Canada

Abstract: Progressive cervical spinal cord injury (cSCI) results in subclinical and mild respiratory dysfunction in contrast to the acute and traumatic cSCI, despite the significant disruption of the cervical neural network. Using a mouse model of progressive cSCI, we found a significant loss of phrenic motoneurons (PMNs) that innervate the main inspiratory muscle, without severe respiratory insufficiency similar to what is observed in humans with this disease. Observation of progressively increased Vglut2 positive boutons on the preserved PMNs indicate that despite the significant PMNs loss the respiratory motor output is maintained via glutamatergic synaptic plasticity onto preserved PMNs. Retrograde tracing from the diaphragm using pseudorabies technology in *vglut2::cre; tdtomato* mice demonstrated that this increased input derives from cervical glutamatergic interneurons. To confirm the role of the cervical glutamatergic synaptic input in promoting respiratory plasticity and ventilation in progressive cSCI, we injected *AAV-FLEX-PSAML141F–GlyR-IRES-eGFP* in the ventromedial area of C3-7 spinal levels of *Vglut2::cre* mice two week prior to the induction of cSCI. Subsequently, PSEM-mediated silencing of these neurons disrupted ventilation in CSM mice. Further, pharmacogentic stimulation of cervical glutamatergic neurons following acute and traumatic cSCI promoted

significant respiratory recovery compared to control mice after injury. In conclusion, this study provides novel insights into mechanisms of respiratory plasticity that can be exploited to promote respiratory recovery following traumatic SCI.

Neurosurg., Toronto Western Hosp., Toronto, ON, Canada

Abstract: Spinal cord injury (SCI) is devastating, causing significant locomotor deficits and potential paralysis with no optimal treatment available to date. Many approaches for restoring locomotor function have focused on reestablishing the necessary excitation by either coaxing axons across the lesion to their synaptic partners, or directly activating the CPG using electrical stimulation based on the assumption that the lumbar networks remain intact after trauma. However, the extent to which the intrinsic anatomical properties of these distal circuits remain intact following rostral SCI has been conspicuously overlooked. Using mice and human with cervical SCI (cSCI), first we demonstrate significant neuronal loss in the ventromedial regions of the distal lumbar spinal cord following cSCI. Ablation of the lumbar projecting cervical neurons in naïve mice reproduces this disintegration lumbar locomotor network. Anatomical and spatial analysis of the lumbar spinal cords of transgenic mice demonstrated that cSCI induces significant loss of excitatory cells in the rhythmogenic core of the locomotor CPG, ventromedial area of the upper lumbar spinal cord, while there was no change in the inhitory population. Moreover, we found a significant loss of motoneurons within the lumbar enlargement of cSCI compared to sham ChAT-GFP mice. With the preserved motoneurons displaying altered morphological characteristics such as decreased dendritic arborizations and soma size. These findings dramatically alter the way in which we approach the development of treatments to restore walking in cSCI patients. Indeed, targeted and exogenous stimulation of lumbar excitatory

neurons immediately after cSCI was able to prevent this degeneration distal locomotor network and promote functional outcome.

Title: Epigenomic signatures

Authors: I. PALMISANO¹, M. C. DANZI², A. HERVERA¹, E. MACLACHLAN¹, L. LEVI⁴, E. ELLIOTT⁴, V. LEMMON³, J. L. BIXBY⁵, *S. DI GIOVANNI¹ ¹Imperial Col. London, London, United Kingdom; ³Neurolog. Surgery, ²Univ. of Miami, Miami, FL; ⁴Bar Ilan Univ., Bar Ilan University, Israel; ⁵Miami Proj to Cure Paralysis, Univ. Miami, Miller Sch. Med., Miami, FL

Abstract: Following injury, peripheral nervous system (PNS) axons mount a regenerative response while axons in the central nervous system (CNS) fail to regenerate. The dorsal root ganglia (DRG) bipolar neurons are a well-suited model to investigate the molecular mechanisms of this differential regenerative ability: a cell body extends one regenerative competent axon in the peripheral nerves and one regenerative incompetent in the CNS spinal cord. A sciatic nerve lesion elicits gene expression changes, including in regenerative pathways, which are radically distinct from those that follow a spinal cord lesion. While recent evidence suggests that epigenetic modifications can underlie this differential response a systematic study of epigenetic states upon regenerative vs non-regenerative axonal injury is still missing. To this end, we have performed combined high throughput studies including RNAseq, ChIPseq for both active (H3K27ac and H3K9ac) and repressive (H3K27me3) histone modifications, and ATACseq (Assay for Transposase-Accessible Chromatin sequencing) that explores chromatin accessibility, from L4-L6 DRG in response to a peripheral (sciatic nerve axotomy- SNA,) vs a central spinal (dorsal column axotomy- DCA) axonal injury. The combined genome wide analysis showed that: 1) SNA leads to a more robust transcriptional response than DCA, with upregulated genes involved in regulation of transcription and regenerative signalling cascades, and downregulated genes involved in ion transport, axonogenesis and synapse formation; 2) transcriptional response to SNA occurs via increased H3K27ac/H3K9ac occupancy at promoters of genes involved in transcription; 3) in contrast, following DCA, genes related to transcription are enriched for

H3K27me3; 4) H3K9/K27ac enriched genes upon SNA lie in genomic region characterized by a differential chromatin accessibility with respect to DCA; 5) injury-dependent genes are enriched in binding sites to CTCF, a well -known chromatin folding organizer and gene expression regulator, involved in neuronal function. Together, these data suggest that a looser chromatin conformation characterized by active histone marks represents the epigenomic signature discriminating regenerative versus non-regenerative states following peripheral or spinal axonal injury respectively. As proof of principle that proper chromatin folding is required for axonal regeneration, CTCF null mice failed to respond to conditioning-dependent increase in DRG outgrowth and showed drastically reduced axonal regeneration after sciatic nerve injury.

Title: Transplantation of mitochondria following spinal trauma in rats

Authors: *S. P. PATEL¹, J. L. GOLLIHUE¹, K. C. ELDAHAN¹, D. H. COX², P. G. SULLIVAN³, A. G. RABCHEVSKY¹

¹Spinal Cord & Brain Injury research Center, Dept. of Physiol., ²Spinal Cord & Brain Injury research center, ³Spinal Cord & Brain Injury research center, Dept. of Neurosci., Univ. of Kentucky, Lexington, KY

Abstract: We sought to test whether transplanting purified mitochondria into contused rat spinal cords results in 1) incorporation into various host cell types, 2) preservation of acute host cell bioenergetics, and 3) long-term functional neuroprotection. For visualization of transplanted mitochondria, we used transgenically modified PC-12 cells in which mitochondria were labeled with tGFP. Alternatively, and for clinical relevance, we also transplanted mitochondria isolated from syngeneic rat soleus muscle. Freshly isolated tGFP (50, 100 or 150 μ g total) or muscle (50 or 100 μ g total) mitochondria were microinjected into the penumbra of severely contused spinal cords within 1 hr after injury at L1/L2 (250 kdyn, IH Impactor) in adult female Sprague-Dawley

rats. Depending on outcome measures, they survived 24 hr, 48 hr, 7 days or up to 6 weeks. Results showed that transplantation of either tGFP (n=6-7/group) or muscle (n=3-4/group) mitochondria significantly (p<0.05) maintained bioenergetics of injured spinal cord tissues 24 hr after injury, with maximum effects at the 100ug dosage. Confocal imaging showed prominent rostro-caudal spread of exogenous tGFP mitochondria from injection sites after 24-48 hr that dissipated by 7 days (n=4/time point). At the earlier time points, tGFP mitochondria co-localized conspicuously with microglia/macrophages and endothelial cells, with less incidences in astrocytes and oligodendrocytes, and none in neurons. Assessments of hindlimb functional recovery (BBB-LRS) and paw withdrawal latencies (Von Frey hair) over 6 weeks after transplanting 100ug tGFP or muscle mitochondria (n=8-11/group) showed no significant differences in hind limb locomotion or mechanical hypersensitivity compared to vehicle-injected injured groups. Morphometric analyses further showed no differences in grey or white matter tissue sparing. In summary, while intraspinal injections of mitochondria after spinal trauma improved cellular bioenergetics acutely, such maintenance of respiration did not translate into improved long-term functional neuroprotection. Ongoing studies are more fully characterizing the cell-type incorporation propensities and investigating the comparative effects of delayed grafting times.

Abstract: Injury to the adult mammalian central nervous system (CNS) leads to permanent deficits in sensory and motor function. Dorsal root ganglion (DRG) neurons are essential for sensorimotor function as they receive and convey sensory information from the environment to motor circuits in the spinal cord and ultimately, the brain. Here, we show that exposing mice to environmental enrichment (EE) prior to an injury induces a long-lasting increase in the regenerative potential of DRG neurons, priming them for robust axon regeneration after injury in both the peripheral and central nervous systems. The EE-mediated increase in axon regeneration is dependent on proprioceptive afferent feedback and increased neuronal activity leading to epigenetic reprogramming via CREB Binding Protein (CBP)-dependent histone acetylation. This results in gene expression changes in proprioceptive DRG neurons, increasing their intrinsic growth capacity. These findings highlight prior exposure to EE as a robust physiological means of priming sensory neurons for enhanced axon regeneration. Finally, we were able to mimic exposure to EE by delivering a small-molecule activator of the acetyltransferase CBP/p300 after spinal cord injury that promoted axonal regeneration and functional recovery.

Title: Phosphatidylethanolamine-binding protein reduces mu opioid receptor induced βarrestin2 recruitment and promotes opioid mediated antinociception

Authors: *J. E. LAVIGNE¹, K. A. EDWARDS², J. M. STREICHER¹

¹Dept. of Pharmacol., Univ. of Arizona Col. of Med., Tucson, AZ; ²Biomed. Sci., Univ. of New England, Biddeford, ME

Abstract: There is currently an opioid abuse epidemic occurring in the United States, due to many factors including over-prescribing and the lack of effective, side-effect null opioids. Current efforts employ multiple strategies to increase the therapeutic index of analgesics. These strategies include restricting opioid drugs to the site of injury, creating functionally selective compounds to elicit only therapeutic effects, and developing non-opioid drugs as analgesics. Unfortunately these methods have not fulfilled their promise or are slow to develop. Part of the reason is due to a lack of understanding of the signaling cascades and regulators involved in opioid receptor signaling. There are three opioid receptors, mu (MOP), delta (DOP), and kappa (KOP), with the majority of clinical opioid analgesic effects being mediated through the MOP. A proteomic screen performed after chronic morphine treatment has shown an upregulation of phosphatidylethanolamine-binding protein (PEBP) in the brain. PEBP is a novel kinase inhibitory protein which in its monomeric form binds and inhibits Raf-1 signaling; however after phosphorylation it dimerizes and binds g-protein receptor kinase 2 (GRK2). It has not been previously implicated in MOP signaling, however its interactions with Raf-1 and GRK2 suggest the potential. Here we utilize a combination of target knockdown using siRNA and pharmacological inhibition to show that PEBP decreases ßarrestin2 recruitment and increases morphine-mediated anti-nociception in vitro and in vivo. PEBP knockdown in vitro causes an increase in Barrestin2 recruitment to MOP by 30.2% without altering downstream Raf-1 to MAP kinase signaling. Disruption of the interaction between PEBP and its binding partners, Raf-1 and GRK2, via a covalent PEBP inhibitor locostatin causes a 41.7% decrease in the effectiveness of morphine in the tail flick assay, without altering performance in the rotarod test. Taken together these results suggest a role for PEBP whereby phosphorylation and subsequent dimerization can inhibit GRK2 and Barrestin2 recruitment, therefore enhancing opioid receptor signaling and antinociception. Investigation of the molecular mechanisms by which PEBP regulates MOP signaling and anti-nociception are currently under investigation. Eventually, PEBP may be

exploited for the creation of novel drug screening and development strategies, based on the elucidated function and mechanism we show here.

Title: Modulation of alcohol reward by a truncated variant of the mu opioid receptor gene OPRM1

Authors: T. G. BROWN¹, S. MARTINEZ², J. XU⁴, G. W. PASTERNAK⁵, Y. PAN⁴, *G. C. ROSSI³

¹Biochem. and Neurosci., Villanova Univ., Villanova, PA; ²Psychology and Biomed. Sci., ³Long Island Univ., Greenvale, NY; ⁴Neurol., ⁵Mem Sloan Kettering Cancer Ctr., New York, NY

Abstract: Alcohol use remains a global problem with approximately 10-20% of chronic alcohol users becoming alcoholics. Despite severe consequences, alcohol continues to be a rewarding and highly addictive substance as other drugs of abuse. The opioid system has long been hypothesized to involve alcohol reward. Recent work in our laboratories has led to the generation of a knockout (KO) mouse model in which exon 11 (E11) of the mu opioid receptor gene (OPRM1) was disrupted. In E11-KO mice, analgesia for several mu opioids, including M6G, fentanyl and heroin, was significantly reduced, while analgesic action for morphine and methadone was intact. Moreover, the analgesic action for a novel class of opioids, such as IBNtxA, that fails to produce the typical side effects associated with traditional opiates, was completely lost in E11-KO mice. To investigate the role of E11-associated variants in alcohol reward, we evaluated chronic alcohol self-administration in wild-type (WT) and E11 knockout (E11-KO) mice using a two bottle choice paradigm. Total consumption was measured over a 30day period with escalating concentrations of alcohol (2-10%). Results showed E11-KO mice drank significantly higher amounts of alcohol as compared to WT control mice, suggesting involvement of E11-associated variants in the rewarding effects of alcohol. Although alcohol is presumed to have a very different mechanism of action than heroin, the physiological properties of reward might use a common E11 genetic map.

Title: The nitric oxide-cGMP-ATP-sensitive K^+ channel pathway participates in the peripheral antinociceptive effect of nalbuphine, but not of buprenorphine on the rat formalin test

Authors: *M. I. ORTIZ¹, R. CARIÑO-CORTÉS¹, H. A. PONCE-MONTER¹, E. FERNÁNDEZ-MARTÍNEZ¹, G. CASTAÑEDA-HERNÁNDEZ² ¹Área Académica De Medicina, ICSA, UAEH, Pachuca de Soto, Mexico; ²Dept. de Farmacología, CINVESTAV. IPN., Ciudad de México, Mexico

Abstract: The aim of this study was to examine if the peripheral antinociceptive effects of the opioid agonist/antagonist nalbuphine and the opioid partial agonist buprenorphine involve the sequential participation of nitric oxide (NO) and cyclic guanosine monophosphate (cGMP) synthesis followed by potassium channel opening. We evaluated the participation of this pathway in the formalin test. Female Wistar rats (180-220 g) were injected in the dorsal surface of the right hind paw with 50 microliter of formalin (1%). Nociception was quantified as the number of flinches of the injected paw during 1 hour, whereas a reduction of the number of flinches was considered antinociception. Rats received a subcutaneous (s.c.) injection (50 microliter) into the dorsal surface of the right hind paw of vehicles or increasing doses of nalbuphine (50-200 µg/paw), buprenorphine (1-5 µg/paw) or pinacidil (a potassium channel opener; 25-100 µg/paw) 20 min before formalin injection into the ipsilateral paw. All compounds produced significant local peripheral antinociception (p<0.05). Nalbuphine effect was reverted by the s.c. injection into the ipsilateral paw of NG-L-nitro-arginine methyl ester (L-NAME, an inhibitor of NO synthesis; 10-100 µg/paw), by methylene blue (a non-selective inhibitor of guanylyl cyclase; 100-500 µg/paw), by glibenclamide or glipizide (ATP-sensitive K⁺ channel inhibitors; 10-100 µg/paw) and by 4-aminopyridine and tetraethylammonium (voltagedependent K⁺ channel inhibitors; 10-100 µg/paw). Pinacidil effect was blocked by glibenclamide and glipizide. The antinociceptive effect produced by buprenorphine was blocked by the s.c. injection of 4-aminopyridine (10-100 µg/paw) and tetraethylammonium (50-200 µg/paw), but not by glibenclamide (100 µg/paw), glipizide (100 µg/paw), L-NAME (100 µg/paw) or methylene blue (500 µg/paw). The present results suggest that the NO-cGMP-ATP-sensitive K⁺ channel pathway is involved in the peripheral antinociceptive effect of nalbuphine, but not of buprenorphine, and thus provide evidence for differences in peripheral mechanisms of action among these opioid drugs.

Title: Targeting delta opioid receptor- kappa opioid receptor (DOR-KOR) heteromers in peripheral pain sensing neurons: A strategy for peripheral analgesic drug development

Authors: *M. M. PANDO¹, B. A. JACOBS², E. M. JENNINGS², T. A. CHAVERA², W. P. CLARKE², K. A. BERG² ²Pharmacol., ¹Univ. of Texas Hlth. Sci. Ctr. San Antonio, San Antonio, TX

Abstract: Activation of DOR-KOR heteromers expressed on rat pain-sensing neurons (nociceptors) produces robust, peripherally-mediated, antinociception (Berg et al., 2012). Here we show that the ligand 6'-guanidinonaltrindole (6'-GNTI) is a selective agonist for DOR-KOR heteromers in peripheral nociceptors. Further, we provide evidence that DOR-KOR heteromers may be viable targets for peripheral analgesic drug development. Opioid-mediated inhibition of PGE2-stimulated adenylyl cyclase (AC) activity was measured in primary cultures of adult rat peripheral sensory neurons (ex vivo model). The efficacy of 6'-GNTI to inhibit AC was lost after siRNA knockdown of either DOR or KOR expression. Further, under these conditions, 6'-GNTI acted as an antagonist at both KOR and DOR suggesting that 6'-GNTI binds both DOR and KOR but agonist activity requires simultaneous occupancy of both receptors. To further validate that 6'-GNTI activates DOR-KOR heteromers in peripheral nociceptors, we tested effects of a TAT- peptide corresponding to the TM1 domain of DOR on a rat behavioral model of thermal nociception in response to DPDPE (DOR agonist), U50488 (KOR agonist) or 6'GNTI. Intraplantar injection of the DOR TM1-TAT peptide had no effect on DPDPE- or U50488-mediated reduction of PGE₂-evoked thermal allodynia, however, the anti-allodynic response to 6'-GNTI was lost completely. By contrast, a control TAT peptide had no effect on the antinociceptive response to 6'-GNTI. We next determined the ability of 6'-GNTI to reduce thermal nociception following induction of inflammation in the rat hind paw with carrageenan. Even though 6'-GNTI, as well as DPDPE and U50488 each inhibited carrageenan-induced nociceptive responses completely when injected 15 min after carrageenan, only 6'-GNTI inhibited nociception when tested 3h or 24h after carrageenan administration.

These results suggest that, unlike DOR and KOR, the DOR-KOR heteromer remains responsive for a prolonged period of time following inflammation induced by carrageenan. Thus, DOR-KOR heteromers expressed in peripheral nociceptors may be attractive targets for the development of drugs for improved treatment of pain.

Title: Functional selectivity profiles of U50,488 analogues at kappa opioid receptors (KOR) expressed in peripheral nociceptors

Authors: J. C. ZAMORA¹, T. A. CHAVERA¹, E. M. JENNINGS¹, S. N. JOHNSON², T. E. PRISINZANO², W. P. CLARKE¹, *K. A. BERG¹

Abstract: Functional selectivity describes the ability of agonists to differentially regulate individual signaling pathways coupled to a given receptor. By fine-tuning the structure of a ligand, the activity of therapeutically efficacious signaling can be enhanced whereas signaling that leads to adverse effects can be minimized. We have found that inhibition of peripheral painsensing neurons by activation of peripheral KOR has profound antinociceptive effects in rats. However, in addition to activation of Gai signaling leading to antinociceptive efficacy. The goal of this study was to determine if replacement of either the diamino group (analogues SJ-1-147 and SJ-1-163) or the phenacyl group (the analogue SJ-1-171) of U50488 altered KOR-mediated signaling and peripheral antinociceptive responses.

In primary cultures of adult rat peripheral sensory neurons (ex vivo model), all three analogues inhibited PGE2-mediated cAMP accumulation with similar potencies and efficacies as U50488. However, unlike U50488, all three analogues did not increase ERK activity. Ex vivo, U50488 inhibited release of the neuropeptide, CGRP, however, the concentration response curve (CRC) was U-shaped but rendered monotonic in the presence of the ERK inhibitor, U0126. By contrast, the CRCs for inhibition of CGRP release by SJ-1-147 and -163 were monotonic (not U-shaped) which is consistent with the loss of ERK signaling due to the structural modifications.

Interestingly, the CRC for SJ-1-171-mediated inhibition of CGRP release was U-shaped despite the loss of ERK signaling. In a rodent model of thermal nociception, intraplantar (ipl) injection of peripherally-restricted doses of U50488 produced antinociception with an inverted U-shaped dose response curve (DRC). By comparison, ipl injections of SJ-1-147 and -163 reduced PGE2-evoked thermal allodynia with monotonic DRCs. Consistent with the U-shaped CRC for inhibition of CGRP release, SJ-1-171 produced antinociception with an inverted U-shaped DRC. Overall, our data suggest that structural modifications of a KOR ligand can selectively alter its efficacy for individual signaling cascades, which may lead to improved therapeutic outcomes for peripherally-mediated analgesia.

Title: siRNA screening of Regulator of G Protein Signaling (RGS) and adenylyl cyclase (AC) genes to determine the mechanism of endomorphin cAMP biased signaling

Authors: A. KERESZTES, J. LAVIGNE, D. CHIEM, K. OLSON, *J. M. STREICHER Pharmacol., Univ. of Arizona, Tucson, AZ

Abstract: The opioid receptor family consists of three G-protein coupled receptors, the mu, delta, and kappa (MOR, DOR, KOR). These receptors are responsible for a constellation of overlapping (anti-nociception) and non-overlapping (reward, sexual behavior, etc.) physiological roles, and are often expressed together in the same synaptic regions. These receptors can be endogenously activated by opioid peptides such as endorphins, enkephalins, endomorphins, and dynorphins. However, we performed *in vitro* studies using human opioid receptors expressed in CHO and N2a cells, which revealed that these ligands possess similar potencies and efficacies in ³⁵S-GTP_γS coupling at MOR and DOR (except that endomorphins were selective for MOR, while only dynorphins activated the KOR). This creates a problem for how endogenous opioid peptides can selectively signal to different opioid receptors present in the same physical location. We hypothesized that biased agonism could be a potential mechanism to explain endogenous

ligand selectivity. We thus screened Dynorphin A and B, Endomorphin 1 and 2, Leu-enkephalin, and Met-enkephalin, along with reference ligand controls, in ³⁵S-GTP_YS coupling, βarrestin2 recruitment, and cAMP inhibition in CHO and N2a cells expressing the human opioid receptors. We found a significant bias of both Endomorphin 1 and 2 for cAMP signaling (vs. ³⁵S-GTP_YS coupling) at the MOR in both CHO and N2a cells. Seeking a mechanism for these changes, we reasoned that differential RGS protein regulation or differential AC isoform coupling could explain the bias of Endomorphin for cAMP signaling. By performing the cAMP assay in permeabilized cells in the presence of $GTP\gamma S$, we were able to equalize the potency of Leuenkephalin with the endomorphins, supporting our hypothesis and suggesting the involvement of RGS proteins in endomorphin biased signaling. However, the RGS4 inhibitor CCG-50014 had no effect on Leu-enkephalin vs. Endomorphin potencies, suggesting that this isoform is not involved. Since no other RGS inhibitors are commercially available, we designed and optimized an siRNA screen to sequentially knock down each of the ~22 RGS genes and 10 AC genes in MOR-N2a cells, to comprehensively test which of the genes is responsible for Endomorphin cAMP biased signaling. We report here our progress to date in carrying out this screen. Once identified, we will further test the molecular mechanism of the identified gene in Endomorphin biased agonism, and further confirm the role of the gene in vivo. This study thus promises to identify an important molecular mechanism of biased signaling, which could explain in part how endogenous peptides selectively signal in vivo.

Title: Characterization of DALDA peptides following bolus intrathecal delivery (1)

Authors: *S. A. WOLLER¹, S. KOKUBU¹, K. A. EDDINGER¹, P. W. SCHILLER^{2,3}, T. L. YAKSH¹

¹Anesthesiol., UCSD, La Jolla, CA; ²Montreal Clin. Res. Inst., Montreal, QC, Canada; ³Pharmacol. and Physiol., Univ. of Montreal, Montreal, QC, Canada

Abstract: The present studies characterized the potency and side effect profile of a series of small opioid peptides with high affinity for the mu opioid receptor. Male Sprague Dawley rats were prepared with chronic intrathecal catheters, assessed on hind paw thermal escape and

evaluated for side effects including Straub tail, truncal rigidity, pinnae and corneal reflex. In this work, TICP ([Dmt1]DALDA-(CH2)2-NH-TICP[psi]; MW=1519), DMT-DALDA (H-Dmt-D-Arg-Phe-Lys-NH2 MW=981), H-Dmt (H-Dmt-Cit-Phe-Lys-NH2 MW=868), Nle (H-Dmt-D-Cit-Phe-Nle-NH2 MW=739), and TAPP (H-Tyr-D-Ala-Phe-Phe-NH2 MW=659) were examined. 1) All agents resulted in a dose-dependent reversible effect upon motor function (Straub Tail > Truncal rigidity). 2) The ordering of analgesic activity (%MPE) at the highest dose (pmol) lacking reliable motor signs after bolus delivery was: DMT-DALDA (80%±6/3 pmol); H-DMT (75%±8 /1 pmol); Nle (84%±10 /300 pmoL); TAPP (56%±12 /10 nmol); TICP $(52\% \pm 27/300 \text{ pmol})$. 3) All analysic effects of all drugs were reversed by naltrexone (1mg/kg). Naltrindole (3 mg/kg) had minimal effect upon the maximum usable dose. Antagonists failed to reverse effects upon motor function. 4) Tolerance and cross-tolerance development after daily repeated bolus of DMT-DALDA (3 pmoL) and morphine (30 nmoL) revealed both agents displayed progressive decline over 5 days. Cross-tolerance assessed on day 5 revealed a significant reduction in the response to morphine in the DMT-DALDA treated animal but not DMT-DALDA in the morphine treated animal indicating an asymmetric cross- tolerance. These results emphasize the potent mu agonist properties of the DALDA structure series and their propensity to produce tolerance. The asymmetric cross-tolerance between equiactive doses may reflect upon the relative intrinsic activity of morphine and DMT-DALDA. (Supported by NIH R01-DA015353)

Title: Sustained release buprenorphine induces acute analgesic tolerance

Authors: *C. LARSON¹, K. KITTO², G. L. WILCOX³, C. A. FAIRBANKS⁴

²Neurosci., ¹Univ. of Minnesota, Minneapolis, MN; ³Dept Neurosci, Pharmacol, Dermatol, Univ. Minnesota Med. Sch., Minneapolis, MN; ⁴Depts Pharmaceut, Pharmacol & Neurosci, Univ. Minnesota, Minneapolis, MN **Abstract: Background:** A sustained-release formulation of buprenorphine is a widely used formulation in animal care and veterinary medicine. The manufacturer states serum levels are sustained for 72 hours following a single injection. Dose recommendations range from 0.5-1 mg/kg but veterinary recommendations range up to 2 mg/kg. These doses have not been comprehensively assessed for analgesic tolerance or opioid-induced hyperalgesia. We report that SR-Bupe 1 mg/kg induces analgesic tolerance within hours of delivery and high dose (2 mg/kg) induce responses suggestive of opioid-induced hyperlageisa.

Methods: Male ICR mice were injected with Complete Freund's Adjuvant in the hind paw and allowed to induce inflammatory hyperalgesia for 3 days prior to further testing. 0.1, 0.3, 0.5, 1, and 2 mg/kg doses (varied by volume of injectate) of sustained-release buprenorphine were delivered and paw von Frey thresholds were monitored for 1, 2, 3, and 24 hours post-injection. **Results:** The 1 mg/kg dose provided a 60% reversal in vF threshold responses for 1 and 2 hours which was greatly diminished by 3 hours and gone by 24 hours post-injection. Lower doses resulted in small analgesic effects. A high dose of 2 mg/kg showed no analgesia and some evidence of hypersensitivity.

Conclusion: Sustained-release buprenorphine induces rapid analgesic tolerance and high doses may evoke opioid-induced hyperalgesia.

Title: Optogenetic dissection of the descending pain modulatory system

Authors: *M.-H. LI, Q. CHEN, K. L. SUCHLAND, Y. ZHANG, M. M. HEINRICHER, S. L. INGRAM

Neurolog. Surgery, Oregon Hlth. and Sci. Univ., Portland, OR

Abstract: The descending pain modulatory system regulates nociceptive processing via projections from the brainstem to the spinal cord dorsal horn. Cortical and midbrain modulation

of pain is integrated by the periaqueductal gray (PAG) and rostral ventromedial medulla (RVM). RVM output neurons to the spinal cord can both facilitate and suppress nociception. This system also contributes to abnormal pain in animal models. We have used optogenetics to further understand the "bottom-up" inputs to RVM neurons, relays from spinal cord through the parabrachial area (PB), as well as "top-down" inputs from the PAG to RVM. Channelrhodopsin (ChR2) AAV viral vectors (AAV9.hSyn.hChR2(H134R)-EYFP.WPRE.hGH, Penn Vector Core) were microinjected into the PB complex and whole-cell patch-clamp recordings from in vitro brain slices containing the RVM were done 2-4 weeks later. Light stimulation of ChR2expressing terminals from PB to RVM elicited synaptic currents in 29 neurons. 21/29 of the neurons had synaptic currents that were blocked by glutamate antagonists but were unaffected by a GABA_A receptor antagonist bicuculline (BIC) indicating a direct glutamate projection. The remaining 8/29 RVM neurons had light-evoked synaptic currents that were blocked by BIC but were unaffected by glutamate antagonists indicating that they were direct GABAergic inputs. These data provide evidence that direct PB inputs to RVM neurons release either glutamate or GABA but not both onto individual RVM neurons. Microinjections of ChR2 into the PAG elicited a different profile of inputs to the RVM. Many RVM neurons receive both direct glutamate and GABA inputs. There is also evidence of local recurrent synaptic activity following light stimulation of ChR2-expressing terminals from PAG. Examination of opioid and cannabinoid modulation of inputs from these specific circuits demonstrates differential sensitivity to these modulators. One striking result is that the mu opioid receptor agonist, metenkephalin, strongly inhibits glutamate inputs from both PB ($80 \pm 5\%$, n = 6) and PAG ($56 \pm$ 8%, n = 11), in addition to the canonical inhibition of GABA inputs from the PAG ($43 \pm 9\%$, n = 6). In contrast, the cannabinoid agonist WIN 55,212 inhibits only PAG GABA inputs to RVM neurons $(39 \pm 7\%, n = 8)$ with little effect on glutamate inputs $(9 \pm 3\%, n = 12)$. We have previously demonstrated plasticity in the endocannabinoid system in persistent inflammation. These results indicate that opioids and cannabinoids may target separate circuits, providing a cellular substrate for new pain therapies via selective targeting of specific descending circuits that mediate pain inhibition versus pain facilitation.

Title: Imatinib prevents morphine tolerance without inducing MOR endocytosis

Authors: *S. PUIG, P. M. WHITE, S. R. SZOTT, H. B. GUTSTEIN Univ. of Pittsburgh, Pittsburgh, PA

Abstract: Analgesic tolerance limits the use of opioids for the treatment of chronic pain. It was previously hypothesized that sustained signaling by the mu opioid receptor (MOR) could cause morphine tolerance, which could be prevented by promoting MOR endocytosis. However, some studies have challenged this theory. We have shown that Imatinib, by inhibiting PDGFR- β (platelet-derived growth factor receptor-beta), selectively prevents morphine tolerance. In this study, we determine whether inhibition of morphine analgesic tolerance with Imatinib involves endocytosis of the MOR. Rats were injected i.t. with either vehicle, 0.6 nM morphine, 10 µg imatinib or morphine + imatinib. Analgesia was measured daily using tail flick latency (TFL). After either one or five days of treatment, spinal cords were extracted and processed for immunohistochemistry with anti-NeuN (Millipore) and anti-MOR (Abcam) antibodies. Images of the substantia gelatinosa (SG) were analyzed using confocal microscopy. The average number of internalized vesicles containing MOR in neurons was determined utilizing an automated, unbiased software algorithm (Imaris, Bitplane). Co-administration of Imatinib with morphine prevented tolerance without altering morphine's analgesic effect. Interestingly, the levels of MOR internalization in SG neurons were not different between groups. Our results show that imatinib did not prevent tolerance by promoting MOR endocytosis, challenging the hypothesis that the lack of MOR internalization could be the cause of morphine tolerance.

Federal de Mato Grosso do Sul, Campo Grande, Brazil

Abstract: Background: Spinal opioids yield potent naloxone-reversible analgesia. Continuous infusion produces masses (granulomas) composed of meningeally-derived fibroblasts in a collagen matrix. The initiating step may be degranulation of meningeal mast cells through a nonopioid-receptor-mediated mechanism (*Anesthesiology*.118:664,2013). We examined spinal opioid analgesic molecules for their ability to degranulate mast cells in vivo (mast-cell-dependent flare after intradermal injection in dog) and in vitro (degranulation of primary human mast cell (hMC) cultures).

