California Davis, Sacramento, CA

Abstract: Differentiation of oligodendroglial progenitor cells (OPCs) into myelinating oligodendrocytes is regulated by the niche where they differentiate. However, it has not been clarified whether or not oligodendroglial lineage cells (OLCs) derived from different anatomical regions of the central nervous system (CNS) respond to microenvironmental cues in the same manner. Here, we compared pure OPCs from rat neonatal forebrain and spinal cord in the same *in vitro* conditions. We found that forebrain and spinal OLCs respond differently to the same external factors. They were distinct in proliferation responses to mitogens, oligodendrocyte phenotype after differentiation, and cytotoxic responses to α-amino-3-hydroxy-5-methyl-4-isoxazolepropionate-type glutamate receptor-mediated excitotoxicity at immature stages of differentiation in a cell-intrinsic manner. Moreover, transcriptome analysis identified genes differentially expressed between these OPC populations, including those encoding transcription factors, cell surface molecules, and signaling molecules. Particularly, forebrain and spinal OPCs retained the expression of region-specific transcription factors, such as Foxg1 and Hoxc8, respectively, even after serial passaging *in vitro* indicating that OPCs maintained regional identity of their origins through the multiple cell divisions. Given the essential role of these transcription factors in the regional identities of CNS cells along the rostrocaudal axis, our

results suggest that CNS region-specific gene regulation by these transcription factors may cause cell-intrinsic differences in cellular responses between forebrain and spinal OLCs to extracellular molecules. Further understanding of the regional differences among OPC populations will help to improve treatments for demyelination in different CNS regions and to facilitate the development of stem cell-derived OPCs for cell transplantation therapies for demyelination.

Title: Prospective identification and regulation of Glast positive cells in the mouse hypothalamus

Authors: L. TIROU[1], M. DAYNAC[1], H. FAURE[1], M.-A. MOUTHON[2], F. BOUSSIN[2], *M. RUAT[1]

Abstract: The hypothalamus (HPT), a central regulator of energy homeostasis, controls food intake, metabolism and body temperature. Emerging evidence indicates that active neurogenesis occurs in the post-natal and adult mammalian HPT and that new neurons are added to the appetite and energy-balance regulating centers in young and old animals (Sousa-Ferreira et al, *Trends Endocrinol Metab*, 2014). Tanycytes, ependymocytes, subventricular astrocytes and parenchymal glial cells that are located next to the third ventricle (3V) represent potential stem and progenitor cell candidates. However, the precise location and identity of these cells are not known yet. We have developed a conditional mouse (GlastCre^{ERT2}-YFP) reporter line where YFP is expressed in Glast^{+} cells (astrocyte-specific glutamate transporter expressed in astrocytes and astrocyte-like Neural Stem Cells (NSCs)) upon administration of tamoxifen (Daynac et al, *Stem Cell Reports*, 2016). We have observed that ten days after tamoxifen administration in young adult mice, the reporter activity is detected in all tanycyte populations at the level of the median eminence. These cells were located in the ventricular zone of the 3V and extended basal processes as shown by intense YFP signals. The signal was also evident in the parenchyma in agreement with its expression in Glast^{+} astrocytes. Using this reporter mouse model, we have purified Glast-YFP cells from HPT of adult mice by fluorescence-activated cell sorting (FACS). We labelled the YFP cells with a Glast antibody to distinguish Glast-expressing recombined cells (Glast^{+}YFP^{+}) from their progeny that no longer express Glast (Glast^{-}YFP^{+}). Experiments are in progress to further quantify and characterize YFP expression in Glast^{+} cells and in their progeny

6 and 10 months after tamoxifen administration and to delineate the molecular mechanisms (single cell RNAseq) regulating the maintenance of these cells. These experiments will bring novel methods and genetic tools to investigate the role of Glast$^+$ cells and their progeny in feeding behaviors, energy-balance and in neurodegenerative diseases.

Title: Pdgfra$^+$ progenitor cells differentiate in both oligodendrocytes and pericytes in the developing mammalian central nervous system

Authors: *E. M. FLORIDDIA, D. DIAS, S. MARQUES, C. GÖRITZ, G. CASTELO-BRANCO
Karolinska Institutet, Stockholm, Sweden

Abstract: Oligodendrocytes (OLs) and pericytes (PCs) have very distinct functions. OLs myelinate and metabolically support axons of the central nervous system, while PCs are involved in angiogenesis, blood flow regulation, and are essential to maintain the integrity of blood-brain barrier. We have recently identified a *Pdgfrα*$^+$ cell subpopulation (a widely accepted marker of OL precursor cells) that belongs to the pericyte lineage by single-cell RNA-sequencing analysis of the OL lineage (Marques and Zeisel et al, 2016, Science). OL progenitor cells and PCs also share other markers such as NG2 (*Cspg4*). Moreover, Sox10 is a pan marker for the oligodendrocyte lineage but Sox10$^+$ neural crest progenitors have been reported to originate PCs (Simon et al, 2012, Genesis). To address whether OLs and PCs have a common multipotent progenitor, we fate mapped Pdgfrα$^+$ cells at embryonic (E) day 13.5 and observed that they differentiate in both OLs (expressing Pdgfrα and CC1) and PCs (expressing Col1α1) in the brain and spinal cord. We also fate-mapped pericytes at embryonic and juvenile stages, using the *Col1α1CreER^{T2}-TdTomato* reporter mouse line. We observed that a subpopulation of Col1α1$^+$ pericytes express markers such as Pdgfrα$^+$ and Sox10$^+$ in vitro and in vivo, but not markers of OL differentiation, such as MOG, CNPase, or MBP. We are further investigating the fate of the Col1α1$^+$ pericytes in case of demyelination. We aim to unveil whether a cell type within the pericyte lineage has the ability to transdifferentiate into oligodendrocyte and contribute to self-repair following demyelinating injuries.

Title: Postnatal development of Gli1 astrocytes in the mammalian cortex

Authors: ***E. C. GINGRICH**[1], B. TING[1], O. OLUKOYA[3], M. WALOGORSKY[3], C. HARWELL[3], A. D. R. GARCIA[2]
[2]Neurobio. and Anat., [1]Drexel Univ., Philadelphia, PA; [3]Neurobio., Harvard Univ., Boston, MA

Abstract: Astrocytes encompass a large and heterogeneous population of cells whose molecular and functional diversity remain poorly understood. We previously showed that in the adult mammalian cortex, a subpopulation of astrocytes express the transcription factor, Gli1, indicating active and high level Sonic hedgehog (Shh) signaling. These Gli1 astrocytes exhibit a layer specific distribution such that Layers 4 and 5 exhibit the highest density of Gli1 astrocytes, while Layers 1 and 2/3 are relatively sparse. The developmental origins of cortical Gli1 astrocytes are not known. In addition, whether Shh signaling in astrocytes is restricted to mature, post-mitotic cells or whether it occurs in astrocyte precursors that produce Gli1 cells remains to be determined. In this study, we examined the developmental origins of cortical Gli1 astrocytes across postnatal development. We found that the number of cells expressing Gli1 increases dramatically over the first two postnatal weeks, reaching adult expression levels by postnatal day 14 (P14). Proliferation studies with BrdU showed that few Gli1 cells are dividing at P7, although 30% of cells are double labeled at P3, suggesting that the early postnatal cortex harbors a population of Gli1 expressing progenitor cells. In order to map and trace the lineage of proliferating, Gli1 expressing precursors, we performed genetic inducible fate mapping (GIFM) using Gli1CreER mice crossed with the Ai14 Rosa26 tomato reporter line (*Gli1*$^{CreER/+}$*;R26*$^{tdTom/tdTom}$). In animals that received tamoxifen at P7 and were analyzed at P14, marked cells show a distribution consistent with that observed in adult tissues, with the majority of cells localized in Layer 5. In contrast, animals that received tamoxifen at P3 show numerous marked cells in superficial cortical layers. Additionally, we observed a greater number of marked

cells at P3, compared with P7, suggesting that proliferation of Gli1 cells occurs primarily during early postnatal development. Single cell, colocalization analysis with tomato and cell-type specific markers showed that the vast majority of Gli1 cells marked by tamoxifen at any age express S100ß, suggesting that these cells predominantly generate astrocytes. We did not observe any marked cells that correspond to oligodendrocytes. Taken together, these data suggest that Gli1 astrocytes are derived from a Gli1 expressing precursor cell in the early postnatal cortex. Moreover, these data show that in contrast to the embryonic CNS, where Shh regulates specification and proliferation of oligodendrocyte precursor cells, Shh signaling in the early postnatal cortex occurs predominantly in astrocyte progenitor cells.

Title: FGF signaling directs neural stem cells in the subventricular zone toward oligodendrocyte lineage and improve cell regeneration after demyelination

Authors: *W. KANG[1], J. M. HEBERT, 10461[2]
[1]Albert Einstein Col. of Med., Bronx, NY; [2]Dept. of Neurosci., Albert Einstein Col. of Med., Bronx, NE

Abstract: FGF signaling plays a critical context-dependent role in both dorsal-ventral cell fate specification and neurogenesis during brain development. But its role in the regulation of adult stem/progenitor cells in the subventricular zone (SVZ) in vivo is not clear. Here in this study, a conditional mouse genetic approach was used to modulate FGF signaling specifically in adult neural stem/progenitor cells in the SVZ, and the effects of both loss and activation of FGF signaling on stem/progenitor cell fate specification was examined. The results showed that although FGF signaling is not essential for the neurogenesis in the SVZ, its increased activity leads to a greatly increased generation of Olig2+ transit amplifying progenitor (type C) cells that are committed to oligodendrocyte lineage at the expense of neurogenic progenitor cells. Importantly, upon demyelination, the increased generation of oligodendrocyte lineage progenitor cells in the SVZ results in an improved cell regeneration and replacement in the corpus callosum, whereas the neurogenesis from the SVZ is temporarily decreased, likely due to the re-directed differentiation of stem/progenitor cells toward oligodendrocyte lineage. Whether the oligodendrocyte fate specification by FGF signaling can lead to improved remyelination and functional recovery after demyelination will be further examined. The finding that the fate of

neural stem cells in the SVZ can be re-specified toward oligodendrocyte fate by FGF signaling has important implications for the potential use of endogenous stem/progenitor cells in demyelinating diseases.

Title: Deletion of integrin linked kinase in neural progenitor cells disturbs neuron/glia balance during early spinal cord development

Authors: *R. HUSSAIN[1,2], W. B. MACKLIN[3]
[1]Dept. of Cell and Developmental Biol., Univ. of Colorado Sch. of Med., Aurora, CO; [2]Dept. of Neurosurg., Univ. of Rochester, Center for Translational Neuromedicine, NY; [3]Dept Cell & Dev Biol., Univ. Colorado Med. Sch., Aurora, CO

Abstract: Integrin linked kinase (ILK) is a serine/threonine protein kinase, localized at the inner margin of the plasma membrane, where it also serves as a scaffolding protein/focal adhesion mediator. Its presence has been reported in neurons, astrocytes and oligodendrocytes in the central nervous system, but its exact role during the embryonic development of the glial/neuronal profile in brain and spinal cord remain unknown. We selectively knocked out ILK in embryonic neural progenitor cell populations in Cre-lox experiments driven by promoter of the the 2'3 cyclic nucleotide phosphodiesterase (CNP) gene or the promoter of the transcription factor Olig1 gene. These promoters are both active in spinal cord by E12.5. Deletion of ILK severely reduced the number of proliferating (Ki67+) oligodendrocyte progenitor cells (OPCs) in both transgenic lines, which ultimately resulted in reduced OPCs in different regions of the embryonic spinal cord. ILK deletion not only reduced OPC proliferation, but also increased the number of apoptotic OPCs, identified by TUNEL staining. $CNP^{cre+/-}$ X $ILK^{fl/fl}$ (CNP-ILK cKO) embryos were embryonic lethal, and even $Olig1^{cre+/-}$ X $ILK^{fl/fl}$ (Olig1-ILK cKO) embryos often died in utero. Importantly, Olig1-ILK cKO embryos had altered neuron/glia ratios by E14.5. As detected by NeuN, Pax6, GABA, ASCL1, ISLET1, and HuD immunostaining, in the absence of ILK, the normal neuron-glia balance shifted towards production of more neuronal cells. In conclusion, ILK is important for the normal neuron-glia profile during development of the embryonic spinal cord, and its absence reduces oligodendrocyte number by reducing proliferation and increasing apoptosis.

Title: Impact of growth factors on human neuroglial cell morphology

Authors: ***V. B. KNIGHT**, T. M. NUNN, E. E. SERRANO
Biol., New Mexico State Univ., Las Cruces, NM

Abstract: Understanding the plasticity of human neural cell types and neural cell fate decisions are critical milestones in the path toward the regeneration of nervous tissue after injury. A primary normal human astrocyte (NHA) cell line with phenotypic plasticity was chosen for the evaluation of the potential role of growth factors in cell fate decisions. Using phase contrast microscopy, we made a morphological assessment of NHA cell fate after 10 days in culture under spontaneous (Knockout DMEM/F-12, Glutamax, and StemPro Neural Supplement; Gibco) and neuronal (Neurobasal Media, Glutamax, and B27 Supplement; Gibco) differentiation conditions. Metamorph® software was used to evaluate (1) the number of phase-bright structures, and (2) the length of processes protruding from the cell body in NHA cultured in the two distinct growth factor combinations. Objects with a width less than 180 nm and a length more than 900 nm were considered processes. In some cases, a phasedark irregularly shaped structure interrupted objects otherwise considered processes. Objects were nevertheless counted as processes, and the number of phasedark irregularly shaped structures was tallied for each image. Our findings suggest that both the number of long processes and the number of phase-bright structures are increased in NHA cultured under neuronal differentiation conditions. Additional studies will compare neuronal beta tubulin in NHA cultured with the distinct growth factor combinations. Research supported by the NMSU Manasse Endowment.

Title: Generation of cortical oligodendrocytes from dorsal forebrain radial glia requires Shh signaling during embryonic development

Authors: *C. WINKLER, S. FRANCO
Univ. of Colorado Sch. of Med., Aurora, CO

Abstract: Radial glial cells (RGCs) in the ventral and dorsal forebrain can give rise to committed oligodendrocyte precursor cells (OPCs) that migrate into the cortex in successive waves to generate mature oligodendrocytes. The vast majority of oligodendrocytes in the mature cortex arise from the dorsal Emx1 domain, although it has previously been thought that dorsally-derived OPCs only begin to arise during postnatal ages in the mouse forebrain. We now show that dorsal RGCs in the embryonic mouse forebrain begin to produce large numbers of OPCs as early as E15.5, during the peak of upper layer neurogenesis. Furthermore, we have identified a subpopulation of dorsal RGCs, marked by expression of the transcription factor Ascl1, that generate only cortical oligodendrocytes, but not excitatory projection neurons or astrocytes. We also show that the sonic hedgehog (Shh) signaling pathway is critical for generating these dorsal $Ascl1^+$ RGCs and for producing normal numbers of cortical OPCs and oligodendrocytes. Using a variety of Cre mouse lines to knock out Shh from various regions of the embryonic forebrain, we provide evidence that the embryonic cerebral spinal fluid is a critical source of Shh for generating oligodendrocytes from dorsal RGCs. Taken together, our results suggest a model in which a late embryonic Shh signal initiates a neuron-glia switch in a subset of dorsal RGCs to drive cortical oligodendrogenesis.

Title: Barx2 can drive expression of astrocytic and neuronal markers similar to glioma "asteron" cells

Authors: C. RUSSO[1], K. MCKAY[2], *M. K. TAYLOR[3]
[1]LabMate, Boston, MA; [2]Central Michigan Univ., Mt. Pleasant, MI; [3]Biomed. Sci., Grand Valley State Univ., Allendale, MI

Abstract: The characterization of candidate regulators of stem cell differentiation can be performed in the chick embryo using quantitative PCR and anatomical techniques. Here we focus on one gene of interest, Barx2, on neural progenitor differentiation in the developing chick neural tube. Barx2 is highly enriched in neural stem cell populations, making it an interesting target of study in terms of stem cell self renewal. However, overexpression of Barx2 resulted in the formation of hybrid cells that ectopically express both neuronal and astroctyic markers. These features resemble “asterons”, previously reported both as intermediate cells in neurosphere transdifferentiation in vitro and as prevalent cell types in many forms of aggressive glioma tumors. Additionally, we found that Barx2 drove the expression of multiple proteins known to be highly expressed in astrocytoma. Future work will determine potential expression patterns of Barx2 in glioma tumors and further classify the progression of the “asteron” cell type following Barx2 overexpression.

Title: Investigating the role of astrocytes in BOLD fMRI signal

Authors: *Z. SKACHOKOVA, F. SCHLEGEL, A. SCHROETER, M. RUDIN
Inst. for Biomed. Engin., ETH, Zuerich, Switzerland

Abstract: Functional magnetic resonance imaging (fMRI) is a technique widely used in research and in clinics, however the biological mechanism underlying the generation of BOLD fMRI signals remains incompletely understood. Astroglial cells are the central elements of the neurovascular unit that link neural circuitry with local blood flow and metabolic support. It has been proposed that release of vasoactive substances by astrocytes couples neuronal activity to changes in cerebrovascular blood flow. However, the contribution of astrocytes to the fMRI BOLD response remains controversial. In order to investigate this question further, we measured simultaneously the calcium activity of astrocytes and neurons in the somatosensory cortex, while

performing fMRI, with the use of genetically encoded calcium indicators (GECIs). This revealed differential time course responses of the two cell types during sensory stimulation, that was diversely correlated with the BOLD signal. In addition, specific activation of astrocytes using DREADDs further contributed to changes in the BOLD signal. Our results point to a novel role of astroglia in the generation of BOLD signal and may further hep the interpretation of fMRI data.

Title: Regulated control of glial cell outgrowth in primary rodent neuronal cultures by CultureOne™ supplement

Authors: M. DERR, D. BEACHAM, N. KAUR, *Y. YAN, D. KUNINGER
Div. of Cell Biol., Thermo Fisher Scientific, Frederick, MD

Abstract: Primary neurons derived from rodent fetal brain are used extensively throughout neuroscience research providing scientists with dynamic and convenient model systems to study basic neuronal function and morphology, disease modeling, drug development, and neurotoxicity. Cryopreserved primary neurons significantly reduce the resources, variability, and time, necessary to isolate these cells from embryos and are routinely used for electrophysiological recording, excitability experiments, and high-throughput and High-Content Screening (HCS) studies. A common complication observed when culturing primary neurons is the presence of contaminating glial cells. The levels of glial cell contamination can vary widely with different isolation methods, age of embryos used, the composition of different media systems, and species of origin. Glial cell contamination and overgrowth can affect assay sensitivity, resolution, and reproducibility. Current methods for reducing glial cell populations in primary neuronal cultures involve treatment with anti-mitotic molecules, such as Cytosine Arabinoside (Ara-C), which have been shown to be toxic to neurons in culture. Gibco CultureOne™ supplement was developed for the differentiation of human pluripotent stem cell-derived neural stem cells (NSCs) into neurons by suppressing the proliferation of NSCs and accelerating the maturation of differentiating neurons. Here we show that addition of CultureOne™ supplement to neuronal culture medium can suppress the outgrowth of contaminating glial cells (astrocytes and oligodendrocytes) in primary rat (E18) cortical neurons, and mouse (E17) cortical and hippocampal neurons. We also demonstrate CultureOne supplement does not impact neuron numbers, morphology, or function. To quantify glial cells

and neurons we employed Immunocytochemistry (ICC) and quantitative image analysis with a High-Content Analysis platform. Depolarization induced calcium influx (Fluo4 Direct assay) and Multi-Electrode Array (MEA) analysis were used to assess neuronal function. Treatment of primary neuron cultures with CultureOne™ supplement at time of cell plating resulted in nearly complete elimination of contaminating glial cells assessed following 14 and 21 days in culture with no significant impact on neuron numbers or morphology. In contrast, delaying the addition of CultureOne™ 3, 7, and 10 days following plating, resulted in increasing levels of glial cells. The results suggest that glial cell levels can be controlled or optimized by adjusting CultureOne™ treatment schedule.

Title: Regulation of Reelin function by specific proteolysis

Authors: *M. HATTORI, H. OGINO, E. OKUGAWA, Y. YAMAKAGE, T. KOHNO
Grad. Sch. Pharmaceuti. Sci., Nagoya City Univ., Nagoya, Japan

Abstract: The secreted glycoprotein Reelin regulates embryonic brain development and adult brain functions. It has been suggested that reduced Reelin activity contributes to the pathogenesis of several neuropsychiatric and neurodegenerative disorders, such as schizophrenia and Alzheimer's disease; however, non-invasive methods that can upregulate Reelin activity *in vivo* have yet to be developed. The proteolytic cleavage of Reelin within Reelin repeat 3 (N-t site)

abolishes Reelin activity. We partially purified the enzyme that mediates the N-t cleavage of Reelin from the culture supernatant of cerebral cortical neurons. This enzyme was identified as A Disintegrin And Metalloproteinase with Thrombospondin motifs-3 (ADAMTS-3). Recombinant ADAMTS-3 cleaved Reelin at the N-t site. ADAMTS-3 was expressed in excitatory neurons in the cerebral cortex and hippocampus. N-t cleavage of Reelin was markedly decreased in the embryonic cerebral cortex of ADAMTS-3 knock-out (KO) mice. Importantly, the amount of Dab1 and the phosphorylation level of Tau, which inversely correlate with Reelin activity, were significantly decreased in the cerebral cortex of ADAMTS-3 KO mice. Conditional KO mice, in which ADAMTS-3 was deficient only in the excitatory neurons of the forebrain, showed increased dendritic branching and elongation in the postnatal cerebral cortex. Our study shows that ADAMTS-3 is the major enzyme that cleaves and inactivates Reelin in the brain. Therefore, inhibition of ADAMTS-3 may be an effective treatment for neuropsychiatric and neurodegenerative disorders.
ADAMTS-3 is known to cleave many proteins other than Reelin. Therefore, the phenotypes observed in the brain of ADAMTS-3 KO mice may not derive from the decrease of Reelin N-t cleavage. We thus generated knock-in (KI) mice in which the N-t cleavage site of Reelin had been mutated. The N-t cleavage was dramatically diminished in the brain of the KI mice. More results on these mice will be presented in the meeting.

Title: Dendritic expansion and spine formation regulated by signaling pathways of unfolded protein response

Authors: *A. SAITO[1], K. IMAIZUMI[2]
[1]Stress Protein Processing, Inst. of Biomed. & Hlth. Sci., [2]Biochemistry, Inst. of Biomed. & Hlth. Sci., Hiroshima Univ., Hiroshima city, Japan

Abstract: The endoplasmic reticulum (ER) is central organelle responsible for calcium ion storage, lipid metabolism, protein synthesis and post-translational modification of secretory and membrane proteins. Various cellular abnormalities such as disturbance of calcium ion homeostasis in ER lumen lead to the disruption of ER function and the accumulation of unfolded proteins (ER stress). The ER stress transducers, IRE1, PERK and ATF6 are activated in response to ER stress, followed by transducing signals from ER to cytoplasm or nucleus to avoid cellular damages (Unfolded Protein Response, UPR). Recent studies have uncovered novel UPR functions not only in dealing with unfolded proteins but also in regulating cellular homeostasis. The well-developed ER network has a highly dynamics that is constantly remodeled and complexly extended from cell soma to distal dendritic segment of neurons, indicating that ER functions could orchestrate local events contributing to dendritic capabilities. In the present study, we focused on the machinery for dendritic functions manipulated by ER-derived signaling including UPR. The phosphorylation levels of IRE1 and PERK were transiently up-regulated by the pre-treatment and washout of primary cultured mouse hippocampal neurons with tetrodotoxin to induce spontaneous excitatory synaptic activity. The activation of these ER stress transducers was observed at post-synaptic sites. We found that the phosphorylation levels were reduced by inhibiting calcium ion outflow from ER, suggesting that the acceleration of calcium ion outflow and its depletion in ER lumen by the excitatory synaptic activation triggers the induction of UPR at post-synaptic sites. The blocking of UPR signaling by the knockdown of UPR-related genes using lentiviruses expressing shRNA inhibited the extension and branching of dendrites. Furthermore, the impaired dendritic spine formation was shown in these knockdown-neurons. Immunofluorescence analysis in the knockdown-neurons revealed that the ER failed to elongate and invaginate into the spine segments. Thus, UPR signaling may regulate the development of intricately branched dendrites and dendritic spine formation through the spatio-temporal fine-tuning of the dendritic ER-dynamics.

Title: Function of the actin nucleators Spire and Capu in dendrite organisation in *Drosophila*

Authors: *T. STÜRNER[1], H. CUNTZ[2], E. KERKHOFF[3], G. TAVOSANIS[1]
[1]AG Tavosanis, DZNE E.V. Bonn, Bonn, Germany; [2]Ernst Strüngmann Inst. (ESI), Frankfurt, Germany; [3]Univ. Hosp. Regensburg, Regensburg, Germany

Abstract: The correct morphology of dendrites is essential for the function of the nervous system. The underlying cytoskeleton defines the shape and dynamics of dendritic branches under the control of complex protein networks. The aim of this study is to elucidate how regulators of the actin cytoskeleton define the diverse characteristic shapes of dendritic arbors.
Investigating the differentiation of *Drosophila* larva dendritic arborisation (da) neurons, we previously demonstrated that WAVE through recruitment of the Arp 2/3 complex promotes the formation of a branched actin patch at the base of a newly forming branchlet. To elucidate the mechanisms of actin organization following this initial step, we asked whether additional actin nucleating factor are required for branching in these neurons. Here, we focus on the actin nucleators Spire and Capu. While the role of Spire and of the formin Capu in forming a transient actin meshwork during oogenesis has been the object of intensive studies, little is known about the function of these proteins in the nervous system. Spire is negatively regulated by the transcription factor Lola, controlling outgrowth and guidance of axons in the *Drosophila* larval nervous system. In addition, a recent report suggested a role for Spire downstream of Lola also in the establishment of appropriate dendrite morphology of larval da neurons.
We found that Spire and Capu play a role in the formation of the terminal branchlets of Class III da neurons. Class III da neurons have highly actin enriched terminal branchlets and the distinguished dynamics of these branches are essential for the function of the neuron. $Spire^{1/2F}$ or $capu^{1/EE}$ mutant larvae show a reduced number specifically of these characteristic branchlets. Therefore, we analysed this phenotype further by performing *in vivo* time-lapse recordings and are developing quantification methods in the “Trees Toolbox” in Matlab. This data revealed a reduced branchlet extension and retraction in s$pire^{1/2F}$ mutant larvae. Further ongoing studies will elucidate the subcellular localization of these molecules during branch formation and extensions.
Taken together our results suggest a function of Spire and Capu specifically in the formation and dynamics of terminal branchlets of Class III da neurons.

Title: A novel role for Notch in mechanosensory neuron connectivity in *C. elegans*

Authors: *G. W. BROWN, V, R. EL BEJJANI
Davidson Col., Davidson, NC

Abstract: Notch receptors are conserved transmembrane proteins that regulate key developmental processes and promote stem cell proliferation and renewal. Notch signaling remains active in the nervous system from birth to adulthood. Notch pathway genes are highly conserved across many species, including humans, and extensive work to decipher Notch signaling was initially done in *Caenorhabditis elegans*. While these animals' mechanosensory neurons have been well characterized behaviorally, little is known about the late stage development of the connections between them. We show that animals lacking the Notch metalloprotease *sup-17/*ADAM10 have significantly higher rates of ALM-AVM nerve ring breakage than wild type animals. Significantly higher rates of breakage were found also found in Notch receptor and gamma-secretase complex mutant animals, confirming that the Notch pathway is involved in ALM-AVM connection at the nerve ring. Notch mutants did not exhibit different break rates across life stages. This suggests that the defect is likely to be developmental rather than degenerative or the result of a developmental delay. To ask if Notch functions cell-autonomously, we are currently performing tissue specific rescue experiments for both the mechanosensory neurons and the surrounding glia. We are also assessing the functional role of the nerve ring connection in mechanosensory neurons with optogenetic experiments comparing Notch and wild type worms.

Title: The conserved microtubule-associated protein mini spindles regulates dendrite branching and self-avoidance in *Drosophila* c4da neurons

Authors: *C. KITTOCK, N. ANVERY, M. MISRA
Colgate Univ., Hamilton, NY

Abstract: Dendrite dysgenesis is a common feature of disparate neuropsychiatric and neurodevelopmental disorders, underscoring the need for a more comprehensive understanding of the molecular mechanisms underlying neuronal morphogenesis. The dendrites of Drosophila larval class IV dendritic arborization (c4da) neurons, a subset of cutaneus nociceptive sensory neurons, provide an excellent model system to study the regulation of dendrite morphogenesis because their complex branching patterns show clear parallels to those seen in vertebrates, and their two-dimensional organization on the surface of the larva allows for easy visualization. Recently, a screen for dendrite-localized mRNAs identified the gene *mini spindles* (*msps*) as a positive regulator of dendrite growth. *msps* encodes a microtubule associated protein homologous to XMAP215-family proteins in vertebrates. Previous studies have demonstrated that *msps* regulates microtubule nucleation and promotes dynamic instability. We therefore hypothesized that it might play a role in regulating cytoskeletal events important for the growth and/or retraction of dendrite branches in da neurons during development. RNAi-mediated knockdown of *msps* in c4da neurons resulted in a significant loss of branching and total dendrite length, supporting this initial hypothesis. In addition, reduced *msps* expression resulted in decreased receptive field coverage. Strikingly, a loss of *msps* also impaired intraneuronal dendrite self-avoidance, and $msps^{RNAi}$ neurons exhibited more than twice as many self-crossings as control yw neurons. Self-crossing events have previously been linked to the enclosure of dendrites by overlying epidermal cells; immunostaining for Coracle, a marker of enclosure, confirmed that self-crossing dendrites in $msps^{RNAi}$ neurons also exhibit this behavior. The localization of *msps* mRNA to dendrites and the disorganization of dendrites in the absence of Msps protein preliminarily suggest a model in which local control of *msps* expression could regulate cytoskeletal dynamics in response to signals exchanged between neurons and epidermal cells.

Title: Pink1 regulates brain derived neurotrophic factor signaling to stimulate dendrite outgrowth and mitochondrial function

Authors: *R. K. DAGDA, T. DAS BANERJEE, M. DAGDA, M. SWAIN, R. Y. DAGDA
Pharmacol., Univ. of Nevada Sch. of Med., Reno, NV

Abstract: PTEN-induced kinase 1 (PINK1), which is linked to Parkinson's disease, is a neuroprotective kinase that regulates dendrite remodeling, mitochondrial trafficking and function (Dagda *et al*., 2014, Journal of Neurochemistry, 128(6):864-77). The molecular mechanisms by which PINK1 stimulates dendrite outgrowth remain to be elucidated. Like PINK1, brain-derived neurotrophic factor (BDNF) is a potent stimulator of dendrite outgrowth and maturation. Hence, we surmised that PINK1 regulates dendrite outgrowth via BDNF. Immunohistochemical analyses of brain slices derived from 10 month old PINK1 knockout mice show that PINK1-deficient cortical and hippocampal neurons have reduced intracellular levels of BDNF and a concomitant reduction in dendrite length. *In vitro*, time-dependent analyses of dendrite length and complexity revealed that PINK1-deficient primary neurons exhibit significantly decreased outgrowth rates and retraction of dendrites upon reaching maturation in culture. Treating PINK1-deficient neurons with recombinant human BDNF was able to restore dendrite length in PINK1-deficient cortical neurons to similar levels as wild-type neurons. Conversely, treating PINK1-overexpressing SH-SY5Y cells with inhibitors of the BDNF receptor (TrkB) blocked the ability of PINK1 to enhance neurite outgrowth. These results suggest that PINK1 stimulates dendrite outgrowth through BDNF-mediated activation of TrkB. Mechanistically, PINK1 activates PKA signaling to enhance BDNF levels as transfecting neuroblastoma SH-SY5Y cells with an inhibitor of Protein Kinase A (PKI) was able to block PINK1's ability to enhance intracellular levels of BDNF. Primary neurons treated with human recombinant BDNF (2-24 hours) showed enhanced oxygen consumption rates (basal, maximal and ATP-linked OCRs), increased rates of glycolysis, increased anterograde mitochondrial trafficking, increased mitochondrial content and fusion suggesting that BDNF phenocopies the ability of PINK1 to enhance the bioenergetics status of the cell. Overall, our data suggest the existence of a new neuroprotective signaling axis in which PINK1 stimulates BDNF by activating PKA signaling to modulate dendrite outgrowth and enhance mitochondrial function in neurons.

Title: Contribution of ADMATS family members to Reelin inactivation in the postnatal brain

Authors: *M. KATO[1], T. KOHNO[2], M. HATTORI[2]
[1]Grad. Sch. Pharmaceuti. Sci., Nagoya City Univ., Nagoya-Shi, Japan; [2]Grad. Sch. Pharmaceuti. Sci., Nagoya City Univ., Nagoya, Japan

Abstract: Reelin is a large secreted protein that is essential for normal brain development. In the postnatal brain, Reelin plays important roles in modulating synaptic plasticity and functions. Accordingly, downregulation and hypoactivity of Reelin in the postnatal brain have been suggested to be involved in the pathogenesis of several neuropsychiatric and neurodegenerative disorders, such as Alzheimer's disease and schizophrenia. Therefore, upregulation of Reelin activity can be a therapeutic strategy for these disorders. Reelin binds to its cell-membrane receptors and induces phosphorylation and subsequent degradation of intracellular protein Dab1. A specific cleavage of Reelin, called N-t site cleavage, virtually abolishes Reelin's ability to induce phosphorylation and degradation of Dab1 (Kohno et al., 2009). Previously, we identified ADAMTS-3 (A disintegrin and metalloproteinase with thrombospondin motifs 3) as the major proteinase in charge of the N-t site cleavage in the embryonic and the early postnatal brain (Ogino et al., 2017). However, it was also suggested that other proteinase(s) may contribute to N-t site cleavage in the postnatal brain. The domain structure of ADAMTS-3 is almost identical to that of ADAMTS-2 and -14, and these three molecules compose the subfamily of ADAMTS family members called procollagen N-proteinases, suggesting that ADAMTS-2 and -14 may also cleave Reelin at the N-t site. The aim of this study is to clarify the contribution of ADAMTS-2 and -14 to the N-t site cleavage of Reelin in the postnatal brain. The recombinant ADAMTS-2 protein had the ability to cleave Reelin at the N-t site, whereas ADAMTS-14 did not. The mRNA of ADAMTS-2 was expressed in the postnatal brain, whereas ADAMTS-14 was not. These results suggested that ADAMTS-2 is the good candidate proteinase in charge of N-t site cleavage in the postnatal brain. We then generated ADAMTS-2 knock-out mice by using the CRISPR/Cas9 system. We are now analyzing these mice to understand the contribution of ADAMTS-2 to the N-t site cleavage of Reelin.

Title: *In vivo* dendritic development of cerebellar Purkinje cells

Authors: *Y. TAKEO, E. MIURA, M. YUZAKI
Dept. of Neurophysiol., Keio Univ. Sch. of Med., Tokyo, Japan

Abstract: Neurons exhibit a specialized dendritic morphology, which is specific to the neuronal types and closely related to their function in the neural circuit. However, molecular mechanisms underlying *in vivo* dendritic development are largely unknown. Cerebellar Purkinje cells (PCs) have a unique dendritic architecture characterized by a single primary dendrite with a finely branched, flat fan-like arborization. These features of dendrites are established through dynamic morphological remodeling during early postnatal ages. At birth, post-migratory PCs exhibit fusiform shape with long primitive dendrites. In the next few days, these primitive dendrites are retracted, and the PCs enter the “stellate cell” stage with multiple short dendrites radiated in all directions. Shortly thereafter, by around P8 in mice, the PCs suddenly turn into the “young PC” stage equipped with the typical single stem dendrites and flatten branches. The molecular mechanism of this remodeling process from the “stellate-cell” stage to the “young PC” stage has been one of the great mysteries of dendritic morphogenesis. To address this question, we investigated how single stem dendrites and flatten branches are generated by *in vivo* two-photon imaging of developing PCs in mouse cerebellum. We revealed that dendrites actively change their length and branching patterns during transition from the “stellate-cell” stage to the “young PC” stage. We also found that the neuronal activity of PCs is required for this process by overexpression of the inwardly rectifying potassium channel (Kir2.1) *in vivo*. Our study shed light on how a cell-type specific three-dimensional dendritic morphology is established *in vivo*.

Title: Premature birth reduces CA1 hippocampal dendrite branching, spine density, and neurocognitive function

Authors: D. KLEBE[1], M. TIBREWAL[4], B. CHENG[1], P. DOHARE[1], P. R. MOUTON[5], K. DOBRENIS[2], J. VELISKOVA[4], *P. BALLABH[3]

Abstract: Preterm-born children and adolescents suffer neurological and behavioral disorders. These neurobehavioral conditions might be attributed to the effect of premature birth, suboptimal nutritional support or rearing practices (breast vs. formula feeding) on brain development. The hippocampus plays distinctive roles in memory, learning, flexible cognition, and social behavior. Therefore, we hypothesized that premature birth and formula feeding of preterm newborns might impact neurobehavioral function, hippocampal dendritic arborization, and density of dendritic spines. To test our hypotheses, we compared preterm (E28.5) and term (E32) rabbit pups at an equivalent post-conceptional age (P28) for neurobehavioral function and dendritic length, branching, and spines in the CA1 area of the hippocampus. Preterm pups were reared in an infant incubator and were gavage fed, whereas term pups were reared by mother rabbit. Neurobehavioral tests included open field test, novel object recognition (NOR; recognition memory), elevated plus maze, three chambered socialization test, and Barnes Maze test, using video tracking system (ANY-maze, Stoelting Co.). Dendritic length, branching, and spines in pyramidal neurons of the CA1 area of the hippocampus were evaluated in Golgi-stained sections and all the quantifications were done by computerized stereology (Stereologer, SRC Biosciences, Tampa, FL). We found that preterm pups spent more time in arena center compared to term pups ($P<0.05$). The speed of locomotion and distance travelled in the arena were comparable between two groups. Preterm pups spent less time with the novel object compared to term pups ($P<0.05$). Three chambered socialization test revealed that preterm pups showed less interest in the stranger compared to term pups ($P<0.05$). Dendritic branching and dendritic spine density were significantly reduced in preterm rabbits compared to term controls ($P=0.025$ and 0.037). Dendritic length showed a non-significant decrease in preterm rabbits compared to controls. These data suggest preterm rabbits lack preference for novelty and display poor learning and memory, which can be ascribed to reduced dendritic arborization and fewer dendritic spines in

the CA1 area of the hippocampus. Premature birth and postnatal rearing practices in humans might result in enduring microstructural changes in brain growth and development.

Title: The γ-Protocadherins regulate dendrite arborization in the cerebral cortex through both common and isoform-specific intracellular signaling mechanisms

Authors: K. MAH[1], A. M. GARRETT[2], R. W. BURGESS[3], *J. A. WEINER[4]
[1]Biol., Univ. of Iowa, Iowa City, IA; [2]The Jackson Lab., Bar Harbor, ME; [3]Jackson Lab., Bar Harbor, ME; [4]Dept. of Biol., The Univ. of Iowa, Iowa City, IA

Abstract: A key component of neural circuit formation is the elaboration of complex dendritic arbors, the pattern of which constrains inputs to the neuron and thus the information it processes. As such, many neurodevelopmental disorders such as autism and Down, Rett, and Fragile X Syndromes are associated with reduced forebrain dendrite arborization. The *Pcdhg* gene cluster encodes a family of 22 homophilic cell adhesion molecules, the γ-Protocadherins (γ-Pcdhs), that we have shown are critical for the elaboration of complex dendrite arbors in the cerebral cortex. Each γ-Pcdh isoform is unique in its extracellular and proximal cytoplasmic domain, but all 22 γ-Pcdhs share the same C-terminal constant domain. We recently found that PKC phosphorylation at a serine residue in the constant domain prevents the γ-Pcdhs from promoting dendrite complexity through inhibition of FAK in cultured neurons (Keeler et al., *JBC* 2015). In a separate study, we found that the unique cytoplasmic domain of one isoform, γ-Pcdh-C3, can inhibit Wnt signaling in HEK293 cells through its interaction with and stabilization of Axin1, a protein also necessary for dendrite arborization (Mah et al., *Sci. Rep.* 2016). Here, we have utilized CRISPR/Cas9 genome editing to generate 3 new mouse lines: 1) $Pcdhg^{S/A}$, in which the PKC target serine residue in the constant domain is mutated to an alanine, preventing PKC phosphorylation of all γ-Pcdhs; 2) $Pcdhg^{CTD}$, in which an early stop codon results in all γ-Pcdhs lacking the C-terminal 15 amino acids of the constant domain (including the PKC target serine); and 3) $Pcdhg^{C3KO}$, in which a 13 bp deletion near the ATG of the *PcdhgC3* variable exon

generates a null for this isoform. All mice are viable and fertile, and the expected protein modifications are observed: γ-Pcdhs are entirely unphosphorylated at the C-terminal serine in both *Pcdhg*$^{S/A}$ and *Pcdhg*^{CTD}, and the C3 isoform (and only this isoform) is absent in *Pcdhg*^{C3KO}. We utilized *Thy1-YFPH* mice to label cortical layer V pyramidal neurons and analyzed dendrite arborization at 3 and 6 weeks of age. Arborization was significantly altered in all 3 lines: an increase in arbor complexity in both *Pcdhg*$^{S/A}$ and *Pcdhg*^{CTD} animals, and a decrease in complexity in *Pcdhg*^{C3KO} mice. As predicted, we also observe increased canonical Wnt signaling in *Pcdhg*^{C3KO} brain, assayed using a Wnt reporter allele; current experiments are aimed at confirming Axin1 as an effector of γ-Pcdh-C3's promotion of dendrite complexity *in vivo.* These observations confirm that γ-Pcdhs can regulate dendrite arborization through multiple intracellular pathways, and provide new *in vivo* tools for the genetic dissection of Pcdh mechanisms of action.

Title: Effects of antipsychotics and NMDA receptor agonists on expression and function of NOS1AP, a protein encoded by a schizophrenia susceptibility gene

Authors: *K. SVANE, E. ASIS, B. L. FIRESTEIN
Rutgers Univ., Piscataway, NJ

Abstract: Schizophrenia is a debilitating mental illness that affects 1% of the U.S. population and includes positive, negative, and cognitive symptoms. Current antipsychotics target dopamine signaling and are unable to treat all symptom domains of the disorder. Therefore effective treatments for schizophrenia represent a significant unmet medical need. *N*-methyl D-aspartate (NMDA) receptor signaling has also been implicated in the pathophysiology of schizophrenia and NMDA receptor agonists represent promising potential treatment options. Nitric Oxide Synthase 1 Adaptor Protein (NOS1AP) is a protein encoded by a schizophrenia susceptibility gene that negatively regulates NMDA receptor signaling. Moreover, NOS1AP protein is overexpressed in the dorsolateral prefrontal cortex (DLPFC) of postmortem tissue of patients

with schizophrenia and has been found to reduce dendrite branching, which is also observed in individuals with schizophrenia. Here, we found that the NMDA receptor agonist D-serine is able to significantly reduce NOS1AP protein expression in embryonic rat cortical neurons and is able to rescue NOS1AP-mediated reductions in dendrite branching. On the other hand, traditional antipsychotics such as clozapine, haloperidol, and fluphenazine have no effect on NOS1AP expression or dendrite branching. Ultimately, our research will shed light on the therapeutic potential of D-serine as a treatment for schizophrenia and the mechanism by which D-serine takes effect.

Title: The role of adaptor complex AP2 in formation of dendritic arbors of hippocampal neurons

Authors: A. KOSCIELNY, A. MALIK, E. LISZEWSKA, J. ZMORZYNSKA, A. TEMPES, B. TARKOWSKI, *J. JAWORSKI
Intl. Inst. of Mol. and Cell Biol., Warsaw, Poland

Abstract: Introduction: The proper dendritic branching is a highly regulated process. Among its regulators are membrane proteins internalized via clathrin-mediated endocytosis. AP2 adaptor complex is a key player in this process, but its role in mammalian dendritogenesis has not yet been tested. **Aim:** The aim of this study was to find how AP2 complex contributes to shaping dendritic tree of developing hippocampal neurons. **Methods:** To study role of AP2 complex in dendritic arborization we used primary hippocampal neurons expressing AP2b1 (β-adaptin) shRNA alone or in combination of functional rescue constructs (i.a. GluA2, $S6K1^{ca}$). The effect was also tested *in vivo* by lentiviral injections to newborn rats. Upon β-adaptin knockdown, we tested GluA2 trafficking via internalization assay and GluA2 level by Western blot and immunochemistry. GluA2 degradation and mTOR dependent biosynthesis were investigated by e.g. cycloheximide or rapamycin treatment. **Results:** We showed that knockdown of β-adaptin led to reduction in dendritic arbors of developing hippocampal neurons *in vitro* and *in vivo*. The knockdown of AP2 also led to decreased level of GluA2, what is a result of impaired mTOR dependent GluA2 biosynthesis. However, the overexpression of functional GluA2 or restoration of mTOR activity rescued this effect. **Conclusions:** AP2 adaptor complex regulates the dendritogenesis of mammalian neurons via mTOR dependent GluA2 biosynthesis.

Title: Identifying new molecular cues that guide development of retinal direction-selective circuitry

Authors: *C. L. PRIGGE, J. N. KAY
Neurobio., Duke Univ., Durham, NC

Abstract: During development, some neurons that share a role in neural processing arborize in the same synaptic layers, avoiding inappropriate layers, implying neurons can distinguish between each other—a mechanism likely involving molecular recognition cues. We seek to discover molecules that guide the selective lamination and wiring between neurons of the mouse retinal direction-selective (DS) circuit. This well-characterized circuit comprises three cell types—DS bipolar cells, starburst amacrine cells, and DS ganglion cells—that project to two specific layers in the inner plexiform layer (IPL). Because these cells can be genetically manipulated and marked, we can study how their selective connections arise. To identify candidate molecules that mediate laminar recognition in this circuit, we queried our microarray dataset which contains gene expression profiles of 19 retinal cell types at postnatal day 6, an important time for retinal synaptogenesis. We selected genes predicted to encode cell-surface or secreted proteins, which could act as guidance cues. Secondary screens for molecular interactions among candidates were also performed, and the data considered when selecting candidates. Here we focus on two candidates, *Tgfb3* and *Unc5c*. *Tgfb3*, which encodes a transforming growth factor beta signaling protein, was enriched in starbursts. TGF-beta superfamily members have broad roles in signaling and development, including regulation of extracellular matrix and synapse formation in fly neuromuscular junction. *Tgfb3* is therefore well positioned to act as a circuit-specific ligand promoting laminar targeting or synapse formation. *Unc5c*, which encodes a repulsive guidance receptor, is excluded from the DS circuit, but one of its ligands, FLRT2, is localized to the circuit, suggesting it might function in laminar restriction

of DS circuit arbors. We characterized the expression patterns of these molecules to confirm selective expression. We found that *Tgfb3* mRNA and protein were exclusive to starbursts. *Unc5c* mRNA colocalized with the majority of GAD65+ GABAergic cells, a population which avoids the DS layers. To ask if these molecules are required for DS circuit development we used Hb9-GFP mice (which mark DS ganglion cells) and ChAT-Cre mice (a starburst-specific Cre) to examine DS neuron IPL laminar targeting and single cell morphology in mutant mice. Sporadic laminar targeting errors were observed in both *Tgfb3* and *Unc5c* mutants. Altered starburst dendritic branching in *Tgfb3* mutants suggests synaptic connectivity may be affected. We are now investigating the role that these molecules may play in DS circuit laminar targeting and synapse formation.

Title: Characterizing cell surface receptor multimeric complexes for homotypic recognition in developing retinal circuits

Authors: *J. WANG, J. N. KAY
Duke Univ., Durham, NC

Abstract: In the central nervous system, billions of neurons interconnect with precision to form morphologically complex and functionally diversified neural circuits. The stereotypical fashion by which neurons assemble suggests that cell-surface molecular cues can act as identity tags during development. In many cases, cell surface receptors bind ligands expressed on other cells in order to distinguish homotypic neighbors. Two closely-related transmembrane receptors containing multiple epidermal growth factor (EGF)-like domains, *Megf10* and *Megf11*, were previously identified to mediate homotypic recognition of certain retinal cell types. Genetic evidence suggests that MEGF10 acts as both ligand and receptor to initiate cell-cell repulsion. MEGF11 can also act as a ligand, but even though retinal neurons express both molecules, genetic evidence suggests it does not act through MEGF10. To complicate things further, MEGF10 and 11 ligands and their receptors are co-expressed in the same neurons during

development. These observations raise many questions about the biochemical basis of the receptor and ligand signaling complex. If these complexes are multimeric, selective *cis* interactions between MEGF10 and 11 might generate complexes with distinct properties, thereby increasing the complexity of homophilic interactions. To address this question, we first tested whether MEGF10 can interact homophilically in *cis*. We expressed MEGF10 with two epitope tags in the same cells. Through co-immunoprecipitation (IP), we discovered that MEGF10 indeed interacts. Since MEGF10 does interact in *cis* configuration, which domain(s) of MEGF10 is responsible for such binding? First we deleted the entire intercellular domain and replaced it with epitope tags. Co-IP demonstrated that MEGF10 *cis* interactions likely occur through its ectodomain. To discover the crucial regions responsible for this interaction, extracellular domain truncations were constructed. Similar experiments are underway for MEGF11. Once we have mapped the interaction region(s) responsible for *cis* interactions, these can be used for *in vivo* functional study to evaluate the biological importance of such interaction. Our results set the stage to uncover the molecular mechanism by which MEGF10 and 11 mediate cell-cell recognition.

Title: Neuron dendrograms are produced by an asymmetrical process

Authors: *R. FARHOUDI[1], D. ROLNICK[2], P. RAMKUMAR[3], K. P. KORDING[4]

Abstract: Neuroscience has compiled huge databases of neuron morphologies, and describing their structure is thus an exciting scientific topic. A morphology consists of many aspects, including segmental shapes, angular relations across segments, and the topological dendrogram. The established growth model for dendrograms is the Galton-Watson process, which splits a branch with a certain probability and otherwise produces a leaf node. We find that it cannot be improved by adding depth dependency of the probability. We find, however, that it can be improved with a simple asymmetrical growth model. In this model, each split produces two different edges, where each of them has a different probability of branching vs. dying. This

model considerably outperforms the other tested models over our dataset of around 60000 trees. Our result suggests that the generative process for neuron dendrograms exhibits asymmetrical processes.

Title: Choline supplementation ameliorates dendrite complexity impairments in developing iron-deficient hippocampal neurons

Authors: *T. W. BASTIAN[1,2], W. C. VON HOHENBERG[1], L. M. LANIER[2], M. K. GEORGIEFF[1]
[1]Pediatrics, [2]Neurosci., Univ. of Minnesota, Minneapolis, MN

Abstract: Iron deficiency (ID), with or without anemia, affects an estimated 2 billion people worldwide. ID is particularly deleterious during fetal/neonatal brain development, leading to neurological impairments, including deficits in hippocampal-mediated learning and memory. These deficits often persist into adolescence and adulthood despite early-life iron repletion. Unfortunately, in some iron-deficient populations nutritional iron supplementation is either not realistic or can even be dangerous (e.g., in malaria endemic countries). Because iron therapy is not always possible or effective, it is necessary to develop alternative treatment strategies targeting the underlying neurodevelopmental deficits of early-life ID. Supplementation with choline in conjunction with iron repletion therapy improves adult rat learning and memory following recovery from early-life ID.
The cellular basis of choline's restorative effect on ID-induced learning and memory impairments was determined using embryonic hippocampal neuronal cultures made iron-deficient by adding 10 μM deferoxamine (DFO, an iron chelator) beginning at 3 days in vitro (DIV). At 11 DIV, iron-deficient cultures were treated with iron, choline (30 μM), iron/choline, or left untreated. At 18 DIV, the dendritic arbors for individual neurons were manually traced and Sholl analysis was performed to assess dendritic arborization.
Consistent with our previous findings, DFO treatment significantly reduced complexity

throughout the dendritic arbor by reducing the length, but not the number, of primary dendrites and branches. Choline treatment, alone or in combination with iron, recovered dendritic arbor complexity, including dendrite and branch lengths to levels indistinguishable from control or iron-repleted neurons. Our findings show, for the first time, that choline acts directly on neurons and does not require iron repletion to mediate its restorative effect following early-life ID. While the molecular mechanism(s) of choline action during early-life ID remain unclear, choline may have clinical potential for iron-deficient children when iron supplementation is not advised.

Title: Investigating the role of Csmd2 in Reelin-mediated dendrite formation and synaptogenesis

Authors: *M. A. GUTIERREZ[1], S. J. FRANCO[2]
[1]Univ. of Colorado Denver, Anschutz Med., Aurora, CO; [2]Pediatrics, Univ. of Colorado Sch. of Med., Aurora, CO

Abstract: Reelin is a secreted glycoprotein that regulates development of the cerebral cortex. By initiating a signaling cascade through the downstream adaptor protein, Dab1, Reelin has been extensively studied as a migration guidance cue for immature neurons in the developing brain. Emerging evidence indicates that Reelin signaling continues to play a key role in mature neurons, as it is important for dendritic branching and synapse formation, thereby affecting learning and memory. However, the mechanisms downstream of Reelin and Dab1 that regulate these functions are not currently known. Here, we have identified a novel interaction between Dab1 and Csmd2, a single-pass transmembrane protein of unknown function. We demonstrate that Dab1 binds to the FENPxY motif in the cytoplasmic tail of Csmd2. Additionally, we show that Csmd2 is required for Reelin-mediated enhancement of dendritic branching in cultured hippocampal neurons. Interestingly, we find that Csmd2 also interacts with several synaptic scaffolding proteins and localizes to synapses in vitro and in vivo. Furthermore, knockdown of Csmd2 mRNA or expression of a truncated form of Csmd2 in mouse cortical and hippocampal neurons causes a significant reduction in dendritic spine number and density. Together, these data indicate a role for Csmd2 in dendritogenesis and synapse formation, and suggest that Csmd2 may be a critical factor downstream of Reelin/Dab1 during neuronal maturation and differentiation.

Abstract: Mouse LLP homolog (mLLP) is a novel cell-permeable protein and it has roles in regulation of neural development as nuclear/nucleolar protein. Following our experiment, mLLP is strongly expressed in neural development, and modulation of mLLP level during maturation of cultured neurons affected synaptic transmission and neuronal growth. In addition, ectopic overexpression of mLLP protein increased dendritic arborization, demonstrating the non-cell-autonomous effect of mLLP. Futhermore, we found upstream and downstream components of mLLP, and also found that CCCTC-binding factor (CTCF) as well as transcriptional regulation factor interacts with mLLP. This interaction can modulate gene expression involved in neuronal growth. Taken together, these results demonstrate that mLLP has important roles in modulating neural development, and it can affect synaptic transmission and neuronal growth.

Title: Neurodevelopmental consequences of reducing gamma-protocadherin isoform diversity with CRISPR/Cas9 genome editing

Authors: *A. M. GARRETT[1], J. A. WEINER[2], R. W. BURGESS[1]
[1]The Jackson Lab., Bar Harbor, ME; [2]Dept. of Biol., The Univ. of Iowa, Iowa City, IA

Abstract: The mammalian *Pcdhg* gene cluster on human chromosome 5q31 and mouse chromosome 18 consists of 22 variable exons and 3 constant exons. Promoter choice mechanisms involving differential methylation and DNA looping generate transcripts encoding the gamma-protocadherins (γ-Pcdhs), a family of 22 distinct cadherin superfamily cell adhesion molecule isoforms. The majority of each isoform (6 extracellular cadherin repeats, a transmembrane domain, and a variable cytoplasmic domain) is encoded by a single variable exon, while a common cytoplasmic C-terminus is encoded by the constant exons. The γ-Pcdhs are expressed broadly throughout the nervous system, with individual cells expressing ~7 of the 22 isoforms, including ~4 of the stochastically expressed gamma-A and –B subfamily genes plus the 3 ubiquitously expressed gamma-C subfamily genes. The proteins form combinatorial multimers promiscuously in *cis*, but the binding specificity across membranes in *trans* is strictly homophilic at the multimer level. Thus, through isoform combination, the γ-Pcdhs themselves could generate thousands of distinct recognition units; given that γ-Pcdhs can also be found in complexes with the α- and β-Pcdhs, encoded by adjacent *Pcdha* and *Pcdhb* gene clusters, possibly billions. The γ-Pcdhs critically regulate multiple neurodevelopmental processes, including synapse formation, neuronal survival, dendrite self-avoidance, and dendrite arborization, but the role of isoform diversity in these functions is still unclear. Previous experiments testing isoform variety used the relatively blunt tools of complete cluster knockouts and single isoform transgene overexpression. To more precisely ask whether molecular diversity is essential for normal γ-Pcdh functions, we used CRISPR/Cas9 genome editing to generate an array of mutant and internal deletion alleles in the *Pcdhg* locus in mice. Single guide RNAs were designed to target sequences near the ATG of each of the 22 *Pcdhg* variable exons, and were injected together as a mixture into fertilized eggs. We used an Illumina TruSeq Custom Amplicon panel to sequence the targeted genomic regions and the top predicted off-target sites in the resultant mice, and established 30 new lines with between 1 and 16 disrupted variable exons.

Multiple lines with substantially reduced isoform diversity are viable as homozygotes, despite the neonatal lethality of *Pcdhg* cluster null mice. Currently, we are generating homozygous mutants for additional lines to analyze neurodevelopmental phenotypes, and are using whole genome sequencing to validate mutations.

Title: Early life vitamin C deficiency does not alter CA1 neuronal morphology or markers of synaptic plasticity in a guinea pig model

Authors: *S. N. HANSEN[1], J. R. NYENGAARD[2], J. LYKKESFELDT[1], P. TVEDEN-NYBORG[1]
[1]Dept. of Vet. and Animal Sci., Univ. of Copenhagen, Frederiksberg C, Denmark; [2]Dept. of Clin. Med., Aarhus Univ., Aarhus, Denmark

Abstract: Background: Vitamin C (VitC) deficiency affects up to 10 % of the population including children. VitC is highly concentrated in the brain, acting as an essential antioxidant and partaking in monoaminergic neurotransmitter synthesis and glutamate reuptake. We have shown that early life VitC deficiency impairs spatial memory and reduces hippocampal (HP) neuron numbers and maturation and HP volume in guinea pigs. Neuronal morphology and synaptic plasticity are crucial in establishing functional circuits in the brain, thus impairments could likely reduce signal transmission and decrease functionality. As a precocial species and one of few mammalian species unable to synthesize VitC, guinea pigs - like humans- depend exclusively on a dietary supply, making them a unique *in vivo* model within this specific field.
Objective: To investigate if early life VitC deficiency impairs the morphology of hippocampal *cornu ammonis* 1 (CA1) pyramidal neurons and reduces the expression of molecular markers of synaptic plasticity in HP, frontal cortex (FC) and striatum (S).
Methods: Seven days old guinea pigs (n=30) were block randomized to three weight stratified groups receiving either: 1500 mg VitC/kg diet (CTRL), 100 mg VitC/kg diet (Def) or 0 (first two weeks) to 50 mg VitC/kg diet (Sev-def) for eleven weeks. The right hemispheres from CTRL and Sev-def animals were Golgi-stained and Z-stacks from 5-6 neurons from CA1 of the HP were reconstructed in 3D and analyzed. Left hemisphere HP, FC and S were analyzed for markers of synaptic plasticity.

Results: The Def and Sev-def groups showed mild growth retardation, but showed no difference in adjusted brain weight. Cortical VitC levels were reduced in Def and Sev-def. Neither apical nor basal CA1 neuronal dendrites or spines were affected by VitC status. Plasticity markers, brain-derived neurotrophic facor, p-/synapsin-1, p-/ Ca^{2+}/calmodulin-dependent protein kinase II, did not significantly differ.
Conclusion: Early life VitC did not compromise neuronal morphology in the CA1 and caused no regional changes in the markers of synaptic plasticity. Whether VitC deficiency alters other markers and regions, including astrocyte VitC recycling, should be explored further.

Title: Trafficking of the TrkA signaling endosome

Authors: *K. A. BARFORD[1], K. MCDANIEL[1], C. YAP[3], C. DEPPMANN[2], B. R. WINCKLER[4]
[2]Biol., [1]Univ. of Virginia, Charlottesville, VA; [3]Cell Biol., Univ. of Virginia Sch. of Med., Charlottesville, VA; [4]Dept Neurosci, Univ. of Virginia Dept. of Neurosci., Charlottesville, VA

Abstract: Protein trafficking is involved in all aspects of neuronal function including development, axon/dendrite growth, and synaptic function. Neurons have distinct trafficking challenges because of the extreme length of their axons and dendrites. For this reason, neurons express special endosomal machinery to regulate protein trafficking. Peripheral neurons, including sympathetic neurons, are among those in distinct need of specialized protein transport due to their long axons. One receptor that is critical for the development of the sympathetic nervous system, TrkA, has been shown to undergo complex trafficking events. In sympathetic neurons, TrkA is expressed during development and encounters its high-affinity ligand, Nerve Growth Factor (NGF), once the axon reaches its final target tissue. TrkA binds NGF and the

complex is internalized into a signaling endosome. The NGF-TrkA signaling endosome is critical in the axon for outgrowth and branching, but it is also transported retrogradely to the soma and to dendrites where it is necessary for survival signaling and synapse formation, respectively. We hypothesize that NGF-TrkA signaling endosomes undergo functional diversification allowing for a multitude of outputs, such as survival and synapse development. This diversification can be achieved through unique trafficking steps and association with distinct effector proteins. Our lab has previously identified the first known effector of the retrograde signaling endosome in the soma, Coronin-1a. Loss of Coronin-1a causes a decrease in the number of surviving neurons in vivo, fewer long lived signaling endosomes, and loss of a new trafficking event that we call signaling transcytosis. We have identified a second novel effector of the retrograde signaling endosome in the soma: Neuron enriched endosomal protein of 21kDa (Neep21). In the CNS, Neep21 has been shown to affect the trafficking of multiple receptors, including promoting transcytosis and lysosomal evasion. However, it's role in the PNS is unknown. We show that Neep21 is present both in tissues dependent on NGF-TrkA for survival and on TrkA signaling endosomes. In regard to the trafficking of retrograde TrkA, Neep21 is present on the signaling endosome but does not co-localize with Coronin-1a. In contrast to knockout of Coronin-1a, we show that Neep21 knockout causes re-routing of signaling endosomes through the signaling transcytosis pathway. These data suggest a model of molecular diversification of the TrkA signaling endosome in order to achieve functional specificity with Coronin-1a and Neep21 playing distinct roles.

Title: Ultrasound modulate on axonal function

Authors: *R. R. ZHANG1, Z. QIU, S. KALA, L. SUN
The Interdisciplinary Div. of Biomed. Engin., The Hong Kong Polytechnic Univ., Hong Kong, Hong Kong

Abstract: In central nerve system, each neuron generates forces to extend an axon during development and to perform axonal function such as the formation of dendritic spines during learning and memory. In addition, the neurons are subjected to heterogeneous mechanical environment. How the mechanical properties of CNS influence axon growth and axon functioning in vivo are currently unknown, and the potential neuronal response to mechanical signals in vivo is poorly understood. To date, it is emergent to develop a mechanical based stimulation strategy for in vivo studies. Ultrasound is considered as a promising tool for brain stimulation. It is shown to be able to trigger neuron like cells to outgrowth, axon branching, and accelerate nerve regeneration. We hypothesize that neurons can sense ultrasonic waves by mechanosensitive ion channels e.g. piezo1, to regulate the axon development and functioning. To test this hypothesis, N2A, retinal ganglion cell (RGC), and primary cultured neurons, with high Piezo1 expression, were utilized as in vitro model. Piezo1 knockdown cells with siRNA and Piezo1 blocker GsMTx-4 pre-treated cells were severed as control to test the role of Piezo1 in sensing ultrasound. The real-time calcium imaging was used to test the acute effects of ultrasound on neurons and axons. The axon lengths and structure after 24 h, the extension velocity of axons for all the experimental groups were analyzed from live cell imaging data. In addition, the dynamics of actin and tubulin were visualized in live neurons. At last, the expression level and activity of CREB which are correlated to learning and memory were also investigated by western blot and fluorescence energy transfer imaging (FRET). Our results show that ultrasound stimulation on wild type N2A cell and primary cultured RGC could induce calcium signaling on cell body and axons and promote axon outgrowth. The long term stimulation on primary neurons could increase the generation of dendritic spines. Ultrasound stimulation could modulate the actin and tubulin dynamics and activate CREB activity. The axon length and the extension velocity for Piezo1 knockdown and GsMTx-4 blocked neurons is significant decreased. These results showed that ultrasound as a mechanical wave is able to stimulate neurons and modulate the axon function. The detailed biophysical and molecular mechanism remains unclear the role of piezo1 needs to be confirmed. Given the ability of focusing into small region in deep human brain non-invasively, it is capable to investigate the mechanisms of mechanical effects on neural axon function in vivo.

Title: Neuromorphological characterization of CA1 pyramidal cells expressing chimeric NMDAR GluN2 subunits: Changes during hippocampal development

Authors: *C. HUNG[1], M. J. KEITH[2], R. E. KEITH[3], M. F. BADAKHSH[4], T. C. DUMAS[5]
[1]Krasnow Inst. For Advanced Study, Fairfax, VA; [2]Northern Virginia Community Col., Fairfax Station, VA; [3]Neurosci. Dept., [4]Neurosci., [5]Psychology, George Mason Univ. Krasnow Inst. for Advanced Study, Fairfax, VA

Abstract: N-methyl-D-aspartate receptors (NMDARs) at hippocampal excitatory synapses are largely responsible for dendritic and synaptic development. Two signaling properties of NMDARs that have been independently linked to hippocampal plasticity are calcium conductance into the postsynaptic spine and direct intracellular protein interactions. These properties vary with the composition of the NMDAR such that, compared to NMDARs with GluN2A subunits, NMDARs with GluN2B subunits conduct calcium for a longer period following activation and display greater affinity for the synaptic plasticity protein, CaMKII. Conductance regulating domains exist in the GluN2 extracellular amino (A) terminus and transmembrane (TM) regions. Intracellular signaling domains exist in the intracellular carboxy (C) terminus. Prior to the third postnatal week, most NMDARs contain GluN2B. Across the third postnatal week, GluN2B subunits are replaced by GluN2A subunits. To determine the separate influences of the ionotropic and metabotropic properties of NMDARs on dendritic development, we constructed GluN2 chimeras and generated two transgenic mouse lines, one expressing the A-terminus and TM regions of GluN2A fused to C-terminus of GluN2B (termed ABc) and, vice versa, the other expressing the A-terminus and TM regions of GluN2B fused to C-terminus of GluN2A (termed BAc). Transcription was regulated by the TET-off expression system with tetracycline transactivator protein (tTA) expression under control of the CaMKII minimal promoter. tTA expression was seen in many forebrain regions, but predominantly in hippocampal pyramidal cells. We measured neuromorphological characteristics of hippocampal CA1 pyramidal neurons in two distinct postnatal periods: P17-P19, and P22-P24. Utilizing Thy-1 GFP fluorescence methods, confocal microscopy, and Neurolucida tracing, dendritic arbor complexity was measured. Sholl analyses demonstrate a trend for increased arbor length in ABc animals and a smaller arbor in BAc animals at P17-P19. This is also true of the basal dendrite, with neurons in ABc mice exhibiting higher length and branch intersections. Branching analyses results agree with these trends. In the P22-P24 cohort, there are fewer differences between genotypes. While these results are not yet based on comparative statistics, and current sampling is low, these preliminary results suggest that GluN2B C-terminal signaling in ABc animals increases dendritic growth, while in BAc animals, the GluN2A C-terminus reduces dendritic arbor size. Overall, these results support the need for further dissection of GluN2 subunit signaling domains with respect to hippocampal maturation.

Title: Single cell analysis of Purkinje cell death induced by diphtheria toxin

Authors: T. R. IQBAL, *L. MA
Neurosci., Thomas Jefferson Univ., Philadelphia, PA

Abstract: Cell ablation at the single cell level allows us to address how an individual cell responds to direct injury and how neighboring cells respond to cell death. Here, we study cell death in Purkinje cells (PC) using Cre-induced expression of Diphtheria toxin receptor (DTR) in transgenic mice. Cre delivered specifically to PCs via adeno-associated virus-8 (AAV8) renders only a few cells sensitive to diphtheria toxin (DT), making it feasible to study single cell responses. AAV8 that expresses Cre and green fluorescent protein (Cre-GFP) is co-injected with AAV8 expressing red fluorescent protein (RFP) into the cerebellum of DTR mice at p0-3. While Cre-GFP-PCs express DTR, RFP-PCs do not and thus serve as a control. To induce cell death, DTR mice were injected intraperitoneally with DT at postnatal day (P) 21. An age matched group was injected with saline as a control. Cerebella were collected 1-3 days later for morphological analysis. First, DTR homozygous mice were given a single dose of DT at 100 or 400 ng. Analysis of the ratio of GFP and RFP cells (1:1 GFP:RFP) showed no significant change between single DT application and saline controls. Next, homozygous DTR mice were given DT at 100 or 400 ng once a day for 5 consecutive days. This treatment revealed a significant decrease in GFP cells compared to RFP cells when compared to saline controls (from 2:1 to 1:1 GFP:RFP), demonstrating that GFP-expressing PCs are susceptible to DT. Next, in order to test the effect of gene dosage, heterozygous DTR mice were treated with 100 ng DT for 5 days. The decrease in GFP cells was less pronounced (from 6:1 to 5:1 GFP:RFP), suggesting the dosage dependence of DT-induced PC death. Under these conditions, there were no obvious cellular changes in an intermediate stage of degeneration, that is, membrane blebbing or reduced branching. Finally, in an effort to capture these cellular changes, DTR homozygous and DTR heterozygous mice were treated with DT for 3 days, and analyzed 1 or 3 days after treatment. Preliminary studies revealed some examples of changes in dendritic trees, specifically loss of self-avoidance. Thus, application timing and changes to DTR levels can allow different stages of cell death to be visualized. Further development of these DT-directed ablation paradigms can be used to characterize aspects of cellular degeneration in the cerebellum. For example, determining whether tiling is altered or maintained after death of neighboring cells, or whether dendrites or axons are more susceptible to damage.

Title: Caffeine exposure during hippocampal synaptogenesis alters network circuitry and hippocampal-dependent memory

Authors: ***S. LÉVI**, J. C. PRESSEY, F. G. CASTRO, M. GOUTIERRE, M. RUSSEAU, J. PONCER
INSERM, Paris, France

Abstract: In the adult brain, adenosine, a degradation product of ATP, controls neurotransmitter release and synaptic plasticity through G protein coupled A1 and A2A receptors. The activity of these receptors is essential in normal behaviour, including learning and memory, sleep and arousal, locomotor activity and exploration, feeding behaviour and mood and motivation. However, the role of these receptors in development is not well known. In collaboration with C. Bernard's laboratory (INS, Marseille), we have recently identified a novel mechanism by which the adenosine signaling pathway acts as a detector and stabilizer of active nascent inhibitory GABAergic synapses in primary hippocampal cultures. Based on recent findings, we propose that the deleterious consequences of *in utero* and post-natal brain exposure to caffeine (Sci Transl Med. 2013; 5(197), an antagonist of A1 and A2A receptors, are primarily due to A2A receptor-dependent alterations in synaptogenesis. We are now testing this hypothesis *in vivo* by assessing synaptic protein expression, synapse density as well as neuronal and network activity in the hippocampus. These experiments are performed in both juvenile and adult mice injected daily during the period of hippocampal synaptogenesis (post-natal days 3-16) with caffeine or the selective A2A receptor antagonist SCH58261. Supporting our hypothesis, our data demonstrate caffeine and SCH85261 treatments alter hippocampal synaptogenesis, increase network activity, and leads to long-term deficits in hippocampal-dependent memory tasks in adult mice. Furthermore, juvenile animals exhibited sensitivity to pharmacologically induced epilepsy after treatment with caffeine and SCH85261. Our findings provide a better understanding of the pathological mechanisms engaged upon early-life exposure to caffeine.

Abstract: In the adult brain, adenosine, controls neurotransmitter release mainly through inhibitory A1 and facilitator A2A receptors. However, its role in development remains to be elucidated. Here, we addressed the role of A2AR-mediated signalling during GABAergic synaptogenesis in the hippocampus. We found a preferential postsynaptic expression of A2ARs during synaptogenesis in the hippocampus in vitro and in vivo. This developmental expression of A2ARs was correlated with a role of A2ARs in the stabilization of nascent GABA synapses during synaptogenesis. Downregulating A2AR expression with a shRNA approach in isolated postsynaptic cells led to a loss of synapses equivalent to that seen following A2AR activity blockade, demonstrating that the A2AR-mediated synapse stabilization is a cell autonomous process that requires A2AR activation in the postsynaptic cell. ATP and adenosine can be secreted by both glia and neurons. We found that activity-dependent release of neuronal ATP/adenosine is sufficient to stabilize newly formed GABA synapses. Using live cell imaging, we showed that adenosine signalling stabilizes active nascent inhibitory synapses. We then characterized the molecular mechanism downstream postsynaptic A2AR. We identified the Adenylyl cyclase/cAMP/Protein Kinase A (PKA) signalling cascade as the main molecular

pathway and we identified the postsynaptic scaffolding molecule gephyrin as the main target of PKA activation. Finally, we showed the A2AR-mediated stabilization of the post- and pre-synapse required the trans-synaptic Slitrk3-PTPδ complex. These results allow us to propose that A2ARs act as coincidence detectors to stabilize newly formed GABAergic synapses during synaptogenesis.

Title: Functional mapping of neuronal activity in the facial nucleus of the rat embryo: Optical recording with a voltage-sensitive dye

Authors: *K. SATO[1], Y. MOMOSE-SATO[2]
[1]Dept. of Hlth. and Nutr. Sci., Komazawa Women's Univ, Fac. of Human Hlth., Tokyo, Japan; [2]Dept. of Nutr. and Dietetics, Kanto Gakuin University, Col. of Nutr., Yokohama, Japan

Abstract: During mammalian development, facial motoneurons are generated in rhombomere 4 and migrate caudally, forming a unique axonal trajectory called the "genu", a loop of facial motor axons around the abducence nucleus. It is one of the interesting questions in developmental neuroscience when and how this unique structure is established, and what the correlation between morphogenesis and functiogenesis is. We applied optical recording with a voltage-sensitive dye (VSD) and the DiI staining method to the facial nerve (N.VII)-brainstem preparations dissected from E16-18 rat fetuses, and examined developmental processes of the motor nucleus/bundles of the N.VII. The DiI staining revealed the location of the facial motor nucleus and the pathway of the N.VII. The VSD recording showed that (1) two types of fast spike-like signals, which corresponded to action potentials, were detected, and (2) the fast signal identified in the facial motor nucleus exhibited a long duration, whereas those detected in the N.VII bundles had a shorter duration. We suceeded in analyzing spatiotemporal patterns of N.VII

responses in the early developing rat brainstem, which confirmed the usefulness of VSD recording in funcional mapping of a 3D-complexed neuronal population.

Title: In ovo blockade of the spontaneous depolarization wave inhibits the formation of synaptic networks in the embryonic brainstem

Authors: *Y. MOMOSE-SATO[1], K. SATO[2]
[1]Dept. of Nutr. and Dietetics, Kanto Gakuin University, Col. of Nutr., Yokohama, Japan; [2]Dept. of Hlth. and Nutr. Sci., Komazawa Women's Univ, Fac. of Human Hlth., Tokyo, Japan

Abstract: During development, spontaneous activity is observed well before sensory pathways are functionally organized. One of the earliest activities expressed within the central nervous system is a widely propagating wave-like activity, which we referred to as the depolarization wave. The depolarization wave is expressed during a specific period of embryogenesis, at which time functional synapses are generated between cranial/spinal sensory nerves and postsynaptic neurons in the brain/spinal cord. This developmental profile has led to the hypothesis that the depolarization wave plays a fundamental role in synaptogenesis, which is known to be activity-dependent. In the present study, we tested this hypothesis by blocking the depolarization wave *in ovo* and examining its effects on functional synaptogenesis in vagus nerve-related brainstem nuclei. Postsynaptic responses were detected from the nucleus of the tractus solitarius (NTS), the contralateral non-NTS region, and the parabrachial nucleus (PBN) using optical recordings with a voltage-sensitive dye. Chronic inhibition of the depolarization wave had no significant affect on the developmental time course, amplitude, and spatial distribution of monosynaptic EPSPs (excitatory postsynaptic potentials) in the first-order nuclei of the vagal sensory pathway (the NTS and the contralateral non-NTS region), but markedly reduced polysynaptic responses in the higher-order nucleus (the PBN). These results suggest that the depolarization wave plays an indispensable role in the initial process of functional synaptic expression in the brainstem, especially in the higher-order nucleus of the cranial sensory pathway.

Abstract: In the mammalian central nervous system, GABAergic interneurons provide the majority of inhibitory synaptic transmission onto principal neurons to balance glutamatergic excitation. Imbalance of excitation and inhibition in synaptic transmission has been implicated in many psychiatric and neurological disorders, such as epilepsy, schizophrenia, and autism spectrum disorders (ASD). Thus, it is important to understand the molecular mechanisms underlying the development of excitatory and inhibitory synapses. While extensive studies have been focused on the development of glutamatergic excitatory synapses, much less is known about inhibitory synaptogenesis. Recently, numerous molecules, including trans-synaptic adhesion molecules, sub-membranous scaffolding proteins, intracellular signaling molecules, and secreted factors, have been identified to function in inhibitory synapse development. However, it remains largely unknown whether there is a unifying mechanism for development of diverse inhibitory synapses. In the present study, we have employed cell biological and biochemical techniques, and shRNA knockdown, molecular replacement and gene targeting approaches to examine two inhibitory synaptic cell adhesion molecules (CAMs), Neuroligin2 (NL2) and Slitrk3 (ST3), in GABAergic synapse development in hippocampal neurons. We have found that, in the early developing neurons, the establishment of GABAergic synapses mainly depends on NL2, but not ST3. As the neuron matures, both NL2 and ST3 are required for GABAergic synaptogenesis. Importantly, NL2 and ST3 interact with each other through their extracellular domains. Functionally, NL2 interaction with ST3 facilitates ST3 trafficking to the plasma membrane and augments their synaptogenic ability to induce GABAergic synapse formation. Furthermore, perturbation of the NL2-ST3 interaction strongly impairs inhibitory synaptic transmission *in vitro*. We have also generated mutant mouse line in which the NL2-ST3 interaction is abolished, and have found that both GABAergic synaptic transmission and synapse density in hippocampal CA1 neurons are significantly reduced, suggesting that the NL2-ST3 interaction is critical for GABAergic synapse development *in vivo*. In summary, these findings demonstrate how different postsynaptic CAMs, NL2 and ST3, work in concert to control

inhibitory synaptogenesis, and establish a general molecular framework essential for GABAergic synapse development in hippocampus.

Title: Trans-synaptic regulation of sensory circuit connectivity in the spinal cord by neurexins and neuroligins

Authors: *B. A. COPITS, K. C. MCKENZIE, J. J. YOO, S. K. VOGT, R. W. GEREAU, IV

Abstract: Understanding the assembly and wiring of neural circuits, and how they integrate and process information, is a formidable task. Developmental studies at the interface of the central and peripheral nervous systems have provided significant insights into how diverse molecular families coordinate the positioning and innervation of target regions in the spinal cord. However, we lack a detailed understanding of how connectivity in these circuits is specified. Synaptic adhesion molecules are key coordinators of synapse specificity and diversity, and *trans*-synaptic interactions between the large variety of alternatively spliced presynaptic neurexins and postsynaptic neuroligins have been suggested to impart a combinatorial code for neural connectivity. Despite this hypothesis, little is known about how these molecules govern synapse and circuit formation to specify behavioral responses.
Somatosensory circuits represent intriguing systems for studying the molecular and cellular mechanisms of synapse specificity and connectivity. The wealth of unique recombinase-expressing mouse lines permit genetic access to molecularly-defined populations of sensory neurons without confounding effects in other regions of the nervous system. Additionally, there exists a substantial number of well-defined modality-specific behavioral tests to investigate how distinct molecular families alter circuit processing. Here we employ a conditional genetic strategy to understand how presynaptic neurexin ligands specify synaptic connectivity of sensory circuits in the spinal cord. We found that genetic deletion of β-neurexins in $Na_v1.8+$ sensory neurons, which includes both nociceptors and mechanosensitive fibers, led to modality specific

alterations in sensory behaviors. While these manipulations did not alter mechanical or heat sensitivity, mice exhibited an increased sensitivity to cold. Despite normal heat thresholds, inflammation-induced thermal hypersensitivity, which engages plasticity mechanisms in the spinal cord, was completely absent. To understand how these manipulations regulate synaptic plasticity and connectivity, we have created conditional optogenetic knockout lines to selectively stimulate fibers lacking neurexins. In spinal cord slices, loss of neurexins weakens synaptic transmission, alters AMPA/NMDAR ratios, and decreases synaptic connectivity. We are now using a combination of approaches, both *in vivo* and *in vitro*, to understand how distinct combinations of neurexins and neuroligins regulate synaptic specificity in these circuits.

Title: A MIG-15/JNK-1 MAP kinase cascade opposes RPM-1 signaling in synapse formation and learning

Authors: *B. GRILL, A. C. GILES, R. BIRNBAUM, S. KASHYAP, O. CRAWLEY
Neurosci., Scripps Res. Inst., Jupiter, FL

Abstract: The Pam/Highwire/RPM-1 (PHR) proteins are conserved intracellular signaling hubs that regulate synapse formation and axon termination. The *C. elegans* PHR protein, called RPM-1, acts as a ubiquitin ligase to inhibit the DLK-1 and MLK-1 MAP kinase pathways. We have identified a new MAP kinase pathway that suppresses synapse formation defects, but not axon termination defects, in the mechanosensory neurons of *rpm-1* mutants. This pathway includes: MIG-15 (MAP4K), NSY-1 (MAP3K), JKK-1 (MAP2K) and JNK-1 (MAPK). Transgenic overexpression of kinases in the MIG-15/JNK-1 pathway is sufficient to impair synapse formation in wild-type animals. The MIG-15/JNK-1 pathway functions cell autonomously in the mechanosensory neurons, and kinases in the pathway localize to presynaptic terminals providing further evidence of a role in synapse development. Behavioral analysis indicates loss of MIG-15/JNK-1 signaling increases habituation to repeated mechanical stimuli, a type of short-term learning that is dependent upon mechanosensory neurons. Habituation results also show the

MIG-15/JNK-1 pathway functions as a parallel opposing pathway to RPM-1. Thus, the MIG-15/JNK-1 pathway is required to restrict both glutamatergic synapse formation and short term learning.

Title: Roles of the Rac1 activator Farp1 in mammalian synapse and dendrite development

Authors: *A. J. COLEMAN[1], L. LI[2], J. COTTRELL[2], T. BIEDERER[3]
[1]Neurosci. Grad. Program, Tufts Univ. - Sackler Sch., Boston, MA; [2]Stanley Ctr. for Psychiatric Res., Broad Inst. of MIT and Harvard, Cambridge, MA; [3]Dpt. of Neurosci., Tufts Univ. Sch. of Med., Boston, MA

Abstract: Regulators of the actin cytoskeleton are critical for the structural and functional maturation of neurons, and mutations in genes encoding regulators of the cytoskeleton are linked to intellectual disability and autism-spectrum disorders. Select small G proteins, including the Rho GTPase Rac1, control actin dynamics in developing neurons and at excitatory synapses. The differential roles of Rac1 regulators across brain regions and during specific developmental time windows remain an important knowledge gap. We have previously characterized the roles of the Rac1 activator Farp1 (FERM RhoGEF and pleckstrin domain-containing protein 1) in regulating synapse and dendrite development in hippocampal neurons. We report here that an autism-linked variant of Farp1 exhibits reduced expression. To address the roles of Farp1 and investigate loss-of-function effects, we have generated Farp1 conditional knockout (cKO) mice. Glutamatergic neurons from juvenile Farp1 cKO mice exhibit altered dendrite structure, including reduced spine density in CA1 pyramidal neurons. We have probed the effect of Farp1 loss on its signaling partners including the trans-synaptic adhesion molecule SynCAM1 and members of the Semaphorin/Plexin signaling pathway. Additionally, we have characterized the role of Farp1 in hippocampal-dependent learning and memory in juvenile and adult animals. These *in vivo* studies are complemented by an *in vitro* analysis of dynamic roles of Farp1 in modulating synaptic plasticity and we report on the contribution of activity-dependent phosphorylation of

Farp1 to synaptic remodeling in long-term potentiation. Our results highlight the functions of Farp1 in neuronal differentiation and how its activity is modulated by its signaling partners to regulate multiple aspects of connectivity.

Title: The carbonic anhydrase-related proteins ca10 and ca11 are conserved pan-neurexin cis-ligands

Authors: *F. H. STERKY[1], J. H. TROTTER[2], S. LEE[3], T. C. SUDHOF[2]
[1]Clin. chemistry and transfusion medicine, Univ. of Gothenburg, Gothenburg, Sweden; [3]Mol. and Cellualr physiology, [2]Stanford Univ., Stanford, CA

Abstract: Neurexins are pre-synaptic cell adhesion receptors that interact with diverse post-synaptic ligands to shape the molecular architecture and properties of the synapse. Mutations in neurexin-encoding genes have repeatedly been linked to neuropsychiatric disease, but despite being extensively studied, the physiological functions of the neurexin complex and role in human disease are not well understood. In proteomic studies of Nrxn1 complexes immuno-isolated from mouse brain, we identified carbonic anhydrase-related proteins CA10 and CA11, two homologous, secreted glycoproteins of unknown function that are predominantly expressed in brain. We found that CA10 directly binds in a *cis*-configuration to a conserved membrane-proximal, extracellular sequence present in □α-, β- and γ-neurexins. The CA10/neurexin complex is stable and stoichiometric, and results in formation of an intermolecular disulfide bond between conserved cysteine residues in neurexins and CA10. This interaction promotes surface-expression of α- and β-neurexins, suggesting that CA10 may form a complex with neurexins in the secretory pathway that facilitates surface-transport and/or stability of neurexins. These results expand our understanding of the neurexin complex and provide a means to further address its posttranslational regulation.

Title: Lissencephaly heterotopia and effects on the development of cellular microcircuitry

Authors: *J. D'AMOUR[1], T. G. EKINS[3], C. J. MCBAIN[2]
[2]Lab. Cell/Molec Neurosci, [1]NIH, Bethesda, MD; [3]NIH/Brown Univ., Bethesda, MD

Abstract: In this study, we are examining cellular layering and its role in the development of synaptic microcircuitry. Principal cells of the developing mouse hippocampus arise in proliferative waves of cell birth and subsequent radial migration over embryonic day 13-16, to ultimately appear as a compacted layer of excitatory neurons. In the neocortex a similar process of cell birth but temporally separate radial migration patterns produces six distinct cell-layers in an inside-out fashion. The resulting cortical layers have specialized microcircuitry essential to information processing carried out in that cortical region. Here we investigate whether similar excitatory cell sub-populations and birthdate specified microcircuitry also exist within the hippocampal principal cell layer (PCL). Among the first evidence of excitatory subpopulations in the radial axis of the PCL (superficial to deep) in region CA1, is restricted calbindin expression to the superficial rows of principal cells, while deeper principal cells are typically calbindin negative. Recent studies further support radial subdivisions among PCL excitatory cells and suggest an intricate synaptic connectivity of local excitatory and inhibitory sub-populations. However, it remains a daunting problem to disentangle the effects of cellular birthdate, positioning and genetic identity in the establishment of microcircuitry. Toward this goal, we make use of a mouse model of a human neurodevelopmental disorder, in which cellular layering and positioning are effected. Lissencephaly occurs in about 0.001% live human births, and is caused by mutations in genes essential to cell migration. In hippocampi from heterozygous Lis1 mice (Lis+/-), the PCL is often fragmented into radially divided heterotopic bands or cell-clusters. Our data from Lis+/- animals indicate that calbindin positive principal cells occupy the deeper heterotopic cell band (in contrast to their superficial positioning in the wild type PCL) and may reflect an inversion of excitatory cell positioning. This observation could carry interesting ramifications for inhibitory connectivity, particularly among parvalbumin positive interneurons that have been demonstrated to preferentially innervate deeper principal cells in the wild-type hippocampus, area CA1. Additionally, our parvalbumin and somatostatin staining indicate these interneuron types migrate to abnormally superficial locations. Future experiments

will examine connectivity between these cell types, with hopes of better understanding how developmental challenges such as cellular heterotopia shape synaptic connectivity.

Title: A novel cell polarity program during innervation of a non-laminar nucleus in the auditory brainstem

Authors: ***P. S. HOLCOMB**[1], A. N. BRANDEBURA[1], D. R. KOLSON[1], S. H. BERZINGI[1], D. R. JACKSON[1], T. J. DEERINCK[2], M. H. ELLISMAN[2], G. A. SPIROU[1]
[1]Sensory Neurosci. Res. Ctr., West Virginia Univ. Sch. of Med., Morgantown, WV; [2]Natl. Ctr. for Microscopy and Imaging Res., Univ. of California San Diego, La Jolla, CA

Abstract: Laminar sensory structures—rod and cone cells of the retina, hair cells of the cochlea—confine innervation to specific sites through polarized expression of synaptic proteins and lateral cell-cell connections that structurally segregate these cells into apical and basal regions. Many cells in the central nervous system, however, are not arranged in a laminar fashion necessary to make such a polarized distinction. Are these populations of cells still structurally polarized, and does this polarity inform the placement and growth of synaptic terminals? The calyx of Held (CH) - principal cell (PC) connection in the medial nucleus of the trapezoid body (MNTB) of the mouse provides a valuable model system to examine these questions, due to its short developmental window (<72 hours), large terminal size, and a clear monoinnervated endpoint. We acquired, segmented, and reconstructed PCs and their associated terminals from postnatal day (P)2-9 mice using serial block-face scanning electron microscopy and both manual and semi-automated segmentation techniques. An “intrasomatic polarity”, or asymmetric arrangement of the nucleus and organelles into a nucleus-poor “cytoplasmic” pole and a nucleus-

filled “nuclear” pole, was present in all PCs reconstructed (n=97) This polarity increases significantly during development due to asymmetric growth of the PC away from the nucleus, and relaxes somewhat by P30, suggesting a role specifically in development. Additionally, the nucleus is morphologically polarized, with large invaginations solely on the surface facing the cytoplasmic pole. Polarity also influenced the location of the growing calyx; we found that the CH:PC connection not only becomes larger but also more polarized as development progresses, with greater than 80% of the ASA of the largest terminals at P6 occupying the cytoplasmic pole surface opposite the nucleus. Cells with competing inputs (2-3 inputs/cell with less than 1:5 ratio in size) fell into three categories: (1) the largest terminal is most polarized, (2) the second largest terminal is most polarized, or (3) the two largest terminals are equally polarized. This suggests a “flip-flop” of largest for second largest terminal may be taking place, such as is seen in neuromuscular junction development. These findings demonstrate a novel cell polarity program in a non-laminar cell group that influences the placement and growth potential of terminals in the formation of the CH:PC circuit.

Title: NRX assembles synapses independent of NL and tunes synaptic plasticity by antagonizing NL *In vivo*

Authors: *P. KURSHAN, K. SHEN
Biol. Dept, Stanford Univ., Stanford, CA

Abstract: A central conundrum in the field of synaptic development is why synaptic inducers identified in cell culture assays, such as Neurexin and Neuroligin, fail to show major synaptogenesis defects when knocked out *in vivo*. Instead, their role seems limited to subtle effects on synaptic function and plasticity. Here we report dual, opposing functions of pre- vs post-synaptic Neurexin on both synapse assembly and synaptic plasticity at the same *in vivo* synapse in *C. elegans*. Moreover we report a novel antagonistic relationship between Neurexin and Neuroligin in mediating this plasticity. We find that presynaptic neurexin cell-autonomously mediates synapse assembly, in a manner independent of Neuroligin, and in fact independent of the entire neurexin extracellular binding domain. In contrast, postsynaptic Neurexin at the same synapse induces downregulation of specific active zone proteins involved in presynaptic

plasticity. This inhibitory action of Neurexin is blocked by presynaptic, perisynaptically localized Neuroligin, suggesting a novel antagonistic role of the two proteins in mediating synaptic plasticity.

Abstract: Inhibitory synaptic inputs control neuronal excitability and the firing patterns of targeted neurons and further regulate brain circuit formation. The proper balance between excitatory and inhibitory synaptic inputs is crucial for maintaining normal brain functions. Accumulating evidence suggests that impaired development of central inhibitory synapses leads to neuropsychiatric disorders such as schizophrenia, autism spectrum disorders, and anxiety, highlighting the importance of our understanding of the molecular mechanisms of inhibitory synapse development. However, the molecular mechanism governing the development of

GABAergic inhibitory synapses is poorly understood.
Synapse development requires not only physical contact between axons and target neurons but also chemically-matched pre- and post-synaptic differentiation. Synapse organizers, synaptic adhesion molecules with the ability to induce synaptic differentiation, form trans-synaptic complex, called synapse organizing complexes. These complexes have been demonstrated as essential molecular signals for synapse development, represented by the neuroligin (NLG)-neurexin (NRX) complex. Although many synapse organizers induce excitatory or both excitatory and inhibitory synapses, there is only a few synapse organizer selectively inducing inhibitory synapse.
Here, we report the identification of immunoglobulin superfamily member 21 (IgSF21) as a novel inhibitory synapse organizer that induce only inhibitory presynaptic differentiation. Through further proteomics screen, we isolated NRX2α as an IgSF21-interacting presynaptic organizer. Interestingly, IgSF21 selectively binds to NRX2a but not any other NRX isoforms and recruits NRX2α to presynaptic sites in a trans-interaction manner, which is essential for the synaptogenic activity of IgSF21. To characterize the physiological function of IgSF21 in the central nervous system, we comprehensively characterized IgSF21 mutant mice. We found that IgSF21 positively regulates inhibitory presynaptic organization and GABA-mediated synaptic transmission in the hippocampal CA1 pyramidal neurons and that IgSF21 is indispensable for normal sensorimotor gating. Together, our findings suggest that IgSF21 selectively organizes inhibitory synapses via its trans-synaptic interaction with axonal NRX2α and that this is essential for normal brain function.

Title: Expression analysis of miRNA-26b involved in synaptogenesis in embryonic neural stem cells from diabetic mice

Authors: *S. RAMYA[1], S. SHYAMASUNDAR[2], B. BOON HUAT[2], S. T. DHEEN[2]
[1]Anat., Natl. Univ. of Singapore, Singapore, Singapore; [2]Anat., Natl. university of Singapore, Singapore, Singapore

Abstract: Maternal diabetes causes neural tube defects in embryos and neuropsychological deficits in infants. Several molecules and epigenetic factors have been identified to be deregulated in developing brain of embryos by maternal diabetes, although the exact mechanism remains unknown. Recently, miRNAs have been shown to regulate brain development. Therefore, we hypothesized that maternal diabetes alters the expression of miRNAs that regulate genes involved in synaptogenesis and brain development during embryogenesis. In order to address this, embryonic neural stem cells (NSCs) from embryos of normal and streptozotocin-induced diabetic mice were isolated and cultured *in vitro*. High throughput miRNA expression profiling revealed altered expression of several miRNAs in NSCs isolated from embryos of diabetic pregnancy when compared to control. Among the differentially expressed miRNAs, expression of miR-26b, which has been shown to be involved in neurogenesis and neuronal differentiation, was significantly upregulated in NSCs from embryos of diabetic pregnancy when compared to the control. Among the several predicted targets of miR-26b, methyl CpG binding protein2 (Mecp2) and post synaptic density 95 (Psd95) that are involved in brain development, synaptic maturation and plasticity were selected for further study, since the expression levels of Mecp2 and Psd-95 protein were significantly downregulated in NSCs from embryos of diabetic pregnancy when compared to the control. Overexpression of miR-26b resulted in the downregulation of Mecp2 and Psd-95 proteins suggesting that they may be putative targets of miR-26b. These results warrant further investigation as Psd-95 protein is an integral part of the glutamate receptors especially N-methyl-D-aspartate receptor (NMDA) which has a pivotal role in transmission of glutamate in excitatory synapses.
Taken together, this study reveals that maternal diabetes upregulates the expression of miR-26b resulting in down regulation of its predicted targets, Mecp2 and Psd-95 proteins. Decreased expression of Mecp2 and Psd-95 that are crucial for brain development and synapse formation especially excitatory synapses may underlie defective brain development and patterning and manifest as neuropsychological disturbances that are observed in offspring of diabetic pregnancy.

Title: Investigating the structural role of GABAA receptors in inhibitory synapse formation and circuitry of the basal ganglia

Authors: *J. N. JOVANOVIC[1], J. E. ARAMA[1], S. K. TYAGARAJAN[2], P. PANZANELLI[3], J.-M. FRITSCHY[2]

Abstract: Gamma-aminobutyric acid (GABA) is the main inhibitory neurotransmitter in the brain. Its fast synaptic actions are mediated by GABAA receptors (GABAARs), which are chloride/bicarbonate-permeable ligand-gated channels. GABAergic transmission is essential for neuronal development and maturation, and for coordination of neuronal activity underlying all physiological and behavioral processes. The molecules and mechanisms that regulate the assembly and maturation of GABAergic synapses during ontogeny remain largely unknown. Our recent work has demonstrated that GABAARs exhibit synaptogenic activity in heterologous co-culture model systems in which their presence at the postsynaptic plasma membrane is sufficient to promote the adhesion and functional maturation of GABAergic axon terminals. Furthermore, synapse initiation in this system occurs with a high degree of selectivity with respect to the postsynaptic GABAAR composition and it is mediated by the large N-terminal extracellular domains of GABAAR subunits. To investigate this synaptogenic role of GABAARs *in vivo*, we have carried out a quantitative immunohistochemical analysis of GABAergic synapses in the nuclei of the basal ganglia of the alpha1- or alpha2-GABAAR knockout mice using antibodies specific for the main pre- and postsynaptic markers. We have characterized the number and size of the postsynaptic alpha1/2/3 or 5 or gamma2-containing GABAAR clusters, the number of co-localized VGAT or GAD65 positive GABAergic terminals, the number and size of synaptic gephyrin and neuroligin-2 clusters, and the density of TH-positive dopaminergic terminals. Our results demonstrate the loss of inhibitory synapses and profound structural changes in the remaining synapses in those basal ganglia regions in which the most abundantly expressed isoform of the alpha subunits was genetically ablated. This indicates that synaptogenic effects of GABAARs in vivo depend on their individual subunit composition in which the main role in initiation and selectivity of synaptic contacts is mediated by the alpha subunits.

Abstract: The etiology of schizophrenia is largely attributed to genomic variation. However, environmental challenges contribute to the development of schizophrenic symptoms as well. But, the synergistic effect of genetic factors and environmental challenges to schizophrenia remains to be elucidated. Here, by using a genetic animal model of molecular pathology associated with schizophrenia, we tested how life-threatening events during pregnancy affect the pathophysiology of schizophrenia in offspring. KCNH2-3.1, which encodes a primate-specific and brain-selective isoform of the potassium voltage-gated channel, is associated with schizophrenia in gene expression studies in post-mortem brain. We administered a variable and unpredictable stress paradigm to female pregnant mice with transgenic overexpression of human KCNH2-3.1. Prenatal stress resulted in a decrease in mushroom dendritic spine number, as well as spine area, but not in stubby dendritic spine and filopodia, in hippocampal CA1 pyramidal neurons of KCNH2-3.1 transgenic mice at 2 weeks of age compared with control mice at the same age. In addition, we observed a marked increase of inhibitory perisomatic GAD65 synapses on hippocampal CA1 pyramidal neurons in both 2-week-old and 6-week-old KCNH2-3.1 transgenic mice exposed to prenatal stress. Interestingly, this phenotype was not found in GAD67 boutons on CA1 pyramidal cells in KCNH2-3.1 mice after maternal stress. Our results suggest that environmental challenge during pregnancy leads to the imbalance of excitatory-inhibitory synapse formation within the hippocampus in the context of a genetic alteration related to schizophrenia.

Abstract: Forward genetic screens have been invaluable for identifying genes that regulate synaptogenesis in invertebrates, but few such screens have been performed in mammals owing to the expense and difficulty of germ-line mutagenesis. Here, we propose an alternative approach: purification of synaptic partners at key developmental stages; transcriptional profiling (RNA-seq) to identify candidate mediators of their interactions; and somatic CRISPR/Cas9-based mutagenesis to assess their roles in vivo. We applied this strategy to mouse outer retina, in which axons of rod and cone photoreceptors form synapses on dendrites of rod bipolar and cone bipolar interneurons, respectively, in a thin neuropil called the outer plexiform layer (OPL). We purified and profiled these four cell types, identifying hundreds of genes encoding cell surface and secreted proteins that were differentially expressed among them as synapses are forming. We then generated guide RNAs to inactive a set of them, and introduced them into outer retina by electroporation, along with Cas9 and a fluorescent marker to identify transduced cells. Using this strategy, we found that inactivation of Wnt5a and 5b, which are selectively expressed by rod bipolars, leads to formation of a supernumerary OPL. To investigate Wnt5's mechanism of action, we used cell type-specific promoters to inactivate 8 candidate signal transduction components. We found that Wnt5 acts on rods through a non-canonical pathway using Ryk, Fzd4 and Fzd5 as receptors. Neither the initial screen nor the investigation of signaling mechanism could have been performed in a timely manner using germ-line constitutive and conditional mutagenesis. These methods can be employed to study circuit development in many parts of the developing mouse brain.

Title: Alpha2delta1-mediated synaptogenesis *In vitro* and during adult neurogenesis

Authors: K. A. BEESON[1], G. L. WESTBROOK[2], *E. SCHNELL[3]
[1]Oregon Hlth. and Sci. Univ., Portland, OR; [2]Vollum Inst., Portland, OR; [3]Portland VA Med. Ctr., Portland, OR

Abstract: Identification of the molecules that control synaptic integration of new neurons is fundamental to our understanding of neural plasticity in health and disease. The α2δ proteins have been identified as receptors for the glial-secreted thrombospondins, which are potent synaptogenic proteins. Excitatory synapse formation is positively regulated by the expression of α2δ during development and in vitro. Although α2δ proteins have been implicated in neural development, and mutations in α2δ can result in striking neurophysiological phenotypes, their contribution to the functional integration of developing and adult-born neurons is not well understood. Interestingly, a commonly prescribed anti-epileptic and analgesic drug, gabapentin, binds α2δ proteins with high affinity and antagonizes thrombospondin-mediated synaptogenic signaling. Using whole cell electrophysiology in organotypic slice cultures, we demonstrate that gabapentin reduces miniature excitatory post-synaptic current frequency, and that α2δ-1 overexpression in single neurons enhances evoked excitatory post-synaptic currents; consistent with a role for α2δ proteins in synaptogenesis. Furthermore, gabapentin significantly reduced dendritic spine width in adult-born granule cells in vivo, indicating that α2δ contributes to synapse formation during adult neurogenesis. Using in vitro and in vivo models of neuronal development paired with single-cell morphology and electrophysiology, we hope to decipher the contribution of α2δ proteins to synaptogenesis in adult-born neurons.

Title: Presynaptic LRP4 promotes synapse number and function of excitatory CNS neurons

Authors: *T. J. MOSCA[1], D. LUGINBUHL[2], I. WANG[3], L. LUO[2]
[1]Neurosci., Thomas Jefferson Univ., Philadelphia, PA; [2]Dept. of Biol., [3]Dept. of Neurobio., Stanford Univ., Stanford, CA

Abstract: Precise coordination of synaptic connections ensures proper information flow within circuits. The activity of presynaptic organizing molecules signaling to downstream pathways is essential for such coordination, though such entities remain incompletely known. We show that LRP4, a conserved transmembrane protein known for its postsynaptic roles, functions presynaptically as an organizing molecule. In the *Drosophila* brain, LRP4 preferentially localizes to excitatory neuron terminals at or near active zones. Loss of presynaptic LRP4 reduces excitatory (not inhibitory) synapse number, impairs active zone architecture, and abolishes olfactory attraction - the latter of which can be suppressed by reducing presynaptic $GABA_B$ receptors. LRP4 overexpression increases synapse number in excitatory and inhibitory neurons, suggesting an instructive role and a common downstream synapse addition pathway. Mechanistically, LRP4 functions via the conserved kinase SRPK79D to ensure normal synapse number and behavior. This highlights a presynaptic function for LRP4, enabling deeper understanding of how synapse organization is coordinated.

Title: The synaptic organizer neurexin coordinates cholinergic connectivity with GABAergic neurons

Authors: *M. L. LEMONS[1], A. PHILBROOK[2], S. RAMACHANDRAN[2], D. OLIVER[2], C. LAMBERT[2], M. M. FRANCIS[2]

[1]Dept. of Natural Sci., Assumption Col., Worcester, MA; [2]Neurobio., Univ. of Massachusetts Med. Sch., Worcester, MA

Abstract: In the central nervous system, individual neurons often project divergent synaptic connections to multiple postsynaptic partners. However, we have only a limited understanding of how synaptic specificity across postsynaptic partners is established, and the mechanisms that govern differential patterns of synaptic connectivity. Dyadic excitatory synapses in the *C. elegans* motor circuit provide a useful model for elucidating the molecular basis of synaptic specificity. Excitatory cholinergic motor neurons synapse onto both inhibitory GABAergic neurons and body wall muscles. While genes required for muscle cholinergic synaptic assembly have been well defined, excitatory synaptic connections onto GABAergic neurons appear to require a distinct molecular scaffold. We found that the cell adhesion molecule neurexin/*nrx-1* is specifically required for the assembly of synaptic inputs onto GABAergic neurons. In the absence of *nrx-1*, both cholinergic receptor localization and the formation of synapse-associated morphological features of GABAergic dendrites are disrupted. As a result, excitatory transmission onto GABAergic neurons is severely impaired. *nrx-1* expression in cholinergic neurons is coregulated with cholinergic neuron identity, and is required for proper synaptic connectivity with GABAergic neurons. Surprisingly, synaptic development is not affected by mutation of neuroligin, neurexin's most well characterized binding partner. We therefore propose that neurexin expression in cholinergic neurons organizes synaptic connectivity with GABAergic neurons through a neuroligin-independent trans-synaptic signaling pathway. Our findings provide evidence that cholinergic neurons utilize distinct molecular signals to govern the establishment of synaptic connectivity with GABAergic motor neurons and body wall muscles, offering a novel view into molecular mechanisms responsible for generating divergent patterns of synaptic connectivity.

Title: Ultrasonic vocalization and sociability deficits in mice lacking SRPX2

Authors: *B. SOTEROS[1], G.-M. SIA[2]
[1]Pharmacol. Dept, UT Hlth. San Antonio, San Antonio, TX; [2]Pharmacol., Univ. of Texas Hlth. Sci. Ctr. at San Antonio, San Antonio, TX

Abstract: Synapse formation and maintenance are critical for the development of proper neural circuitry. SRPX2, the sushi-repeat containing domain protein x-linked 2, is a human language associated protein which regulates synapse formation and vocalizations in mice. We report here that mice lacking SRPX2 display deficits in ultrasonic vocalization and sociability. SRPX2-KO mice also show a lack of preference for social novelty in the three-chamber sociability task. SRPX2 is broadly expressed in the brain and is enriched in the cortex. Deletion of SRPX2 results in a reduction in VGLUT2 staining in cortical layer IV. Golgi staining revealed reduced spine density in layer V cortical pyramidal neurons, specifically on the apical dendrite which extends through layer IV. Abnormalities in cortical spine density are observed as early as P6, which parallels the onset of deficits in ultrasonic vocalization. These studies suggest that SRPX2 is important for the development of ultrasonic vocalization and cortical synapse formation in mice. Future studies are necessary to determine whether SRPX2 regulates synapse formation in vocalization-related circuitry in mice.

Title: The Ig transmembrane protein Borderless is required for synaptic development and function in the *Drosophila* visual system

Authors: *H. S. SHAW, S. A. CAMERON, W. CHANG, Y. RAO
Neurol. and Neurosurg., McGill Univ. Hlth. Ctr., Montreal, QC, Canada

Abstract: The fruit fly visual system is an excellent model to study the general mechanisms by which cell adhesion molecules regulate synaptic development and function. Recently, our lab has identified a conserved homophilic cell adhesion molecule Borderless (Bdl). Down-regulation of Bdl is required for photoreceptor axonal tiling and targeting. The *in vivo* function of Bdl in photoreceptor axons, however, remains unknown. Interestingly, IgSF9B, the mammalian homolog of Bdl, has recently been shown to contribute to inhibitory synapse formation *in vitro*. To determine the potential role of Bdl in photoreceptor axons, we developed a phototactic behavioral assay and showed that loss of *bdl* impaired the fruit fly's ability to detect blue and green light. Since detection of blue and green light in the fly visual system is mediated by R8 photoreceptors, these results suggest a role for Bdl in the control of R8 connectivity and/or function. To further determine the exact role of Bdl in R8 axons, we examined the effects of *bdl*

mutations on synaptic structures. We found that in the absence of Bdl, synaptic vesicles were mislocalized to the non-synaptic section of the R8 axon. We then performed cell-type-specific rescue and genetic mosaic analysis, which showed that Bdl is required both pre- and post-synaptically for proper localization of synaptic vesicles. These results support a model in which Bdl acts in a homophilic manner to facilitate the interactions between R8 axon and its target neurons for the assembly and function of presynaptic complexes.

Title: Proteolytic regulation of GABAergic synapse formation by neuroligin-2

Authors: *T. TOMITA, Y. NAO, R. NAGATOMO, K. YAMASHITA, M. KIMURA
The Univ. of Tokyo, Tokyo, Japan

Abstract: Neuroligin (NL) is one of the most characterized postsynaptic cell adhesion molecules. NL binds to presynaptic partner neurexin, and plays a role for synapse formation and maturation during development. Neuroligin-2 (NL2) locates at inhibitory postsynapse, and associates with molecules involved in the inhibitory postsynaptic assembly, such as gephyrin and collybistin. NL2 induces the GABAergic synapse formation and maturation in heterologous culture system. However, relationship between its protein metabolism and synaptogenic activity is not well-understood. We have previously described the proteolytic regulation of NL1-mediated excitatory synapse formation by sequential cleavages by ADAM10 and gamma-secretase (Suzuki et al., Neuron 2012). Here, we analyzed the proteolytic cleavage and function of NL2. In rat primary neuronal culture, soluble N-terminal fragment of NL2 (sNL2) and a membrane-associated C-terminal fragment in cultured medium and cell lysates, respectively, were detected. Production of sNL2 was diminished upon treatment of metalloproteinase inhibitors, TAPI2 and GM6001, but not by ADAM protease inhibitor INCB3619. Then we screened the effect of membrane associated matrix metalloproteinases. We found that NL2 shedding was augmented and decreased by co-expression or RNAi knockdown of MT3-MMP/MMP16, respectively, suggesting that MMP16 is involved in the shedding of NL2 in primary neurons. Systematic mutagenesis analyses revealed that the stalk region of NL2 was shed, and cell surface level as well as synaptogenic activity of NL2 was correlated with the shedding efficiency. Finally, we found that GABAergic activation modulates the shedding of NL2 in primary neurons. From these results, we speculate that NL2 is proteolytically processed in the brain, and this cleavage regulates the NL2 protein level and its synaptogenic function.

Title: Highly selective cell-type programs regulate synaptic target specificity

Authors: R. DEOGRACIAS, E. FAVUZZI, A. MARQUES-SMITH, D. EXPOSITO-ALONSO, P. MAESO, *B. RICO
King's Col. London, London, United Kingdom

Abstract: Neuronal circuitries underlying the function of the mammalian cerebral cortex collectively constitute one of the most complex biological systems. As such, unraveling the mechanisms that control their development represents one of the most challenging questions in science. During development, the specificity of neuronal wiring is achieved through the coordination of multiple cues, which first guide axons to the right target area, then to the proper cellular partner and, finally, to the precise subcellular compartment onto which synapses will be formed. Subcellular segregation of synapses occurs for all types of inputs, but it reaches its highest diversity for inhibitory GABAergic terminals. Much is known about the general machinery controlling axon guidance in the developing brain; in contrast, the mechanisms of synapse segregation remain largely unknown. To understand the molecular codes that control GABAergic synaptic target specificity, we combined cell sorting approaches and high-throughput RNA-sequencing techniques to obtain the transcriptome profile of different interneurons populations during synapse formation. Our unbiased screening has unveiled different candidate genes that could be putatively involved in synapse formation. Using a structural and functional analysis in vivo, we revealed selective cell-type unique programs that regulate GABAergic synapse formation onto pyramidal neurons.

Title: Kit, an RTK linked to neurodevelopmental disabilities, regulates the specification of connectivity in the developing murine cerebellum

Authors: *M. R. WILLIAMS[1], C. P. RIZZUTO[2], J. LEE[2], B. W. LUIKART[3]
[1]Physiol. & Neurobio., Dartmouth Med. Sch., Lebanon, NH; [2]Dartmouth Col., Lebanon, NH; [3]Mol. and Systems Biol., Dartmouth Col. Geisel Sch. of Med., Lebanon, NH

Abstract: Autism spectrum disorder (ASD) has a large genetic component. Our objective is to understand the role of ASD candidate genes in brain development and ultimately identify therapeutic targets. Here, we study the receptor tyrosine kinase, Kit (KitR). KitR mutations are rarer than would be expected in the population, suggesting a deleterious effect of its loss of function. Indeed, in case studies with known or suspected KitR mutations, children present with profound syndromic ASD and/or intellectual disability. KitR is enriched in brain areas germane to the symptoms of ASD, including hippocampus (learning and memory), striatum (repetitive behaviors), and cerebellum (sensorimotor learning and function). It has been known that KitR and its ligand KitL are expressed in opposing synaptically coupled cells within these circuits. This pattern suggests that KitL/KitR may influence synaptogenesis in these structures. If so, loss of KitR may disrupt the development and dependent behaviors of these circuits, contributing to the emergence of ASD. Here, we begin testing this model by determining if KitL attracts innervation by KitR expressing cells during development. In human and mouse cerebellum, KitL is abundantly expressed by Purkinje cells (PCs) and KitR is expressed by Molecular Layer Interneurons (MLIs). In development, MLIs migrate to and synapse upon Purkinje cells. We have used viral and transgenic strategies to manipulate KitL and KitR in the developing mouse cerebellum, and we have used electrophysiology and immunohistochemistry to study the impacts on MLI migration, morphology, and synaptogenesis. We find that the ectopic expression of KitL is sufficient to attract the migration of and functional innervation by MLIs, and that the MLI expression of Kit is necessary for the normal innervation of PCs. We also provide evidence that the expressivity of KitL and KitR throughout the brain support the model that Kit signaling modulates the patterning of synaptic connectivity in the developing brain.

Title: Shunting $GABA_A$ transmission restrains glutamtergic synapse formation in the developing hippocampus

Authors: *C. K. SALMON[1], H. PRIBIAG[2], G. QUESSEVEUR[3], M. A. WOODIN[4], K. K. MURAI[1]
[1]Ctr. For Res. In Neurosci., Montreal, QC, Canada; [2]UCSD, LA Jolla, CA; [3]Ctr. for Res. in Neurosci., Montreal, QC, Canada; [4]Univ. of Toronto, Toronto, ON, Canada

Abstract: GABA is the main inhibitory neurotransmitter in mature neurons, but depolarizes immature neurons during development. GABA's early depolarizing action controls numerous aspects of circuit formation, in particular glutamatergic synapse formation and refinement. Interestingly, during the peak of gluatmatergic synapse formation in the hippocampus, $GABA_A$ transmission changes from depolarizing, to shunting, to hyperpolarizing. Thus, the question of timing is central when probing the role of GABAergic transmission in circuit development. We therefore asked the question, how does $GABA_A$ transmission regulate glutamatergic synapse formation as it shifts from depolarizing to fully inhibitory. To do so we turned first to the organotypic hippocampal slice. As the literature suggests, blocking hyperpolarizing GABA transmission for 48 hours in these cultures caused loss of dendritic spines due to over-excitation. In contrast, blocking GABA transmission for 48 hours just prior to the switch, when GABA is shunting, caused a marked increase in dendritic spines, synaptic proteins and mEPSC frequency. These changes lasted for up to a week following washout of the GABA blockade and were associated with elevated BDNF and cFos mRNA levels. Furthermore, slices from mice heterozygous for BDNF fail to increase expression of synaptic markers following GABA blockade over the same period of time. Our work emphasizes the necessity for intact $GABA_A$ transmission during nervous system development and uncovers a narrow developmental time window in which GABA restrains synapse formation. Moving forward, to investigate whether this phenomenon occurs *in vivo*, we established methods for TetOn-based doxycycline-mediated gene expression using *in utero* electroporation, and also developed a panel of doxycycline-

inducible GABA-disrupting plasmids. Using these tools we will assess the role of $GABA_A$ transmission in developmental synapse formation with temporal and spatial precision *in vivo*.

Title: Decreased cohesin in the brain leads to defective synapse development and anxiety-related behavior

Authors: *Y. FUJITA, T. YAMASHITA
Dept Mol Neurosci, Grad Sch. Med, Osaka Univ., Suita, Osaka, Japan

Abstract: The cohesin complex, composed of four subunits, including Smc3, plays a role in sister-chromatid cohesion. Although expression of cohesin in dividing cells is well established, cohesin is also expressed in post-mitotic cells. Recent studies demonstrate that cohesin is involved in forming chromatin loops at particular loci and regulates gene expression in vitro. However, if cohesin plays a role in terminally differentiated cells in vivo is unknown. Therefore, we generated conditional Smc3-knockout mice and examined their brain phenotype. We observed greater dendritic complexity and larger numbers of immature synapses in the cerebral cortex of Smc3 heterozygous deficient mice than in wild-type mice. Neuron-specific Smc3-knockout mice showed the same phenotype, indicating that Cohesin function in neurons are required for proper neuronal network formation. Smc3 heterozygous deficient mice also exhibited more anxiety-related behavior, which is a symptom of Cornelia de Lange syndrome. Further, a gene-ontology analysis following RNA sequencing suggested the enrichment of immune processes, particularly the response to interferons, in the Smc3 heterozygous deficient mice. Indeed, fewer synapses formed in their cortical neurons, and this phenotype was rescued by STAT1 knockdown. Thus, low levels of cohesin expression in the developing brain leads to changes in gene expression that in turn lead to a specific and abnormal neuronal and behavioral phenotype.

Abstract: Synapse formation and its maintenance accomplished by synapse organizers are crucial for the proper development of the brain and their disruption would lead to neuropsychiatric diseases so called “synapse diseases”. Extracellular scaffolding proteins (ESPs), such as cerebellin 1 (CBLN1) and neuronal pentraxin 1 (NPTX1), are the recently identified new class of synaptic organizers. It is noteworthy that the application of recombinant ESPs has been shown to rapidly regulate synapse formation and plasticity *in vitro* and *in vivo*, indicating that ESPs could serve as potential tools to arbitrarily control synapse formation and its function. Here we developed a novel synapse connector protein, Cerebellin-Pentraxin chimeric protein (CPTX) which is composed of the stalk domain of CBLN1 and the pentraxin domain of NPTX1. CPTX is designed to make selective and simultaneous connection between presynaptic neurexins with splice site 4 and postsynaptic AMPA receptors via respective domains. As expected, CPTX specifically bound to HEK cells expressing neurexins with splice site 4 and N-terminal domain of AMPA receptor subunits (GluA1-4). Treatment of CPTX *in vitro* induced the synapse formation between either CBLN1-null cerebellar granule neurons or wild-type hippocampal neurons and HEK cells expressing the N-terminal domain of AMPA receptor. CPTX accumulated between pre- and postsynaptic elements *in vitro* and *in vivo*. To examine the functional effect of CPTX *in vivo*, we tried to rescue motor discoordination in two different model mice, CBLN1-null and GluD2-null mice, both of which show ataxia because of the few synapse formation in cerebellum. Remarkably, CPTX injection into cerebellar vermis of the either mouse rescued the motor discoordination. Furthermore, electron microscopic and electrophysiological analysis revealed that CPTX injection restored functional synapse formation in both mice. These results suggest that CPTX can connect excitatory synapses and modulate the

motor performance. This research would lead to potential new avenues for the treatment of "synapse diseases".

Title: Neurexin, neuroligin and wishful thinking in synaptic cytoarchitecture and growth at NMJ

Authors: *S. BANERJEE
Physiol., UT Hlth. Sci. Ctr. At San Antonio, San Antonio, TX

Abstract: Trans-synaptic interactions involving Neurexins and Neuroligins are thought to promote adhesive interactions for precise alignment of the pre- and postsynaptic compartments and organize synaptic macromolecular complexes across species. In *Drosophila*, while Neurexin (Dnrx) and Neuroligins (Dnlg) are emerging as central organizing molecules at synapses, very little is known of the spectrum of proteins that might be recruited to the Dnrx/Dnlg trans-synaptic interface for organization and growth of the synapses. Using full length and truncated forms of Dnrx and Dnlg1 together with cell biological analyses and genetic interactions, we report novel functions of Dnrx and Dnlg1 in clustering of pre- and postsynaptic proteins, coordination of synaptic growth and ultrastructural organization. We show that Dnrx and Dnlg1 extracellular and intracellular regions are required for proper synaptic growth and localization of Dnlg1 and Dnrx, respectively. *dnrx* and *dnlg1* single and double mutants display altered subcellular distribution of Discs large (Dlg), which is the homolog of mammalian post-synaptic density protein, PSD95. *dnrx* and *dnlg1* mutants also display ultrastructural defects ranging from abnormal active zones, misformed pre- and post-synaptic areas with underdeveloped subsynaptic reticulum. Interestingly, *dnrx* and *dnlg1* mutants have reduced levels of the Bone Morphogenetic Protein (BMP) receptor Wishful thinking (Wit), and Dnrx and Dnlg1 are required for proper localization and stability of Wit. In addition, the synaptic overgrowth phenotype resulting from the overexpression of Dnrx fails to manifest in *wit* mutants. Phenotypic analyses of *dnrx*/*wit* and *dnlg1*/*wit* mutants indicate that Dnrx/Dnlg1/Wit coordinate synaptic growth and architecture at

the NMJ. Our findings also demonstrate that loss of Dnrx and Dnlg1 leads to decreased levels of the BMP co-receptor, Thickveins and the downstream effector phosphorylated Mad at the Neuromuscular Junction (NMJ) synapses indicating that Dnrx/Dnlg1 regulate components of the BMP signaling pathway. Together our findings reveal that Dnrx/Dnlg are at the core of a highly orchestrated process that combines adhesive and signaling mechanisms to ensure proper synaptic organization and growth during NMJ development.

Title: Compartmentalized regulation of the InR/PI3K pathway by the Prl phosphatase directs spatial specificity of CNS synaptogenesis

Authors: *O. URWYLER[1,2], A. IZADIFAR[2], S. VANDENBOGAERDE[2], K. VINTS[3], A. KREMER[3], D. SCHMUCKER[2]
[1]Inst. of Mol. Life Sci., Univ. of Zürich, Zürich, Switzerland; [2]VIB & KU Leuven, Leuven, Belgium; [3]VIB BioImaging Core, Leuven / Gent, Belgium

Abstract: Precise subcellular and spatial control of synapse number or synapse type is of central importance for CNS circuit development. We use genetic tools and correlative light and electron microscopy (CLEM) to investigate synaptogenesis at single-neuron resolution in the *Drosophila* CNS. In an *in vivo* RNAi screen and subsequent validation with loss-of-function mutants, we uncovered a role for Phosphatase of regenerating liver (Prl-1) specifically in spatially restricted formation of synapses. Loss of Prl-1 strongly reduces the number of presynaptic endings at terminal axonal arborizations but not the number of en-passant synapses. Our results indicate that the synaptogenic function of Prl-1 involves an axon branch specific regulation of the Insulin Receptor - Pi3K pathway, as well as compartmentalized activation of Akt. We propose a model of the cellular and molecular mechanisms for Prl-1 mediated modulation of signaling pathways that control spatial specificity of synapse formation in the developing CNS.

Title: Electrophysiological correlates of simulated language acquisition in autism spectrum disorder

Authors: *E. ISENSTEIN[1], A. KEY[2], J. H. FOSS-FEIG[1]
[1]Seaver Autism Ctr., New York, NY; [2]Dept. of Hearing and Speech Sci., Kennedy Ctr. for Res. on Human Develop., Nashville, TN

Abstract: BACKGROUND: Autism spectrum disorder (ASD) is a neurodevelopmental disorder affecting 1 in 68 children. Almost 40% of affected individuals never develop speech, and lack of language skills associates with cognitive impairment and poorer functional outcomes in this population. Therefore, understanding the neural basis of language learning in ASD can provide insight into a core deficit. It also may inform who will benefit from certain language interventions and treatment options.
METHOD: EEG data were recorded continuously at 1000Hz using a 128-channel geodesic net for 28 individuals (15 with ASD; 13 typically developing (TD)) who heard prerecorded “non-word” stimuli during a passive-listening task meant to simulate language learning. A randomly selected non-word was repeated 50 times throughout the paradigm; all other non-words were presented once. Following pre-processing procedures, amplitude and latency for the positive deflection 250-550ms after stimulus onset were extracted over temporal-parietal electrodes, separately for Repeated and Single stimuli.
RESULTS: Both groups (ASD, TD) showed significant differentiation of neural response to Repeated versus Single non-word stimuli: both showed greater amplitude in the Repeated condition (main effect, $F(1,26)=5.34$, $p<.05$). However, latency differences were observed between groups. Across Conditions, latency was faster in ASD, (main effect of Group, $F(1,26)=10.85$, $p<.01$). However, whereas latency was faster to Repeated versus Single non-words in TD, latency was slower to Repeated vs. Single non-words in ASD (Group-by-Condition Interaction, $F(1,26)=5.41$, $p<.05$).
CONCLUSION: Our results demonstrate significant differences between ASD and TD in the electrophysiological response to language-like stimuli. In TD, neural response is quicker for repeated stimuli, likely reflecting a learning effect wherein repeated (learned) words are

processed more efficiently. In ASD, however, response latency was slower to repeated non-word stimuli. This finding could indicate an attention bias to novel words and, consequently, fewer cognitive resources for processing repeated words. The end result of such a bias may be slower, less efficient processing of stimuli to be "learned." Notably, both groups showed greater amplitude to Repeated non-word stimuli, demonstrating that language learning is associated with more robust neural response regardless of diagnosis. Coupled with this amplitude finding, the ASD latency finding could suggest that language learning (i.e. response to repeated non-word stimuli) occurs in ASD, but is associated with relative slowing of neural processing.

Title: Microstructure and morphometry of the pons in response to balance training in individuals with autism

Authors: *I. GALLAGHER[1], A. GOMEZ[1], O. DADALKO[1], K. MCLAUGHLIN[1], O. J. SURGENT[1], B. KOEHN[1], B. TRAVERS[2,3,1]
[1]Waisman Ctr., Madison, WI; [2]Occup. Therapy Program in the Dept. of Kinesiology, Madison, WI; [3]Univ. of Wisconsin-Madison, Madison, WI

Abstract: Background: Autism spectrum disorder (ASD) is a neurodevelopmental disorder defined by continuous deficits in both verbal and nonverbal communication, and the presence of restricted and/or repetitive behaviors. Individuals with ASD have been shown to exhibit challenges in postural stability that have been positively associated with autism symptom severity. The pons region of the brainstem is known to subserve postural stability, but it is unclear how the pons microstructure and/or volume is associated with postural stability in ASD, and whether a balance-training intervention changes neurobiological properties of the pons. **Objective**: To examine how the pons morphometry, myelin volume fraction, and tissue microstructure relate to postural stability in ASD before and after intensive balance training. **Methods**: The study involved over 30 adolescents with ASD and typical development (TD) who participated in 6-week balance training (balance group) or sedentary computer games (control

group). Postural sway area was calculated under eyes-open, eyes-closed, and biofeedback conditions. High-resolution structural MPnRAGE scans measured morphometric properties; brainstem-optimized DWI and McDESPOT images assessed tissue microstructure and myelin volume fraction, respectively.
Results: Within the ASD group, morphometry of the pons was insignificantly related to the postural stability measures, but myelin volume fraction of the pons showed significant association with mean sway area. Tissue microstructural properties of the pons associated with postural stability measures pre- and post-balance training differently in the ASD group compared to TD individuals.
Conclusions: The results indicate that in ASD higher myelination but not mean volume is related to more postural sway (i.e., poorer balance). Considering that higher myelination is positively associated with balance in TD individuals, our results suggest that there may be a compensatory developmental mechanism in ASD. Future research will focus on investigating what subregions within the pons (i.e., gray matter nuclei or white matter substructures) relate to postural stability in individuals with ASD and how tissue microstructural properties may change with balance training in ASD and typical development.

Title: Comparative study of supression of neuroinflammation by resveratrol and curcumin in the experimental paradigm of autism spectrum disorders

Authors: *R. BHANDARI[1], A. KUHAD[2]
[1]Panjab Univ., Chandigarh, India; [2]Panjab Univ., CHANDIGARH, India

Abstract: Objective: Neuronal dysfunction caused as a result of neuroinflammation triggered by the stimulation of matrix metalloproteinases and the subsequent release of pro-inflammatory cytokines is one of the probable mechanisms involved in the pathogenesis of autism spectrum disorders (ASD). The aim of the present study was to compare the ameliorative potential of resveratrol and curcumin on neuroinflammation in the experimental paradigm of neuroinflammatory model of ASD in rats
Method: 1M Propanoic acid (PPA)(4µl) was infused over 10 minutes into the anterior portion of the lateral ventricle to induce ASD like symptoms in rats. Resveratrol (5, 10 and 15 mg/kg) as well as curcumin (50, 100 and 200 mg/kg) was administered starting from the 2nd day of the

surgery and continued upto 28th day. Rats were tested for various behavioural paradigms such as social interaction, stereotypy, locomotor activity, anxiety and novelty, depression, spatial learning and memory, repetitive and pervasive behaviour between the 7th day and 28th day. In addition, biochemical tests for oxidative stress, mitochondrial complexes, TNF-α and MMP-9 were also assessed.
Results: Intracerebroventricular injection of propanoic acid produced neurological, sensory, behavioural, biochemical and molecular deficits which were assessed as endophenotypes of autism spectrum disorders. Treatment with resveratrol as well as curcumin for four weeks restored, significantly and dose dependently, all these endophenotypes in PPA induced ASD in rats. It was found that curcumin is more potent antioxidant even at low doses as indicated from its ability to reduce nitrite levels, Complex 4 activity as well as GSH levels. Also its effectiveness in restoring sensorimotor dysfunction, locomotor activity as well as memory and pervasiveness as compared to resveratrol could give an indication of this.
Conclusion: The major finding of the study is that though both resveratrol as well as curcumin could restore the core and associated symptoms of autistic phenotype by suppressing oxidative-nitrosative stress, mitochondrial dysfunction, TNF-α and MMP-9 expression in PPA induced ASD in rats. However, on comparison curcumin appears to be more potent antioxident but it needs further investigation.

Title: Sensory challenges in autism are associated with microstructural atypicalities in the brainstem

Authors: *B. TRAVERS[1,2], O. DADALKO[3], K. AUSDERAU[3,2], K. MCLAUGHLIN[3]
[2]Occup. Therapy Program in the Dept. of Kinesiology, [3]Waisman Ctr., [1]Univ. of Wisconsin-Madison, Madison, WI

Abstract: Background: Autism spectrum disorder (ASD) is a neurodevelopmental disorder effecting 1.5% of the US population. An estimated 40-90% of individuals with ASD experience debilitating sensory symptoms, including hypo- and hyper-responsiveness as well as sensory seeking and enhanced perception. Neurobiological causes of such behavioral impairments are not well understood, encumbering the search for effective treatments. Lesion studies and research in animal models suggest that sensory challenges may stem from the aberrant neurophysiology in the brainstem. Examining how brainstem substructures are associated with sensory symptoms in ASD will provide neurobiological basis for these symptoms, leading to the development of effective treatments.Objective: To examine microstructure in select white matter tracts and gray matter nuclei of the brainstem in children with ASD and how it relates to their sensory symptoms. Methods: More than 40 children with ASD and without ASD (6-10 years of age) participated in this study. High-resolution structural MPnRAGE scans were used in combination with the brainstem-optimized DWI images to achieve highly precise segmentation of the brainstem substructures. DTI indices (fractional anisotropy [FA], axial, mean, and radial diffusivity) were measured to assess tissue microstructure in select ROIs of the brainstem. Highly precise segmentation was achieved using MRTrix software. Sensory features were measured using the Sensory Experience Questionnaire, 3.0, a caregiver-report tool. Results: Within the ASD group, hypo-responsivity alone was highly associated with the microstructure of the brainstem pyramidal tracts (as measured by FA). Intriguingly, no sensory features in ASD were related to the microstructure of the medial lemniscus, which is commonly considered a sensory tract.
Conclusions: To our knowledge, this study is the first to provide a quantitative characterization of brainstem white matter microstructure in relation to the sensory challenges commonly reported in ASD. Further analyses will examine sensory features in ASD as a function of additional brainstem nuclei.

Title: Generation of microglial developmental index: Bridging the gap between mice and humans

Authors: *R. HANAMSAGAR[1], M. ALTER[2], C. L. BLOCK[3], H. SULLIVAN[4], J. L. BOLTON[5], S. D. BILBO[6]
[1]Lurie Ctr. for Autism, Massachusetts Gen. Hosp., Charlestown, MA; [2]Univ. of Pennsylvania, Philadelphia, PA; [3]Pscyhology and Neurosci., [4]Duke Univ., Durham, NC; [5]Dept. of Anat. & Neurobio., Univ. of California-Irvine, Irvine, CA; [6]Pediatrics, Harvard Med. School/MGH, Charlestown, MA

Abstract: Purpose: Considering the critical role of microglia in integration of neurons into brain, proper circuitry and synaptic pruning, there is a pressing need to understand 1) mechanisms underlying normal and abnormal microglia development, 2) their interactions with specific neuronal subsets, and 3) the utility of microglial analyses in preclinical models for human tissue. The goal was this study was (i) to analyze microglial development over time in purified mouse tissue using a data simplification strategy, (ii) to assess potential sex differences in the microglial development, (iii) to assess sex differences in the microglial response to immune challenge, and (iv) to adopt and validate via multiple measures the same data simplification strategy for analyzing heterogeneous human brain tissue.
Materials & Methods: We isolated microglia from male and female mice hippocampi from different developmental ages from embryonic day 18 (E18) to postnatal day 60 (P60). Following whole transcriptome analysis in purified microglia, we developed a microglia-specific developmental index (MDI) based on global gene expression patterns. Specifically, genes were identified based on whether they were significantly up- or down-regulated during development and gene expression was scaled to equally weigh all genes. MDI was calculated by taking the ratio of the averaged scaled expression of all developmentally up-regulated genes and that of all the down-regulated genes for each sample. To measure microglial development in human brain tissue samples, genes common between purified microglial transcriptome and the human brain transcriptome datasets were identified. Developmentally regulated genes were identified and a sub-index for each human sample as calculated as above.
Results: MDI tracked with chronological age as expected in purified microglia. As microglia developed, the expression of immune-related molecules increased. At P60, female microglia were more developed than male microglia, but male microglia were more immune reactive than female microglia. Using multiple validation tests, we showed that MDI derived from mice can be applied to human brain transcriptome datasets. Upon applying MDI to human transcriptome datasets of autism, we found that in the diseased brain, microglial development is significantly accelerated compared to controls.
Conclusion: In conclusion, we show that microglial development is closely related to immune activity and can be used to determine the immunoreactive state in healthy and diseased human brain.