Methods: The area of skin flares produced by intradermal (ID, 50µL) injections in anesthetized male Beagle dogs were measured 30 minutes after injection. Degranulation of primary hMC was determined using ß-hexosaminidase concentrations in culture supernatant. Drugs studied included nonpeptide and peptide opioid agonists and an N-type Ca channel blocker (ziconotide). **Results:** Ordering of flare area after ID delivery of nonpeptidic opioids (0.1-10mg/mL) was: (morphine, hydromorphone, methadone, morphine-3- glucuronide, morphine-6- glucuronide) >> (alfentanil, fentanyl) = 0. For peptides, rank ordering was ziconotide > (DPDPE, TICP, DMT-DALDA, [Dmt¹,Nle⁴]DALDA) >0 (see AAPSJ. 14:E560-5, 2005 for structures). Flares were reduced by cromolyn (10mg/kg, IM), a mast cell stabilizer, but not naltrexone (3mg/kg). In hMCs, ordering of degranulation potency covaried with cromolyn-sensitive flare activity. Conclusions: Agents producing intrathecal masses in dogs and/or humans showed a high correlation with the ability to produce a cromolyn-sensitive flare and hMC degranulation (morphine, hydromorphone, methadone, DPDPE) whereas those that did not yield a flare have not been observed to yield a granuloma (alfentanil, fentanyl). Ziconotide is a potent mast cell degranulator, but is not associated with granulomas, presumably because concentrations required to produce analgesia are lower than those required to degranulate mast cells. Accordingly, the propensity to produce a cromolyn-sensitive flare increases the likelihood of a granuloma if the therapeutic concentration required approaches those producing degranulation. Title: Inhibition of fatty acid amide hydrolase in the insular cortex produces analgesic effects in neuropathic rats

Authors: *K. KIM^{1,2}, M. KIM^{1,2}, B. LEE^{1,2}

¹Yonsei University, Grad. Sch. Dept. of Med. Sci., Seoul, Korea, Republic of; ²Brain Korea 21 PLUS Project for Med. Sci., Yonsei University, Seoul, Korea, Republic of

Abstract: The insular cortex (IC) is one of important brain regions involved in the processing of pain information and emotions. According to recent studies, lesion of the IC induced pain asymbolia and reversed neuropathic pain. Previously, anodynes such as anti-inflammatory drugs, anticonvulsants, and opioids were used to treat neuropathic pain despite the lack of efficacy or unexpected side effects. Cannabinoids have been used for treating diverse illnesses including pain for centuries. However, cannabinoids have several unpredictable outcomes in animals and humans. Particularly, plant-derived cannabinoids have critical side effects such as euphoria, hyperphasia and hyperphagia. These physiological actions are produced via an endogenous cannabinoid neurotransmission system that involves mainly the G-protein coupled receptors named cannabinoid 1 Receptor (CB1R) and cannabinoid 2 receptor (CB2R). Increasing the endocannabinoid anandamide by blocking fatty acid amide hydrolase (FAAH) has shown analgesic effects in neuropathic pain models. However, analgesic effects via FAAH inhibition in the IC have yet to be determined in neuropathic pain rats. Therefore, the present study was conducted to reveal the analgesic effect of the selective FAAH inhibitor URB597. Under pentobarbital anesthesia, male Sprague-Dawley rats were subjected to nerve injury. Behavioral test with electronic von Frey was performed. Nerve-injured rats were treated with microinjections of or vehicle in the IC. In addition, the FAAH signaling pathway-related proteins were extracted and quantitatively analyzed from the IC tissue. Neuropathic pain was developed indicative of decreased level of hind paw withdrawal thresholds 14 days following nerve injury, In addition, the expression of CB1R increased significantly in neuropathic pain group compared to the sham-operated control group. In the behavioral test followed by microinjections, the mechanical threshold significantly decreased in the group treated with 2 nM and 4 nM URB597. As a result, the level of NAPE-PLD increased in the group injected with 2nM and 4nM URB597. These results suggest that the microinjection of FAAH inhibitor into the IC exhibits an analgesic effect, indicating the increase in NAPE-PLD, a synthetic enzyme of AEA in the IC. This work

Title: Reduced antinociceptive responses to mu but not kappa opioid agonists in aged rats

Authors: *E. JENNINGS, H. SMITH, L. SULLIVAN, R. JAMSHIDI, K. A. BERG, W. P. CLARKE

Pharmacol., UT Hlth. San Antonio, San Antonio, TX

Abstract: Moderate to severe pain can significantly increase risk of disability and reduce quality of life in the elderly. Therefore improved pain management in the aged population is a major concern for both health care providers and researchers. Opioid drugs that target mu opioid receptors (MOR) continue to be the gold standard for treatment of pain. Unfortunately there are serious adverse effects that limit their use particularly in the elderly. Peripherally restricted opioids that inhibit the function of pain-sensing neurons (nociceptors) and do not enter the CNS would be safer and better tolerated drugs to relieve suffering in older adults. However little is known regarding the effects of aging on nociceptor responsiveness in the periphery and there is some evidence that aging is associated with reduced peripheral sensitivity to MOR agonists. We examined the effects of MOR agonists morphine (100 µg, 150 µg) and DAMGO (20 µg, 40 µg) and the kappa opioid receptor (KOR) agonist, Salvinorin A (0.1 µg), in young (4-months-old) and aged (26-months-old) Fisher x Brown Norway rats. Behavioral responses to noxious heat were measured following intraplantar injections of opioid agonists. In addition, we measured mRNA expression of MOR and KOR in the L4-L6 dorsal root ganglia (DRG) of aged and young rats using RT-qPCR. Intraplantar administration of Salvinorin A produced significant antinociceptive responses in both aged and young rats. However morphine and DAMGO failed to attenuate nociceptive behavior in aged rats while producing a robust antinociceptive effect in young rats. Additionally we found that MOR expression in the DRG was 7 times higher in aged rats compared to young, suggesting compensatory mRNA overexpression. By contrast, there was
no difference in KOR expression. Overall these data suggest that peripherally restricted kappa agonists may be more effective analgesics than mu agonists to treat pain in the elderly.

Title: DOPr displays constitutive internalization and sorting to the rapid recycling pathway

Authors: *S. GRASTILLEUR¹, J. SIMARD¹, V. BLAIS², J.-L. PARENT², C. LAVOIE², L. GENDRON²

¹Univ. De Sherbrooke, Sherbrooke, QC, Canada; ²Pharmacol. & Physiol., Univ. of Sherbrooke, Sherbrooke, QC, Canada

Abstract: The delta opioid receptor (DOPr) is currently among the most promising targets for the development of new analgesic therapies. Despite a low efficacy under normal conditions, we have previously demonstrated that chronic inflammation or a treatment with morphine can improve DOPr-mediated antinociception. Interestingly, this effect is paralleled by an increased density of DOPr at the neuronal plasma membrane, but the underlying mechanism explaining this increase remains elusive. In the current study, we investigated constitutive internalization as a potential mechanism controlling the level of DOPr expressed at the cell surface. In HEK293 cells stably expressing Flag-tagged DOPr, we first confirmed that DOPr internalizes constitutively, *i.e.* in the absence of agonist. Immunofluorescence experiments revealed that internalized DOPr colocalizes with Rab5-positive early endosomes. When a constitutively active Rab5 mutant (Rab5 QL) was expressed, we found that internalized DOPr remains trapped in early endosomes. Conversely, an inactive form of Rab5 (Rab5 SN) decreases internalization of the receptor. The absence of DOPr colocalization in Rab7-positive late endosomes suggests that constitutively internalized DOPr is not directed to lysosomes for degradation. The presence of DOPr in Rab4- and Rab11-positive endosomes, which are respectively involved in rapid and late recycling pathways, was also studied. Within these compartments, we observed that DOPr mainly colocalizes with Rab4-positive endosomes. Altogether, these results suggest that upon constitutive internalization through a Rab5-dependent pathway, DOPr is rapidly recycled to the

cell surface via Rab4-positive endosomes. Undergoing experiments aim at determining whether this process can be modulated by morphine under chronic pain conditions. Understanding the mechanisms regulating this process may lead to the identification of a new pharmacological target for pain management by DOPr activation.

Abstract: Opioids are the most effective pharmacological tools to treat moderate to severe pain; however, the use of opioids for the treatment of chronic non-cancer pain is controversial due to concerns about tolerance, abuse, and addiction. MPEP, an mGluR₅ antagonist, has been shown to increase the analgesic efficacy of opioids while simultaneously decreasing the development of analgesic tolerance and addiction. MMG22 is a novel bivalent ligand made of two pharmacophores derived from oxymorphone, a MOR agonist, and M-MPEP, an allosteric mGluR₅ antagonist, linked via a 22-atom spacer. Previous studies have shown intrathecal administration of MMG22 to be incredibly potent at decreasing inflammatory pain without tolerance or respiratory depression. In the present studies, we sought to characterize the ability of MMG22 to modulate neuropathic pain, evaluate its abuse potential and elucidate its site of action. These studies used the spared nerve injury model of neuropathic pain in male C57/B6 mice. Hyperalgesia was quantified by determining the frequency of withdrawal responses evoked by a von Frey monofilament with a bending force of 3.5 mN applied to the plantar surface of the paw. To evaluate the antinociceptive effects of MMG22 or morphine, paw withdrawal frequency

(PWF) was determined before and after subcutaneous (sc) administration of each drug at doses ranging from 0.001mg/kg to 1mg/kg. We also assessed the rewarding properties of MMG22 as compared to morphine in naïve mice using a conditioned place preference assay. Expression and localization of mGluR₅ and MOR in the mouse spinal cord superficial dorsal horn were assessed using immunohistochemistry and fluorescence microscopy. Preliminary results show that while MMG22 is effective in producing antinociception, supra-threshold doses do not produce conditioned place preference. Both MOR and mGluR₅ are expressed in the superficial dorsal horn of the spinal cord of Naïve mice, suggesting the spinal cord as a potential site of action. MMG22 has the potential to be an effective therapeutic for the treatment of neuropathic pain that may lack the addictive properties of traditional opioid analgesics.

Title: A conditional knockin mice to study the delta opioid receptor in pain pathways

Authors: *L. GENDRON¹, K. ABDALLAH¹, J. DEGRANDMAISON¹, V. BLAIS¹, K. BRADBURY², F. BERGERON¹, K. FONTES², C. LAVOIE¹, C. M. CAHILL³, J. BOULTER⁴, J.-L. PARENT¹ ¹Univ. De Sherbrooke, Sherbrooke, QC, Canada; ²Bishop's Univ., Lennoxville, QC, Canada;

³Anesthesiol. & Perioperative Care, Univ. of California Irvine, Irvine, CA; ⁴Univ. of California Los Angeles, Los Angeles, CA

Abstract: Due to their limited adverse effects, delta opioid receptors (DOPrs) represent a promising target for the treatment of chronic pain and emotional disorders. Although DOPr agonists produce only weak analgesic effects in healthy animals and in acute pain models, we and others have previously shown an increased in their potency to relieve chronic pain (e.g. inflammatory, neuropathic, and bone cancer-induced pain). Interestingly, we observed that this increase in the analgesic effects of DOPr agonists is paralleled by a translocation of DOPr from the intracellular compartment to the plasma membrane. In order to study the roles of DOPr *in*

vivo and to study the molecular and cellular mechanisms regulating its trafficking, we have generated a genetically-engineered mouse in which a Flag epitope has been introduced between the first and second amino acids of DOPr. A floxed translational stop cassette was also introduced upstream of the initiation codon. In the absence of recombination, these mice (STOP::Flag-DOPr) behave as DOPr knockout mice. A mouse line expressing a Flag-tagged DOPr in place of the endogenous receptor (Flag-DOPr knockin) was then generated by breeding the STOP::Flag-DOPr mice with Zp3-Cre mice. A thorough characterization of these mice reveals that the Flagged receptor is expressed at similar levels and in the same areas as its endogenous counterpart. In these mice, we found that DOPr agonists produce similar behavioral effects than in wildtype animals, suggesting that the Flag-DOPr knockin mice display similar pharmacological and behavioral properties than mice expressing endogenous DOPr. These appear as a useful complement to already available genetic mouse models (ex. DOPr-KO and cKO-, DOPr-eGFP knockin) to study the role and the regulation of DOPr, *in vivo*. In particular, one could use these mice to identify the role of DOPr in a specific brain region/subpopulation of neurons or to identify new protein partners in a natural environment.

Title: NR2B subunit mRNA is upregulated in the spinal cord following development of analgesic tolerance to intrathecal opioids and inflammation

Authors: *H. VERMA¹, C. PETERSON², K. PFLEPSEN³, C. A. FAIRBANKS⁴, K. KITTO³, G. L. WILCOX⁵

¹Pharmaceutics, Univ. of Minnesota Twin Cities, Minneapolis, MN; ²Pharmaceutics, ³Univ. of Minnesota, Minneapolis, MN; ⁴Depts Pharmaceut, Pharmacol & Neurosci, Univ. Minnesota, Minneapolis, MN; ⁵Dept Neurosci, Pharmacol, Dermatol, Univ. Minnesota Med. Sch., Minneapolis, MN

Abstract: Background: The NMDA receptor is known to contribute to the development of analgesic tolerance to spinal administration of opioids as well as development of chronic pain. It is thought that the NR2B receptor subunits are expressed in a site-specific manner that could

may offer an advantage in therapeutic targeting. Little is known about the expression of specific subunits of the NMDA receptor in spinal cord dorsal horn under conditions of chronic opioid exposure and pain. We evaluated mRNA expression of NR2B and NR2A specific subunits following chronic spinal morphine and CFA exposure.

Methods: ICR male mice were injected intrathecally twice daily for up to 4 days with 10 nmol of morphine or saline (5 μ L). Thermal sensory responses to tail flick (52.5°C) were monitored daily 10 min. following the second daily injection. In a second set of animals, CFA was injected to induce inflammation and von Frey thresholds monitored. At conclusion of the tolerance induction schedule or the CFA inflammation time course, mice were anesthetized and spinal cords, DRGs, were extracted and prepared for mRNA analysis. Total RNA was isolated by TRIzol method and the mRNA abundance for NR2A, NR2B & 18S was determined by one-step RT-qPCR. The fold change in expression levels of NR2A & NR2B in morphine group v/s saline group were calculated by relative quantitation method.

Results: Thermal sensory responses diminished daily with increasing numbers of injections of morphine as expected. Analgesic tolerance was induced. The mRNA expression was increased 9-28 fold for NR2B in mice exposed to morphine, but not saline. In mice exposed to CFA, mRNA expression was increased 15-fold on day 3 and 2-fold on day 7 for NR2B. For NR2A, mRNA levels were not changed in any group.

Conclusion: This study supports the hypothesis that the NR2B subunit is upregulated under conditions of neuroplasticity, including opioid induced tolerance.

Title: Decreased morphine analgesia in t-cell deficient mice

Authors: *S. F. ROSEN¹, B. HAM¹, M. HAICHIN², S. TOHYAMA², S. SOTOCINAL², J. S. MOGIL²

¹Psychology, ²McGill Univ., Montreal, QC, Canada

Abstract: It is now known that neurons are not the only cell type involved in pain processing, which involves cell of the immune system, such as T-cells. Many pain researchers have adopted the use of T-cell deficient mice in their experimental methods to elucidate the role of T-cells in neuropathic pain (Yu et al., 2004; Costigan et al., 2009), and T cells have been shown to release endogenous opioids (Bouè et al., 2011). While it is well known that opioids have varying effects on T-cell populations (Wang et al., 2003), very little attention has been given to how T-cells may affect opioid regulation. Here, we observe that T-cell deficient mice (CD-1 nude and Rag1 null mutant) exhibit pronounced deficiencies in morphine analgesia, measured using the tail withdrawal or formalin test. In addition, T-cell deficient mice do not exhibit stress-induced analgesia after restraint. The adoptive transfer of CD4+ T-cells into nude mice rescues the morphine analgesia. Furthermore, there are reported sex differences in morphine analgesia, with females requiring 2-3 times more morphine than males to produce equal analgesia. We observe an equivalent sex difference in CD1 mice, however T-cell deficient mice do not exhibit a sex difference in morphine analgesia. The sex difference in morphine analgesia is restored in nude male and female mice receiving CD4+ T-cells from their respective sex. These results suggest that CD4+ T-cells play a role in opioid analgesia, and may be a driver of the observed sex differences in morphine analgesia.

Title: Opiod activation of fibroblast

Authors: *R. RAMACHANDRAN¹, Y. HE¹, Y. ZHU¹, D. QUANG¹, F. WERREN¹, Z. WANG², S. MALKMUS¹, B. ELICEIRI³, A. DINARDO², T. L. YAKSH¹ ¹Anesthesia, ²Dermatol., ³Surgery, UCSD, LA Jolla, CA

Abstract: Background: Continuous intrathecal infusion of morphine can produce a potent analgesia and in several species including humans produce a space-occupying mass composed of

meningeal fibroblasts in a collagen matrix. This effect is not prevented by naltrexone (Anesthesiology, 118:664-678,2013). We addressed the effects of opiates on the migration and proliferation of mouse embryonic fibroblasts (MEFs) and meningeal fibroblasts. **Methods:** MEFs (ATCC #CRL-2214) were cultured in media consisting of 1x DMEM supplemented by 10% non-heat inactivated fetal bovine serum, 1% Pen Strep, 1% sodium pyruvate (100mM), 1% Glutamax 100x and 1% MEM non-essential amino acids. Cells were Incubated at 37°C in a humidified 5% CO2 environment and grown to 70---90% confluence. For cell migration assay, cells were plated onto the top of trans-well plates (50K/well/200 ul) precoated with collagen (1µg/mL) and incubated for 4 hrs. Cells were counted after removing the top layer and staining. To assess proliferation MEFs were seeded (2x 10⁴ cells/chamber) in 12 well plates and incubated for 24 hrs, followed by 48 hrs incubation with test material. In both assays, cells were exposed to concentration of morphine or fentanyl and then with naloxone at the optimal concentration. We also measured collagen I mRNA in rat meningeal fibroblasts following morphine treatment.

Results: In the migration assay, morphine and fentanyl treatment on MEF cells induced significant migration at doses 2-20 μ M and 0.2-2 μ M, respectively. At higher doses, suppression of migration was observed. Naloxone (20 μ M) did not reverse migration induced by both morphine and fentanyl. In the proliferation assay, morphine enhanced proliferation of MEF cells in a dose-dependent manner with maximum effect observed at 0.3 μ M. At higher doses, a suppression of proliferation was observed. Fentanyl, however, did not show similar effects on proliferation as morphine. Morphine at 10 μ M dose showed 1.73-fold significant increase in collagen type I mRNA in rat meningeal fibroblasts.

Conclusions: These results show that morphine increased both migration and proliferation of MEF's, whereas fentanyl increased migration but not proliferation. The effects of morphine and fentanyl on migration occurred in a naloxone-independent fashion. Further, increase in collagen type I mRNA suggests that morphine enhances the synthesis of collagen type I in MEF's that forms the matrix in granuloma formation. These results suggest that these two opiates enhance fibroblast function independent of the opiate receptors.

Title: An investigation of the influence of endogenous anxiety on opioid sensitivity in a model of osteoarthritis pain

Authors: *A. LILLYWHITE¹, J. BURSTON¹, G. J. HATHWAY², V. CHAPMAN¹ ¹Sch. of Life Sciences/ Arthritis Res. UK Pain Ctr., ²Sch. of Life Sci., Univ. of Nottingham, Nottingham, United Kingdom

Abstract: Introduction

Osteoarthritis (OA) is often associated with joint pain that can be difficult to treat. Patients with OA and co-morbid anxiety or depression experience more pain, take more medication and experience worse outcomes than patients without these co-morbidities. In particular, opioid use to provide analgesia is associated with catastrophizing after total joint replacement and may be a predictor of risk for opioid misuse in chronic pain patients. The aim of this study was to use an animal model to investigate the mechanisms underlying the relationship between anxiety, knee pain and opioid receptor function in a model of OA pain. Methods

The Wistar-Kyoto (WKY) strain of rats, which is more vulnerable to anxiety, was used with Wistar rats as normal anxiety controls. Male adult rats (125-150g) were anaesthetised (3% isoflurane) and received an intra-articular injection of 1mg monosodium iodoacetate or vehicle into the left knee. Sensory processing was measured using weight bearing asymmetry (WB) and mechanical hindpaw withdrawal thresholds (PWTs) up to day 21 post injection. The open plus maze was used to measure anxiety prior to intra-articular injection (day 0) and 21 days later. At this timepoint, 3 doses of morphine (0.5, 2.0 and 3.5mg/kg, cumulative dose 6 mg/kg) were injected subcutaneously (hourly) in MIA-treated WKY and Wistar rats, WB and PWTs were measured. In separate groups of rats 21 days following intra-articular injection, the opioid receptor antagonist naloxone was administered subcutaneously (0.1, 0.3 and 1mg/kg, hourly) and PWTs were measured. Data were analysed with a 2-way ANOVA with GraphPad Prism 7.01. Results

MIA-treated Wistar rats and WKY rats exhibited significant pain behaviour at day 21. Only the WKY rats showed an anxiety-like phenotype at baseline and this was increased at day 21, irrespective of the treatment received. 0.5 mg/kg of morphine significantly inhibited pain behaviour (WB: 29.89g versus 54.57g, p=<0.0001; PWTs: 22.2g versus 15.7g, p= 0.035) in the MIA-treated Wistar rats, whereas only 6mg/kg inhibited pain behaviour in MIA-treated WKY rats, weight bearing asymmetry (p= 0.0023) and PWTs (p = 0.0024). Naloxone (0.3 and 1 mg/kg) lowered ipsilateral PWTs, irrespective of whether they had received intra-articular injection of MIA or vehicle, in WKY rats but not in Wistar rats. These data suggest there are changes in opioid receptor function / endogenous tone in WKY rats which may lead to the reduced opioid sensitivity of pain behaviour in the MIA model of joint pain.

Title: An essential role of RGSz1 in signal transduction events underlying opioid tolerance and addiction-related behaviors

Authors: S. GASPARI¹, I. PURUSHOTHAMAN¹, V. COGLIANI², L. SHEN¹, *V. ZACHARIOU³

¹Fishberg Dept. of Neurosci., Icahn Sch. of Med. at Mount Sinai, New York, NY; ²Fishberg Dept. of Neurosci. and Friedman Brain Inst., Icahn Sch. of Med. at Mount Sinai, New York, NY; ³Neurosci., Mount Sinai Sch. of Med., New York, NY

Abstract: Regulator of G protein signaling z1 (RGSz1) is a member of the RGS family of proteins, known to modulate the amplitude and direction of signal transduction of several G protein coupled receptors (GPCR) by binding to activated Galpha subunits. RGSz1 is expressed in moderate amounts throughout the brain, and is present in several regions expressing mu opioid receptor (MOPR). Using genetic mouse models for global or brain region-targeted manipulations of RGSz1 expression, we demonstrate that the analgesic efficacy of MOPR agonists such as morphine, fentanyl and methadone is increased by preventing RGSz1 action. Specifically, the downregulation of RGSz1 delays the development of morphine tolerance in male and female mice, while decreasing the sensitivity to rewarding and locomotor activating effects. Using biochemical assays and next-generation RNA sequencing, we identified a key role of RGSz1 in the periaqueductal gray (PAG) in intracellular adaptations associated with morphine tolerance. Our analysis revealed a robust downergulation of the Wnt/beta-catenin signal transduction pathway in the PAG of morphine tolerant mice. Chronic morphine administration promotes RGSz1 activity in the PAG, which in turn modulates transcription mediated by the Wnt/betacatenin signal transduction pathway and promotes analgesic tolerance to morphine. Conversely, prevention of RGSz1 action stabilizes Axin2-Galphaz complexes, and promotes the action of beta-catenin as transcriptional activator. These data show that the regulation of RGS complexes, particularly those involving RGSz1-Galphaz, represents a promising target for optimizing the analgesic actions of opioids without increasing the risk of dependence or addiction.

Title: Test

Authors: *A. E. KALYUZHNY, R. REED, J. HAGEN, N. HOPP, M. GRAHEK, A. PTAK, J. HUMPHREY, G. DU, P. MURTHA, B. AGGELER Bio-Techne, Minneapolis, MN

Abstract: Mu-opioid receptors encoded by OPRM1 gene mediate the actions of different narcotic analgesic including morphine and fentanyl which are widely used in hospitals all over the world. It has been found that mu-opioid receptors exist as multiple splice variants of the OPRM1 gene mediating different pharmacological activity of opioids. For example, C-terminal splice variants such as MOR1, MOR1A and MOR1B are widely distributed in rat CNS with levels of MOR1 and MOR1A being greater than MOR1B. To study the anatomical distribution of MOR1A expressing neurons among all OPRM1 neurons in rat brain we combined RNAscope® ISH protocol using a MOR1A probe with IHC. For IHC detection we generated rabbit anti-rat mu-opioid receptor monoclonal antibodies directed at the N-terminus. The open reading frame for rat mu-type opioid receptor (OPRM1/MOR1, amino acid 1-398, P33535) was isolated from a rat cDNA library by PCR. After the DNA sequence was confirmed, the construct was cloned into an expression vector with an antibiotic selection marker. The expression plasmid was transfected into HEK293EBNA cells by calcium phosphate precipitation and stable clones were selected. Expression levels were measured by fluorescence intensity using flow cytometry. Using 10 um thick formaldehyde-fixed frozen rat brain tissue sections we developed a 2-color fluorescence detection protocol allowing to identify neurons co-labeled for OPRM1 protein and MOR1A splice variant message. We observed a low number of double-labeled neurons in brain cortex, hippocampus and caudate putamen. A more profound double-labeling was observed in ventral lateral PAG and rostral ventral medulla representing the descending antinociceptive brainstem circuit. All ISH-positive neurons were always IHC-positive indicating that our rabbit monoclonal antibodies are highly specific for rat OPRM1. The number of neurons doublelabeled by IHC and ISH was a fraction of all OPRM1-immunoreactive neurons suggesting that such neurons express splice variants of mu-opioid receptor other than MOR1A. Combining ISH and IHC can be a useful tool to study the ratio of neurons expressing different OPRM1 splice variants in different brain regions.

Abstract: Concerns over the unwanted side effects of commonly used opioids have increased interest in the development of novel treatments which provide adequate pain relief without the associated risk for addiction. The impact of drugs that target peripheral opioid receptors on the activity of nociceptors has not been fully explored. Loperamide (Lo) is a highly efficacious μ -opioid receptor agonist that does not activate receptors in the central nervous system, and oxymorphindole (OMI) is a δ -opioid receptor agonist that shows a synergistic effect with morphine or loperamide in the spinal cord. Behavioral studies have shown that these drugs have a synergistic analgesic effect when administered peripherally, including by topical application to the hindpaw. To test the impact of these drugs on nociceptor activity, our study used teased-fiber electrophysiology in the tibial nerve of adult *Na*_v*1.8*⁺-*ChR2* mice, which co-express the voltage-gated sodium channel Na_v*1.8* along with the light-sensitive channelrhodopsin2. In C-fiber nociceptors (*n* = 4) that were responsive to blue light stimulation, transdermal application of a

series of Lo/OMI concentrations (0.5 μ M, 5.0 μ M, and 50.0 μ M) reduced the number of impulses in response to a 5 s suprathreshold blue light stimulus 15 min after application. The degree of attenuation increased with dose, consistent with behavioral studies. Ongoing studies aim to determine how Lo/OMI affects nociceptor sensitization during ongoing inflammatory pain.

Title: Peripherally restricted opioid combination therapy synergizes in multiple pain states

Authors: *D. J. BRUCE¹, C. D. PETERSON², K. F. KITTO³, C. HARDING-ROSE⁴, K. D. WICKMAN¹, C. A. FAIRBANKS⁵, G. L. WILCOX⁶

¹Pharmacol., ²Exptl. and Clin. Pharmacol., ³Neurosci., ⁴Diagnos. and Biol. Sci., ⁵Pharmacology, Exptl. and Clin. Pharmacology, Neuroscience, Pharmaceutics,, ⁶Pharmacology, Neuroscience, Dermatol., Univ. of Minnesota, Minneapolis, MN

Abstract: The adverse effects of opioid pharmacotherapy are largely mediated by the activation of mu-opioid receptors (MORs) in the central nervous system. However, opioid receptors also mediate analgesia on the peripheral terminals of primary sensory afferents. Despite more than a decade of research directed at developing peripherally restricted opioids, no analgesic to date has delivered on the promise of effective pain control without the risk for addiction and diversion. Therefore, we studied the ability of loperamide (Lo), a highly efficacious MOR agonist that is excluded from the CNS, and oxymorphindole (OMI), a DOR agonist that was shown to synergize with morphine spinally, to mediate peripheral analgesia when administered alone, or in combination. We studied this combination in spinal cord slices to determine whether Lo and

OMI synergize spinally to inhibit neurotransmitter release from the central terminals of nociceptors. Our recordings indicate a 100-fold synergism when the two agonists are combined spinally. Subsequently, we investigated the behavioral analgesic profile of the combination in inflammatory, nerve-injured, post-operative, and tumor-induced pain models. Efficacy studies using intraplantar, systemic, or topical applications showed that when combined in a 1:1 dose ratio OMI-Lo produces a robust anti-hyperalgesic synergy. This synergy was blocked by the peripherally restricted opioid antagonist, naloxone methiodide, reinforcing the peripheral localization of the effect. The synergistic interaction is also completely ablated when G proteincoupled, inwardly rectifying potassium channels (GIRKs) are blocked or knocked out. Although supra-therapeutic doses induce tolerance, therapeutic doses do not. Initial self-administration studies also indicate a significantly reduced abuse liability compared to prescription opioids such as oxycodone. We conclude that MOR agonists significantly synergize with DOR agonists at peripheral sites of action, providing strong evidence in support of peripherally restricted combination opioid therapy. The systemic and topical efficacy of the combination, along with loperamide's extremely low abuse liability, suggests that this combination might be therapeutically useful to control multiple pain modalities in the clinic.

Title: Expression of Gi-insensitive adenylyl cyclase isoform AC2 in mouse sensory neurons: Contributions to nociceptive signaling

Authors: *J. J. HAVELIN¹, J. R. YASKO², C. ESANCY¹, R. GEGUCHADZE¹, K. M. BAUMBAUER³, T. E. KING¹, D. C. MOLLIVER¹ ¹Biomed. Sci., Univ. of New England, Biddeford, ME; ²Dept. of Neurosci., Uconn Hlth., Farmington, CT; ³Sch. of Nursing, Univ. of Connecticut, Storrs, CT

Abstract: Gs-coupled metabotropic receptors play a significant role in the sensitization of nociceptors in response to inflammatory insult or injury by activating the adenylyl cyclase (AC)-cAMP-protein kinase A (PKA) pathway. Conversely, ACs are inhibited by Gi/o-coupled receptors, which is one mechanism underlying analgesia provided by opiates. Type II AC isoforms are uniquely regulated in that they can be activated by protein kinase C or Gbetagamma as well as Galpha-s, making them integrators of signaling through multiple second messenger pathways usually considered to be distinct. Coincident activation of Gq/11-coupled receptors

(leading to activation of PKC) and Gs-coupled receptors is likely to occur in response to peripheral injury or insult. Furthermore, Type II ACs are insensitive to inhibition by Gi/ocoupled receptors, suggesting the possibility that these AC isoforms, if expressed in primary afferent nociceptors, could contribute to persistent pain resistant to exogenous opiates or descending inhibitory influences. Therefore, we examined the distribution of Type II ACs ADCY2, ADCY4 and ADCY7 in sensory neurons of the dorsal root ganglion (DRG) from adult male mice. Real-time PCR revealed mRNA for all 3 isoforms in whole DRG (ADCY2 > ADCY7 > ADCY4). Single cell quantitative PCR was performed on acutely isolated cutaneous DRG afferents retrogradely labeled with either IB4 or wheat germ agglutinin (n=40). Widespread expression of AC2 was identified in afferents co-expressing TRPV1 and/or MrgprD, used to identify subsets of putative nociceptors. The functional role of ADCY2 in nociception was examined by evaluating the impact of local or spinal administration of an inhibitor of AC2, SKF 83566 (10 or 30 µM), on acute responses to noxious heat stimulation and the formalin test. Withdrawal latencies to noxious heat were not altered by spinal administration the AC2 inhibitor, suggesting little contribution of AC2 to acute noxious heat responses. In contrast, both spinal and local (intraplantar hindpaw) administration of inhibitor attenuated nocifensive responses in both phase 1 (1-15 min post-injection) and phase 2 (15-45 min post injection) of the formalin test. These results support a role for AC2 in formalin-evoked pain. Ongoing experiments are investigating a role for AC2 in a model of persistent behavioral hypersensitivity known as hyperalgesic priming.

Title: Dopamine receptor modulators enhance opioid analgesia in a rodent model of spinal cord injury

Authors: E. EVANS¹, J. JENKINS¹, J. YOW¹, S. CLEMENS², *K. L. BREWER¹ ¹ECU Emergency Med., ²Dept. of Physiol., Brody Sch. Med. East Carolina Univ., Greenville, NC

Abstract: Background: Opiate agonists such as morphine are often ineffective in neuropathic pain related to spinal cord injuries (SCI) and also carry a high risk for addiction and dependence. There is a need to identify other possible analgesic agents that are effective at managing chronic SCI-related pain, without the unwanted side effects of opiates. Purpose: This study examined the

pairing of low-dose morphine with dopamine D3 and D1 receptor modulators to improve analgesia for SCI-related pain, while reducing morphine's rewarding effects. Methods: 55 female, Long-Evans rats were tested for mechanical thresholds prior to receiving a spinal contusion (SCI) or sham surgery. Mechanical pain thresholds were measured 21-27 days postsurgery under the following conditions: Morphine alone (1.0 or 2.5 mg/kg); Morphine (1.0 or 2.5 mg/kg) + 0.1 mg/kg Pramipexole (PRAM; D3R agonist); Morphine (2.5 mg/kg) + 0.1 mg/kg SCH23390 (SCH: D1R antagonist); 0.1 mg/kg Pramipexole alone; 0.1 mg/kg SCH23390 alone. Conditioned Place Preference (CPP) to each drug combination was assessed to determine the addictive potential of that specific combination. Results: In sham animals, the addition of PRAM to 1.0 mg/kg of morphine increased mechanical thresholds over that of baseline and morphine alone. PRAM had no additional effect when added to 2.5 mg/kg morphine. Neither PRAM nor SCH alone provided analgesia in sham animals compared to baseline. In SCI animals, PRAM and SCH increased analgesia over morphine alone when combined with 2.5 mg/kg of morphine. Neither PRAM nor SCH exacerbated CPP to morphine at either dose in sham or SCI animals. Conclusions: Pairing a dopamine D3 receptor agonist with low-dose morphine provides better analgesia than morphine alone without exacerbating the addictive potential of morphine for SCIrelated pain. This combination therapy may represent a potential clinical therapeutic intervention for neuropathic pain.

Title: Combining neurotensin and opioid receptor agonists to relieve pain

Authors: *E. EISELT, V. BLAIS, J.-M. LONGPRÉ, P. SARRET, L. GENDRON Pharmacol. and Physiol., Sherbrooke Univ., Sherbrooke, QC, Canada

Abstract: Opioid and neurotensin receptors are expressed in both the central and peripheral nervous systems where they modulate nociceptive responses. Nowadays, opioid analgesics like morphine remain the most prescribed drugs for the treatment of moderate to severe pain. However, commonly used opioids, known to activate the mu opioid receptor (MOPr) are also responsible for most unwanted effects (tolerance, constipation or respiratory depression). Previous studies have established that the strong analgesic action of neurotensin (NT) is independent of the opioid system. However, NT acting at the NTS1 receptor site also causes hypothermia and hypotension, thus limiting the development of new analgesic drugs. Here, we

hypothesized that the combined use of NT and opioid compounds would require lower doses to produce significant analgesic effects, hence decreasing the unwanted effects induced by either drug classes. In this study, we used isobologram analyses to determine if the combination of a NT brain-penetrant analog with morphine results in an inhibition, a synergic or an additive analgesic response. We found that intravenous administration of the NT analog reduced by 90% the nocifensive behaviors induced by formalin injection, at the dose of 0.018 mg/kg. Likewise, subcutaneous morphine attenuated the pain behaviors by 90% at the dose of 1.8 mg/kg. Importantly, the use of isobologram analyses revealed that the co-injection of the NT agonist together with morphine induced an additive analgesic effect in the rat formalin test. We finally assessed the effects of these mu opioid and NT compounds on the gastrointestinal tract motility using the charcoal meal test. As opposed to morphine which significantly reduced the intestinal transit time at the analgesic effective dose of 1.8 mg/kg, the NT brain-penetrant analog did not affect the progression of the charcoal meal in the intestine at the dose of 0.018 mg/kg. Interestingly, at the dose providing 90% pain relief in the formalin test, the co-administration of morphine (0.09 mg/kg) with the NT analog (0.009 mg/kg) reduced the constipation profile of morphine. Altogether, these results suggest that the combination of NT derivatives with morphine may improve its analgesic benefit/adverse effect ratio.

Title: Muscarinic allosteric modulation alleviates chronic post-ischemia pain in rats

Authors: V. GOURA, A. VUYYURU, R. KALLEPALLI, P. JAYARAJAN, *S. M. IRAPPANAVAR, R. NIROGI SUVEN LIFE SCIENCES LTD, HYDERABAD, India

Abstract: Patients with chronic complex regional pain syndrome (CRPS-I) shows tissue abnormalities caused by microvascular dysfunction in the blood vessels of skin, muscle and nerve. Chronic post-ischemia pain (CPIP) is a neuropathic-like pain syndrome following prolonged hind paw ischemia and reperfusion, which models CRPS-I. In this study we evaluated the effect of muscarinic allosteric modulator, on microvascular dysfunction and neuropathic pain like syndrome caused by CPIP in rats. Mechanical allodynia was assessed using Von-Frey monofilaments in CPIP rats. Laser doppler flowmetry of plantar blood flow was used to examine the effects of BQCA on CPIP-induced alterations in post-occlusive reactive hyperemia (reflecting microvascular dysfunction). Further, we investigated to translate "bedside-to-bench" outcomes from the human pain phenotype to rodents for the first time in CPIP rats through burrowing behavior (which evaluates non-evoked and unbiased pain response). Muscarinic allosteric modulator significantly attenuated mechanical allodynia and reduced reactive hyperemia. The natural burrowing deficits in CPIP rats were significantly ameliorated. An improvement in microvascular function might account for its analgesic activity in our experimental model of CRPS-I.

Title: Evaluation of Mygalin anti-nociceptive activity, analogue synthesized from natural acylpolyamine of the A. gommesiana (Araneae, Theraphosidae) hemolymph, in a model of neuropathic pain in Wistar rats

Authors: *A. C. MEDEIROS¹, J. L. LIBERATO¹, P. MEDEIROS², R. L. FREITAS², P. I. SILVA, Jr.³, N. C. COIMBRA², W. F. SANTOS¹

¹Dept. de Biologia, Faculdade De Filosofia Ciências E Letras De Ribeir, Ribeirão Preto, Brazil; ²Faculde de Medicina de Ribeirão Preto - Univ. de São Paulo, Ribeirão Preto, Brazil; ³Inst. Butantam - Univ. de São Paulo, São Paulo, Brazil

Abstract: Pain is a recurring sensation that affects one third of the world population, associated with this are the unwanted side effects and limited effectiveness of current drugs. In this sense, the study of natural compounds, such as Mygalin (MY), is an alternative. This is a polyamine synthesized from the natural molecule present in the hemolymph of the spider *Acanthoscurria gomesiana*. Polyamines are characteristic of the modulation of *L*-glutamate receptors, which in turn are closely linked to the pathway of pain. In this way MY is a molecule with analgesic potential. The objective of this study was to evaluate the effect of MY on the neuropathic pain

model induced by partial sciatic nerve ligation (PLS). Wistar rats were submitted to PLS surgery and, after 14 days, underwent stereotactic surgery to implant a guide cannula in the dorsal raphe nucleus (ND). After seven days, the behavior of these rats were evaluated in the tests of mechanical allodynia and hyperalgesia, both in heat and cold. The tests adopted were: von Frey (VF), Tail Flick (TF), Hot Plate (HP) and acetone test (AC). These experiments were applied at regular intervals of 15 and 30 minutes after treatment. Three concentrations of MY (0.2, 0.02, $0.002 \mu g/\mu L$) were used. There are also control groups like sham (Sh) and vehicle (Ve). The project was submitted to the Committee of Ethics in the Use of Animals (CEUA) of the University of São Paulo - Campus of Ribeirão Preto under protocol 0134/2017. When compared to Ve, the MY group presented a significant difference in both the VF (p < 0.001) and the TF (p<0.001) and HP (p<0.05) groups, showing antinociceptive effect from the first minutes (5 min). In these same tests the effect lasted until the end of the tests (90 min), with only the last time (120 min) and peak between 60 and 90 min. The treatments with MY of lower concentration showed a more significant effect in relation to the other groups, as well as a more prolonged effect Based on the data obtained so far, the lowest concentration (0,002 μ g/ μ L) of MY had an antinociceptive effect. In view of these results we can conclude that MY acts in other ways besides glutamatergic.

Title: Analgesic properties of plant-derived analgesic compounds in infant rats

Authors: C. J. MASCARENHAS¹, R. LIU², *G. A. BARR³

¹Biol. Bases of Behavior, Univ. of Pennsylvania, Philadelphia, PA; ²Dept. of Anesthesiol. and Critical Care, Perelman Sch. of Medicine, Univ. of Pennsylvania, Philadelphia, PA; ³Anesthesiol. and CCM, Children's Hosp. of Philadelphia, Philadelphia, PA

Abstract: Premature and ill neonates undergo multiple painful but medically necessary procedures while hospitalized. Such procedures are associated with negative neurodevelopmental outcomes such as hindered cognitive and motor development, altered cortical rhythmicity, and

altered cortical thickness. Although opiate drugs are sometimes administered as analgesics, problems associated with their side effects, tolerance, and potential dependence compel research into alternative pain-relieving medication. Here we tested two plant-derived analgesic compounds for analgesia in infant rats: sinomenine, an alkaloid found in the root of Sinomenium acutum; and salvinorin A, isolated from Salvia divinorum, In adult animals both sinomenine and salvinorin A alleviate hyperalgesia, allodynia, and neuropathic pain, but the mechanisms of action of each compound is not understood, and neither has been tested in infants. To assess the effects of sinomenine and salvinorin A on pain during development, we used the formalin and thermal plantar tests in 3-day-old (for salvinorin A only), 7-day-old, and 21-day-old rats to determine how varying systemic doses of each drug affected the behavioral signs of inflammatory pain and acute thermal withdrawal latencies. In addition, brain sections were stained using Fos immunohistochemistry to examine patterns of brain activation in the midbrain periaqueductal gray and the paraventricular nucleus of the hypothalamus. Thermal and formalin test results from salvinorin A groups showed no analgesic drug effect at any age or dose (0.05 -0.45 mg/kg). Sinomenine treated groups showed an analgesic drug effect in both the formalin and thermal tests at 21-days of age. Multiple comparisons of 21-day sinomenine doses (20, 40, 80 mg/kg) showed that the high and middle doses reduced nociceptive responses in the formalin test and all three doses increased thermal withdrawal latencies. At 7-days of age the highest dose was lethal and there was no effect of sinomenin in the formalin test (10, 20, 40 mg/kg). Only the highest dose (40 mg//kg) elevated response latencies in the thermal test at this age. Analysis of Fos expression in the sinomenine treated animals showed no drug effect, in contrast to the behavioral results, although the Fos data are preliminary at this point. Thus, sinomenine might act at different sites or by different mechanisms. The increased effectiveness of sinomenine in older animals and the lack of a salvinorin A drug effect suggest that the compounds act on sites that develop during infancy (sinomenine) or after infancy (salvinorin A).

Title: Developmental expression of the mechanically-gated channel Piezo2

Authors: *C. I. FÜRST, G. R. LEWIN, A. HAMMES-LEWIN Max-Delbrueck-Center For Mol. Med., Berlin, Germany

Abstract: Mechanotransduction is the conversion of mechanical stimuli into electrical signals, a process crucial for a variety of many biological functions. On a molecular level, the mammalian

mechanosensitive ion channel Piezo2 has been described to act as a highly sensitive mechanosensor in several cell types. Piezo2 is required for mechanotransduction in the proprioceptive system and also for mechanoreceptors and touch in the somatosensory system. Furthermore it has also been described to be an airway stretch sensor crucial for normal respiration. The importance of mechanosensitive ion channels in the human body was revealed in clinical studies in which patients with mutations in PIEZO2 were described to suffer from Gordon syndrome, Marden-Walker syndrome or Distal Arthrogryposis type 5. Symptoms of these syndromes include congenital contractures of hands and feet, ophthalmoplegia, scoliosis or cleft palate. In addition, patients with loss of function *PIEZO2* mutations display a selective loss of discriminative touch perception and proprioception. Although many functions of Piezo2 have been described in the adult mouse, there are as yet no thorough studies of *piezo2* expression throughout development. To better understand the mechanisms underlying the etiology of PIEZO2 related diseases we aimed at defining the spatial and temporal expression of Piezo2 in the mouse embryo. Using in situ hybridization on embryonic mouse sections we discovered a localized and dynamic expression pattern of the peizo2 mRNA. At embryonic day 14 piezo2 is strongly expressed in the trigeminal ganglion, the dorsal root ganglia and in a restricted cellular population in the spinal cord. As Piezo2 acts as a mechanosensor in dorsal root ganglia its expression early on probably correlates with the early onset of mechanotransduction in these cells. To further elucidate the fate of *piezo2*-positive cells we used a reporter mouse line which expresses the red fluorescent protein tdTomato dependent on Cre recombinase activity driven from the *piezo2* locus. First results with these reporter lines indicate a wide spread expression pattern for *piezo2*. The identity of these *piezo2*-positive cells will be further characterized with co-expression studies using different cell type specific markers. Our results suggest expression of the mechanically-gated ion channel Piezo2 in a variety of different tissue types throughout development.

Title: Effects of vincristine on Piezo2 channels and tactile responses of whisker hair follicles

Authors: *M. SONEKATSU, W. CHANG, H. KANDA, J. LING, J. GU Dept. of Anesthesiol. and Perioperative Med., Univ. of Alabama at Birmingham, Birmingham, AL

Abstract: Chemotherapy induced peripheral neuropathy (CIPN) is a dose-limiting factor for treating cancers by a number of important drugs including vincristine. Clinical symptoms of CIPN include numbress, tingling sensation, and neuropathic pain. The pain aspect of CIPN induced by vincristine and other chemotherapy drugs is thought to be due to afferent demyelination and axon degeneration induced by chemotherapy drugs. Although numbress or loss of touch sensitivity is one of the earliest and most common symptoms of CIPN, mechanisms underlying the numbress aspect of CIPN remain poorly understood. The sense of touch is mostly transduced by specialized tactile end organs. Merkel disc is a main type of tactile end organ located in mechanically sensitive spots of the epidermis including whisker hair follicles. A Merkel disc consists of a Merkel cell and an Aβ-afferent fiber. We have recently shown that Merkel cells use Piezo2 channels to transduce mechanical stimulation into electrophysiological tactile responses manifested as slowly adapting type 1 (SA1) impulses. In the present study, we characterized mechanical sensitivity and membrane excitability of mouse Merkel cells. We further investigated effects of vincristine on whisker afferent SA1 responses. We found that treatment of animals with vincristine resulted in the reduction of Piezo2-mediated mechanically activated currents and also the suppression of SA1 impulses of whisker afferents. Our findings show that vincristine affect mechanical transduction of Merkel cells to subsequently compromise the tactile sensitivity of whisker hair follicles, providing a putative mechanism underlying the numbness aspect of CIPN in patients treated with vincristine.

Title: Characterizing the expression and function of TMC proteins in dorsal root ganglia neurons

Authors: *K. M. WEBSTER, R. C. KNABLE, W. R. SCHAFER MRC Lab. of Mol. Biol., Cambridge, United Kingdom **Abstract:** The role of transmembrane channel-like family member proteins in mechanosensation in the inner ear has been well characterized. Although challenges with heterologous expression systems have kept the field from definitively demonstrating that these proteins serve as the poreforming subunit in the receptor complex, it is well accepted that Tmc1 and Tmc2 are required for the transduction of the mechanosensory signal in hearing. However, the role the proteins from TMC sub-family A (Tmc1, 2, & 3) elsewhere in the nervous system have been poorly characterized. Here, we show that sub-family A Tmc proteins are expressed in the peripheral nervous system, particularly in the dorsal root ganglia of mice. Through RT-PCR, we characterized the isoforms of the proteins expressed specifically in peripheral tissue and have identified at least two different isoforms of Tmc3. Additionally, through immunofluorescence, we show that Tmc1 has limited expression in a subset of low-threshold mechanoreceptors and Tmc3 is expressed in two different populations, a subset of low-threshold mechanoreceptors and A-delta fibers, responsible for thermosensation. Ectopic expression of the mammalian Tmc1 & 3 in *C. elegans* neurons confers mechanosensitivity to pairs of neurons that do not usually respond to mechanosensitive stimuli. Combining mechano-clamp and whole-cell electrophysiology, we are able to test whether Tmc1 and Tmc3 contribute to the mechanical currents in specific subsets of known mechano-sensitive neurons in the dorsal root ganglia. We will compare cells from subgroups of interest from dissociated wild type, Tmc1^{-/-}, and Tmc3^{-/-} ganglia in culture. Using a motor-driven glass probe, we will deform the cell body membrane and record whole-cell mechano-sensitive currents. Thus, we will present a characterization of the expression and function of Tmc1 and Tmc3 in DRG neurons.

Title: Evidence for mechanosensitive channel activity of tentonin 3/TMEM150C

Authors: *G. HONG, J. WEE, U. OH Korea Inst. of Sci. & Technol., Seoul, Korea, Republic of

Abstract: Mechanosensation is essential for various physiological processes, and it is mediated by mechanotransductionchannels. Recently, we reported that TMEM150C/Tentonin 3 (TTN3)

confers mechanically activated currents with slow inactivation kinetics in several cell types, including dorsal root ganglion neurons(Hong et al., 2016). The accompanying Matters Arising by Dubin, Murthy, and colleagues confirms that naive heterologous cells demonstrate a mechanically activated current, but finds that this response is absent in CRISPR-Cas9 Piezo1 knockout cell lines and suggests that TTN3 is a modulator of Piezo1. We present and discuss evidence based on coexpression of TTN3 and Peizo1 and mutant variants of the pore region of TTN3 to support that TTN3 is a pore-forming unit, not an amplifying adaptor for Piezo1 activity. This Matters Arising Response paper, along with Zhao et al. (2017), addresses the Matters Arising from Dubin et al. (2017), published concurrently in this issue of Neuron.

Title: Polarized initiation of neuronal varicosities

Authors: *C. GU, Y. GU Biol. Chem. and Pharmacol., Ohio State Univ., Columbus, OH

Abstract: Little is known about mechanical regulation of morphological and functional polarity of central neurons. Here we report that mechanical stress specifically induces varicosities in the axons but not the dendrites of central neurons by activating TRPV4, a Ca^{2+}/Na^+ -permeable mechanosensitive channel. This process is unexpectedly rapid and reversible, consistent with the formation of axonal varicosities *in vivo* induced by mechanical impact in a mouse model of mild traumatic brain injury (mTBI). By contrast, prolonged-stimulation of glutamate receptors induces varicosities in dendrites but not axons. We further show that axonal varicosities are induced by persistent Ca^{2+} increase, disassembled microtubules and subsequently reversible disruption of axonal transport, and are regulated by stable tubulin-only polypeptide (STOP), a microtubule-associated protein. Finally, axonal varicosity initiation can trigger action potentials to antidromically propagate to the soma in retrograde signaling. Therefore, our studies demonstrate a new feature of neuronal polarity—axons and dendrites preferentially respond to physical and chemical stresses, respectively.

Title: Sensory afferent coding of non-noxious thermal perception in mice

Authors: *R. PARICIO MONTESINOS^{1,2}, F. SCHWALLER¹, A. UDHAYACHANDRAN^{1,2}, G. R. LEWIN¹, J. F. A. POULET^{1,2}

Abstract: Alongside an object's texture, its temperature gives important contextual information to help form an accurate somatosensory percept during active tactile exploration. However, little is known about the perceptual thresholds and neural coding of non-noxious thermal stimuli. Here, we trained head-fixed mice to report non-noxious warming and cooling stimuli using a behavioral paradigm that allows spatial and temporal control of a thermal stimulus delivered to the right forepaw and went on to correlate perception with thermal responses of primary sensory afferent neurons using a skin/nerve preparation. Mice took 2-3 days to learn to report a 10°C cooling stimulus (32 to 22°C), using a small diameter Peltier element (3x3mm), but 1-2 weeks to learn to report a warming stimulus of the same amplitude (32 to 42°C). Using a larger diameter Peltier element (8x8mm) improved the speed of learning to detect a warming stimulus to 3-4 days, while cooling was possible to learn in the very first session. Perceptual thresholds reflected the difference in learning times with cooling being detected with lower threshold (0.5°C) than for warming (1°C). Mice trained to report warming stimuli withheld licking to cooling and cool trained mice withheld licking to warm stimuli hinting at segregated neural pathways for warm and cool processing. Thermal responses in afferent neurons were mostly restricted to C-fibres and reflected behavioural data with robust responses to cooling from ~ 15% of all tested neurons, and a weak, but distinct, response to warming in a lower proportion of tested neurons. Our data

indicate that the sparser coding of warming by cutaneous C-fibres correlates with the low fidelity of behaving mice to learn to report skin warming in comparison to skin cooling.

Title: STIM-Orai channels may detect cold in the somatosensory and sympathetic nervous system

Authors: *T. J. BUIJS, P. A. MCNAUGHTON

Wolfson CARD, King's Col. London, London, United Kingdom

Abstract: Introduction: Cold temperatures are sensed by specific cold-activated nerve fibres in the somatosensory nervous system. In these fibres, non-noxious cool temperatures around 25°C are detected by the menthol-sensitive TRPM8 ion channel, but how lower noxious cold temperatures <15°C are detected remains unclear. Previous evidence for a role of one candidate -TRPA1 - in noxious cold sensation has been disputed, because genetic deletion of TRPA1 has little effect on behavioural sensation of cold¹. The sympathetic nervous system is also coldsensitive, but does not express TRPM8². Similarly, TRPA1 is expressed in less than 4% of sympathetic neurons, which is far fewer than the observed cold sensitivity in >75% of neurons³. We sought to determine the mechanism of extreme cold sensation in the somatosensory and sympathetic nervous systems, and hypothesized that cold sensitivity may be mediated by activation of the STIM-Orai system for calcium entry, which is normally responsible for replenishing intracellular calcium stores. Methods: Adult C57BL/6 mouse sensory (dorsal root) and sympathetic (superior cervical) ganglia were removed, dissociated using enzymes, and cultured on glass coverslips for one day before use. Intracellular calcium levels were measured using ratiometric calcium imaging. During recording, neurons were perfused with a cold ramp to 5°C to test the effect of various Orai channel antagonists on the calcium increase evoked by cold. **Results:** In sympathetic neurons, cold responses were abolished by $Gd^{3+}(1 \mu M)$ which blocks both Ca_V and Orai channels. The selective Orai channel blocker YM58483 (3 µM) caused a 70% reduction in cold-response amplitude. Furthermore, YM58483 (3 μ M) completely abolished cold

sensitivity in the presence of Cav1 L-type calcium channel blocker *verapamil (100 \muM)*. Similarly, in the sensory nervous system *YM58483 (3 \muM)* caused a 50% reduction in coldresponse amplitude in neurons that do not express TRPM8, TRPA1, or TRPC5. **Conclusion:** Both the somatosensory and sympathetic nervous system probably use Orai channels to detect cold <15°C. Activation of peripheral nerves by extreme cold may trigger cold-induced vasodilation, a mechanism responsible for preventing frostbite. *References:* 1. Bautista DM et al. (2007). Title: Glucosylsphingosine, an endogenous pruritogen in atopic dermatitis, activates serotonin receptor 2a and 2b

Authors: *W.-S. SHIM¹, A. RAMSHA²

¹Col. of Pharm., ²Gachon Univ., Incheon, Korea, Republic of

Abstract: Recent reports claimed that glucosylsphingosine (GS) is highly accumulated and specifically evoking itch-scratch responses in the skins of atopic dermatitis (AD) patients. However, it was unclear how GS can trigger itch-scratch responses, since there were no known molecular singling pathways revealed yet. In the present study, it was verified for the first time that GS can activate mouse serotonin receptor 2a (mHtr2a) and 2b (mHtr2b), but not 2c (mHtr2c) that are expressed in HEK293T cells. Specifically, effects of GS on all mouse serotonin receptor 2 subfamily were evaluated by calcium imaging techniques. The GS-induced intracellular calcium increase was dose-dependent, and antagonists such as ketanserin (Htr2a antagonist) and RS-127445 (Htr2b antagonist) significantly blocked the GS-induced responses. Moreover, the proposed GS-induced responses appear to be mediated by phospholipase C (PLC), since pretreatment of a PLC inhibitor U-73122 abolished the GS-induced responses. Additionally, the GS-induced calcium influx is probably mediated by endogenous TRPC ion channels in HEK293T cells, since pretreatment of SKF-96365, an inhibitor for TRPC, significantly suppressed GS-induced response. In conclusion, the present study revealed for the first time that GS can stimulate mHtr2a and mHtr2b to induce calcium influx, by utilizing PLC-dependent pathway afterwards. Considering that GS is regarded as a pruritogen in AD, the present study implicates a novel GS-induced itch signaling pathway.

Title: Change in pupillary autonomic activity by mandible grinding with different types of simulated dental occlusion

Authors: *H. YOSHIMI^{1,2}, M. SHINOMIYA¹, Y. KOMORIYA¹, Y. ONO²

¹Dept. of Prosthodontic Dent. for TMJ and Occlusion, Med. Corp. Jivaka Yoshimi Dent. Office, Machida shi, Japan; ²Dept. of Electronics and Bioinformatics, Sch. of Sci. and Technology, Meiji Univercity, Kawasaki, Japan

Abstract: Key words: Intraoral occlusal conditions, Autonomic nervous activity, Pupillary Light Reflex Irregular condition of dental occlusion has been considered to cause autonomic imbalance and its associated health problem. Generally, good and bad dental occlusions are defined by the canines and the molar teeth contacts dominantly during a grinding motion, respectively. However the definition of 'good dental occlusion' is still in debate. The aim of the current study is therefore to clarify whether the differences in intraoral occlusal conditions affect the autonomic nervous activity. Healthy 8 volunteers took part in the study. All subjects had excellent oral health and the tested teeth were intact and found healthy by means of clinical and radiographic findings. The local ethics committee approved the study. All volunteers gave their written informed consent to participate. We measured pupil diameter and pupil light reflex using Iriscorder Dual C10641 (Hamamatsu Photonics, Shizuoka, Japan) with simultaneous electromyogram (EMG) measurements of the masseter muscle using Multi Channel Telemeter WEB-1000 (Nihon Kohden Co., Ltd., Tokyo, Japan). Subjects performed mandibular grinding for 30 seconds, which was immediately followed by a recording of pupil light reflex. We installed metal overlays into either the canines or the first molars to simulate optimal or nonoptimal occlusal conditions. In addition, subjects performed another run of pupil light reflex after grinding with their natural occlusion as control condition. Subjects performed grinding with all occlusal conditions in a random order. Analysis were carried out observing the initial pupil diameter (D1) and minimum pupil diameter (D2) during the pupillary light reflex. The rectified EMG waveform is smoothed with a 5 Hz low pass filter and normalized with Maximum Voluntary Contraction (MVC). Two subjects who had no change in the masseter muscle activity during grinding were excluded from statistics. We found statistically significant increase in D2 of the left eye with optimal occlusal condition compared to control condition. Parasympathetic

nerve activity may be suppressed during grinding with optimal condition. Our results suggest that the occlusal condition affect autonomic nervous activity.

Title: Connective tissue does not mediate the therapeutic effect of acupuncture

Authors: *Y. FAN¹, Y.-H. RYU², S. CHANG¹, O.-S. KWON², S. BANG², N. KIM¹, D.-H. KIM¹, H. KIM¹, E. JANG¹, C. YANG¹, H. KIM¹ ¹Col. of Korean Medicine, Daegu Haany Univ., Daegu, Korea, Republic of; ²Acupuncture, Moxibustion& Meridian Res. Center, Div. of Standard Research, Korea Inst. of Oriental Med., Daejeon, Korea, Republic of

Abstract: Acupuncture has been used to treat a variety of disease and symptoms for more than 2500 years. While previous studies have suggested that acupuncture needle stimulates peripheral nerve in acupuncture point to generate the therapeutic effects of acupuncture, some of researchers have insisted that connective tissue during needling would initiate acupuncture signals. To determine which, nerve or connective tissue, mediate acupuncture effects , we developed a twisting acupuncture instrument; TAI which mimicked a twisting-rotating acupuncture needle manipulation by acupuncturists and examined the role of nerve or connective tissues in generation of acupuncture effects, by pharmacologically blocking nerve or connective tissues during twisting acupuncture in cocaine-induced locomotion, hypertension, and colitis models.

When connective tissues were destroyed by by injecting type I collagenase in acupoints, the torque force during needle rotation/twisting was declined but acupuncture effects on cocaine-induced locomotion, hypertension or colitis were not affected, compared to the corresponding control groups. On the other hand, pretreatment of bupivacaine, a local, long-lasting nerve blocker, into completely blocked the acupuncture effects in cocaine-induced hyperactivity, hypertension and colitis rat models.

Our findings suggest that nerve, but not connective tissue is a culprit in generating acupuncture effects.

Title: Effect of chronic radio frequency exposure in the superior olivary nuclear complex: An immunohistchemical study

Authors: *D. MASKEY¹, M. KIM², H.-G. KIM³

¹Ctr. For Advanced Imaging, Brisbane, Australia; ²Anat., ³Pharmacol., Dankook Univ., Cheonan, Korea, Republic of

Abstract: Exponential growth of mobile communication has raised concerns on the possible health risk to human due to radiofrequency (RF) exposure on human brain owing to its close proximity during usage. Alterations in intracellular calcium (Ca²⁺) concentration could trigger aberrant synaptic action or cause neuronal apoptosis, which may exert an influence on the cellular pathology in the central auditory brain stem nucleus such as superior olivary nuclear complex (SOC). Calcium binding proteins (CaBPs) such as calbindin D28-k (CB) and calretinin (CR) are able to bind Ca²⁺ ions with high affinity. Changes in Ca²⁺ ion concentrations via CaBPs can disturb Ca²⁺ homeostasis leading to cell death. Inhibitory molecule such a glycine that is dominantly localized in the auditory brainstem, play a major role in interplay auditory processing along with excitation molecules interaction while the neurotrophic factors like brain-derived neurotrophic factor (BDNF) and glial-derived neurotrophic factor (GDNF), which is present in the auditory system, are responsible for the maintenance of the auditory neurons. The present study applied RF exposure at SAR 1.6 W/kg (E1.6 group) and sham-control 0 W/kg (SC group) for three months to determine the distribution of CB, CR, GlyR, BDNF, GDNF and GFAP in the mice's SOC through immunohistochemistry. ABR analysis performed revealed significant

elevation of threshold in the E1.6 group, which may implicate auditory dysfunction. Significant loss of CB and CR IRs in the neuropil as well as cells in the different nuclei of SOC of E1.6 was noted. A decrease in the number of GlyR immunoreactive cells was also noted (LSO-36.85%, SPN-24.33%, MSO-23.23%, MNTB-10.15%) in E1.6. Neuropil staining with BDNF and GDNF IRs in the nuclei of SOC were significantly decreased in the E1.6 while GFAP increased significantly when compared with the SC. Decrease in CaBP and GlyR IRs could lead to impairment of Ca²⁺ homeostasis and decrease ability to segregate sounds leading to auditory dysfunction while decrement of neurotrophic factors insinuate detrimental effect. The present study showed susceptibility of the auditory brainstem region to chronic RF exposure with changes in the ABR suggesting a possibility of detrimental effect in the auditory brainstem circuit.

Title: Anodal transcranial direct current stimulation modulates structural plasticity in the rat auditory cortex and counteracts cortical alterations induced by chronic exposure to noise

Authors: *M. V. PODDA¹, F. PACIELLO², R. ROLESI³, S. COCCO¹, A. R. FETONI³, G. PALUDETTI³, C. GRASSI¹, D. TROIANI¹

¹Inst. of Human Physiology, Univ. Cattolica, Rome, Italy; ²Inst. of Cell Biol. and Neurobiology, CNR, Rome, Italy; ³Dept. of Head and Neck Surgery, Univ. Cattolica, Rome, Italy

Abstract: Transcranial direct current stimulation (tDCS) is a non-invasive tool capable of modulating cortical functions by affecting neuronal excitability and synaptic plasticity. Here we investigated the effects of anodal tDCS on structural plasticity of auditory cortex (AC) in healthy (H) rats and following noise-induced hearing loss (NIHL). Rats were exposed to noise (100 dB, 60 min/day for 10 days), subjected to anodal tDCS over the left AC (350 μ A for 20 min for two days) starting from 24 h after the end of NIHL paradigm, and sacrificed 21 days later for morphological analyses by Golgi-Cox staining and electrophysiological field recordings.

In agreement with our previous report (*Fetoni et al., 2013*) NIHL decreased spine density in layer 2/3 and 5-6 AC pyramidal neurons. Interestingly, we found that tDCS counteracted the NIHL-induced spine loss both in apical and basal arborizations. In particular, in NIHL rats spine loss in neurons of layer 2/3 was~30% in apical dendrites and~40% in basal dendrites, while in those exposed to tDCS (NIHL-tDCS) spine density was not significantly different from that of H rats (p=0.82).

Of note, tDCS increased spine density (+20-30%) in apical dendrites of layer 2/3 and 5-6 neurons in H rats with normal auditory function similarly to what reported following auditory environmental enrichment.

Twenty-four hours after tDCS Bdnf levels in the AC increased both in H and NIHL rats (p=0.01 and 0.02, respectively). Similarly, the expression of synaptophysin was enhanced by tDCS in H (+80%, p=0.01) and NIHL rats (+60%, p=0.04).

Field recordings were performed from AC slices to assess tDCS impact on basal synaptic transmission at layer 2/3 horizontal connections. Comparison of the input-output (I-O) curves showed that in NIHL rats the amplitude of field excitatory post-synaptic potentials was significantly smaller than in H rats (p=0.01). Interestingly, responses to current pulses were significantly increased in NIHL-tDCS group compared to sham-stimulated NIHL rats (p=0.003) and I-O curves of NIHL-tDCS rats were similar to those of H rats, suggesting that tDCS counteracted the effects of noise on synaptic function.

Our findings provide novel evidence that anodal tDCS affects structural plasticity in the AC and counteracts the detrimental effects of sensory deafferentation. These results widen the horizons on brain areas whose plasticity is targeted by tDCS and open the way to the possibility to exploit tDCS to treat diseases thought to be related to altered plasticity like tinnitus.