Title: Age-related cortical thickness differences in adults with autism spectrum disorder

Authors: *C. RIECKEN[1], *C. RIECKEN[1], B. B. BRADEN[2]
[1]Speech and Hearing Sci., Col. of Hlth. Solutions, Tempe, AZ; [2]Dept. of Speech and Hearing Sci., Arizona State Univ. - Tempe Campus, Tempe, AZ

Abstract: Age-Related Cortical Thickness Differences in Adults with Autism Spectrum Disorder
Background: Over the course of the last 30 years, autism spectrum disorder (ASD) diagnoses have grown exponentially, thus identifying a large group of aging individuals with ASD. Currently, little is known about how aging will affect these individuals on a neuroanatomical level, compared to aging in a typically developing (TD) population. Brain aging in ASD is of concern due to the anatomical overlap of ASD-related pathology and age-related cortical thinning. Both phenomenon follow an anterior-posterior severity gradient, resulting in frontal lobe vulnerability and relative sparing of the occipital lobe.
Methods: To investigate whether adults with ASD experience exacerbated brain aging, compared to TD adults, two studies were performed using available data from the Autism Brain Imaging Data Exchange (ABIDE). The first study compared differences in cortical thickness via FreeSurfer between ASD (n=16) and TD (n=14) participants in two age groups: young adults (YA), between 18 and 25 years of age (n = 30) and middle-aged (MA), from 39 to 58 years of age (n = 30). There were no significant differences in IQ between ASD and TD participants within YA and MA groups. The second study compared correlations between cortical thickness and age in adult ASD (n = 146) and TD groups (n = 160), controlling for IQ, to investigate the interaction of cortical thickness and age between the two groups.
Results: Study 1 found significant interactions between diagnosis group (ASD and TD) and age group (YA and MA) for the frontal and parietal lobes, and the interaction approached significance for the temporal lobe. As predicted, no interaction was observed for the occipital lobe. Study 2 found significant differences between diagnosis groups in the relationship between age and cortical thickness for areas of the left anterior insula, middle, inferior, and fusiform temporal gyri, and superior parietal cortex. Both studies demonstrated greater age-related cortical thinning in adults with ASD, compared to TD.
Conclusion: As predicted, adults with ASD demonstrated exacerbated age-related brain differences, as measured by cortical thickness, compared to TD. These difference largely followed the anterior-to-posterior gradient, with relative sparing of the occipital lobe. Findings

demonstrate significant age-related anatomical differences between ASD and TD individuals into middle-age years. Future work is warranted to investigate whether differences in brain age trajectories will translate to unique behavioral needs in older adults with ASD.

Title: Age-related developmental changes in the neural response to faces from childhood through adolescence in autism spectrum disorder

Authors: *D. YANG[1,2,3], A. WESTPHAL[3], K. A. PELPHREY[1,2]
[1]Autism & Neurodevelopmental Disorders Inst., The George Washington Univ., Ashburn, VA; [2]Children's Natl. Hlth. Syst., Washington, DC; [3]Yale Univ., New Haven, CT

Abstract: Objective: In typically-developing individuals, recent neuroscientific research demonstrates age-related growth in the face selectivity of the fusiform face area (FFA; Peelen et al., 2009, Dev Sci, 12, F16-25; Gomez et al., 2017, Science, 355(6320), 68-71). However, it remains unclear whether individuals with Autism Spectrum Disorder (ASD) exhibit similar developmental trajectories. Here, we examined age-related changes in the neural response to faces in children and adolescents with ASD.
Methods: Participants included 40 youth (10 females) diagnosed with ASD (age *M*=10.18, *SD*=4.03; IQ *M*=95.47, *SD*=23.32), characterized using gold-standard diagnostic tests. During fMRI at 3T, participants viewed alternating 5 blocks of fearful faces (FACE; 12 sec per block) and 5 blocks of houses (HOUSE; 12 sec per block). The fixation (FIX) at the beginning (10 sec) and end (20 sec) was treated as an implicit baseline. The group-level fMRI analysis utilized mixed-effects modeling and was thresholded at $Z>2.33$ (voxel) and $p<.05$ (cluster), with IQ and sex as covariates of no interest.
Results: Across the whole brain, on average, neural response to FACE>FIX was observed in the fusiform gyrus, while the neural response to HOUSE>FIX was observed in the parahippocampal gyrus. Moreover, the whole-brain analysis showed that age was linearly and positively correlated with the level of activation to FACE>FIX specifically in the fusiform gyrus. The scatterplot between age and activation within the region is illustrated in **Figure 1**. In contrast, there were no age-related neural correlates with the contrast of HOUSE>FIX across the whole brain.
Conclusions: The results revealed that in ASD, there was an age-related increase in the neural response to FACE>FIX from childhood through adolescence (4-17 years of age) in the fusiform gyrus. The results are specific to this contrast and this brain region, as there were no age-related

correlates in the contrast of HOUSE>FIX, and the age correlates were seen particularly in the fusiform gyrus, but not elsewhere in the brain.

Title: Neurofunctional properties of cognitive reappraisal for circumscribed interests in autism

Authors: *L. D. ANTEZANA, M. C. COFFMAN, J. A. RICHEY
Dept. of Psychology, Virginia Tech., Blacksburg, VA

Abstract: Background: Autism spectrum disorder (ASD) is characterized by restricted and repetitive behaviors (RRB) and difficulties in social communication. Circumscribed interests (CI) are one of the key features of RRB. While it is known that individuals with ASD demonstrate increased affective responses toward CI images (e.g., hyperarousal; Sasson et al., 2012), it is unknown whether approach-related motivation is a consequence of broader deficits in executive function, particularly emotion regulation (ER). Prior neuroimaging work from our group has highlighted that social deficits in ASD may be related to impaired ER mechanisms in ASD (Richey et al., 2015), however this principle is less understood in the context of CI.
Objective: To apply an ER framework and identify specific neurofunctional impairments in ASD that may underlie emotional responses to CI images using fMRI during ER instructions in adults with ASD versus matched controls (CON).
Hypotheses: We hypothesize that the ASD group will have difficulty modulating affect toward CI, as demonstrated by decreased dorsolateral prefrontal cortex (dlPFC) activation during ER instructions, compared to CON.
Methods: A total of 30 adults (ASD=15; CON=15) participated in this study. Groups were matched on age (ASD M=26.1; CON M=27.4) and IQ (ASD M=113.3; CON M=116.3). fMRI data were collected during an ER task on a 3T General Electric Signa Excite HD scanner. For stimuli, each individual with ASD was asked to bring ten photographs of their CI. After standardized training in cognitive ER techniques, participants viewed each image for 4 seconds (free viewing period) and were then asked to "Think Positive," or "Think Negative" about the images. To control for intra-individual variation (between ASD and CON) in the subjective level of interest in a CI image, we covaried for self-reported arousal and affective valence in our fMRI models.
Results: Whole-brain analyses revealed group differences between ASD and CON groups for think-negative vs. baseline (pre-instruction) and think-positive vs. baseline conditions ($p<0.05$). Contrary to predictions, the control group showed significantly increased activation in the precuneus and posterior cingulate cortex (PCC), compared to the ASD group for both conditions.
Conclusions: Individuals with ASD showed decreased activation in PCC, a region thought to be related to self-referential processing (Lynch et al., 2013) during ER instructions for CI. These results held after covariate adjustments for arousal and valence. These findings may indicate that modulation of self-referential processing, rather than emotion, may be linked to approach-related symptoms such as CI.

Abstract: Background: Autism spectrum disorders (ASDs) are a phenotypically and etiologically complex group of neurodevelopmental conditions that are broadly behaviorally defined as clinical phenotypes involving communicative, social, and behavioral impairments. There has been considerable lag in progress made towards understanding the relationship between suspected disease gene variants in ASD and how these variants result in the cell-based phenotypes to which they are associated.
Objective: The aim of this study is to identify key differences in the function of important neurobiological processes, and in the expression patterns of molecular gene networks that regulate them, both in a temporal and neural-specific manner.
Methods: We examined the transcriptional differences between cortical neurons from patients with idiopathic ASD and healthy unaffected control individuals over the course of their in vitro development. We derived iPSCs from peripheral blood mononuclear cells (PBMCs) from idiopathic ASD individuals (DeRosa et al., 2012) and unrelated male controls and differentiated them into cortical neurons over a 135 day time course.
Results: Transcriptional analyses of ASD and control neurons at culture days 35, 85, and 135 of their in vitro development showed ASD-specific molecular phenotypes mainly affecting pathways/networks involved in neuronal differentiation, the cytoskeletal matrix structure formation (i.e. axon guidance and cell migration), regionalization, patterning, DNA and RNA metabolism. Additionally, developing networks of neurons were interrogated with multi-electrode array (MEA) recordings, measurements of calcium transients using Fluo-4, fixed and stained for relevant morphological markers and subjected to cell migration assays at time-points aligning with our transcriptional analyses. Lines from ASD individuals demonstrated significantly decreased network spiking activity from MEA recordings as well as decreased numbers of calcium transients. Additionally, ASD lines showed significant differences in measures of neurite morphology, and decreased cell migration at early neuronal differentiation times.
Conclusions: The results of this study suggest that in iPSC-derived neurons derived from individuals with ASD, there may be early deficits in network activity and morphology based on a combination of cell based assays, including MEA, Fluo-4 measured calcium transients, and quantification of neurite outgrowth that converge with transcriptomic analyses. Taken together, this suggests that for our cohort of individuals with idiopathic autism, there are convergent pathophysiological processes.

Title: Reassessing the autistic phenotype using big-data from the autism brain imaging data exchange repository

Authors: *C. CABALLERO[1], S. MISTRY[2], C. WHYATT[3], E. B. TORRES[4]
[1]Rutgers University. Psychology Dept., Piscataway, NJ; [2]Mathematics, Rutgers Univ., Piscataway, NJ; [3]Rutgers Univ. - Busch Campus, Piscataway, NJ; [4]Psychology Dept, Rutgers Univ. Dept. of Psychology, Piscataway, NJ

Abstract: Large open-access repositories of imaging data sets have initiated a new avenue of enquiry in Autism Spectrum Disorders (ASD). Along with the gaining of access to imaging data from different cognitive and psychological experiments interspersed with resting state (RS) fMRI, it is now also possible to examine large cross-sectional demographic data. This provides unprecedented statistical power to draw inferences about many aspects of the autistic phenotype. Furthermore, several sites provide longitudinal data for the same subjects set, permitting as well the derivation of dynamic outcome measures to track disorder progression, longitudinal effects of medication intake, among other queries that such Big-Data enables. Despite these great benefits to advance basic research and enrich clinical knowledge in ASD, we face several challenges when combining data from different sites in the repository harnessed under disparate sampling resolution (SR). For example, in the Autism Brain Image Date Exchange (ABIDE) data sets some sites have SR above 1Hz while others have SR below 1Hz. Given that several parameters for statistical inference can be derived from imaging data, and queries performed according to demographic data, here we ask if the raw head-motion signal derived from time series acquired under different SR may be representing different stochastic processes according to the noise type their inherent variability has. Using methods to assess stochastic processes and derive noise signatures from head motion data in RS-fMRI, we find that sites across ABIDE I and II repositories with SR above 1Hz have range in the pink-noise regime while those below 1Hz have noise range in the Brownian-motion regime. These results caution against pooling data

from all sites to derive statistical inferences. Further, we provide a new standardized data type (amplitude fluctuations' micro-movements) insensitive to these nuances and perform several queries on sex differences in ASD, medication intake and age-dependent evolution of the stochastic signatures and their rates of change. We report statistically significant differences between (1) ASD and AS females in relation to age-matched TD females; (2) medication vs. no medication intake; (3) age-dependent rates of change in stochastic signatures and further report outcomes on stochastic assessment of longitudinal data. Our results are discussed within the context of dynamic biomarkers for Precision Medicine and Computational Psychiatry.

Title: Early electrophysiological markers of neural network development in infants at risk for autism spectrum disorder (ASD)

Authors: *A. DICKINSON[1], E. LIN[1], A. SCHEFFLER[1], D. SENTURK[1], M. DAPRETTO[2], S. S. JESTE[1]

Abstract: Aberrant neural connectivity is present in adults with autism spectrum disorder (ASD), and is widely cited as a neurobiological mechanism underlying the condition (e.g. Wass, 2011). Connectivity between brain regions develops extensively throughout infancy, underlying the formation of increasingly sophisticated neural networks. Disruptions in neural networks may be evident during infancy, preceding the emergence of ASD symptoms. Investigating early brain development in ASD requires studying infants who are too young to receive a diagnosis but are considered at 'high risk', based on family history of ASD. Using this approach, we can study how early brain development differs in the proportion of children go on to develop ASD.
Large scale synchronous neuronal activity is mediated by the integrity of neural networks. Measurement of oscillatory brain activity using electroencephalography (EEG) can therefore be used to assay neural network development. Oscillations within the alpha range (6-12Hz) show clear developmental changes which reflect developing neural networks (Rodríguez-Martínez *et al.* 2017). Peak alpha frequency (PAF) and alpha band coherence are particularly sensitive to developmental change, both increasing with age during typical development (Miskovic *et al.* 2015; Gmehlin *et al.* 2011).

Here we study spontaneous EEG data collected from 31 high risk, and 29 low risk infants, at 3, 6, 9 and 12 months of age in the UCLA Center of Autism Research and Treatment. PAF was computed by removing the 1/f trend from the calculated power spectra, and fitting a Gaussian curve to accurately capture power modulations in the alpha range. EEG data were transformed into current source density to study phase coherence between electrode pairs. A permutation test with a false discovery rate adjustment for multiple testing, was used to identify electrode pairs which demonstrated significantly altered phase coherence in high risk infants.
Preliminary data analysis suggests that alterations in PAF and alpha phase coherence are present during the first year of life in infants at high risk for ASD. Lower PAF at 6 months of age is also associated with higher degree of ASD concern at 18 months of age. This suggests that variability in the integrity of neural networks during the first year may map onto later clinical heterogeneity. Further analysis will explore how individual variability in the timing and location of neural network disruptions may inform the clinical heterogeneity of ASD. We will discuss the potential utility of scalable electrophysiological markers of network development to facilitate precisely targeted interventions and prediction of outcomes.

Title: Functional connectivity predicts language ability in infants at risk for ASD

Authors: *X. A. TRAN[1], C. KURE LIU[1], A. DICKINSON[1], M. DAPRETTO[2], S. S. JESTE[3]
[2]Dpt Psych & Biobehav Sci., [1]UCLA, Los Angeles, CA; [3]68-237A, UCLA Semel Inst. of Biobehavioral Sci., Los Angeles, CA

Abstract: Evidence from genetics and neuroimaging studies suggests that autism spectrum disorder (ASD) is characterized by disruptions in neural connectivity. Infants with an older sibling with ASD (high risk) are at heightened risk for developing ASD. We examined electrophysiological (EEG) measures of neural connectivity in gamma band oscillations, which are critically involved in cognitive and language development, with a focus on regional coherence. We asked whether: 1) functional connectivity in the gamma band during an auditory

language processing task differs between infants with high risk (HR) for ASD and low risk (LR) infants, and 2) functional connectivity at 3 months can predict language ability at 18 months. Our study is based on an overarching hypothesis that neural connectivity is disrupted in infants at high risk for ASD, with the biggest differences found in those infants who have delayed or atypical development.
Participants included 31 HR infants and 30 LR infants from an ongoing longitudinal study of brain development in high risk infants. EEG was acquired at 3 months while each subject listened passively to a language processing task for 2 minutes. EEG was collected using NetStation, filtered at 1-50 Hz and cleaned using EEGlab. Independent component analysis was applied and non-neural components were removed. Laplacian filter was applied using the CSD toolbox. Functional connectivity (coherence) was calculated between electrode pairs using the EEGlab function “newcrossf”. Mean left frontal-parietal coherence in the gamma frequency band (30-50 Hz) was averaged across left frontal-parietal electrode pairs. Language ability was assessed at 18 months using the Mullen Scales of Early Learning (Mullen). We used independent samples t-test to compare coherence values between HR and LR groups, and Pearson’s correlations to examine the relationship between coherence and Mullen language scores.
HR infants had higher mean left frontal-parietal coherence than LR infants, which was driven by two electrode pairs – “Fp1-P3” and “F9-P9”. In the HR group, coherence in “Fp1-P3” electrode pair negatively correlated with Mullen verbal and expressive language t-scores. Correlations between coherence and language were insignificant in the LR group.
Compared to LR infants, HR infants had higher regional functional connectivity during auditory language processing at 3 months that may be evident of underlying atypical neural connectivity. Elevated functional connectivity in HR infants may serve as an early marker of atypical language development, as this negatively correlated with later language ability.

Title: Hemispheric and developmental differences in the neural processing of mutual eye contact in individuals with autism spectrum disorder

Authors: *K. A. MCNAUGHTON, A. NAPLES, T. C. DAY, M. J. ROLISON, A. CHANG, T. MCALLISTER, J. MCPARTLAND
Child Study Center, Yale Univ., New Haven, CT

Abstract: Autism spectrum disorder (ASD) is defined by differences in processing of social information compared to individuals with typical development (TD). While these differences have been characterized in terms of neural response to static face stimuli, gaze-responsive stimuli offer an opportunity to examine social interactions in a more ecologically valid context. This study expanded on previous research identifying neural markers of dynamic mutual eye contact in adults with TD (Naples et al., 2017) by investigating the neural response to eye contact in children and adults with ASD and TD. Individuals with ASD (n=43, 7 female, age 10-32 years) and individuals with TD (n=48, 21 female, age 8-35 years) matched on age, IQ, and handedness participated in a gaze-contingent experiment with co-registered electroencephalography and eye-tracking. Participants viewed faces that responded to their gaze in four conditions: fixate on eyes, eyes open (eye:eye); fixate on eyes, mouth opens (eye:mouth); fixate on mouth, eyes open (mouth:eye); fixate on mouth, mouth opens (mouth:mouth). The N170, an event-related potential previously identified as a neural marker of eye contact, was analyzed. There was a main effect of condition for N170 amplitude (F(3, 267)=40.27, p<0.01) and N170 latency (F(3, 267)=19.99, p<0.01). N170 response was stronger and faster for mutual eye contact (eye:eye) than for the other three conditions (ps<0.01). There was also a hemisphere by diagnosis interaction for N170 amplitude (F(1, 89)=12.27, p<0.01), in which individuals with ASD had a stronger N170 response in the right hemisphere than in the left (t(42)=3.60, p<0.01), while the response for individuals with TD did not differ between hemispheres (p>0.05). There were developmental differences in latency of N170 response to mutual eye contact (eye:eye) and gaze-contingent mouth movement (mouth:mouth), as indicated by a trending interaction between age and condition (F(1, 88)=3.74, p=0.06). Children under age 16 had faster N170 responses to mutual eye contact compared to mouth movement (t(43)=4.47, p<0.01)) while individuals over age 16 did not differ in response to the two conditions (p>0.05). These results support the N170 as a selective marker for mutual eye contact. They also provide evidence that individuals with autism may demonstrate atypical lateralization patterns during processing of gaze-responsive social stimuli. Given the nature of autism as a developmental disorder and the developmental shifts in the N170 as a marker of mutual eye contact, future research is required to characterize the relationship between this neural marker and social function across the lifespan.

Title: Sex differences in the brain surface area of children with autism spectrum disorders

Authors: *C. CHEN, J. VAN HORN
USC, Los Angeles, CA

Abstract: *Background:* Autism spectrum disorder (ASD) is marked by social communication deficits and restricted repetitive behavior. Sex differences in ASD diagnosis in the U.S. are striking, with a male to female ratio of nearly 5:1 in recent years (Chen, Van Horn et al. 2016). Few research studies have examined sex differences in the neuroanatomy of children with ASD. Those that do have focused on sex differences in brain volume (Bloss and Courchesne 2007, Schumann, Bloss et al. 2010) and have low sample sizes of girls. Our goal is to map sex differences in the brain surface area of girls versus boys with ASD.
Methods: Five research institutions were involved in data collection: USC, UCLA, Seattle Children's Institute, Harvard, and Yale. The sample included 96 children with ASD (44 girls) and 82 typically developing (TD) children (40 girls), ages 7 to 17. Diagnosis was based on the Autism Diagnostic Interview-Revised (Lord, Rutter et al. 1994) and Autism Diagnostic Observation Schedule-II (Lord C. 2012). Freesurfer (Dale, Fischl et al. 1999) was used to determine brain surface area for 146 cortical regions extracted from the Destrieux atlas (Destrieux, Fischl et al. 2010). Multivariate ANOVA analysis was performed on all cortical brain regions, with sex and diagnosis as independent variables. Intracranial volume, pubertal status, handedness, socioeconomic status, and MRI scanner type served as covariates. Multiple comparisons were taken into consideration with a stringent $p<.01$.
Results: A main effect of sex was found on the right lateral occipito-temporal sulcus (rLOTS; $p=.009$), while a main effect of diagnosis was found on the right parahippocampal gyrus (rPG; $p=.003$). A sex by diagnosis interaction was found on the right triangular part of the inferior frontal gyrus (rTIFG; $p=.006$).
Conclusion: Previous research discovered that girls with ASD exhibit greater temporal gray and white matter volumes, relative to boys with ASD (Bloss and Courchesne 2007). Our results indicate that boys have greater rLOTS surface area than girls, while TD children possess greater rPG surface area than ASD children. Additionally, boys with ASD have greater rTIFG surface area compared to girls with ASD and TD boys, while TD girls have greater rTIFG relative to

girls with ASD and TD boys. In contrast to previous findings that girls with ASD have abnormally enlarged volumes in many regions, TD boys and boys with ASD display enlargement in several brain surface areas related to face processing and impulse control (Pageler, Menon et al. 2003, Aron, Robbins et al. 2004). Further research should be conducted to see how these brain regions contribute to sex differences in autistic behavior.

Title: Impact of the enriched environment on the multiunitary activity of the cerebellum in the autistic rat

Authors: *O. E. CRUZ MAGOS[1], G. HERRERA MEZA[2], J. MANZO[3], L. I. GARCIA[4], P. PACHECO[5], J. A. PEREZ, SR[6]
[1]CENTRO DE INVESTIGACIONES CEREBRALES, UNIVERSIDAD VERACRUZANA, Xalapa Enríquez, Mexico; [2]Unidad De Investigaciones Alimentarias (UNIDA) Ins, Xalapa, Mexico; [3]Univ. Veracruzana, Xalapa, Ver. Mexico, Mexico; [4]Ctr. de Investigaciones Cerebrales, Xalapa, Mexico; [5]Inst. de Investigaciones Biomédicas, Univ. Nacional Autonoma de México, Xalapa, Mexico; [6]cerebrales, UV, xalapa, Mexico

Abstract: Autism is a neural developmental disorder that is observed in children as a spectrum of behavioral alterations between 2 and 3 years of age. Although the number of studies in this regard increases annually, significant physiological manifestations that allow to make laboratory diagnoses are still unknown. To date, autism continues to be diagnosed only on the basis of subject's behavior. This is why it is relevant to find approaches to allow physiologicals determinations of the disorder. It is known that one of the structures invariably altered in autistic subjects is the cerebellum. Therefore, in this work we proposed that the encephalographic record of this structure could serve as a basis for spectrum´s physiological analysis. To do this, a posnatal autistic model was used in Wistar rats by the posnatal injection of a daily dose of 150 mg / kg of valproic acid to pups from day P6 to P12. Four groups, Controls (Ct) in standard (SE) and enriched environment (EE), and Autistic (At) in SE and EE were used. All of them had a multi-unit recording of the cerebellar vermis. Results showed that EE increased the cerebellar response amplitude in the Ct, but the At in SE presented a significant increase in the amplitude equivalent to that of Ct-AE, which was reduced when they were submitted to EE. Thus, we first

observe that it is possible to identify encephalographic variations characteristic of autism in the cerebellum cortex, and that these increased variations can return to a Ct level after the subject is submitted to an environmental enrichment program. The significance of this amplitude in the discharge of the cerebellar cortex requires further studies. Conacyt Scholarship No. 574809 (OECM); Cuerpo Academico de Neurociencias (UV-CA-28).

Title: Sex differences in the resting-state functional connectivity of the cerebellum in autism spectrum disorders

Authors: *R. E. SMITH[1], J. AVERY[1], L. KENWORTHY[2], S. J. GOTTS[3], A. MARTIN[4]
[1]Lab. of Brain and Cognition, Natl. Inst. of Mental Hlth., Bethesda, MD; [2]Children's Natl. Hlth. Syst., Washington, DC; [3]Lab. of Brain and Cognition, NIMH/NIH, Bethesda, MD; [4]Natl. Inst. of Mental Hlth., Bethesda, MD

Abstract: Human neuroimaging studies have documented sex-specific differences in the development, structure, and function of the cerebellum (Nguon et al., 2005). This part of the brain, in conjunction with the cortex, is involved in both sensorimotor and socio-affective processes. These two domains of function are both impaired in autism spectrum disorders (ASD), and not surprisingly, the cerebellum has been highlighted in neuroimaging studies of males with ASD. Behavioral studies have also found sex differences in ASD prevalence and phenotype. Given what we know about the relationship between ASD and the cerebellum, and the sex differences associated with each, we were interested in whether there may be sex-dependent changes in the cerebellum's functional architecture in ASD. The aim of the current study was to explore this using resting-state functional magnetic resonance imaging (fMRI). We collected resting-state fMRI scans from 47 women (23 ASD, and 24 controls) and 120 men (56 ASD, and 64 controls), matched on age, head motion and IQ. Using a measure of global functional connectivity, we ran a linear mixed effects analysis across both groups to determine whether there was a sex-by-diagnosis interaction associated with resting state functional connectivity.
Two clusters in the left and right cerebellum exhibited a diagnosis-by-sex interaction in global

connectivity ($p < 0.005$ with small volume correction in the cerebellum). Compared to controls, females with ASD showed *hyper*connectivity between those cerebellar clusters and the cortex, whereas males with ASD showed the opposite pattern (*hypoco*nnectivity with the rest of the brain). Follow-up analyses of seed-based connectivity effects underlying these global connectivity differences (using a 6mm spherical region of interest centered on the peak voxel in each cerebellar cluster) revealed significant diagnosis-by-sex interactions between the cerebellum and several cortical regions including the right fusiform, right inferior frontal gyrus, right precentral gyrus, mid-cingulate, precuneus, middle temporal gyrus, and thalamus.
These results shed light on the sex-specific pathophysiology of ASD. This pattern of sex-dependent, aberrant cerebellar connectivity in ASD might explain some of the abnormalities in motor and socio-affective abilities seen in this population.

Title: Brain-wide mapping of the developmentally regulated expression of the oxytocin receptor in mice

Authors: *Z. T. NOLAN[1], S. HIDEMA[2], K. NISHIMORI[3], Y. KIM[4]
[1]Penn State Col. of Med., Hershey, PA; [2]Mol. Biol., Grad. Sch. of Agr. Sciences/Tohoku Un, Sendai-Shi, Japan; [3]Tohoku Univ., Sendai, Japan; [4]Col. of Medicine, Penn State Univ., Hershey, PA

Abstract: Oxytocin is a neuropeptide whose functions include the development and expression of social behavior. Impairment of oxytocin signaling has been implicated in many neurodevelopmental disorders such as autism. The oxytocin receptor (OxtR) is the main mediator of oxytocin ligand. Despite its significance, brain-wide spatial and temporal expression patterns of OxtR remain largely unknown. To investigate this, we have examined the expression patterns of oxytocin receptor positive neurons throughout the whole brain at developmental time points (P7, P14, P21, P28) and in adulthood (P56) using a transgenic reporter line (OxtR-Venus). This data was acquired using a scanning serial two-photon tomography and a data processing

pipeline that allows us to map fluorescently labeled cells throughout the entire brain with standardized 3D atlases. We found that overall expression peaks at P21. Moreover, OxtR neurons in different brain regions showed quantitatively different developmental regulation. For instance, we found that endopiriform nucleus expresses OxtR from P7 through P28 peaking at P21. The anteromedial nucleus of thalamus however, does not begin to express OxtR until P14 and continues to increase expression through P28. We then asked whether decreased oxytocin receptor positive neurons in adult is caused by programmed cell death or receptor downregulation without cell death. We tracked cumulative OxtR expression by using OxtR-cre:Ai14 (cre dependent expression of tdTomato) in different developmental periods. We did not observe a decreased number of cells in the OxtR-cre:Ai14, suggesting that OxtR expression decreased without cell death. We envision that our highly detailed OxtR expression map will guide future circuit based investigation to understand mechanism of oxytocin signaling in various behavioral assay. Our future work will be directed at determining if this developmental profile of the oxytocin receptor is altered in mouse models of autism spectrum disorder.

Title: Cyclic adp-ribose and heat regulate oxytocin release via cd38 and trpm2 in the hypothalamus during social or psychological stress in mice

Authors: *S. AMINA[1,2], H. HIGASHIDA[3]
[2]MIND Inst., [1]Univ. of California, Davis, Sacramento, CA; [3]Dept. of Basic Res. on Social Recognition and Memory, Res. Ctr. for Child Mental Dev, Kanazawa Univ., Kanazawa, Japan

Abstract: CD38, a transmembrane protein that triggers proliferation and immune responses in lymphocytes. cADPR, catalyzed by CD38, was considered as an intracellular second messenger. But how it exerts its role in neurons was unknown. Using a neuronal cell line, NG108-15 mouse neuroblastoma x rat glioma hybrid cells, it was shown that extracellular application of cADPR, together with heat, activates cation influx downstream of OT receptor signaling in neuronal cells. Our data further suggested that a possible involvement of TRPM2 channels in OT release in the mammalian brain. As a next step, we investigated and found similar effect in intact mouse hypothalamus primary cell culture. In addition, we recently reported that OT release from the isolated hypothalamus of male mice in culture was enhanced by extracellular application of

cADPR. This OT release differed markedly between individual mice when they were group housed, due to stress. That is, when male mice received cage-switch stress and eliminated due to their social subclass, significantly higher levels of OT release were found in subordinates compared with ordinates. These results showed that cADPR/CD38 and heat/TRPM2 are co-regulators of OT secretion and suggests that CD38 and TRPM2 are potential therapeutic targets for OT release in psychiatric diseases caused by social stress.

Title: Discriminating between attention deficit hyperactivity disorder and autism spectrum disorder using surface-base resting state functional connectivity

Authors: *M. JUNG, Y. TU, C. LANG, J. KONG
Dept. of Psychiatry, Massachusetts Gen. Hosp., Harvard Med. Sch., Charlestown, MA

Abstract: Introduction: Attention-deficit hyperactivity disorder (ADHD) and autism spectrum disorder (ASD) are highly prevalent neurodevelopmental disorders, and are often comorbid with one another. The underlying neurological mechanisms of this comorbidity, as well as the distinction between the two disorders remain unclear. This study aimed to construct diagnostic models for ADHD and ASD based on resting state functional brain connectivity using support vector machine (SVM) classification. **Methods:** Data from individuals with ASD (n = 86; mean age, 11.4 ± 2.1 years) and typical development (TD) (n = 125; mean age, 10.9 ± 1.6 years) were obtained from the Autism Brain Imaging Data (ABIDE). Data from individuals with ADHD (n = 83; mean age, 11.2 ± 1.9 years) were taken from the ADHD-200 data set (http://fcon_1000.projects.nitrc.org/indi/adhd200/). To investigate diagnostic features between ADHD and ASD, ROI-to-ROI (162x162 brain regions) functional connectivity analysis was

performed based on gray matter surface parcellation in each participant using FreeSurfer. The parcellation was based on the Desikan-Killiany parcellation atlas. A feature selection approach combining univariate t test and multivariate support vector machine-recursive feature elimination (SVM-RFE) was used to identify the most discriminative features between three groups: TD vs. ASD, TD vs. ADHD and ASD vs. ADHD. We classified the three groups (two-by-two) using a 10-fold cross-validation. **Result** The classification accuracies for discriminating TD from ASD, TD from ADHD and ASD from ADHD were 76.3% (sensitivity 82.4%, specificity 61.7%), 84.1% (sensitivity 88.0%, specificity 78.3%), and 79.1% (sensitivity 79.1%, specificity 80.1%), respectively. **Conclusions:** Our findings demonstrate the potential of discriminating ASD from ADHD, as well as ASD and ADHD from TD with surface-based resting state functional connectivity analysis. **Acknowledgement:** Jian Kong is supported by R01AT006364, R01AT008563, P01 AT006663, R61AT009310, and R21AT008707 (NIH / NCCIH). Title: Sex-related patterns of intrinsic brain function in females with autism

Authors: *D. FLORIS[1], M.-C. LAI[2], M. P. MILHAM[3], A. DI MARTINO[1]
[1]Dept. of Child and Adolescent Psychiatry, NYU Child Study Ctr., NYU, New York, NY; [2]Psychiatry, Child and Youth Mental Hlth. Collaborative at the Ctr. for Addiction and Mental Hlth. and The Hosp. for SIck Children, Toronto, ON, Canada; [3]Ctr. for the Developing Brain, Child Mind Inst., New York, NY

Abstract: Introduction In studying the role of biological sex in autism spectrum disorder (ASD), we previously demonstrated coexisting patterns of both shifts towards masculinization and feminization in the intrinsic functional brain properties of males with ASD. Such characterization was not possible in females due to the limited availability of female ASD datasets before. The recent expansion of the Autism Brain Imaging Data Exchange (ABIDE) has overcome this limit allowing for the examination of sex differentiation in the intrinsic brain in females with ASD. **Methods** To explore whether atypical intrinsic brain properties in females with ASD show atypical masculinization and/or feminization, we calculated the spatial overlap between four statistical group difference maps stemming from an autism dataset of females

(ABIDE; ASD vs. neurotypicals [NT]) and an independent normative sample (NT males vs. NT females). The ABIDE sample comprised resting state fMRI (R-fMRI) data from 251 neurotypical females and 111 females with ASD (5.2-46.6 years of age). The normative sex difference sample comprised 471 NT males (NT M) and 357 NT females (NT F; age 8-85 years) selected from the 1000 Functional Connectome Project. We examined a range of R-fMRI measures previously shown to be atypical in ASD and be affected by biological sex. Spatial overlap (conjunction) analyses were performed with logical 'AND' masking of the statistical maps stemming from the ABIDE (ASD vs. NT) and FCP (NT M vs. NT F) comparisons. Two pairs of contrasts represented masculinization (ASD>NT AND NT M> NT F; NT>ASD AND NT F>NT M) and another two represented feminization in ASD (ASD>NT AND NT F>NT M; NT>ASD AND NT M>NT F). Statistical significance was based on the null distribution of random overlap estimated based on 5000 Monte Carlo simulations for any voxel-level thresholds between p=0.05 and 0.0001. **Results** Across all R-fMRI metrics there were consistent, non-random overlaps between regions showing normative sex differences and those showing ASD-NT differences, irrespective of the voxel-level threshold. Similar to previously shown in males with ASD, regions exhibiting masculinized patterns mainly centred around frontal and posterior regions of the default network. Feminization was less pronounced and mainly around somatomotor and ventral attention networks. **Conclusion** These results suggest that atypical intrinsic brain properties of females with ASD partly reflect atypical sexual differentiation. Given the mixed pattern of feminization and masculinization, it is possible that factors involved in typical sex mosaicism are involved in the neurobiology of ASD.

Title: Atypical functional connectome gradients in autism

Authors: *S.-J. HONG[1,2], R. VOS DE WAEL[1,2], S. L. VALK[3], D. S. MARGULIES[4], B. C. BERNHARDT[1,2]
[1]Multimodal Imaging and Connectome Analysis Lab., Montreal, QC, Canada; [2]Montreal Neurolog. Inst., Montreal, QC, Canada; [3]Dept. of Social Neurosci., Max Planck Inst. for Human Cognitive and Brain Sci., Leipzig, Germany; [4]Max Planck Inst. For Human Cognitive and Brain Sci., Leipzig, Germany

Abstract: ***Background.*** Autism spectrum disorder (ASD) is a life-long condition increasingly conceptualized in terms of aberrant brain connectivity [1]. The behavioral symptomatology has

been related to both low- and high-level functions, ranging from atypical sensory processing to disrupted social interactions and language [2]. To study anomalies along the hierarchical organization of the functional connectome in autism, we used a non-linear dimensionality reduction technique to map the principal gradient representing spatial variations in whole-brain connectivity.

Methods. We studied 107 subjects with ASD and 113 typically developing controls from the autism brain imaging exchange (ABIDE) dataset [3]. In all subjects, we mapped resting-state functional MRI signals to corresponding cortical surface models, followed by 3mm surface-based smoothing and the generation of high-dimensional functional connectomes between all pairs of surface-points. Applying a diffusion embedding algorithm [4] to the connectomes identified principal modes/ gradients of connectivity variation across regions. Surface-based linear models compared cortical gradient values between ASD and controls.

Results. Compared to controls, individuals with ASD showed significant alterations in gradient organization (**FIGURE**). Specifically, we observed decreases in gradient strength primarily in bilateral medial and anterior prefrontal cortices - regions co-localizing with core hubs of the default mode network. On the other hand, we observed gradient increases mainly in fronto-parietal and attention networks.

Conclusion. By using a novel connectome gradient mapping, we studied whole-brain functional organization in ASD, and demonstrated an imbalance in the segregation of large-scale functional systems. Further studies will clarify the behavioral relevance of these system-level network reconfigurations.

Figure. Altered functional connectome gradients in autism spectrum disorders | A) Group-level functional gradient maps were computed based on averaged similarity matrices of whole-brain connectivity across controls (=113) and individual with autism spectrum disorders (=107). B) A statistical linear model identified group-level differences between controls and ASDs, after correcting for the effects of age, site (*i.e.*, NYU, USM, PITT) and indices of functional signal quality (*i.e.*, Mean framewise displacement and the number of framewise displacement > 0.2mm). The clusters survived for family-wise error controls (random field theory) were highlighted with a sold boundary while the tendency was shown with a semi-transparent color. To help the understanding, an established functional parcellation map (Yeo TT, et al. *J Neurophysiol.* 2011) was shown, indicating specific subnetworks affected in ASD.

Title: Analyzing functional connectivity underlying social/communicative deficits in an autism mouse model

Authors: *B. AN[1], E. THOMSON[2], L. JARED[2], A. H. SUGI[2], A. J. PADILHA[2], C. BAKISKAN[2], M. NICOLELIS[2]

Abstract: Autism spectrum disorder (ASD) is a group of neurobiological developmental conditions which are characterized by impaired social/communication abilities and stereotypic behaviors. There has been growing consensus that ASD is associated with aberrant anatomical and functional connectivity throughout the brain, although its neurobiological origins have not been fully elucidated. To examine brain connectivity patterns involved in social/communication impairments of ASD, we employed an ASD mouse model that lacks cereblon gene (CRBN) which has been shown to be involved in intellectual disabilities and speech delay. We examined behaviors of ASD mice in a social context where a mouse was introduced to a stranger mouse, and found that ASD mice displayed less interaction with a stranger mouse and profoundly less vocalization compared to wild type mice. We then investigated whole brain functional connectivity among 16 brain areas implicated in ASD, such as prefrontal cortex, striatum, and amygdala in the social context. We found that signal power throughout the brain of ASD mice was altered: in particular, theta band power was decreased in multiple brain regions, including the striatum and nucleus accumbens (NAc). We further examined pairwise coherence between all recorded regions, and found that theta power coherence was increased between limbic structures of ASD mice. An analysis of functional connectivity, using Granger causality analysis, showed that the amygdala of ASD mice receives stronger inputs from prefrontal cortex, striatum and NAc, suggesting that emotional representation might be altered in ASD mice.

Title: Subclinical markers of autism affect low-level visual information processing

Authors: *A. ALINK[1], N. HASSAN[2], F. BOXFORD[2], A. RUNGAPILLAY[2], *S. ONAT[1], C. BÜCHEL[1], I. CHAREST[2]

Abstract: Previous research suggests that individuals with autism spectrum conditions (ASC) exhibit atypical visual information processing. It is unclear, however, whether visual information processing differs solely between healthy participants and individuals with clinical ASC or whether visual information processing is in general affected by markers of autism. To assess this, we developed a novel experimental paradigm which allows us to obtain a measure of how low-level features of objects contribute to successful object recognition - which we refer to as visual feature diagnosticity (VFD). During the experiment, visual features of cat and dog portrait images were extracted using 1000 Gabor wavelets varying in position, orientation and spatial frequency. On a given trial, participants were presented with a random sample of these features (150) and performed a cat vs. dog classification task. 48 healthy participants took part in this study which included an assessment of their autism-spectrum quotient (AQ) scores - which were all subclinical (below 32). 1000 VFD values for each of the ten stimuli (five cats and five dogs) were obtained for each participant. We determined how VFD values varied as a function of AQ score using a mixed linear model analysis. Because an atypical processing of eyes and of local vs. global information is frequently reported in ASC research we included spatial frequency of visual features and the distance of visual features from the nearest eye as additional predictors in the model. We observed a significant interaction between AQ scores and the distance of a visual feature from the nearest eye. This indicated that a general tendency of visual features closer to the eyes being more important for cat vs. dog discrimination is reduced for individuals with higher AQ scores. Second, our analysis revealed a significant interaction between AQ scores and the spatial frequency of visual features. This interaction highlights a negative relationship between feature spatial frequency and VFD (lower spatial frequencies being more diagnostic) which is more prominent in individuals with higher AQ scores. The first finding is readily reconcilable with previous reports of ASC effects on visual face processing. The second finding appears to be somewhat at odds with previous reports of individuals with ASC being particularly attentive to local details. Importantly, our study reveals a general relationship between markers of autism and visual perception. This opens up the intriguing possibility that also other

personality traits, e.g. extrovertism, are related to individual differences in visual information processing strategies.

Abstract: Mutations in the Cyclin-dependent kinase-like 5 (CDKL5) gene cause severe neurodevelopmental disorders accompanied by intractable epilepsies, i.e. West syndrome or atypical Rett syndrome. Here we report generation of the Cdkl5 knockout mouse and show that

CDKL5 controls postsynaptic localization of GluN2B-containing N-methyl-D-aspartate (NMDA) receptors in the hippocampus, and regulates seizure susceptibility, as well as emotional behaviors and memory. Cdkl5 -/Y mice exhibited significantly enhanced anxiety-like behaviors and significant impairment in reference and working memory. Cdkl5 -/Y mice showed normal sensitivity to kainic acid; however, they displayed significant hyperexcitability to NMDA. In concordance with this result, electrophysiological analysis in the hippocampal CA1 region disclosed an increased ratio of NMDA/α-amino-3-hydroxy-5-methyl-4-isoxazolepropionic acid (AMPA) receptor-mediated excitatory postsynaptic currents (EPSCs) and a significantly larger decay time constant of NMDA receptor-mediated EPSCs (NMDA-EPSCs) as well as a stronger inhibition of the NMDA-EPSCs by the GluN2B-selective antagonist ifenprodil in Cdkl5 -/Y mice. Subcellular fractionation of the hippocampus from Cdkl5 -/Y mice revealed a significant increase of GluN2B and SAP102 in the PSD (postsynaptic density)-1T fraction, without changes in the S1 (post-nuclear) fraction or mRNA transcripts, indicating a distribution shift of these proteins to the PSD. Immunoelectron microscopic analysis of the hippocampal CA1 region further confirmed postsynaptic overaccumulation of GluN2B and SAP102 in Cdkl5 -/Y mice. Furthermore, ifenprodil abrogated the NMDA-induced hyperexcitability in Cdkl5 -/Y mice, suggesting that upregulation of GluN2B accounts for the enhanced seizure susceptibility. These data indicate that CDKL5 plays an important role in controlling postsynaptic localization of the GluN2B-SAP102 complex in the hippocampus, and that aberrant NMDA receptor-mediated synaptic transmission underlies the pathological mechanisms of the CDKL5 loss-of-function.

Abstract: Neurological diseases are a heterogeneous group of disorders caused by alterations in nervous system function and due to technological advances over the last decade; many of these disorders can be attributed to genetic factors such as chromosomal aberrations or gene mutations. Early onset epileptic encephalopathies are among the most devastating conditions among pediatric populations. Our research is focused on methods to reactivate the healthy *CDKL5* gene on the silenced X-chromosome in CDKL5-deficient patient cells and cell lines. Our team has validated several novel genomic targets that can regulate *CDKL5* expression in human neuronal cells. This technique utilizes CRISPR guide RNAs (gRNAs) with deactivated Cas9 fused VP64 (dCas9-VP64) targeted to regulatory domains in the *CDKL5* gene and results in significant upregulation of the gene when transfected with a pooled group of gRNAs. We believe this to be the first description of a true regulatory domain in the *CDKL5* promoter. We have performed chromatin immunoprecipitation qPCR to examine the recruitment of sustainable and durable changes to the epigenetic landscape following co-transfection or transduction with the same pooled gRNAs paired with dCas9-VP64 into human neurons. We have also expanded the library of effector domains that can be paired with our pooled gRNAs and successfully drive gene activation. These novel effector domains may be able to provide a more durable and sustainable reactivation of the silenced X-chromosome in a therapeutic setting. In addition, we have designed, cloned, and validated gRNAs for both the murine and rat *CDKL5* gene to be able to perform gene activation studies in transgenic rodent models of CDKL5-deficiency. Our group specializes in the creation of TALE and CRISPR to target and permanently reverse aberrant genetic mutations that contribute to disease. To our knowledge we are the first to demonstrate significant up-regulation of endogenous *CDKL5* using DNA binding domains. This approach holds great potential for children suffering from CDKL5-deficiency.

Title: MECP2 mutation causes abnormal effect of D2R agonist on locomotor and thermoregulation in mice

Authors: *B. LU, Z. XIONG
Lab. of Neurobio. of Diease, Inst. of Neurosci., Shanghai City, China

Abstract: X-linked *MECP2* gene plays an essential role in development of central neuron system. Its mutation is the main cause of neurodevelopmental disorder Rett syndrome. Mutations in *MECP2* cause motor skill impairment as well as kinds of neuropsychiatric syndrome in humans. The mechanisms mediating these features, however, remain unclear. Here we reported that Mecp2 is involved in the functional maturation of dopamine D2-like receptors in motor and thermoregulation circuits. Our data showed that Mecp2 mutant mice displayed abnormal locomotion in response to administration of D2-like receptor agonist (quinpirole) in novel environment. We also found that hypothermia effect of quinpirole was reduced in Mecp2 mutant mice compared to their wild type littermates. In addition we found that the phenotype of abnormal locomotion and thermoregulation in response to quinpirole just existed in adult mice but not in pup (P18-P20). The present study indicated the important role of Mecp2 in postnatal maturation of D2R-associated circuits in locomotor and thermoregulation, which may provide insights into the cellular and circuitry mechanisms underlying the pathogenesis of Rett syndrome.

Title: Neuronal redox imbalance in Rett syndrome: a key player in neuronal network dysfunction and altered neurotransmitter responsiveness?

Authors: K. CAN, K. FESTERLING, S. KÜGLER, *M. MUELLER
Univ. Goettingen, Goettingen, Germany, Germany

Abstract: Rett syndrome (RTT) is a neurodevelopmental disorder, affecting almost exclusively girls. Its main genetic cause are *de novo* mutations in the methyl-CpG binding protein 2 gene (*MECP2*). After a short and apparently normal development, a RTT child enters a developmental stagnation, followed by neuronal and autonomic dysfunction, which manifest as mental retardation, erratic breathing, epilepsy, loss of speech, stereotypical hand movements and motor disturbances. Furthermore, RTT is associated with early mitochondrial dysfunction and systemic oxidative stress. We showed previously that mitochondria of MeCP2-deficient (*Mecp2*$^{-/y}$) mouse

hippocampus operate at increased turnover rates. In concert with impaired cell-endogenous scavenging systems, this culminates in cellular redox dysregulation. To uncover molecular details of this redox impairment, we extended optical redox imaging specifically to neurons. Taking advantage of viral vectors (AAV-6), we expressed genetically-encoded redox sensors in either cytosol (roGFPc) or mitochondrial matrix (roGFPm). In dissociated cell cultures, stimulation by glutamate, dopamine, serotonin, and norepinephrine consistently evoked intensified oxidizing shifts in the cytosol of *Mecp2*$^{-/y}$ neurons, suggesting that even physiological stimuli such as neurotransmitters are sufficient to provoke overshooting redox responses. In mitochondria, neurotransmitter-evoked redox changes were more moderate than in cytosol, and genotypic differences between WT and *Mecp2*$^{-/y}$ neurons were less pronounced. Cellular Ca^{2+} overload due to massive Ca^{2+} influx can be excluded as a primary cause for the neurotransmitter-induced redox responses and their overshooting characteristics in *Mecp2*$^{-/y}$ neurons. Instead, by pharmacological intervention we confirmed a leading role of NADPH- and xanthine oxidases in cytosolic ROS production. This identifies the cytosol as an important ROS source, but also as an unsufficiently redox-buffered compartment. Interestingly, the very route of activation of these oxidases apparently differs among *Mecp2*$^{-/y}$ and WT neurons. All of these changes were evident already in neonatal and presymptomatic mice. Therefore, it will be crucial to map cellular redox conditions as RTT progresses in severity. A crucial tool for this future endeavor will be our recently generated redox-indicator mice, which are currently crossbred with Rett mice. Only then, it will become evident to what degree early neuronal redox alterations contribute to neuronal network dysfunction and promote the further progression of RTT.

Abstract: The X-linked Methyl-CpG-Binding Protein 2 (MeCP2) gene encodes for a multifunctional protein ubiquitously expressed from developmental stages to adulthood. Mutations in *MECP2* are linked to Rett syndrome (RTT), the most common genetic cause of severe intellectual disability in females. Although MECP2 plays a crucial role in the maintenance of proper neuronal functionalities, several evidences now suggest that early signs of the pathology can be observed (in both humans and animal models) long before the typical RTT symptoms become overt. We focused on the development of the embryonic cerebral cortex of *Mecp2* null animals, as our published transcriptional analyses suggest that the mechanisms of embryonic corticogenesis are delayed. Based on this observation, we assessed the dynamics of neuronal differentiation in embryonic and early postnatal cortical tissues. Our data show that the expression of transcripts that are typical of neuronal progenitors is retained by null newborn neurons, while the level of transcripts expressed by maturing or fully functional neurons are reduced in null cortexes. Altogether, our data suggest that already during embryonic and early post-natal life lack of Mecp2 affects the ability of newborn neurons to drop the transcription of genes that are outdated (like those defining cortical progenitors) while acquiring new, more refined, postmitotic identities. We believe this evidence demonstrates that the transcriptional noise typically affecting adult *Mecp2* null tissues is a feature already displayed at an early stage of differentiation. The impairments displayed by adult RTT animal models can thus be considered the worsening of a condition that is already generated during embryogenesis.

Title: Innovative pregnenolone-based therapeutic approaches for neurological disorders linked to mutations in X-linked Cyclin dependent kinase-like 5 (CDKL5)

Authors: *I. BARBIERO[1], D. PERONI[1], M. TRAMARIN[1], L. RUSCONI[1], P. MOTTA[1], P. SINISCALCHI[1], N. LANDSBERGER[2], M. BIANCHI[3], C. KILSTRUP-NIELSEN[1]

Abstract: Mutations in the X-linked cyclin-dependent kinase-like 5 (CDKL5) gene cause neurologic disorders characterized by the early onset of seizures, intellectual disability, impairment of gross motor skills, and sleep disturbances. CDKL5 is a serine/threonine kinase the molecular network of which is not yet fully understood. Loss of CDKL5 both in vitro and in vivo leads to altered neuronal morphology including defective polarization, dendritic arborization and spine morphology suggesting a link between CDKL5 and the cytoskeleton.
Recently, we identified IQGAP1 as a novel interactor of CDKL5. IQGAP1 is a scaffold protein that regulates cytoskeleton dynamics by linking the actin and microtubule (MT) networks through its association with Rac1 and the MT plus end binding protein (+TIP) CLIP170. CDKL5 deficiency interferes with the formation of the IQGAP1/CLIP170/Rac1 ternary complex with repercussions on the MT association of CLIP170. These findings allowed us to recognize the neurosteroid pregnenolone (P5) as an innovative candidate drug for CDKL5-related disorders. Indeed, CLIP170 acts as an intracellular receptor for P5 that promotes microtubule dynamics by blocking CLIP170 in its active conformation. Accordingly, we find that treatment of CDKL5 deficient cells with P5 is capable of restoring the MT association of CLIP170 and a proper neuronal morphology.
Although P5 has well-known positive effects on cognition and neuronal morphology in animal models and has proven to be well tolerated in clinical tests, there is some concern about its clinical application due to the possible side effects of its downstream metabolites. In such a scenario, synthetic P5 derivatives like pregnenolone-methyl-ether, PME, which maintain the biological action but cannot be converted into other steroids, is therefore of high clinical relevance. These molecules are currently considered innovative drug candidates for psychiatric and neurodegenerative disorders. Here we present data showing that a range of morphological and molecular defects in primary neuronal cultures from Cdkl5-null mice can be restored upon treatment with either P5 or PME suggesting their potential therapeutic relevance for CDKL5-related disorders.

Title: Efficacy of ANAVEX 2-73, a Sigma-1 receptor agonist, in the MECP2 mouse model of Rett syndrome

Authors: *J. S. SPROUSE, N. REBOWE, D. KLAMER, C. MISSLING
Anavex Life Sci., New York, NY

Abstract: BACKGROUND: The Sigma-1 receptor (σ1R) is an intracellular chaperone protein located at the endoplasmic reticulum - mitochondria interface with important roles in inter-organelle communication and the cellular response to stress. ANAVEX 2-73 (AV2-73) is a σ1R agonist that has previously demonstrated favorable safety, bioavailability, and tolerability in Phase 1/2 clinical trials. Data from the ongoing Phase 2a study in Alzheimer's disease patients demonstrate signs of dose-dependent cognitive improvement. Given the reported ability of the σ1R to restore cellular functionality, neurodevelopmental disorders may respond to the activation of σ1R in a disease-modifying manner. One such disorder is Rett syndrome and the MECP2 HET mouse is a well-characterized model with a behavioral profile that mimics many aspects of the clinical picture.
METHODS: Female MECP2 HET and wild type (WT) mice were used throughout (N=19-20 per treatment arm). Chronic daily dosing of AV2-73 (10 or 30 mg/kg/day PO) starting at 5.5 weeks of age was conducted throughout a 12-week period of testing. Behavioral paradigms measured different aspects of motor coordination, reflex reactivity, and species-specific behavior (clasping). In a separate study, 4 weeks of daily dosing starting at 6.5 months of age was followed by optokinetic analysis of relative visual acuity and changes in respiration by whole body plethysmography. Significance at $p<0.05$ was determined by ANOVA and post-hoc comparisons.
RESULTS / DISCUSSION: In the younger cohort of mice, chronic dosing with AV2-73 significantly improved performance of the MECP2 HETs in different motor and gait paradigms, and reduced clasping behavior to WT levels. Among the older cohort, relative visual acuity in AV2-73-treated HET mice was returned to WT levels at the slower rotating speed. A reduction in apnea counts (~35%) relative to WT levels was observed in HETs receiving AV2-73.
CONCLUSIONS: AV2-73 significantly improves an array of behavioral phenotypes in the Rett syndrome mouse model in a dose-related manner. Based on these data, Anavex Life Sciences will start a U.S. multicenter Phase 2 clinical trial of AV2-73 for the treatment of Rett syndrome with the support of Rettsyndrome.org.

Title: Impact of arousal on visual processing in Rett syndrome

Authors: *P. ARTONI[1], G. A. EWALL[2], G. RANKIN[1], C. CHEN[1], T. K. HENSCH[2], M. FAGIOLINI[1]
[1]F. M. Kirby Neurobio. Ctr., Boston Children's Hospital, Harvard Med. Sch., Boston, MA; [2]Mol. and Cell. Biol., Harvard Univ., Cambridge, MA

Abstract: Proper sensory processing is actively modulated by arousal states. Growing evidence implicates abnormal visual and auditory processing in Rett Syndrome (RTT), a neurodevelopmental disorder caused by *de novo* mutation of the X-linked MECP2 gene. RTT is characterized by an initial period of apparent normal development followed by stagnation and subsequent regression of sensory processing, cognition and motor function. Onset of epilepsy and anxiety-like behavior often occur later. How neuronal cortical circuits are disrupted during disorder progression and whether arousal states contribute further to such disruptions is still largely unknown. Here, we performed longitudinal *in vivo* 2-photon imaging of Ca^{++} transients in visual cortical circuits of freely moving $MeCP2^{stop/y}$ and wild-type (WT) littermate mice while tracking motor activity, pupil diameter and gaze. At postnatal day P30 (before regression begins and RTT-like phenotype increases), animals were injected with AAV9-GCaMP6s into visual cortex and implanted with a cranial window and head post. After a 2-week habituation to the running ball set-up and head restraint, mice were imaged from the binocular area of visual cortex during their active phase (nocturnal). We alternately measured Ca^{++} transients of spontaneous or evoked activity in layer 2/3 cells in the absence of stimulation (grey screen) or in response to visual input (drifting gratings of different spatial frequencies, 100% contrast, 4Hz temporal frequency), respectively. Mice underwent multiple imaging sessions over the course of the disease progression. We sorted the data into two groups: active regression (AR, P45- P80) and late regression (LR, P80 - P110). We found that the spontaneous activity in MeCP2-deficient mice was significantly lower both in AR and in LR stages compared to WT (WT: N=5 mice, n=489 cells; AR: N=4, n=133; LR: N=5, n=149, respectively). Receptive field properties such as direction and orientation selectivity or spatial resolution of individual cells progressively deteriorated from AR to LR stages. In contrast to the increase displayed in WT mice, there was no significant positive modulation of spontaneous activity levels across arousal states in the mutant mice. Moreover, visual acuity and response reliability were detrimentally impacted by the high arousal state. Overall, our data suggest that in mice lacking MeCP2, the decline of visual cortical processing correlates with the onset of the disorder, and it is further disrupted by heightened arousal states.

Title: Replication and comprehensive evaluation of neurobehavioral outcomes in a rat model of Mecp2

Authors: *S. VEERARAGAVAN, S. G. HUANG, C. S. WARD, R. C. SAMACO
Mol. and Human Genet., Baylor Col. of Med., Houston, TX

Abstract: Rett syndrome (RTT) is an X-linked disorder caused by loss-of-function mutations in gene encoding the transcriptional modulator Methyl-CpG-Binding Protein 2 (MeCP2). Typical RTT occurs in girls and women and is characterized by a brief period of normal development followed by regression of acquired hand skills and language, and the onset of anxiety, autistic features, seizures and autonomic dysfunction. However, rare cases of boys that possess similar mutations in *MECP2* present with severe congenital encephalopathy accompanied with severe developmental delay, hypotonia, seizures and severe autonomic dysfunction. Furthermore, these affected boys do not survive past early childhood. Recent studies by our group and others have demonstrated the value of a novel *Mecp2* rat model for both mechanistic and translational studies for MeCP2-related disorders. However, to avoid experimental pitfalls such as issues of reproducibility and reliability, especially for neurobehavioral outcomes commonly studied in mouse models of ASD/IDD including *Mecp2* mouse models, we set out to evaluate male rats completely lacking MeCP2, choosing to confirm and expand upon the limited behavioral data so far reported in *Mecp2* male rats. Two of the three reports on the *Mecp2* rat model examined spontaneous exploratory activity, with one study conducting additional tests for grip strength and sociability, and another study evaluating gait. Consistent with previous findings, we observed a significant decrease in overall spontaneous exploratory activity in *Mecp2* male rats. Our additional behavioral studies also uncovered features not previously reported including decreased anxiety-like behavior, enhanced self-grooming, evidence for decreased aspects of juvenile play, and sensorimotor gating abnormalities. We also tested aversive and episodic-like learning and

memory in the *Mecp2* male rats and observed no significant differences across genotypes. This replication study provides a timely assessment of the robustness and reproducibility of current findings, as the field rapidly pushes forward in incorporating this novel rodent model as a key component in studies of biological mechanisms and potential therapies for MeCP2-related disorders.

Title: Microglia phenotype varies regionally in in a Mecp2-heterozygous model of Rett Syndrome

Authors: *C. O'FERRALL[1], A. FOWLER[3], E. S. SMITH[1], M. S. LANGE[3], G. E. HOFFMAN[3], M. E. BLUE[4], S. KANNAN[2]

Abstract: Microglia have been implicated in the neuropathology observed in mouse models of Rett Syndrome (RTT). However, many of the impairments in microglia function seem to be independent of MeCP2 presence within the cell, as others have shown expression of MeCP2 in *Mecp2*-null mice is insufficient in repairing behavioral deficits. Much less is known about the role of microglia in *Mecp2*-heterozygous female mice, which match the genotype of human RTT. The current study tested the hypothesis that microglia phenotype/profile varies across affected brain areas in a mouse model of RTT. Brain tissue from 6-12 month old *Mecp2*-heterozygous female mice were fixed, preserved and processed for Iba-1, CD68 (marker of phagocytosis) and ferritin (protein integral in iron storage) immunocytochemistry. The distribution of microglia was examined in hippocampus, striatum, arcuate nucleus, amygdala, and prefrontal cortex. Different morphologic parameters of microglial cells including cell size, process number and process length were quantified using Neurolucida imaging software. The morphological analyses demonstrated a distinct M1/pro-inflammatory microglial profile (larger somas, fewer, shorter processes) in the arcuate nucleus that was particularly marked in overweight *Mecp2*-heterozygous mice. Patterns of CD68 and ferritin immunostaining were

distinctive in hippocampus but not in other brain regions studied. The results indicate region-specific differences in microglia phenotype/profile in *Mecp2*-heterozygous mice. Ongoing studies are characterizing the interactions between microglia and the larger neuronal environment within these brain regions to further elucidate the contributions of microglia to the neuropathology in RTT.

Title: Ketamine treatment rapidly reverses cortical synaptic spine deficits in a mouse model of Rett syndrome

Authors: C. J. HOWELL, 44120[1], S. U. LAD[2], F. E. ABOUELSOUD[2], *D. M. KATZ[3]
[1]Neurosciences, [3]Dept Neurosciences, [2]Case Western Reserve Univ., Cleveland, OH

Abstract: Rett syndrome (RTT), a severe disorder caused by loss-of-function mutations in the *MECP2* gene, is characterized by neurological regression leading to deficits in motor, respiratory and autonomic control and cognitive function. Similar to other autism spectrum disorders, RTT is characterized by abnormal synaptic connectivity, including reduced density and maturity of cortical dendritic spines. In the medial prefrontal cortex (mPFC), a region critical for behaviors disrupted in RTT, spine deficits on Layer 5 pyramidal neurons are associated with decreased excitatory synaptic drive and reduced neuronal activity (Sceniak et al., 2015; Kron et al., 2012). Moreover, hypoactivity of mPFC pyramidal neurons appears to underlie or contribute to neurological deficits in *Mecp2* mutant mice (Howell, et al., 2016), suggesting that restoration of excitatory connectivity in the mPFC could be of therapeutic benefit in RTT. Therefore, the present study was designed to test the reversibility of spine defects in *Mecp2* null (Null) mice in response to ketamine, an NMDA antagonist which promotes dendritic spine growth in rodent models of depression (Li et al., 2010). We also examined the impact of ketamine on signaling mechanisms that are associated with spine growth and are in deficit in the Null brain (Ricciardi et al., 2011), including phosphorylation of the ribosomal protein S6, a target of mTOR (*mechanistic target of rapamycin*). To approach these issues we compared phospho-S6 signaling

and dendritic spine density in the mPFC of symptomatic Null and wildtype (WT) mice treated with a single sub-anesthetic dose of ketamine. To visualize dendritic spines, we used Thy1-GFPm *Mecp2* Null or WT mice in which GFP is expressed in a subset of layer V pyramidal neurons. 24 hours after treatment, the density of spines on oblique dendrites was significantly increased to WT levels in ketamine-treated *Mecp2* mutants. This rescue was due in part to significant increases in the density of stubby and thin spines. To determine if these effects of ketamine were associated with changes in S6 signaling in the mPFC, we compared levels of total and phospho-S6 in saline- and ketamine-treated Wt and Null mice using Western blot. Within 1 hour of treatment, phospho-S6 levels were significantly increased to WT levels in ketamine-treated *Mecp2* mutants. Thus, even in the absence of MeCP2, spine deficits in cortical pyramidal neurons can be rapidly reversed with a single sub-anesthetic dose of ketamine. These data support the potential of low-dose ketamine treatment to improve neurological function in RTT by promoting restoration of excitatory synaptic connectivity.

Title: Methyl-CpG binding domain protein 2 is a master regulator of neuronal gene pathways and behavior

Authors: *E. M. LAX, S. DO-CARMO, Y. ENUKA, N. MAHMOOD, S. RABBANI, C. A. CUELLO, Y. YARDEN, M. SZYF

Abstract: DNA methylation is a major epigenetic modification that alter gene expression. Methyl-CpG-binding domain (MBD) proteins recognize and bind methylated DNA. Several MBDs are involved in neurodevelopment and maintenance of brain functions. However, not much is known about the role of Methyl-CpG-binding domain 2 (Mbd2) in the brain. We found MBD2 knockout mice show deficits in cognitive, social and emotional functions. Chromatin immunoprecipitation (ChIP-seq) revealed that Mbd2 binds to regulatory DNA regions of

neuronal genes in the Hippocampus. Loss of Mbd2 alters the expression of hundreds of genes with a robust down-regulation of neuronal gene pathways. Further, a genome-wide DNA methylation analysis found an altered DNA methylation pattern in regulatory DNA regions upon loss of Mbd2. Taken together, our data suggest Mbd2 regulates hippocampal DNA methylation landscape to control neuronal gene expression and behavior.

Neuroimaging Lab., Nathan S. Kline Inst., New York, NY

Abstract: ABSTRACT
Data quality is increasingly recognized as one of the most important confounders in brain imaging research. It is particularly important for studies of brain development, where age is negatively related to in-scanner motion and data quality. Prior work has demonstrated that in-scanner head motion biases estimates of structural neuroimaging measures. Yet, objective measures of data quality are not available for most structural brain images. Here we sought to

identify reliable, quantitative measures of data quality for T1-weighted volumes, describe how such measures of quality relate to common measures of brain structure, and delineate how this in turn may bias inference regarding brain development in youth. Three expert raters provided manual ratings for 1601 T1-weighted volumes acquired as part of the Philadelphia Neurodevelopmental Cohort. Manual ratings were compared to automated quality measures, which derived measures from the Preprocessed Connectomes Project's Quality Assurance Protocol (QAP). Generalized linear mixed-effects models using the automated quality measures were constructed in a training sample (n = 1067) to: 1) identify unusable images with significant artifacts, and 2) quantify subtle artifacts in usable images. These models were then tested in an independent validation dataset (n = 534). Results reveal that unusable images can be detected with a high degree of accuracy: a model including background kurtosis and skewness achieved an AUC of 0.95 in the training dataset and 0.94 in the independent validation dataset. While identification of subtle artifact was more challenging, an 8-parameter model achieved an AUC of 0.80 in the training dataset, and 0.92 in the validation dataset. Notably, quantitative measures of image quality were related to cortical thickness and gray matter density; measures of cortical volume were less affected by artifact. Furthermore, these quantitative measures of image quality explained more variance structural biomarkers then estimates of motion derived from other imaging sequences acquired during the same protocol. Finally, data quality significantly altered estimated structural brain maturation occurring during adolescent development. Taken together, these results indicate that reliable measures of data quality can be automatically derived from T1-weighted volumes, and that failing to control for data quality can systematically bias the results of studies of brain development.

Abstract: Connectomics provides a powerful analytical framework for delineating brain development during adolescence. One challenge in MRI studies of brain network development in childhood and adolescence is data quality: younger subjects tend to move more during image acquisition, and differences in head motion have been shown to significantly bias developmental patterns of functional connectivity. Despite this fact, the impact of motion artifact on structural connectivity networks remains poorly characterized. Here, we evaluated the impact of head motion on estimates of structural connectivity using a sample of 949 participants (ages 8-23 years) who passed a rigorous quality assessment protocol for diffusion tensor imaging (DTI) acquired as part of the Philadelphia Neurodevelopmental Cohort. Structural connectivity was measured after constructing brain networks using both deterministic and probabilistic tractography methods, while head motion was estimated by the mean relative displacement between non-diffusion-weighted volumes in the DTI acquisition. We hypothesized that subtle variation in head motion would bias estimates of structural connectivity in a distance-dependent manner, as observed in previous studies of functional connectivity.
Even following rigorous manual quality assurance and retrospective head motion correction with FSL's *eddy*, in-scanner motion impacted the strength of structural connectivity in a distance-dependent manner (permutation-based $p<0.0001$): specifically, increased head motion was associated with reduced estimates of structural connectivity for long-range, consistent connections with high mean fractional anisotropy. In contrast, motion inflated estimates of structural connectivity for short-range, inconsistent connections with low mean fractional anisotropy. Head motion also systematically impacted measures of structural network topology derived from both deterministic and probabilistic tractography, including network density (r=-0.43, $p<10^{-10}$), global efficiency (r=-0.34, $p<10^{-10}$), and modularity (r=-0.16, p=1.2 x 10^{-5}). Controlling for the contributions of subject motion also mitigated estimated age effects on structural connectivity, suggesting that observed developmental changes in structural brain networks may be inflated by age-related differences in head motion. Taken together, these data delineate the systematic impact of head motion on structural connectivity using a variety of brain network construction methods, and provide a critical framework for quantifying and mitigating motion-related confounds in studies of structural brain development.

Title: Investigating postnatal human brain development using diffusion tensor based morphometry (DTBM)

Authors: A. NAYAK, M. IRFANOGLU, N. SADEGHI, *C. PIERPAOLI
Quantitative Med. Imaging Section, NIBIB, NIH, Bethesda, MD

Abstract: MRI can be used to assess postnatal brain development. Tensor Based Morphometry (TBM), performed from T1weighted images (T1WIs), is used to measure local differences in volume when a brain is warped to another brain or a template[1]. However, T1W signal is homogenous in white matter and can not be used to detect volume changes in specific white matter pathways. Diffusion Tensor Imaging (DTI) allows the identification of specific white matter pathways that appear homogeneous on T1WIs. The novel approach of this work is to assess morphometric changes in specific white matter pathways performing TBM with DTI. We name this approach: DTBM.
We used DTI data from182 subjects in the NIH MRI Normal Brain Development public database[2] to create 19 age specific DTI average brain templates. The templates were created by co-registering data of individual subjects in each age range using the recently proposed Diffeomorphic Registration for Tensor Accurate Alignment of Anatomical Structures (DR-TAMAS) algorithm[3]. An adult template for the population was created from subjects in the 18-21yr old age group. Each age-specific template was then registered to the adult template using DR-TAMAS. The voxelwise Log of the determinant of the Jacobian (Log J) was computed to quantify local volume differences with respect to the adult template. ROIs were drawn on several white matter pathways on the adult template and average Log J values were computed for each age specific template.
In the figure it is interesting to note that different white matter pathways have very different volume growth trajectories (VGT). for example, PLIC VGT is aligned with the overall brain VGT. CST and CC have much larger volume changes, with very different rate of change.
In conclusion, our resuts indicate that DTBM could be a valuable tool to assess volume growth trajectories of specific white matter pathways in postnatal brain development, and potentially help in the clinical assessment of developmental delay.

Abstract: Functional magnetic resonance imaging (fMRI) studies show that functional connectivity in resting state networks (RSNs) develop across the lifespan. RSNs are seen as early as in utero (Schöpf et al., 2012) and develop through adolescence (Supekar et al., 2010). However, while several studies have investigated age differences in RSNs, few have considered the impact of major life transitions, such as the transition to college during late adolescence.

Also, while experience in higher education is associated with changes in structural brain connectivity (Bennett and Baird, 2006), little is known about its relationship with functional connectivity. Thus, here we focus on RSN developments across this important life transition. We examined RSNs of 28 adolescents (11 male, Mean Age = 16.9 years) in high school and 26 young adults (10 male, Mean Age = 19.8) in college. Because we were interested in both age-related effects and changes attributable to social environments (high school vs. college), we compared RSNs both with and without including age as a covariate. Based on previous work showing longitudinal changes in functional connectivity in the Default Mode Network (DMN) and Central Executive Network (CEN) during early adolescence (Sherman et al., 2014), we focused on these two networks, as well as the Salience Network (SN), which is thought to regulate the switch between DMN and CEN activity (Sridharan et al., 2008).
All participants underwent a 6-minute resting state, eyes-open scan on a 3T MRI scanner. Functional connectivity was assessed using 10 mm-diameter seed regions placed in the left precuneus, right dorsolateral prefrontal cortex (dlPFC), and right anterior insula (AI) to generate maps of the DMN, CEN, and SN respectively. No significant differences in RSNs were observed when comparing high school and college students (i.e., no effect of age). Importantly, however, when age was regressed out, significant group differences were observed in the CEN and SN, suggesting that developmental life stage was the key modulator of changes in connectivity. Specifically, college students showed greater connectivity in the CEN between the right DLPFC and the right superior parietal lobe than high school students. As compared to college students, high school students showed greater connectivity in the SN between the right AI and the right temporal pole, as well as between the right AI and the right paracingulate gyrus. These findings indicate that environmental and experiential changes taking place during the transition from late adolescence to early adulthood significantly impact the development of network connectivity above and beyond any effect of age.

Title: Multivariate pattern analysis shows that age-specific brain activity is shared by a broad range of cognitive tasks

Authors: *P. STIERS[1], M. BIRKISDÓTTIR[2], E. H. H. KEULERS[2]
[1]Fac. of Psychology and Neuroscience, Maastricht Univ., Maastricht, Netherlands; [2]Dept. of Neuropsychology and Psychopharmacology, Maastricht Univ., Maastricht, Netherlands

Abstract: Adolescence is characterized by dramatic changes in behavioral. Many studies have tried to pinpoint the specific neurocognitive processes that cause these behavioral changes. But, neuroanatomical studies report widespread changes in grey matter and brain connectivity that suggest a global, unspecific increase in neural efficacy that improves performance in a broad range of behavioral tasks. Consequently, age-related changes in brain activity should not be specific to particular neurocognitive processes. In line with this, we previously found that multivariate pattern classification of age from adolescents' brain activity generalizes across cognitive tasks - i.e., a classifier trained to decode age from brain activity during a go-nogo task can above chance predict age from brain activity during a complex gambling task, and vice versa (Keulers ea., 2012, NeuroImage, 60:1250-65). Despite obvious differences, these two tasks share the stimulus-response mapping structure typical of cognitive tasks. In the present study we test the generalizability of age classification between three tasks that do not share this structure: a metacognitive agenda setting task requiring a choice response based on self-reflexive evaluation; a word-pair encoding task involving a visualization strategy without an overt response; a passive visual perception task exposing participants to photos of objects, faces and movement scenes in 24 second blocks. Adolescents aged 13 (n=25) and 17 yrs. (n=22) performed the tasks in a 3T MRI scanner. For each task several condition specific percent signal change maps were computed per participant and used as examples in a support vector machine learning analysis with recursive feature elimination and leave-one-subject-out cross-validation. Within tasks, age classification accuracies were 62 to 72%, depending on task and parameters, and were significantly above chance (125 label randomization analyses). Between tasks, generalization of age decoding from the metacognitive to the encoding task was 75% accurate ($p<0.01$), while the reverse generalization yielded 69% accuracy ($p<0.01$). These accuracies were not dependent on the univariate task-responsive voxels. Generalization to the visual maps yielded 65% ($p<0.01$) when training was on metacognition and 63% ($p<0.05$) for training on encoding activity. We conclude that age-related changes in brain activation are not task specific, but common to a broad range of cognitive functions, from metacognitive judgement to passive perception. Thus, brain maturation in the teen years reflects a global increase in neural efficiency, most likely driven by increased long-range connectivity.

Title: Development of visual P3 components from childhood to adulthood and associations with cortical structure: A study combining electrophysiology and MRI

Authors: *K. OVERBYE, R. J. HUSTER, K. B. WALHOVD, A. M. FJELL, C. K. TAMNES
Dept. of Psychology, Univ. of Oslo, Oslo, Norway

Abstract: Visual attention improves dramatically during development. The P3 component of the event related potential is assumed to indicate how the brain forms a bridge from stimulus processing to response processing, possibly related to the role of the parietal cortex in allocating attention to internal processes. However, how P3 relates to brain maturation is far from understood. In the present study, we aimed to investigate age-related differences in early visual and P3 components, and how individual differences in these components were related to cortical structure. A group of 88 healthy children and adolescents 8.2-19.7 years old completed a three-stimulus visual oddball task while high-density EEG data was recorded. Additionally, MRI data was acquired on a separate day and T1-weighted images were processed using FreeSurfer to estimate vertex-wise cortical thickness and surface area. Group-level data blind source separation was applied to EEG recordings to estimate components representative of neural sources commonly expressed across the whole sample. The resulting components included one P3 component with a parietal maximum, and also a component with a frontal maximum that in terms of latency and shape was deemed P3-like, as well as one component assumed to reflect early visual processing. Differences across age was found for all three components, with the two P3-like components being stronger for older participants while the early visual component was stronger for younger participants. Stronger P3-like components were associated with increased task speed and precision, independently of age, while the opposite was true for the strength of the early visual component. Finally, the strength of the parietal P3 was associated with a larger cortical area in the lateral temporal lobe in the left hemisphere. This was found to hold independently of age and after correction using cluster size inference. It is suggested that the age differences in the strength of components reflects the maturation of attentional mechanisms, with increased electrophysiological responses to task-relevant stimuli, representing an increased ability to effectively focus on relevant information and respond quickly and efficiently.

Title: Visual search becomes faster during adolescence

Authors: *R. BURGGRAAF WINGENS, ESQ[1], J. N. VAN DER GEEST[2], M. A. FRENS[3], I. HOOGE[4]
[1]Neurosci., Erasmus MC, Bosch En Duin, Netherlands; [2]Erasmus MC - Dept Neurosci. (ee12), Rotterdam, Netherlands; [3]Erasmus MC Rotterdam, Rotterdam, Netherlands; [4]applied psychology, Ignace Hooge, Utrecht, Netherlands

Abstract: A child's brain is changing tremendously during adolescence. We hypothesized that visual search will also change during this period of life. In particular, we are interested in the reaction time and accuracy of visual search and the use of selection of elements to fixate, in order to direct fixations mainly to elements most similar to the target.
A large group of adolescents (N=140; 12-19 years; 53% male) participated in a visual search experiment. Each trial showed a stimulus display with 36 Gabor patches placed on a hexagonal grid. The target consisted of a vertical oriented element with a high spatial frequency. Non-targets differed from the target in spatial frequency and/or orientation. The experiment was composed of 144 trials (50% target present) and participant had to decide whether the target was present or not.
Search performance and behavior changed during adolescence. Shorter fixation durations coincided with decreasing reaction time. The number of fixations and the selection of elements to fixate did not change, which could possibly explain the finding that search accuracy did not change with age.
In general we conclude that the process of gathering visual information does not change during adolescence, but children become faster in processing this information.

Title: Context-dependent neurodevelopment of vta-accumbens connectivity: A longitudinal fmri study

Authors: *V. P. MURTY[1], D. F. MONTEZ[2], W. F. FORAN[2], F. J. CALABRO[3], B. LUNA[4]

Abstract: The mesolimbic dopamine system continues to mature throughout adolescence into early adulthood. Neuroimaging has characterized increases in ventral striatal activation across adolescence during reward-motivated behavior; however, relatively less work has investigated interactions between the ventral tegmental area, the source of mesolimbic neurons, and its targets in the striatum. In the current study, we characterized this neural circuit in children, adolescence, and adults in rewarding and neutral contexts using an accelerated longitudinal fMRI design. fMRI data was collected in 170 individuals ranging in age between 10-30 years old. Participants completed both a resting-state (neutral context) and reward-motivated anti-saccade task (rewarding context) over the course of 1-3 visits. Visits were separated by approximately 1 year. To compare results across tasks, we characterized 'background connectivity' of the reward motivated anti-task, which reflects intrinsic connectivity between regions that are related to task contexts. Longitudinal fMRI analyses revealed a significant decrease in VTA-nucleus accumbens coupling in rewarding contexts as individual's approached adulthood ($p < 0.001$). Conversely, there were no differences in VTA-nucleus accumbens as a function of age in neutral contexts ($p= 0.93$; difference in contexts $p < 0.01$). These findings support a model by which connectivity of the VTA with its mesolimbic targets is relatively stable across adolescence, however, the ability to engage this circuit in motivationally relevant contexts continues to mature into early adulthood.

Title: Association of sex and pubertal status on cortical thickness in typically-developing children

Authors: *J. BARONE[1], K. M. REDING[1], J. S. KIPPENHAN[1], S.-M. WEI[1], T. NASH[1], M. ZAWADZKI[1], A. BOROSHOK[1], S. MURRAY[1], H. RAAB[1], P. MARTINEZ[2], D. E. BOYLE[3], E. ROBINSON[3], P. KOHN[1], L. NIEMAN[4], P. J. SCHMIDT[2], K. F. BERMAN[1]

Abstract: Background: Adolescence is a time of increased neuropsychiatric disease onset, and a critical period for the emergence of sex differences in these disorders. Neuroimaging studies of brain development document structural and functional changes during adolescence, but often assume that observed age- and sex-related differences coincide with the pubertal transition and subsequent rise in sex hormones. Here, to better understand both sex and pubertal effects, we examined cortical thickness (CT) both before and after pubertal onset as defined by clinician-rated Tanner Staging (TS). **Methods:** Eighty typically-developing children and adolescents were categorized by pubertal status: prepubertal (TS1, N=48, 8.7±0.3yrs; 18 girls) and pubertal (TS2-5, N=32, 13.0±0.7yrs; 15 girls). Multi-echo MPRAGE scans acquired on a GE 3T MRI scanner were processed with FreeSurfer v5.3. CT was computed as the distance between pial and white matter surfaces, resampled to a standardized mesh using SUMA, and smoothed with a 25mm kernel along the cortical ribbon. Data were analyzed in a 2x2 ANOVA with sex and pubertal group (prepubertal [T1] vs, pubertal [T2-5]) as between-subjects variables. For clusters showing effects of pubertal status, we ran post-hoc partial correlations between CT and individual TSs (1-5), controlling for age. For clusters showing interaction effects, we ran pairwise comparisions between pubertal groups within each sex, and between sex in each pubertal group. **Results:** We identified robust effects of pubertal status ($p<.05$, FDR-corrected) in the prefrontal cortex (PFC), sensorimotor cortex, and dorsal and ventral visual processing streams. These regions all showed greater prepubertal than pubertal CT. Post-hoc partial correlations between individual TSs and CT, controlling for age, showed a trend-level negative relationship in left frontal cortex and right dorsal stream regions ($p's=.074$). There was a main effect of sex ($p<.001$, uncorrected) with greater parietal and occipital CT in boys in both pubertal groups. Sex by pubertal status effects ($p<.001$, uncorrected) were seen in the medial(m) PFC, and both dorsal and rostral anterior cingulate cortex (dACC, rACC). Post-hoc pairwise comparisons suggest that for all these regions CT decreased with pubertal status in girls (all $p's<.001$) while no differences were seen in boys. Additionally, in the mPFC and dACC, girls showed greater CT compared to boys within the prepubertal group only. **Discussion:** Our data suggest that CT may decrease as a function of TS, controlling for age, and that prefrontal and cingulate regions show sex differences in CT both prepubertally and across puberty.

Title: Socioeconomic status and brain structure and function across development: A multimodal investigation

Authors: *M. L. ROSEN[1], *M. L. ROSEN[1], M. A. SHERIDAN[3], K. A. SAMBROOK[2], A. N. MELTZOFF[1], K. A. MCLAUGHLIN[1]

Abstract: Growing evidence suggests that childhood socioeconomic status (SES) influences neural development, which may contribute to well-documented SES-related disparities in academic achievement. Here, we apply a multimodal neuroimaging approach to investigate the associations of childhood SES with cortical structure, white matter microstructure, and neural function during a WM task across development. The sample included 66 children and adolescents (age 6-19 years). Higher SES was associated with better academic achievement and performance on the WM task. SES was unrelated to cortical thickness after FDR-correction. However, higher family income-to-need ratio was also associated with greater fractional anisotropy in the right and left superior longitudinal fasciculi (SLF). Greater connectivity in left SLF, in turn, was associated with higher academic achievement. Additionally, higher income-to-needs was associated with greater BOLD signal across many regions in the prefrontal and temporal cortex during WM encoding, maintenance, and retrieval; greater activation in these regions was associated with better task performance and higher levels of academic achievement. Taken together, these findings suggest potential neural mechanisms that link SES with both WM performance and academic achievement, including prefrontal cortex activation and the integrity of white matter connectivity within the frontoparietal network.

Title: Socioeconomic status and minority status effects on brain structure and cognitive function: A multivariate analysis of the PING study dataset

Authors: *C. CARDENAS-INIGUEZ, M. G. BERMAN
Univ. of Chicago, Chicago, IL

Abstract: Childhood low socioeconomic status (SES), widely associated with increased psychosocial and environmental stress, has been previously associated with differences in brain morphometry and cognitive function. The current study investigates this finding further by using multivariate analysis approaches, such as Partial Least Squares (PLS) and Canonical Correlations, to explore the relationship between cortical thickness and cortical surface area, and conditions associated with SES, such as household income and parental education, in addition to racial/ethnic minority status, also previously associated with increased psychosocial and environmental stress. Drawing from the Pediatric Imaging, Neurocognition and Genetics dataset (PING), a dataset of 1108 diverse participants ages 3-20 (570 male, 538 female), we analyzed cortical thickness and cortical area data parcellated into lobular regions (4 per hemisphere for a total of 8 regions) using a data-driven, fuzzy clustering technique highlighting genetic similarities in cortical areas using Freesurfer. We implemented Partial Least Squares (PLS) and Canonical Correlation analyses so as to uncover significant relationships between cortical morphometry across various cortical regions and multiple demographic variables. Consistent with previous investigations in the literature, our initial PLS analyses on cortical surface area revealed that even after controlling for age and gender, all cortical lobe areas (bilateral parietal, occipital, temporal, and frontal) showed a reliable and significant positive relationship with household income and parental education, such that lower SES was associated with a smaller surface area. We did not find a significant or reliable relationship between SES measures and cortical thickness using PLS. Canonical Correlation analyses on cortical thickness and demographic variables revealed a latent variable showing a strong negative relationship between cortical thickness across all lobes and age, but a positive relationship with being White and having higher parental education. Canonical Correlation analyses on cortical surface and demographic variables revealed a latent variable showing a strong positive relationship with being White and having both higher income and higher parental education and being male, but a strong negative relationship with being Black. Our multivariate analyses are consistent with previous reports indicating childhood SES during has a differential impact on brain development, while also showing evidence to support that minority status may also have an impact on brain morphometry.

Title: Developmental stabilization of neural gain signals improves mean behavioral performance and behavioral variability

Authors: *D. F. MONTEZ[1], B. LUNA[2]
[1]Psychiatry, Univ. of Pittsburgh, Pittsburgh, PA; [2]Dept Psychiatry, Lab. Of Neurocognitive Develop., Pittsburgh, PA

Abstract: Introduction
Behavioral variability is an important barometer of cognitive functioning. During adolescent development behavioral responses both improve on average as well as stabilize. Mechanistically accounting for the stabilization of behavior is critical to our understanding of adolescent neural development. Here, we report results from a longitudinal working memory study performed over 10 years. We develop a computational model of memory-guided saccade (MGS) performance and demonstrate that improvements in mean behavioral performance and behavioral variability can be accounted for solely in terms of stabilizing neural variability.
Methods
We studied and accelerated longitudinal cohort of 126 subjects between the ages of 8 and 33 years as they performed a variant of the memory-guided saccade task. We developed a computational model of behavioral responses based on a high-dimensional drift-diffusion race model framework that incorporates variability in gain signals. The resulting model allows us to model reaction times as well as continuous metrics of response accuracy in the memory-guided saccade task
Results
We find that behavioral performance in the memory-guided saccade task improves and stabilizes during adolescence. By incorporating multiple sources of independent gain variability in a high-dimensional drift diffusion race model that we can account for the improvements in mean behavior and behavioral variability that are observed during adolescent development. Analysis of the trial-to-trial relationship between memory-guided saccade reaction times and accuracies reveals a peculiar U-shaped speed-accuracy relationship. Further analysis shows that this relationship can be accounted for by a balance of independent variability affecting working memory and response threshold gain signals.
Conclusion

Results from our computational model indicate that independent trial-to-trial variability in gain signals that affect working memory maintenance and response thresholds can account for peculiar speed-accuracy relationships observed in our data. Moreover, in addition to qualitatively accounting for the stabilization of behavioral responses, e.g. reaction time variability and saccade precision, our computational model of memory-guided saccade performance can account for improvement in mean reaction time. Thus, it appears that changes in both mean behavioral performance and behavioral variability observed during development may be the results of stabilizing of neural gain signals.

Ctr., Pécs, Hungary

Abstract: Childhood obesity is a rising problem caused in part by unhealthy food choices. Food choices are based on a value signal encoded in the ventromedial prefrontal cortex (vmPFC), and self-control involves modulation of this signal by the dorsolateral prefrontal cortex (dlPFC). We

examined the effects of development, body weight and body weight history on the neural correlates of healthy food choice in children. 141 children from the I.Family/Idefics cohort (aged 10-17y) from Germany, Hungary and Sweden performed a food choice task while being scanned with fMRI and provided health and taste ratings of the foods. During the choice task participants considered either the healthiness or tastiness of the food or chose naturally. Overall, children made healthier choices when asked to consider healthiness. However, younger children and children who had gained weight chose less healthy foods when considering healthiness. dlPFC activation during food choice correlated positively with pubertal development and negatively with BMI (Fig. 1). There was a positive correlation between weight change and visual processing activation in the bilateral calcarine sulcus and lingual gyrus. When considering healthiness, cerebellum activation correlated positively with BMI and negatively with pubertal stage, and there was a positive correlation between weight change and activation in the inferior parietal gyrus. In conclusion, in younger children and children who have gained weight the positive effect of considering the healthiness of foods on their choices was smaller. Furthermore, younger children and children with a higher body weight had less activation in an area important for self-control during food choice. Pubertal development, current body weight and body weight change influenced the effect of health considerations on different areas involved in saliency. Thus the effectiveness of interventions that rely on self-control or that call attention to health aspects of food may be diminished in younger children, children who are gaining weight and overweight children.

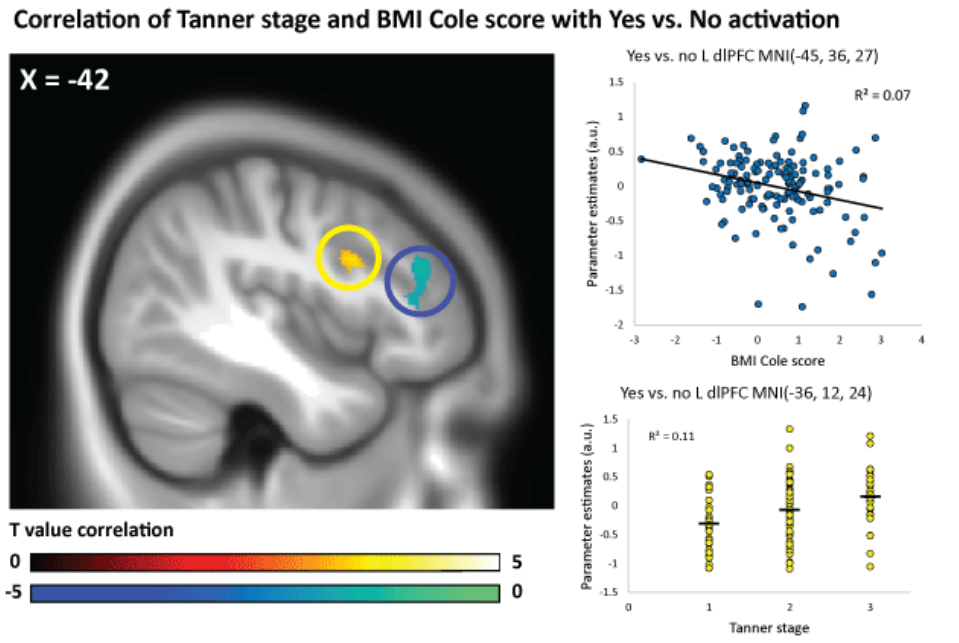

Figure 1. Correlation of Tanner stage and BMI Cole score with modulation of choice activation by yes vs. no. Blue circle denotes negative correlation with BMI Cole score and yellow circle denotes positive correlation with pubertal stage (Tanner stage). Peaks listed are significant at $p < 0.05$ level based cluster level corrections (individual voxel threshold = $p < 0.001$, cluster extent = 30 voxels, 3x3x3 mm voxels).

Title: The association between cortical maturation and the development of impulsive choice in binge-drinking adolescents

Authors: *S. A. JONES[1], A. MORALES[3], B. J. NAGEL[2]
[2]Psychiatry & Behavioral Neurosci., [1]Oregon Hlth. and Sci. Univ., Portland, OR; [3]Oregon Hlth. & Sci. Univ., Portland, OR

Abstract: Previous research has shown a developmental decrease in impulsive choice across adolescence that is diminished or absent in youth who engage in binge drinking. Further, magnetic resonance imaging (MRI) has shown lateral regions of the prefrontal cortex to be associated with impulsive choice behavior. However, few studies have investigated how cortical maturation is associated with the development of impulsive choice across adolescence, and no study to our knowledge has investigated how this association differs in the context of alcohol use. In the current study, 25 binge-drinking adolescents (≥4 drinks/occasion, ≥3 times in the past 3 months) and 21 controls (matched at baseline for age, gender, and pubertal development) completed a baseline T1-weighted MRI and delay discounting procedures, prior to alcohol use, and again at follow-up (mean time between scans = 2.8 years). Multilevel modeling was used to assess the association between cortical thickness in the dorsolateral prefrontal cortex (DLPFC), and the development of delay discounting behavior across age in both binge-drinking adolescents and controls. In the right rostral middle frontal gyrus, there was a significant association between cortical thickness and discounting behavior (i.e. impulsive choice) that varied across age in control adolescents (b = -2.25, $p < 0.05$), such that less thickness earlier in adolescence (age 14) was associated with significantly lower impulsive choice (b = 7.85, $p < 0.01$), an effect that diminished and was non-significant by late adolescence/early adulthood. The association of this interaction effect, between cortical thickness and age, with impulsive choice was significantly altered in binge-drinking adolescents (group-by-thickness-by-age interaction, b = 3.39, $p < 0.05$). As a result, binge-drinking youth showed no association between cortical thickness and impulsive choice across adolescence. Together, these findings demonstrate that thinner DLPFC earlier in adolescence, representative of a developmentally typical synaptic pruning process, is associated with lower rates of impulsive choice, an effect that diminished across adolescence into early adulthood in non-alcohol users. However, cortical thickness was not associated with the development of impulsive choice in those who went on to drink, suggesting a disconnect in the

relationship between cortical thickness and impulsive choice behavior, which precedes initiation of alcohol use. This disruption in structure-function may render adolescents more prone to engage in risky decision making, such as the decision to drink.

London, London, United Kingdom; [8]Psychiatry, Univ. of Vermont, Burlington, VT

Abstract: Across age groups, differences in connectivity between the striatum and prefrontal cortex co-vary with trait impulsivity (IMP) and sensation-seeking (SS). IMP and SS are also known to increase during early adolescence as maturation of subcortical structures outpaces that of the prefrontal cortex. While an imbalance between the striatum and prefrontal cortex is considered a normal developmental process, higher levels of adolescent IMP and SS are associated with an increased risk for diverse problems, including obesity. To examine these associations further we assessed relationships between body weight, IMP, SS, and connectivity of nuclei in the striatum and dopaminergic midbrain in young adolescents. Data were collected from 116 children between the ages of 12 and 14, and included resting state functional magnetic resonance imaging, personality measures from the Substance Use Risk Profile Scale, and body mass index Z-score for age (BMIZ). Voxel-wise analyses indicated that the connectivity of the left and right sub-thalamic nucleus (STN), ventral striatum (VS), ventral tegmental area (VTA) and substantia nigra (SN) with other cortical and limbic regions of the brain, were correlated with BMIZ, IMP and SS. The voxel-wise connectivity data was reduced by calculating the mean connectivity for each of 135 anatomical atlas regions, for each of the four seeds. The shared

variance for the connectivity of each seed, and the IMP, SS and BMIZ measures, were then analyzed using partial least squares correlations. This analysis identified a single significant striato-limbic network that was connected with the VS, VTA and SN ($p = 0.006$). This limbic network, defined using a bootstrap cut-off ratio of -3 or less, included the bilateral hippocampi, amygdalae, medial anterior temporal lobes, parahippocampal gyri and red nuclei, as well as the left perirhinal cortex, thalamus, SN and STN. Connectivity between these regions and the striato-limbic network was correlated positively with IMP and BMIZ scores and inversely with SS. Finally, results from the initial voxel-wise analysis were used to generate reverse inference maps in the NeuroSynth database. This analysis found that the voxel-based regions had been identified in prior studies on reward and risk-taking. Together, these findings emphasize that, in addition to the well-established role that striato-frontal circuits play in the development of adolescent personality traits, connectivity of limbic regions with the striatum and midbrain also impact IMP, SS and eating behaviour in adolescents.

Title: Sexual dimorphism of the effect of DRD2 AUD-risk genotype on gray matter volume (GMV) and adolescent substance initiation

Authors: *R. A. SCHROEDER[1], B. W. STEVENS[1,2], V. L. DARCEY[1,2], E. J. ROSE[3], D. H. FISHBEIN[3], J. W. VANMETER[1]

Abstract: Adolescence is a period of development marked by significant brain and behavioral changes that are further influenced by genetic and sexually dimorphic factors. One source of variation is the single nucleotide polymorphism rs6277 in the dopamine receptor D2 (DRD2) gene, in which the C allele has shown an increased risk for Alcohol Use Disorder (Padmanabhan & Luna, 2014). Since little is known regarding the effects of DRD2 genotype and sex during adolescence, we analyzed gray matter volume (GMV), future initiation of drug or alcohol use, and reward-based planning behavior.

Data are from healthy, drug and alcohol naïve adolescents, ages 11-13, N = 101 (55 F), enrolled in the Adolescent Development Study, a prospective longitudinal neuroimaging study of drug and alcohol use in adolescents. Significant differences were found between high and low risk DRD2 allele groups in race ($p < 0.001$), IQ ($p < 0.001$) and SES ($p = 0.003$), with the latter two significantly correlated ($p < 0.001$).
GMV was quantified using a T1-weighted MPRAGE (voxel size = 1mm3) acquired on a Siemens 3T scanner. GMV was assessed using voxel-based morphometry using DARTEL performed in SPM8. Statistical modeling compared groups using a 2x2 ANOVA including sex and DRD2 (T/T combined with T/C vs. C/C), while controlling for IQ and race. Intracranial brain volume was used to normalize results to avoid volume-based sex differences and multiple comparisons were controlled using Non-Stationary Cluster Correction.
No main effects for DRD2 or sex were found, however, whole brain analysis revealed an interaction between DRD2 and sex, with greater GMV found in low risk females and high risk males when compared to high risk females and low risk males (723 voxels, $p = 0.045$) in the left superior temporal gyrus (STG; peak -46, -19, -1), which has been shown to be involved with reward planning, impulsivity, and goal achievement (FitzGerald et al., 2014; Marsh et al., 2010; Gerlach et al., 2014). Within sexes, males had significant differences between high and low risk ($p < 0.001$).
Temporal discounting, a measure of reward-based planning, also had a significant interaction between sex and DRD2 genotype ($p = 0.004$), with high risk indicating a preference for immediate reward. To measure the influence of DRD2 on drug and alcohol use, an odds ratio determined that future male users with high risk versus low risk genotype were not significantly different. However, females with the low risk genotype were significantly more likely to become users (12 low risk vs. 6 high risk) at $p = 0.019$. These results suggest DRD2 has a sexually dimorphic effect on adolescent substance initiation that could be related to its differential effect on GMV in the STG.

Title: Dimensional relationships between basal ganglia iron and psychosis-spectrum symptoms in youth

Authors: *L. M. BEARD[1], A. ROSEN[2], M. A. ELLIOT[2], D. R. ROALF[3], K. PRABHAKARAN[2], R. CIRIC[4], M. E. CALKINS[2], T. M. MOORE[2], K. RUPAREL[2], R. GUR[2], R. C. GUR[5], D. H. WOLF[2], T. D. SATTERTHWAITE[2]

Abstract: Elevated levels of dopamine in the basal ganglia is thought to be a critical mechanism for the development and maintenance of psychosis. Iron is implicated in dopamine transport, and individual differences in basal ganglia iron have been associated with variation in extracellular dopamine levels and reuptake. Iron can be measured non-invasively using R2* weighted magnetic resonance imaging (MRI), allowing in vivo quantification. Prior work has suggested that lower R2* signal is associated with lower iron content, which is thought to correspond to higher extracellular dopamine levels. Furthermore, it is known that basal ganglia iron and dopamine evolve dramatically during adolescence, which is also when symptoms of psychosis typically emerge. Here, we used R2* MRI to quantify basal ganglia iron in a large sample of youth; ages 8-23 imaged as part of the Philadelphia Neurodevelopmental Cohort (PNC, n=1,147, 54% female). We hypothesized that greater levels of psychosis-spectrum symptoms would be associated with lower R2*, which is consistent with higher extracellular dopamine. To test this, we used an advanced multi-atlas labeling procedure to derive subject-specific segmentations of each basal ganglia structure. Mean R2* signal in each structure was modeled using generalized additive models with penalized splines to capture both linear and nonlinear developmental effects. Replicating prior work, R2* increased with age ($p<0.001$ for all basal ganglia regions). Critically, lower R2* signal was associated with higher psychosis-spectrum symptoms in the bilateral putamen ($p<0.002$), consistent with higher extracellular dopamine. This result provides novel evidence for dopamine dysregulation associated with subthreshold psychotic symptoms during adolescence and highlights the utility of this non-invasive proxy of basal ganglia dopamine.

Title: Abnormal gyrification and cortical thickness in the schizophrenia prodrome: A developmental perspective

Authors: *K. DAMME[1,2], T. D. GUPTA, 60208[2], J. BERNARD[3], D. DEAN[3], R. NUSSLOCK[2], V. MITTAL[2]
[1]Northwestern Univ., Chicago, IL; [2]Psychology, Northwestern Univ., Evanston, IL; [3]Univ. of Colorado, Boulder, CO

Abstract: Psychotic disorders are characterized by abnormal cortical features, which may be informative about timing of developmental insult or specific pathogenic factors. It is unclear is if cortical abnormalities primarily manifest after onset or reflect abnormal neurodevelopment. With regard to the latter, it is unclear if they carry over from in utero development, or if in fact, emerged/changed during the significant adolescent neuro-reorganization that overlaps with the psychosis prodrome period. To date, a handful of studies in this prodromal period focus on change over time, but none have looked at the range of available surface characteristics (e.g., sulcal depth, curvature, thickness) in the same sample, over time.
A total of 43 ultra high-risk (meeting criteria for a prodromal syndrome; UHR) and 38 Healthy Control (HC) participants completed a structural scan at two-time points. Freesurfer v.5.3.0 automatic segmented structural images, T1-MPRAGE. Right and left hemispheres were tested separately and FDR $p<.05$ using QDEC to control for gender and medication status, comparing cortical thickness, curvature, and sulcal depth.
In a whole brain analyses, the UHR and HC groups differed in curvature and sulcal depth revealing nine significant clusters. UHR and HC groups differed in cortical thickness in several significant clusters as well. Group differences survived correction for age, and medication status. Sulcal depth and curvature demonstrate a similar regional pattern of gyrification distinguishing UHR from typically developing controls, consistent with a distinguishing early developmental insult. Cortical thickness represented a lager unique pattern of cortical thinning related to later adolescent neuro-reorganization. The present findings play a vital role in helping to reconcile the body of literature highlighting cortical feature anomalies in psychosis, with the neurodevelopmental perspective of schizophrenia.

Title: Prenatal exposure to population-wide folic acid fortification impacts cortical maturation and psychosis risk in youth

Authors: *H. ERYILMAZ[1], F. C. HUNTINGTON[1], A. RODRIGUEZ-THOMPSON[1], T. W. SOARE[1], K. F. DOWLING[1], J. C. BLOSSOM[2], R. L. GOLLUB[1], E. SUSSER[3], R. C. GUR[4], M. E. CALKINS[4], R. E. GUR[4], T. D. SATTERTHWAITE[4], J. L. ROFFMAN[1]

Abstract: Maturation of the cerebral cortex through adolescence supports cognitive, social, and emotional development. Disruptions of the brain's normal growth curve, such as accelerated age-related cortical thinning, characterize several neuropsychiatric conditions that emerge in the first decades of life. Epidemiologic studies of one such disorder, schizophrenia, hint that variation in gestational folate levels may influence post-natal brain development in ways salient to disease risk. To test this idea, we leveraged a "natural experiment": we contrasted cortical thickness among comparable groups of 8- to 18-year-old youth who gestated before, during, or after the rollout of mandatory grain product fortification (1996-97), a population-wide intervention that rapidly doubled blood folate levels in women of child-bearing age.

We purposely sampled the MGH Research Patient Data Registry to identify matched groups of pre-rollout, rollout, and post-rollout youth with normative clinical MRI scans that survived stringent quality control (n=315 scans). A second, deeply phenotyped cohort born around the time of the rollout (Philadelphia Neurodevelopmental Cohort, PNC, n=881 scans) was used to verify effects of fetal fortification exposure on cortical thinning, and to relate thickness changes to psychosis risk. Finally, temporal specificity of these effects was established by using a third cohort (NIH MRI Study of Brain Development, NIH) comprising 385 scans from youth born exclusively before the rollout.

Within the MGH cohort, we observed diffuse pre- to post-rollout increases in cortical thickness in 29 of 68 cortical regions-of-interest ($p<.05$, FDR corrected). The post-rollout group also exhibited delayed cortical thinning in 14 of these regions ($p<.05$, FDR corrected). This pattern replicated in 7 regions within the PNC sample ($p<.05$), with delayed thinning apparent in the post-rollout group; but was only seen in 1 region in the NIH sample. Within the PNC sample, flatter thinning profiles in each replicated region (bilateral inferior parietal lobule; right inferior temporal, middle temporal, and precentral gyri; and left lateral occipital cortex) in turn predicted reduced psychosis risk ($0.06>p>.001$).

Programming of cortical maturation in youth is sensitive to fetal folate levels, potentially reflecting alterations in the fetal epigenetic milieu. Further, that these cortical changes predicted reduced psychosis risk may portend an important and unexpected public health benefit of folic acid fortification.

Title: Brain maturation effect on functional network graph metrics of patients with attention deficit hyperactivity disorder differs from normal children and adolescents. Assortativity as a measure of brain maturation

Authors: *B. MOHAJER[1], N. ABBASI[2], A. ABDOLALIZADEH[2]
[1]Student Scientific Res. Ctr. of Tehran Unive, Tehran, Iran, Islamic Republic of; [2]Tehran Univ. of Med. Sci., Tehran, Iran, Islamic Republic of

Abstract: Introduction: Attention deficit hyperactivity disorder (ADHD), as one of the most common childhood and adolescent's neuropsychiatric disorders, has shown to demonstrate impairments of structural and functional neural connectivity networks, a finding that occurs in the maturation and pruning period of the brain synapses. Comparing the effect of aging on brain network development between healthy children and adolescents and ADHD patients would help to clarify this process.**Methods:** We used restingstate functional correlation matrices of 190 ADHD patients, and 330 age and sex matched healthy children and adolescents from ADHD200 study (umcd.humanconnectomeproject.org). Minimum, maximum and average ages were 7.17, 21.74 and 11.83 years respectively. Each matrix consisted of undirected weighted correlations between 200 regions in fMRI of subjects (Craddock atlas). Graph theoretical analyses were performed using the Brain Connectivity Toolbox. To enable comparison of global network properties across groups, we applied 20% sparsity threshold based on previous studies. Global efficiency, Transitivity, Assortativity, and Modularity were calculated as global network measures. Using R for statistical analyses, measures were fed into General Linear Model (GLM), to investigate the age effect controlled for gender effect.**Results:** We found a significant decrease in Assortativity with the increase of age in healthy subjects after FDR correction (P value=0.018, tvalue=2.3) compared to non-significant result with a slower slop of assortativity decrease in ADHD (P value=0.19, t value=1.3) patients. The remaining measures did not reveal any significant changes with the increase of age.**Discussion:** Number of neighboring nodes that

sharing an edge with a node, defines as the degree. Assortativity indicates how preferentially nodes of similar degree connect to each other. As previously shown, adult and child functional brain networks both demonstrate smallworld features, although consisting of different communities of nodes. The difference here is nodes arrangement: children's communities arranged by anatomical proximity on the other hands, adults' predominantly reflect functional relationships. Above results may indicate architectural changes in the functional network of normal population, from anatomical proximity connectivity through functional relationships. This connectivity pattern shift may be the main reason behind neural network malfunctions in ADHD, what reflects of assortativity. Future functional connectivity studies focusing on the regional measures may clarify network dynamics in ADHD population

Title: Amygdala response to distress cues and callous-unemotional traits; moderation by trauma

Authors: *H. MEFFERT, P. M. TYLER, M. L. BOTKIN, A. K. ERWAY, V. KOLLI, L. C. THORNTON, K. POPE, S. F. WHITE, J. R. BLAIR
Ctr. for Neurobehavioral Res., Boys Town Natl. Res. Hosp., Boys Town, NE

Abstract: Youth displaying disruptive behavior show amygdala hypo-responsiveness to fearful expressions as a function of a callous-unemotional (CU) traits (i.e., reduced guilt and empathy). However, some research suggests that trauma exposure may moderate this relationship. Specifically, work has identified two groups of disruptive youth with equivalent high levels of CU-traits, but differing levels of anxiety and trauma exposure. The objective of the first of two studies was to examine whether trauma exposure influenced the neurobiology underlying fear expression processing in 72 youth with varying levels of disruptive behavior and trauma exposure. Participants performed a gender discrimination task while viewing morphed expressions (0%, 50%, 100%, 150% fear). A linear regression analysis on the BOLD data, using level of CU-traits and trauma exposure as covariates, showed a significant CU-traits-by-trauma interaction within right amygdala; CU-traits were *negatively* associated with fear intensity modulated amygdala responses in low trauma participants, but *positively* associated with fear intensity modulated amygdala responses in high trauma participants. The second study aimed at examining how the neurobiology underpinning fear expression processing predicted social

behavior as a function of trauma exposure. Participants were invited back to complete a social goals task. Data suggest that stronger fear responsivity in the amygdala predicts prosocial behavior in low trauma youth, whereas stronger fear responsivity predicts non-social behavior (revenge) in high trauma youth. These data suggest that there is not a unique pathophysiology associated with increased CU-traits. In youth with low trauma exposure, CU-traits relate to a reduced empathic response to distress cues. This is expressed at the neural level as a reduced amygdala response to these distress cues. However, in youth with high trauma exposure, an environmental insult known to increase threat sensitivity, CU-traits relate to a heightened response to fearful expression stimuli. Importantly, the current data strongly reinforce the importance of determining the pathophysiology underpinning a particular behavioral presentation; interventions need to be tailored to the individual's pathophysiology rather than their behavioral presentation alone.

Title: Age-related changes in amygdala functional connectivity in children

Authors: *T. IARAJULI, A. ROY
Neurosci., Fordham Univ., Bronx, NY

Abstract: The amygdala is a small brain region that is responsible for emotional expression, particularly fear, rage and aggression. The affective and cognitive processes involved in emotion regulation are thought to emerge from connections between the amygdala and the prefrontal cortex. Recent evidence suggests that maturation of amygdala-prefrontal circuits during childhood underlie the development of emotion regulation skills. Many studies have been conducted that compare amygdala connectivity between children and adult groups, but few have focused solely on amygdala development during middle childhood (ages 5-9 years), a time during which emotional and behavioral dysregulation often emerges. The present study used resting-state functional magnetic resonance imaging to examine the relationship between amygdala functional connectivity and age in a sample of typically developing children, ranging from 5-9 years old (n=39). We further examined how this connectivity was directly related to

emotion lability and emotion regulation using a parent-report scale, the Emotion Regulation Checklist (ERC). Results show decreases in intrinsic functional connectivity (iFC) between the right and left amygdala with increasing age. No age-related changes were observed in amygdala –PFC iFC. Additional analyses revealed that right amygdala iFC to left amygdala correlated with the ERC Lability/Negativity scale (r=0.32, p=0.04), but not ERC Emotion Regulation scale (r=-0.13, p=0.44) in typically developing children. These findings suggest that bilateral iFC of the amygdala may play a role in decreasing emotional lability across this age range.

Title: Regional developmental patterns within components of grey-/white matter intensity contrast and modulatory effects of mental health in youth

Authors: *L. C. NORBOM[1], N. T. DOAN[2], D. ALNÆS[2], T. KAUFMANN[2], L. T. WESTLYE[2], C. K. TAMNES[3]

Abstract: Adolescence is a maturational period with extensive brain reorganization and coincides with the onset period of numerous mental disorders. Cortical dysmyelinisation is a possible mechanism for several of these disorders including psychotic disorders. Cholesterol in myelin is a major determinant of the signal intensity in T1-weighted MRI and the *contrast* between grey matter (GM) and white matter (WM) intensity is thus believed to be sensitive to myelin content both in WM and within the cerebral cortex. In the current study, we investigated GM/WM contrast to indirectly explore patterns of typical and atypical cortical myelinisation in adolescence, using the Philadelphia Neurodevelopmental Cohort (N=935, 8-22 years old). T1-weighted images were processed in FreeSurfer. Average GM intensities (0-60% into the cortical ribbon) and average WM intensities (0-1.5mm into subcortical WM) were sampled vertex-wise along the cortical surface, and subsequently a GM/WM contrast map was calculated. Next, we performed independent component analysis (ICA) on the contrast map, and tested for associations with age, gender, IQ, as well as a set of 7 clinical ICA components reflecting different clinical domains using linear models. Preliminary results of 10 contrast components reflected global patterns of reduced contrast with age. Over and above the global components, which explained a large portion of the data variance, regional contrast variations were reflected in a set of components, which showed either reduced or increased contrast with age. Mental

health and IQ was moderately associated with component loadings. For instance, high loading on certain clinical components were associated with increased contrast in several regions, while decreased contrast was associated with higher IQ score. Preliminary results also indicated some interaction effects between clinical components and age on GM/WM contrast. High loadings on several clinical components were associated with increased contrast for younger individuals, but not for older individuals. Our preliminary results suggest that independent modes of GM/WM contrast variation may be sensitive to global and regional maturational processes, likely related to cortical myelinisation, and that these age-related patterns to some extent are modulated by mental health and IQ.

Title: Circadian perturbation reveals time sensitivity to reward-related behavior during adolescence

Authors: *M. A. HILDEBRAND[1], C. A. VADNIE[2], R. W. LOGAN[3], M. M. TORREGROSSA[1], C. A. MCCLUNG[4]
[1]Psychiatry, [2]Dept. of Psychiatry, Univ. of Pittsburgh, Pittsburgh, PA; [3]PSYCHIATRY, UNIVERSITY OF PITTSBURGH, PITTSBURGH, PA; [4]Psychiatry, Univ. of Pittsburgh Med. Sch., Pittsburgh, PA

Abstract: Adolescence is a vulnerable time for perturbations in sleep patterns and circadian rhythms. Adolescents prefer later sleep and wake times, which has been attributed to a biologically driven delay in circadian rhythms. Since school start times are early in the morning, many adolescents may experience chronic circadian misalignment and sleep deprivation. Numerous studies support that sleep and circadian rhythm disruptions are risk factors for increased reward seeking behavior, suggesting that adolescents with poor sleep quality and misaligned rhythms may be more susceptible to uncontrolled reward seeking. Thus, we sought to determine the effects of circadian disruption on reward-related behavior in adolescent rats. The circadian rhythms and sleep patterns of adolescent male Wistar rats were monitored in non-

invasive Piezo Sleep boxes (Signal Solutions LLC) from age P25-P35 in constant dark to determine their sleep/circadian phenotype. Rats were subsequently tested for operant self-administration of sucrose pellets during their active phase from approximately age P39-P56 to determine if their motivation for reward was associated with their sleep/circadian phenotype. On the final two days, rats responded on a random ratio (RR3) schedule during their inactive phase to determine if there were associations between reward-related behavior and sleep/circadian phenotype during an acute disruption of sleep and circadian rhythms. The change in performing operant sucrose self-administration during their active phase relative to their inactive phase produced two distinct phenotypes. Time sensitive rats (n=10) decreased more than 20% in their performance, whereas time insensitive rats (n=10) had less than a 10% decrease in performance during the inactive phase. These two groups differed in their responding for sucrose reward ($p < 0.001$). The time insensitive group showed a trend for more fragmented sleep than the time sensitive group ($p = 0.093$). The time insensitive group also took longer to learn a reversal of the active lever ($p < 0.01$). Adolescent rats that had more fragmented sleep showed increased reward-related behavior during their inactive phase. This suggests that poor sleep quality might increase reward-seeking behavior. Developing a model system to understand the mechanisms underlying the associations between sleep and circadian phenotypes and reward-related behavior could allow us to develop novel treatments to reduce substance use disorders in adolescents.

Title: Investigating the role of CXCR-4 in the adolescent sensitization to amphetamine

Authors: *B. M. MASON, S. DONALDSON, C. CALHOUN, V. WOYTOWICZ, L. PINA, R. KANDA
Univ. of Massachusetts Boston, Boston, MA

Abstract: Drug addiction remains a significant health problem in the U.S., with about 21 million people presenting with substance use disorders. For many, the first experience with an illicit substance is in adolescence, which warrants investigative studies of drug-related behavior at this age. Neuroinflammation has recently been found to contribute to the pathology of addiction in animals, and has been implicated in the plasticity contributing to psychostimulant sensitization,

through the activation of a chemokine receptor, CXCR-4. In our current study, we investigated whether 4-day amphetamine (4.0 mg/kg/ml, IP, every 48 h) locomotor sensitization could be attenuated by the CXCR-4 antagonist, AMD3100 (5.0 mg/kg per ml) in Long-Evans adolescent males (N=39). Indeed, we observed a significant diminution in locomotor, rearing and stereotypy counts in rats pre-treated with AMD3100 prior to amphetamine administration. Further, when challenged with a low dose of amphetamine (1.0 mg/kg/ml, IP) one week later, AMD3100 pre-treatment reduced locomotor and rearing counts, and stereotypies. Additionally, we found reduced CXCR-4 counts in the medial prefrontal cortex (mPFC) of AMD3100 -pretreated rats as compared to rats given amphetamine alone. Collectively, the data suggest that amphetamine sensitization in adolescence may involve, at least in part, activation of the neuroinflammatory CXCR-4 receptor, and these lasting changes may produce the vulnerability to persistent drug-taking in adulthood.

Title: IL-1b promotes investment in present versus future outcomes

Authors: *J. GASSEN
Psychology, Texas Christian Univ., Fort Worth, TX

Abstract: Exposure to adversity early in life has been associated with risk-taking, impulsivity, and other Life history theory predicts that exposure to adversity early in life leads to the development of a faster life history strategy, characterized by investment in reproductive effort and a preference for current over future rewards. As a strong link exists between childhood adversity and measures of inflammation, we predicted that proinflammatory cytokines, such as interleukin-1 beta (IL-1β) may mediate the relationship between childhood adversity and the suite of behaviors and attitudes that together define an individual's life history strategy. We found that levels of serum IL-1β predicted more reported impulsivity, less preference for delaying gratification, and a more present temporal orientation. Analysis of *in vitro* IL-1b release by participant peripheral blood-derived mononuclear cells (PBMCs) after stimulation revealed that higher levels of IL-1b predicted a reduced expectation of future longevity. These results were not found with IL-6 or TNF-a. Taken together, these results provide evidence to suggest that proinflammatory cytokines, in particular IL-1b, are involved in shaping an individual's life history strategy.

Title: Dopamine development to the orbital prefrontal cortex is protracted and sensitive to amphetamine in adolescence

Authors: *D. HOOPS[1], L. REYNOLDS[1], J.-M. RESTREPO-LOZANO[1], C. FLORES[2]
[1]Dept. of Psychiatry, [2]Dept of Psych, McGill Univ., Verdun, QC, Canada

Abstract: Introduction Exposure to drugs of abuse in adolescence alters prefrontal cortex development and adult function. We now know that exposure to abused doses of amphetamine in adolescence alters the development of the dopamine input to the medial prefrontal cortex (mPFC) and that this is dependent on the guidance cue receptor DCC. In contrast, the impact of drug exposure on orbital prefrontal cortex (oPFC) dopamine development is unknown. We do know that the maturation of oPFC-dependent behaviours depends on DCC signalling in dopamine neurons and is altered by amphetamine in adolescence. To examine the potential impact of drugs of abuse in the oPFC, we first determined whether dopamine development in the oPFC is protracted across adolescence. Then, we examined whether exposure to abused doses of amphetamine during adolescence disrupts oPFC dopamine development, and if DCC is implicated in this disruption. **Methods** We counted dopamine varicosities in the oPFCs of adolescent and adult mice using neuroanatomical methods established in our laboratory. We also counted dopamine varicosities in the adjacent piriform cortex as a control. We then treated adolescent mice with saline or amphetamine using a treatment regimen known to disrupt mPFC dopamine development via DCC. Once the mice reached adulthood, we counted dopamine varicosities and dopamine/DCC varicosities. **Results** Dopamine varicosity density doubles between early adolescence and adulthood in the lateral and insular oPFC, indicating protracted dopamine development across adolescence. In contrast, dopamine development in the piriform cortex was not protracted. Remarkably, chronic administration of amphetamine during adolescence dramatically reduces (by ~30%) adult dopamine varicosity density in these regions. This drug effect results in more DCC-expressing axons in the oPFC. **Discussion** These findings provide a potential mechanism underlying the changes in oPFC-mediated behaviours linked to adolescent drug abuse. Building on these findings, we are now using viral vector mediated cell type-specific fluorescent markers to confirm that dopamine axons are growing to the oPFC during adolescence, and where these axons are located prior to the onset of adolescence.

Title: Social stress and the dietary environment affect infant brain volumes in macaques: Modulation by maternal factors

Authors: *M. H. KYLE[1], ***M. H. KYLE**[1], *M. H. KYLE[2], M. PINCUS[1,2], J. GODFREY[1,2], Y. SHI[3], M. STYNER[3], L. LI[1], B. R. HOWELL[4], K. ETHUN[2], M. E. WILSON[1,2], M. SANCHEZ[1,2,5]
[1]Emory Univ., Atlanta, GA; [2]Yerkes Natl. Primate Res. Ctr., Atlanta, GA; [3]Dept of Psychiatry, Univ. of North Carolina, Chapel Hill, NC; [4]Univ. of Minnesota, Inst. of Child Develop., Minneapolis, MN; [5]Ctr. for Behavioral Neurosci., Atlanta, GA

Abstract: Social stress has adverse effects on brain structure and function linked to psychopathology, including changes to amygdala and prefrontal volumes. It is not well understood how these alterations emerge during development and interact with other risk factors, including obesogenic diets. Here we examined the potential for a synergistic impact of social stress and diet on infant brain development longitudinally, using a translational macaque model of social subordination stress. We also probed whether maternal care and breast milk mediate the effects of stress and diet on neural development. Forty-four socially-housed rhesus monkey infant-dam pairs (n=21 dominant (DOM), n=23 subordinate (SUB)) were randomly assigned to either a chow-only, low-calorie diet (LCD) condition, or had access to both LCD and high-calorie diet (HCD) from birth (choice). Behavioral observations of the infant-dam pairs were

collected from birth through 6 months, and maternal care quality was also rated. Plasma cortisol and structural MRI scans were collected at 2 weeks and 6 months. Preliminary results of the 6-month imaging data reveal significantly larger overall brain volumes in infants on the choice diet, with regional increases in the caudate, and insular, cingulate, and parietal cortices. SUB infants had larger amygdala and hippocampal volumes. The SUB and the choice conditions were associated with larger white matter (WM) volume in the frontal lobe, and a diet by social rank interaction was detected for WM in temporal visual and auditory cortices, with DOM LCD infants showing the smallest volumes. Baseline cortisol at 6 months was higher in the choice than LCD condition, which predicted larger right amygdala volumes. Among several rank (and diet) effects on maternal care, those on maternal permissiveness/attachment at 2 weeks were interesting, as stronger attachment predicted smaller left amygdala volume at 6 months. Greater milk yield at 6 weeks also predicted larger brain development, particularly of amygdala, and cingulate and frontal cortices WM. These preliminary findings suggest that exposure to social subordination and obesogenic diet early in life impacts infant brain development and stress hormones. Maternal care was also influenced by rank and diet, with more competent maternal care seeming to protect against some of the negative impacts of stress and diet on brain development, specifically in the amygdala.

Title: Environmental Enrichment alters the behavioral phenotype of a unique animal model of mood disorders

Authors: *A. M. O'CONNOR, C. A. TURNER, E. L. AURBACH, E. K. HEBDA-BAUER, S. J. WATSON, H. AKIL
MBNI Univ. of Michigan, Ann Arbor, MI

Abstract: Selectively bred High-Responder (bHR) and bred Low-Responder (bLR) rats present a novel rodent model of mood disorders. bHR animals emulate externalizing mood disorders such as addiction and impulsivity, and bLR animals emulate internalizing mood disorders such as depression and anxiety. Environmental enrichment (EE) has previously been shown to decrease anxiety-like behavior of adult bLRs and alter social behaviors of adult bHRs. Adolescence is a critical window for the development of emotional centers within the brain, and is a time of increased negative social interactions; by early adolescence, bHR and bLR animals show differential behavioral phenotypes. The effect of EE during adolescence on emotional behavior in these lines has not yet been determined. This study investigates the impact of adolescent EE on anxiety-like behavior of bHR and bLR animals following a social stressor. Male animals from generations F49 and F53 of the colony maintained at the University of Michigan were placed into enriched environments (E) for one hour a day, 5 days a week starting at 35 days postnatal (P35) and ending at P60. Control animals were handled and placed into large cages for the same time period (C) or left in standard housing with no handling (S). Half of all animals underwent social defeat (SD) from P60 until P64. All animals underwent behavioral testing P65 - P67. P65 and P66 testing consisted of a two day social interaction assessment; on day one animals were exposed to an empty open field and on day two a novel animal was present within the open field. Elevated Plus Maze (EPM) testing was carried out on day P67. All animals were sacrificed on P68, brains collected and snap frozen for processing. Exposure to EE decreased anxiety-like behaviors in bHRs, with animals exposed to EE spending more time in the center of the open field (P=0.024) and on the open arms of the EPM (P=0.011). EE prior to SD decreased social anxiety in bLRs, with EE + SD animals showing decreased social avoidance compared to bLR S + SD animals (P=0.028). EE decreased social interaction anxiety in bHRs, regardless of SD status (P=0.020). bLR animals that experienced EE prior to SD showed “bHR-like” patterns of behavior during social interaction testing, with a similar ratio of social interaction/avoidance when a novel animal was present in the open-field. It appears that exposure to EE during adolescence “flips” the bLR phenotype regarding social behavior when animals are subject to SD, suggesting that both genotype and environment influence animals’ response to stressors.

Title: Transgenerational effects of early life stress: DNA methylation in brain and blood

Authors: *E. COLEY[1], P. GANGULY[1], M. S. TRIVEDI[3], H. C. BRENHOUSE[2]
[2]Psychology, [1]Northeastern Univ., Boston, MA; [3]Neuro-Pharmacology, Nova Southeastern Univ., Fort Lauderdale, FL

Abstract: Childhood adversity can compromise neural structure and function, thereby increasing susceptibility to various psychopathologies including schizophrenia and major depression. It has been shown that the hypothalamus-pituitary-adrenal (HPA) axis is dysregulated in individuals exposed to psychosocial stress at critical developmental periods. The NR3C1 gene, which encodes for the glucocorticoid receptor, is a key component in the normative functioning of the HPA axis via negative feedback on the stress response. Prior evidence from animal studies involving early life stress paradigms indicates epigenetic modulation of the NR3C1 gene. It is unclear the extent to which such epigenetic modifications are inherited by subsequent generations, and if the environment after birth compounds or ameliorates these changes. This study explores (1) the effects of early life stress (ELS) on epigenetic modification of the NR3C1 gene, and subsequent impacts on behavior and corticosterone production, (2) transmission of these modifications to following progeny, and (3) influence of early life parenting environments on such epigenetic inheritance. We used a rodent maternal separation model, which is an ethologically relevant ELS paradigm. F0 litters were either exposed to maternal separation or left undisturbed. At young adulthood (P60) rats from each group were either mated within experimental group, or subjected to behavioral paradigms including open field and social preference, to test anxiety and social behavior, respectively. Following behavioral tests, trunk blood (serum) and brain tissue (prefrontal cortex and dorsal and ventral hippocampus) were collected. F1 pups were either cross-fostered across experimental group (ELS → CON or CON → ELS), or raised by their biological mothers. The pups were allowed to grow undisturbed, and at P60, the same behavioral assessments were performed, followed by blood and brain tissue collection. Data collection strategies included: bisulfite sequencing of dorsal hippocampus tissue and serum, ELISA assay on serum to measure corticosterone concentration, RT-PCR assay on selected brain regions and serum to quantify expression of glucocorticoid receptor mRNA, and behavioral tests to assess anxiety and antisocial behaviors.Results will illuminate the transgenerational epigenetic inheritance of early life stress effects and related behaviors. Clarifying these mechanisms may inform efforts towards prevention and treatment of relevant physical and psychiatric conditions.

Title: The developmental relationship between microglia and dopamine d1 receptors in the nucleus accumbens is altered by adolescent morphine exposure

Authors: *A. M. KOPEC[1], N. R. AYRE[2], S. C. SWEAT[2], S. D. BILBO[1]
[1]Pediatrics, Harvard Med. School/Massachusetts Gen. Hospi, Charlestown, MA; [2]Duke Univ., Durham, NC

Abstract: Drug taking is often initiated in adolescence when the dopaminergic "reward circuitry," including the nucleus accumbens (NAc), is developing, and thus vulnerable to external influences. Indeed, male rats given a 5-day morphine treatment during adolescence, but not young adulthood, have persistently impaired molecular signaling in the NAc and increased risk of reinstatement (i.e. relapse) much later in life. However, how the reward circuitry develops naturally, and how addictive substances modify this development, is unknown. The immune cells of the brain, microglia, are important for normal neural development, notably via engulfment and elimination of synapses 'tagged' by the complement system of proteins, including complement protein C3 (i.e. synaptic pruning). Moreover, microglia have been implicated in playing a critical role in the adverse effects of drugs of abuse. Our data suggest that NAc dopamine D1r receptors are 'tagged' by C3 for microglial-dependent synaptic elimination during adolescent development in male rats. Five days of morphine during the adolescent period increases microglial engulfment of D1rs and reduces D1r levels after drug cessation, raising the possibility that the developmental pruning process may be over-activated by drug use. If so, increased (i) C3 levels, (ii) C3-tagged D1rs, and (iii), microglial engulfment of C3-tagged D1rs, may occur prior to D1r elimination. C3 levels are, indeed, increased after drug cessation, but there is no change in C3-tagged D1rs and decreased engulfment of C3-tagged D1rs. These data collectively suggest that adolescent morphine exposure dysregulates the C3 tagging process, thus resulting in uncoordinated and exaggerated microglial elimination of D1rs in the NAc.

Title: Parental alcohol exposure in binge pattern during puberty in rodent model impairs offspring development through puberty

Authors: *A. ASIMES[1], A. CUARENTA[2], C. K. KIM[1], A. P. AUGER[3], T. R. PAK[1]
[1]Cell and Mol. Physiol., Loyola Univ. Chicago Dept. of Cell and Mol. Physiol., Maywood, IL; [2]Univ. of Wisconsin, Madison, WI; [3]Psychology, Univ. Wisconsin, Madison, Madison, WI

Abstract: Parental inheritance extends beyond mere genetics, or DNA sequence, and can impact offspring traits through epigenetic mechanisms. Recent work has shown that preconception behaviors of both mothers and fathers, such as drug exposure, can impact offspring outcomes. The most widely abused drug in the United States is alcohol with more than 5.3 million Americans under the age of 21 engaging in binge pattern drinking. This type of rapid consumption during pubertal development can have long lasting effects in the brain. Recently, our lab has shown that alcohol-naïve offspring of animals exposed to alcohol during adolescence show altered DNA methylation patterns in the hypothalamus, a region of the brain involved in regulation of pubertal development, stress regulation, and behavior. Therefore, our current work aims to characterize functional consequences in these offspring. Our hypothesis is that offspring of binge-alcohol exposed parents will have altered development associated with hypothalamic function, including improper pubertal development, impaired socialization, and dysregulated stress response. We used an established rodent model of repeated adolescent binge alcohol (EtOH) exposure. Wistar rats received 3g/kg of 20% (v/v) EtOH via oral gavage once daily for 3 days, then 2 days vehicle, and another 3 days EtOH at both early and late puberty (PND37, 67). Animals were paired (EtOH-EtOH, vehicle-vehicle) for mating 24h after the last EtOH dose. Litters were culled to 10 pups per dam and were left with their biological mother until weaning at PND23 when they were separated into same-sex groupings of 5. Behavioral observations were made from recordings of home cage activity daily from PND25 - 30. Animals were then separated into paired-housing and randomly assigned to EtOH or vehicle treatment using the same adolescent binge-alcohol paradigm described above. All animals were euthanized 1h following last gavage at PND44. Cortisol levels were not significantly impacted by parental treatment, nor was expression of stress-mediator genes. However, offspring whose parents received alcohol displayed less social interaction play behaviors. Male offspring were also smaller than control counterparts, although there was no difference in weight at birth or PND7.

Subsequent alcohol exposure decreased male weights further, as well as lowered circulating testosterone and luteinizing hormone. Overall, these results show that preconception alcohol consumption by parents can impact the social and pubertal development of offspring, and can be exacerbated by offspring alcohol consumption.

Title: Stress during adolescence does not alter the total number or morphology of microglia in the male or female mPFC in adulthood

Authors: *C. DRZEWIECKI[1], J. WILLING[2], L. CORTES[3], J. M. JURASKA[2]
[1]Univ. of Illinois at Urbana/Champaign, Champaign, IL; [2]Psychology, [3]Univ. of Illinois, Champaign, IL

Abstract: Adolescents are particularly susceptible to the effects of stress, though the neurobiological basis of this vulnerability remains unknown. Stress in adolescence is also a prominent risk factor for various neuropsychiatric illnesses associated with aberrant prefrontal cortex (PFC) functioning, including depression and schizophrenia. We have previously shown that within adolescence, the period of pubertal onset is associated with a number of neuroanatomical changes in the rodent mPFC, including neuron, dendritic, and synaptic pruning. It is hypothesized that the rapidly changing pubertal brain may confer a unique vulnerability to external stressors in adolescents. In support of this, we have previously demonstrated that pubertal stress, but not post-pubertal stress, exerts sex-specific deficits on pre-pulse inhibition and forced swim test performance in adulthood. Additionally, pubertal stress leads to decreased frontal white matter volume in female subjects; this was not the case in adolescent females stressed following the period of pubertal onset. Microglial cells have been implicated in the stress response and play a role in neural development, and recent work suggests that adolescent microglia take on a more activated morphology than adults following an LPS treatment. Moreover, a role for aberrant microglia activation has been implicated in the etiologies of depression and schizophrenia. In this experiment, we exposed male and female rats to a

combination of isolation and restraint stress during the onset of puberty or during the post-pubertal period of adolescence, with an additional unstressed control group. Brain tissue was collected from these subjects in adulthood and immunologically stained for IBA-1, a marker for microglia cells. Microglia were quantified and categorized according to their activation states. We found that in both males and females, neither pubertal nor post-pubertal stress led to long-term changes in microglia numbers or activational states. Future research should focus on more acute changes to microglia number and morphology following stressors in adolescence, which could explain long-term changes in behavior induced by pubertal stress.