Title: Channelrhodopsin-assisted circuit mapping of ascending and commissural synaptic inputs to VIP neurons in mouse inferior colliculus

Authors: *D. GOYER, P. T. MALINSKI, A. P. GEORGE, M. T. ROBERTS Kresge Hearing Res. Inst., Univ. of Michigan, Ann Arbor, MI

Abstract: The inferior colliculus (IC), the midbrain center of the auditory pathway, is a major hub for nearly all auditory information coming from the brainstem and a critical station in sound

processing. To better understand how neural circuits in the IC process sounds, a robust method for identifying the different neuron types within the IC is necessary. It is also essential to know how identified neuron types function within the local circuitry of the IC and in the ascending auditory pathway. So far, it has proven difficult to delineate specific neuron types with standard anatomical and physiological techniques.

Recently we identified a novel class of stellate cells that are labeled in Vasoactive Intestinal Peptide (VIP)-IRES-Cre mice. We crossed VIP-IRES-Cre mice with Ai14 reporter mice to drive tdTomato expression in Cre-expressing VIP neurons. Fluorescently labeled VIP neurons were distributed throughout the central region of the IC with the highest density in the caudal pole of the IC. We targeted whole cell recordings to fluorescent VIP neurons in the IC in acute brain slices of mice aged 10 to 57 days (median = 28.5 days). VIP neurons had a moderate input resistance of 199 M Ω (± 158.5 M Ω), membrane time constant of 13.4 ms (± 7.7 ms), moderate to no hyperpolarization activated cation current (Ih) and 88% (82/93) exhibited a sustained firing pattern with relatively little spike frequency adaptation (SFA ratio < 2). Post hoc reconstruction of recorded neurons showed that VIP neurons have stellate morphologies and all but one had spiny dendrites (31/32).

We are currently using Channelrhodopsin-assisted circuit mapping to identify ascending and commissural sources of synaptic input to VIP neurons. Specifically, we inject recombinant adeno-associated viruses (rAAV2/5.Syn.Chronos-GFP or rAAV2/1.Syn.Chronos-

GFP.WPRE.bGH) encoding the optogenetic protein Chronos into one hemisphere of the IC or in select auditory brainstem nuclei. After allowing the virus to express for 3-4 weeks, we perform whole cell recordings from VIP neurons while activating Chronos-expressing inputs with flashes of blue light (1 - 10 ms, 3.0 - 14.3 mW/mm²). Activation of commissural inputs elicits a mixture of excitatory and inhibitory postsynaptic potentials in VIP neurons. In addition, activation of ascending input from the dorsal cochlear nucleus evokes excitatory postsynaptic potentials that are often coupled with GABA-mediated feedforward inhibition.

Together, these experiments identify VIP neurons as a novel subclass of IC stellate cells and suggest that individual VIP neurons might integrate input from the dorsal cochlear nucleus and the contralateral IC.

Title: Characterization of a brainstem-amygdala pathway important for attention processing

Authors: *J. C. CANO¹, K. FENELON²

¹Biol. Sci., Univ. of Texas at El Paso Dept. of Biol. Sci., El Paso, TX; ²Biol. Sci., Univ. of Texas at El Paso, El Paso, TX

Abstract: Sensorimotor gating is a pre-attentive neural filtering process that allows our brain to suppress irrelevant sensory information, and helps us to focus attention. Patients suffering from neuropsychiatric disorders, such as schizophrenia and anxiety, exhibit sensorimotor gating deficits that greatly impact their daily lives. Clinically, sensorimotor gating can be measured using the prepulse inhibition (PPI) of the acoustic startle reflex task. During PPI in healthy subjects, a non-startling sound (prepulse) will inhibit the startling effect of a subsequent startling sound (pulse). Previously, in vivo and in vitro animal studies have shown that the brainstem caudal pontine reticular nucleus (PnC) is at the core of the PPI pathway, relaying sensory inputs from several brain regions directly to spinal and cranial motor neurons. In fact, the PnC has been shown to receive cholinergic inputs from the pedunculopontine tegmental nucleus (PPTg). Initially thought to be an essential connection for PPI, recent in vivo rat studies suggest that the PPTg-PnC cholinergic connection is no longer considered critical for PPI. Therefore, we hypothesized that other brain pathways contribute to sensorimotor gating, and need to be investigated. The central nucleus of the amygdala (CeA) is another region directly connected to the PnC. Interestingly, the CeA modulates PnC neuronal activity, and lesions to the amygdaloid complex can disrupt PPI. However, the potential role of the CeA-PnC connection in sensorimotor gating remains to be determined. Therefore, here, we investigated the contribution of the CeA-PnC connection to PPI in mice using immunohistochemistry and electrophysiological recordings paired with optogenetics in acute brain slices (N=7 mice). Our results suggest that the CeA sends monosynaptic glutamatergic projections to the PnC. In addition, when the PPI task was mimicked in vitro in PnC slices, PPI was modified by the photo-stimulation of the CeA inputs. Our results will contribute to better understand the neural pathways underlying PPI, and allow us to identify potential therapeutic targets for diseases associated with sensorimotor gating deficits.

Title: A novel mutual information estimator to measure spike train correlations in a model of the thalamocortical network

Authors: *E. D. GRIBKOVA^{1,2}, B. A. IBRAHIM^{1,3}, D. A. LLANO^{1,2,3} ²Neurosci. Program, ³Mol. and Integrative Physiol., ¹Univ. of Illinois At Urbana-Champaign, Urbana, IL

Abstract: The impact of the various states of the thalamus on information transmission to the cortex remains poorly understood. This limitation exists due to the rich dynamics displayed by thalamocortical networks and because of the inadequate tools available to investigators to characterize those dynamics. Herein, we introduce a novel estimator of mutual information between spike trains and use this estimator to determine the impact of a computational model of thalamic state on information transmission. A limitation of previously employed mutual information estimators is their reliance on fixed partitions of spike trains. Therefore, we developed a mutual information estimator with an adaptive partition for signals with different time scales and used this estimator to compare input spike trains to output spike trains. It was observed that this estimator was superior to other mutual information estimators with fixed partitions when used to analyze simulated spike train data with different mean spike rates, as well as electrophysiological data from simultaneously recorded neurons, since it provided estimates that were closer to expected values and trends. When the estimator was applied to a thalamocortical model, it was found that thalamocortical (TC) cell calcium T-current conductance (T-current) influences mutual information between the input and output from this network. In particular, a T-current of about 50 nS appears to produce maximal mutual information between the input to this network (conceptualized as an afferent input to the TC cell) and the output of the network at the level of a cortical layer 4 neuron. Furthermore, at particular combinations of inputs to TC and thalamic reticular nucleus (TRN) cells, thalamic cell bursting correlated strongly with recovery of mutual information between thalamic afferents and L4. These studies suggest that a novel mutual information estimator using adaptive partitions has advantages over previous estimators, and that TRN activity can enhance mutual information between thalamic afferents and thalamorecipient cells in the cortex, while the cortex can recover mutual information between these thalamic afferents and thalamorecipient cells that is otherwise lost due to thalamic bursting.

Title: Age-related changes in the expression of glutamic acid decarboxylase (GAD67) and NMDA receptor (NMDAR1) in the human inferior colliculus

Authors: *I. PAL¹, T. G. JACOB¹, R. DADA¹, D. N. BHARDWAJ², T. S. ROY¹ ¹Dept. of Anat., ²Forensic Med. & Toxicology, All India Inst. of Med. Sci., New Delhi, India

Abstract:

The inferior colliculus (IC) is an important nucleus of auditory pathway, where all projections from ascending auditory nuclei converge, it is also connected with several descending pathways that is essential for normal hearing. GABA and glutamate are the major inhibitory and excitatory neurotransmitters in the IC respectively and critically involved in the temporal processing of acoustical stimuli. The balance between excitatory and inhibitory neurotransmission here is crucial for normal hearing. Declining levels of GABA have been found in the auditory region of patients and in animal models presbycusis. Earlier, we have reported decline in the number of neurons in the cochlear nucleus occurring from 6th decade of life. Therefore in the present study, we planned to investigate the changes in the transcription and translation of GAD67 and NMDAR1 in human IC at various ages by using quantitative real-time PCR and immunohistochemistry that was quantified by unbiased stereology (optical fractionator probe), respectively. For this study, 27 human IC were obtained from the mortuary with proper ethical clearance and divided into three age groups- 11-30 years, 31-50 years and >51 years (n=9 in each group). The 11-30 years' age group served as control group for comparison with the other two groups. We observed a significant decline in the number and expression of GAD67 and NMDAR1-immunoreactive neurons and their relative genes in the age group 51 years and above (p=0.001). The relative expression of GAD67 and NMDAR1 mRNA in the 31-50 age groups were 0.82 and 0.42 (p=0.02) and in the old age group was 0.56 and 0.55 (p=0.02) respectively. Hence, the balance between excitatory and inhibitory neurotransmission in IC is altered in the human IC with age and this may be affecting the normal hearing leading to pathogenesis of presbycusis.

Title: Differential contribution of presynaptic calcium channels to synaptic transmission at the mouse medial olivocochlear-outer hair cell synapse at two developmental stages

Authors: L. VATTINO¹, A. B. ELGOYHEN^{1,2}, *E. KATZ^{1,3}

¹INGEBI (CONICET), Buenos Aires, Argentina; ²Facultad de Medicina, Inst. de Farmacología, ³Facultad de Ciencias Exactas y Naturales, Dpto. de Fisiología, Biología Mol. y Celular, Univ. de Buenos Aires, Buenos Aires, Argentina

Abstract: The mammalian auditory epithelium contains two types of mechanosensory cells, inner and outer hair cells (IHCs and OHCs, respectively). IHCs transduce sound stimuli into electrical signals that travel to the central nervous system while the OHCs, by virtue of their electromotile properties, are mainly involved in sound amplification. OHC electromotility is regulated by descending medial olivocochlear (MOC) fibers. The MOC-OHC synapse is cholinergic and inhibitory and is mediated by the $\alpha 9\alpha 10$ cholinergic nicotinic receptor coupled to the activation of Ca²⁺-activated K⁺ channels that hyperpolarize the OHCs. During development, before reaching the OHCs, MOC fibers transiently innervate the IHCs (from birth to hearing onset, postnatal day (P)12 in mice). The ion channels coupled to transmitter release at the MOC-IHC synapse have been previously described (Zorrilla de San Martin et al., 2010), however, nothing is known about the ion channels coupled to this process at the MOC-OHC synapse. Using acutely isolated mouse cochleas we show, by whole-cell voltage-clamp recordings in OHCs while electrically stimulating the efferent axons, that ACh release is mediated by both P/Q and R-type voltage-gated Ca²⁺ channels (VGCC) at P11-13 and by P/Q- and N-type VGCCs at P20-22. In addition, we show that at P11-13, large conductance Ca²⁺-activated K⁺ channels (BK) are functionally expressed at the MOC-OHC synapse as block by iberiotoxin (200 nM) significantly increases release (control 0.16±0.02; Ibtx 0.30±0.05, n=7; p<0.01). Interestingly, both the L-type VGCC antagonist nifedipine $(3 \mu M)$ and the agonist BayK $(10 \mu M)$ significantly increased release (control 0.19±0.06; Nife 0.30±0.07, n=6; p<0.001; Control 0.32±0.10; BayK 0.66 ± 0.25 , n=6, p<0.05). Occlusion experiments with iberiotoxin and BayK indicate that Ca²⁺ flowing in through L-type VGCC is both activating BK channels and partially supporting ACh release at P11-13. In addition, after loading the efferent terminals with EGTA-AM the contribution of L-type VGCC to release was completely abolished. At P20-22, however, BayK decreased release (control 0.47 \pm 0.16; BayK 0.22 \pm 0.07, n=6, p<0.05), indicating that Ca²⁺ influx through L-type VGCC is only activating BK channels at this stage. These results show that the VGCCs coupled to ACh release at the MOC-OHC synapse at P11-13 are the same as those at the MOC-IHC synapse at early developmental stages (P4-7; Kearney et al., ARO Abstracts 2014), while at P20-22, they resemble those of the MOC-IHC synapse at more mature stages (P9-11; Zorrilla de San Martín et al., 2010). Our results suggest that the MOC-OHC synapse is still functionally immature at the onset of hearing.

Title: A reticular-limbic ascending pathway for transmitting aversive auditory signals

Authors: *G. ZHANG^{1,2}, W. SUN⁴, B. ZINGG³, H. TAO⁵, L. I. ZHANG² ¹Dept. of Neurobio., Third Military Med. Univ., Chongqing City, China; ³Neurosci. Grad. Program, ²USC, Los Angeles, CA; ⁴City Univ. of HongKong, Hong Kong, China; ⁵USC Keck Sch. Med., Los Angeles, CA

Abstract: It is well recognized that in the mammalian brain auditory information is processed along a central ascending pathway into the auditory cortex (AC). However, whether there exist any major auditory pathways beyond this canonical neuraxis remains unclear. In awake mice, we found that neurons in the entorhinal cortex (EC) exhibited auditory responses with so short latencies that cannot be explained by a previously proposed relay from AC. Screening input sources of EC with combined anatomical/functional tracing, optogenetic and pharmacological manipulations, we discovered that EC received auditory input primarily from the medial septum (MS). A previously uncharacterized auditory pathway was then revealed: it branched from the cochlear nucleus, via caudal pontine reticular nucleus, pontine central gray, MS, and reached EC. Interestingly, neurons along this non-canonical pathway all exhibited selective responses to high-intensity noise, rather than tone stimuli. Such reticular-limbic pathway may be specialized in transmitting aversive auditory signals for memory functions.

Title: Tuning of cortical gain, sound frequency selectivity and auditory-driven behaviors by synaptically released zinc

Authors: *M. KUMAR¹, C. T. ANDERSON¹, S. XIONG¹, T. TZOUNOPOULOS² ¹Dept. of Otolaryngology, ²Otolaryngology and Neurobio., Univ. of Pittsburgh, Pittsburgh, PA

Abstract: Activity-dependent tuning of sensory processing modifies behavior advantageously, but the underlying signaling mechanisms remain unknown. Here, we imaged sound-evoked neuronal activity in the auditory cortex of awake mice, and discovered that synaptically released zinc reduced the gain of sound-evoked responses of layer (L) 2/3 principal neurons and interneurons and sharpened sound frequency selectivity of L2/3 principal neurons. In the absence of cortical synaptic zinc, mice showed reduced ability in detecting behaviorally meaningful signals from their auditory environment, such as changes in sound frequencies. By establishing a previously unknown link between synaptically released zinc and auditory cortical processing, our findings advance understanding about cortical synaptic mechanisms and create a new framework for approaching and interpreting the role of the auditory cortex in normal and pathological neuronal processing.

Title: Hearing with an oversized inferior colliculus - is bigger better?

Authors: ***A. BURGHARD**¹, N. MOREL², D. L. OLIVER¹ ¹Neurosci., UConn Hlth., Farmington, CT; ²Univ. of Connecticut, Storrs, CT

Abstract: The inferior colliculus (IC) is a major hub of auditory processing. After different aspects of an acoustic signal are processed in the auditory brainstem nuclei, this information converges in the central nucleus of the IC (ICC) onto one tonotopic map. According to the synaptic domain theory, the inputs from different auditory brainstem nuclei to the ICC cluster in specific sub-regions and, thus, form functional zones superimposed on the single tonotopic map. These sub-regions may send this information via the thalamus to distinct areas of the core auditory cortex with different functions. One approach to the detailed study of function and anatomy in the ICC sub-regions is to genetically manipulate the IC during development. In the present study, we used a mouse model with an oversized IC. Developed by Dee et al. (2016), MEK1 (also referred to as mitogen-activated protein 2 kinase 1, MAP2K1) is overexpressed in this mouse in the tectal stem cell zone from which the IC originates. Consequently, the stem cells remain in the proliferation stage longer, thus increasing the number of stem cells, but also delaying neurogenesis. This results in more, but later developed IC neurons. The gross anatomy shows that in all MEK1 mice the IC is massively enlarged compared to littermate controls. We tested the hearing thresholds of MEK1 mice using the click-evoked auditory brainstem response (ABR) and the amplitude-modulated frequency following response (AMFR). To obtain the AMFR audiogram, we used narrow-band noise (0.3 octave) centered at frequencies 2-40 kHz and a modulation frequency of 42.9 Hz. We tested 5 and 13 week old MEK1 mice as well as age-matched littermate controls. Our preliminary electrophysiological evaluation of the MEK1 mice showed a diverse phenotype. In comparison to the audiograms of littermate controls, some MEK1 mice had an almost normal audiogram, while others showed elevated thresholds. We also measured the growth in the AMFR signal amplitude in response to increasing sound level intensity. In some MEK1 mice there was a reduced growth function especially close to threshold. Interestingly, the hearing threshold did not predict the amplitude growth function or vice-versa. We also measured the peak synchrony of the AMFR signal and found that synchrony was slightly degraded in most MEK1 mice in comparison to littermates. In summary, our preliminary observations of a mouse with a massively enlarged IC suggest that this structural change may result in more than one type of alteration in the circuitry of the auditory midbrain and more than one hearing phenotype. Bigger may not be better.

Title: Principal neurons in the anteroventral cochlear nucleus express cell-type specific glycine receptor subunits

Authors: S. LIN, *R. XIE

Neurosciences, Univ. of Toledo, Toledo, OH

Abstract: Cochlear nucleus is the first station in the central auditory system that gates all sound information from the periphery. Signal processing in the principal neurons of the anteroventral cochlear nucleus (AVCN), including bushy, T-stellate and D-stellate neurons, are modulated by extensive inhibition mediated by glycine receptors. It has been shown that glycinergic inhibition in AVCN exhibits cell-type specific IPSC kinetics that differentially shapes the neural responses of the target cells. However, it remains unclear what glycine receptor subunits are involved in the inhibitory transmission to these AVCN principal neurons. In this study, we performed whole-cell patch clamp recording in AVCN brain slices from CBA/CaJ mice (either sex), electrophysiologically identified these three types of principal neurons, and characterized the properties of IPSCs in these neurons evoked by stimulating the inhibitory inputs from the dorsal cochlear nucleus. Neurons were filled with Alexa Fluor 488 during the recording, followed by fixation of the brain slices and standard immunostaining with primary antibodies against different types of glycine receptor subunits, and secondary antibodies conjugated with Alexa Fluor 594. Images of the filled neurons and the expression patterns of glycine receptor subunits were obtained using confocal microscope. We found that bushy neurons with slow IPSC kinetics express glycine receptor alpha4 subunit, whereas both T-stellate and D-stellate neurons that show fast IPSC kinetics express glycine receptor alpha1 subunit. The results suggest that the differential effects of glycinergic inhibition in AVCN rely on the distinct expression of cell-type specific glycine receptor subunits in the principal neurons.

Abstract: Auditory processing is important for verbal communication in our social environment. In order to study its neural mechanisms in more detail, its anatomical connection must be revealed. The auditory cortex in the primate is thought to be divided into three regions: core, belt, and parabelt. Each region further contains subregions. As a first step, we aimed to reveal axonal projections from the auditory belt regions of a New World monkey, the common marmoset (Callithrix jacchus), which has rich vocal communication with other conspecifics. We injected an AAV, which works as an anterograde tracer by expressing either green or red fluorescent proteins in infected neurons, to three sites in the auditory belt regions of two adult marmosets. Each injection site was chosen based on a tonotopy map made by optical imaging while presenting auditory stimuli to the animal under anesthesia. After a three week waiting period, the animal was perfused and the post-mortem brain was sectioned in a thickness of 50 um. The sections were served to obtain fluorescent images to examine fluorescently labeled axonal projections and processed with myelin and Nissl substance staining to identify brain areas. The brain area annotations were based on a marmoset brain atlas (Paxinos et al 2012). Each injection site was histologically confirmed in either AL, ML or CL in the auditory belt regions. The three belt regions had projections to the entire auditory cortex (core, belt, and parabelt regions), except AL case which had a weak projection to the layer 1 of the core region. Projections to other areas in the temporal cortex were also prominent, including STR, TPO, FST, FSTv and MST (except AL case). The insular cortex, DI, Ipro and Tpro (except ML case) received the projections. For the frontal cortex, projections to 120 and A10 (except ML case) were commonly found. Thus the AL, ML, and CL regions had projections to similar regions with

some variation. This tendency in the projection might reflect the auditory processing done in each area.

Abstract: Although many traditional anatomical studies have shown the connectivity between the higher-order auditory thalamus and other brain areas, data showing cell type-specific connectivity for different subdivisions has been lacking. Previous immuno-histological studies demonstrated localized expression of two types of calcium binding proteins, calbindin (CB) and calretinin (CR), in the higher-order auditory thalamus. Using anterograde and retrograde viral tracing in CB- and CR-Cre mice, we found largely distinct cortical and subcortical connection patterns for the three subdivisions of the higher-order auditory thalamus: MGBd, MGBm and PIN. In addition, although CB and CR neurons exhibited generally similar connection patterns, they do show some differences depending on the specific subdivision injected. The most significant difference is in their connectivity with subcortical structures. Our results show that, due to the localized expression of CB and CR in the higher-order auditory thalamus, diffusion of traditional tracers into the first-order part is not an issue anymore. Most importantly, our results suggest that CB- and CR-Cre mice can be used as a powerful tool to explore the functions of specific pathways between the higher-order auditory thalamus and other brain areas. These anatomical findings and potential functional studies will deepen our understanding of the role of the high-order auditory thalamus in information processing and animal behavior.

Title: Functional topography of raphe-collicular projections: Contributions of dorsal raphe subregions to the inferior colliculus of the mouse

Authors: *C. L. PETERSEN, L. M. HURLEY

Evolution, Ecology and Behavior, Indiana University, Bloomington, Bloomington, IN

Abstract: The ability to process auditory signals in a context-dependent manner is highly adaptive and pervasive in vertebrate animals. One mechanism through which mice (Mus *musculus*) are able to add context to acoustic processing is via the release of the neuromodulator serotonin into the inferior colliculus (IC) within the auditory midbrain. Serotonin release into the IC is context dependent. Levels of serotonin increase within the IC of mice during sexual and non-sexual social encounters. Interestingly, within individual sexual encounters, levels of IC serotonin relate negatively to the amount of rejection-like behavior male mice receive. The vast majority of serotonergic projections to IC arise from the dorsal raphe nucleus (DRN), while other raphe nuclei such as the median raphe account for the rest. However, the rodent DRN can be broken down into at least 7 anatomically and functionally distinct sub-regions, and whether each DRN sub-region projects to the IC is unknown. Elucidating how individual sub-regions contribute to serotonergic innervation of IC is the first step in understanding the neural pathways that facilitate context-dependent release of serotonin in the auditory system. To this end, we injected the retrograde tract tracer Fluoro-Gold (FG) into the IC of CBA/J mice, which were perfused 5-7 days post surgery. To test the hypothesis that sub-regions of the DRN differentially innervate IC, we visualized neurons immunoreactive (-ir) for FG as well as tryptophan hydroxylase (TPH; the rate-limiting enzyme in serotonin production) throughout the extent of DRN. We report that FG-TPH co-labeled neurons were localized to several DRN sub-regions, specifically the dorsal part (DRd), and the "lateral wings" which includes the lateral DRN (DRl) as well as the posterodorsal raphe. Additionally, we found FG-ir neurons that are nonserotonergic, providing support for the observation that not all modulatory input to IC from DRN is serotonergic. Given that DRd and DRl respectively receive projections from distinct forebrain and brainstem nuclei, we can begin to establish a network model of how different DRN afferents may gate serotonin involvement in auditory processing.

Title: Role of Kv1 channels in regulating the excitability and firing patterns of neurons in the medial geniculate body

Authors: A. M. PEDERSON, A. B. KARAGOZ, D. DEAN, K. E. DEMBNY, M. DODLA, L. DUNCAN, R. FAHMY, A. KUO, V. RAMIREZ, D. B. HAIMES, *N. L. GOLDING Dept. of Neurosci., Univ. of Texas at Austin, Austin, TX

Abstract: Potassium channels play a vital role in controlling the threshold and pattern of action potential firing in neurons of the medial geniculate body of the thalamus. In other thalamic regions, previous experiments have implicated fast-inactivating Kv4 family potassium channels (so-called "A-current") in raising spike threshold and delaying the onset of action potential firing during depolarizations. However, other studies suggest that low threshold, Kv1 family potassium channels play the dominant role in shaping the timing of firing. Thus the respective roles of these channels in medial geniculate neurons remains unclear. To address this question, we performed whole cell current-clamp recordings in neurons of the medial geniculate body in the rat auditory thalamus (near-horizontal slices, 17 postnatal day animals, 24-26°C). Recordings were made in all subdivisions of the nucleus. In a fraction of recordings 1% biocytin was included in the pipette solution for subsequent morphological analysis. In response to one second long current pulses, medial geniculate neurons typically exhibited a ramping depolarization and a delayed onset of action potential firing, the magnitude of which was dependent on the amplitude of the stimulus. These delays could be sharply reduced by the injection of 500 ms pre-pulses to the cell that produced depolarizations spanning the subthreshold voltage range (max. decrease in delay from 332.16 ± 74.3 ms to 57.25 ± 7.8 ms, n=5). This delay to firing was also strongly reduced by the application of 80nM -dendrotoxin (DTX), a selective blocker of the Kv1 family of potassium channels (Ctl, 332.16 ± 74.3 ms delay; DTX, 159.76 ± 38.6 ms, n=5). While DTX did not alter the input resistance of cells significantly, DTX typically lowered action potential threshold to more hyperpolarized values and reduced spike afterhyperpolarizations. The slopes of frequencyintensity curves were steeper in DTX, with firing saturating at lower values of current injection. These results indicate that Kv1 channels play a critical role in controlling the excitability of neurons throughout the medial geniculate nucleus. Activation of Kv1 channels in responses to sound stimuli in vivo would be expected to increase both their frequency selectivity and dynamic

range, as well as enable medial geniculate neurons to encode a broader range of sound intensities.

Title: Modularity of intrinsic inputs within the lateral cortex of the mouse inferior colliculus

Authors: *A. M. LESICKO¹, D. LLANO²

¹Univ. of Illinois At Urbana-Champaign, Urbana, IL; ²Univ. of Illinois at Urbana-Champaign, Urbana, IL

Abstract: The lateral cortex of the inferior colliculus contains a network of modules characterized by dense labeling for glutamic acid decarboxylase-67 (GAD-67) and other neurochemical markers. Previous studies from our laboratory have shown that the extrinsic sensory inputs to the lateral cortex are patterned: somatosensory inputs terminate within these neurochemical modules, while auditory inputs target the extramodular regions of the lateral cortex. While the topography of extrinsic inputs to the lateral cortex is well defined, the degree and directionality of intrinsic connectivity between neurons in this region remains unknown. In the present study, we sought to characterize the intrinsic inputs to neurons in the lateral cortex of the mouse inferior colliculus and determine if these connections also exhibit modularity. Experiments were performed in brain slices from the GAD-67-GFP knock-in mouse, in which modular and extramodular areas of the lateral cortex can be clearly distinguished. GAD-67positive and GAD-67-negative cells in both regions were recorded from in either a single or dual-channel whole-cell voltage clamp configuration while potential pre-synaptic sites throughout the ipsilateral colliculus were stimulated using laser photostimulation of caged glutamate. Preliminary results include a heterogeneous set of input maps. Presynaptic stimulation generated both excitatory and inhibitory responses in cells within the lateral cortex; excitation resulted predominately from direct stimulation of the recorded cell, while strong synaptic inhibition was seen for the majority of cells. Neurons within modular regions of the lateral cortex received inputs primarily from presynaptic sites within a module, while extramodular cells were predominately activated from sites outside of the modules. These preliminary data indicate that

the intrinsic connections within the lateral cortex may also exhibit modularity that is predicted by the underlying neurochemical modularity within this structure. Potential interconnectivity between modular and extramodular regions of the lateral cortex could have important implications for processing of multisensory information in the lateral cortex.

Title: A Cre mouse line labeling stellate cells of the ventral cochlear nucleus

Authors: *G. E. ROMERO¹, L. O. TRUSSELL²

²Oregon Hearing Res. Ctr., ¹Oregon Hlth. and Sci. Univ., Portland, OR

Abstract: T-Stellate (planar multipolar) cells of the ventral cochlear nucleus (VCN) are excitatory neurons that receive frequency specific input from auditory nerve and whose axons have wide ranging targets, including local collaterals, superior olive, dorsal cochlear nucleus and inferior colliculus. We have been interested in identifying mouse lines that mark t-stellate cells in order to perform cell specific anatomical, electrophysiological, and optogenetic studies. Here we report an analysis of labeling of t-stellate cells in a somatostatin-cre mouse line. This line was crossed to an Ai9 tdTomato reporter to generate mice with tdTomato in cre positive cells. In histological sections, labeled cells were observed throughout the VCN, with only sparse somata found in the dorsal cochlear nucleus (DCN). This line was then crossed to a GlyT2-GFP BAC transgenic line to double label for cre and glycinergic neurons. In the VCN, most cells were not double labeled, suggesting that the majority of cre+ cells were excitatory neurons. A few large, double-labeled cells were observed, consistent with labeling of D-stellate neurons, a large inhibitory projection cell. In the medial nucleus of the trapezoid body (MNTB), an occasional calyx of Held was apparent in each section, suggesting that relatively few globular bushy cells label. Thus, the majority of tdTomato labeled VCN cells are neither bushy cells nor inhibitory. To probe their identity further, we conducted patch clamp recordings on labeled cells in brain slices to assess their intrinsic firing properties, and related those results to known properties of different VCN cell classes. We found that 81% (71 of 88) of tdTomato+ cells exhibited repetitive firing in response to steady inward current steps. Peristimulus time histograms of spike firing in these repetitively firing cells closely resembled the chopping profile of t-stellate cells recorded in vivo in a variety of species. Dye in injections into cells generally revealed a dendritic layout

consistent with the t-stellate cell's narrow band acoustic input and morphology. Finally, dense concentrations of labeled boutons were present both in the superior olivary nuclei and in the DCN, two known targets of t-stellate projections. Additional observations in this study are that an apparently random subset of MNTB neurons are also cre positive, as are a large set of neurons throughout the inferior olive. We propose that this line may be of use in virally driven tract tracing and functional optogenetic studies of auditory circuitry.

Title: Neuronal organization in the inferior colliculus revisited with cell-type dependent monosynaptic tracing

Authors: *C. CHEN¹, M. CHENG¹, T. ITO², S. SONG¹ ¹Tsinghua Univ., Beijing City, China; ²Kanazawa Med. Univ., Kanazawa, Japan

Abstract: The inferior colliculus (IC) is viewed as the first integration center in auditory pathway. It is generally accepted that core IC receives ascending inputs, while shell IC receives descending and core inputs, and inputs are combined to innervate groups of neurons. Moreover, IC is composed of excitatory and inhibitory projection neurons.

Here, we utilized the monosynaptic rabies tracing technique, combined with excitatory and inhibitory Cre driver mouse lines to characterize the brain-wide inputs to specified IC neuron types within specific subdivisions. Furthermore, with the *in situ* hybridization method, we clarified the cell type of commissural inputs on specific cell types.

First, we uncovered two long-range disinhibitory connections in core and shell IC. The core inhibitory neurons received more inhibitory inputs from ventral nucleus of lateral lemniscus than excitatory neurons, suggesting this inhibitory feedforward tectothalamic circuit could be effectively inhibited. In addition, shell inhibitory neurons received more ascending ventral cochlear nucleus inputs than excitatory neurons. Furthermore, inhibitory neurons preferentially received inhibitory inputs from contralateral shell IC. We suppose that the candidate neurons for multisensory integration of shell IC are subsets of GABAergic neurons.

Second, with covariance analysis of input nuclei, we found that core excitatory neurons received

modular ascending inputs, while shell excitatory neurons received the other modular inputs, which was composed of descending, neuromodulatory nuclei and contralateral inputs. On the other hand, inhibitory neurons received mixed inputs. The differential pattern of inputs suggests excitatory and inhibitory neurons play different roles in auditory pathway. Lastly, we revealed that shell excitatory and inhibitory neurons both received dominant ascending inputs, rather than descending or core inputs. This is consistent with anterograde tracing studies which have clearly shown that the deep layer of shell is innervated by numerous ascending fibers. Similar with the excitatory neurons between core and shell, within shell, we found excitatory neurons which received modular ascending inputs distinct from those received other inputs. Together, we suggest that tripartite pathways may exist within IC. Primary lemniscal pathway locates within core, secondary nonlemniscal pathway locates within shell, and third polysensory pathway locates within shell deep layer.

This is the first systematic and cell-type defined study on the IC, and lays the foundation for further physiological and behavioral experiments.

Title: OHC glutamate signaling: OHC VGLUTS and cochlear nucleus neurons activated by Type-II afferents in response to sound

Authors: *C. J. WEISZ¹, C. S. ECKARD², C. B. DIVITO³, K. N. FANTETTI⁴, S. A. DETTWYLER², M. E. RUBIO², K. KANDLER⁵, R. P. SEAL³ ¹Natl. Otolaryngology, Univ. of Pittsburgh Sch. of Med., Pittsburgh, PA

Abstract: Outer hair cells (OHCs) are critical for normal hearing and work through an electromotile mechanism, which amplifies sound and sharpens the frequency tuning curve. However OHCs also form synapses with centrally projecting type II afferents and release vesicular glutamate. Unlike inner hair cells (IHCs), which clearly show the presence of VGLUT3 by immunostaining, the VGLUT(s) used by outer hair cells have been more difficult to discern. Here we used a number of approaches including RT-PCR, distribution of floxed reporter proteins in VGLUT-Cre expressing mice and patch clamp recordings of OHC-type II afferent synapses in VGLUT knockout mice to demonstrate that VGLUT3 is the predominate isoform in the OHCs, but that VGLUT2 is also expressed at least at early postnatal ages. In addition, we examined the distribution of cochlear nucleus neurons activated as a consequence of specifically inducing OHCs to signal in response to sound. For this study, we took advantage of a Cre mouse line that expresses the recombinase in only IHCs and not OHCs and crossed it to our conditional VGLUT3 knockout mice to eliminate VGLUT3 from inner and not outer hair cells. After exposure of the mice to a 115 dB SPL broadband noise, we assessed the distribution of c-Fos, a marker of neuronal activity, within the cochlear nucleus. Post-hoc analyses of the cochleae demonstrate no loss of hair cells or cilia. The study shows the functional recruitment of neurons specifically within the granule cell layer of the cochlear nucleus. Data presented here provide important new information about OHC-type II afferent glutamate signaling that will aid in determining the role of this signaling pathway in auditory function.

Title: A layer-specific corticofugal input to the mouse superior colliculus

Authors: *H. ZURITA¹, C. ROCK², J. PERKINS³, A. APICELLA¹ ¹Univ. of Texas At San Antonio, San Antonio, TX; ²Biol., ³Univ. of Texas at San Antonio, San Antonio, TX

Abstract: In the auditory cortex (AC), corticofugal projections arise from each level of the auditory system and are considered to provide feedback "loops" important to modulate the flow of ascending information. It is well established that the cortex can influence the response of neurons in the superior colliculus (SC) via descending corticofugal projections. However, little is known about the relative contribution of different pyramidal neurons to these projections in the SC. We addressed this question by taking advantage of anterograde, retrograde neuronal tracing, and optogenetics to directly examine the laminar distribution, long-range projections, electrophysiological properties, and thalamic synaptic input of pyramidal neurons projecting from the AC to the SC of the mouse brain. Here we show that layer 5 cortico-superior-collicular pyramidal neurons act as bandpass filters, resonating with a broad peak at \sim 3 Hz, whereas layer 6 neurons act as low-pass filters. The dissimilar subthreshold properties of layer 5 and layer 6 cortico-superior-collicular pyramidal neurons can be described by differences in the hyperpolarization-activated cyclic nucleotide gated cation h-current (Ih). Ih also reduced the summation of short trains of artificial excitatory postsynaptic potentials injected at the soma of layer 5, but not layer 6, cortico-superior-collicular pyramidal neurons, indicating a differential dampening effect of Ih on these neurons.

Title: Laminar differences in responses to naturalistic texture in macaque V1 and V2

Authors: *R. K. PEREZ, J. PAI, C. M. ZIEMBA, L. E. HALLUM, C. SHOONER, J. G. KELLY, J. A. MOVSHON Ctr. for Neural Sci., New York Univ., New York, NY

Abstract: We recently reported that neurons in V1 and V2 of visual cortex are differentially selective to the naturally occurring higher-order statistics of visual textures. Most single units recorded from macaque V2 respond with higher firing rates to synthetic texture images containing "naturalistic" higher-order statistics than to spectrally-matched "noise" images lacking these statistics. In contrast, few single units recorded from macaque V1 show this property. To better understand the possible origins of sensitivity to the statistics of naturalistic textures, we explored how the strength and dynamics of response vary across the different layers of visual cortex.

We recorded neuronal activity in V1 and V2 of four anesthetized macaque monkeys using a laminar probe with 32 contacts spaced 0.1 mm apart. We briefly presented samples from a large set of synthetic images matched to the statistics of 32 different ancestral photographic images. The stimulus set included noise images, matched only in their power spectra, as well as naturalistic textures, matched for a rich set of higher-order statistics. The areal and laminar location of recording contacts was estimated from analysis of current source density and histology.

We measured multi-unit and gamma-band activity in response to naturalistic textures and spectrally-matched control images. We defined the sensitivity to the difference in response at each contact and time point in units of d'. As expected, recordings in V2 showed consistently stronger responses to naturalistic texture, and correspondingly robust values of d'. In contrast to earlier single unit work, V1 multi-unit activity showed some sensitivity to texture statistics, and gamma-band activity showed even higher sensitivity, comparable in magnitude to V2. Sensitivity to naturalistic texture in V1 was evident in the upper and lower layers, but weak in middle layers, suggesting that it might result from feedback from V2. To test this, we measured multi-unit visual response latency, and the time course with which reliable multi-unit sensitivity for the naturalistic images emerged. Visual responses were first evident in the middle layers of V1, then propagated to upper and lower layers of V1, and then emerged in V2. Texture sensitivity emerged 10-30 ms later, first in the upper layers of V2, then in the remainder of V2, and finally in V1.

Our results demonstrate laminar differences in the encoding of higher-order statistics of natural texture in both V1 and V2. Response dynamics suggest that sensitivity first arises in V2 and is fed back to weakly modulate the firing of individual V1 neurons.

Title: Organization of binocular signals in macaque V1 and V2

Authors: *L. E. HALLUM, C. SHOONER, J. G. KELLY, R. RAGHAVAN, M. J. HAWKEN, J. A. MOVSHON Ctr. for Neural Science, New York Univ., New York, NY

Abstract: The cortical organization of binocular signals is only partly understood. We recorded multi-unit signals using a 32-contact linear probe with 0.1 mm contact spacing implanted normal

to the opercular surface in V1 and V2 of two anesthetized, paralyzed, visually normal macaques. We presented large sinusoidal grating patches of optimal orientation and spatial frequency to each eye. At 100 ms intervals, we independently randomized patch contrast (0, 50, 100%) and spatial phase (0, 45, ... 315 deg). Using responses to 100%-contrast stimuli, we quantified ocular dominance on a seven-point scale. We measured relative phase-selectivity by plotting response against interocular phase difference and calculating the modulation ratio (F1/F0). To capture linear responses to modulations around mean contrast, we pooled over stimulus phase and computed the spike-triggered average (STA) of the stimulus appearing in each eye (0, 50 and 100% contrasts were represented by regressor values -1, 0 and 1, respectively). We also computed a spike-triggered average of the product of the regressors representing the stimuli in the two eyes, capturing nonlinear interactions of eye signals. We reconstructed the recording locations histologically. We recorded from 260 V1 sites and 89 V2 sites. Approximately 75% of V1 sites were binocular and 95% of V2 sites were binocular. Comparing binocular sites, V2 was more selective for relative phase than V1. At binocularly activated sites in V1, STAs revealed that responses to contralateral eye stimulation peaked, on average, 8 ms earlier than those of the ipsilateral eye, whereas in binocular V2 we found no such latency difference. At approximately 15% of sites in V2, we observed two response types not seen in V1: stimulation of one eye suppressed cortical responses to stimulation of the other eye; and the nonlinear response to interactions between signals from the two eyes was comparable in magnitude to the linear response to contrast. The diverse patterns of response we have observed presumably reflect processes that support specific binocular functions, including stereopsis and interocular suppression.

Title: Curvature sensitivity of V2 neurons in amblyopic monkeys

Authors: *Y. WANG¹, B. ZHANG², X. TAO³, G. SHEN³, J. M. WENSVEEN¹, I. OHZAWA⁴, E. L. SMITH, III¹, Y. M. CHINO¹

¹Col. of Optometry, Univ. of Houston, Houston, TX; ²Col. of Optometry, Nova Southeastern Univ. Col. of Optometry, Davie, FL; ³Baylor college of Med., Houston, TX; ⁴Osaka Univ., Suita, Osaka, Japan

Abstract: Experiencing binocular imbalance early in life leads to binocular vision disorders and often amblyopia. Amblyopic humans show the reduced capacity for judging the relative position of a visual target in reference to nearby stimulus elements (position uncertainty) and often experience visual image distortion. Abnormal pooling of local stimulus information by neurons beyond striate cortex (V1) is often suggested as a neural basis of these deficits. The receptive field (RF) of neurons in visual area V2 in normal monkeys is made up of multiple subunits that are thought to reflect V1 inputs and are capable of encoding the spatial relationship between local stimulus features. We previously found that unlike in normal monkeys, the subunit maps of V2 neurons in amblyopic monkeys were severely disorganized: the overall difference in preferred orientations and spatial frequencies between subunits were far greater than that in normal monkeys (Tao et al, 2013). This discovery suggests that the ability of V2 neurons to encode the degree and direction of curved contours in image sub-regions may be compromised in amblyopic monkeys. In this study we investigated the sensitivity of V2 neurons to curvature (degree and direction) in anesthetized amblyopic monkeys that were reared with chronic monocular defocus. We used dynamic dense noise stimuli and a novel analysis method of quantifying the neuron's selectivity to stimulus orientation and curvature (Transform Domain Reverse Correlation or TDRC)(Arai et al, 2017). The TDRC computes spike-triggered average of stimuli after transforming them into curvature domain. We found that 1) the proportion of curvature sensitive neurons driven by the amblyopic eye was slightly lower compared to that driven by the fellow eye, 2) the average signal strength and reliability (z-score) of curvature sensitive neurons driven by the amblyopic eye was significantly lower than that for neurons driven by the fellow eye, 3) although the spatial organization of curvature selectivity within RF (subunit map) was generally similar between amblyopic and fellow neurons, the curvature selectivity index for each neuron (defined as an absolute value of summed z-scores of all nonzero curvature subunits divided by the sum of all z-scores) was significantly lower for amblyopic neurons compared to that for fellow neurons, 4) there was no difference between "amblyopic neurons" and "fellow neurons" with respect to the distribution of preferred direction. These results suggest that the curvature sensitivity of V2 neurons is lower for those V2 neurons driven by the amblyopic eye compared to that for the fellow eye.

Title: Spiking noise in V2 neurons of infant monkeys

Authors: *B. ZHANG¹, Y. WANG², X. TAO⁴, G. SHEN², J. WENSVEEN³, E. L. I. SMITH³, Y. M. CHINO⁵

¹Col. of Optometry, Nova Southeastern Univ. Col. of Optometry, Davie, FL; ²Col. of Optometry, ³Univ. of Houston, Houston, TX; ⁴Baylor Col. of Med., Houston, TX; ⁵Univ. of Houston Col. of Optometry, Houston, TX

Abstract: We previously reported that spiking of neurons in visual area V2 of amblyopic monkeys is noisy; the square of the coefficient of variation in inter-spike intervals (CV^2) and the trial-to-trial fluctuation in spiking (m-FF) are abnormally elevated in monkeys reared with monocular defocus (Wang et al, 2017). Moreover the noisiness of spiking was stimulus contrast dependent and correlated with the level of binocular suppression measured for the same V2 neurons. These results suggest that interocular decorrelations of cortical inputs by experiencing early monocular chronic defocus disrupted the normal maturation of cortical circuitry in V2. However, to better understand how abnormal spiking noises emerge in V2 of amblyopic monkeys, it is necessary to know how noisy the spiking of V2 neurons is in normal infant monkeys around the time when binocular imbalance was introduced in our previous study (3-4 weeks of age). In this study, therefore, we analyzed the spike trains of V2 neurons in 4- and 8week-old 'normal' infant monkeys. More specifically, we quantified the spiking noise in response to brief (640 ms) sine wave gratings that were optimized for orientation and spatial frequency for each neuron and varied for contrast between 0% and 80%. We calculated CV² and mean matched Fano Factor (m-FF) for stimulus contrasts 0%, 10%, 25%, 50% and 80%. We found that both the magnitude of spiking irregularity (CV²) and the trial-to-trial fluctuation (m-FF) was much *lower* in spike trains of V2 neurons in infant monkeys than those in adult monkeys for all stimulus contrasts. Our findings suggest that the enhanced noise in spiking of

amblyopic V2 neurons in our previous study resulted from 'active' disruptions of developing cortical connections due to abnormal visual experience instead of passively maintaining ('freezing') the immature state of cortical connections around 3-4 weeks of age.

Title: Three organizing principles for feature selectivity in V2

Authors: *R. ROWEKAMP¹, T. O. SHARPEE²

¹Salk Inst. CNL-T, La Jolla, CA; ²CNL-T, Salk Inst., La Jolla, CA

Abstract: Object recognition relies on a series of transformations among which only the first cortical stage is relatively well understood. Already at the second stage, the visual area V2, the complexity of the transformation precludes a clear understanding of what specifically this area computes. Previous work has found multiple types of V2 neurons, with neurons of each type selective for multi-edge features. Here we analyze responses V2 neurons to natural stimuli using a quadratic convolutional model along with linear and non-convolutional alternatives. We found that the quadratic convolutional model outperformed the predictive power of linear model on a reserved dataset by a factor of 3.9. The quadratic convolutional models had an average of 7.6 excitatory and 5.8 suppressive features, with the number of each strongly correlated.Further analysis of the models shows three organizing principles. First, the relevant edges for V2 neurons can be grouped into quadrature pairs, indicating invariance to local translation. Second, the

excitatory edges have nearby suppressive edges with orthogonal orientations. Third, the resulting multi-edge patterns are repeated in space to form textures or texture boundaries. The cross-orientation suppression increases the sparseness of responses to natural images based on these complex forms of feature selectivity while allowing for multiple scales of position invariance. Finally, we could divide the neurons into two subpopulations based on the spread of the orientations that excited the neurons.

Title: A deep convolutional energy model of ventral stream areas V1, V2 and V4

Authors: *M. D. OLIVER¹, J. L. GALLANT²

¹UC Berkeley, Berkeley, CA; ²Univ. of California Berkeley, Berkeley, CA

Abstract: The ventral stream areas V1, V2 and V4 are crucial for visual object recognition. While V1 responses have been extensively and successfully modeled using a variety of approaches, there has been much less success building general models of areas V2 and V4. In order to build models that can generalize to any stimulus set, we recorded from neurons while awake animals viewed clips of large, full color natural movies. The chronic recordings were stable enough that neurons could often be held for several days. This allowed us to collect responses to hundreds of thousands (up to over 1 million) distinct movie frames, for hundreds of different V1, V2 and V4 neurons. This large volume of data allowed us to fit a highly flexible, yet biologically inspired and constrained model to the responses of each neuron. The model incorporates insights from the Adelson-Bergen energy model, the scattering transform and deep convolutional neural networks. We call this the deep convolutional energy model. A two-stage version of the model is used to model V1 and V2. To model V4, the first stage of the model is simply repeated to create a three-stage model. In addition, for the V4 model stimuli are preprocessed with a log-polar transform to account for the fact that the large receptive fields in V4 are warped by V1's cortical magnification of the visual field. These models are simple and interpretable, and predict V1, V2 and V4 responses significantly better than previous models. In particular, deep convolutional energy models fit to V1 and V2 neurons stimulated with natural

movies approach the noise-ceiling of prediction performance. For the first time, a model can predict most of the variance in most of the recorded neurons in V1 and V2. In V4, the model can not only predict responses to natural movies better than previous models but can also accurately predict V4 responses to various types of synthetic curvature stimuli similar to those used in previous studies of V4. Furthermore, the models can also be used to interpret the response properties of each neuron by generating optimal excitatory and inhibitory stimuli. This allows the direct visualization of usually invisible features such as the inhibitory surround. The deep convolutional energy model thus presents a unified framework for modeling and understanding the ventral stream.

Title: Different cell types project from L4B of V1 to V2 in macaque monkey

Authors: *J. T. YARCH¹, H. LARSEN², M. CHEN², M. FIEDEL², A. ANGELUCCI³ ¹Moran Eye Inst., ²Ophthalmol, Moran Eye Inst., Univ. of Utah, Salt Lake City, UT; ³Ophthalmol, Moran Eye Inst., Univ. of Utah, Salt Lake Cty, UT

Abstract: Layer (L) 4B of the macaque primary visual cortex includes two morphological types of excitatory projection neurons: pyramidal cells, which receive functional inputs from both magno- (M) and parvocellular (P) divisions of L4C, and spiny stellate cells, which receive only

M inputs from L4Ca. Previous studies found that area MT receives 80% of its L4B inputs from spiny stellates, while area V2 receives 80% of its L4B inputs from pyramids (Nassi & Callaway, 2007). As V2 consists of distinct cytochrome oxidase stripes, which receive segregated projections from V1 L4B, we asked whether projections to distinct stripes arise from distinct L4B cell types. L4B neurons were labeled by injecting a GFP-expressing G-deleted rabies virus into either the thick or thin stripes of V1 (n= 6 injections in 5 animals), identified in vivo by optical imaging, and the somata and dendrites of 63 cells (42 thick-projecting and 21 thinprojecting) were fully reconstructed. We found a larger amount of spiny stellate input from L4B to both thick and thin stripes than in previous studies, with greater stellate input to thick (55% of total) than to thin (40% of total) stripes. This finding suggests a greater M contribution from V1 to V2 than previously thought and, therefore, to both the dorsal and ventral visual streams, to which thick and thin stripes project, respectively. We also measured several morphological properties for these cells: soma area, soma perimeter, total dendritic length, dendritic perimeter, dendritic area, and dendritic complexity. Unbiased cluster and PCA analyses, using these metrics, revealed that both spiny stellate and pyramidal cells separate into 3 different groups (small, medium, large). Only the largest stellates showed stripe-type specificity, projecting only to thick stripes, and resembling those previously reported to project only to area MT. These large stellates constitute only 7% of all the stellate cells we characterized. The other cell groups projected equally to thin or thick stripes. Our results indicate that L4B stellate and pyramidal cells projecting to V2 each consist of 3 different types differing in size and dendritic complexity, but not in their targeted V2 stripe, except for the giant stellates that project only to thick stripes. Neurons with different dendritic field sizes and complexity suggest different abilities for visuospatial integration, and may correlate with the different known functions of L4B neurons including orientation, direction, and disparity tuning.

Title: Kv3.1b expression in putative excitatory subpopulations in macaque V2: Quantitative laminar investigation of Kv3.1b, PV, and GABA co-immunoreactivity

Authors: *J. G. KELLY, M. J. HAWKEN

Ctr. for Neural Sci., New York Univ., New York, NY

Abstract: The Kv3.1b potassium channel subunit, which facilitates the fast-spiking phenotype characteristic of parvalbumin (PV)-expressing inhibitory interneurons, is also expressed by a subpopulation of excitatory neurons in macaque V1 that are concentrated in layers $4C\alpha$ and 4B. It was unknown whether this pattern was specific to V1 and/or to the magnocellular (M) pathway. We examined whether there were also Kv3.1b⁺ excitatory neurons in area V2 and quantified their laminar distribution. Parasagittal sections from dorsal V2 of three macaque monkeys were immunofluorescence labeled for Kv3.1b, PV, and GABA and examined using confocal microscopy and an automated image analysis-based counting method. Densities of neurons of each type were measured across cortical depth and compared with overall neuronal densities measured previously. Results were compared to our previous observations from V1. The GABAergic population comprised 13% of all neurons, lower than previous estimates. Across layers 2-6 the proportion of GABAergic neurons ranged from 10-13%. In V2, Kv3.1b and PV were frequently co-expressed: 80% of Kv3.1b⁺ neurons and 88% of PV⁺ neurons expressed both Kv3.1b and PV. In a previous study in V1 we found that Kv3.1b⁺ neurons expressing either GABA or PV almost always co-expressed the other substance. In V2, this was often, but not always, the case: 87% of Kv3.1b⁺, PV⁺ neurons were also GABA⁺, and 91% of Kv3.1b⁺, GABA⁺ neurons were PV⁺. Kv3.1b⁺, GABA⁺, PV⁻ neurons were most frequently observed in layers 2 and 3.

Kv3.1b⁺, GABA⁻, PV⁻ neurons were present in dorsal V2 and were largely restricted to layer 3B, comprising 4% of the total neuronal population and 34% of all Kv3.1b⁺ neurons in this layer. Many of these neurons could be identified as pyramidal neurons. Therefore, there is a population of putative excitatory neurons in layer 3B that are likely to show relatively narrow spike widths and that may be capable of high firing rates, the signature of Kv3.1b⁺ excitatory subpopulations are not specific to area V1 and may be common across primate cortical areas.

Title: Properties of layer 1 inputs to layer 1 neurons of the medial secondary visual cortex in mice

Authors: *Y.-W. LAM¹, S. SHERMAN²

¹Univ. of Chicago, Chicago, IL; ²Dept Neurobiol, Univ. Chicago, Chicago, IL

Abstract: Layer 1 of the neocortex consists of loosely packed GABAergic neurons scattered among apical tufts of pyramidal neurons and horizontally oriented axons. These axons derive from the "matrix" thalamus and other cortical areas. Last year we reported on local inputs to these layer 1 cells from lower-layers in slice preparations from the medial secondary visual cortex of the mouse brain. Here we study the responses of these cells to stimulation of their afferents at a horizontal distance within layer 1 in coronal slice preparations of the medial secondary visual cortex.

Stimulation was achieved via a concentric bipolar electrode placed in layer 1 100 to 500 µm lateral to the recording site. Such stimulation evoked biphasic responses in voltage-clamp mode. When the excitatory currents were isolated by including the GABAergic antagonist, 4,4'-Dinitro-stilbene-2,2'-disulfonic acid (DNDS), in the intracellular solution, these currents exhibited paired-pulse depression, and they were blocked by application of iGluR blockers (DNQX & AP5); further high frequency stimulation failed to evoke mGluR responses in two experiments, suggesting that these glutamatergic inputs, whether from thalamic or cortical origin, have "driver" properties. In other experiments, inhibitory currents remained in the presence of iGluR antagonists and showed pair-pulse depression; these currents were blocked by a GABAA antagonist, gabazine.

A long-lasting excitatory current was revealed after both glutamatergic and GABAergic currents were blocked. This current was partially inhibited by a serotonergic antagonist, methiothepine maleate (10 μ M), whereas muscarinic (10 μ M scopolamine) and dopaminergic (10 μ M clozapine) antagonists had no effect. More experiments will be conducted to study the composition of this current.

Title: Functional relationship between primary and higher-order visual cortices

Authors: *R. BELTRAMO, M. SCANZIANI

UCSF, San Francisco, CA

Abstract: The mouse visual cortex consists of a primary visual area (V1) surrounded by at least 9 retinotopically organized higher-order visual areas which are functionally tuned to specific features of the visual scene. Unraveling how information flows between primary and higher cortical areas is a crucial step in understanding the mechanisms of visual perception. V1 receives retinal inputs through the dorsal lateral geniculate nucleus of the thalamus, and heavily projects to higher order visual areas. However, despite the dense projections, the extent to which V1 actually *drives* the activity of higher-order cortical areas is a matter of debate. To address this issue, we optogenetically silenced the primary visual cortex of awake mice and simultaneously recorded, with multichannel electrodes, the visual areas was heavily affected by V1 silencing, the activity of others was minimally influenced. These results show that the neural activity of higher-order visual cortices differentially relies on V1 inputs. Characterizing the source of V1-independent visual information that reaches higher cortices will expand our knowledge on potential V1-bypassing pathways in the mouse visual system.

Title: The transformation of visual information through the mouse visual cortex

Authors: *S. E. DEVRIES¹, M. A. BUICE¹, J. LECOQ², G. K. OCKER³, D. MILLMAN³, N. H. CAIN¹, D. FENG¹, R. REID⁴ ¹Allen Inst. For Brain Sci., Seattle, WA; ²Structured Sci., Allen Inst., Seattle, WA; ⁴Neural Coding, ³Allen Inst. for Brain Sci., Seattle, WA

Abstract: A prominent question of sensory processing is how information is transformed by the neural circuit in order to create perceptions and ultimately guide behavior. Physiological recordings from different stages in the circuit can shed light on these transformations, but often suffer from using different stimulus sets or experimental paradigms. The Allen Brain Observatory is a public dataset of neural activity in the mouse visual cortex created by the Allen

Institute for Brain Science. Using high throughput 2-photon calcium imaging of transgenically expressed GCaMP6f under the control of specific Cre drivers, we have captured the neural activity of specific neuron populations in response to a standard set of visual stimuli, including gratings, noise stimuli, natural images and movies. To date, we have released over 200 datasets collected from neurons in six cortical visual areas using six excitatory Cre lines spanning from layer 2/3 to layer 5. Neurons are individually characterized by their spatial receptive field structure, their temporal dynamics, and their orientation, spatial and temporal frequency tuning. Further, responses to natural images and movies serve to compare the spatial and temporal response properties to activity in a more naturalistic context. Using this dataset, we examine single cell responses and population coding to explore how the representation of visual information changes through the mouse cortical circuit. We observe that many response features remain largely unchanged through the circuit, while others show marked changes. For example, while the orientation selectivity of neurons measured in response to grating stimuli is largely the consistent across distinct visual areas and layers, direction selective responses are more prominent in V1 than in the higher visual areas. Similarly, population decoding of natural scenes performs better in V1 than in higher visual areas. We will explore these differences in visual representation throughout the mouse visual cortex, and consider the implications this has on prevailing models of cortical computation in the visual cortex.

Abstract: Although it is known that mice have roughly ten distinct visual areas, the specific function of each area and interactions between areas remain poorly understood. In this study, we used wide-field imaging from awake, head-fixed mice, which transgenically expressed GCaMP6f, to segment the entire visual cortex into functionally different areas and investigate each areas' responses to a battery of visual stimuli, including simple drifting gratings (varying orientation, spatial frequency and temporal frequency), random moving dots and natural movies. Despite the well-known "salt-and-pepper" distribution of orientation preference at a microscopic scale in mouse V1, we found a retinotopically dependent mesoscale bias of averaged orientation preference and spatial and temporal frequency preferences, in response to drifting gratings. In addition, we found higher orientation selectivity in the binocular region. Representation of the amplitude and phase of natural movies were biased towards the binocular zone and monocular zone respectively. In addition to these conventional input-output characterizations, we also applied various machine learning techniques on this dataset to explore its intrinsic structure. Specifically, we used supervised Gaussian Mixture Models (GMM) and unsupervised agglomerative clustering of Maximum a Posteriori (MAP) model to estimate area borders. The generated models in both cases predicted area borders consistent with that of the physiologically identified retinotopic map, suggesting that each area had consistent and correlated responses to visual stimuli. In another experiment, we observed that spatial temporal change points in the visual stimuli correlated well with the change points in the cortical responses. Altogether, by integrating tools developed from mouse genetics, large-scale imaging and modern statistical analysis, we obtained novel insights into the functional organization of mouse visual cortex. These hypotheses are being verified with further experiments.

Title: A hierarchical organization of mouse visual cortical areas

Authors: *R. D'SOUZA¹, Q. WANG^{1,2}, W. JI¹, A. MEIER¹, H. KENNEDY³, K. KNOBLAUCH³, A. BURKHALTER¹

¹Dept of Neurosci., Washington Univ. Sch. of Med., Saint Louis, MO; ²Allen Inst. for Brain Sci., Seattle, WA; ³Inserm U846, Bron, France

Abstract: The mammalian visual cortex is a mosaic of multiple, distinct areas that communicate with each other through the axons of pyramidal neurons. Previous studies in monkeys (Maunsell and Van Essen, 1983; Felleman and Van Essen, 1991) and rats (Coogan and Burkhalter, 1993) have shown that the laminar termination patterns in the target area formed by these axons depend on the hierarchical organization of the connecting areas. The interareal pathways have been classified as being feedforward if they transmit signals from lower to higher areas of the cortical hierarchy, feedback if they send descending inputs from higher to lower areas, or lateral if they belong to the same hierarchical level. Due to the tractability of the mouse model in examining cortical circuit physiology and function, constructing the hierarchy of mouse visual cortex is a crucial step in understanding how sensory processing is achieved across a distributed neocortical system. To do this, we first injected the anterograde tracer, biotinylated dextran amide, into each of ten previously identified visual areas, and examined the axonal termination patterns in each of the other nine. Areas were identified by the locations of the axonal projections relative to retrogradely-labeled callosal landmarks, and by their locations relative to each other. Feedforward projections from primary visual cortex (V1) terminated strongest in layers 2 to 4 (L2-4) while selectively avoiding layer 1 (L1) in each of the target areas. On the other hand, feedback projections from each of the higher areas to V1 showed a strong preference for terminating in L1 and only weakly targeting L2-4. We therefore reasoned that the ratio of the density of axonal afferents in L2-4 to that in L1 ('density ratio', DR) would provide for a quantitative measure of hierarchical distance between two connecting areas. We generated a 10x10 connectivity matrix of 80 interareal pathways, which included 37 bidirectional areal pairs. A beta regression analysis of all 80 DRs showed that the ten areas occupy seven hierarchical levels, with areas POR (postrhinal area) and AM (anteromedial area) at the highest level of the hierarchy. We further separated the areas depending on whether they belong to the dorsal or ventral stream (Wang et al., 2012), and propose a hierarchy for each stream. Additionally, electrophysiological mapping of receptive fields of neurons in each area showed that receptive field sizes increase with increasing hierarchical position, indicating that the structural organization of cortical hierarchy is consistent with increasing convergence of feedforward inputs.

Title: Area specialization of feature selectivity in the mouse visual cortex

Authors: *X. HAN^{1,2,3}, B. VERMAERCKE^{1,2,3}, V. BONIN^{1,2,3}

¹Neuro-Electronics Res. Flanders, Heverlee, Belgium; ²KU Leuven, Leuven, Belgium; ³Vlaams Inst. voor Biotechnologie, Gent, Belgium

Abstract: The mouse visual cortex is composed of primary sensory area (V1) and multiple secondary visual areas that receive distinct inputs from V1. So far mouse visual cortical responses were probed mainly with drifting grating stimuli. While all visual areas show highly selective responses for orientation, selectivity for spatiotemporal frequency differs widely across visual areas, indicative of functional specialization. There is little data on how these properties impact responses to more complex visual stimuli.We used cellular imaging and visual noise stimuli to probe the responses of neurons in layer 2/3 of V1 and four higher visual areas (LM, AL, AM and PM) of awake mice. To measure cellular activity, we used Thy1-GCaMP (GP4.12) mice, which express the calcium indicator GCaMP6s in a subset of cortical excitatory neurons. We stimulated neurons with spectrally-controlled noise stimuli with different peak spatiotemporal frequencies and peak orientations. To activate a broad population, we used noise stimuli of variable orientation power, ranging from isotropic (non-oriented) to anisotropic (oriented).Consistent with previous studies, around 70 percent of spatiotemporally-tuned cells showed responses to oriented stimuli. Two-thirds of these cells also responded to isotropic stimuli. Surprisingly, over a quarter of tuned cells were driven by isotropic but not anisotropic stimuli, showing a strong preference for non-oriented stimuli. Neurons responding to anisotropic and isotropic stimuli showed similar spatiotemporal tuning. We used spectral clustering to compare response patterns across visual areas. Neural responses fell into broad groups that were differentially represented across areas. V1 had the largest fraction of cells tuned to low frequencies and of cells responding to non-oriented stimuli. In contrast to V1, higher visual areas were comprised of distinctly tuned groups with mixed preferences for oriented or non-oriented stimuli. LM had fewer low frequency tuned cells and were biased toward mid frequencies (0.1 cpd, 2 Hz). A good fraction of neurons in AL and AM were tuned for low spatial frequencies, high temporal frequencies (0.025 cpd, 8 Hz). PM was composed of two main groups responding to low or high spatial frequencies (0.025 and 0.32 cpd) and low temporal frequencies (1 Hz). Taken together, our results demonstrate rich feature selectivity and functional specialization in the mouse visual cortex. We are currently investigating the circuitry underlying these responses.

Title: Modular organization of inputs to mouse postrhinal cortex involved in contextual visual processing

Authors: *A. M. MEIER¹, Q. WANG², A. H. BURKHALTER³

¹Washington Univ. Sch. of Med., Saint Louis, MO; ²Allen Inst. for Brain Sci., Seattle, WA; ³Neurosci., Washington Univ. Med. Sch., Saint Louis, MO

Abstract: Postrhinal cortex (POR) is a higher visual cortical area upstream of the entorhinal cortex and hippocampus which is essential for contextual learning and affective responses gated by input from the amygdala. We found that POR shows modular organization, in which muscarinic acetylcholine receptor 2 (M2) is strongly expressed in repeating 'patches' in cortical layer 1 (L1) interdigitating with weakly M2-expressing 'interpatches.' In primary visual cortex (V1), which is also modularly organized, layer 2/3 neurons lying below patches have distinct spatiotemporal tuning properties from those lying below interpatches. Here we tested the hypothesis that inputs from areas involved in motion and affective processing, rostrolateral cortex (RL) and lateral amygdala (LA), target different modules in POR than the dLGN and lateral posterior nucleus (LP) which are involved in bottom-up and attention-related processing. We first used retinotopic mapping of projections from V1 to POR to determine the location and borders of POR relative to M2 expression. Using transgenic mice expressing M2 tagged with tdTomato (ChM2-tdT), we found that POR lies within a region of higher M2 expression surrounded by areas P, ECT, PORa, LM, and LI. Next, we examined the projection pattern of inputs from LA, dLGN, LP, and RL to L1 of POR. LA receives cortical projections driving aversive and reward-related behaviors. dLGN provides retinotopically precise bottom-up input to L1 of V1. LP, a homologue of the pulvinar, is a higher thalamic nucleus carrying contextual information extracted from self-motion and optic flow. RL is an extrastriate area specialized for processing motion and is a possible homologue of primate MT. We injected adeno-associated virus expressing EGFP, an anterograde tracer, into these four areas to determine the projections to L1 of POR. After injections, mice were perfused with fixative and the cortex was removed and flattened. Cortices were cleared using the ScaleS protocol, then EGFP-labeled projections and ChM2-tdT expression were imaged with confocal microscopy. We found that dLGN and LP projections are biased toward targeting patches, with dLGN projections being more patchspecific. LA and RL inputs to POR more strongly targeted POR interpatches, with LA projections showing greater interpatch specificity. These projection patterns demonstrate that the patchy organization of POR serves to cluster L1 inputs from specific sets of areas: patches receive more inputs from visual thalamic structures (dLGN and LP), while interpatches receive inputs from areas related to fear and reward (amygdala) and moving objects (RL).