Title: Transcriptome and cellular analyses in the human dorsolateral prefrontal cortex: associations with adolescent cannabis use

Authors: *S. MUKHERJEE[1], S. PARK[2], B. GADAD[1], S. PAWAR[1], D. DURAKOGLUGIL[1], I. DOZMOROV[3], K. GLEASON[1], C. TAMMINGA[1], T. HWANG[2], S. GHOSE[1]
[1]Dept. of Psychiatry, [2]Dept. of Clin. Sci., [3]Immunol., UT Southwestern Med. Ctr., Dallas, TX

Abstract: While the acute use of cannabis negatively impacts cognitive function, the long term cognitive effects are controversial. When cannabis use is initiated during adolescence, however, the findings are more consistent with several studies reporting associations between adolescent cannabis use (ACU) and persistent neuropsychological impairment. To determine the molecular and cellular underpinnings of these potential long term effects of ACU, we assembled a cohort of human post mortem brain tissue collected from individuals with a history of adolescent cannabis users (ACU+) and compared them to a cohort of non-cannabis users (ACU-; n=10/group). We conducted whole transcriptome sequencing followed by ingenuity pathway analysis and WGCNA R-package analyses. In addition, we quantified pyramidal neuron somal areas in Layer 3 and Layer 5 in 3 sections of the DLPFC (n=5/group; 80-100 cells//case). About 2000 genes were differentially expressed between ACU+ and ACU- groups. After correcting for multiple comparisons, only 3 genes were significantly different between groups, namely HSPA6, HSPA7 and SERPINA3 (FDR 0.018 to 0.048). Two of these genes belong to the heat shock protein 70 (HSP 70) group and all 3 genes are known to be involved in protein folding and unfolding, processes by which proteins acquire three dimensional structures essential to their biologic

activity. Our network analyses identified differential expressed genes involved in maintaining cellular morphology. Cellular analyses show that layer 3 pyramidal neuronal somal sizes were significantly larger in ACU+ (235.8 $\pm$ 12.4 μm^2) compared to ACU- (186.7 $\pm$ 8.5 μm^2) groups (p=0.01). There were no differences in layer 5. These data suggest that adolescent cannabis use leads to persistent changes in HSP 70 genes which are typically expressed in response to stressors that damage proteins, cause protein unfolding and aggregation. Hsp70 prevents protein aggregation, allows refolding and participates in the disposal of damaged proteins. The increased expression of HSPA6, HSPA7, and SERPINA3 in the ACU+ group could be a compensatory response to potentially deleterious effects of ACU on proteostasis. The differences in genes related to cellular morphology and the increase in layer 3 pyramidal neuronal somal size could reflect a primary process by which ACU increases the neuronal size or could be related to the compensatory responses in an effort to maintain normal cellular physiology in the ACU+ group. These post mortem brains tissue studies are descriptive but do suggest that cannabis use during adolescence leads to persistent molecular and cellular sequelae in the human brain.

Title: Identification of cell type-specific ErbB4 isoform expression using a novel sensitive *In situ* hybridization approach

Authors: *L. M. ERBEN[1,2], M.-X. HE[3], A. LAEREMANS[3], E. PARK[3], A. BUONANNO[1]
[1]Section on Mol. Neurobiology, NICHD, NIH, Bethesda, MD; [2]Inst. of Mol. Psychiatry, Univ. of Bonn, Bonn, Germany; [3]Advanced Cell Diagnostics, Newark, CA

Abstract: Alternative splicing is ubiquitous in humans, particular prevalent in the central nervous system (CNS) and aberrant splicing is frequently observed in cancers and a hallmark of the psychiatric diseases schizophrenia (SZ). Among the many genes aberrantly spliced in SZ are the neurotrophic factor Neuregulin-1 (NRG-1) and its cognate receptor tyrosine kinase ErbB4. Both *NRG-1* and *ERBB4* polymorphisms are well known for their association with schizophrenia. Four ErbB4 isoforms are generated by alternative splicing of exons in the juxtamembrane (either JMa or JMb variants) and cytoplasmic regions (either CYT-1 or CYT-2

variants) with distinct processing and signaling properties. Several studies reported both the cleavable JMa ErbB4 isoform and the CYT-1 isoform to be increased in postmortem dorsolateral prefrontal cortex of SZ patients. ErbB4 isoform expression is also altered in different brain cancers (e.g. medulloblastoma, astrocytic glioma).
However, the analysis of the expression of ErbB4 isoforms has been limited to quantitative real-time PCR disregarding pivotal information about the regional distribution and cell-type. Here, we analyze ErbB4 isoform expression in the adult mouse brain using a novel sensitive non-radioisotopic *in situ* hybridization (ISH) approach. First, using ErbB4 mutant mice lacking a single exon as controls, we demonstrate that a single pair of paired probes targeting about 50bp at exon junctions provides sufficient sensitivity and specificity to detect exon-exon boundaries. We go on to show that ErbB4 isoforms are differentially expressed in the adult mouse brain. Consistent with our data from quantitative real-time PCR, JMb and CYT-2 are the major ErbB4 isoforms expressed in the mouse brain (e.g. in the hippocampus and cortex). However in the corpus callosum and thalamus, JMa and to a lesser extent CYT-1 are the major ErbB4 isoforms. By combining this new ISH approach with transgenic mice and post-hoc immunohistochemistry, we show that these differences are due to cell type-specific expression of juxtamembrane isoforms. While GABAergic neurons mainly express JMb, oligodendrocytes mostly if not exclusively express the JMa isoform. Our study provides a valuable tool to analyze single-exon splice variants in the brain and other tissue including archival and patient tissue. Further, it highlights novel insights in the function of ErbB4 in oligodendrocytes and the potential implication of this cell type in SZ.

Title: Neuronal processing and axonal targeting of neuregulin 3

Authors: *D. VULLHORST, T. AHMAD, A. BUONANNO
Section on Mol. Neurobio., NICHD, NIH, Bethesda, MD

Abstract: The Neuregulin/ErbB4 signaling pathway is an important modulator of GABAergic inhibitory interneurons, synaptic plasticity and neural network synchronization. Our recent studies indicate that NRGs with a single transmembrane (TM) domain (i.e. NRG1 types I/II and NRG2) accumulate as unprocessed pro-forms at somatic subsurface cistern (SSC)-type ER-PM junctions, where they can signal in paracrine or autocrine fashion following their activity-dependent release. On the other hand, earlier studies showed that the dual-pass transmembrane neuregulin CRD-NRG1 targets to axons and presynaptic terminals where it signals in juxtracrine mode. While NRG3 constitutes one of the most highly expressed NRGs during pre- and postnatal development and has attracted attention for its association with psychosis and its role in interneuron migration, little is known about its subcellular distribution and signaling mode. Using different molecular and cellular biological approaches in cultured hippocampal neurons, here we show that NRG3, like CRD-NRG1, is a dual-pass TM protein. Moreover, NRG3 is also trafficked to axons where it signals in juxtacrine mode via ErbB4 receptors located on dendrites of GABAergic interneurons. In contrast to single-pass TM NRGs that are processed by metalloproteinases on the cell surface, both NRG3 and CRD-NRG1 are processed by BACE in the cell body. In fact, BACE-mediated processing is a prerequisite for axonal accumulation of NRG3, as interference with processing by pharmacological or genetic means causes accumulation of the pro-form in the trans-Golgi network. Lastly, live-imaging experiment indicate that axonal trafficking of processed NRG3 occurs via Rab4 containing vesicles. These results reveal previously unknown molecular mechanisms underlying NRG3 processing and trafficking in neurons, which has important implications for its biological functions and possible involvement in psychiatric disorders. Furthermore, taken together with our work on single-pass NRG isoforms, these findings demonstrate that NRG isoforms can be classified into two major groups based on their distinct transmembrane topologies and their subcellular distribution that likely regulate neuronal functions in fundamentally different ways.

Abstract: Single nucleotide polymorphisms in genes for Neuregulin 1 (NRG1) and its receptor ErbB4 confer susceptibility for schizophrenia, a neurodevelopmental disorder characterized by dopamine (DA) dysfunction and excitatory/inhibitory imbalance. ErbB4 is abundantly expressed in parvalbumin (PV)+ interneurons in the hippocampus and cortex, and in midbrain tyrosine hydroxylase (TH)+ neurons. Although NRG/ErbB4 signaling has been reported to regulate synaptic plasticity, oscillatory activity and behaviors relevant in psychiatric disorders, it presently is unclear relative the contribution of ErbB4 signaling in either PV+ or dopaminergic (DAergic) neurons in regulating these functions. Prior studies reported that local administration of NRG1 by reverse microdialysis into the dorsal hippocampus of freely moving rats results in a rapid increase of extracellular DA levels (Kwon et al, 2008), suggesting that NRG1-ErbB signaling regulates extracellular DA levels either by directly modulating DAergic neurons or by indirectly regulating inhibition of DAergic processes. Here we provide neurochemical, biochemical and behavioral evidence demonstrating that ErbB4 signaling in DAergic axonal projections directly regulate *in vivo* DA homeostasis in brain areas reportedly to be affected in

psychiatric disorders, such as hippocampus, medial prefrontal cortex and striatum. Additionally, we used Lund Human Mesencephalic (LUHMES) cells, an immortalized DAergic cell line that releases DA and express ErbB4, to show that ErbB4 activation also regulates extracellular DA levels by reducing DAT-dependent uptake. Interestingly, mice lacking ErbB4 in TH+ neurons exhibit a dual DA imbalance reminiscent to schizophrenia and cognitive-related behavioral deficits that can be ameliorated if ErbB4 is specifically reintroduced in midbrain TH+ neurons. Based in our findings, it is tempting to suggest that studies exploring the role of the NRG-ErbB4 signaling in excitatory/inhibitory balance should not limit their interpretation to effects originating exclusively from ErbB4-expressing GABAergic interneurons, but also should consider the neuromodulatory effects of DAergic signaling. *This work was kindly supported by the Eunice Kennedy Shriver NICHD Intramural Research Program, NIH.*

Abstract: Prior studies have associated polymorphisms in the genes encoding Neuregulin-1 (NRG1) and its receptor ErbB4 with endophenotypes relevant to psychiatric disorders, including schizophrenia. Although the role of NRG1 in neurophysiological and behavioral phenotypes has

been extensively studied, little is known about the function of NRG2 - the closest NRG1 homologue. NRG2 transcript levels increase postnatally after birth in brain areas that are affected in psychiatric disorders, such as the striatum and medial prefrontal cortex (mPFC), while NRG1 expression is widespread in the embryonic and fetal brain but becomes more restricted during adulthood. We therefore generated NRG2-KO mice to investigate to what extent signaling via this ligand accounts for the phenotypes observed in ErbB4 mutant mice that include an imbalance in extracellular dopamine (DA) levels, altered synaptic plasticity and numerous behavioral deficits relevant to psychiatric disorders (Shamir et al. JNS 2012). Using *in vivo* microdialysis, we found that NRG2-KO mice show high extracellular DA levels in dorsal striatum but low levels in the mPFC - a regional DA imbalance that is similar to that reported for schizophrenia subjects. Moreover, like ErbB4-KO mice, NRG2-KOs showed altered performance in a battery of behavioral tasks requiring striatal and mPFC function, including deficits in working memory during T-maze. Interestingly, acute systemic administration of the atypical antipsychotic clozapine in NRG2-KO mice ameliorated working memory deficits, and the improvement in working memory coincided with a rapid increase in extracellular DA levels in the mPFC. In addition to the altered DA function, NRG2-KO mice also showed augmented NMDA receptor synaptic currents at hippocampal glutamatergic synapses sensitive to ifenprodil, suggesting an increased contribution of GluN2B-containing NMDA receptors. Together, our findings point to a novel role for NRG2 in the adult rodent brain regulating excitatory/inhibitory balance potentially modulated by DA and behaviors with relevance to psychiatric disorders. *This work was kindly supported by the Eunice Kennedy Shriver NICHD Intramural Research Program, NIH.*

Abstract: The dopaminergic system is linked to locomotor as well as motivated behaviors including feeding and reward. On the other hand, ErbB4 receptors that bind neuregulin-1 (NRG1) are expressed, among other brain sites, in dopamine (DA) and GABA neurons in the midbrain and are involved in myelin formation, axon migration and neuronal survival. Moreover, injection of neuregulin-1 directly in the substantia nigra (SN) increases DA release in the corpus striatum (STR) confirming a link between neuregulin-ErbB4 and the neurotransmission process. In the present report, we have monitored DA release in the STR, following injection of the ErbB receptor tyrosine kinase inhibitor PD158780 (PD15) in the SN. In a separate set of rats, PD15 was injected in the SN and free feeding was monitored during the active and inactive circadian cycle of the rat. Finally, the effect of PD15 in the SN on the hedonic value of a palatable food was tested using the sucrose preference test. The injection of PD15 (80 nMoles) into the SN decreased DA levels in the STR to 56.7 ± 10% ($F(7,91)=2.946, p<0.01$). This was correlated with a significant decrease in food chow consumption. Rats injected PD15 at the beginning of the active cycle ate significantly less (0 ± 0 g during the first hour and 5 ±1.5 g after 4 hr) than control animals (5.9 ± 2 g at the hour and 10.7 ± 2.1 after 4 hr) ($T(10)=3.219$, $p<0.01$ 1st hr and $T(10)=2.371$, $p<0.05$ 4hr total). PD15 injected at the beginning of the inactive cycle also decreased food ingestion (1.1 ± 0.6 g and 3 ± 0.6 g, 1-hr and 4-hr respectively in PD15 compared to 2.4 ± 0.6 g and 6.3 ± 1.2 g 1-hr and 4-hr post injection in controls ($T(10)=1.558$; N.S. for 1st hr, $T(10)= 2.545$, $p<0.05$ for 4hr total). Drinking was not significantly affected by injection of PD15 in the SN neither did it affect the sucrose preference index. These results show that ErbB4 receptors in the SN are not only important in DA-neuron development and survival, but are also involved in directly modulating DA neurotransmission in the STR as supported by a decrease in DA release when the ErbB4 antagonist was injected. This modification is correlated with a change in feeding suggesting that normal function of the nigrostriatal in ingestive behavior is dependent, among other systems, on neuregulin-ErbB4. This could be useful in finding new therapeutic approaches in the treatment of obesity.

Title: TrkB regulates activity-dependent translocation of ZDHHC8 to dendrites through its phosphorylation by PKC

Authors: *A. YOSHII[1], K. P. KOSTER[2], Y. MURATA[3]
[1]Dept of Anat. & Cell Biol., UIC, Chicago, IL; [2]Dept. of Anat. and Cell Biol., Univ. of Illinois at Chicago, Chicago, IL; [3]Pharmacol. and Physiol., George Washington Univ., Washington, DC

Abstract: Post-synaptic density protein-95 (PSD-95) is a major scaffolding protein for ionotropic glutamate receptors and signaling molecules. It mediates many forms of synaptic plasticity and is critical for brain maturation, learning, and memory. In the rodent visual pathway, PSD-95 becomes redistributed to synapses within a few hours of eye-opening at postnatal day 13 when the patterned vision starts. The Increase in synaptic activities activates brain-derived neurotrophic factor (BDNF) and its receptor TrkB signaling pathway, and regulates the vesicular transport of PSD-95 to synapse. Attachment of PSD-95 to the cargo membrane requires palmitoylation of the protein. This lipid modification also facilitates proper subcellular localization of a modified protein to a membranous microdomain, lipid raft. PSD-95 palmitoylation is critical for synaptic connections and refinements. However, the regulatory mechanisms are largely unknown. Previously, we showed that palmitoylation of PSD-95 is regulated by BDNF through phospholipase C (PLC) and a PKC variant. We also identified the palmitoylation enzyme ZDHHC8 as the target of PKC phosphorylation but not other members of ZDHHC family. This pathway indeed regulated trafficking of PSD-95 to synapses in developing brains *in vivo*. Here, we used a phospho-proteomic approach, and identify phosphorylation sites of ZDHHC8. We generated mutated ZDHHC8 constructs by targeting the phosphorylation sites. We performed immunoprecipitations to directly assess the mutant proteins using an antibody specific to a PKC phosphorylation motif, and confirmed that one of the mutations are regulated by a PKC. In cultured neurons, the mutant PKC mutant ZDHHC8 localized in the Golgi apparatus while the intact enzyme was distributed throughout dendrites. In layer 2/3 pyramidal neurons of the visual cortex, eye-opening trigger ZDHHC8 trafficking from soma to dendrites *in vivo*. However, the phosphorylation-inactivated mutant ZDHHC8 remained predominantly in the soma even after eye-opening. Inhibition of TrkB suppresses PSD-95 trafficking to visual cortical synapses upon eye opening. An overexpression of the intact but not the mutant ZDHHC8 rescued the synaptic redistribution of PSD-95. Therefore, TrkB regulates the PKC phosphorylation of ZDHHC8 and facilitates palmitoylation of PSD-95. This study is the first complete example of how a receptor signaling pathway can regulate phosphorylation of a palmitoylation enzyme, thereby triggering protein palmitoylation and synaptogenesis. Our findings have broad implications for various brain disorders in both children and adults.

Title: TrkB deletion from serotonergic neurons leads to impairment in memory and antidepressant efficacy

Authors: *M. PRIYADARSHINI SAHU[1], A. STEINZEIG[2], O. BOROWIECKI[2], V. VOIKAR[2], E. CASTREN[3]
[1]Univ. of Helsinki, Helsinki, Finland; [2]Neurosci. Center, Univ. of Helsinki, Helsinki, Finland; [3]Neurosci. Ctr., Helsinki, Finland

Abstract: Antidepressants mainly the selective serotonin reuptake inhibitors (SSRI) drugs activate neurotrophin signaling and neuronal plasticity. Brain derived neurotrophic factor (BDNF) together with its high affinity cognate receptor, tyrosine kinase B (TrkB) plays a significant role in neuronal survival and synaptic plasticity and have been concomitantly related with serotonin (5-HT) in a myriad of neurochemical and behavioral responses with SSRI treatment. The mechanism of this interplay between BDNF/TrkB with 5-HT is limited. To investigate the interaction between these signalling molecules, we have used a conditional knockout for TrkB receptors from tryptophan hydroxylase2 (Tph2) producing serotonergic neurons in the mice. The inducible cre-lox recombination system was used by injecting tamoxifen to six weeks old mice. These knockout mice have been characterized in a series of behavior tests related to depression and anxiety and observed increased hyperactivity. We further investigated antidepressant efficacy of fluoxetine in the knockouts. The knockouts responded to acute effects of fluoxetine but the chronic effect was attenuated. There was no signs of aggression in the knockouts using the resident intruder paradigm. We monitored the metabolic changes in these mice, using CLAMS (Comprehensive lab animal monitoring system). The knockouts were leaner in comparison to the control littermates while no change in feeding behavior was observed. Furthermore, we assessed the learning and memory in these mice by contextual fear conditioning. The results suggest impairment in memory consolidation in the knockouts. At the cellular and molecular levels, serotonin levels in different brain regions have been measured and was found to be augmented. Thus impairment of TrkB signalling in the Tph2 neurons in early adulthood leads to disturbances in the 5-HT neurotransmission and BDNF

signalling. These functional deficits contribute to blunted memory consolidation and response to SSRI. Further studies on the downstream signalling cascades and serotonin receptors could possibly shed more information on the critical balance between the two systems that contribute to neuronal development, synapse formation and plasticity.

Title: Whole transcriptome analysis of the BDNF-induced JAK/STAT response in neurons and in a TLE model of epilepsy

Authors: ***K. M. HIXSON**[1], M. COGSWELL[2], A. BROOKS-KAYAL[3], S. J. RUSSEK[4]
[1]BUSM Pharmacol., Dorchester, MA; [2]Pharmacol. and Exptl. Therapeut., Boston Univ., Boston, MA; [3]Neurol., Children's Hosp, Aurora, CO; [4]Pharmacol. and Grad Prog for Neurosci., Boston Univ. Sch. Med., Boston, MA

Abstract: Deleterious alterations in molecular signaling cascades and cellular remodeling initiate years prior to the onset of temporal lobe epilepsy (TLE). Despite many upstream cellular and molecular changes, most drugs only target neurotransmission to increase inhibition. Over 30% of patients are refractory to all of these medications. Understanding the molecular basis of acquired epilepsy and developing efficacious drugs to target intracellular signaling pathways is vital in the advancement of patient therapy. Upregulation of brain-derived neurotrophic factor (BDNF) is long established as a contributing factor to epilepsy development in humans and animal models. More recently, our lab discovered that BDNF induces activation of the Janus Kinase/Signal Transducer and Activator of Transcription (JAK/STAT) pathway in neurons and its inhibition attenuates spontaneous seizures in a TLE animal model. In this study, we elucidate key gene expression changes involved in the BDNF-induced JAK/STAT pathway through deep RNA-sequencing of primary cortical neurons treated with different concentrations of the

JAK/STAT inhibitors, WP1066 and Ruxolitinib. This work has led to the development of a molecular fingerprint to investigate alterations in the transcriptome that occur in transgenic mice engineered to conditionally knockdown expression of STAT3 as well as the BDNF receptor, p75NTR, two proteins that form intracellular complexes in neurons and are associated with TrkB mediated activation of JAK/STAT pathway. Of great interest to us is the observation that the genes most associated with BDNF-induced responses that are blocked by JAK inhibitors are mapped to neurological diseases, with the top four categories being relevant to epileptic seizures and epilepsy. In addition, both classes of inhibitors target the expression of type A GABA receptor subunits as well as Scn1A, a gene implicated in early onset epileptic encephalopathies such as Dravet Syndrome. The emerging landscape of the transcriptome for BDNF-induced JAK/STAT signaling suggests that it may be useful for early-detection biomarkers that inform seizure susceptibility as well as contain new targets for the future treatment of intractable epilepsies.

Title: Effects of the JAK2/STAT3 activator CNTF on Arc expression in the rat orbitofrontal cortex

Authors: *M. GIROTTI[1], D. A. MORILAK[2]
[1]Pharmacol., [2]Pharmacol. and Ctr. for Biomed. Neurosci., Univ. of Texas Hlth. Sci. Ctr. at San Antonio, San Antonio, TX

Abstract: Cognitive flexibility is the ability to modify established behaviors or previous learning in response to a change in the environment, for example, by a change in stimulus-reward contingency. Reversal learning is a specific form of cognitive flexibility predominantly mediated by the orbitofrontal cortex (OFC), and is impaired in a range of psychiatric conditions, including depression and obsessive compulsive disorder. In previous work, we reported that basal activity of the JAK2/STAT3 signaling pathway in the OFC is required for optimal performance on a reversal learning task under healthy control conditions. Ciliary neurotrophic factor (CNTF) is an

endogenous activator of JAK2/STAT3 signaling in the brain, and is known to exert pro-survival effects on both neurons and oligodendrocytes. In preliminary studies using primary neuronal cultures, we found that CNTF induced the synaptic plasticity protein Arc. This suggested that CNTF could potentially influence neuronal plasticity underlying reversal learning in the OFC. Indeed, we found that blocking endogenous CNTF with an intra-OFC microinjection of a neutralizing CNTF antibody was sufficient to produce reversal-learning deficits. In the current work, we present evidence that the local microinjection of CNTF induces the phosphorylation of both JAK2 and STAT3 in the OFC in a dose dependent manner, but with slightly different profiles. While both JAK2 and STAT3 were induced by 100 nM CNTF, only JAK2, but not STAT3, was activated by 50 nM CNTF. Arc expression also was induced by CNTF in the OFC. Interestingly, the CNTF dose profile of Arc expression followed that of JAK2 activation, peaking at 50 nM and actually declining at 100 nM CNTF, suggesting the possibility that JAK2 is specifically involved in modulating Arc levels. Supporting this hypothesis, in cultured neurons, we have found that silencing JAK2 but not STAT3 reduces Arc expression.
Arc is specifically expressed in glutamatergic pyramidal neurons. Using immunohistochemistry we have found that CNTF induces JAK2 in CamK-II positive excitatory neurons. Thus, we hypothesize that CNTF, at low concentrations, increases Arc expression in pyramidal neurons by a JAK2-dependent mechanism, and that this phenomenon is required for optimal reversal learning. In future work we will test this hypothesis using a viral vector containing a CamK-II driven silencing hairpin RNA against JAK2. We expect that knocking-down JAK2 in glutamatergic neurons will reduce Arc expression and produce deficits in reversal learning.

Abstract: Multiple genes and their pleiotropic interactions are involved in the etiology of complex neuropsychiatric disorders such as schizophrenia. Although many genes have been identified, the signaling pathways have not been fully understood. In this study, we investigated two of these genes, the Ankyrin Repeat-rich Membrane Spanning Protein/Kinase D-Interacting Substrate of 220 kDa (*ARMS/Kidins220)* and the TRIO Rho guanine nucleotide exchange factor (*TRIO*). Both genes harbored missense coding mutations and rare polymorphisms, which were discovered by targeted exome capture in schizophrenia-related psychosis cases. The ARMS/Kidins220 gene displayed a novel mutation in its proline-rich domain (H1085R) that has not been observed before. ARMS/Kidins220 is a scaffold protein involved in neurotrophin signaling and a hub for multiple signaling pathways. TRIO harbored one rare missense coding variant (K3037M) and one novel mutation in its C-terminal kinase domain (V2941I). TRIO is a RHO-GEF involved in cytoskeletal organization and cell migration and an interaction partner of ARMS/Kidins220. Here, we created mutants of ARMS/Kidins220 and TRIO using site-directed mutagenesis and overexpressed the wildtype constructs in comparison to the mutants in HEK293 cells and primary cortical neurons from rats. Using biotinylation, overexpressed ARMS/Kidins220 H1085R yielded less cell surface expression in comparison to the wildtype control in HEK293 cells. Ectopic expression of the ARMS/Kidins220 H1085R in primary rat cortical neurons resulted in impaired transport of the mutant ARMS/Kidins220 protein from soma into neuronal projections. In contrast, the TRIO variants (V2941I and K3037M) did not alter mutant protein localization. We conclude that missense coding variants in ARMS/Kidins220 and TRIO have demonstrable effects on neuronal phenotypes and may provide a potential influence in neuropsychiatric disorders through their interaction.

Title: Role of Nerve growth factor and Brain derived neurotrophic factor in regulation of central nervous system myelination

Authors: *J. M. LANGHNOJA, L. BUCH, P. PILLAI
Zoology, The Maharaja Sayajirao Univ. of Baroda, Vadodara, India

Abstract: Neurotrophins are a family of proteins essential for the development and regulation of Central Nervous System (CNS) and are widely implicated as potential modulator for important CNS functions such as neural stem cells differentiation, cell migration, myelination and synaptic plasticity. Neurotrophins comprises of four structurally related factors: brain derived neurotrophic factor (BDNF), nerve growth factor (NGF), neurotrophin-3 (NT-3) and neurotrophin-4/5 (NT-4/5). In CNS myelination, oligodendrocytes form a stable and rigid layer of tightly packed lipid and protein layer known as myelin sheath which is wrapped around the axon of neurons. The oligodendrocytes undergo a specific lineage involving migration, proliferation and ultimately differentiating into the myelinating oligodendrocytes. In adult, oligodendrocytes also differentiate from Neural Stem Cells (NSCs). This lineage progression and differentiation is supported by a number of extracellular cues like growth factors- PDGF and neurotrophins from the surrounding environment. NGF, a major neurotrophin is known to be involved in promoting growth, survival, and stabilization of primary afferents neurons and neurons axonal dendrites along with the differentiation of NSCs into neurons. BDNF, another vital neurotrophin, plays an important role in the initiation of the CNS myelination and stimulation of migration of cerebellar granule cells and Schwann cells. Neurotrophins also support for survival of myelinating cells and remyelination during inflammation and in chronic injury conditions where the myelin proteins' level goes down. However, the signaling mechanisms underlying the molecular action of neurotrophins in the differentiation of NSCs, oligodendrocyte migration and lineage progression along with their role in remyelination is still not well understood. Present study indicates important role of these neurotrophins in the differentiation of NSCs into brain cells majorly into Myelin Basic Protein (MBP) positive oligodendrocytes via the ERK pathway. Moreover, NGF and BDNF also enhance Oligodendrocytes precursor cells' (OPCs) migration; this action being mediated by specific neurotrophins' receptors. Up-regulation of MBP expression in TNF-α induced demyelination shows remyelination potential of neurotrophins in CNS myelination. Overall, our study reveals that NGF and BDNF regulate CNS myelination by NSC differentiation, OPCs migration and may be remyelination in TNF-α induced demyelination.

Title: Frequency of the BDNF Val66Met polymorphism in Brazilian healthy subjects

Authors: *M. SCHULTZ, D. FONTES, L. S. SANTOS, M. PEDRAZZOLI
Univ. of Sao Paulo, Sao Paulo, Brazil

Abstract: Purpose. The Val66Met single-nucleotide polymorphism (rs6265) of the BDNF gene has been implicated to central nervous system (CNS) dysfunctions by interfering on neurotrophin production and transportation. The present study reports the frequency of BDNF Val66Met in 1284 Brazilian healthy volunteers. Stratification by race was performed to identify patterns of distribution. **Methods.** The total of subjects was 1284 healthy college students, 752 men (48.3%) and 806 women (51.7%), with averaged age of 21.53±4.71, from three regions in Brazil: north (Alagoas), south (Rio Grande do Sul) and southeast (São Paulo). The Ethics Committee of the School of Arts, Sciences and Humanities of University of São Paulo approved the study. The subjects auto-declared their race and were divided in five groups: yellow, white, black, brown and indigenous, according to the Brazilian Institute of Geography and Statistics. The DNA was obtained from buccal epithelial cells. For Val66Met genotyping, the Restriction Fragment Length Polymorphism (RFLP) was applied using the High Resolution Melt (HRM) as tool. PCR amplifications were carried using the primer BDNF-RS6265 (*Invitrogen*, USA). The genotypes Val/Val, Val/Met and Met/Met were determined by the melting curve in the PCR, according to the previous parameters. The Hardy-Weinberg equilibrium was used for genotypic and allelic distribution. **Results.** The genotypic distribution was 66.08% for Val/Val, 30.38% for Val/Met and 3.54% for Met/Met. Allele frequencies were 81% for Val and 19% for Met. Genotype and allelic distributions were similar in men and women. The analysis of genotypic distribution by the race reveals the total of 826 white subjects distributed as follow: 530 (64,2%) Val/Val, 260 (31,5%) Val/Met and 36 (4,4%) Met/Met. The brown race has had the total of 342 subjects: 246 (71,9%) Val/Val, 90 (26,3%) Val/Met and 6 (1,8%) Met/Met. 55 subjects were yellow: 28 (50,9 %) were Val/Val, 23 (41,8%) Val/Met e 4 (7,3%) Met/Met. Black individuals were 56 and the genotypes were: 45 (80,4%) Val/Val and 11 (19,6%) Val/Met. Five subjects were indigenous: 4 (80%) were Val/Val and only 1 (20%) had have Val/Met. None black and indigenous subjects had have Met/Met genotype. **Conclusion.** The present study aimed to characterize the Val66Met in healthy Brazilians and to identify patterns of distribution by the race. Brazilian population is a resultant of cross-cultural relations, which involves migration flux along the history. Even considering an interracial characteristic, our findings confirm a higher occurrence of the Val66Met in yellow race and absent of the polymorphism in black and indigenous people, corroborating to the other studies.

Title: Microglia-derived neuregulin expression in psychiatric disorders

Authors: *D. IKAWA, M. MAKINODAN, T. YAMAUCHI, Y. YAMASHITA, T. KOMORI, T. KISHIMOTO
Nara Med. Univ., Kashihara / Nara, Japan

Abstract: Considerable evidence shows that neuregulins (NRGs) are involved in brain function and psychiatric disorders. While NRGs have been regarded as neuron- or astrocyte-derived molecules, our research has revealed that microglia also express NRGs, levels of which are markedly increased in activated microglia. Previous studies have indicated that microglia are activated in the brains of individuals with autism spectrum disorder (ASD). Hence, we investigated microglial NRG mRNA expression in multiple lines of mice considered models of ASD. Curiously, while maternal immune activation (MIA) mice exhibited identical microglial NRG expression to controls, NRG expression significantly increased in the microglia of BTBR and socially-isolated mice compared to those in controls. Furthermore, we observed a positive correlation between NRG expression in microglia and peripheral blood mononuclear cells (PBMCs) in mice. This finding suggests that NRG expression in human PBMCs may mirror microglia-derived NRG expression in the human brain. To translate these findings for application in clinical psychiatry, we measured levels of NRG1 splice-variant expression in clinically available PBMCs of patients with ASD. Levels of NRG1 type III expression in PBMCs were positively correlated with impairments in social interaction in children with ASD (as assessed using the Autistic Diagnostic Interview-Revised test: ADI-R). These findings indicate the possibility that immune cell-derived NRGs may be implicated in the pathobiology of psychiatric disorders such as ASD.

Title: Exercise combined with low-level $GABA_A$ receptor inhibition modulates the expression of BDNF in the hippocampus accompanied by changes in epigenetic regulation

Authors: ***H. MAEJIMA**[1], S. NINUMA[2], A. OKUDA[2], T. INOUE[3], M. HAYASHI[3]
[1]Dept. of Rehabil. Science, Fac. of Hlth. Sci., [2]Dept. of Hlth. Sciences, Sch. of Med., [3]Grad. Sch. of Hlth. Sci., Hokkaido Univ., Sapporo, Japan

Abstract: Neurotrophins play a crucial role in neuroplasticity, neurogenesis, and neuroprotection in the central nervous system. Aerobic exercise is known to increase expression of neurotrophins, particularly brain-derived neurotrophic factor (BDNF), in the hippocampus and to improve cognitive function. Several animal studies have evaluated the tonic inhibition of GABAergic synapses to enhance hippocampal plasticity as well as learning and memory. Epigenetic mechanism plays a crucial role to regulate gene transcription. Specifically, the activity levels of histone acetyltransferases (HATs) and histone deacetylases (HDACs) regulate histone acetylation and modulate gene transcription. The objective of the present study was to examine the interactive effect of low-level $GABA_A$ receptor inhibition and exercise on behavior tests (cognitive function and locomotion activity), expression of BDNF and epigenetic regulations, including the activity of HATs and HADCs in the hippocampus. ICR mice were randomly distributed among 4 groups based on two factors of $GABA_A$ receptor inhibition and exercise, i.e. control group, an exercise group, a bicuculline group, and an exercise plus bicuculline group. We administered $GABA_A$ receptor antagonist, bicuculline intraperitoneally to the mice (bicuculline and exercise plus bicuculline group) at a non-epileptic dose of 0.25 mg/kg, whereas the mice (exercise and exercise plus bicuculline group) were exercised on a treadmill for 1 h a day, 5 days a week. After four week intervention, the expression of mRNA and protein abundance of BDNF, activity of HAT and HDAC in the hippocampus were assayed using real time PCR and ELISA following behavioral tests. All study procedures were approved by the ethics committee for animal research of Hokkaido University in Japan. Although we could not confirm a significant improvement of cognitive function assessed by a novel-object recognition test, exercise in the presence of bicuculline administration increased locomotion activity, indicating that exercise combined with low-level $GABA_A$ receptor inhibition enhanced physical

activity level of the mice. Aerobic exercise increased mRNA expression and protein abundance of BDNF in the hippocampus, accompanied by enhanced HAT activity in epigenetic regulation. Alternatively, bicuculline administration increased HDAC activity in the hippocampus in epigenetic regulation. Altogether, it was expected that exercise combined with low-level $GABA_A$ receptor inhibition beneficially contribute to neuroprotection of the hippocampus accompanied by the up-regulation of BDNF expression and changes in epigenetic regulation.

Title: Aging and an immune challenge lead to reduced levels of BDNF and cholinergic receptor mRNAs in hippocampal synapses in a rodent model of delirium

Authors: *N. TANAKA, S. L. PATTERSON
Biol., Temple Univ., Philadelphia, PA

Abstract: Delirium is an acute failure in brain function, characterized by deficits in cognition and attention. Aging increases the risk of delirium after surgery, injury, or infection (~ 50% of 65-year or older patients in hospitals). Delirium is usually temporary, but its occurrence is associated with an increased risk of eventually developing dementia. The molecular pathophysiology of the disorder remains poorly understood, but animal models may provide some clues. 24-month-old Fischer Brown Norway (F344xBN) rats are generally healthy agers with no major physical or cognitive deficits. However, after a peripheral immune challenge (an i.p. injection of *E. coli*), they exhibit an exaggerated and prolonged inflammatory response in the brain. 4 days after infection, although they have physically recovered (no more fever nor loss of appetite), these aging animals show deficits in a long-term memory task (contextual fear conditioning) as well as elevated levels of hippocampal IL-1β protein (Barrientos et al., 2009). In contrast, their younger counterparts (3-month-old) display no deficits in the memory task and normal levels of IL-1β at this time point. Intriguingly, our time-course studies (4 - 21 days after infection) show that the impairments in memory and IL-1β are paralleled by reductions in hippocampal area CA1 theta burst-evoked late-phase long-term potentiation (L-LTP, a memory-related form of long-lasting synaptic plasticity) and in levels of mature brain-derived neurotrophic factor (mBDNF, required for long-term memory and L-LTP). This suggests that

BDNF may play a role in linking activity in the central immune system to alterations in synaptic plasticity. In order to further investigate how age and an infection can compromise the capacity for BDNF-dependent memory-related synaptic plasticity, we are examining plasticity-related mRNAs in hippocampal subcellular fractions. Levels of BDNF mRNA transcripts containing a long 3' untranslated region (thought to be trafficked to dendrites for local protein synthesis) and the protein coding domain (common to all the mRNA isoforms of BDNF) are both reduced in hippocampal synaptoneurosomes of aged animals 4 days after infection. Reduced availability of BDNF at synapses might contribute to the deficits in memory-related synaptic plasticity. Since BDNF is thought to promote cholinergic neuronal function and survival and mounting evidence suggests that cholinergic deficiency may contribute to delirium and dementia, we are also investigating cholinergic receptor mRNAs. We have examined one isoform of the receptor, and the transcript is reduced in hippocampal synaptoneurosomes of these aged *E. coli* animals.

Title: Molecular basis of Obsessive-Compulsive Disorder: Involvement of TrkB/Slitrk5 in corticostriatal dysfunction

Authors: *M. SONG[1], A. LI[2], I. DINCHEVA[4], S. SHMELKOV[5], I. NINAN[6], F. LEE[3]
[1]Korea Brain Res. Inst., Daegu, Korea, Republic of; [2]Sackler Inst. for Developmental Psychobiology, [3]Weill Cornell Med. Col., New York, NY; [4]Columbia Univ., new york, NY; [5]Neurosci. and Physiol., NYU Sch. of Med., New York, NY; [6]Psychiatry, New York Univ. Sch. of Med., New York, NY

Abstract: Obsessive Compulsive Disorder (OCD) displays a substantial heritable component but few specific molecular genetic risk factors have been identified. Knockout mice lacking Slitrk5 expression display an OCD-like phenotype involving pathologic grooming that is responsive to serotonin reuptake inhibitors and corticostriatal dysfunction. To examine whether Slitrk5 function contribute to the genetic risk for OCD, we re-sequenced the complete protein coding sequence of SLITRK5 in a population sample of human OCD subjects. Direct functional testing of identified OCD-specific rare non-synonymous mutations in Slitrk5 found that all mutations

showed impaired synaptogenic activity as well as diminished binding to PTPδ, a trans-synaptic binding partner of Slitrks. These results demonstrate that rare mutations in SLITRK5 contribute to the genetic risk for OCD in human populations. We previously reported that Slitrk5 modulates BDNF-dependent biological responses through direct interaction with TrkB receptors. Under basal conditions, Slitrk5 interacts primarily with PTPδ; however, upon BDNF stimulation, Slitrk5 shifts to cis-interactions with TrkB. Interestingly, genetic facilitation of TrkB signaling rescued repetitive phenotype of Slitrk5 KO mice while deletion of BDNF expression in OCD circuit induced increase in grooming behavior. The networks of genes implicated in OCD remain obscure, however, these findings suggest that BDNF-dependent regulation of TrkB, Slitrk5, and PTPδ interactions at the synapse may mediate proper functioning of key corticostriatal circuits implicated in OCD.

Title: Intrahippocampal injection of Ouabain triggers dendritic branching in neurons and memory improvement in adult rats

Authors: *C. SCAVONE, A. M. M. ORELLANA, J. A. LEITE, P. F. KINOSHITA, A. R. VASCONCELOS, M. M. CARARO, D. Z. ANDREOTTI, L. S. LIMA, G. F. XAVIER, E. M. KAWAMOTO
Univ. of Sao Paulo, Sao Paulo, Brazil

Abstract: Ouabain (OUA) is a well-known endogenous cardiotonic steroid that binds to Na,K-ATPase (NKA) and can trigger the activation of signaling pathways, such as NFκB, through intracellular Ca^{2+} levels oscillation. Particularly in neurons, the NFκB signaling has been described to have an important role in molecular switch from short to long-term memory also regulating PKA/CREB signaling cascade. Furthermore, CREB activation can lead to an increase in BDNF that can modulate AKT and Wnt/β-Catenin signaling pathways. The aim of this study was to verify whether intrahippocampal injection of OUA (10 nM) was able to modulate the main signaling pathways involved in morphological plasticity and memory formation in hippocampus of male adult rats. For the first time in the literature, our study suggests that intrahippocampal injection of OUA 10 nM can activate WNT/β-Catenin signaling pathway as

well as CREB/BDNF, AKT and NFκB leading to important changes in cellular microenvironment that results in increased dendritic branching in CA1 and DG neurons, with spatial reference memory improvement. Therefore, molecular mechanisms trigged by low doses of OUA seems to be a promising therapeutic strategy to improve morphological plasticity and cognition in adult hippocampus.

Title: Developmental and synaptic roles for FRS adapter proteins: Implications for neurotrophin and FGF signaling in the hippocampus

Authors: *S. NANDI[1], K. ALVINA[2], P. J. LITUMA[2], P. E. CASTILLO[2], J. M. HEBERT[1]
[1]Departments of Neurosci. and Genet., [2]Dept. of Neurosci., Albert Einstein Col. of Med., Bronx, NY

Abstract: Neurotrophins (NTRs) and FGFs are implicated in a wide spectrum of brain functions including neurogenesis, dendritogenesis, spinogenesis, synaptic transmission, and plasticity. The mechanism of signal transduction by NTRs and FGFs from their respective cell-surface receptors (NTRKs and FGFRs) in mediating these processes is poorly understood. Using the mouse hippocampus as model we assessed the role of the FGF Receptor Substrate (FRS) family (FRS2 and FRS3), one of the first identified intracellular family of adapter proteins, which transduces signal from both NTRKs and FGFRs. Transcripts of one of several *Ntrk* and *Fgfr* genes (*Ntrk2* and *Fgfr1*, respectively), as well as *Frs2*, were strongly expressed throughout the hippocampus. Within the dentate gyrus (DG), *Ntrk2* and *Fgfr1* expressions were particularly robust in the sub-granular zone, while the granule cell layers showed stronger expressions for *Ntrk2* and *Frs2*. Using brain-specific and germline mutants, we found that FRS2 and FRS3 regulate DG

morphogenesis and postnatal neurogenesis, roles attributed to both NTRK2 and FGFR1. Two-photon imaging further showed that FRS adapters are required for dendritic branch and spine formation in DG granule cells, roles that were so far described for NTRK2. Consistent with a synaptic function for FRS adapters, *Frs* mutant mice displayed reduced excitatory synaptic transmission at glutamatergic perforant path inputs onto DG granule cells without significantly affecting presynaptic function as found by electrophysiological recordings in acute hippocampal slices. These observations reveal important roles for FRS adapters during DG development and postnatal neurogenesis. They further suggest maturational/synaptic function for FRS in DG granule cells. We reason that both NTRs and FGFs can utilize FRS in a contextual, receptor-specific manner in the hippocampus. Whether FRS signaling is directly required for these synaptic functions as well as for activity-dependent, long-term plasticity remains to be determined.

Title: Blocking BDNF-TrkB signaling reduces taste function, particularly, to sour stimuli

Authors: *J. RIOS-PILIER, A. CLEMENTS, R. LUNDY, R. F. KRIMM
Anatom. Sci. and Neurobio., Univ. of Louisville, Louisville, KY

Abstract: BDNF-TrkB signaling regulates taste bud innervation, both during development and in adulthood. In the central nervous system, BDNF can function as a neuromodulator and influence neuronal function. In the taste bud, Car4+ cells, which transduce sour taste, express BDNF and synapse with TrkB expressing nerve fibers. However, it is unclear whether BDNF-TrkB signaling plays a functional role in taste. To test this possibility, we used a chemical-genetic approach, which allowed TrkB-signaling to be reversibly blocked with 1-NMPP1 in mice with a specific point mutation (*TrkB*^{F616A}). *TrkB*^{F616A} and wild type mice were injected with 1-NMPP1, three hours before taste function was assessed, using both chorda tympani (CT) whole nerve responses and brief-access behavioral tests. There was an overall decrease in taste responses to all stimuli tested. To determine if one stimulus was impacted more than others CT

responses were plotted relative to 0.1M NH_4Cl responses. Relative CT responses to 0.02M Citric acid and 0.01N HCl were significantly reduced in *TrkB*^{F616A} treated with 1-NMPP1 compared to wild type mice with 1-NMPP1 ($p<0.017$ and $p<0.008$, respectively) and *TrkB*^{F616A} vehicle treated mice ($p<0.036$ and $p< 0.033$, respectively). There were no behavioral taste differences in brief-access tests between *TrkB*^{F616A} and wild type mice when treated with 1-NMPP1. We also examined taste bud innervation in *TrkB*$^{CreER/+}$:tdtomato:*TrkB*^{F616A} mice after 3 hours of 1-NMPP1 to confirm that any changes in taste function were not a result of morphological changes in TrkB afferent fibers. There were no differences in branching patterns of TrkB expressing fibers after blocking TrkB signaling for three hours. These data suggests that BDNF-TrkB signaling may modulate taste function, especially on neurons innervating taste receptor cells transducing sour taste.

Title: Role of Wnt-5a on GluN2B expression

Authors: *E. RAMOS[1,2], N. C. INESTROSA[1,2]
[1]Pontificia Univ. Católica, Santiago de Chile, Chile; [2]Ctr. for Aging and Regeneration, Santiago, Chile

Abstract: The Wnt-5a ligand is a secreted glycoprotein which interacts with the G-protein coupled receptor Frizzled 9. This interaction activates PLC and triggers the intracellular calcium increase through the non-canonical Wnt pathway. Among their roles, Wnt-5a is able to increase the clustering of PSD-95, also increases nitric oxide (NO) production, stimulates the translocation of NMDA receptor to the plasma membrane and up regulates NMDA currents. However, the specific Wnt-5a pathway involved in the regulation of the NMDAR function and the postsynaptic density structure is not clearly understood. Here we provide data showing that the activation of the Heme Regulated Eukaryotic Initiation Factor 2α (eIF2α) kinase (HRI), a kinase involved in memory consolidation, is essential to explain how Wnt-5a modulates NMDAR function through the production of NO. Using primary neuron cultures, synaptosomes from C57/BL/6J mouse, a specific inhibitor (iHRI) and genetic tools, we found that HRI kinase

has a role in GluN2B expression. Moreover, Wnt-5a treatment increases GluN2B expression generating new functional receptors, modulating postsynaptic density structure and dendritic spine number. All these effects are abolished with the iHRI. Our results suggest that NO produced by Wnt-5a, activates HRI kinase which in turn, phosphorylates eIF2α factor, allowing the translation of the GluN2B subunit of NMDAR to the postsynaptic density.

Title: Postsynaptic serine racemase regulates NMDA receptors

Authors: *J. M. WONG[1,2], E. V. BARRAGAN[1,2], J. A. GRAY[1,3]
[1]Ctr. for Neurosci., [2]Neurosci. Grad. Group, [3]Dept. of Neurol., Univ. of California Davis, Davis, CA

Abstract: NMDA receptors (NMDARs) are glutamate-gated ion channels which uniquely require a co-agonist for activation: either glycine or D-serine. The identity of the co-agonist is developmentally regulated and spatially restricted in the brain, with many synapses using glycine early on and later switching to D-serine. Despite the importance of these co-agonists in regulating excitatory synaptic transmission, neuronal function, and synaptic plasticity, the source and regulation of D-serine remains controversial. Although D-serine and its biosynthetic enzyme serine racemase (SR) were originally thought to be localized in astrocytes, recent studies using SR constitutive & conditional knock-out mice combined with more selective antibodies instead suggest a predominantly neuronal localization. Furthermore, SR both complexes and colocalizes with PSD-95 suggesting that SR is localized at the postsynaptic density. Thus, to examine the potential role of postsynaptic SR in synaptic physiology, we assessed synaptic AMPAR- and NMDAR-EPSCs in SR conditional knockout (SRcKO) mice (generous gift of Dr. Joseph Coyle). We injected neonatal SRcKO mice with AAV expressing Cre-recombinase and GFP and obtained simultaneous dual whole-cell recordings from transduced and neighboring control neurons. This genetic approach utilizes sparse, localized transduction of single cells in order to rigorously analyze the cell-autonomous effects of SR deletion while avoiding presynaptic effects and the circuit-wide effects of global genetic or pharmacologic NMDAR manipulations. Synaptic recordings at Schaffer collateral-CA1 and perforant path-dentate gyrus (DG) synapses in the hippocampus from P45-60 mice show an approximately 40% reduction in NMDAR-EPSC amplitude in CA1 and a 70% reduction in DG in transduced versus control neurons while no effects of SR deletion were detectable in earlier development (P14-P21). AMPAR-EPSC

amplitudes were not significantly different from control at any assessed time point in either CA1 or DG. Overall, these results suggest a cell-autonomous neuronal regulation of NMDAR co-agonist occupancy by postsynaptic SR.

Abstract: Dopamine receptor signalling is essential for normal basal ganglia function but in Parkinson's Disease (PD) substantia nigra (SNc) dopaminergic (DAergic) neurons degenerate with consequent loss of dopamine signalling. SNc DAergic neurons express D2 autoreceptors (D2Rs) and somatodendritically released dopamine mediates a negative feedback via D2Rs on DAergic neuron activity. D2Rs have been shown to mediate inhibition of NMDA responses in both hippocampus and striatum while $G_{\alpha s}$-coupled adenosine A2A receptors (A2ARs) have the potential to counteract the action of $G_{\alpha i}$ -coupled D2Rs. Here we tested whether D2R activation with ropinirole, a D2 receptor agonist currently used in PD therapy, modulates DAergic neuron NMDA responses in the SNc. To prevent D2R desensitization, a GRK 2/3 inhibitor, compound-101, was introduced via the intracellular pipette solution. Lastly, an A2AR agonist, CGS-21680, was applied in the presence and absence of ropinirole to test for any A2AR - D2R interaction. Whole-cell patch clamp recordings were made from DAergic neurons in the SNc of acute midbrain slices from neonatal (P7, P21 and P28) rats. DAergic neurons were identified by the presence of a prominent hyperpolarisation-activated inward current (In P7 rats, amplitude, 173 ±

34 pA; activation time constant, 797 ± 113 ms; mean ± SE, n = 11) in response to a voltage step from -60 to -120 mV. In each cell, two successive responses to 20 υM NMDA with 10 uM glycine were recorded. In P7 rats, control experiments gave NMDA responses of 919 ± 89 pA (1^{st} response) and 881 ± 113 pA, n = 11 (2^{nd} response) while in P28 rats the control NMDA responses were 790 ± 110 pA (1^{st} response) and 800 ± 93 pA, n = 10 respectively. In P7, P21 and P28 rats, upon application of 200 nM ropinirole, the steady state NMDA current was not significantly changed suggesting D2R activation may not modulate NMDARs in neonatal rat SNc. It is also possible a D2 effect might be observed in older rats. Furthermore, limitations involved in the whole-cell patch-clamp configuration, such as dilution of cellular components could affect the result. An A2AR agonist, CGS-21680 (1 or 10 υM) was applied to P28 DAergic neurons to determine the effect of activating this $G_{\alpha s}$ - coupled receptor which may be in a D2R-A2AR heteromeric complex. 1 υM CGS-21680 gave a 46 ± 16 % increase in inward current (P = 0.06, paired t-test; n = 12) while in the presence of 10 υM CGS-21680 and 200 nM ropinirole, the NMDA current increased 59 ± 16 % (P = 0.002, n = 16).

Abstract: NMDA receptors (NMDARs) are ionotropic glutamate receptors important for synaptic plasticity, memory, and neuropsychiatric health. NMDAR hypofunction contributes to multiple disorders, including anti-NMDAR encephalitis (NMDARE), a neuro-autoimmunological condition characterized by autoantibodies against CNS NMDARs and by NMDAR internalization. Symptoms include psychosis, seizures, cognitive deficits, and death. With immunotherapy, about 75% of patients recover. However, there remains unmet therapeutic need; immunosuppression onset can be slow, and there is incomplete recovery and relapse. Here

we characterize functional/pharmacological consequences of antibody exposure and introduce an alternative/adjunct treatment using positive allosteric modulators (PAMs) of NMDAR function. Staining of fixed mouse brain tissue slices incubated in cerebrospinal fluid (CSF) from a NMDARE patient yielded labeling with anti-human secondary antibody yielded labeling consistent with NMDAR distribution, confirming clinical diagnosis. Incubation (48 h) of rat hippocampal neurons in NMDARE patient CSF, but not asymptomatic CSF or multiple sclerosis CSF, exhibited attenuated NMDA-induced current. We characterized residual NMDAR function. Using open-channel blocker kinetics, we detected no change in P_{open} of remaining surface NMDARs. There was also no preferential loss of synaptic versus extrasynaptic or of GluN2A versus GluN2B NMDARs. These experiments suggest that broad-spectrum PAMs could be a viable intervention. We employed two PAMs, SGE-301 and SGE-550, that are analogues of the natural cholesterol metabolite 24S-hydroxycholesterol. Co-application of SGE-301 or SGE-550 with CSF for 24 h, following an initial 24 h in CSF alone, restored NMDAR function, even in the nominal absence of PAMs during evaluation. Memantine kinetics following 24 h SGE-301/550 incubation revealed increased P_{open}, consistent with PAM action. Furthermore, persisting restorative effects of SGE-301/550 were reversed by brief incubation with γ-cyclodextrin, a cyclic oligosaccharide used as a steroid/sterol scavenger. Thus, it appears that the effects of SGE-301/550 lie in persisting drug presence. Together, our studies demonstrate restoration of NMDAR functionality through augmentation of remaining NMDAR function. Further studies of the pathogenesis of NMDARE and PAM intervention will inform new treatments for this disorder and others involving NMDAR hypofunction.

Title: Effects of amines on GluN1/GluN2A and GluN1/GluN2B subtypes of NMDA receptor

Authors: *Y. YAMADA, T. YABUKI, K. NISHII
Fac. of Engineering, Kindai.Univ., Higashihiroshima-Shi, Japan

Abstract: NMDA-type glutamate receptors (NMDA receptors) are widely distributed in the central nervous system and play critical roles in synaptic plasticity and excitotoxicity. Dysfunctions of NMDA receptors are involved in several central nervous system disorders, including stroke, chronic pain and schizophrenia. There are a few NMDA receptor antagonists available for clinical use, including ketamine and most importantly, mematine, both of which act as channel blockers. Polyamines, such as putrescine, spermine and spermidine, are poly basic aliphatic amines that were ubiquitously present in prokaryotic and eukaryotic cells. Extracellular polyamines have multiple effects on NMDA receptors. Spermine is known to inhibit or activate the channel activity of NMDA receptor subunits dependent manner. Only NMDA receptors containing the GluN2B subunits display polyamine potentiation. The study of the channel block activity with the polyamine derivative is applied to a study of the structure activity correlation of the receptor, development of the brain function or improvement medicine. It was known that over 1000 different ingredients such as sugars, amino acids, amines and organic acids are included in sake, traditional Japanese alcoholic beverage made from rice. The components of sake were measured using CE-TOFMS and 186 components were identified. Twelve amines of 186 components were examined the effects on the channel activity of GluN1/GluN2A- and GluN1/GluN2B- subtypes of NMDA receptor using *Xenopus* oocyte expression system and elevated plus-maze test. Agmatine, putresine, tyramine, 2-phenylethylamine, ornithine, choline, 5-oxoproline, cysteic acid,and N-acetylglutamic acid inhibited the activity of both receptors. It was indicated that isoamylamine and betaine acts as antagonists of the GluN1/GluN2B receptor, but activators for GluN1/GluN2A receptor. Trimethylamine N-oxide promoted the activity of both receptors. Isoamylamine, 2-phenylethylamine and ornithine indicated significant anxiolytic effects by an elevated plus-maze test. Observed differences in activity between the receptor subtypes, it may be able to elucidate the mechanism of amines action on the NMDA receptor channel opening. These results indicate that these compounds from sake will be useful for the elucidation of regulation of NMDA receptors and the development of agents that target and alter NMDA receptor function may have therapeutic benefit.

Title: Computer simulations of NMDA receptors with all-atom resolution: A new tool to study the dynamics of NMDARs

Authors: *A. SINITSKIY, V. S. PANDE
Chem., Stanford Univ., Stanford, CA

Abstract: N-methyl-D-aspartate (NMDA) receptors are transmembrane proteins playing the key role in various cognitive processes, including learning and memory formation. Understanding the structure and dynamics of NMDA receptors (NMDARs) with atomic resolution is critically important for knowing how the brain works, and for developing new drugs to treat NMDAR-associated disorders. Several full all-atom structures of NMDARs in closed and inhibited functional states have recently been determined by X-ray crystallography and cryoEM. However, the dynamics of NMDARs at atomic resolution, especially on submillisecond timescales, is not sufficiently understood. It is also unclear how the published atomic structures of NMDARs relate to various functional states of NMDARs established from electrophysiological experiments. Here, we report the results of our computer simulations of an apo and an agonist-and-coagonist-bound NMDARs. To the best of our knowledge, these are the first reported all-atom simulations of a full NMDAR under physiological conditions. In total, 300 molecular dynamics (MD) trajectories were generated, each 100 ns long, leading to the aggregate sampling of 30 μs. Markov state models (MSMs) were used to estimate the equilibrium and nanosecond-to-microsecond dynamic properties of NMDARs from these finite-length trajectories.
Our simulations have revealed that the conformational transitions in the amino terminal domain (ATD) of NMDARs, previously discovered by cryoEM, occur much faster (~ 0.4 μs) than transitions between various functional states of the receptor (~ 1-100 ms). For this reason, we conclude that despite significant structural differences between four 'non-active' cryoEM structures of NMDARs (up to 10-20 Å), these four structures (PDB codes 5FXH, 5FXI, 5FXJ, 5FXK) may refer to the same functional state of the receptor, namely one of the closed states. Overall, computational modeling, and specifically all-atom MD simulations, can serve as a powerful tool for investigating NMDARs and yield information unavailable from experimental techniques alone.

Title: Regulation of NMDAR trafficking by protein phosphatase 1

Authors: *A. M. CHIU, L. W. BARSE, A. SANZ-CLEMENTE
Northwestern Univ., Chicago, IL

Abstract: N-methyl-D-aspartate receptors (NMDARs) are glutamate receptors that are responsible for the molecular basis of learning and memory through their ability to control processes such as synaptic plasticity and synaptic maturation. NMDARs are able to achieve these phenomena through their ability to initiate specific intracellular cascades in response to receptor

activation. The subunit composition and localization of the receptor regulate which intracellular cascades are triggered upon NMDAR activation. Thus, a key aspect of NMDAR regulation and function is tight control over trafficking of the receptor.
Posttranslational modifications are a crucial component of receptor trafficking. We have previously investigated how phosphorylation within the PDZ-binding domain of the GluN2B subunit of NMDARs results in the disruption of NMDARs from scaffolding proteins to reduce the synaptic content of the receptor. More recently, we sought to understand how the complementary reaction, dephosphorylation of this site, is controlled. Using primary cortical neurons and acute cortical slices, we have identified that calcium influx into the cell following activation of extrasynaptic GluN2B-containing NMDARs triggers the dephosphorylation of surface-expressed GluN2B-containing NMDARs.
In an effort to better understand the mediators of this dephosphorylation, we screened protein phosphatases and have identified protein phosphatase 1 (PP1) as being responsible for dephosphorylating the GluN2B PDZ-binding domain. However, because PP1 is a constitutively active phosphatase, there exist a number of molecular modes of regulation to control its activity. These include inhibitory PP1 phosphorylation, association with endogenous inhibitor proteins, and subcellular substrate targeting. Because canonical PP1 regulation involves a mixture of these forms of regulation, we are examining how each of these mechanisms may play a role in regulating PP1 activity against GluN2B's PDZ-binding domain. Ultimately, we believe that understanding how PP1 regulates this posttranslational modification and its consequence on NMDAR trafficking and localization will help to understand how physiological NMDAR trafficking occurs and how this is altered in disease.

Title: Bortezomib induces neuropathic pain through PKC-mediated activation of presynaptic nmda receptors in spinal cords

Authors: *H.-L. PAN[1], S.-R. CHEN[2]
[1]Univ. Texas-MD Anderson Cancer Ctr., Houston, TX; [2]Anesthesiol. & Perioperative Med., Univ. of Texas MD Anderson Cancer Ctr., Houston, TX

Abstract: The glutamate N-methyl-D-aspartate receptors (NMDARs) at the spinal cord level are critically involved in the synaptic plasticity associated with neuropathic pain. In this study, we determined whether treatment with bortezomib, a proteasome inhibitor, affects the NMDAR activity of spinal dorsal horn neurons. Systemic treatment with bortezomib in rats did not significantly affect postsynaptic NMDAR currents elicited by puff application NMDA directly to dorsal horn neurons. Bortezomib treatment markedly increased the baseline frequency of miniature excitatory postsynaptic currents (EPSCs), which was completely normalized by the NMDAR antagonist 2-amino-5-phosphonopentanoic acid (AP5). AP5 also reduced the amplitude of monosynaptic EPSCs evoked by dorsal root stimulation in bortezomib-treated, but not vehicle-treated, rats. Furthermore, inhibition of protein kinase C (PKC) with chelerythrine fully reversed the increased frequency of miniature EPSCs and the amplitude of evoked EPSCs in bortezomib-treated rats. Intrathecal injection of AP5 and chelerythrine both profoundly attenuated mechanical allodynia and hyperalgesia induced by systemic treatment with bortezomib. In addition, treatment with bortezomib induced striking membrane translocation of PKC-βII, PKC-δ, and PKC-ε in the dorsal root ganglion. Our findings indicate that bortezomib treatment potentiates nociceptive input from primary afferent nerves via PKC-mediated tonic activation of presynaptic NMDARs. Targeting presynaptic NMDARs and PKC at the spinal cord level may be an effective strategy for treating chemotherapy-induced neuropathic pain.

Title: Memantine inhibition of native synaptic NMDA receptors is Ca^{2+}-dependent

Authors: *N. V. POVYSHEVA[1], N. G. GLASGOW[2], J. W. JOHNSON[1]
[1]Neurosci., [2]Neurobio., Univ. of Pittsburgh Dept. of Neurosci., Pittsburgh, PA

Abstract: Memantine is an NMDA receptor (NMDAR) channel blocker approved for treatment of Alzheimer's disease, and with broad potential as a neuroprotective agent. Several studies have

suggested that memantine inhibits extrasynaptic NMDARs, which are hypothesized to be strongly linked to excitotoxic pathways, more effectively than synaptic NMDARs. Our investigation of mechanisms that could be responsible for preferential inhibition of extrasynaptic NMDARs revealed that memantine stabilizes a Ca^{2+}-dependent desensitized state of GluN1/2A NMDARs. Here we address whether this novel mechanism of action of memantine is applicable to native neocortical NMDARs. We studied effects of memantine on NMDAR excitatory postsynaptic currents (EPSCs) in layer II/III pyramidal neurons from prefrontal cortical slices of wild-type mixed background C57BL/6J, BALB/cJ mice of either sex. NMDAR EPSCs were evoked by extracellular stimulation at the border of layer VI and white matter. Memantine (10 μM) was applied in two conditions: (1) "High Ca^{2+}" condition, with 2 mM external Ca^{2+} and no Ca^{2+} buffer in the internal solution; and (2) "Low Ca^{2+}" condition, with 1 mM external Ca^{2+} and 10 mM BAPTA in the internal solution. External solution also contained 0.5 mM Mg^{2+} and 10 μM glycine. NMDAR EPSCs were isolated by addition of GABAA, AMPA and kainate receptor blockers. Since Ca^{2+}-dependent desensitization is more pronounced toward the end of stimulus trains, we assessed effects of memantine on the amplitude of the 10^{th} response to trains of 10 stimuli. Strikingly, whereas under high Ca^{2+} conditions 10 μM memantine decreased the amplitude of the 10^{th} response by 49 ± 7%, under low Ca^{2+} conditions the decrease was only 22 ± 2% ($p<0.01$). Our results support the conclusion that memantine stabilizes Ca^{2+}-dependent desensitized states of native as well as recombinant NMDARs. However, interpretation of these experiments could be complicated by the presence of presynaptic NMDARs at the stimulated synapses. Memantine block of presynaptic NMDARs could affect Ca^{2+} influx more substantially in high than in low external Ca^{2+}, resulting in a more pronounced reduction of EPSC amplitude under high Ca^{2+} conditions. Thus, we assessed potential presynaptic effects of memantine by measuring the paired- pulse ratio (PPR) before and after memantine application. Under both high and low Ca^{2+} conditions, the PPR was not significantly affected by memantine. Elucidating memantine mechanisms of action can provide important information for development of more effective neuroprotective drugs. Here we identify NMDAR Ca^{2+}- dependent desensitization as a novel target for drug development.

Title: Molecular insight into the N-methyl-D-aspartate receptor channel gating

Authors: *M. LADISLAV[1,2], J. CERNY[3], J. KRUSEK[1], K. SKRENKOVA[1], M. HORAK[1], A. BALIK[2,1], L. VYKLICKY JR[1,2]
[1]Cell. Neurophysiol., Inst. of Physiol. CAS, Prague, Czech Republic; [2]Cell. Neurophysiol., Inst. of Physiol. CAS, Vestec, Czech Republic; [3]Structural Bioinformatics of Proteins, Inst. of Biotech. CAS, Vestec, Czech Republic

Abstract: N-methyl-D-aspartate receptors (NMDARs) are heterotetramers containing two obligatory glycine-binding (GluN1) and two glutamate/glycine-binding (GluN2/3) subunits. These receptors mediate excitatory synaptic transmission in the central nervous system and it has been shown that dysregulation of NMDARs is involved in the pathophysiology of neurological and psychiatric disorders. Channel opening is the key step in the NMDAR gating that allows the flux of ions including Ca^{2+} across the membrane. Several lines of evidence indicate that the rearrangement of M3 helices in activated receptor makes the central cavity of the channel accessible therefore implying a crucial role of the M3-S2 linkers in channel opening. To answer the fundamental question, what are the initial steps in NMDAR channel opening, we embarked on functional, molecular biology and molecular dynamics studies of GluN1/GluN2B receptors and focused on the M3 and initial segments of the M3-S2 linkers. The results of our experiments show that deletion mutations and glycine substitution mutations in the M3-S2 linker of GluN1 and GluN2B subunits profoundly affect the NMDAR channel function: i. Mutated NMDARs open spontaneously and as a consequence of receptor activation by a single agonist; ii. The effect of deletions is stratified - spontaneous activity and single-ligand induced responses are more pronounced at deletions closer to the M3 helix; iii. The degree of spontaneous activity and single-agonist responses, as well as the size of the region affected by deletion mutations, differ for GluN1 and GluN2B subunits; iv. Irrespective of whether deletions were introduced in GluN1 or GluN2B subunits, the application of glutamate or glycine promoted receptor channel activity; v. Irrespective of whether the deletion was introduced to the M3-S2 linker of GluN1 and GluN2B, responses induced by glycine were (on average) larger than those induced by glutamate; vi. None of the single- and double-deletions in the linker region mimicked receptor activation by a single-agonist (insensitive to glutamate and sensitive to glycine or vice versa insensitive to glycine and sensitive to glutamate); vii. There is a bell-shaped relation between the spontaneous activity and single-agonist induced activity. Combining functional data with those of results of computational biology we show that the extracellular channel gate is formed by GluN1(L657) and GluN2B(I655) (LILI motif). Our data provide new insight into the mechanism of NMDAR ion channel gating and describes LILI motif crucial for the transduction of the energetics of agonist binding to the ligand binding domain to pore opening.

Title: Epilepsy-related mutations of GluN2A subunit of NMDA receptors

Authors: *D. A. SIBAROV[1], N. BRUNEAU[2], S. M. ANTONOV[1], P. SZEPETOWSKI[2], N. BURNASHEV[2], R. GINIATULLIN[3]
[1]Comparative Neurosci., IEPHB RAS, Sankt-Peterburg, Russian Federation; [2]INMED, Aix-Marseille Univ., Marseille, France; [3]Univ. of Eastern Finland, Kuopio, Finland

Abstract: Genetic variants of the glutamate activated NMDA receptor (NMDAR) subunit GluN2A are associated with the hyperexcitable states manifested by epileptic seizures and interictal discharges in patients with disorders of the epilepsy-aphasia spectrum. Deciphering the consequences of pathogenic GRIN2A variants would surely help in better understanding of the underlying mechanisms. This emphasizes the need for functional studies to unravel the basic functional properties of each specific NMDAR variant. In the present study, we have used patch-clamp recordings to evaluate kinetic changes of mutant NMDARs reconstituted after co-transfection of cultured cells with the appropriate expression vectors. Three previously identified missense variants found in patients or families with disorders of the epilepsy-aphasia spectrum and situated in the N-terminal domain (p.Ile184Ser) or in the ligand-binding domain (p.Arg518His and p.Ala716Thr) of GluN2A were studied in both the homozygous and heterozygous conditions. Relative surface expression and current amplitude were significantly reduced for NMDARs composed of mutant p.Ile184Ser and p.Arg518His, but not p.Ala716His, as compared with WT NMDARs. Amplitude of whole-cell currents was still drastically decreased when WT and mutant p.Arg518His-GluN2A subunits were co-expressed, suggesting a dominant-negative mechanism. Activation times were significantly decreased in both

homozygous and heterozygous conditions for the two p.Ile184Ser and p.Arg518His variants, but not for p.Ala716His. Deactivation also significantly increased for p.Ile184Ser variant in the homozygous but not the heterozygous state while it was increased for p.Arg518His in both states. Our data indicate that p.Ile184Ser and p.Arg518His GluN2A variants both impacted on NMDAR function, albeit differently, whereas p.Ala716His did not significantly influence NMDAR kinetics, hence partly questioning its direct and strong pathogenic role. This study brings new insights into the functional impact that GRIN2A variants might have on NMDAR kinetics, and provides a mechanistic explanation for the neurological manifestations seen in the corresponding human spectrum of disorders.

Abstract: N-Methyl-D-aspartate (NMDA) receptors are a member of the ionotropic glutamate receptor family of ligand-gated ion channels that mediate the majority of excitatory neurotransmission in the mammalian CNS. They are expressed primarily in the CNS but also in peripheral locations such as pancreatic islet cells, sensory nerve terminals in skin and cardiac ganglia. Seven subunits of the NMDA receptor have been identified, NR1, NR2A-D and NR3A-B2, they assemble as a tetramer consisting of two NR1 subunits and either two NR2 subunits or a combination of NR2 and NR3 subunits. Activation of NMDA receptors requires the simultaneous binding of glutamate and glycine. Calcium entry through NMDA receptors plays an important role in development and synaptic plasticity and is proposed to underlie higher processes such as learning and memory. It is also proposed to play a role in a number of neurological diseases such as epilepsy and Alzheimer's. Indeed, memantine is an NMDA antagonist which has been approved for the treatment of moderate to severe Alzheimer's. NMDA antagonists may also be targets for the treatment of neuropathic pain, major depression and Parkinson's disease. We present data of NMDA receptor combinations NR1 with either NR2A, 2B, 2C or 2D expressed in HEK cells recorded on a high throughput automated patch

clamp system. NMDA-mediated responses were elicited using glutamate and glycine. Mean current amplitudes varied from -127 ± 9 pA for NR1/NR2C (n = 188), -288 ± 21pA for NR1/NR2D (n = 191), -1.72 ± 0.19 nA for NR1/NR2A (n = 360) and -2.99 ± 0.33 nA for NR1/NR2B (n = 372) receptor combinations. The currents mediated by NR1/NR2A were potentiated by pregnenolone sulfate with an EC_{50} of approximately 40 µM (n = 284). NR1/NR2B-mediated currents were potentiated by spermine with an EC_{50} of 134 µM (n = 290) and blocked by ketamine with an IC_{50} of 2.26 ± 0.38 µM (n = 321). The currents mediated by NR1/NR2C and NR1/NR2D were potentiated by CIQ with an EC_{50} of 4.3 µM (n = 169) and 5.5 µM (n = 149), respectively. Interestingly, we could detect differences in potency of compounds such as ifenprodil on NR1/NR2A versus NR1/NR2B containing receptors. In addition to NMDA expressed in cell lines, we have also investigated the presence of NMDA receptors in stem cell-derived neurons. Glutamate (in combination with glycine) was used to elicit NMDA-mediated responses using automated patch clamp and MEA. In this way, we could record whole cell patch clamp data and compare this with extracellular field potential recordings in intact neuronal networks of stem cell-derived neurons.

Title: Ca^{2+}/calmodulin mediates strong negative coupling of NMDA receptor gating

Authors: *G. IACOBUCCI[1], G. K. POPESCU[2]
[1]Biochem., State Univ. of New York At Buffalo, Buffalo, NY; [2]Biochem., Univ. at Buffalo, SUNY, Buffalo, NY

Abstract: In the central nervous system, NMDA receptors generate large and highly regulated Ca^{2+} signals, which are critical for synaptic development, plasticity, and apoptosis. NMDA receptors are highly clustered at postsynaptic dendritic spines and exhibit spatially heterogeneous surface expression along dendrite arbors. Whether the spatial arrangement of NMDA receptors affects their signal is unknown. Synaptic NMDA receptor currents are subject to Ca^{2+}-dependent inactivation (CDI), a type of activity-dependent inhibition that depends on intracellular Ca^{2+} and calmodulin (CaM). We asked whether Ca^{2+} influx through a single NMDA receptor influences the activity of nearby NMDA receptors. We used cell-attached current recordings from GluN1-2a/GluN2A receptors expressed in HEK293 cells and from NMDA receptors native to dissociated hippocampal neurons. We measured transition probabilities (P_O) in multi-channel patches and analyzed these data with a coupled Markov chain model of cooperative gating to calculate the coupling factor, κ. In the absence of extracellular Ca^{2+}, we observed no cooperativity ($\kappa < 0.1$), whereas in 2 mM of external Ca^{2+}, both recombinant and native channels showed modest but significant cooperativity ($\kappa = 0.2$). This cooperativity was strongly reduced by pretreating cells with BAPTA-AM and by overexpressing a Ca^{2+}-insensitive CaM mutant. These results strongly indicate that NMDA receptor gating is coupled and the decrease in P_O depends on intracellular Ca^{2+} and CaM, as expected for CDI. Further, we altered NMDA receptor clustering by overexpressing PSD-95, a postsynaptic scaffolding protein and observed larger fluorescent puncta by immunofluorescence and much stronger cooperativity ($\kappa = 0.6$). Together, these results demonstrate Ca/CaM dependent negative cooperativity of NMDA receptor gating and suggest a possible role for channel clustering in activity-dependent NMDA receptor modulation.

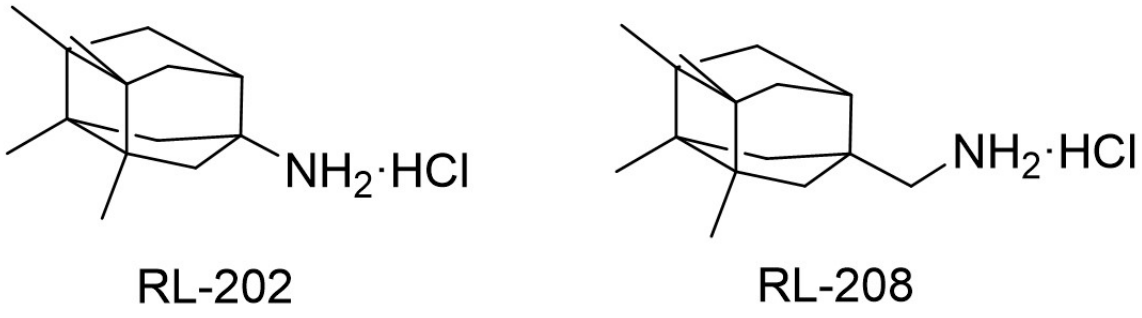
Title: Characteristics of NMDA receptor inhibition by the novel channel blockers RL-202 and RL-208

Authors: *M. B. PHILLIPS[1], R. LEIVA[2], S. VÁZQUEZ[2], J. W. JOHNSON[1]
[1]Neurosci., Univ. of Pittsburgh, Pittsburgh, PA; [2]Dept. of Pharmacology, Toxicology, and Therapeut. Chem., Univ. of Barcelona and IBUB, Barcelona, Spain

Abstract: NMDA receptors (NMDARs) are a class of ionotropic glutamate receptors (iGluRs) expressed at nearly all vertebrate synapses. NMDARs display a variety of properties unique amongst iGluRs, including dependence upon co-agonists, voltage-dependent Mg^{2+} block, slow kinetics, and permeability to Ca^{2+}. NMDAR activity is critical for many types of synaptic plasticity and is a key player in memory formation and learning. Conversely, aberrant NMDAR activation is implicated in a variety of nervous system disorders. Pharmacological targeting of NMDARs with channel blockers has shown therapeutic promise for protection from excitotoxicity as well as the treatment of Alzheimer's disease and major depressive disorder. Despite sharing similarities in binding site and mechanism of inhibition, the clinical utility of NMDAR channel blockers with differing structure can vary dramatically. Further investigation into how channel blockers differentially affect receptor function may provide insight into their varying clinical efficacy and aid in future drug design. Here we describe the synthesis and pharmacological characteristics of two novel NMDAR channel blockers, the polycyclic amines RL-202 and RL-208 (Figure 1). RL-202 and RL-208 were synthesized from 2,3-dimethylbutadiene and dimethyl acetylenedicarboxylate through a straightforward synthetic route. Recordings from NMDARs expressed in tsA201 cells revealed that both compounds share similarities with the well-characterized NMDAR channel blocker memantine, including moderate IC_{50} (RL-202 IC_{50} = 2.8 μM; RL-208 IC_{50} = 1.0 μM), strong voltage dependence of block, and second site inhibition. Second site inhibition is a form of antagonism exhibited by some, but not all, NMDAR channel blockers that involves drug binding to a site outside the NMDAR channel in the absence of agonist. Interestingly, both compounds display notably greater second site inhibition than memantine. Our findings suggest that these compounds could be useful tools for elucidating and differentiating mechanisms of NMDAR inhibition by channel blockers.



Structures of RL-202 and RL-208.

Title: PSD<->95 deficiency alters glutamatergic transmission in the prefrontal cortex during development

Authors: *A. A. COLEY, W.-J. GAO
Dept. of Neurobio. and Anat., Drexel Univ. Col. of Med., Philadelphia, PA

Abstract: Postsynaptic density protein-95 (PSD-95) is a major regulator in the maturation of excitatory synapses by interacting and trafficking N-methyl-D-aspartic acid receptors (NMDAR's) and α-amino-3-hydroxy-5-methyl-4-isox-azoleproprionic acid receptors (AMPAR's) to the postsynaptic membrane of the dendritic spine. PSD-95 disruption has recently been connected to neuropsychiatric disorders such as schizophrenia and autism. However, the effects of PSD-95 deficiency within the prefrontal cortex (PFC)—a brain region responsible for cognition, working memory, emotional control, and sociability—has yet to be investigated. We hypothesize that PSD-95 deficiency will disrupt synaptic maturation during critical periods of neurodevelopment due to an increase in NMDAR/AMPAR-glutamatergic transmission that leads to impairments in PFC development and function. Therefore, using a PSD-95 knockout mouse model (PSD-$95^{-/-}$), we examined how PSD-95 deficiency affects NMDAR and AMPAR expression and function in the medial prefrontal cortex (mPFC) at postnatal days 21, 35 and 70, i.e., juvenile, adolescent and adult periods, respectively. We found significant increases in total protein levels of NMDAR subunits NR1, and NR2B, accompanied with a trending decrease in AMPAR subunit GluR1 during adolescence. Whole-cell patch clamp recordings of NMDA- and AMPA-mediated currents reveal significant increases in NMDAR/AMPAR-mediated current amplitude, indicating an increase in silent synapses. However, no significant changes in NMDAR/AMPAR protein expression or function were observed during juvenile time points, indicating that the adolescence age range is a critical period at which PSD-95 influences NMDAR and AMPAR expression levels in the mPFC. Behaviorally, using a 3-chamber social interaction task, we show PSD-$95^{-/-}$ mice show a lack of social exploration and novelty that could be indicative of social withdrawal symptoms. These data indicate that PSD-95 deficiency disrupts mPFC synaptic function and behavior at a critical age range. This study describes the importance of PSD-95 during neurodevelopment in the mPFC and its potential association in the pathogenesis of cognitive and learning deficits in schizophrenia and/or autism.

Initiative, Oslo, Norway; [7]Dept. of Med. Biol., [8]Mol. Pharmacol. and Toxicology, UiT - The Arctic Univ. of Norway, Tromsø, Norway

Abstract: The NMDA receptor ion channel is activated by the excitatory neurotransmitter glutamate and is present in virtually every nerve cell in the CNS. It is essential to neurophysiological processes and is implicated in pathological neurodegeneration after stroke, epilepsy, Alzheimer's, Parkinson's and other CNS diseases. The composition and localization of NMDAR subunits is dynamic and varies across the CNS during development. Rodent nerve cell cultures are widely used models to characterize drugs binding to the NMDA receptor. We have used cultures of embryonic chicken forebrain neurons as an alternative to mammalian cultures in order to screen for neuro-active compounds aimed at NMDA receptor subtype NR2B. We hypothesized that chicken embryo forebrain neurons, with an abundance of cortical cells, express NR2B-containing NMDA receptors. The predicted amino acid sequences of chicken NMDA receptor subunits are very similar to those of rat. Advantages associated with the chicken model are; a) cells are dissected from 10 day old embryos (from eggs, E10) and such embryos are not yet subject to EU regulations for animal experiments, b) the model is economical and does not require animal house facilities, c) there are less allergies associated with dissection or handling of chicken embryos and d) as they are easily accessible, embryos may be injected with drugs prior to dissection to test for neurotoxic or developmental effects (Bjørnstad et al., JPET 355: 386-96, 2015). We have measured NMDA-mediated calcium influx using Fura-2 in chicken embryo neurons. Commercially available NR2B-subunit specific inhibitors Ro 04-5595 and ifenprodil reduced calcium influx with similar IC50 values as in rat neurons whereas spermine potentiated calcium influx, demonstrating functionally active NR2B-containing NMDA receptors, particularly abundant on DIV1 in culture. New potential NR2B-subunit specific inhibitors based on the structure of Ro 04-5595 were synthetized and shown to have a structure-activity relationship to NMDA-mediated calcium influx. Western blot analysis confirmed expression of NR2B in chicken forebrain cultures. Chicken forebrain showed increased NR2B

expression during development from E7 toE18, comparable to rat postnatal development described in literature. We conclude that the chicken embryo nerve cell culture from forebrain is comparable to murine models, and additionally, that it meets the principle of the three R`s in animal experiments (Replacement, Reduction and Refinement).

Title: Development of glutamatergic synapses onto layer 2/3 PV interneurons in the visual cortex during the critical period

Authors: *R. C. FERRER FIERRO[1], A. BAEZ[1], H. HSIEH[3], L. P. WOLLMUTH[2]
[1]Dept. of Neurobio. and Behavior, [2]Dept. of Neurobio. and Behavior & Dept. of Biochem. and Cell Biol., Stony Brook Univ., Stony Brook, NY; [3]Dept. of Surgery, Stony Brook Univ. Hosp., Stony Brook, NY

Abstract: Parvalbumin-expressing (PV) interneurons constitute a subgroup of inhibitory interneurons that regulate circuit dynamics in the brain. The inhibitory role of PV interneurons is mediated by the release of GABA, which is driven in part by the excitatory input that the interneuron receives. Excitatory glutamatergic synapses onto PV interneurons are mediated by both AMPA and NMDA receptors, but compared to pyramidal neurons, they have a small NMDA receptor component and a high proportion of calcium permeable AMPA receptors (GluA2- lacking) to signal excitatory inputs and consequent calcium influx. The normal development of PV interneurons is important for circuit maturation and regulates the critical period for visual plasticity in the visual cortex, but little is known about the dynamics of glutamatergic synapses onto PV interneurons during development. We characterized the properties of excitatory synapses onto PV interneurons in layer 2/3 in the visual cortex during the critical period, specifically addressing how the AMPA receptor (AMPAR) vs. NMDA receptor (NMDAR) components change during development. We found that the overall AMPAR component decreases during the critical period, evidenced by the decrease in the frequency of AMPAR-mediated miniature EPSCs (mEPSCs). On the other hand, the frequency of NMDAR-mediated mEPSCs was highly variable throughout development but showed a notable increase during the critical period. Accordingly, in paired recordings between pyramidal and PV interneurons in layer 2/3, the NMDAR-to-AMPAR ratio is higher during the critical period compared to adult stages. Translaminar glutamatergic connections, from layer 5 to layers 2/3,

showed a dramatically reduced NMDAR-to-AMPAR ratio, suggesting input specific developmental patterns. The developmental changes in NMDAR and AMPAR components during the critical period may influence synaptic integration and calcium dynamics mediated by glutamate receptors and could potentially alter the functional properties of PV interneurons.

Title: Modulation of NMDA receptors by group I mGlu receptors delivered via two different pathways

Authors: *S. SYLANTYEV, N. O'NEIL, N. KOMIYAMA, M. STEFAN
Univ. of Edinburgh, Edinburgh, United Kingdom

Abstract: NMDA receptor (NMDAR) hypofunction is one of the key factors provoking schizophrenia development. Another element, whose dysfunction is tightly associated with susceptibility to schizophrenia, is group I metabotropic glutamate receptors (mGluRIs)-mediated signalling. mGluRIs modulate NMDARs via two main pathways. First, metabolic signalling via G-proteins, the inhibition of which is associated with development of schizophrenia. Second, direct potentiation through a Homer1-containing protein interlink. Homer1-knockout animals with destroyed mGluRI-NMDAR interlink exhibit abnormalities consistent with schizophrenia symptoms thus suggesting Homer1 as potential molecule preventing schizophrenia development. Another factor, which destroys Homer-containing molecular interaction, are naturally occurring "short" Homers, such as Homer1a. However, expression of Homer1a protein is upregulated by anti-schizophrenia drugs haloperidole and clozapine. The aim of our study is to resolve this apparent discrepancy and find an approach allowing optimization of anti-schizophrenia drugs action. We set out to research interaction between inputs delivered from mGluRI to NMDR via two different pathways. Based on our pilot data, we hypothesized that mGluRs modulate NMDARs simultaneously via (i) direct molecular interaction through Homer-containing link and (ii) classical G-protein signalling cascade which modify competitively NMDAR functional parameter(s) (opening probability, affinity to agonist, etc.). We investigated this question

through a combination of electrophysiological experimental methods: whole-cell and nucleated patch recordings from control neurones and neurones overexpressing Homer1a. We found, that modulatory impact mediated by Homer proteins is lower than that delivered by G-proteins; fast Homer-delivered effects prevail at short-term time intervals, whereas slow G-protein-delivered input prevails on long-term intervals. Depending on cell type - dentate gyrus granule cells (DGCs) or cerebellar granule cells (CGCs) - Homer-delivered input may potentiate (in DGCs) or antagonize (in CGCs) G-protein delivered input from mGluRs to NMDARs. Our results thus confirmed necessity of the cell-type-specific insight for optimization of anti-schizophrenia drugs action.

Title: The NMDA receptor modulator NYX-2925 demonstrates therapeutic potential in preclinical models for the treatment of neuropathic pain

Authors: *N. GHOREISHI-HAACK[1], J. PRIEBE[1], J. DUNNING[1], J. BURGDORF[1,2], T. MADSEN[1], M. KHAN[1], C. CEARLEY[1], J. MOSKAL[1,3]
[1]Aptinyx Inc., Evanston, IL; [2]Biomed. Engin., Northwerstern Univ., Evanston, IL; [3]Bimedical Engin., Northwestern Univ., Evanston, IL

Abstract: Aptinyx has developed a novel class of small molecule NMDA receptor modulators with broad applicability across neurologic and psychiatric diseases. Aptinyx's lead compound NYX-2925 is currently in Phase 2 studies for treatment of pain associated with diabetic neuropathy. The present studies examine the effect of NYX-2925 in rat models of neuropathic pain when administered over a wide dose range either as a single dose or two weeks of daily dosing.
The analgesic effect of NYX-2925 was evaluated in the rat chronic constriction injury (CCI) model and the streptozotocin (STZ) model of diabetic neuropathy as measured by mechanical hypersensitivity.
A single oral dose of NYX-2925 produced a rapid-acting (1h post-dosing) and long-lasting (24h and 1 week post-dosing) analgesia in the CCI and STZ models with statistically significant efficacy over vehicle seen between 1-30 mg/kg in the CCI model and 1-10 mg/kg in the STZ model. In contrast, gabapentin (150 mg/kg PO) only produced analgesic effect 1h post-dosing in the both models. Daily oral administrations of NYX-2925 over 14 days results in significant efficacy over vehicle that was sustained throughout the dosing period. The effect of NYX-2925

is both NMDA and AMPA receptor dependent, as systemic co-administration of either the NMDAR antagonist CPP (10 mg/kg, IP) or the AMPAR antagonist NBQX (10 mg/kg, IP) abolishes the analgesic effect of NYX-2925 in the rat CCI model.
These data show that NYX-2925 has therapeutic potential as a daily administered neuropathic pain compound with both rapid acting and long-lasting therapeutic effects that are both NMDAR- and AMPAR-dependent.

Title: Subunit-specific enhancement by 24S-hydroxycholesterol of NMDAR-mediated tonic currents in mouse dentate gyrus granule cells

Authors: *X. WEI[1], T. NISHI[3], S. KONDO[3], H. KIMURA[3], I. MODY[2]
[1]Dept. of Neurol., [2]Dept. of Neurol. and Physiol., The David Geffen Sch. of Med. at UCLA, Los Angeles, CA; [3]Research, Takeda Pharmaceut. Co. Ltd, Fujisawa, Japan

Abstract: 24S-hydroxycholesterol (24HC) is the major metabolic breakdown product of cholesterol in the brain, where it is produced by the enzyme cholesterol 24S-hydroxylase (CYP46A1). 24HC is an endogenous regulator of a variety of neuronal functions. The N-methyl-D-aspartate receptor (NMDAR or GluN) is an important ligand-gated ion channel in the CNS, and its dysfunction is present in several neuropsychiatric disorders, including schizophrenia, depression, autism, Alzheimer's diseases and others. The function of NMDARs is modulated by multiple endogenous and exogenous compounds. One of the endogenous modulators is 24HC, but its mechanism of action onto intact NMDARs in the brain is poorly understood. Here, by using whole-cell patch clamp recordings in dentate gyrus granule cells of mouse brain slices, and pharmacological methods, we recorded isolated NMDAR-mediated (I_{NMDA}) tonic currents and

evoked postsynaptic currents. We found that 1 μM 24HC significantly enhanced tonic I_{NMDA}, but not evoked $I_{NMDA.}$ We next applied PEAQX (a GluN2A antagonist) and Ro25-6891(a GluN2B antagonist) to identify the subtype of GluN modulated by 24HC. Preincubation of the slices for 30 min with PEAQX (300 nM) or Ro25-6891 (1 μM) to block GluN2A and GluN2B respectively, had dramatic effects on the modulatory potential of 24HC. In our preparation where the tonic I_{NMDA} had both GluN2A and GluN2B components, Ro25-6981 blocked the enhancing effect of 24HC on tonic $I_{NMDA,}$ while preincubation with PEAQX had no effect. This indicates that 24HC mostly acts via NMDARs containing GluN2B subunits in intact granule cells. In CYP46A1 knockout mice, where little or no endogenous 24HC is present, 1 or even 10 μM 24HC had no effects on tonic I_{NMDA}, indicating that endogenous 24HC is necessary for maintaining the modulatory function of 24HC on NMDARs in the normal brain. As the subunit composition of NMDARs is different in interneurons (INs) than in principal cells, we also wanted to know whether the subunits present in parvalbumin (PV) INs are also modulated by 24HC. We applied 1 μM 24HC to dentate gyrus PV-INs in mice where PV-INs were labeled with tdTomato (PV cre X Ai14 mice). 24HC had no effect on tonic I_{NMDA} of PV-INs, indicating that the subunits present in these cells (mainly GluN2A and GluN2D) are not targets of 24 HC modulation. Taken together, our results revealed a subunit-specific modulation of NMDARs by 24HC, suggesting a new potential for cholesterol metabolites to influence the function of NMDAR in the brain.

Title: How NMDA receptor disruption affects prefrontal cortical neurophysiology essential for executive function

Authors: *M. A. BINKO[1], C. A. MIELNIK[2], A. J. RAMSEY[1,2], E. K. LAMBE[1]
[1]Dept. of Physiol., [2]Dept. of Pharmacol. & Toxicology, Univ. of Toronto, Toronto, ON, Canada

Abstract: The cognitive deficits of schizophrenia include impaired executive function, attention problems and distractibility, indicative of prefrontal cortical disruption. Converging evidence suggests that such cognitive symptoms arise from glutamatergic abnormalities, specifically from N-methyl-D-aspartate (NMDA) receptor hypofunction. Indeed, deficits in executive function are found in transgenic mice with reduced expression of the obligate GluN1 subunit of the NMDA receptor. Here, we examine functional brain changes in the prefrontal cortex of GluN1 knockdown mice relative to wild-type littermate controls. In a tripartite approach, we examined layer 5 pyramidal neurons in acute prefrontal brain slices: (1) measuring basic electrophysiological properties, (2) probing the integrity of synaptic and extra-synaptic NMDA receptor responses, and (3) evoking network activity as an integrated measure of regional brain function. Overall, these experiments paint a striking portrait of the prefrontal cortex in the GluN1 knockdown mice. Many aspects of cellular electrophysiology are largely preserved in the face of lifelong NMDA receptor knockdown, including near-normal NMDA currents to synaptic stimulation. Yet, responses to extra-synaptic NMDA stimulation are clearly disrupted, and electrically evoked network activity is absent under our experimental conditions in the GluN1 prefrontal cortex. As such network activity is thought to be essential for executive function, its disruption in GluN1 knockdown mice would contribute to their observed cognitive deficits. Ongoing work examines the potential enhancement of network activity in GluN1 knockdown and wild-type controls.

Title: GluN2B subunit selective NMDAR antagonist enhances the excitation/inhibition balance and disinhibits CA1 pyramidal cells only when estrogen is present in female rats

Authors: *A. J. WIDMAN[1], L. L. MCMAHON[2]
[1]Univ. of Alabama at Birmingham (UAB), Birmingham, AL; [2]Dept Cell, Developmental, and Integrative Biol., UAB, Birmingham, AL

Abstract: At low doses, NMDAR antagonists, including ketamine, generate a promising rapid antidepressant response in patients with Major Depressive Disorder (MDD) and in preclinical models with ketamine being the most effective. However, the psychotomimetic properties and abuse potential limit the use of ketamine, making it important to evaluate other NMDAR antagonists. Furthermore, identifying whether mechanistically different NMDAR antagonists impart the same or distinct changes in synaptic network activity in critical brain regions involved in MDD could potentially explain differences in their antidepressant efficacy. Previously, in male rats, we investigated the rapid effects of ketamine and the GluN2B subunit selective NMDAR antagonist, Ro 25-6981, on hippocampal circuits. 1μM ketamine decreases inhibitory input onto pyramidal cells and disinhibits them. In contrast, 1μM Ro 25-6981 had no effect on inhibitory input or pyramidal cell excitability, which correlates with the antidepressant efficacy of each drug. To date, no clinical study has addressed sex differences in response to ketamine, but two preclinical studies show ketamine has a greater antidepressant-like response in ovary-intact females than males (Carrier and Kabbaj, 2013; Franceschelli et al., 2015). Our lab has previously shown that proestrous-like levels of 17β-estradiol (E2) increase GluN2B-containing NMDARs on pyramidal cells (Smith and McMahon, 2006; Vedder et al., 2013). In addition, published studies show acute E2 treatment reduces inhibitory drive onto CA1 pyramidal cells (Huang and Woolley, 2012), suggesting the possibility that a synergistic relationship exists between E2 and NMDAR antagonists in enhancing the excitation/inhibition (E/I) balance in hippocampus. We investigated the rapid effects of ketamine and Ro 25-6981 on hippocampal circuits in ovariectomized female rats following treatment with proestrous-like levels of E2. Results show that 1μM ketamine shifts the E/I balance towards excitation and disinhibits pyramidal cells in female rats independent of E2 levels. However, 1μM Ro 25-6981 only shifts the E/I balance towards excitation and disinhibits pyramidal cells when female rats are treated with proestrous-like E2. These findings indicate the therapeutic dose and antidepressant effectiveness of NMDAR antagonists may fluctuate with varying levels of plasma E2.

Title: Asymmetrical pH-dependence in the activation of GluN1 and GluN2A N-methyl-D-aspartate receptor subunits

Authors: *N. N. JACKSON, K. S. JONES
Dept. of Pharmacol., Univ. of Michigan Med. Sch., Ann Arbor, MI

Abstract: The N-methyl-D-aspartate receptor (NMDAR) is one of the major subtypes of ionotropic glutamate receptors that mediate excitatory transmission in the central nervous system. NMDAR current is strongly attenuated by extracellular proton concentration (pH), which can vary drastically during pathological states. Structure-function studies have identified several amino acid residues in the transmembrane domains of NMDAR subunits that contribute to pH sensitivity, but the biophysical mechanisms are not fully resolved. The M3 transmembrane domain of the NMDAR forms a gate at the narrowest region of the NMDAR ion channel pore. Here we use the Substituted Cysteine Accessibility Method (SCAM) to examine the influence of extracellular pH on gating-induced translocation of residue A647 in the M3 domain. Cysteine residues were substituted at position A647 and A648 of the GluN1 (GluN1-A7C) and GluN2A (GluN2A-A7C). Mutant NMDAR subunits were expressed in Xenopus oocytes and NMDAR current was measured by two-electrode voltage-clamp electrophysiology. The pH sensitivity of GluN1-A7C- or GluN2A-A7C-containing NMDARs did not differ substantially from WT NMDARs (pH IC_{50} =7.2, WT; 7.3, GluN1-A7C/GluN2A; and 7.1, GluN1/GluN2A-A7C). Bath application of the sulfhydryl-specific compound (2-Aminoethyl) methane-thiosulfonate (MTSEA) did not alter the function of WT NMDARs. We previously showed that bath application of MTSEA alone does not alter the function of NMDARs comprised from A7C-mutant subunits. However, co-application of MTSEA in the presence of agonist dramatically slows channel deactivation (Jones, et al 2002). Here we show MTSEA attenuates pH sensitivity of NMDARs comprised from GluN1-A7C or GluN2A-A7C subunits. MTSEA modifies NMDARs comprised from GluN1/GluN2A-A7C subunits more rapidly and more completely than GluN1-A7C/GluN2A subunits. MTSEA modification increases the net amplitude of current evoked from GluN1/GluN2A-A7C receptors at all pH values tested (pH 6.4-8.4). Curiously, MTSEA modification *increases* the net amplitude of current evoked from GluN1-A7C/GluN2A receptors at acidic values ($pH \leq 7.0$), but *decreases* net amplitude of current evoked at basic values ($pH \geq 7.3$). These differences suggest gating elements in the GluN1 and GluN2A subunits exhibit distinct sensitivities to pH and that protons may induce unique conformations in each subunit. One hypothesis to explain differences in pH sensitivity of the A7C mutants is that cysteine substitution at GluN1-A647C permits the formation of a pH sensitive disulfide bond that is not present in GluN2A-A7C. Data addressing this hypothesis will be presented.

Title: Static magnetic field modulates cortical synaptic plasticity *In vitro* through an NMDA receptor-dependent pathway

Authors: Y. SUN[1,2,3], P. A. ROSENBERG[1,3], A. PASCUAL-LEONE[4], *A. ROTENBERG[1,2,4]
[1]Dept. of Neurol. and the F.M. Kirby Neurobio. Ctr., [2]The Neuromodulation Program and the Div. of Epilepsy and Clin. Neurophysiol., Boston Children's Hosp., Boston, MA; [3]Program in Neurosci., Harvard Med. Sch., Boston, MA; [4]Berenson-Allen Ctr. for Noninvasive Brain Stimulation, Div. of Cognitive Neurol., Dept. of Neurol., Beth Israel Deaconess Med. Center, Harvard Med. Sch., Boston, MA

Abstract: Background: There is growing evidence that moderate-intensity (1 mT to 1 T) static magnetic fields (SMF) influence cellular membrane channel function in the nervous system. For example, SMF exposure can affect the calcium and sodium current activation kinetics. The mechanism may be explained by the diamagnetic anisotropic properties of membrane phospholipids, which result in a deformation of imbedded ion channels. However, the effects of magnetic fields on neuronal functions are not fully characterized. We examined the SMF influence on neocortical synaptic plasticity in mouse primary motor cortex (M1) in vitro to obtain further insight into SMF effects and underlying mechanisms at the neurotransmitter receptor levels. **Methods:** Field excitatory postsynaptic potentials (fEPSPs) evoked by stimulating the layer 5 to layer 2/3 pathway was recorded in mouse M1 slices using a multichannel electrode array (MED64). Neocortical long-term potentiation (LTP) or depression (LTD), were induced either electrically (200 Hz for LTP; 1 Hz for LTD) or by selective pharmacologic activation of the N-methyl-D-aspartate receptor (NMDAR) or group 1 metabotropic glutamate receptor (mGluR1/5), by NMDA or R,S-dihydroxyphenylglycine (DHPG), respectively. %change of fEPSP slope was monitored before and after LTP/LTD induction with or without SMF (~100mT) exposure which started before LTP/LTD induction and continued for the entire length of the recording. **Results:** Electrically-induced cortical LTP (150.3 ± 12.8% of baseline, $p<0.05$) was eliminated by SMF (105.2 ± 9.3% of baseline, $p>0.05$; and $p<0.05$ as compared to control; n=6). Similarly, electrically-induced cortical LTD (52.9 ± 4.1% of baseline, $p<0.001$) was also significantly attenuated by SMF (78.2 ± 9.1% of baseline, $p>0.05$; and $p<0.05$ as compared to control; n=4). Pharmacologic LTD, generated by brief NMDA (8 μM, 2 min) bath application (52.6 ± 9.8% of baseline, $p<0.01$) was also partially

blocked by SMF (84.4 ± 2.4% of baseline, $p<0.001$; and $p<0.05$ as compared to control; n=6), which suggests an NMDAR-dependent SMF mechanism. In contrast, mGluR-mediated LTD induced by DHPG (50 μM, 5 min) was unaffected by SMF (control: 70.9 ± 7.8% of baseline, $p<0.05$; SMF: 70.8 ± 9.3% of baseline, $p<0.05$ and $p>0.05$ as compared to control; n=3). **Conclusion:** Taken together, our data demonstrate that moderate SMF exposure modulates cortical plasticity in vitro and this modulation is dependent on the NMDAR signaling pathway, and independent of the mGluR1/5 signaling. These findings will be important for understanding the mechanism of therapeutic SMF effects in clinical applications.

Title: SLK-01, a novel blocker of slack Na+-activated K+ channels

Authors: *D. P. JENKINS[1], V. GRIBKOFF[2], L. K. KACZMAREK[3]
[1]Pharmacol., [2]Intrnl. Medicine: Endocrinol., Yale Univ., New Haven, CT; [3]Yale Univ. Sch. Med., New Haven, CT

Abstract: The sodium-activated K^+ channel (KNa1.1, Slack, Slo2.2) is expressed throughout the brain, and directly couples increases in intracellular sodium to outward hyperpolarizing potassium currents. The Slack channel is thought to mediate a negative feedback system. Surprisingly, gain-of-function mutations in Slack are associated with development of several early onset epileptic encephalopathies. Quinidine, which blocks Slack channels, has recently been used to treat Slack mediated epilepsies. Its low potency and negative side effects profile, however, indicate that development of improved Slack channel blockers is key for the treatment of hyperexcitability-related disorders. SLK-01, originally synthesized for a targeted BK potassium channel activator program, was previously found to have off-target inhibitory activity on Slack channels expressed in Xenopus oocytes. We have now synthesized SLK-01 and have examined its efficacy and preliminary mechanism of action as an inhibitor of Slack currents. Heterologous expression of Slack channels in HEK293T cells showed that SLK-01 was four times more potent than Quinidine. Moreover, analysis of whole-cell current traces and docking simulations indicate that SLK-01 is an open-channel blocker, suggesting that it could be more potent on mutant gain-of-function Slack channels than on wild-type channels. We propose that

development of SLK-01 provides a new tool for investigating ion channel properties, and, critically, establishes a new line of research for discovering novel clinical therapeutics for treating Slack mediated epilepsies.

Title: Lithium may block the delay current (I_D) in olfactory projection neurons

Authors: P. KANTHAKUMAR, *B. I. HYLAND, P. HEYWARD
Univ. of Otago, Dunedin, New Zealand

Abstract: Bipolar disorder is a debilitating neuropsychiatric disease characterized by periodic depressive and manic episodes, associated with altered ion channel gene expression and disturbed brain network activity. Lithium (Li^+) is a first-line treatment for bipolar disorder, but its therapeutic mechanism of action remains unknown. Hypothetical targets for the action of Li^+ range from intracellular signalling messengers to membrane transporters and ion channels. We used whole-cell patch clamp recordings to investigate the effect of Li^+ on the integration of simulated excitatory post synaptic potentials (sEPSPs) by main olfactory bulb output (mitral) cells. The olfactory bulb is a part of the limbic system that is concerned with behaviour and mood and possesses an archetypal cortical modular organization. We found that Li^+ increased mitral cell action potential frequency, decreased after-hyperpolarization (AHP) amplitude, and decreased the decay slope of action potentials. These findings indicate that Li^+ blocks an outward current that plays a role during repolarization and AHP phases of action potentials. Further, Li^+ decreased the delay to action potential generation during a train of sEPSPs, consistent with cumulative inactivation of an outward current. Finally, application of 4-aminopyridine (4-AP) at a concentration that selectively blocks I_D (5 micromolar), reproduced the effects of Li^+ on mitral cell responses to sEPSPs and on action potential phases. Together, these data are consistent with an action of Li^+ on the delay-current (I_D). This current contributes to temporal integration of depolarizing signals due to its exceptionally long kinetics of inactivation and recovery from inactivation, and so can influence cortical network synchrony and spike time precision. Li^+ actions on I_D might therefore influence cortical network activity, contributing to its therapeutic effects in bipolar disorder.

Title: Kv3.3 potassium channel subunits are required to maintain fast synaptic transmission in the auditory brainstem

Authors: A. RICHARDSON[1], S. NEWTON[1], N. PILATI[3], C. H. LARGE[4], V. MARRA[1], *I. D. FORSYTHE[2]
[1]Neuroscience, Psychology & Behaviour, [2]Univ. of Leicester, P.O. Box 138. Leicester, United Kingdom; [3]Autifony Srl Labratories, Verona, Italy; [4]Autifony Therapeut. Limited, London, United Kingdom

Abstract: Voltage-gated potassium channels (Kv) control neuronal excitability, with high voltage-activated Kv3 channels mediating rapid action potential (AP) repolarisation, giving short APs and promoting high frequency firing with temporal precision (*Brew & Forsythe, J. Neurosci. 15, 8011–22, 1995*). Expression across the auditory brainstem nuclei is vital for accurate processing of sound localisation, but specific roles (if any) of the expressed subunits are unknown. Immunohistochemistry shows that of the four Kv3 subunits, Kv3.1 and Kv3.3 dominate in the superior olivary complex (SOC); so functional channels (requiring assembly of 4 subunits) could be as homomers or heteromers. One rationale for multiple subunits could be to influence biophysical properties, another would be to specify trafficking and/or location of the channel to different subcellular compartments.
In vitro patch recording in brainstem slices and *in vivo* auditory brainstem response (ABR) studies were conducted on wildtype and knockout ($Kv3.1^{-/-}$ & $Kv3.3^{-/-}$) CBA/Ca mice to assess synaptic transmission and auditory processing, respectively. ABR recordings using high frequency sound stimuli (24 kHz) were compromised in both knockout mice, while those using low frequency stimuli (12 kHz) were comparable to controls. Voltage clamp recordings during stimulation of the Calyx of Held showed reduced amplitude of synaptic response during high frequency stimulation trains in $Kv3.3^{-/-}$ mice. In contrast, $Kv3.1^{-/-}$ mice showed EPSC failures consistent with axonal action potential transmission failure. Together these data suggest that Kv3.3 is as critical as Kv3.1 for high frequency auditory processing: Kv3.3 has a primary role in

the giant presynaptic terminal, while Kv3.1 predominates in the postsynaptic neuronal soma and in axonal compartments.

Title: TBK1/ ubiquitination/autophagy pathways are activated by Kv3.3 channels

Authors: ***Y. ZHANG**[1], L. VARELA[2], T. L. HORVATH[2], L. K. KACZMAREK[3]
[1]Yale Univ. Sch. Med., New Haven, CT; [2]Yale Univ., New Haven, CT; [3]Yale Univ., New haven, CT

Abstract: The KCNC3 gene encodes the voltage-dependent potassium channel Kv3.3. These channels are expressed at particularly high levels in Purkinje cells in the cerebellum. Mutations in the KCNC3 gene result in Spinocerebellar ataxia type 13 (SCA 13), a human autosomal dominant disease characterized primarily by degeneration of the cerebellum. Our recent work found that Kv3.3 channel subunits binds Hax-1, an anti-apoptotic protein that is absolutely required for the survival of cerebellar neurons. The interaction of Kv3.3 with Hax-1 leads to the formation of a stable subcortical actin cytoskeleton adjacent to the channels. A human Kv3.3 mutant channel (G592R Kv3.3), which results in late onset SCA13, binds Hax-1 but fails to build the underlying cytoskeleton. Binding of Hax-1 to the channel is required to prevent channel inactivation during sustained depolarization. To probe further how an abnormal interaction between Kv3.3 and Hax-1 leads to cerebellar degeneration, we have now generated G592R knock-in mice, and found that the activity and levels of Tank Binding Kinase-1 (TBK1) are increased four-fold in the cerebellum of G592R Kv3.3 mice over levels in wild type mice. In Kv3.3 expressing cells, Kv3.3 is colocalizes with TBK1, and is immunoprecipitated with this kinase. Depolarization of cells expressing Kv3.3 enhances TBK1 activity. A basal level of TBK1 activity is required to keep Hax-1 bound to Kv3.3, such inhibitors of TBK1 cause the

dissociation of Hax-1 and promote rapid channel inactivation. TBK1 has both serine/ threonine kinase and ubquitin binding domains that allow this enzyme to trigger the binding of ubiquitinated membrane proteins to pre-phagocytic membranes, prior to their internalization into autophagosomes for degradation. By electron microscopy, we find that the enhanced activation of TBK1 in cells expressing the G592R Kv3.3 mutant is associated with increased enhanced formation of intracellular multivesicular bodies and presumed autophagosomes that contain Hax-1. Levels of CD63, a protein marker of multivesicular bodies, are also increased in mutant cells over those in wild type cells. This suggests that Kv3.3 channel activity directly controls the turnover of neuronal components and further suggests that TBK1 activity may regulate neuronal excitability.

Title: Behavioral deficits following withdrawal from chronic ethanol are influenced by slo channel function in *C. elegans*

Authors: *J. T. PIERCE, L. SCOTT, S. DAVIS, S. NORDQUIST, G. ORDEMANN
Univ. of Texas at Austin, Austin, TX

Abstract: Symptoms of withdrawal from chronic alcohol use are a driving force for relapse in alcohol dependence. Thus, uncovering molecular targets to lessen their severity is key to breaking the cycle of dependence. Using the nematode *Caenorhabditis elegans*, we tested whether one highly conserved ethanol target, the large-conductance, calcium-activated potassium channel (known as the BK channel or Slo1), modulates ethanol withdrawal. Consistent with a previous report, we found that *C. elegans* displays withdrawal-related behavioral impairments after cessation of chronic ethanol exposure. We found that the degree of impairment is exacerbated in worms lacking the worm BK channel, SLO-1, and is reduced by selective rescue

of this channel in the nervous system. Enhanced SLO-1 function, via gain-of-function mutation or overexpression, also dramatically reduced behavioral impairment during withdrawal. Consistent with these results, we found that chronic ethanol exposure decreased SLO-1 expression in a subset of neurons. In addition, we found that the function of a distinct, conserved Slo family channel, SLO-2, showed an inverse relationship to withdrawal behavior, and this influence depended on SLO-1 function. Together, our findings show that modulation of either Slo family ion channel bidirectionally regulates withdrawal behaviors in worm, supporting further exploration of the Slo family as targets for normalizing behaviors during alcohol withdrawal.

Title: The potassium channel Kv4.2 regulates seizure susceptibility in mouse models

Authors: *D. TIWARI[1], L. SCHROEDER[1], R. DANZER[1], A. BUNK[1], S. C. DANZER[2,3], C. GROSS[5,4]
[2]Dept Anesthesia, [1]Cincinnati Children's Hosp. Med. Ctr., Cincinnati, OH; [3]Dept. of Anesthesiol., [4]Dept. of Pediatrics,, Univ. of Cincinnati, Cincinnati, OH; [5]Neurol., Cincinnati Childrens Hosp. Med. Ctr., Cincinnati, OH

Abstract: The voltage-gated potassium channel Kv4.2 is a critical regulator of dendritic excitability in the hippocampus, and is crucial for dendritic signal integration. Kv4.2 mRNA and protein expression as well as function are reduced in several genetic and pharmacologically induced rodent models of epilepsy. However, so far it is not known if reduced Kv4.2 is just an epiphenomenon of epilepsy, or if it causes neuronal hyperexcitability and increased seizure susceptibility. Our previous studies suggest that microRNA-induced downregulation of Kv4.2 contributes to seizure development in a mouse model of kainic-acid induced *status epilepticus*. In the present study, we used Kv4.2 heterozygous mice and adult-onset manipulation of hippocampal Kv4.2 expression in mice to assess Kv4.2's role in regulating hyperexcitability and neuronal morphology in the brain. Western blot and quantitative real-time PCR analyses confirmed a significant reduction of Kv4.2 protein and mRNA levels in the Kv4.2 heterozygous mice. Using EEG analyses, we show that the latency to onset of kainic acid-induced seizures is

significantly shortened in Kv4.2 heterozygous mice compared to wildtype littermates. In addition, a significant increase in total EEG power was observed. No changes in anxiety or overall activity could be detected. Preliminary studies suggest that intrahippocampal CA1 injection of lentivirus overexpressing Kv4.2 delays seizure onset compared to GFP-expressing controls. Overall, these results show that Kv4.2 expression levels regulate seizure onset and severity. In the future, manipulation of Kv4.2 expression and function may be used to alter seizure susceptibility in epilepsy.

Title: Regulation of ether-à-go-go potassium channel expression by RING E3 ubiquitin ligases

Authors: *Y.-C. FANG[1,2], C.-Y. TANG[2], C.-J. JENG[1]
[1]Inst. of Anat. & Cell Biol., Natl. Yang-Ming Univ., Taipei, Taiwan; [2]Dept. of Physiol., Natl. Taiwan Univ., Taipei, Taiwan

Abstract: The *ether-à-go-go* (Eag) potassium channel belongs to the superfamily of voltage-gated potassium channel. In mammals, the expression of Eag potassium channels is neuron-specific and is widely distributed over various brain regions. Two Eag isoforms have been identified in rat, Eag1 and Eag2. We have applied the yeast two-hybrid screening system to identify rat Eag1 (rEag1)-interacting proteins from a rat brain cDNA library. Here we report the identification and characterization of RING E3 ubiquitin ligases as rEag1-binding partners. The physical interaction between RING E3 ubiquitin ligases and rEag1 were confirmed with GST pull-down assays and co-immunoprecipitation, which was in agreement with their co-localization with rEag1 at synaptic regions in cultured neurons. rEag1 protein expression level was significantly increased when endogenous RING E3 ubiquitin ligase expression in HEK293T cells was knocked down. Over-expression of RING E3 ubiquitin ligases led to reduced protein level, enhanced ubiquitination, accelerated protein turn-over, and decreased current density of rEag1 channels. The RING E3 ubiquitin ligase-induced rEag1 protein reduction was rescued by the proteasome inhibitor MG132 and the lysosomal inhibitor chloroquine. Together, our results indicate that RING E3 ubiquitin ligases contribute to both endoplasmic reticulum and peripheral protein quality control of rEag1 channels.

Title: A Cav2.3-Kv4.2 ion channel complex imparts local Ca^{2+} enhancement of A-type K^+ current

Authors: ***J. G. MURPHY**, L. LIN, E. E. GRAY, J. GUTZMANN, J. HU, D. A. HOFFMAN
Natl. Inst. for Child Hlth. and Human Develop., NIH, Bethesda, MD

Abstract: The rapidly inactivating A-type K^+ current mediated by Kv4.2 regulates action potential repolarization, subthreshold dendritic excitability, and synaptic plasticity in CA1 pyramidal neurons of the hippocampus. Kv4.2 channels assemble with the auxiliary subunits Dipeptidyl aminopeptidase-like proteins (DPP6/10) and members of the K^+ channel interacting protein family (KChip). KChips bind to the intracellular N-terminus of Kv4.2 and function to increase channel expression and function. Importantly, KChips bear 4 EF-hand motifs that are hypothesized to bestow Ca^{2+} regulation upon Kv4.2 channels. Recent evidence suggests that Kv4.2 function is regulated by R-type Ca^{2+} channel (Cav2.3) mediated Ca^{2+} entry in a KChip-dependent manner. However, the molecular nature of a Kv4.2-Cav2.3 interaction has not been explored.
Here we present evidence for a direct Kv4.2-Cav2.3 interaction that imparts Ca^{2+} regulation upon Kv4.2. We first identified Cav2.3 and Kv4.2 as interaction partners in a tandem affinity purification mass spectrometry screen using Kv4.2 as bait. We confirmed the interaction by coimmunoprecipitation of a Kv4.2-Cav2.3 complex from both HEK293 cells and hippocampal lysates and by immunogold labeling and electron microscopy. Next, photobleaching and sensitized emission Förster resonance energy transfer (FRET) experiments provided the evidence for a direct interaction between Cav2.3 and Kv4.2 that is independent of auxiliary subunits. Kv4.2-CFP fluorescence recovery after photobleaching (FRAP) demonstrated a small mobile fraction of Kv4.2 as we previously published. By comparison, Cav2.3-YFP has a large mobile fraction. Coexpression of Cav2.3-YFP and Kv4.2-CFP dramatically decreases the mobility of Cav2.3-YFP, suggesting Kv4.2 mediates recruitment of Cav2.3-YFP into a relatively immobile protein complex. To determine whether a Cav2.3-containing complex regulates Kv4.2 function, we measured K^+ currents under whole cell voltage clamp in HEK293FT cells expressing Kv4.2 and KChip2a alone or with Cav2.3. Under these conditions, K^+ currents are increased ~25%, while replacing EGTA with BAPTA in the patch pipette or extracellular application of the

Cav2.3 antagonist Ni^{2+} reversed this increase. Additionally, whole cell recordings in CA1 hippocampal neurons revealed a decrease in A-type K^+ current density in Cav2.3 knockouts when compared to wild-type mice. Taken together, these results support a direct Cav2.3-Kv4.2 interaction in which Ca^{2+} entry through Cav2.3 increases Kv4.2 function in hippocampal neurons. Ongoing efforts are exploring how the Cav2.3-Kv4.2 interaction regulates excitability in the hippocampus.

Title: Activity dependent phosphorylation of Kv4.2

Authors: *J.-H. HU, G. TABOR, Y. LIU, D. A. HOFFMAN
NICHD, Bethesda, MD

Abstract: Kv4.2, the prominent A-type voltage-gated potassium channel expressed in hippocampal CA1 pyramidal neuron dendrites, plays an important role in regulating the back-propagating action potentials and limiting the propagation of local dendritic spikes (Hoffman DA, 1997; Lai HC and Jan LY. Nat Rev Neurosci 2006). Kv4.2 control of dendritic excitability impacts neuronal plasticity and contributes to learning and memory (Lugo JN, 2015). Kv4.2 is regulated by its auxiliary subunits (DPP6/10 and KChIPs) and phosphorylation (Jerng HH, 2004). Previous findings showed that Kv4.2 can be phosphorylated at T602, T607 and S616 by ERK in vitro (Adams JP, 2000). However, it is still unknown if phosphorylation is regulated in brain and what function it has. Here, we report that Kv4.2 is dynamically phosphorylated at T607 in mouse brain. We first identified endogenous Kv4.2 phosphorylation sites in cultured hippocampal neurons using tandem affinity purification followed by mass spectrometry analysis. We found that Kv4.2 is phosphorylated at ERK sites and that T607 phosphorylation is increased when neurons were stimulated with AMPA. To further study Kv4.2 phosphorylation, we characterized specific antibodies against phosphor-T602 and phosphor-T607 using Kv4.2 mutations. We then detected phosphor-T602 and phosphor-T607 of Kv4.2 in mouse brain using the characterized antibodies. Interestingly, T607 phosphorylation was induced by seizure triggered by pentylenetetrazol administration, while T602 phosphorylation remained unchanged. We also found that about 10% of Kv4.2 is phosphorylated at T602 and 5% at T607 in mouse

brain, and that dual phosphorylation at T602 and T607 exists in mouse brain. To further investigate the role of T607 phosphorylation, we generated a knockin mouse with T mutated to A at 607 site using Crispr-Cas9 techniques. These mice will be analyzed for learning and memory behaviors. Taken together, these data support the idea that Kv4.2 is dynamically phosphorylated at T607 in brain and suggest it may play an important role in regulation of brain function.

Title: DPP6 loss results in behavioral impairments in recognition, learning and memory

Authors: L. LIN[1], J. G. MURPHY[2], R.-M. KARLSSON[3], R. S. PETRALIA[4], H. A. CAMERON[3], *D. A. HOFFMAN[1]

Abstract: DPP6 plays an important role as an auxiliary subunit of Kv4-mediated A-type K+ channels. However, in our recent previous studies, we found a novel role for DPP6 in synaptic development and function, which may be independent of its role as a K+ channel auxiliary subunit (Lin et al, 2013, 2014). In this study, we investigated the behavioral consequences of DPP6 loss.
We found that DPP6-KO mice were impaired in hippocampal dependent novel object recognition and object's spatial location tasks. Results from the Morris water maze, showed that DPP6-KO mice exhibit slower learning and reduced memory performance. In the T-Maze task, the success rate of WT mice increased over the course of the training whereas DPP6-KO mice showed no significant improvement throughout the training. The locomotor activity of DPP6-KO mice are not significantly difference than WT mice in both light and dark phases in the home cage task. Taken together these results show that impaired synaptic development, results in spatial learning and memory deficiencies in adult DPP6-KO mice. Ongoing experiments are aimed at determining the molecular mechanisms behind the synaptic developmental changes.

Title: SUMOylation of the mouse voltage-gated potassium channel Kv4.2 decreases the maximal conductance of the A-type potassium current (I_A)

Authors: *M. A. WELCH[1], L. A. FORSTER[2], D. J. BARO[1]
[1]Biol., [2]Neurosci. Inst., Georgia State Univ., Atlanta, GA

Abstract: Small ubiquitin-like modifier (SUMO) is ~100 amino acid peptide post-translationally added to a lysine residue within a SUMOylation consensus site on a target protein. SUMOylation usually facilitates protein-protein interactions and is an important mediator of neuronal function. SUMOylation is necessary for several forms of synaptic plasticity and intrinsic plasticity mechanisms could also rely on SUMOylation because it has been shown that ion channel surface expression can vary with the extent of channel SUMOylation. The voltage-gated potassium channel Kv4.2 mediates I_A. In hippocampal neurons, Kv4.2 surface expression can be regulated in an activity dependent manner such that there is a protein kinase A (PKA) dependent internalization of Kv4.2 channels following synaptic stimulation or during long-term potentiation (LTP). Our data suggest that SUMOylation could be involved in Kv4.2 channel internalization. Using the SUMOplot analysis program, we identified several putative SUMOylation sites on the Kv4.2 channel including one high probability site (79%) that is also present in the Kv4.3 channel. To test the hypothesis that SUMOylation at this site regulates the surface expression of Kv4.2 channels, a GFP-tagged mouse Kv4.2 channel was stably expressed in human embryonic kidney (Hek) cells (Hek-Kv4.2g). Baseline SUMOylation was or was not increased by transiently transfecting Hek-Kv4.2g cells with SUMO and the SUMO conjugating enzyme Ubc9. Whole cell patch clamp recordings showed that when baseline SUMOylation was enhanced, I_A maximal conductance was significantly reduced (37.6±3.7μS vs. 24.1±2.1μS, $p<0.05$, t-test). The voltage dependence of activation and inactivation and the kinetics of inactivation were unaltered. Changing lysine to arginine within the high probability SUMO consensus site prevented the decrease (27.0±2.7μS vs. 27.9±2.8μS, $p=0.8$, t-test). These data suggest that the Kv4.2 channel is SUMOylated at the high probability consensus site in Hek-Kv4.2g under baseline conditions and that increasing SUMOylation decreases Kv4.2 surface expression. Immunoprecipitation experiments with an anti-GFP antibody followed by western blotting with antibodies against SUMO and Kv4.2 indicated that Kv4.2 channels were SUMOylated in Hek-Kv4.2g cells. Currently we are quantifying SUMOylation and surface expression of wild type and mutant Kv4.2 channels in a heterologous expression system. Similar experiments are being performed with the mouse Kv4.3 channel and we are examining Kv4.2 and Kv4.3 channel SUMOylation in

the mouse CNS. This work will enhance our understanding of SUMO's role in regulating Kv4.2 and Kv4.3 surface expression.

Title: BK channels are structurally and functionally coupled with NMDA receptors and postsynaptically regulate synaptic transmission and plasticity

Authors: X. GUAN[1], J. ZHANG[1], Q. LI[1], A. MEREDITH[2], H.-L. PAN[1], *J. YAN[1]
[1]Dept. of Anesthesiol. and Perioperative Med., Univ. of Texas MD Anderson Cancer Ctr., Houston, TX; [2]Dept. of Physiol., Univ. of Maryland Sch. of Med., Baltimore, MD

Abstract: The large conductance calcium- and voltage-activated potassium (BK) channel is widely expressed in the central nervous system. The physiological roles of BK channels and the calcium sources of their activation in mammalian brains remain not well-understood. Our proteomic and biochemical analyses of BK channels and the calcium-permeable NMDA receptors have found that they form protein complexes in whole brain and various brain regions, consisting of the obligatory BK channel alpha (BKα) and GluN1 subunits and at least the regulatory GluN2A and GluN2B subunits. We examined the cellular colocalization and functional coupling of BK channels to NMDA receptors in mice hippocampal dentate gyrus. We found that they colocalized within nanodomains in dentate gyrus and BK channels were robustly activated by NMDAR-mediated Ca^{2+}-influx in granule cell somas. We observed that blockade of BK channels by paxilline increased the amplitude of excitatory postsynaptic potentials (EPSPs) of granule cells evoked by stimulation in the perforant path-granule cell synapses, which was prevented by blockade of postsynaptic NMDARs or BK channels via pipette delivery of MK-801 or paxilline or by genetic ablation of BKα. We also found that blockade of postsynaptic BK channels and genetic ablation of BKα both abolished long-term potentiation (LTP) of granule cells. We thus inferred that by complex formation and functional coupling with NMDA receptors, postsynaptic BK channels are critically involved in synaptic transmission and LTP in hippocampal dentate gyrus.

Title: Temperature-sensitive outward currents through two-pore domain K^+ channels in nociceptive-like primary afferent neurons

Authors: *V. VIATCHENKO-KARPINSKI, F. EROL, J. LING, J. G. GU
Anesthesiol., Univ. of Alabama At Birmingham, Birmingham, AL

Abstract: Two-pore domain K^+ channels (K2P) play important roles in setting resting membrane potentials and neuronal excitability. Activity of K2P channels has been found to be highly temperature-dependent, raising a possibility that these channels may be involved in setting neuronal excitability at different temperatures in primary afferent neurons. In the present study we seek to characterize K2P channels in nociceptive type of primary afferent neurons in rat dorsal root ganglia (DRG) to determine their temperature sensitivity and pharmacological properties. Under the condition when cations flowing through voltage-gated ion channels were inhibited, we measured outward currents to determine K2P channel activity in nociceptive-like DRG neurons acutely dissociated from adult rats. The outward currents were recorded using whole-cell patch-clamp recordings with a Cs^+-based intracellular recording solution, which had reversal potentials near -80 mV. Based on the current amplitude and thermal sensitivity of the outward currents, cells could be classified into three types. In the first type (type I), outward currents had large amplitude at the temperature of 22^{o}C, and the amplitude of the outward currents increased when temperature increased to 30^{o}C and reduced when temperature dropped to 14^{o}C. In the second type (type II), outward currents had large amplitude at the temperature of 22^{o}C, and the amplitude of the outward currents did not increase when temperature increased to 30^{o}C but reduced when temperature dropped to 14^{o}C. In the third group (type III), outward currents had small amplitude at the temperature of 22^{o}C, and the amplitude of the outward currents did not increase when temperature increased to 30^{o}C but increased when temperature dropped to 14^{o}C. Pharmacological properties of the temperature sensitive outward currents in these three types of cells were examined. Outward currents in type 1 cells but not type 2 and type 3 cells could be inhibited by PGF2α, a compound that has recently been shown to have effects on

K2P channels. Gd^{3+} and riluzole, two compounds that can inhibit K2P channels, were also tested and they appeared to produce inhibitory effects on the outward currents of type I and type II cells. Taken together, this study may suggest that different types of K2P channels are present in functionally distinct groups of nociceptive neurons, and their functions in setting nociceptive neuron excitability need to be determined in future studies.

Title: 17β-Estradiol potentiates TREK-1 activity through G protein-coupled estrogen receptor

Authors: *N. CHOUDHURY, S. K. SIKDAR
Mol. Biophysics Unit, Indian Inst. of Sci., Bangalore, India

Abstract: TREK-1 ($K_{2P}2.1$), a two-pore domain leak potassium channel, is implicated in controlling the excitability in neurons owing to its current properties. It is involved in physiological and pathophysiological processes such as pain, anesthesia, epilepsy, ischemia, and depression. Activity of TREK-1 is modulated by various chemical and physical stimuli including membrane receptor - coupled second messengers. Previous studies have shown an inhibitory effect of G_s and G_q Protein - Coupled Receptors on TREK-1 channel activity. However, much less is known about GPCR mediated activation of TREK-1. In the present study we investigate the modulation of TREK-1 by 17β-Estradiol, a reproductive hormone as well as a neuromodulator, using cell-attached patch clamp recordings of TREK-1 ion channel currents. 17β-Estradiol can activate several signaling pathways in the cell on binding to its membrane bound receptor G - Protein coupled Estrogen Receptor (GPER). Experiments in HEK293 cells expressing GPER and TREK-1 indicate about 4 - fold increase in TREK-1 channel activity within minutes of 17β-Estradiol application in a pertussis toxin - sensitive manner. The involvement of GPER is confirmed with its agonist G-1 and antagonist G-15. Pharmacological inhibition of signaling pathways indicate involvement of the α - subunit of G_i with the resulting decrease in cAMP leading to reduced activity of Protein Kinase A and thus activation of TREK-1. Mutational studies indicate the serine residues in the C-terminal domain of TREK-1 to be the sites of action of 17β-Estradiol through GPER. The study reveals the potentiating role of 17β-Estradiol on TREK-1 channel activity through GPER by decreasing phosphorylation in the C-terminal domain of TREK-1. This may be one of the mechanisms by which 17β-Estradiol controls cellular excitability and acts as a neuroprotectant.

Title: The functional modulation of sodium-activated potassium (Slack) channels by Phactr1

Authors: *S. R. ALI, L. KACZMAREK
Dept. of Pharmacol., Yale Univ., New Haven, CT

Abstract: The Slack gene encodes sodium-activated potassium channels that are abundantly expressed in the central nervous system. Human mutations alter the function of Slack channels, resulting in epilepsy and intellectual disability. Most of the disease-causing mutations are located in the extended cytoplasmic C-terminus of Slack channels and most result in increased Slack current. Previous experiment using a yeast two-hybrid system indicate that the C-terminus of Slack channels binds a number of cytoplasmic signaling proteins. One of these is Phactr1, a protein that is believed to target protein phosphatase 1 (PP1) to its phosphoprotein substrates. Phactr1 is also known to be an actin-binding protein. We have now found by co-immunoprecipitation that all three components, Phactr1, PP1 and actin exist in a complex with Slack channels. Upon activation of protein kinase C, Phactr1 dissociates from the Slack channel. Conversely, pharmacological activation of PP1 increased the binding of Phactr1 to Slack channels. We have also monitored the association/dissociation of Slack channels with Phactr1 using a fluorescence resonance energy transfer (FRET) assay. As in the biochemical experiments, activation of PP1 stimulated the association of Phactr-1 with the channel. In parallel experiments using whole-cell patch clamp recordings of Slack currents we found that co-expression of Phactr1 produced a suppression of Slack current. Because phosphorylation of Slack channels at serine residue 407 produces an increase in current, our findings are consistent with the hypothesis that Phactr1 recruitment of PP1 to the channel results in dephosphorylation and loss of current amplitude. Our findings suggest that targeting Slack-Phactr1 interactions may be helpful in developing novel therapies for brain disorders associated with the malfunction of Slack channels.

Title: Mouse model of slack-associated epilepsy

Authors: *I. H. QURAISHI[1], M. MERCIER[2], Y. ZHANG[3], D. P. JENKINS[4], K. P. MANGAN[5], L. K. KACZMAREK[2]
[1]Dept. of Neurol., [2]Yale Sch. of Med., New Haven, CT; [3]Yale Univ. Sch. Med., New Haven, CT; [4]Pharmacol., Yale Univ., New Haven, CT; [5]Cell. Dynamics, Intl., Madison, WI

Abstract: Mutations in the potassium channel Slack (also called KCNT1 or KNa1.1) lead to various types of epilepsy including autosomal dominant frontal lobe epilepsy (ADNFLE) and epilepsy of infancy with migrating focal seizures (EIMFS). In the past few years, it has become clear that this is an important epilepsy gene, with over 20 epilepsy-causing mutations identified. Slack is important in the synchrony of high frequency neuronal activity, survival from electroshock seizures, and in the regulation of neuronal protein translation. Almost all the mutations that have been tested to date by heterologous expression in Xenopus oocytes cause an increase in the sodium-activated potassium current. Using CRISPR-Cas9 we have now developed a mouse model of Slack-associated epilepsy with the R455H mutation, which was identified in patients with epilepsy of infancy with migrating focal seizures (EIMFS). Homozygotes have low survival. Heterozogotes have spontaneous subclinical and tonic-clonic seizures on video EEG monitoring as well as interictal epileptiform discharges. Latencies for pentylenetetrazole-induced seizures are substantially reduced in heterozygous mice. The mice have deficits in procedural learning, as was also seen in Slack knockout mice. In addition to the mouse model, we evaluated neurons derived from induced pluripotent stem cells and engineered to have Slack P924L, another mutation associated with EIMFS. Whole cell voltage clamp recordings confirmed a gain of function of the sodium-activated current. In addition, multielectrode array recordings demonstrated an increase in bursting behavior. We have begun screening for selective modulators of the Slack channel as there are currently no specific drugs available. We identified a potent activator as well as the first state-dependent blocker of the

channel. Taken together, these results will form the framework for identifying the mechanisms of Slack-associated epilepsy and for targeted anti-epileptic drug discovery.

Title: The effects of organophosphate flame retardants on the M-current in NPY neurons in adult mice

Authors: *G. VAIL[1], T. A. ROEPKE[2]
[1]Toxicology, Rutgers Univ., New Brunswick, NJ; [2]Animal Sci., Rutgers, The State Univ. of New Jersey, New Brunswick, NJ

Abstract: The hypothalamus regulates many important biological functions such as reproduction, thermoregulation, and energy balance. Orexigenic NPY neurons located in the arcuate nucleus (ARC) of the hypothalamus play an essential role in energy homeostasis. Disruption of this balance can cause metabolic disease states such as obesity and anorexia. EDCs such as organophosphate flame retardants (OPFR) are a potential cause of hypothalamic disruption as they accumulate in human tissues and impinge on endogenous nuclear receptors such as ERα and PPARγ. Previously, we demonstrated that OPFR oral treatment in adult mice decreased ARC expression of neuropeptide Y and increased growth hormone secretagogue receptor (GHSR) and KCNQ channel subunit expression in a sex-dependent manner. We hypothesized that these effects would augment the activity of the M-current in NPY neurons leading to a suppression of NPY excitability and a reduction in food intake. We will use voltage clamp, whole-cell patch-clamp to record the M-current in NPY neurons utilizing selective KCNQ channel blocker XE991 with standard activation and deactivation protocols from male and females after OPFR treatment. These experiments will be coupled with single cell-type quantitative real-time PCR to measure expression of neuropeptides, GHSR, and KCNQ subunits in NPY pools. Our data suggests that adult exposures to EDC especially flame-retardants may

impact the hypothalamic melanocortin neurocircuitry leading to dysregulation of energy homeostasis.