Title: Visual cortex activation modulated by relative head direction changes is stronger in secondary areas

Authors: *M. KANG, H. YANG, Y. JEONG

Dept. of Bio and Brain Engin., KAIST, Daejeon, Korea, Republic of

Abstract: Integrating visual information with relative head direction is essential for forming coherent representation of environment. For instance, static visual stimuli move in the opposite direction when head is rotated whereas moving visual stimuli does not. This can also be seen in virtual navigation setups where motor input and somatosensory inputs from head-to-body angle changes are coupled with changes in visual stimuli. Indeed, recent studies have reported motor activity driven modulation of visual cortex. However, little is known about which cortical regions/projections mediate the integration of somatosensory information such as changes in head-to-body angle and visual stimuli at mesoscopic level. To identify the regions activated and to characterize the dynamics of brain activity, we modulated head-to-body angle in awake, behaving Thy1-GCaMP6s transgenic mice while the cortical activity was recorded at mesoscopic level. We observed sequential activation of the cortex starting from somatosensory trunk area to secondary motor cortex, retrosplenial cortex and visual cortices. Modulation of head-to-body angle alone could drive the sequence of activity. However, the activation level was clearly higher in secondary visual cortices compared to primary visual cortex. This pattern was dependent on the depth of focus. This suggests that secondary visual cortices receive higher level of somatosensory input compared to primary visual cortex. We speculate that the selective activation of secondary visual cortices in response to head-to-body angle modulation may be mediated by the midline brain regions that send disproportionate projections to secondary visual cortices

Abstract: Understanding the brain requires more than a census of its genes or a catalog of its parts--we need to watch it in action as it performs the tasks that give rise to activity and perception

In 2016, the Allen Institute for Brain Science launched the Allen Brain Observatory: the first tool of its kind to provide a highly standardized survey of cellular-level activity in the mouse visual system. With the data and tools in this resource, researchers around the world are empowered to investigate how circuits in the mouse brain process a wide range of visual stimuli.

The first data released in June 2016 in the Allen Brain Observatory surveyed four areas in the mouse visual cortex at multiple depths, sampling more than 18,000 neurons in total. The mice were presented with a large variety of visual stimuli to determine the "tuning," or preference, of each individual cell to visual features like motion and shape orientation, as well as complex images like natural scenes and movies. Two additional data releases were carried out in 2016 and 2017, extending the scope of the observatory dataset with the inclusion of new visual areas as well as new cre-lines. In addition, we also added new metrics to quantify both previously and newly released datasets.

The Allen Brain Observatory is also a foundational platform for future system neuroscience efforts both inside and outside of the Allen Institute. As such, it is essential that we carry out careful, iterative and data driven improvements to our operational, software and hardware infrastructure. Here we describe some of these improvements along with their supportive analysis. In many such instances, we leveraged our access to a large amount of data to capture biological variability. For instance, we systematically assessed the eye gaze location to position our visual stimulation screen in an optimal location or we leveraged our platform to adjust the locally sparse noise stimulation parameters for Higher Visual Areas (HVAs).

Our final goal is to provide a comprehensive functional characterization of layers, cell types and visual areas in the mouse visual cortex. This dataset will provide key landmarks to guide future research on cortical computation during behavior task.

Title: Relationship among sensory tuning profiles across stimulus sets in mouse primary visual cortex

Authors: *D. MILLMAN, N. CAIN, G. OCKER, P. LEDOCHOWITSCH, C. REID, J. LECOQ, M. BUICE, S. DE VRIES Neural Coding Group, Allen Inst. For Brain Sci., Seattle, WA

Abstract: When characterizing the selectivity of visual sensory neurons, an exhaustive sampling of all possible stimulus features is not tractable. Instead, one or a few classes of stimuli are typically used to characterize specific aspects of a cell's selectivity, often in an attempt to efficiently sample along the presumed principal dimensions of the feature space. Significant selectivity within a stimulus class can be illustrated, for instance, through the ability to map spatial receptive fields or derive an orientation tuning curve. We investigated the relationships in the selectivity of individual neurons across multiple classes of visual stimuli with 2-photon calcium imaging in mouse primary visual cortex, including data in the Allen Brain Observatory that surveys multiple cre-lines and cortical layers. Although cells are not expected to maintain similar feature selectivity across stimulus classes with very different visual statistics (e.g. locallysparse noise versus natural scenes), cells would be expected to have similar selectivity across stimulus classes that have similar visual statistics (e.g. locally-sparse noise versus static gratings). However, we found that the presence or absence of selectivity within one stimulus class did not predict whether the same cell would exhibit selectivity within another class of stimuli, even in cases where visual statistics were similar across the stimulus classes. We explored this phenomenon in detail by comparing the responses of single neurons to locallysparse noise and static gratings in order to leverage existing knowledge about the relationship

between tuning for these two types of stimuli. Surprisingly, we found a substantial fraction of neurons that had significant receptive fields as mapped with locally-sparse noise, but lacked selectivity among the set of static gratings or failed to respond to them at all. Furthermore, we found a substantial fraction of cells that reliably responded to a particular class of stimuli overall, such as locally-sparse noise, without exhibiting selectivity among the stimuli within that class. Our results highlight important considerations for the design of sensory stimulus sets as well as the interpretation of neuronal selectivity within and across stimulus sets.

Title: Hierarchical models of processing in the mouse visual cortex

Authors: *N. H. CAIN¹, R. IYER¹, Y. N. BILLEH², A. ARKHIPOV¹, M. A. BUICE¹, S. MIHALAS¹

¹Allen Inst. For Brain Sci., Seattle, WA; ²Allen Inst., Seattle, WA

Abstract: How do cell types and connectivity give rise to experimentally recorded responses in the mouse visual cortex? A data-driven modeling approach can help dissect the laminar and cell type circuit that gives rise to cortical activity. By combining two large-scale data resources, the Allen Mouse Brain Connectivity Atlas (http://connectivity.brain-map.org/) and the Allen Brain Observatory (http://observatory.brain-map.org/visualcoding/), we develop a framework for testing models of feedforward columnar computation.

We first construct models of neuronal visual responses in dorsal lateral geniculate nucleus (LGd) parameterized using data from electrophysiological recordings [1]. The model contains multiple cell classes modeled as separable spatio-temporal filters. Cell classes were determined on the basis of the spatial profile and temporal kinetics of responses to sparse noise and drifting grating stimuli. For each cell-class, model parameters were optimized by minimizing the sum of squares of differences between experimental and model response metrics based on these stimuli. This model can transform a wide range of visual stimuli into a putative input for primary visual cortex (VISp).

We then construct models of VISp responses; preliminary results indicate that these models can be fit to responses from the Allen Brain Observatory when the processing of the early visual system is included. A staged approach in which we characterize the set of neuronal responses in a population (area and layer) followed by populations which directly receive its inputs can then be iteratively applied to the Allen Brain Observatory. Such an approach requires a large sample of responses throughout the cortical hierarchy, such as the systematic recordings provided in the Allen Brain Observatory.

Title: Developing a virtual environment for studying spatial orientation in rotating visual environments

Authors: H. DRILLICK¹, E. DOROKHIN¹, L. GOETZ¹, *T. RAPHAN² ¹Brooklyn Col. of CUNY, Brooklyn, NY; ²Brooklyn Col. of the City Univ. of New York, Brooklyn, NY

Abstract: Vertigo and motion sickness can be generated by moving visual stimuli in the same way that head and body movement can induce vertiginous and motion sickness sensations. The same stimuli that induce motion sickness have also been shown to be effective in the habituation of motion sickness following repeated exposure to these stimuli. The purpose here is to describe the development of a virtual reality head mounted system that can be used to determine spatial orientation in the presence of a rotating visual environment. The system was developed using the Oculus Rift virtual reality display and the OpenGL graphics API to generate rotating environments in three dimensions. The system generates stripes whose width can be set by a simple user interface. The speed of rotation of the stripes and the axis about which they rotate can also be set through the user interface. The program was developed in Windows using C++ together with Oculus Rift 64-bit libraries. The program was compiled and linked using the 64-bit open source MinGW compiler. The spatial orientation estimate was determined by having subjects give a haptic representation of the spatial vertical by pointing the thumb in the direction of the spatial vertical by pointing the thumb in the direction of the spatial vertical. The Leap Motion hand sensor was used for this purpose since it is capable of determining the directions of the finger tips relative to its coordinate frame. Our initial

investigation in a single subject shows that thumb pointing is stable for at least ten seconds when the subject is asked to point towards the spatial vertical. The initial data also suggest that motions of the environment induce disorientations, especially in roll. Thus, a virtual reality display and a Leap Motion hand sensor can potentially be coordinated to study perception of the vertical in static and visual motion environments with the head in different orientations relative to gravity.

Title: Descending interneurons controlling visually-evoked escape in Drosophila

Authors: *M. Y. PEEK, S. NAMIKI, P. BREADS, W. R. WILLIAMSON, J. M. ACHE, G. M. CARD

HHMI Janelia Res. Campus, Ashburn, VA

Abstract: To understand rapid sensorimotor processing underlying a behavior essential to survival, we investigated the role of descending interneurons in the control of loom-evoked escape behavior in Drosophila. Using the an automated behavioral assay, we performed a neural activation and silencing screen across a collection of fly lines targeting specific descending interneuron cell types. A subset showed robust escape phenotypes, including seven with putatively shared visual inputs. To test whether these neurons are active in the context of loom-evoked escape, we characterized their visual tuning using in vivo somatic whole-cell patch clamp electrophysiology. Recordings show strong excitatory loom responses which suggests that these neurons serve as parallel descending pathways to downstream takeoff motor centers that coordinate escape.

Title: Looming sensitivity in Drosophila visual projection neurons

Authors: *N. C. KLAPOETKE, A. NERN, M. PEEK, E. ROGERS, G. RUBIN, M. REISER, G. CARD

Janelia Res. Campus, Ashburn, VA

Abstract: Animal early visual systems process primitive information from the photoreceptor level to encode higher-level representations of ethologically relevant visual features. It is thought that looming motion should be encoded by the early visual system in order to detect imminent collision or dangers such as an approaching predator. Recently Wu et al. (2016 eLife) described more than 20 different classes of Drosophila visual projection neurons that transmit information from the early visual system to higher order brain regions. We here examined looming sensitivity in a subset of these visual projection neurons using in vivo two-photon calcium imaging. We found that different classes of visual projection neurons encode distinct spatiotemporal features of looming motion. Furthermore, we characterized visual response properties on a single cell level and found a strong correspondence between an individual neuron's anatomy and its functional properties. Our results suggest that looming motion is encoded by parallel channels in the Drosophila early visual system.

Title: Control of landing in Drosophila

Authors: *J. M. ACHE, S. NAMIKI, A. LEE, K. BRANSON, G. M. CARD HHMI/Janelia Res. Campus, Ashburn, VA

Abstract: Animals respond to sensory cues in a context-specific manner, an ability that is critical for survival. Even innate sensorimotor responses are flexible, such that an identical cue elicits different actions in different situations. How the brain achieves this context-dependent flexibility is unclear. Here, we describe the sensorimotor pathways controlling visually-evoked landing in *Drosophila*. Landing exemplifies a context-specific behavior because flies only initiate landing actions in response to expanding visual cues if they are flying, and the landing motor sequence is suppressed during other behaviors.

Using patch-clamp recordings, optogenetics and quantitative behavioral analysis, we identified the most important components of the landing pathways and their role in extracting visual features and controlling the landing motor sequence. We show that descending neurons mediating landing integrate visual and mechanosensory cues and control leg extensions in a graded fashion while the fly is flying. Our recordings reveal that visual responses in these descending pathways are shut down when the fly is not flying. Moreover, we found that this gating of visual input occurs via two different mechanisms in two different landing descending neuron cell types. Our findings suggest that state-dependent gating of descending pathways is one mechanism that controls the brain's access to different motor networks, thus enabling flexible, context-dependent action selection.

Title: A cell type specific driver line library targeting wing motor circuits in the ventral nerve cord of *Drosophila*

Authors: *E. E. EHRHARDT, S. NAMIKI, H. OTSUNA, I. COHEN, D. STERN, M. DICKINSON, W. KORFF, G. M. CARD Card Lab., HHMI Janelia Res. Campus, Ashburn, VA

Abstract: A primary function of a fly's wings is to produce rapid, agile aerial maneuvers. Yet male flies also use their wings to create a precise, species-specific courtship song required for reproduction. The patterns of activity in the 12 wing steering muscles during flight and courtship must be distinct. However, how potentially overlapping neural circuits in the ventral nerve cord drive distinct patterns is unclear. In order to enable the systematic analysis of neural circuits underlying flight and courtship song, we created cell-type specific driver lines targeting cells in the wing and haltere neuropils using the split-GAL4 system. In split-GAL4 lines, two different enhancers each drive the expression of one domain of the split-GAL4 transcription factor. Only cells that express both domains generate a functional GAL4 protein and thus drive expression of the gene of interest. Well-chosen combinations of enhancers can produce very sparse lines with expression limited to one or a few specific cells. To rapidly screen existing enhancer expression patterns for potential overlap, we created a library of over 14,000 auto-brightness adjusted maximum intensity projections (MIPs) of expression patterns in Janelia Generation 1 GAL4 lines. These were registered to a common ventral nerve cord template and color-coded to indicate the position of each point on the dorsal-ventral axis. We developed a Fiji plugin which enables users to draw an area of interest around a cell or neurite, and then uses this mask to search the MIP library for GAL4 lines which including matching cells. Depending on the mask and settings used, the program can narrow down the search to a few hundred suggested matching images (1-3% of the original images), which can then be used as candidates in choosing split intersections. Using this system, we have made over 100 split-GAL4 lines targeting sensory neurons of the wing and haltere, haltere motoneurons, direct wing muscle motoneurons, indirect or power motoneurons, descending interneurons, ascending interneurons, local interneurons, bilateral interneurons, and intersegmental interneurons. We are currently using these cell-specific drivers to screen for activation and silencing effects on flight or courtship song.

Title: An apparatus for automated, high-throughput, and detailed assessment of individual *Drosophila* free behavior

Authors: *W. R. WILLIAMSON, M. PEEK, P. BREADS, C. BRIAN, G. M. CARD HHMI Janelia Res. Campus, Ashburn, VA

Abstract: New genetic methods in *Drosophila* make it possible to modulate the activity of single neuronal cell types. However, the behavioral consequences of such modifications are often context-specific, may occur over small temporal and spatial scales, and are sometimes incompletely penetrant. One can enhance detection of such behavioral changes by assaying more animals, by reducing noise in a given assay (for example, eliminating background behavior generated by social interactions), or by monitoring the motor patterns at higher temporal and spatial resolutions. Here we present a new, automated apparatus that simultaneously implements all three of these approaches to quickly characterize large populations of unrestrained individual flies during visual or optogenetically-induced behaviors. As a proof of principle for detailed description of behavior, we use flyPEZ to observe the sequence of optomotor behaviors in response to a rotating grating, and we characterize the direction of takeoff in response to looming disk stimuli. FlyPEZ is also equipped with red LEDs for optogenetic activation of neurons, and we show how different patterns of light stimulation affect behavior. Finally, to demonstrate flyPEZ's temporal sensitivity and ability to detect loss-of-function phenotypes, we genetically silence visual output neurons and identify a novel phenotype which occurs on a millisecond timescale.

Title: Quantitatively tuned internal predictions orchestrate visual signaling in Drosophila

Authors: ***A. J. KIM**¹, L. M. FENK¹, C. LYU¹, G. MAIMON² ²Lab. of Integrative Brain Function, ¹The Rockefeller Univ., New York, NY

Abstract: Vision influences behavior, but ongoing behavior also modulates vision in animals ranging from insects to primates. The function and biophysical mechanisms of most such modulations, however, remain unresolved. We studied how motor-related inputs dynamically influence visual signaling in flying *Drosophila*. We first showed via genetic silencing experiments that a network of eighteen identified motion-sensitive visual neurons participates in gaze-stabilizing head movements. We then performed patch-clamp electrophysiology to comprehensively measure motor-related inputs arriving to these neurons during rapid flight turns in tethered, flying *Drosophila*. We found that the motor-related inputs arrive to all visual

neurons, but the strength of the input varied systematically across cell types. Why are some visual neurons modulated more strongly than others? Insight into this question arose from examining each cell's visual responses to rotational optic flow. We found that the stronger a neuron responded to optic flow about the yaw axis, the larger was the measured motor-related modulation in that cell. This result supported the hypothesis that the motor-related inputs selectively abrogate the yaw stability function in this neural network, while leaving the stability function for other rotational axes active. This idea, however, appeared incompatible with the body kinematics during turns, which consist of stereotyped banked turns that would induce optic flow feedback about all axes of rotations. In order to resolve the paradox, we measured the head movements via high-speed videography, while magnetically tethered, flying flies make rapid turns. We found that Drosophila attempt to maintain their heads stable along roll axes during turns, in agreement with previous studies in freely flying larger flies, which can act to confine the effective visual feedback in the yaw rotational axis. Together, our data support the hypothesis that these optic-flow sensitive neurons regulate gaze-stabilizing head movements and that motorrelated inputs aim to mute the predicted visual responses to yaw visual motion in this population during turns, thus facilitating an anti-stability yaw head movement toward the new gaze direction. This work proposes a function for a behavioral modulation of visual processing and illustrates how the brain can remove one sensory signal from a neural network carrying multiple related signals.

Title: Cortical sensorimotor transformations in a mouse visual detection task

Authors: *D. B. SALKOFF¹, E. ZAGHA², D. A. MCCORMICK³ ¹Neurosci., Yale Med. Sch., New Haven, CT; ²Dept. of Psychology, Univ. of California Riverside, Riverside, CA; ³Dept. Neurobiol, Yale Univ. Sch. Med., New Haven, CT

Abstract: Sensory to motor transformations in cerebral cortex evolve over both time and space. The spatio-temporal properties of cortical processing and contributions of diverse cortical regions to sensory-guided behaviors are still under investigation. We recorded wide-field calcium (GCaMP6s) activity in mice trained to perform a visual Go/No-Go detection task. Mice were trained to lick a reward port in response to a visual stimulus (target) and ignore an auditory

stimulus (distractor). Mice performed the task well (d' 1.4 to 3.5) while head-fixed and free to run on a wheel. During task performance, we imaged contralateral dorsal cortex transcranially at 20 Hz. Calcium activity increased first in V1 ~100 ms after target stimulus presentation. Frontal cortex was highly correlated with all licking (hits, false-alarms, spontaneous licking). Surprisingly, a parietal region spanning trunk/limb somatosensory cortex was active prior to the response and was not associated with running or spontaneous licking, suggesting a role in decision making. To understand how behavioral and brain state affects task performance, we compared running speed, pupil diameter, and pre-stimulus calcium activity on hit and miss trials. On average, pre-stimulus calcium activity in parietal and occipital regions was higher on miss trials than hit trials, suggesting that high spontaneous activity interferes with the generation and/or propagation of sensorimotor representations. The magnitude and timing of activity in disparate cortical regions is indicative of the function of these cortical regions during learned behavior and may further reveal how sensorimotor transformations occur.

Title: Hiding in plain sight: Neuronal integration of specific changes in luminosity encode perceived threat and leads to behavioral freeze

Authors: *J. A. JELLIES¹, M. R. KING², V. PARIKH³, T. K. H. GROVES² ²Biol. Sci., ¹Western Michigan Univ., Kalamazoo, MI; ³Kalamazoo Area Math and Sci. Ctr., Kalamazoo, MI

Abstract: Animals distinguish between threats and innocuous events using sensory computations. Leeches are counter-shaded annelids that are active during the day and are therefore themselves vulnerable to visually guided predators. They will often undulate in a rhythmic motion with the rear sucker attached, and such "ventilation" behavior may attract unwanted attention and render the leech vulnerable. Accordingly leeches suddenly "freeze" when a shadow passes over. To characterize this we used small groups of juvenile leeches in defined light environments and exposed them to either a decrease in luminosity (shadow, lights-off) or a comparable increase (lights-on) using a calibrated green LED. Each of 20 groups received 20 trials of lights-off and lights-on while individuals (tracked by video) were ventilating. Shadow proved a much more effective stimulus (74.6%) than lights-on (16.9%) at inducing a freeze. Refinements in stimulus presentation allowed us to determine optimal shadow durations and rates of change, suggesting that the system also encodes temporal cues. Since photoreceptors

produce action potentials in response to lights-on, we hypothesized that there must be discrete interneurons selectively activated to encode the "off" response. To examine this we assessed the shadow response of a known visually responsive interneuron, the S-cell. There is a well-characterized S-cell response to lights-on and so we used this feed-forward interneuron as an assay for visual activity evoked within the CNS. Examining midbody S-cells using intracellular electrophysiology in semi-intact preparations we found that shadows elicited a depolarizing response in almost half (48%) of the preparations, sometimes causing spiking. Typically there was a barrage of complex depolarizing PSPs with a long, variable latency (200-800 ms), consistent with a polysynaptic pathway. This was in contrast to the lights-on response (as the shadow was removed) that occurred 100% of the time with shorter, more consistent latency (~200 ms). We suggest that there must be interneurons that invert the sign of visual information by spiking in response to lights-off stimuli having particular temporal characteristics, and that these interneurons then inhibit the ventilation circuitry. Thus, synaptic interactions between photoreceptors and interneurons in the CNS may provide substrates for synaptic computation for visual feature extraction by a system lacking image-forming eyes.

Title: A link between brains, learning and recurrent neural networks

Authors: *M. STERN^{1,2}, K. CHAMPION¹, A. S. ROKEM³, D. R. OLLERENSHAW², S. MANAVI², S. R. OLSEN², E. T. SHEA-BROWN¹ ¹Applied Mathematics, Univ. of Washington, Seattle, WA; ²Allen Inst. For Brain Sci., Seattle, WA; ³eScience Inst., The Univ. of Washington, Seattle, WA

Abstract: New brain-wide data acquisition techniques provide the opportunity to explore how activity patterns change over the course of learning complex tasks. We use models of neural networks to understand essential changes in the dynamical trajectories of networks during learning. We look for evidence of these learning-related changes in brain activity. We train models of recurrent neural networks to perform various tasks using reservoir computing [Jaeger

and Haas 2004, Sussillo and Abbott 2009]. The tasks span from learning a sinusoidal wave output to more complicated change-detection tasks that parallel behavioral tasks we use in behavioral experiments conducted in mice. We search for common footprints in the altered posttraining dynamics across tasks. To this end we analyze the dominant low-dimensional latent variables. First, we find changes in the number of latent dimensions: specifically, fewer dimensions are required to explain the bulk of the activity after learning. The correlations responsible for this collapse in dimensions, in reservoir computing, are created via feedback. They then allow for controlled dynamics, from which we can read the desired output. Indeed, correlated activity of single neurons in a specific brain area, while the animal is engaged in a task, has been shown to rise during learning [Huber et al 2012, Peters et al 2013]. Here we explore this phenomenon in brain recordings that span multiple areas. We train mice to perform a visual change detection task and use wide-field calcium imaging to measure mesoscale activity across mouse cortex over the course of task learning - from the naïve mouse to expert. Our recordings show that higher-order brain areas correlate their activity with the visual cortex in a mouse that has successfully learned the task. As our reservoir computing results suggest, the input to higher areas is altered, giving rise to correlated activity driven by the stimulus. We expect the latent variables that describe the activity to change accordingly as well.

Title: Automatic adjustment of walking speed by optic flow benefits from binocular vision

Authors: *S. TAKAMUKU¹, T. NAGASAWA², H. GOMI¹ ¹NTT Communication Sci. Labs., Kanagawa, Japan; ²Nagaoka Univ. of Technol., Nagaoka, Japan

Abstract: How we estimate self-motion from optic flow has been an important topic for decades. While numerous studies have revealed the computational process underlying our perception of self-motion (i.e., vection), less is known on the process underlying our implicit visuo-motor control. This is especially the case for walking speed adjustments based on optic flow. Several earlier studies on postural response induced by optic flow assumed error correction mechanism which minimizes retinal motion (and in some cases retinal motion parallax).

However, such mechanisms could fail in explaining the walking speed adjustment because retinal motion velocities depend on the distances of our surroundings and do not directly represent the physical walking velocities per se. Here, to understand how our brain deals with the issue, we measured head velocity of participants walking in a virtual corridor. The corridor was built upon the HTC Vive system which enables free walking in virtual reality environments. When the side walls of the corridor, painted with checkerboard patterns of white and black squares, moved occasionally either towards or against the walking direction with a velocity proportional to the head velocity, their walking velocity increased and decreased respectively as previously been reported. In our first experiment, we measured the walking velocity under different velocities (gain of 0.5 or -0.5 or 0.0) and distances (0.5 and 1.0 m) of the same side walls (identical checkerboard patterns). Two-factor-repeated-measures ANOVA on average walking velocity revealed statistically significant effect of only the physical velocity of the walls (but neither of the distance of the walls nor the interaction between the distance and the velocity). In the second experiment, we changed the pattern of the near wall so that the spatial frequency as well as the area of the checkerboard patterns on the retina closely mimic that of the far wall. Furthermore, we had the participants walk with either monocular or binocular vision, the order of the two conditions counterbalanced among the participants. In this case, the effect of distance was statistically significant in both monocular and binocular conditions, but the effect was smaller in the case of binocular vision (statistically significant effect of interaction between vision condition and distance). While relevance of depth cues remains rather controversial in case of posture control, our findings suggest that the walking speed adjustment based on optic flow is robust to changes in distances of our surroundings and that the robustness depends on the accuracy of our depth estimation.

Title: Neuronal integration of spectral contrast information: Receptive field properties of visually sensitive neurons in the medicinal leech

Authors: *T. K. GROVES, J. A. JELLIES Dept. of Biol. Sci., Western Michigan Univ., Kalamazoo, MI

Abstract: For animals lacking image-forming eyes, the role of visual circuitry in extracting visual features remains to be characterized. Our central hypothesis is that two-dimensional pixel arrays of simple eyes can be used to extract low-resolution image features. We examined visual

circuitry of the medicinal leech, *Hirudo verbana*, to learn how extraction of distributed visual input drives adaptive behavior. Hirudo possesses 5 pairs of pigmented cephalic eyecups at the margin of the anterior sucker and a distributed, segmentally iterated array of 7 pairs of dermal sensilla positioned dorsal to ventral along the central annulus of each mid-body segment. With this photosensory input, Hirudo discriminates between green and near ultraviolet (UV) light and rotates to minimize ventral, but not dorsal UV exposure. We argue that the distributed array of dermal sensilla can act as a "spectral statocyst" to maintain 3-D body position. Combining light stimulation with extracellular recordings, we characterized sensillar responses across wavelength and luminosity to determine the contribution of primary sensillar photoreceptors in discriminating spectral information. Ventral sensilla appeared to be preferentially narrowly responsive to UV light, while dorsal sensilla were more broadly responsive to green light. Therefore, we suggest that spatially discrete spectral contrast information is established at the primary sensory level. Interactions between sensillar axons and interneurons in the CNS may form the substrates for synaptic computation and extraction of visual features that inform behavior. Considering the location-specific spectral sensitivity documented in the S-cell, we predicted that intracellular inspection of select paired and unpaired visually sensitive CNS neurons would reveal receptive field patterns that reflect the asymmetrical rotation to reduce ventral UV exposure. To determine if the response properties of these neurons can be modulated by exposure to specific wavelengths from spatially constrained inputs, we are comparing their electrophysiological profiles in leeches having all input pathways with those in animals receiving constrained stimuli (i.e. unilateral ventral or dorsal input). Coupled with a similar characterization of motor and premotor neurons that may coordinate body rotation, receptive field properties of the neurons characterized herein should reflect the observed asymmetric rotational behavior and facilitate information circuit identification in the leech visual system.

Title: Phototactic responses of histamine-deficient Drosophila mutants

Authors: *J. BORYCZ¹, J. A. BORYCZ¹, I. A. MEINERTZHAGEN^{1,2} ¹Dept. Psychology & Neurosci., ²Dept. Biol., Dalhousie Univ., Halifax, NS, Canada

Abstract: The advanced genetics, short life cycle and anatomy of its compound eye make the fruit fly a perfect model to study visual processes. Histamine (HA) is released at Drosophila photoreceptor terminals. Most is recycled, depending on two enzymes: Ebony, expressed in surrounding epithelial glia, where it conjugates HA with β -alanine to form β -alanylhistamine (carcinine); and Tan in photoreceptors, which mediates hydrolysis of carcinine to liberate HA and β -alanine. Mutant *tan* and *ebony* have abnormal electroretinograms (Hotta & Benzer, 1969); both also have significantly reduced head HA (Borycz et al., 2002). Phototaxis paradigms have been widely applied to Drosophila, conveniently simple methods that complement molecular and biochemical techniques. Our goals were to assess: 1) whether tan and ebony, known to recycle histamine abnormally, can still detect light; and 2) the effect of a HA supplement on phototactic behaviour. We used wild-type Oregon R; hdc, which is unable to synthesize HA; tan and ebony. Phototaxis was measured using a T-Maze and two illumination paradigms: 1) a light/dark choice; and 2) a green/blue choice using 525 nm and 467 nm LEDs. Wild-type flies mostly explored the lit arm (72%) in a light/dark choice; only 22% entered the dark arm and 6% remained in the loading chamber. In a green/blue choice 62% of wild-type chose the blue-lit arm, 20% the greenlit arm, and 18% remained in the loading chamber. In hdc, which cannot synthesize HA and is reportedly blind, 67% of flies remained in the loading chamber in a light/dark choice; only 17% and 16% explored either lit or dark arm. In a green/blue choice, the number of immobile hdc flies increased to 85%; only 5% and 10% entered either green or blue arm, respectively. tan showed some phototactic behaviour entering either the lit- (33%) or dark- (24%) arm, the remaining 43% being immobile, whereas ebony had 43, 5 and 52%, respectively. In a green/blue choice 31% of tan entered the green arm, 45% the blue and 24% remained inside the loading chamber. Corresponding numbers for *ebony* in the same task were 15, 48 and 37%. A 5% HA supplement for 24 h completely rescued-wild type phototactic behaviour in hdc either in a dark-light paradigm or a blue/green choice. The same treatment increased by 12% the number of wild-type entering the lit-arm with a parallel reduction of flies entering the dark-arm. Drinking 5% HA improved T-maze performance in tan whereas it was a median lethal dose for ebony, with approximately 50% flies dead after 24h access to HA. Thus, despite lacking HA recycling, tan and *ebony* still show some phototactic responses, possibly from *de novo* HA synthesis.

Title: Processing of passive and motion-induced visual percepts in the rat dorsomedial striatum

Authors: *A. J. NAGY¹, Y. TAKEUCHI², A. BERENYI^{2,3} ¹Univ. of Szeged, Fac. of Med., Szeged, Hungary, Hungary; ²Univ. of Szeged, Szeged, Hungary;

³Neurosci. Inst., New York Univ., New York, NY

Abstract: One of the inevitable gains of the evolutionary development of vision is the capacity to detect moving objects. The utility is two-fold: the concordant shift of the elementary visual features reflects the voluntary or involuntary movement of the observer and discordant changes can be identified as independently moving 'third party' objects. Making a distinction between these percepts and recognizing the moving prays or predators are essential for survival. Such sensory information allows focusing the attention, adapting behavior and adjusting the motor patterns; however, we have very scarce knowledge on how the appropriate motor output is generated by integrating the sensory information. Motor habits and action selection are often associated with the basal ganglia, and especially the striatum. This process requires continuous monitoring of ongoing behavior to provide its meaningful interpretation, but the nature of the striatal multisensory integrative functions during dynamic behavior is still largely unknown. In the current set of experiments, we set out to decipher that which aspects of the visual information are reaching the dorsomedial caudate nucleus (CPu) of freely moving rats. We also explored how these inputs shape the activity of the striatal neurons by simultaneously performing large-scale high-density extracellular recordings in the CPu and in the visual cortex, while the animals perform various behavioral tasks involving visual stimulation. We found that fastspiking interneurons are particularly sensitive to visual motion, and this sensory information may have a cortical origin. Our data show that besides the presence of space and reward related activity, discrete gamma bursts generated by the visual cortex also appear in the CPu with a few tens of ms delay, and modulate the firing patterns of the same striatal neurons. Consequently, our results suggest that the CPu acts also as an integrator, and adjusts the procedural motor functions by the internal representation of the past experiences and the present circumstances.

Abstract: Virtual reality (VR) experimental behavior setups enable cognitive neuroscientists to study the integration of visual depth cues and self-motion cues into a single percept of threedimensional space. Rodents can navigate a virtual environment when locomotion is simulated by running on a spherical treadmill; however, two-dimensional navigation is markedly reduced when their ability to turn freely is restricted. Besides making movement more difficult, this reduced exploration may also stem from sensory conflict between the visual and vestibular systems, as head translation produces no change in the visual perspective of the virtual environment. In humans, vestibulo-visual conflict reduces the subject's immersion in the virtual environment and produces sensations of nausea. Updating the virtual environment via the subject's head movements solves both the vestibulo-visual and sensorimotor conflict issues, however, and in 2014, we demonstrated the utility of real-time VR via rodent head tracking in a proof-of-principle CAVE system. Here, we show that these freely-moving rats demonstrate immersion in virtual environments by displaying height aversion to virtual cliffs, exploration preference of virtual objects, and spontaneously modify their locomotion trajectories near virtual walls. These experiments help bridge the classic behavior and virtual reality literature by showing that rats display similar behaviors to virtual environment features without training.