Title: Loss of Kv1.3 potassium channels impairs auditory function

Authors: *L. EL-HASSAR[1], L. SONG[2], V. R. GAZULA[1], D. NAVARATNAM[3], J. SANTOS-SACCHI[2], L. K. KACZMAREK[1]
[1]Pharmacol. department SHMB 309, Yale Univ. Sch. of Med., New Haven, CT; [2]Surgery, [3]Neurol., Yale Sch. of Med., New Haven, CT

Abstract: Kv1.3 is a voltage-dependent potassium channel involved in various physiological functions such as cell volume regulation, proliferation, and insulin signaling. Within the central nervous system, deletion of the Kv1.3 gene from mitral cells of the olfactory bulb has been found to increase dramatically the sensitivity of the olfactory system. To test the effects of loss of Kv1.3 on another sensory system, we have analyzed its expression in the auditory system. We used an anti-Kv1.3 antibody to localize these channels to bouton-like structures on inner and outer hair cells within the cochlea. Specificity of staining was confirmed by the finding that immunostaining of these structures is completely absent in Kv1.3 $^{-/-}$ mice. Our group has also shown that Kv1.3 channels are present in presynaptic terminals of the medial nucleus trapezoid body (MNTB) within the auditory brainstem. We next combined *in vivo* with *in vitro* approaches to test the contribution of these channels to auditory function in the peripheral and central auditory system. Measurements of auditory brainstem responses (ABR) show that auditory thresholds are elevated in Kv1.3 $^{-/-}$ mice over those in wild type (WT) mice. Latencies of peaks I, II and IV, which represent transfer of auditory information from the cochlea to midbrain, are prolonged in Kv1.3 $^{-/-}$ mice. In addition, we found a desynchronization of ABR waves in Kv1.3 $^{-/-}$ mice suggesting an alteration of synaptic transmission and changes in spike fidelity within these auditory pathways. To further investigate the mechanisms of these alterations in ABR waves, we carried out patch-clamp recordings of the high-fidelity calyx of Held/MNTB synapse. Our results show that lack of Kv1.3 channels significantly increases the firing frequency of

presynaptic terminals (Calyxes of Held) in response to square pulses of injected currents. In contrast, no difference between wild type and Kv1.3$^{-/-}$ animals was detected in postsynaptic MNTB neurons. This result suggests that loss of Kv1.3 channels impairs auditory function primarily by influencing the properties of presynaptic terminals. Ongoing experiments are characterizing synaptic transmission between the calyx of held and MNTB principal neurons in both Kv1.3 $^{-/-}$ and wild type mice.

Title: Upregulation of microglial Kv1.3 potassium channels in neuroinflammatory disorders

Authors: *H. M. NGUYEN[1], Y.-J. CHEN[2], H. WULFF[2], I. MAEZAWA[3], L.-W. JIN[4]
[1]Pharmacol., Univ. of California Davis, Davis, CA; [2]Pharmacol., UC Davis, Davis, CA; [3]M.I.N.D. Inst, UC Davis, Sacramento, CA; [4]M.I.N.D. Inst. UC Davis, Davis, CA

Abstract: Microglia effector functions are widely associated with specific phenotypes, which are referred to as M1 and M2, in response to cues from the surrounding brain microenvironment. While classically activated M1 microglia release pro-inflammatory cytokines and neurotoxic molecules and have been associated with neurological damage in ischemic stroke, Alzheimer's and Parkinson's diseases, alternatively activated M2 microglia exhibit beneficial immunological effector functions such as phagocytosis of debris and release of anti-inflammatory and neurotrophic factors. We have previously identified three major types of K^+ channels in M(LPS)- and M(IL-4)-differentiated cultured primary mouse microglia based on their biophysical and pharmacological fingerprints: Kv1.3, Kir2.1, and KCa3.1. However, whether these K^+ channels are preferentially expressed in M1-like microglia in diseases *in vivo* is unknown. We first demonstrated higher Kv1.3 current densities by whole-cell patch-clamp electrophysiology in acutely isolated CD11b-positive microglia from brains of mice injected with the pro-inflammatory stimulus lipopolysaccharide **(**LPS). The AD-related toxin amyloid-β oligomer (AβO) also induced increased Kv1.3 in mice when injected but with the addition of the Kir2.1

channel expression, suggesting this stimulus involves a different activation pathway. These microglia also exhibit increased expression of the pro-inflammatory mediators TNF-α, IL-1β, IL-6 and iNOS, confirming that upregulation of Kv1.3 channels are indeed occurs in activated microglia. To demonstrate its physiological relevance, we showed elevated Kv1.3 current expression from microglia from the infarcted hemisphere of mice subjected to middle cerebral artery occlusion (MCAO) and brains of 5xFAD mice, animal models of ischemic stroke and AD, respectively. Importantly, using immunohistochemistry, we observed strong Kv1.3 expression on microglia/macrophage in human stroke and AD biopsies. These findings validate Kv1.3 as potential target for inhibitors as potential therapeutic agents for preferentially inhibiting pro-inflammatory M1 microglia functions in ischemic stroke and other neurological diseases such as Alzheimer's and Parkinson's disease.

Title: Synaptic activation tunes action potential shape through a BK-channel-mediated feedback pathway

Authors: *E. S. NIKITIN[1], M. V. ROSHCHIN[1], M. MATLASHOV[2], V. N. IERUSALIMSKY[1], P. M. BALABAN[1], V. BELOUSOV[2], G. KEMENES[3], K. STARAS[3]

Abstract: In central mammalian neurons, large conductance Ca2+-activated voltage-dependent K+ channels (BK channels) are known to influence the repolarization phase of action potentials and serve as a unique detector of coincidental intracellular Ca2+ elevation and membrane depolarization. This raises the possibility that the spike-evoked transient Ca2+ rises in synaptic boutons or axonal structures could potentially drive BK channel activity and thus contribute to shaping subsequent spikes, providing a novel feedback mechanism linking synaptic function and AP expression. Here we investigate this in layer 5 cortical neurons using Ca2+ uncaging and

imaging, patch clamp recording, and channel blockers. We show that a single spike-driven Ca2+ rise in a proximal synaptic bouton or first node of Ranvier significantly narrows the subsequent action potential and that this is mediated by a form of BK channel-dependent intrinsic feedback. This activity-dependent plasticity mechanism likely serves to limit runaway spike-broadening during repetitive firing, allowing a neuron to fine-tune its action potential expression based on synaptic firing history.

Title: Cav2.3 contributes to hippocampal excitability through activation of calcium-dependent potassium channels

Authors: *J. J. GUTZMANN, D. A. HOFFMAN
NICHD, NIH, Bethesda, MD

Abstract: Fragile X syndrome (FXS) is an inherited form of intellectual disability with a high co-morbidity with autism and epilepsy. FXS results from a mutation in a single gene, Fragile X Mental Retardation Protein (FMRP), on the X chromosome. FMRP is an mRNA regulating protein, thus its loss leads to the perturbation of a wide range of cellular functions and endows FXS with a challenging, multi-facetted disease presentation. One of the prominent features of FXS is neuronal hyperexcitability and propensity for epilepsy, suggesting the potential dysregulation of voltage-gated ion channels.
High-throughput sequencing of mRNAs regulated by FMRP, and thus potentially disrupted in FXS, has recently identified voltage-gated Ca^{2+} (Cav2.3) and K^{+} (Kv4.2) channels to be among the affected proteins in FXS. We investigated the effect of Cav2.3 loss on the electrophysiological properties and neuronal excitability in the mouse hippocampus, a brain area important for learning, and prone to epileptic activity. Using whole-cell patch-clamp recordings from hippocampal CA1 pyramidal neurons, we found that these cells exhibited higher firing frequencies, larger frequency-dependent action potential broadening, and reduced after-hyperpolarization in Cav2.3-KO mice compared to WT. Using pharmacological blockade of different channels involved in action potential generation, we show that the hyperexcitability is caused by a reduced function of Ca^{2+}-dependent K^{+} channels. Specifically, using whole-cell and single-channel recordings, we find that both Ca^{2+}-gated (BK) and Ca^{2+}-modulated (Kv4.2) K^{+}

currents are significantly reduced in Cav2.3-KO neurons.To elucidate how the altered membrane properties of CA1 neurons affect their output function, we analyzed the short-term plasticity between CA1 and the subiculum, a brain region downstream of CA1. Paired pulse facilitation experiments demonstrated a much larger facilitation effect in Cav2.3-KO animals compared to WT, in line with altered action potentials observed in CA1.In summary, our data shows for the first time that Cav2.3 is the Ca^{2+} source for Ca^{2+}-dependent K^{+} channels regulating action potential repolarization. This leads to increased excitability and altered synaptic plasticity. Cav2.3 emerges therefore as a promising target for addressing circuit level hyperexcitability in FXS mouse models.

Title: Activation of Slack potassium channels triggers an increase in mRNA translation

Authors: *T. J. MALONE[1], P. LICZNERSKI[2], E. A. JONAS[2], L. K. KACZMAREK[3]
[1]Cell. and Mol. Physiol., [2]Intrnl. Medicine/Section Endocrinol., [3]Cell. and Mol. Physiol./Pharmacology, Yale Univ. Sch. of Med., New Haven, CT

Abstract: The Slack ion channel is a member of a family of large conductance sodium-activated potassium channels. It is expressed predominantly in neurons of the central nervous system where it regulates neuronal excitability. FMRP, an important regulator of mRNA translation, binds both Slack mRNA and the Slack protein. The association of Slack with FMRP stimulates channel activity, raising the possibility that activation of Slack channels may also regulate the function of FMRP. Our laboratory has previously identified Slack as required for a protein translation-dependent recovery from an extended period of inhibition in Aplysia neurons following stimulation, further suggesting that Slack may play a role in the regulation of mRNA translation. Here we provide the initial evidence for such a role. We transfected cells with a fluorescent reporter for mRNA translation, which contains the 5’ and 3’ sequences of the mRNA for β-actin, but with the coding region replaced with that for the irreversibly-photoconvertible fluorescent protein dendra2. We were able to visualize real-time translation in mouse cortical

neurons and in HEK cell cultures. Based on the observed translation levels in neurons from wild-type, Slack knockout, and FMRP knockout mice, we propose a mechanism whereby Slack activation causes an increase in translation that is enhanced in the absence of FMRP. Additionally, experiments in HEK cell culture using silencing RNA knockdowns suggest that the Slack binding partners CYFIP1, another FMRP binding protein; and Phactr-1, a PP1 binding protein, also modulate this activation-dependent translation. This mechanism of Slack-dependent translation potentially represents the first instance of the direct modulation of mRNA translation by activation of an ion channel.

Title: Evidence for the participation of TASK potassium channels in formalin induced acute and chronic inflammatory pain

Authors: *R. NORIEGA, G. GARCÍA, V. A. MARTÍNEZ-ROJAS, J. MURBARTIÁN
Farmacobiologia, Cinvestav, Ciudad De Mexico, Mexico

Abstract: Inflammatory pain is generated as a consequence of tissue damage, where various inflammatory mediators such as H^+ are produced, which cause extracellular acidification and increase excitability. TASK potassium channels activation is inhibited by acidification of extracellular medium, which makes them potential candidates as regulators of nociceptive transmission. In this study the participation of TASK channel in acute and chronic inflammatory pain induced by formalin was determined. In the acute inflammatory pain model, subcutaneous formalin injection (1%, in PBS) on the dorsal surface of the right hind paw of Wistar rats, produced a characteristic biphasic response of the test. Pretreatment with ML365 specific blocker for TASK-1 (100μM-3mM) and PK-THPP for TASK-3 (3μM-300μM), administered intrathecally, significantly increased the effect of nociceptive responses in both phases, in a dose-dependent manner. Chronic inflammatory pain was assessed 6 days after injection of formalin into the right paw by testing secondary mechanical allodynia and hyperalgesia behaviors evoked by mechanical stimulation with the use of von Frey filaments. Pretreatment with the TASK1 and TASK3 channel blockers significantly increased allodynia in a dose-dependent manner and hyperalgesia only increased with PK-THPP at 100μM. In post-treatment the drugs significantly increase both behaviors, in a dose-dependent manner. The pharmacological and behavioral data suggest that blockade of TASK potassium channels produces a pro-allodynic and pro-

hyperalgesic effect, whereby TASK potassium channels play an important role in reducing acute inflammatory pain and reducing the development and maintenance of allodynia and hyperalgesia in chronic inflammatory pain.

Title: Facile conjugation of the peptide margatoxin to luminescent quantum dots for targeted delivery towards the voltage-gated potassium channel Kv1.3 in the olfactory bulb

Authors: *A. SCHWARTZ[1], A. KAPUR[2], Z. HUANG[3], R. ANANGI[5], Z. DEKAN[5], E. FARDONE[3], G. PALUI[2], G. F. KING[5], H. MATTOUSSI[2], D. A. FADOOL[4]

Biophysics Program, Program in Neuroscience, Dept. of Biol. Sci., Florida State Univ., Tallahassee, FL; [5]Inst. of Mol. Biosci., The Univ. of Queensland, Brisbane, Australia

Abstract: Venom-derived ion channel inhibitors typically have high levels of channel selectivity, potency and stability, but, like most drug molecules, targeting to a specific location can be problematic. Kv1.3 is a voltage-gated potassium channel (K*v*) that has select distribution and is well characterized for its role in immunity, glucose metabolism and olfaction. Our interests lie in the ability of Kv1.3 to regulate excitability in mitral cells of the olfactory bulb (OB), where it has the potential to serve as a metabolic target to balance body weight and enhance olfactory ability. To aid in targeted delivery, we have developed protocols for conjugating the venom-derived Kv1.3 inhibitor margatoxin (MgTx) to luminescent quantum dots

(QDs). Previously, we described a protocol using carbodiimide crosslinking chemistry for effective conjugation of the native peptide to QDs and observed a retention of biophysical properties associated with block of the vestibule of Kv1.3 by the QD-MgTx conjugate compared to that of MgTx. Here, we have improved upon our initial methodology such that MgTx could be conjugated to QDs in a controlled orientation and facile manner through insertion of a polyhistidine tag on the N-terminus of MgTx (HisMgTx). Using recombinant expression and synthetic chemistry, we produced three forms of HisMgTx. When measured by whole-cell patch-clamp electrophysiology, the produced peptides potently inhibited 80% of the outward current in Kv1.3-transfected HEK-293 cells and had an IC_{50} of 100 - 350 pM. When conjugating to QDs using His-conjugation, as many as 40 HisMgTx peptides can be bound to an individual QD, as quantified by a shift in mobility on an agarose gel. This QDHisMgTx conjugate labeled Kv1.3 expressing HEK-293 cells with 90 nanograms of peptide. Using whole-cell, patch-clamp electrophysiology, the QDHisMgTx conjugate could similarly inhibit 80% of the outward current flow in Kv1.3 expressing HEK-293 cells. Towards targeted delivery of the QDHisMgTx conjugate to Kv1.3 in the OB, we have begun preliminary experiments using surgically-implanted osmotic mini-pumps and intranasal delivery approaches, where we are observing the effects of the conjugate on whole-body metabolism and its distribution following delivery.

Title: Structure-activity relationship studies of SK channel positive allosteric modulators

Authors: Y. NAM, R. ORFALI, A. VIEGAS, *M. ZHANG
Chapman Univ. Sch. of Pharm., Irvine, CA

Abstract: The cerebellar Purkinje Cells (PCs) are affected in many types of ataxia. The dysfunction of PCs, more specifically the loss of firing precision of PCs is one of the primary mechanism underlying the symptom of ataxia, including spinocerebellar ataxia. Disruptions of regular pacemaking activity of PCs have been identified in studies with mouse models of ataxia.

Drugs that normalize the regular firing of PCs have been suggested as therapeutics for the symptom of ataxia patients. Small conductance Ca^{2+} activated potassium (SK) channels emerged as one of the principle ion channels involved in PCs pacemaking. Positive allosteric modulators (PAMs) targeting the SK channels have been shown to alleviate behavioral and neuro-pathological symptom in animal models of ataxia. Despite this progress, many SK channel PAMs often suffer from low potency and/or poor pharmacokinetic properties. Lack of knowledge about the binding site for the compounds was a major reason that hinders the development of more effective therapeutics targeting SK channels. We recently determined the crystal structures of the PAMs such as 1-EBIO and NS309 in complex with their binding pocket. Further analyses show a strong correlation between the potency of the PAMs and their interaction energy within the binding pocket. These structure-activity relationship studies of SK channel modulation by PAMs might facilitate drug discovery targeting SK channels.

Title: The effects of single nucleotide polymorphisms (SNPs) on human BK channel currents

Authors: *A. PLANTE, *A. PLANTE, *A. PLANTE, B. MCNALLY, M. LAI, A. MEREDITH
Physiol. Dept., Univ. of Maryland, Baltimore, Baltimore, MD

Abstract: Large-conductance, Ca^{2+}-activated K^+ (BK) channels are important regulators of membrane excitability. One mechanism with the potential to alter BK currents is natural genetic variation via single nucleotide polymorphisms (SNPs). The BK channel gene, *Kcnma1*, contains >100 nonsynonymous SNPs, but the effects of most SNPs on BK function are unknown. Using standard patch clamp electrophysiology in HEK293 cells, we screened the effects of six SNPs (A138V, C495G, N599D, R800W, R640Q/R645Q) selected based on either disease linkage or their predicted ability to alter BK current properties. C495G and R800W had the largest impact on BK currents. In symmetrical and physiological K^+, C495G significantly shifted the half-maximal voltage of activation ($V_{1/2}$) to more hyperpolarized potentials (-15 to -20 mV) and

speeded activation, indicating C495G confers gain of function properties. In contrast, R800W significantly shifted the $V_{1/2}$ to more depolarized potentials (+15 to +35 mV) and slowed activation in symmetrical K^+, indicating R800W confers loss of function properties. Surprisingly, R800W slowed activation but did not shift the $V_{1/2}$ in physiological K^+. Although C495 was previously identified as a redox modulated residue, C495G did not alter the effects of peroxide or DTT on BK currents, suggesting C495G does not produce a gain of function effect by altering redox modulation of the BK channel. To explore which amino acid properties were responsible for the loss of function effects of R800W, R800 was substituted for residues with different (R800A, R800E, R800Q) or similar (R800F) properties to W. No substitution recapitulated R800W current properties, indicating that the altered size, charge, and hydrophobicity alone does not fully account for the loss of function effect of R800W. The impact of C495G and R800W on action potential (AP)-evoked BK currents was tested with AP commands from suprachiasmatic nucleus neurons, sinoatrial node, and bladder myocytes. C495G significantly increased the peak amplitude of AP-evoked BK currents, while R800W did not have an effect. However, when R800W was expressed in parallel with the epilepsy-linked, gain of function mutation D434G (D434G/R800W), the $V_{1/2}$ was not shifted, but activation was slowed and the peak amplitude of AP-evoked BK current was decreased compared to D434G alone. These results suggest that in a physiological context, C495G can have a gain of function effect, while R800W could oppose the aberrant effects of an epilepsy-linked mutation on the BK current properties. These results suggest natural genetic variation (SNPs) in the BK channel could potentially alter the severity and penetrance of D434G-linked epilepsy.

Title: Decreased expression of Kir K^+ channel in iPSC-derived astrocytes in subjects with Monge's disease

Authors: W. WU[1], *H. YAO[1], J. WANG[1], G. G. HADDAD[1,2,3]
[1]Dept Pediat, UCSD, LA Jolla, CA; [2]Dept Neurosci, UCSD, La Jolla, CA; [3]Rady Children's Hospital-San Diego, San Diego, CA

Abstract: Monge's disease, also called chronic mountain sickness (CMS) is a disease in highlanders whose blood has abnormal low level of oxygen. The prevalence of CMS patients can

be as high as 15-20% while the majority of highlanders (non-CMS) are rather healthy in high altitudes. CMS patients typically experience a variety of neurologic symptoms such as migraine, mental fatigue, confusion, dizziness, loss of appetite and memory loss. The cellular and molecular mechanisms underlying CMS neuropathology is not fully understood. Our previous study employed an induced pluripotent stem cells (iPSCs) approach and revealed that altered sodium channel properties and resulting decreased neuronal excitability in the iPSCs-derived neurons from CMS patients. Here, we further characterize the electrophysiological properties of iPSCs-derived astrocytes from both CMS and non-CMS subjects. Our patch clamp experiments showed that there was no significant differences of cell capacitance and input resistance between CMS and non-CMS astrocytes. The membrane potential of CMS group (-24.9±2.7 mV, n=44) is significantly more depolarized than that of non-CMS group (-43.9±3.7, n=26) (p<0.01). We further compared the current densities of each type of ion channels expressed in the iPSC-derived astrocytes. We found that the current densities of the inwardly-rectifying potassium (Kir) channels in CMS astrocytes (-5.7±2.2 pA/pF at -140 mV, n=20) were significantly reduced as compared to non-CMS subjects (-28.4±3.4 pA/pF at -140 mV, n=30) (p< 0.01). In contrast, there were no significant differences of current densities of voltage-gated potassium channels between CMS and non-CMS astrocytes. We also found a subpopulation (~15%) of astrocytes expressing voltage-gated sodium channels and the current density in CMS astrocyte was not altered. Finally, inward currents induced by stepping extracellular [K^+] from 3 to 12 mM and 60 mM (reflecting K^+ uptake ability) in CMS astrocytes (-12.7±6.4 pA and -290.8±182.0 pA) is significantly less than that in non-CMS astrocytes (-341.6±210.6 pA and -1484.3±374.9pA) (n=5-17, p<0.05). Since glial Kir K^+ channels are critical for K^+ homeostasis and regulation of neuronal excitability in brain, our findings of decreased Kir channels and K^+ uptake ability in CMS astrocytes indicate a potential likely link between CMS symptoms and the Kir channel abnormalities.

Title: Differential regulation of delayed-rectifying voltage-gated potassium channel dynamics by the mutant sigma1-receptor underlying ALS16

Authors: *M. J. ABRAHAM[1], A. Y. WONG[2], R. BERGERON[2,1]
[1]Dept. of Cell. and Mol. Medicine, Neurosci. Program, Univ. of Ottawa, Ottawa, ON, Canada; [2]Ottawa Hosp. Res. Inst., Ottawa, ON, Canada

Abstract: The Sigma-1 Receptor (sig-1R) is a highly conserved endoplasmic reticulum (ER) resident protein, which is expressed in most cell types throughout the body. It involved in diverse functions, including modulation of plasma-membrane ion channels, mediation of Ca^{2+} signalling from the ER to the mitochondria, and the ER stress response. Unexpectedly for a protein with such ubiquitous expression, mutations in the sig-1R have been associated with neuromuscular disease. The most widely described mutation is a single point mutation, E102Q, which results in a severe, juvenile-onset form of Amyotrophic Lateral Sclerosis (ALS16). As a hallmark of ALS is motorneuron hyperexcitability and the sig-1R modulates ion channels that control action potential repolarization, we speculated that aberrant modulation of these channels by sig-1R-E102Q may represent a hitherto uncharacterized mechanism of neuronal excitability in ALS. To test this, we transiently transfected HEK293 cells with a neuronal (Kv1.2) or a cardiac (Kv1.5) delayed rectifier K^+-channel subunit together with either WT sig-1R or sig-1R-E102Q. Electrophysiological recording of whole cell K^+ currents from these cells show that activation of the sig-1R results in a 20% decrease in current amplitude for both Kv1.2 and Kv1.5. Both Kv1.2 and Kv1.5 show a significant increase in steady-state inactivation with increasing voltage, and Kv1.2 inactivation was significantly enhanced following sig-1R activation. When HEK293 cells were transfected with sig-1R-E102Q, the voltage-dependence of steady-state inactivation of Kv1.2 was abolished, voltage-dependence of inactivation was inhibited, yet activation of sig-1R-E102Q produced no additional modulation. In contrast, steady-state inactivation and voltage-dependence of inactivation of Kv1.5 was less affected by sig-1R-E102Q Despite their high homology, our data suggest that there is differential modulation of Kv1.2 and Kv1.5 by the sig-1R. Furthermore, we observe aberrant modulation of only neuronal Kv channels (Kv1.2) by sig-1R-E102Q, which may underlie the hyperexcitability phenotype in ALS. Taken together, our work provides insights into why sig-1R mutations only affect motorneurons but leave all other systems apparently intact.

Abstract: Principal neurons encode and project information by varying their firing rates and patterns that are precisely defined by inhibition from GABAergic interneurons. However, the molecular basis underlying inhibitory control remains elusive. We find that excessive presynaptic GABA release from interneurons dramatically attenuates the firing rate of Purkinje neurons in the cerebellum of Fragile X mental retardation protein (FMRP) knockout mice. This inhibitory overtone is resulted from increased excitability of the interneuron terminals where Kv1.2 potassium channels are downregulated in the absence of FMRP. We further reveal that the N-terminus of FMRP directly binds the C-terminus of Kv1.2, only when specific serine residues in Kv1.2 are phosphorylated. This interaction promotes the function of Kv1.2 at the nerve terminal, providing a key mechanism for dynamic tuning of inhibition; and further understanding of the novel molecular locus will help develop genetic and pharmacological therapies to rectify excitation/inhibition imbalance in neuropsychiatric disorders such as Fragile X syndrome and autism.

Abstract: Methamphetamine (METH) is a highly addictive stimulant. METH addicts continue to take the drug despite adverse medical, social, financial, and legal consequences. To investigate the biochemical and molecular dysfunctions that may subsume METH addiction we used a self-administration model with footshock paradigm in the present study. Foot-shocks cause animals to divide into a subpopulation of rats that continue to lever press for METH even in the presence of footshocks: these rats are called shock-resistant (SR) or “addicted” rats. In contrast, other rats progressively decreased their METH intake with increasing shock intensity. These are shock-sensitive (SS) or “non-addicted” rats. In addition, we also included two additional controls groups that were yoked to receive non-contingent footshocks when SR (yoked SR) and SS (yoked SS) rats received footshocks. Herein, we have measured the expression of genes that code for several subfamilies of potassium channels. Interestingly, the SR rats showed increased mRNA expression of *inward-rectifier* potassium channels (Kir-*Kir2.1 and Kir2.4*) in comparison to controls, YSR, and SS groups. In contrast, the SS rats showed increased mRNA expression of *Kir1.1* in comparison to control and YSS rats. Together, our results provide further evidence for the potential involvement of potassium channels in METH addiction.

Title: Phosphatidylinositol 4,5-bisphosphate (PIP_2) regulates afterhyperpolarizations by modulating voltage-gated Ca^{2+} channels in oxytocin neurons of the supraoptic nucleus

Authors: *M. KIRCHNER[1], R. C. FOEHRING[3], W. E. ARMSTRONG[2]
[2]Neurosci. Inst., [1]Univ. of Tennessee Hlth. Sci. Ctr., Memphis, TN; [3]Anat. & Neurobio., Univ. Tennessee Hlth. Sci. Ctr., Memphis, TN

Abstract: Oxytocin- (OT) and vasopressin- (VP) secreting magnocellular neurosecretory cells play a crucial role in numerous physiological functions including lactation, parturition (OT) and cardiovascular regulation (VP). The release of both hormones is optimized by a burst-firing pattern of action potentials. The after-hyperpolarization (AHP) plays a crucial role in shaping bursts and thus is critical for robust hormone release. Previous work in our lab demonstrated that availability of the membrane-bound lipid phosphatidylinositol 4,5-bisphosphate (PIP_2) modulates the medium (mAHP) and slow (sAHP) duration AHPs in supraoptic neurons. Using simultaneous whole cell recording, calcium imaging, and photolytic uncaging, we evaluated the interaction of PIP_2 availability and specific Ca^{2+} channels with AHPs of both OT and VP cell types in brain slices. We previously showed that depleting PIP_2 blocked both mAHP & sAHP, as well as inhibited somatic Ca^{2+} in OT neurons while leaving these measures unaffected in VP neurons. This hinted that PIP_2 was inhibiting Ca^{2+} entry in OT neurons. This idea was supported when AHPs were generated by photolytic uncaging of Ca^{2+}, where we observed no inhibition of either the mAHP or sAHP by PIP_2 depletion. Furthermore, PIP_2 depletion significantly inhibited isolated whole cell Ca^{2+} currents in OT neurons, demonstrating that PIP_2 controls Ca^{2+} entry. Previous work has shown that coupling of specific voltage-gated Ca^{2+} channels (VGCCs) to the AHP is cell type dependent. Therefore, we tested the VGCC blockers 5 µM nifedipine (L-type), 1 µM conotoxin GVIA (N-Type), and 500 nM agatoxin-IVA (P/Q-type) on the mAHP & sAHP. Only conotoxin GVIA had a significant effect on the AHP, inhibiting the mAHP and sAHP components by 65% and 40%, and corresponding peak $[Ca^{2+}]_i$ by 61% & 73%, respectively in OT neurons. VP neurons displayed smaller inhibition of mAHP & sAHP (25% & 26%) while demonstrating similar $[Ca^{2+}]_i$ reductions to OT neurons (59% & 71%). Small reductions of $[Ca^{2+}]_i$ were observed in response to nifedipine and agatoxin-IVA, even though both AHPs were unaffected. Application of Cd^{2+} inhibited the mAHP by 90% and abolished the sAHP at 1000 ms

in voltage clamp, suggesting that a strong majority of the current is VGCC-dependent, but that a Ca^{2+}-independent component exists. Future experiments will be designed to verify N-channel modulation by PIP_2, and determine the mechanism of this modulation in OT neurons.

Abstract: Tyrosine 3-monooxygenase/tryptophan 5-monooxygenase activation proteins (14-3-3), also known as PKC inhibitory proteins (KCIP-1), are a family of adaptor proteins that bind to specific recognition motifs denoted as: mode-1 (RSXpS/TXP) and mode-2 (RXXXpSXP). The 14-3-3 family of proteins are ubiquitously expressed in the central nervous system where they mediate phospho-regulatory pathways including: protein trafficking, signal transduction, metabolism, apoptosis, cell proliferation, and cycle regulation. In this study, we investigated the role of 14-3-3 zeta in Protein Kinase C (PKC) regulation of Slack channels. The Slack C-terminus contains several predicted mode-1 14-3-3 binding sites. Using proteomic mass spectrometry we determined that 14-3-3 zeta belongs to the Slack channel interactome in dorsal root ganglion (DRG) neurons. Next, we conducted co-immunoprecipitation assays and immunohistochemistry to confirm that Slack channels and 14-3-3 zeta co-localize and bind with each other in intact DRG neurons and within the dorsal horn of the spinal cord. Secondly, to determine the functional role of the Slack/14-3-3 interaction, we used whole-cell patch-clamp to measure changes heterologous expressed Slack currents. We found that co-expression of 14-3-3 zeta did not affect the Slack current, however, in the presence of the PKC activator PMA, 14-3-3 zeta was found to inhibit the typical PMA induced up-regulation of Slack-current. Using biotinylation assays we demonstrated that after PMA stimulation there was a robust increase in membrane Slack expression, whereas membrane Slack expression decreased in cells co-transfected with Slack and 14-3-3 zeta after stimulation by PMA. Finally, we investigated the regulation of 14-3-3 zeta on Slack channels in native neurons. We used small interfering RNAs

to knockdown 14-3-3 zeta expression. siRNA mediated knockdown of 14-3-3 zeta resulted in an unexpected decrease total potassium current, broadening of action potential duration and repetitive firing when compared to DRG neurons treated with scrambled siRNA. Finally, in behavioral studies 14-3-3 zeta knockout mice exhibit a pronounced basal thermal hyperalgesia. Overall, our data strongly suggests 14-3-3 zeta is a powerful regulator of Slack currents and DRG neuronal excitability.

Title: PKA-induced Slack channel internalization from the neuronal membrane occurs by AP-2 Clathrin mediated endocytosis

Authors: *A. BHATTACHARJEE[1], S. GURURAJ[1], K. EVELY[2], K. D. PRYCE[3]

Abstract: The sodium-activated potassium (K_{Na}) channel Slack (Kcnt1) is abundantly expressed in nociceptor neurons of the dorsal root ganglion (DRG), where they transmit the large outward conductance I_{KNa} and arbitrate membrane excitability. Expression of Slack channels at the DRG membrane is necessary for their characteristic firing accommodation during maintained stimulation and reduced membrane channel density produces hyperexcitability (Nuwer et al., J Neurosci 30:14165-72, 2010). We have previously shown that in the pro-inflammatory state, decrease in channel density leading to reduced Slack-mediated I_{KNa} underlies DRG neuronal sensitization. An important component of inflammatory signaling, Protein Kinase A (PKA) caused Slack channels to internalize from the DRG membrane, reduced I_{KNa} and produced DRG hyperexcitability when activated in cultured primary DRG neurons. Here, we show that this PKA-induced retrograde trafficking of Slack channels occurs *ex vivo* in intact spinal cord slices and that it is carried out by AP-2 clathrin-mediated endocytosis (CME) in DRG neurons. We provide mass spectrometric and biochemical evidence of native neuronal AP-2 adaptor proteins' association with Slack channels and specifically, that the binding site is a di-leucine motif housed in the cytoplasmic Slack C-terminus. We created a competitive peptide blocker of AP-2-Slack binding to empirically demonstrate that this interaction is essential for Clathrin recruitment

to the DRG membrane, Slack channel endocytosis and resultant DRG hyperexcitability, subsequent to PKA activation. Together, these findings identify AP-2 and Clathrin proteins as novel players in Slack channel regulation. Given the significant role played by Slack channels in nociceptive neuronal excitability, the AP-2 CME trafficking mechanism provides a promising approach to target peripheral and possibly, central neuronal sensitization.

Abstract: Epilepsy of infancy with migrating focal seizures (EIMFS) is a severe form of childhood epilepsy characterized by an early onset, refractory seizures, global developmental delay and cognitive disability. *De novo* mutations of the sodium activated potassium channel gene KCTN1 have been found in up to 50% of the patients. The p.Pro924Leu mutation has been found in 2 patients with EIMFS and *in vitro* studies in heterologous expression systems have shown a gain of function effect of the mutation, resulting in large potassium currents compared to the wild type (WT) channel. We have characterized a knock-in mouse model expressing this gain-of-function mutation to explore the mechanisms by which the altered channel translates to the disease phenotype. To assess seizure susceptibility, video electrocorticogram(video/ECoG) analysis, thermal and chemoconvulsant (Pentylenetetrazole and Loxapine) tests were performed. Heterozygous Kcnt1$^{(L/+)}$ mice display no increased susceptibility to thermal or chemically induced seizures compared to Kcnt1 WT$^{(+/+)}$ mice. No differences were found on the video/ECoG for Kcnt1$^{(L/+)}$ and Kcnt1 WT$^{(+/+)}$ mice. In contrast, homozygous Kcnt1$^{(L/L)}$ mice exhibit spontaneous tonic clonic seizures, impaired nesting behaviour and a shortened lifespan. We also detected ictal discharges that coincide with convulsive seizures as well as interictal spikes in these mice. Kcnt1$^{(L/L)}$ mice provide a model of epileptic encephalopathy that will be valuable for studying the in vivo effects of gain of function KCNT1 mutations and the response to targeted therapeutic interventions.

Title: Inhibition of Kv3.4 channels is implicated in the potentiation of excitatory synaptic transmission in superficial dorsal horn neurons

Authors: *T. MUQEEM[1], V. PINTO[2], B. CHARSAR[1], E. BROWN[1], A. C. LEPORE[1], M. COVARRUBIAS[1]
[1]Dept. of Neurosci., Thomas Jefferson Univ., Philadelphia, PA; [2]ICVS/3Bs, Univ. of Minho, Braga, Portugal

Abstract: Kv3.4 channels underlie a majority of the high-voltage activating K^+ current in dorsal root ganglion (DRG) nociceptors, and are expressed in all functional compartments of these neurons, including synaptic terminals. Kv3.4 channels in DRG neurons regulate the rate of action potential repolarization in a manner that depends on phosphorylation of the channels' inactivation domain. Additionally, loss of Kv3.4 channel surface expression is implicated in the pathophysiology of spinal cord injury-induced chronic pain. We hypothesize that, through their ability to facilitate action potential repolarization, Kv3.4 channels help keep nociceptive synaptic transmission in check. Inhibition of the Kv3.4 channel would, therefore, promote pain transduction. To test this hypothesis, we have investigated excitatory synaptic transmission in the superficial dorsal horn under conditions that inhibit the Kv3.4 current in DRG nerve terminals. We used an ex vivo rat cervical spinal cord preparation suitable for whole-cell patch clamping of secondary neurons in the dorsal horn. Since Kv3.4 channels are hypersensitive to submillimolar concentrations of 4-aminopyridine (4-AP) and tetraethylammonium (TEA), we tested their effects on excitatory post-synaptic currents (EPSCs) in laminae I and II of the dorsal horn. We found that 500 μM TEA potentiates the EPSCs by 26% ($p = 0.01$, paired t-test, N=9). Similarly, 50 μM 4-AP potentiates the EPSCs by 34% ($p = 0.007$, paired t-test, N=9). Alternatively, the BK channel blocker iberiotoxin, the Kv7 channel blocker XE991, and the Kv1 channel blocker

dendrotoxin had little effect on the EPSCs. Paired pulse and spontaneous neurotransmission experiments were conducted to localize the effect to the presynaptic nerve terminal. Therefore, we conclude that the Kv3.4 channel expressed in nociceptors is a plausible regulator of nociceptive synaptic transmission in the spinal cord. Currently, we are exploring more specific knock down strategies to assess the role of the Kv3.4 channel as a regulator of nociception in vivo. Title: KCNQ channels regulate firing properties of the calyx of Held

Authors: Y. ZHANG[1], L. O. TRUSSELL[2], *H. HUANG[1]
[1]Dept. of Cell and Mol. Biol., Tulane Univ., New Orleans, LA; [2]Oregon Hearing Res. Ctr., Oregon Hlth. and Sci. Univ., Portland, OR

Abstract: Globular bushy cells of the cochlear nucleus faithfully relay auditory signals to the medial nucleus of the trapezoid body (MNTB) principal neurons through a giant glutamatergic synapse, the calyx of Held. Reliability and precision of synaptic transmission are required in the calyx-MNTB synapse in order to encode timing with submillisecond delays at high frequencies. The waveform of the presynaptic action potential (AP) shapes the presynaptic calcium transient, and thus is crucial in determining timing and strength of synaptic transmission. During moderate to high-frequency trains, the presynaptic AP of several central synapses such as mossy fiber boutons are altered and the half-duration of action potentials is substantially increased. However, the calyx of Held shows very minor AP broadening at frequencies up to hundreds of hertz. We previously demonstrated that KCNQ5 channels control the presynaptic resting properties and release probability of the calyceal synapses. Here we found that KCNQ channels are activated during high-frequency AP activity, have profound effects on AP firing, and indeed are required to maintain the normal AP waveform of the calyceal terminal. Blocking KCNQ channels with XE991 increased presynaptic excitability, reduced the AP height, and broadened the AP duration during 333-Hz stimulation. Further experiments showed that blocking KCNQ leads to inactivation of presynaptic Na^+ and Kv1 channels and thereby indirectly affects the AP

waveform. Inactivation of Na^+ channels shortens the AP amplitude while inactivation of Kv1 broadens the AP and increases excitability. Application of low doses of TTX and margatoxin to partially block Na^+ and Kv1 channels could mimic the AP waveform change during high frequency stimulation. Resistance to changes in the AP waveform during activity ensures that the calyx can reproducibly trigger calcium influx and glutamate release. We conclude that KCNQ is activated during high-frequency activity and its activation prevents inactivation of Na^+ and Kv1 channels and thus plays key roles in maintaining a stable presynaptic AP waveform.

Title: KCNQ/K_V7 potassium channels contribute to the control of mouse nodose airway C-fiber excitability

Authors: *H. SUN, S. MEEKER, B. J. UNDEM
Johns Hopkins Univ., Baltimore, MD

Abstract: The M-current is carried by members of K_V7 family of K^+ channels encoded by *KCNQ* genes. It is now well established that the M-current is modulated by numerous mediators and functions as a "brake" on repetitive action potential (AP) discharges in both central and peripheral nervous systems. It has been shown that pharmacological activation of M-current suppresses epilepsy and alleviates pain. Yet, whether and how the KCNQ/K_V7 channel regulates the excitability of vagal airway nociceptive C-fibers remain to be elucidated. In this study we have used perforated patch clamp technique and extracellular recording of single Vagal nerve fiber terminal activities to address this issue. A voltage step from the holding potential of -30 mV to -60 mV evoked a small outward tail current and stepping back to -30 mV elicited a slowly activating and non-inactivating outward current in isolated mouse nodose neurons, both of which were nearly abolished by 10 μM XE991, a KCNQ/K_V7 channel blocker. The XE991-sensitive current was observed in every neuron studied. It activates around -65 mV with 50% activation being occurred at -38.2±2.1 mV and a maximal conductance of 10.3±1.3 nS/pF (n=8). The current has an activation constant of 212±23 ms at -30 mV and deactivates biexponentially. The KCNQ channel opener retigabine at 10 μM significantly accelerated its activation and slow down the deactivation, and negatively shifted its activation by 27 mV. Thus, the XE991-sensitive current recorded in mouse nodose neurons exhibits similar biophysical and pharmacological

properties previously reported for endogenous M-currents. Inhibition of M-current by XE991 slightly but significantly depolarized the nodose neurons (-60.1±1.2 vs. -62.9±1.0 mV, n=14) while opening the channels by retigabine markedly hyperpolarized the membrane (-73.1±0.9 vs. 60.4±0.7 mV, n=13) and this effect was reversed by simultaneous application of XE991. Retigabine also significantly increased the amount of depolarizing current needed to evoke an AP (25±5 *vs.* 133±20 pA, n=5). In a vagus-innervated isolated moue lung preparation, retigabine eliminated the spontaneous AP discharges in nodose C-fibers innervating the mouse lungs (n=3) and abolished AP discharge evoked by 3μM α,β-methylene ATP (AP number: 47 ± 7 vs. 0 ± 0, n=5). In conclusion, our results indicate that KCNQ/K_V7 channels play a role in maintaining the resting membrane potential of mouse nodose neurons and in regulating the excitability of vagal C-fibers at both the cell soma and nerve terminals within the airways. Activation of M-currents may represent a useful approach to suppressing airways hyperreflexivity associated with chronic cough, COPD, and asthma.

Title: Novel drugs that augment KCNQ (Kv7,"M-type") potassium channels as a post-event treatment for Traumatic Brain Injury

Authors: *M. HOBBS[1], F. A. BORGES-VIGIL[1], E. BOZDEMIR[2], R. J. VERAZA[1], V. BUGAY[1], L. ESPINOZA[1], D. M. HOLSTEIN[2], S. M. SPRAGUE[3], I. SANCHEZ[1], J. CARVAZOS[4], S. H. CHUN[2], R. BRENNER[1], J. LECHLEITER[2], M. S. SHAPIRO[1]

Abstract: Traumatic brain injury (TBI) is a strong risk factor for the development of different neuronal disorders, such as epilepsy. Here, we hypothesize that reducing neuronal excitability early in the process of epileptogenesis moderates or prevents development of epilepsy. Since

enhancing KCNQ channel activity causes silencing of neurons and prevents seizures, we tested whether a drug that augments KCNQ K^+ currents, such as the FDA-approved antiepileptic drug, Retigabine (RTG), reduces development of seizures, cytotoxic brain cell swelling and the inflammatory response. We tested our hypothesis using the controlled closed-cortical impact TBI model, which mimics TBIs commonly experienced by civilians. Mice were administered RTG *(i.p. 1 mg/kg*) or vehicle within 30 minutes of TBI. Twenty-four hours after the TBI, EEG electrodes were implanted and electrical activity recorded the following day to assess spontaneous seizures. To assay for the reduction of seizure susceptibility by RTG treatment after TBIs, animals were challenged with pilocarpine (3X, 75 mg/kg, 6 days after TBI), and the percentage of animals responding with seizures compared between groups. Seizure susceptibility was assayed for 24 hours after pilocarpine; where the latency of the first seizure occurrence and percentage of animals that displayed seizures were both quantified. A different cohort of mice were sacrificed 24h after TBI and brain slices Nissl-stained to quantify cell soma areas. Finally, a third dual cohort of animals were sacrificed 6 days after CCCI and both hemispheres used for immunoblotting analyses of CD40L, a known marker of inflammation. We found that TBI caused spontaneous seizures in ~1/3 of vehicle only-treated mice. On the other hand, for animals treated with RTG, no animals displayed spontaneous seizures. Whereas 54% of the control animals displayed seizures within 24 hours after pilocarpine challenge, only 30% of RTG treated mice responded with seizures. RTG treatment also increased the latency to first seizure by about two-fold. RTG treatment also significantly reduced TBI-induced cytotoxic cell soma swelling 24h after TBI, and impaired TBI-induced increase in CD40L. Therefore, KCNQ-enhancing drugs may serve as a novel, effective treatment for the deleterious effects that follow TBIs.

Title: Ablation of KCNQ2/3 from either pyramidal neurons or interneurons leads to increased excitatory transmission in mouse hippocampus

Authors: H. SOH[1], K. SPRINGER[2], *A. TZINGOUNIS[3]
[1]Physiol. and Neurobio., [2]Univ. of Connecticut, Storrs, Storrs, CT; [3]Univ. of Connecticut, Storrs, CT

Abstract: In contrast to the wealth of knowledge on the role of KCNQ2/3 channels in excitatory neurons, the KCNQ2/3's ability to regulate interneuron excitability has been largely overlooked. To examine whether KCNQ2/3 channels could regulate interneuron intrinsic excitability, we developed mouse lines that lack *Kcnq2/3* specifically in MGE-derived PV^+ and SST^+ interneurons via Cre recombinase technology (using *Nkx2-1BAC*^{cre}; *SST-Cre;* or *PV-Cre* mice). We also crossed these mice to a reporter line (*Ai14*) that expresses the fluorescent protein tdTomato in cells in which Cre recombinase has been active, allowing for the identification of Cre-expressing PV^+ and SST^+ interneurons. Using these mice we have found that neocortical and hippocampal PV^+, but not SST^+, interneurons are more excitable in the absence of KCNQ2/3 channels. Surprisingly, we also found that ablation of *Kcnq2/3* from PV^+/SST^+ interneurons from an early period led to a significant elevation of the spontaneous and mini EPSC frequency (mEPSC) in CA1 pyramidal neurons later in development, at P16-P19. Importantly, these effects are specific to *Kcnq2/3* ablation from PV^+/SST^+ interneurons, as we did not find any changes to the mEPSC frequency in CA1 pyramidal neurons from *Kcnq2* pyramidal null neurons (*Emx1-Cre; Kcnq2*$^{f/f}$). Rather, in these neurons, the spontaneous EPSC frequency was elevated, consistent with increased axonal excitability. Therefore, KCNQ2/3 loss of function in either pyramidal neurons or interneurons could lead to network hyperexcitability.

Title: Suppressive effects of amyloid peptide fragments (1-42) and the toxic "core" (25-35) on Kv1.1 channel activity

Authors: *K. DEBOEUF, M. ISLAM, N. THELEN, J. FARLEY
Psychology and Neurosci., Indiana Univ. Bloomington, Bloomington, IN

Abstract: Past studies have shown that Aβ's role in the pathogenesis of Alzheimer's disease (AD) involves eventual disruption of Ca^{2+} homeostasis and synaptic communication, as well as

impairment of long-term potentiation (LTP), but the underlying mechanism(s) is still unclear. Work in the Farley lab suggests that Aβ-inhibition of voltage-dependent K^+ channels (e.g., Kv1.1) activity is among the earliest steps. Using murine Kv1.1 channels expressed in *Xenopus* oocytes, our lab previously elucidated a pathway in which Ca^{2+}-dependent activation of PP2B, PKC, PTKs, and RhoA all participated to produce rapid strong suppression of Kv1.1 activity. Because Kv1.1 and related channels are activated during an action potential, regulate depolarization Ca^{2+} influx, and inhibition of Kv1 channels can be neurotoxic, we speculate that Aβ-suppression of Kv1 channels could contribute to AD pathology. We assessed the effects of the Aβ(1-42) peptide and the core fragment [Aβ(25-35)] on Kv1.1 channels expressed in oocytes. Bath application of 1 μM Aβ(1-42) produced ~50% suppression of macroscopic Kv1.1 current within 30 m. Aβ suppression of Kv1.1 was partially Ca^{2+}- and PP2B-dependent, being reduced by ~50% when cells were loaded with BAPTA-AM, or exposed to the PP2B-inhibitor cyclosporine A (CsA). Patch-clamp results suggest that Aβ-suppression of Kv1.1 involves both PP2B-dephosphorylation and direct protein-protein interaction of Aβ with Kv1.1 channel subunits. Exposure of inside-out single Kv1.1 in ripped-off oocyte patches to application of purified, catalytically-active PP2B produced gradual reductions in *p*(open), followed by abrupt disappearance of Kv1.1 activity. Application of Aβ to the intracellular face of Kv1.1 channels under conditions where little enzymatic activity could occur also produced dramatic reductions in *p*(open). Additional results indicate that 2 μM of Aβ(25-35) suppressed Kv1.1 currents by ~40%. Using "tip-dip" artificial membrane methods, 1 μM Aβ(25-35) exposure eliminated Kv1.1 channel activity when applied to the intracellular face. Preliminary results indicate that "aging" the peptide at room temperature also affects suppression, with greatest suppression (~60%) seemingly occurring at 6-7 hrs for 1 μM Aβ(25-35) and 22-24 hrs for 1 μM Aβ(1-42).

Title: Validation of human iPSC models of psychiatric diseases for target ID and phenotypic screening

Authors: M. NAUJOCK, V. KIZNER, S. FELK, A. SPEIDEL, S. JAEGER, G. LEPERC, K. FUNDEL-CLEMENS, T. HILDEBRANDT, C. DORNER-CIOSSEK, *B. SOMMER, F. GILLARDON
Boehringer Ingelheim Pharma GmbH & Co. KG, Biberach, Germany

Abstract: Over the past few years human induced pluripotent stem cells (iPSC) have become valuable tools for the in-vitro modeling of neuropsychiatric diseases. Starting with the neuronal differentiation of iPSC from sporadic schizophrenia patients, multiple groups reported disease associated phenotypes to proof this concept. In the present study, we differentiated 2 iPSC lines each derived from 2 healthy donors and 2 patients affected with idiopathic schizophrenia towards neuronal forebrain lineage. After around 8 weeks of total differentiation we observed spontaneous spiking and burst-firing during multi-electrode array recordings (MEA, 24- and 96-well). The human neurons also showed sensitivity to the application of neuromodulators such as bicuculline and NBQX. We further demonstrated homeostatic synaptic plasticity of iPSC-derived neurons. We then screened for disease-associated pathophysiologies using MEA and calcium imaging (FLIPR, 384-well) and observed hypoactive and hypoexcitable forebrain neurons in our schizophrenia lines. To identify underlying pathomechanisms, we performed RNA sequencing and found the potassium channel Kv4.2 subunit DPP6 being highly upregulated in neurons from schizophrenia patients. By high content imaging analysis we further observed decreased synaptic density which could be another contributor to the electrical hypoactivity. We started rescue experiments using Kv4.2 blocking compounds (AmmTx3) and lentiviral DPP6 shRNA vectors and we are minimizing the observed assay variability to enable robust phenotypic screens.

Title: Sorting Nexin 27 in midbrain dopamine neurons regulates addictive behavior to cocaine

Authors: *R. RIFKIN, J. CALLENS, J. LANDRY, G. EGERVARI, Y. HURD, P. A. SLESINGER
Neurosci., Icahn Sch. of Med. at Mount Sinai, New York, NY

Abstract: Exposure to addictive drugs, like cocaine, increases dopamine (DA) levels in the brain's reward circuit. G protein-gated inwardly rectifying potassium (GIRK) channels have emerged as important negative regulators of DA neuron firing. Previously, we identified Sorting Nexin 27 (SNX27) as a regulator of GIRK channels. Here, we selectively deleted SNX27 from tyrosine hydroxylase-expressing neurons ($SNX27_{TH}$ KO) and characterized the effects on $GABA_B$- and D_2-receptor activated GIRK currents. Using a retrograding, Cre-dependent virus (DIO.eYFP), we selectively recorded from ventral tegmental area (VTA) DA neurons projecting to nucleus accumbens (NAc), or substantia nigra pars compacta (SNc) DA neurons projecting to dorsal striatum (DS). In both pathways, we found that $GABA_BR$- and D_2R-GIRK currents were significantly reduced in $SNX27_{TH}$ KO mice compared to TH-$Cre^{+/-}$ controls. Further, $GABA_BR$-dependent inhibition of evoked firing was significantly decreased. Given the enhanced DA neuron excitability, we hypothesized that $SNX27_{TH}$ KO mice exhibit greater locomotor sensitization to cocaine. Mice (male/female 4-8 months) received daily IP injection of saline, followed by a subthreshold dose of 3.75 mg/kg cocaine for 5 days. Whereas 3.75 mg/kg cocaine induced little locomotor activity in TH-$Cre^{+/-}$ mice, $SNX27_{TH}$KO mice exhibited a significantly heightened response. Rescue of GIRK currents in VTA DA neurons of $SNX27_{TH}$ KO mice restored locomotor sensitization to that in control mice. We next compared self-administration of cocaine (FR1) in $SNX27_{TH}$KO mice and TH-$Cre^{+/-}$ mice. Like locomotor sensitization, $SNX27_{TH}$KO mice self-administered more cocaine (0.5 mg/kg/infusion) than TH-$Cre^{+/-}$ mice during early self-administration sessions. Similarly, $SNX27_{TH}$KO mice showed an initial higher sensitivity to self-administer cocaine at a lower dose (0.1 mg/kg/infusion) than TH-$Cre^{+/-}$ animals. Interestingly, irrespective of the dose both $SNX27_{TH}$KO and control mice eventually self-administered similar amounts cocaine at later sessions. $SNX27_{TH}$KO mice also displayed greater inactive lever-pressing activity, suggesting an underlying hyperactivity phenotype. Taken together, these experiments establish that SNX27 acts via GIRK channels in midbrain DA neurons to regulate the sensitivity to cocaine.

Title: Synaptic failure and functional network activity

Authors: *M. BUDAK[1], M. R. ZOCHOWSKI[2]
[1]Biophysics, Univ. of Michigan Ann Arbor, Ann Arbor, MI; [2]Physics, Univ. of Michigan, Ann Arbor, MI

Abstract: Human brain is a complex network including 10^{11} neurons connected by 10^{14} synapses. Information processing occurs in distinct, functionally specialized regions, which coordinate and integrate efficiently for the brain to function. The information transmission between neurons and brain regions occurs via synapses. Failures at these synaptic connections have detrimental effects such as loss of consciousness or neurodegenerative diseases. Our objective is understanding the effect of decreased synaptic transmission on functional connectivity of brain networks. We specifically investigate how synaptic failure affect scale free networks of interconnected integrate- and-fire excitatory neurons. Synaptic failure is introduced to the system through transmission probability, a parameter which randomly determines whether neurons transmit EPSP to other cells they're connected to or not. This parameter depends on the spiking history of the neurons, i.e. synapses are more likely to fail if the presynaptic neuron is more recently fired. The level of dependence on the synaptic history is introduced to the model with a time constant T.

We measure formation of coherent and synchronous states of activity in the network as a function of transmission probability. We demonstrate that scale-free networks with different directionalities respond to synaptic failure in different ways. However, neurons with moderate degrees are more coherent than other neurons in all scale-free network structures. We also observed that the dependence on spiking history affects synchronization and coherent state formation in different ways for different network structures. Networks with hubs of mostly outgoing connections become more coherent for an optimal range of T, then are fully disconnected with longer history dependence. These results may be applied to understand how anesthetics bring the loss of consciousness by changing brain dynamics and early diagnosis of some neurodegenerative diseases such as Alzheimer's and ALS, in which cases synaptic failure is the earliest symptom [2,3].

Abstract: Basal forebrain (BF) cholinergic projections shape sensory processing in the main olfactory bulb (MOB), but the precise underlying circuitry remains unclear. Here, we report the identification of a BF cholinergic projection that innervates neurons in the MOB internal plexiform layer (IPL). Optogenetic activation of this projection elicits monosynaptic nicotinic and GABAergic currents in glomerular layer (GL)-projecting interneurons, implicating neurotransmitter co-transmission in the regulation of this inhibitory microcircuit.

Title: Summation of metabotropic $GABA_B$ receptor mediated postsynaptic potentials in the supragranular layer of the neocortex

Authors: *A. OZSVÁR[1], G. KOMLÓSI[1,2], J. SZABADICS[1,3], G. OLÁH[1], G. MOLNÁR[1], G. TAMÁS[1]

Abstract: Integration properties of synaptic inputs scattered over the neuronal surface are crucial in understanding input-output characteristics of neurons. Contrary to ionotropic responses however, experiments addressing the interaction of postsynaptic signals through metabotropic receptors are scarce. We investigated the summation properties of IPSPs elicited by individual neurogliaform cells, suggested to operate by volume transmission activating synaptic and extrasynaptic ionotropic and metabotropic GABA receptors. We characterized the parameters of neurogliaform cell to pyramidal cell synaptic transmission in layers 1 to 3 of the somatosensory cortex of rats with Bayesian quantal analysis and estimated the probability of vesicular release, the number of functional release sites and the size of postsynaptic potentials mediated by single vesicle release. Next, we developed a three dimensional model of all neurogliaform cells and their terminals in the upper cortical layers and calculated the number of neurogliaform cells which potentially release GABA into the same voxel of cortical volume. This model suggests that two neighbouring presynaptic neurogliaform cells represent all or a substantial portion of neurogliaform cells potentially effective in a postsynaptic voxel. We then assessed the summation of neurogliaform cell evoked postsynaptic potentials directly by recording simultaneously from three neurons and coactivated two presynaptic neurogliaform cells to evoke combined $GABA_A$ and $GABA_B$ mediated responses on pyramidal neurons. The fast, $GABA_A$ receptor mediated component of the compound responses summated slightly nonlinearly in both input combinations. In contrast, blockade of $GABA_A$ receptors revealed predominantly linear summation of the $GABA_B$ receptor mediated component of convergent IPSPs. In conclusion, metabotropic GABAergic postsynaptic interactions in the upper layers of the neocortex are

mainly linear even if all presynaptic interneurons of the same, particularly effective class in recruiting $GABA_B$ receptors, are active.

Abstract: The vast majority of data describing the functional properties of neurons and their synapses comes from animal models, mainly rodents. However, it is unclear how these results generalize to humans. This is a particularly pressing issue as animal models are increasingly being used to guide development of potential therapies for human brain disease. The degree to which these models accurately represent human neuron physiology is likely key in predicting success. We tested the hypothesis that human and rodent cortical principal neurons may exhibit differences in the biophysics of synaptic integration, as has recently been proposed. We applied whole-cell patch-clamp electrophysiology combined with two-photon imaging and glutamate uncaging to acute slices of human temporal cortex obtained from surgical resection. We first used local application of high osmolality solution to map miniature excitatory post-synaptic potentials (mEPSPs) at different dendritic locations. These values were used to guide two-photon glutamate uncaging probe branch-level input-output processing. We also measured backpropagation of action potentials (bAPs) using Ca^{2+} imaging. Despite their much larger dendritic arbors, human and rodent neurons exhibited similar input impedance, mEPSPs amplitudes, and bAPs, as well as broadly comparable dendritic spikes driven by multisite glutamate uncaging. These results suggest human neurons possess passive or active biophysical specializations counteracting the decreased excitability and enhanced cable filtering that would normally result from their larger and more elaborate morphologies.

Title: Voltage-dependence of spatial coding in hippocampal pyramidal neurons supported by persistent sodium current

Authors: *C.-L. HSU[1], X. ZHAO[1], A. D. MILSTEIN[2], N. SPRUSTON[1]
[1]Janelia Res. Campus, HHMI, Ashburn, VA; [2]Neurosurg., Stanford Univ. Sch. of Med., Stanford, CA

Abstract: The hippocampus is critically implicated in the formation and storage of episodic memories, for which spatial information is a key component. The activity of hippocampal pyramidal neurons forms a neural representation of space, which has been postulated to provide a foundation for memories. To unambiguously encode multiple memory engrams, these neurons need to adapt their coding scheme for different spatial, non-spatial and behavioral contexts. A thorough understanding of such information processing requires detailed knowledge of how the spatial selectivity of pyramidal-neuron firing arises as a consequence of circuit and neuron properties. Existing models usually assume that the spatial tuning of pyramidal neuron output is exclusively determined by the properties of the synaptic inputs they receive; however, recent evidence suggests that pyramidal neuron excitability also plays important roles. Using whole-cell patch-clamp recording in the hippocampal CA1 region of awake, freely moving rats, Lee et al. (2012; Science *337*, 849-853) found that a small modulation of somatic membrane potential can switch the functional identity of a pyramidal neuron between a silent cell (without well-defined spatially tuned synaptic responses or firing) and a place cell (with strong spatially tuned synaptic responses and firing in well-defined locations of the animal, called place fields), and these effects were rapidly reversible. Remarkably, the spatial tuning of synaptic responses observed below action potential threshold had a highly nonlinear dependence on baseline membrane potential at the soma.
To determine what kinds of cellular mechanisms support this striking voltage dependence of spatial coding, we applied patch-clamp recordings in acute brain slices (*in vitro*) and in awake, behaving mice (*in vivo*) during virtual navigation. Our experiments and computational models revealed that a voltage-gated sodium current—which strongly activates in a subthreshold voltage range and persists during depolarization over behaviorally relevant timescales—critically contributes to the voltage-dependent amplification of synaptic responses with high gain, consequently driving spatially dependent firing of CA1 pyramidal neurons upon small

depolarization. In addition, motivated by a finding that dendritic plateau potentials can induce the formation of new place fields (Nat. Neurosci. *18(8)*, 1133-1142), we found that dendritic plateau potentials were facilitated by dendritic depolarization. Therefore, we propose a model whereby depolarization influences both the readout and the formation of space-dependent activity in hippocampal pyramidal neurons.

Title: Coexpression of AMPA and NMDA receptors reduces variability in synaptic transmission

Authors: *C. LI[1], A. T. GULLEDGE[2]
[1]Dartmouth Col., Hanover, NH; [2]Mol. and Systems Biol., Geisel Sch. of Med. At Dartmouth Col., Hanover, NH

Abstract: Glutamate is the major excitatory neurotransmitter in the vertebrate brain. AMPA and NMDA receptors (AMPARs and NMDARs) are two widely-distributed ionotropic glutamate receptor subtypes with distinct kinetics and voltage-dependencies. The efficacy of synaptic input in driving action potential generation is influenced by several factors, including distance of the synapse from the axon hillock, and the membrane potential at the time of synapse activation. Voltage attenuation in dendrites weakens distal inputs arriving at the axon, whereas membrane potential influences the driving force for synaptic current. Here, using computational simulations of simplified and realistic neuron morphologies, we show that coexpression of AMPARs and NMDARs may represent a novel intrinsic mechanism that limits variability in synaptic efficacy. When synapses contained both AMPAR and NMDAR conductances, somatic voltage responses were less dependent on dendritic location or membrane potential than were responses driven by synapses containing either conductance type alone. In ball-and-stick neurons comprising an axon, a soma, and a single passive dendrite, we simulated stochastic patterns of synaptic input along the dendrite within narrow spatial and temporal ranges to find the minimum number of co-activated synapses required to fire one action potential. Coefficients of variation in threshold synapse numbers were calculated for synapses with AMPA conductances, NMDA conductances, or both, for inputs placed at different dendritic locations or activated from different “resting”

membrane potentials. Relative to trials using AMPA or NMDA conductances alone, trials simulating both AMPA and NMDA conductances had lower coefficients of variation across resting potential and dendritic location. Similar results were found in realistic neuron morphologies: in simulated CA3 pyramidal cells and dentate granule cells, combining AMPA and NMDA conductances resulted in lower variability in the number of synapses required to generate a somatic EPSP of a given magnitude across input location and resting membrane potential. These results suggest that coexpression of NMDARs and AMPARs at excitatory synapses intrinsically limits location- and voltage-dependent variability in synaptic efficacy.

Title: Excitation/inhibition dendritic integration in fast spiking interneurons of the dentate gyrus

Authors: *C. ELGUETA, M. BARTOS
Freiburg Univ., Freiburg Im Breisgau, Germany

Abstract: Fast-spiking (FS) interneurons provide powerful inhibition into principal cells, enabling cortical circuits to perform complex operations. Despite their important role in network computations, we know little about how excitatory and inhibitory signals are processed in their dendritic trees. Using localized activation of glutamate and GABA receptors and single-cell computational modelling we studied integrative properties of FS interneurons in the dentate gyrus (DG) and compared it to granule cells (DGGCs). First, we observed that irrespective of their spatial distribution, summation of excitatory signals at FS interneurons was sub-linear or linear, while in contrast DG granule cells (DGGCs) showed supralinear summation. We examined how $GABA_A$ receptor-mediated inhibition interacts with excitatory inputs in both cells by analyzing the effect of localized GABA uncaging onto EPSPs evoked by glutamate microiontophoresis. We observed that in FS interneurons distal (off-path) inhibition reduced more efficiently EPSP amplitude than proximal (on-path) inhibition, in contrast in GCs proximally located inhibition was more efficient. This differential effect depended on EPSP size and on the distribution of the $GABA_A$ reversal potential, which was shown to be different for FS

interneurons and GCs as measured using perforated patch recordings. Measurements of GABA conductance combined with detailed single cell models, suggest that distal inhibition in FS interneurons is boosted by a combination of denser distal GABA conductance and a somato-dendritic gradient in membrane resistivity. Depolarizing on-path inhibition together with strong hyperpolarizing off-path inhibition in FS interneurons allowed GABAergic inhibition to control action potential generation independent of its spatial location, while in DGGCs on-path inhibition is most suited to regulate neuronal discharge. In summary we show that FS interneurons and principal cells differentially integrate excitatory and inhibitory signals at their dendrites adding another layer of complexity to neuronal processing in the DG.

Title: Backpropagating action potentials boost dendritic inhibition

Authors: *G. TESTA-SILVA[1], M. HAUSSER[2], G. J. STUART[1]
[1]Eccles Inst. of Neurosci., The Australian Natl. Univ., Canberra, Australia; [2]UCL, London, United Kingdom

Abstract: Probing the interaction between action potentials (APs) and synaptic events is crucial to a full understanding of how neurons process their inputs. While it is commonly assumed that APs cause a complete reset of synaptic integration, we have shown this reset is variable and cell type-dependent during excitatory postsynaptic potentials (EPSPs) (Hausser et al. Science, 2001). Here, we extend these results to examine the interaction between APs and inhibitory synaptic potentials (IPSPs). Whole-cell patch-clamp recordings were made from neocortical layer 5 pyramidal neurons in slices from somatosensory cortex maintained at physiological temperatures. APs were generated antidromically, or by somatic current injection at various times relative to IPSPs simulated by somatic or dendritic current injection or evoked by extracellular stimulation. APs recorded in isolation were digitally subtracted from the combined IPSP/AP waveform to reveal their impact on IPSP amplitude and kinetics. As with EPSPs, APs timed to occur after the onset of somatic IPSPs led to a reduction in IPSP peak and integral, which was more pronounced when IPSPs were simulated by direct current injection compared to those simulated as a conductance change using dynamic clamp. In contrast, dendritic IPSPs simulated using dynamic clamp were transiently boosted by APs. Similar observations were made when IPSPs were generated by synaptic stimulation near the soma or at distal dendritic locations. Consistent with the idea that the boosting of dendritic IPSPs occurs due to an increase

in the driving force for inhibitory current flow generated by backpropagating APs (bAPs), we found that blocking AP backpropagation by local dendritic TTX application reduced boosting of dendritic IPSPs. Finally, we tested whether the boosting of dendritic inhibition by bAPs has a functional impact on the input-output relationship (f/I curve) of the neuron. Blocking bAPs with local TTX application reduced the impact of dendritic applications of GABA on the f/I curve obtained during somatic current injection, indicating that the capacity of APs to boost dendritic inhibition has functional consequences. These experiments indicate that the interaction between APs and IPSPs depends on the relative timing and location of inhibition, and that this interaction can boost the efficacy of dendritic inhibition. These effects can have a pronounced impact on the input-output relationship of pyramidal neurons.

Title: Behavioral timescale synaptic plasticity underlies place selectivity in CA1

Authors: *C. GRIENBERGER[1], K. C. BITTNER[1], A. D. MILSTEIN[2], S. ROMANI[1], J. C. MAGEE[1]
[1]HHMI/ Janelia Res. Campus, Ashburn, VA; [2]Neurosurg., Stanford Univ. Sch. of Med., Stanford, CA

Abstract: One of the most important properties of synapses is the ability to undergo activity-dependent changes in synaptic strength, or synaptic plasticity, providing a very compelling cellular model for learning and memory formation. The Hebbian rule, which represents one of the predominant models for synaptic plasticity, can be summarized as “neurons that fire together wire together”. Here we describe in hippocampal CA1 place cells a novel synaptic potentiation mechanism that is markedly different from this Hebbian rule. We found, combining experimental and computational approaches, that a complex spike, which is known to be associated with a dendritic plateau potential, was able to cause the formation of a new place field in a single trial by potentiation of synaptic inputs that arrived several seconds before and after this complex spike event. Moreover, the synaptic inputs that become potentiated were not initially coincident with any significant action potential firing or membrane potential depolarization. Thus, this potentiation mechanism, which we name “behavioral timescale synaptic plasticity”, affects inputs that were neither causal nor close in time to postsynaptic activation. The presence of such

plasticity was confirmed in slice recordings, and further experiments revealed a similar pharmacological profile for the in vitro plasticity and the in vivo place field formation. Thus, CA1 place fields are generated by a form of synaptic plasticity, which operates on a very long timescale of several seconds and is, therefore, very suitable for supporting hippocampal-dependent forms of learning.

Title: CA1 pyramidal neurons receive spatially clustered synaptic inputs during sharp waves/ripples *Ex vivo*

Authors: *T. ISHIKAWA[1,2], Y. IKEGAYA[2]
[1]Pharmacol., Keio Univ., Tokyo, Japan; [2]Grad Sch. Pharma Sci, Univ. Tokyo, Tokyo, Japan

Abstract: Spontaneous reactivation of neurons involved in recently acquired memories during hippocampal sharp wave/ripples (SWRs) is crucial for memory consolidation. Neurons fire an action potential when the sum of synaptic inputs reaches the spike threshold. During this integrating processing, dendrites perform complex computations through their nonlinear electrical properties. The dendritic computations may depend on the spatiotemporal patterns of excitatory synaptic inputs, but it remains to be known about how synaptic inputs during SWRs are spatiotemporally orchestrated and determine neuronal output. Excitatory synaptic inputs were optically monitored *en masse* from hundreds of dendritic spines of individual pyramidal neurons in spontaneously active networks at video frame rates of 100-333 Hz while local field potentials were recorded from the CA1 pyramidal layer in cultured hippocampal slices. Spine activity significantly increased around the peak of SWs, and the SWR-locked activity was more spatially clustered on dendrites compared to baseline activity outside SWRs. The number of dendritic compartments that received clustered inputs increased during the SWR periods. These results may reify nonlinear synaptic integration in hippocampal pyramidal cells and neuronal reactivation during SWRs.

Title: The effect of extracellular calcium on the E/I -ratio in pyramidal neurons in the hippocampus

Authors: *M. FORSBERG[1], H. SETH[2], A. BJOREFELDT[3], E. L. HANSE[4]
[1]Neurosci. and Physiol., [2]Univ. of Gothenburg, Gothenburg, Sweden; [3]Inst. of Neurosci. and Physiol., Gothenburg, Sweden; [4]Goteborg Univ., 40530 Goteborg, Sweden

Abstract: Ionized calcium in the extracellular space may affect evoked synaptic transmission via several opposing mechanisms. An increase in the concentration of extracellular calcium will decrease neuronal excitability, negatively affect release probability via G-protein coupled calcium sensors, and increase release probability via increased influx through voltage-gated calcium channels. The net effect of increasing the concentration of extracellular calcium is generally an increased evoked synaptic transmission, but it is unclear whether inhibitory ad excitatory synapses are equally affected.
In this study, we exposed pyramidal neurons in the CA1 region in acute slices (Wistar rats, p20-30) to two different concentrations of extracellular calcium, 1 and 2 mM. We patch-clamped the neurons and stimulated the Shaffer collaterals to evoke synaptic activity. While voltage-clamping the neurons at -70 mV we recorded EPSCs via glutamatergic AMPA receptors and while clamping at 0 mV we recorded the GABAergic IPSCs. The EPSCs and the IPSCs were decreased to the same extent when extracellular calcium was decreased from 2 to 1 mM.
One possible confounder is the presence of di-synaptic IPSCs. To investigate this we recorded the amplitude of the IPSC before and after wash in of the AMPA receptor blocker CNQX, thus getting a ratio of di-/monosynaptic inhibitory input to each cell. If extracellular calcium preferentially affects glutamatergic synapses, the neurons with less disynaptic inhibitory input would be less affected by changes in calcium. No such correlation was found. We next studied spontaneous events (sIPSC/sEPSC) and saw no changes in frequency when extracellular calcium was altered from 1 to 2 mM (sEPSCs: 0.52 ± 0.07 Hz to 0.53 ± 0.07 Hz, sIPSCs: 4.1 ± 0.51 Hz to 3.91 ± 0.32 Hz).
In conclusion, changing extracellular calcium between 1 and 2 mM does not change the E/I-ratio at synapses between CA1 and CA3 pyramidal neurons in the hippocampus.

Title: A computational model of two-photon calcium imaging with a genetically encoded calcium indicator in spines and dendrites

Authors: B. SCHNEIDERS[1], *A. ABOUZEID[2], W. L. KATH[3]
[1]Engin. Sci. and Applied Mathematics, [3]Applied Mathematics, Neurobio., [2]Northwestern Univ., Evanston, IL

Abstract: Fluorescent calcium indicators are commonly used to image neuronal activity, as changes in calcium concentration accompany voltage-mediated events such as EPSPs, action potentials and dendritic spikes. The recently developed GCaMP family of calcium sensors has opened the door for genetically targeted, high resolution neuronal activity to be recorded in awake, behaving animals in vivo. However, interpreting the calcium signal can still be challenging.

We present a morphologically detailed computational model of the CA1 pyramidal cell, featuring calcium buffering dynamics and simulated GCaMP6 fluorescence throughout the dendrites and spines. The GCaMP construct combines green fluorescent protein (GFP) and calmodulin (CaM). We therefore model the calcium-binding kinetics of GCaMP based on those of CaM. Additionally, our model incorporates sources of calcium influx into the cytosol such as voltage-gated calcium channels, AMPA and NMDA receptors, as well as endogenous buffers and transmembrane pumps that extrude calcium from the cell.

We verify that the model reproduces a wide range of reported results from two-photon imaging experiments of CA1 pyramidal neuron dendrites and spines. In particular, the somatic, dendritic and spine compartments exhibit appropriate levels (both absolute and relative) of membrane depolarization, calcium concentration changes and indicator fluorescence in response to simulated synaptic stimulation.

Simulating GCaMP6 in dendrites provides a tool to inform our understanding of the mechanisms associated with synaptic integration by constraining the possible interpretations of calcium imaging experiments. It provides a window into the causal mechanisms that may give rise to observed calcium signals, such as sodium-mediated depolarizations, regenerative calcium-mediated events and NMDA spikes. The model also serves as a platform for generating hypotheses for further experimentation.

Title: Electrical structure of dendritic spines: A voltage imaging study with patterned illumination based on computer-generated holography (CGH)

Authors: J.-Y. WENG[1], D. TANESE[2], V. ZAMPINI[2], V. DE SARS[2], M. CANEPARI[3], V. EMILIANI[2], *D. ZECEVIC[1]
[1]Dept Cell & Mol. Physiol, Yale Univ. Sch. Med., New Haven, CT; [2]Neurophotonics Lab., Paris Descartes Univ., 75270 Paris, France; [3]Lab. for Interdisciplinary Physics, Univ. Grenoble Alpes, Saint Martin d'Hères, France

Abstract: Additional research is necessary to clarify the electrical structure of dendritic spines. Notwithstanding decades of theoretical and modelling studies, as well as calcium, sodium, and voltage imaging experiments and nano electrode recordings, the elementary question of the value of spine neck resistance relative to the input impedance of thin spiny dendrites is controversial. Currently, there is contradictory evidence in support and against the hypothetical electrical isolation of synapses on spine heads caused by a narrow spine neck. Such electrical isolation of synapses on spines, if present, could be responsible for a set of specific functions that would not be supported by synapses on dendrites. To obtained direct evidence, we previously used an electrochromic voltage-sensitive dye (JPW3028) as a transmembrane optical voltmeter with a linear scale capable of recording simultaneously electrical signals from individual spines and parent dendrites (Popovic, Carnevale, Rozsa, Zecevic, 2015). The results showed that the spine neck does not electrically isolate synapses on spines; electrically, these synapses behave as if they are located directly on dendrites. From these measurements, we found that the success rate (limited by light scattering and by the extent of photodynamic damage) was too low to allow studies of more complex electrical phenomena. Thus, further improvements in voltage-sensitive dye recording was necessary. Here we demonstrate a dual-color Computer Generated Holography (CGH) illumination system especially designed to perform functional recording from dendritic spines, where a first optical path is used to generate a multi-site intensity graded

patterns, allowing localization and intensities adjustment of the illumination of dendrites and spine heads, and the second path permits a simultaneous multisite uncaging. Intensity graded illumination patterns were shaped in a way to practically eliminate contamination of spine optical signals by the scattered light from the parent dendrite increasing the effective spatial resolution of functional recording. The results also suggest that the localization of the illumination exclusively on the regions of interest (spine heads and small sections on parent dendrites) can significantly reduce photodynamic damage. Finally, we showed that voltage imaging with CGH at 532 nm excitation light could be combined with patterned illumination for a simultaneous multisite glutamate uncaging.

Title: Electrical compartmentalization of dendritic spines prevents synaptic voltage-clamp

Authors: *L. BEAULIEU-LAROCHE, M. T. HARNETT
Brain and Cognitive Sci., MIT, Cambridge, MA

Abstract: Whole-cell voltage-clamp is routinely employed to measure synaptic conductances involved in a variety of neuronal processes, but little attention has been given to the limitations of this approach. Here, we reveal that voltage-clamp is completely ineffective for dendritic spines, the locus of most excitatory synapses in the mammalian brain. Combining simple compartmental modeling with dendritic patch-clamp recordings and two-photon optical techniques, we find that the spine neck resistance prevents voltage control of synaptic events, leading to large spine depolarization. As a consequence, voltage-clamp both substantially underestimates synaptic conductance and allows the recruitment of voltage-gated channels. These results question the utility of whole-cell voltage-clamp in studying synaptic physiology. To provide new, accurate measurements of synaptic parameters, we develop an approach to estimate AMPA conductance at single spines. Our results in cortical layer 5 pyramidal neurons indicate that single synapse AMPA conductance is much larger (IQR: 0.96-2.53 nS) than previously appreciated. Future work should consider the highly compartmentalized nature of central neurons in interrogating synaptic transmission and plasticity but also in the approaches taken to tackle those questions

Title: Effects of focal ischemia on cortical excitation in the UCH-L1 knock-in mice

Authors: N. V. POVYSHEVA[1], F. ZHANG[2], M. E. ROSE[2], J. S. BANTON[2], S. GRAHAM[2], *G. BARRIONUEVO[1]

Abstract: Ischemic stroke is a devastating neurological disorder and one of the leading causes of disability in the US and all over the world. While there is a massive cell loss in the ischemic core, the neurons in the surrounding areas that were exposed to ischemia and survived can sustain chronic pathological changes both reversible and irreversible that are not well understood. We showed previously that focal ischemia results in decreased excitation in the brain as indicated by the loss of excitatory connections and slower axonal conduction velocity (Povysheva et al. 2016, SFN abstract). It was also shown that Ubiquitin C-terminal hydrolase L1 (UCH-L1) activity can protect primary neurons from hypoxic/ischemic injury induced by cyclopentenone prostaglandins (Liu et al., 2015). Here, we study the effects of focal ischemia on cortical excitation in the UCH-L1 knock-in mice to explore the neuroprotective role of UCH-L1 C152A mutation. Middle cerebral artery occlusion (MCAO), and sham surgeries were performed in UCH-L1 C152A mice as previously described (Zhang et al., 2014), and physiological properties of penumbral neurons as well as axonal conduction velocity were assessed 7 and 21 days later in brain slices. Whole-cell recordings were made from pyramidal neurons in layer 2-3 of the mouse neocortex located near to the ischemic core in the MCAO, and in similar locations in the sham mice. Spontaneous excitatory postsynaptic currents (sEPSCs) were recorded at the holding potential of -70 mV in the presence of gabazine (10 μM). Unlike in the WT, in UCH-L1 knock-in, MCAO did not result in altered amplitude and frequency of sEPSCs (ANOVA, $p>0.1$). Similarly, action potential-independent, miniature EPSCs recorded in the presence of TTX, were resistant to the MCAO in mutant mice. Axonal conduction velocity was assessed in the brain slices by placing stimulating and recording electrodes in the corpus callosum ipsilaterally and contralaterally in the MCAO affected hemisphere. Axonal conduction velocity for myelinated fibers was decreased in the MCAO as compared to sham animals (ANOVA, $p<0.001$). Importantly, this decrease was observed in 7 days MCAO, but not in 21 days. Axonal conduction velocity for unmyelinated fibers was unaffected by the MCAO (ANOVA, $p>0.1$). Thus, we

provide further evidence for the neuroprotective role of the UCH-L1 activity against the ischemic insult.

Title: Differential regulation of calcium sensors involved in asynchronous release by $G_{i/o}$-coupled GPCRs

Authors: Z. ZURAWSKI[1], B. PAGE[2], S. T. ALFORD[3], *H. E. HAMM[4]
[1]Pharmacol., Vanderbilt Univ., Nashville, TN; [3]Dept. of Anat. and Cell Biol., [2]Univ. of Illinois at Chicago, Chicago, IL; [4]Dept. of Pharmacol., Vanderbilt Univ. Sch. of Med., Nashville, TN

Abstract: Presynaptic inhibition mediated by G protein-coupled receptors can involve a direct interaction between liberated Gβγ and the vesicle fusion machinery. In this way, Gi/o-coupled GPCRs regulate both evoked and spontaneous release through G-protein beta gamma (Gβγ) subunits. In addition, Gβγ mediates this inhibits inhibition of both synchronous and asynchronous evoked release at and downstream ofby modulating presynaptic calcium entry but also acting downstream of this calcium entry. We have previously demonstrated that Gβγ inhibits exocytosis downstream of calcium entry via competition with the fusogenic calcium sensor, synaptotagmin I (syt I) for binding sites on SNARE complexes with the calcium sensor synaptotagmin I (syt I), implicated in these forms of release. Here, we demonstrate the differential ability of Gβγ to compete with several types of calcium sensor proteins implicated in asynchronous evoked release and augmentation of release during repetitive stimulation. Gβγ is able to compete with syt I and Doc2, but not syt VII, for binding to SNAREs and inhibition ofconsequently to inhibit Ca^{2+} and calcium sensor-dependent lipid mixing and exocytosis. In contrast to syt I, which requires tens to hundreds of μM Ca^{2+} to evoke fusion, B both Doc2 and syt VII display high lipid mixing activity at μM levels of Ca^{2+} insufficient for robust syt I activity. syt Syt VII, but not Doc2, is activated by Sr^{2+} in lipid mixing assays, supporting the hypothesis that Sr^{2+}-driven asynchronous release in neurons is mediated by the synaptotagmin family of calcium sensors. Together, this these data suggests that release evoked during stimulus trains and asynchronous release evoked by different types of Ca^{2+} sensors has differential sensitivity to regulation by the Gβγ-SNARE mechanism.

Title: 2D and 3D neuronal cultures exhibit significantly different spontaneous activity patterns

Authors: *M. HASAN[1], Y. BERDICHEVSKY[1,2]
[1]Dept. of Electrical and Computer Engin., [2]Bioengineering Program, Lehigh Univ., Bethlehem, PA

Abstract: In-vitro models of dissociated neuronal cultures are extensively used in the field of neuroscience to model disease and investigate brain functions. However, most of these models are two dimensional and cannot accommodate for the multi-layer connectivity between neurons found in the brain in-vivo. Here, we present a simple yet novel method to develop 3D neuronal culture. We used Polydimethylsiloxane to create 100 µm high micro-wells of different diameter (400-900 µm). These wells were then used to confine dense solution of cortical neurons obtained from neonatal rats. Diluted solution of same neurons was also seeded to create 2D cultures for comparison. R-GECO1 (fluorescent [Ca2+] indicator) (1) was expressed in cultures starting from first day in vitro. Optical recordings of [Ca2+] indicator (R-GECO1) showed synchronous activity across the whole culture from DIV8 for both 2D and 3D cultures. Our investigation showed significant difference between 2D and 3D neuronal culture spontaneous synchronous activity duration and interval. Effects of culture size and cell number on activity patterns were also determined. This study can potentially help the development of more effective neurological disease models and can further assist the investigation of brain functionality and neuronal circuits.

Title: Stimulus-evoked Ca^{2+} influx at a single active zone varies through a variable and small population of voltage-gated Ca^{2+} channels

Authors: *S. RODRIGUEZ[1], S. RAMACHANDRAN[3], E. C. CHURCH[2], S. T. ALFORD[4]
[2]Grad. Program in Neurosci., [1]Univ. of Illinois At Chicago, Chicago, IL; [3]Univ. Illinois, Chicago, Chicago, IL; [4]Dept. of Anat. and Cell Biol., Univ. of Illinois at Chicago, Chicago, IL

Abstract: Stimulus-evoked Ca2+ influx through voltage-gated Ca2+ channels, localized to the presynaptic release face membrane, evokes neurotransmitter release. Differing spatio-temporal Ca2+ requirements for release have been proposed in different presynaptic terminals, either gated by Ca2+ influx through many or a few open channels, with varying structural relationships to the release machinery. In most synapses, determining the variability of channel opening to stimulation is difficult because the channels and terminals are inaccessible to direct recording approaches and imaging lacks temporal and spatial resolution to determine channel activity and Ca2+ entry at active zones. We utilized the lamprey giant reticulospinal synapse to overcome these limitations. Using an acute dissociation of the lamprey spinal cord we recorded from acutely isolated reticulospinal axons, with functional presynaptic terminals devoid of apposing postsynaptic projections. Ca2+ channels were characterized at individual terminals by low-noise single channel electrophysiological recordings. We determined channel subtypes present at these terminals and estimated their probability of opening on depolarizing stimuli. The number of channels at a terminal was determined for each of the subtypes present; N-type (4-10; mean 6), P/Q-type (3-9; mean 6), R-type (4-32; mean 12) and L-type (3-17; mean 10). A small number of Ca2+ channels (up to 68, mean 33) were found to be present at a terminal. Furthermore, a very small number (3-6, mean 4) of Ca2+ channels opened in response to a stimulus, suggesting that Ca2+ influx through few open channels may gate release in these terminals. Therefore, we tested the variability of Ca2+ transients in these synapses over many active zones using high speed imaging of Ca2+ entry to the presynaptic terminal in response to an external stimulus. We found that over extended stimulation, among the active zones detected (n=12), 7 showed Ca2+ transients that did not vary beyond the variance in noise, but 5 showed distinctly variable Ca2+ transients. This variability in Ca2+ transients along with the small subset of Ca2+ channels that open in response to a stimulus suggests that there is variability in the population of Ca2+ channels that open at some active zones. This result has profound implications for the reliability and function of evoked neurotransmitter release.

Title: Neuron-Specific Gene 2 (NSG2) regulates excitatory synaptic transmission via modulation of AMPAR surface expression

Authors: *P. CHANDER[1], J. P. WEICK[2]
[2]Neurosciences, [1]Univ. of New Mexico, Albuquerque, NM

Abstract: Multiple adaptor proteins have been shown to regulate the dynamic shuttling of AMPA-type glutamate receptors between intracellular compartments and the plasma membrane during synaptic plasticity. However, whether the same or novel vesicular adaptor proteins affect trafficking of AMPARs to post-synaptic membranes during synaptogenesis or under basal conditions remains unknown. Neuron specific gene 2 (NSG2) is one of the most highly expressed proteins during the period of maximal synaptogenesis in rodent and human and belongs to the Neep21/Calcyon/P19 family of endosomal proteins, but its function has remained uncharacterized. Here we show that NSG2 is found in discrete punctae restricted to somatodendritic arbors of developing neurons, and a significant proportion of NSG2 punctae co-localize with surface-expressed AMPAR subunits GluA1 and GluA2. Immunoprecipitation of overexpressed proteins in HEK293T cells, as well as from mouse brain lysates, revealed that NSG2 physically interacts with both GluA1 and GluA2. Interestingly, CRISPR-mediated knock out of NSG2 in primary hippocampal neurons selectively impaired miniature excitatory post synaptic current (mEPSC) frequency without affecting mEPSC amplitude or AMPAR surface expression. In contrast, NSG2 overexpression caused a significant increase in the amplitude of mEPSCs without significantly affecting mEPSC frequency. However, NSG2 overexpression did cause alterations in $PSD95^{+}$ expression at post-synaptic densities, suggesting a possible indirect mechanism for altering AMPAR localization and mEPSCs. Together these data show that NSG2 is an AMPAR-binding protein that regulates basal excitatory synaptic transmission during early periods of neuronal development and is required for proper synapse formation.

Title: Voltage-sesitive dye signal analysis of inhibitory components in mouse perirhinal-entorrhinal cortical slices

Authors: *Y. WAKAYAMA[1], S. KAMADA[2], Y. YAMADA[2], T. TOMINAGA[3], R. KAJIWARA[2]
[1]Electronics and Bioinformatics, [2]electronics and Bioinformatics, Meiji Univ., Kawasaki-Shi, Japan; [3]Inst. of Neuroscience, Tokushima Bunri Univ., Sanuki, KAGAWA, Japan

Abstract: The perirhinal cortex (PC) communicates with the hippocampus via the entorhinal cortex (EC). Since the PC receives diverse inputs from unimodal and polymodal association cortices, the functional linkage between the PC and the entorhinal- hippocampal network is thought to be essential for the formation and recall of memories. However, previous electrophysiological experiments in the rodents indicated that propagation of neural activity between PC and EC occurs with an extremely low probability. This phenomenon strongly suggests that inhibitory system in the PC could control the information transfer from the PC to the hippocampus via the EC. To reveal the layer distribution of inhibitory system in the PC, we analyzed the pattern of neural activities induced by electrical stimulation to superficial and deep layers of the PC respectively, on mice brain slices using voltage-sensitive dye(VSD) imaging technique. In the experiment, we perfused the 0.5 μM of gabazine, a type A gamma-aminobutyric acid (GABAA) receptor antagonist. The gabazine increased the peak value of the optical signal and prolonged the responses. To evaluate the amount of inhibitory action in the circuit, we calculated the time-integral of the optical signal (an area from baseline) at each pixel. We also calculated a pixel-wise ratio of the area before and after the perfusion. The ratio was markedly larger in the deep layer than the superficial layer. That is, the activity of the deep layer is more sensitive to the inhibition of GABAergic system than the superficial layer, thus should be under the strong control of GABAA system. Subsequently, we examined the effect of CGP-55845, a GABAB receptor antagonist. However, the CGP-55845 did not cause significant change of responses in the PC and EC. These results suggest that inhibitory mechanisms via GABAA receptors have a predominant role in the neural excitation propagation from the PC to the EC. To investigate how the excitatory response in the PC will break the wall of inhibition in the PC, we also examined the effect of the 4-aminopyridine (4-AP), which reduce the slowly inactivating potassium current (ID) of perirhinal neurons at micromolar concentrations. By the co-application of the 40 μM of 4-AP with gabazine, the stimulation to deep layers evoked large depolarized responses in EC. After washing off the gabazine, however, both deep and superficial layers stimulation in area 36 did not evoke the EC response. Our results in this study may suggest that the strong inhibitory system in deep layer of PC acting on the firing rate of perirhinal excitatory neurons may control the activation of the entorhinal-hippocampal network.

Title: The glutamatergic synaptic cleft alkalinizes, rather than acidifies, during neurotransmission, a phenomenon that ameliorates depression during burst firing

Authors: *M. STAWARSKI[1], R. HERNANDEZ[2], G. T. MACLEOD[2]
[1]Dept. of Neurosci., [2]Florida Atlantic Univ., Jupiter, FL

Abstract: Recently published data give credence to the idea that the pH of the synaptic cleft is highly dynamic and that pH shifts may influence neurotransmission due to the pH sensitivity of ion channels and neurotransmitter receptors facing the cleft. However, the valence and kinetics of cleft pH transients are as of yet unknown. Using a variety of fluorescence imaging approaches, we demonstrate that cleft pH transients are spatially and temporally linked to activity-evoked postsynaptic Ca^{2+} efflux. Single action potentials evoke rapid alkalinization of the cleft of ~0.02 pH log units (~3% change in proton concentration) within ~20 ms. Although modest in amplitude, these events summate during burst firing in vivo, leading to transients that exceed 1 pH log unit. Cleft alkalinization is blocked by agents that desensitize glutamate receptors, and which also block Ca^{2+} entry to the postsynaptic compartment and its ensuing acidification. This suggests that alkaline transients in the cleft are a function of acid flux across postsynaptic membranes through plasmamembrane Ca^{2+}-ATPases. The kinetics of cleft pH transients (decaying with a time course of 60 ms) suggest that they may be relevant to fast forms of short-term synaptic plasticity. We hypothesize that activity-dependent cleft alkalinization has been incorporated into gain mechanisms that sustain neurotransmission during action potential bursts.

Title: Localization of glycinergic neurons in the mouse thalamus

Authors: *P. A. LOZANO
The Univ. of Texas At El Paso, El Paso, TX

Abstract: Glycine acts as inhibitory neurotransmitter and as a co-agonist of glutamate at the excitatory NMDA receptor in the central nervous system. Glycine Transporters (GlyT1 and 2) are responsible for the reuptake and recycling of the neurotransmitter glycine at the synaptic cleft. Recent published data and our preliminary studies suggest the presence of GlyT1 in the mouse thalamus; whether this immunoreactivity corresponds to glia cells or neurons is something that has not been clearly defined. The thalamus is considered a critical hub integrating a complex array of motor and sensory functions. The detailed anatomy of some thalamic neuronal networks, local circuits, inputs from and to the brain stem and cortex are well known. While the overall topography is well understood, the position and contribution of glycinergic networks to thalamic functions need to be elucidated. To address this question, the retrograde tracer FluroGold and two Adeno-Associated vectors expressing mCherry under synapsin or GFP under GFAP promoters, have been injected into the mouse ventral posteromedial thalamus and their distribution analyzed. Combined staining of GlyT1 with neuronal markers suggests co-localization, indicating a GlyT1 neuronal expression rather than glia cells. In addition, FluoroGold injections and labeling with GlyT1 suggest that these glycinergic neurons are interneurons rather than projection neurons. These results should shed light into the glycinergic network in the thalamus. Understanding the neural pathways containing glycine transporters will allow us to have a better knowledge about the inhibitory inputs in the control of sensory-motor integration.

Title: $nNOS^+$ interneurons contribute to inhibition and neurogenesis in the dentate gyrus

Authors: *A. F. MANUEL, J. C. GONZALEZ, R. J. VADEN, E. W. ADLAF, A. J. NIVER, J. I. WADICHE, L. OVERSTREET-WADICHE
Neurobio., Univ. of Alabama At Birmingham, Birmingham, AL

Abstract: The dentate gyrus (DG) is a unique brain region that exhibits very low levels of neural activity, wherein only a small percentage of principal granule cells (GCs) are active at any time, and active GCs display low spiking frequencies. The DG is also one of only two regions in the mammalian brain where adult neurogenesis occurs. GABAergic interneurons of the DG not only maintain sparse GC firing, but also provide newly generated GCs with depolarizing GABA as a trophic factor for survival and synaptic integration into the existing network. It is well established that parvalbumin (PV) expressing DG interneurons are important for DG inhibition and neurogenesis, but here we assess how a slow-spiking interneuron family called Ivy/neurogliaform cells that express neuronal nitric oxide synthase (nNOS), contribute to inhibition and neurogenesis. We crossed nNOS-CreER mice with Ai14(RCL-tdT)-D or Ai32(RCL-ChR2(H134R)/EYFP) and gave tamoxifen chow for one week after weaning. We found that all $nNOS^+$ interneurons showed slow maximal firing rates and slow action potential kinetics. $nNOS^+$ cells often had delayed spiking phenotypes, afterhyperpolarizations, and morphology characteristic of Ivy/neurogliaform cells. In contrast, PV^+ interneurons had high maximal firing rates, fast action potential kinetics, and basket cell morphology. We also crossed each ChR2-expressing mouse line with POMC-eGFP reporter mice, allowing us to record synaptic responses from both mature and newborn GCs. Optogenetic activation of $nNOS^+$ interneurons generated slow-rising and decaying $GABA_A$-mediated postsynaptic currents (PSCs) in both mature and newborn GCs that were enhanced by NO711, consistent with volume transmission from Ivy/neurogliaform cells. Single light pulses also generated $GABA_B$ PSCs in mature GCs, another hallmark of Ivy/neurogliaform-mediated transmission that differs from fast synaptic signaling by PV^+ interneurons. The combined $GABA_A$- and $GABA_B$-mediated inhibition generated by optogenetic activation of $nNOS^+$ interneurons robustly inhibited GC spiking for hundreds of milliseconds, with a slow $GABA_B$-mediated component. Furthermore, optogenetic activation of $nNOS^+$ interneurons (5Hz for four minutes, repeated every five minutes for 60 minutes), increased the number of Ki-67 labeled proliferating progenitors. Together, these data suggest that $nNOS^+$ interneurons display characteristics of Ivy/neurogliaform cells and shape both inhibition and neurogenesis in the DG.

Title: Habenula-driven protracted feed-forward inhibition mediated by 5-HT_{1A} receptors in the dorsal raphe nucleus

Authors: *M. B. LYNN[1], S. D. GEDDES[2], S. MAILLÉ[2], D. LEMELIN[2], R. BERGERON[2], S. HAJ-DAHMANE[3], J.-C. BÉÏQUE[2]

Abstract: The habenulo-raphe pathway is believed to be involved in orchestrating behavioral responses to aversive, threatening or stressful environments. The mechanistic details of how the long-range input from the lateral habenula (LHb) to the dorsal raphe nucleus (DRN) is organized and processed is, however, largely unknown. Here, using a variety of optogenetic strategies in combination with whole-cell electrophysiology, we outlined a novel form of protracted feed-forward processing in the DRN network. We found that the LHb input to the DRN provides a powerful direct monosynaptic glutamatergic drive to 5-HT neurons that also triggers a canonical, rapid, $GABA_AR$-mediated feedforward inhibition. Intriguingly, however, train stimulation of the LHb input to the raphe also triggered a singularly distinct form of feedforward inhibition. This LHb-driven hyperpolarizing response lasted for seconds, its induction was steeply dependent on the frequency of LHb inputs and was mediated by a GIRK conductance activated by 5-HT_{1A}Rs. Optogenetic manipulations in the DRN suggest that this protracted inhibition is mediated not by a cell-autonomous autoinhibition mechanism, but rather by a feedforward inhibition enacted by 5-HT neurons organized in an unsuspected recurrent network architecture. Thus, this mechanism provides the LHb inputs with the ability to outcompete parallel inputs to the DRN. More broadly, these functional connectivity features provide an effective and perhaps generalizable neural strategy to implement a dynamic input selection mechanism in hub-like networks.

Title: Elevated O-GlcNAcylation modulates inhibitory neurotransmission in hippocampal area CA1

Authors: *L. T. STEWART[1], J. C. CHATHAM[2], L. L. MCMAHON[3]
[2]Pathology, [3]Cell, Developmental, & Integrative Biol., [1]Univ. of Alabama At Birmingham, Birmingham, AL

Abstract: Studies from our lab have begun to characterize the role of protein O-GlcNAcylation on hippocampal synaptic transmission and learning and memory. This post-translational modification involves the O-linkage of β-*N*-acetylglucosamine to Ser/Thr residues on target proteins. O-GlcNAcylation is as dynamic as protein phosphorylation and is carried out by the enzyme O-GlcNAc transferase (OGT), which attaches the O-GlcNAc moiety, and O-GlcNAc (OGA) transferase, which catalyzes its removal. Together, this enzymatic set represent the final step of the Hexosamine Biosynthetic Pathway, the sole metabolic pathway for all O-GlcNAcylation in the body. Immunohistochemical staining for O-GlcNAcylated proteins in rat and human hippocampus shows pronounced immunoreactivity in all regions of hippocampus, with expression in excitatory pyramidal cells, GABAergic interneurons, and astrocytes. Using brain slice electrophysiology, we previously reported that acutely increasing O-GlcNAcylation, using either the substrate glucosamine or the OGA inhibitor Thiamet-G, induces a novel NMDAR-independent form of LTD at CA3-CA1 synapses that requires O-GlcNAc modification of GluA2 AMPAR subunits (Taylor et al., 2014). In more recent studies, we have found that increasing O-GlcNAcylation dampens ongoing epileptiform activity at these same synapses. To date, there have been no studies investigating whether GABAergic inhibition is modulated by O-GlcNAcylation, or whether this is specific for excitatory transmission. Using whole-cell voltage-clamp recordings from CA1 pyramidal cells, we investigated whether increasing O-GlcNAcylation using the OGA inhibitor Thiamet-G modulates the frequency or amplitude of spontaneous IPSCs. Preliminary experiments show a reduction in IPSC amplitude following bath application of Thiamet-G, with no change in IPSC frequency, suggesting a possible postsynaptic site of action. Further experiments will examine possible changes in evoked IPSCs onto CA1 pyramidal cells. As the balance of excitatory to inhibitory input controls the final output of CA1 pyramidal cells, E/I ratios will be measured in the presence of elevated O-GlcNAcylation. Collectively these data will further characterize the role of protein O-GlcNAcylation in modulating hippocampal function.

Title: Presynaptic actions of isovaline reduce inhibitory and excitatory postsynaptic currents in thalamic neurons

Authors: *K. A. ASSERI[1,2], B. A. MACLEOD[3], S. K. W. SCHWARZ[4], E. PUIL[4]
[1]Dept. of Anesthesiology, Pharmacol. and Therapeut., Univ. of British Columbia, Vancouver, BC, Canada; [2]Dept. of Pharmacol., King Khalid Univ., Abha, Saudi Arabia; [3]Pharmacol., Dept of APT UBC, Vancouver, BC, Canada; [4]Dept. of Anesthesiology, Pharmacol. & Therapeut., The Univ. of British Columbia, Vancouver, BC, Canada

Abstract: Isovaline is a non-proteinogenic amino acid that inhibits thalamocortical neurons in ventrobasal nuclei. Since isovaline produces analgesia *in vivo* through activation of metabotropic glutamate group II (mGlu II) in addition to $GABA_B$ receptors, we investigated if isovaline acts on thalamic neurons in a similar fashion. We hypothesized that isovaline inhibits inhibitory and excitatory synaptic postsynaptic currents (IPSCs and EPSCs) by activating presynaptic mGlu II or $GABA_B$ receptors. Whole-cell patch clamp recordings from thalamocortical neurons of ventrobasal nuclei were performed in brain slices from Sprague-Dawley rats (P9-12). Electrical stimulation of the somatosensory input, medial lemniscus, evoked both IPSCs and EPSCs. The IPSCs and EPSCs were isolated from each other by using a holding potential that minimized outward currents (V_h = 0 mV) or inward currents (V_h = -70 mV). Kynurenic acid was applied to block inotropic glutamate currents. Internal Cs^+ was applied to eliminate postsynaptic effects of agonists of $GABA_B$ or mGlu II receptors. Bath application of the $GABA_B$ agonist, baclofen, and mGluR II agonist, LY354740, suppressed the IPSCs and EPSCs. These effects were selectively antagonized by $GABA_B$ antagonist, CGP52432, and mGlu II antagonist, LY341495, indicating the presence of $GABA_B$ and mGlu II receptors on presynaptic elements. Application of isovaline (30-1000 µM) decreased the peak amplitudes of IPSCs (EC_{50} = 284 µM; 95% CI, 76-170). Isovaline (400 µM) decreased the peak amplitudes of EPSCs by 44% (95% CI, 59-224). Isovaline did not affect the decay-time constants of IPSCs and EPSCs. Isovaline-depressions of IPSCs and EPSCs were blocked by co-application of CGP52432 or LY341495. Isovaline activation of metabotropic mGlu II and $GABA_B$ receptor subtypes on nerve terminals may affect release of glutamate or GABA. These studies demonstrate that isovaline produces inhibition of GABAergic IPSCs and glutamatergic EPSCs by actions that are mediated by metabotropic $GABA_B$ and mGlu II receptors.

Title: Inhibitory neurotransmission drives endocannabinoid degradation during memory consolidation

Authors: *C. DUBOIS, J. LIU
Dept. of Cell Biol. and Anat., LSUHSC, New Orleans, LA

Abstract: The endocannabinoid system represents a major regulator of brain activity by reducing synaptic transmission and neurons activity. In the cerebellar cortex, 2-AG is released on-demand from Purkinje and stellate cells and activates presynaptic CB1 receptors, which reduce the release of glutamate and GABA. MAGL is the enzyme responsible for 2-AG degradation, and thus controls the temporal profile of the endocannabinoid action. We tested the hypothesis that endocannabinoid degradation is actively regulated by neuronal activity and plays a critical role in learning. Here we show that fear conditioning increased MAGL expression in the cerebellar cortex and accelerated endocannabinoid degradation. Learning also induced a lasting increase in evoked and spontaneous GABA release from cerebellar stellate cells. Using pharmacology and optogenetics, we found that a learning-induced increase in GABA release is necessary and sufficient to enhance endocannabinoid degradation. Using DREADD technologies, we show that activation of Gq-coupled receptors in cerebellar Purkinje cells reduced GABA release in the cerebellar cortex through an endocannabinoid-dependent pathway. Pharmacogenetic activation of Purkinje cells *in vivo* after fear learning disrupted cued but not contextual learning. Therefore a learning-induced increase in GABA release accelerates 2-AG degradation in the cerebellum and promotes the consolidation of fear memory. Our finding that

fear conditioning potentiates endocannabinoid degradation by increasing MAGL expression contrasts with the widely accepted view that endocannabinoid signaling is mainly determined by “on-demand” release. This novel form of degradation-dependent plasticity remodels synaptic integration and information processing within a neuronal circuit.

Title: Faulty mGluR activation of the inhibition, a mechanism for homeostatic control of somatosensory cortex hyperexcitability in fragile X syndrome

Authors: *C. A. CEA-DEL RIO[1], A. F. NUNEZ-PARRA[2], S. FREEDMAN[3], D. RESTREPO[4], M. M. HUNTSMAN[3]
[1]CIBAP, Facultad de Ciencias Medicas, Univ. de Santiago de Chile, Santiago, Chile; [2]Inst. de Ciencias Biomedicas, Univ. Autonoma de Chile, Santiago, Chile; [3]Dept. of Pharmaceut. Sci., Univ. of Colorado at Denver - Anschutz Med. Campus, Aurora, CO; [4]Cell & Dev. Biology, Neurosci. Program, Univ. of Colorado Anschutz Med. Campus, Denver, CO

Abstract: Fragile-X Syndrome (FXS) patients exhibit behavioral phenotypes reflective of hyperexcitable circuitry across different brain regions. In the FXS mouse model, the disruption in the function of a the Fragile X Mental Retardation1 (*Fmr1) gene*, results in a variety of neurological consequences related to problems with the development and maintenance of synaptic function. In this study, we hypothesize that faulty activation of inhibitory interneuron subclasses by glutamate through metabotropic glutamate receptors (mGluRs) renders a major component of the inhibitory neurotransmitter system dysfunction in layer 2/3 of the somatosensory cortex. Whole-cell experiments suggests that: 1) While mGluR activation increases both sIPSC amplitude and frequency in control animals, DHPG (a mGluR agonist) application fails to increase sIPSC activity in *Fmr1* KO mice. 2) Somatostatin-positive interneurons (Sst) showed concentration-dependent mGluR activation, which triggers high frequency action potential firing in control animals. In contrast, Sst-interneurons from *Fmr1* KO mice showed a decreased action potential frequency in response to mGluR activation. 3) mGluR-

dependent plasticity mechanism of the inhibition such as slow self-inhibition (SSI) and inhibitory long term depression (LTDi) were both altered in the *Fmr1* KO mice. Thus, the overall mGluR-mediated activation of inhibitory synaptic plasticity is altered in *Fmr1* KO mice suggesting an increased inhibitory drive onto pyramidal cells. Concurrently, we also tested sensory responsiveness to stimulation of whiskers and neuronal cell activation in L2/3 of somatosensory cortex in anesthetized *Fmr1* KO mice. Tetrode recordings and single unit analysis revealed that the baseline rate of the recorded units is higher in KO mice. These are the first *in vivo* experiments showing that the cortex in *Fmr1* KO mice is hyperexcited at a basal state. Furthermore, when contralateral whiskers are stimulated with air puff, we find that subsets of cells respond differentially with either increases or decreases in firing rate in both groups. In the *Fmr1* KO, a higher percentage of units decrease their spike rate in response to whisker stimulation, suggesting the possibility of an enhanced inhibitory drive. Taken together these data suggest that neurons of the KO mice are hyperexcited and that the failure of mGluR-mediated mechanisms could compromise the normal inhibitory control of the network and further contribute as a homeostatic mechanism to the hyperactivity of the somatosensory cortex.

Title: *In vivo* detection of endogenous octopamine and serotonin upon conditioning-training stimuli in *Drosophila* mushroom bodies

Authors: *S. I. HIDALGO, N. FUENZALIDA-URIBE, D. F. MOLINA-MATEO, J. M. CAMPUSANO
Pontificia Univ. Católica De Chile, Santiago, Chile

Abstract: Biogenic Amines (BAs) are a group of molecules that act as neurotransmitters in the brain to modulate complex behaviors, including learning and memory formation. *Drosophila melanogaster*, an animal model with important genetic tools that shows similar mechanisms of neurotransmitter storage, release and recycling as compared to mammalian systems, has been extensively used in assays of aversive learning. In these protocols, a Pavlovian conditioning

approach is used. For instance, an electric shock is applied to flies (unconditioned stimulus, US) while they are exposed to an odorant (conditioning stimulus, CS). One of the open questions regarding this approach is what are the changes in fly brain neurotransmission during conditioning. To advance on this issue, we generated a new setup to measure the *in vivo* release of BAs in fly brain (fast scan cyclic voltammetry, FSCV) when the US and CS are applied.
A single male fly head was fixed to a recording chamber and the brain was exposed surgically. Using a carbon fiber electrode, we measured BAs release in fly brain scanning from −0.4 to 1.2 V and back (vs Ag/AgCl reference electrode; scan rate of 400 V/s at 10 Hz). As positive control for the identification and quantification of endogenous BAs in the fly brain, ATP-activated ion channels ($P2X_2$ receptors) were expressed in specific aminergic neuronal populations and activated by ATP. The electrode was placed in the Mushroom Body calycal region, identified by expression of GFP under the control of the c309-gal4 driver. Flies were exposed to a single electric shock (10 V) every 5 seconds via an electric grid. In addition, we used a vacuum pump to deliver one of two odorants; benzaldehyde or ethyl acetate.
Our results show that when ATP Is applied in flies expressing $P2X_2$ receptors in octopaminergic, tdc2-positive neurons, only octopamine is detected. When the ligand is applied in flies expressing the channel in ddc-positive neurons, the release of dopamine and serotonin is evidenced. On the other hand, release of octopamine is revealed in the Mushroom Body calyx upon application of electric shocks and mostly 5-HT is recorded upon odorant stimulation in this fly brain region. No release of BAs is detected when flies are stimulated using a nominal zero calcium solution, suggesting the amine release depends on synaptic processes.
Our results show a differential release of endogenous BAs in brains of flies exposed to stimuli relevant to olfactory learning and memory conditioning, consistent with the proposed roles for the different amines in this physiological process.

Title: L-proline,a metabolite linked to neuropsychiatric disorders and associated with the 22q11.2 deletion syndrome, specifically disrupts high-frequency GABA-ergic transmission

Authors: *G. W. CRABTREE[1], *G. W. CRABTREE[1], *G. W. CRABTREE[1], *G. W. CRABTREE[1], ***G. W. CRABTREE**[1], J. A. GOGOS[2,3]

Abstract: Accumulation of L-proline within the CNS, has been repeatedly correlated with predisposition to psychotic disorders. Proline dehydrogenase (PRODH), which degrades L-proline, resides within the 22q11.2 deletion a strong genetic risk factor for schizophrenia further suggesting L-proline maybe neuroactive and directly contribute significantly to neuropsychiatric symptomology. Previously we have shown that L-proline is GABA-mimetic. L-proline can activate both GABA-A and GABA-B receptors, however this only occurs far above CNS disease-relevant L-proline levels. At disease-relevant concentrations, L-proline GABA-mimesis appears limited to competitive blockade of glutamate decarboxylase (GAD) and causes reduced GABA production. Employing a mouse with a severely hypomorphic *Prodh* allele, we have shown with recordings from layer II/III mPFC pyramidal neurons in acute brain slices that mice with elevated CNS L-proline show isolated and specific disruptions of high-frequency GABA-ergic transmission. These deficits in GABA-ergic transmission were attributable to GAD-blockade due to elevated L-proline levels as revealed by pharmacological studies targeting GAD and GABA transaminase.
The interneuronal subtypes responsible for the observed alterations GABA-ergic transmission remain unknown although our previous results strongly suggest that parvalbumin-positive neurons (PV+) may be involved in the observed pathophysiology. Employing a PV-Cre mouse we have targeted channelrhodopsin expression to PV+ interneurons in the mPFC and performed a detailed assessment of light-evoked GABA-ergic transmission at layer II/III pyramidal neurons. Furthermore, as assessment of high-frequency synaptic transmission with channelrhodopsin can be problematic due to kinetic limitations of these channels, we employed two channelrhodopsin variants (ChETA and ChIEF) which showed marked performance differences under high-frequency stimulation. We have also initiated an exploration of GABA-ergic therapeutics that successfully rescue synaptic transmission deficits and behavioral alterations in hyperprolinemic mice. Together these findings provide evidence that deficient GABA-ergic transmission arising from PV+ interneurons may underlie the synaptic and gamma-oscillation deficits that arise due to elevated L-proline levels with wider implications for other disease-related GABA-mimetic metabolites. Further we show the promise of precisely targeted therapeutics in genetically well-defined neuropsychiatric disorders. This work was supported by NIH grants R21MH10069 and R01MH096274.

Title: Modulating effects of MDMA on spontaneous firing of the subthalamic nucleus neurons: a quantitative study

Authors: *C. MAHAPATRA[1], R. MANCHANDA[2]
[1]IIT Bombay, IIT Bombay, Powai,Mumbai, India; [2]Indian Inst. of Technol. Bombay, Mumbai, India

Abstract: MDMA has diverse psychological and physiological effects, particularly rewarding and addicting influences in both humans and animals. MDMA is considered as substrate of various neurotransmitter transporters to stimulate the efflux of neurotransmitter from vesicles into the cytosol. The subthalamic nucleus (STN) plays dominant role in several function of basal ganglia and its activity is regulated by 5-HT. This study presents a quantitative study of modulating effects of the MDMA on the firing pattern of the STN neuron via 5-HT receptors. Here the interpretation of MDMA and 5- HT are based on differential equations, where all parameters are borrowed from published data. Then, this neurotransmitter mechanism is incorporated into a published STN electrophysiological model. A brief square pulse of varied duration and magnitude is applied as an external stimulus current (I_{stim}) to trigger action potential (AP) in the whole cell model. Then MDMA concentration is varied to investigate the modulated response in AP and resting membrane potential. The single STN neuron model mimicked vigorous spontaneous action potential activity and the tonic firing pattern with regular inter-spike intervals similar to those found in experiment. The MDMA is simulated from 2 to 20 μM. We found that the mean and median firing rates in the simulation increased moderately and in a concentration- dependent manner with the application of MDMA. This finding from the simulation of STN neuron by MDMA agrees with the notion found in experimental studies, which mention that the effects of drug to its motor effects. The future extension of this preliminary study will reveal the heterogenic modulatory effects of MDMA in STN cell.

Title: An outward potassium current (M-current) is an estimate of the neuron's input

Authors: *A. R. ASILADOR[1,2,3], E. C. JOHNSON[2,3,4], R. RATNAM[1,2,3,5,6]
[1]Neurosci. Program, [2]Beckman Inst. for Advanced Sci. and Technol., [3]Coordinated Sci. Lab., [4]Electrical & Computer Engin., [5]Hlth. Care Engin. Systems Ctr., Univ. of Illinois at Urbana-Champaign, Urbana, IL; [6]Advanced Digital Sci. Ctr., Illinois at Singapore Pte Ltd, Singapore, Singapore

Abstract: Neural spike-trains carry information about the input to the neuron in the average rate of spikes or spike-times, etc. Recently we showed that a code that maximizes the fidelity of the coding for a given long-term spike-rate (a proxy for the neuron's metabolic energy consumption), will lead to a spike-timing code. We argued that a neuron is a precise coder where each spike is timed to optimize the energy-fidelity trade-off. Coding fidelity is determined from a reconstruction of the input signal from the spike-times. A prediction of this code is that the reconstruction is ongoing with the spike generation, and manifests as a dynamic or adaptive threshold. Here we explore the biophysical mechanisms that support these ideas, and in particular postulate that the muscaranic or M-current (an outward potassium current) is the reconstruction of the input. The M-current has been implicated in spike-frequency adaptation. We tested this idea using *in vitro* current-clamp data from L5 pyramidal neurons in the rat somatosensory cortex (available from the International Neuroinformatic Coordinating Facility or INCF, Spike-time Prediction Challenge, 2009; see Gerstner and Naud, 2009). We first constructed a conductance-based (Hodgkin-Huxley type) single-neuron model with 8-10 conductances. We next determined the best values of linear and nonlinear gating and conductance parameters so that for a given injected current, the predicted time-varying membrane potential matched the experimental data. The best match to the data was determined from an optimization method proposed previously by the Abarbanel group (Meliza et al., 2014). There is good match of the sub-threshold membrane potential, spike waveform, and spike-timing with a few missed or added spikes. Analysis of currents through various channels show that the M-current is the dominant outward current that closely matches the injected current, and may

serve as a candidate decoder for reconstructing the stimulus from the ongoing spike train. Having an internal decoder allows the neuron to monitor the fidelity of coding on a moment-by-moment basis, and rapidly regulate the timing of action potentials to minimize coding error. In this process, the long-term spike rate (energy consumption) sets a bound on the coding error. These results broadly support the idea that selection pressure has most likely led to biophysical mechanisms for energy-efficient high fidelity coding.

Title: Light-induced activation of dopamine, glutamate and GABA release on striatal medium spiny neurons in brain slices

Authors: *E. MCKIMM, T. PASTIKA, M. B. SINGH, J. A. WHITE, S. D. ANTIC
Inst. of Systems Genomics, Univ. of Connecticut Hlth., Farmington, CT

Abstract: The nigrostriatal pathway, originating in the substantia nigra (SN) and terminating in the striatum, plays a critical role on cognitive and motor functions relevant to a variety of disorders including Parkinson’s disease, addiction, and schizophrenia. Striatal medium spiny neurons (MSNs) bear dopaminergic receptors whose activation influences behavior and cognition. A transgenic mouse with light-sensitive channels in dopaminergic neurons (DAT-ChR2) is routinely used to evaluate the physiology of dopamine (DA) neurotransmission. The present study explores the simultaneous transmission of DA, glutamate and GABA, upon blue light (475 nm) activation of DAergic axons in the striatum (brain slices) by whole-cell recordings of the postsynaptic responses in MSNs. Repetitive light activation of striatal DAergic fibers revealed a strong depression of the amino acid neurotransmitter output from these fibers, with a relative refractory period of approximately 10,000 ms. However, successive light pulses on the cell bodies of DAergic neurons in SN showed a 100-fold shorter refractory period (100 ms) for firing somatic action potentials. These differences in recovery time suggest inefficient transmission of information from DA axons to MSNs, or likely the result of severing the axons in slice preparations. A pharmacological block of DA receptors did not produce any effects on light-induced synaptic currents in MSNs. In other words, DA release appeared not to have any effect on the postsynaptic glutamate and GABA currents, although both glutamate, GABA and DA were stimulated by the same pulse of light. Further exploration of light- and synaptically-

induced DA-glutamate co-release will allow for a more thorough understanding of the complex relation between glutamate and DA on neuropsychiatric disorders influenced by the nigrostriatal pathway.

Title: A new $GABA_A$ anesthetic that discriminates between tonic, fast and slow synaptic inhibition

Authors: *N. S. CAYLA[1], B. A. DAGNE[1], M. F. DAVIES[1,2], Y. WU[1], E. R. GROSS[1], M. B. MACIVER[1], E. J. BERTACCINI[1,3]
[1]Anesthesia, Stanford Sch. of Med., Stanford, CA; [2]Dva, [3]DVA, VA Hlth. Care system, Palo Alto, CA

Abstract: Background: GABA receptors are important molecular targets for anesthetics, but it remains unclear how these receptors are involved in producing unconsciousness or contributing to unwanted side effects. Our group has developed new anesthetic agents that specifically target $GABA_A$ receptors. Using an *in silico* docking-based screening program, a novel molecular core was designed to target the same binding site as etomidate and eliminate the common side effect of adrenal suppression. The top ten compounds generated by the program were first tested on tadpoles, then in rat brain slice electrophysiology experiments. Finally, *in vivo* experiments were conducted with propofol, etomidate, and the most promising compound (BB) to compare their hemodynamic effects.
Methods: For the *in vivo* studies, the compounds were pipetted into the amphibians' water and rats were administered drugs by intravenous bolus. For electrophysiology, rat brain slices were submerged in artificial cerebrospinal fluid (ACSF). In the hippocampal CA1 region, bipolar tungsten stimulating electrodes were used to evoke field potentials via Schaffer-collateral fibers. Field potentials were recorded using a microelectrode placed near the pyramidal cell body. Control recordings were acquired with brain slices in ACSF before and after compound

exposure. Additionally, we compared BB to propofol and etomidate, agents known to selectively increase $GABA_AR$-mediated inhibition, and picrotoxin, a chloride channel blocker coupled to $GABA_ARs$.
Results: When exposed to BB, tadpoles and rats quickly lost consciousness, then fully recovered. Also rats' heart rate and blood pressure appeared more stable compared to propofol's exposure. Our electrophysiology results show that BB and etomidate produced a reversible enhancement of $GABA_AR$-mediated inhibition that appeared to be more selective than propofol. All of BB's effects occurred through the specific $GABA_A$-slow receptors, like etomidate. Propofol, in contrast, clearly enhanced other forms of $GABA_AR$-mediated inhibition. The effects of both agents were fully reversed by picrotoxin.
Conclusion: BB has an anesthetic effect via $GABA_ARs$ as predicted. BB were more selective than propofol, which acts mainly on $GABA_A$-fast and -tonic receptors, instead of the $GABA_A$-slow receptors that are most sensitive to BB. This $GABA_AR$ selectivity could account for the observed decrease in undesirable side effects on hemodynamics compared to propofol. Thus, our results suggest that anesthetic action on subtypes of $GABA_ARs$ contributes to both desired and undesired effects, so more selective targeting holds great promise for developing safer anesthetics.

Title: Towards a maximalist α-amino-3-hydroxy-5-methyl-4-isoxazolepropionic acid receptor-centric biochemical model of the synapse and its application in neurodevelopmental disease research

Authors: *R. FITZPATRICK[1], U. S. BHALLA[2], M. I. STEFAN[1]
[1]Univ. of Edinburgh, Edinburgh, United Kingdom; [2]Natl. Ctr. For Biol. Sci., Bangalore, India

Abstract: α-amino-3-hydroxy-5-methyl-4-isoxazolepropionic acid (AMPA) receptors are a class of ionotropic glutamate receptors primarily responsible for fast synaptic transmission in the central nervous system. Their action is critically linked to learning and memory, and are tightly regulated within the postsynaptic environment. To date, there have only been a few attempts to model AMPA receptor (AMPAR) activity at the synapse in any great detail. In most cases, these models focus on specific aspects of AMPAR function or lifecycle (e.g Gallimore, 2016, Dutta-

Roy *et al.*, 2015), and avoid simulation of the surrounding biochemical environment. This model, utilising the Complex Pathway Simulator (COPASI) modelling software, has a core of two major signalling pathway models. The first is an AMPA receptor (AMPAR) trafficking model generated by Hayer and Bhalla (2005), which also includes NMDA receptor-mediated CaMKII autophosphorylation. The second is the mGluR signalling cascade from Iyengar and Bhalla (1999). This component includes Ras/Raf activity and MAPK pathways, and connects to the other core component via PP1 and CaMKII activity. The combined model allows for mGluR activation to modulate AMPARs within a generic hippocampal pyramidal cell dendrite. This affects the rate of trafficking of receptors from the endocytic pool to the membrane to initiate stable 'high states' during pseudo-LTP situations. Additionally, the CaMKII autophosphorylation acts as a bistable switch to further retain information across days of simulation. The model thus acts to retain system state information without the maintenance of the original molecules being necessary. Our current goal is twofold. First is to build upon this to generate a comprehensive postsynaptic signalling model comprising of pre-existing and novel models. Second is to retain a focus on AMPA receptors within this model to allow for future focus on how their dynamics alter in neurodevelopmental disease states such as Fragile X Syndrome. We present here the initial undertakings of the model, showcasing the retention of each individual sub-models' published outputs, and how well the model describes other experimental work surrounding AMPAR trafficking and modulation by other pathways. These *in silico* experiments may now act as a bedrock to use this model with more explanatory analyses in mind.

Title: Adenosine A1 receptor agonist induces gene expression changes in light induced retinal degeneration

Authors: M. SOLIÑO[1], I. M. LARRAYOZ[2], E. M. LÓPEZ[1], M. REY-FUNES[1], A. MARTÍNEZ[2], E. GIRARDI[1], *J. J. LOPEZ-COSTA[1]

Abstract: A1 receptor (A1R) has been described in the retina and has been linked to the control of the characteristics of the subretinal space. A1R plays a role in inflammation, neuronal and trophic factor activity. Recently, in our lab, the modulation of A1R emerged as an effective neuroprotective strategy of the retina in the model of light induced retinal degeneration (LIRD). In order to further characterize the neuroprotective effects underlying A1R agonist treatment, mRNA changes induced by N6-cyclopentyladenosine (CPA), an A1R agonist, were studied in the retina using a LIRD model. Sprague Dawley rats received a single intravitreal injection of either CPA or vehicle, and then were subjected to continuous illumination (CI) (12000 lux) during 1 day. After this, the retinas were extracted and processed by RT-PCR. We selected as genes of interest adenosine receptors (A1, A2a, A2b and A3), proangiogenic factors (adrenomedullin and VEGF), an antiangiogenic factor (PEDF), inflammation mediators (IL-1b, iNOS, nNOS, and TNF) and a glial reactivity marker (GFAP). Data were statistically analysed using t-test on the Graphpad Prism software. RT-PCR results showed a significant decrease of A1, A2a, and A2b receptor mRNA in the retina of CPA treated eyes ($p<0.05$ in every case) while no changes in A3 mRNA were observed. A strong trend ($p=0.0515$) towards a decrease in adrenomedullin mRNA was observed), while VEGF expression did not change. Surprisingly, PEDF mRNA also decreased significantly ($p<0.05$) in CPA treated eyes. IL-1b, iNOS, and TNFα also showed a tendency to lower levels of expression in the retinas of CPA treated eyes although they were not statistically significant. nNOS mRNA did not change. GFAP mRNA was also significantly reduced by CPA ($p<0.05$). Our results show that CPA, an A1 agonist, is able to prevent the retinal damage induced by excessive light exposure. We believe that this is, at least, partially accomplished by a shift in the regulation of gene expression at the transcriptional level of diverse genes implicated in adenosine mediated transmission, angiogenesis, inflammation, and glial reactivity. Obviously, other genes such as those encoding programmed cell death or survival and/or proliferation signals may be also affected. Further research is needed to test to the full extent the potential therapeutic effects of A1R in retinal degenerations, a set of still untreatable maladies.

Title: A dynamic clamp on every rig

Authors: *N. S. DESAI, R. GRAY, D. JOHNSTON
Ctr. for Learning and Memory, Univ. of Texas at Austin, Austin, TX

Abstract: The dynamic clamp should be a standard part of every cellular electrophysiologist's toolbox. That it is not, even 25 years after its introduction, comes down to three issues: money, the disruption adding dynamic clamp to an existing patch clamp rig entails, and the technical prowess required of experimenters. These have been valid and limiting issues in the past, but no longer. Technological advances associated with the so-called "maker movement" render them moot. We demonstrate this by implementing a fast (>20 kHz) dynamic clamp system using an inexpensive microcontroller (Teensy 3.6). Assembling the system requires no prior electronics experience and modifying it - for example, to add Hodgkin-Huxley-style conductances - requires no prior programming experience. The system works together with existing patch clamp data acquisition systems (for Macintosh, Windows, and Linux); it does not attempt to supplant them. Moreover, the process of assembling, modifying, and using the system constitutes a useful pedagogical exercise for students and researchers with no background but an interest in electronics and programming. We demonstrate the system's utility by implementing conductances as fast as a transient sodium conductance and as complex as the Ornstein-Uhlenbeck conductances of the "point conductance" model of synaptic background activity.

Title: Fast-scan cyclic voltammetry to differentiate structurally similar monoamines

Authors: *A. M. BELLE, B. J. BELMONT, A. M. YORITA, C. SUPIN
Materials Engin. Dept., Lawrence Livermore Natl. Lab., Livermore, CA

Abstract: Fast-scan cyclic voltammetry is an established technique that allows for selective, quantitative electrochemical detection of many key neurotransmitters including but not limited to dopamine (DA) and norepinephrine (NE). But, even with the application of specialized voltammetric waveforms and the addition of selective membranes to the electrode surface the

technique cannot differentiate structurally similar molecules. For example, despite the very distinct functions they serve in the body, the difference structurally between DA and NE is only a single hydroxyl group. Here we present a method that allows fast-scan cyclic voltammetry to determine and differentiate a pure or mixed monoamine signal. This differentiation occurs through the application of different voltammetric waveforms to four distinct electrodes in close proximity to one another followed by interpretation of signal ratios from the electrode array. The use of additional electrodes and waveforms allows us to separate otherwise similar signals through use of slight differences in kinetics and adsorption of two very similar molecules. In vitro results show that there are differences in the sensitivity of different voltammetric waveforms to NE and DA. Through optimization of the waveforms used with this technique the signal ratios from all waveforms create a distinct signature for both NE and DA. Use of these distinct ratios allows in vitro determination of the purity of a DA or NE signal. Finally, use of singular value decomposition analysis combined with this multi-waveform, multi-electrode technique shows promise for its use differentiating DA and NE in vivo as well.

Title: Reconstructing circuit development in the zebrafish embryonic spinal cord at the single-cell level

Authors: *Y. WAN[1], Z. WEI[2], S. DRUCKMANN[3], P. KELLER[4]
[1]HHMI Janelia Res. Campus, Ashburn, VA; [2]Janelia Res. Campus, Ashburn, VA; [3]Howard Hughes Med. Inst. Janelia Farm Res. Campus, Ashburn, VA; [4]HHMI Janleia Res. Campus, Ashburn, VA

Abstract: Spontaneous, patterned neuronal activity has been closely linked to developmental mechanisms shaping the early nervous system and is suggested to play a key role in the fine-tuning of developing circuits. However, little is known about how patterned activity emerges de novo and what factors control this maturation process. The lack of functional recordings at the whole-circuit level with single-neuron resolution and throughout the period over which patterned activity emerges has been a major limitation to understanding the roles of individual neurons in circuit formation. Here, we use Simultaneous Multi-view (SiMView) Light-sheet Microscopy to image the emergence of patterned activity in the developing spinal cord of embryonic zebrafish

and mapped calcium activity in all post-mitotic neurons for a large fraction of the developing spinal cord at a temporal resolution of 4 Hz. These data show that spinal cord neurons undergo a rapid transition from sporadic single-neuron activity to ipsi-laterally correlated and contra-laterally anti-correlated activity between 18 and 22 hours post fertilization. We developed a computational model to reconstruct the maturation process of this spinal cord circuit from our image data at the single-neuron level, characterized dynamic changes in functional connectivity as a function of time, and mapped the process onto a digital anatomical atlas. We found that early activity first emerges in neurons with conserved segmental distribution, and neighboring communities subsequently merge by synchronization to form a patterned network. Finally, we identified the cell types of active neurons using genetic and histological markers and found that different types of neurons play distinct roles in circuit maturation. Motor neurons appear to serve as pioneers in the emergence of local functional communities, whereas dorsal commissural neurons may play a key role in establishing and maintaining the phase-locked state between left and right hemi-segments of the spinal cord. The function of glycinergic commissural neurons was further confirmed by ablation and characterization of genetically manipulated fish with abnormal glycinergic transmission. By combining this characterization of the functional maturation process with developmental imaging we furthermore established a method for systematically studying the role of cell lineages and embryonic morphogenesis in the context of circuit formation.

Title: Imaging membrane potential of the endoplasmic reticulum with a genetically-encoded voltage indicator

Authors: *M. SEPEHRI RAD[1], L. B. COHEN[1,2], B. J. BAKER[1]
[1]Korea Inst. of Sci. and Technol., Seoul, Korea, Republic of; [2]Yale Univ. Dept. of Cell. and Mol. Physiol., New haven, CT

Abstract: In eukaryotic cells, the endoplasmic reticulum (ER) is the largest continuous membrane-enclosed network which surrounds a single lumen. Using a newly designed genetically encoded voltage indicator (GEVI), we applied the patch clamp technique to HEK293 cells and found that there is an electrical interaction between plasma membrane and ER membrane. We have optically monitored the voltage changes in both of these membranes simultaneously. The optical signal of the GEVI in the plasma membrane is consistent from trial to trial. However, the ER signal decreases in size with repeated trials while the plasma membrane resistance remains constant. This dynamic behavior of the internal signal suggests that voltage may stress the ER causing it to remodel and change its resistance. Our findings further suggest that the ER may transfer electrical signals from the plasma membrane to the nuclear envelope.

Abstract: There has been needs for better models of neurological and neurodegenerative disorders besides rodents and other animal models. Human iPS cell (hiPSc) and hiPSc-derived neuronal models have emerged as novel cell models and drug screening platforms for these disorders. We have established multiple human iPS-derived neural and organoid models for autism, schizophrenia, epilepsy and Alzheimer's disease, etc.Our neural networks fully represent the excitatory and inhibitory balance of human brain and contain PV, nNOS and other interneurons that are critical for these disorders.Comparing to control hiPSc-derived neural networks, these patient hiPSc-derived neural networks show siginificant deficits in mutltiple assays and readouts. Our hiPSc neural models will greatly promote drug and biomarker discovery for these neurological disorders.