Title: Cerebellar granule cells mediate transient sensory-evoked locomotor inhibition in larval zebrafish

Authors: *A. A. BHANDIWAD, H. A. BURGESS Div. of Developmental Biol., NIH/NICHD, Bethesda, MD

Abstract: Sensorimotor behaviors are strongly influenced by the behavioral state of an animal. In this study, we demonstrate that exposure to a strong low frequency stimulus results in a transient inhibition of locomotor activity, which persists for 1-2 min after cessation of the stimulus. The magnitude of inhibition and its recovery time are both stimulus-dependent. During the inhibitory period, selective auditory and visual escape responses are also suppressed, suggesting that this is a novel behavioral state in zebrafish. Inhibition is abolished by prior bath application of 300 mM ethanol, and the inhibitory effect is exaggerated after ethanol washout. We also demonstrate that this effect can be disrupted by ablating the lateral line neuromasts, but disruption of the visual or auditory/vestibular systems has no effect. In order to identify the neural substrates mediating this inhibitory state, we utilized a circuit breaking screen using a library of gal4 enhancer trap lines. We identified a gal4 line, Et(REx2-SCP1:kGal4ff)y318, which labels cerebellar neurons that co-express *vglut2a* and *gata1*, suggesting that these are glutamatergic granule cells. Genetic ablation of these cells results in a ~33% reduction of inhibitory state, and recovery time is also unchanged. Further investigation will explore the role of these neurons in the zebrafish cerebellum in processing lateral line information and regulating this novel behavioral state.

Title: Sensori-motor processing during heat perception in larval zebrafish

Authors: *M. HAESEMEYER¹, D. N. ROBSON³, J. M. LI³, A. SCHIER², F. ENGERT² ¹Harvard Univ. Biolabs, ²Mol. and Cell. Biol., Harvard Univ., Cambridge, MA; ³Rowland Inst. at Harvard, Cambridge, MA

Abstract: Thermosensation provides us with crucial information about our environment. It allows us to judge whether the drink we are holding has a pleasant temperature, while sensing noxious heat or cold enables us to avoid dangerous environmental conditions. While temperature sensation is well understood at the cellular-molecular level, especially in vertebrates fairly little is known about central processing of heat information.

The larval zebrafish is an ideal model to identify temperature processing centers and strategies in

the brain. Like most other animals, larval zebrafish need to avoid extreme hot and cold to maintain a suitable internal temperature. Indeed, from five days post fertilization zebrafish readily navigate thermal gradients seeking out a suitable temperature range. To understand the sensori-motor transformations underlying temperature sensation we previously used random white-noise stimuli to characterize heat perception in larval zebrafish (Haesemeyer et al., Cell Systems, 2015). This approach revealed that zebrafish modulate swimming by integrating temperature information over short timescales and that both changes in temperature and absolute heat levels influence swim initiation.

Using brain-wide functional calcium imaging in head-restrained larval zebrafish we have now identified stereotyped responses related to temperature processing in the central nervous system. Our data indicate that temperature is represented in the brain on different timescales from very slow dynamics on the order of minutes in the pre-optic area to quickly adapting neurons in the hindbrain.

At the periphery, trigeminal sensory neurons detect fluctuations in external temperature and encode these in ON and OFF channels. While temperature representation in the trigeminal ganglion is simple and highly correlated, responses in their hindbrain target area become highly diversified. This decorrelation of responses seems to underlie the generation of behavioral output by hindbrain motor centers and is hence a critical step in the sensori-motor transformation.

Title: Visual guidance of flight mode transitions in birds

Authors: *D. L. ALTSHULER, R. DAKIN

Zoology, Univ. of British Columbia, Vancouver, BC, Canada

Abstract: Vision is the primary sense that many animals use to develop a dynamic map of the surrounding environment. Visual information is interpreted through guidance algorithms that are specific to different modes of locomotion. For example, recent studies with flying birds have revealed that, like in humans, visual motion (specifically, pattern velocity) is interpreted

differently when stationary (i.e., hovering) than when moving forward. During hovering flight, hummingbirds drift to compensate in relation to the magnitude of pattern velocity in all three major axes. During forward flight, these animals ignore fore- and aft- pattern velocity with respect to flight trajectory, but will adjust altitude to compensate for vertical pattern velocity. The lateral aspect of trajectories for forward flight control are more consistent with a guidance strategy based on balancing visual expansion. The ability of birds to smoothly transition between forward and hovering flight when docked at a flower requires a shift in visual guidance strategy that reflects changes in behavior and in neural signals. How animals control locomotor transitions to accomplish complex movements is not well understood. As a first step to determining the neural mechanisms underlying smooth transitions between locomotor modes, we investigated the flight trajectories of hummingbirds with the sequence: takeoff, cruise, deceleration, and hovering. Experiments were performed in a virtual reality tunnel that allowed for separate stimuli on the sidewall and frontal field. We systematically tested the combined effects of visual pattern velocity and expansion cues on flight mode transitions. Flights were tracked using machine vision that permitted automated tracking of body position and velocity. Collectively, the results reveal how and when hummingbirds shift their use of frontal and lateral cues as they transition between flight modes. These results are interpreted relative to the welldescribed circuits between the avian retina and pre-motor areas.

Title: The Purkinje cell climbing fiber calcium response increases after induction of parallel fiber long term depression

Authors: *F. SANTAMARIA¹, Z. YANG²

¹Biol., Univ. Texas San Antonio, San Antonio, TX; ²Biol., UTSA, San Antonio, TX

Abstract: We performed simultaneous Purkinje cell whole-cell patch-clamp recordings and calcium imaging obtained from 16-23 day-old mice cerebellar slices. We induced parallel fiber to Purkinje cell long term depression (LTD) in voltage clamp mode by pairing parallel fiber stimulation and somatic depolarization. We measured the changes in intracellular calcium in response to climbing fiber stimulation before and after LTD induction. We found that the calcium response to climbing fiber activation increases in regions near and around the synaptic

LTD induction site, while dendritic regions far from the conditioning site are not affected. Furthermore, this enhanced calcium response after LTD induction are localized in spiny dendrites, but not in smooth main dendrites, even when they are in close vicinity to conditioning sites. Thus, our results show that the climbing fiber evoked calcium response increases in spiny dendrites around the synaptic LTD induction site. Given the dependence of synaptic plasticity on calcium concentration, this could facilitate synapses that underwent LTD to reach the threshold for further synaptic plasticity.

Title: Dual mode representation of efference copy in purkinje neurons

Authors: *M. SENGUPTA¹, S. NARAYANAN¹, C. WYART², V. THIRUMALAI¹ ¹Natl. Ctr. For Biol. Sci., Bangalore, India; ²Inst. Cerveau Et Moelle Epiniere, Paris, France

Abstract: The cerebellum is important for maintaining balance, for generating co-ordinated locomotion and for motor adaptation and learning. Purkinje neurons in the cerebellum are critical for cerebellar function yet how they shape cerebellar output is not yet clearly understood. We recently established that Purkinje neurons in vivo exhibit membrane potential bistability. In the 'up state they generate sodium spikes tonically, interspersed with calcium spikes while in the 'down' state, they are quiescent and fire bursts of sodium action potentials. Yet, how such single neuron dynamics like membrane potential bistability is used by the whole population of Purkinje neurons to influence behavior remains unknown. We wanted to address this question by using calcium imaging to monitor populations of Purkinje neurons during behavior. Specifically we wanted to ask whether Purkinje neurons switched mode during motor episodes. For this, one first needs to establish the relationship between calcium signals recorded optically and membrane potential. Therefore, we first performed combined imaging and whole-cell patch clamp from single Purkinje neurons. We observed that the optical signals corresponded to calcium spikes in the up state and bursts in the down state. These results demonstrated that calcium imaging in Purkinje neurons yields information regarding different types of cellular signals, depending on

the membrane potential of the neuron. We also discovered that calcium spikes in the up state and bursts in the down state were driven by CF input and also correlated with motor bout initiation. As such the GCaMP signals in Purkinje neurons faithfully follow the motor code. We next monitored fictive swim episodes during open loop optomotor responses (OMR) while imaging populations of Purkinje neurons in their somata and dendrites. We report interesting spatiotemporal dynamics within ensembles of these neurons during sensory stimulus and motor activity. Taken together, our results show that Purkinje neurons represent motor bouts using two modes (tonic spiking vs. bursting) depending on their membrane potential. Thus bistability in Purkinje neurons seems to endow them with an additional degree of freedom for the representation of motor outputs.

Title: Mechanisms of Purkinje cell-dependent instructive signaling in the cerebellum

Authors: *J. M. CHRISTIE¹, C. A. BAKER³, M. G. PINO¹, M. BOLTON², A. BONNAN⁴ ¹Synapse Physiol. Group, ²Disorders of Neural Circuit Function, Max Planck Florida Inst., Jupiter, FL; ³Allen Inst. For Brain Sci., Seattle, WA; ⁴MPFI, Jupiter, FL

Abstract: The cerebellum is known to play a crucial role in motor learning. Purkinje cells (PC) give rise to the sole output of the cerebellar cortex and are therefore pivotal in this process. PCs can fire two different types of spikes: simple spikes (SS) in response to parallel fiber (PF) stimulation and complex spikes (CS) as a result of climbing fiber input. The CS is a multi-component response that includes a burst of sodium spikes at the soma and a dendrite-wide Ca²⁺ transient. A classic theory of cerebellar function postulates that CFs carry instructive signals to PCs that guide learning. However, recent findings indicate that learning may occur independent of CF activity suggesting the existence of other candidate instructive signals. To study the mechanistic basis of instructive signaling, we used the vestibulo-ocular reflex (VOR), a compensatory eye movement in response to head motion that is subject to re-calibration through cerebellar-dependent plasticity. We used optogenetics to selectively manipulate PC activity during vestibular stimulation and probe for the consequences of this activity by examining the gain of the VOR. Using several techniques to induce PC activity either with or without dendritic

 Ca_{2+} influx during vestibular stimulation, we found that PC activity associated with dendritic Ca^{2+} was sufficient to induce a change in VOR gain after repeated pairing with vestibular stimulation. However learning did not occur when Purkinje cells were activated without a dendritic Ca^{2+} transient. Our results suggest that Ca^{2+} influx in PC dendrites is a key component for learning and point to PC dendrites as the initial site of plasticity as predicted by early theories.

Title: Inhibitory control of climbing fiber-mediated plasticity and motor learning in the cerebellum

Authors: *M. J. ROWAN¹, A. BONNAN¹, S. B. AMAT¹, E. M. PATINO², J. M. CHRISTIE¹ ¹Max Planck Florida Inst., Jupiter, FL; ²Florida Atlantic Univ., Jupiter, FL

Abstract: The synaptic properties of Purkinje cell dendrites will contribute to the effectiveness of converting climbing fiber (CF)-mediated complex spikes into meaningful instructive signals that guide motor learning. Molecular layer interneurons (MLIs) inhibit Purkinje cell dendrites yet their role in modulating dendritic excitability related to climbing fiber instruction is poorly understood. Using optogenetics to precisely control MLI output, we found that molecular layer inhibition potently diminished dendritic Ca²⁺ spiking in Purkinje cells evoked by CFs. Because Ca²⁺ spikes provide the biochemical trigger for inducing long-term depression (LTD) at coincidently active parallel fiber synapses, suppressing CF-mediated Ca²⁺ influx prevented LTD and, instead, revealed opposite direction plasticity indicative of multiplexed instructive signaling through distinct mechanisms. To evaluate the effect of ML inhibition on CF-mediated learning we used a dual-color optogenetic approach allowing for the independent actuation of both MLIs and CF. Examining for adaptation of the vestibulo-ocular reflex (VOR), optogenetic activation of CFs in the flocculus during vestibular stimulation in the dark could be used to implant an artificial motor memory resulting in a long-lasting learned increase in the VOR. Interestingly, when MLIs were co-activated with CFs, learning occurred in the opposite direction; there was a

decrease in eye movement relative to head rotation. These findings point to a potential profound role for MLIs in directing (or ensuring) the accuracy (or appropriateness) of learning through their potent influence on Purkinje cell dendritic excitability and plasticity.

Title: Capturing the functional importance of graded climbing fiber bursts using calcium imaging in awake mice

Authors: *A. FANNING^{1,2}, J. SIEGEL^{1,2}, R. CHITWOOD^{1,2}, D. JOHNSTON^{1,2}, H. NISHIYAMA^{1,2}

¹The Univ. of Texas at Austin, Austin, TX; ²Ctr. for Learning and Memory, Austin, TX

Abstract: Climbing fibers (CFs) are the axons originating from excitatory neurons in the inferior olive that provide instructive signals driving cerebellar-dependent motor learning. CFs are activated by erroneous movement or unexpected sensory activation providing error feedback to Purkinje cells (PCs) in cerebellar cortex and triggering plasticity that makes way for a learned motor response to be expressed. CFs exhibit variable, high-frequency bursts of 1-6 action potentials, yet the consequence of this variable activity has been largely ignored. This is due to the fact that even a single action potential can produce a massive all-or-none postsynaptic PC response. Recent evidence suggests CF burst size may encode parametric features of a sensory stimulus and possibly determine the speed and direction of learning. However, in previous studies, CF burst size has been inferred based on PC recordings, which may be affected by factors other than CF activity, such as non-CF inputs into and the intrinsic excitability of the PC. Using calcium (Ca²⁺) imaging to directly measure CF activity in awake mice we show that CF burst size serves multiple functions. CFs differentiate unexpected sensory events from spontaneous activity by increasing burst size. During eyeblink conditioning, CFs are initially more reliably responsive to the unconditioned stimulus (US; air puff) before learning occurs, but switch to become more reliably responsive to the conditioned stimulus (CS; a light) as learning progresses. As the switch to become primarily CS-responsive occurs, the magnitude of Ca²⁺ transients increases, whereas repeatedly presenting only the CS (unpaired) results in a decrease in the magnitude of CF Ca^{2+} transients. These data suggest that CF burst size serves multiple

functions: to encode unexpected sensory stimuli, provide positive error feedback, and to attach saliency to cues that reliably predict aversive stimuli presentation.

Title: Long-term depression of intrinsic excitability accompanied by the synaptic depression in the cerebellar Purkinje cells

Authors: *H. SHIM¹, D. JANG², S. KIM¹

¹Seoul Natl. Univ. Col. of Med., Seoul, Korea, Republic of; ²Col. of Science, Dept. of Brain and Cognitive Sci., Seoul Natl. Univ., Seoul, Korea, Republic of

Abstract: One remarkable question in neuroscience is how the brain stores novel information from the environment and makes modification in behavior. Of interest, many implications reveal that the activity-dependent plasticity of synaptic efficacy and intrinsic excitability underlie the learning rule. The long-term depression (LTD) at the parallel fiber (PF) and Purkinje cell (PC) synapses has been found to be cellular basis of the cerebellum-dependent motor learning. In order to transfer information formed at cerebellar cortex to the postsynaptic regions such as the vestibular nuclei (VN) and the cerebellar nuclei (CN), the activity-dependent changes in the intrinsic excitability might be manifested for appropriate signal transduction within motorlearning circuitry. Here, we show that pairing of the PF and climbing fiber (CF) for PF-PC LTD induction evokes long-term depression of intrinsic excitability (LTD-IE) in the cerebellar PCs from male C57BL/6 mice. Interestingly, this intrinsic plasticity showed different kinetics from synaptic plasticity, but both forms of plasticity share Ca^{2+} signaling and protein kinase C (PKC) pathway as their underlying mechanism. While small-conductance Ca²⁺-activated K⁺ channels (SK channels) play important roles in long-term potentiation of intrinsic excitability (LTP-IE), no direct implication was found in LTD-IE. After PF-PC LTD induction, neither the temporal summation of dendritic EPSP nor the power of spike frequency adaptation is changed, indicating that cerebellar LTD executes the information processing in a quantitative way without quality changes of synaptic integration and generation of output signals. Our results suggest that LTD-IE may have a synergistic effect with synaptic depression on the total net output of neurons by amplifying the modification of PF synaptic transmission.

Title: Enhanced intrinsic excitability in cerebellar Purkinje cells following delay eyeblink conditioning in mice

Authors: *G. V. WATKINS¹, H. K. TITLEY¹, C. LIN², C. WEISS², J. F. DISTERHOFT², C. HANSEL¹

¹Neurobio., Univ. of Chicago, Chicago, IL; ²Physiol., Northwestern Univ., Chicago, IL

Abstract: Cerebellar learning is canonically thought to rely on synaptic plasticity, particularly at the inputs to Purkinje cells. Recently, however, other complementary mechanisms have been identified. Intrinsic plasticity is one such mechanism, and depends on a down-regulation of calcium-dependent SK-type K channels, which is associated with an increase in neuronal activity. In the hippocampus, SK-mediated intrinsic plasticity has been shown to play a role in trace eyeblink conditioning learning; however, it is not yet known how intrinsic plasticity contributes to a cerebellar learning task such as delay eyeblink conditioning. Here we show that after delay eyeblink conditioning, Purkinje cells in lobule simplex / lobule HVI were more excitable than controls consistent with an increase of intrinsic excitability. Whole cell recordings were obtained from acute cerebellar slices from mice 48 hours after the final training session. Groups of mice received over a period of repeated training sessions either distinctly paired trials of a tone co-terminating with a periorbital shock (conditioned mice), unpaired trials of only a tone or a shock (pseudoconditioned mice) or neither a tone or a shock (naïve mice). We found that Purkinje cells from conditioned mice exhibited more evoked activity than cells from control animals, resulting in a shift to the left in the I-F curve following a gradual current injection protocol. The current and potential threshold needed to evoke spikes was decreased in the conditioned mice. Furthermore, following the stimulation of parallel fibers or climbing fibers, the Purkinje cell responses from conditioned mice were more excitable showing a increased number of spikelets in complex spikes, a greater area and reduced duration of depolarization, a

reduced afterhyperpolarization, and shorter latency to the minimum amplitude in both complex spikes and bursts of parallel fiber activity. This increase in excitability may indicate that SK-dependent intrinsic potentiation occurs during eyeblink conditioning, as the conditioned mice also showed reduced changes in excitability following the application of an intrinsic plasticity protocol, suggesting an occlusion effect in conditioned mice.

Title: Functional coordination of parallel fiber and climbing fiber inputs during multi-sensory association and timed motor behavior in cerebellar cortex

Authors: *S. TSUTSUMI, O. CHADNEY, M. HÄUSSER

Wolfson Inst. for Biomed. Res., Univ. Col. London, London, United Kingdom

Abstract: Cerebellar Purkinje cells (PCs) form the sole output of the cerebellar cortex and receive two major excitatory synaptic inputs: parallel fibers (PFs), the axons of granule cells (GCs), and a climbing fiber (CF). GCs integrate multi-modal information from multiple sources to deliver patterns of inputs via PFs, whereas CFs send instructive signals such as sensorimotor error signals and/or timing signals to PCs. Coincident PF and CF inputs cause plastic changes in PC firing, a process which is thought to be crucial for multi-modal integration and precise adaptation of motor action. However, how PF and CF inputs interact to regulate PC output during behavior is not well understood. To address this question, we used two functional fluorescent probes with different colors to monitor PF and CF inputs simultaneously during a multi-sensory association task, to visualize how these inputs are spatiotemporally coordinated to achieve precisely timed behavior. RCaMP2 was expressed in PCs to monitor CF inputs, while GCaMP6f was expressed in GCs to directly monitor PF inputs to the PCs. Imaging was performed in Crus I, the region responsible for orofacial sensorimotor processing. Head-fixed mice were trained on a multi-sensory go/no-go task in which they had to lick during brief (0.5 s) combined sensory stimuli with different modalities such as air-puff, LED flash, or a tone, but not to single-modality sensory stimulus. Mice refined their lick behavior during learning so that licking in response to combined stimuli became quicker, shorter, faster and more regular. Simultaneous imaging of PF and CF inputs to the same PCs revealed that these inputs became

more coupled during performing the task. Along with learning, PF responses to cues became temporally precise, whereas CF responses for non-rewarded trials were diminished. Both PF and CF inputs became bimodal in licking trials: the first peak appeared just after the cue and the second peak was observed after lick offset. Muscimol injection into the Crus I in expert mice deteriorated task performance through a decrease in hit rate and increase in latency of licks after the combined cue (lick onset latency: 0.236 ± 0.006 s to 0.363 ± 0.007 s, p < 0.001). These results suggest that spatiotemporal coupling of PF and CF inputs to PCs is important for immediate multi-sensory processing necessary for rapid motor initiation and reliable suppression of unnecessary movement. Optogenetic manipulation of PCs, PF and CF inputs will allow further dissection of the roles of individual inputs and PC outputs in this form of cerebellum-dependent motor adaptation.

Title: Ablation of TFR1 in Purkinje cells inhibits mGlu1 trafficking and impairs motor coordination, but not autistic-like behaviors

Authors: *J. ZHOU¹, L. ZHOU¹, C. DE ZEEUW^{2,3}, Y. SHEN¹

¹Inst. of Neurosci. Zhejiang Univ., Hangzhou Zhejiang, China; ²Dept. of Neuroscience, Erasmus MC, Rotterdam, Netherlands; ³Netherlands Inst. for Neuroscience, Royal Dutch Acad. for Arts & Sci., Amsterdam, Netherlands

Abstract: Group 1 metabotropic glutamate receptors (mGlu1/5) are critical to synapse formation and participate in synaptic long-term potentiation (LTP) and long-term depression (LTD) in the brain. mGlu1/5 signaling alterations have been documented in cognitive impairment, neurodegenerative disorders, and psychiatric diseases, but the underlying mechanisms for its modulation are not clear. Here, we report that transferrin receptor 1 (TFR1), a trans-membrane protein of the clathrin complex, modulates the trafficking of mGlu1 in cerebellar Purkinje cells

(PCs). We show that conditional knockout of TFR1 in PCs does not affect the cyto-architecture of PCs, but reduces mGlu1 expression at synapses. This regulation by TFR1 acts in concert with that by Rab8 and Rab11, which modulate the internalization and recycling of mGlu1, respectively. TFR1 can bind to Rab proteins and facilitate their expression at synapses. PC ablation of TFR1 inhibits parallel fiber-PC LTD, whereas parallel fiber-PC LTP and PC intrinsic excitability are not affected. Finally, we demonstrate that PC ablation of TFR1 impairs motor coordination, but does not affect social behaviors in mice. Together, these findings underscore the importance of TFR1 in regulating mGlu1 trafficking, and suggest that mGlu1 and mGlu1-dependent parallel fiber-LTD are associated with regulation of motor coordination, but not autistic behaviors.

Title: Population coding in the Purkinje cell network during execution of goal directed action

Authors: *D. KOSTADINOV, M. BLANCO POZO, M. BEAU, M. HAUSSER Wolfson Inst. for Biomed. Res., Univ. Col. London, London, United Kingdom

Abstract: The activity of Purkinje cells (PCs), the sole output neurons of the cerebellar cortex, is important for both execution of accurate motor programs and learning of new actions. Activation and suppression of many PCs is capable of directly inhibiting and driving movements, respectively, and coincident activation of climbing fibre and parallel fibre input pathways to PCs drives plastic changes in firing that is a major locus of cerebellar learning. Our goal is to uncover how PC populations acquire the response properties necessary for driving goal-directed motor execution, and how these representations change under altered sensorimotor conditions. To address these questions, we have recorded the activity of groups of PCs in mice trained to perform a virtual-reality based sensorimotor integration task. Mice were head-fixed in front of an array of monitors and trained to use a steering wheel placed in front of their forepaws to translate a virtual object from eccentric positions to the midline to get a reward. Thus, trial outcomes consisted of undershoots, correct trials, and overshoots. Over several weeks of training, mice learned to make accurate movements at rates well above chance. To monitor activity in PCs

during behaviour, we virally expressed GCaMP6f in these neurons and used resonant-scanning 2-photon microscopy to record dendritic calcium transients, which predominately reflect complex spiking activity, simultaneously across ~200 PCs while mice performed the task. In well-trained mice, movement initiation produced calcium transients in similar groups of PCs, irrespective of trial outcome. However, PC populations exhibited a stereotyped activation sequence in correct trials that was not present in undershoot and overshoot trials: PC calcium signals synchronized just prior to movement onset, paused during movement execution, and resynchronized at movement termination. We also observed that many PCs are active upon delivery of reward on correct trials and absence of reward delivery on incorrect trials. PC populations encoding movement dynamics were not independent populations from the ones encoding reward and error related activity. Thus, calcium signals in PCs contain information about the execution of actions as well as the evaluation of their outcome. We are currently using chronic imaging of PC populations over days to explore how PCs acquire these response properties as animals learn the task, determine the reliability of PC responses on single trials, and track the dynamics of responses as animal adapt their actions under changing sensorimotor coupling.

Abstract: Cerebellar tDCS has been reported to enhance motor associative learning and motor adaptation, holding promise for future clinical application in patients with movement disorders.

However, behavioral benefits from cerebellar tDCS are highly inconsistent across the literature and further characterization of predictive factors of treatment success is necessary. Therefore, we studied the role of BDNF Val66Met in classical eyeblink conditioning and VOR adaptation and the interaction with cerebellar tDCS. We undertook two large tDCS studies in genotyped subjects performing either an classical eyeblink conditioning task (N=117, between design) or a VOR adaptation task (N=46 subjects, within-design). Our results show faster eyeblink conditioning for carriers compared to non-carriers (βCarriers=20.7 [1.3 38.0]) with a supportive role for anodal tDCS only in the slower non-carrier group βAnodal,Non-carriers=19.7 [2.8 36.1] but not in the faster carrier group βAnodal, Carriers=-1.0 [-21.6 17.3]. In addition, cathodal tDCS was ineffective in both genetic groups (βCathodal,Non-Carriers=-1.6 [-19.6 21.1], βCathodal, Carriers=2.7 [-13.8 18.7]). The VOR adaptation experiment did not show an effect of BDNF Val66Met, tDCS or the interaction (βCarriers=-4.8 [-11.8 2.0], βAnodal, Carriers=5.0 [-1.4 11.0], βAnodal, Non-Carriers=0.7 [-3.6 4.5]). These results suggest that BDNF Val66Met (1) can determine effectiveness of cerebellar tDCS by modifying learning rate in some cerebellardependent tasks and (2) has a currently unknown role in cerebellar-dependent associative learning.

Title: Alcohol induces input-specific aberrant synaptic plasticity in the rat dorsomedial striatum

Authors: *T. MA, B. BARBEE, X. WANG, J. WANG Texas A&M Hlth. Sci. Ctr., Bryan, TX

Abstract: Accumulated evidence suggests that the dorsomedial striatum (DMS) of the basal ganglia plays an essential role in pathological excessive alcohol consumption. The DMS receives multiple glutamatergic inputs. However, whether and how alcohol consumption distinctly affects these excitatory afferents to the DMS remains unknown. Here, we used optogenetics to selectively activate the rat medial prefrontal cortex (mPFC) and basolateral amygdala (BLA)

inputs in DMS slices, and measured the effects of alcohol consumption on glutamatergic transmission in these corticostriatal and amygdalostriatal circuits. We found that excessive alcohol consumption increased AMPA receptor- and NMDA receptor (NMDAR)-mediated neurotransmission, as well as the GluN2B/NMDAR ratio, at the corticostriatal input to the DMS. The probability of glutamate release was increased selectively at the amygdalostriatal input. Interestingly, we discovered that paired activation of the mPFC and BLA inputs using dual-channel optogenetics induced robust long-term potentiation (LTP) of the corticostriatal input to the DMS. Taken together, these results indicate that excessive alcohol consumption potentiates glutamatergic transmission via a postsynaptic mechanism for the corticostriatal input and via a presynaptic mechanism for the amygdalostriatal input.

Title: Stroke triggers nigrostriatal plasticity and increases alcohol consumption in rats

Authors: *J. WANG, C. HUANG, T. MA, E. HELLARD, X. WANG, A. SELVAMANI, J. LU, F. SOHRABJI

Dept. of Neurosci. & Exptl. Therapeut., Texas A&M Hlth. Sci. Ctr., Bryan, TX

Abstract: Excessive alcohol consumption is a known risk factor for stroke, but the effect of stroke on alcohol intake is unknown. The dorsomedial striatum (DMS) and midbrain areas of the nigrostriatal circuit are critically associated to stroke and alcohol addiction. Here we sought to explore the influence of stroke on alcohol consumption and to uncover the underlying nigrostriatal mechanism. Rats were trained to consume alcohol using a two-bottle choice or operant self-administration procedure. Retrograde beads were infused into the DMS or midbrain to label specific neuronal types, and ischemic stroke was induced in the dorsolateral striatum (DLS). Slice electrophysiology was employed to measure excitability and synaptic transmission in DMS and midbrain neurons. We found that ischemic stroke-induced DLS infarction produced significant increases in alcohol preference, operant self-administration, and relapse. These

increases were accompanied by enhanced excitability of DMS and midbrain neurons. In addition, glutamatergic inputs onto DMS D1-neurons was potentiated, whereas GABAergic inputs onto DMS-projecting midbrain dopaminergic neurons was suppressed. Importantly, systemic inhibition of dopamine D1 receptors attenuated the stroke-induced increase in operant alcohol self-administration. Our results suggest that the stroke-induced DLS infarction evoked abnormal plasticity in nigrostriatal dopaminergic neurons and DMS D1-neurons, contributing to increased post-stroke alcohol-seeking and relapse.

Title: Chronic intermittent ethanol potentiates goal-directed behavior via dorsomedial striatal adenosine A2A receptor

Authors: *S.-I. HONG¹, S.-Y. CHANG², D.-S. CHOI¹ ¹Mol. Pharmacol. and Exptl. Therapeut., Mayo Clin. Col. of Med., Rochester, MN; ²Mayo Clin., Rochester, MN

Abstract: Chronic intermittent ethanol (CIE) exposure promotes voluntary ethanol consumption. Previously we have reported that inhibition of the adenosine A2A receptor ($A_{2A}R$) in the dorsomedial striatum (DMS) increases reward seeking when mice were tested in random ratio (RR) paradigm of nose-poke operant chamber, which is implicated in goal-directed behavior. However, the mechanisms underlying how CIE exposure regulates the goal-directed behavior under devalued and valued conditions remain unknown. Here, we investigated whether the $A_{2A}R$ in the DMS contributes to goal-directed behavior in mice exposed to CIE. Our results show that CIE exposure elicited anxiety-like behavior in elevated plus maze test without affecting working memory in y-maze test. During acquisition of instrumental behavior training in C57BL/6J mice, CGS21680 (0.3 mg/kg, i.p.), A_{2A}R agonist, and optogenetic stimulation of A_{2A}R-expressing neurons in the DMS abolished goal-directed behavior for sweetened 10% ethanol, whereas ZM241385 (20 mg/kg, i.p.), A_{2A}R antagonist, did not impede goal-directed behavior under valued condition. Interestingly, A_{2A}R activation prevented voluntary ethanol consumption in operant chamber even after 24 hours following CGS21680 (0.3 mg/kg, i.p.) injection. Taken together, activation of the A_{2A}R in the DMS dampens goal-directed behavior and alcohol drinking, suggesting that activation of DMS A_{2A}R could be a potential target for the treatment of alcohol use disorder.

Title: Retrograde mapping of afferent inputs to direct- and indirect-pathway neurons in the dorsomedial striatum

Authors: *Y. CHENG, J. LU, B. BARBEE, X. WANG, J. WANG Dept. of Neurosci. and Exptl. Therapeut., Texas A&M Univ. Hlth. Sci. Ctr., Bryan, TX

Abstract: The dorsomedial striatum (DMS) is crucial for goal-directed behavior and heavily implicated in drug and alcohol addiction. Our recent study indicated an opposite role of DMS dopamine D1 receptor (D1R)- and D2R-expressing medium spiny neurons (MSNs) on alcohol consumption (Cheng et al. 2016). However, the cell type of presynaptic neurons that project to DMS D1- versus D2-MSNs remains unknown. To assess whether these presynaptic neurons also contain D1Rs or D2Rs, we used a state-of-the-art rabies viral-based monosynaptic retrograde tracing technology together with D1-/D2-Cre;Ai14 transgenic mice to map these neurons brainwide. We found abundant DMS-projecting neurons in the different cortical regions, amygdala, thalamus, and midbrain. Interestingly, we found that most D1-MSN-projecting neurons did not express D1Rs, and similarly, most D2-MSN-projecting neurons did not express D2Rs. We only observed a few D1-MSN-projecting neurons in the cortex and thalamus that contained D1Rs; a few D2-MSN-projecting neurons in the same brain regions that expressed D2Rs. In addition, using optogenetic slice electrophysiology and D1-/D2-Cre;Ai32 mice, we found that DMS D1-MSNs received glutamatergic inputs mainly from D2-neurons outside of the striatum, whereas

glutamatergic inputs onto DMS D2-MSNs were predominately from D1-neurons. These results suggest that the D1-D2 and D2-D1 projections are the dominant connections in brain-wide, which is an important question in the addiction field that has not been addressed before. Since drugs of abuse and alcohol affect dopaminergic system brain-wide, understanding these connections will improve our knowledge of the DMS circuits in drug addiction.