Abstract: Establishing specific cell lineages from human induced pluripotent stem cells (ihPSCs) is vital for novel cell therapy approaches in regenerative medicine, particularly neurodegenerative disorders. Human neural precursors have been induced from ihPSCs. The establishment of human neural stem cells from ihPSCs (ihNSCs), with characteristics that are vital to warrant cGMP certification and clinical usage and that match those of allogeneic fetal hNSCs used in phase I/II clinical trials, has yet to be accomplished. By a virus-free technique, we established ihNSCs whose characteristics were compared and confirmed to overlap with those of the clinical grade hNSCs, successfully used in a phase I clinical trial on ALS patients. iPSCs lines were generated by the nucleofection of adult fibroblasts with episomal vectors that do not integrate into the host genome, and subsequently neuralized by using a chemically defined, serum free medium that permitted the exclusive expansion of the hNSCs. The 5 ihNSCs lines that fulfill all the functional requirements to be considered *bona fide* stem cells according to the Neurosphere Assay (long-term proliferation, self-renewal and multipotency). These lines steadily maintain their functional properties after extensive *in vitro* manipulation (up to 25

passages), critically depend on EGF and FGF2 for extensive self-renewal and spontaneously differentiate into astrocytes, oligodendrocytes and neurons upon their removal ex-vivo. Whole transcriptome sequencing of ihNSCs, followed by stringent bionformatic scrutiny, confirmed the neural and stem identity of these cells. Karyotype stability over passages and long term transplantation studies (6 months) into the brain of immune-deficient animal, have further confirmed the safety and non-tumorigenicity of ihNSCs. To validate the use these cells for therapeutic purposes we have molecularly and functionally compared the ihNSCs with clinical grade, fetal brain-derived hNSCs and showed that the proliferation rate, the differentiation abilities and safe integration into the CNS are coinciding between the hNSCs derived from the two sources.
This technique, which will be promptly translated into a cGMP compliant setting, paves the way to the establishment of clinical-grade certified, ihNSC lines for standardized clinical trials.

Title: Differential input resistance underlies asymmetrical electrical coupling between identified cardiorespiratory neurons

Authors: G. Z. ZHU[1], A. AZIZ[1], Y. GU[1], *N. S. MAGOSKI[2]
[1]Biomed. and Mol. Sci., [2]Queen's Univ., Kingston, ON, Canada

Abstract: Electrical transmission ensures firing synchrony and recruitment within neuronal circuits. Coupling is often symmetrical, where the extent to which a voltage change in one neuron alters the voltage of a second neuron is the same in both directions. However, coupling can also be asymmetrical, where the postsynaptic voltage change is different depending on the direction. Possible mechanisms for asymmetry include differential junctional conductance or differential input resistance. The present study examines asymmetrical coupling between two neurons from the freshwater pond snail, *Lymnaea stagnalis*. The neurons in question, identified as Visceral Dorsal 1 (VD1) and Right Parietal Dorsal 2 (RPD2), are tonically active, innervate the heart, mantle, and pneumostome, and synthesize both a met-enkephalin-like peptide as well

as so-called VD1/RPD2 peptides. Dual sharp-electrode current-clamp recordings from isolated brains found that the VD1 to RPD2 coupling coefficient was greater than that of RPD2 to VD1. Prior work showed the junctional conductance between VD1 and RPD2 to be equal in both directions; thus, we examined input resistance and observed that VD1 was more resistive than RPD2. If the neurons were hyperpolarized, both the input resistance of RPD2 and the RPD2 to VD1 coupling coefficient increased, while the VD1 resistance or the VD1 to RPD2 coupling remained stable. To employ a more physiological stimulus, dopamine was pressure-applied to the soma of either VD1 or RPD2. This resulted in transient inhibition of a given neuron, which also transferred to the coupled partner asymmetrically; similar to the coupling coefficients, this transfer of inhibition was greater from VD1 to RPD2 than vice versa. These data suggest that the VD1-RPD2 asymmetrical coupling is due to differential input resistance, where current, either from the recording electrode or the dopamine response, arising in the higher-resistance VD1 flows more readily through the junction to RPD2. Hyperpolarization renders the synapse symmetrical by causing a selective increase in RPD2 resistance and subsequently promoting current flow to VD1. The role of VD1 and RPD2 is to provide a constant stimulatory drive to the heart and various respiratory organs, with VD1 serving as the master oscillator and RPD2 as the follower. Asymmetrical coupling may guarantee that at resting membrane potential, or at least in a manner analagous to coupling coefficient, interspike membrane potential, RPD2 always follows the output of VD1.

Title: A synthetic neurotransmission system to selectively modulate synaptic strength with intrinsic encoding and connectivity

Authors: *C. MCKENZIE, H. JANOVJAK
IST Austria, Klosterneuburg, Austria

Abstract: A major challenge in neuroscience research is to dissect the circuits that orchestrate behavior in health and disease. Proteins from a wide range of non-mammalian species, such as microbial opsins, have been successfully transplanted to specific neuronal targets to override their natural communication patterns. The goal of our work is to manipulate synaptic communication in a manner that closely incorporates the functional intricacies of synapses by

preserving temporal encoding (i.e. the firing pattern of the presynaptic neuron) and connectivity (i.e. target specific synapses rather than specific neurons). Our strategy to achieve this goal builds on the use of non-mammalian transplants to create a synthetic synapse. The mode of modulation comes from pre-synaptic uptake of a synthetic neurotransmitter (SN) into synaptic vesicles by means of a genetically targeted transporter selective for SN. Upon natural vesicular release, exposure of the SN to the synaptic cleft will modify the post-synaptic potential through an orthogonal ligand gated ion channel. To achieve this we have functionally characterized, in human embryonic kidney (HEK) 293 cells, primary dissociated neurons, and co-cultures, a mixed cationic methionine (met) gated ion channel from Arabidopsis thaliana and multiple prokaryotic uptake systems that are substrate specific for met. Synthetic synapses will provide a unique opportunity to manipulate synaptic communication while maintaining the electrophysiological integrity of the pre-synaptic cell. In this way information may be preserved that was generated in upstream circuits and that could be essential for concerted function and information processing.

Title: Reduction of the crayfish caudal photoreceptor firing rate during anesthesia

Authors: *J. R. DEARWORTH, Jr., S. C. NESBIT
Lafayette Col., Easton, PA

Abstract: Ketamine and pentobarbital are two anesthetics that have been shown to inhibit activity of crayfish cells, whereas xylazine is an anesthetic that had not previously been tested in the animal. Xylazine was predicted to reduce action potential firing rate because the drug exhibits its anesthetic effects by blocking calcium ion flow into the neuron. One type of neuron that was used to test the effects of xylazine anesthesia in the crayfish was the caudal photoreceptor. Two of these cells are located in the crayfish sixth abdominal ganglion and they respond to light presentation by increasing firing rate and are thought to be involved in circadian rhythmicity. The caudal photoreceptor light response served as an assay to compare the effects of the aforementioned drugs on the non-image-forming visual system. Doses of drugs were first determined by their ability to block cheliped closure and eyestalk withdrawal reflexes. ED_{100} of xylazine, ketamine, and pentobarbital were 128 mg/kg, 125 mg/kg, and 160 mg/kg, respectively. *In vitro* extracellular electrical recording done in 60 crayfish showed administration of anesthetics at ED_{100} reduced the caudal photoreceptor firing rate during light presentation. In

addition, latency of light response was increased by ketamine administration, but spontaneous activity was not affected. These results suggest that anesthetic administration in the crayfish can interfere with functions of the caudal photoreceptors.

[1]King's Col. London, London, United Kingdom; [2]Mol. and Cell. Biol., [4]Ctr. for Brain Sci., [3]Harvard Univ., Cambridge, MA; [5]MRC Ctr. Dev. Neurobiol., London, United Kingdom

Abstract: One of the key questions in modern neurobiology is how the environment influences the brain. How does the brain respond to alterations in experience to plastically modify itself at the cellular level? Since the first demonstration of functional synaptic plasticity, two additional broad classes of neuronal plasticity - intrinsic and structural - have been characterized. Up to now these processes have largely been studied in isolation. Neurons,however,do not singularly adopt plasticity mechanisms, and it has become of primary importance to understand how they combine within individual cells and how they impact information processing in neuronal networks. Here we describe an integrated synthesis of sensory-induced neuronal plasticity - structural, intrinsic and synaptic - in a well-defined cell population: dopaminergic (DA) neurons in the olfactory bulb (OB). Bulbar DA neurons are extremely plastic, and act at a crucial point in the olfactory pathway to inhibitinformation transmission from nose to cortex. Using a reliable, physiologically-relevant and reversible means of altering sensory experience, we compared activity-dependent plasticity in OB DA neurons in juvenile mice subjected to 24h unilateral naris occlusion. We combined *ex vivo* immunohistochemistry, *in vitro* patch-clamp recordings and *in vivo* functional imaging to uncover activity-dependent structural modifications of the axon initial segment that are tightly linked with intrinsic firing properties, and are associated with striking decreases in odour-evoked activity. These integrated plastic changes at the cellular level have the potential to underlie network-level compensatory adaptation to alterations in sensory input, allowing maintained levels of sensory performance in an ever-changing world.

Title: Cell-autonomous homeostatic mechanisms activated by activity deprivation

Authors: *V. VALAKH, S. NELSON
Biol., Brandeis, Waltham, MA

Abstract: Homeostatic regulation of neuronal function is an important form of plasticity that allows for stability of the brain circuit throughout development and in response to activity perturbation. The importance of these changes is illustrated by the network response to chronic activity deprivation. *In vivo*, as well as in organotypic slice culture model, prolonged activity deprivation via tetrodotoxin (TTX) causes the network to develop frequent, highly synchronous bouts of activity. This network response to global activity withdrawal is accompanied by profound changes in cortical excitatory synaptic input and inhibitory synaptic input, as well as intrinsic excitability of both inhibitory and excitatory neurons. While some of these changes, such as excitatory synaptic input, are known to be driven cell-autonomously in excitatory cells, the time scale and whether other synaptic and intrinsic changes in excitatory and inhibitory cell types are similarly regulated is much less clear. The focus of this research is to understand the mechanisms that drive each of these changes and whether cell-autonomous silencing of individual neurons is sufficient to drive this form of plasticity. We have employed optically-activated anion channels (Govorunova et al., 2015) to reversibly silence individual cells in an otherwise non-perturbed network. Since the organotypic slice culture network develops spontaneous bouts of activity, termed Up states, it is important for the inhibition to be strong enough to prevent the cell from firing even during the strong excitatory input the cell receives during one of those Up states. Indeed, during light stimulation, the cells expressing the anion channel rhodopsin do not fire action potentials in response to a series of depolarizing steps or during an Up state, while the rest of the network remains intact. Upon 3 days of continuous light activation, silenced pyramidal neurons become more excitable demonstrating that changes in intrinsic excitability are driven by cell-autonomous mechanisms and 3 days of silencing is sufficient. Further experiments will determine whether inhibitory synaptic input is also regulated cell-autonomously and whether the same type of regulation exists in other cell types.

Title: Metaplasticity at CA1 synapses by homeostatic control of presynaptic release dynamics

Authors: *J.-C. BEIQUE[1], C. SOARES[2], K. F. LEE[3]
[1]Cell. and Mol. Med., [3]Cell. & Mol. Medicine, RGN3501N, [2]Univ. of Ottawa, Ottawa, ON, Canada

Abstract: Hebbian and homeostatic forms of synaptic plasticity operate on different time scales to regulate synaptic strength. The degree of mechanistic overlap between these plasticity processes, and their mutual influence, are still incompletely understood. Here, we found that the homeostatic synaptic strengthening that develops in response to prolonged network inactivity was accompanied by a compromised ability of CA1 synapses to exhibit LTP. This effect could not be accounted for by an obvious deficit in the postsynaptic capacity for LTP expression, since neither the fraction of silent synapses nor the ability to induce LTP by two-photon glutamate uncaging were reduced by the homeostatic process. Rather, optical quantal analysis revealed that homeostatically strengthened synapses displayed a markedly reduced capacity to maintain glutamate release fidelity during repetitive stimulation, ultimately impeding the induction, and thus expression, of LTP. By regulating short-term dynamics of glutamate release, the homeostatic process thus influences key features of dynamical network function and exhibits features of metaplasticity.

Title: GABAergic and AMPAergic synaptic scaling appear to have different trigger mechanisms in mouse cortical neurons

Authors: *C. E. GONZALEZ-ISLAS[1,3], P. BUELOW[4], P. A. WENNER[2]
[2]Physiol., [1]Emory Univ. Sch. of Med., Atlanta, GA; [3]Ciencias Biológicas, Univ. Autonoma de Tlaxcala, Tlaxcala, Mexico, Mexico; [4]Physiol. & Cell Biol., Emory Univ., Atlanta, GA

Abstract: Neuronal networks respond to challenges to their activity levels by triggering a set of homeostatic mechanisms aimed to stabilize the network firing rate. Such mechanisms are generically known as homeostatic plasticity. The most widely studied form of homeostatic plasticity is called synaptic scaling, characterized by multiplicative changes in the strength of the synaptic inputs onto a neuron. In a recent study, we demonstrated in cortical cultures that AMPAergic upscaling was triggered by reduced AMPAergic neurotransmission (receptor activation) rather than reduced spiking activity. We were able to do this by optogenetically maintaining spike rate while blocking AMPAergic transmission. In addition, we enhanced AMPA receptor activation while blocking activity with TTX by increasing mEPSC amplitude and frequency (cyclothiazide - CTZ) for 24hrs and found that this attenuated scaling. Our findings suggested that AMPAergic scaling was a mechanism of synaptic compensation rather than a homeostatic regulation of a cell's spike rate. In the current study, we intend to repeat the above experiments and test the distinct roles of spiking and neurotransmission as triggers for GABAergic scaling in mouse cortical cultures. Here we are reporting that 24hr treatment with Na+ channel blocker TTX or AMPA receptor (AMPAR) antagonist CNQX, produced a downscaling of GABAergic miniature postsynaptic current amplitude (GABA mPSC, reduced to ~53% of controls) with no significant change in GABA mPSC frequency. Simultaneous treatment of TTX and CTZ for 24hr to restore some AMPAergic neurotransmission produced a GABAergic downscaling that was no different than TTX treatment alone (reduced to ~56% of controls). These results are consistent with the idea that GABAergic synaptic scaling is triggered by reductions in spiking levels rather than AMPAergic transmission and therefore, the triggers for AMPAergic and GABAergic scaling are different. We will continue testing this possibility by maintaining spike activity optogenetically in the presence of AMPAR antagonists.

Title: Binding of calcium/calmodulin to PSD-95 N-terminus mediates homeostatic synaptic downscaling

Authors: *D. CHOWDHURY[1,2], M. TURNER[3], T. PATRIARCHI[2], C.-Y. CHEN[2], J. B. AMES[3], J. W. HELL[2]

Abstract: The postsynaptic density scaffold protein PSD-95 is a key organizer of excitatory synapses. Abundance of glutamate receptors at the synapse, and thereby synaptic strength, is determined largely by synaptic PSD-95 abundance which, in turn, is regulated by activity. However, the mechanisms underlying the activity-induced regulation of PSD-95 synaptic localization are not clearly understood. Previous work from our lab has shown that influx of calcium following synaptic activation induces dispersal of PSD-95 from dendritic spines via binding of Ca^{2+}/Calmodulin (CaM) to the N-terminus of PSD-95 that reduces its palmitoylation (Zhang et al., *EMBO J,* 2014). The current study elucidated the role of PSD-95-CaM interaction in mediating removal of PSD-95 from synapses that accompanies homeostatic synaptic scaling down. Using peptide screening and NMR structural analysis, we identified E17 and T19 within PSD-95 N-terminus as the critical residues interacting with CaM. We generated CaM-binding-defective mutants (E17R and T19K) to test their role in PSD-95 mobilization seen in homeostatic scaling down. Using fluorescence microscopy, we observed that chronic elevation of network activity with the GABA-A receptor antagonist bicuculline reduced PSD-95 spine enrichment in cultured hippocampal neurons, but replacement of endogenous PSD-95 with either mutant blocked this effect. Moreover, each mutant blocked reduction of surface AMPA-type glutamate receptors (AMPARs) during scaling down. Further, charge inversion mutations of the interacting residues on CaM, compensating for PSD-95 mutations, restored scaling down of AMPARs. Using miniature excitatory postsynaptic current (mEPSC) analysis, the role of this interaction in regulating synaptic AMPARs in scaling down was confirmed. Overall, our findings define a specific molecular step in homeostatic synaptic scaling down. Reference: Y. Zhang, L. Matt, T. Patriarchi, Z.A. Malik, D. Chowdhury, D.K. Park, A. Renieri, J.B. Title: PRG1 acts as a modulator of lipid signaling at the dendritic spine

Authors: *G. PAYRHUBER[1], W. FAN[1], A. STROH[1], R. NITSCH[2], J. VOGT[1]
[1]Univ. Med. Ctr. Mainz, Mainz, Germany; [2]Univ. Med. Ctr. Münster, Münster, Germany

Abstract: Plasticity related gene 1 (PRG1) is a transmembrane protein expressed at the postsynaptic density of excitatory neurons where it is supposed to interact with lysophosphatidic acid (LPA). Synaptic LPA binds to and activates the presynaptic LPA2 receptor leading to an increased glutamate release probability from presynaptic terminals (Trimbuch et al., 2009). Using fast 2-Photon-Microscopy live imaging and fluorescence-labeled LPA (TF-LPA), we can now show that PRG-1 plays a crucial role in LPA-uptake in postsynaptic compartments. A short puff of TF-LPA onto a dendritic spine resulted in an increase in fluorescence in the adjacent dendritic spine. This increase lasted for about 4.5 seconds in wildtype neurons, before the fluorescence level dropped down to baseline levels. However, in PRG1 KO neurons the increase in fluorescence in the spine was significantly shorter (around 2 seconds) when compared to the wildtype neurons. Using Pitstop2, a specific blocker of clathrin-dependent endocytosis, we could exclude endocytosis as a mechanism of postsynaptic LPA-uptake. Together with further pharmacological and electrophysiological characterization of this postsynaptic LPA uptake, our data suggests that PRG-1 at the postsynaptic density exerts a “pore or channel like” function critically important for synaptic LPA-uptake into postsynaptic compartments.

Title: The long-term maintenance of homeostatic synaptic plasticity is reversible, temperature sensitive, and controlled by an intracellular calcium-handling pathway

Authors: *C. FRANK[1], T. D. JAMES[2], C. J. NEFF[3]
[1]Anat. and Cell Biol., [2]Dept. of Anat. and Cell Biol., [3]Interdisciplinary Grad. Program in Neurosci., Univ. of Iowa, Iowa City, IA

Abstract: Synapses and circuits employ homeostatic regulatory mechanisms to ensure physiologically appropriate levels of synaptic output. Improved knowledge about how forms of homeostatic synaptic plasticity (HSP) are induced and sustained throughout life should lead to an improved understanding of neurological disorders that occur when synapse stability is lost. The *Drosophila melanogaster* neuromuscular junction (NMJ) is an excellent model synapse to uncover such information. At the NMJ, genetic and pharmacological manipulations can decrease the sensitivity of postsynaptic receptors to single vesicles of neurotransmitter (quantal size). Decreased quantal size triggers retrograde, muscle-to-nerve signaling that drives increased transmitter release. In recent years, the NMJ has been key in characterizing some conserved presynaptic processes that trigger a rapid homeostatic potentiation of neurotransmitter release. However, growing evidence also demonstrates that additional factors drive the long-term maintenance of HSP. We previously described how a tyrosine kinase-based signaling system in the muscle – consisting of C-terminal Src kinase (Csk), the Neural Cell Adhesion Molecule Fasciclin II (FasII), and the Heartless (Htl) FGFR receptor – sustains the homeostatic capacity at the NMJ for long periods of developmental time. This postsynaptic signaling system activates molecules in the muscle like Target of Rapamycin (TOR) to drive HSP. We extend this prior knowledge by identifying new factors in the neuron that integrate muscle-to-nerve homeostatic signaling over long periods of developmental time. First, we identified a neuronal Phospholipase C-Beta homolog, Plc21C, as essential for the long-term maintenance of HSP. Canonically, active PLC-Beta propagates intracellular signaling by cleaving phosphatidylinositol 4,5-bisphosphase (PIP_2) into diacylglycerol (DAG) and inositol triphosphate (IP_3). These molecules then direct many cellular processes and properties, including intracellular calcium signaling and neurotransmission. Through a combination of genetic, pharmacological and electrophysiological approaches, we found that either chronic or acute perturbations in IP_3 signaling disrupt the long-term maintenance of HSP but not its short-term induction. Further, we found that this entire homeostatic maintenance process is reversible and labile at high temperatures. We propose that the IP_3 signaling pathway is essential for the long-term maintenance of homeostatic plasticity at synapses like the Drosophila NMJ, and potentially higher order synapses and circuits.

Title: Considerations in repetitive activation of light sensitive ion channels for long-term studies: Channel rhodopsin in the *Drosophila* model

Authors: *M. X. MATTINGLY, J. HIGGINS, C. HERMANNS, R. COOPER
Biol., Univ. of Kentucky, Lexington, KY

Abstract: For nervous systems to function properly, the efficacy of synapses should be finely regulated and adjustable to respond to changing circumstances and requirements. Too high or too low synaptic output results in inappropriate communication to target cells. This is most apparent during development and maturation. As the size of postsynaptic cells dramatically increases, a matched increase of neurotransmitter release and/or sensitivity of postsynaptic cell to the transmission is required. On the other hand, the nerve terminals also grow rapidly, both in size and output, and continuously show different types of remodeling to maintain proper synaptic output throughout the life of the animal. We are addressing homeostatic regulation in synaptic function at the larval Drosophila NMJ throughout development. We have examined this through optogenetic manipulation of the motor nerve terminal and muscle. The biological significance and aim of this study is to demonstrate that in controlling particular neurons or targets of neurons, over time, and throughout development, one will have a better understanding of the dynamic nature of forward and retrograde communication in regulating synaptic formation and maintenance. Optogenetics has provided a useful tool, but there are limitations in the extent of activation and inhibition which needs careful consideration. We have noted long term (minutes) unexpected effects (i.e., neuron refractory in electrical excitability) from only 10 seconds of activation of channel rhodopsin (ChR-XXL) targeting motor neurons (D42 expression). Paralysis and inability to eat are considerations for long term neural developmental studies when manipulating neurons and muscles.

Title: Coordination of short and long-term homeostatic plasticity by an innate immune signaling pathway

Authors: *N. HARRIS[1], D. J. BRASIER[2], R. D. FETTER[1], A. TONG[1], G. W. DAVIS[1]
[1]UCSF, San Francisco, CA; [2]Carnegie Mellon Univ., Pittsburgh, PA

Abstract: It is clear that homeostatic signaling systems act throughout the central and peripheral nervous systems to stabilize the active properties of nerve and muscle. Evidence for this has accumulated by measuring how nerve and muscle respond to the persistent disruption of synaptic transmission, ion channel function or neuronal firing. In systems ranging from *Drosophila* to human, cells have been shown to restore baseline function in the continued presence of these perturbations by rebalancing ion channel expression, modifying neurotransmitter receptor trafficking and modulating neurotransmitter release. A hallmark of homeostatic plasticity is the ability to rapidly and accurately offset the magnitude of a perturbation and then sustain the homeostatic response for the duration of the perturbation, which can persist for the life of an organism. This fact raises many important questions about the nature of the homeostatic response over time. By analogy with other biological systems under homeostatic control, if a perturbation is deleterious to an organism, then an energetically costly but rapid response is warranted. If the perturbation persists, the homeostatic response can shift to an energetically less demanding, consolidated state. The nature of this transition has yet to be defined in neural homeostatic plasticity. Presynaptic homeostatic plasticity (PHP) can offset the inhibition or loss of postsynaptic neurotransmitter receptors by potentiating presynaptic vesicle release and, thereby, maintaining the gain of synaptic transmission. At the NMJ of organisms ranging from *Drosophila* to human, PHP preserves muscle excitation, thereby stabilizing movement and respiration. PHP can be rapidly induced (10 min) and stably maintained for months and even decades depending on the organism. We previously demonstrated that the innate immune receptor PGRP-LC resides at the presynaptic terminal and is essential for PHP. We now dissect the canonical signaling system downstream of PGRP-LC. We present evidence for a novel bifurcation of this signaling system in neurons. One branch of this signaling system leads to the action of a kinase, Tak1 (MAP3K), which we show is necessary for the rapid induction of PHP. The other branch signals to the NFkB-type transcription factor Relish, which is essential for the

long-term consolidation of PHP. Thus, signaling downstream of the PGRP receptor initiates, and thereby coordinates, the rapid induction and sustained, transcription-dependent consolidation of PHP. Finally, as part of our characterization, we describe the action of Tak1 on the presynaptic release mechanism.

Title: Post-synaptic PI3-kinase controls the set point for presynaptic homeostatic plasticity

Authors: *A. G. HAUSWIRTH, K. J. FORD, A. TONG, G. W. DAVIS
Dept. of Biochem. and Biophysics, Kavli Inst. for Fundamental Neuro, Univ. of California, San Francisco, San Francisco, CA

Abstract: Presynaptic homeostatic plasticity (PHP) is an evolutionarily conserved form of homeostatic plasticity that is expressed at synaptic connections throughout the central and peripheral nervous systems. At the neuromuscular junction (NMJ) of organisms ranging from *Drosophila* to human, PHP is induced by impaired postsynaptic neurotransmitter receptor function. The rapid induction of PHP potentiates presynaptic neurotransmitter release in seconds to minutes and precisely offsets the magnitude of postsynaptic neurotransmitter receptor inhibition. Thus, PHP can rapidly offset a postsynaptic perturbation and sustain muscle depolarization at normal baseline, set point values. Although molecular mechanisms responsible for PHP are beginning to emerge, most genes identified to date function within the presynaptic terminal to effect a change in presynaptic vesicle release. Among the few postsynaptic genes known to be required for PHP, none have been shown to be involved in the rapid induction of PHP. We sought to identify the genes necessary for the rapid induction of PHP, especially those that may act in muscle as a homeostatic sensor or as a component of the homeostatic retrograde, trans-synaptic signaling system. To do so, we performed an unbiased, RNAi-based screen of over 270 *Drosophila* kinases and phosphatases, representing 81% of the phosphatome. We identified the *Drosophila* orthologue of a class II PI3-kinase (*Pi3K68D)* as an essential post-

synaptic kinase for the rapid induction and long-term maintenance of PHP. We present cellular and genetic evidence in support of a model in which a PI(3)P membrane compartment, produced by *Pi3K68D*, creates a postsynaptic signaling platform that establishes and sustains the homeostatic set point for synaptic transmission. The concept of a 'set point' is integral to systems that are under homeostatic control, yet the cellular and molecular mechanisms that can generate a set point remain generally unknown. We propose that the set point for synaptic gain may emerge from action of a postsynaptic membrane recycling system controlled by *Pi3K68D*.

Title: Evidence for involvement of glia and epigenetic signaling in presynaptic homeostatic plasticity

Authors: *T. WANG, N. HARRIS, R. WERCBERGER, G. DAVIS
Dept. of Biochem. and Biophysics, Univ. of California, San Francisco, San Francisco, CA

Abstract: It is well-established that homeostatic signaling systems stabilize the functional properties of nerve cells and neural circuitry. Homeostasis is defined as the ability of a cell or system of cells to respond to a perturbation. If baseline neural function is precisely restored in the continued presence of a perturbation, then the process is considered to be homeostatic. The homeostatic control of presynaptic neurotransmitter release is evolutionarily conserved from *Drosophila* to human. In response to a decrease in postsynaptic neurotransmitter receptor sensitivity, a homeostatic increase in presynaptic vesicle release can precisely offset the postsynaptic perturbation and restore baseline postsynaptic depolarization. The Davis laboratory has pursued large scale forward genetic screens, using electrophysiology as the primary assay, to identify genes that are necessary for presynaptic homeostatic plasticity. To date, these studies have highlighted the action of effector proteins that are present within the presynaptic nerve terminal and, in most instances, function cell autonomously. We have uncovered evidence for the non-cell autonomous involvement of glia in presynaptic homeostatic plasticity. Synapses throughout the central and peripheral nervous systems incorporate glia into what has been termed a tripartite synapse composed of pre- and postsynaptic neuronal partners and a glial interface. We have discovered that peripheral glia are engaged by the persistent disruption of postsynaptic glutamate receptors at the *Drosophila* neuromuscular junction (NMJ). We have identified a glial-

dependent signaling system that is essential for the long-term maintenance of presynaptic homeostatic plasticity that includes the recently established function of the extracellular matrix protein Multiplexin (homologue of Collagen XVIII) and the proteolytically derived signaling molecule Endostatin. This signaling system includes evidence of epigenetic transcriptional control that may be directly involved in the glial-dependent, persistent regulation of presynaptic neurotransmitter release during homeostatic plasticity.

Title: Genetic intersection of autism gene mutations and homeostatic plasticity

Authors: *O. GENC, G. W. DAVIS
UCSF, San Francisco, CA

Abstract: Autism spectrum disorders (ASD) are considered to have strong genetic basis and a large number of genes have been identified that confer high risk for ASD in humans. Yet, it remains unknown how genetic risk translates into the phenotypic severity of ASD in a given individual. We hypothesize that homeostatic plasticity represents a physiological buffer that limits the phenotypic severity of an ASD-associated gene mutation. An extension of this hypothesis is that an ASD mutation could genetically interact with one or more second site, heterozygous mutations in the genetic background of an organism. In rare instances, if these genetic interactions cause homeostatic plasticity to fail, then the buffering effect of homeostatic plasticity would be limited and the phenotypic severity of the ASD mutation would be enhanced. To test this hypothesis, we are systematically combining heterozygous ASD mutations with deficiency chromosomes that uncover defined regions of the Drosophila genome. In each genetic combination, we assess the expression of presynaptic homeostatic potentiation (PHP) by direct quantification of synaptic transmission. The results of this large-scale, functional genetic screening effort will be presented, including the identification of gene-specific mutations that functionally interact with, and enhance, the phenotype of heterozygous ASD mutations. Based on the results of this screen, we propose that failure of presynaptic homeostatic plasticity may be a common underlying pathophysiology relevant to the phenotypic penetrance of rare de novo mutations that confer high risk for ASD in human.

Title: Circadian genes, sleep, and alcohol in *Drosophila*

Authors: *A. GHEZZI[1], M. E. RAMIREZ[1], J. L. AGOSTO[1], N. S. ATKINSON[2]
[1]Dept. of Biol., Univ. of Puerto Rico, Rio Piedras, San Juan, PR; [2]Dept. of Neurosci., The Univ. of Texas at Austin, Austin, TX

Abstract: Exposure to alcohol is known to trigger homeostatic adaptations in the brain that lead to the development of drug tolerance and dependence. These adaptations are also believed to be the root of a collection of sleep disturbances that often manifest during the development of alcoholism. Because both, alcohol dependence and sleep modulation are under homeostatic regulation, we hypothesize that these processes share common mechanisms. Here we use a Drosophila model system to test this hypothesis. We find that in Drosophila, acute alcohol exposure causes disturbances in sleep patterns that resemble those described in mammals. These disturbances include an increase in total sleep duration, decrease sleep latency, as well as an increased number of sleep episode per day (fragmented sleep). Furthermore we show that many of the genes implicated in the neural adaptations behind alcohol tolerance, have also been implicated in the regulation of sleep cycles. Using a novel genomic approach that exploits the analysis of epigenetic modifications and transcription factor binding we identify a network of alcohol-induced genes that is directly controlled by the circadian clock genes Clock and cycle. These results support our hypothesis that sleep and alcohol neuroadaptation share a common regulatory mechanism, and brings us closer to understanding the interaction between these two homeostatic processes.

Title: Membrane depolarisation, inactivation of A-type K^+ channels and transient saturation of Ca^{2+} buffers, mediated by mGluR1, synergistically control the spatial segregation of climbing fibre signalling in cerebellar Purkinje neurons

Authors: *K. AIT OUARES, L. FILIPIS, M. CANEPARI
Liphy, Saint Martin D Héres, France

Abstract: Several forms of associative synaptic plasticity depend on the coincidence between local synaptic activation and transient widespread membrane depolarisation. In cerebellar Purkinje neurons, the transient depolarisation that regulates parallel fibre (PF) synaptic plasticity is provided by the climbing fibre (CF), but the precise machinery permitting this unspecific dendritic depolarisation to produce a Ca^{2+} signal localised in activated synaptic regions has been elusive. Here we used a series of advanced optical techniques to reveal in detail the sequence of events following activation of PF synapses and leading to a local large Ca^{2+} signal associated with the CF depolarisation. Using ultrafast Ca^{2+} imaging with the low affinity indicator Oregon Green BAPTA-5N, computational extraction of Ca^{2+} currents and membrane potential imaging, we demonstrate that the nonlinear amplification of the CF-associated Ca^{2+} signal is determined by the synergy of several mechanisms. Burst activation of PF inputs initially produces sustained dendritic depolarisation and Ca^{2+} entry via voltage gated Ca^{2+} channels. With a delay of a few tens of milliseconds, the released glutamate, activates type-1 metabotropic glutamate receptors (mGluR1s) enhancing inactivation of A-type K^+ channels in combination with dendritic depolarisation. The fast cytosolic Ca^{2+} elevation, initially via T-type Ca^{2+} channels Ca^{2+} influx, and later via mGluR1-activated TRP3 channels, transiently saturates the endogenous Ca^{2+} buffers. Thus, when a CF excitatory postsynaptic potential (EPSP) occurs at the peak of mGluR1 activation, the inactivation of A-type K^+ channels leads to activation of P/Q-type Ca^{2+} channels and the previous Ca^{2+} binding to endogenous buffers amplifies the fast Ca^{2+} elevation associated the CF-EPSP locally in the small dendritic region adjacent to the activated mGluR1s. In this

way, the non-selective CF depolarisation can produce a triggering signal only in activated PF synaptic regions.

Title: Action potential-induced calcium responses actively backpropagate in spinal cord lamina I neurons

Authors: *E. K. HARDING[1,2], M. W. SALTER[1,2]
[1]Hosp. For Sick Children, Toronto, ON, Canada; [2]Physiol., Univ. of Toronto, Toronto, ON, Canada

Abstract: Spinal cord lamina I neurons function as a hub of nociception, and exhibit hyperexcitability in chronic pain models. Calcium is a second messenger critical to the induction of many cellular processes, including long-term potentiation (LTP) in many types of neurons. With LTP and lamina I neuron hyperexcitability sharing many characteristics, it is possible that calcium entry could be a critical mechanism underlying hyperexcitability. However, the function of calcium in lamina I neurons is poorly understood. To address this, we combined two-photon calcium imaging with whole cell electrophysiology. We made current-clamp recordings from lamina I neurons in spinal cord slices, loading the calcium indicator OGB-1 and control fluorophore AF-594 via the patch pipette. Neuronal calcium levels before, during, and after action potential (AP) generation were quantified as ΔG/R (change in OGB-1 intensity as compared to AF-594). Recordings were made from over 180 lamina I neurons. In 99% of neurons a single AP was sufficient to increase ΔG/R in the somatic cytosol (ΔG/R=0.11, n=179 cells), nucleus (ΔG/R=0.047, n=179 cells), dendrites (ΔG/R=0.15, n=179 cells), and dendritic spines (ΔG/R=0.091, n=20 spines). These calcium responses were ablated by the VGCC blocker cadmium. Responses did not degrade along dendrites from 20µm (ΔG/R=0.10, n=6 dendrites) to 160µm (ΔG/R=0.13, n=6 dendrites) away from the soma, indicating dependence on VGCCs and actively backpropagating action potentials (bAPs). We found no differences when grouping calcium responses by cellular morphology (fusiform, multipolar, pyramidal) or firing-type (tonic, phasic, single spike, delayed onset). We compared lamina I neuron calcium responses to

hippocampal CA1 neurons, and found that lamina I responses (cytosol ΔG/R=0.063, decay rate=1.73s; nucleus ΔG/R=0.022, decay rate=6.84s; dendrite ΔG/R=0.067, decay rate=1.48s, n=4 cells) had a decreased amplitude and decay rate compared to hippocampal neurons (cytosol ΔG/R=0.18, decay rate=0.49s; nucleus ΔG/R=0.055, decay rate=3.65s ; dendrite ΔG/R=0.13, decay rate=0.35s, n=4 cells). This is suggestive of increased immobile calcium buffer in lamina I neurons. Together, these findings strongly suggest that all lamina I neurons regardless of cell type produce active bAPs that invade the entire dendritic arbour. The presence of active bAPs gives lamina I neurons the capacity to readily undergo both short and long-term potentiation through temporal summation and spike-timing dependent plasticity (STDP) respectively.

Title: Multiscale model of feedback and activity modulation in stimulus sequence recognition by chemical signaling in dendrites

Authors: *U. S. BHALLA
Natl. Ctr. For Biol. Sci., Bangalore, India

Abstract: Introduction:
We propose that the key neuronal computation of sequence discrimination occurs through chemical signaling in dendrites on length scales of 5-30 microns, and on behavioural timescales of ~1 second per stimlus. Synaptic input arriving on a series of closely spaced (~2 microns) synapses, in sequential order, is discriminated from scrambled input. In these systems, synaptic input triggers electrical as well as chemical activity through calcium influx. In turn, signaling cascades modulate electrical excitability through channel phosphorylation and receptor insertion. We investigated the interplay between these scales of signaling in the context of sequential vs. scrambled synaptic input, with different kinds of background activity and neuromodulation.
Methods:
We performed detailed multiscale simulations using experimental neuronal morphologies from rat hippocampal neurons (e.g., NeuroMorpho.org accession VHC-neuron.CNG.swc), embroidered with ~5500 dendritic spines. We incorporated voltage-gated ion channels and

calcium dynamics all over the cell, and added AMPA and NMDA receptors on all spines. We also incorporated a reaction- diffusion system based on MAPK signaling throughout the dendrites, and calcium signaling including buffering by calmodulin, in all spines and dendrites. The model was simulated using stochastic calculations in the spines, and deterministic calculations in the dendrites. The computations were done using the MOOSE simulator (moose.ncbs.res.in) on Linux workstations and supercomputers.
Results:
We demonstrate that a single neuron can discriminate thousands of input sequences in parallel over its dendritic tree, responding only when at least one of these sequences arrives on successive synapses in the correct order. We investigate how the preferred timing for sequence recognition can be modulated by stimulus amplitude, background activity, and neuromodulators. We find that the feedback between electrical and chemical signaling leads to runaway activation for some parameter domains, but there is a substantial domain where there is good sequence selectivity followed by modulation of cellular firing activity.

Title: Fast 3D imaging of dendritic activity in pyramidal cells of visual cortex

Authors: *T. J. YOUNTS, C. BARAGLI, A. SILVER
Neuroscience, Physiol. and Pharmacol., Univ. Col. London, London, United Kingdom

Abstract: How sensory information is represented in dendrites in vivo is poorly understood because it is difficult to measure activity within morphologically complex dendrites. We used a custom built 3D two-photon acousto-optic lens microscope to measure dendritic activity in pyramidal cells in mouse primary visual cortex. Pyramidal neurons were sparsely co-labelled with the genetically-encoded Ca^{2+} indicator GCamp6f (to measure activity) and with the red fluorophore TdTomato (to detect and later correct for movement). Random access point measurements were collected at 80-120 Hz from hundreds of dendritic locations distributed in 3D. Patterns of activity were characterized in layer 2/3 and layer 5 pyramidal cells during

presentation of square wave gratings in animals that were anaesthetized, awake and stationary, or running on a wheel. Layer 2/3 neurons exhibited Ca^{2+} transients that were mainly local. Somatic Ca^{2+} transients were rarely accompanied by global events in the full dendritic tuft. Dendritic activity was affected little by anaesthesia and locomotion. In the tuft of layer 5 neurons, Ca^{2+} transients tended to be either localized to few dendritic branches or to occur in the full-dendritic tuft (and soma when measurable). Dendrites showed little response to visual stimuli, but they were strongly modulated by the state of the animal: anaesthesia suppressed activity while locomotion enhanced activity when compared to rest. To investigate the mechanisms underlying these dendritic activity patterns observed in vivo (i.e. global vs. local), we made whole cell patch clamp recordings from layer 2/3 and layer 5 pyramidal cells in acute visual cortical slices. 3D dendritic imaging of GCaMP6f or the synthetic Ca^{2+} fluorescence indicator Cal520 revealed that single and bursts of action potentials produce Ca^{2+} transients that backpropagate and invade the distal dendritic tuft of both cell types in young (<P30) mice, but responses to single spikes were not detected in the tuft of layer 5 cells in adult mice (>P60). These data indicate that layer 2/3 and layer 5 pyramidal neurons exhibit different patterns of activation in their dendritic trees. Our in vivo results are consistent with the view that layer 2/3 neurons are predominantly driven by bottom-up feedforward visual inputs, while top-down inputs conveying information about the animal's state are effective in activating the apical dendrites of layer 5 cells.

Title: Optimal signal transfer from dendrite to soma in mouse L5 pyramidal neurons

Authors: *E. P. COOK[1], R. A. GRAY[2], D. JOHNSTON[2], B. E. KALMBACH[3]
[1]McGill Univ., Montreal, QC, Canada; [2]Ctr. for Learning and Memory, The Univ. of Texas At Austin, Austin, TX; [3]Allen Inst. for Brain Sci., Seattle, WA

Abstract: What is the optimal dendritic input for producing either somatic depolarizations or somatic action potentials (APs)? We addressed this question using previously published simultaneous dendrite and soma electrophysiological recordings from PFC mouse L5 pyramidal

neurons stimulated with white-noise dendritic current injections. Specifically, we focused on how the energy contained in the dendritic input signal is transformed into somatic depolarizations or action potentials. An optimal input signal is defined as one that produces an equivalent somatic response with the least amount of energy. Using a white-noise dendritic stimulus is an advantageous approach because it allowed us to easily identify the shape of the optimal input that maximized the energy transfer from the dendrites to the soma. For each neuron (N = 16), we identified two unique optimal input signals: First, we estimated the linear transfer function (Gdep) that converted input current into subthreshold somatic depolarization. Second, we computed the average noise stimulus that preceded each AP (the spike-triggered average or Gap). These two functions describe the stimulus shape that results in optimal energy transfer from the dendrite to either somatic depolarization (Gdep) or AP (Gap). We found that Gdep and Gap had very different shapes. Although both Gdep and Gap showed theta-band resonance, Gdep attenuated input energy at frequencies above ~10 Hz while Gap contained substantial energy above 100 Hz. Importantly, the signal energy required to produce subthreshold somatic depolarizations was highly dependent on dendritic location (range of 50 to 380 μm), while the amount of signal energy preceding an AP was not dependent on dendritic location. Thus, the optimal input signal for producing a somatic AP contained high frequencies that would normally be eliminated by the passive filtering properties of dendrites. Although this result seems contradictory, a previously described functional model of the dendritic nonlinearity and somatic integrator reproduced our experimental observations. Our results show that by adding energy to the dendritic input, the dendritic nonlinearities normalize dendritic location and shape the optimal input signal that maximally transfers energy to the soma.

Title: Active dendrites broaden membrane bandpass filtering and decrease temporal synchrony in a looming-sensitive neuron

Authors: *R. B. DEWELL[1], F. GABBIANI[2]
[1]Dept of Neurosci., Baylor Col. of Med., Houston, TX; [2]Baylor Col. Med., Houston, TX

Abstract: Filtering and integration of synaptic inputs is critical for neural computations. A well-studied looming-sensitive neuron in the locust that integrates ~15,000 retinotopically organized excitatory synaptic inputs has long served as a model for understanding the neural computations underlying collision avoidance behaviors. This neuron, the lobula giant movement detector (LGMD) is precisely tuned for the pattern of retinal activation generated by an object approaching on a collision course. Previous work has shown that active dendritic channels, including Ih, increase the LGMD's neuronal and the animal's behavioral specificity through improved discrimination of the resulting spatiotemporal synaptic patterns. The LGMD contains prominent h and M currents, both of which can produce membrane resonance and bandpass filtering in neurons. Additionally, Ih has also been shown to increase the detection of temporally synchronous inputs within some cortical neurons by reducing the phase lag of signals as they propagate from distal dendrites toward the site of spike initiation. Surprisingly, we found that in the LGMD these currents combine to make the membrane less resonant and more broadband. Ih also increased the phase lag of dendritic signals propagating towards the spike initiation zone, which could increase the ability of the LGMD to discriminate between spatiotemporal patterns of synaptic inputs. As the spatiotemporal pattern of synaptic inputs into the LGMD is important both for the computations carried out within the neuron and the animal's escape behavior, this neuron represents an attractive model to investigate the influence of active conductances on the resonance and filtering of synaptic inputs.

Title: Finding thresholds in active dendrites

Authors: *W. L. KATH
Applied Mathematics, Northwestern Univ., Evanston, IL

Abstract: The integration of synaptic inputs in a neuron can be nonlinear not just at the axon, but also locally in the dendrites if they contain active voltage-gated ion channels. For example, CA1 pyramidal neurons have high densities of sodium and potassium and currents in their dendrites, and the densities can vary substantially with location in the arbor. When combined

with diameter changes at branch points in the dendritic tree, such nonlinearities can lead to compartmentalized responses to inputs: each branch can act as an individual nonlinear unit in which action-potential-like events known as dendritic spikes occur.
To fully comprehend how pyramidal neurons integrate their inputs, it is therefore necessary to understand the conditions under which combined synaptic inputs initiate dendritic spikes, and how and when these spikes interact with other inputs to generate a somatic action potential.
In contrast to single cell neuron models, however, the dividing line between an active and non-active event in a full compartmental model is a steady-state, unstable, spatially-varying solution. These properties (in particular, instability and spatially variation) make finding such dividing lines and the critical synaptic conductance(s) leading to them troublesome.
The steady-state solution often has only a single unstable eigenvalue, however, leading to several methods to find the dividing line between super- and sub-threshold events. First of all, a projective shooting method that focuses on dynamics in the unstable direction can be used. Second, one can employ a Recursive Projection Method, a functional iteration devised to find steady-states with a finite number of unstable eigenmodes. Finally, Newton's method can be used. The pros and cons for each of these methods will be discussed. In addition, examples will be given showing how the method determines changes in the threshold for dendritic spikes due to variations in branch geometry or ion channel densities.

Title: The role of dendritic spikes in inducing timing dependent plasticity in CA1 pyramidal neurons

Authors: *T. BOCK[1], S. A. SIEGELBAUM[2]
[1]Dept. of Neurosci., Columbia Univ., New York, NY; [2]Dept of Neurosci., Columbia Univ. Coll P & S, New York, NY

Abstract: Input time dependent plasticity (ITDP), a powerful form of heterosynaptic plasticity in CA1 pyramidal neurons (PNs), has been implicated in contextual learning and object memory storage. ITDP requires precisely timed pairing of perforant pathway (PP) input from entorhinal cortex (EC) to the distal dendrites of CA1 PNs with excitatory input to CA1 proximal dendrites from the CA3 Schaffer collaterals (SC) after a 20 ms delay, leading to a 2-3 fold enhancement of

the SC-CA1 PSP, largely caused by CB1 receptor-mediated LTD of feedforward inhibition from CCK-positive interneurons. Induction of ITDP is associated with the firing of dendritic calcium spikes in the dendrites of CA1 PNs during paired stimulation, although these spikes have little impact on somatic voltage. Here we report that dendritic spikes are both necessary and - in conjunction with SC input alone - sufficient to induce ITDP. We paired direct current injection into distal apical dendrites through a dendritic patch pipette with synaptic stimulation of SC inputs. This pairing protocol was sufficient to induce a 2-fold increase in the SC PSP that was blocked by bath application of the CB1 cannabinoid receptor blocker AM251 during ITDP induction and was occluded by blocking GABA receptors, demonstrating that this plasticity shared a similar expression mechanism with synaptically induced ITDP. Furthermore, dendritic spikes were necessary for ITDP induction. Closed loop negative current injection into the distal dendrite was used to prevent spike firing without altering subthreshold EPSPs. Spike inhibition in this manner prevented the induction of ITDP during paired PP and SC stimulation. Thus we conclude that dendritic spikes are both sufficient and necessary to induce ITDP in CA1 pyramidal neurons. The main impact of the EC-CA1 pathway on ITDP induction is likely through the combined effects of distal dendritic depolarization combined with disinhibition of the distal apical dendrite through long-range inhibitory projections onto dendrite-targeting CCK interneurons. This form of precisely timed disinhibition facilitates the generation of dendritic spikes in the distal apical dendrite during SC stimulation, which in turn are the main drivers of ITDP induction.

Title: Neuronal responses to distributed synaptic inputs are generally independent of dendritic length and branching structure

Authors: *H. CUNTZ[1,2], A. D. BIRD[1,2], M. BEINING[1,2,3], F. Z. HOFFMANN[1,2], S. PLATSCHEK[3], T. DELLER[3], P. JEDLICKA[3]
[1]Ernst Strüngmann Inst. (ESI), Frankfurt, Germany; [2]Frankfurt Inst. for Advanced Studies, Frankfurt, Germany; [3]Inst. of Clin. Neuroanatomy, Goethe Univ., Frankfurt, Germany

Abstract: Reducing neuronal size results in less cell membrane and therefore lower input conductance. Consequently, smaller neurons show an increase in excitability and an altered input-output function in response to current injections in the soma [1, 2]. However, the general consequences of this relation for responses to distributed synaptic inputs have yet to be studied in detail. Using analytical cable theory we find that distributed synaptic inputs effectively encounter an apparent input conductance corresponding to the collapsed membrane leak of the entire dendrite onto the soma. As a consequence more synaptic currents are precisely compensated by more dendritic leak and the voltage response at the soma is independent of dendritic length, complexity or topology. Assuming a given synaptic density, voltage responses only depend on the average diameter and the specific membrane conductance in the dendrite. We show in passive and active model simulations that this relation holds for realistic morphologies and is reflected in invariant numbers of spikes for a given synaptic input frequency. In conclusion, principles of neural architecture seem to provide for neural input-output functions that are generally independent of dendrite length and shape within the range of most realistic biological neurons. This represents a homeostatic dendritic input-output relation that dendritic non-linearities and synaptic plasticity can freely modulate.

Title: Input pattern dependent cooperative synaptic plasticity in dendrites of hippocampal CA1 pyramidal cells

Authors: A. MAGO, J. WEBER, *J. K. MAKARA
Inst. of Exptl. Med., Budapest, Hungary

Abstract: Synaptic inputs arrive to neurons in various patterns, defined by their number, synchrony and spatial distribution in the dendritic tree. Depending on the input pattern, dendrites may integrate synaptic voltage signals either linearly, sublinearly or supralinearly (the latter prominently by local dendritic spikes), allowing the cell to specifically process and respond to different synapse patterns. It is less clear how long-term plasticity of synaptic inputs depend on their pattern and dendritic integration mode. We have recently shown that, in distal segments of perisomatic dendrites of CA1 pyramidal cells, coactivation of a few spatially clustered synapses can lead to their local interaction that produces linear voltage integration but supralinearly amplified synaptic NMDA receptor mediated Ca^{2+} signals. Furthermore, repetitive synchronous activation of four clustered distal inputs can induce NMDAR dependent long-term potentiation (LTP) of the activated synapses (Weber et al., 2016 Nature Comm.). Here we characterized the pattern requirements of this plasticity in details, and examined how cooperative plasticity of different input patterns depends on the voltage integration mode by the dendrite. We used two-photon imaging and multisite glutamate uncaging combined with whole cell current clamp recordings to evoke linear or supralinear dendritic responses by different spatial input patterns at various dendritic locations. We found that cooperative LTP with linear voltage integration could be evoked by 3-4 clustered synapses, but only at distal and not at proximal dendritic sites. On the other hand, spatially distributed distal synapses evoked LTP only if they generated dendritic spikes. At proximally located inputs, LTP could be only evoked by patterns that generated dendritic, or backpropagating somatic spikes, but not by subthreshold synapse clusters. These results indicate that the induction mode of cooperative LTP follows location dependent rules in dendrites, and suggests a gradual switch from global to more local mechanisms of LTP along the proximodistal axis of individual thin branches. The diversity of pattern dependent cooperative synaptic plasticity rules may enrich the versatility of hippocampal information storage.

Abstract: The back propagating action potential (bAP) is considered a global dendritic signal that broadcasts the neuron's spike output to the synaptic input sites on its dendrite. Thus, it is thought to have a key role in Hebbian plasticity and synaptic integration. However, our understanding of bAPs is derived mostly from rodent neurons, thus it is unknown to what extent the properties of rodents' bAPs apply in other species. Here, for the first time, we used somato-dendritic patch clamp and two-photon calcium imaging to record the bAP in human layer 3 neocortical pyramidal cell (L3PC) apical dendrites and spines obtained from resected brain tissue of epileptic patients. We found that the bAP in human L3PC dendrites severely attenuates; although L3PC dendrites often extend up to more than 1 mm, the bAP did not reach beyond 500 μm from the soma. However, high frequency bursts (200 Hz) invaded significantly farther into the dendrite. Furthermore, in some cases, sustained depolarization of the dendrite caused repetitive dendritic spikes that propagated forward to the soma - i.e., forward-propagating dendritic spikes (fAPs). Often, fAPs were capable of reliably triggering somatic spikes. In conclusion, this study shows that AP propagation in the apical dendrites of human L3PCs is bidirectional, a result that has important implications for communication between soma and dendrites and plasticity rules in the human brain.

Title: Cellular mechanisms for multimodal integration in retrosplenial cortex

Authors: *M.-S. VAN DER GOES[1], M. LAFOURCADE[2,1], D. BARNAGIAN[2,1], M. T. HARNETT[1,2]
[1]Dept. of Brain and Cognitive Sci., MIT, Cambridge, MA; [2]MIT, McGovern Inst. for Brain Res., Cambridge, MA

Abstract: How association cortices in the mammalian brain perform multimodal integration of sensory, contextual, and motor information remains unknown. We hypothesized that this process could occur at the level of individual cortical pyramidal neurons as a result of active dendritic mechanisms controlling the interaction of compartmentalized synaptic input streams. We tested this hypothesis in retrosplenial cortex (RSC), a cortical association area engaged in spatial navigation, specifically the integration of world-centered (i.e. directional) and egocentric signals (i.e. visual). First, we used monosynaptic retrograde tracing to identify a variety of brain regions that directly targeted specific neuron classes in RSC. These regions include primary visual (V1) areas, secondary visual (V2) and motor (M2) areas, and cingulate cortices, as well as thalamic and subcortical nuclei processing head orientation, suggesting that multiple streams of information converge onto single cells. Channelrhodopsin-assisted subcellular input mapping was then used to reveal the synaptic connectivity logic of a subset of identified input regions (V1, anterior and lateral dorsal thalamic nuclei, and M2). We observed discrete and spatially organized dendritic input targeting specific RSC cell classes, suggesting the presence of highly-structured, dedicated channels for information processing at the cellular level. Finally, we employed a combination of patch-clamp electrophysiology with two-photon Ca^{2+} imaging and glutamate uncaging to reveal multiple, distinct dendritic integration mechanisms segregated to particular dendritic domains in RSC pyramidal neurons potentially congruent with observed input connectivity maps. Specifically, we found that basal dendrites exhibit canonical NMDA receptor-mediated supralinear input-output processing, while proximal apical dendrites integrate in a surprisingly linear manner until action potential initiation. We conclude that the functional and anatomical organization of excitatory synaptic inputs and the presence of diverse dendritic decoding motifs provide a cellular substrate for multimodal integration in RSC. Future experiments in head-fixed, task-performing mice will test how subcellular connectivity and dendritic processing operations interact with pre- and post-synaptic circuit-level dynamics to generate the computations in RSC that guide spatial behavior.

Authors: ***M. DEROCHE**[1,2], F. MICHEL[1], O. MANZONI[1]
[1]Inserm Unit 901, Inmed, Marseille, France; [2]Aix-Marseille Univ., Marseille, France

Abstract: The nucleus accumbens located at the center of mesocorticolimbic system regulates emotional and reward-related behavior. We have performed a comprehensive morphological and electrophysiological description of the morpho-functional properties of identified cell types (i.e. D1R or D2R-expressing GABAergic medium spiny neurons) in the nucleus accumbens mice core. To this aim, we have systematically audited the tri-dimensional organization of dendritic trees, intrinsic neuronal properties, synaptic transmission and plasticity at optogenetically-disambiguated synapses on identified neuronal subtypes (i.e. D_1R+ or D_1R- accumbens medium spiny neurons) ex-vivo. Finally, to establish a link between structural organization and functional output, we visualized the whole brain connectivity map of the excitatory afferents to identified accumbens neurons with clarifying approaches. Our multiparametric dataset reveals the precise hierarchical organization of the excitatory inputs to accumbens medium spiny neurons.

Title: Dendritic plateau generation model in cortical pyramidal neurons: A link to cortical ensembles

Authors: *P. GAO[1], J. W. GRAHAM[2], S. ANGULO[2], S. DURA-BERNAL[2], W. W. LYTTON[2], S. D. ANTIC[1]
[1]Univ. of Connecticut Hlth. Ctr., Farmington, CT; [2]Physiol. & Pharmacol., SUNY Downstate, Brooklyn, NY

Abstract: Synaptic and glutamatergic inputs to the basal dendrites of cortical pyramidal neurons activate NMDA and AMPA receptors which can bring the dendrites into a long-lasting depolarized state which can spread into the soma. The resulting plateau potentials increase the excitability of the neuron by bringing membrane potential closer to threshold and reducing membrane time constant.
In such an "activated" state, the pyramidal cells can respond to synaptic inputs more quickly and easily, facilitating synchronization of firing. We hypothesize that a multiple embedding of neuronal ensembles would allow for the binding of multimodal inputs into coherent object perception based on binding-by-synchrony theory, while simultaneously allowing information transfer via temporal coding. The first level of embedding is the activated neurons among their larger populations, and the second level consists of the activated neurons which are firing synchronously. Synchronized temporal coding within an area may provide the substrate for a broad distributed ensemble across areas that would allow binding-by-synchrony.
We are developing two data-driven models of cortical pyramidal neurons in NetPyNE for the NEURON simulator: 1) a morphologically-simplified model with seven compartments and 2) a morphologically-accurate model reconstructed from a prefrontal cortex Layer 5 pyramidal neuron. Electrophysiological data is available from dendrites and soma simultaneously with glutamate-uncaging experiments utilizing voltage-sensitive dyes in dendrites and whole-cell patch recording in the soma.
Model cell properties were fitted to mouse M1 current-clamp results using PRAXIS and Evolutionary Multi-objective Optimization (EMO) algorithms. Dendritic active current properties were tuned to match experimentally observed back-propagating action potentials. An AMPA receptor model generates the fast-response to glutamate stimulation while an NMDA receptor model accounts for the extended plateau activation.
The AMPA/NMDA receptor properties were explored to determine their effect on dendritic and somatic plateaus. The receptors were modeled both directly on a basal dendrite and on spines. Spine properties, glutamate stimulation properties, and stimulation location were all explored and quantified. These models are being used to develop cortical meso-scale network models to develop and explore EEE theory.

Title: Pinging the network - Causal modulation of pairwise correlations using optogenetics

Authors: *A. R. ANDREI, S. POJOGA, R. JANZ, V. DRAGOI
Neurobio. & Anat., Univ. of Texas Hlth. Sci. Ctr. At Houston, Houston, TX

Abstract: Noise correlations, or correlated variability, represent a well-studied measure of cortical networks that have been shown to vary across many conditions, such as cortical layers, attentional and arousal states, or task demands. Further, pairwise correlations have been proposed to limit the amount of information encoded by a network. To test whether changes in correlations impact information coding, causal manipulations in the absence of concomitant firing rate changes are necessary. Here we show that using optogenetic stimulation of glutamatergic neurons in primary visual cortex (V1) of awake macaque monkeys, pairwise correlations can be modulated independent of firing rate. This technique could be used to test theoretical predictions about the functional impact of correlated variability. We delivered the channelrhodopsin (ChR2) gene to multiple sites in V1 using a lentivirus vector with a CaMKII promoter in two monkeys (*macaca mulatta*). Starting 4 weeks after the injection, single and multi-unit activity were recorded using laminar electrodes and a laser-connected fiber optic cable. Monkeys performed a fixation task and half of the trials were paired with simultaneous optical stimulation (10 pulses at 35 Hz). Only trials with no visual stimulus in which monkeys maintained fixation on a central spot on a computer screen and correctly reported the absence of a visual stimulus were considered. We recorded a total of 1,478 cell pairs across 20 sessions, of which 89% were responsive to the optical stimulation. We computed noise correlations across trials for all pairs of neurons by aligning trials with the onset of the laser pulses. We found that for pairs of neurons in which both cells were responsive to light, the mean firing rates of neurons increased during light presentation, and then returned to baseline almost immediately following a very brief drop 50 ms after laser offset. Interestingly, correlations showed no change during optical stimulation, but dropped significantly below the mean correlation in control trials (without optical stimulation) after laser offset ($P<0.002$, rank sum test, with Bonferroni correction). This significant drop in correlations lasted hundreds of milliseconds, and then returned to baseline. These results have the potential to provide causal methodology to subsequently test the impact of noise correlations on neural coding and behavioral decisions.

Title: Morphofunctional interrogation of *In vitro* neuronal networks exposes modulators of synaptic connectivity

Authors: *P. VERSTRAELEN[1], M. VERSCHUUREN[1], J. DETREZ[1], R. M. NUYDENS[2], A. EBNETH[2], J.-P. TIMMERMANS[1], W. H. DE VOS[1]

Abstract: Orchestrated activation of genetic programs and spontaneous electrical activity guide the wiring of neuronal networks. Mature networks are characterized by the expression of synaptic markers, synchronized electrical activity and the presence of dendritic spines. While neurodevelopmental disorders are thought to result from defective neuronal network formation, neurodegenerative disorders are characterized by progressive synapse loss. Today, basic knowledge about the underlying mechanisms at the cellular and neuronal network level seems insufficient to develop disease-modifying treatments.
We established a model based on mouse primary and human iPSC-derived neurons that recapitulates features of mature networks [1-3]. An image analysis script was developed in Acapella® (PerkinElmer) to quantify neurite- and synapse density, i.e. colocalizing pre- and postsynaptic puncta. To facilitate dendritic spine analysis in dense cultures, sparse labelling strategies such as AuNP-mediated photoporation were explored. Calcium fluctuations, serving as a proxy for electrical activity, were detected in neurons expressing the GCaMP6f reporter. These readouts were integrated into one classification scheme that accurately predicts culture maturity. Morphofunctional connectivity was analysed at different timepoints after pharmacological or molecular biological perturbation. Using microtubule (MT) stabilizing- and depolymerizing compounds, we found that MT stability is an important mediator of synaptic connectivity [5]. This finding was substantiated by overexpressing Tau forms with different microtubule-stabilizing capacity, and by modulating tubulin acetylation. We also saw that dendritic spine density was decreased by inducing a cellular hypoxia response.
This platform for interrogation of morphofunctional connectivity in neuronal networks represents an attractive model for high-content screening in the context of neurodevelopmental or neurodegenerative disorders.

Title: Two oscillatory modes of introducing cortical plasticity in human motor cortex: a transcranial alternating current stimulation study

Authors: *M. TAKEMI[1,2], J. KESSELHEIM[2], M. G. JØNSSON[2], H. R. SIEBNER[2,3]
[1]Grad. Sch. of Educ., The Univ. of Tokyo, Tokyo, Japan; [2]Danish Res. Ctr. for Magnetic Resonance, Copenhagen Univ. Hosp. Hvidovre, Hvidovre, Denmark; [3]Dept. of Neurol., Copenhagen Univ. Hosp. Bispebjerg, Copenhagen, Denmark

Abstract: Transcranial alternating current stimulation (TACS) is a non-invasive neuromodulatory technique capable of interacting with endogenous brain oscillations. It enables to study the causal role of brain rhythms in motor, sensory and cognitive functions and to induce cortical plasticity in a frequency-specific manner. Recently it has been suggested that neurons are susceptible to low-frequency sinusoidal envelope that modulates the amplitude of a high frequency carrier [1]. Such amplitude-modulated tACS (am-TACS) could avoid contamination of stimulation artifacts into the frequency bands of low-frequency physiological oscillations [2], possibly allowing for online assessment of neural oscillations during TACS. However, it remains to be determined how the physiological effects of am-TACS compare to standard TACS at constant amplitude (con-TACS).

In 20 healthy participants, we applied am-TACS with the amplitude of a 140 Hz carrier being modulated by a sinusoidal envelope at 5, 10 or 20 Hz and con-tACS at 5, 10, 20 and 140 Hz. We assessed the lasting effects of TACS on corticospinal excitability, as indexed by motor evoked potentials elicited by TMS (Experiment 1), and brain oscillations using EEG (Experiment 2). Two 9 cm^2 tACS electrodes were placed over the hand area of left primary motor cortex and the midline of the parietal cortex. Single session consisted of one online block (6 min of 1 mA TACS) and three offline blocks (0−1, 5−6 and 10−11 min after TACS). In Experiment 1, we found online enhancement of the corticospinal excitability by beta (20 Hz) con-TACS and theta-gamma (5 Hz envelope with 140 Hz carrier) am-TACS. However, in Experiment 2 these two interventions induced different online effects for brain oscillations. The beta con-TACS increased beta EEG power on the left sensorimotor and parietal cortices, whereas the theta-gamma am-TACS globally decreased beta EEG power and increased theta EEG power. We also found that, contrary to the previous study [2], EEG data during am-TACS were still contaminated by stimulation artifacts at the frequency of low-frequency envelope.
These results reveal two different modes of inducing corticomotor plasticity by externally applied alternating electric fields. We speculate that beta con-TACS directly resonate with beta oscillations, prevalent in sensorimotor cortex, whereas theta-gamma am-TACS remotely interact with motor cortical activities, resulting in suppression of beta rhythms.

Title: Effect of higher alfaxalone anesthesia on brain functional connectivity in rhesus monkeys

Authors: *C. LI[1], D. KEMPF[1], L. HOWELL[1,2], X. ZHANG[1,2]
[2]Div. of Neuropharm. and Neurologic Diseases, Yerkes Natl. Primate, [1]Emory Univ., Atlanta, GA

Abstract: Alfaxalone is suggested to be an optimal anesthetic in preclinical studies and has been increasingly used in non-human primates (NHPs). However, little is known about its impact on neural activity in anesthetized subjects. In the present study, adult rhesus monkeys (n=4, 9-13 years old) were used to examine its impact on brain functional connectivity such as default-mode network (DMN). Alfaxalone was first given as an intramuscular injection (5 mg/kg) followed by intravenous infusion (0.125 or 0.156 mg/kg/min) to anesthetic effect for about 1 hour. Then alfaxalone was stopped and followed with ~0.8% isoflurane to provide continuous anesthesia. Resting state functional MRI (rsfMRI) data were acquired using a multiband EPI sequence (TR/TE=1090 ms/25ms, spatial resolution= $1.5\times1.5\times1.5mm^3$) and started ~15 minutes after animals were moved into the scanner (Siemens 3T Trio with an 8-channel Tx/Rx volume coil). rsfMRI data were processed by FSL and AFNI. The averaged time course of rsfMRI signal in PCC (posterior cingulate cortex) was used for seed-based correlation analysis separately. *Z* transformation was applied to the individual correlation maps to show normalized correlation maps. The averaged *z* values of connectivity between PCC and ACC (anterior cingulated cortex) or DMPFC (dorsal/media prefrontal cortex) were examined for statistical differences. The results demonstrate that high dosage alfaxalone significantly reduces functional connectivity in the dominant DMN such as PCC-ACC ($p<0.05$) and PCC-DMPFC ($p=0.06$) connectivity compared to 0.8% isoflurane administration. Also, high dosage alfaxalone showed a stronger inhibiting effect than low dosage alfaxalone by significantly reducing functional connectivity in PCC-DMPFC ($p=0.05$) but not in PCC-ACC with low dosage alfaxalone. These findings reveal that alfaxalone suppresses neural activity more dramatically than isoflurane anesthesia in experimental animals in a dose-dependent manner, suggesting such dose-dependent effects should be considered when choosing anesthetic protocols to examine neuronal function in neuroimaging.

Title: Mutations causing alternating hemiplegia of childhood disrupt normal neural network activity patterns

Authors: *K. MCSWEENEY[1], E. HEINZEN[2], M. BOLAND[2], D. GOLDSTEIN[2]
[1]IGM, [2]Inst. for Genomic Med., Columbia Univ., New York, NY

Abstract: Alternating Hemiplegia of Childhood (AHC) is a rare and debilitating neurological disorder affecting one in a million children. Greater than 80% of known cases are caused by de

novo mutations in the *ATP1A3* gene. ATP1A3 is exclusively expressed in neurons and is thought to restore basal ionic concentrations in neurons after periods of fast firing. However, the underlying mechanism of pathogenesis of AHC-causing mutations is still unknown, and there are currently no universally effective treatments. We use a multi-well microelectrode array (MEA) platform to evaluate the spontaneous activity of neuronal cultures possessing AHC-causing mutations. MEAs are powerful tools for detecting spontaneous neuronal activity and are an emerging platform for identifying targeted therapies. We recorded neuronal activity 15 minutes each day to collect spike, burst, and network synchronicity data. Preliminary data gathered from primary cortical cultures from two mouse models of AHC - Myshkin (I810N) and Mashlool (D801N) - indicate aberrant organization of neuronal firing patterns in comparison to primary cultures from wild-type littermates. We hypothesize that aberrant activity is due to an imbalance of inhibitory and excitatory signals in the neuronal cultures. To test this hypothesis, we evaluate the effect of several compounds with known mechanisms of action on the activity of cultured neuronal networks. Any identified compound that corrects the aberrant activity patterns will then be tested *in vivo* in the mouse models. Preliminary data indicate a strong shift in the response of mutant neuronal cultures to ATP, providing evidence for decreased ATPase activity in mutant cultures. These experiments illustrate the utility of the MEA platform in the evaluation of genetic mutations in rare neurological disorders and the response of such cultures to compounds. This platform will be used to identify candidate targeted therapeutics for patients with AHC.

Title: Subthreshold divisive normalization controls gain and timing in hippocampus

Authors: *S. MOZA, A. BHATIA, U. S. BHALLA
Natl. Ctr. For Biol. Sci., Bangalore, India

Abstract: We report that tightly balanced feed-forward inhibition performs Subthreshold Divisive Normalization (SDN), and controls the peak timing of post-synaptic potentials (PSPs) in the hippocampal CA3-CA1 circuit. SDN is a novel form of gain control, which expands the

range of inputs that a single neuron can accommodate before it reaches spike threshold. While there are several reports of divisive normalization at the firing rate level in sensory cortices (Olsen, 2008; Carandini, 1997), this is the first report, to our knowledge, of such a mechanism at the subthreshold level.
We used a DLP projector (60Hz refresh rate) to project 16um x 16um spots (10ms pulse) on channelrhodopsin-2 expressing CA3 neurons in acute mouse hippocampal slices. Each stimulus combination produced a PSP, which we read out from a patched CA1 neuron. In order to explore a wide dynamic range of inputs, we presented > 100 combinations of 1, 2, 3, 5, 7, or 9 input spots to each cell. We first presented single spots individually and calculated sums of their PSPs (linear sum). We then presented combinations of spots simultaneously, and measured their response (observed sum).
We compared the linear sum from individual spots to the observed sum of the corresponding spots presented together. It turns out that over a large range of inputs, the responses fit a divisive normalization model better than subtractive or divisive inhibition. Blocking inhibition in the slice abolishes SDN.
To further understand the role of inhibition in the mechanism of SDN, we went on to look at the relationship between excitation and inhibition for every single combination of projected spots. Surprisingly, we discovered that excitation and inhibition were very tightly balanced for every one of those combinations. We also built a conductance model which supports divisive normalization in a tightly balanced feedforward inhibitory network. Our observations are in agreement with theoretical ideas of tight E/I balance (Deneve, 2016; Vogels, 2009), which predict that neurons in a tightly balanced network are efficient temporal coders.
While SDN allows integration of a large range of inputs, at large input amplitudes, SDN results in saturation of PSP peaks. The accompanying saturation implies loss of information of input amplitudes. Interestingly, we find that this information is not lost, but simply transferred from amplitude to time of peak of the PSP, with larger number of inputs leading to earlier time to peak. This is a way by which spike timing can be controlled at millisecond time scales, which is relevant to phenomenon like hippocampal replay of memories (Jadhav, 2011).

Title: Spontaneous neural dynamics and functional connectivity in cortical circuits across timescales

Authors: *R. FERNANDEZ GALAN[1], N. KODAMA[2], T. FENG[3], J. J. ULLETT, 44106[3], S. S. SIVAKUMAR[3]
[1]Dept Neurosci, [2]Dept. of Neurosciences, [3]Case Western Reserve Univ., Cleveland, OH

Abstract: Spontaneous activity in brain circuits provides a means to investigate neuronal interactions and measure their functional connectivity, which is crucial to understand how the brain processes information. We investigated spontaneous neural activity in cortical circuits from the mouse neocortex *in vitro* using high-density, multielectrode arrays (MEA). The arrays consist of 120 electrodes evenly spaced over an octagonal area of 1.2 squared mm, which enables the study of activity patterns with unprecedented temporal and spatial resolutions across the six cortical layers over a few cortical columns. Using spike-sorting algorithms, action potentials from multiple cells were resolved from each electrode in the MEA. This allowed us to investigate the spontaneous activity and interactions of hundreds of neurons for up to 30 min. We found that cortical neurons display very diverse firing patterns across multiple frequencies and timescales: some neurons fired tonically, some transiently, and some in regular bursts. The timescales of bursting ranged from milliseconds to several seconds. To investigate the functional connectivity of cortical circuits across timescales, we first treated the spike trains as count processes, that is, we “binned” the firing of each neuron using bins of increasing duration, from 1 ms to 32 s across 20 timescales evenly spaced in logarithmic units. We then computed the cross-correlations in the spike count across neurons for each timescale. On fast timescales, up to the order of a second, interactions between neurons are dominated by sparse and positive correlations. In contrast, on slower timescales, up to the order of tens of seconds, cortical circuits self-organize into two competing, heterogeneous networks with negatively correlated firing fluctuations. One of these networks co-localizes with layer 2/3; the other with layer 5/6. In terms of network properties, the assortativity of functional connections increases dramatically on slower timescales, and the number of functional connections is maximal on intermediate timescales on the order of 1-2 seconds. Altogether, our results demonstrate that neuronal interactions in cortical circuits are qualitative and quantitatively different on different timescales.

Title: The role of local excitatory networks in the lateral amygdala in emotional memory learning

Authors: *M. ABATIS[1], R. NIU[1], R. PERIN[2], G. GIOBELLINA[1], H. BITO[3], H. MARKRAM[4], R. STOOP[1]
[1]Dept. of Psychiatry, CHUV, Prilly, Switzerland; [2]Brain Mind Institute, EPFL, Lausanne, Switzerland; [3]Univ. Tokyo Grad Sch. Med., Tokyo, Japan; [4]EPFL, Blue Brain Project, Lausanne, Switzerland

Abstract: Introduction: Fear conditioning combines an unconditioned stimulus with a conditioned stimulus (CS) so that the CS alone can subsequently elicit fear-related responses. While the convergence of signals onto single lateral amygdala (LA) neurons has been extensively studied, little is known about how a putative local network could perform memory encoding and recall through pattern completion. Recent findings in network organization of the hippocampal CA3 suggest that sparse networks are capable of pattern completion (Guzman et al., Science, 2016).
Aims: We hypothesized that threat-related signals are re-integrated in the LA through local neuronal assemblies. To address this, we aimed to characterize the LA's network organization, and plasticity-induced changes.
Methods: We used whole-cell patch-clamp recordings to simultaneously access up to 12 neurons at a time. The connectivity of over 563 neurons was assessed by delivering, successively, trains of 8 pulses at 20 Hz and monitoring for induced post-synaptic potentials. Neuronal memory-recruitment was assessed by expressing either a destabilized GFP or Channelrhodopsin-2 (Tamoxifen-inducible Cre-recombinase) under an enhanced Arc promoter, after threat memory recall.
Results: We observed ~2% connectivity biased towards close-proximity neurons. Analysis of the peak excitatory post-synaptic current amplitudes by simple binomial analysis suggested 1-5 release sites, with a quantal size of 10±3 pA and probability of release of ~0.5 ± 0.2 (±SD). Furthermore, these connections were amenable to spike-timing-dependent plasticity which led to a 30% increase in excitatory post-synaptic potential (EPSP) amplitude. Next, we assessed plasticity among neurons participating in the recall of a threat memory trace. Recruited neurons had higher probability to observe an EPSP (0.5±0.04 %) compared to controls (0.4±0.01%; ±s.e.m.). This suggests that either more efficient connections enhance local network excitability and favor memory recruitment or that the observed changes result from memory recruitment. Finally, we investigated the contribution of memory-recruited neurons in pattern completion *in vivo*. We found that both CS and optogenetic activation - but not a neutral tone - could reproduce similar activation patterns.
Conclusions: The LA network follows a "small-world" network organization, with memory-recruited neurons forming stronger connections capable of pattern completion. This suggests either that enhanced local network excitability favors memory recruitment or that neurons are biased to be recruited among efficient network nodes, to be determined by future experiments.

Title: Changes of intracellular calcium concentrations induced by oxytocin and vasopressin on dorsal horn cells from spinal cord slices: Implications in nociception modulation

Authors: *I. TELLO-GARCÍA[1], G. MARTÍNEZ-LORENZANA[1], A. GONZÁLEZ-HERNÁNDEZ[1], J. PÉREZ-ORTEGA[2], J. BARGAS[2], M. CONDÉS-LARA[1]
[1]Univ. Nacional Autónoma De México, Queretaro, Mexico; [2]Inst. De Fisiología Celular - Univ. Nacional Autónoma De México, México, Mexico

Abstract: Recently, oxytocin (OT) and vasopressin (AVP) have been studied as potential modulators of endogenous analgesia. At spinal level the precise molecular mechanisms of this modulation are still unknown. Some studies suggest that such modulation involves the oxytocin receptor(OTR) while others support the vasopressin receptor (V1aR) hypothesis. In this way, it is unknown how these neuropeptides alter the dynamics of intracellular calcium concentrations, $[Ca^{2+}]_{i,}$ to modulate the transmission of information in the spinal cord cells.
As an initial approach, the aim of this study was to evaluate the effect of OT and AVP on intracellular Ca^{2+}-dependent cellular activity of the dorsal horn of the spinal cord. We used Ca^{2+} video-microscopy analysis on lumbar portion of spinal cord slices of neonatal rats. To identify projection neurons populations, the rats were previously injected with neuronal retrograde tracer (dextran tetramethylrhodamine) in the Gracile nucleus or in the ventral posterolateral thalamic nucleus (VPL). The slices were incubated with Fluo-8AM® and subsequently videos of spontaneous activation on spinal dorsal horn was recorded before (spontaneous or basal activity) and after OT (5 μM) or AVP (5 μM). Data analysis was carried out using algorithms written in LabView® and MatLab® where changes in fluorescence of regions of interest (ROI's) corresponding to cells were measured and normalized to evaluate their change over time. Also, coactivity, clustering and connectivity analysis were performed to estimate the changes in activation of cell populations over time.

Cellular activation of the spinal cord was modified by both OT (5 μM) and AVP (5 μM). OT produces an increase on intracellular Ca^{2+} concentrations mainly in superficial laminae (I-III) of the dorsal horn, promoting the: (i) coactivation of groups of cells, (ii) formation of microcircuits, and (iii) interaction between them. In contrast, AVP induces a decrease on intracellular Ca^{2+}-dependent activation along the dorsal horn laminae (I-VI). In addition, AVP abolishes the coactivation of groups of cells and the interaction between them. The results suggest that both OT and AVP modulate changes in cellular activation dynamics dependent of intracellular Ca^{2+} variations, changes that could be responsible for the antinociceptive functions attributed to these peptides. However, it is necessary to evaluate and identify how the activation dynamics of specific cellular populations changes by the OTR or V1aR activation.

Title: Hierarchical heterogeneity of circuit properties across human cortex shapes multiple temporal scales of spontaneous dynamics

Authors: *M. DEMIRTAS[1], M. HELMER[2], J. B. BURT[3], J. JI[3], S. SOTIROPOULOS[5], A. ANTICEVIC[4], J. D. MURRAY[2]
[1]Psychiatry Dept., [2]Dept. of Psychiatry, [4]Psychiatry, [3]Yale Univ., New Haven, CT; [5]Univ. of Oxford, Oxford, United Kingdom

Abstract: A central challenge in systems neuroscience is to understand how the large-scale organization of brain function emerges from structured long-range interactions among local neural circuits. Noninvasive neuroimaging studies, such as fMRI, have shown that human brain

is organized into large-scale networks. Yet neuroimaging cannot directly inform the state of cortical physiology. One approach to bridge this gap is to develop biophysically-based models of large-scale brain circuits that capture key features of neuronal and synaptic dynamics. These models can be integrated with multimodal human neuroimaging constrained by structural connectivity, and optimized to match functional dynamics. Early modeling studies have focused on how structural connectivity shapes patterns of resting-state functional connectivity (rs-FC). However, it remains unclear how local circuit properties, and their heterogeneity across brain areas, contribute to these large-scale dynamical patterns. To investigate these issues, we developed a large-scale cortical model of rs-FC that incorporates heterogeneity of local microcircuit properties along the cortical hierarchy (from sensory to association cortex). We parametrized hierarchical differences of circuit properties using a noninvasive MRI-derived measure of structural heterogeneity. To test the model, we harnessed a state-of-the-art multimodal dataset from the Human Connectome Project (HCP): resting-state BOLD, structural connectivity of inter-areal projections derived from Diffusion-Weighted Imaging, maps of local structural heterogeneity, and resting-state MEG. We found the ability of the model to quantitatively fit empirical BOLD rs-FC patterns is substantially improved with hierarchical specialization of circuit properties, specifically with a gradient of increased local recurrent strength along the hierarchy. Furthermore, hierarchical heterogeneity allows the model to capture empirically observed inter-individual variability in rs-FC patterns. Beyond rs-FC of the BOLD signal, the underlying synaptic activity of the heterogeneous model predicted regional heterogeneity in the spectral properties of higher-frequency neural activity. We found that the topography of spectral variation predicted by the model matches to empirical measurements from MEG. Our findings suggest that heterogeneity of local circuit properties across the cortical hierarchy plays an import role in shaping the large-scale organization of resting-state cortical dynamics.

Title: Hierarchical organization of microcircuit specialization across human cortex captured by myelin topography

Authors: *J. B. BURT[1], M. DEMIRTAS[1], W. J. ECKNER[1], J. WANG[1], N. NAVEJAR[2], L. JI[1], A. BERNACCHIA[3], A. ANTICEVIC[1], J. D. MURRAY[1]
[1]Yale Univ., New Haven, CT; [2]Tulane Univ., New Orleans, LA; [3]Univ. of Cambridge, Cambridge, United Kingdom

Abstract: Hierarchy is a general principle underlying the large-scale organization of primate cortex that describes differences in structural and functional properties across cortical areas. Structural hierarchy is determined by the laminar patterns of interareal projections, as measured by anatomical tracer studies. Functional specialization, including in representational selectivity and temporal dynamics, has been found to correlate with structural hierarchy. Yet the neural circuit basis of areal specialization remains an open question. It remains unclear how cortical microcircuit properties vary with hierarchy, especially in the human, where structural hierarchy cannot be measured through invasive tracer studies.
In this study, we validated a noninvasive neuroimaging correlate of structural hierarchy, and found that it captures the dominant spatial pattern of variation in gene expression across human cortex. One MRI-derived measure of regional heterogeneity in cortex is the myelin map, which reveals intracortical differences in myelin content. We found that in the macaque monkey, the myelin map predicts anatomically-defined hierarchical relationships among cortical areas. This validates the myelin map as a noninvasive neuroimaging-based proxy measure for hierarchy which can be applied to human cortex.
Leveraging the human myelin map, we examined hierarchy-related patterns of gene expression variation across human cortex using the Allen Human Brain Atlas. We observed hierarchical gradients in expression profiles for genes regulating synaptic receptor subunit composition, and hierarchical gradients in genes implicated in neuronal subtype specificity, which we show follow trends present in quantitative anatomical measurements in the macaque. Moreover, human cortical myelin map topography was remarkably similar to the first principal component of gene expression variation, indicating that myelin maps capture the dominant mode of gene expression variation across human cortex. Furthermore, we found that risk genes for neurodegenerative disorders exhibit hierarchically graded expression patterns, highlighting the importance of hierarchy for understanding cortical function.
Our findings suggest that hierarchy is a general principle of large-scale cortical organization in primates that underlies structural and functional specialization of local cortical microcircuits. Cortical hierarchy thereby provides a rich theoretical framework for relating human brain function to circuit physiology.

Title: Functional connectivity of the human claustrum

Authors: *F. A. BARRIOS, L. RODRÍGUEZ, S. ALCAUTER
Univ. Nacional Autonoma de Mexico, Queretaro, Mexico

Abstract: The claustrum is a bilateral, small cerebral structure integrated mainly by somas. It is located between the capsula extrema and the putamen's capsula externa. Structural brain connectivity studies show the claustrum is profusely connected to cortical and sub-cortical structures. High resolution tractographyc studies described 4 main groups of neural tracts; anterior projecting to the prefrontal cortex, posterior projecting to the visual cortex, superior to the sensorimotor cortex and lateral to the auditory cortex. Presently, it has not been determined the claustrum's main function, beyond a relay capacity, due its abundant cortical and sub-cortical connectivity. In this work, we present a high resolution functional connectivity study based on 40 resting state studies taken from the Human Connectome Project (HCP, NIH Bleuprint: The Human Connectome Project), with 2x2x2 mm^3 voxel resolution, equivalent to the high resolution tractographyc studies. Functional connectivity was estimated with seed to voxel correlations from anterior and posterior carefully constructed anatomical seeds, placed at the claustrum using Conn (V17, Functional connectivity toolbox, NITRC). Functional connectivity of the claustrum was found ($p<0.05$, p-FDR corrected) with the right and left temporal pole, the right and left pre-central gyri, right and left insular cortex, the anterior cingulate cortex, the superior pre-central gyrus, orbitofrontal cortex, among others. We estimated a general claustrum network shown in the figure, also an anterior posterior segmentation of the functional connectivity of the claustrum was estimated.

Abstract: Locomotor pattern generator (LPG) in mammals has remained a ‘black box’ where inputs to the network were manipulated and the outputs interpreted. However, it has been already

known that spinal interneurons are organized into networks that control the activity and output of the motor system. Recently, it has been elucidated that not only neurons but also glial cells, especially astrocytes, play active roles in various functions in the brain and spinal cord, such as rhythm generation of respiration and mastication. We applied electrophysiological and Ca imaging techniques to the isolated lumber cord preparations and investigated whether not only neurons but also astrocytes are actively involved in generation of rhythmic locomotor-like activities in the LPG during fictive locomotion. Rhythmic locomotor-like neural activity was induced by adding 5-HT and NMDA to the superfusate, and activities of cells in the L5 ventral horn were recorded with a Ca imaging system together with rhythmic neural output from the L4/5 ventral root. Recorded cells were classified into neurons and astrocytes by lowering the superfusate potassium concentration in the presence of TTX (Dallwig and Deitmer, 2002). The detected activities in the neurons and astrocytes, and the output activity were analyzed by cross correlation and causality analyses to illuminate the interaction among the activities of the astrocytes, neurons, and locomotion-like neural output. We found that fractions of not only neurons but also astrocytes revealed rhythmic activities in synchrony with locomotor-like neural output. It was suggested that not only neurons but also astrocytes are involved in the formation of the rhythm and pattern of locomotor neural output in the developing lumbar cord.

Title: Effect of induced hippocampal knockout of Ryanodine Receptor 2 on CA1 cellular activity

Authors: *M. MITTAG, L. WISCHHOF, F. BERTAN, L. SOSULINA, S. REMY, D. BANO, P. NICOTERA, M. FUHRMANN
German Ctr. of Neurodegenerative Dis. (DZNE), Bonn, Germany

Abstract: Calcium (Ca^{2+}) signaling, mediated by entry of Ca^{2+} through the plasma membrane or release from the endoplasmic reticulum (ER), plays an important role in neuronal function. Elevation of intracellular Ca^{2+} triggers release of neurotransmitters at the synapse, contributes to dendritic spikes, induces activity-dependent changes in gene expression and regulates synaptic plasticity. Although much of the entry of Ca^{2+} into neurons occurs through plasma membrane

channels, the ER is the major dynamic pool for intracellular Ca^{2+}. Release of Ca^{2+} from the ER into the cell is mediated by the family of Ryanodine Receptors (RyR). RyR2, a RyR isoform, is abundant in the hippocampus and considering its role in Ca^{2+} homeostasis this raises questions about its contributions to learning and memory processes. We want to investigate the effect of a local knockout of RyR2 in the hippocampus on cellular activity of principal neurons in CA1 and if knockout results in deficiencies in hippocampus-dependent learning. By stereotactic injection of an AAV-based virus carrying the gene for cre-recombinase into the hippocampus, we induce the specific knockout of RyR2 in a RyR2 flx/flx mouse model. We tested learning in a Novel Object Recognition (NOR) task and a Radial Arm Maze (RAM). The combination of two-photon microscopy, a chronic hippocampal window and virally expressed Ca^{2+}-indicators allows the recording of the activity of large neuronal populations in awake animals. We could observe spatially tuned firing in CA1 cells in RyR KO mice. For the future, we aim to further characterize the firing properties of hippocampal neurons in the RyR KO model. We also want to investigate if there are functional alterations that relate to performance in learning tasks.

Title: A chemogenetic-rsfMRI study in awake rats revealed the inactivation of anterior cingulate cortex in the brain functional network

Authors: *W. TU[1,2], Z. MA[1], Y. MA[1], D. CHAU[1], Y. LIU[1], N. ZHANG[1,2]

Abstract: Brain functional network can be described as a collection of nodes (brain regions) connected by edges (functional connectivity). Similar to human studies, connectivity-based parcellation analysis of brain functional network on awake rats exhibited a topological organization with specialization and integration. Cingulate cortex is crucial for mediating emotion, cognition, and motion. It is recognized as a functional hub region of resting-state rats, characterized by its high degree of connectivity to other brain regions. Inhibition of a hub node

has a profound impact on the brain functional network. However, our understanding on the role of anterior cingulate cortex in the whole brain level was mostly limited to anatomical research. The present study combined the designer receptors exclusively activated by designer drugs approach and resting-state functional magnetic resonance imaging (chemogenetic-rsfMRI) to elucidate the impact of anterior cingulate cortex inhibition on the brain functional network in awake animals. We introduced genetically encoded modified muscarinic G-protein-coupled receptors hM4Di into dorsal anterior cingulate cortex (dACC) using adeno-associated viral vector. Clozapine-N-oxide (CNO) was injected intraperitoneally (IP) 30-45min before the rsfMRI scan to drive the expression of hM4Di in dACC. Functional blood-oxygenated-level dependent signal was measured to assess the dynamics on functional connectivity. Using the Chemogenetic-rsfMRI approach, we were able to reveal the functional circuit underlying the dACC-related processes in awake state.

Title: Behavior dependent antagonistic synchronization of beta and low frequency hub neurons in the macaque fronto-parietal grasping network

Authors: *S. SHESHADRI, B. DANN, H. SCHERBERGER
German Primate Ctr., Goettingen, Germany

Abstract: Synchronization in different frequency bands has been identified as an important mechanism for selective communication within and between different cortical areas. Recent studies in the fronto-parietal network have shown that this synchronization is coordinated by a group of hub neurons. However, it is unknown how network coordination changes with respect to behavior. To this end, we trained two macaque monkeys to perform a delayed grasping task with randomly mixed instructed and free-choice trials, in which a handle had to be grasped with one of two possible grip types. Neuronal activity was recorded in parallel from the fronto-parietal grasping network including the ventral premotor cortex (area F5) and the anterior intraparietal area (AIP) with 64 electrodes chronically implanted in each area. Single unit and local field potential (LFP) activity, representing the local population activity, was extracted from all channels. The degree of synchronization between single units and LFP signals was calculated

using pairwise phase consistency (PPC). Importantly, PPC is a spike-rate independent metric that allows the comparison of different behavioral conditions associated with different single-unit firing rates. The large number of simultaneously recorded units and LFPs allowed us to analyze the synchronization network structure by calculating PPC of all single unit and LFP pairs. Beta (18-35Hz) and low frequency (2-8Hz) bands turned out to be the dominant frequency bands in the network. In beta band, almost exclusively a group of single units in AIP were synchronized with larger populations in both areas. In contrast, synchronization in the low frequency range was largely confined to a group of single units in F5. The average synchronization of single units with LFPs was heterogeneously distributed, confirming that the strongly synchronized groups of units in both frequency bands are hubs. Interestingly, there was hardly any overlap between the two groups although there was a strong overlap of local population activity to which they were synchronized. We found that beta hubs were predominantly synchronized to the network during passive periods (fixation and memory), whereas low frequency hubs dominated synchronization during active periods (cue and movement). In contrast, condition-dependent differences were associated with changes in both beta and low frequency network connectivity. These findings suggest that behavior-relevant changes in the cortical motor network are coordinated by distinct groups of hub units selectively synchronizing network activity in the beta and low frequency range.

Title: Steady-state visual stimulation frequency modulates functional networks

Authors: *Y. CHAI, D. A. HANDWERKER, J. GONZALEZ-CASTILLO, P. A. BANDETTINI
Section on Functional Imaging Methods, NIMH, NIH, Bethesda, MD

Abstract: Background: Studies of the primary visual cortex tend to use stimuli with less than a 20 Hz flickering rate and focus on the occipital cortex. It’s known that steady-state visual evoked potentials (SSVEP) are widely distributed over not only occipital cortex but also multiple functionally distinct brain areas. Additionally, Iaccarino & Singer et al. (2016) showed physiological changes accompanying 40 Hz visual stimuli. We hypothesized that steady-state visual stimulation will drive the large scale functional network changes across the whole brain, and that these changes will dependent on the stimulation frequency. To test these hypotheses, we measured fMRI in humans while applying steady-state visual stimulations at multiple

frequencies, and examine changes in functional networks; as well as their relationship to visual activation. **Methods:** Twelve subjects were scanned on a Siemens 3T system. Steady-state visual stimulation at 4 different frequencies (1 Hz, 10 Hz, 20 Hz and 40 Hz) was applied through reversing the pure black and white screens. Data were collected with continuous stimulation for 386 sec (and a control run with no stimulation) and with a block-designed stimulation (10 sec ON, 20.6 sec OFF). Simultaneous multi-slice (SMS) EPI was used with TR/TE = 1700/28 ms, matrix 90×90, 2.5 mm isotropic voxels, 52 slices, SMS factor = 2. After standard fMRI preprocessing, graph-based modularity analysis was employed to identify different network modules during steady-state visual stimulations, and further investigated the modulation of intra and inter network interactions at different stimulation frequencies. **Results:** At the low stimulation frequency (1 Hz), network strength and efficiency (both local and global) inside visual module is significantly higher in comparison to other higher stimulation frequencies. As the stimulation frequency increased, the network strength and efficiency decreased within the visual module while increased within salience network and sensorimotor modules. The thalamus showed the largest correlation with visual module at 10 Hz. Subjects with stronger correlations between the thalamus and visual module at 40 Hz, also have larger amplitude responses of visual activation to 40Hz block stimulation.

Title: The neural circuit mechanism of spatial orientation in *Drosophila* -- connectomic analysis and modeling

Authors: *C. LO[1], T.-S. SU, 300[2], W.-J. LEE[2], Y.-C. HUANG[3], C.-T. WANG[3]
[1]Natl. Tsing Hua Univ., Hsinchu, Taiwan; [2]Inst. of Systems Neurosci., [3]Natl. Tsing Hua Univ., Hsinchu city, Taiwan

Abstract: The ability of maintaining spatial orientation is crucial for an animal to perform goal-directed movements. Recent *Drosophila* studies have revealed the critical role of the ellipsoid body (EB) in tracking spatial orientation, but the precise circuitry and underlying mechanisms

remain unclear. We analyzed connectomic data of *Drosophila* central complex and discovered that the circuit connecting EB and the protocerebral bridge (PB) form symmetric and asymmetric rings. The asymmetric rings can be further divided into two sub-rings, one with counterclockwise and the other with clockwise patterns. Interestingly, the circuits involving the sub-rings are delicately organized in a way that each sub-ring can be individually activated by a pair of neurons that innervate PB. We further constructed a spiking neural circuit model based on the circuits reconstructed from the connectomic data. We demonstrated that the symmetric ring is capable of sustaining persistent neural activity that encodes spatial orientation, while the asymmetric rings perform angular path integration and update orientation when the body rotates in the dark. The model reproduces several key features of EB activity and makes experimentally testable predictions, providing new insight into how spatial orientation is maintained and tracked at the cellular level.

Title: Preliminary investigation of pain-related changes in cerebral blood volume in patients with neuropathic pain after scrambler therapy

Authors: *S. JOO, C. SEO
Hangang Sacred Heart Hosp., Seoul, Korea, Republic of

Abstract: OBJECTIVE:
Pain Scrambler therapy is a patient-specific electrocutaneous nerve stimulation device. Post burn neuropathic pain is often difficult to treat effectively. The neuropathic pain may result from injury to sensory nerves that hampers conductance of neuronal messages along the large A and small C afferent fibers to the spinal cord. We utilized MRI to measure CBV in patients who treated by Scrambler therapy following burn injury to investigate changes in the pain network associated with neuropathic pain.
INTERVENTIONS
The intensity of neuropathic pain was measured using the Visual Analogue Scale (VAS). 8 subjects were recruited to participate in this study. The subjects complained of severe neuropathic pain that was rated at least 5 on the visual analogue scale (VAS), despite treatments with medications and physical modalities. Each Scrambler Therapy with the MC-5A Pain Scrambler Therapy® technology device was performed for 45min daily (Monday through Friday) for 10 consecutive days. The stimulus was increased to the maximum intensity bearable by the

individual patient without causing any additional pain or discomfort. Voxel-wise comparisons of relative CBV maps were made between before Scrambler therapy and after 10 sessions Scrambler therapy over the entire brain volume. The relationship between individual participant CBV (measured in voxels) and VAS score was also examined.

RESULTS

Compared to CBV before Scrambler therapy, the patients had a decrease CBV on primary somatosensory cortex, secondary somatosensory cortex, insular cortex(IC) and anterior cingulate cortex [ACC]) after 10 sessions Scrambler therapy.

CONCLUSIONS

We observed changed CBV in regions associated with cerebral pain network of patients who had undergone burn injury. This study suggests that CBV changes were related to neuroplasticity associated with neuropathic pain after Scrambler therapy.

Title: Parvalbumin interneurons control spike output in deep layer principal neurons in the *In vitro* mouse perirhinal - entorhinal cortex

Authors: *N. L. CAPPAERT[1], J. G. WILLEMS[2], W. J. WADMAN[3]

[1]Univ. Amsterdam, Amsterdam, Netherlands; [2]Swammerdam Inst. for Life Sci., Univ. of Amsterdam, Amsterdam, Netherlands; [3]Univ. Amsterdam, Amsterdam, Netherlands

Abstract: The perirhinal cortex (PER) and the lateral entorhinal cortex (LEC) link the neocortex with the hippocampus and are involved in cognitive functions like learning and memory and object recognition. Even though anatomical connections from the neocortex to the hippocampus exist, the information transfer through the PER/LEC network occurs with a low probability. It is hypothesized that this gating is most likely controlled by inhibitory interneurons and this study investigated the role of parvalbumin positive (PV) interneurons located in the deep layers of the PER and LEC.

The response to stimulation of the adjoining superficial agranular insular cortex (AiP) was measured in PV interneurons and principal neurons in the deep layer PER/LEC network in acute horizontal mouse brain slices in whole cell patch recordings. Action potential firing was rarely observed in principal neurons in response to AiP stimulation (6% of the cases) confirming the

hypothesis that information transfer through this network occurs with a low probability. Linear decomposition of the evoked synaptic currents was performed to separate the excitatory from the inhibitory conductance. AiP stimulation resulted in a small excitatory conductance and a substantially larger inhibitory conductance in principal neurons. Simultaneous recordings of a principal neuron and an adjacent PV interneuron were performed to address the origin of this large inhibitory conductance evoked in principal neurons. The same AiP stimulus evoked a larger synaptic input with a shorter latency in PV interneurons compared to the principal neurons. Moreover, the PV interneurons were capable of firing action potentials in response to stimulation.
The aggregated results demonstrated that the inhibitory conductance observed in the principal neurons could well be the result of a response to the spikes in the population of PV interneurons. In conclusion, the excitatory input from the AiP onto deep layer PER/LEC principal neurons is, in these experimental conditions, under strong control of PV interneuron inhibition. Our results indicate an essential gating role for PER/LEC PV interneurons in the signal transfer from the AiP through the PER/LEC network.

Title: Slow-wave cortical activity within local circuits during REM-like state revealed by fast Voltage-Sensitive Dye imaging

Authors: *M. NAZARIAHANGARKOLAEE, J. KARIMI, M. TATSUNO, M. H. MOHAJERANI
CCBN, Univ. of Lethbridge, Lethbridge, AB, Canada

Abstract: Sleep in mammals consists of two basic stages: non-rapid eye movement (NREM) and rapid eye movement (REM) sleep. NREM sleep can be distinguished by slow and high-amplitude cortical EEG signals while REM sleep is characterized by “desynchronized” low-amplitude fast cortical rhythms. While until recently it has been widely believed that cortical activity during REM sleep is globally desynchronized, using sparse electrophysiological recording a recent study (Funk et al., 2016) showed local slow waves in primary cortical areas

during REM sleep. However, the electrophysiological technique has been unable to resolve the regional structure and dynamics of these activities due to relatively sparse sampling. Here, we investigated local changes in neuronal activity during REM state using mesoscale imaging. Urethane anaesthesia was used as a model of sleep as it induces spontaneous alternation of brain state between REM- and NREM-like in rodents in which cortical and hippocampal activities resemble to those of natural sleep (Clemet et al., 2008). The wide-field VSD imaging from neocortex was combined with LFP recording from ipsilateral hippocampus and motor/somatosensory cortex with a unilateral preparation in anesthetized mice. Generally, urethane anesthesia induced state alternation in VSD signal which was concurrent with LFP state changes. However, in REM-like state slow cortical activity were not globally reduced; while midline and posterior areas typically showed desynchronized patterns, anterior and lateral regions showed synchronized activity. Our data also revealed that synchronized/desynchronized regions during individual REM-like episodes can be dynamic. Our results suggest that brain state alternation under urethane anesthesia could change the cortical ensembles activity reported by VSD imaging and provide evidences for the locality of cortical desynchronization during REM-like state.

Title: Cortical ensembles based on dendritic plateau generation in the prefrontal cortex

Authors: *S. ANGULO[1], J. W. GRAHAM[1], P. GAO[2], S. DURA-BERNAL[1], S. A. NEYMOTIN[3], S. D. ANTIC[2], W. W. LYTTON[1]
[1]Pharmacol. and Physiol., SUNY Downstate Med. Ctr., Brooklyn, NY; [2]Inst. for Syst. Genomics, Univ. Connecticut Hlth. Ctr., Farmington, CT; [3]Dept. of Neurosci., Brown Univ., Providence, RI

Abstract: Prefrontal cortex (PFC) performs executive functions, which require the selection of relevant information from inputs from multiple brain areas. At the cellular level, cortical pyramidal neurons in Layer 5 of the PFC can produce dendritic plateaus, sustained depolarizations with AMPAr and NMDAr activation in basal dendrites. Our embedded-ensemble encoding theory (EEE) hypothesizes that dendritic plateaus put individual cells in a Standby state. Cells in this state have reduced threshold to firing and can more readily produce

synchronized firing in response to afferent synaptic activity. Cells that are firing together are in the Embedded state, in which ensemble neurons exhibit synchronized firing within the column or across columns. Dendritic plateaus have been well characterized at the cellular level, but their implications at the network level remains unknown. We hypothesize that the generation of dendritic plateaus in the pyramidal neurons will be relevant for the formation of neural ensembles. For this, we modeled and simulated a PFC columnar network with a connectivity that leads to dendritic plateaus, and studied the effects of subpopulations of neurons in Standby or Embedded states. We used the NetPyNE package, which extends the NEURON simulator to facilitate building and parallel optimization of neuronal networks. We built a network simulating the architecture of PFC in rats that includes layers 2/3, 5, and 6. A simplified excitatory pyramidal neuron model was included in L2/3 and L6. An excitatory pyramidal neuron in L5 was optimized to simulate experimental findings that generate dendritic plateaus. Interneurons were added to the model to every layer (parvalbumin, somatostatin, and VIP positive interneurons) with proportions and connectivity according to previous reports. Local excitatory connectivity included mainly AMPA receptors. Long-range input connectivity was designed to target the basal dendrites of L5 pyramidal neurons. Long-range connectivity included AMPA and NMDA receptors with different synaptic weights to obtain dendritic plateaus. L5 pyramidal neurons receiving long-range inputs were able to induce dendritic plateaus and a high frequency rate in comparison with other network subpopulations. The generation of dendritic plateaus induced standby and embedded ensembles in our PFC network model and may be essential for the processing of multimodal cortical information.

Title: Functional and effective connectivity in a motor control center

Authors: *R. FOLLMANN, C. J. GOLDSMITH, W. STEIN
Sch. of Biol. Sci., Illinois State Univ., Normal, IL

Abstract: Nervous systems continuously receive sensory inputs from various modalities that are processed in many neural centers, including premotor circuits that are involved in controlling motor output and action selection. However, little is known about how premotor networks

process multiple individual and concurrent sensory information. Using the crustacean stomatogastric nervous system, we investigate the dynamic restructuring of a premotor circuit under distinct modulatory and sensory conditions, exploring the functional and effective connectivities of the premotor neurons network (Bullmore and Sporns, 2009; Seth et al., J Neurosc, 2015). The stomatogastric motor circuits are under continuous modulatory control by descending projection neurons located in a premotor region that receives various sensory inputs (Stein, J Comp Physiol A, 2009). We have previously characterized the 3D structure of this premotor region, the location of descending neurons, and their contribution to motor pattern selection in different sensory and modulatory conditions (Follmann et al., J Comp Neurology, 2016; Goldsmith et al, Neuroscience Meeting, 2017).
Here, we stimulated chemosensory and mechanosensory pathways known to produce distinct motor outputs (Hedrich et al., J Neurophysiol, 2009), and recorded the neuronal population in this premotor region at individual neuron resolution using voltage-sensitive dye imaging. Experimental data processing consisted of a drift removal function in combination with a nonlinear energy function, and a spike threshold based on the variance of the signal. To assess sensory responses, we first characterized the functional connectivity between neurons using pairwise correlations of their activity responses. The majority of neurons responded to both sensory modalities, with the mechanosensory input consistently eliciting stronger responses. Our analysis indicate that distinct dynamic network structures exist to process the two sensory modalities. For concurrent inputs, a new functional network emerged, distinct from both individual networks, indicating a shared premotor network that is dynamically reconfigured according to changes in sensory conditions. We are currently investigating such dynamic reconfigurations using Granger causality measure (Granger, Econometria, 1969) to infer directed causal interactions between the premotor neurons. The resulting effective connectivity of the premotor neurons may reveal strategic directional influences among the premotor neurons necessary for the functional reconfiguration of the network.

Title: Patterns of coherence and incoherence driven by structural connectivity in human connectome

Authors: *K. BANSAL[1], G. LIEBERMAN[2], T. D. VERSTYNEN[3], J. M. VETTEL[2,4,5], S. F. MULDOON[1]
[1]Univ. at Buffalo, SUNY, Buffalo, NY; [2]US Army Res. Lab., Aberdeen Proving Ground, MD; [3]Carnegie Mellon Univ., Pittsburgh, PA; [4]Univ. of Pennsylvania, Philadelphia, PA; [5]Univ. of California, Santa Barbara, CA

Abstract: Dynamic patterns of coordinated activity in human brain networks capture and predict human behavior. Fundamentally, this activity originates as interacting neural populations form domains of coherence and incoherence, a phenomenon referred to as a 'chimera state' in a complex systems framework. The appearance of chimera states is due to an interplay between the characteristic dynamics of the interacting network elements, topology, and coupling functions, but the exact conditions that give rise to these states remain unknown in complex environments. Here, we analyze the emergence of chimera states using brain data across a cohort of thirty individuals. Using diffusion weighted imaging, anatomical white matter connectivity matrices are derived for each individual and used in a data-driven computational model of individual brain dynamics. We observe characteristic differences in chimera patterns across individuals, suggesting that the model serves as a valuable tool to understand between-subject variability. We identify that default mode and subcortical sub-networks of the brain show patterns of chimeras that are similar across subjects. This could indicate a limited role of these regions in driving individual variability.

Title: Hallmarks of criticality under subsampling

Authors: *Y. KARIMIPANAH, D. PLENZ
NIMH, NIH, Bethesda, MD

Abstract: In the cortex, numerous experimental studies have demonstrated that ongoing or evoked activity in superficial layers of neocortex is scale-invariant in space and time. Such scale-invariance has been hypothesized to be a signature of a critical state; a state at the transition between two phases of short-lasting and long-lasting activity, which conveys several advantages

in information processing. All experimental evidence collected so far, however, suffers from the problem of subsampling, which in simulations has been clearly shown to degrade numerous measures of criticality such as power law distributions in sizes and durations or branching parameter estimates. Given these model prediction of subsampling, experimental identifications of true power law scaling should be rare, which is in contrast to what has been reported. Here we address this apparent contradiction between predicted effects of subsampling from theory and simulations and the established power law scaling in experimental reports. Using a minimal computational model of binary probabilistic neurons with sparse random connectivity, we show that adjusting the temporal resolution of the analysis to that of the average network inter-event interval not only retrieves power law distributions for even a small number of sampled neurons, but it also reveals the scaling relation between their exponents if network dynamics is truly critical. This adjustment, which is commonly applied to experimental findings, was further studied analytically and we discuss potential constraints on its applicability for conventional avalanche analysis techniques. Furthermore, we show, both analytically and numerically, that the compelling measure of 'critical slowing down' does not require a particular temporal resolution, yet is also robust to subsampling effects. Our results show that certain signatures of criticality can be reliably retrieved in critical networks even under subsampling conditions.

Title: A brain imaging study of functional MRI using ASSR in bipolar disorder

Authors: *K. TAKAO
Natl. Hosp. Organization Hizen Psychiatric C, Kanzaki-Gun, Japan

Abstract: Introduction: The auditory steady state response (ASSR) is one of the indexes of the neural network function of the hearing processing. There are reported that much abnormalities of the gamma band activity in schizophrenia patients. In the functional MRI (fMRI) using ASSR task, there is reported that the 80-Hz stimulation evoked larger blood oxygenation level dependent (BOLD) responses, compared with the other stimulation frequencies in acute phase schizophrenia. However, there is no fMRI using ASSR task study in mood disorders.Objective: In this study, we examined the reaction of the ASSR task in bipolar disorder in using fMRI.Methods: 20 patients of bipolar disorders and 20 normal controls participated in this study. We presented auditory stimulation using a 4-min-block-design paradigm with 8 blocks of 15 seconds of rest and 15 seconds of stimulation including 15click trains. The stimuli were 1-ms

clicks, presented binaurally as trains of clicks for each frequency (29, 30, 40, and 80-Hz). We measured BOLD signals, using a 1.5-T MRI made in Philips Company. Image processing and statistical analyses were performed using the statistical parameter mapping software SPM12 within MATLAB R2015a.Results: We conducted a group analysis between 20 patients of bipolar disorder and 20 normal controls. There is an interaction effect between BOLD responses of patients and healthy people with 40-Hz and 80-Hz stimuli in left FO frontal opeculum (p=0.000001, uncorrected). There is an interaction effect at 40-Hz and 80-Hz stimuli in Post-Hoc analysis (p=0.00004, uncorrected).Conclusion: These results suggested a left frontal lobe dysfunction in the bipolar disorders patients.

Title: The role of parvalbumin- and cholecystokinin expressing interneurons in CA3 pattern completion vs. separation

Authors: *S. K. RASHID[1], M. A. DUFOUR[2], R. ZEMLA[2], J. BASU[1]
[1]Neurosci., [2]Neurosci. Inst., New York Univ. Sch. of Med., New York, NY

Abstract: The hippocampus has long been implicated as a center for encoding and recalling episodic memory related to the knowledge of people, places, objects, and events. Pyramidal cells in area CA3 of the hippocampus are essential for retrieval of contextual fear memories and spatial reference memory. These neurons have been shown to be involved in both pattern completion and pattern separation, two important processes for accurate memory recall. Pattern completion allows for an accurate generalization from partial input (i.e. recognizing a friend from behind) and pattern separation allows for distinguishing overlapping inputs as different (i.e. recalling two similar experiences as different events). CA3 can shift between pattern completion and separation based on the overlap between two comparative inputs, but the cellular and circuit mechanisms controlling these two opposing functions have not yet been elucidated. Activity

dynamics in the highly recurrent CA3 auto-associative network must allow context dependent maintenance of stable and distinct place cell sequences while retaining the flexibility to remap in response to changing environmental demands through plasticity mechanisms. Parvalbumin- and cholecystokinin expressing interneurons drive strong synchronous and asynchronous inhibition respectively upon CA3 pyramidal neuron somata to modulate the CA3 output across different time scales and frequency regimes. To understand how local inhibition in CA3 is recruited, we are using two-photon imaging to characterize behaviorally triggered Ca^{2+} events in these two populations in vivo during a head fixed spatial navigation task where mice are exposed to similar and dissimilar multisensory contexts. Using a loss of function approach we are testing whether PV and CCK interneurons contribute differentially to the stability and plasticity of spatially tuned sequences in CA3. We are testing the hypothesis that modulation of GABAergic input from these interneuron populations plays a potential role in regulating CA3 input-output transformation to mediate the switch from pattern completion to pattern separation functions.

Title: Human iPSC-derived neuronal cultures form synchronously bursting cultures and display a seizurogenic response to excitatory pharmacology

Authors: K. MANGAN, *B. D. ANSON, L. HARMS, E. ENGHOFER, C. CARLSON, C. KANNEMEIER
Ceullar Dynamics, Madison, WI

Abstract: The mammalian brain requires a proper balance between excitation and inhibition (E/I ratio). Imbalances in the E/I ratio are associated with numerous neurological abnormalities; increased E/I ratios result in higher excitability, prolonged neocortical circuit activity, stimulus hypersensitivity, cognitive impairments, and even epilepsy while decreased E/I ratios are linked to stronger inhibitory drive, impaired social interactions, autistic behaviors, and mental retardation. During neuronal development the E/I ratio changes and evolves, with excitation decreasing and inhibition increasing, and any deviations to this natural process may give rise to neurological disorders.
A major challenge in neuroscience research and the identification of new drugs is access to clinically-relevant cell models. However, induced pluripotent stem cell (iPSC) technology enables access to previously unattainable human neuronal cell types. Using this technology, we have generated iPSC-derived frontal cortical neurons of an appropriate, brain-similar E/I ratio

(~80% excitation), that develop and display network-level, synapse-coupled, coordinated neuronal activity *in vitro*. Using multi-electrode arrays (MEA) to measure the electrophysiological activity, we are able to capture periodical and synchronized bursting patterns and analyze these data via numerous parameters (including Poisson and ISI statistics). These neuronal cultures contain excitatory synapses (as shown by HOMER1 and synapsin co-staining) that modulate the synaptically-driven and synchronous bursting behaviors observed on the MEA. Importantly, these signals can be blocked by AP5 and DNQX.
To better understand how excitatory pharmacology alters network-level neuronal interactions, we investigated alterations in the regular bursting properties of glutamatergic neurons after addition of (0.003 to 300 uM dose response) various excitatory agents (e.g. bicuculline, chlorpromazine, pentylenetetrazol, amoxapine, 4-aminopyridine, and glutamic acid), common anti-epileptic drugs (e.g. ganaxalone and valproate), as well as a negative (acetaminophen) and vehicle controls (e.g. ethanol and DMSO). Activity metrics displaying dose-dependent responses with pharmacology include: 'single-channel' Poisson bursts (rate, intensity and duration), 'network-level' ISI bursts (rate, intensity and duration), and synchrony measures. The presented data illustrates how human iPSC-technology can be leveraged to create an unprecedented investigatory space for understanding the intricacies of how excitatory synapses control network-connected populations of human neurons.

Title: Cerebrospinal fluid from Dementia With Lewy body patients alters neuronal network function *In vitro*

Authors: *S. THEISS[1], H. KOCH[2], G. ELSEN[2], C. NITURAD[2], W. MAETZLER[3], C. DEUSCHLE[3], H. LERCHE[2], M. DIHNÉ[2]
[1]Inst. of Clin. Neurosci., Univ. of Duesseldorf, Duesseldorf, Germany; [2]Ctr. for Neurol. and Hertie Inst. for Clin. Brain Research, Dept. of Epileptology, [3]Ctr. for Neurol. and Hertie Inst. for Clin. Brain Research, Dept. of Neurodegenerati, Univ. of Tübingen, Tübingen, Germany

Abstract: Neuroactive substances associated with central nervous system (CNS) disease can be transmitted throughout the brain via the cerebrospinal fluid (CSF) compartment (*volume transmission*). CSF samples from patients suffering from traumatic brain injury, anti-NMDA-receptor encephalopathy, mild cognitive impairment and Alzheimer's disease have been shown to induce electrophysiological activity changes when applied to mature networks of rodent neurons cultured on microelectrode arrays (MEAs) equipped with 60 Ti/TiN electrodes (30 µm diameter, 200 µm spacing; Multichannel Systems). In order to establish a neuronal *in vitro* model for functional CSF testing, we exposed hippocampal neuronal networks from E17 mice cultured on MEAs to CSF samples from (1) healthy control subjects, (2) Parkinson's disease (PD) patients without signs of dementia and (3) dementia with Lewy bodies (DLB) patients with fluctuating consciousness. CSF samples were collected by routine diagnostic lumbar puncture, and each group comprised ten individual patients. All participants had normal levels in CSF cell count, albumin and IgG index indicating absence of inflammatory CNS disease and blood-brain-barrier disturbance. DLB patients showed significantly lower CSF levels of $Abeta_{1-42}$ monomers compared to controls and PD patients, while h-tau and p-tau levels associated with neurodegeneration were not significantly different. Three weeks after plating, hippocampal networks on MEAs were functionally mature and exhibited spontaneous neuronal activity (spikes) in synchronous network bursts across all 60 recording electrodes. In each 25-minute experiment with these 21 DIV networks, neuronal network activity was recorded on MEAs first in culture media (5 min), then in artificial CSF (aCSF, baseline, 10 min) and finally human CSF (either control subject, PD or DLB patient; 10 min, adjusted to pH 7.4). Under aCSF, networks showed 2,786±396 spikes/min (mean ± SEM, n=10 CSF samples) in 17±3 network bursts/min. Under human control CSF, activity increased to 5705±868 spikes in 23±4 bursts/min (p=0.014, Mann-Whitney test). While applying CSF from PD patients increased spike activity 2.6-fold from aCSF levels—even more than control CSF (2.1-fold), CSF from DLB patients left aCSF activity patterns rather unchanged. We speculate that this statistically significant difference in network responses to PD and DLB patient CSF may be due to additional functional disease related factors in DLB beyond slow neurodegenerative processes. Neuronal network activity on MEAs may be a useful *in vitro* model for the study of pathological candidate factors within human CSF.

Title: Amacrine cells influence the regenerative capacity of adult retinal ganglion cells

Authors: *Q. FENG[1], Y. LI[1], S. PETERSON[1], H.-Y. GILBERT[1], A. BURGESS[2], L. I. BENOWITZ[1]
[1]Boston Children's Hospital/Harvard Med. Sch., Boston, MA; [2]MIT, Boston, MA

Abstract: Mature retinal ganglion cells (RGCs) fail to regenerate their axons after optic nerve crush (ONC) injury due to intrinsic as well as extrinsic suppressors of growth. In vitro data indicate that during development, RGCs lose their intrinsic ability for robust axon growth and regeneration as a result of contact by amacrine cells (ACs), the inhibitory interneurons of the retina. However, it is not known whether ACs continue to contribute to the poor regenerative ability of mature RGCs. To investigate this question, we used a Cre-inducible diphtheria toxin receptor (DTR) approach to express the DTR in ACs, which can then be ablated upon intravitreal administration of diphtheria toxin. After confirming ≥ 90% loss of ACs in the retina, we investigated axon regeneration in the optic nerve. AC ablation nearly eliminated the inner plexiform layer of the retina, in which RGC dendrites receive synaptic input from ACs and bipolar cells, the excitatory interneurons, but surprisingly did not alter the survival of either RGCs or bipolar cells. More importantly, AC ablation enabled RGCs to regenerate injured axons well beyond the site of nerve damage even in the absence of additional treatment. AC ablation significantly increased phosphorylation of ribosomal protein S6 kinase substrate S6 in RGCs, indicating that the presence of ACs normally suppresses S6 kinase activation. Deleting the gene for phosphatase and tensin homolog (pten) in RGCs, another pro-regenerative treatment partially through increasing the activity of S6 kinase, did not synergistically enhance the effect with ACs ablation, whereas other treatments (e.g. zymosan) were complementary. Our results suggest that amacrine cells may exert a suppressive effect on RGC's growth capacity in the adult retina, in part by suppressing S6 kinase activation.

Sch. of Med., Kyoto, Japan; [6]Neurosurg., Ehime Univ. Grad. Sch. of Med., Toon city, Japan

Abstract: [Objective]The superior parietal lobule (SPL) plays a key role in cognitive processes such as somatosensory and visuomotor, i.e. multimodal integration and visuospatial attention. On the other hand, the medial parietal cortices, especially the precuneus and posterior cingulate cortex belong to default mode network (DMN) being active in resting state. Little is known about connections from the superior and medial parietal cortices in humans. Our objective is to delineate their functional connectivity by means of an electrical, tract-tracing method of cortico-cortical evoked potential (CCEP). [Methods]Subjects were five patients with partial epilepsy and three with a brain tumor, who underwent chronic subdural electrode placement covering the superior or medial parietal cortices (IRB#443). Single-pulse electrical stimuli (1 Hz, pulse width 0.3 msec, 6-12 mA) were delivered to the medial parietal cortex (a total of 35 pairs of electrodes) and the SPL (21 pairs). CCEPs time-locked to the stimuli were obtained by averaging electrocorticograms recorded from subdural electrodes in the frontal (8-72 electrodes/patient), parietal (13-72 electrodes/patient) and occipital (30-39 electrodes/patient) areas. [Results]As for stimulation of the medial parietal area, 1) the precuneus (16 pairs in 6 patients) elicited 66 remote, short-latency CCEPs in the inferior parietal lobule (IPL) (19 remote responses), the SPL (13) and the dorsal premotor area (dorsal PM) (11) as the most active 3 sites. 2) The posterior cingulate cortex (10 pairs in 4 patients) stimulation elicited 36 remote CCEP at the IPL (10), the middle cingulate cortex (5), and the SPL (4). As for the dorsal parietal area, the SPL stimulation (21 pairs in 5 patients) elicited remote 75 CCEPs at the precuneus (17), precentral gyrus (12),

and the dorsal PM (6). [Conclusion]This study implicated i) reciprocal connections between the superior and the medial parietal cortices, and ii) different connectivity pattern to the frontal cortex between the precuneus and the posterior cingulate cortex: the former more with the lateral area, whereas the latter more with the medial area. The findings may explain the mechanism of functional differentiation between these two areas. They also clinically helps us understand seizure propagation network in patients with parietal lobe epilepsy.

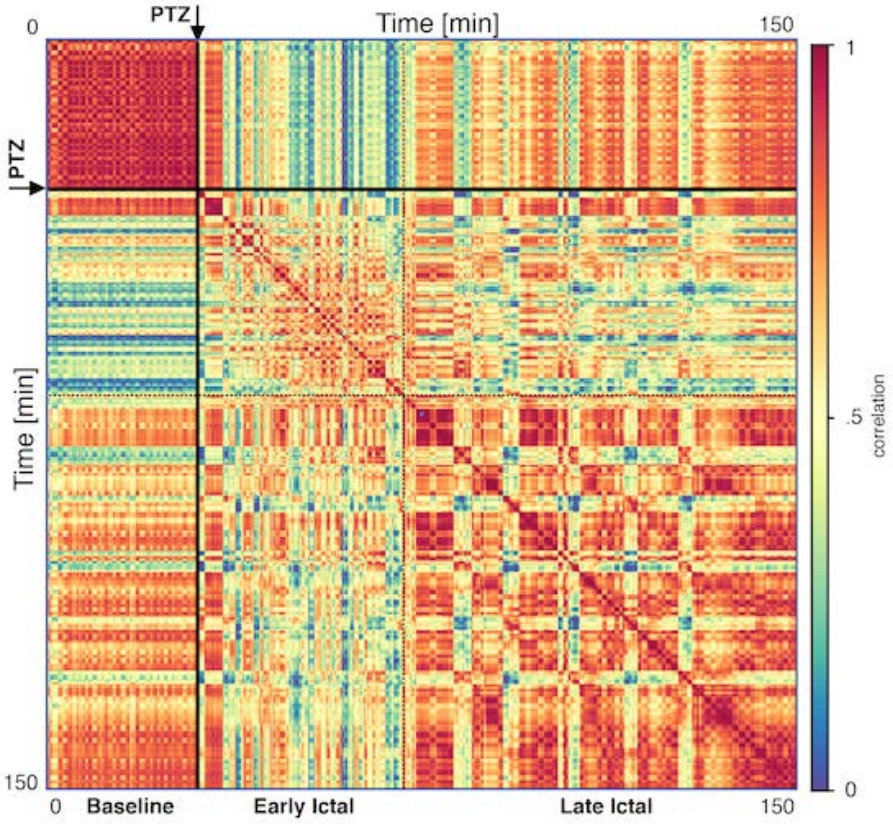
Title: Network-wide changes in effective connectivity and synaptic dynamics during epileptic seizures in the larval zebrafish brain

Authors: ***R. E. ROSCH**[1], P. HUNTER[2], T. BALDEWEG[1], K. J. FRISTON[1], M. MEYER[2]
[1]Univ. Col. London, London, United Kingdom; [2]King's Col. London, London, United Kingdom

Abstract: Epilepsy is one of the most common neurological conditions. Pathophysiological explanations typically focus on either the micro/mesoscale (i.e. cortical microcircuitry), or on the macroscale (i.e. functional networks). However, linking abnormalities across different scales remains challenging, partly because of technical limitations in measuring dynamic dysfunction at

a range of observational scales. Recently zebrafish larvae have emerged as a unique model organism to understand epileptic pathophysiology at levels ranging from genetics to whole-organism phenotypes. Furthermore, light sheet calcium microscopy in the larval zebrafish now allows the study of neuronal function in large-scale networks at high temporal resolution in the intact brain *in vivo*. Here we report a computational analysis of functional brain recordings from larval zebrafish during acute epileptic seizures induced with pentylenetetrazole (PTZ).



PTZ causes widespread spectral changes in neuronal activity across all areas. The image above is a dynamic correlation matrix, showing correlation between the distribution of oscillatory power (0-10Hz) across brain areas (optic tectum, midbrain, cerebellum, hindbrain) over time, revealing distinct phases in the seizure. We model these using neural mass models allowing Bayesian inference on the changes in effective network connectivity and synaptic dynamics underlying the neuronal signatures. This dynamic causal modelling (DCM) approach reveals a macroscale shift in network connectivity with a reduction of the influence of higher brain areas during the seizure. Furthermore, seizures are best explained using a combination of changes in inhibitory self-modulatory connections, as well as their synaptic dynamics.
This is consistent with the known mechanism of PTZ, whilst integrating observations into a fully parameterised neural network model of the zebrafish brain. In future work, the detailed single-cell resolution afforded by light-sheet microscopy may be used to validate model prediction made from whole-brain dynamics.

Title: Exercise induced altered functional connectivity in resting state networks in patients with benign epilepsy at alpha band

Authors: G. R. KOIRALA[1], H. KIM[2], N.-Y. KIM[1], *D. LEE[2,3]
[1]Kwangwoon Univ., Seoul, Korea, Republic of; [2]Pediatrics, [3]Epilepsy Res. Inst., Yonsei Univ. Col. of Med., Seoul, Korea, Republic of

Abstract: This study aims to explore the effect of exercise in patients with benign epilepsy through the functional connectivity (FC) measures between 36 cortical region of interests (ROIs) that epitomize five resting state networks: default mode network (DMN), dorsal attention network (DAN), control network (CON), salience network (SAL), and sensorimotor network (SAN). Resting state 19 channel EEG data from six consented patients at three different conditions: pre (before exercise), post1 (after the completion of 5 weeks of supervised as well as home based exercise), and post2 (after the completion of post 1 followed by 30 weeks of home based exercise), were preprocessed and 15 3-s artifact-free epochs were extracted for further analysis. Functional connectivity was evaluated at alpha band (8-13 Hz) using imaginary coherence. Inter-and intra- network alteration in FC was observed following the exercise. Furthermore, post1 betweenness centrality at CON was significantly different from pre-state. The increased connectivity and betweenness centrality after the exercise might be the indication of modulated neuropsychological functions in patients with benign epilepsy.

Title: Neocortical loss of PGC-1a protects against *In vitro* epileptiform activity

Authors: C. MACKENZIE-GRAY SCOTT[1], R. R. PARRISH[1], R. M. COWELL[2], *C. RACCA[1], A. J. TREVELYAN[1]
[1]Newcastle Univ., Newcastle-upon-Tyne, United Kingdom; [2]Psychiatry, Univ. of Alabama At Birmingham, Birmingham, AL

Abstract: A balance of excitatory and inhibitory transmission is required for proper functioning of the nervous system. Hyperexcitation can cause spontaneous seizures while hypoexcitation can impair learning and memory. Of the interneuron cell types, the parvalbumin-positive (PV+) interneurons exert the greatest control over excitability of pyramidal neuron populations. This is due to their fast-spiking, non-accommodating properties and numerous contacts onto pyramidal neuron somata and axon initial segments. As such, PV+ interneurons are largely responsible for the synchronization of pyramidal neuron networks in the cortex, all being controlled by tight homeostatic regulation of genes and proteins. Alterations in PV+ interneuron function has been associated with epilepsy in humans, and seizures in animal models, possibly due to loss of homeostatic control over gene and protein expression. Evidence from the Cowell lab indicates that the transcriptional coactivator PGC-1α [peroxisome proliferator activated receptor γ (PPARγ) coactivator 1α] is required for the induction of PV in cortical interneurons and normal GABAergic signaling in mice. In addition, the Cowell lab has found that mice lacking PGC-1α, systemically and specifically in PV+ interneurons, exhibit deficiencies in the expression of transcripts involved in synchronous neurotransmitter release. We have found that the initial transcriptional response to seizures involves the induction of PGC-1α and PGC-1α-dependent genes in the neocortex. Since PGC-1α has been shown to influence transmitter release, this suggests that one particular adaptation of PV interneurons to seizure activity is towards more synchronous GABAergic release, thereby promoting synchronicity of cortical networks, which in turn may contribute to further seizure activity and epileptogenesis. In support of this we have found that deletion of PGC-1α in PV+ interneurons delays onset of seizure-like activity in the 0 Mg^{2+} model of epilepsy and decreases overall epileptiform activity. Our RT-PCR studies suggest that this is due to a loss of activity-induced regulation of synaptotagmin 2 (SYT2) and complexin 1 (Cplx1) (molecules involved in synchronous neurotransmitter release), along with loss of PV expression in the PGC-1α knockout mice. We postulate that loss of these genes causes an increase in asynchronous GABA release during evolving epileptiform activity, thereby reducing seizure activity. While we are actively exploring this possibility, these studies open up a set of new transcriptional targets that may be modified to reduce and control seizure severity by altering GABAergic function.

Title: Mechanisms of norepinephrine and serotonin in prevention of seizure-induced respiratory arrest

Authors: *S. W. KRUSE[1], K. G. DAYTON[2], B. S. PURNELL[2], N. K. LEIBOLD[3], G. F. BUCHANAN[2,3]
[1]Univ. of Iowa Col. of Engin., Iowa City, IA; [2]Neurosci. Grad. Program, Univ. of Iowa, Iowa City, IA; [3]Dept. of Neurol., Univ. of Iowa Carver Col. of Med., Iowa City, IA

Abstract: Epilepsy is a highly prevalent disease. About one-third of patients with epilepsy become refractory to medications. Refractory epilepsy patients are at high risk for sudden unexpected death in epilepsy (SUDEP), the leading cause of death in these patients. Seizure-induced respiratory arrest (S-IRA) is an important contributing factor to SUDEP. Serotonin (5-HT) regulates breathing, and 5-HT modulates seizures. A body of circumstantial evidence suggests the 5-HT system may play a critical role in SUDEP, especially in S-IRA. Other neurotransmitters, such as norepinephrine (NE), modulate breathing, affect seizures, and are affected by seizures. Furthermore, NE interacts with 5-HT in many physiological processes. We hypothesized that NE may be involved in regulating breathing following a seizure. Here we examined the effects of pharmacological manipulation of the 5-HT and NE neurotransmitter systems on S-IRA and survival following maximal electroshock (MES)-induced seizures in adult male wild type (WT; *Lmx1b*$^{f/f}$ and C57BL/6) mice, DSP-4 treated NE neuron deficient mice, and transgenic 5-HT neuron deficient (*Lmx1b*$^{f/f/p}$) mice. Mice were implanted with EEG, EMG and EKG electrodes, treated with serotonergic and/or noradrenergic agents, and subjected to MES induced seizures with concomitant respiratory, cardiac and video-EEG monitoring. Seizure severity, mortality, and cardiorespiratory sequelae were assessed. In mice that died, MES induced terminal apnea, while cardiac activity persisted for ≤ 10 min. *Intraperitoneal* (*i.p.)* administration of the norepinephrine reuptake inhibitor (NRI) reboxetine (30 mg/kg) and selective-serotonin reuptake inhibitor (SSRI) fluoxetine (10 mg/kg) 30 min prior to seizure

induction reduced S-IRA in WT and *Lmx1b*$^{f/f/p}$ mice compared to vehicle controls. Application of the α1 receptor antagonist prazosin (10 mg/kg) 15 min prior to SSRI or NRI blocked the protective effects of these agents. The SSRI, citalopram (20 mg/kg) prevented S-IRA in saline treated C57BL/6 mice, but not in C57BL/6 mice subjected to NE neuron destruction with DSP-4 (50 mg/kg x 2). *Intracerebroventricular* administration of the α1 receptor agonist phenylephrine (1 μM) prevented S-IRA and death in WT mice. Taken together, these data suggest NE augmentation with NRI prevents S-IRA and death through an α1-mediated mechanism. That α1 blockade could prevent the protective effects of SSRI, and SSRI was ineffective in mice in which NE neurons were destroyed, suggests that 5-HT and NE interact to modulate breathing after a seizure. Additional work is required to further understand mechanisms of S-IRA and inform prophylactic strategies for SUDEP.

Title: Maturation of motor cortex excitability in children with focal epilepsy as measured by navigated transcranial magnetic stimulation

Authors: *H. L. KAYE[1], G. BLOCK[4], A. JANNATI[4], C. VEGA, III[2], K. RAKESH[2], K. KAPUR[2], L. M. OBERMAN[5], R. GERSNER[2], A. BOES[6], A. PASCUAL-LEONE[4], A. ROTENBERG[3,4]

Ctr., Boston, MA; [5]Bradley Hosp., Riverside, RI; [6]Departments of Pediatrics, Neurol. & Psychiatry, Univ. of Iowa, Iowa City, IA

Abstract: Objectives
(1) To measure the developmental trajectory of corticospinal tract (CST) excitability as a function of hemispheric lateralization and proximity to seizure focus in children with epilepsy, undergoing navigated transcranial magnetic stimulation (nTMS); (2) To test the relationship between CST excitability and patient IQ.
Methods
137 patients (≤18 y) with intractable focal epilepsy underwent nTMS for functional motor

mapping to measure bilateral resting motor threshold (rMT). Only patients with rMT <100% machine output were included for analysis. Comparisons between healthy and epileptic hemispheres were performed by a linear mixed-effects model to account for within-subject correlations, with age, lesion, and age x lesion interaction as fixed-effects. Further analysis was performed using mixture modeling to detect clustering of rMT with respect to age per hemisphere. Bayesian Information Criterion was used to choose number of clusters in the mixture models. Multiple regression analyses examined the relationship between rMT and verbal IQ, while controlling for age, for the clusters identified above.