Title: Pharmacologic and genetic targeting of the neural extracellular matrix to ameliorate aging-related cognitive decline

Authors: *A. D. RICHARD¹, X. TIAN³, X. W. YANG⁴, X. LU²

¹Pharmacology, Toxicology, and Neurosci., ²Dept. of Pharmacology, Toxicology & Neurosci., Louisiana State Univ. Hlth. Sci. Ctr., Shreveport, LA; ³Pharmacol., LSU, Shreveport, LA; ⁴Psychiatry, UCLA Hlth. Syst., Los Angeles, CA

Abstract: The percentage of the global population aged 65 years and older is projected to double from 8% to 16% by the year 2050. With no effective prevention and treatment, cognitive decline is a major concern of the aging population, presenting a large financial burden on public health care systems worldwide. The brain's extracellular matrix (ECM) has been implicated in mediating neural structural stability by enwrapping synaptic connections fundamental for long term memory storage and other cognitive functions. We hypothesize that aging-dependent accumulation of neural ECM impairs the structure and function of cognitive neural circuitry (e.g, striatum), therefore pharmacologic and genetic modulations of the neural ECM can restore/reverse aging-dependent cognitive decline. Young (6-7 month old) and aged (22-24 month old) mice were analyzed for multiple cognitive functions. Aged mice manifested significant decline in motor skill learning, working memory, object recognition memory, and adaptive learning compared to younger counterparts. The cognitive decline was accompanied by a significant aging-dependent accumulation of the striatal neural ECM. To establish a functional link between aging-dependent striatal ECM accumulation and cognitive decline, we performed

stereotaxic infusions of chondroitinase ABC (ChABC) into striatum to eliminate CSPGs in aged mice, in order to reverse aging-related decline of object recognition memory and motor skill learning. Furthermore, to identify an endogenous genetic target of the striatal neural ECM, we have genetically targeted an orphan sugar-nucleotide transporter as a potential modulator of neural ECM proteoglycans synthesis. AAV-mediated overexpression was shown to drive striatal ECM accumulation. Our study unravels a causal link between cognitive decline and neural ECM accumulation, affording new therapeutic targets for guided neuroplasticity to reverse age dependent cognitive decline.

Title: Anatomical evidence that multiple striatal regions influence motor cortex

Authors: *S. AOKI^{1,2}, M. IGARASHI¹, P. COULON³, J. R. WICKENS⁴, T. J. RUIGROK² ¹Okinawa Inst. of Sci. and Technol., Okinawa, Japan; ²Erasmus MC Rotterdam, Rotterdam, Netherlands; ³Inst. de Neurosciences de La Timone, Marseille Cedex 05, France; ⁴Neurobio. Res. Unit, OKINAWA INSTITUTE OF SCIENCE AND TECHNOLOGY, Onna-son, Japan

Abstract: Striatum receives monosynaptic cortical input and sends multisynaptic output back to the cortex. Dorsolateral striatum (DLS) receives motor cortical input but dorsomedial (DMS) and ventral striatum (VS) do not. However, accumulated evidence suggests the involvement of DMS and VS in motor action such as goal-directed and Pavlovian approach behaviors. Those findings raise the possibility of output from DMS and VS to motor cortex, despite an absence of motor cortical input. We address this possibility by retrograde transneuronal tracing using rabies virus (RABV). RABV was co-injected with an anterograde monosynaptic tracer (cholera toxin b-subunit, CTb) into the rat motor cortex, which resulted in third-order RABV+ striatal neurons and CTb+ cortico-striatal fibers. DLS showed both RABV and CTb labeling, suggesting a closed-loop between DLS and motor cortex. Surprisingly, a few clusters of RABV+ neurons were observed in DMS, VS, and the tail of striatum. These areas were devoid of CTb labeling but made output connections to motor cortex, suggesting an open-loop structure. In another set of

rats, injection of RABV/CTb into prefrontal cortex resulted in RABV labeling in DMS and VS but not in DLS. Since these RABV-labeled regions receive prefrontal input, this suggests a closed-loop structure. These results demonstrate co-existence of closed- and open-loop structures between the striatum and motor cortex, but a closed-loop structure for the striatum and prefrontal cortex. The present study provides an anatomical basis for understanding how the striatum can access motor cortex.

Title: Predicting the PSTH for inhibitory conductance input to substantia nigra pars reticulata

Authors: *D. SIMMONS, M. H. HIGGS, C. J. WILSON

Univ. of Texas At San Antonio, San Antonio, TX

Abstract: Rhythmically firing neurons in substantia nigra pars reticulata (SNr) receive inhibitory synaptic input from direct pathway striatal spiny neurons. To investigate how direct pathway input could affect spike timing in SNr neurons, we characterized the direct pathway synaptic input, measured the post-stimulus time histogram (PSTH) for simulated inhibitory input, and interpreted the results using a model based on the phase resetting curve (PRC). To characterize direct pathway inhibition, a virus containing a Cre-inducible channelrhodopsin was injected into the striatum of Tac1-IRES2-Cre-D mice. The 20 - 80 % rise time and decay time constant were measured from photo-evoked currents in whole-cell voltage-clamp mode. The reversal potential (Erev) was measured from photo-evoked IPSPs recorded in perforated-patch current-clamp mode. To measure PRCs and characterize the spike responses to simulated direct pathway inhibition, we recorded from SNr neurons in perforated-patch configuration. To obtain the PRC, we injected zero-mean current noise and analyzed the spike responses by a previously described multiple linear regression method. To investigate the spike responses to direct pathway input, we used dynamic clamp to apply trains of simulated inhibitory post-synaptic conductances (IPSGs) with kinetics and Erev based on our experimental data. The PSTH was computed with respect to the onset of each IPSG. The main feature of the PSTH was a rapid dip in firing rate typically

lasting on the order of 10 ms. In some cells the dip was followed by a period of firing above the baseline rate. To understand the PSTH shapes, we developed a PRC-based phase model augmented with an approximation of the phase-dependent membrane potential, Vm(phi). Given the experimental Erev, Vm(phi) provides a phase-dependent driving force to convert input conductance into current, which changes the cell's phase according to the PRC. The same IPSG trains injected into each neuron were applied to each phase-voltage model, and the model PSTH was calculated. The models generally produced a PSTH closely resembling the cell data. Our data indicate that, rather than only reducing firing rate, direct pathway inhibition can produce dynamic, bidirectional changes in spike probability. These changes were well explained by our phase-voltage models, providing a tool to explore the potential impact of more complex patterns of input arriving from multiple pathways.

Title: Predicting the PSTH for excitatory current input to substantia nigra pars reticulata neurons

Authors: *M. H. HIGGS, D. V. SIMMONS, C. J. WILSON Biol., Univ. of Texas at San Antonio, San Antonio, TX

Abstract: Autonomous oscillator neurons in substantia nigra pars reticulata (SNr) integrate synaptic input from the direct, indirect, and hyperdirect pathways, including synaptic excitation from the subthalamic nucleus (STN). Synaptic input perturbs the oscillation phase of SNr cells, producing changes in spike timing that can be quantified by the phase resetting curve (PRC). When a rhythmically firing neuron receives inputs that do not cause immediate spiking, small changes in spike timing underlie the average response measured by the post-stimulus time histogram (PSTH). Thus, we tested the ability of phase models based on the PRC to predict the PSTH of SNr neurons in response to excitatory currents. Perforated-patch, current-clamp recordings were obtained from SNr neurons in mouse brain slices. Episodes of noise stimulation used to estimate the PRC were alternated with episodes of EPSC waveforms designed to mimic synaptic input from the STN. PRCs were computed by a previously described multiple linear regression method. The PRCs were type-1, showing only shortening of the inter-spike interval

(ISI) by depolarizing stimulus pulses. Most of the PRCs had a strong rightward skew, indicating greater sensitivity to stimuli arriving late in the ISI, and many had a prominent peak at late phase. Phase models were constructed based on the PRC for each neuron and run with the same EPSC trains delivered to the real cell. The PSTH was then measured for each cell and the corresponding model. Overall, the models captured the major features of the experimental PSTHs, including a large, brief peak shortly after EPSC onset, often followed by a dip below the baseline rate. However, some quantitative differences between the cells and models were observed. In particular, cells with very high sensitivity at late phases often showed a larger PSTH peak and a more prominent dip than predicted by the models. Thus, nonlinear mechanisms deviating from ideal phase-oscillator behavior increase the sensitivity and temporal precision of SNr neurons' responses to fast EPSCs. These properties of SNr neurons may facilitate the transmission of fast signals along the hyperdirect pathway from cortex to STN to SNr.

Title: Oscillatory entrainment of striatal low threshold spike interneurons

Authors: *J. C. MORALES, C. J. WILSON Biol., Univ. of Texas At San Antonio, San Antonio, TX

Abstract: Striatal low-threshold spike (LTS) interneurons are autonomous oscillators that receive input from the cortex, the thalamus, and local neurons within the striatum. Oscillatory activity in the cortex and thalamus is transmitted to the striatum, where it produces oscillatory synaptic currents in striatal neurons. A previous study found that striatal LTS interneurons show a spiking resonance with frequencies between 5 and 30 Hz when stimulated with broadband noise, suggesting that they might amplify oscillations in that frequency range and become synchronized by these inputs. We characterized the oscillatory entrainment of striatal LTS interneurons by applying small (10-20 pA) sinusoidal intracellular currents to mimic oscillatory synaptic currents over a frequency range from 1 to 30 Hz. LTS neurons were identified in B6.FVB-Tg(Npy-hrGFP)1Lowl/J transgenic mice, in which they express green fluorescent protein. The applied sinusoidal currents did not alter the average firing rate of the cells, but had
strong effects on their firing patterns at all stimulus frequencies. LTS cells were most strongly phase-locked to the stimulus when its frequency matched the cells' unperturbed firing rate. To determine whether a shared oscillation might synchronize the population of LTS cells, we targeted channelrhodopsin to LTS cells by viral delivery in a somatostatin-cre (Sst^{tm2.1(cre)Zjh}/J) mouse line. Sinusoidal blue light was used to generate an oscillatory current in all the LTS cells in the region of the injection, and single cells were recorded in cell-attached configuration. Application of the sinusoidal current produced no change in firing rate, and changes in firing pattern were indistinguishable from those seen with intracellular current, indicating that the network did not synchronize. To determine whether oscillations in the LTS cell population could be transferred to postsynaptic spiny projection neurons (SPNs), we measured spontaneous inhibitory postsynaptic currents in SPNs during sinusoidal optogenetic stimulation of the LTS cell population. The data showed a strong transfer of oscillations from entrained presynaptic LTS cells to the synaptic currents produced in SPNs. These results may suggest that presynaptic entrainment of LTS cells will generate an oscillating input to SPNs, which could interact either constructively or destructively with oscillating inputs reaching SPNs directly from the cortex or thalamus.

Title: Involvement of the store operated calcium entry in the long-lasting calcium transient in the striatal GABAergic neuron

Authors: S. KIKUTA^{1,2}, Y. YANAGAWA³, N. HOMMA^{2,4}, M. TAKADA¹, *M. OSANAI^{2,4} ¹Primate Res. Institute, Kyoto Univ., Inuyama, Japan; ²Tohoku Univ. Grad Sch. Med., Sendai, Japan; ³Gunma Univ. Grad. Sch. of Med., Maebashi, Japan; ⁴Grad Sch. Biomed Eng, Tohoku Univ., Sendai, Japan

Abstract: We previously reported that the long-lasting spontaneous Ca^{2+} transients (spontaneous $[Ca^{2+}]_i$ transients), which lasted up to about 300 s, were observed in striatal cells. These Ca^{2+} transients were mainly caused by the Ca^{2+} release from the intracellular Ca^{2+} store (ER) via IP3

receptors. But, the mechanisms that underlie the spontaneous $[Ca^{2+}]_i$ transients remain unclear. Store operated Ca^{2+} entry (SOCE) is thought to be activated by the depletion of Ca^{2+} in ER. Thus, we investigated whether SOCE involved in the spontaneous $[Ca^{2+}]_i$ transients or not. At first, we confirmed the presence of SOCE in the striatal neurons using Ca^{2+} imaging in the striatal slice preparations. In the striatum more than 95% neurons are GABAergic, thus, the GAD67-GFP knock-in mice were used for visualization of the GABAergic neurons. After depletion of Ca^{2+} in the ER by the application of thapsigargin, $[Ca^{2+}]_i$ was elevated when the extracellular Ca²⁺ concentration returned to normal level from the Ca²⁺-free condition. This $[Ca^{2+}]_i$ elevation was blocked by the application of the blocker of the SOCE, SKF96365. Thus, striatal GABAergic neuron has SOCE. Next, we investigated the contribution of SOCE in the spontaneous $[Ca^{2+}]_i$ transients. To quantify the amount of the Ca^{2+} influx, we used the method of the Mn^{2+} quenching of the fluorescent Ca^{2+} indicator. The time constant of the quenching was faster in the neurons exhibiting the spontaneous $[Ca^{2+}]_i$ transients compared with the neurons not exhibiting the [Ca²⁺]_i transients under of TTX administration. SKF96365 tended to decrease the frequency of the spontaneous $[Ca^{2+}]_i$ transients. These results suggested that the spontaneous $[Ca^{2+}]_i$ transients led to activate SOCE in the striatal cells, and that SOCE might contribute to the maintenance of the high $[Ca^{2+}]_i$ levels during the spontaneous $[Ca^{2+}]_i$ transients.

Title: Dopaminergic modulation of striatal cholinergic interneurons governs sequence learning

Authors: *J. H. CHANCEY¹, D. M. LOVINGER²

¹LIN, NIH-NIAAA, Rockville, MD; ²Chief, Lab. Integrative Neurosci, Natl. Inst. on Alcohol Abuse and Alcoholism Rockville Office, Rockville, MD

Abstract: Learning action sequences is necessary for normal daily activities, such as tying your shoes. The dorsal striatum (dStr) has been shown to encode learned action sequences. Specifically dorsal striatal medium spiny neurons (MSNs), change their firing rate at the start and/or stop of action sequences and are able to encode entire learned action sequences as a single event through sustained changes in firing throughout the sequence. Acetylcholine (ACh), released from tonically active cholinergic interneurons (CINs), regulates striatal function by

acting on a diverse group of ACh receptors found on MSNs, presynaptic glutamate and dopamine terminals, and GABAergic interneurons, which regulate MSN excitability, neurotransmitter release, and striatal synaptic plasticity. CINs in the dStr pause their tonic firing during learned action sequences, but the significance of this physiology for behavioral performance has not been explored. We hypothesize that CIN pausing is critical to regulate dopamine and glutamate release and MSN excitability, allowing for plasticity necessary for learning. Activation of dopamine type-2 receptors (D2Rs) on CINs drives pauses in firing. Here we show that genetic deletion of D2Rs specifically from CINs by crossing D2-floxed mice with Chat-Cre mice (D2F-ChatCre) inhibits this D2R-mediated pausing. D2F-ChatCre mice show deficits in learning an operant action sequence task and lower breakpoints in a progressive ratio task, suggesting a reduced motivation to work for sucrose reward, but show no deficits in an accelerating rotarod task, indicating that motor skill learning is intact. Additionally, D2F-ChatCre mice perform similar to controls in an operant reversal learning task, indicating normalthat behavioral flexibility, an aspect of cognitive function impaired y is normal, which is impaired in CIN ablation studies. Using in vivo recordings of unit activity in dStr throughout acquisition of the sequence task we found that D2F-ChatCre mice have deficits in sequence encoding, with fewer MSNs encoding action entire action sequences compared to controls., suggesting that Thus, CIN D2 deletion appears to impairs a neural substrate of action chunking. Virally replacing D2Rs in CINs in the dStr, improves action sequence learning, but does not rescue the lower breakpoints, further suggesting that D2Rs on CINs in the dorsal striatum are critical for sequence learning, but not for driving the motivational aspects of the task.

Title: Differential impact of specific midbrain to striatal cholinergic interneurons pathways in conditioned behavior

Authors: *K. TAN, Z. LI, A. MERLI, G. RIZZI Univ. of Basel, Basel, Switzerland

Abstract: Cholinergic interneurons (CINs) represent 1 to 2% of the striatal population, yet they play a determining role in learning. Their firing pattern makes them unique; they are spontaneously active, exhibit profound after hyperpolarization activity and respond to salient

stimuli irrespective of the valence, mainly through a brief firing suppression. This pause can be preceded or followed by an acute excitation. Such responses have been shown to mediate the acquisition of the association between a predictive cue and an external stimulus, and as such, the CIN pause response has been proposed to represent a neural correlate of classical conditioning. This response has been shown to be linked to midbrain dopamine (DA) neuron's activity. Specifically, it is absent in DA depleted animals and time-locked to an increase of DA neuronal firing. At the circuit level, midbrain inputs to CINs have been described, however it is still not clear how these inputs impact CIN mediated conditioning. More specifically, the midbrain is composed of several neuronal types including glutamatergic, GABAergic and DAergic cells. Furthermore, DA neurons have been shown to be able to co-release glutamate or GABA. Although a few studies have investigated midbrain to striatal neurons circuitry, the results come from independent and different experimental conditions making the observations hard to reconcile. Here, we aim to systematically dissect the midbrain to CIN pathways and evaluate how each midbrain cell type and related pathway influences CINs firing response in order for them to support conditioned behavior. Our preliminary data suggest that all three neuronal cell types contact CINs but only the glutamatergic and GABAergic inputs (vglut2- and vgat-cre expression) form monosynaptic contacts whereas DA neurons (manipulated trough dat-cre expression) inhibit CINs but via an indirect pathway. Optogenetic manipulation of these pathways in a contextual fear conditioning design differentially affects acquisition of the contextual cues.

Title: Subcellular functional analysis of direct pathway striatal spiny projection neurons in patch versus matrix compartments of the dorsal striatum

Authors: *E. M. PRAGER, C. CUHNA, M. HARNETT, J. L. PLOTKIN Dept. of Neurobio. and Behavior, Stony Brook Univ., Stony Brook, NY

Abstract: The dorsal striatum has the complex computational task of integrating highly convergent excitatory afferents from diverse cortical and subcortical brain regions, in order to guide action selection and motor decision-making. One way the striatum deals with this

challenge is by distributing inputs among specialized neuronal subtypes, including striatal spiny projection neurons (SPNs), which are situated in two different chemically- and anatomicallydefined compartments (referred to as patches and matrix). Differential engagement of patch vs matrix SPNs during specific behaviors has been proposed, but our understanding of the cellular properties that may underlie such differential engagement is limited. This is due to the relative low density of patches within the striatum, and an inability to distinguish compartments in live tissue slices using traditional microscopy. To overcome these limitations, we have crossed Nr4a1-eGFP transgenic mice, in which GFP is preferentially expressed in patches, with Drd1tdTomato mice, which label D1-type dopamine receptor-expressing direct pathway SPNs (dSPNs), allowing comparable SPN types to be functionally compared in patches and matrix. In agreement with previous studies, the soma of dSPNs located in patches were more excitable than those in the matrix, as reflected by higher input resistance and lower somatic current injection required to elicit action potentials. Because patch and matrix SPNs receive different constellations of glutamatergic inputs, all of which synapse on dendrites that are spatially and electrically distant from the soma, we used 2-photon imaging and 2-photon uncaging of glutamate to assess postsynaptic dendritic synaptic integration in an input-unbiased manner. Dendritic spine density and NMDA/AMPA receptor mediated current ratios were similar in dSPNs in patch vs matrix compartments. Postsynaptic integration of spatially and temporally coordinated synaptic inputs was also similar in patch vs matrix dSPNs: there was no difference in the number of neighboring activated spines required to evoke regenerative plateau potentials in distal dendrites, nor was there a difference in the duration of these plateau potentials. Thus, although somatic excitability is higher in SPN patches, postsynaptic dendritic integration of glutamatergic inputs is similar between the two compartments. Despite similarities in synaptic integration, preliminary data suggest that D1-type dopamine receptor modulation of synaptically evoked dendritic plateau potentials may be restricted to dSPNs residing in the matrix. The mechanism underlying this compartment disparity is currently being explored.

Title: Parallel striatal pathways collaboratively control the dynamics and fate of actions

Authors: *C. MENG¹, J. ZHOU², A. PAPANERI², G. CUI² ¹Lab. of Neurobiology/ In Vivo neurobiology group, NIH/NIEHS, Durham, NC; ²NIH/NIEHS, Research Triangle Park, NC

Abstract: The striatum is the central hub of the basal ganglia that integrates glutamatergic inputs from the cortex and the thalamus, and dopaminergic input from the substantia nigra pars compacta. We have recently reported that the two types of striatal projection neurons (SPNs), the D1 dopamine receptor-expressing direct-pathway SPNs and the D2 dopamine receptorexpressing indirect-pathway SPNs, are both activated during action initiation. To further investigate the relationship between these two pathways and their roles in movement control, we have developed a novel spectrally resolved fiber photometry method that allows for simultaneous monitoring of neural activity from two or more molecularly defined groups of neurons. By intrastriatal infusion of a mixture of rAAV vectors expressing Cre-On red calcium indicator jRGECO1a and Cre-Off green calcium indicator GCaMP6f in D1-Cre and A2A-Cre mice, we were able to simultaneously measure the neural activity from direct- and indirect- striatal pathways in freely moving mice. We have found that strong activation in the direct pathway in conjunction with weak activation in the indirect pathway in one hemisphere leads to a 'start and go' type of contraversive movement in the arena, whereas strong activation in both pathways in one hemisphere produces a 'start and stop' type of movement featuring quick initiation of a contraversive movement immediately followed by an abrupt stop. Our results suggest that balance between striatal direct- and indirect-pathways determines the dynamics and fate of actions.

Title: Molecular tools for In vivo spectrometry: Viral vectors designed to target neuronal subsets

Authors: *A. PAPANERI, C. MENG, J. ZHOU, C. MAZZONE, G. CUI Neurobio., NIEHS, Research Triangle Park, NC

Abstract: Recent technological and molecular biological advancements have broadened the capabilities for understanding neuronal circuitry, which is a shared pursuit that would provide countless benefits to the scientific and medical communities. Currently, novel optical imaging technologies are being paired with novel foreign gene delivery vectors to improve signal detection sensitivity as well as gene expression efficiency. Additionally, the employment of site-

directed DNA recombination technology and tissue-specific promoters in viral vectors has enabled a refined targeting of neuronal populations with great functionality and flexibility. We use these molecular techniques to produce adeno-associated viruses (AAVs) with fluorescent genetically encoded calcium indicators (GECIs) to visualize the activity of neuronal subsets in behaving mice. Optical fiber photometry is used to record from multiple probe sites within the active mouse brain. Data is thereby collected only from the effected neuronal population and can be analyzed not only for neuronal activity, but also connectivity, kinetics, and degradation, among other measures. Multiple combinations of AAVs with various tissue-specific promoters, recombinases and their recognition sites are possible. By focusing more precisely than tissuespecific promoters, we hope to achieve accuracy and efficiency with even greater specificity. For example, the hSynapsin promoter, known for its exclusive activity in neurons, is often used instead of the more general CAG or Ef1a promoters to target expression of foreign genes to neurons. We now move to the use of promoters of individual proteins associated with neuronal subsets, such as those for dopamine receptor (DAR), pro-opiomelanocortin (POMC) or agoutirelated protein (Agrp) positive neurons. For instance, AAVs expressing Cre recombinase under the control of promoters specific for DARs type I (D1) and/or type II (A2A) can be used in conjunction with AAVs expressing double floxed inverted reporter genes to limit data collection to those specific neurons. We can use this format to study mouse models of Parkinson's Disease (PD). From in vivo recordings in mice, spectral data collected over time can distinguish between normal and degraded neuronal activity, which may correlate with declining motor behavior. This visualization of PD-like disease progression in the brain could be used to evaluate potential treatment methods and prevention strategies in real time. We continue to work to expand this existing molecular toolkit to provide greater flexibility and convenient adaptability for future research studies.

Title: Simultaneous dual color recording of neural activity from parallel striatal pathways

Authors: ***J. ZHOU**¹, C. MENG², A. PAPANERI⁴, G. CUI³ ¹NIEHS/NIH, Research Triangle Park, NC; ²Lab. of Neurobiology/ In Vivo neurobiology group, NIH/NIEHS, Durham, NC; ³Neurobio. Lab., NIH/NIEHS, RTP, NC; ⁴Neurobio., NIEHS, Research Triangle Park, NC

Abstract: Monitoring the cellular and molecular events in specific types of cells in behaving animals using genetically encoded fluorescent sensors is a powerful approach to decode neural correlates of specific behaviors, and to uncover the mechanisms underlying the psychiatric and neurological disorders. Here we report a novel in vivo method that allows for high speed (50 Hz) continuous recordings of fluorescence signals with high spectral resolution (7.7 nm) and wide spectral range (350-1100 nm) from deep brain structures through a small diameter (125 micron OD) optical fiber in freely moving animals. By applying linear unmixing algorithm on the recorded emission spectra of multiple fluorescent sensors, the new photometry method can be used to simultaneously measure multiple cellular events in a local brain circuit when the animals are performing behavioral tasks. To simultaneously record neural activity from striatal directand indirect-pathway neurons, we infused Cre-On DIO-jRGECO1a (red calcium indicator) and Cre-Off Lox-FAS-GCaMP6f (green calcium indicator) rAAV vectors into the dorsal striatum of D1-Cre and A2A-Cre mice. We found that although the striatal direct and indirect pathways are mostly activated at the same time during voluntary movements, the differences in the magnitude of activation in these two pathways often lead to different behavioral consequences. Using this method, we are studying how dopamine modulates the activity in these two striatal pathways.

Title: Striatal representation of competing cortical information

Authors: *M. ISRAELASHVILI, I. BAR-GAD Bar Ilan Univ., Ramat Gan, Israel

Abstract: Abstract

The striatum, which is the main input nucleus of the basal ganglia, receives excitatory input from most of the cerebral cortex. The striatum contains feedforward and feedback GABAergic connections encompassing both projection neurons and interneurons, forming an extensive inhibitory network. This unique architecture prompted the hypothesis that the function of the basal ganglia in general and specifically of the striatum is to select a single action out of a

multitude of actions presented by massive convergent cortico-striatal inputs. In this context, the GABAergic network inhibits all the actions presented by the cortex except for a single "selected" action. Currently, there are limited physiological evidences for the functional role of the striatal inhibitory network and for the validation of this hypothesis. In this study we examine the processing of competing cortical input in the striatum in freely behaving rats. We used electrical and optical stimulation of multiple cortical areas in conjunction with somatosensory input while simultaneously performing extracellular recordings from the striatum. Characterization of the neuronal activity of the striatum that occurs during separate as well as simultaneous stimulation of different cortical areas was performed. We observed both synergistic and antagonistic interactions between cortical inputs in the striatum, supporting a complex representation of the cortical activity by the striatum. This remapping of cortical information suggests that the research of cortico-basal ganglia information processing requires the progression to the study of the interaction between multiple sources of input to this pathway.

Title: Differences in LTP between dorsolateral and dorsomedial striatum: Induction frequency, D1 receptors, and Trkb receptors

Authors: *V. LEWITUS¹, A. KAISER², R. KEITH³, K. T. BLACKWELL² ¹Sch. of Systems Biol., ²Bioengineering, ³Interdisciplinary Neurosci. Program, George Mason Univ., Fairfax, VA

Abstract: The striatum of the basal ganglia is associated with learning a variety of behaviors such as motor control and habit formation, and has been implicated in habitual drug use. The dorsolateral (DL) striatum receives input from the primary sensorimotor cortex and is involved in procedural learning and habit formation, while the dorsomedial (DM) striatum receives input from the association cortex and is involved in spatial learning and goal-oriented behavior. Previous studies have found that DM neuron spiking is entrained to a higher theta frequency than DL neuron spiking. In addition, previous studies disagree about the requirement for D1 receptors, with some showing that D1 receptors are required for long term potentiation (LTP) in the DM striatum (Hawes et al., 2013) but others showing that D1 receptors are not required in the DL striatum (Park et al., 2014). These two studies used different stimulation paradigms, so it

is possible that the apparent regional difference may instead be attributed to different stimulation protocols, which may recruit different molecular mechanisms. To investigate the extent of regional differences in striatal LTP, we measure whether a larger LTP is produced by a lower theta frequency in the DL striatum, corresponding to *in vivo* theta rhythms. We use extracellular field recording on adult C57B16 mouse brain slices to measure LTP in response to a theta-burst stimulation of either 10.5 Hz or 5 Hz. Our results show that 10.5 Hz but not 5 Hz produces LTP dorsomedially; in contrast, both 10.5 Hz and 5 Hz produce similar LTP amplitudes dorsolaterally. We test LTP induction in both male and female mice and find that male mice exhibit greater LTP than females, independent of estrus status. Using 5 Hz to induce LTP, we demonstrate that blocking D1 receptors with SCH23390 in the DL striatum prevents LTP, suggesting that this molecular mechanism does not differ between striatal regions. This study also investigates the role of BDNF in the DM and DL striatum by repeating LTP induction while blocking TrkB receptors. In conclusion, although no difference between the DM and DL striatum is found in D1 receptor requirement for LTP, a difference is found in temporal sensitivity, suggesting that other molecular mechanisms may differ between the two regions.

Title: Fast-spiking interneurons regulate ensemble calcium signaling and striatum-dependent learning

Authors: *S. F. OWEN¹, J. D. BERKE², A. C. KREITZER¹ ¹Gladstone Inst. of Neurolog. Dis., San Francisco, CA; ²UCSF, San Francisco, CA

Abstract: The striatum is the primary input nucleus of the basal ganglia, a set of sub-cortical nuclei that are essential for motor planning and action selection. Parvalbumin-expressing fast-spiking interneurons (FSIs) in the dorsal striatum have been linked to decision making during goal-directed behavior, while defects in striatal FSIs have been associated with movement disorders including tics and dyskinesias. However, their role in learning and network plasticity is less clear. Within the striatum, the primary input nucleus of the basal ganglia, loss of FSI

function has been associated with involuntary movements in animals and Tourette's Syndrome in human patients. Our results indicate that selective ablation of striatal FSIs is not sufficient to impair acute motor performance. Instead, loss of FSI function disrupted striatum-dependent forms of learning. To investigate the mechanism underlying these striatal learning deficits, we combined in vivo optogenetic control of FSIs with Ca2+ imaging of striatal medium spiny projection neurons (MSNs) in freely moving mice. Together, our data support a model in which striatal FSIs facilitate adaptive motor learning through coordination of task-related Ca2+ signaling and plasticity in MSN networks.

Title: Spatiotemporal GABAergic inhibition regulates cooperative spine calcium signaling in a spiny projection neuron model

Authors: *D. B. DORMAN, K. T. BLACKWELL Krasnow Inst. for Advanced Study, George Mason Univ., Fairfax, VA

Abstract: Spiny projection neurons (SPNs) of the striatum contribute to goal-directed and habit learning by integrating glutamatergic input from cortex and thalamus. SPNs also receive GABAergic input from multiple types of striatal interneurons and SPN collaterals. Experimental work has demonstrated that temporally-aligned glutamatergic activation of 10-20 neighboring spines located distally on SPN dendrites elicits regenerative, NMDA-dependent plateau potentials that resemble the transitions observed *in vivo* from hyperpolarized downstates to depolarized upstates. These results suggest that NMDA plateau potentials may drive state transitions and, due to strong calcium transients accompanying plateau potentials, may control synaptic plasticity in SPNs. Though GABAergic inhibition is important to SPN function *in vivo*, its effect on dendritic and spine calcium dynamics evoked by plateau potentials has not been examined. Here we investigate the effects of spatial and temporal distributions of GABAergic inhibition on distally clustered glutamatergic input in a biologically detailed SPN computational model with sophisticated calcium dynamics. Specifically, we examine the effects of dendritic location and timing of GABA_A synapses (relative to glutamatergic activation of a distal cluster of

spines) on nonlinear spine and dendritic calcium transients. Additionally, as GABA_A currents from neurogliaform synapses exhibit significantly slower kinetics than currents from fast spiking interneurons, low threshold spike interneurons, or SPN collaterals, we investigate the effects of GABA_A kinetics on regulating glutamatergic integration. We find that GABA inhibition can diminish supralinear spine calcium transients evoked by glutamatergic activation of clustered spines when GABA_A synapses are close to the site of glutamatergic activation and within a time window from 50-100 ms before to 25 ms after glutamatergic activation. In contrast, proximal GABA_A synapses did not exhibit an inhibitory effect. Further, we find that slow GABA_A kinetics have a stronger inhibitory effect than the faster GABA_A synapses. These results suggest that distal synapses regulate distally clustered glutamatergic activation and calcium signaling, while the proximally synapsing fast spiking interneurons are unlikely to do so. Together, our results indicate that GABAergic signaling in the striatal network is important for regulating NMDA-plateau potentials and calcium signaling in SPNs.

Abstract: The dorsal striatum is critical for action selection. The output of this nucleus is regulated by powerfully inhibitory GABAergic fast-spiking interneurons (FSIs), which comprise roughly 1% of the total population of striatal neurons. By virtue of the presence of electrical synapses between FSIs, modeling studies propose that these neurons synchronize *in vivo*. However, *in vivo* electrophysiological recordings to date suggest that these neurons fire idiosyncratically. To resolve this and to provide insight into how these neurons encode action, we employed *in vivo* Ca²⁺ imaging and optogenetics in mice in conjunction with *ex vivo* whole-cell patch clamp electrophysiology. We find that rapid integration of cortical inputs to FSIs combined with a moderate degree of electrical coupling between FSIs provides a possible substrate for our *in vivo* observation that coordinated FSI activity encodes action velocity. Additionally, optogenetically manipulating FSIs *in vivo* further implicates this population in action control. These results substantiate the critical role of FSI feed-forward inhibitory

governance of striatal output and provide insight into movement disorders, such as Tourette syndrome, that are associated with FSI deficits.