Results

In patients without CST lesion there is no rMT difference between epileptic and healthy hemispheres. Age is the major determinant of rMT, which decreases by ~7 V/m per year in childhood (p<.001); this maturational trajectory does not differ between hemispheres. Cluster analysis reveals two groups corresponding to (1) mature, minimal rMT after age ~15 y and (2) a progressive maturation from age 7 to 15 y. In a subgroup of patients (n=14) with CST injury in the epileptic hemisphere, average rMT is lower in the epileptic hemisphere (p<.01). In this group, rMT decreases by ~9 V/m per year in the healthy hemisphere (R^2 = .57; p<.01), but does not change with age in the epileptic hemisphere (R^2=.005; p=.82). The difference in maturational trajectory is significant between the two hemispheres (p<.01). After controlling for age, healthy hemisphere rMT correlates negatively with verbal IQ in the age □15 y group (R^2=.39; p=.036), but not in the age 7-15 y group. Epileptic hemisphere rMT is not correlated with verbal IQ in either group (p's > .44).

Conclusions

Cortical excitability increases with age until ~ age 15 yrs. We thus describe for the first time the rate and endpoint of CST maturation. Neither rate of maturation nor absolute rMT differ between healthy and epileptic hemispheres in patients with focal epilepsies without CST injury. However, in patients with a unilateral CST lesion, the maturational trajectory is absent in the injured hemisphere. We also identify a positive correlation between rMT and verbal IQ in patients with mature CST excitability.

Title: Human induced pluripotent stem cell (hiPSC) -derived neurons respond to convulsant drugs when co-cultured with hiPSC-derived astrocytes

Authors: *M. N. ISHII[1], K. YAMAMOTO[2], M. SHOJI[2], A. ASAMI[2], Y. KAWAMATA[2]

Abstract: Accurate risk assessment for drug-induced seizure is expected to be performed before entering clinical studies because of its severity and fatal damage to drug development. Induced pluripotent stem cell (iPSC) technology has allowed the use of human neurons and glial cells in toxicology studies. Recently, several studies showed the advantage of co-culture system of human iPSC (hiPSC)-derived neurons with rodent/human primary astrocytes regarding neuronal functions. However, the application of hiPSC-derived neurons for seizure risk assessment has not yet been fully addressed, and not at all when co-cultured with hiPSC-derived astrocytes. Here, we characterized hiPSC-derived neurons co-cultured with hiPSC-derived astrocytes to discuss how hiPSC-derived neurons are useful to assess seizure risk of drugs. First, we detected the frequency of spikes and synchronized bursts hiPSC-derived neurons when co-cultured with hiPSC-derived astrocytes for 8 weeks. This synchronized burst was suppressed by the treatment with 6-cyano-7-nitroquinoxaline-2,3-dione, α-amino-3-hydroxy-5-methylisoxazole-4-propionic acid (AMPA) receptor antagonist, and D-(-)-2-amino-5-phosphonopentanoic acid, an N-Methyl-D-aspartate (NMDA) receptor antagonist. These data suggested that co-cultured hiPSC-derived neurons formed synaptic connections mediated by AMPA and NMDA receptors. We also demonstrated that co-cultured hiPSC-derived neurons showed epileptiform activity upon treatment with gabazine or kaliotoxin. Finally, we performed single-cell transcriptome analysis in hiPSC-derived neurons and found that hiPSC-derived astrocytes activated the pathways involved in the activities of AMPA and NMDA receptor functions, neuronal polarity, and axon guidance in hiPSC-derived neurons. These data suggested that hiPSC-derived astrocytes promoted the development of action potential, synaptic functions, and neuronal networks in hiPSC-derived neurons, and then these functional alterations result in the epileptiform activity in response to convulsant drugs. Our study indicates the possibility that co-culture system of hiPSC-derived neurons with astrocytes could be useful in the risk assessment of drug-induced seizure.

Title: Alterations in pre-ictal oscillation of pilocarpine model of epilepsy and the effects of MGE-grafted precursor cells

Authors: *M. VENDRAMIN PASQUETTI[1], S. A. A. ROMARIZ[2], Í. F. MESSIAS[1], B. MONTEIRO LONGO[2], M. E. CALCAGNOTTO[1]
[1]Univ. Federal Do Rio Grande Do Sul, Porto Alegre, Brazil; [2]Univ. Federal de São Paulo, São Paulo, Brazil

Abstract: Introduction: GABAergic interneurons are crucial for local circuitry and have major role in epilepsy. Most of GABAergic interneurons originates from medial ganglionic eminence (MGE). MGE-derived cells grafted into brain of animal models of epilepsy migrate, differentiate into mature GABAergic cells, recover inhibition, restore brain rhythms and reduce spontaneous recurrent seizures (SRS). However, their effect on pre-ictal oscillation at seizure onset (SO) has not been explored. Methods: We analyzed pre-ictal pattern oscillations in pilocarpine model of epilepsy. Seven days after Pilocarpine induced *Status epilepticus*, rats received or not MGE grafts into hippocampus. The animals were video-monitored (9h/d-90d) and reduction of SRS frequency was observed in MGE-Pilo group. Later, cortical and intrahippocampal electrodes were implanted for video-EEG recording (24h/d-7d). The EEG data were decomposed by Matlab, in delta:1-4Hz, theta:4-12Hz, low gamma:20-50Hz, high gamma:60-100Hz and ripples:100-200Hz oscillations at 5min and 20s before SO. Ethical committee approval: 0024/12. Results/Discussion: Both groups had a decrease in cortical and hippocampal delta and theta and hippocampal low gamma waves 20s before SO. Cortical high gamma decrease in Pilo animals, but not in MGE-Pilo. Ripples increased in both structures in MGE-Pilo group. Theta/delta ratio decreased in both groups in cortex, but in hippocampus that happen only in MGE-Pilo group. That could contribute to reduction in SRS frequency observed in the transplanted animals. Understanding how changes in neuronal circuitry tuned brain oscillation before SO may have predictive and therapeutic value.

Title: Disruption of seizures with high resolution targeted optical stimulation *In vitro*

Authors: *K. P. LILLIS[1,2], K. J. STALEY[1,2]
[1]Neurol., Harvard Med. Sch. Dept. of Neurol., Charlestown, MA; [2]Neurol., Massachusetts Gen. Hosp., Boston, MA

Abstract: Currently available anti-seizure therapies broadly affect activity in the brain by altering ion channels/neurotransmission (drugs), metabolic processes (diet), or regional activity (electrical stimulation). The non-specific nature of these treatments naturally results in undesirable neurological side effects. In this work we are determining the minimum intervention that is sufficient to prevent ictogenesis, using targeted optogenetic activation of individual neurons.

Organotypic hippocampal slice cultures, which generate spontaneous periodic seizures after approximately one week in culture, were prepared from animals transduced with AAV vectors coding for the light-sensitive, high-current channelrhodopsin CoChR and the red-shifted calcium indicator jRCaMP1a. When imaging relatively thin samples with sparse expression, it is possible to resolve activity in individual neurons using standard single photon widefield microscopy with a low-magnification objective lens, whose field-of-view spans the entire slice culture. Furthermore, we incorporated a digital micromirror device (DMD) in the conjugate image plane of the blue excitation light pathway, which enabled projection of high resolution patterns onto the slice. By co-registering the camera and DMD, we could target any subset of individually imaged neurons for optical stimulation.

While optically monitoring seizure activity using the jRCaMP1a signal, we disrupted activity by periodically stimulating neurons in one of three hippocampal subregions: *s. radiatum, s. pyramidale,* or *s. oriens*. For each region 360 selected cells were divided into 6 groups of 60 cells. The 60-cell patterns were cycled through at 6 Hz, resulting in 1Hz stimulation per targeted cell. Preliminary data show that stimulation of cells in s.p. reliably prevents seizures for > 30 minutes in slices that were undergoing 60 second seizures at every 3 minutes at baseline. Immediately after turning off the stimulation light, slices returned to their baseline seizure pattern. Stimulation of s.o. and s.r. were less effective, preventing seizures for a maximum of 15

minutes before seizures emerged despite ongoing optical stimulation. We are characterizing the impact of different stimulation strategies on spontaneous network activity, and exploring the vast stimulation parameter space to identify the smallest population of neurons whose manipulation prevents seizures, with minimal disruption of baseline activity.

Title: Stress testing cortical networks: Using simple pharmacological challenges to understand the effects of genetic mutations on cortical network excitability

Authors: N. CODADU[1], R. R. PARRISH[2], D. C. DE VIVO[3], M. TANG[4], C. A. SCHEVON[4], U. MONANI[5], W. N. FRANKEL[6], *A. J. TREVELYAN[1]

Abstract: Bathing brain slices in modified cerebro-spinal fluid (CSF) has proved a useful experimental tool for understanding epileptic activity. The two most commonly used modifications are either to remove Mg^{2+} ions from the bathing medium, or to add the K channel blocker, 4-aminopyridine (4AP). These two manipulations however, induce activity that evolves in very different and highly characteristic ways. As such, these simple pharmacological models provide a wide range of metrics, many of which can be related to specific components of the network. Rather than using these models to examine the endstage, full ictal activation, instead, we use them to “stress test” cortical preparations from different transgenic animals. We will present data from a range of wild-type and transgenic mouse lines to illustrate how these studies can expand our understanding of the effects of specific mutations on cortical network function. Horizontal brain slices, including the hippocampal, entorhinal and neocortical territories, were prepared from young adult mice, and evolving network activity was recorded extracellularly at multiple cortical locations, as the tissue was perfused with either 0 Mg or 4AP CSF in an

interface chamber. Our initial explorations of wild-type animals showed that the results were sensitive to the animal age and preparation protocol, highlighting the importance of using age-matched, littermate, wild-type controls for comparison with the recordings of transgenic animals. Recordings and the initial analyses of the transgenic / wild-type animals were made blind to the genotype. Brain slices were laid over a 96 microelectrode array (400µm separation, Blackrock Microsystems), to provide a dense sampling of all cortical regions. We will present our initial analyses of 3 different transgenic lines, carrying mutations in the Dnm1 and Glut1 genes. Both these mutations have been associated with severe epileptic phenotypes in clinical cases.

Title: In-vitro slow moving focus in the epileptic hippocampus mimics propagation of human seizures

Authors: *C.-C. CHIANG[1], X. WEI[2], A. ANANTHAKRISHNAN[2], D. M. DURAND[3]
[1]Biomed. Engin., [2]Case Western Reserve Univ., Cleveland, OH; [3]Dept Biomed. Eng, Case Western Res. Univ., Cleveland, OH

Abstract: Fast and slow neural waves have been observed to propagate in the human brain during seizures using recording arrays. Yet the nature of these waves is difficult to determine in a surgical setting. Here we report the observation of fast and slow waves propagate in the hippocampus in-vitro at speeds similar to those in human tissue. The fast and slow waves were recorded with a genetically encoded voltage sensitive fluorescent protein (VSFP Butterfly 1.2) and a high speed camera. The results of this study indicate that the fast wave is NMDA-sensitive but does not require synaptic transmission for propagation. Image analysis indicates that the slow wave is the source of the fast wave and is therefore a moving focus of the seizure-like activity (see Figure). This slow moving focus is associated with a propagating neural calcium wave detected with calcium dye (OGB-1) but is independent of NMDA receptors, not related to ATP release, and cannot be explained by potassium diffusion. Computer simulation suggests that the

slow moving focus is a calcium spike and propagates by ephaptic coupling. These results indicate that a seizure-like focus can propagate non-synaptically and provide an alternative explanation for seizure progression in the brain.

Title: Distinct inhibitory regulation of dentate granule and semilunar granule cells

Authors: *M. AFRASIABI, V. SANTHAKUMAR
Pharmacology, Physiol. and Neurosci., Rutgers, New Jersey Med. Sch., Newark, NJ

Abstract: The dentate gyrus has been proposed to serve as a functional “gate” that regulates inputs into the hippocampus. Apart from the classical dentate projection neurons, Granule Cells (GCs), recent studies have identified a new group of excitatory neurons, Semilunar Granule Cells (SGCs). SGCs support feedback inhibition of GCs and thereby maintain the dentate gate. We previously reported that SGCs receive higher frequency of spontaneous inhibitory post-synaptic currents (sIPSCs) than GCs, and unlike GCs, show reduced sIPSC frequency after brain injury,

indicating distinctive inhibitory regulation of the two cell types. Based on their morphology, we propose that SGCs are not under the strong gating feedback inhibitory regulation as GCs. Here we examined whether parvalbumin-expressing presumed fast-spiking interneurons (PV-IN) and GABAergic neurons expressing the cannabinoid receptor type 1 (CB1R) have differential contributions to basal and evoked synaptic inhibition in SGCs and GCs. Consistent with data from rats, whole cell recordings and biocytin immunostaining in hippocampal sections from mice showed that SGCs can be distinguished from GCs by somato-dendritic structure and intrinsic physiology. SGCs receive significantly higher sIPSCs than GCs and show sustained firing upon perforant path (PP) stimulation. In contrast, PP activation resulted in a greater and more sustained increase in IPSCs in GCs compared to SGCs. Optogenetic silencing of PV-INs failed to reduce sIPSC frequency in SGCs while optogenetic activation of them resulted in a greater increase in sIPSC frequency in GCs than in SGCs (GC: 719.13±141.61%, n=14, SGC: 355.59±40.16%, n=14, p=0.02 by t-test). WIN-2 (a CB1R agonist) failed to reduce baseline sIPSC frequency in both cell types showing that CB1R sensitive interneurons, which include dentate CCK-expressing and total molecular layer (TML) interneurons, have limited contribution to baseline sIPSC frequency in GCs or SGCs. Our data demonstrate that SGC have limited baseline and evoked inhibition from PV interneurons and may elude the robust dentate inhibitory gate.

Title: Reduced voltage-gated K^+ channel function in gabaergic nts neurons in a murine model of acquired TLE and SUDEP

Authors: *I. DERERA[1], B. N. SMITH[1,2]
[1]Dept. of Physiol., [2]Epilepsy Ctr., Univ. of Kentucky, Lexington, KY

Abstract: Sudden unexpected death in epilepsy (SUDEP) accounts for approximately 17% of epilepsy-related deaths. Altered voltage-gated K^+ channel function in neurons of the brainstem nucleus tractus solitarius (NTS) and vagal afferent fibers may contribute to SUDEP in genetic epilepsy models; hippocampal voltage-gated K^+ channel function and expression is altered in the

pilocarpine-induced status epilepticus (SE) model of acquired temporal lobe epilepsy (TLE) in rodents. However, little is known regarding possible changes in voltage-gated K^+ channels in NTS neurons during development of acquired TLE. GABAergic NTS neurons receive information via vagal afferent fibers regarding cardiac and respiratory function and serve to integrate, filter, and modulate this information to regulate cardiorespiratory function. In a genetic epilepsy model with a voltage-gated K^+ channel mutation, altered NTS neuron function contributed to cardiorespiratory collapse and sudden death after seizures. However, there is a paucity of information regarding epilepsy-related changes in NTS neuron channel function in acquired epilepsy, which affects a greater proportion of the patient population. We hypothesized that voltage-gated K^+ channel function in GABAergic NTS neurons is altered in the pilocarpine-induced SE model of TLE. Pilocarpine (282 mg/kg) was administered to 4 week old male mice that express GFP in a subset of GABAergic NTS neurons (FVB-Tg(GADGFP)4570Swn/J; ie. GIN mice) to induce SE and eventual development of TLE. *In vitro* electrophysiological results show an increase in action potential firing rate and action potential half-width in GABAergic NTS neurons from mice 12 weeks after SE (i.e., TLE mice) compared to age-matched controls. Upon application of 4-AP (5mM), action potential firing rate and half-width in GABAergic NTS neurons from control mice was increased to levels similar to that in neurons from TLE mice, suggesting that A-type K^+ current function may be suppressed following TLE development. Characteristics of the A-type K^+ current were therefore assessed in voltage-clamp recordings in GABAergic NTS neurons from control and TLE mice. Preliminary data suggest that peak A-type K^+ current is decreased in GABAergic NTS neurons from TLE mice compared to controls, consistent with the increase in action potential firing and half-width in TLE mice. These results suggest voltage-gated K^+ channel function is reduced in the NTS of mice with acquired TLE, which contributes to increased neuronal activity and may also increase SUDEP risk.

Title: Seizure characterization and electroencephalographic features in TLR379 triple knockout mice

Authors: *N. SALEH-SUBAIE[1], O. ARIAS-CARRION[2]
[1]UNAM, México City, Mexico; [2]Trastornos Del Movimiento Y Sueño (TMS), Hosp., MEXICO CITY, Mexico

Abstract: Epilepsy is a disabling neurological disorder characterized by recurring, unprovoked seizures and affects about 1% of the population. It involves several processes, such as neuronal loss, neurogenesis, and inflammation. The role of inflammatory mediators such as Toll-like receptors (TLRs) is under review. TLRs were involved in several neuronal disorders like Parkinson and Epilepsy. Nevertheless, the roles of TLRs in the CNS, are still poorly understood. In a recent study, it has been demonstrated that TLR 3 induces expression of a range of neuroprotective mediators such as interleukin-9 (IL9), IL10 and IL11, moreover, several other molecules that regulate cellular growth, differentiation, and migration. These results demonstrated that the expression of TLR3 in human brain slice cultures mediates a neuroprotective response in a pro-inflammatory reaction. Most recently, a role of TLR9 contributing to the neuronal protection has been described by used a model of epilepsy in mice (kainic acid). However few studies link the receptors in epilepsy. The inflammatory mechanisms that are involved with the disease are still not fully elucidated. It was published that TLR379 triple knockout mice showed that in spleen and thymus the mice express strong amounts of uncontrolled endogenous retroviruses. Furthermore, those mice showed spontaneous epileptic seizures. This suggests that enhanced activity of TLR 3, 7, or 9 could be used to treat epilepsy, as they may reduce seizure frequency. For that reason, the aim of this project was to characterize the electrographic and behavioral activity in TLR379 triple knockout mice. TLR379 triple knockout mice were on a C57BL/6 background. For a first approach, we performed cFos immunostaining one hour after an event that exhibited behavioral characteristics corresponding with stage 5 of the Racine seizure scale. We also analyzed the brains for abnormalities and cellular density (Nissl staining). To characterize, the electrographic activity mice were implanted with a unipolar electrode into the left ventral hippocampus and were registered up to seven days. The electrographic activity of hippocampus was analyzed using fast Fourier transform method throughout all the experiment. The animals were sacrificed and the brains used to evaluate the site of electrode implantation (Nissl staining). To assess the behavioral changes, in spatial memory acquisition we performed a water maze tests. We found seizure activity and epileptiform activity in TLR379 triple knockout mice and significant changes in spatial memory acquisition as well compare with our control group.

Title: Calpain/STEP pathway contributes prenatal stress-induced epileptic spasms in infant rat

Authors: H. KWON[1], J. HONG[2], D. KIM[4], *J. KANG[3]
[1]Med. science, Chungnam Natl. Univ. Sch. of Med., Daejeon, Korea, Republic of; [3]Pediatrics, [2]Chungnam Natl. Univ., Daejeon, Korea, Republic of; [4]Anat., Chungnam Natl. Univ. Sch. Med., Daejeon, Korea, Republic of

Abstract: Infantile spasms (IS) is a serious epileptic syndrome that occurs in the early infantile age. Recent studies revealed prenatal stress exposure is a risk factor of IS. Our previous study showed that prenatal stress with betamethasone altered the maturation of GABAergic progenitors and resulted in the lack of GABA input, which in turn, decreased KCC2 expression and lowered the seizure threshold. However, the mechanisms on the seizure susceptibility to N-methyl-D-aspartate (NMDA)-triggered spasms on postnatal day still need to be clarified. Prenatal stress with betamethasone on gestational day 15 increased seizure susceptibility to NMDA-triggered spasms on postnatal day 15. Compared to the control group, the protein level of NMDA receptor 2B (NR2B) was not different, but the protein level of phosphorylated-NR2B/NR2B ratio was decreased in the cortex of the prenatally stressed model. We further confirmed increased expression levels of STEP, phosphorylation of p38, cleaved caspase-3, and decreased calpain2. Our study suggest that calpain2 and STEP pathway and downstream p38 are related with increased sensitivity of seizure threshold of prenatal stress-induced cortex, and it would be considered as a new treatment approach of infantile spasms.

Title: Pharmacoresponsivness of seizures and sleep-wake patterns of Kcna1-null mice, a model of temporal lobe epilepsy with co-morbid sleep disorders to conventional anti-seizure drugs (ASDs)

Authors: *M. DEODHAR[1], B. THOMAS[2], L. ADAMIAN[3], S. MATTHEWS[3], K. A. SIMEONE[4], T. A. SIMEONE[5]
[1]CREIGHTON UNIVERSITY, Omaha, NE; [2]Creighton UNiversity, Omaha, NE; [3]Creighton Univ., Omaha, NE; [4]Dept. of Pharmacol., [5]Pharmacol., Creighton Univ. Sch. of Med., Omaha, NE

Abstract: Objective: Thirty percent of patients affected with epilepsy are resistant to conventional ASDs. Kcna-1 null mice are well recognized as a model for temporal lobe epilepsy and more recently for SUDEP. These mice exhibit severe generalized tonic clonic seizures, extensive neuropathology in the brain, and also a co-morbid sleep disorder, all of which are risk factors for refractory epilepsy. Recently, it has been demonstrated that Kcna1-null mice respond to dietary and investigational therapies; however, whether Kcna1-null mice respond to conventional drugs is unknown. Here, we aimed to determine the effects of the conventional ASDs phenobarbital, carbamezapine, phenytoin and levetiracetam, on seizures and sleep-wake patterns in the Kcna-1 null mice. Based on the risk factors exhibited, we hypothesized that Kcna1-null mice will not respond to multiple ASDs.
Methods: Kcna-1 null littermates were housed in a 12 hr light-dark cycle with access to food and water *ad libitum*. At P27-29, subdural EEG electrodes were implanted and a head-mount was attached to the mice for EEG recordings. Following a seven-day recovery period, mice were i.p. injected with vehicle once daily for two consecutive days, followed by two consecutive days of once daily injections of the ASD. Continuous video-EEG recordings were carried out throughout this period. Seizure activity and sleep-wake was analyzed for all 96 hours of recording per animal using Sirenia and Spike2 software.
Results: Phenobarbital eliminated seizures for 24 hours post-injection and significantly increased sleep duration when compared to the vehicle. Phenytoin caused an initial non-significant reduction in seizures but then returned back to baseline after 4 hours. Carbamezapine caused an initial non-significant reduction followed by an exacerbation in seizures after 4 hours. Phenytoin and carbamezapine both caused non-significant increases in sleep duration. Analyses for effects of levetiracetam are ongoing.
Conclusions: Kcna1-null mice were responsive to the GABAA receptor modulator phenobarbital and unresponsive to the sodium channel blockers phenytoin and carbamazepine suggesting that Kcna1-null mice can be tentatively labeled as a model of refractory epilepsy. Whether this

refractoriness is limited to ASDs that have sodium channel inhibition as primary mechanisms of action requires further studies.

Title: Temporal dynamics of high-frequency oscillations in a pilocarpine rat model using a novel automated detector

Authors: *J. SCOTT, S. REN, S. GLISKE, H. LUNA-MUNGUIA, W. STACEY
Univ. of Michigan, Ann Arbor, MI

Abstract: Most automated detectors of high-frequency oscillations (HFO) in humans are designed for interictal time periods, and exclude other epochs (e.g. ictal, preictal) from detection. However, our prior work has shown that HFO morphology evolves temporally as seizure onset is reached. Further investigation into these dynamics therefore necessitates the development of an automated HFO detector capable of continuous detection across all epochs. Optimization of translational epilepsy therapies requires that any automated detector function properly within the constraints of an animal model. Here we present a continuous rat HFO detector, and with it an analysis of HFOs recorded intracranially across all time epochs in a pilocarpine rat model of temporal lobe epilepsy. Using the detector, we find statistically significant increased median HFO rates in epileptic animals (n=16) over controls (n=11). Utilizing unsupervised learning methods such as PCA, we find further that feature distributions of preictal HFOs differ significantly from those at baseline within individuals. Our findings suggest that evolving HFO dynamics play a role in seizure generation. By exploiting these changes, future work could lead to more effective patient-specific treatment modalities - such as more accurate seizure prediction algorithms, or even adaptive closed-loop neural stimulation systems using HFOs as an input control signal.

Abstract: Neurocysticercosis (NCC) is caused by Taenia solium larva stage, infecting the central nervous system. It is the principal responsable of late-onset epilepsy in endemic countries. Our group has development a model rat to understand the physiology for neurocysticercosis allowing us to describe the EEG waveforms of seizures. This novel model offers the development of viable cysticerci and the main clinical manifestation of the disease, which is epilepsy, making the development of the disease in the rat model similar than in humans. In a preliminare study we observed that 9% of the rats after 5 months of infection, develop generalized clonic-tonic seizures. Our goal is to characterizate of the electroencephalogram record generated by neurocysticercosis in a rat model, and to determinate if the pattern in the EEG register is associated with spontaneous seizures. Male Holtzman rats received intracranial infection with activated T. solium oncospheres between 12-15 days of birth, MRI T2 were performed in order to detect the presence of the cysticercus in the rat brain, after 3 months of infection. Selected Infected rats (n=10) and not infected rats (n=5), implanted with cortical electrodes, were continuously recorded by telemetric electroencephalography (tEEG) to monitor the brain activity and detect spontaneous seizures for five weeks. We found variations in the electroencephalographic record in a rat model of neurocysticercosis, with a pattern of sharp

waves and spikes, spontaneous seizures were observed in all infected rats, varying the frequency and number of seizures per rat.

Title: Excess GIRK2 activity is necessary but not sufficient to confer susceptibility to Infantile Spasms

Authors: *K. JOSHI[1], L. SHEN[2], M. A. CORTEZ[2], O. SNEAD[2]
[1]The Hosp. For Sick Children, Toronto, ON, Canada; [2]Hosp. for Sick Children, Toronto, ON, Canada

Abstract: Infantile spasms (IS) is a catastrophic childhood seizure disorder. It is characterized by extensor and/or flexor spasms, cognitive deterioration and a characteristic EEG pattern of a spike-wave followed by an electrodecremental event (EDR), which refers to the flattening of the EEG waveform. The mechanism/circuitry contributing to the disorder is unknown. Children with Down Syndrome (DS) are especially vulnerable to IS. In this regard, we chose to use a mouse model of DS, the Ts65Dn mutant mouse (Ts) to create an animal model of IS in DS (Cortez et al. 2009). This model entails the treatment of Ts mice with a GABA(B)R agonist to which these mutant animals are equisitely sensitive. Typically, we use γ- butyrolactone [GBL], the prodrug of γ- hydroxybutyric acid [GHB] in this regard. GBL produces a phenotype in the Ts mice that recapitulates the semiological, developmental, and electrophysiological features of IS in children with DS. One of the genes triplicated in Ts mice is the *kcnj6* gene which codes for the GIRK2 protein. We have demonstrated that when we carried out a genetic and pharmacological knockdown of GIRK2 in Ts to create a Ts mouse that was disomic for GIRK2 (Ts65Dn-GIRK2$^{+/+/-}$), we rescued the spasms and EDR to WT levels in the resultant Ts65Dn- GIRK2$^{+/+/-}$ (Joshi et al. 2016). These data indicate that the excess GIRK2 is necessary to confer susceptibility to IS in a DS mouse model. Recently, we asked the question whether the excess GIRK2 is sufficient to confer susceptibility to IS in a DS mouse model. To address this question, we used *kcnj6* triploid mice to determine whether excess GIRK2 alone is sufficient to confer susceptibility to IS. We now show that *kcnj6* triploid mice did not show increased spasms or

EDR compared to WT mice. Therefore, excess GIRK2 is necessary, but not sufficient to confer susceptibility to IS in DS. It is therefore likely that GIRK2 is working in concert with another factor or factors in Ts that produce the IS phenotype. This study is important, because it helps us elucidate the mechanism of IS in DS, thereby providing potential therapeutic interventions in the future.

Title: Model-guided neurostimulation reduces epileptiform activity in mice

Authors: *J. MODOLO, F. MINA, P. BENQUET, F. WENDLING
INSERM U1099, Rennes, France

Abstract: Drug-refractory epileptic patients have little therapeutic options, since surgical resection is an option for only 10-15% of these patients. Neurostimulation therapy therefore holds great promises for managing these patients. However, one major roadblock is that the involved mechanisms are not fully elucidated, and rational identification of optimal stimulation parameters is still an open issue.
To overcome this roadblock, we developed a model-guided approach consisting in using a biologically grounded neural mass model of brain tissue to identify *in silico* potential candidates for neuromodulation therapy. The model reproduced successfully hippocampal paroxysmal discharges (HPD) characteristics recorded experimentally. Using this model, we explored a simple DC stimulation protocol, and identified an optimal stimulation polarity along with a candidate stimulation site, which should result in a decrease of hyperexcitability.
We tested model predictions *in vivo* using a kainate mouse model of epilepsy. Hyperexcitability was quantified using the number and duration of HPD, which are sustained (up to 60 seconds) epileptiform discharges in the epileptic hippocampus originating in the dentate gyrus (DG). We stimulated the DG in a group of n=5 kainate mice using 11 blocks of 50 seconds of cathodal stimulation (1 µA intensity, electrodes 400 µm apart, 125 µm diameter). Our results revealed a significant decrease in HPD duration and occurrence rate, confirming *in silico* model predictions. Overall, we successfully identified a neurostimulation protocol that decreases hyperexcitability in epileptic mice, based on a model-guided approach. The next step of this model-guided strategy will be to develop neurostimulation protocols based on biphasic, charge-balanced stimulation waveforms usable safely in clinical applications.

Title: Preliminary characterization of a new genetic mouse model of adult-onset epilepsy

Authors: *T. N. FERRARO[1], L. YOUNG[1], R. DACI[1], I. SALEM[2], A. BATTERMAN[1], D. MILLER[3], F. PARDO-MANUEL DE VILLENA[3], R. J. BUONO[1], L. D. SIRACUSA[2]

Abstract: Epilepsy is a common neurological disease with highest incidence in the youngest and oldest segments of the population. Genetic mouse models have led to important clues regarding the nature of epilepsy; however, the phenotypes of known mouse mutants that express spontaneous, recurring seizures emerge early in life, generally by one month of age. We report here the preliminary characterization of a novel mouse model of epilepsy in which generalized seizures are observed in adult animals, not before 5 months of age, and as late as 18 months of age. The index case was a male mouse identified in a cohort from the Collaborative Cross strain CC039/Unc. This male successfully mated, and the seizure phenotype has now been propagated through 4 generations, with more than one-third of offspring (7 of 18) exhibiting spontaneous seizures, including both males and females. There is a significantly longer latency to the onset of seizures in females compared to males. Whole-genome single nucleotide polymorphism analysis of DNA from a number of seizure and non-seizure CC039/Unc mice identified several genomic regions of heterozygosity that are being assessed with regard to their segregation with phenotype. We also discovered a 350 kilobase deletion on chromosome 16 which may affect the promotor sequence of a novel candidate gene, and this factor too is being evaluated in association with phenotype. In further studies, a CC039/Unc male with seizures was mated with females from the FVB/NJ inbred strain. To date, 30 F1 offspring have been generated, 9 of which (4 females; 5 males) have started to express seizures. Another CC039/Unc male with seizures was mated to FVB/NJ females, and their F1 offspring (16 females; 11 males) were tested for electrical seizure threshold at 10-12 months of age. No relationship between seizure threshold and spontaneous seizure phenotype was observed in this cohort. Preliminary characterization of this new mutant mouse strain with spontaneous seizures suggests that the phenotype is inherited in an autosomal dominant manner, but with incomplete penetrance. Another possibility is that the model reflects a two-locus genetic mechanism. An N2 backcross mapping strategy is being followed to localize

the chromosomal position of the factor(s) mediating this novel seizure phenotype. Genetic dissection of this model may lead to new information relevant to adult-onset epilepsy in humans.

Title: Theta and high-frequency oscillation phase-amplitude coupling in stress-induced seizures following traumatic brain injury

Authors: ***P. S. JUNG**[1,2], C. NARLA[1,2], F. BAUTISTA[1,2], J. C. MARTINEZ-TRUJILLO[1,2], M. O. POULTER[1,2]
[1]Western Univ., London, ON, Canada; [2]Robarts Res. Inst., London, ON, Canada

Abstract: Introduction: Traumatic brain injury (TBI) is a substantial cause of epilepsy, accounting for 30% of all cases. In addition, stress has been shown to increase the incidence and severity of seizures following TBI. However, the mechanism underlying the interaction among TBI, seizures, and stress in epilepsy is unclear. High-frequency oscillations (HFOs), biomarkers of seizure genesis, can be informative in understanding this interaction, especially when considered in relation to simultaneous oscillations in slower frequency bands. Furthermore, corticotropin-releasing factor (CRF) released in the amygdala during stress has been shown to be involved in the exacerbation of seizures. Here, we investigate cross-frequency coupling between theta and HFO bands occurring in the amygdala during stress in a brain-injured rat model, with and without a CRF receptor antagonist.
Hypothesis: CRF receptor antagonist decouples the coupling between theta phase and HFO power present during stress in brain-injured rats.
Methods: We used the controlled cortical impact model to simulate TBI in adult male Sprague-Dawley rats (n=6), tail pinch to effect stress, and a CRF receptor 1 (CRFR1) antagonist to attenuate the stress response. Recordings from electrodes implanted *in vivo* in the injured rat amygdala were taken during tail pinch, then repeated 1 hour after intraperitoneal injection of CRFR1 antagonist, and finally after washout 4 hours post-injection. The strength of coupling

between theta phase and HFO power for each recording was quantified using the Modulation Index (MI; Tort et al. 2010 J Neurophysiol 104: 1195-1210). Results: In TBI but not sham-TBI rats, a tail pinch stressor induced an increase in HFO activity (> 120 Hz) in the basolateral amygdala. We observed that the power of high-frequency oscillations was coupled to the phase of the theta band during stress (mean MI = 0.0193 ± 0.0052). This relationship was decoupled 1 hour after a CRF receptor antagonist injection (mean MI = 0.0044 ± 0.0017), but recoupled 4 hours later after washout (mean MI = 0.0197 ± 0.0077). As well, rats exhibited decreased epileptic behaviour during stress when the CRFR1 antagonist was present, compared to baseline and washout.
Conclusion: The power of HFOs was found to be coupled to the phase of simultaneous theta oscillations during stress in the TBI-affected rat. Furthermore, this phase-amplitude coupling decoupled when CRFR1 antagonist was present, indicating the role of stress in this response. Our findings provide insight into the mechanism by which stress and epilepsy interact in individuals affected by TBI.

Title: Exacerbated epileptic phenotype in miR-22 knockout mice

Authors: *L. F. ALMEIDA SILVA, C. R. RESCHKE, T. ENGEL, D. C. HENSHALL
Physiol. and Med. Physics, Royal Col. of Surgeons In Ireland, Dublin, Ireland

Abstract: Epilepsy is a brain disease that affects over 50 million people worldwide and is characterized by recurrent seizures. Temporal lobe epilepsy is the most common form of epilepsy in adults and these patients present high pharmacoresistance. Acquired epilepsy is associated with large-scale changes in gene expression which underlie the cell and network-level changes during epileptogenesis. Evidence emerged that miRNAs, a class of non-coding RNAs that fine tune gene expression, play an important role in epilepsy. MiR-22 regulates key epileptogenic-related processes, such as inflammation and apoptosis. Our group detected miR-22 as the most expressed miRNA in the contralateral hippocampus after status epilepticus induced by kainic acid intra-amygdala injection. In this model, the contralateral hippocampus experiences seizures, however does not present neuronal damage. Thus, the contralateral hippocampus could

serve as a source of anti-epileptic molecules. Moreover, we found that silencing miR-22 exacerbates epilepsy. Here, we sought genetic evidence that miR-22 protects against epilepsy. Firstly, we characterized naïve miR-22$^{-/-}$ mice and compared to wild-type littermates. No differences were observed in the brain morphology, gliosis or astrocytosis. We also analyzed levels of miRNAs that are relevant in epilepsy and epileptogenic process. No difference was observed in the level of these miRNAs. When injected with KA intra-amygdala mice lacking miR-22 presented similar seizure severity, measured by EEG total power and amplitude, when compared to wild-type mice. This EEG phenotype was followed by similar neuronal damage in the hippocampus. Interestingly, miR-22 knockout mice presented increased number of spontaneous seizures, when monitored for 2 weeks (average of 19 seizures/day for miR-22$^{-/-}$, and 2 seizures/ day for miR-22$^{+/+}$). Here, we also verified that the intra-nasal administration of miR-22 mimics can be an effective delivery route, once we were able to increase miR-22 hippocampal levels at 4h after administration. These genetic and pharmacological data indicate that miR-22 plays a role in the pathophysiology of epilepsy, and that targeting this miRNA may be a promising approach for epilepsy treatment.

Title: Role of dorsal medial hypothalamus (DMH) in phenotype of spasms

Authors: *C.-R. CHERN, L. VELISEK
Dept. of Cell Biol. and Anat., New York Med. Col., Valhalla, NY

Abstract: Our two-hit model of infantile spasms consists of prenatal priming with betamethasone and postnatal trigger of spasms with N-methyl-D-aspartic acid (NMDA) in infant rats and involves activation of hypothalamus. Additionally, in our previous study microinfusions of a $GABA_A$ receptor agonist muscimol into the paraventricular hypothalamic nucleus (PVN) *per se* (without any additional trigger) induced a specific phenotype of spasms in rat pups. If combined with a trigger of spasms utilizing NMDA, this muscimol-induced phenotype of spasms appears before NMDA becomes effective. Dorsal medial hypothalamus (DMH) is one of the hypothalamic nuclei projecting directly to PVN. In this project we determined the role of DMH in the control of spasms by functional inhibition of DMH with muscimol microinfusions. We found that muscimol microinfused into DMH modifies the NMDA-induced phenotype of spasms compared to vehicle controls. In muscimol infused animals, we observed an early onset of loss of

posture with imposed long lasting clonic seizures, which was a phenotype that typically occurs during a terminal stage of the NMDA-induced spasms without muscimol microinfusion. Initially, these clonic seizures are interrupted with occasional brief spasms but then advance into long lasting spasms. Additionally, muscimol extended period of spasm occurrence: After NMDA trigger in saline-infused pups, the spasms terminate within 60-75 minutes. In contrast, in muscimol-infused animals, these long-lasting spasms can persist for at least four hours. Our finding suggests that inhibition of DMH activity makes the phenotype of spasms significantly more severe suggesting attenuating role of DMH in this seizure syndrome.

Title: Decrease of gamma event coupling in hippocampal-prefrontal cortex associated with epileptogenesis

Authors: *L. LI[1,2], J. ALMAJANO[1], J. ENGEL[1,2,3], A. BRAGIN[1,2]
[1]Neurol., [2]Brain Res. Inst., [3]Neurobio. and Psychiatry and Biobehavioral Sci., Univ. of California Los Angeles, Los Angeles, CA

Abstract: It is accepted that epilepsy is a network phenomenon with changes of both functional and anatomical brain networks. The medial prefrontal cortex (PFC) and hippocampus (HIP) are key brain areas for memory consolidation processes. We hypothesize that dysfunction of these networks could lead to memory impairment and could be early biomarkers of epileptogenesis. Our study aims to investigate PFC and HIP network changes during the latent period in an animal model of temporal lobe epilepsy (TLE). Experiments were conducted on 15 rats with 8 microelectrodes implanted in symmetrical sites of PFC and HIP. After one week of baseline recordings KA was injected in the left anterior hippocampus to evoke status epilepticus (SE). Animals were divided into two groups: with epilepsy and without epilepsy during/after 2 month of recording. Functional connectivity was quantified by the measurement of *gamma event coupling* (GFC), in which Shannon entropy was computed. A sequence of gamma events with amplitude higher than 3SD were considered as *Gamma oscillations (GO)*. Peri-event histogram analysis was performed to study the synchrony between GEC and GO and multi-unit discharges

(MUDs) within HIP and between HIP-PFC. Group-level comparisons of GEC and synchrony of GS and MUDs were performed between latent period and baseline. We found a decrease of GEC between HIP & PFC ipsilateral to the KA lesion during the 1st week after SE in rats that later developed epilepsy, while no significant changes in GEC between HIP and other recorded brain areas. We further determined that this decrease in GES was associated with decreased of synchrony of MUD in both in HIP and PFC on the lesion side. No significant change of GEC and synchrony in MUD between HIP and PFC in the non-epilepsy group. Furthermore, we found that 40% of GEC occurred during PFC gamma oscillations (PFC-GO) in all animals, although the total number of PFC-GO was much less in the group with epilepsy. Our results also revealed a significant decrease in synchrony of HIP MUD during PFC-GO on the lesion side in the group with epilepsy, but no changes were observed in the group without epilepsy. The changes in functional connectivity related to epileptogenesis are detectable using GEC, while GO is less sensitive in the assessment of epileptogenic related connectivity changes. Because gamma activity mostly is related with activity of interneuronal networks, changes in GEC may indicate deterioration in the relationship between HIP and PFC via inhibitory mechanisms. Interruption of this network could be an early biomarker of epileptogenesis and may have implication for the detecting of psychiatric comorbidities during epileptogenesis.

Title: Characteristics of evolving epileptiform activity in different cortical areas in brain slices

Authors: *N. CODADU[1], A. TREVELYAN[2]
[2]Inst. of Neurosci., [1]Newcastle Univ., Newcastle Upon Tyne, United Kingdom

Abstract: Understanding regional differences in the susceptibility to the development of epileptic activity and the nature of brain state transitions in its evolution remains a major goal for epilepsy research. One such transition, of potentially great importance for drug development, is from a pharmaco-sensitive to a pharmaco-resistant pattern of discharges that occurs in a widely used, rat, in vitro model (low Mg^{2+} bathing medium). Early epileptiform activity, including interictal discharges and sustained events that mimic clinical tonic-clonic seizure activity, is suppressed by many anti-epileptic agents (Dreier et al., 1998). There then follows a transition into a late pattern of repeated discharges that are resistant to the same drugs. The nature of this

critical transition, however, has remained a mystery. We have replicated these patterns in mouse brain slices, and report here that the transition reflects a change in the involvement of hippocampal networks and how they interact with the other cortical networks. Early ictal discharges only involve neocortical and entorhinal networks. Epileptiform events in hippocampus develop much later, but once these start, they quickly entrain the neocortex to their, more regular, discharge pattern. Notably, this entrainment persists following transection of the major axonal pathways between hippocampus and neocortex, indicating that it is mediated through a non-synaptic route. Analyses of the timing of these events demonstrate that the hippocampal activity is the pacemaker of this late-stage pattern of discharges. In a second in vitro model of epilepsy, induced instead by bathing brain slices in the K^+ channel blocker 4-aminopyridine (4AP), activity evolves over a period of tens of minutes to show both tonic-clonic like discharges, and eventually, a pattern of repeated spike and wave discharges. In these regards, both low Mg^{2+} and 4AP models appear similar, but the evolution to this stage is very different. While the low Mg^{2+} model involves hippocampal networks only in the late stage, the 4AP model induces pathological discharges in the hippocampal networks very early. Our results illustrate the multifaceted nature of epileptiform activity, providing many metrics for characterising drug actions, and for understanding phenotypes in genetic models of epilepsy.

Title: Transhemispheric network interaction for hippocampal ictogenesis revealed by combined optogenetic and chemogenetic interrogation *In vivo*

Authors: *F. BERGLIND, M. S. ANDERSSON, M. KOKAIA
Epilepsy Center, Lund Univ., Lund, Sweden

Abstract: The hallmark of epilepsy is synchronous repetitive firing of neuronal ensembles, manifested as seizures. The manner in which neurons are recruited to this network in the initial stages of disease development and the minimal neuronal circuit needed to generate progressive seizure activity is, however, not known. By selectively activating principal neurons using a

protocol for repetitive optogenetic stimulation in one hemisphere of the hippocampus of anaesthetized transgenic CaMKII-ChR2 mice, we observed a rapid development (within 15-25 stimulations, 1-2 hours) of progressively intensifying epileptic afterdischarges (ADs) generated concurrently in both hemispheres, as measured by bilateral local field potential (LFP) recordings. This corroborated earlier data suggesting that progressively intensifying ADs strongly correlated with activation of the contralateral dentate gyrus (DG) area of the hippocampus. To further test this hypothesis we utilized a loss-of-function approach: when the DG contralateral to optogenetic stimulation was inhibited by Gi-DREADD (a designer receptor exclusively activated by the otherwise biologically inert molecule CNO), the progressive intensification of ADs was abrogated. These findings suggest that transhemispheric bilateral DG activation is required for the establishment of the minimal hyperexcitable neuronal circuit that supports early stage progressive intensification of ADs in the hippocampus, which may eventually lead to permanent changes in the hippocampal networks towards increased excitability and development of epilepsy.

Title: Bilateral evolution of fast-ripples and interictal spikes during epileptogenesis

Authors: *P. BENQUET[1,2], J. MODOLO[3], M. VERIN[3], F. WENDLING[3]
[1]INSERM U1099 -LTSI, Rennes, France; [2]Univ. of Rennes 1, Rennes, France; [3]INSERM U1099-LTSI, Rennes, France

Abstract: In focal epilepsies, seizures are triggered in a circumscribed brain region often referred to as the epileptogenic zone (EZ). Accurate EZ delineation is an essential step in planning the best therapeutic strategy. To achieve this, intracranial electrophysiological recordings remain the most precise identification method to record dysfunctional biomarkers characteristic of underlying epileptogenic networks.
Several types of interictal activity are observed in depth-EEG signals recorded with intracerebral electrodes in the epileptic brain, such as fast-ripples (FRs), which are brief (a few tens of milliseconds), high-frequency oscillations (HFOs; 250-600 Hz). FRs have been a topic of increasing interest for the past two decades since i) FRs seems to be generated locally within the EZ; and ii) resection of brain tissue producing FRs demonstrated the potentially significant diagnostic value of HFOs in focal epilepsies. To a lesser extent, interictal epileptic spikes (IESs) have also been considered as potentially useful makers, however one drawback is that this

biomarker can propagate outside the EZ. The generation and diffusion of these biomarkers during the slow pathological plasticity associated with the epileptogenesis phase is still not well characterized.
In this study, we used the *in vivo* kaïnate mouse model of epilepsy to study the evolution, characteristics and propagation of fast-ripples and epileptic spikes during epileptogenesis both in the EZ (kaïnate injected side, right hippocampus) but also in the control hippocampus (non-injected side, left hippocampus).
During the three weeks of epileptogenesis, the occurrence rate of IESs and FRs not only increased, but a significant difference in term of localization and propagation of these biomarkers was quantified. Significant changes in IES morphology and in FRs spectral dynamic were also recorded. Bilateral recordings revealed that IES generated in the left hippocampus could trigger FR in the contralateral side. We used computational modeling to provide mechanistic insights regarding the evolution of these biomarkers.

Abstract: Astrocytes express a variety of G-protein coupled receptors. Type 1 Protease Activated Receptors (PAR1) are G-protein coupled receptors activated by bloodstream serine proteases, like thrombin and plasmin. These proteins diffuse out of the bloodstream under pathological conditions like small hemorrhagic stroke. What is not known is whether PAR1 activation affects glutamate uptake, one of the main function of astrocytes. Here we combine

electrophysiology, imaging and modeling approaches to show that PAR1 activation speeds glutamate clearance by astrocyte transporters in the mouse hippocampus. This effect is not due to changes in glutamate transporter expression or to widespread changes in the diffusion properties of the neuropil. Instead, the faster clearance is associated with rapid restructuring of astrocytic processes in the immediate vicinity of excitatory synapses. This includes changes in the number, surface area and proximity of astrocytic processes to synapses. By using realistic 3D Monte Carlo reaction-diffusion simulations, we show that all these effects can lead to faster glutamate clearance in and out of the synaptic cleft. Astrocyte remodeling due to PAR1 activation alters short- and long-term synaptic transmission. Taken together, these findings identify PAR1 as a key regulator of excitatory synaptic function in the hippocampus and a potential target to prevent cognitive impairment and decline following small hemorrhagic stroke.

Title: Astrocytes are a primary target for neuronal BDNF: Implications for the regulation of astrocyte morphological complexity

Authors: *L. HOLT[1,3], M. L. OLSEN[2]
[2]Sch. of Neurosci., [1]Virginia Tech., Blacksburg, VA; [3]Cell, Integrative, and Developmental Biol., Univ. of Alabama at Birmingham, Birmingham, AL

Abstract: Most astrocytes are born during the 2-4th postnatal week in rodents. This is followed by a period of morphological maturation including the development and extension of fine dense processes, which eventually enwrap synapses and blood vessels. The developmental time window of astrocyte morphological maturation and refinement is well defined but the molecular mechanisms that underlie this process are not understood. Brain derived neurotrophic factor (BDNF) is a critical growth factor secreted largely by neurons and involved in the development and maturation of neurons, including neuronal growth and synapse refinement. In the current study we demonstrate that astrocytes express high levels of the BDNF receptor TrkB when

compared to neurons. Quantitative PCR indicates astrocytes predominantly express the truncated version of TrkB, TrkB.T1, which lacks the canonical kinase domain. TrkB.T1 expression is highest in astrocytes during the critical period of astrocyte morphological refinement and maturation, a developmental time window that coincides with the highest neuronal BDNF mRNA expression levels. These findings have led us to hypothesize that BDNF/TrkB.T1 signaling is an important mediator of astrocyte morphological maturation. Indeed, preliminary data demonstrates that exposure to BDNF increases astrocyte cellular complexity. Ongoing studies are aimed at understanding the relative importance of BDNF/TrkBT.1 signaling in astrocyte morphological maturation.

Title: Role of NAD^+ availability and Sirt6 expression in the regulation of antioxidant defenses in astrocytes

Authors: *B. HARLAN, K. M. KILLOY, M. PEHAR, M. R. VARGAS
Cell and Mol. Pharmacol., Med. Univ. of South Carolina, Charleston, SC

Abstract: Nicotinamide adenine dinucleotide (NAD^+) is an essential redox molecule and a key player in several signaling pathways that govern fundamental biological processes. In redox reactions, a hydride equivalent is reversibly transferred at the nicotinamide moiety causing a switch between oxidized (NAD^+) and reduced (NADH) forms of the nucleotide. In contrast, NAD^+-dependent signaling involves the cleavage of NAD^+ (degradation) coupled to post-translational modifications of proteins or the production of second messengers. Activation of NAD^+-dependent signaling pathways has a major effect in the capacity of the cell to modulate mitochondrial function and counteract the deleterious effects of increased oxidative stress. Sirtuins (Sir2-like enzymes) are NAD^+-dependent deacylases that play a key role in transcription, DNA repair, metabolism, and oxidative stress resistance. There are seven mammalian sirtuins (Sirt1-7) with diverse subcellular localization, enzymatic activity and protein substrates. Sirt6 is a chromatin-associated nuclear protein involved in DNA repair, telomere maintenance, gene expression, and metabolism. Here we explore the role of Sirt6 over-expression and increased NAD^+ availability in astrocyte antioxidant defenses and astrocyte-motor neuron interaction. Astrocytes play a key role determining the progression of the

neurodegenerative process in amyotrophic lateral sclerosis (ALS). Accordingly, astrocytes over-expressing ALS-linked mutant hSOD1 induce the death of co-cultured motor neurons. We have previously shown that up-regulation of antioxidant defenses reverts astrocyte-mediated neurotoxicity. We observed that increasing NAD^+ availability or Sirt6 over-expression induced Nrf2-driven gene expression and revert the neurotoxic phenotype of $hSOD1^{G93A}$-expressing astrocytes. Together, our results suggest that Sirt6 could be a potential therapeutic target in ALS.

Title: Downregulation of Sonic hedgehog in reactive astrocytes after injury

Authors: *R. ALLAHYARI, P. SAKTHIVEL, K. L. CLARK, A. D. R. GARCIA
Biol., Drexel Univ., Philadelphia, PA

Abstract: Following injury to the central nervous system, the molecular signaling pathway Sonic hedgehog (Shh) has been shown to promote various cellular activities, including proliferation of adult neural stem cells (NSCs) and increased neurite outgrowth. Both Shh and its target gene, Gli1, have been shown to be upregulated following injury. This suggests that Shh signaling may play a role in neural repair processes. More specifically, Shh is a known mitogen in the developing nervous system and adult NSC niches, suggesting it may be responsible for regulating injury induced proliferation. We previously identified a subpopulation of astrocytes in the adult cortex that express Gli1. The precise role of Gli1 astrocytes in CNS injury is not well understood. In this study we used molecular genetic strategies to examine Gli1 astrocytes after forebrain stab injury. Our data show that following a forebrain stab injury, there are fewer Gli1 astrocytes in the lesion area at 24 hours, compared to uninjured controls. This reduction in Gli1 cells persists for up to 7 days after injury. Using genetic inducible recombination strategies, our data show that Gli1 astrocytes are not dead, but rather, that Gli1 expression is downregulated. This suggests that Shh signaling is downregulated in response to acute forebrain stab injury. Our data also show that Shh and Gli1 expression returns to the injured cortex 14 days post injury, as confirmed by multiple transgenic mouse models and ddPCR, suggesting that Gli1 astrocytes

undergoing reactive astrogliosis transiently downregulate Shh signaling. These data are consistent with a recent study in the lung epithelium showing that Gli1 is similarly downregulated in mesenchymal progenitor cells following injury. Ongoing studies are aimed at investigating the functional consequences of downregulation of this pathway in the injury response.

Abstract: In most of the optogenetic approaches, microbial opsins are expressed in neurons to elicit or inhibit neuronal activity via light-induced generation of ionic transmembrane currents, leaving other intracellular signalings remain to be optogenetically studied. Here we optogenecically modulated the intracellular levels of cAMP in vivo, using photoactivated adenylyl cyclase (PAC). PAC, which was originally identified as a photosensor of the flagellate *Euglena gracilis*, is activated by blue light and rapidly changes its conformation to synthesize cAMP from ATP. Recently, several new PACs including bPAC from the soil bacterium Beggiatoa have been discovered. We successfully developed a mouse line which carries both bPAC and GFP genes downstream of TetO operator sequences. By crossing these mice with lines that express tTA under different promoters, we managed to express PAC in astrocytes, microglia and neurons, separately. PAC is expressed in most of astrocytes across the brain in Mlc1-PAC mice, almost half of microglia in Iba1-PAC mice, and neurons in specific regions including CA1, habenula, and stiatum and orbital frontal cortex (5HT5b-PAC mice). We confirmed an increase of the intracellular cAMP levels in response to blue light illumination in

cultured astrocytes prepared from Mlc1-PAC mice, using a newly developed red cAMP sensor. Further, in vivo light stimultion in Mlc1-PAC mice induced CREB phosphorylation in PAC-expressing astrocytes and learnig and memory-related behavioral changes. Thus, our TetO-PAC mice will be useful for studying the role of cAMP in brain cells in vivo.

Abstract: Consolidated evidence highlight the importance of astrocytes ion channels and aquaporin 4 (AQP4) in brain physiology and pathological conditions. Studying ion channels and AQP4 in a controlled and reliable in vitro model might promote increasing knowledge on nervous system function and dysfunction or degeneration and on neuro regenerative medicine. However, when astrocytes are grown in culture, they lose their characteristic star-like shape. Also, astrocytes in vitro loose the peculiar polarized localization of AQP4 and ion channels in the plasma membrane observed in astrocytes endfeet *in vivo*. In this view, our goal is to define and characterize cell culture model of astrocytes in vitro resembling the features of astrocytes in vivo and to identify molecular, biophysical and chemical factors that might be relevant in the regulation/modulation of the expression and functionality of ion channels and AQP4 in astrocytic membrane. To address this issue we sought to investigate on the effect on primary rat cortical astrocytes growth and physiology of innovative nanostractured material interface based on inorganic silicon/gold nanowires (SiAunw) and on organic polymers polycaprolactone (PCL) electrospun nanofibers. By means of cell viability assays we found that siAunw as well as PCL

electrospun nanofibers promote strong adhesion of astrocytes without need of additional coating with values comparable to those obtained by using glass coverslips treated with Poly-D-lisine. Optical and fluorescent imaging at different time points revealed that nanostructures promote modification of astrocytes morphology. Scanning Electron Microscopy and Atomic Force Microscopy confirms the capability of astrocytes to respond to substrate topography. We show how interfaces can promote astrocytes differentiation with three dimensional growth and by promoting endfeet sprouting from the cell body lining and enveloping the interface nanostructure. The differentiation is not due to gliotic reaction as GFAP values are unchanged respect to the control. Also, PCL nanofibre alignment promote astrocytes growth and orientation along the fibre with induction of F-actin fibre alignment and vinculin polarization, as revealed by immunofluorescence and fluorescent confocal microscopy. Finally, by whole-cell recording patch-clamp, the eletrophysiological properties of the cells have been characterized, revealing promising features in the expression of ion conductance resembling those expressed by astrocytes in vivo also in the case of PCL fibres with polyaniline nanowires. This work is supported by AFOSR projects ASTROMAT, FA9550 16 1 0502 and ASTRONIR, FA9550-17-1-0502.

Title: Effect of Zinc ions on astrocytic calcium oscillations in mice

Authors: *Y. A. CHO[1], S. KIM[2], S. HWANG[2], K. NOH[3], W.-H. CHO[3], E. BARCELON[3], S. YOON[3], S. LEE[3], S. JUN[2]

Abstract: Communication between neuron and astrocyte has become emerging issue in brain science. Recently intracellular calcium oscillations in astrocytes are spotlighted for encoding memory functions. It was known that presynaptic glutamate release increases the intracellular calcium level of neighboring astrocyte and presumably induces oscillation of astrocytic intracellular calcium throughout the brain. In addition, it was reported that labile zinc ions affect the signaling of neurons and astrocytes at specific brain regions such as hippocampus. Zinc ions exist in glutamatergic synapses and believed to regulate the glutamate release in order to maintain the glutamate homeostasis and to prevent glutamate excitotoxicity. This study investigates the zinc influence in astrocytic Ca^{2+} oscillation with optical imaging technique. Hippocampal brain slice from astrocyte-specific GCaMP5 transgenic mice was prepared for calcium imaging to monitor the intracellular calcium level of astrocyte. Since the activation of astrocytes are closely related with neurons, neuronal activities was electrically recorded via microelectrode arrays simultaneously with calcium imaging. In order to trigger Ca^{2+} oscillation in astrocytes, neurons were electrically or chemically evoked. When external zinc ions were applied to the brain slices, the frequency change of astrocytic calcium oscillation was observed. This study showed the possibility that zinc ions modulated the astrocytic Ca^{2+} oscillation in the brain.

Title: Automated analysis of in-vivo astrocyte activities from large-scale calcium imaging data

Authors: *G. YU[1], Y. WANG[1], K. POSKANZER[2]
[1]Virginia Tech., Arlington, VA; [2]Biochem. and Biophysics, Univ. of California, San Francisco, San Francisco, CA

Abstract: The advent of modern microscopy and highly sensitive protein calcium sensors enables the recording of astrocyte activities on large population of cells over a long time period. However, sophisticated analytical tools lag far behind the impressive capability of generating the data. The analysis of astrocyte activities is particularly challenging due to the complexity of astrocyte calcium signaling. The current practice of using such information-rich data relies heavily on manual analysis, which not only limits the scale of study but also potentially

introduces analysis bias and misses subtle yet important information. Previously, we built an automated data-driven and robust tool to analyze in-vitro astrocyte data. Here, applying advanced machine learning theory and using computational techniques, we extend the tool to deal with in-vivo astrocyte data. The in-vivo data has special characteristics that need to be carefully modeled. Firstly, we allow for flexible signal propagation. For different pixels associated with the same calcium event, propagation patterns cannot be accounted for by time shift only, instead that the signal can shrink, expand or be initiated asynchronously but terminated simultaneously. Propagation patterns are also likely to differ from event to event. Secondly, an event-oriented view is taken. In in-vitro data, we have assumed all pixels in an ROI (region of interest) share a common activity pattern (curve). This is not true for in-vivo data, because some pixels may participate one event but keep silent for another event. Essentially, the concept of ROI is inappropriate due to the fact that the given region is heterogeneous with respect to different events. Hence, we take an event-oriented view, with an event defined jointly by its spatial occupancy and temporal dynamics. Lastly, but not least importantly, computational techniques and algorithmic innovation are exercised to speed up the analysis. The in-vivo recording can easily result in a large data set. For example, we routinely see data set with file size over gigabytes and with hundreds of thousands calcium events.

Title: Self administration of cocaine or heroin reduces S-glutathionylation of cofilin and enhances glial fine process motility

Authors: *A. KRUYER, M. SCOFIELD, J. UYS, P. W. KALIVAS
Med. Univ. of South Carolina, Charleston, SC

Abstract: Spillover of synaptically-released glutamate in the nucleus accumbens (NA) is a fundamental feature underlying relapse to addictive drugs. Perisynaptic astroglial processes containing glutamate transporters, which maintain glutamatergic tone at NA synapses, retract during extinction from cocaine or heroin use, though the cellular mediators of this process are not understood. We hypothesize that repeated acute oxidative stress produced in the NA by

cocaine or heroin self-administration leads to long-lasting post-translational de-glutathionylation of the actin-binding protein cofilin, an important regulator of glial fine process morphology. Using a variation of the *in situ* S-glutathionylation switch protocol, we have examined the S-glutathionylation of cofilin *ex vivo* in the context of extinction from cocaine or heroin self-administration and reinstated drug seeking. Following at least 10 days of extinction from cocaine or heroin self-administration we found an enduring reduction in the glutathionylation state of cofilin. Furthermore, when cocaine-trained animals underwent cue-induced reinstatement of cocaine seeking, S-glutathionylation of cofilin was also decreased, and the decrease was strongly correlated with the number of active lever presses enacted during the 15-minute reinstatement session prior to extraction of NA tissue. Cofilin is a well-known regulator of actin and cell morphology, and may contribute to drug-induced changes in the presence of fine glial processes in the vicinity of excitatory synapses in the NA. Indeed, we find that after extinction from cocaine or heroin self-administration there is a reduction in proximity of astroglial surface to the synaptic marker Synapsin I, and that after 15 minutes of cue-induced heroin seeking, astroglial processes are in greater proximity to the synaptic marker. Our preliminary data support the overarching hypothesis that post-translational modification based on tissue redox status is a mechanism by which drugs of abuse may encode long-lasting changes in glutamatergic circuitry.

Title: Hippocampus-based contextual memory alters the morphological characteristics of astrocytes in the dentate gyrus

Authors: *M. CHOI
Seoul Natl. Univ., Seoul, Korea, Republic of

Abstract: Astrocytes have been reported to exist in two states, the resting and the reactive states. Morphological changes in the reactive state of astrocytes include an increase in thickness and number of processes, and an increase in the size of the cell body. Molecular changes also occur, such as an increase in the expression of glial fibrillary acidic protein (GFAP). However, the

morphological and molecular changes during the process of learning and memory have not been elucidated. In the current study, we subjected Fvb/n mice to contextual fear conditioning, and checked for morphological and molecular changes in astrocytes. 1 h after fear conditioning, type II and type III astrocytes exhibited a unique status with an increased number of processes and decreased GFAP expression which differed from the typical resting or reactive state. In addition, the protein level of excitatory excitatory amino acid transporter 2 (EAAT2) was increased 1 h to 24 h after contextual fear conditioning while EAAT1 did not show any alterations. Connexin 43 (Cx43) protein was found to be increased at 24 h after fear conditioning. These data suggest that hippocampus-based contextual memory process induces changes in the status of astrocytes towards a novel status different from typical resting or reactive states. These morphological and molecular changes may be in line with functional changes.

Sciences, Universiti Sains Malaysia, Kota Bharu, Kelantan, Malaysia; [3]Dept. of Pathology, [4]Sch. of health Sci., Sch. of Med. Sciences, Universiti Sains Malaysia, Kota Bharu, Malaysia

Abstract: Oxygen is the most vital element in maintaining the homeostasis and ensures efficiency of human body systems. Lacking of this chemical element or disruption of balance between its supply and its demand may cause disparity changes. A condition where oxygen availability is limited can be described as hypoxia. Many studies used different kinds of cell lines of animals as well as human to find out the mechanisms of cell death and duration following hypoxia. However, no study has not been evaluated the effect of hypoxia particularly on human hippocampal astrocyte cell line. Therefore, the present study aimed to investigate the underlying mechanisms of cell death in human hippocampal astrocyte cell line. Following exposure to hypoxia. Based on the preliminary screening, almost 80% of cell death occurred after 20 min and

60% cell death occurred in 15 min after exposed to chronic hypoxia, 3% of oxygen level ($p<0.05$). From the data gained, 15 minutes was chosen as the time point and the cells were exposed to different oxygen percentage. Analysis from Trypan blue viability assay showed about 15% of cells were dead in 15% oxygen, 25% dead cells in 10% oxygen, 48% dead cells in 5% oxygen and 65% dead cells in 3% oxygen ($p<0.05$). For the immunofluorescence assay, a reliable marker GFAP was used in order to portray the architecture and morphology of astrocytes cells. Fluorescence scanning microscope revealed a filamentous and clear nucleus appearance in a control. In contrast, the rupture nuclei along with no rigid structure of cell were displayed in chronic hypoxia group, the 3% oxygen exposure. The control and hypoxia cells also were stained with the Annexin V FITC and then observed under a fluorescence microscope. Astrocyte cells after hypoxia showed higher expression of nuclei but not in control. Merged between PI and FITC clearly showed the differences of nuclei expression between the control and hypoxia exposed group. Along with that, the HIF-1 staining was performed to confirm the cell death due to hypoxia exposure. Based on the fluorescence microscope viewed, there were dramatic expression of HIF-1α was displayed in exposed astrocyte cells compare to the control. Besides, GAPDH, HIF-1α and Bcl_2 genes were observed in RT-PCR. Thus, we could conclude that morphological changes of astrocyte cells begins within 15 minutes with chronic hypoxia which clearly showed the damages as their nuclei ruptured and expression of apoptotic genes. **Key words:** Hypoxia, human hippocampal astrocytes, oxygen percentage, cell viability, morphological changes, FITC Annexin V staining, GFAP marker, HIF-1α, GAPDH, Bcl_2.

Abstract: Inflammatory insult-induced astrogliosis plays important roles in the neuronal survival and injury repair after brain injuries. Previous studies have shown that indoleamine 2, 3-dioxygenase (IDO)-aryl hydrocarbon receptor (AhR) pathway has immune modulatory effect on peripheral immune responses. We previously showed that AhR, a ligand-activated transcription factor activated by environmental toxins and tryptophan metabolites, can aggravate N-methyl-D-aspartate receptors (NMDARs)-mediated excitotoxicity. Peripheral inflammation has been shown to induce neuroinflammation that is associated with mental and cognitive impairment in animal models. In this study, we investigated the role of AhR in astrocyte-neuron interaction under lipopolysaccharides (LPS) stimulation. We found that LPS treatment could activate AhR as well as both AhR and IDO were induced by LPS in cultured astrocytes. Besides, knockdown of AhR profoundly enhanced the LPS-induced IDO expression. Conversely, IDO knockdown decreased LPS-induced AhR expression. As a result, the LPS-induced proinflammatory cytokine IL-6 and TNFα expression were found negatively regulated by the LPS-induced AhR and IDO expression in astrocytes. Notably, the peripheral LPS treatment impaired novelty-related social-cognitive behaviors including novel object recognition and social novelty in WT mice, and both effects were worsened in neural lineage-specific AhR conditional knockout mice (Nestin-Cre/Ahr-flx, nAhrCKO) mice. In summary, our data suggest that LPS-induced astrogliosis involves the activation of IDO-AhR pathway to negatively feedback the LPS-induced proinflammatory responses, and this mechanism of action might account for the maintenance of cognitive function after peripheral inflammation insult.

Title: Layer specific cortical astroglia regulate dendritic branching and spine density

Authors: *S. J. MILLER, J. D. ROTHSTEIN
Neurology/Cellular & Mol. Med., Johns Hopkins Sch. of Med., Baltimore, MD

Abstract: Astrocytes are the most abundant cell type in the CNS, playing essential roles in maintaining the homeostasis, interactions with local microglia and oligodendroglia, synaptic pruning and synaptic generation, and blood brain barrier maintenance. Historically, astrocytes have been classified into two groups: protoplasmic astrocytes of the grey matter and fibrous astrocytes of the white matter. More recently however, groups are unraveling the heterogeneity of astrocytes in different neuroanatomical regions, although the unique functions of these astrocyte subgroups is largely unknown. To better understand astrocyte heterogeneity, we created a transgenic mouse model that retains tdTomato-expression in a well defined neuroatomically limited subset of grey matter astrocytes. In the cortex, these astrocytes are limited to layer 5 and a smaller subset to layer2/3. To understand if these these cells have unique molecular, biochemical and/or physiological properties, we FACs sorted adult Td-Tom positive astrocytes and compared them to the remaining cortical astrocytes. These cells were subjected to microarray and proteomic analyses, following by immunostaining in vivo to validate genes highly expressed and/or unique to these this astrocyte subset. We also were able to study these unique astrocytes in vitro as well as in populations of human iPS derived astrocytes. After extensive 'omic and bioinformatic analyses we uncovered several unique genes to this subset. Interestingly, a selected neuronal gene encodes a secreted protein and the cognate G-protein coupled receptor (GPCR) for this protein was localized to the regional cortical layer 5 specific astrocytes. Next, we began to elucidate this GPCR's signaling pathway in cortical layer V. We found that this astrocyte subset signals through this GPCR by responding to neuronal input and evokes the release of specific polypeptides that act to increase neighboring neuron dendritic branching and spine density. After removal of this astrocyte GPCR and/or its downstream astrocyte specific polypeptide, we see a dramatic effect on spine density in vivo which strongly correlates to phenotypes seen in neural disorders including mental retardation. This is one of the first studies of its kind to unravel a specific astrocyte subset in cortical layer specific signaling, which appear to aid in the regulation and/or development of layer specific neuronal processes and which may act to promote neuronal health.

Title: Measurement of H^+ fluxes from cultured mouse hippocampal astrocytes using self-referencing H^+ selective microelectrodes

Authors: *J.-I. CHOI[1], R. P. MALCHOW[2]
[1]Biol. Sci., Univ. of Illinois at Chicago, Chicago, IL; [2]Dept. Biol. Sci. & Ophthalmology, Univ. of Illinois at Chicago Dept. of Biol. Sci., Chicago, IL

Abstract: pH regulation in the brain is important and even small changes in intracellular or extracellular pH influence the functions of numerous enzymes and ion channels. Activities such as extracellular glutamate removal process done by glial cells are associated with change in extracellular levels of H+, which can by itself have a potent modulatory effect on neuronal excitability and synaptic transmitter release. In the present study, we have used self-referencing H+-selective microelectrodes to examine standing levels of extracellular H+ from quiescent hippocampal astrocytes cultured from mice and have also examined changes in the level of extracellular H+ that occur upon addition of the different neurotransmitters. Cultured astrocytes recorded in a 24 mM bicarbonate-based saline solution or1 mM HEPES buffered solution exhibit a standing acidic flux. The standing flux observed in the 1 mM HEPES condition remained when all of the extracellular sodium was replaced with choline . Application of glutamate induced a transient extracellular alkalinization, consistent with its transport into the glial cells. Application of adenosine triphosphate (ATP) induced a pronounced extracellular acidification. These results are the first to show extracellular H+ levels adjacent to isolated glial cells using self-referencing electrodes and suggest the possibility that changes in extracellular H+ by glial cells in response to the release of different neurotransmitters may play a role in modulation of activity within the nervous system.

Title: Cathepsin D activity in the mouse hippocampus in various developmental stages, revealed by the cleavage of prolactin into vasoinhibins

Authors: *E. ARNOLD[1], F. MACÍAS[2], R. M. AROÑA[2], C. CLAPP[2], G. MARTÍNEZ DE LA ESCALERA[2]
[1]Catedrática CONACYT-Instituto de Neurobiología, Univ. Nacional Autónoma de México (UNAM), Queretaro, Mexico; [2]Inst. de Neurobiología, Univ. Nacional Autónoma de México (UNAM), Querétaro, Mexico

Abstract: Vasoinhibins are a family of peptides derived from the pituitary hormone prolactin (PRL), named for their inhibiting effects on angiogenesis, vasopermeability and vasodilation. Vasoinhibins are generated via proteolytic cleavage of PRL by several proteases, including cathepsin D, matrix metalloproteases, and bone morphogenic protein-1. Vasoinhibins share the NH2-terminal region of PRL and range in molecular mass between 11 and 18 kDa. PRL and vasoinhibins have been detected in different regions of the central nervous system, where they trigger opposite effects. However little is known about the presence of vasoinhibins in the hippocampus, thus in the present study we explored the activity of the converting enzymes, particularly cathepsin D in the hippocampus from mice in different stages of the life cycle. For that purpose the hippocampus from 16 days old embryos (E16), neonates (N) and adult (A) mice were obtain and lysated in a lysis buffer (1M Tris-HCl, EGTA 0.2M, EDTA 0.2M, 1% Igepal, 0.1M Na_3VO_4, 0.05M NaF, 5mM $Na_4P_2O_7$, 0.26M sucrose). It is well known that astrocytes express and secrete cathepsin D during development and pathological conditions, thus we also isolated astrocytes from hippocampus of E16 and N mice. Astrocytes cultures were lysated in the same buffer. Then, increasing amounts of the hippocampal and astrocytes lysates were incubated with 50 ng of a rat PRL standard in a pH 5 buffer (0.1M Citric acid, 0.1M Na_2HPO_4, NaCl 0.15 M) during 24h at 37°C in the presence or absence of the enzymatic inhibitor pepstatin A, that inhibits the action of cathepsin D. The levels of PRL and vasoinhibins were measured by immunoblotting. Our results show vasoinhibins in all the samples, suggesting the hippocampal expression of enzymes that cleaves PRL into vasoinhibins at the three stages of development tested. A hippocampal cathepsin D cleaves PRL into a vasoinhibin of 16kDa in the three stages analyzed. Moreover, we found that neonatal astrocytes posses higher cathepsin D proteolytical activity in comparison with embryonic astrocytes lysates, since lower concentrations of lysates are able to cleavege PRL into vasoinhibins. Altogether these findings show that a regulation of the PRL-vasoinhibins axis operates in the hippocampus of the mice, and that it is developmental-related to the enzymatic activity of cathepsin D in astrocytes.

Title: KIR4.1 potassium channel in hyperglycemic conditions: Downregulation via MIR-205 overexpression in astrocytes

Authors: *D. E. RIVERA-APONTE[1], M. P. MENDEZ-GONZALEZ[2,4], K. MELNIK-MARTINEZ[3], C. MALPICA-NIEVES[2], F. TEJEDA-BAYRON[2], S. SKATCHKOV[3], M. J. EATON[1]
[1]Biochem., Univ. Central Del Caribe, Bayamon, PR; [2]Biochesmitry, [3]Physiol., Univ. Central del Caribe, Bayamon, PR; [4]Natural Sci., Univ. of Puerto Rico Aguadilla, Aguadilla, PR

Abstract: Astrocytes play a critical role in protecting neurons by maintaining extracellular homeostasis, preventing neurotoxicity and regulating the neuronal network through glutamate uptake, potassium buffering and gliotransmitter release. These functions are supported by the presence of potassium channels, mainly by Kir4.1 inwardly rectifying potassium channels, in the membranes of astrocytes and other glial cells. Hyperglycemia affects patients who suffer from diabetes and its effects on the central nervous system could be critical since astrocytes grown in hyperglycemic conditions have decreased levels of Kir4.1 potassium channels as well as impaired potassium and glutamate uptake. The link between hyperglycemic condition and functional downregulation of Kir4.1 is still missing, however previous studies performed in human corneal epithelial cell injury demonstrated that regulation of Kir4.1 expression occurs via microRNAs, specifically miR-205. The aim of the present study is to test 1) if astrocytes express miR-205 and 2) if miR-205 regulates Kir4.1 expression under hyperglycemic conditions. We used q-PCR to assess the levels of miR-205 in astrocytes grown in high glucose (25 mM) DMEM compared to control astrocytes grown in normal glucose (5 mM). We found that not only was miR-205 expressed in astrocytes, but its expression was increased when astrocytes were grown in hyperglycemic conditions. Astrocytes grown in high glucose had a 6-fold up-regulation of miR-205 levels compared to astrocytes grown in normal glucose condition. Transfection of miR-205 mimic and inhibitor was performed to alter the levels of miR-205 in astrocytes followed by Western blot to assess Kir4.1 channel levels in these cells. Astrocytes treated with mimic miR-105 had a 32.7% reduction of Kir4.1 protein levels compared to control (mock-transfected) cells. In contrast, astrocytes transfected with inhibitor miR-205 were significantly up-regulated compared to mock 39%. Taken together, our data indicate that miR-205 negatively regulates the expression of Kir4.1 in astrocytes during high glucose conditions.

Title: Kir4.1, a novel target for MeCP2

Authors: *U. KAHANOVITCH[1], V. A. CUDDAPAH[2], N. L. PACHECO[2], L. M. HOLT[1,2], A. K. PERCY[3], M. L. OLSEN[4]

Abstract: Rett Syndrome (RTT) is an X-linked neurodevelopmental disorder typified by apparently normal development until 6-18 months of age, when motor and communicative skills regress and hand stereotypies, autonomic dysfunction, and seizures present. Over 95% of all reported RTT is caused by spontaneous mutations in a single gene, methyl-CpG-binding protein 2 (MeCP2). Nearly all RTT research has focused on neuronal dysfunction in RTT, however, it was recently demonstrated that restoration of MeCP2 function selectively to astrocytes reversed several deficits in a murine model of RTT, suggesting astrocytes contribute to the RTT phenotype. The mechanism of this rescue is unknown. Here we demonstrate that Kir4.1, a glia-specific inward-rectifying potassium channel that mediates several critical astrocyte membrane properties is disrupted in MeCP2 deficient mice. Astrocytes from MeCP2-deficient mice express significantly less Kir4.1 mRNA and protein, which corresponds with a 50% reduction in Ba^{2+}-sensitive Kir4.1 mediated currents. Indeed, Kir4.1 protein and mRNA expression is significantly reduced well before symptom onset. ChIP analysis revealed a direct molecular interaction between MeCP2 and the Kir4.1 gene promoter in WT animals, an interaction that is lost in MeCP2 deficient mice. These are the first data implicating a direct molecular target of MeCP2 in astrocytes and provide novel mechanistic insight explaining how astrocytic dysfunction may contribute to RTT. Future work will concentrate on elucidating the role of MeCP2 loss in the brainstem in the breathing dysfunction phenomenon in RTT.

Title: Glial heterogeneity in the molecular layer of hippocampal dentate gyrus

Authors: *G. NASERI KOUZEHGARANI[1,2], M. U. GILLETTE[1,2,3]
[1]Neurosci. Program, [2]Beckman Inst. for Advanced Sci. & Technol., [3]Dept. of Cell & Developmental Biol., Univ. of Illinois at Urbana-Champaign, Urbana, IL

Abstract: Glia are emerging as heterogeneous elements within the molecular layer of the dentate gyrus (ML-DG). Astrocytes, which display linear voltage-current (IV) curves, are coupled through gap junctions, whereas oligodendrocyte precursor cells (NG2+) exhibit voltage-dependent currents and lack gap-junction coupling. Little is known about the morphological, electrophysiological, or coupling dynamics of these glial cells with regards to the time of day. Using whole-cell patch-clamp recording, sulforhodamine-B, a gap-junction permeable dye, was injected to a single cell in morning or evening, and its spread to other cells was analyzed along with identifying cell-specific markers. Astrocytes displayed linear IV profiles, as expected, with very low resistances (< 20 MΩ) at both times-of-day, but the number of cells coupled as a cluster was significantly higher during the evening. In the case of NG2 cells, sulforhodamine-B was not transferred to other cells, indicating the lack of coupling. Cells with two different types of morphologies with distinct membrane properties were observed: (1) isolated cells displayed a non-linear IV curve with a high resistance (250-350 MΩ), and (2) NG2-NG2 pairs with direct somatic contact and extended processes in opposite directions. These cells, termed 'NG2 doublets', exhibited linear IV profiles with lower resistances (< 100 MΩ). No coupling was found between NG2 cells and astrocytes. Immunohistochemistry with double staining of the recorded slices post-fixation confirmed the identity of the injected cell as either astrocyte (GFAP-positive, non-radial glia) or oligodendrocyte precursor cell (NG2-positive). Quantification of NG2 cells at the two timepoints provides insights into the cell dynamics. Thus, within hippocampal ML-DG, we find different morphological, electrophysiological, and coupling properties of two types of glia with respect to the time of day.

Abstract: It has becoming apparent that glial cells play pivotal roles in the pathogenesis of neurodegenerative disease. To achieve pathologic elucidation and innovative drug development targeting the disease, it is useful to establish disease-in-a-dish model. However, there is few robust methodology for the rapid and efficient preparation of disease-specific astrocytic cells. Here, we estabslished a polycistronic episomal expression vector which expressed astrocyte-inducing factors using the self-cleavage 2A peptide. To validate this system, we introduced the vector onto human neural progenitors, and efficiently generated astrocytic cells. Furthermore, as a proof-of-concept trial, we generated astrocytic cells from Alzheimer's disease patient-derived cells and performed functional analyses and transcriptome analysis. We found the pathways associated with inflammatory signaling were upregulated in Alzheimer's disease-patient astrocytes, adding new layers of pathogenesis of Alzheimer's disease involving neuroinflammatory response evoked by astrocytes.

Abstract: Astrocytes are known to exhibit different morphologies and functions in different parts of the brain and spinal cord. The origin of this molecular and functional heterogeneity is largely unknown. Utilizing astrocytes generated from regionally-specified neural progenitors derived from pluripotent stem cells, we analyzed the transcription profiles by RNA sequencing and assessed the functional properties and effects of regional astrocytes on neurons and blood-brain barrier formation. We found distinct molecular profiles that are associated with each region, including predicted homeodomain transcription factors as well as transcripts which suggest different functional properties. Functional analysis of these regional astrocytes revealed differences in membrane potential and calcium signaling as well as differential effects on neurite outgrowth, synaptic formation and blood-brain barrier permeability in co-culture models. These results suggest that differences in regional astrocytes and their functional properties are partly attributed to their developmental origins.

Title: Spatiotemporal modulation of neuronal activity by astrocytic second phase calcium oscillation

Authors: *T. KIKUCHI, Y. SHINDO, K. HOTTA, K. OKA
Keio Univ., Yokohama, Kanagawa, Japan

Abstract: The relative number of astrocytes to neuronal number increases dramatically in association with the brain complexity. It is plausible that the large number of astrocytes with brain evolution could be a function of network complexity; in fact, increasingly dense and sophisticated synaptic networks require greater degrees of local modulation and fine control by astrocytes. Recent studies show that astrocytes are actively participating to synaptic transmission by releasing transmitters. Their spatiotemporal dynamic involvement in neural plasticity is now widely accepted; however, details of gliotransmission associated with calcium increase are still unclear. We report the first evidence that astrocytes show second phase calcium oscillation, which is minute order and long-lasting, by glutamate stimulation. Interestingly, this second phase oscillation makes certain “firing pattern” in the global field. We also uncover P2 purinergic receptor antagonists, suramin, inhibits this oscillation, suggesting that ATP release from astrocytes provokes second phase calcium oscillation. The lower cell density also suppresses significantly their second phase calcium oscillation, indicating that cycle of this oscillation depends on the quantity of receivable ATP released from neighboring astrocytes. To further pursue the mechanism of this event, we constructed a FRET-based ATP indicator, which can be localized specifically outside of cell membrane, named outATeam3.10. We combined two existing genetically encoded fluorescent sensors: ATeam3.10 for the ATP sensing compound and iGluSnFR for the extracellular membrane localization tag. This sensor has linearity in the range between 0.1 μM to 20 μM ATP. Using this newly created outATeam3.10 and R-GeCO, we successfully recorded simultaneous imaging of astrocytic ATP release and the temporal change of second phase calcium oscillations. To further understand the spatiotemporal astrocytes’ implication for CNS, our method for real-time monitoring of ATP levels outside of individual living cells could be one useful approach. The long-lasting second phase calcium oscillation in

astrocytes might be explained by spatiotemporal gliotransmission modality; and hence, they probably involve in the regulation of neural activity.

Title: Focal stimulation and network activation of astrocytes and glial networks using microfluidics

Authors: ***L. J. MILLET**[1], A. JAIN[2], M. U. GILLETTE[3]
[1]Joint Inst. Biol. Sci., Univ. of Tennessee., Oak Ridge, TN; [2]Dept. of Cell and Develop. Biol., Univ. of Illinois at Urbana-Champaign, Urbana, IL; [3]Dept. of Cell & Developmental Biol., Univ. of Illinois, Urbana, IL

Abstract: Glia function to maintain homeostasis, myelinate neurons, recycle neurotransmitters, modulate neuronal function, and shuttle energy to neurons. Astrocytic glia coordinate with neighboring glia, neurons and endothelial cells through cellular extensions that form functional cellular domains. Here we investigate how individual astrocytic processes respond to chemical cues and propagate calcium signals within the cell and throughout glial networks. We create microenvironments that enable controlled fluidic domains that are amenable for stimulating glial appendages without biasing the network to the stimuli. Nanoliter-scale microfluidic cell culture and imaging platforms are fabricated through a novel, sequential process that involves solvent-extracted polydimethylsiloxane (PDMS) and hydrothermal annealing. Primary glial cells from the cerebral cortex are cultured within this platform to enable focal application and imaging of sub-cellular calcium transients. Using immunochemistry and confocal microscopy, we evaluate glial morphology and find that glia extend fine, micron-scale processes into neighboring domains. Sub-cellular and network level calcium transients are imaged using Fluo-4 AM and a

Zeiss LSM-510 Meta NLO system equipped with an argon laser. The activation of calcium transients is achieved by focal application of ATP and glutamate, Ca^{2+} wave propagation occurs at a rate of 11-12 micron/sec. Repeated elevated Ca^{2+} transients in distant glial cells are also achieved; individual responses and sustained oscillations show prototypical morphology and are reminiscent of microburst activity. Our findings extend previous studies of glial signaling to evaluate local signaling at single processes that sense, respond to, and transmit information regarding environmental cues. Our approach demonstrates a simple, yet powerful system to interrogate the activity of individual cells and networks of glia in an unprecedented way using microfluidics.

Title: Dopamine exposure induces phenotypic changes in rat hippocampal astrocytes

Authors: *A. GALLOWAY[1], A. ADELUYI[2], S. MATHEW[2], J. R. TURNER[2], P. I. ORTINSKI[1]

Abstract: Dopamine, a major neuromodulator, is critical for processing of reward and is implicated in etiology of drug addiction. The effects of dopamine on glial cells have been historically understudied, yet research indicates that astrocytes express dopamine receptors and respond to dopaminergic neuron activity. Using an *in vitro* model of elevated extracellular dopamine, our evidence reveals a rapid dopamine-induced switch from fibroblast-like to stellated morphology in cultured rat hippocampal astrocytes. A one hour exposure to dopamine (75µM) produced a pronounced increase in the number of primary astrocyte processes which was accompanied by a decrease in GFAP-positive area. Exposure to antioxidants N-acetylcysteine or sodium metabisulfite in the presence of extracellular dopamine did not disrupt dopamine effects on astrocyte morphology. However, treatment with dopamine receptor antagonists significantly blunted dopamine-induced stellation. Morphological changes were associated with a decrease in acetylated tubulin, consistent with decreased GFAP-positive area. RNA-sequencing revealed that a number of immediate early genes (IEGs) previously linked to structural and functional adaptations in neurons are also differentially expressed in dopamine-treated astrocytes. At the functional level, dopamine treatment had no effect on the amplitude of astrocytic intracellular Ca^{2+} transients, but increased Ca^{2+} wave duration. Together these findings indicate that elevated extracellular dopamine induces phenotypic changes in cultured astrocytes. Physiological implications for astrocyte-mediated dopamine effects in the context of drug addiction remain to be examined.

Title: Fibroblast growth factor receptor 1 expression in animal models of chronic stress and injury

Authors: *K. M. SMITH[1], J. C. COLLETTE[2], H. TORRES[2], L. B. RUBIN[2]
[2]Biol., [1]Univ. of Louisiana At Lafayette, Lafayette, LA

Abstract: Fibroblast Growth Factor Receptor 1 (FGFR1) is an important regulator of cortical development, function, and response to injury. We have studied the cellular expression of the Fgfr1 gene by employing the *tgFgfr1-EGFP* mouse line. This BAC transgenic line was generated by the GENSAT project, and our previous studies demonstrated that GFP is expressed in a manner that is consistent with known roles of FGFR1 in development and function. In development, GFP expression was found in telencephalic radial glia, hippocampal anlage, and rhombic lip where it is known to play roles in stem cell maintenance and amplification; it was also expressed in midline radial glia, where FGFR1 is crucial to the formation and migration of midline radial glial astrocytes; and in Bergmann Glia, where FGFR1 and FGFR2 signaling cooperate to maintain Bergmann Glia morphology and attachment to the pial membrane. In adult mice, we also found expression in GFAP positive astrocytes throughout the brain, Olig2+ cells, a minority of cortical and hippocampal neurons, BLBP+ cells of the lateral subventricular zone, and hippocampal DG and CA regions, as well as the hypothalamus. Here, we investigate whether the *tgFgfr1-EGFP* mouse line can be used to investigate changes in GFP expression after chronic unpredictable stress (CUS), and in response to injury. Our purpose was to validate whether this model responds to manipulations that have previously been reported to lead to changes in *Fgfr1* expression. We found that chronic unpredictable stress leads to upregulation of *Fgfr1* in the CA region of the hippocampus. The injury model we chose to study was the cuprizone model of demyelination, which is achieved by ingestion of 0.2% cuprizone in the feed. We found that *Fgfr1* driven GFP was upregulated in the recovery period of chronic cuprizone administration. Interestingly, this upregulation of GFP in the corpus callosum was colocalized with GFAP, indicating that the upregulation in the corpus callosum was due to increased numbers of astrocytes expressing *Fgfr1*, as opposed to oligodendrocyte or oligodendrocyte precursors. Current and future studies will investigate whether inactivation of *Fgfr1* in postnatal astrocytes leads to impaired injury response to demyelination injury, or changes in astrocyte and stem cell function.

Title: Calcium signals in LC axons and astrocytes in the hippocampus during navigation

Authors: *A. KAUFMAN, W. LI, J. BOWLER, E. M. BALOUGH, A. LOSONCZY
Columbia Univ., New York, NY

Abstract: Astrocytes exhibit increases in calcium in response to certain neurotransmitters. Astrocytes have been shown to respond to norepinephrine in barrel cortex, cerebellum, and visual cortex. Using a two-photon microscope, we are simultaneously imaging catecholaminergic axons projecting from the locus coeruleus and astrocytes in the hippocampus of awake, behaving mice. We are examining the correlation between astrocyte calcium signals and axon calcium signals during goal-oriented reward learning on a cued treadmill belt, as well as when these signals occur in relation to behavior. We are examining both specific behavioral epochs such as the start of running and reward-seeking behavior, and larger behavioral events such as learning the location of the reward. We can compare this to random foraging for reward on a cued belt, in which the animals do not need to learn the location of a reward. In addition, we are characterizing the responses of both the axons and astrocytes during the presentation of stimuli of positive, negative and neutral valences.

Abstract: Astrocytic ATP release is essential for brain functions such as synaptic long term potentiation for learning and memory. However, whether/how ATP is released via exocytosis

remains in hot debates. Most of previous studies on non-vesicular ATP releases are studied with relative indirect procedures. In contrast, two recent works report vesicular ATP release using more direct assays. In the present work, we re-investigated astrocytic ATP release at single vesicle resolution in cultured hippocampal astrocytes. Following a mechanical stretch stimulation (Mstim) on a single astrocyte we studied Ca^{2+}*-dependence of* ATP releases, which are in comparison to Ca^{2+}*-dependent* quantal ATP release in chromaffin cells. The astrocytic ATP release did not require lysosome exocytosis but was inhibited by either selective-antagonist or genetic knock-down of a nonselective cation channel. In summary, there is a Mstim-induced ATP release through a cation channel in hippocampal astrocytes.

Title: Identification of a novel regulator of astrocyte development and maturation

Authors: *K. T. BALDWIN[1], J. A. STOGSDILL[1], R. ESTEVEZ[2], C. EROGLU[1]
[1]Dept. of Cell Biol., Duke Univ., Durham, NC; [2]Departament de Ciències Fisiològiques II, Univ. of Barcelona, Barcelona, Spain

Abstract: Astrocytes, the major glial cells of the brain, play critical roles in a wide variety of brain functions, including synapse formation, ion homeostasis, and formation of the blood-brain barrier. The functional complexity of astrocytes is reflected in their elaborately branched morphology. Astrocytes form extensive arbors terminating in thousands of fine processes that structurally and functionally interact with synapses. Despite the vital role of astrocytes in the brain, the cellular and molecular mechanisms that drive astrocyte development are poorly understood. Furthermore, it is unclear how disruptions to astrocyte development affect astrocyte function and drive disease pathogenesis. To address these critical knowledge gaps, we performed a candidate screen of astrocyte-enriched, disease-linked genes to identify novel regulators of astrocyte development and maturation. This screen identified the cell adhesion molecule

HepaCAM (also known as GlialCAM) as a critical regulator of astrocyte morphological development, both in vitro and in vivo. Knockdown of HepaCAM severely reduces astrocyte morphological complexity in astrocyte-neuron co-cultures, and impairs astrocyte development in mouse visual cortex. In humans, mutations to the extracellular domain of HepaCAM cause developmental brain disorders, namely Megalencephalic Leukoencephalopathy with Subcortical Cysts (MLC), and macrocephaly with intellectual disability and autism. Ongoing studies are investigating how these disease mutations alter astrocyte development and contribute to astrocyte dysfunction that is associated with disease pathogenesis.

Title: Ng2 knock-out in the neu7 reactive astrocyte cell line to promote neuronal regeneration

Authors: *S. M. CIOMBOR, A. HAY, M. HABERMAN, M. FALLERT, D. R. COOK-SNYDER
Carthage Col., Kenosha, WI

Abstract: Stroke remains a leading cause of death and disability worldwide. After an ischemic stroke, neuronal regeneration is prohibited due to the astrocytes surrounding the tissue becoming reactive. Reactive astrocytes are non-permissive to axon outgrowth, and improving our understanding of astrocyte reactivity can facilitate development of more targeted therapies for neuronal regeneration. Neu7s are an astrocyte cell line that models this reactive phenotype due to an increased production of inhibitory chondroitin sulfate proteoglycans. Of these proteoglycans, chondroitin sulfate proteoglycan 4 (NG2) has been found to be the most inhibitory to axon regeneration. A7 cells are a model cell line for astrocytes that are permissive to axon outgrowth, having a downregulated production of NG2. The CRISPR/Cas9 system was used to produce NG2 knockout Neu7 and A7 cell lines. NG2 is a 35,046 base pair long gene with ten exons. We created guide sequences targeting exons 1, 3, 5 and 10. Bacterial cloning was used to construct plasmids containing guide sequences, Cas9 and green fluorescent protein (GFP). Sanger sequencing and alignment identified correctly constructed plasmids. Neu7 cells were transfected with plasmids containing NG2 guide sequences. Ongoing experiments will continue to determine conditions to increase transfection efficiency, transfect A7 cells, identify unique cellular markers, and develop neuronal co-cultures with transfected astrocytes. These co-cultures will help assess the role of NG2 in axon outgrowth inhibition. We believe these experiments will aid in the development of new therapies for neuronal regeneration.

Title: The role of astrocytic GABA transport during sensory processing in visual cortex

Authors: *G. O. SIPE[1], R. GARCIA[2], R. V. RIKHYE[2], J. C. PETRAVICZ[2], M. SUR[2]

Abstract: Increasing evidence indicates that astrocytes actively modulate neuronal network activity through dynamic neurotransmitter clearance at the synaptic cleft. Although neurotransmitter clearance maintains synaptic homeostasis, it can also affect synaptic efficacy and subsequent information processing. Most work on astrocytic neurotransmitter clearance focuses on glutamate uptake via the transporters GLT-1 and GLAST, however astrocytes also express the GABA transporters GAT-1 & GAT-3. In particular, multiple studies have indicated that GAT-3 is selectively expressed in astrocyte processes near synaptic clefts and is thought to mediate tonic inhibitory states. Though GAT-3 blockade has been shown to delay the onset of seizure events in epilepsy models, it is not known how GAT-3 activity influences cortical information processing. To explore this question, we investigated the function of GAT-3 in primary visual cortex of the adult mouse. We characterized GAT-3 function in the cortex using immunohistochemistry and confirmed previous reports that GAT-3 expression heavily co-localizes with astrocytic processes and displays layer-specific heterogeneity. We then characterized GAT-3 function in the visual cortex using a combination of 2-photon microscopy, optogenetic activation, and slice electrophysiology. Our data suggests that neuronal reliability and tuning properties are disrupted with GAT-3 blockade. In conjunction with previous work in the lab investigating the role of astrocytic GLT-1 in visual cortex, these data indicate that astrocytes contribute to the crucial balance of excitation and inhibition necessary for cortical information processing.

Abstract: Astrocytes are extensively connected with each other through gap junctions to form the largest syncytium. The astrocyte syncytium is increasingly recognized to function as a system in the critical homeostatic and signaling roles to distribute energy substrates and regulate interstitial ion and neurotransmitter levels for optimal synaptic transmission. However, the involved ultrastructural basis that underlies these syncytial functions remains largely unclear. In addition, it has not been resolved if the general cytoarchitecture of astrocytes extend in a tree-like (arborization) manner, as is the case for other CNS cells, or in a unique spongiform branching pattern that self-connect through reflexive gap junctions. We used an innovative technique in correlative confocal microscopy and serial block-face scanning electron micrography (SBFEM) to resolve, for the first time, the entire ultrastructure of coupled astrocytes in the hippocampus. We show that astrocytes exhibit a predominantly spongiform morphology that enwrap neural processes. We also show two neighboring astrocytes make multiple parallel contacts only at their fine processes. Mathematical modeling suggests this contact patterning, in part, explains the low resistance pathway between astrocytes. These multiple parallel processes also exist in specialized astrocyte end-feet processes that establish contact with blood vessels. Our data favor the view that astrocytes adopt a spongiform cytoarchitecture with extensive reflexive processes, and establish contacts with other cells with parallel terminal processes. These results are expected to expand our understanding of the structure-function relationship of astrocytes, the astrocyte syncytium, and its role in brain function and disease.

Title: Estimation of metabolic energy balance in neurons by using fluorescent imagings

Authors: *M. IIZUMI, R. SUZUKI, R. YAMANAKA, Y. SHINDO, K. HOTTA, K. OKA
Keio Univ., Yokohama-Shi, Japan

Abstract: Animal cells including neurons produce ATP by two pathways: anaerobic glycolysis and oxidative phosphorylation. Pyruvate is located at a branch point of two pathways and lactate is the end product of anaerobic glycolysis. Thus, simultaneous measurement of lactate and pyruvate concentrations allows the estimation of metabolic energy balance between these two pathways. We expect that estimation of the balance between two pathways sequentially and simultaneously would reveal the optimal energy strategy in individual neurons, which are required for heavy information tasks with high metabolic energy consumption. To measure the concentrations of lactate and pyruvate in a single cell with real-time and high temporal resolution, we used genetically-encoded Forester Resonance Energy Transfer(FRET)-based lactate and pyruvate sensors (San Martin *et al*.,2013; San Martin *et al*.,2014). Both of these two sensors use mTFP and Venus as FRET pair fluorescent proteins, we therefore changed recombining FRET pair of pyruvate sensor to mOrange and mCherry for simultaneous imaging in single cells. After recombination, we evaluated FRET pair-changed pyruvate sensor in vitro. FRET pair-changed pyruvate sensor had two peaks for mOrange and mCherry at 565 nm and 610 nm, respectively. Application of pyruvate caused an increase in mOrange fluorescent intensity and decrease in mCherry fluorescent intensity. And exposure to higher concentrations of pyruvate showed that FRET pair-changed pyruvate sensor increased its FRET efficiency, and we confirmed that FRET pair-changed pyruvate sensor worked normally in vitro. In conclusion, we recombined FRET pair of pyruvate sensor and this allows us dual imaging of lactate and pyruvate in the same cell simultaneously. We expect dual imaging of pyruvate and lactate would also reveal the process of cell death in neurodegenerative disease cells.

Title: Impairments in both brain and liver glucose metabolism are restored by fructose 1,6-bisphosphate administration in the chronic pilocarpine-SE mouse model

Authors: *T. MCDONALD[1], M. P. HODSON[2], K. BORGES[1]
[1]Univ. of Queensland, St Lucia, Australia; [2]Australian Inst. for Bioengineering and Nanotechnology, Univ. of Queensland, St Lucia, Australia

Abstract: There is growing evidence that suggests that metabolic disturbances contribute the development and progression of seizures. Here we aimed to elucidate which pathways involved in brain glucose metabolism are impaired during the chronic stage of the pilocarpine-status epilepticus (SE) model of epilepsy, and how the treatment of fructose 1,6-bisphosphate (F16BP) altered this metabolism.
Mice were injected with F16BP (1 g/kg, i.p) daily for 6 days, beginning two weeks after pilocarpine-induced SE. Mice were then injected with [U-^{13}C] glucose (558mg/kg, i.p) and sacrificed 15 minutes later. The percent enrichment of carbon-13 was measured in metabolites of the hippocampal formation and liver using LCMS/MS and GCMS, and enzyme activities were measured via spectroscopy.
Mice that developed SE had a reduction in the percent ^{13}C enrichment in most glycolytic intermediates (17-22%, $p<0.05$) in the hippocampal formation, with no change in glycolytic enzyme activities. This suggests that glucose uptake is impaired. Furthermore, the incorporation of ^{13}C in the TCA cycle intermediates was reduced (17-35%, $p<0.05$), coupled with 33% and 55% loss in the activities of pyruvate dehydrogenase and 2-oxoglutarate dehydrogenase, respectively ($p<0.05$ for both). Together this indicates that in the chronic phase of the pilocarpine-SE model the TCA cycle is also impaired in the hippocampus. A loss of ^{13}C enrichment was also observed in both lactate (33%, $p<0.05$) and alanine (31%, $p<0.05$) in the liver of mice that developed SE, indicating a loss in glucose uptake or glycolytic activity in the liver. Chronic administration of F16BP restored the % 13C enrichment of all metabolites both peripherally and in the brain, except for lactate where a 16% decrease was observed in the hippocampus ($p<0.05$).
Overall this suggests that in the chronic epileptic hippocampal formation glucose metabolism is impaired by reductions in glucose uptake and activities of key TCA cycle enzymes. However, these impairments in glucose handling are not limited to the CNS, but also occur peripherally,

and the administration of F16BP restored both brain and peripheral glucose metabolism. We are currently investigating potential mechanisms for the improvement of glucose metabolism by F16BP.

Title: Sirtuins confer the neuroprotective activity of the ketogenic diet and the ketone body β-hydroxybutyrate

Authors: H. OH[1], S.-C. MA[1], A. J. SHACKELFORD[2,1], J. M. RHO[3], *D. KIM[1]
[1]Barrow Neurolog. Institute, St. Joseph's Hosp. & Med. Ctr., Phoenix, AZ; [2]Dept. of Dent. & Oral Hlth., A.T. Still Univ., Mesa, AZ; [3]Dept. of Pediatrics, Clin. Neuroscience, Physiol. and Pharmacol., Alberta Children's Hospital, Univ. of Calgary, Calgary, AB, Canada

Abstract: A growing number of studies indicate that metabolism-based treatments such as the high-fat anticonvulsant ketogenic diet (KD) and calorie restriction can exert neuroprotective activity, possibly through modulation of mitochondrial function and neuroinflammation. Although the specific mechanisms underlying these effects remain unclear, there are rapidly emerging links between cellular metabolism and nicotinamide adenine dinucleotide-dependent deacetylases (i.e., sirtuins, Sirt1-7), some of which affect epigenetics, neurometabolism, and inflammation. Given that administration of either the KD or β-hydroxybutyrate (βHB; a key metabolic byproduct of the KD) has been shown to attenuate neuronal death and pro-inflammatory responses against lipopolysaccharide (1μg/ml LPS; an endotoxin), a mitochondrial respiratory complex I inhibitor; 1 μM rotenone, and hydrogen peroxide (H_2O_2; 250 μM) (SFN 2016, #516.15), we investigated whether: 1) gene expression levels of Sirt1-7 are elevated in KD-fed mice brain and βHB-treated hippocampal HT22 cells or microglial BV2 cells; and 2) blockade of Sirt3 activity counteracts βHB-induced neuronal protection and anti-inflammatory effects. In hippocampus from C57BL/6J mice fed the KD for 2 wks, PCR analysis of genomic DNA using primers for Sirt1-7 revealed a significant increase in mRNA expression levels of all sirtuins compared with standard diet-fed mice. Consistent with these *in vivo* data, cell lines

exposed to 1 mM βHB for 24-hr led to upregulation of Sirt1-7 gene expression; notably, the most robust changes were seen in Sirt3 and Sirt6 expression. Pharmacological blockade of Sirt3 (1 ug/ml 5-amino-2-phenyl-benzoxazole) activity had no influence on HT22 cell viability, whereas βHB-induced neuronal protection against H_2O_2 was strongly reversed by inhibition of Sirt3 activity. Blocking Sirt3 activity in BV2 cells for 6-hr strongly enhanced release of pro-inflammatory mediators, compared to BV2 cells treated with either rotenone or LPS. βHB failed to induce anti-inflammatory effects under conditions of reduced Sirt3 activity. Collectively, our data support the notion that activation of sirtuins underlies some of the therapeutic benefits of βHB and the KD.

Title: Ketogenic diet produces rapid, region-specific alterations in brain NAD^+/NADH

Authors: *M. ELAMIN[1], D. N. RUSKIN[2], S. A. MASINO[2], P. SACCHETTI[1]
[1]Neurosci. program, Dept. of Biol., Univ. of Hartford, Hartford, CT; [2]Neuroscience/Psychology, Trinity Col., Hartford, CT

Abstract: Numerous studies establish anti-epileptic effects of a ketogenic diet (KD), and recent research highlights its therapeutic potential in developmental disorders such as autism spectrum disorder and in neurodegenerative diseases such as Alzheimer's disease. A KD's composition of high fat, low carbohydrate, and moderate protein induces a metabolic shift that lowers glucose availability, increases ketone utilization as an energy source, and improves mitochondrial function. However fundamental mechanisms underlying its beneficial effects across diverse disorders are not well understood. Based on differential utilization of nicotinamide adenine dinucleotide (NAD) during glucose-based versus ketone-based generation of cellular ATP we hypothesized that a primary mechanism is altered levels of NAD. NAD is an essential metabolic coenzyme and a signaling molecule that exists in oxidized and reduced forms, NAD^+ and NADH, respectively. We fed normal rats ad libitum with regular chow or KD for either two days

or three weeks and quantified the regional NAD^+/NADH ratio in frontal cortex and hippocampus. In animals fed a KD for three weeks we observed region-specific effects: the NAD^+/NADH ratio was increased significantly in the hippocampus but not in the frontal cortex, thus suggesting that some brain regions may be more sensitive than others to this metabolic shift. Furthermore, the increased ratio in the hippocampus was detected already within two days of KD feeding and remained elevated, indicating an early as well as a persistent metabolic shift during diet administration. These effects paralleled metabolic changes in blood ketones: rats were also already in ketosis at two days of KD feeding. The hippocampus is a key brain region for seizure generation and memory formation and has a high metabolic rate - perhaps relevant to selective KD-induced changes in NAD^+/NADH. In general increasing NAD^+ is a coveted therapeutic endpoint - considered a marker for mitochondrial and cellular health, and postulated to increase longevity. Here we found that a KD induces a rapid and region-specific increase in NAD^+/NADH, a change that may be a primary mechanism behind diverse beneficial effects of this metabolic therapy.

Title: Ketogenic diet shifts cerebrospinal fluid metabolome and has differential effects in responsive vs. non-responsive pediatric epilepsy patients

Authors: *D. N. RUSKIN[1], M. LINDEFELDT[2], N. FREEDGOOD[1], M. DAHLIN[2], S. A. MASINO[1]
[1]Trinity Col., Hartford, CT; [2]Karolinska Hosp., Stockholm, Sweden

Abstract: The low carbohydrate, high fat ketogenic diet (KD) can be an effective anticonvulsant treatment in some pharmacoresistant epileptic patients. Its mechanism(s) of action, however, remain uncertain. We performed metabolomic analysis of CSF samples taken before diet and during KD treatment in five complete responders and five complete non-responders to search for differential diet effects in these two groups. Responders and non-responders had similar age ranges and included both males and females. Seizure types and epileptic etiology or syndromes

varied widely, and did not appear to differ systematically between responders and non-responders. 271 metabolites were identified in CSF. Principal component analysis showed a strong effect of KD treatment on metabolites, particularly lipids, ketone bodies, carnitine derivatives, and sugars. Comparing responders and non-responders for the hallmark metabolic effects of KD, there was a greater elevation of ketone bodies and a larger drop in glucose in responders. Exploratory random forest analysis compared during-KD data between responders and non-responders to find other metabolites that could be relevant to differential seizure responsiveness. Top scoring metabolites included multiple lipids, amino acids, carbohydrates, and xenobiotics. These data show that KD feeding strikingly modifies the central metabolome, and that responders may have a stronger metabolic response to KD feeding.

Title: Glycolytic inhibition with 2-deoxyglucose attenuates epileptiform activity following traumatic brain injury

Authors: *C. G. DULLA[1], D. CANTU[2], J. KOENIG[2]
[1]Neurosci., [2]Tufts Univ. Sch. of Med., Boston, MA

Abstract: Following a traumatic brain injury (TBI), post-traumatic epilepsy (PTE) can occur. Chronic seizures can be a significant cause of disability for TBI patients, especially when the seizures are refractory to medical anticonvulsant therapies. To study TBI, we have used a model known as controlled cortical impact (CCI) in mice. Using this approach we found cortical network hyperexcitability, increased glutamatergic signaling, and a loss of parvalbumin and somatostatin interneurons following injury. Glycolytic inhibition has begun to be explored as a therapeutic target for seizures, but has not yet been utilized to prevent post-traumatic epileptogenesis. We hypothesize that 2-deoxyglucose (2DG), a glucose analog that competitively inhibits glycolysis at the rate-limiting enzyme hexokinase, is neuroprotective and anti-epileptogenic following TBI. In vitro 2DG application attenuated epileptiform activity in acute cortical slices from injured brains. Additionally, in vivo 2DG treatment prevented the

development of epileptiform activity following injury and attenuated the loss of parvalbumin-expressing interneurons and the increase in reactive astrocytes following CCI. Our preliminary data also suggests that glycolytic inhibition with 2DG has different effects on the excitability of different neuronal subtypes, specifically that 2DG may decrease the excitability and membrane resistance of excitatory pyramidal cells while having no effect (or even increasing) the excitability of inhibitory interneurons. Our research supports a role for glycolytic inhibition in the prevention of epileptogenesis following TBI and may reveal a novel cell type-specific coupling of metabolism to neuronal excitability.

Title: Correlation between tryptophan catabolism and cognitive decline in old women

Authors: *L. A. RAMOS[1,2], P. CARRILLO-MORA[3], B. GARCÍA[3], D. GONZÁLEZ-ESQUIVEL[4], D. RAMÍREZ-ORTEGA[4], C. RIOS[4], V. PÉREZ-DE LA CRUZ[4], B. PINEDA[5], G. ROLDÁN-ROLDÁN[2]

Abstract: Aging is a multifactorial degenerative process and is characterized by progressive deterioration in physiological functions and metabolic processes; these changes drive to numerous age-related disorders. Cellular alterations during aging process involve oxidative stress, inflammation, mitochondrial dysfunction, cognitive and immune response decline. Recently, it was found that changes modifications in the tryptophan metabolism are also observed during the aging. Tryptophan is an essential amino acid required for synthesis of proteins and it is mainly metabolized via the kynurenine pathway conducing to several metabolites with neuroactive and/or redox properties. Particularly, kynurenic acid -an

endogenous antagonist of α7nACh and NMDA receptors- and quinolinic acid, an agonist of NMDA receptors, have been related with neurodegenerative diseases. Due to kynurenine pathway metabolites have been related with aging and some ageing-related diseases, we investigated whether the imbalance of kynurenine pathway components could be related with cognitive decline and alteration in redox status in old women. Participants ranged in age from 50 to 95 years. A brief neuropsychological tests serie (NEUROPSI), standardized, was performed. The NEUROPSI tests serie includes assessment of orientation, attention, memory, language, visuoperceptual abilities, motor skills, and executive functions. Serum levels of tryptophan, kynurenine, kynurenic acid and QUIN were determined in seventy old women without dementia, as well as lipoperoxidation and GSH levels in the same samples. Cognitive decline increased during aging. GSH levels decreased whereas lipid peroxidation increased during aging. Tryptophan levels decreased in relation to the age and correlated with the cognitive decline ($P < 0.0019$). Additionally, QUIN / Trp ratio also correlated with cognitive decline. Our data suggest that tryptophan catabolism is more active as the age advances and it is involved in the cognitive detriment found in older women.

Title: Inhalation anesthetics induce abnormal locomotor activity in mice

Authors: *H. TON[1], L. YANG[2], Z. XIE[3]
[1]Dept. of Anesthesia, Critical Care and Pain Med., Massachusetts Gen. Hosp., Boston, MA; [2]Massachusetts Gen. Hospital- Harvard Med. Sch., Boston, MA; [3]Anesthesia, Critical Care and Pain Med., Massachusetts Gen. Hosp. and Harvard Med. Sch., Charlestown, MA

Abstract: Delirium is one of the most common postoperative complications in geriaric patients and can lead to 2- to 20-fold increase in mortality, long term functional impairment, postoperative cognitive dysfunction, and increased costs of medical care. However, its causes,

neuropathogenesis and targeted intervention(s) remain largely to be determined, partially owing to the lack of animal model(s). The mouse activity was recorded before, during and after anesthesia with sevoflurane or isoflurane [0.2-, 0.5-, 1- and 2-fold minimum alveolar concentration (MAC)] at 37^0 C. The total walking distance, velocity of movement and the time visiting the central zone of the box were measured and quantified as indexes of hyperactivity and agitaiton-like behaviors. Both isoflurane and sevoflurane at all the tested concentrations changed the motility of the mice in a time-dependent manner. During the anesthesia, sevoflurane and isoflurane markedly increased locomotion. After anesthesia, the locomotion increased in a very short time (within 5 min) and markedly reduced up to 2 hours after treatment. Interestingly, food intake and body weight decrease up to 48 hours after the anesthesia in the anesthetized mice as compared to control mice. Our results provide the evidence for the first time that inhalation anesthetics induce short-term hyperactivity and agitation-like behavior, and long-term depressive-like behavior in the mice. These data would help us to establish an animal model to study emergence and postoperative delirium, ultimately leading to the understanding the neuropathogenesis of postoperative delirium and the development of targeted inverventions.

Title: Altered levels of neurotrophic factors and neurotransmitters in the brain as the probable causes of decreased longevity of WNIN obese rats

Authors: *S. GHOSH[1], J. K. SINHA[1,2], N. GIRIDHARAN[1], M. RAGHUNATH[1]
[1]NATIONAL INSTITUTE OF NUTRITION, Hyderabad, India; [2]CSIR-CENTRE FOR CELLULAR AND MOLECULAR BIOLOGY, Hyderabad, India

Abstract: Wistar NIN obese (WNIN/Ob) rats developed at the National Institute of Nutrition are the heaviest inbred rat strain in the world. These rats are hyperphagic, hyperinsulinemic, hyperleptinemic and have reduced longevity (an average lifespan of 15-18 months in contrast to 36 months in normal Wistar rats). In the WNIN/Ob rats, we intend to delineate the factors responsible for reduced longevity. Neurotrophic factors are responsible for the survival of developing neurons and the maintenance of mature neurons. We have estimated levels of key

neurotrophic factors using BioPlex assay and done neuro-glial profiling using Immunohistochemistry in different brain regions of these rats (n=6). As Glutamate (Glu) and Gamma-aminobutyric acid (GABA) are the major excitatory and inhibitory neurotransmitters in mammalian CNS, we have looked at their levels in different brain regions of WNIN/Ob rats (n=4) and age-matched normal rats (n=4) using Magnetic Resonance Spectroscopy. We have evaluated if there are any volumetric differences in the brain of WNIN/Ob rats in contrast to the age-matched controls using Magnetic Resonance Imaging. Our findings show that the levels of key neurotrophic factors like BDNF and IGF-1 are altered in the WNIN/Ob rats. MRS data indicates altered neurotransmitter metabolism in the brain of WNIN/Ob rats. But there are no significant volumetric changes in the brain of the WNIN/Ob rats when compared to controls. Altered levels of neurotrophic factors and neurotransmitters in the brain are one of the many factors behind decreased longevity of WNIN obese rats.

Title: Adiponectin receptor 1 regulates AKT-FOXO mediated cell survival via facilitating insulin signaling

Authors: *M.-W. KIM, G.-H. YOON, M.-G. JO, F. U. AMIN, M. IDREES, M.-O. KIM
Gyeongsang Natl. Univ., Jinju-Si, Gyeongsangnam-Do, Korea, Republic of

Abstract: Adiponectin, adipocyte-derived hormone, is considered as master regulator for anti-diabetes and insulin resistance by sensitizing insulin signaling on peripheral tissues. Since neuro-pathology has been termed as Type-3-diabetes, adiponectin-adiponectin receptors have been regarded as a therapeutic target. Previously, we reported that AdipoR1 deficiency exhibited neuronal apoptosis and spatial learning and memory impairment. To extend the mechanisms of how AdipoR1 regulates neuronal apoptosis, we focused on the insulin signaling-apoptosis axis. Using PEI-mediated gene therapy for in vivo knockdown, we found that AKT phosphorylation at serine 473 region (p-AKT) was highly down-regulated in AdipoR1 shRNA group. Accordingly, AKT-mediated glucose uptake by insulin-stimulation was decreased. Moreover, we checked whether down-regulated p-AKT by AdipoR1 suppression attenuates FOXO1 phosphorylation. We confirmed this AKT mediated FOXO1 phosphorylation was prevented by AdipoR1 shRNA.

This facilitates FOXO1 nuclear translocation as well as transcribing its apoptotic-related genes. Taken together, our findings suggest a specific role of AdipoR1 in insulin signaling mediated cell survival, and point to the modulation of AdipoR1 as a therapeutic target of neurodegeneration.

Title: Oxidative stress: Possible modulator of hormone replacement therapy action

Authors: *P. DUONG[1], C. MCCUISTON[2], R. CUNNINGHAM[1]
[1]CANDR, [2]Texas Col. of Osteo. Med., UNT Hlth. Sci. Ctr., Fort Worth, TX

Abstract: One of the hallmarks that delineates reproductive aging in women is menopause. Menopause is a gradual process that begins to manifest in women as they approach 45-55 years of age. Prior studies have found equivocal effects of hormone replacement therapy (HRT) on brain health for women in menopause. HRT initiation prior to the manifestation of menopause has been shown to be protective. However, HRT initiation in women 10 years post-menopausal can induce adverse effects, such as stroke. Oxidative stress is a key characteristic in aging, menopause, and stroke. Therefore, we propose that oxidative stress may be a switch that determines if HRT is neuroprotective or neurotoxic. To examine our hypothesis we used an immortalized neuronal cell line $1RB3AN_{27}$ (N27) derived from female fetal mesencephalic tissue. Hydrogen peroxide (H_2O_2) was used as an oxidative stressor to model menopause. Common HRTs prescribed by physicians include testosterone (T), 17β-estradiol (E2), and membrane impermeable - dihydrotestosterone (DHT-BSA). Therefore, we exposed N27 cells to HRT either before or after H_2O_2 treatment. Cell viability was assessed using MTT. Results showed that HRT prior to H_2O_2 was protective, regardless of the type of HRT. However, if HRT was applied after H_2O_2, N27 cell loss was exacerbated. These results indicate that oxidative stress may be a switch that determines if HRT is neuroprotective or neurotoxic. Furthermore, this study provides further support and extends the Healthy Cell Bias of Estrogen Signaling.

Abstract: Curcuma is a natural compound that has shown neuroprotective properties, and has been reported to prevent aging and improve memory. While the mechanisms underlying these effects are unclear, they may be related to increases in neural plasticity. Morphological changes have beenreported in neuronal dendrites in the limbic system in animals and elderly humans with cognitive impairment. In this regard, there is a need to use alternative therapies that delay the onset of morphologies and behavioral characteristics of aging. Therefore, the objective of this study was toevaluate the effect of curcuma on cognitive processes and dendritic morphology of neurons in the prefrontal cortex , the CA1 and CA3 regions of the dorsal hippocampus, the dentate gyrus, and the basolateral amygdala of aged rats. 18-month-old rats were administered curcuma 100 mg/kg daily for 60 days. After treatment, recognition memory was assessed using the novel object recognition test. Curcuma-treated rats showed a significant increase in the exploration quotient. Dendritic morphology was assessed by Golgi-Cox staining and followed by Sholl analysis. Curcuma-treated rats showed a significant increase in dendritic spine density and dendritic length in pyramidal neurons of the PFC, the CA1 and CA3, and the BLA. The preservation of dendriticmorphology was positively correlated with cognitive improvements. Our results suggest that curcuma induces modification of dendritic morphology in the aforementioned regions. These changes may explain how curcuma slows the aging process that has already begun in these animals, preventing deterioration in neuronal morphology of the limbic system and recognition memory.

Title: Age-dependent vulnerability of axons to aglycemia is not caused by a decline in the astrocyte-neuronal lactate shuttle

Authors: *C. BASTIAN, C. DOHERTY, C. FRANKE, A. FARIS, S. BRUNET, S. BALTAN
Cleveland Clin. Fndn., Cleveland, OH

Abstract: The effects of aging on the central nervous system (CNS) predominantly impact the white matter (WM) compared to the gray matter. Age-dependent WM changes contribute to many CNS neurodegenerative diseases including dementia, ataxia, motor neuron diseases and stroke. We have previously shown that aging axon function is more vulnerable to ischemia and that age-related structural changes in myelin, mitochondria, and endoplasmic reticulum are associated with reduced energy production and Ca^{2+} dysregulation. Because it is well-established that glial cells support axon function, we tested the impact of aging on glial cells and its impact on axon-glia support. The astrocyte-neuron lactate shuttle (ANLS) is required to support axon function by providing lactate during periods of aglycemia or increased activity as an alternative energy substrate to glucose. We hypothesized that aging axon function is more vulnerable to reduced glucose availability and that this vulnerability is partly mediated by a decline in the ability of aging astrocytes to provide lactate to axons.
We utilized, mouse optic nerve (MON), a pure WM tract obtained from 2- or 12-month old mice to quantify axon function using electrophysiology. Axon function was quantified by monitoring the area under evoked compound action potentials (CAPs). To assess structural changes in aging astrocytes, MONs were immunostained with GFAP (astrocytes) and Sytox (nuclei). Aging astrocytes displayed thicker processes that extended parallel to axons. This contrasted with young astrocytes, which had shorter, thinner processes that traversed axons vertically. Aging axons were more susceptible to aglycemic injury (0 mM glucose for 1 h), recovering significantly less compared to young axons. However, when incubated with high glucose (30 mM for 1h) to increase glycogen stores in astrocytes to provide lactate during aglycemia, both young and aging axons showed delayed loss-of-function during aglycemia and recovered more following aglycemia. Furthermore, aging axon function recovery benefited more compared to

young axons when L-lactate was supplied during aglycemia. However administration of L-lactate following aglycemia did not improve axon function recovery in either young or aging axons.
Overall our results suggest that aging axons are more vulnerable to aglycemia and there are age-dependent structural changes in astrocytes. However, ANLS function to support axon function is not the underlying reason for this increased vulnerability. Further studies are in progress to uncover the mechanisms of increased vulnerability of aging axons to lack of glucose.

Title: C-terminus of HSC70-Interacting Protein (CHIP) is a functional homologue of Atg5

Authors: *B. N. LIZAMA-MANIBUSAN[1], A. M. PALUBINSKY[2], J. W. MCLAUGHLIN[3], D. D. SZYMKIEWICZ[3], V. A. RAVEENDRAN[3], A. M. MOORE[3], B. MCLAUGHLIN[4]
[2]Neurosci. Grad. Program, [1]Vanderbilt Univ. Med. Ctr., Nashville, TN; [4]Neurol., [3]Vanderbilt Univ., Nashville, TN

Abstract: Autophagic protein and organelle degradation is an essential, highly conserved process that regulates normal and pathophysiological processes such as cancer and neurodegeneration. Autophagy Protein 5 (Atg5) and Atg12 work cooperatively in the formation of pre-autophagosomes, and mutations in Atg5 have been shown to result in profound deficits in autophagic signaling. Mice with global deletion of Atg5 die shortly after birth and Atg5 mutations were recently identified in two patients with ataxia. This phenotype is consistent with that of patients with an early onset, recessive form of spinocerebellar ataxia who have mutations

in the E3-ligase CHIP.
Animals with CHIP deficiency exhibit profound deficits in motor and cardiovascular function and premature death. Our prior proteomic and biochemical analysis of CHIP knockout (KO) animals indicates that CHIP is essential for energetic and redox homeostasis. We found that in response to acute bioenergetic failure, CHIP relocates to mitochondria and colocalizes with the autophagy protein LC3. In this work, we used electron and fluorescence microscopy to demonstrate that CHIP KO mouse embryonic fibroblasts (MEFs) exhibit increased numbers of swollen, misshapen mitochondria with malformed cristae. Similarly, Atg5 KO cells demonstrate mitochondria with unstructured or inapparent cristae.
To assess the CHIP domains necessary for mitochondrial targeting, we transfected CHIP KO primary neurons with plasmids containing the human CHIP sequence (hCHIP) or mutated CHIP sequences in which E3 ligase activity is eliminated (H260Q) or TPR-domain binding is blocked (K30A). We found that these mutations did not affect the ability of CHIP to localize to mitochondria; however, they did abolish the ability of CHIP-tagged mitochondria to undergo mitophagy. We also examined the ability of Atg5 to compensate for defects in mitophagy caused by CHIP deletion by transfecting CHIP KO MEFs and primary neurons with an Atg5 overexpression plasmid. Given the rapid localization of CHIP to mitochondria during stress and the role of CHIP in maintaining basal energetic homeostasis, we propose that CHIP is essential for mitophagy in the neuronal autophagic pathway. Ongoing work is aimed at identifying the interactions of CHIP with autophagy proteins and in non-mitophaghic pathways, as well the overall role of CHIP/Atg signaling in response to bioenergetic stress.

Title: High-fat diet-induced insulin disruption in CX3CR1 knockout mice on dementia-related pathology

Authors: *A. S. MURTISHAW[1], M. M. BOLTON[2], A. J. BOREN[2], A. M. SALAZAR[2], J. E. TOUGHLIAN[2], A. A. ORTIZ[2], J. W. KINNEY[2]
[1]Neurosci., UNLV Neurosci. Doctoral Student, Las Vegas, NV; [2]Psychology, Univ. of Nevada Las Vegas Dept. of Psychology, Las Vegas, NV

Abstract: Alzheimer's disease (AD) is the most common form of dementia. Inflammation and insulin signaling perturbations have emerged as important risk factors associated with AD. Recent studies have also demonstrated an interaction between alterations in insulin signaling and inflammation. Many studies support the relationship between AD and metabolic disorders, particularly diabetes mellitus. Fractalkine (CX3CL1) is a chemokine that has been shown to protect the brain from the damaging consequences of chronic inflammation by interacting with its obligate receptor (CX3CR1) on microglia. Additionally, recent studies have demonstrated that the CX3CL1/CX3CR1 system plays a regulatory role in pancreatic β-cell function and insulin secretion. To further explore the relationship that fractalkine plays with insulin signaling and dementia-related pathology, we administered a high-fat diet (HFD) to CX3CR1 knockout mice for six months to evaluate alterations in dementia-related pathologies. We chose HFD as our diabetic model to more closely mirror our clinical population of insulin resistance stemming from obesity and Type-2 diabetes. Animals were tested in the novel object recognition task and spatial learning in the Barnes maze. Following completion of behavioral training, brains were removed for biochemical examination, including markers of inflammation, metabolic alterations, and histopathological markers relevant to dementia.

Title: HDAC2 and associated co-repressor sin3a regulate synaptic plasticity gene expression and memory consolidation during scopolamine-induced amnesia

Authors: *S. SRIVAS, M. K. THAKUR
Inst. of Science, BHU, Varanasi, India

Abstract: Memory is a vital brain function which declines in several conditions including physiological state of advancing age and in neurodegenerative pathologies. Memory decline, also

referred as amnesia, may affect different stages of memory processes. Memory consolidation is a protein synthesis dependent process. A group of synaptic plasticity genes, neuronal immediate early genes (IEGs), play a crucial role in memory consolidation. The expression of these genes changes during physiological and pathological conditions. Recent reports have shown that expression of synaptic plasticity genes is modulated by chromatin remodeling due to DNA methylation and histone post-translational modification, which in turn regulate learning and memory. However, the epigenetic regulation of IEGs is largely unexplored in amnesia. Therefore, the present study elucidates the expression and epigenetic regulation of IEGs (Arc, Egr1, Homer1 and Narp) in a male *Mus musculus* model of amnesia by administration of scopolamine. Scopolamine-induced amnesia was validated by radial arm maze test followed by expression analysis of neuronal IEGs. The expression of chromatin modifying enzymes (CREB binding protein (CBP), histone deacetylase (HDAC) 2, DNA methyltransferase (DNMT) 1, 3a and 3b) was studied at mRNA and protein level. DNA methylation and histone acetylation (H3K9/14Ac) status was assessed by methylated DNA immunoprecipitation and chromatin immunoprecipitation followed by qPCR at the promoter of neuronal IEGs. The results revealed that scopolamine significantly reduced memory consolidation and expression of neuronal IEGs, but increased the expression of DNMT1 and HDAC2 in the hippocampus. Further, scopolamine treatment increased DNA methylation and decreased histone H3K9/14 acetylation at the promoter of IEGs. As, HDAC2 binds on DNA in conjunction with DNMT associated co-repressor complex, we assessed the expression of co-repressor molecule Sin3a at mRNA and protein level in the hippocampus of mice. We found increase in the expression of Sin3a during amnesia. Further, we silenced Sin3a in the hippocampus of amnesic mice by administration of siRNA. Sin3a silencing in amnesic mice increased memory consolidation by increasing the expression of neuronal IEGs. Taken together, our study showed that DNMT1 and HDAC2 expression is associated with downregulation of IEGs in the hippocampus and thereby decline in memory consolidation during amnesia. Further, Sin3a inhibition restored memory consolidation in amnesic mice. Such alteration in HDAC2 and associated Sin3a complex may be used as a target to develop potential therapeutic interventions for amnesia.

Title: Optogenetic function is maintained through late aging (25 mo) in neurons from ChR2-eyfp (vGlut2 and vGAT) BAC mice

Authors: *D. W. DUBOIS, K. S. MONTGOMERY, A. S. FINCHER, E. A. BANCROFT, V. E. PROVASEK, E. A. MIGUT, D. A. MURCHISON, W. H. GRIFFITH

Abstract: Our lab studies the relationship between altered synaptic physiology, calcium homeostasis and age-related cognitive impairment in the rodent basal forebrain (BF). Our goal is to understand how youthful synapses can be preserved and cognitive decline prevented during aging. The current study is designed to support the use of optogenetic (vGlut2- and vGAT-ChR2 (H134R)-eYFP BAC) mice as aging models. These strains express the light-sensitive channelrhodopsin 2 (ChR2) in neurons with vesicular transporters specific to glutamatergic and GABAergic neurons respectively. We utilize patch-clamp recording, 470nm light stimulation, fura-2 microfluorimetry and behavioral testing in young (2-8 mo), middle (10-14 mo) and aged (17-25 mo) mice. We have found that ChR2 expression is functionally maintained during aging. In GABAergic BF neurons, light-evoked ChR2 inward currents (peak current density, pA/pF) were unchanged with age (young: 4.6 ± 1.42, middle: 3.18 ± 0.59, aged: 4.23 ± 1.41; n = 6-11). ChR2 current densities were also maintained in glutamatergic thalamic neurons during aging (young: 4.61 ± 1.42, middle: 3.17 ± 0.59, aged: 4.23 ± 0.58; n = 9-14). We next sought to determine whether our optogenetic mouse model displayed age-related changes in synaptic transmission, calcium buffering and behavioral status as observed in our rat BF model. Optogenetic inhibitory postsynaptic currents (oIPSCs) were evoked using brief light pulses (2-5 ms) in BF slices of vGAT-ChR2 mice. There was a decrease in oIPSCs with age: young, 37.5 ± 5.1 pA/pF, n = 40; aged, 22.3 ± 4.7 pA/pF, n=17 (p = 0.058). There was also an increase in intracellular calcium buffering during aging. A significant decrease in slope (increased buffering) of buffering curves (Ca-transient amplitude x stimulus duration) was seen in BF neurons from aged mice of both genders with no difference between genotypes. This parallels previous findings in rat BF. The slope values for WT mice were: young, 46.8 ± 4.8 (n=26) and aged, 31.3 ± 3.3 (n=40, $p<0.01$). There were no differences in baseline [Ca] in any of the groups. Neurons were confirmed as cholinergic by spot-checking with scRT-PCR. In 16/16 such neurons ChAT sequence was detected. We assessed behavioral status in mice using the Barnes Maze for a spatial memory task, open field for a measure of anxiety and the rotarod to monitor motor coordination. Preliminary data, as predicted, showed age-related deficits across the battery of tests. We are currently refining our analysis of behavioral differences across genotypes, genders and age. These results demonstrate that these optogenetic BAC mice are excellent models for investigation of synaptic aging.

Title: Utilization of KKA_y diabetic model to elucidate the role of metabolic dysfunction in the development of Alzheimer's disease pathology

Authors: *J. GRIZZANTI[1], S. SAHU[2], P. RAMAN[2], H.-G. LEE[3], G. CASADESUS[1]
[1]Sch. of Biomed. Sci., Kent State Univ., Kent, OH; [2]Northeast Ohio Med. Univ., Rootstown, OH; [3]Univ. of Texas at San Antonio, San Antonio, TX

Abstract: A strong body of evidence exists suggesting that type II diabetes and obesity are risk factors for the development of Alzheimer's disease. Furthermore, numerous studies have utilized diet to induce obesity in rodent models of AD and have demonstrated increases in AD pathology related markers. However, few studies have utilized obese and/or diabetic models to assess the effects of metabolic hormone resistance on hallmark AD pathology in rodent models lacking AD-related genes. Here, we utilized KKAγ mice, a model that demonstrates a robust diabetic and obese phenotype, to survey the effects of insulin and leptin resistance on markers that contribute to the production of AD hallmark pathology. KKAγ mice showed significantly elevated body weight, blood glucose levels, free fatty acids, and blood leptin levels compared to littermate controls. Interestingly, KKAγ mice showed no significant changes in AD pathology-associated markers within the brain 4 months post development of the diabetic phenotype. Together, these data suggest that the ability of metabolic dysregulation to induce AD pathology may be mediated via fundamental neurotoxic mechanisms such us inflammation, mitochondrial dysregulation, and/or increased oxidative stress rather than directly through altering pathology related aspects.

Title: The influence of childhood trauma, major depressive disorder and telomere length on HIV-associated neurocognitive disorders

Authors: *J. S. WOMERSLEY, G. SPIES, G. TROMP, S. HEMMINGS, S. SEEDAT
Univ. of Stellenbosch, Cape Town, South Africa

Abstract: Background: HIV-associated neurocognitive disorders (HAND) continue to prevail in countries affected by HIV/AIDS, despite improved access to antiretroviral therapies. Previous research has suggested that this is in part due to the complex interactions between stress-related exposures and depression, which may aggravate the development of neurocognitive impairment. Telomere length (TL) attrition is a marker of biological aging that has been independently associated with childhood trauma (CT), depression and HAND. We therefore sought to investigate whether TL shortening may act as a biomarker for HAND when examined in the context of CT and depression. **Methods:** HIV-positive (n=133) and negative women (n=150) underwent a battery of neuropsychological tests to measure seven domains of cognitive function: motor skill, verbal fluency, attention and working memory, processing speed, learning, recall, and executive function, from which a global cognitive score was calculated. Participants also completed the Childhood Trauma Questionnaire and the Centre for Epidemiological Studies Depression Scale. Quantitative polymerase chain reaction using primers specific to telomeric repeats and the reference gene human β-globin was performed on DNA extracted from peripheral blood mononuclear cells. Baseline differences in relative TL and neuropsychological parameters between HIV-positive and negative individuals were assessed using a t-test. The relationship between TL, cognitive function, CT and depression was probed using multiple linear regression models with age as a covariate. Data were analysed using the R statistical language, and an alpha value of less than 0.05 was deemed statistically significant. **Results:** HIV-positive individuals had significantly reduced relative TL ($t(275.45) = 5.731$, $p<0.0001$) and self-reported higher levels of CT ($t(262.59) = -7.671$, $p<0.0001$). Regression analysis revealed that including the interaction between CT and HIV status in the statistical model explained significantly more of the variance in TL ($p=0.035$). HIV status, CT, depression and TL individually did not affect cognitive function. However, the interaction of CT and depression explained significantly more of the variance in global cognitive scores across participants ($p=0.022$). In contrast, including the interaction between depression and TL explained significantly more of the variance in global

cognitive function in HIV positive individuals (p=0.025). **Conclusions:** Our data suggest that HIV is associated with decreased TL and that the interaction between this biomarker and psychological ill health may influence cognitive status.

Title: Regulation of glucose metabolism in neurons by Wnt signaling and a possible molecular link with the adipokines in the context of Alzheimer disease and obesity interaction

Authors: *P. CISTERNAS[1], N. C. INESTROSA[2]
[1]CARE-UC, Pontificia Univ. Católica de Chile, Santiago, Chile; [2]Ctr. For Aging and Regeneration (CARE),P. Catholic Univ. of Chile, Santiago, Chile

Abstract: The brain is an organ with a high rate of glucose consumption and in several disorders it has been described a decrease in the brain capacity to utilize glucose including in Alzheimer´s disease (AD) and obesity. Despite the importance of this process little is know about the regulation in this process in both pathologies. In the lasts year has been described that obesity (increase in fat tissue) increase the risk of AD in several models. The proposal mechanism for explain this results evolve the action of adipokines, released by the fat tissue. In the present work we described for first time the effect of Wnt signaling activation over the glucose metabolism. Also, we described in cortical neurons that the effect of Wnt ligands are similar with the effects of adiponectin (an adipokine down regulated during obesity) over the glucose metabolism. In both cases we used glucose radiolabeled analogous to determine the values of K_m and V_{max} in primary cortical neurons and we observed an increase in the affinity for glucose uptake in both cases. Also, we observed different changes in the activity of pentose phosphate pathway (PPP) depended of the Wnt ligands used. This study suggests that the Wnt and adiponectin signaling stimulates the energy metabolism of neurons, and that these effects could be central to prevent metabolic impairment described in obesity and AD.

Title: Effect of phycoerythrin-derived tryptic peptide of Pyropia yezoensis on glutamate-induced endoplasmic reticulum stress and neuronal senescence

Authors: *J. OH
Pukyong Natl. Univ., Busan, Korea, Republic of

Abstract: Glutamate recycling in synaptic cleft is impaired by increasing age, which induced glutamate accumulation that over-stimulates post-synaptic neurons. Glutamate-induced excitotoxicity has been involved in various neurodegenerative disorders such as cognitive dysfunction. Previous studies have demonstrated that peptides from the edible red alga *Pyropia yezoensis* have antioxidant and chemoprotective activities in various cell lines. This study was to investigate whether a phycoerythrin-derived tryptic peptide of *Pyropia yezoensis* (PYP) reduces glutamate-induced excitotoxicity and neuronal senescence in primary rat hippocampal neurons. Exposure to 100 μM glutamate significantly decreased cell viability and increased expression of endoplasmic reticulum (ER) stress response protein, glucose-regulated protein 78 (GRP78) from 60 min after glutamate exposure, which were downregulated by pretreatment of PYP (1 μg/ml). The glutamate-induced increase in GRP78 expression was downregulated by blockade of NMDA receptor and inhibition of JNK phosphorylation, MK801 (10 μM) and SP600125 (10 μM), respectively, and also phosphorylation of JNK by glutamate was decreased by blockade of NMDA receptor. Pretreatment of PYP downregulated glutamate-induced increase in GRP78 expression and JNK phosphorylation, which was abolished by inhibitions of TrkB receptor, PI3K, and ERK1/2, with cyclotraxin B (200 nM), LY294002 (20 μM), and SL327 (10 μM), respectively. In addition, PYP downregulated increase in GRP78 expression, senescence-associated β-galactosidase activity and neurite degeneration in aging hippocampal neurons. These findings indicate that activation of TrkB receptor-mediated ERK1/2 by PYP attenuates glutamate-induced ER stress and could contribute to survival of hippocampal neurons with age.

Title: Determination of Cholesterol 24 Hydroxylase (CYP46A1) in hippocampus of rats with obesity induced by different hypercaloric diets

Authors: *N. GOMEZ-CRISOSTOMO[1], E. MARTÍNEZ-ABUNDIS[2], E. DE LA CRUZ-HERNÁNDEZ[2]
[1]UNIVERSIDAD JUAREZ AUTONOMA DE TABASCO (DIVISION A, Comalcalco, Mexico; [2]LABORATORIO DE INVESTIGACION EN ENFERMEDADES METABÓLICAS E INFECCIOSAS, UNIVERSIDAD JUAREZ AUTONOMA DE TABASCO (DIVISION A, COMALCALCO, TABASCO, Mexico

Abstract: Several studies have described an association between neurodegenerative disorders and abnormalities in the metabolism of cholesterol, related with the obesity and metabolic syndrome. The cholesterol in the Central Nervous System (CNS) is involved in the formation of myelin, its homeostasis is regulated by several metabolic pathways and for its elimination is indispensable the participation of the Cholesterol 24 Hydroxylase (CYP46A1). This enzyme oxidize cholesterol to 24S-hydroxycholesterol for been exported through the blood brain barrier (BBB). In vitro studies have shown that high levels of cholesterol in the CNS may induced neurodegeneration, suggesting that a deficit of CYP46A1 could contribute to the development of neurodegenerative diseases. The aim of this study is to determine whether obesity modify cholesterol homeostasis into the CNS. Four groups of male Wistar rats were fed for 2, 4 and 6 months with different hypercaloric diets: 1. Normal diet, 2. High sucrose diet, 3. High fat diet, and 4. High sucrose+high fat diet. Our preliminary results showed that all hypercaloric diets induced obesity. The expression of CYP46A1 decreases in the hippocampus of the rats fed with the high sugar and high fat diet groups, but not in the high sucrose+high fat group. The low levels of CYP46A1 could contribute to the increase in cholesterol levels into CNS and thus to the development of neurodegeneration; feature that share neurodegenerative disorders such as Alzheimer's Disease, Parkinson's Disease, and others. These data are a preamble for the search of the molecular mechanism involved in association between obesity and neurodegenerative diseases.

Title: Changes in hippocampal protein expression following diet supplementation of Kale, Arugula, or Dandelion in diet induced obese pre-diabetic C57BL/6 mice

Authors: *D. HICKS[1], A. A. OYETUNDE[1], D. FOSTER[2], B. TENG[1], L. R. BANNER[1]

Abstract: Diabetes is a chronic disease that can lead to serious long-term complications. Type 2 diabetes has been associated with impaired cognitive performance and dementia. Correlations between increased body mass and an elevated risk for neurodegeneration and dementia have been documented. There is also evidence that links increased body mass to changes in hippocampal and spatial learning. These cognitive effects begin as early as childhood and adolescence in type 2 diabetes and include both structural and functional alterations in humans and animal models. Changes in diet are the most effective way to treat type 2 diabetes, however, 97% of dieters regain their lost weight within 3 years. Treatment with dietary supplements may prove a practical means by which to counter the cognitive impairment associated with diabetes. To examine the effect of these supplements, a high-fat diet (HFD) prediabetes mouse model was used. Obese and control mice given a dietary supplement of kale, arugula,dandelion for 22 weeks exhibited attenuated cognitive decline. The molecular mechanisms underlying this improvement will be analyzed by quantification of various marker proteins for neurogenesis, synaptic density, neuroinflammation, and aberrant brain insulin signaling in hippocampus. To this end, the expression of PSD95, syntaxin, GFAP, DCX, BDNF, IRS-1, and others will be compared by western blot. IL-1β, IL-6, and TNF-α will also be compared by ELISA. PSD95 and syntaxin are synaptic markers that localize to postsynaptic and presynaptic terminal respectively. GFAP is expressed in activated astrocytes in neuroinflammation. IL-1β, IL-6, and TNF-α are pro-inflammatory cytokines. While neuroinflammation is an important process in the healthy brain, chronic inflammation, as has been observed in diabetes and in obesity, can lead to tissue damage, neurodegeneration, and dementia. BDNF promotes the generation of new neurons and synapses. Decreased levels of BDNF have been implicated in various dementias and BDNF in plasma has been shown inversely correlated with blood glucose in diabetes. DCX is a marker of dividing neuronal precursor cells. IRS-1 is a substrate of brain insulin receptors whose abnormal

phosphorylation is associated with tau hyperphosphorylation seen in various diabetes-linked dementias including Alzheimer's. Furthermore, IRS-1 is upstream in a signaling pathway that phosphorylates GSK3β which can act as a tau kinase. Preliminary results show changes in the expression of PSD95, GFAP, and DCX in HFD-treated animals. Analysis of these, and other, molecular markers will shed light on the mechanism of diet-induced cognitive changes in type-2 diabetes.

Title: Impaired synaptic mitochondrial spare respiratory capacity in aging and age-related neurodegenerative disease

Authors: *K. L. STAUCH, K. EMANUEL, B. LAMBERTY, B. MORSEY, H. FOX
Pharmacol. and Exptl. Neurosci., Univ. of Nebraska Med. Ctr., Omaha, NE

Abstract: Although studies have begun to elucidate the physical, biological, chemical, and psychological changes that occur during aging, the underlying molecular mechanisms involved in both healthy and pathological brain aging remain incompletely characterized. Mitochondrial dysfunction has been identified as a major player leading to age-associated alterations in the brain and has been implicated in the pathogenesis of age-related neurodegenerative diseases including Alzheimer's and Parkinson's. Additionally, as HIV+ individuals are living longer, the impact of aging on HIV-associated neurocognitive disorder and antiretroviral drug toxicity is an emerging challenge, as antiretrovirals and other drugs can affect mitochondria. Increasing evidence implicates mitochondrial malfunction as a trigger leading to synaptic failure and synaptic alterations in normal aging are linked to cognitive impairment. Therefore, we have examined the synaptic mitochondrial alterations that occur in animal models of aging and age-related neurodegenerative disease. Bioenergetic functional analysis revealed similar alterations in mitochondrial spare respiratory capacity between different disease states, which we propose underlies synaptic dysfunction. Further, we found that antiretroviral drug exposure perturbs this same functional parameter in synaptic mitochondria. This work highlights commonalities

between synaptic mitochondrial changes in different neurodegenerative disease states, providing a framework for future studies that will lead to improvements in the treatment of neurocognitive deficits in both age-related diseases and HIV.

Title: Impact of chronic stress on sex-divergent CRF1 expression and behavioral deficits in APP/PS1 mouse model of Alzheimer's disease

Authors: *H. DONG[1], Y. YAN[2,1], G. RODRIGUEZ[1], R. GAO[1], J. G. CSERNANSKY[1]
[1]Dept Psychiatry and Behavioral Sci., Northwestern Univ. Feinberg Sch. of Med., Chicago, IL; [2]Physiol., Zunyi Med. Univ., Zunyi, China

Abstract: Alzheimer`s disease (AD), one of the most common neurodegenerative diseases, is characterized by progressive cognitive deficits and dementia. Accumulation of amyloid-beta protein plaques (Aβ) and hyperphosphorylated tau tangles are the pathological hallmarks of AD. Clinical studies have consistently demonstrated that women are disproportionately affected by AD with respect to both incidence and severity. Studies have shown that out of the 5.4 million American patients diagnosed with AD, 3.4 million, roughly 70%, are women. In addition, studies have found that the estimated lifetime risk for Alzheimer's specifically at age 65 was 17 percent for women and 9 percent for men. While clinicial studie cases have shown a sex gender difference in incedence, the biological mechanisms underlying this sexual divergence have not been well explored. In our previous work, we demonstrated that sex-specific biochemical differences in the central stress response, mediated by the corticotrophin releasing factor 1 receptor (CRF1) biases female mice towards pro-AD signaling on a phosphoproteomic level. In this study, we investigated whether chronic stress induced sex-divergent CRF/CRF1 downstream signaling pathways mediate AD pathology and memory function deficits in APP/PS1 mice. A total of 40 APP/PS1^{+} mice (20 males and 20 females) at 5 months of age were used for this study, with half exposed to chronic unpredictable mild stress (CUMS) and the other half without any stress for 21 days. Following the 21 days, a series of behavioral tests, including the tests for anxiety-like behavior and learning/memory function, were conducted. Brain tissues were subsequently collected for biochemical and neuropathological analysis of CRF1 and PKA

expression, as well as amyloid plaque measurement. We found that APP/PS1$^+$ female mice increased anxiety-like behavior and memory deficits as compared to APP/PS1$^+$ male mice after CUMS. Female mice also displayed more plaques in the cortex and hippocampus as compared to stressed males and non-stressed females. Moreover, in parallel with the sex biases behavioral and pathological changes, we found that stressed APP/PS1$^+$ female mice displayed higher expression of CRF1 and PKA in the hippocampus as compared to stressed APP/PS1$^+$ males and non-stressed females. Our results indicate during chronic stress, the CRF1 signaling pathway may display a sex-dependent response in regulation of neuronal function and neuropathogenesis of AD in an animal model.

Title: The role of Dnmt3a2 in regulating neuronal and age-associated cognitive functions

Authors: D. CUI[1], S. NEUBER[1], I. INGO VOIGT[1], Y. YAYOI OBATA[2], *X. XU[3,4]
[1]Epigenetic regulation of mammalian ageing, Max Planck Inst. For Biol. of Ageing, Cologne, Germany; [2]Dept. of Biosci., Tokyo Univ. of Agr., Tokyo, Japan; [3]Epigenetic regulation of mammalian aging, Max Planck Inst. For Biol. of Aging, Cheshire, CT; [4]Yale Univ. Sch. of Med., New Haven, CT

Abstract: Emerging evidence suggests that DNA methylation plays a crucial role in the pathogenesis of age-related neurological symptoms. Findings from our study and the literature indicate that DNA methyltransferase 3a2 (Dnmt3a2), an isoform of Dnmt3a, may be a key factor for maintaining normal hippocampal function and confers an epigenetic mechanism for age-related defects in cognitions. To test this hypothesis, Dnmt3a2 overexpression and knock-down neuronal cells, and the forebrain neuron-specific Dnmt3a2 transgenic (TG) mouse lines were generated and applied for the study. Our results show that the expression level of Dnmt3a2 in neuronal cells positively regulates the expression of synaptic plasticity genes and strengthens the cell resistance to stress insults by epigenetically modulating the transcription of neuronal genes

and cell apoptotic pathways. Moreover, we found that Dnmt3-like (Dnmt3L) protein can enhance the protective function of Dnmt3a2 in neuronal cells against the stress stimulus by increasing Dnmt3a2 nuclear localization. Meanwhile, the forebrain neuron-specific Dnmt3a2 and Dnmt3a2/Dnmt3L TG mouse lines were established and characterized, respectively. The cognitive behaviour measurement, cellular and molecular functional studies for both TG lines are ongoing. Taken together, our study will provide an epigenetic mechanism that DNA methylation contributes to neuronal and brain aging as well as the age-related deficit on learning, memory and cognition.

Title: Nuclear pore complex composition in the mammalian cns: Regional and cell type specific differences

Authors: *J. C. GRIMA, S. VIDENSKY, A. N. COYNE, T. PHILIPS, J. G. DAIGLE, K. ZHANG, M. MATUNIS, J. D. ROTHSTEIN
The Solomon H. Snyder Dept. of Neurosci., The Johns Hopkins Univ. Sch. of Med., Baltimore, MD

Abstract: Nuclear Pore Complexes (NPC) are large molecular structures that serve as the main gateways between the nucleus and cytoplasm. They not only directly control the exchange of

protein and RNA into and out of the nucleus but also serve transport-independent functions such as regulating genome organization and gene expression. The proper functioning and biogenesis of these large channels are critical for cell homeostasis and survival. NPCs consist of 30 different proteins called nucleoporins (NUPs) that are organized into five distinct anatomical regions of the NPC. Increasing evidence shows that each of these NUPs play very unique and specific roles. For instance, NUP50 serves a critical role in nuclear import, XPO1 plays an essential function in nuclear export, and GLE1 plays a significant part in mRNA export. Also, each NUP has been shown to traffic unique subsets of macromolecules thus adding another layer of diversity and specificity. One can begin to imagine that cells may be able to regulate certain cellular processes, given cell type-specific constraints and context-dependent needs, by altering the composition of NPCs and that this may provide an explanation for tissue-specific diseases that arise from mutations in various NUPs. For instance, mutations in NUP62 cause Infantile Bilateral Striatal Necrosis, the selective degeneration of the striatum in infants, and mutations in GLE1 cause Lethal Motoneuron Syndrome (LCCS1), a fetal motor neuron disease, as well as rare forms of Amyotrophic Lateral Sclerosis (ALS). It is possible that NUP62 is responsible for the trafficking of a transcription factor that is absolutely necessary for striatum viability. The same can be postulated for GLE1 and motor neurons. Although the overall structure of the NPC is conserved across different cell types, the aforementioned data suggests that protein composition of NPCs may vary among cell types and tissues. Lastly, very little is known about NPC structure and function in the mammalian CNS and whether brain cells use unique combinations of different NUPs to create NPCs bearing distinct properties and specialized functions. To this end, we have employed a novel method to isolate and purify NPCs from specific cell types and across different tissues of the CNS and characterize the composition of these NPCs using mass spectrometry and super resolution imaging analyses. We believe these ongoing experiments will provide critical insight into NPC neurobiology, which is relatively unknown. This will in turn provide a foundation for understanding CNS nucleocytoplasmic transport, which is a new and exciting focus for neurodegeneration pathobiology.

Title: Age-dependent differences in TNFR1 response after global cerebral ischemia

Authors: *E. FONT BELMONTE[1], B. ANUNCIBAY SOTO[2], M. SANTOS GALDIANO[3], D. PEREZ-RODRIGUEZ[1], P. GONZALEZ-RODRIGUEZ[1], M. REGUEIRO-PURRIÑOS[4], A. FERNANDEZ-LOPEZ[1]
[1]Univ. de Leon, Inst. de Biomedicina, Leon, Spain; [2]Area de Biologia Celular, Univ. Leon. Inst. De Biomedicina, Leon, Spain; [3]Univ. de Leon. Inst. de Biomedicina, Leon, Spain; [4]Hosp. Veterinario de León. Univ. de León, León, Spain

Abstract: Age is one of the most important factor in the development of neurodegenerative or cerebrovascular diseases such as ischemic stroke, due to this, stroke is one of the most important cause of death in the elderly population. Unfortunately, the studies that reach neuroprotection in animal models of stroke, don't reach succeeded results in clinical assays. A possible explanation of the discrepancies between the research results and the clinical assays could be the different response to an ischemic insult that occurs as consequence to the age. However the majority of the studies are performed in young animals, which are not good models of the ischemic effects on the neural tissues in the elderly individuals. So how the age modifies the molecular response after a stroke is not clear. After a severe stress like an ischemic stroke, TNFR1 can elicit both a pro-survival NF-κB dependent signal or initiates regulated cell death that includes apoptosis or necroptosis. In the lasts years necroptosis has emerged as a different modality of regulated cell death, which can be used as a therapeutic target in several pathologies.Here we present an aging study comparing the response in young and old animals. We perform global cerebral ischemia model with 2 vessel occlusion combined by a partial exsanguination. In this report we analyzed the TNFR1 mediated response and the hallmarks of the necroptosis pathway 48h after the ischemia in young and aged animals in two areas which present different vulnerability to the ischemic damage (cerebral cortex and hippocampus). We measured by qPCR or Western blot changes in the receptor (TNFR1) and its associated ubiquitin-ligases (cIAP1), in the NF-κB transcriptional activity (IκB mRNA levels) and in the induction of regulated cell death process (MLKL, pMLKL, cFLIP). We conclude that aging enhance the necroptotic signal after ischemia, and can modify the inflammatory response exerting changes in the TNRF1 signaling and modifying the NF-κB transcriptional activity. Title: Stroke 1-2-0 fills the gap for prehospital delay for stroke victims in China

Authors: *J. ZHAO
Fudan University,Minhang Hosp., shanghai, China

Abstract: Background
Although intravenous thrombolytic therapy is available in China, studies indicated that only 1.6-4.0 % of ischemic stroke patients received such thrombolytic therapy due to significant prehospital delay with the median time of the delay has 15 hours.[1] To reduce prehospital delay in China, we engineered stroke 120, a stroke educational program suitable for China for a rapid stroke recognition and quick response. This study examined whether this novel tool is well accepted in China via online survey and onsite survey. This investigation protocol was approved by the Institutional Review Board of the Minhang Hospital affiliated to Fudan University. There were total of 927 people from 30 different regions (province or cities) participated online survey. 45% are males and 55% are females. 60% of the responders had family member, relative or friends who had stroke in the past. While majority of the people (85%) recognize that it is critical to identify stroke and transport patients to hospitals, knowledge for the timing of the therapy and which hospital should the patient sent to are very deficient. 49% thought that stroke 1-2-0 is best suitable for China for stroke awareness and rapid response, 21% thought that FAST (“Face”, “Arm”, “Speech”, “Time”) should be used. 61% of the survey responders thought that a consent is needed for thrombolitic therapy. The onsite survey obtained similar results in 584 participants, majority of the participants thought that Stroke 120 is the best program to be used for stroke awareness education, 18% of them thought FAST is the best program. Based on this survey results, it clearly indicated that stroke 1-2-0 is suitable for and is well accepted in China.

Abstract: Alzheimer’s disease (AD) is the most common form of dementia, with no effective preventative strategies or treatments. One of the major obstacles of developing novel therapies for AD is the lack of predictive animal models to be used in preclinical trials of therapeutics. One reason for this may be that existing models are based on familial mutations, while the vast majority of the clinical population has non-familial late-onset AD (LOAD). The Model Organism Development and Evaluation for Late-onset AD (MODEL-AD) Center has been established as a consortium consisting of Indiana University, The Jackson Laboratory, and SAGE Bionetworks. The goals of the Center are: to identify novel genetic variants, genes and biomarkers from AD patient data; to generate and validate new animal models based on these LOAD variants; and to utilize these novel models in a preclinical testing paradigm. The Bioinformatics and Data Management Core (BDMC) is prioritizing novel sequence variants, creating analytical pipelines for human-mouse phenotype comparisons, and analyzing phenotypic data. Biomarkers and disease model endophenotypes will be compared to patient data wherever possible. All data will be made available through the SAGE-Synapse portal. The Disease Modeling Project (DMP) is creating new mouse models based on variants identified by the BDMC. *APOE4* and *Trem2* alleles are the strongest genetic risk factors for LOAD; as such we have created a novel model expressing both human *APOE4* and the R47H allele of *Trem2*. This is being phenotypically characterized using functional assays, neurodegeneration, amyloid and tau pathology, transcriptional and metabolic profiling, and *in vivo* imaging. Existing familial models (5XFAD, APP/PS1, and hTau) are being evaluated for comparative purposes. The *APOE4/Trem2* model will serve as the standard background as we introduce additional LOAD genetic variants, including *ABCA7*, *IL1RAP* and *CR1*. Humanized *APOE3* and *APOE2* models,

to be used as controls, are also being generated. The Preclinical Testing Core (PTC) has established a tertiary screening pipeline with predetermined go/no go criteria to evaluate novel compounds in new models that have been shown to have an AD-like phenotype. These criteria include exposure levels in target tissues, target engagement and disease modifying effect, and *in vivo* functional activity and therapeutic index. The pipeline is currently being validated using levetiracetam in the 5XFAD model. All models, protocols, and data sets are to be made widely available. We seek input and collaborations from the research and pharma/biotech communities. For more information see www.model-ad.org.

Abstract: Historically, preclinical screening of test compounds for Alzheimer’s Disease (AD) employed behavioral endpoints in rodent models as the primary screen. Often the rodent models used did not necessarily have construct validity for AD, and experiments often evaluated the ability of a test compound to reverse an acute pharmacological deficit (e.g. scopolamine induced memory deficit) in wild-type or normal animals. Other screens evaluated the ability of the test compound to normalize a behavioral phenotype, and these studies rarely used biomarkers or other clinically translational endpoints. Young or naïve wild-type animals were often used in place of aging animals, and critically pharmacokinetic (PK) and pharmacodynamic data in the AD model at the biologically and pathologically relevant ages had not been evaluated. The

Model Organism Development and Evaluation for Late-onset AD (MODEL-AD) program has been established with the goals of: 1) identifying novel genetic variants, genes and biomarkers from LOAD patient data; 2) generating and validating mouse models with construct and face validity for LOAD; and 3) developing a preclinical testing strategy to evaluate potential therapeutic agents for the treatment of AD in these new models. The Preclinical Testing Core (PTC) has established a streamlined preclinical strategy with go/no-go decision points that allow critical and unbiased assessments of potential therapeutic agents while matching each test compounds' specific mechanism of action to the animal model best suited to interrogate its symptom and/or disease modifying activity. The PTC screening strategy includes an initial primary screen to determine appreciable mutli-dose PK and target tissue activity in the disease model at the pathologically relevant age followed by predictive PK/PD modeling. A secondary screen evaluating target engagement and disease modifying activity of the test compound utilizing non-invasive PET/MRI as a pharmacodynamic readout of cerebral changes in metabolism (18F-FDG), cerebral blood flow (64Cu-PTSM), beta amyloid deposition (18F-AV45), and tau deposition (18F-AV1451). Provided the compound meets the a priori criteria for success in the primary and secondary screens, the tertiary screen will evaluate symptom modifying effects of the test compound to normalize a disease-related phenotype in cognition tests, relative to the age- and sex-matched littermate WT controls. All raw data, standard operating procedures, methods and protocols will be made publicly accessible via the external facing SAGE portal to the AD research community at large.

Title: Novel candidate loci for Alzheimer's disease from whole-genome and whole-exome sequencing

Authors: *G. CARTER[1], X. WANG[2], C. PREUSS[1], V. PHILIP[1], G. ANANDA[3], C. J. ACKLIN[1], K. KARUTURI[3], M. SASNER[1], G. R. HOWELL[1]

Abstract: Recent initiatives such as the Alzheimer's Disease Sequencing Project (ADSP) have created sequencing-based study cohorts for late-onset Alzheimer's disease. While this resource provides nucleotide-level resolution of genetic variants, it suffers from relatively small sample size and population substructure that limits association power. We addressed this limitation by devising a method of genome-wide association that implements a generalized linear mixed model in a Bayesian context. Our approach, Bayes-GLMM, has four main features: (1) support of categorical, binary and quantitative variables; (2) cohesive integration of previous GWAS results for related traits; (3) correction for sample relatedness by mixed modeling; and (4) model estimation by both Markov chain Monte Carlo (MCMC) sampling and maximal likelihood estimation. We applied Bayes-GLMM to the ADSP whole-genome sequencing cohort, which includes categorical disease diagnoses of 570 individuals drawn from 111 families. We also analyzed ADSP whole-exome data from 9134 individuals to identify rare and common coding variants. From the whole-genome sequencing cohort, we identified four variants in three loci significantly associated with Alzheimer's disease. The loci were not identified using traditional methods. The four variants (rs10490263, rs74944275, rs149372995, rs140233081) are located in intergenic regions with the closest genes not previously associated with AD. The two linked variants lie between the genes *PRKAR1B* and *PDGFA*. These proteins are localized to the glial-vascular unit, further implicating vascular function in modifying susceptibility to AD. Analysis of whole-exome sequences validated association of many known loci (e.g. *TREM2, ABCA7*) and identified potentially novel variants, including both rare and common alleles. This work provides new candidates loci for Alzheimer's disease, obtained from the first implementation of a flexible, generalized mixed model approach in a Bayesian framework for sequence-based association studies.

Abstract: Creation of the next generation of animal models in the Model Organism Development and Evaluation for Late-onset Alzheimer's Disease (MODEL-AD) consortium will require extensive data analysis, curation, and distribution. To this end, a central Bioinformatics and Data Management Core (BDMC) has been created to integrate information from large-scale data resources including the Alzheimer's Disease Sequencing Project, Alzheimer's Disease Neuroimaging Initiative, the Accelerating Medicines Partnership for Alzheimer's Disease (AMP-AD), Molecular Mechanisms of Vascular Etiology of Alzheimer's Disease, and others. We are creating bioinformatic pipelines to: (1) identify key genetic variants that confer risk of AD from genome-wide association studies; (2) translate candidate variants into mouse models; (3) align human disease and animal model phenotypes to specify the optimal research use of each animal and characterize the effects of multiple genetic variants; and (4) broadly disseminate all data and preclinical research protocols for community use. Here we present our early results and future plans to meet these needs. To date, multiple variants have been identified through the integration of results from multiple genetics studies, at both novel and known genetic loci. Genomic, epigenetic, and functional data have been used to predict the consequences of candidate variants, thereby prioritizing specific genetic alterations for animal modeling via genetic engineering. Molecular phenotypes, including transcriptomics data from the brains of mouse models, have been systematically compared to similar data from clinical cohorts to identify pathways altered in both human and mouse. Finally, we are broadly sharing data via the AMP-AD Knowledge Portal hosted by Sage Bionetworks. Future work will expand all of these findings and resources, and additionally integrate data and protocols from preclinical studies that use the animal models. In sum, the BDMC is creating a resource to integrate a broad knowledgebase to serve the creation and study of multiple animal models to effectively model late-onset Alzheimer's disease *in vivo*.

Title: MODEL-AD: The disease modeling project

Authors: *M. SASNER[1], A. OBLAK[2], H. WILLIAMS[1], G. HOWELL[1], B. T. LAMB[2]
[1]The Jackson Lab., Bar Harbor, ME; [2]Stark Neurosciences Res. Inst., Indianapolis, IN

Abstract: The Alzheimer's Disease (AD) patient population consists almost entirely (~98%) of the late-onset form of AD (LOAD); however, most mouse models used to study AD are based on familial AD mutations in *APP*, *PSEN1* or *PSEN2*. The Model Organism Development and Evaluation for Late-onset AD (MODEL-AD) Center was created to develop, characterize, and distribute more precise preclinical models for AD.
The Disease Modeling Project (DMP) of MODEL-AD will use CRISPR genome editing to generate at least 40 novel mouse models that carry various combinations of human risk alleles for LOAD that have been identified by the Bioinformatics and Data Management Core (BDMC). In the early years of the Center, we will prioritize understanding known GWAS variants (*ABCA7* and *CR1*) as well as novel variants identified by BDMC analyses of the AD Neuroimaging Initiative dataset (*IL1RAP*).
We will utilize a two-phase screening strategy. At least 24 models will undergo high capacity screening at 12 months of age, which includes functional assays and AD-related pathology. The most promising models will advance to the deep phenotyping phase, which will occur independently at Indiana University and The Jackson Laboratory to ensure reproducibility of data. In the deep phenotype screening, cohorts of mice will be evaluated at three time points (2, 6, and 12 months). We will prioritize clinically relevant endpoints including *in vivo* imaging, blood and tissue biomarkers, and genomics, and compare these to more traditionally used endpoints such as battery of functional assays. All data will be provided to the BDMC to determine the predictive potential for each mouse model, which will then be prioritized and selected for the preclinical testing core (PTC). To test our pipeline, we will deep phenotype models currently used for studying familial AD (APP/PS1, 5XFAD, hTau). In addition, we will also deep phenotype a new model of LOAD that we have created. This model carries the two greatest genetic risk factors for LOAD, *APOE4* and the R47H variant of *TREM2*. Our strategy closely integrates human and mouse data, with the aim that these new AD models will show a high degree of clinical translatability for preclinical testing of new therapeutic targets.
All models created will be made available at the earliest opportunity through the JAX AD Mouse Mutant Resource. All protocols and data will be made available via the SAGE Synapse portal (www.synapse.org); we anticipate that we will be able to provide not only improved models, but also validation protocols and data so that the research community can efficiently adopt these new models. For more information, see *model-ad.org.*

Title: Comparison of gene expression profile in Alzheimer's disease using a novel stratifying algorithm

Authors: *S. CANCHI[1], R. SASIK[2], P. D. JAGER[3,4], D. A. BENNETT[4], R. A. RISSMAN[5]
[1]Univ. of California San Diego, LA Jolla, CA; [2]Univ. of California San Diego, La Jolla, CA; [3]Ctr. for Translational & Computat. Neuroimmunology, Dept. of Neurol., Columbia Univ., New York, NY; [4]Rush Alzheimer's Dis. Ctr., Rush Univ. Med. Ctr., Chicago, IL; [5]Neurosci, UCSD Sch. Med., La Jolla, CA

Abstract: The discovery of mutations in *Amyloid precursor protein (APP), Presenilin 1 (PSEN1),* and *Presenilin 2 (PSEN2)* as a cause of autosomal dominant Alzhiemer's disease (AD) and the identification of the ε4 allele of *Apolipoprotein E* (*APOE*) as strong genetic risk factor have been instrumental in understanding the pathological processes underlying AD; the findings from GWAS re-emphasize the multifactorial nature of AD dementia. Despite these advances, translation of genetic findings into functional mechanisms that are biologically important in disease pathogenesis and treatment design remains a challenge. Using a novel stratifying algorithm 640 subjects from the Religious Orders Study (ROS) and the Rush Memory and Aging Project (MAP) cohorts were segregated into six relevant diagnosis groups. Expression data (fpkm) were first normalized using a multi-loess method and batch effect was removed using ComBat implemented in the *R* package *sva*. We were interested in genes that are differentially expressed between the diagnostic groups controlling for the covariates sex, age, and ApoE status. We modeled the (log-)expression of a gene as a linear combination of sex, age, ApoE status, and diagnosis, using the *R* package *limma*. Formally, expression~0+sex+ApoE+age+diagnosis. Tests for significant differences between pairs of diagnoses were obtained by implementing a Bayesian strategy, *eBayes*. For each pair of diagnoses (the 15 comparisons) we sorted the genes by their posterior error probability (PEP). In each comparison, the difference between diagnosis effects equals the natural log of expression ratio between the two diagnoses, adjusted for other co-variates. Compared to the control subjects, 1410 genes were differentially expressed in the high probability AD group, 692 genes in the intermediate probability AD group and 43 genes in the Non-AD dementia group as defined by the modified NIA classification. Functional enrichment for the number of significant genes (PEP < 0.1) in all comparisons conducted using ToppGene revealed distinct pathways and gene families implicated in AD when compared to controls and

Non-AD dementia. The results are further discussed in the light of conventional diagnosis of AD dementia which help identify the differences in the transcriptome signature by diagnostic group.

Title: Conditional deletion of APP, APLP1, and APLP2 in excitatory neurons of the postnatal forebrain does not cause neurodegeneration

Authors: *J. KANG, A. HO, H. WATANABE, J. SHEN
Harvard Med. School/Bwh, Boston, MA

Abstract: The amyloid precursor protein (APP) has been implicated in both familial and sporadic Alzheimer's disease (AD). Despite its importance in AD pathogenesis, the study of its normal physiological role has been complicated by functional redundancy of its family members, the amyloid precursor protein like 1 and 2 (APLP1 and APLP2), and by the perinatal lethality of germline inactivation of *APP/APLP1/APLP2*. To determine the normal physiological role of the APP family, we generated postnatal forebrain-restricted *APP/APLP1/APLP2* conditional knockout (cKO) mice, in which the *APP*, *APLP1* and *APLP2* genes are deleted by Cre recombinase expressed under the control of the *αCaMKII* promoter in excitatory neurons. Despite the abundance of APP, APLP1 and APLP2 in excitatory neurons of adult cerebral cortex, their inactivation does not cause age-dependent neurodegeneration, as evidenced by the normal cortical volume and neuron number up to 21 months of age in *APP/APLP1/APLP2* cKO mice relative to littermate controls. In addition, *APP/APLP1/APLP2* cKO mice at 3 months of age exhibit mild learning and memory deficits in the Morris water maze, as shown by significant increases of latency during training and reduced quadrant occupancy in post-training probe trial, but they perform normally in the open field and rotarod tests. Furthermore, RNA-seq analysis of the hippocampal transcriptome of *APP/APLP1/APLP2* cKO mice at 3 months revealed significant alterations in mRNA levels of 305 genes with increases of 104 genes and decreases of 201 genes, consistent with a potential function of APP family in transcriptional regulation. Some of these alterations have been confirmed by quantitative RT-PCR and protein analysis; for example, calbindin1 mRNA and immunoreactivity are decreased in hippocampus of *APP/APLP1/APLP2* cKO mice. These findings provide insights into normal physiological

function of APP family and demonstrate that APP family is not required for cortical neuronal survival during aging.

Title: Genome-wide association analysis of amyloid-β and tau tangle deposition identifies enrichment of neurogenesis-related pathways

Authors: *E. HORGUSLUOGLU-MOLOCH[1], K. NHO[2], S. RISACHER[2], A. J. SAYKIN[3]
[1]Med. and Mol. Genet., [2]Radiology and Imaging Sci., Indiana University, Sch. of Med., Indianapolis, IN; [3]Radiology and Imaging Sci., Indiana Univ. Sch. of Med., Indianapolis, IN

Abstract: Introduction: Alzheimer's disease (AD) is characterized by the presence of senile (amyloid) plaques and neurofibrillary tangles. Tau plays a crucial role for neurogenesis and synaptic maturation of newborn hippocampal granule neurons and the absence of tau can result in retarded neurogenesis and neuronal differentiation (Pallas-Bazarra et al, 2016). While amyloid-beta (Aβ) accumulation has a negative effect on adult neurogenesis, Aβ precursor protein (APP) plays an important role in neuronal survival and maturation (Mu et al, 2011). To investigate whether tau tangles and Aβ deposition are significantly associated with neurogenesis-related pathways, we performed gene-set enrichment analysis on a genome-wide association study (GWAS) from the Alzheimer's Disease Neuroimaging Initiative (ADNI). **Methods:** Using non-Hispanic Caucasian participants from the ADNI cohort, GWAS was conducted using CSF levels ((N=975) $A\beta_{1\text{-}42}$, (N=1,154) t-tau, and p-tau_{181p}) and global cortical tau and Aβ deposition from [^{18}F] AV-1451 Flortaucipir tau (N=99) and [18F] florbetapir (N=800) PET scans as phenotypes controlling for age, sex and diagnosis. GSA-SNP was used to identify pathways enriched against Aβ and tau accumulation. **Results:** We identified 47, 54, and 43 pathways with enrichment for CSF t-tau levels, CSF p-tau_{181p} levels, and tau PET accumulation, respectively (FDR-corrected *p*-value < 0.05). 45 pathways were common with CSF t-tau and p-tau_{181p} levels, and related to neurogenesis, neuron differentiation, axonogenesis, neuron/neurite development, cellular differentiation, generation of neurons, and kinase activities. Of 45 enriched pathways, 12 pathways also were enriched for tau PET accumulation. . For 1,272 genes linked to the 45 common pathways enriched with CSF t-tau and p-tau181p levels, a gene-based association analysis identified APOE, PVRL2, and APOC4 as significantly associated with CSF t-tau and p-

tau181p levels after multiple comparison adjustment. In addition, Gene-set enrichment analysis of CSF $A\beta_{1-42}$ level and PET Aβ deposition identified 36 common significantly enriched biological pathways, which were related to neurogenesis processes including generation of new neurons, neuronal development, and neuronal migration and differentiation. **Conclusion:** Neurogenesis-related pathways which drive neural stem cell proliferation, maintenance in the adult neurogenic niche, and differentiation into mature neurons, were significantly enriched for tau and amyloid-β biomarker endophenotypes. The identification of enriched pathways contributes to the understanding of biological processes related to AD pathophysiology.

Inst., Indianapolis, IN

Abstract: The Alzheimer’s Disease (AD) patient population consists almost entirely of the late-onset form of AD; However, there is a paucity of animal models that reflect the entire, pathological spectrum of Alzheimer’s Disease (AD). The Model Organism Development and Evaluation for Late-onset AD (MODEL-AD) Center was created to develop, characterize and distribute more precise preclinical models for AD. To this end, we are phenotyping the age related progression of neuronal pathology in one of the most commonly utilized mouse models of AD, the 5XFAD mouse model. These mice carry a total of five mutations in two of the genes that result in familial AD, *amyloid precursor protein (APP)* and *presenilin 1 (PS1)*, which leads to an overproduction of Aβ. This not only incrementally increases Aβ plaque deposition, but also results in neuron loss and cognitive deficits. Since our histological analysis of amyloid deposition highlighted the cortex, hippocampus, thalamus and the medulla as the primary regions

where pathology develops at 4 months of age, we chose to characterize neuron pathology in these 4 regions of interest. Using AT8 and AT180 to label hyperphosphorylated Tau epitopes and LAMP1 to identify neuronal dystrophy, distinct patterns of neuronal pathologies, namely inclusions of hyperphoshorylated tau in neuronal soma and/or axons and dystrophic neurites are observed. Histological labeling of AT8+ neurons shows the presence of AT8+ neuronal inclusions limited to the superficial layers of the prefrontal and frontal cortex and in the soma of neurons of the CA3, with no axonal labeling. However, predominant AT8 pathology is observed as dystrophic neurites in the deeper cortical layers, hippocampus, subiculum, thalamus and the medulla. Conversely, the primary pathology seen with AT180 is the presence of intraneuronal inclusions in all regions of interest, with very rare AT180+ dystrophic neurites. Interestingly, AT180+ axonal labeling is prevalent and restricted to the deep cortical layers. Histology with LAMP1 shows a complete absence of LAMP1+ dystrophic neurites in the superficial layers of the cortex with extensive LAMP1 labeling in the deep cortical layers as well as in the other regions of interest. This data is the first to describe a region-specific distribution of distinct neuronal pathologies in the 5XFAD model.

Title: Gene expression and methylation analysis of ABCA7 in patients with Alzheimer’s disease

Authors: *K. YAMAZAKI
Ehime Univ. Hosp., Ehime, Japan

Abstract: *Background/Aim*: The aim of this study was to examine the blood gene expression and methylation of ATP-binding cassette sub-family A member 7 gene (ABCA7) as a biological marker of AD. ***Methods*:** AD subjects (n = 50; 11 males, 77.7 ± 6.05 years old) and age- and sex-matched healthy controls (n = 50) were recruited. A single nucleotide polymorphism in *ABCA7* (rs3764650), methylation rates of CpG sites in the *ABCA7* promoter region, and *ABCA7* mRNA expression levels in peripheral blood were examined. ***Results*:** The distribution of the rs3764650 polymorphism in AD subjects was not different from that of controls. Although the methylation rates of AD subjects were not significantly different from those of controls, the *ABCA7* mRNA expression level in AD subjects was significantly higher than that in controls. Additionally, the *ABCA7* mRNA expression level in AD subjects was significantly correlated with Mini Mental State Examination recall, the Alzheimer’s Disease Assessment Scale total score, and the Clinical

Dementia Rating score. We also found a significant correlation between the *ABCA7* mRNA expression level and duration of illness. ***Conclusion*:** The *ABCA7* mRNA expression level in peripheral blood may be a marker for early stages of AD and disease progression regardless of rs3764650 and the methylation rate of its promoter.

Title: Charting epigenetic reprogramming of gene regulatory elements in AD mice

Authors: *A. J. PHIPPS[1], M. D. ROBINSON[4], J. C. VICKERS[2], T. R. MERCER[5], A. WOODHOUSE[2], P. C. TABERLAY[3]
[2]Wicking Dementia Res. and Educ. Ctr., [3]Sch. of Med., [1]Univ. of Tasmania, Hobart, Australia; [4]Inst. of Mol. Life Sci., Univ. of Zurich, Zurich, Switzerland; [5]Transcriptomics Res. Laboratory, Genomics and Epigenetics Div., Garvan Inst. of Med. Res., Sydney, Australia

Abstract: Introduction: Alzheimer’s disease (AD) is a terminal progressive neurodegenerative disorder, yet the underlying cause of sporadic AD cases remains unknown. Epigenetics allows for dynamic regulation of chromatin structure, and complex interaction between the DNA and our environment. Epigenetic alterations such as DNA methylation and post-translational histone modifications may contribute to the pathological pathways implicated in the onset and progression of sporadic AD. **Methods**: APP/PS1 AD mice closely recapitulate the pathology present in human early-AD cases, including beta-amyloid plaque deposition and plaque-associated synapse loss. APP/PS1 mice enable us to examine the earliest pre-pathology epigenetic changes that occur in AD, as well as a time course of disease progression. Neuronal nuclei from the forebrain of APP/PS1 mice and age-matched wild-type control mice (n=5 per genotype at 3,6,12 months of age) were isolated, then purified with FACS and subject to chromatin immunoprecipitation and next-generation sequencing (ChIP-seq) with antibodies detecting H3K4me3, H3K27me3, and H3K27Ac. **Results**: Enhancer (H3K27Ac) and promoter

(H3K4me3, H3K27me3) marks are lost from regulatory regions in APP/PS1 mice compared to age-matched controls ($p<0.05$). Specifically, both enhancer and promoter marks were lost from key risk factor genes for sporadic AD (*PICALM, BIN1*; $p<0.05$) or at known differentially expressed genes in sporadic human cases and transgenic AD mice (*PICALM, TBXA2R, F2RL2, SORBS3*; $p<0.05$). **Conclusions:** These data show that epigenetic reprogramming occurs in a mouse model of early AD, affecting both enhancers and promoters. Epigenetic dysregulation may be a key aspect of AD onset and pathology.

Title: Towards multivariate genetic models predicting phenotypes of Alzheimer's disease risk

Authors: *B. C. RIEDEL[1], N. JAHANSHAD[2], D. A. BENNETT[3], P. M. THOMPSON[4]
[1]Neurosci., USC, Los Angeles, CA; [2]Neurol., IGC-INI @ USC, Marina Del Rey, CA; [3]Rush Univ., Chicago, IL; [4]Stevens Inst. for Neuroimaging & Informatics, Univ. of Southern California (USC), Marina del Rey, CA

Abstract: Alzheimer's disease (AD) has a variable phenotype and strong genetic component, indicative of multifactorial etiologies and trajectories. Apolipoprotein E (APOE) is the most established susceptibility gene for AD. Twin studies estimate heritability at up to 80%, yet APOE accounts for under 1/3 of this, and is not necessary to cause AD. Genome-wide association studies (GWAS) identify over 30 AD susceptibility genes, with most clustering in biological pathways such as lipid or glucose metabolism, yet many factors remain unknown. AD risk loci are likely difficult to replicate due to weak effects, heterogeneity, or interactions with other variants. We hypothesized the missing component in understanding genetic contributions to AD-risk require moving beyond univariate associations towards multivariate genetic models. Using the GWAS Catalog to identify single nucleotide polymorphisms (SNPs) with replicated association with AD, and the ENDEAVOR prioritization tool trained on the top 10 replicated AD-risk genes, we identified 37 AD risk genes showing evidence of systems interactions in mediating risk. After identifying multiple AD datasets with GWAS, data was filtered by

ethnicity to focus on individuals of western European descent. Data was combined across sites and filtered by allele frequency within the genes and surrounding upstream/downstream regions, Hardy-Weinberg equilibrium, and missingness. Top SNPs were determined using the fixation index and D Jost difference scores between controls and AD populations. Using the 12 SNPs across 7 genes identified, the ideal number of clusters with the Bayesian Information Criterion in the AD cohorts was found to be four. Clusters represent different genetic phenotypes associated with AD. APOE was associated with AD in 3 of the clusters. However, one cluster showed the least genetically driven profile and was not associated with APOE4. Ongoing work is exploring interactions using peripheral and brain gene expression arrays, RNA-seq, and structural brain imaging to create systems level insights into genetic phenotypes of AD risk.

Demographic Characteristics of AD and Healthy Controls					
		Total	Age (Mean ±SD)	Education	APOE4+
Controls	*N = 2638*		79.3 (8.6)	15.6 (3.3)	31%
	Males	1232	81 (8.4)	16 (3.2)	29%
	Females	1260	77.3 (8.4)	15.3 (3.3)	33%
AD	*N = 2371*		77.6 (9.8)	14.5 (3.7)	63%
	Males	982	80.1 (10.6)	15 (3.5)	58%
	Females	1117	75.7 (8.5)	14 (3.7)	68%

Table 1. Combined demographics of the four cohorts included in the study. These cohorts are the Religious Orders Study, the Rush Memory and Aging Study, the Harvard Brain Bank, the Alzheimer's Disease Neuroimaging Initiative, and the Late onset Alzheimer's Disease Family Study.

Genes Included in Multivariate SNP Analaysis of Alzheimer's Disease				
ABCA1	APOE	DSG2	MMP3	SORL1
ABCA7	BIN1	EPHA1	MS4A4E	SPON1
ACE	CD2AP	FERMT2	MS4A6A	TNF
APOC1	CD33	GRIN2B	NOS3	TOMM40
APOC2	CLU	HFE	PICALM	TRIP4
APOC4	CR1	MEF2C	PVRL2	ZCWPW1

Table 2. Genes identified through the GWAS catalogue, and prioritized using the ENDEAVOR pathway analysis tool. SNPs on genes were then filtered using Fst and D Jost to determine which showed the greatest differentiation between controls and AD.

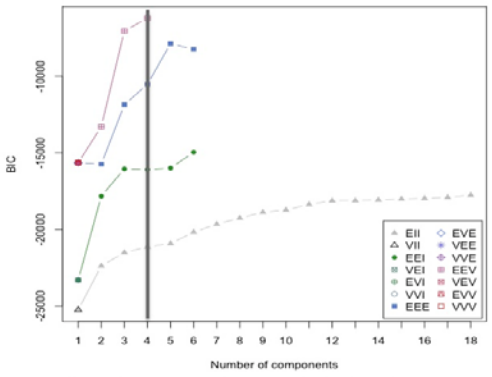

Figure 1. We used Bayesian Information Criterion (BIC) to determine the ideal number of clusters in our data. The vertical gray bar indicates an inflection point that was used to make this decision.

Cluster Groups				
	Cluster 1	Cluster 2	Cluster 3	Cluster 4

Title: Molecular profiling of brain and retina to understand earliest stages of Alzheimer's disease

Authors: *S. R. CHINTALAPUDI[1], A. UYAR[2], H. WILLIAMS[1], X. WANG[3], G. CARTER[1], G. R. HOWELL[1]
[1]The Jackson Lab., Bar Harbor, ME; [2]The Jackson Lab., Farmington, CT; [3]Eisai Andover Innovative Medicines (AiM) Inst., Andover, MA

Abstract: Alzheimer’s disease (AD) is the most common form of dementia in the world. Lack of understanding of its prodromal phase precludes us effectively designing therapeutic interventions to target AD-vulnerable brain regions. Therefore, there is a dire need for the identification of novel molecular triggers that could serve as early markers and possible therapeutic targets for the disease. While AD-related pathology in the brain is well documented, the disease has also been reported to affect the retina, a developmental outgrowth of the brain. Our objective is to determine whether the retina can be used to ‘stage’ AD prior to significant development of AD in the brain. Our approach combines high-throughput transcriptomics with classical histological assessments and functional testing to identify novel molecular disease signatures during early disease stages in neural tissue initially, using *APP/PS1* mice, a commonly used model relevant to early-onset AD (EOAD). In the future, we plan to expand this approach to include additional existing EOAD models and new models of late-onset AD (LOAD) we are creating through Model Organisms Development and Evaluation for LOAD (MODEL-AD), a NIA-funded collaboration between The Jackson Laboratory, Indiana University and Sage Bionetworks.
To determine the earliest processes occurring prior to, and at the onset of, plaque deposition we performed gene expression profiling by RNA sequencing (RNA-seq) of brains and retinas from female *APP/PS1* mice and C57BL/6J (WT) controls at 2, 4, 5, and 6 months of age (prior to and during the onset of plaque deposition in the *APP/PS1* mouse). Differential expression analysis identified activation of the Janus kinase/signal transducer and activator of transcription (JAK/STAT) pathway and long-term potentiation as early events in the brain, in agreement with other published studies. Our analyses have identified phosphorylation of STAT3 in multiple cell types including astrocytes, microglia and neurons suggesting multiple roles for the JAK/STAT pathway in this model.
To explore the potential of the retina as a biomarker in AD, gene set enrichment using STRING identified vascular dysfunction as one of the critical early events in both the eye and the brain

which is being validated using a variety of *in-vivo* and histological approaches. Elucidation of vascular dysfunction as a marker and possible early driver for AD in both these tissues could represent a significant advance in understanding the biological underpinnings of AD and at the same time it may facilitate the identification of causal proteins and pathways for novel therapeutic approaches.

Title: TET3-mediated DNA demethylation regulates AD neurodegeneration

Authors: *J. LI
Kunming Inst. of Zoology, Chinese Acad. Scie, Yunnan, China

Abstract: AD neurodegeneration has been associated with abnormal alterations in multiple epigenetic systems including aberrant DNA methylation/demethylation patterns. DNA 5-Hydroxymethylcytosin (5-hmC), a new epigenetic hallmark which was discovered recently, is becoming an interesting topic in brain ageing and age-related neurodegenerative disorders. However, the exact function of this base remains being poorly elucidated.Here, we found thatDNA dioxygenaseTET3-mediated conversion from DNA 5-methylcytosine (5-mC) to 5-hmC was involved in AD neurodegeneration.In both mouse and human ADbrain, a significant loss of 5-hmC was also found in specific brain regions including PFC and CA1 but not cerebellum in postmortem samples from patients with confirmed diagnosis of AD in comparison to age- and sex-matched healthy control subjects. Genome-wide analysis of 5hmC-seq data shows a significant shift in 5hmC enrichment in both regulatory and elements and repeated regions in AD neurons. Aβ directly attenuates TET3-mediated 5hmC production. Manipulation of TET3 activity affects the degenerative process of AD neurons.These results indicate that the involvement of 5-hmC in the pathology of neurodegenerative disorders and points out common and particular signatures that might aid in differential diagnosis as biomarkers or in the discovery of novel therapeutic targets.

Title: Apoe locus dna methylation in alzheimers disease

Authors: Y. SHAO[1], G. D'ALEO[1], M. KHRESTIAN[1], J. ZAHRATKA[1], S. RAO[2], J. PILLAI[2], J. LEVERENZ[2], *L. BEKRIS[3]
[1]Genomic Med., [2]Luo Ruvo Ctr. for Brain Hlth., Cleveland Clin., Cleveland, OH; [3]Cleveland Clin. Genomic Med. Inst., Cleveland, OH

Abstract: In humans and in mouse models, *APOE* ε2 carriers have higher apoE levels, compared to ε3 and ε4 (ε2>ε3>ε4), and are protected against Alzheimer's disease (AD) pathology, such as the toxic Aβ peptide, suggesting that *APOE* ε2 plays an important role in the central nervous system. It has been suggested that if apoE2 or apoE3 protein levels are therapeutically increased, without increasing apoE4, this would allow for better clearance and less deposition of the toxic Aβ in amyloid plaques in AD brain. Many questions still remain on how *APOE* expression is regulated by distal elements at this locus and how they might be exploited to modulate apoE levels in AD. We have described the underlying mechanistic influence by *APOE* exon 4 regulatory element at the *APOE* ε2/ε3/ε4 haplotype location. Notably, the activity of this exon 4 regulatory element appears to depend on epigenetic factors that either enhance transcription or decrease expression depending on the *APOE* ε2/ε3/ε4 haplotype. The central hypothesis of this investigation is that the complex regulatory structure surrounding the *APOE* gene is regulated by key epigenetic factors depending on tissue type and disease status. DNA was extracted from human brain (n=12) and whole blood (n=85) and percent methylation was measured using the EZ DNA Methylation™ Kit (Zymo Research) and Infinium HumanMethylation450 BeadChip Kit (Illumina). Percent methylation of each cg site was evaluated for an association with disease status and age using a multivariate analyses (SPSS). Extended methylation analysis of the *APOE* locus suggests that methylation at *TOMM40* and *APOC1*, but not the *APOE* exon 4-3'UTR CpG, are different between AD and controls in the hippocampus. Methylation at the *APOE* exon 4-3'UTR CpG island, *APOC1* and *APOC1P1* is different in MCI compared to controls in whole blood. This exploratory DNA methylation analysis of an extended region of the *APOE* locus identified regions outside of the *APOE* gene that are differentially regulated according to disease status. These results suggest that regions surrounding the *APOE* gene, in addition to *APOE*, are differentially methylated according to disease status, and identifies regions that may be regulated by methylation at this locus.

Title: PRKDC and alzheimer's disease: A candidate gene study

Authors: *J. L. WEBB
Iowa State Univ., Ames, IA

Abstract: Background: A DNA-dependent protein kinase responsible for repairing non-homologous DNA strand breakage is encoded by the *PRKDC* gene. DNA repair deficiency is hypothesized to predispose individuals to neurodegenerative disease by affecting reactive oxygen species that damage neurons. The effects of mutations in genes regulating DNA repair such as PRKDC on clinical, cognitive and neurobiological indices have yet to be characterized in humans. This candidate gene study examined how PRKDC variation influences outcomes across the Alzheimer's disease (AD) spectrum using gene based and single variant association analysis. **Methods:** 757 non-Hispanic Caucasian participants from the AD Neuroimaging Initiative (ADNI) cohort underwent whole genome sequencing, where 404 of those subjects underwent T1-weighted structural MRI scanning. Genomic data was imputed from Illumina Human610-Quad BeadChip data and exported in SPSS 24 to assess main effects of genomic variants on neuroimaging, plasma and cerebrospinal fluid (CSF) biomarkers. FreeSurfer 6.0 measured cortical thickness and surface area of neuroanatomical structures. Covariates included age, gender, education, and baseline diagnosis. **Results:** 1239 variants were extracted from a region ±2 kb from PRKDC. Logistic regression models highlighted that subjects carrying the minor allele at rs10097783 were at a 27% increased risk of developing AD (Wald=4.211, P=0.041). Minor allele carriers also displayed lower CSF $A\beta_{1\text{-}42}$ ($F=3.99$, $P = 0.032$), MMSE score ($F=6.01$, $P < 0.01$), and increased insulin resistance ($F=5.66$, $P < 0.01$). Whole gene analysis indicated that the PRKDC gene is associated with bilateral entorhinal cortex surface area. **Conclusions:** These results suggest that PRKDC may affect AD risk by modulating putative peripheral and central biomarkers, highlighting the need to validate these results in independent, larger samples. Overall these results demonstrate that neuroinformatic approaches may identify additional genetic variation explaining unaccounted heritability in AD.

Abstract: The chances to develop Alzheimer’s disease (AD) result from a combination of genetic and non-genetic risk factors, the latter likely mediated by epigenetic mechanisms. Genetic risk factors are usually interrogated by genome-wide association studies (GWAS), which have identified an important number of loci associated with AD pathology in the past. However, GWAS tend to result in strong statistical associations of only large portions of the genome, for which a causal relationship is difficult to establish. In contrast, locus-specific or epigenome-wide association studies (EWAS) identify site-specific epigenetic alterations providing mechanistic insights for a particular risk gene, but lack the statistical significance of GWAS. Combining both approaches, it has recently become possible to identify single nucleotide polymorphisms (SNPs) that correlate with alterations in DNA methylation levels - so-called methylation quantitative trait loci (mQTLs) - the importance of which for complex diseases has just started to be recognized. mQTLs have been reported for several neurological disorders including schizophrenia, obsessive-compulsive and bipolar disorder, but, thus far, not for neurodegenerative diseases such as AD.
Here, we report a hitherto unidentified association of the Peptidase M20 domain-containing protein 1 (PM20D1) with Alzheimer’s disease (AD). We find that PM20D1 is a methylation/expression quantitative trait locus (mQTL/eQTL) coupled to an AD-risk associated haplotype, which displays enhancer-like characteristics and contacts the PM20D1 promoter via a CTCF-mediated chromatin loop. PM20D1 is increased following AD-related neurotoxic insults, at symptomatic stages in the APP/PS1 mouse model of AD and in human AD non-risk haplotype

carriers, while its overexpression reduces oxidative stress-induced cell death and amyloid-β levels.

Section, LNS, Intramural Res. Program, Natl. Inst. On Aging, NIH, Baltimore, MD; [7]Dept. of Psychiatry, Indiana Univ. Sch. of Med., Indianapolis, IN

Abstract: Alzheimer disease (AD) and several retinopathies, including Age related macular degeneration (AMD) are linked to protein accumulation, in particular the Alzheimer amyloid beta protein (Aβ) and the microtubule associated protein Tau (MAPT). both been identified as major risk factors for AD and AMD. Interestingly, the amyloid β protein of 42 aa (Aβ42) is deposited in extracellular lesions in both these diseases. A number of studies have focused on reducing Aβ42 for treating AD. Critical to the understanding of AD is the recognition that Aβ accumulation does not take place in most individuals. Homocysteine and cholesterol were both identified as important risk factors liked to increases in AD pathology and dementia. Homocystinuria, a disease linked to failure of methionine catabolism leads to neurodegeneration with poor brain development and retinal function. The only treatment available to patients is restriction of methionine to prevent homocysteine accumulation. Lifelong restriction of methionine in diets preserves function in children with homocystinuria. Mice expressing FAD mutant APP or genomic human MAPT show retinal dysfunction as determined by

electroretinograms (ERGs). We find that restricting methionine in cell cultures drastically modifies Aβ protein precursor (APP) processing to reduce levels of its C-terminal fragments (CTFs) generated by α- and β-secretases, and also reduces the yield of Aβ. Moreover, a diet restricting methionine while maintaining calorie and nitrogen content reduces APP-CTFs and Aβ in an AD transgenic mouse model. In addition to APP processing, the post-transcriptional regulation of APP cannot be ruled out. Indeed, we are testing the effects of the treatment on microRNAs (miRNA) that specifically target APP and BACE1 protein expression. In summary, the treatment in our conditions improves retinal function, as measured by ERG and also corrects behavior deficits as measured by novel object preference after methionine restriction. We expect that this type of dietary restriction can be readily incorporated in persons at risk to prevent AD and AMD.

Title: Specific MicroRNAs regulating expression of proteins involved in Alzheimer's disease

Authors: *D. K. LAHIRI[1], N. CHOPRA[1], B. L. BAYON[2], N. H. GREIG[3], K. SAMBAMURTI[4]
[1]Dept. of Psychiatry, [2]Dept. of Med. & Mol. Genet., Indiana Univ. Sch. of Med., Indianapolis, IN; [3]Intramural Res. Program, Natl. Inst. On Aging, NIH, Baltimore, MD; [4]Dept. of Neurosciences, MUSC, Charleston, SC

Abstract: Small non-coding RNAs, in particular, have been the focus of many studies and their functional role in neurodegenerative diseases is currently being investigated. MicroRNAs (miRNAs) are non-coding small RNAs that are regulators of gene expression (post-transcriptionl) and consequently of many cellular processes. But their expression is often dysregulated in human diseases, including Alzheimer's disease (AD). Recently miRNAs were discovered in body fluids (serum, plasma) and brain tissues and their levels have often been reported to be altered in patients. Here we present evidence to show how particular miRNA species regulate neuronal genes involved in AD using neuronal cultures and human brain tissue specimens from control and AD subjects. AD results, in part, from over-production of amyloid-β peptide (Aβ), a proteolytic product of Aβ precursor protein (APP). Expression studies suggest

that dysregulation of proteins involved in Aβ production, such as APP and β-secretase, or BACE1, and/or Aβ degradation, such as neprilysin (NEP), contribute to excess Aβ deposition. Elucidating the regulation of these proteins' expression would ultimately reveal new drug targets. We report the regulation of these gene products by distinct miRNAs. Our results reveal a novel regulatory interaction between important AD-related genes (APP, BACE1 and NEP) and specific endogenously-expressed miRNA species. We also observed specific miRNAs (miR-101, miR-20b miR-153 and miR-346) regulating APP levels via interactions with the APP-3'UTR or APP-5'UTR in human primary neuronal cultures. These regulatory interactions may serve as novel therapeutic targets and enable the development of treatment strategies beneficial for AD.

Abstract: Alzheimer's disease (AD) is characterized by extracellular amyloid-beta deposition. BACE1 is the beta-secretase responsible for the rate-limiting cleavage of amyloid precursor protein (APP) to amyloid-beta (Aβ). Sp1 binding sites on both the APP and BACE1 promoters implicate its potential role in AD. We demonstrate how these perturbations in Sp1 and other TFs may differ in activation in mammalian cells treated with Sp1 modulating drugs. To test the involvement of Sp1 in the regulation of APP, we treated several mammalian cells lines and post-mitotic human neuronal cells with mithramycin A (MTM), MTM analogs (MTM-SDK, MTM-SK), and tolfenamic acid (TA). Real time imaging was used to record changes in the neurobiology of cells during treatments. Sp1 inhibition via drug treatment or via siRNA transfection yielded minimal changes in confluence, cytotoxicity, neurite length, and neurite outgrowth. Treatment with MTM led to a significant decrease in APP and BACE1 expression and Aβ40 levels. Treatment with TA did not change Aβ40 levels or APP and BACE1 expression. Combination treatment of MTM and TA or of Sp1 siRNA transfection in TA treated cells led to high cytotoxicity. Our results suggest that when treated with MTM, a compensatory mechanism allows for neuronal cell survival perhaps via other members of the Sp family or other TFs. We also show that at non-toxic doses, MTM can decrease Aβ40 levels in human cells. Targeting TF

activity is a novel means to manipulate the amyloid pathway. Compounds modifying Sp1 and other TF binding to sites on the BACE1 and APP promoters may provide a means to limit the production of amyloid-beta and slow the symptoms of AD.

Abstract: The genetic basis for inter-individual differences in mental processing speed with aging is not well understood**.** Animal studies provided a link between enhanced N-methyl-D-aspartate receptor function, particularly involving the GluN2B subunit encoded by the GRIN2B gene, and increased memory performance. We investigated the role of a single nucleotide polymorphism rs3764030 (G>A) within the human GRIN2B gene promoter in mental processing speed in healthy, cognitively intact, older adults. The A allele predicted creation of an E26 transcription factor family binding site. We performed in vitro DNA-binding and reporter gene expression assays of different rs2764030 allele combinations in transfected cells to show that the A allele was a gain-of-function variant, increasing GRIN2B mRNA levels. We tested the hypothesis that the A allele would be associated with better memory performance, e.g. faster reaction times during working memory. Twenty-eight older adults (ages 65-86) were recruited

and performed a visual working memory task. The rs3764030 polymorphism was genotyped and participants were grouped based on the presence of the A allele into GG and AA/AG. Carriers of the A allele maintained their processing speed over age compared to GG carriers (p= 0.026 slope of the regression line between AA and AG versus GG groups). To validate the results, 16 older adults from the same cohort participated in a different version of the short-term memory task. We found that reaction times were significantly slower with age in older adults with G allele ($p < 0.001$). Together, these findings support a role for rs3764030 in memory performance.

Title: Molecular links of DNA replication to apoptosis in ß-amyloid-treated neurons

Authors: F. CARACI[1], R. SANTANGELO[1], A. MUNAFÒ[1], F. NICOLETTI[2], *A. G. COPANI[1]
[1]Univ. of Catania, Dept. Drug Sci., Catania, Italy; [2]Univ. Sapienza, Roma, Italy

Abstract: Expression of cell cycle proteins and replicative DNA synthesis have been observed in neuronal populations that eventually degenerate in the Alzheimer’s disease (AD) brain (Herrup et al., J Neurosci 24, 2004). In cultured rodent neurons, synthetic ß-Amyloid (Aß) reproduces the neuronal cell cycle re-entry observed in the human AD brain, and blockade of cell cycle activation prevents Aß-induced neurodegeneration (Copani et al., J Neurosci 26, 2006). DNA polymerase-ß (DNA pol-ß) plays a causal role in the DNA replication process that contributes to generate a death signal in neurons (Copani et al., J Neurosci 26, 2006; Merlo et al., J Nat Prod 78, 2015). Analysis of the molecular mechanism(s) linking DNA replication to neuronal apoptosis might lead to the identification of new neuroprotective strategies. In pure rat neuronal cultures challenged with synthetic Aß(1-42) oligomers, we are examining the role of claspin, a protein required for the activation of the conserved checkpoint pathway started by DNA replication stress (Lee et al., *J Mol Cell*. 11, 2003). On cross-linked nucleoprotein fragments from Aß-treated neurons, we found that claspin co-immunoprecipitated with cell division cycle 45 (Cdc45) at early times following Aß treatments, and disappeared at times coinciding with neuronal apoptosis (as assessed by cytofluorimetric analysis). We also found that

selective inhibitors of caspase-7, an enzyme known to promote claspin inactivation, kept neurons in S phase and reduced apoptosis. These data suggest that claspin and the downstream checkpoint signaling kinase, Chk1, might constitute the molecular link between DNA replication and apoptosis in Aß-treated neurons.

Title: AC253 improved acute cognitive deficits caused of β-amyloid and human amylin delivered by an intracisternal injection in conscious mice

Authors: *R. KIMURA[1], M. ZAYASU[2], M. SAIKI[2], A. INOUE[3]
[1]Ctr. for Liberal Arts and Sci., [2]Dept. of Applied Chemistry, Fac. of Engin., Tokyo Univ. of Science, Yamaguchi, Sanyo-Onoda, Japan; [3]Dept. of Neurology, Fac. of Med., Kyoto Univ., Kyoto, Japan

Abstract: The amylin receptor is a potential target receptor for expression of the deleterious actions of soluble oligomeric β-amyloid peptide (Aβ) species, and AC253, a novel amylin receptor antagonist, neutralizes the depressant effects of Aβ and human amylin on hippocampal long-term potentiation (LTP) in mice brain slice experimentation. In addition, depressed levels of LTP observed in 6- to 12-month-old transgenic mice, which overexpress amyloid precursor protein (TgCRND8), is also restored with AC253 (Kimura et.al. J Neurosci 2012). Those show that the effects of Aβ and human amylin on LTP are expressed via the amylin receptor, and blockade of this receptor by AC253 increases LTP even in transgenic mice that show increased brain amyloid burden. In this study, our purpose is to elucidate whether acute care of AC253 improves cognitive deficits in a model mouse of Alzheimer's disease. In order to accurate delivery of these peptide quickly, we administered directly into the brain stem. By that means, we adopted a bent needle with special angle for intracisternal (i.cist.) injection into conscious mice (Ueda at.el. EUR J PHARMACOL 1979). To determine whether the peptide affects cognitive function, we performed Y-maze Spontaneous Alternation test at 30 min after i.cist, administration. First, for making sure of drug administration, we tested the effect of accute 0.01 ml Scopolamine (1 mM) or PBS administration on Y-maze test, and found the clearly difference in the levels of spontaneous alternation performance, but not number of arms entered. Next, we

investigate that 0.01 ml Aβ (1 mM) or human Amylin (1 mM) administration in mice. Both showed dramatically reduced levels of spontaneous alternation performance in the Y-maze as compared with 0.01 ml PBS administration as a control. Furthermore, another i.cist. administration of AC253 (5 mM) at 30 min before Aβ or human Amylin administration recovered from the depressant effects on spontaneous alternation performance in the Y-maze. Our next step should be to examine whether depressed levels of spontaneous alternation performance on Y-maze test observed in transgenic mice, which overexpress amyloid precursor protein (5XFAD), could be restored with AC253. Then we show that human Amylin receptor antagonists serve as potentially useful therapeutic agents in severe level of Alzheimer's disease.

Title: Live cell integrated surface plasmon resonance sensing system for monitoring and electrical modulation of neuron signaling

Authors: *M. MOZNEB, A. NILCHIAN, C.-Z. LI
Biomed. Engin., Florida Intl. Univ., Miami, FL

Abstract: Being the 6th leading cause of death in the United States, Alzheimer's Disease (AD) is the most common form of dementia, in which symptoms gradually worsen over a number of years. It is believed that damage to the brain starts a decade or more prior to surfacing symptoms and cognition loss, therefore early detection of universal biomarkers is essential in diagnosis and treatment of the disease. Amyloid, Tau and Cholinergic hypotheses are the leading thoughts on which most currently available drug therapies exist. Nevertheless, the major cause of AD is yet unknown. Due to lack of comprehensive human cellular models, it has been a challenge to study the disease under all its physiological factors. A compatible cellular model would ideally include the effect of electrical and magnetics brainwaves as well as its chemical interactions and cellular communications. Our recent studies have been on evaluating different strategies to identify the fastest and most efficient way of immobilizing and orienting Immunoglobulin G (IgG) antibody. Using electrochemical surface plasmon resonance (EC-SPR), we have established and formulated protocols to orient antibodies under specific electrical charge for higher affinity of

interaction and better detection. Developmental studies were carried out on several trials for voltage, time and pH optimization of the immobilized IgGs. The results suggest that applying positive voltage to immobilized IgGs will give a higher affinity to antibodies for influenza peptide detection, than any other chemical immobilization methods. Our current research is focused on developing a 3D SPR based model for studying the relationship of Amyloid beta (Aβ) oligomers with neuron signaling under electrically controlled and stimulated environment. Human neurons will be grown inside of the SPR flow cell gasket and will be exposed to physiological amounts of Aβ peptides. The accumulation of Aβ and cell signaling will be monitored over time using EC-SPR while the system is being exposed to different electrical signals and electrical fields of varying strengths. We hypothesize that our model will provide better understanding of the effect of Aβ oligomers on neuron signaling and its related neurotransmitter release.

Title: The influence of β1-42-amyloid and cyclosporine A on the calcium channels of hippocampal neurons

Authors: *I. KRAVENSKA, V. YAVORSKY, I. MELNICK, O. LUKYANETZ
Bogomoletz Inst. of Physiol. of NASU, Kyiv, Ukraine

Abstract: The disorders of cellular calcium homeostasis may play an important role in the development of Alzheimer's disease. The aim of our studies was to establish the role of membrane calcium channels of neurons and the mitochondrial permeability transition pores in the development of Alzheimer's disease. The study was performed on rat hippocampal cultured neurons. The model of Alzheimer's disease was realized using incubation of cells with β1-42-amyloid (2 μM, 24 h). The contribution of mitochondrial pores in the studied process was evaluated by the effect of their specific inhibitor cyclosporine A (1.25 μM). It was used a patch-clamp ("whole cell") for calcium current measurements. The densities of calcium currents per the capacity of cell membranes were compared. The results were obtained with 57 hippocampal neurons, selected by their pyramidal shape. We have shown that the densities of calcium currents in neurons were not significantly affected by β1-42-amyloid and cyclosporine A (9% and 35% of the cells compared to control respectively) because of wide range of value scattering. The amplitudes of the currents were also independent on the capacity of control cell membranes and those incubated with experimental agents. However, under control conditions the maximum of

voltage-current curve of calcium currents was observed at the test membrane depolarization from +5 to +15 mV (100% of the cells), while after incubation with β1-42-amyloid and cyclosporine A at 0 mV (17% and 13% of the cells respectively).Thus, according to the chosen cellular model of Alzheimer's disease we did not observe significant changes in the amplitudes and densities of membrane calcium currents in neurons after incubation with β-amyloid and cyclosporine A. Although in number of cells we observed the shift of voltage-current curves toward to the hyperpolarization after the treatment.

Title: Investigating Aβ toxicity using differentiated neuronal human stem cell cultures

Authors: *M. S. TAN[1], R. CAPPAI[1], M. DOTTORI[2], G. D. CICCOTOSTO[1]
[1]Dept. of Pathology, [2]Ctr. for Neural Engin., The Univ. of Melbourne, Parkville, Australia

Abstract: Alzheimer's disease (AD) is a neurodegenerative disease that primarily affects individuals aged 65 years and over. It is pathologically characterized by abnormal deposition of extracellular amyloid plaques and intraneuronal neurofibrillary tangles, progressive brain atrophy, and gradual synaptic and neuronal losses. Although the aetiology of AD remains elusive, studies have shown that amyloid beta (Aβ), a cleavage product from amyloid precursor protein (APP), is a key protein causing AD. More recent studies have shown that soluble low molecular weight Aβ oligomers correlate better with synaptic losses and are a better predictor of disease than amyloid plaque or neurofibrillary tangles (Sokolow, 2012). In the brain of individuals with AD, different neuronal subpopulations appear to exhibit vulnerability to Aβ; particularly the basal forebrain cholinergic and hippocampal glutamatergic neurons, while GABAergic neurons appear to remain relatively unaffected till later disease stages. Current treatments targeting cholinergic and glutamatergic systems only alleviate symptoms and are generally ineffective in halting disease progression.
Previous studies in our lab has shown a time and concentration dependent increase in Aβ binding that correlated with neurotoxicity in mouse cortical cultures (Jana, 2016). We hypothesize that Aβ exerts its neurotoxic effects by binding to a subpopulation of mature neurons. To better understand the mechanism(s) of Aβ-mediated toxicity on human neurons as well as human

neuronal subpopulation vulnerability, we generated human glutamatergic and GABAergic neurons using the human embryonic stem cell line H9. These neurons were cultured up to 12 weeks and treated with exogenously administered Aβ. We observed a concentration dependent increase in Aβ binding that correlated with neurotoxicity. Interestingly, we observed a trend of decreasing Aβ bound to cells at the later ages in both glutamatergic and GABAergic cultures. To identify the specific oligomeric Aβ species that is associated with cell death these differentiated neurons are being treated with purified Aβ oligomeric species (monomers, dimers, trimmers and tetramers) and correlated with toxicity.

Title: Transcriptome profile of nicotinic receptor-linked beta amyloid neurotoxicity

Authors: *K. ARORA[1], M. BELCAID[2], R. A. NICHOLS[1]
[1]Cell and Mol. Biol., John A Burns Shool of Medicine, Univ. of Hawaii, Honolulu, HI; [2]Pacific Ctr. for Emerging Infectious Dis. Res., John A. Burns Sch. of Medicine, Univ. of Hawai'i, Honolulu, HI

Abstract: A better understanding of the global gene changes underlying the progression of Alzheimer's disease (AD) pathogenesis could help develop potential therapeutic strategies for the management of this significant neurodegenerative disorder. RNA sequencing (RNA-seq) technology is a powerful way to profile the transcriptome with great efficiency and higher accuracy. RNA-seq technology has been recently employed in various neurological disorders. In this study, we used RNA-seq technology to analyze global differential gene expression in the model neuroblastoma cell line NG108-15, transfected with or without α4β2 nAChRs, and treated or untreated with full-length beta amyloid ($A\beta_{1-42}$), to gain insights into the underlying mechanisms of beta amyloid-induced neurotoxicity. Cells were treated with media or 100nM of $A\beta_{1-42}$ for 3 days, followed by extraction and purification of their RNA. Multiplexed RNA-seq libraries were prepared from the cellular RNA and paired-end 100-bp sequencing was conducted using an Illumina HiSeq 2500 sequencer. Fold changes in the expression of transcripts (and

hence, genes) between untreated and Aβ-treated samples were determined. Ingenuity pathway analysis (IPA) was employed to determine the cellular pathways. Similar experiments were conducted to compare gene expression between receptor expressing and mock (no receptor) control cells, treated or untreated with $A\beta_{1-42}$.
Our results demonstrate that treatment with $A\beta_{1-42}$ in α4β2 nAChR-transfected cells differentially modulated the expression of 15 prominent genes as compared to that of untreated cells. Differentially modulated genes included Rcan3, Chrna4, Apba3, Irak-1, Rab11 and Kif1c. Most notably, chrna4 and rcan3 (Regulator of Calcineurin), were upregulated 3-fold and 2-fold, respectively. The differential gene expression identified by RNA-seq was confirmed by real time PCR. We further confirmed the change in the protein expression of these genes by western blot. Experiments are ongoing to delineate the role of these genes in mediating beta amyloid-induced neurotoxicity.
In conclusion, this is the first study to conduct an entire transcriptome profile of model nerve cells expressing a defined high-affinity target receptor, namely nAChR, for beta amyloid. Characterizing the genes associated with neuronal death after beta amyloid treatment will have significant impact on developing neuroprotective agents to reduce or prevent neuronal death in AD patients.

Title: Mediators released by astrocytes in response to AβOs increase neuronal oxidative tone and decrease nuclear distribution of pSerStat3

Authors: *Y. A. MUÑOZ[1], A. PAULA-LIMA[2], M. T. NUÑEZ[1]
[1]Dept. of Biol., [2]Inst. for Res. in Dent. Sci., Univ. of Chile, Santiago, Chile

Abstract: Amyloid-beta oligomers (AβOs) have been found in Alzheimer's disease (AD) brains and there is vast evidence that supports a role of AβOs, which would trigger synapse failure and memory impairment in animals. Astrocytes respond to AβOs through a process called reactive astrogliosis, which generates reactive oxygen/nitrogen species (ROS/RNS) and inflammatory

cytokines that affect adjacent neurons. Stat3 is a crucial transcription factor involved in maintenance and function of nervous system and its deregulation has been implicated, with strong but controversial data, in AD. Growth factors induce serine-727 phosphorylation and this modification is associated with modulation of transcriptional activity of Stat3. The main goal in this work is determine whether hippocampal neuronal Stat3 is affected by reactive astrocytes. **Methods**: Primary hippocampal neuron and astrocytes cultures were used. Changes in pSerStat3 distribution were detected by immunocytochemistry. The oxidative tone and ROS production were evaluated by redox cytochemistry and Hyper strategy. Protein and mRNA levels were determined by Western blotting and qPCR, respectively. **Results:** We found that AβOs induced no changes in protein, mRNA Stat3 levels and pSerStat3 cellular distribution, in neurons. However, AβOs treatment in mixed neuron-astrocytes cultures induced notorious neuronal pSerStat3 redistribution. Reactive astrocytes increased the expression of pro-inflammatory cytokines, and astrocyte-conditioned media treated with AβOs (ACM-AβOs) increased the neuronal oxidative tone which it was abolished the antioxidant treatment. ACM-AβOs induced a decrease of Stat3 target genes (survival response) and an increase of pro-apoptotic Bax/Bcl2 ratio. **Conclusion:** We propose that in hippocampal neurons, pSerStat3 is a sensor for stressor astrocyte-produced induced by AβOs activation. **Financial support:** This work was supported by CONICYT Ph.D. fellowship 21130445 to YM and Fondecyt Grants 1150736 to APL and 1130068 to MTN.

Abstract: Amyloid beta (Aβ) is an abundant brain protein involved in synaptic physiology and also critical to the pathogenesis of Alzheimer's disease (AD). In this study, we examined the distribution of Aβ in the brain of young subjects free of AD lesions. We used the 11A1 antibody, targeting a toxic form of Aβ, and immunofluorescence to localize 11A1 immunoreactivity in the parietal cortex in 35 subjects 30-65 years of age. We observed 11A1 immunoreactivity already present in cortical neurons, astrocytes, neuropil and pericapillary spaces at 30 years of age. Approximately 85% of neurons have the Aβ immunoreactivity, which colocalizes with the lysosomal marker Cathepsin D, suggesting degradation of the peptides in these neurons. Around 75% of protoplasmic astrocytes also contain the Aβ immunoreactivity. The proportion of neurons and astrocytes containing the Aβ immunoreactivity remains stable with age. The Aβ immunoreactivity was also identified in nearly 30% of the perivascular space of capillaries during the fourth and fifth decades. The Aβ immunoreactivity was also present in the neuropil as 1-2 µm round particles. Imaging of these novel particles with vesicle markers showed colocalization limited to CD63, which was also detected in astrocytes but not in neurons. This finding suggests that astrocytes participate in the processing of Aβ. Notably, in the sixth decade, at the same time that the proportion of pericapillary spaces with the Aβ immunoreactivity declined to nearly 20%, the number of neuropil Aβ particles sharply increased. In summary, Aβ is normally present in various cell types and brain structures, and appears to be constitutively produced, degraded and intracellularly-extracellularly trafficked in the brain. This state is reflected by a stable presence of Aβ in the neuropil until age 50 years. However, around this age, this steady state of Aβ changes with a decrease of pericapillary Aβ and a concomitant increase in neuropil Aβ. Autopsy tissues were obtained in collaboration with the Human Brain Tissue Repository of the Lieber Institute, directed by Thomas M. Hyde, M.D., Ph.D. and Joel E. Kleinman, M.D., Ph.D.

Title: Subtle genomic DNA damage leads to increase in production of Amyloid-β(1-42) without inducing reactive oxygen species

Authors: *H. DAS, S. C. BISWAS
Cell Biol. and Physiol., CSIR-Indian Inst. of Chem. Biol., Kolkata, India

Abstract: Alzheimer's disease (AD) is a progressive neurodegenerative disorder which is also known as the most common form of dementia worldwide. The factors associated with aging like mitochondrial dysfunction, genomic instability, loss of proteostatis etc contribute to the progression of this disease. A sudden misbalance between the formation and degradation/ clearance of intracellular amyloid beta (Aβ) starts appearing way before the real manifestation of the disease. In this study the major objective was to correlate the chemistry of an aging cell in vitro by introducing a very subtle amount of DNA damage inside differentiated SHSY5Y cells, hypothesizing whether this could in turn increase intracellular Aβ level or not. Series of doses of Camptothecin (CPT) starting from 5 nM to 10 µM was treated in differentiated SH-SY5Y cells for 24 h to check cellular viability and it was observed that upto 500 nM dose of CPT there was no significant amount of cell death. A window of dose of CPT was selected (5 nM- 50 nM) for further studies to measure the intrinsic stress response of differentiated SH-SY5Y cells under that minimal level of stress. A sign of very subtle genomic DNA damage (increased expression of pH2AX), hyper fused mitochondria (by Mito tracker red staining),hyper polarization of mitochondrial membrane (TMRM intensity) was observed from 5 nM dose itself but there was no increased level of intracellular reactive oxygen species (by DCFDA fluorescence) production up to 50 nM CPT. Interestingly there was an increased expression of complex V of oxidative hosphorylation chain of mitochondria but the expression of other complexes (I-IV) were unaltered when the cells were treated with 5 nM dose of CPT for 24 h. There is also a change in the expression of Mfn2 and VDAC1 from 5 nM CPT itself. Along with that there was an increase in the intracellular Aβ (1-42) level from 5 nM dose of CPT. Taken together this data suggest that increase of intracellular Aβ (1-42) is a stress response of a neuronal cell which is under subtle genomic DNA damage. Thus we propose that age related subtle genomic DNA damage may lead to increased Aβ (1-42) production which may cause oxidative stress and further production of Aβ (1-42).

Abstract: One of the pathological hallmarks of Alzheimer disease (AD) is a senile plaque, which is composed of aggregated amyloid-β peptides (Aβ). Several lines of evidence suggest that the aggregation process from monomer Aβ to its aggregates is associated with the neurotoxicity. Thus, inhibition of Aβ aggregation would provide therapeutic approaches against AD. Biochemical and cell biological studies indicate that oxygenated Aβ exhibits low aggregation potency and neurotoxicity than those of native Aβ, suggesting that artificial oxygenation of Aβ is a candidate for AD therapeutics. Thus, we synthesized a photooxygenation catalyst, which is activated by light and oxygenates Aβ (Taniguchi *et al*., Nat Chem 2016). This catalyst selectively oxygenated the synthetic aggregated Aβ and inhibited further aggregation and neurotoxicity. However, the effect of the catalyst on the aggregated Aβ *in vivo* remains unclear. To verify this issue, we carried out photooxygenation experiments of Aβ derived from AD model mice (NL-G-F mice, Saito et al., Nat Neurosci 2014) and analyzed by biochemical techniques. First, to check the photooxygenation activity for aggregated Aβ derived from the brains of AD model mice, the catalyst was mixed with the brain lysate and irradiated with 660 nm light. We confirmed the oxygenated Aβ peaks were detected using MALDI-TOF-MS. In addition, western blotting analysis showed the higher molecular weight bands (oxy-Aβ bands) than that of monomer Aβ by photooxygenation. Stepwise fractionation of photooxygenated brain lysate revealed that oxy-Aβ bands were detected in the insoluble fraction. These data indicated that catalyst has specifically oxygenated the aggregated Aβ in AD model mice brain. To further elucidate the effect of photooxygenation of Aβ in living animals, we constructed the repeated photooxygenation system for AD model mice. Catalyst was injected into hemi-hippocampus following the irradiation using LED fiber through the surgically inserted guide once in a day. Reactions were repeated for 7 times, and isolated hippocampi were analyzed. We observed the appearance of oxy-Aβ bands, indicating that oxygenation reaction for Aβ is occurred in living animal. Taken together, in this study, we revealed that photooxygenation catalyst oxygenates not only synthetic Aβ, but also aggregated Aβ derived from AD model mice. These data indicate therapeutic possibility of photooxygenation catalyst for AD.

Title: *In vivo* Aβ clearance from interstitial fluid and efflux through the choroid plexus are negatively influenced by peptide oligomerization

Authors: *A. A. ROSTAGNO, E. CABRERA, P. GIANNONI, F. MCINTEE, T. A. NEUBERT, J. GHISO

Abstract: Amyloid β (Aβ) is the major constituent of the brain deposits found in parenchymal plaques and cerebral blood vessels (CAA) of patients with Alzheimer's disease (AD). Several lines of investigation support the notion that synaptic pathology, one of the strongest correlates to cognitive impairment, is related to the progressive accumulation of neurotoxic Aβ oligomers. The process of oligomerization/fibrillization is concentration-dependent and is therefore highly reliant on the homeostatic mechanisms that regulate the steady state levels of Aβ influencing the delicate balance between rate of synthesis, dynamics of aggregation and clearance kinetics. Emerging new data suggest that reduced Aβ clearance, particularly in the aging brain, plays a critical role in the process of amyloid formation and AD pathogenesis. We have used a combination of intracerebral stereotaxic injections in C57BL/6 wild-type mice with biochemical and mass spectrometric analyses of CSF to evaluate the brain clearance and catabolism of well-defined monomeric and low molecular mass oligomeric assemblies derived from Aβ1-40 and Aβ1-42. Our data clearly demonstrate that Aβ physiologic removal from the brain is extremely fast, is negatively modulated by age, and involves local proteolytic degradation leading to the generation of heterogeneous C-terminally cleaved proteolytic products, while providing clear indication of the detrimental role of oligomerization for brain Aβ efflux. Immunofluorescence confocal microscopy studies provide insight into the cellular pathways involved in the brain removal and cellular uptake of Aβ. The findings indicate that clearance from brain interstitial fluid follows local and systemic paths and that in addition to the blood-brain barrier, local enzymatic degradation and the bulk flow transport through the choroid plexus into the CSF play significant roles. Our studies highlight the diverse factors influencing brain clearance and the participation of various routes of elimination opening up new research opportunities for the

understanding of altered mechanisms triggering AD pathology and for the potential design of combined therapeutic strategies.

Title: Amyloid β-induced mitochondrial dysfunction is mediated by changes on PGC-1α and Mfn1/Drp1 on cellular models of Alzheimer Disease

Authors: ***J. FUENTEALBA**[1], J. PANES-FERNANDEZ[3], T. CELIS-MUÑOZ[2], T. SILVA-GRECCHI[2], D. MENNICKENT[2], P. A. GODOY[2]

Abstract: Increased production of amyloid-beta (Aβ) peptide is one of the main features of Alzheimer's disease (AD). Soluble oligomers of Aβ (SOAβ) are postulated as the main toxic agent involved in the disease pathogenesis. Multiple toxic effects have been described in AD development, and could be replicated in different studies employing SOAβ: one of these features is mitochondrial dysfunction. The aim of this work was to evaluate the effects of SOAβ in two important mechanisms of mitochondrial function regulation, mitochondrial biogenesis and dynamics. Mitochondrial biogenesis is regulated by the key transcription regulator peroxisome proliferator-activated receptor gamma coactivator 1-alpha (PGC-1α), which is in turn deacetylated and activated by the silent mating type information regulation 2 homolog (SIRT1) protein. On the other hand, mitochondrial dynamics are a highly regulated process involving fission and fusion events orchestrated by several proteins, including fusion protein Mitofusin 1 (Mfn1) and fission dynamin-related protein 1 (DRP1). Through western blot and immunofluorescence techniques, we observed decreased SIRT1 protein levels after SOAβ treatments (2h: 47±6%, 5h: 51±15%, 24h: 45±10%). onversely, an increment of PGC-1α protein was detected after 5h incubations (218±33%), though reduced levels were obtained after 1 and 24 h treatments (30±8%, 42±7% respectively). We studied the interaction between these two proteins after a 24 h SOAβ exposure, and curiously, the interaction was lost, which correlates

with a change in PGC-1α distribution, increasing its immunoreactivity in the cytoplasm (177±7%) and decreasing in the nucleus (38±3%). On the other hand, after 2 h incubations we observed a reduction in Mfn1 protein levels (42±11%), and an increase in DRP1 protein (198±27%); additionally, DRP1 presented a distribution shift on hippocampal neurons, increasing its immunoreactivity in neuronal processes. Changes regarding mitochondrial protein levels correlate with an alteration of mitochondrial network morphology, noted by fragmented mitochondrial populations in SOAβ-treated PC12 cells (< 2 μm, granular pattern), compared to control populations (2-6 μm, tubular pattern). Finally, these results suggest a SOAβ-induced imbalance in mitochondrial dynamics, through an early response mechanism to injury, represented by a fission potentiation and decreased mitochondrial biogenesis, thus blocking the pathway that lead to the cell to have functional mitochondrias and support the metabolic requeriments of the cell in the presence of SOAβ.

Title: Single D-peptide treatment causes local long-term changes in Aβ deposition in Tg AD model mice

Authors: *T. VAN GROEN[1], I. KADISH[1], N. JIANG[2], D. WILLBOLD[2]
[1]Cell, Developmental and Integrative Biol., Univ. Alabama-Birmingham, Birmingham, AL; [2]Forschungszentrum Jülich Gmbh, Jülich, Germany

Abstract: Our two transgenic mouse lines express two genes with AD mutations, i.e., PS1 (ΔE9 mutation) and APPswe or one gene with AD mutations APPswe/dutch/iowa. They develop plaques at about four months of age, and we have described that two types of deposits are present, plaques (with a thioflavine S positive core) and diffuse deposits. Furthermore, plaques are surrounded by activated glial cells, but diffuse deposits are not. We hypothesized that these distinct amyloid deposits would present differently following single intracerebral (hippocampus) fluorescently labeled anti Aβ42 oligomer targeted D-peptide injections in these mice.
We sacrificed and transcardially perfused the mice at two weeks and 3 months following the injections. The brains were cut and immunohistochemically stained for Aβ species, and GFAP and Iba-1.

Following the two week survival time the AD mice displayed a clear labeling of Aβ in the overlying cortex and hippocampus, and, locally a reduction in Aβ deposition was noted. No change was present in the number of labeled neurons. Further, the labeled Aβ is present in lysosomes in neurons near the injection site, but surprisingly no labeled Aβ is present in astrocytes or microglia. Labeled Aβ deposits seem to stay labeled over the researched timeframe, whereas the diffuse extracellular labeling (not bound to Aβ) disappears. Following the three months survival time the AD mice displayed a clear labeling of Aβ in the overlying cortex and hippocampus, and, locally a reduction in Aβ deposition was noted. It should be noted that none of these injections is associated with any glial activation, neither in the cortex nor in the hippocampus.
Thus, likely the D-peptides attach to the Aβ42 present in these amyloid deposits that develop in these AD model mice, and prevent the growth and buildup of these deposits.

Title: Developmental Exposure to particulate air pollutants impairs hippocampal dependent memory, reduces hippocampal neurogenesis, and causes depressive behaviors

Authors: *N. C. WOODWARD[1], R. G. JOHNSON, III[2], F. SHIRMOHAMMADI[1], C. SIOUTAS[1], S. E. KANOSKI[1], C. E. FINCH[3], T. E. MORGAN[4]

Abstract: Traffic-related air pollution (TRAP) has increasing interest due to evidence linking increased risk of autism spectrum disorders to exposure to TRAP derived ambient particulate matter (PM) (Volk et al., 2013). This study examined the impact of nPM exposure during the critical window of development on longer term cognition. Sprague Dawley rats were exposed to nanoscale particulate matter (nPM, diameter < 200nm) from gestation to 28 weeks of age. nPM was collected adjacent to the CA-110 freeway in downtown Los Angeles, and is composed of the water-soluble fraction of ambient PM, composed primarily of organic carbons, nitrate, sulfate, ammonium. Pregnant rats were exposed 3 days/week, for 5 hours/day to 340 ug/m^3 nPM.

Developmental air pollution exposure impaired hippocampal dependent contextual memory, measured by novel object in context test. At six months of age, prenatally exposed rats spent less time exploring the novel object, resulting in a 20% reduction in the discrimination index, and a 60% reduced shift from baseline (investigation above chance levels). Exposed rats had a 30% decreased latency to first period of immobility, and spent 80% more total time immobile. nPM exposure also caused increased depressive behavior, measured by forced swim. Neurogenesis was impaired. The EDU assay of adult male hippocampal sections revealed decreased neurogenesis in the Cornu Ammonis 1 (CA1) and dentate gyrus (DG) by 60% or more, with no change in the CA3. The CA3 showed no effect of air pollution exposure in any subregion. Forced swim performance showed strong correlation with neurogenesis in, CA1, and DG. The behavioral deficits could be driven by an observed reduction in neurogenesis in the CA1 and DG of the dorsal hippocampus. The present data corroborates epidemiological findings of a developmental cognitive vulnerability to air pollution, and highlight the importance of reducing air pollution exposure in the population.

Title: Estradiol protective roles against air pollution mediated amyloidogenesis in neuroblastoma cells

Authors: *N. SAFI[1], ***N. SAFI**[1], M. CACCIOTTOLO[1], F. SHIRMOHAMMADI[2], C. SIOUTAS[2], T. MORGAN[1], C. FINCH[1]

Abstract: Older women (particularly after menopause) are at higher risk of Alzheimer's Disease (AD), compared to men (Barnes et al; 2005). Physiological levels of 17-β-estradiol (E_2) can decrease the amyloid β-peptide (Aß) released by primary neuronal cultures derived from rodent and human cerebral cortex (Xu et al; 1998). However, the hormonal mechanism and the interaction with environmental factors during AD pathogenesis are not well understood (Janicki et al; 2010). Recent analysis of Women's Health Initiative Memory Study (WHIMS), showed that residence in polluted areas with elevated fine Particulate Matter ($PM_{2.5\mu m}$) had 92% higher risk of dementia (Cacciottolo et al; 2017). We hypothesized that E_2 may have a protective effect

against AD pathogenesis and air pollution particles. To test this, mouse neuroblastoma (N2a) cells expressing Swedish mutant APP (K595N/M596L) (N2a-APP/swe) were exposed to nano-sized sub fraction of $PM_{2.5\mu m}$ (nPM) (5 μg/ml) in presence and absence of 20 nM E_2 (physiological level). The toxicity was assessed by MTT and the transcriptional changes in APP, BACE1, and mERβ were analyzed by qPCR. In the MTT assay, nPM reduced mitochondrial activities of N2a/APPswe by 50% ($p<0.001$). Treatment with E_2 attenuated nPM effects on MTT by 30% ($P<0.001$). Similarly, the 2-fold nPM-induced increase of APP and BACE1 mRNA levels was attenuated by E2 ($p<0.0001$). In contrast mERβ was not induced by nPM, but was induced by E2. These findings suggest potential neuroprotection by E2 in resistance to air pollution PM.

Title: Long term exposure to urban nano particulates has negative effects on cognitive functions and affects Alzheimer’s disease pathological hallmarks

Authors: *C. D'AGOSTINO[1], M. CACCIOTTOLO[1], F. SHIRMOHAMMADI[2], C. SIOUTAS[2], T. E. MORGAN[1], C. E. FINCH[1]
[1]USC Leonard Davis Sch. of Gerontology, Los Angeles, CA; [2]USC Viterbi Sch. of Engin., Los Angeles, CA

Abstract: In experimental rodent studies, chronic exposure to nano-sized particles from traffic-associated particulate matter (nPM- TRAP) robustly induced neuro- inflammatory responses (Morgan et al. 2011), amyloid accumulation and neurodegeneration (Cacciottolo et al., 2017). This study analyzed the impact of chronic nPM (< 200 nm) exposure on memory function and Alzheimer markers (Aβ38-40-42 accumulation) in wild type mice (C57BL/6J). Male mice aged 3 months were exposed to re-aereosolized nPM (350 $\mu g/m^3$) or to control filtered ambient air for 5 hours a day, 3 days per week, for 8 weeks. Memory was assessed by the ‘novel object recognition in contest (NOIC) test’ for hippocampal-mediated spatial recognition memory and learning. Mice exposed to nPM showed 25% deficit of memory compared to non-exposed

controls. Cerebral cortex lysates (PBS soluble supernatant, 100,000g x 60 min) were analyzed by ELISA for Aβ peptides. Exposed mice showed elevated soluble Aβ40 and -42 peptides in cerebral cortex by 1.7 and 2-fold vs controls. Our findings confirm studies of Fonken et al (2011) which showed impaired spatial learning from 9 months of TRAP exposure in the same mouse genotype, C57BL/6J males. Moreover, we found that the increase of Aβ was negatively correlated with memory function in nPM exposed mice, but not in control group. These findings suggest that endogenous rodent Aβ has synaptic activity relevant to cognitive functions. This association was not expected because rodent Aβ differs from the human in three amino acids that reduce its aggregation and toxicity (De Strooper et al 1995, Boyd-Kimball et al 2004). Thus, memory decline associated with TRAP in human populations may be due to increased levels of Aβ peptides, even in absence of detectable plaques.

Title: Developmental Exposure to particulate air pollutants causes neuroinflammation

Authors: *R. G. JOHNSON, III[1], N. C. WOODWARD[2], F. SHIRMOHAMMADI[3], C. SIOUTAS[3], S. E. KANOSKI[4], T. E. MORGAN[2], C. E. FINCH[2]
[2]Leonard Davis Sch. of Gerontology, [3]Viterbi Sch. of Engin., [4]Dornsife Col. of Letters, Arts and Sci., [1]USC, Los Angeles, CA

Abstract: Traffic-related air pollution (TRAP) has drawn interest due to evidence linking exposure to TRAP derived particulate matter (PM) and the risk of dementia (Cacciottolo2017) and autism-spectrum disorders (Volk 2015). This study focuses on nanoscale particulate matter, a subset of TRAP with a diameter of less than 200 µm. This study examined effect of nPM on exposure from before birth into adult life on systemic and neurodegenerative inflammatory markers. Sprague Dawley rats were exposed to nPM from gestation to 28 weeks of age. The nPM was collected adjacent to the CA-110 freeway in downtown Los Angeles. Rats were exposed on an alternate day intermittent schedule of three days per week, for five hours per day at 340 ug nPM/m3; controls were exposed to HEPA filtered air. Serum from nPM exposed rats at

the time of euthanasia had decreased levels of cytokines putatively associated with the M2 macrophage phenotype: IL-4, -20%; IL-10, -25%; IL-13, -15%. There was no change in serum levels of IL-6 and TNFα. In the hippocampus, microglial staining with Iba1 was increased by 40% in the dentate gyrus (DG) polymorphic layer, without change in the DG molecular layer. In the CA1 oriens layer, Iba1 staining was 30% higher in nPM animals vs controls, but with no difference in the CA1 radiatum. Also in the hippocampus, staining for the vascular endothelial cell maker (Zo-1) was reduced 75% in the CA1 oriens of the nPM exposed, with no difference in the CA1 radiatum.
These data show that exposure to nPM from early development into adult life may induce low grade systemic inflammation resulting from reductions in serum anti-inflammatory markers which could lead to increased neuroinflammation. Furthermore, the decrease in endothelial Zo-1 suggests alterations of the blood brain barrier. These changes may underlie some of the hippocampal-mediated behavioral deficits observed in this same study (Woodward et al).

Title: Urban traffic-derived nanoparticulate matter promotes pro-amyloidogenic APP processing through increase of oxidative stress and lipid raft disruption

Authors: *M. CACCIOTTOLO[1], A. SAFFARI[2], C. SIOUTAS[2], T. E. MORGAN[1], C. E. FINCH[1]
[1]USC Leonard Davis Sch. of Gerontology, Los Angeles, CA; [2]USC Viterbi Sch. of Engin., Los Angeles, CA

Abstract: Traffic related air pollutants (TRAP) increase the risk of accelerated cognitive decline and Alzheimer Disease (AD). A possible mechanism is the increased levels of brain Aβ, shown in several rodent models. We recently reported that exposure to urban traffic-derived nano-sized

particulate matter (nPM, <0.2 um; PM0.2u) increased Aβ levels in a mouse model of AD, and induced oxidative stress in primary glia culture and in hippocampal slices. Here we investigate the molecular mechanism of nPM induced pro-amyloidogenic APP processing, which we hypothesize are mediated by oxidative stress and lipid raft disruption. Mouse neuroblastoma cells expressing human APP harboring Swedish mutated APP (N2a-APP/swe) were exposed to 1-5-10 μg/ml nPM for 24h. Exposure resulted in dose-dependent increases of Aβ38, -40, and 42 peptides, with increased oxidative stress (NO production, Mitosox, 3-nitrotyrosine -3NT and 4-Hydroxynonenal -4HNE) and altered sub-localization of lipid raft and APP. Treatment with n-acetyl-cysteine (NAC) reduced both oxidative stress and Aβ induced by nPM. We propose that nPM-induced oxidative stress mediates the pro-amyloidogenic processing of APP, with a dose-dependent hierarch. While lower nPM induces rapid NO increase, its increase is below the threshold of oxidative stress required for increased Aβ production.

Title: Comparison of Aβ levels in brains and saliva of Alzheimer’s disease mouse models

Authors: *A. M. FLODEN, G. D. MANOCHA, K. L. PUIG, C. K. COMBS
Biomed. Sci., Univ. of North Dakota, Grand Forks, ND

Abstract: Beta amyloid (Aβ) peptide containing plaque aggregations in the brain are a hallmark of Alzheimer’s Disease (AD). However, Aβ is produced by cell types outside of the brain suggesting that the peptide may serve a broad physiologic purpose. It has been documented that elevated levels of Aβ found can be found in the saliva of AD patients but the source and function of this salivary Aβ is not fully understood. Based upon our prior work documenting expression of amyloid precursor protein (APP) in intestinal epithelium we hypothesized that salivary epithelium might also express APP and be a source of Aβ. To begin testing this idea, we compared C57BL/6 wild type mice to two mouse models of AD, littermate control APP/PS1 mice and the newly characterized APP (NL-G-F) mouse line. At 12-15 months of age, salivary

secretion was stimulated from all three lines and compared to, salivary gland, serum, and brain Aβ levels to determine whether a specific relationship existed between saliva, blood, and brain in either line. As expected, both APP/PS1 and APP (NL-G-F) lines demonstrated robust brain increases in Aβ 1-40/42 with lower levels of Aβ 1-40 in APP (NL-G-F). Both APP/PS1 and APP (NL-G-F) mice also showed an increase in Aβ 1-42 levels in serum with higher Aβ 1-40 levels in APP/PS1 compared to APP (NL-G-F) mice. On the other hand, significantly increased levels of Aβ 1-42 were quantified from saliva of only APP (NL-G-F) mice. These data support the idea that a ratiometric relationship exists between saliva, blood, and brain Aβ levels and indicate that AD mouse models may be useful for exploring the diagnostic potential of this relationship as well as the source and function of salivary Aβ.

Title: Morphological characterization of glia reveals circuit specific propagation of amyloid beta pathology in Alzheimer's disease

Authors: *F. ABDURROB, R. CANTER, N. DEDIC, K. CHUNG, L.-H. TSAI
Picower Inst. for Learning and Memory, Dept. of Brain and Cognitive Sci., MIT, Cambridge, MA

Abstract: Glia play a crucial role in maintaining homeostasis in the brain and supporting the functioning of neurons. A complex network of inflammatory and neurodegenerative responses, coupled with amyloid beta (Aβ) deposits, tau tangles, and oxidative stress characterize Alzheimer’s disease (AD). Activation and proliferation of microglia and astrocytes are important in the inflammatory response, which ultimately affects disease progression. Consequently, the synergistic changes that occur during gliosis have become an intense topic of investigation, but remain poorly defined. This study utilizes the 5xFAD AD mouse model, as well as healthy age-matched control animals, to spatiotemporally characterize amyloid spread and glial cell response in the brain as aging occurs. Cutting-edge CLARITY and SWITCH labeling techniques are used to visualize the cellular landscape of the diseased brain and create a spatially unbiased map of

endogenous Aβ accumulation. We observe a network-specific spread of amyloid pathology along the Papez long-term memory circuit as a region of vulnerability to early amyloid aggregation and results in physiological impairment. The 4D nature of these data also allow for the visualization of affliction in the fornix, the long-range white matter tract which connects the major nodes of the Papez circuit: the hippocampus, subiculum, and mammillary body. Morphological and proliferative changes in microglia and astrocytes are found in nodes that harbor increased plaque load. The interaction of these immune cells with the vasculature is also examined to explore potential impacts on amyloid clearance. Ultimately, a clearer picture of glial changes during pathology progression along vulnerable neurocircuits will allow for a better understanding of the dynamic pathophysiology that underpins neurodegeneration.

Abstract: Alzheimer’s disease (AD) is a progressive neurodegenerative disease that results in gradual memory loss and impairment in the ability to learn or carry out daily tasks. The development of therapies for AD has been hindered by limited availability of relevant cell models for basic research and drug discovery. Using induced pluripotent stem cell (iPSC) technology, we have created an unlimited source of human neurons available for studying the mechanisms of AD progression and to streamline the identification of novel drug treatments for this disease. A hallmark of AD pathology is the development of plaques in the brain that contain toxic beta amyloid peptides (Abeta). Therefore, a key focus of AD research is to discern the specific contributions of Abeta to the disease. We have taken two strategies to generate an iPSC-based “disease-in-a-dish” approach for modeling AD *in vitro*. The first is based on genome engineering of an apparently healthy normal iPSC line to introduce mutations in the gene coding for amyloid precursor protein (APP) and then create human neurons from genetically distinct

samples. We rigorously tested the cell by high content imaging, PCR arrays, biomarker production, and multi-electrode array (MEA). Our data were in general agreement with results observed in other model systems for A673V (known to influence AD progression) and A673T (protective from the disease). Uniquely presented, however, functional assessment on MEA with multi-parametric analysis revealed the APP A673V mutant had a significantly different phenotype than A673T or the isogenic WT control. Secondly, we have examined the effects of exogenous exposure to Abeta peptides. Addition of oligomeric Abeta(1-42) to GABAergic and glutamatergic neurons results in cytotoxicity as read out by ATP and LDH assays. Next, synchronous cultures of excitatory glutamatergic neurons - which can be analyzed on MEA to quantify bursting patterns - display a dose-dependent decrease in network bursting prior to decay in firing rates and subsequent to cell death. Detailed evaluation of the burst structure and action potential morphology will be presented. Importantly, these alterations were not observed in control experiments with Abeta(1-40). Our studies demonstrate the utility iPSC technology to create readily accessible human cell models for AD that recapitulate some of the functional neuronal phenotypes that are associated with this complex disease. Ultimately, the promise is that such gene-associated or in vitro disease models can be used to screen for compounds that rescue these phenotypes and significantly reduce the time and cost to develop new AD therapies and improve patient outcomes.

Title: Traffic-related air pollution (TRAP) mediates amyloidogenesis through TNF signaling

Authors: *A. HAGHANI[1], M. CACCIOTTOLO[1], N. SAFI[1], K. R. DOTY[2], F. SHIRMOHAMMADI[3], B. XIN[4], R. ROHS[4], T. C. TOWN[2], C. SIOUTAS[3], T. E. MORGAN[1], C. E. FINCH[1]

Abstract: Traffic-related air pollution (TRAP) accelerates cognitive aging, exacerbates white matter loss, and increases the risk for dementia. In prior studies we showed that TRAP-related nano sized particles (nPM) induces inflammatory responses and amyloidogenesis. Current studies investigate inflammatory signals that are enriched in the cortex transcriptome of the male and female APOE3 or APOE4 transgenic mice exposed to TRAP-related nano sized particles (nPM). This RNA-seq analysis revealed that nPM targets the acute phase response, including TNF pathways, and induces amyloidogenesis pathway at different levels. Based on these results, we hypothesized that TNFα may mediate nPM-induced amyloidogenesis. Accordingly, an in vitro experiment investigated the TNFα signaling pathway in transgenic N2a/APPswe cell line. nPM increased TNFα and APP mRNA in N2a/APPswe cell line, with high correlation. Silencing of TNFR1 by siRNA in N2a/APPswe cells reduced TNFα mRNA levels and ameliorated the upregulation of APP gene during nPM treatment. Next, we screened the TNFR1 downstream transcriptional factors (TFs) that might connect this TNF to APP. Among the analyzed TFs, ZFP, RELA, DAXX, RBCK1 and STAT1 mRNA levels significantly changed following TNFR1 silencing. Further structural bioinformatics analysis and in vitro experiments will document whether any of these TFs have a binding site on APP promotor that can affect the expression of this protein during nPM toxicity. In conclusion, the TNF pathway may be a good target against TRAP-induced amyloidogenesis. Future evaluation of these identified targets in a mouse model exposed to TRAP particles will help us to understand the underlying association between air pollution and Alzheimer disease neuropathology.

Title: Early sphingolipid signatures of mutant huntingtin expression in neuronal cell

Authors: *A. M. TRZECIECKA, M. PIQUERAS, S. K. BHATTACHARYA
Ophthalmology, Univ. of Miami, Miami, FL

Abstract: Dysregulation of sphingolipid metabolism has been reported in many neurodegenerative disorders. Yet much remains to be understood about alterations of sphingolipid metabolites in Huntington's disease. Our goal in this study was to provide a picture of the early and thus preferentially primary consequences of mutant huntingtin (htt) expression on neuronal cell sphingolipidome.
We used stable doxycycline-inducible neuronal (PC12) cell lines that express htt exon 1 with 23 (control) or 74 (mutant htt) CAG repeats length. Post-mitotic cells (6 day differentiation with 100 ng/mL NGF under low-serum conditions) were induced with 1 µg/mL doxycycline for 8 h. Samples were spiked with internal standards and lipids extracted using Bligh&Dyer method with alkaline hydrolysis. Untargeted profiling analysis was carried out using reverse phase liquid chromatography coupled to high-resolution mass spectrometer (Q Exactive). Subsequently, peak extraction, identification and alignment were performed using Lipid Search 4.1 software. Quantification is based on the ratio to respective internal standard and normalized to total DNA content.
Based on MS/MS spectra we identified a total of 831 species from 8 sphingolipid subclasses, of which 383 (46%): 132 ceramide (Cer), 36 hexosyl-ceramide (CerG1), 29 dihexosyl-ceramide (CerG2), 96 ceramide 1-phosphate (CerP), 3 lysosphingomyelin(LSM) , 67 sphingomyelin (SM), 15 sphingoid base (So) and 5 sphingoid base 1-phosphate (SoP) species changed significantly upon mutant htt expression (t-test $p<0.05$). We found increase in total concentrations of Cer, CerG1, CerG2, LSM, SM, SoP, and decrease in CerP and So (t-test $p<0.05$). Interestingly, contrary to all other subclasses that followed up- or down-regulation pattern, we observe two distinct populations of SM differentially regulated upon mutant htt expression - increasing SM (45%) and decreasing SM (55%). A closer look at these two reveal structural differences in backbone sphingoid base composition and saturation of fatty acid chains.
In conclusion, profound alterations in sphingolipid profile occur as early events upon mutant htt expression in neuronal cell. However, further studies are needed to elucidate functional significance of these findings.

Title: Developing and testing of small molecules that specifically degrade HDAC4 protein

Authors: H. A. WILKINSON[1], G. MCALLISTER[3], O. LAZARI[3], N. MACABUAG[3], L. URBONAS[3], M. EZNARRIAGA[3], R. JARVIS[4], P. BRECCIA[4], R. VAN DE BOSPOORT[5], *D. MACDONALD[2], E. DOHERTY[1], T. VOGT[1], I. MUNOZ-SANJUAN[1], C. DOMINGUEZ[1]
[1]CHDI Management, Inc., Princeton, NJ; [2]CHDI Management, Inc., Los Angeles, CA; [3]Biol., [4]Charles River, Cambridge, United Kingdom; [5]Charles River, Leiden, Netherlands

Abstract: Huntington's disease (HD) is a lethal autosomal dominant neurodegenerative disorder resulting from a polyglutamine-encoding CAG expansion in the Huntingtin (*HTT*) gene. HDAC4 co-localizes with mutant HTT (mHtt) cytoplasmic inclusions in two HD mouse models (the R6/2 fragment model and the *Hdh*Q150 full length knock-in model) and genetic reduction of HDAC4 delayed mHTT aggregation in CNS tissue. HDAC4 genetic reduction in the R6/2 HD mouse model ameliorated motor and CNS neurophysiological deficits and improved survival.
This led us to develop several small molecule deacetylase inhibitors suitable for pre-clinical testing of the hypothesis that inhibition of HDAC4 activity would alter aggregation kinetics and phenotypic endpoints in HD animal models. In addition to direct HDAC4 inhibition, we have conjugated an exemplar of our lead series to an E3 Ubiquitin ligase ligand in order to generate a proteolysis targeting chimera (PROTAC) tool which can be used to reduce total HDAC4 protein levels.
We validated that the new chimeric molecules were direct HDAC Class IIa (HDAC4, 5, 7 & 9) deacetylase inhibitors in recombinant biochemical assays and retained the ability to inhibit Class IIa HDACs in a variety of mammalian cell lines. Surprisingly, these PROTAC molecules acted as selective and potent degraders of HDAC4, with DC50 values in the low nM range in a variety of cell types when tested by western blot and MSD assay.
Testing the molecules in human ES cell derived and primary neuronal cells showed potent knockdown of HDAC4 levels in agreement with the data from non-neuronal cell types. We are now working towards proof of principle testing of these molecules *in vivo* in rodent models.
This specific protein degradation approach will ultimately be compared with the effects of direct deacetylase catalytic site inhibitors to see if the PROTAC approach more closely replicates the prior results showing genetic Hdac4 hemizygous knock-out ameliorates the phenotype of a transgenic HD mouse model.

Title: Functional connectivity and dynamics in Huntington's disease striatal cultures revealed through large-scale calcium imaging

Authors: S. FERNÁNDEZ-GARCÍA[1,3,4], *M. MASANA[1,3,4], J. G. ORLANDI[1,3,4,2,5], G. GARCÍA-DÍAZ BARRIGA[1,3,4], J. SORIANO[2,6], J. ALBERCH[1,3,4]

Abstract: Striatum, the main hub of the basal ganglia circuitry, is the most affected region in Huntington’s disease (HD). In HD, mutant-huntingtin (mHtt) causes an excitatory-inhibitory imbalance of the basal ganglia output pathways and induces motor symptoms. Although alterations of striatal Medium-sized Spiny Neurons (MSN) occur at early stages of the disease, little is known about how this translates into functional changes in the network dynamics. Using high-speed, high-resolution calcium imaging, we have recorded simultaneously hundreds of cells from striatal primary cultures in WT and the R6/1 mouse model of HD and characterized the spontaneous activity patterns of every cell as well as their collective activity. Although most of the striatum is composed by inhibitory neurons, we showed that isolated striatal cultures are functionally active, without the need of excitatory inputs. The percentage of active population is ~10% whilst in cortex ~50% of the population showed spontaneous active in basal conditions. At the single cell level, we identified three populations based on their fluorescence activity traces in

both WT and R6/1. Type 1 (fast increase/exponential decay) characteristic of neurons; Type 2 (slow calcium transients) characteristic of astrocytic calcium waves; and Type 3 (non-detectable fluorescence changes). Heterogeneity in cell populations was confirmed by immunocytochemistry against neuronal and glial (MAP2/GFAP) markers. At the population level, both WT and R6/1 include a subset of neurons that display highly coherent activity, indicating the presence of a functional network. Bursting properties of this group are similar between genotypes. Blockade of $GABA_A$ receptors by bicuculline increased number of active neurons while decreased astrocytic signal. Also, the previously reported silent population became active, showing a characteristic neuronal activity profile. The large silent population was inhibited in basal conditions, but the underlying network is revealed through system-wide disinhibition. Indeed, bicuculline boosts coherent activity throughout the culture and increases burst duration and amplitude, but not frequency, in both genotypes. These results indicate that striatal network dysfunction in HD may not arise from local disinhibition but probably from aberrant afferent activity. Therefore, further analysis is required to characterize the contribution of different neurotransmitter systems to the striatal network dynamics in healthy and HD cultures. Understanding functional network alterations mediated by mHtt is fundamental to decipher initial key mechanisms to finally target early symptoms in HD.

Title: Inhibiting sphingosine kinase 2 mitigates mutant huntingtin-induced neurodegeneration

Authors: *N. UZOR[1], J. MORUNO MANCHON[1], M. P. BLASCO[1], S. MANNURU[1], N. PUTLURI[2], E. E. FURR-STIMMING[1], A. S. TSVETKOV[1]
[1]McGovern Med. Sch., Houston, TX; [2]Baylor Col. of Med., Houston, TX

Abstract: Huntington disease (HD) is the most common inherited neurodegenerative disorder. It has no cure. The protein huntingtin causes HD, and mutations to it confer toxic functions to the protein that lead to neurodegeneration. Thus, identifying modifiers of mutant huntingtin-mediated neurotoxicity might be a therapeutic strategy for HD. Sphingosine kinases 1 (SK1) and 2 (SK2) synthesize sphingosine-1-phosphate (S1P), a bioactive lipid messenger critically involved in many vital cellular processes, such as cell survival. In the nucleus, SK2 binds to and inhibits histone deacetylases 1 and 2 (HDAC1/2). Inhibiting both HDACs has been suggested as a potential therapy in HD. Here, we found that SK2 is nuclear in primary neurons and, unexpectedly, overexpressed SK2 is neurotoxic in a dose-dependent manner. SK2 promotes DNA double-strand breaks in cultured primary neurons. We also found that SK2 is hyperphosphorylated in the brain samples from a model of HD, the BACHD mice. These data suggest that the SK2 pathway may be a part of a pathogenic pathway in HD. ABC294640, an inhibitor of SK2, reduces DNA damage in neurons and increases survival in two neuron models of HD. Our results identify a novel regulator of mutant huntingtin-mediated neurotoxicity and provide a new target for developing therapies for HD.

Title: Up-regulation of EAAT2/GLT1 normalizes multiple components of striatal glutamate transmission in the Q175 mouse model of Huntington’s disease

Authors: *C. RANGEL BARAJAS, I. CORONEL-MORALES, G. V. REBEC
Psychological and Brain Sciences, Program in Neurosciences, Indiana Univ., Bloomington, IN

Abstract: Dysregulation of glutamate transmission is a key feature of Huntington’s disease (HD), a dominantly inherited condition characterized by progressive striatal degeneration and dysfunctional corticostriatal circuits. The major glutamate transporter, excitatory amino acid transporter 2 (EAAT2) or its mouse homolog (GLT1), is down-regulated in both HD patients and transgenic mouse models of HD. We previously reported that EAAT2 up-regulation by intravascular administration of recombinant adeno-associated virus serotype 9 (AAV9) reverses some key motor deficits as well as corresponding changes in striatal electrophysiological activity for several months in the heterozygous Q175 mouse model. Here, we determined if AAV9-

mediated up-regulation of EAAT2 also normalizes other components of striatal glutamate transmission, such as the glial cystine/glutamate exchanger (xCT) and the NMDA receptor subunits, NR2A and NR2B. By exchanging intracellular glutamate for cystine, xCT works closely with GLT1 to maintain glutamate homeostasis, which is altered in HD. Moreover, NMDA receptors have been implicated in HD neurodegeneration. For example, although synaptic NMDA receptors activate cellular survival pathways, extra-synaptic NMDA receptors activate pathways that promote cell death (Hardingham and Bading, Nat. Review Neurosci., 11:682-696, 2010). Importantly, these extra-synaptic receptors are preferentially comprised of NR2B subunits, which are increased in the striatum of a pre-symptomatic HD mouse model (Milnerwood et al., Neuron, 65:178-190, 2010). AAV9-EAAT2 or vehicle was administered to Q175 mice or wild-type (WT) controls at 6 or 7 months of age and striatal tissue was evaluated subsequently by western blot at 10 and 14 months of age, when Q175 neurological signs begin to appear. We found that just as the down-regulation of EAAT2 in Q175s was reversed at 10 and 14 months of age, AAV9-EAAT2 also reversed the decreased expression of xCT at the same ages. Interestingly, AAV9-EAAT2 differentially affected the NMDA receptor subunits. Expression of the NR2B subunit, which is elevated in vehicle-treated Q175 relative to WT mice, was significantly decreased at both 10 and 14 months. In contrast, NR2A expression, which declines in vehicle-treated HD mice relative to WT, is at least partially elevated by AAV9-EAAT2. Collectively, these data show that restoration of EAAT2 expression in the Q175 model normalizes multiple components of striatal glutamate transmission and thus could serve as a therapeutic strategy for HD.

Title: Transcriptomic analysis of the YAC128 HD mouse model shows disease mechanisms are ameliorated by pridopidine

Authors: R. KUSKO[1], M. GEVA[2], J. DREYMANN[2], M. POULADI[3], *J. ROSS[1], Y. CHA[1], R. ESCALANTE[1], B. ZESKIND[1], D. LAIFENFELD[2], A. ORBACH[2], R. LAUFER[2], I. GROSSMAN[2], M. R. HAYDEN[2]
[1]Immuneering Corp., New York, NY; [2]Teva Pharmaceut. Industries Ltd, Netanya, Israel; [3]Natl. Univ. of Singapore, Singapore, Malaysia

Abstract: Huntington Disease (HD) is a neurodegenerative disorder hallmarked by the expression of a mutant form of the huntingtin gene (mHtt). A therapeutic goal for HD treatment involves the restoration of neurobiological pathways disrupted by mHtt. Pridopidine, an investigational HD drug candidate, has been shown to improve motor symptoms in both preclinical models as well as in HD patients. While originally described as a dopaminergic stabilizer, in vitro binding studies show highest affinity of pridopidine to the sigma-1 receptor. We previously reported that pridopidine upregulates BDNF, glucocorticoid receptor (GR), and dopamine 1 receptor (D1R) signaling pathways in WT rat striatum. To expand on these findings and explore molecular changes specific to HD, we repeated this study in a YAC128 HD mouse model whereby mice were treated with pridopidine or vehicle starting at postnatal week 6 and sacrificed after 11.5 months of age. We then performed RNAseq data analysis on the striatum. We identified 1346 differentially expressed genes (DEGs) in vehicle treated YAC128 mice vs. healthy controls, 221 DEGs in YAC128 mice treated with 30 mg/kg of pridopidine vs. vehicle, and 73 DEGs in YAC128 mice treated with 10 mg/kg of pridopidine vs. vehicle (all adj.$p<0.05$). In addition, the previously reported pridopidine-induced upregulation of BDNF, GR, and D1R pathways was confirmed after treatment with either dose (adj.$p<0.05$), and alternatively spliced genes after 30 mg/kg of pridopidine compared to YAC128 vehicle are enriched for the BDNF pathway (adj.$p<0.05$). Further, pathway analysis of DEGs after 30 mg/kg dosage revealed enrichment for biological processes related to synaptic transmission, including upregulation in the key HD-impaired processes - cAMP and calcium signaling (adj.$p<0.05$). Lastly, since mHtt was shown to induce neurotoxicity by promoting M1 microglia that secrete proinflammatory cytokines, enrichment analysis tested for microglial markers. Treatment with 30 mg/kg of pridopidine led to the downregulation of genes associated with M1 activation (adj.$p<0.05$). To summarize, pridopidine induces transcriptional modifications reversing genes in HD-impaired pathways involved in neuronal transmission and protection in the YAC128 striatum.

Abstract: Huntington's disease (HD) is an autosomal dominant genetic disorder characterized by cognitive and motor deficits. Currently, there is no cure for HD, only therapies to relieve symptoms. Since HD is progressive and has a generally late-onset, isolating early and reliable markers of the disease is important for targeted therapeutic intervention. Electrophysiological dysfunction long precedes neuronal death and may therefore serve as a useful biomarker. Specifically, EEG oscillatory disturbances are seen in premanifest gene-positive patients and may serve as an early biomarker. Identification of these biomarkers may be useful in testing the efficacy of potential treatment strategies. We used Q175 heterozygotic mice to measure disturbances in oscillatory synchrony in basal ganglia and cortical circuits during disease progression. Using 4 different age groups (8-18 weeks, 19-29 weeks, 30-40 weeks, and 41-51 weeks) spanning presymptomatic through symptomatic stages and recording EEGs/LFPs from the striatum, thalamus, frontal cortex, and occipital cortex, we found age-dependent disruptions in relative delta power in the striatum and thalamus as well as a disruption in the anterior posterior gradient of qEEG power at the delta and alpha frequencies. After identifying these alterations, the striatum was injected with a zinc finger protein (ZFP), thought to reduce mutant huntingtin aggregates (mHtt), in a separate cohort of mice (aged 30-50 weeks). We verified a 30% reduction of mHtt aggregates in the striatum 8 weeks post ZFP injection. The mHtt aggregate reduction was associated with an attenuation of the EEG oscillatory dysfunction seen in the basal ganglia and cortex of HD mice. Overall, these studies suggest that disruptions in oscillatory synchrony may be a useful early biomarker in HD and that ZFP-induced reduction in mHtt aggregates is a promising treatment strategy.

Abstract: Postmortem analysis of patients with Huntington's disease (HD) has shown extensive degeneration of striatal medium-sized spiny neurons (MSNs), the major output projection neurons in the striatum. MSN degeneration has been well characterized in several mouse models of HD, including the Q175 knock-in model that contains the human mutant huntingtin allele (mHtt) with an expanded CAG tract (~175 repeats) within the native mouse huntingtin gene. However, few reports describe how striatal GABAergic interneurons are affected in these mice as the disease progresses. In order to assess how interneurons may contribute to the HD phenotype, we crossed heterozygous Q175 mice with Lhx6-EGFP mice allowing for visualization of fast-spiking interneurons (FSIs) and persistent low-threshold spiking (PLTS) interneurons. Using whole-cell patch clamp electrophysiology, we characterized these two populations of GABAergic interneurons in presymptomatic (2-3 month-old) and symptomatic (12 month-old) mice. In 12 month-old mice we found FSIs exhibited abnormal passive membrane properties (decreased cell capacitance, increased input resistance and decreased membrane time constant), suggestive of degenerative changes in symptomatic mice, while PLTS interneurons appeared spared. However, both types of interneurons displayed increased excitability. The resting membrane potential was more depolarized in Q175 FSIs compared to wild-type at only the symptomatic age and input-output curves showed increased firing in these interneurons. Moreover, PLTS interneurons, that normally display spontaneous firing, exhibited an increase in the frequency of burst firing in symptomatic mice when compared to wild-types. We also showed that Q175 FSIs receive fewer spontaneous excitatory synaptic inputs at the older age, while inhibitory inputs remained unchanged throughout the disease progression. There were no differences in the frequency of spontaneous synaptic input in PLTS interneurons at both ages tested. Based on these observations, we conclude that both FSIs and PLTS interneurons are distinctly affected in this HD model as the disease progresses, which ultimately can lead to an imbalance in inhibitory tone in the HD striatum.

Title: Cdk5 contributes to Huntington's disease learning and memory deficits via modulation of brain region-specific substrates

Authors: E. ALVAREZ-PERIEL[1,2,3], M. PUIGDELLIVOL[1,2,3], V. I. BRITO[1,2,3], F. PLATTNER[4], J. A. BIBB[5], J. ALBERCH[1,2,3], *S. GINES-PADROS[1,2,3]

Abstract: Cognitive deficits are a major hallmark of Huntington´s Disease (HD) with a great impact on the quality of patient's life. Gaining a better understanding of the molecular mechanisms underlying learning and memory impairments in HD is therefore, of critical importance. Cdk5 is a proline-directed Ser/Thr kinase involved in the regulation of synaptic plasticity and memory processes that has been associated with several neurodegenerative disorders. In this study, we aim to investigate the role of Cdk5 in learning and memory impairments in HD using a novel animal model that expresses mutant huntingtin (mHtt) and has genetically reduced Cdk5 levels. Genetic reduction of Cdk5 in mHtt knock-in mice attenuated both corticostriatal learning deficits as well as hippocampal-dependent memory decline. Moreover, the molecular mechanisms by which Cdk5 counteracts the mHtt-induced learning and memory impairments appeared to be differentially regulated in a brain region-specific manner. While the corticostriatal learning deficits are attenuated through compensatory regulation of NR2B surface levels, the rescue of hippocampal-dependent memory was likely due to restoration of hippocampal dendritic spine density along with an increase in Rac1 activity. This work identifies Cdk5 as a critical contributor to mHtt-induced learning and memory deficits. Furthermore, we show that the Cdk5-downstream targets involved in memory and learning

decline differ depending on the brain region analysed suggesting that distinct Cdk5 effectors could be involved in cognitive impairments in HD.

Title: Characterization of the onset and severity of synaptic plasticity deficits in the Q175FDN knock-in mouse model of Huntington's disease

Authors: *J. G. QUIRION, M. P. PARSONS
Biomed. Sci., Mem. Univ. of Newfoundland, St John's, NL, Canada

Abstract: Huntington’s Disease (HD) is a progressive neurodegenerative disease characterized by motor, psychiatric and cognitive disturbances and is caused by a CAG repeat in the first exon of the gene encoding the huntingtin protein. Few studies have examined the cellular mechanisms underlying the cognitive deficits in HD, although many patients report the cognitive symptoms to be the most debilitating. Currently, there is a poor understanding of how the disease-causing mutant huntingtin protein affects cognition at the cellular level. Changes in synaptic plasticity in the hippocampus are thought to underlie cognitive processes such as learning and memory. As such, studying hippocampal synaptic plasticity can foster an understanding of the neural underpinnings of cognitive deficits in HD. This study aimed to examine the progression of synaptic correlates of cognitive decline in HD by studying hippocampal long term potentiation (LTP) at different stages of disease progression in Q175FDN mice, a slowly-progressing knock-in mouse model of HD with clear cognitive deterioration in both heterozygous and homozygous mutation carriers. Golgi staining was also used to examine changes in pyramidal neuron spine density and morphology in order to relate these findings to any observed changes in synaptic excitability and plasticity. Surprisingly, despite the high expression level of mutant huntingtin and the clear cognitive deficit at 9 months of age in this model, heterozygous Q175FDN mice had intact LTP, spine density and spine morphology at three, six, and nine months of age. In stark contrast, homozygote Q175FDN mice showed clear deficits in LTP starting at three months as well as an increase in basal excitability and spine density that were later decreased at nine

months. Thus, the LTP deficit in homozygote mice is unlikely to be explained solely by weak synaptic connectivity under basal conditions. As Q175FDN mice have higher expression levels of mutant huntingtin compared to prior knock-in models, the dramatic difference in synaptic plasticity between heterozygous and homozygous mice suggests a potential protective role for the presence of non-pathogenic huntingtin in the heterozygous mice. Future studies will explore the possibility that long-term reductions in non-pathogenic huntingtin may impact synaptic plasticity. In all, our data suggests that the plasticity deficits in the HD hippocampus are complex and are heavily impacted by the expression level of mutant huntingtin and/or the loss of non-pathogenic huntingtin.

Title: TSPO-PET imaging using ^{18}F-PBR06 is a potential biomarker for monitoring therapeutic Efficacy in Huntington's Disease: preclinical evidence with the small molecule p75^{NTR} ligand LM11A-31

Authors: *D. A. SIMMONS[1], M. L. JAMES[2], N. P. BELICHENKO[1], S. SEMAAN[1], C. CONDON[1], J. C. KUAN[1], A. SHUHENDLER[2], Z. MIAO[2], F. T. CHIN[2], F. M. LONGO[1]
[1]Neurol. and Neurolog. Sci., [2]Dept. of Radiology, Mol. Imaging Program, Stanford Univ., Stanford, CA

Abstract: Huntington's Disease (HD) is a fatal neurodegenerative disorder caused by an expanded CAG repeat in the gene encoding the huntingtin protein. No therapy exists for delaying the onset or slowing the progression of HD. The search for disease-modifying treatments would benefit from non-invasive biomarkers that monitor disease progression and therapeutic efficacy in HD mouse models and human trials. One potential biomarker is examining translocator protein 18kDa (TSPO) by positron emission tomography (PET) imaging to detect microglial activation, a key contributor to HD neurodegeneration. PET imaging with [^{11}C]PK11195, a first

generation TSPO tracer with poor specificity and sub-optimal brain permeability, detected activated microglia in pre-symptomatic HD patients and correlated with disease onset and severity. Second generation TSPO-PET radiotracers (e.g., [^{18}F]PBR06) with improved sensitivity have been developed, but have yet to be evaluated in HD patients. Moreover, whether TSPO-PET can detect microglial activation in HD mouse models or monitor therapeutic efficacy in HD is unknown. Thus, the ability of [^{18}F]PBR06-PET to detect microglial activation and to monitor treatment response of the p75^{NTR} ligand LM11A-31, previously shown to reduce microglial activation in HD mice, was assessed in two HD mouse models. LM11A-31 was orally administered (50 mg/kg, daily 5 days/week) to R6/2 and BACHD mice for 7 weeks and 7 months, respectively. [^{18}F]PBR06-PET/CT images were acquired at a late disease stage for R6/2 mice (11-12 weeks old) and early and mid-symptomatic stages for BACHD mice (5 and 9 months old). [^{18}F]PBR06-PET signal was elevated in the striatum, cortex and hippocampus of vehicle-treated R6/2 mice versus age-matched wild-types and LM11A-31-treated R6/2 mice had significantly reduced [^{18}F]PBR06 accumulation. Notably, [^{18}F]PBR06-PET signal was also significantly increased in mid-, but not early, symptomatic BACHD mice in all brain areas examined and ameliorative effects of LM11A-31 on neuroinflammation were discerned. In both mouse models, [^{18}F]PBR06-PET signal correlated with increased immunostaining for IBA-1, an activated microglia marker, and western immunoblotting for TSPO. These results are the first to show that TSPO-PET imaging can track microglial activation and monitor therapeutic efficacy in HD mice, indicating that it is a potential translatable biomarker for preclinical to clinical HD testing. Since LM11A-31 is currently in phase IIa clinical trials for Alzheimer's disease, having a biomarker capable of detecting therapeutic efficacy, as shown here with TSPO-PET, could expedite its advancement to HD clinical trials.

Title: Neuroprotection by NF-κB subunit RelA/P65 in cell culture models of Huntington's disease and spinocerebellar ataxia type-1

Authors: *Y. ZHANG, ***Y. ZHANG**, J. FRANKLIN, S. D'MELLO
Biol. department, Southern Methodist Univ., Dallas, TX

Abstract: We and other labs and previously described that RelA/p65, a subunit of the NF-kB transcription factor, protects cultured neurons against death induced by a variety of apoptosis-inducing stimuli. We have now extended these studies to cell culture models of neurodegenerative diseases. We report that overexpression of p65 is protective in cell culture models of Huntington's disease (HD) and Spinocerebellar ataxia type 1(SCA1) utilizing cortical and cerebellar granule neurons, respectively. We previously described that expression of endogenous p65 is not altered in various paradigms of neuronal apoptosis. We find that expression was not discernibly altered in the striatum of R6/2 mice, a commonly used mouse model of HD. we investigated whether posttranslational modifications including acetylation and phosphorylation sites or protein-protein interactions were involved. Mutation of five different acetylation sites either individually or in combination had no effect on mut-Htt-mediated neuroprotection Similarly, mutation of two separate phosphorylation sites, Ser 467 and Ser 534, had no effect. Co-immunoprecipitation analyses showed that p65 interacted with huntingtin (Htt), but not with SCA-1, a finding that was confirmed through co-localization studies. While interacting between p65 and wild-type Htt was strong, it was lower with mutant-Htt. Further analysis using deletion constructs localized interaction of p65 to the 1 - 75 amino acid region of Htt. Current research is aimed at understanding in more detail the mechanism by which p65 protects against neurotoxicity by mutant-Htt and mutant-SCA1.

Title: Reduced expression of Foxp1 as a contributing factor in Huntington's disease

Authors: *A. LOUIS SAM TITUS[1], S. R. D'MELLO[2]
[1]Dept. of Mol. and Cell Biol., UNIV OF TEXAS AT DALLAS, Dallas, TX; [2]Biol. Sci., Southern Methodist Univ., Dallas, TX

Abstract: Huntington's disease (HD) is an inherited neurodegenerative disease caused by a polyglutamine expansion in the huntington protein (*htt*). The neuropathological hallmark of HD is the loss of neurons in the striatum and, to a lesser extent, in the cortex. *Foxp1* is a member of

the Forkhead family of transcription factors expressed selectively in the striatum and the cortex. In the brain, three major *Foxp1* isoforms are expressed - isoform-A (~90 kDa), isoform-D (~70 kDa) and isoform-C (~50 kDa). We find that expression of *Foxp1* isoforms A and D is selectively reduced in the striatum and cortex of R6/2 HD mice as well as in the striatum of HD patients. Furthermore, expression of mutant *htt* in neurons results in the downregulation of *Foxp1*. Elevating expression of isoform A or D protects cortical neurons from death caused by the expression of mutant *htt*. On the other hand, knockdown of *Foxp1* promotes death in otherwise healthy neurons. Neuroprotection by *Foxp*1 is likely to be mediated by the transcriptional stimulation of the cell cycle inhibitory protein, $p21^{Waf1/Cip1}$. Consistently, *Foxp1* activates transcription of the $p21^{Waf1/Cip1}$ gene promoter and overexpression of *Foxp1* in neurons results in the elevation of p21 expression. Moreover, knocking down of $p21^{Waf1/Cip1}$ blocks the ability of *Foxp1* to protect neurons from mut-Htt-induced neurotoxicity. We propose that the selective vulnerability of neurons of the striatum and cortex in HD is related to the loss of expression of *Foxp1*, a protein that is highly expressed in these neurons and required for their survival.

Abstract: OBJECTIVES: To assess cortical microstructural changes in Huntington's disease (HD) patients and its correlation with cortical thickness and striatal volumes**,** using surface based laminar analysis of diffusion abnormalities. **METHODS:** 6 symptomatic HD patients (CAG repeats: median=45.5; IQR= 4; 55± 10.72 years) and 6 healthy controls (HC, 33±10.7years) underwent Magnetic Resonance Imaging to assess cortical lobes thickness and striatal volumes, Magnetic Resonance Spectroscopy to examine neuronal integrity in deep white matter structure, centrum semiovale (8x8 voxel), and diffusion tensor imaging (DTI) to assess white matter (WM) and grey matter (GM) diffusivity. **RESULTS:** As shown previously, HD patients presented evidence of neuronal loss compared to HC, reflected by reduced average cortical thickness

(frontal: 2.4±0.07mm v. 2.5±0.1; parietal: 2.1±0.2mm v. 2.4±0.1; occipital: 1.9±0.2mm v. 2.1±0.08 lobes), reduced subcortical volumes (caudate: 4.0±1.3mm^3 v. 7.7±1.2mm^3; putamen: 6.0±2.8 mm^3 v. 11.8±0.6 mm^3; pallidum: 1.8±0.6 mm^3 v. 3.4±0.3 mm^3), and reduced N-acetylaspartate to creatinine ratio (1.6±0.2 v. 2.0±0.1). Disruption of tissue architecture was also evidenced by higher radial diffusivity of whole brain WM in HD compared to HC (p=0.03), consistent with previous findings. Moreover, we were able to demonstrate loss of cortical tissue integrity using surface based laminar analysis of GM DTI parameters. A marked increase in axial (AD), radial (RD) and mean diffusivity (MD) was reported in the frontal (p=0.02, 0.01, and 0.02, respectively), temporal (p=0.03, 0.03, and 0.03, respectively), parietal (p=0.03, 0.02 and 0.04, respectively) and occipital lobes (p=0.03, 0.02, and 0.03, respectively) in the HD v. HC. Furthermore, DTI measures were significantly correlated with cortical thickness in the parietal (AD: r=-0.99, p=0.002; RD: r=-0.92, p=0.005; MD: r=-0.99, p=0.002), temporal (MD: r=-0.9, p=0.04; AD: r=-0.9, p=0.04), and occipital lobes (AD: r=-0.95, p=0.01; RD: r=-0.95, p=0.01; MD: r=-0.99, p=0.002). **CONCLUSION:** HD group showed higher cortical MD, AD, and RD, possibly reflecting microstructural changes such as dendritic and synaptic remodeling, and cytoskeletal alterations at the level of cortical neurons prior to degeneration. Diffusivity changes were evident in temporal lobe prior to its thinning, suggesting potential role as an earlier marker to track disease progress.

Title: Irritability in Huntington's Disease: A phase II exploratory clinical trial with a novel vasopressin 1a antagonist, SRX246

Authors: *S. M. HERSCH[1], ***S. M. HERSCH**[1], S.-F. LU[2,3], K. E. ANDERSON[4], M. J. BROWNSTEIN[2], N. G. SIMON[2,3]
[1]Dept Neurol., Massachusetts Gen. Hosp. Dept. of Neurol., Charlestown, MA; [2]Azevan Pharmaeuticals, Inc., Bethlehem, PA; [3]Biol. Sci., Lehigh Univ., Bethlehem, PA; [4]Psychiatry and Neurol., Georgetown Univ. Med. Ctr., Washington, DC, DC

Abstract: Psychiatric symptoms, including irritability and aggression, are common in HD patients. These are among the most distressing aspects of the disease, adversely impact daily life, and often result in institutionalization. Despite their frequent occurrence and severe consequences, these symptoms have received little attention. Effective treatments are lacking and well-validated scales for measuring changes in these symptoms are not available.
The current Phase II clinical trial in HD patients (n=108), Safety and Tolerability of SRX246 In Irritable/Aggressive Subjects with Huntington's Disease (NCT02507284), is designed to rigorously evaluate the tolerability of a new drug, SRX246, for the treatment of irritability and aggression; provide additional safety data; and explore various rating scales for the assessment of changes in these symptoms. The objective is to obtain critical data that can be used to plan future Phase IIb or III clinical trials. STAIR is a 3 arm, multicenter (22 NeuroNEXT Network sites), randomized, placebo-controlled, double-blind, 12-week dose escalation study. Following eligibility determination, subjects are randomized to receive placebo, or escalate from 80 mg (two weeks) to 120 mg, up to a maximum dose 160 mg twice daily of SRX246 for 12 weeks. Each subject has a study partner to assist with visits, taking study medication, and providing feedback about the subject's mood and behavior. As of May 1, 51 subjects were randomized, 23 have completed the protocol, and 16 additional individuals have consented. Compliance has been very good and while we are blinded, the AE profile and tolerability are consistent with other trials that show good safety and tolerability.
The test compound, SRX246, is a first-in-class vasopressin 1a receptor antagonist. It is orally bioavailable, exhibits high affinity and selectivity for its target, has a strong safety profile in healthy volunteers, and excellent pharmacokinetics. Preclinical pharmacology and an experimental medicine fMRI study in healthy volunteers showed that SRX246 has CNS effects after oral administration and that it modulates brain circuits involved in responses to stimuli that elicit aggression/fear. In a recently completed Phase II Exploratory trial for the treatment of Intermittent Explosive Disorder, SRX246 was well tolerated, no serious adverse events were reported, and exploratory analyses revealed statistically significant differences favoring SRX246 in key outcome measures of clinical benefit. These findings strongly suggested that SRX246 might have a beneficial effect on the irritability and aggression seen in a sizable proportion of HD patients.

Title: Identifying functional regulatory units in Huntington's Disease Mouse Models using a population based evolutionary algorithm

Authors: *S. ALLAM, T. H. RUMBELL, T. TRONG, A. PONZI, J. R. KOZLOSKI
Computat. Biol. Ctr., IBM Res., Yorktown Heights, NY

Abstract: Symptomatic R6/2 mouse model and Q175 exhibit numerous electrophysiological variations from the wild type. Passive and active membrane properties such as (membrane voltage, rheobase, average number of spikes per stimulus, spike onset latency) of MSNs are altered and affect the integrative properties of the basal ganglia circuitry. We used a population based evolutionary algorithm to reproduce the range of biophysical features of wild type and Huntington's disease (HD) mouse model MSNs in a computational MSN model built using IBM's Neural Tissue Simulator. Principal component analysis was performed on those models to identify the key functional regulatory units that transform the wild type membrane properties to the HD phenotype. We discuss how our approach for finding low dimensional descriptions of disease phenotypic conversion in neuronal models may allow target identification for pharmacological intervention to alleviate HD symptoms in these neurons.

Title: Results of a phenotypic HTS to identify small molecule modulators of mutant HTT levels in hES cells as HD therapies

Authors: O. LAZARI[1], A. MUKONOWESHURO[1], B. NANCOLAS[1], C. TURNBULL[1], I. GOWERS[1], M. IOVINO[1], C. PAULE[1], R. JARVIS[1], P. BRECCIA[1], T. LADDUWAHETTY[1], G. MCALLISTER[1], E. DOHERTY[2], *J. A. BARD[2], D. MACDONALD[2], A. HOWARD[2], C. DOMINGUEZ[2], I. MUNOZ-SANJUAN[2]
[1]Charles River, Cambridge, United Kingdom; [2]CHDI Management, Inc., Princeton, NJ

Abstract: Lowering of the pathogenic mutant huntingtin (mHTT) protein in Huntington's disease (HD) patients is one of the leading approaches to ameliorate the fatal neurodegeneration caused by the poly-CAG expansion in the *HTT* gene.
Although HTT lowering therapies based on siRNA/ASOs/ZFPs are in development, they all have challenges in terms of invasive dosing routes and schedules, and relatively poor distribution to overcome. Therefore, identification of brain penetrant small molecules, with convenient oral dosing and systemic distribution, would potentially be advantageous over these novel biological agents.
Previous efforts to identify small molecule HTT lowering agents have generally used highly expanded HTT polyQ repeats, non-specific readouts such as cytotoxicity or aggregation, or used the *HTT* gene in a non-native genomic context. These efforts have not delivered clinically relevant candidates.
In an attempt to identify novel agents reducing disease and physiologically relevant mHTT levels, we have developed a phenotypic assay suitable for HTS of large compound collections. HD human ES (hES) cells, with a clinically-relevant CAG expansion [Q48] HTT allele under the control of the endogenous promoter, are plated in a 384-well plate and challenged with small molecules for 48 h. Cells are then lysed and mHTT and total HTT are detected by sensitive antibodies to epitopes in the N-terminal of the protein in a HTRF format. Toxicity is monitored by ATP determination as a surrogate for cell number. Assay statistics (robust Z' >0.4; S:B >4) supported using the assay in an HTS format.
As these assays are able to measure changes in the downstream HTT protein levels, they are not biased to identify molecules which only affect a hypothetical endpoint of HTT toxicity (e.g., aggregation) or a single mode of action (e.g., via changes in transcription, translation, or clearance).
We used this assay to screen a diverse compound library of ~120K compounds from the CHDI collection. Hit matter was reliably detected and showed good translation in an IC50 format, where compounds mediating effects via significant toxicity were removed from the screening cascade.
A screening cascade for hits with a window over toxicity to potentially define different mechanisms of action was used, culminating in the use of HD hES-derived neuronal cells from the primary screening hES line to measure whether the effects of hits are maintained in a neuronal phenotype.
A review of this first successful screening campaign and its output will be presented along with lessons learned and future plans for the phenotypic approach to identify novel compounds suitable for pre-clinical validation as HTT lowering agents.

Abstract: Huntington’s disease (HD) is an autosomal dominant genetic disease caused by the abnormal expansion of the cytosine-adenine-guanine (CAG) repeat in mutant huntingtin gene. The neuronal loss was found initially in the striatum and cortex, later in other brain regions of HD patients. The alteration in synaptic transmission were reported before the initial neuronal loss in striatum and cortex. The detailed mechanisms of altered synaptic transmission in HD has not been fully understood yet. We investigated the input of the vulnerable corticostriatal synapses using real-time imaging at single presynaptic terminals. We measured the exocytosis of synaptic vesicles at single bouton level. We applied lipophilic FM 1-43 (a styryl dye) during electrical stimulation to label synaptic vesicles in cultured cortical neurons of Q175 knock-in (Q175) mice, which is closely relevant to human HD patients. FM de-staining showed that more synaptic vesicles in heterozygous neurons of Q175 mice were released than wild type. Consistently, electrophysiological results also showed decreased paired-pulse ratio in those cortical neurons. Therefore, we concluded that the release probability was increased in cortical neurons of heterozygotes. We further examined possible mechanisms of the increased release probability

using calcium imaging of presynaptic terminals with Cal520-AM (an ultrasensitive fluorescent Ca^{2+} probe). We found significant increase of Ca^{2+} influx during the electrical stimulation. Our results indicate that higher influx of Ca^{2+} during the stimulation may lead to increased release probability at cortical terminals. The application of BAPTA-AM (a Ca^{2+} chelator) rescued altered release probability in heterozygous cortical neurons, which further confirms our hypothesis. Our work will advance the current understanding of synaptic transmission at early stage of HD and contribute to finding therapeutic targets for HD.

Title: Cellular modeling of spiny projection neurons in a Huntington's disease mouse model

Authors: *H. SONG[1], J. GOODLIFFE[2], J. I. LUEBKE[3], C. M. WEAVER[1]
[1]Dept. of Mathematics and Computer Sci., Franklin & Marshall Col., Lancaster, PA; [2]Anat. & Neurosci., [3]Anat. & Neurobio., Boston Univ. Sch. of Med., Boston, MA

Abstract: Huntington’s disease (HD) is a fatal neurodegenerative disease with symptoms including involuntary movement, impaired judgment, personality change and depression. In HD, Spiny projection neurons (SPNs) of the striatum undergo structural and functional neuropathology in HD, but the mechanisms underlying this pathology remain unclear. Q175, a widely used transgenic HD mouse model, exhibits molecular phenotype changes, neuronal dysfunction, and subtle yet significant movement disorders. This study aims to model empirically characterized direct and indirect pathway SPNs (dSPNs and iSPNs respectively) in both wildtype (WT) and Q175 animals, to further our understanding of cellular changes in HD. Adapting a published multicompartment SPN model, we constructed stylized morphologies for dSPNs and iSPNs from WT and Q175 mice. These morphologies were consistent with morphometrics from digital reconstructions, demonstrating extra dendritic branching and lower spine density in Q175. Then we applied our custom-written parameter optimization method, implemented in NEURON, on compartmental conductance-based model SPNs to obtain model

parameters that minimize the difference between model output and empirical data. We fit the model to data from several neurons from WT dSPNs, WT iSPNs, Q175 dSPNs and Q175 iSPNs. Simulations showed that Q175 SPNs generally had lower membrane capacitance, reduced conductance and slower kinetics for the inward rectifying potassium channel at hyperpolarizing current injections, consistent with previous *in vitro* experimental results. Moreover, it was discovered that iSPNs were more excitable than dSPNs at depolarizing current injections, as observed empirically, due to several intrinsic properties differences of channel gating such as an increased conductance of fast sodium channel and decreased conductance of voltage dependent calcium channels. We also modeled synaptic responses (AMPA, GABA and NMDA), to examine how the morphologic and physiological differences of each neuron type might compound the reduced excitatory and increased inhibitory post-synaptic currents seen in Q175 compared to WT mice. This modeling study provides the first cellular model of SPNs in the Q175 HD mouse, predicting how intrinsic and synaptic properties contribute to observed firing patterns in HD, which in turn affect the striatal microcircuit.

Title: Intranasal administration of mesenchymal stem cells leads to improved survival and ameliorates behavioral phenotypes in the R6/2 mice of Huntington disease

Authors: *H. NGUYEN[1], L. YU-TAEGER[1], K. ARNOLD[2], L. DANIELYAN[3], A. STOLZING[2], E. SINGER[1], P. BAMBYNEK-DZIUK[1], J. STRICKER-SHAVER[1], A. NOVATI[1], O. RIESS[4]

Abstract: Objectives: Huntington disease (HD) is a fatal neurodegenerative disease that is characterized by progressive impairment of motor and cognitive function and psychiatric disturbance. Although currently there is no treatment that can reverse the course of HD, studies using mesenchymal stem cells (MSCs) have shown considerable effect to ameliorate the behavioral phenotype and brain atrophy following intrastriatal administration in HD rodent models. However, intrastriatal delivery has certain disadvantages for the clinical use due to

invasiveness and host immune response. Recent updates have shown that intranasal administration (INA) of MSCs is a promising route for cell delivery to the brain. In the present study, we aim to evaluate INA as an alternative route for delivering MSCs in HD.
Methods: Bone marrow-derived MSCs at passage 3 were administered intranasally into 4-week-old R6/2 mice, which express N-terminal mutant huntingtin with approximately 140 CAG repeats. Body weight, food intake and survival rate were evaluated until 11 weeks of age. Locomotor activities and motor function were analyzed using the Labmaster system and rotarod tests.
Results: MSC-treated R6/2 mice showed an increased survival rate and decreased body weight loss at a later disease stage compared to R6/2 littermates only receiving PBS. Significantly reduced fine movements during the light phase were found in the MSC-treated group compared to the vehicle treated group, indicating an ameliorated sleep disturbance. Moreover, MSC-treated R6/2 mice exhibited a trend towards an improved rotarod performance.
Conclusion: Our results demonstrate significantly ameliorated phenotypes of R6/2 mice after MSCs administration via INA. This indicates that INA is an effective delivering route of MSCs to the brain for HD therapy.

Title: A novel antibody to monitor oligomeric mutant Huntingtin as a biomarker for Huntington’s disease

Authors: *C.-P. CHANG[1], M.-S. LIN[1], W.-C. SHEN[1], J.-J. SIEW[1], B.-W. SOONG[2], C.-M. CHEN[3], P.-H. TU[1], Y. CHERN[1]
[1]Academia Sinica, Taipei, Taiwan; [2]Neurolog. Inst., Taipei Veterans Gen. Hosp., Taipei, Taiwan; [3]Dept. of Neurol., Chang Gung Mem. Hosp., Taoyuan, Taiwan

Abstract: Huntington’s disease (HD) is a progressive and hereditary neurological disorder, which results from abnormal CAG/polyglutamine expansion (>35) in the N-terminus of *Huntingtin* (*HTT*). PolyQ expansion contributes to the formation of HTT aggregates in the brain and leads to progressive neurological symptoms (e.g. impaired motor and cognitive function,

psychological disorders, brain atrophy, and shorten life span) of HD patients. Mutant HTT (mHTT) has been reported in multiple peripheral tissues and blood cells. Besides mHTT aggregates, soluble mHTT oligomers are also toxic and have been implicated in the pathogenesis of HD. To date, no sensitive biomarker or effective treatment is currently available for HD. In the present study, we investigated whether accumulation of soluble mHTT oligomers in peripheral blood cells may serve as a sensitive and reliable biomarker for the onset and progression of HD. Using several standard methods (such as immunofluorescence staining, dot blot analysis and ELISA) and a newly developed anti-HTT antibody (Habe1) that recognized oligomers and aggregates of mHTT, we found that 1) Habe1 recognized the progressive accumulation of oligomeric and aggregate forms of mHTT in the brains and peripheral blood cells of HD mice (R6/2); 2) Habe1 recognized the oligomeric mHTT in human peripheral blood cells; 3) the level of oligomeric mHTT was altered in human peripheral blood cells during disease progression. Our results suggest that Habe1 could be a powerful tool to monitor oligomeric mHTT as a sensitive biomarker for HD progression.

Nacional Autónoma de México, México D.F., Mexico; [4]Univ. Nacional Autonoma Mexico, Mexico D.F., Mexico

Abstract: Introduction: The striatum is severely affected during the neurodegenerative process in Huntington's disease (HD). However, the possible white matter (WM) changes contribution to the main motor and cognitive impairments is unclear. **Objective:** to characterize WM changes in

incipient patients with HD, and to describe their correlation with the main motor and visuospatial alterations. **Method:** We recruited 22 patients with early clinical course and genetic diagnosis for HD; and 22 controls matched for sex, age and schooling. To evaluate motor performance, we used the UHDRS scale. For visuospatial performance, we used the Montreal cognitive evaluation (MoCA) and the CANTAB Stockings of Cambridge (SOC).Diffusion tensor images (DTI) were acquired by magnetic resonance, and analyzed using tract-based spatial statistics (TBSS), to describe the WM integrity and finally correlated with behavioral scales. **Results:** We found significant WM differences between controls and patients in the bilateral external capsule, forceps minor, forceps major and right superior longitudinal fasciculus. The UHDRS scores correlated with right anterior thalamic radiation, forceps minor, inferior fasciculus, right occipital front, and superior left longitudinal fasciculus. The MoCA-executive/visuospatial domain scores correlated with corpus callosum, left anterior corona radiata, and right inferior occipital frontal fasciculus. SOC performance correlated between number of movements to solve problems and preservation of right anterior corona radiata, inferior right occipital frontal fasciculus, right uncinated fasciculus and inferior fasciculus; and time to solve problems with left external capsule, forceps minor right and corpus callosum. **Conclusion:** An anatomical characterization of the changes in WM from patients with incipient HD was performed and correlated with the main motor and visuospatial alterations.

Title: Implicit visuomotor learning impairment in Huntington's disease correlates with fronto-parietal and striatal atrophy

Authors: *I. VACA-PALOMARES[1], D. C. BRIEN[2], B. C. COE[2], J. FERNANDEZ-RUIZ[3], D. P. MUNOZ[4]
[1]Facultad de Psicología, Univ. Nacional Autónoma De México, Ciudad DE Mexico, Mexico;

[2]Ctr. for Neurosci. Studies, Queen's Univ., Kingston, ON, Canada; [3]Univ. Nacional Autonoma Mexico, Mexico D.F., Mexico; [4]Ctr. for Neurosci. Studies, Queens Univ., Kingston, ON, Canada

Abstract: Background: Implicit visuomotor learning has been studied with the predictive saccade task. In this task the metronomic temporal pattern of the targets allows the participant to predict the targets and actually start anticipating them. This task provides a reliable measure of visuomotor learning by quantifying the proportion of anticipatory saccades. Furthermore, this task is sensitive to neuropathology of different neurodegenerative diseases such as Huntington's disease (HD). Goals: Investigate implicit visuomotor learning and its relationship with neurodegeneration in HD using predictive-saccade task and structural Magnetic Resonance Imaging. Methods: 22 HD patients with molecular diagnosis, mean age 49.6 years ± 11.4, mean disease duration 4.5 years ± 2.9; and 22 healthy volunteers (Ctrl) with mean age 49.9 years ± 10.6 performed the Prediction Task. There were two blocks with 30 trials each. Each trial started with a red central fixation dot. After a small random fixation period, 15 dots appeared 10° left and right in either a left-right-left-right or a right-left-right-left pattern. In the Predictive block participants had to generate saccades toward a small target that alternated at a constant Inter stimulus interval (ISI) of 1000ms between two fixed locations on the horizontal meridian. In the Reactive block the same target alternating between the same two fixed locations, but one of the five ISIs (500, 750, 1000, 1250, 1500ms) was randomly used for each target step. Mean saccadic reaction time (SRT), amplitude and peak velocity were calculated for saccades within both Predictive and Reactive blocks. The study included a T1 3D volume and Diffusion-weighted imaging for both HD and Ctrl. For statistical analysis we conducted Mixed-design ANOVAs (HD/Ctrl x predictive/reactive). T1 and diffusion images were analyzed through the Voxel-based morphometry and Tract-based spatial statistic methodologies respectively. Results: The main finding showed that HD had a significant SRT increase in the predictive block ($F_{(1,43)}$=21.481, p=0.00). Furthermore, these SRTs correlated with grey-matter degeneration in right putamen, left caudate, left inferior parietal lobe and right frontal lobe Brodmann area 45. Conclusions: Our findings suggest that HD patients have implicit visuomotor learning deficits manifested as difficulties to generate anticipatory saccades in the predictive block. These deficits could be explained by fronto-parietal and striatal degeneration. The study of these processes in neurological populations could be useful to generate markers of the progression of cognitive deficits.

Title: Cortical hyperactivity of neuronal microcircuits in a presymptomatic mouse model of Huntington's disease is re-balanced by metformin treatment

Authors: *I. ARNOUX[1], H. WATARI[1], M. WILLAM[2], P. NARAYAN DEY[3], S. SCHWEIGER[2], A. METHNER[3], A. STROH[1]

Abstract: Huntington's disease (HD) is an autosomal dominantly inherited neurodegenerative disorder caused by a poly-glutamine stretch in the protein huntingtin. The mutation confers toxic gains of function of the protein which generates intranuclear and cytoplasmic inclusions and ultimately results in neurodegeneration. Patients suffer from cognitive, psychiatric and motor disturbances, leading to premature death. It becomes more and more apparent that the late-onset clinical phase of HD is preceded by an extended pre-symptomatic phase with subtle molecular and clinical peculiarities. Here, we asked whether cortical network function is already impaired at the presymptomatic stage of the disease prior to neurodegeneration and motor symptoms, employing a network-centered view on early stages HD. We explored activity patterns of intact cortical microcircuits by employing *in vivo* two-photon Ca^{2+} imaging in layer 2/3 of visual cortex of mouse model of HD (HD150 mice; expressing expanded Htt with 150 glutamine repeats) at 10-15 weeks of age, long before the onset of motor symptoms and appearance of huntingtin aggregates. We identified an early pattern of circuit dysregulation characterized by an overall increase of activity, an enhanced synchronicity and a unique functional subgroup of hyperactive neurons. Exploring the potential cause of cortical dysregulation, we found that striatal but not cortical tissue exhibited increased mitochondrial respiration. Interestingly, treating presymptomatic HD150 mice with metformin rebalanced striatal mitochondrial respiration and restored physiological activity patterns of cortical microcircuit pointing to a striatal pathology behind the cortical hyperactivity. Our results suggest that metformin treatment at this very early stage might ameliorate both cellular and network dysregulations, representing a promising novel treatment strategy.

Abstract: Huntington's disease (HD) is a neurodegenerative disease caused by a CAG repeat expansion in the exon-1 of the huntingtin gene. Striatal projection neurons are the main affected population, but the molecular mechanisms that account for this specific vulnerability are not fully characterized. Mutant huntingtin expression disrupts the normal signaling of the mTOR/Akt pathway, and one of the most important functions of mTOR is the regulation of protein translation. Since dysregulation of mTOR pathway, and consequently protein synthesis, has been proposed as a pathogenic mechanism in different neurodegenerative and neurological disorders, here we sought to analyze whether protein translation is altered in HD. For that, we focused on the study of 4E-BP1, a binding protein substarte of mTOR, that inhibits protein translation and whose function is lost upon phosphorylation. We analyzed the phosphorylation status of 4E-BP1 in the striatum of HD mouse models and affected patients. We found that 4E-BP1 is inactivated in HD by increased phosphorylation leading to an increased formation of the eIF4F complex. Accordingly, we detected aberrant *de novo* protein translation at ages when HD mice suffer from motor deficits. Interestingly, normalization of protein synthesis in R6/1 mice, a transgenic mouse model of HD, prevents motor learning deficits. Finally, we observed that genetically increasing protein translation in adult wild-type mice recapitulates HD phenotype and induces neurodegeneration. Our results seem to indicate that dysregulation of protein synthesis is a novel key event in HD pathogenesis.

Title: Dissecting the regulatory mechanism of ubiquitin E3 ligase activity and understanding the importance of such regulation in polyglutamine pathogenesis

Authors: *E. CHAN, Z. CHEN, L. LI
The Chinese Univ. of Hong Kong, Hong Kong, Hong Kong

Abstract: Polyglutamine (polyQ) diseases, including Huntington's Disease and several types of spinocerebellar ataxias, are caused by the genomic expansion of coding CAG trinucleotide sequences. This expansion leads to the production and accumulation of misfolded polyQ domain-containing disease proteins, which causes cellular dysfunction and neuronal death. As one of the principal cellular protein clearance pathways, the activity of Ubiquitin-Proteasome system (UPS) is tightly regulated to ensure efficient clearance of damaged and toxic proteins. Emerging evidence demonstrates that UPS plays a crucial role in the pathogenesis of polyQ diseases. Ubiquitin (Ub) E3 ligase label proteins for proteasomal clearance by catalyzing the transfer of the Ub tag to protein substrates. We recently identified an E3 ligase that modulates expanded polyQ-induced neurodegeneration in both mammalian and *Drosophila* disease models. We further showed that it promotes polyubiquitination and degradation of expanded polyQ protein. Intriguingly, we found that exocyst complex protein 70 (Exo70/EXOC7) modulates expanded polyQ protein level and toxicity in an opposite manner to E3 ligase. Our data suggest that Exo70/EXOC7 exerts, at least in part, its polyQ-modifying effect by regulating the function of E3 ligase. In summary, this study allows us to better define the role of protein ubiquitination in polyQ pathogenesis and understand how E3 ligase activity can be regulated by Exo70/EXOC7.

Title: Latent toxoplasma gondii infection promotes neurodegeneration and increases soluble mutant huntingtin levels in the YAC128 mouse model of Huntington's disease

Authors: *D. DONLEY[1], *D. DONLEY[1], T. JENKINS[2], M. REALING[2], V. CHOPRA[4], S. HERSH[4], J. GIGLEY[2], J. H. FOX[3]
[1]Neurosci. Program, [3]Vet. Sci., [2]Univ. of Wyoming, Laramie, WY; [4]Mass Gen., Charleston, MA

Abstract: Huntington disease (HD) is a fatal neurodegenerative disorder caused by a dominant CAG repeat expansion in the huntingtin gene that manifests with motor, cognitive and psychiatric symptoms. The kynurenine pathway of tryptophan metabolism is a neuroinflammatory pathway implicated in HD pathogenesis. Activity of the first enzyme in this pathway, indoleamine-2,3-dioxygenase (IDO), is increased in HD mouse and human brain. IDO activation also occurs as part of the immune response to the prevalent neuroinvasive human pathogen, *Toxoplasma gondii (T. gondii)* and is required for prolonged control of the infection. Therefore, latent infection activates an HD-associated pathway and may exacerbate disease. We previously reported that N171-82Q HD mice have an altered response to acute *T. gondii* infection (Donley et al. 2016). However, the effect of latent *T. gondii* infection, characterized by intracellular parasite cysts and inflammation in brain, on HD progression is not known. Here we investigated the effects of latent *T. gondii* infection in YAC128 HD mice. Wild-type and HD mice were orally infected at 2 months of age with *T. gondii* or vehicle. Behavior was monitored longitudinally and mice were sacrificed at 12-months of age. Both infection and HD increased IDO activity but there was no statistically significant difference in IDO enzyme activity in infected HD mice. Interestingly, infection increased soluble mutant huntingtin levels in HD mice compared to HD mice without infection. In addition, brain weight of *T. gondii*-infected HD mice was significantly decreased as compared to both non-infected HD mice and wild-type mice with infection. These results are consistent with HD potentiation by latent *T. gondii* infection in the YAC128 mouse model.

Title: Drug testing in a transgenic zebrafish model of neurodegenerative disease identifies drugs that can remove toxic human proteins

Authors: *A. LAIRD[1], M. WATCHON[2], K. YUAN[1], N. J. COLE[1], G. NICHOLSON[3]
[1]Dept. of Biomed. Sci., Macquarie Univ., Sydney, Australia; [2]Univ. of Sydney, Sydney, Australia; [3]ANZAC Res. Inst., Sydney, Australia

Abstract: Spinocerebellar ataxia-3 (SCA3), also known as Machado-Joseph disease, is a fatal neurodegenerative disease that affects neurons of the brain and spinal cord causing impaired movement. SCA3 is caused by inheritance of a long trinucleotide (CAG) repeat region within the *ATXN3* gene. This CAG repeat region encodes for a polyglutamine (polyQ) tract that usually contains less than 43 glutamines (43Q), but in SCA3 patients contains more than 60Q. We have developed the first transgenic zebrafish model of SCA3, zebrafish that express the human ataxin-3 protein containing either 23Q (wild-type) or 84Q (SCA3-causing). The ataxin-3 84Q zebrafish develop impaired swimming ability as early as 6 days old. We have tested the effects of various drug and small compound treatments on these zebrafish and have identified drugs that improve the swimming of the zebrafish. Immunoblot analysis of protein lysates extracted from the SCA3 zebrafish reveal that the drug treatments have produced removal of the human ataxin-3 protein through activity of the autophagy quality control pathway. Development of an ELISA assay to quantify levels of human ataxin-3 protein confirmed the complete removal of human ataxin-3 by one compound. These findings confirm that our transgenic zebrafish model of SCA3 is a useful model of the human disease. We have also identified candidates for further exploration for the treatment of SCA3, and perhaps other neurodegenerative diseases as well.

Mol. Biol., Thomas Jefferson Univ., Philadelphia, PA; [3]The Univ. of Georgia, Athens, GA; [4]Univ. of Groningen, Groningen, Netherlands

Abstract: Spinal and Bulbar Muscular Atrophy (SBMA; Kennedy's Disease) is an adult-onset, slowly-progressive, X-linked neuromuscular disease. SBMA results from a CAG repeat expansion in the coding region of the androgen receptor (AR) gene, leading to a polyglutamine (polyQ) repeat expansion in the amino-terminal domain of the AR protein. Patients present with weakness and atrophy of muscles of the limbs, mouth, and throat. These symptoms result from the loss of lower motor neurons and skeletal muscle atrophy. A histopathological hallmark of SBMA, as well as other polyQ-repeat diseases, is the presence of intranuclear inclusions of the polyQ-expanded AR protein. To date, there is no curative treatment or effective therapy for SBMA. We have previously shown that hormone-dependent AR acetylation at K630/632/633 is a major modifier of polyQ-expanded AR toxicity and inclusion formation. Tip60 (Tat-interactive protein, 60kDa) functions as a histone acetyltransferase (HAT) and has been shown to directly acetylate the AR at K630/632/633. We are studying the role of Tip60 in SBMA by reducing its protein level and by pharmacologically inhibiting its acetyltransferase activity in various cell models of SBMA. We have found that knock-down of Tip60 protein, as well as pharmacologic inhibition of Tip60, in a PC12 cell model of SBMA, reduces the formation of nuclear inclusions of polyQ-expanded AR. Moreover, pharmacologic inhibition of Tip60 reduces toxicity in both myoblast and primary motor neuron models of SBMA. Mechanistic studies are underway and *in vivo* validation studies are planned for the future. The goal of these studies is to identify whether Tip60 is a viable therapeutic target for the treatment of SBMA.

Title: Reduced cytoplasmic MBNL1 is an early event in a brain-specific mouse model of myotonic dystrophy

Authors: *P.-Y. WANG[1,2], Y.-M. LIN[1], L.-H. WANG[1], T.-Y. KUO[1], S.-J. CHENG[1,3], G.-S. WANG[1]

Abstract: Myotonic dystrophy type 1 (DM1) is caused by an expansion of CTG repeats in the 3' untranslated region (UTR) of the dystrophia myotonia protein kinase (DMPK) gene. Cognitive impairment associated with structural change in the brain is prevalent in DM1. How this histopathological abnormality during disease progression develops remains elusive. Nuclear accumulation of mutant DMPK mRNA containing expanded CUG RNA disrupting the cytoplasmic and nuclear activities of muscleblind-like (MBNL) protein has been implicated in DM1 neural pathogenesis. The association between MBNL dysfunction and morphological changes has not been investigated. We generated a mouse model for postnatal expression of expanded CUG RNA in the brain that recapitulates the features of the DM1 brain, including the formation of nuclear RNA and MBNL foci, learning disability, brain atrophy and misregulated alternative splicing. Characterization of the pathological abnormalities by a time-course study revealed that hippocampus-related learning and synaptic potentiation were impaired before structural changes in the brain, followed by brain atrophy associated with progressive reduction of axon and dendrite integrity. Moreover, cytoplasmic MBNL1 distribution on dendrites decreased before dendrite degeneration, whereas reduced MBNL2 expression and altered MBNL-regulated alternative splicing was evident after degeneration. These results suggest that the expression of expanded CUG RNA in the DM1 brain results in neurodegenerative processes, with reduced cytoplasmic MBNL1 as an early event response to expanded CUG RNA.

Title: Non-invasive and allele-specific silencing of mutant ataxin-3 alleviates neuropathology and motor deficits of Machado-Joseph disease

Authors: R. NOBRE[1,2], J. SARAIVA[1], C. FUSCO[1], S. PAIXÃO[1], M. SANTANA[1,2], M. ESTEVES[3], *L. PEREIRA DE ALMEIDA[1,4]

Department, Gene Therapy Center, Univ. of Massachusetts Med. School, MA, USA, Worcester, MA; [4]Fac. of Pharmacy, Univ. of Coimbra, Portugal, Coimbra, Portugal

Abstract: Machado-Joseph disease (MJD) is the most common dominantly-inherited ataxia. It is associated with the expansion of a (CAG)n tract in the coding region of the MJD1/ATXN3 gene. This abnormal over-repetition is translated into an expanded polyglutamine tract within ataxin-3, conferring toxic properties to this protein and resulting in severe clinical features. Although there is no cure, several preclinical studies have demonstrated that silencing mutant ataxin-3 expression using RNA interference (RNAi) is a promising therapeutic approach. In particular, our group showed that intracranial injection of viral vectors targeting mutant ataxin-3 significantly decreases the severity of the neuropathological abnormalities in rodent models of MJD. However, this is an invasive procedure, which is associated with potential adverse effects and a limited vector distribution in the brain.
The aim of the present study was to develop an adeno-associated virus (AAV)-based system that enables: delivery of RNA interference-based treatments to the brain, the specific silencing of mutant ataxin-3 (mutATAX3) and alleviation of the disease by intravenous (iv) injection.
For that, we used adeno-associated viral vector serotype 9 (AAV9), a vector that has a remarkable ability to bypass the blood-brain barrier (BBB) and transduce the central nervous system of mammals. AAV9 vectors encoding an artificial microRNA that targets the mutant form of ataxin-3 mRNA (AAV9-mirATAX3) were firstly generated. Its efficacy and specificity were firstly confirmed in neuronal cell models and viral-based mouse models and the therapeutic potential was then tested in a severely impaired transgenic mouse model of MJD. Mice were intravenously injected at postnatal day one (PN1); were submitted to behavioral tests at 3 different ages and sacrificed at PN95.
AAV9-mirATAX3 vectors efficiently spread throughout the brain, transducing regions affected in MJD, such as the striatum, cerebellum, brainstem and spinal cord. AAV9-mirATAX3's treatment reduced the number of mutATAX3 aggregates and the cerebellar neuropathology, and treated animals showed a better performance in all behavioral tests. Overall, this study provides compelling evidence that a single iv injection of AAV9-mirATAX3 at PN1 is able to transpose the BBB, silence mutATAX3 and alleviate MJD motor phenotype.
To our knowledge, this is the first time that a non-invasive iv administration of rAAV9 vectors had significant impact on motor deficits of a polyglutamine disorder.

Title: Involvement of the frontotemporal dementia gene C9ORF72 in proteasome- and autophagy- mediated protein degradation pathways

Authors: *S. S. LESKELÄ[1], M. A. TAKALO[2,1], J. LIST[1], M. CARTRÓ FONT[1], H. SOININEN[3,4], A. M. REMES[3,4], M. HILTUNEN[2,4], A. HAAPASALO[1,4]

Abstract: Frontotemporal dementia (FTD) is the second most common cause of dementia within the working-age population. Molecular pathogenesis of FTD is suggested to involve impairment of protein degradation pathways, including the ubiquitin-proteasome system (UPS) and autophagy, leading to formation of intracellular inclusions containing e.g. TAR DNA-binding protein 43, Fused in Sarcoma or ubiquilin proteins. Here, we have studied the involvement of *C9ORF72*, the major genetic contributor to FTD and amyotrophic lateral sclerosis (ALS), in these protein degradation pathways. We have utilized overexpression of C9orf72 protein isoforms A and B and modulation of UPS or autophagy-mediated degradation pathways by the proteasomal inhibitor lactacystin or serum starvation with or without Bafilomycin A1, an inhibitor of autophagosome maturation, in N2a mouse neuroblastoma cells. We observed that the levels of both C9orf72 isoforms significantly increased after proteasomal inhibition, suggesting that C9orf72 protein levels are regulated by proteasomal degradation. There were no signs of C9orf72 aggregation in the cells under these conditions. Induction of autophagy led to a significant decrease in the levels of both C9orf72 isoforms. Co-immunoprecipitation studies did not indicate interaction between C9orf72 and autophagy marker proteins SQSTM1/p62 or LC3B. Despite some recent studies, which have suggested the involvement of C9orf72 proteins in autophagy initiation, we did not observe changes in the induction of autophagy in cells overexpressing either of the C9orf72 isoforms compared to control cells, as indicated by unaltered LC3BII/LC3BI ratio. Our results confirm that C9orf72 proteins are linked to UPS and

autophagy pathways. Ongoing studies will provide further insights on the mechanistic role of C9orf72 proteins in the regulation of these protein degradation mechanisms.

Title: The ALS/FTD associated protein C9ORF72 forms a complex with SMCR8 to regulate ULK1 and play a dual role in autophagy

Authors: *C. LIANG[1,2], M. YANG[1], K. SWAMINATHAN[3], F. LAI[4], R. SHIEKHATTAR[4], J.-F. CHEN[2]

Abstract: The intronic GGGGCC hexanucleotide repeat expansion in chromosome 9 open reading frame 72 (C9ORF72) is the most common genetic cause of both frontotemporal dementia (FTD) and amyotrophic lateral sclerosis (ALS). Reduced C9orf72 expression levels have been reported in C9FTD/ALS patients, however the normal function of C9orf72 remains largely unknown. We report that C9ORF72 is a component of a multiprotein complex containing SMCR8, WDR41, and ATG101. Both C9ORF72 and SMCR8 have been predicted to contain DENN domains. We created Smcr8 knockout mice and found that they exhibit similar splenomegaly and lymphadenopathy as C9orf72 knockout mice, suggesting that the two proteins may have similar functions. Although both C9ORF72 and SMCR8 have been implicated in autophagy, experimental evidence of their functions is lacking. We found that Smcr8 knockout cells exhibit impaired autophagy induction, which is similarly observed in C9orf72 knockdown cells. Mechanistically, C9ORF72/SMCR8 interacts with the key autophagy initiation ULK1/FIP200/ATG13 complex and the interaction is enhanced under amino acid starvation conditions. Smcr8 regulates the expression of the ULK1 complex and has an opposite role in regulating the activity of ULK1 compared with C9orf72. In addition to modulating autophagy induction, the complex also regulates later stages of autophagy. Whereas autophagic flux is increased in C9orf72 knockdown cells, depletion of Smcr8 results in a reduced flux with an

abnormal expression of lysosomal proteases. Thus, C9ORF72 and SMCR8 have similar functions in modulating autophagy induction by interacting with the ULK1 complex and play distinct roles in regulating late steps of autophagy.

Title: Induction of autophagy enhances degradation of causative proteins in cellular models of neurodegenerative diseases

Authors: *H. ADACHI, Z. HUANG, K. OKADA, K. OHNARI, T. HASHIMOTO, T. TOYOTA, Y. IWANAKA
Dept of Neurol., Univ. of Occup. and Envrn. Hlth., Kitakyushu-Shi, Japan

Abstract: Neurodegenerative diseases share the common morphological characteristic of the deposition of abnormal proteins in the nervous system, including neurons. In chronic neurodegenerative diseases such as polyglutamine (polyQ) and Alzheimer disease (AD), commonly observed phenotypes include the abnormal accumulation of disease-causing proteins and the formation of nuclear and cytoplasmic inclusions. Under pathologic conditions, the accumulated level of such misfolded and toxic proteins may exceed the protective ability of the proteolytic machinery; the inability to either maintain misfolded proteins in a soluble form or degrade them results in their accumulation and the formation of inclusions. Autophagy refers to self-phagocytosis and is a process by which cells remove a large amount of proteins with long half-lives as well as damaged organelles. The mechanism of autophagy involves double-membraned autophagic vacuoles encapsulating the cytoplasm and organelles, and their fusion with lysosomes, resulting in the degradation of intracellular components. We examined the effects of the kaempferol in cultured cell models of neurodegenerative diseases. Cells were transfected using Lipofectamine 2000 with plasmids encoding mutant androgen receptor and ataxin-1. Kaempferol decreased the expression of both causative proteins in the neuronal cell models. The expression of the autophagic marker LC-3 II was significantly elevated in the cells after treatment with kaempferol. Kaempferol also decreased the expression of p62. These findings demonstrated that kaempferol induced autophagosome formation and enhanced the preferential degradation of the disease-causative proteins.

Title: PolyQ protein FAM171B expression and localization in mouse brain

Authors: Q. H. TRAN[1], A. K. SUDASINGHE[2], B. JONES[3], D. SHARLIN[3], *G. M. GOELLNER[4]
[1]Biol. Sci., [2]biology department, [3]Minnesota State Univ., Mankato, MN; [4]Biol., Minnesota State Univ- Mankato, Mankato, MN

Abstract: Polyglutamine (polyQ) diseases are inherited fatal neurodegenerative disorders caused by expansion of trinucleotide cytosine-adenine-guanine (CAG) repeats, encoding abnormally long glutamine tracts in respective disease proteins. Currently, there are nine polyQ diseases- including Huntington's disease and a number of Spinocerebellar ataxias. Interestingly, expanded polyQ proteins are prone to aggregate, and this aggregation may underlie neurodegeneration. In this study, we investigate the expression and localization of FAM171B (a novel polyQ protein) in the brain. Western blotting reveals that FAM171B protein is indeed expressed in the developing and adult mouse brain. Furthermore, *in situ* hybridization and immunohistochemical analyses suggests widespread localization of FAM171B to many brain regions- with pronounced expression found in the hippocampus, cerebellar Purkinje cells, and cerebral cortex. As a novel polyQ protein that is expressed in the brain, our observations suggest that FAM171B can be considered a candidate gene for an as yet molecularly uncharacterized neurodegenerative disease.

Title: Ataxin-2 in stress granules regulate nucleocytoplasmic transport in als

Authors: *K. ZHANG[1], J. G. DAIGLE[2], K. M. CUNNINGHAM[3], A. N. COYNE[4], J. C. GRIMA[5], T. E. LLOYD[6], J. D. ROTHSTEIN[4]

Abstract: Nucleocytoplasmic transport defects have been identified as a key pathogenic mechanism in C9orf72-mediated amyotrophic lateral sclerosis (ALS), the most common familial ALS. Recently, they have been also implicated in Huntington's disease and tauopathy and are suggested to be a common pathology underlying cytoplasmic protein aggregation diseases. However, how does cytoplasmic protein aggregations disrupt nucleocytoplasmic transport is unclear. In an effort to understand whether Ataxin-2, an ALS risk factor and also stress granule protein, modulates nucleocytoplasmic transport, we serendipitously identified that Ataxin-2 physically and genetically interacts with Ran GTPase (Ran), a key regulator of nucleocytoplasmic transport. Furthermore, we found that Ran is mislocalized into the stress granules when cells are under stress, potentially through Ataxin-2. Moreover, cells treated with stressors exhibit nucleocytoplasmic transport defects that can be rescued by inhibiting stress granule assembly, suggesting that stress granules regulate nucleocytoplasmic transport. As stress granules also play an important role in ALS pathogenesis, we next tested whether stress granule proteins contributes to the nucleocytoplasmic transport defects observed in C9orf72-mediated ALS. Indeed, we found that molecules inhibiting stress granule assembly suppresses these defects as well as neurodegeneration in fly and/or iPS models of C9orf72-mediated ALS. Hence, our studies delineates the stress granule-nucleocytoplasmic transport pathway that plays a role in pathogenesis of C9orf72-mediated ALS and potentially other cytoplasmic protein aggregation diseases.

Title: Peripheral nervous system pathology in a mouse model of adrenomyeloneuropathy

Authors: *F. LAHEJI, Y. GONG, A. BERENSON, R. KOK, F. EICHLER
Massachusetts Gen. Hosp., Boston, MA

Abstract: X-linked adrenoleukodystrophy (X-ALD) is a devastating neurological disorder caused by mutations in the ABCD1 gene that encodes a peroxisomal ATP-binding cassette (ABC) transporter. The mouse model of X-ALD with ABCD1 deficiency develops a phenotype similar to adrenomyeloneuropathy (AMN), the most common phenotype of X-ALD which manifests as spinal cord axonopathy and peripheral neuropathy. We previously observed mechanical hypersensitivity in the ABCD1-deficient mouse as early as 8 months of age, as detected by Von Frey filament testing. Here, we report various pathological parameters of the peripheral nervous system in an attempt to explain this hyperpathia. Density of PGP9.5-positive nerve fibers in the AMN mouse footpad was diminished at 14 months of age, though not at 8 months of age. Myelination in the sciatic nerve was also diminished at old age. No difference in the percentage of small-size nociceptive neurons in dorsal root ganglia (DRG) as determined by peripherin/neurofilament costaining was seen at either young (1 month) or old age (13 months). DRG neurons from AMN mice displayed a 56% increase in neurite branching at 1 month of age, although neurite length did not differ from wild type mice. The changes in footpad nerve fiber density and sciatic nerve myelination in older mice contribute to the understanding of AMN disease progression, but do not explain the hypersensitivity detected in younger mice. Early changes in DRG neurite branching suggest that developmental morphological changes in DRG neurons may contribute to the observed hyperpathia. Further investigation of neuropathological changes in young mice is underway.

Title: Down regulating mGluR5 in the $SOD1^{G93A}$ mouse model of ALS reduces the reactive phenotype of ex-vivo cultured spinal cord astrocytes

Authors: *C. USAI[1], F. PROVENZANO[2], E. GALLIA[2], M. MILANESE[2,3], T. BONIFACINO[2], G. BONANNO[2,3]
[1]Natl. Rese Council, Genova, Italy; [2]2Department of Pharmacy, Unit of Pharmacol. and Toxicology, Univ. of Genoa, 16132 Genoa, Italy, Genoa, Italy; [3]Ctr. of Excellence for Biomed. Research, Univ. of Genoa, 16148 Genoa, Italy, Genoa, Italy

Abstract: Amyotrophic lateral sclerosis (ALS) is a lethal neurodegenerative disease characterized by a selective death of upper and lower motor neurons (MNs). Although the etiopathogenesis is not completely understood, *in-vitro* and *in-vivo* studies demonstrated that damage within MNs is sustained by the degeneration of non-neuronal cells such as microglia and astrocytes (1). Group I metabotropic glutamate receptors (mGluR1, mGluR5) likely play a role in ALS, since they are over-expressed and functionally altered in different experimental model of ALS (2,3,4). We demonstrated that knocking-down mGluR1 or mGluR5 significantly prolongs survival and ameliorates the clinical progression in the $SOD1^{G93A}$ mouse model of ALS (5,6). The aim of this work is to investigate the effects of mGluR5 knocking-down on the reactive phenotype of astrocytes in ALS. We used here spinal cord astrocyte cell cultures from adult $SOD1^{G93A}$ mice and $SOD1^{G93A}mGluR5^{+/-}$ mice, heterozygous for mGluR5, and WT mice. Experiments with the FURA-2 dye showed a significantly higher cytosolic calcium concentration ($[Ca^{2+}]_i$) in $SOD1^{G93A}$ than in WT mice, both under basal condition and after exposure to the Group I mGluRs agonist 3,5-DHPG (30 μM). mGluR5 knocking-down significantly reduced the excessive $[Ca^{2+}]_i$. Confocal microscopy revealed that the astrogliosis markers GFAP, vimentin and S100β were more expressed in $SOD1^{G93A}$ respect to WT mice and decreased in $SOD1^{G93A}mGluR5^{+/-}$ mice. The same was true for the expression of the authophagy activation marker LC3. Of note, mGluR5 knocking-down also translates in a significant lower presence of misfolded-SOD1 protein when comparing $SOD1^{G93A}mGluR5^{+/-}$ and $SOD1^{G93A}$ mice. To conclude, a lower constitutive level of mGluR5 had a positive impact in $SOD1^{G93A}$ mouse astrocytes, supporting the idea that mGluR5 may be a potential pharmacological target for cell specific therapeutic approaches in ALS, aimed at preserving MNs by acting at the neighboring astroglial cell. 1. Title: Non-conventional DBS stimulation for tremor and non-tremor symptoms of ET

Authors: *S. LEE[1], W. F. ASAAD[2], S. R. JONES[3]
[1]Neurosci., [2]Neurosurg., [3]Dept. of Neurosci., Brown Univ., Providence, RI

Abstract: Essential Tremor (ET) is a movement disorder in which patients experience an involuntary intention tremor at 4-8 Hz. Tremor frequency oscillations have been widely observed during tremor, but whether there is a primary neurophysiological source of this oscillation is not fully known. For medication-refractory ET, deep brain stimulation (DBS) of the ventral intermediate nucleus of the thalamus (VIM) can be an effective treatment. However, DBS is not universally effective and may cause cerebellar-mediated side-effects such as gait imbalance, abnormal timing of motor activities, and deficits in motor learning. Here, we developed a biophysically principled computational neural model of tremor frequency oscillations in VIM, along with simulated DBS. We compared tremor oscillations generated by two candidate mechanisms: intrinsically within the thalamus and driven by cerebellar tremor frequency inputs. We compared the local fields and spiking of both mechanisms to human intraoperative data and show that both mechanisms may be plausible. We then simulated an additional source of cerebellar inputs as a model for non-tremor-frequency information and show that only the driven tremor oscillations were robust to these inputs. We simulated DBS during ongoing tremor and show that both standard and non-standard temporal patterns of DBS reduced tremor frequency oscillations in our model. We present predictions from the simulation results and suggest that improved understanding of the actions of DBS on both tremor and non-tremor activity in VIM may result in improved treatment efficacy.

Title: Implementation of a multilayer perceptron neural network for classifying deep brain stimulation in 'On' and 'Off' modes through a smartphone representing a wearable and wireless sensor application

Authors: *R. C. LEMOYNE[1], T. J. MASTROIANNI[2]
[1]Independent, Running Springs, CA; [2]Cognition Engin., Pittsburgh, PA

Abstract: Essential Tremor is a prevalent movement disorder that is characterized by postural and action tremor. In the event that medication therapy becomes intractable deep brain stimulation (DBS) of the VIM (ventralis intermedius) nucleus of the thalamus provides a viable alternative. However, the tuning process by an expert clinician is a laborious endeavor. The smartphone is equipped with an inertial sensor package comprising an accelerometer and gyroscope. A software application enables the smartphone to function as a wearable and wireless inertial sensor system for measuring the severity of Essential Tremor in a quantified methodology. The status of a subject with the DBS device in 'On' and 'Off' mode can be readily contrasted from a quantified perspective based on the recorded inertial sensor signal. The numeric attributes of the signal can be consolidated into a feature set for machine learning classification, such as through a multilayer perceptron neural network. The multilayer perceptron neural network achieves considerable classification accuracy with regards to distinguishing between a subject with Essential Tremor with the DBS device in 'On' and 'Off' mode through the inertial sensor signal recording of a smartphone functioning as a wearable and wireless sensor application.

Title: Characterizing the deep brain stimulation micro-lesion effect using peripheral sensors

Authors: *S. CERNERA[1], E. OPRI[1], A. GUNDUZ[2]
[2]Biomed. Engin., [1]Univ. of Florida, Gainesville, FL

Abstract: Introduction Essential tremor (ET) is one of the most prevalent hyperkinetic adult movement disorders, affecting roughly 1% of the worldwide population. Involuntary, rhythmic oscillations centered around one or more joints during postural or kinetic action are the classic phenotypes of ET. Surgical resection or deep brain stimulation (DBS) is often an option for medically refractory ET. This study focuses on the micro-lesion effect, the improvement of pathological symptoms after electrode implantation and before initiation of electrical stimulation. We hypothesize that DBS delivered in response to pathology can ameliorate symptoms and provide additional benefits. Herein, we demonstrate that an external wearable sensor can provide a reliable control signal for responsive DBS. Additionally, we show that with external sensors, micro-lesion effects and underlying tremor differences between the contralateral and ipsilateral implantation side can be observed. **Method** Data was collected from ET subjects during unilateral VIM electrode implantation for DBS at University of Florida Health Shands Hospital. During surgery, external wireless sensors that recorded electromyography (EMG) and acceleration data were placed on the hand dorsum, flexor carpi radialis, extensor carpi ulnaris, and bicep brachii muscles. The subjects were instructed to perform a series of tasks that provoked their tremor, such as reaching for a cup and finger to nose task. Each task lasted 2-3 minutes with periods of rest throughout the duration of the task. The patient was cued when to use their left or right hand and when to rest. Videos were recorded during the tasks and labeled for tremor onsets. Data was collected during DBS off trials. To align the data with the onset of tremor, a trigger was sent and picked up by both the video and the sensors. **Results** The coherence between the hand acceleration and flexor EMG during the reaching for a cup task for three patients provides a mean to distinguish between the ipsilateral and contralateral upper extremity. The peak coherence for the ipsilateral hand implant is at the patient's respective tremor frequency, obtained from the inertial data. The contralateral limb, which saw a reduction of tremor due to the micro-lesion effect, had an expected decrease in the coherence between muscle pairs. These results suggest there is a clear distinction between EMG and acceleration correlates recorded from muscles that are ipsilateral or contralateral to the site of implantation. This suggests that the micro-lesion effect may have a significant impact on the patients' tremor characteristics, therefore altering the thalamocortical connectivity.

Title: Calcium imaging of striatal activity evoked by subthalamic nucleus deep brain stimulation

Authors: *J. TREVATHAN[1], E. N. NICOLAI[2], A. J. ASP[4], D. CHENG[5], M. J. SCHACHTER[5], J. J. NASSI[5], S. L. OTTE[6], J. G. PARKER[7], J. LUJAN[3], K. A. LUDWIG[3]
[2]Dept. of Neurologic Surgery, [3]Neurologic Surgery, [1]Mayo Clin., Rochester, MN; [4]Biomed. Engin., Mayo Grad. Sch., Rochester, MN; [5]Inscopix, Inc., Palo Alto, CA; [6]Inscopix, Palo Alto, CA; [7]Dept. of Biol., Stanford Univ., Palo Alto, CA

Abstract: Introduction: Subthalamic nucleus (STN) deep brain stimulation (DBS) is a common surgical treatment for Parkinson's disease that achieves therapeutic benefit through the application of high frequency electrical stimulation. Although, changes in activity from striatal neurons occur following 6-hydroxydopamine (6-OHDA) induced lesioning, a common model of Parkinson's disease, the role of these neurons in the therapeutic response to Parkinson's disease is not well understood. In particular, medium spiny neurons (MSN), the primary striatal outputs, have been shown to form spatially compact coherent clusters encoding locomotion-related information in healthy mice (Barbera et al. 2016). However, in 6-OHDA lesioned animals, MSNs exhibit decreased clustering and specificity (Cho et al. 2002). Here, we demonstrate the first use of calcium imaging to study the effects of DBS on striatal neurons by imaging the stimulation-evoked changes in neural activity with a millisecond resolution.
Methods: Calcium imaging was performed with an nVoke system (Inscopix, Palo Alto, CA) in four 6-OHDA lesioned mice. First, a dopaminergic lesion was performed by injecting 6-OHDA in the substantia nigra pars compacts (SNc). Additionally, dorsal striatal neurons were transfected with GCaMP6m using the adeno-associated virus AAV9. Two weeks after injection, a 1mm gradient index (GRIN) lens was implanted directly above the dorsal striatum and a bipolar stimulation electrode (PlasticsOne, Roanoke, VA) was implanted in the STN. Calcium imaging was performed beginning two weeks after the lens implant. In order to observe stimulation evoked changes in striatal neuron activity recordings were first performed under isoflurane anesthesia and later in behaving animals.
Results: Stimulation evoked neuronal activity was observed in anesthetized animals as a result of STN DBS. Evoked activity showed a non-linear dependency on stimulation parameters.
Conclusion: An animal model combining deep brain optical imaging and DBS was successfully implemented to study changes in neuronal activity occurring at the circuit level. This work represents a first step in studying the effects of stimulation on deep brain activity via optical imaging techniques in freely behaving models of DBS.

Title: Precise MRI-based stereotaxic surgery in large animal models

Authors: A. N. GLUD[1], J. BECH[1], L. TVILLING[1], H. ZAER[1], D. ORLOWSKI[1], L. M. FITTING[1], D. ZIEDLER[2], M. GENESER[2], R. SANGILL[2], A. K. O. ALSTRUP[3], C. R. BJARKAM[4], *J. SORENSEN[5]
[1]Dept. of Neurosurg., Aarhus Univ. Hospital, CENSE Group, Aarhus, Denmark, Aarhus C, Denmark; [2]Dept. of Neuroradiology, [3]PET-centre, Aarhus Univ. Hosp., Aarhus, Denmark; [4]Inst. of Clin. Med., Aalborg University, Denmark; [5]Aarhus Univ. Hospital, Head-Neuro Ctr., Aarhus C, Denmark

Abstract: Stereotaxic neurosurgery in large animals is used widely in different sophisticated models, where precision is becoming more crucial as desired anatomical target regions are becoming smaller. Individually calculated coordinates are necessary in large animal models with cortical and subcortical anatomical differences. We present a convenient method to make an MRI-visible skull fiducial for 3D MRI-based stereotaxic procedures in larger experimental animals. Plastic screws were filled with either copper-sulphate solution or MRI-visible paste from a commercially available cranial head marker. The screw fiducials were inserted in the animal skulls and T1 weighted MRI was performed allowing identification of the inserted skull marker.
Results: Both types of fiducial markers were clearly visible on the MRI´s. This allows high precision in the stereotaxic space. The use of skull bone based fiducial markers gives high precision for both targeting and evaluation of stereotaxic systems. There are no metal artifacts and the fiducial is easily removed after surgery.
Conclusion: The fiducial marker can be used as a very precise reference point, either for direct targeting or in evaluation of other stereotaxic systems.
Discussion: Large animal models of brain diseases are in need of reliable methods for precision targeting of deep brain targets. The fiducial marker can work alone or as a control marker in corporation with framebased fiducial markers, or when other systems with possible MRI distortion artifacts are used in the experimental setup.

Title: Towards an adaptive cortico-thalamic closed-loop deep brain stimulation for the treatment of essential tremor

Authors: *E. OPRI[1], S. L. CERNERA[1], M. OKUN[1], K. FOOTE[1], A. GUNDUZ[2]
[2]Biomed. Engin., [1]Univ. of Florida, Gainesville, FL

Abstract: Essential tremor (ET) is defined as a rhythmical, involuntary oscillatory movement of the limbs and is one of the most common movement disorders. Intention tremor occurs mostly in the upper limbs (with slow oscillations between ~4-12 Hz) during the initiation and execution of goal-directed reaching motions, while it is absent at rest. It has currently been suggested that a synchronous pathological oscillation in a network that includes the premotor (PM) and primary motor (M1) cortices, the ventral intermediate nucleus (Vim), and the cerebellum is suppressed through deep brain stimulation (DBS) by jamming the “tremor cells” in the thalamus. Eight ET patients underwent DBS implantation surgery with the addition of ipsilateral cortical strip placement. A subgroup of patients was also implanted with Activa PC+S neurostimulator. Hence, we show the feasibility of a closed-loop system using thalamocortical neuromarkers evoked during different behavioral tasks, such as moving a hand or reaching a cup, to enable the control of stimulation activation and deactivation. The closed-loop system is being developed to run fully onboard the Activa PC+S device. In addition, analysis between PM, M1 and Vim shed light on the relationship and network between the regions involved in the tremor generation. As a failsafe solution, we are also exploring the use of additional external sources of input for the detection, such as inertial sensors. The fusion between internal and external inputs allows the implementation of “context aware” stimulation patterns, also useful in improving the quality of life of the patients. Our results suggest that the approach proposed would lead to prolonged battery life, fewer stimulation side effects (e.g. balance and speech impairment), while delivering an equally effective treatment.

Title: Closed-loop deep brain stimulation paradigm for Tourette syndrome

Authors: *J. CAGLE, M. S. OKUN, K. D. FOOTE, A. GUNDUZ
Univ. of Florida, Gainesville, FL

Abstract: Tourette syndrome (TS) is a continuous lifelong condition that is highly prevalent and socially embarrassing. Although in most cases motor and vocal tics wane by the late teenage year, some TS sufferers with motor and vocal tics are resistant to medication and to behavioral intervention and the issues persist into adulthood. Deep brain stimulation (DBS) has emerged as a promising treatment option for addressing tics in appropriately screened cases. The neurostimulator, Medtronic Activa PC+S, is a highly novel next generation technology, as it can record brain activity and can be programmed to provide stimulation in response to pathological activity (i.e., responsive stimulation) instead of the standard 24-hour continuous stimulation. Therefore, we proposed the responsive stimulation paradigm for TS using a novel, bidirectional neural interface, which can record LFPs, while simultaneously delivering DBS therapy.Three adult TS patients were recruited for the study. Both deep brain leads and cortical ECoG strips were implanted as part of the responsive stimulation system. LFPs that are time synchronized with tic behavior were collected from the centromedian thalamic (CM) region using DBS leads, and from the primary motor (M1) cortex using chronically implanted ECoG strips. Simultaneous recordings of electromyogram (EMG), accelerometer (ACC), videos, and LFP were collected from adult TS patients recruited in the study. All recordings were time-synchronized for better identification of tic features, and all videos are labeled by the clinicians. Power spectral density prior to tic onset were computed every 500 milliseconds with 250 milliseconds increment, and the frequency band with highest correlation to tic onset were chosen as tic features for detection. A human tic detector were built with the features identified and implemented in Activa PC+S, and the tic severity scores were rated by blinded psychiatrist for both traditional continuous stimulation and the novel responsive stimulation paradigms.The 20 features within 3 seconds prior to Tic onset with highest correlation to the presence of tic includes Beta (20-25Hz) and Alpha (8-12Hz). Beta band shows most promising results as it captures the Tic better than other frequency bands. The tic severity scores for the responsive stimulation paradigm using cortical beta power as detection appears to be no worse than current continuous stimulation paradigm.

Therefore, we conclude that responsive stimulation is as effective as traditional continuous stimulation paradigm, and it can prolong battery-life of the neurostimulator and reduce side-effects on the patients.

Title: Brain abnormalities in catatonia across psychiatric, neurological, and general medical conditions: A systematic review and meta-analysis of neuroimaging findings

Authors: X. CHANG[1], *G. COLLIN[2]
[1]Univ. Med. Ctr. Utrecht, Utrecht, Netherlands; [2]BIDMC, Harvard Med. School, Dept. of Psychiatry, Boston, MA

Abstract: Objective: Catatonia is a striking psychomotor syndrome characterized by dysregulation of motor and behavioral functions. The syndrome occurs in psychiatric, neurologic, and general medical conditions, with marked similarities in symptoms and treatment response, suggesting a common neurobiological substrate. This review explores brain abnormalities in catatonia across clinical conditions.
Methods: A systemic literature search was performed in Pubmed and Embase databases. Relevant documentation published in English up to July 2016 was extracted. A selection procedure was performed to identify relevant articles reporting on brain imaging in catatonia patients. Neuroimaging results were assessed across diagnostic groups and structural vs. functional imaging methods.
Results: A total of 8 case-control studies and 179 case-reports/series were identified. The case-control studies demonstrated abnormalities in sensorimotor, prefrontal, and parietal cortex (more pronounced in right hemisphere) in a total of 58 catatonia patients, as compared to 96 healthy controls and 50 non-catatonic psychiatric controls (Fig. 1A). The case-reports/series describing 197 individual cases with a variety of conditions, showed global or focal brain abnormalities in around two-thirds of cases (Fig. 1B). There was an association between diagnostic group and imaging results ($\chi^2 = 14.25$, $p = .007$), such that the proportion of focal abnormalities was higher in neurologic than psychiatric cases ($\chi^2 = 10.53$, $p = .001$). The regional distribution of abnormalities in frontal, parietal, and temporal cortex, and basal ganglia, was similar across groups (Fig. 1C).
Conclusions: This review shows that global and focal brain abnormalities are common in catatonia across clinical conditions. Neuroimaging results implicate distributed regions in mainly

frontal and parietal cortex, with more pronounced alterations in right hemisphere. The distribution of focal abnormalities was similar for diagnostic groups, consistent with a common neurobiological substrate across clinical conditions.

Title: Role of glial and neuronal TrkB signaling in protection of retinal ganglion cells following optic nerve injury

Authors: *Y. AZUCHI[1,2], A. KIMURA[1], C. HARADA[1], K. NAMEKATA[1], T. HARADA[1]
[1]Visual Res. Project, Tokyo Metropolitan Inst. of Med. Sci., Tokyo, Japan; [2]Envrn. Sci., Grad. Sch. of Science, Toho Univ., Chiba, Japan

Abstract: Glaucoma is characterized by progressive degeneration of retinal ganglion cells (RGCs) and their axons. The optic nerve injury (ONI) model mimics some aspects of glaucoma, including RGC death induced by excitotoxicity and oxidative stress, and therefore, it is a useful animal model for glaucoma. Previous studies have shown that trophic factors, such as brain-derived neurotrophic factor (BDNF) protect RGCs and promote axon regeneration in an ONI model. BDNF is known to regulate neural cell survival and axonal outgrowth mainly by activating TrkB receptors. However, the detailed roles of TrkB in different cell types during retinal diseases such as traumatic injury and glaucoma are still unknown. To investigate the TrkB function in neurons and glial cells, we used two conditional knockout mouse lines, in which TrkB was deleted from retinal glia ($TrkB^{GFAP}$ KO) or retinal neurons ($TrkB^{c\text{-}kit}$ KO). Deletion of TrkB specifically from neurons including RGCs shows no developmental abnormalities and similarly, mice with selective TrkB deletion from glia including Müller glia are viable. We then examined the neuroprotective effect in these mouse lines using an ONI model. Histochemical analysis revealed that compared with WT mice at 7 days after ONI, more severe RGC loss was detected in both mouse lines with the similar levels. These findings suggest that not only neuronal TrkB but glial TrkB also has critical roles for RGC protection during ONI. However, we found that while loss of RGCs continued to increase with time in $TrkB^{c\text{-}kit}$ KO mice compared with WT, no further loss was observed in $TrkB^{GFAP}$ KO mice at 14 days after ONI. Next, we examined if the lack of TrkB signaling in retinal glia or retinal neurons affect expression of retinal neurotrophic factors following ONI. In WT mice, the expression of basic fibroblast growth factor (bFGF) is upregulated at 3 days after ONI. We previously reported that the increase in bFGF is suppressed in $TrkB^{GFAP}$ KO mice, indicating that the main source of bFGF following ONI is glia and it is mediated via glial TrkB signaling. On the other hand, there was no difference in this upregulation between $TrkB^{c\text{-}kit}$ KO and WT mice, suggesting that elevation of bFGF is independent of the neuronal TrkB signaling. Our findings provide the possibility that glial and neuronal TrkB have different pathways on RGC protection and operate at different time points.

Title: N9 murine microglial cell activation is attenuated by rosmarinic acid through down regulation of inflammatory cytokines and cleaved caspase-3

Authors: *P. PEREIRA[1], V. R. COELHO[1], C. M. VIAU[1], R. B. STAUB[2], M. S. DE SOUZA[2], P. F. PFLÜGER[1], J. SAFFI[2]
[1]Federal Univ. of Rio Grande Do Sul, Porto Alegre, Brazil; [2]Federal Univ. of Hlth. Sci. of Porto Alegre, Porto Alegre, Brazil

Abstract: Rosmarinic acid (RA) has shown several biological activities, including antioxidant and anti-inflammatory properties and protective effects in many types of tissue like the brain tissue. Microglial activation has been considered a crucial process in the pathogenesis of neuroinflammation and psychiatric disorders. Microglia could be activated into the classic activated cytotoxic state M1 or the alternative activated neurotrophic state M2. The present study evaluated the ability of RA to inhibit the microglia activation induced by lipopolysaccharide (LPS) in the N9 murine microglial cell line and investigated possible mechanisms involved in this process. The cell line was obtained by immortalization of embryonic brain cultures with 3RV retrovirus carrying an activated v-myc oncogene and was grown in RPMI. Cells (1×10^4 cells/mL) were seeded on 6-well tissue culture plates and grown for 1 day up to 70-80% confluence before treatment with RA. In all tests, N9 murine microglial cells were pretreated with RA (0.1, 1.0, and 10 μM) for 20 hours and exposed to LPS (1μM/mL) for 4 h. Cell viability was measured by Trypan blue exclusion assay (TB). Reactive oxygen species (ROS) detection, quantification of cleaved caspase-3, and mitochondrial electrochemical potential were performed by flow cytometric analysis. iNOS, Arg-1, TNF-α, IL1-β, and IL-6 proteins were examined by Western blotting analysis and their antigens were detected using the chemiluminescence technique. Image analysis was performed using GraphPad Prism v5 program. The effect of RA on DNA was evaluated by Comet assay. In this study, RA attenuated the expression of the M1 marker iNOS and the levels of pro-inflammatory factors including TNF-α, IL1-β, and IL-6; it increased the expression of the M2 marker Arg-1, and inhibited, at least in part, ROS generation and loss of mitochondrial outer membrane permeabilization (MOMP) through the inhibition of cleaved caspase-3 activation. RA also inhibited DNA damage reassuring cell protection. Thus, the results suggested a protective effect of RA down regulating inflammatory cytokines and cleaved caspase-3.

Title: FKBP51 mediates neurotoxicity, astrogliosis, and demyelination via cell type-dependent signaling pathway in excitotoxicity-induced neurodegeneration

Authors: *S.-H. LIN[1], H.-Y. CHUANG[1], Y.-M. KUO[1,5], P.-C. HSU[1,2], I.-H. LEE[6], A.-Y. LIN[3], C.-J. JENG[4], Y.-H. LEE[1,2]
[2]Brain Res. Ctr., [3]Pharmacol., [4]Cell Biol. and Anat., [1]Natl. Yang-Ming Univ., Taipei, Taiwan; [5]Anesthesiol., [6]Neurol., Taipei Veteran Gen. Hosp., Taipei, Taiwan

Abstract: Excitotoxicity induced by glutamate overflow is the most common cause of neurodegeneration following both acute and chronic brain injury. FK506 binding protein 51 (FKBP51), encoded by *Fkbp5* gene, is a cochaperone best known for regulating glucocorticoid receptor (GR) and Akt-dephosphorylating phosphatase. Genetic variants of *Fkbp5* causing FKBP51 elevation have been found in patients with neuropsychiatric disorders, and yet its role in the excitotoxicity-induced neurodegeneration remained unknown. We used intracerebroventricular injection of kainic acid (icv-KA)-induced epilepsy mouse model on wild type (WT) and *Fkbp5*-knockout (*Fkbp5*-KO) mice to investigate the role of FKBP51 in excitotoxicity-induced neurodegeneration. Our data show that *Fkbp5*-KO mice are highly resistant to KA-induced hippocampal damage and demyelination in the white matter regions (corpus callosum and cingulum), accompanied with much weaker astrogliosis in the hippocampus and attenuated seizure activity. Similar injury-resistant effect of *Fkbp5*-KO was observed in the transient hypoxia-ischemia (tHI)-induced brain injury mouse model with much improved survival rate and lessened cerebral infarction. These neuroprotective effects of *Fkbp5*-KO were reproduced in primary mouse cortical neurons, neuron-glia mix culture, and myelin-forming oligodendrocytes (OLs) treated with excitotoxic NMDA and AMPA, respectively. Mechanistic studies further revealed that icv-KA induced GR reduction and Akt phosphorylation in the corpus callosum and hippocampus in a FKBP51-dependent manner, respectively. The FKBP51-dependent GR reduction in the corpus callosm was reproduced in vitro in AMPA-treated OLs, in which FKBP5KO showed elevation of GR signaling and downstream prosurvival gene expression to attenuate OL damage. On the other hand, the FKBP51-dependent Akt phosphorylation effect was found in the NMDA-treated astrocyte-neuron mix culture, but not neuron-enriched culture, accompanied with the NFkB activation and astrocyte reactivation. In

conclusion, these data suggest that *Fkbp5*/FKBP51 mediates excitotoxicity via cell type-dependent regulations of GR and Akt signaling and glia-neuron interaction. Genetic variations of *FKBP5* gene may contribute to the individual susceptibility to insult-induced neurodegeneration.

Title: Intracellular signaling in astrocytes in response to elevated hydrostatic pressure

Authors: *S. KAJA[1,3,2], V. R. RAO[2,3,1], Y. NAUMCHUK[2], A. J. PAYNE[4]
[1]Ophthalmology, [2]Mol. Pharmacol. & Therapeut., Loyola Univ. Chicago, Maywood, IL; [3]Res. Service, Edward Hines Jr. VA Hosp., Hines, IL; [4]K&P Scientific LLC, Oak Park, IL

Abstract: Primary open angle glaucoma (POAG) is associated with elevated intraocular pressure (IOP), manifesting in a pathological triad of optic nerve head remodeling, damage to the optic nerve, and retinal ganglion cell (RGC) loss. Optic nerve head astrocytes (ONHAs), the primary cell type in the optic nerve head, undergo significant pathological changes in POAG. Here, the cellular and molecular consequences of elevated hydrostatic pressure on cultured ONHAs were investigated. To this end, primary adult rat ONHAs were exposed to ambient or elevated hydrostatic pressure (25-30 mm Hg above ambient pressure) for 2 – 30 hr using a cell culture pressure chamber. Cell viability and proliferation were quantified using MTT and lactate dehydrogenase (LDH) release assays, while levels of oxidative stress and nitric oxide (NO) were quantified using fluorescent sensors, CellROX®, H_2DCFDA and DAF-FM.
ONHA cultures exposed to elevated hydrostatic pressure for up to 30 hr did not exhibit altered cell viability, and LDH release was similar between cells exposed to ambient or elevated hydrostatic pressure ($P = 0.651$). However, elevated hydrostatic pressure significantly increased the sensitivity to a subsequent oxidative challenge in the MTT assay ($P < 0.01$) and the LDH assay ($P < 0.01$). Subsequent analysis of ROS levels revealed that elevated hydrostatic pressure caused a statistically significant increase in the level of ROS as early as 2 hr after exposure to elevated hydrostatic pressure, as quantified by CellROX® fluorescent staining and DCFDA

fluorescence. Furthermore, hydrostatic pressure resulted in an up-regulation of nitric oxide synthase 2 (NOS2) with a concomitant increase in NO levels, as assessed by DAF-FM. Our data clearly show that elevated hydrostatic pressure increases the levels of ROS and NO in cultured ONHAs *in vitro*. These data suggest that even modest exposure to elevated IOP in POAG may significantly alter the oxidation response of ONHAs and accelerate neurotoxic signaling early during glaucoma pathogenesis.

Title: Connexin 43 as a mediator of androgen and estrogen-induced protection against oxidative stress in astrocytes

Authors: *N. K. KUBELKA, N. RYBALCHENKO, M. SINGH
Ctr. for Neurosci. Discovery, Univ. of North Texas Hlth. Sci. Ctr., Fort Worth, TX

Abstract: Connexin 43 (Cx43) is a transmembrane protein that is a component of gap junctions and highly expressed in astrocytes. While evidence exists supporting Cx43 in the regulation of non-central nervous system (CNS) cell viability, the roles of Cx43 in CNS protection are not well understood. Our laboratory has described that both estrogens and androgens have protective effects in astrocytes, and that this protection is afforded, in part, by reducing oxidative load. Given the abundance of Cx43, and its role regulating oxidative burden, we determined if the protective effects of either dihydrotestosterone (DHT), its metabolite, 3-beta diol, or estradiol (E2) in astrocytes are mediated by Cx43. Using cortical astrocytes derived from C57Bl/6 mice, we first assessed the effects of these three hormones on the expression of Cx43 mRNA. RTPCR analysis revealed that 3 hr treatment with E2 (100nM) resulted in a significant increase in Cx43

mRNA expression relative to control, while DHT and 3βdiol did not. In order to determine if Cx43 was a key mediator of the protective effects of either hormone, we used conformation-preferring inhibitors of Cx43. While neither E2 alone (100nM) nor Gap19 alone (hemichannel selective Cx43 inhibitor peptide, 10μM) protected against IAA toxicity, application of both E2 and Gap19 resulted in significant protection against IAA toxicity, suggesting a facilitation of E2's protective effects through inhibition of Cx43 hemichannels. The effects of DHT were similarly enhanced in the presence of the Cx43 hemichannel inhibitor (Gap19). When the conformation non-selective inhibitor of Cx43, Gap26, (which inhibits both Cx43 hemichannels and gap junctions) was used, Gap26 alone resulted in significant protection, and protection was further enhanced in astrocytes treated with both Gap26 and E2. As a surrogate measure of Cx43 function, we also evaluated if the three hormones elicited changes in the phosphorylation state of Cx43 using a Cx43 Ser368 phosphospecific antibody. Our data describe, for the first time, the involvement of Cx43 in the cytoprotective effects of E2 and DHT in the brain. As such, regulation of Cx43 may be a mechanistic component of hormone-induced brain protection, and regulating its function may be a crucial component of hormone therapy.

Title: 3-hydroxykynurenine and 3-hydroxyanthranilic acid enhance the toxicity induced by copper in rat astrocytes culture

Authors: *D. RAMÍREZ ORTEGA[1], A. SALAZAR RAMIRO[2], D. GONZALEZ ESQUIVEL[3], C. RIOS[3], B. PINEDA[2], V. PEREZ DE LA CRUZ[3]
[1]Inst. Nacional De Neurología y Neurocirugía Manuel Velasco, México, Distrito Federal, Mexico; [2]NEUROINMUNOLOGIA, [3]NEUROQUIMICA, INSTITUTO NACIONAL DE NEUROLOGIA, MEXICO CITY, Mexico

Abstract: Copper is a heavy metal and an integral component of various enzymes. It is necessary for mitochondrial respiration and other biological functions; however, excess copper is neurotoxic and has been implicated with neurodegenerative diseases as Alzheimer. This metal is able to modify the cellular redox environment, which can influence various cellular functions, signaling and catabolic pathways. In this context, tryptophan degradation through kynurenine pathway (KP) is modulated by the redox environment and produces some metabolites with redox

properties as 3-hydroxykynurenine (3-HK) and 3-hydroxyantrhanilic acid (3-HANA). The imbalance in the production of these kynurenines is related with some neuropathologies, in which the common factors are oxidative stress, inflammation and cell death. The aim of this study was to evaluate the effect of these kynurenines on the cupper toxicity in astrocytes cultures. First, we evaluated the $CuSO_4$ (0-500 µM) effect on MTT reduction, ROS production, mitochondrial membrane potential (MMP) and cell viability on primary cultured astrocytes. Then was evaluated the effect of the co-incubation of $CuSO_4$ (350 µM) whit 3-HK and 3-HANA (100 µM) in the same parameters that were previously tested and also GHS levels. In addition, the chelating copper effect of 3-HK and 3-HANA was evaluated. Our results showed that $CuSO_4$ decreased MTT reduction and MMP, while it increased ROS production and cell death in a concentration-dependent manner. The co-incubation with 3-HK and 3-HANA enhances the toxic effect of copper in MTT reduction, MMP and cell death. Copper also decreased GSH levels around 50%, but the co-incubation with the kynurenines decreased 70% GSH levels. However, the increase in ROS production induced by copper was abolished by 3-HK and 3-HANA. Both 3-HK and 3-HANA are able to chelate cupper in a concentration dependent manner. These data suggest that 3-HK and 3-HANA increased copper toxicity in an independent manner to ROS production; however, their effect on GSH levels could play an important role in the potentiation of cell damage induced by this metal.

Title: Co-culturing with Schwann cells confers protection on dorsal root ganglion neurons against cytotoxicity induced by silver nanoparticles

Authors: *J. C. LAI[1], W. GAO[2], S. W. LEUNG[2]
[1]Idaho State Univ. Col. of Pharm., Pocatello, ID; [2]Civil & Envrn. Engin., Idaho State Univ. Col. of Sci. & Engin., Pocatello, ID

Abstract: Our previous studies have demonstrated that various nanomaterials, including metallic nanoparticles, can induce cytotoxicity in different neural cell types although their underlying neurotoxic and molecular mechanisms are far from being understood. In this study, we developed a co-culture model consisting of immortalized dorsal root ganglion (DRG) neurons

and Schwann cells and employed it to investigate our hypothesis that co-culturing DRG neurons with Schwann cells confers protection on these neurons against neurotoxicity induced by silver nanoparticles. Our results suggested when exposed to silver nanoparticles, cell survival was enhanced in co-culture compared to that in monotypic cultures. Synapsin I expression was increased in DRG neurons when they were co-cultured with Schwann cells and treated with or without nanoparticles. Glial fibrillary acidic protein (GFAP) expression was increased in Schwann cells when they were co-cultured with DRG neurons and treated with nanoparticles. The expression of ERK and p-ERK was altered in treated DRG neurons, Schwann cells, and DRG neurons co-cultured with Schwann cells. Co-culturing with Schwann cells induced morphological differentiation in DRG neurons and rendered them less susceptible to morphological changes and damage induced by silver nanoparticles. Thus, consistent with our hypothesis, our results may assume pathophysiological significance in peripheral nerve degeneration and neurodegeneration induced by silver nanoparticles.

Title: Repeated daily doses of intranasal insulin aspart in young and aged F344

Authors: *K. L. ANDERSON, H. N. FRAZIER, A. O. GHOWERI, K. E. HARGIS, J. C. GANT, L. D. BREWER, N. M. PORTER, E. M. BLALOCK, O. THIBAULT
Pharmacol. and Nutritional Sci., Univ. of Kentucky, Lexington, KY

Abstract: In an attempt to combat decreased insulin signaling in the brain of Alzheimer's disease (AD) patients, several groups have used intranasal insulin in clinical and pre-clinical settings. Results show improved memory in young volunteers, patients with mild cognitive impairment, as well as in animal models of aging, diabetes or AD. We have previously reported that intranasal delivery of different insulin formulations (short and long acting), under either acute (single dose) or short term (9 doses) conditions, can enhance insulin signaling in the brain, alter cerebral blood flow and enhance memory recall. Here, we tested whether long term intranasal insulin (>60 doses) provided a greater enhancement in memory and recall in young and aged animals, or if the continued presence of the ligand might cause receptor downregulation or desensitization. Further, it is not clear how intranasal insulin alters functional communication, improves learning, or facilitates memory retrieval, particularly in animal model of aging. Our

study was therefore designed to address these limitations.
We characterized the impact of long-term (3 months, > 60 daily doses) intranasal insulin aspart (NovoLog®) on behavior using the Morris water maze (MWM) as well as on insulin receptor levels using autoradiography and immunohistochemistry. We also investigated the role of long term daily doses of insulin on hippocampal RNA species using microarray analyses. Saline (0.9%) or insulin aspart (equivalent to 10 IU/day) delivery was accomplished on non-anesthetized animals as previously published by our group (10 uL total volume per day). Learning and memory were evaluated using the classical MWM, and the extended version by including a reversal learning and reversal probe session in young and aged F344 (n=23/age). MWM training started on the 59th dose and study was terminated after the 62-64th dose. As previously shown, young (5 months) and aged (21 months) rats showed differences in learning and memory. Long term intranasal insulin did not raise peripheral blood glucose levels but did ameliorate aspects of memory recall in the aged animals.
These studies address the impact of repeated daily doses across 3 months in young and aged animals and directly test whether measurable changes in insulin signaling/sensitivity/binding occur across age and under conditions which should normally give rise to receptor desensitization. The results further highlight differences in insulin signaling between the brain and the periphery. We suggest that chronic changes in brain insulin using intranasal delivery can inform on therapies designed to increase insulin signaling and redress cognitive decline with aging.

Abstract: Measuring fluorescence using traditional epifluorescence microscopes and charge-coupled devices has long been the standard for quantifying ion changes in neurons and astrocytes during bouts of activation. This technique is well aligned with electrophysiological approaches such that the ion indicator can be delivered to a single cell during the recording process. Even when combined with confocal microscopy, and increased signal to noise, however, this approach lacks in temporal resolution needed to lock imaging with individual action potentials at physiologically relevant frequencies (3-50 Hz). Perhaps more importantly, this approach limits recording and imaging to a single cell. However, the field of Neuroscience has been stepping away from single cell recording and imaging, and has moved toward collection of data from multiple cells and cell ensembles, both *in vivo* and *ex vivo* using multiphoton microscopy. In order to provide higher resolution data on the relationship between cells that are activated in the brain and form the neurovascular unit, with assistance from Scientifica we performed experiments on young and aged rats as well as mice (2x transgenic APP/PS1 mice) both ex vivo and in vivo. We investigated the relationship between neurons and astrocytes, neurons and blood vessels, astrocytes and blood vessels. Because the temporal and spatial relationships between these arrays are best characterized during periods of activity with stimulated some of the tissues at different frequencies (3-50 Hz). Following stereotaxic delivery of GCaMP6s (neurons) and GCaMP6f (astrocytes) 4-6 weeks prior to imaging, and in combination with acute tail vein delivery of rhodamine dextran red, we conducted frequency tuning curves in hippocampal slices from young and aged animals, and examined the relationship between blood vessels and astrocytes in vivo. We describe our results and analysis strategy and also report on the methods used to image calcium changes in young and aged animals, as well as calcium changes in somatosensory cortex of the mice (neurons and astrocytes). For the *ex vivo* work, we focus our analysis on basilar and apical dendrites during activation. The frequency tuning curves for these areas are reported for young and aged animals. For the *in vivo* work in mice, we were able to record spontaneous events in astrocytes and examine the relationship of the astrocytes to the vascular system. These preliminary results demonstrate the feasibility of this approach for studies of aging and AD.

Title: Signaling and expression of a truncated, constitutively active human insulin receptor in hippocampal neurons

Authors: *H. N. FRAZIER[1], K. L. ANDERSON[1], S. MAIMAITI[1], A. O. GOWHERI[1], S. D. KRANER[2], G. J. POPA[3], M. D. MENDENHALL[3], C. M. NORRIS[2], O. THIBAULT[1]

Abstract: Insulin signaling is indispensable in the periphery and it is becoming clear that insulin is also important for normal brain function. Early stage clinical trials report a positive impact of intranasal insulin on memory recall in young subjects and patients with mild cognitive decline or Alzheimer's disease (AD). To address alternative strategies for enhancing insulin signaling in the brain, we have conducted a series of experiments using a constitutively active human insulin receptor (IR). Prior to in vivo experimentation with AAV delivery, lentiviral clones were derived and used to evaluate functional characteristics in rat primary mixed hippocampal cultures.
Cells were infected with either a mammalian expression plasmid encoding a red fluorescence protein (ires-dTomato), or a construct containing the truncated human IR beta subunit (HA-IRβ-ires-dTomato) via a targeted lentiviral system. A synapsin promoter was included to limit expression to neurons. Immunocytochemistry assays using antibody against HA-tagged IRβ confirmed expression of the lentiviral plasmid to neurons. The expression level and effect of IRβ on insulin signaling was confirmed by performing immunocytochemistry and Western immunoblots measuring pAkt/Akt ratio. Whole cell calcium currents were recorded in cultures infected with lentivirus using patch-clamp techniques. Different recording protocols were used to test for specificity of the effect to a subtype of voltage-gated calcium current. To more thoroughly characterize associations between calcium homeostasis and the IR, calcium imaging experiments using Fura-2 were performed. Other outcome measures included direct measures of glucose utilization rates using 2-NDBG.
Lentiviral infection of mixed primary hippocampal cultures was successful for all our constructs. Western blots of infected mixed hippocampal cultures provide evidence that transfection with the truncated IRβ plasmid confers elevated IR signaling compared to controls.
Immunocytochemistry shows the presence of the HA tag in nearly 80% of infected cells. Constitutive activity was also detected. Patch-clamp recordings show calcium currents are a target of insulin receptor activity in IRβ-expressing hippocampal neurons. Calcium levels at rest and during synaptic activity were not altered between the two groups indicating little impact of insulin signaling on resting conditions. Glucose utilization was altered with expression of the constitutively active IR. This characterization provides insights into future intervention approaches to combat cognitive decline in AD and/or aging using molecular methods to enhance insulin signaling.

Title: Macroglial Uncoupling Protein 2 deletion increases retinal ganglion cell survival in glaucoma

Authors: *D. HASS, C. J. BARNSTABLE
Neural and Behavioral Sci., The Penn State Col. of Med., Hershey, PA

Abstract: *Introduction*: Glaucoma is a leading cause of irreversible blindness worldwide. Vision loss in glaucoma is associated with elevated intra-ocular pressure (IOP) that leads to retinal ganglion cell (RGC) death. Growing evidence suggests that elevated IOP causes an imbalance in the retinal oxidation state, favoring the production of reactive oxygen species (ROS). ROS may induce toxicity either directly within RGCs, or through Müller glia and astrocytes (macroglia) that normally provide anti-oxidative support to RGCs. Our goal is to assess whether macroglial anti-oxidative support is relevant to the preservation of vision in glaucoma. Uncoupling protein 2 (UCP2) is a mitochondrial antioxidant that regulates ROS production by decreasing the proton motive force. We tested the hypotheses that macroglial UCP2 protects RGCs from oxidative stress and cell death during glaucoma.
Materials and Methods: In the following studies, we used $UCP2^{fl/fl}$; GFAP-$creER^{T2}$ mice injected with tamoxifen or vehicle. Using MitoTracker and $SeahorseXF^{96}$ assays, we identified the mitochondrial phenotype of astrocytes cultured from these mice, normally and when stressed with 5 μM tert-butyl hydroperoxide (tBHP). *In vivo*, we modeled glaucoma by injecting microspheres in to the anterior chamber of the mouse eye to artificially increase IOP. We then measured optomotor responses and the density of RBPMS+ RGCs. To determine whether UCP2 alters reactive gliosis or retinal oxidative stress, we measured GFAP and 4-hydroxynoneol immunoreactivity.
Results: *In vitro*, UCP2 recombination did not alter mitochondrial number, membrane potential, or H^+ leak. tBHP exposure increased H^+ leak and mitochondrial number in a UCP2-dependent manner. *In vivo*, IOP elevation significantly decreased optomotor responses and RGC survival in bead-injected eyes, relative to PBS-injected control eyes. Macroglial UCP2 deficiency was neuroprotective and blunted glaucomatous RGC loss. Additionally, UCP2-deficiency decreased in retinal oxidative stress and reactive gliosis.

Discussion: The *in vitro* results demonstrate that UCP2 uncouples stressed mitochondria, and may increase mitochondrial fission. While this suggests a well-supported protective function for UCP2, our *in vivo* data indicate that macroglial UCP2 impairs RGC survival and other molecular measures of retinal health. Together, these results suggest that glaucomatous RGCs require the preservation of an ATP-rich state over the impediment of oxidative stress. We are currently investigating this hypothesis in CMV-STOP$^{fl/fl}$-UCP2; GFAP-creER^{T2} mice, where macroglial UCP2 overexpression should impair glaucomatous RGC survival.

Title: Neuronal plasmalemmal damage elicits rapid immune cell activation following diffuse traumatic brain injury in swine

Authors: *K. WOFFORD[1,2,4], K. D. BROWNE[2,4], D. P. BROWN[2,4], M. R. GROVOLA[2,4], J. E. DUDA[3,4], K. L. SPILLER[1], D. CULLEN[2,5]
[1]Drexel Univ., Philadelphia, PA; [2]Ctr. for Brain Injury and Repair, Dept of Neurosurg., [3]Neurol., Univ. of Pennsylvania, Philadelphia, PA; [4]Corporal Michael J. Crescenz Veterans Affairs Med. Ctr., Philadelphia, PA; [5]Ctr. for Brain Injury and Repair, Dept of Neurosurg., Philadelphia, PA

Abstract: It is recognized that disruption of neuronal circuitry from traumatic brain injury (TBI) contributes to acute and persistent symptomology. However, it is not well understood how resident microglia and infiltrating macrophages act to modulate inflammation in the CNS and thereby affect acute neuronal health and homeostasis after TBI. To better elucidate the influence of immune cells on injury progression, we investigated acute immune cell reactivity around injured neurons immediately following TBI. Using a previously characterized closed-head

rotational acceleration injury model in swine, we induced mild or severe TBI and labeled mechanically permeabilized neurons using Lucifer yellow (LY). Acutely after injury (15 minutes), animals were sacrificed and immune cells ($Iba1^+$) were analyzed to investigate their distribution and morphology as a function of distance from neurons exhibiting trauma-induced plasmalemmal disruptions (LY^+). We recently found that regions without permeabilized neurons exhibited no differences in immune cell reactivity in either injured or sham animals. However, activated immune cells were frequently observed adjacent to permeabilized neurons post-injury. Following both mild and severe injuries, immune cell density increased and morphology became more amoeboid in the immediate vicinity of LY^+ neurons in a distance-dependent manner. Interestingly, the increased immune cell density around damaged neurons was not coupled with depletion of immune cell density in LY^- regions, suggesting that additional immune cells may be infiltrating from peripherally-derived monocyte populations. To address this issue, we sought to determine whether acute blood brain barrier compromise and influx of peripheral macrophages contributed to this rapid inflammatory response. Therefore, we examined tissue for evident of IgG, a protein indicative of blood brain barrier disruption. Marginal IgG staining was observed in perivascular regions after TBI. Furthermore, immunohistochemical characterization of CD45, a marker elevated in peripheral monocyte-derived macrophages, was also detected in regions of the brain containing LY^+ neurons suggesting that monocyte-derived macrophages may contribute to this rapid neuroinflammatory response after TBI. Further investigation into the influence of microglia and macrophages on injured neurons could lead to a more robust understanding of neuroinflammation as well as inform the development of immunomodulatory therapeutics.

Title: Comparison of food intake in newly diagnosed multiple sclerosis patients and healthy individuals- a case-control study

Authors: Y. GHAZAVI[1], Z. BAHADORAN[2], M. NIKFARJAM[2], N. BELADI MOGHADDAM[3], P. MIRMIRAN[2], *M. RAZA[4]
[1]Fac. of Med., [2]Res. Inst. for Endocrine Sci., [3]Dept. of Neurology, Fac. of Med., Shahid Beheshti Univ. of Med. Sci., Tehran, Iran, Islamic Republic of; [4]Baqiyatallah Univ. of Med. Sci., Tehran, Iran, Islamic Republic of

Abstract: Introduction: Nutritional factors considerably affect the incidence, severity of symptoms and progression of MS. However, the exact role of specific nutritional factors and dietary impact of various food items remains unknown in MS. In this study we investigated the differences in the nutritional intake of multiple sclerosis patients and compared the data with the sex and age-matched healthy subjects at selected hospitals in Tehran, IR Iran. Methods: Validated food frequency questionnaire (FFQ) for last one-year dietary assessment was used, in MS patients (n=96) and age matched control group (n=97). Data from FFQ was converted into exact values of micronutrients, calories, food items and food group intake. Finally, the data were compared between MS patients and healthy control subjects by SPSS ver. 18. Odds ratio and 95% confidence interval of multiple sclerosis was calculated in different food groups using multiple logistic regression models adjusted for various potentially confounding variables. Results: There was no significant difference between age (34.62 ±9.68vs. 33.96±8.75) and BMI (23.96 ±4.07 vs. 24.47 ±4.07) of MS and control group respectively. FFQ data showed that MS patients had a lower caloric intake (2631 vs. 2683kcal/d) during previous year, however, the difference was not significant. MS patients had a significant lower intake of sodium (7820±1274 vs. 8395±1592 gm/year), and lycopene (6310±2651 vs. 7615±2712 µm/year), during last year compared with controls. Higher intake of non-processed meat, processed meat, starchy vegetables and sweet snacks increased the odds of multiple sclerosis. ($p<0.03$) There was a 4.3 folds higher Odds for multiple sclerosis in second tertile of processed food consumption than the first tertile. ($p=0.04$) Conclusion: We found higher intake of sodium and lycopene in control group compared to Multiple sclerosis patients. Also, we found that higher intake of non-processed meat, processed meat, starchy vegetables and sweet snacks increased the odds of multiple sclerosis. There seems to be a need for advanced studies to evaluate the probable role of these nutritional factors in pathogenesis of multiple sclerosis and inflammation.

Title: Early lead (Pb^{2+}) exposure induces anatomic, ultrastructural and behavioral changes in zebrafish

Authors: L. HUNT[1], F. NIEVES[1], S. NARVAEZ[1], A. MONTEMARANO[1], *S. GUARIGLIA[2,1]

[1]CUNY Col. of Staten Island/Saint Joseph by the Sea High Sch., Staten Island, NY; [2]Col. of Staten Island, Staten Island, NY

Abstract: Exposure to Pb^{2+} during early development has particularly deleterious effects on neurodevelopment that are often permanent. The limbic system is particularly susceptible to toxic insult. Damage to the limbic system can result in the development of aberrant behaviors. Therefore, we sought to determine if early Pb^{2+} exposure led to the development of aberrant behaviors in a zebrafish model and if there were associated histological and ultrastructural changes in the limbic system and associated structures. To address the histological and ultrastructural changes in the limbic system and related structures, we examined brain volume, white matter tracts, and synaptic ultrastructure in the telencephalon of zebrafish exposed to Pb^{2+} during embryogenesis. We found that Pb^{2+} increased the size of the rostral commissure. We did not find any gross anatomical differences in overall size of the brain or any particular brain region. Pb^{2+} did induce an increase in the number of synapses found in the telencephalon. The presynaptic terminal of these synapses exhibited an alteration in vesicular distribution in which vesicular pools were more distant from the presynaptic active zone. Behaviorally, we found that early Pb^{2+} exposure had permanent effects on behavior. Pb^{2+} exposed zebrafish displayed an anxious phenotype in the light-dark box and tank diving tests, impaired learning ability in T-maze and some impairments in social behavior. The sum of our work characterizes novel changes in anatomical and behavioral neurodevelopment that are the result of early Pb^{2+} exposure in a newer and potentially useful model of Pb^{2+} neurotoxicity.

Abstract: Fumarate esters including dimethyl fumarate (DMF) have been recently introduced for the treatment of relapsing multiple sclerosis (MS), a chronic inflammatory condition resulting in neuronal demyelination and axonal loss. The proposed mechanism of DMF action involves the depletion of intracellular reduced glutathione and modification of thiols on Keap1, which in turn induces the expression of genes under the control of the antioxidant response element (ARE), including those that facilitate the synthesis and replenishment of cellular glutathione. However, other intracellular thiol residues in neural proteins may also be DMF targets, leading to the irreversible chemical modification of those protein residues by succination. To study the significance of protein succination by DMF in neural cell types, we acutely treated primary rodent neurons and astrocytes, as well as differentiated N1E-115 cells, with 10 to 100 μM DMF, and detected increased succination of a variety of proteins by immunoblotting with an antibody against succinated cysteine residues (2SC) and by mass spectrometry. Using this approach, we confirmed the identification and site of succination of ~25 novel target proteins, including tubulin and cofilin-1. An in vitro functional assay that measures the ability of cofilin-1 to sever the actin cytoskeleton showed that DMF-succinated cofilin-1 loses some activity, potentially inhibiting cofilin's cytoskeletal remodeling activity, an effect that could be beneficial in the modulation of myelination during MS. In addition, the oxygen consumption rate of N1E-115 cells measured with a Seahorse XF24 analyzer, as well as the expression of mitochondrial proteins related to the mitochondrial energy production, were only slightly affected by the highest doses of DMF, indicating a low probability of DMF toxicity on neural cells. In summary, we demonstrate that in addition to the stimulation of the antioxidant response, DMF increases protein succination in neural cells with a potential blockade of myelin loss and limited adverse effects.

Title: Neuroprotective effect of thymoquinone on cuprizone-induced multiple sclerosis in mice

Authors: *W. M. RENNO[1], H. L. SADEK[2]
[2]Anat., [1]Kuwait Univ., Safat, Kuwait

Abstract: Multiple sclerosis (MS) is a chronic inflammatory disease in which the myelin sheaths surrounding the axons of the CNS are damaged, leading to demyelination and scarring as well as a broad spectrum of symptoms that are considered one of the leading causes of disability in the developed world. The exact cause of MS is still unknown, but some data indicate that it likely occurs as a result of some combination of genetic, environmental and infectious factors. Several studies have shown that *Nigella sativa* and its active ingredient, thymoquinone, have neuroprotective effects against many degenerative diseases. A strong association exists between thymoquinone and the fundamental biological processes that facilitate regeneration, such as anti-oxidant, anti-inflammatory, and anti-apoptotic effects. The aim of this study is to investigate the role of thymoquinone in the neuroprotection and remyelination following cuprizone (CPZ)-induced MS mouse model. **Methods:** Thirty C57BL/6J mice were randomly divided into three groups: (I) Control given normal mouse chow, (II) CPZ+saline-treated and (III) CPZ+thymoquinone-treated groups. The experimental groups will be given 0.2% CPZ in a milled mouse chow mix *ad libitum* for five weeks. The function and severity of the CNS impairment were assessed and the motor neurobehavioral skills were evaluated. The salvaged brains were assessed for histopathological and immunohistochemistry Changes. **Results:** Thymoquinone-treated group showed significant ($P<0.0001$) motor improvement in the rotarod test following two weeks of treatment compared with CPZ-saline-treated mice. A remarkable increase of the Luxol fast blue staining intensity in the corpus callosum (CC) area was observed with a marked increase in cellularity in the thymoquinone-treated animals compared to saline-treated controls. Ultrastructural analysis of the CPZ+Saline mice showed heterogeneous myelin sheaths surrounding axons in the CC with noticeable loose myelin sheaths and few lamella. Further, oligodendrocytes showed apoptotic changes such as condensed and fragmented nuclei compared. In contrast, the thymoquinone-treated animals showed a decrease in apoptotic cell appearance with a remarkable increase in the myelin sheaths and lamellae and oligodendrocytes. **Summary:** Thymoquinone-treated mice showed a faster regenerative morphology and remyelination after two weeks of stopping CPZ administration in contrast to CPZ saline-treated mice. Thymoquinone neuroprotective properties may be useful adjunct therapeutic regimen to alleviate neurobehavioral motor symptoms as well as speed up the remyelination process in the MS mice model.

Title: Neuroprotective effect of monomethyl fumarate on inflammation-driven synaptopathy in a MS preclinical model

Authors: *D. FRESEGNA[1,2], F. DE VITO[1,2], A. MUSELLA[3], A. GENTILE[1,3], S. BULLITTA[1,2], F. RIZZO[1,2], A. PAOLILLO[4], D. CENTONZE[1,2], G. MANDOLESI[3]
[1]Medicina dei sistemi, Univ. of Rome Tor Vergata, Roma, Italy; [2]IRCCS Inst. Neurologico Mediterraneo (INM) Neuromed, Pozzilli (IS), Italy; [3]Lab. of Neuroimmunology and Synaptic Palsticity, IRCCS Fondazione Santa Lucia, Roma, Italy; [4]Biogen, Rome, Italy

Abstract: Excitotoxic synaptopathy is emerging as an early pathophysiological hallmark of multiple sclerosis (MS) and of its mouse model, experimental autoimmune encephalomyelitis (EAE). It includes both structural and functional synaptic dysfunctions induced by inflammation, typically resulting in a marked imbalance of glutamatergic and GABAergic transmissions. In the long-term, excessive synaptic excitation causes neuronal damage, leading to motor and cognitive dysfunctions.
Recently, we highlighted new crucial molecular players linking inflammation and altered glutamate transmission in EAE cerebellum. We demonstrated that both the proinflammatory cytokine interleukin 1 beta (IL-1b) and the microRNA miR-142-3p are expressed in resident as well as infiltrating cells, and participate in a regulatory axis responsible for the downregulation of the glutamate aspartate transporter/excitatory amino acid transporter 1 (GLAST/EAAT1). Inflammation-driven GLAST/EAAT1 reduction compromises the glutamate reuptake from the synaptic cleft and causes increased duration of excitatory currents recorded from cerebellar neurons.
Since EAE/MS synaptopathy is precocious and potentially reversible, it represents an attractive therapeutic target. Thus, we asked whether EAE synaptopathy could be directly targeted by disease-modifying treatments, like the oral drug dimethyl fumarate (DMF) which metabolizes to active metabolite monomethyl fumarate (MMF).
Our e*x vivo* experiments in EAE cerebellar slices showed that acute incubation MMF was able to correct the kinetic abnormalities of glutamatergic currents recorded from EAE Purkinje cells. Mechanistically, we provide evidence that MMF can reestablish glutamate homeostasis by restoring the level of the glial glutamate transporter GLAST/EAAT1, through the reduction of the expression of miR-142-3p, without affecting IL-1b mRNA level.
Consistently with ex vivo incubation of MMF in EAE cerebellar slices, therapeutic intracerebroventricular administration of MMF in EAE mice, given in the symptomatic phase of the disease, was able to mitigate cerebellar synaptic dysfunctions.
Overall, our findings highlighted a novel direct neuroprotective mechanism through which MMF is able to restore glutamate homeostasis in EAE cerebellum and, thus, to prevent glutamate-

dependent excitotoxic damages, by perturbing the detrimental IL-1b-miR-142-3p-GLAST/EAAT1 regulatory axis typical of the EAE cerebellum.

Title: Copper-iron connection in cuprizone-induced oligodendrocyte loss

Authors: *P. JHELUM, E. SANTOS-NOGUEIRA, S. DAVID
The Res. Inst. of the McGill Univ., Montreal, QC, Canada

Abstract: The copper chelator, cuprizone (CZ), induces oligodendrocyte (OL) death and demyelination in the CNS, which is seen particularly well in the corpus callosum. Copper chelation would reduce availability of copper-containing enzymes involved in cellular iron efflux. Therefore, CZ treatment can be expected to alter iron homeostasis in OL and lead to iron accumulation and cell death. As iron is needed for remyelination, increased iron in macrophages may be beneficial during the remyelination phase. In this study, we assessed the loss of mature OL and oligodendrocyte precursor cells (OPCs) from 2 to 5 weeks after start of CZ treatment, and correlated this with changes in expression of ferritin, a surrogate marker for cellular iron. Mature CC1+ OL showed a sharp loss at 2 and 4 weeks suggesting two cycles of cell death. The loss of OL at 2 weeks is correlated with a reduction in the iron efflux protein, hephaestin, which is expressed in OL. The number of OPCs showed loss at 2 weeks followed by a gradual increase

of ~ 2-fold at 5 weeks. Densitometry analysis showed ferritin labeling (sign of iron overload) increased ~2 - 3-fold at 2 and 3 weeks, a sharp reduction at 4 weeks followed by a second phase increase by 3-fold at 5 weeks. The first increase in ferritin occurs in OL, and the second increase occurs in macrophages. These results suggest that loss of copper can lead to iron-mediated OL death at the early time points, and the later increase in macrophages may have a role in remyelination.

Title: The retinoic acid synthesizing enzyme, retinaldehyde dehydrogenase 2 (RALDH2), regulates mouse CNS remyelination

Authors: *S. E. NANESCU, N. WATHIEU, L. ROSKO, D. CHA, J. K. HUANG
Biol., Georgetown Univ., Washington, DC

Abstract: Multiple sclerosis (MS) is an autoimmune-driven neurodegenerative disease characterized by chronic inflammation, demyelination and axonal injury. Retinoic acid (RA), the active form of Vitamin A, is a key signaling molecule in tissue regeneration in many species. Before becoming RA, retinol is first oxidized to retinaldehyde by retinol dehydrogenases, and oxidized further by retinaldehyde dehydrogenases (RALDHs). Among these RALDHs, the most abundantly expressed during development is RALDH2. The objectives of the study were to investigate RALDH2 expression during remyelination and to determine whether local RA synthesis in demyelinating lesions occurs to promote CNS remyelination. In order to assess the role of RA in CNS remyelination, an acute, focal demyelinated lesion was generated by injecting 1% lysolecithin into the mouse spinal cord, and we have used a retinoic acid response element (RARE)-reporter mouse, a mouse that expresses beta-galactosidase (*lacZ*) gene under the control of RARE. As a result, we have found active RA signaling within the remyelinating lesion. To investigate specifically the role of RALDH2 in remyelination, focal demyelination was performed on a tamoxifen inducible RALDH2 knockout mouse line. We found that following demyelination, the Raldh2 conditional KO mice displayed significantly increased pro-inflammatory macrophages in the lesion. Moreover, we found a significant reduction in in the number of oligodendrocyte progenitor cells (OPCs) and mature oligodendrocytes in the lesion. The reduction in OPCs and oligodendrocytes ultimately resulted in decreased remyelination, as

shown by MBP immunohistochemistry quantification. Furthermore, we found that the injection of RA into lesions is able to rescue progenitor and oligodendrocyte numbers in RALDH2 conditional knockout mice by 14 days after injury. Together, these results suggest that RALDH2 is necessary for RA synthesis following CNS demyelination, and that RA production in lesions modulates inflammation and increases the pool of OPCs to promote remyelination.

Title: Resident microglia form rod-shaped structures in cortical regions of neuronal damage and inflammation after diffuse traumatic brain injury

Authors: *K. G. WITCHER[1], B. N. BENNER[2], D. B. MCKIM[2], J. LIFSHITZ[4], D. S. EIFERMAN[3], J. P. GODBOUT[5]
[1]Dept. of Neurosci., Ohio State Univ., Columbus, OH; [3]Surgery, [2]The Ohio State Univ., Columbus, OH; [4]Barrow Neurolog. Inst., Phoenix Children's Hosp., Phoenix, AZ; [5]Neurosci., Ohio State Univ. Dept. of Neurosci., Columbus, OH

Abstract: Traumatic brain injury (TBI) elicits immediate neuroinflammation that contributes to acute cognitive, motor, and affective disturbances. Although acute impairments resolve after mild to moderate TBI, inflammatory processes persist and may underlie neuropsychiatric and cognitive complications that arise long after injury. Microglia, the innate immune cells resident to the brain, are key mediators of acute and chronic inflammation. After diffuse brain injury, microglia form elongated, rod-like structures in the cerebral cortex. While rod-shaped cells have been previously shown to peak in number 7 days post-injury, their derivation and role in pathophysiology is unclear. We first aimed to determine the origin of rod-shaped cells. We found that both rod microglia and nearby activated microglia upregulated CD45. Using GFP bone marrow chimeras, we confirmed that these CD45+ cells were indeed resident CNS microglia. BrdU labeling confirmed that the rod cells were resident microglia and not the result of TBI-induced microglial proliferation. We also found that some rod-shaped microglia aligned with blood vessels, but the frequency was comparable to naïve mice, suggesting that microglia align

with the vasculature at baseline. Here we also show novel data using Thy1-YFP-H transgenic mice that rod microglia were in close proximity to axotomized (ATF-3+) neurons and aligned with apical pyramidal dendrites. Regions with more rod microglia also had increased astrocyte reactivity, as demonstrated by increased GFAP labeling. Genes associated with neuronal injury (CSF-1, ATF-3) and immune reactivity (CCL-2, MHCII, TREM2) are upregulated in cortical homogenate both 3 and 7 dpi. Together, these findings suggest that rod microglia, which were present at the time of injury, form rod-shaped structures in regions susceptible to neuronal injury and are a part of a larger inflammatory response following diffuse TBI. Future studies aim to further delineate the gene expression of rod microglia, nearby activated microglia, injured neurons, and reactive astrocytes following brain injury.

Title: Add insult to injury: microglia activation in neuropsychiatric diseases?

Authors: *C. K. DONAT[1,2], M. SHUKUROGLOU[1], D. R. OWEN[1], L. H. PINBORG[2,3], M. SASTRE[1], J. D. MIKKELSEN[2]
[1]Div. of Brain Sci., Imperial Col. London, London, United Kingdom; [2]Neurobio. Res. Unit, [3]Epilepsy Clin., Copenhagen Univ. Hosp. - Rigshospitalet, Copenhagen, Denmark

Abstract: Several studies implicated the immune response in neuropsychiatric diseases, e.g. schizophrenia and depression. In the brain, immune crosstalk can result in a microglial response, detectable with radioligands for the 18 kDa Translocator Protein (TSPO). However, *in vivo* molecular imaging studies with TSPO tracers have yielded inconsistent results, reporting no changes, decreases or increases when comparing patient populations to controls. To further study the role of TSPO in these diseases, we chose a well-defined cohort (Stanley Medical Research Institute, Neuropathology consortium) including subjects with schizophrenia (SCZ), Bipolar (BP) and Major depressive disorder (MDD), and controls (HC, n=15 each), genotyped for rs6971 single-nucleotide polymorphism. Binding of three TSPO tracers, [^{3}H]PK11195, [^{123}I]CLINDE

and [^{3}H]PBR28 was assessed by autoradiography in consecutive sections from the orbitofrontal cortex and quantified in cortical grey (GM) and white matter (WM).
In MDD, mean specific [^{3}H]PBR28 binding was higher in patients than HC in GM (+45%, p=0.03), and a trend was also observed in WM (+35%, p=0.08). In BP and SCZ, although mean specific [^{3}H]PBR28 binding was higher in both GM (BP: 18%, SCZ: 23%) and WM (BP: 9%, SCZ: 22%), these differences were not significant. Specific binding of [^{3}H]PK11195 and [^{123}I]CLINDE was similar to HC in all 3 diseases, [GM (-2% to +12%) and WM (-8% to +3%)] with no significant differences. Nonspecific binding was different between the tracers, very low in [^{3}H]PBR28 (12%) and higher for [^{3}H]PK11195 (44%) and [^{123}I]CLINDE (57%). Across all subjects, [^{123}I]CLINDE and [^{3}H]PBR28 binding was positively correlated in GM and WM (Pearson's r=0.384, 0.429; p<0.01). [^{3}H]PK11195 binding was weakly correlated with [^{123}I]CLINDE in GM (r=0.269, p=0.03) but not WM and not with [^{3}H]PBR28 (GM: p=0.056, WM: p=0.051).
The findings show a general increase of TSPO in neuropsychiatric diseases when using [^{3}H]PBR28. No differences are found using [^{123}I]CLINDE or [^{3}H]PK11195 and binding properties of the radioligands may account for this discrepancy. The increase in [^{3}H]PBR28 binding was significant in GM of MDD patients, indicating a microglia response and supporting further *in vivo* TSPO PET studies in patients with depression.

Title: Neuroglia glutamate signaling in the adult brain is dependent on mGluR3

Authors: *N. A. SMITH[1], ***N. A. SMITH**[1], L. K. BEKAR[2], J. LIU[1], M. NEDERGAARD[3], V. GALLO[1]
[1]Ctr. for Neurosci. Res., Children's Natl. Hlth. Syst., Washington, DC; [2]Dept. of Pharmacol., Univ. of Saskatchewan Saskatoon SK, Saskatoon, SK, Canada; [3]Ctr. for Translational Neuromedicine, Univ. of Rochester Sch. of Med. and Dent., Rochester, NY

Abstract: The concept of neuroglia signaling in the adult brain has come under question because recent studies have shown that astrocytic mGluR5 is developmentally regulated and is undetectable after postnatal week 3. Thus, ruling out the possibility for glutamate evoked Ca^{2+} signaling in mature astrocytes. However, astrocytes express another major metabotropic glutamate receptor which is mGluR3. Unlike mGluR5, mGluR3 is a Gi couple G-protein receptor that is expressed throughout adulthood. Although mGluR3 activation is known to inhibit adenylate cyclase, new studies have revealed that mGluR3 can also induce intracellular Ca^{2+} changes but the mechanism behind this induction has not been fully explored in astrocytes. To explore mGluR3 Ca^{2+} induction in astrocytes, we employed a new transgenic mouse line that expresses a *Polr2a* based Cre-dependent GCaMP5G Ca^{2+} indicator that has also been tagged with IRES-tdTomato (tdTm) to aid detection of positive cells. These animals have been crossed with an inducible Cre line (GFAPcreER) that drives specific expression of GCaMP5G-tdTm in numerous astrocytes and enables monitoring of intracellular Ca^{2+} dynamics in astrocytes throughout the CNS using 2-photon microscopy. After determining mGluR3 significance in astrocytic Ca^{2+} dynamics, next we evaluated whether mGluR3 evoked Ca^{2+} transients regulate astrocytic modulation of a faster form of synaptic activity know as Transient Heterosynaptic Depression (tHSD). This study redefines the mechanism of neuroglia signaling in the adult brain and places astrocytes as key players in informational processing.

Title: Synergistic role of endogenous and exogenous 17β-estradiol in protection of ischemic neurons

Authors: *R. WANG
MEDICAL RECEARCH CENTER, Norteh CHINA UNIVERSITY OF SCIENCE AND TEHCNOLOGY, TANGSHAN, China

Abstract: Recent studies from our laboratory revealed that brain-derived E2 (BDE2) is elevated in the hippocampal CA1 region after global cerebral ischemia (GCI), and that it exerts a neuroprotective effect, although the mechanisms underlying the neuroprotective effect were unclear. The goals of the current study were to 1) examine the mechanisms underlying BDE2 neuroprotection after GCI, 2) examine whether exogenous E2 regulates aromatase/BDE2, and determine whether BDE2 is required for exogenous E2-mediated neuroprotection. To address these goals, aromatase/BDE2 was inhibited by either central administration of an aromatase inhibitor, letrozole or aromatase antisense oligonucleotide (AS) in ovariectomized adult female rats with or without exogenous E2 following GCI. The results showed that aromatase expression initially decrease at 3h, rebound to basal level at 1d, and then is robustly elevated at 3 d and 7d reperfusion in the hippocampal CA1 region after CGI. Administration of exogenous E2 increased aromatase expression in the hippocampal CA1 region at reperfusion 3h, 1d and 3d. Interestingly, immunofluorescent staining showed that aromatase was primarily expressed in neurons in sham and E2 treatment groups; however, at reperfusion 3d and 7d aromatase was predominantly expressed in reactive astrocytes. Intriguingly, central administration of aromatase AS or letrozole abolished both the GCI and exogenous E2-induced enhancement of aromatase at 7d reperfusion. Furthermore, letrozole and aromatase-AS treatment attenuated both endo- and exogenous E2-induced phosphorylation/activation of the prosurvival factors, ERK1/2 and CREB, as well as synaptic protein expression of PSD95 and synaptophysin after GCI. Taken as a whole, the results suggest that the neuroprotective effects of BDE2 after GCI involve enhancement of prosurvival ERK and CREB signaling and enhanced synaptic plasticity in the hippocampus. Furthermore, BDE2 appears to exert a “priming effect” that is critical for the beneficial neuroprotective effects of exogenous E2 after GCI. Title: Myeloid cell produced VEGF-A contributes to acute ischemic stroke damage

Authors: *A. RAYASAM[1], A. LINDSTEDT[1], J. KIJAK[1], T. KIM[1], M. HSU[1], M. HERBATH[1], J. HARDING[2], A. NAGY[2], R. VEMUGANTI[1], M. SANDOR[1], Z. FABRY[1]
[1]Univ. of Wisconsin - Madison, Madison, WI; [2]Lunenfeld-Tanenbaum Res. Institute, Mount Sinai Hosp., Toronto, ON, Canada

Abstract: Stroke is a widespread disease that affects approximately 15 million people globally every year. During ischemic stroke, secondary damage occurs due to immune cell-mediated reperfusion. Myeloid cells, phagocytic immune cells, are responsible for debris clearance and inflammation during the early stages of reperfusion after acute ischemic stroke, but the molecular mechanisms for how these cells contribute to stroke damage is still unclear. While vascular endothelial growth factor-A (VEGF-A) is known to influence the blood-brain barrier (BBB), limited information is known about how myeloid cell produced VEGF-A contributes to the immune responses after stroke. Using the transient middle cerebral artery occlusion (tMCAO) in mice, we show that myeloid cells are recruited to the ischemic brain rapidly during reperfusion and that a high proportion of these cells produce VEGF-A. Furthermore, we utilize transgenic murine models, which alter levels of VEGF-A and target myeloid cell produced VEGF-A specifically, to test how VEGF-A contributes to the acute phase of ischemic stroke. Overall, these data provide novel information for how VEGF-A contributes to stroke pathology.

Title: ASIC1a mediates autophagy activation and neuronal death induced by ischemic brain injury mice model

Authors: *X. SUN
The First Affiliated Hosp. of Soochow Universit, Jiangsu, China

Abstract: Tissue acidification and cell autophagy in the early days of the ischemic brain injury plays an important role, organization acidification can lead to acid sensitive ion channels (ASICs) abnormal activation. Our previous work showed that ASICs activation could induce the change of autophagy activity and lead to the death of neurons. However, it is unclear that the mechanism of ASIC1a and autophagy participated in the pathological process of ischemic brain injury. In this study, we constructed the middle cerebral artery ligation mice brain ischemia model at different time points and checked the expression of ASIC1a and autophagy activity by Western blot. The results showed that ASIC1a was activated in the ischemic brain damage and expression of autophagy related protein LC3-II was highest increased with p62 was decrease after ischemia 24 h, suggesting that ASIC1a and autophagy were activated in the process of neuronal damage after cerebral ischemia in mice. Furthermore, to investigate whether the autophagy activity was induced by ASIC1a, we constructed the ischemia model in wild-type mice, ASIC1a overexpression, and ASIC1a knockout mice then detected the autophagy activity and neuronal death by Nissl staining. We found that autophagy and neuronal death were induced in ASIC1a overexpression group higher than wild-type and ASIC1a knockout mice, so ASIC1a mediates autophagy increased the activity of neuronal death in the brain after ischemic treatment. Moreover, to verify the role of ASIC1a in the autophagic death pathway of neuronal damage after ischemia in vitro, the primary cultured neurons were treated with hypoxia and acid. The results showed that the expression of ASIC1a and autophagy pathway were increased, and ASIC1a regulated autophagy and neuronal death in vitro. In summary, this is the first report of autophagy pathway and neuronal death were regulated by ASIC1a activation induced by ischemic brain damage, which discuss ASIC1a in ischemic brain injury mechanism of the role of autophagy death pathway, providing a new method to improve the ischemic brain damage and theoretical basis.

Title: Global ischemia activates miR-34b/c mediated by p53 in hippocampal neurons destined to die

Authors: *J.-Y. HWANG, F. PONTARELLI, B. COURT VAZQUEZ, S. ZUKIN
Dept Neurosci, Albert Einstein Col. Med., Bronx, NY

Abstract: Transient global ischemia arising as a consequence of cardiac arrest in humans causes selective, delayed death of hippocampal CA1 pyramidal neurons and cognitive impairment. Effective treatments to ameliorate the neurodegeneration and cognitive dysfunction associated with global ischemia are an unmet need. Emerging evidence points to a widespread role for microRNAs (miRNAs) as key modulators of target gene expression in neurons. Accordingly, dysregulation of miRNAs are implicated in the pathophysiology of neurodegenerative disease and neurological disorders. Our findings, derived *via* miRNA-seq, indicate that a subset of microRNAs is altered in postischemic CA1 including miR-34b/c. Dysregulation of miR-34 has been implicated in pathophysiology of neurological disorder such as Parkinson's disease and epilepsy. However, a role for miR-34 in the pathogenesis of global ischemia is, as yet, unclear. Here we show ischemia induces p53-dependent activation of miR-34b/c and downregulation of its target genes, which together promote neuronal death in selectively vulnerable hippocampal CA1 *in vivo*. Consistent with this, inhibition of miR-34b/c affords neuroprotection in ischemia. These findings document a causal role for p53-dependent activation of miR-34b/c in neuronal death and identify a novel therapeutic target for amelioration of the neurodegeneration and cognitive deficits associated with ischemic stroke.

Abstract: We have previously shown that DETC-MeSO, Sulindac, and G-CSF could result in brain protection from ischemic injury. In this report we further investigate the mechanisms underlying the protection by G-CSF in terms of preventing ischemic damage caused by ER stress, mitochondrial dysfunction and autophagy. Using the middle cerebral artery occlusion (MCAO) model in rat we have established that G-CSF treatment protected against focal ischemia by reducing endoplasmic reticulum (ER) stress induced apoptosis and preserving the ER integrity. G-CSF treatment significantly attenuated the expression of key proteins involved in the ER stress induced apoptosis pathway; ATF4, ATF6, p-p38MAPK and CHOP as well as reducing the level of the intraluminal ER stress sensor, GRP78. In this model, G-CSF also reduced the general cellular stress marker HSP27. Similar alterations have been found in the BCAO mouse model of global ischemia targeting ER stress mechanisms. Furthermore we have shown altered expression caused by ischemia in the BCAO model in expression of the mitochondrial markers Drp1 and Opa1 as well as the autophagy marker Beclin. Expression of these markers was restored to sham non - ischemic control levels by G-CSF treatment. In conclusion this G-CSF mechanism-based therapy was found to afford ischemic protection through preventing tissue damage at the level of ER-, mitochondrial-, and autophagy related signaling events.

Title: Molecular analysis of mutant high-temperature requirement serine protease a1 identified in patients with familial cerebral small vessel disease

Authors: *M. UEMURA[1], H. NOZAKI[2], T. KATO[3], A. KOYAMA[3], O. ONODERA[4]
[1]Brain Res. Inst. (BRI), Niigata Univ., Niigata, Japan; [2]Niigata Univ., Niigata, Japan; [3]Niigata Univerity, Niigata, Japan; [4]Brain Res. Inst. (BRI), Niigata Univerity, Niigata, Japan

Abstract: Background: Cerebral autosomal recessive arteriopathy with subcortical infarcts and leukoencephalopathy (CARASIL), which is a rare familial cerebral small vessel disease (CSVD), is caused by mutations in high-temperature requirement serine protease A1 (HTRA1). Although it has been believed that mutations in HTRA1 cause CARASIL only in a recessive manner,

recent reports suggested that some specific mutations in HTRA1 cause CSVD even in a heterozygous state (Hetero). HTRA1 mutations in Hetero cause CSVD via dominant negative effects, on the other hand, HTRA1 mutations in homozygous or compound heterozygous states (Homo) cause CSVD via loss of HTRA1 protease activity. It has been remained unknown what type of mutated HTRA1 proteins have pathogenicity in Hetero. The aim of this study to investigate the pathogenicity of previously reported mutations in HTRA1 in Hetero.
Methods: Five mutations reported as Homo (R166C, A173T, G295R, A321T, L364P) and 10 mutations in HTRA1 reported as Hetero (S121R, A123S, R133G, R166L, A173P, S284G, S284R, P285Q, F286V, D450H) were analyzed. First, the protease activity of each purified wild type HTRA1 (WT) and mutant HTRA1 proteins was measured by using fluorescein isothiocyanate-labeled casein as a substrate. Second, the protease activity of purified protein from co-expression of WT and each mutant HTRA1 was evaluated. Purified protein of S328A, which was artificially loss of protease activity, was used as a negative control. In addition, HTRA1 oligomeric structure of each mutant protein was analyzed by size-exclusion chromatography system.
Results: The protease activities of 4 mutations in Hetero were similar or higher as compared with those of WT. The other 6 mutations in Hetero (S121R, R166L, A173P, S284R, P285Q, A321T) and all 5 in Homo revealed significantly lower protease activities than those of WT ($p < 0.05$). Using purified protein from co-expression of WT and each mutant, the protease activities of R166L/WT, A173P/WT, S284R/WT, A173T/WT and G295R/WT were significantly decreased as compared with WT/S328A ($p < 0.05$). The size-exclusion chromatography showed that S284R was eluted as a trimer like S328A and WT. The other 4 mutations (R166L, A173P, A173T and G295R) were eluted as a monomer.
Conclusion: Three of 10 mutations reported in Hetero and 2 of 5 HTRA1 mutations in Homo have dominant negative effects. These HTRA1 mutations might cause CSVD even in a heterozygote state. There is a possibility that the other mutants do not contribute to the pathogenesis of CSVD. The significance of the mutations for the pathogenesis of CSVD should be carefully evaluated by the biochemical analysis.

Title: Potential role of endoplasmic reticulum stress in recurrent hypoglycemia-induced increase in ischemic brain damage

Authors: *A. K. REHNI[1], V. SHUKLA[2], K. R. DAVE[2]
[2]Neurol., [1]Univ. of Miami Sch. of Med., Miami, FL

Abstract: Diabetes is a serious metabolic disease and stroke among diabetics is noted to be associated with wide spread brain damage. Anti-diabetic drug therapy related episodes of hypoglycemia cause hypoglycemia associated autonomic failure and eventually lead to development of recurrent hypoglycemia (RH). Our laboratory have previously reported that prior exposure of RH exacerbates ischemic brain injury in insulin-treated diabetic (ITD) rats. However, mechanisms known to cause this injury are least understood. Acute hypoglycemia activates unfolded protein response in liver. Glucose starvation also activates endoplasmic reticulum (ER) stress. Cerebral ischemia activates one of three ER stress pathways namely protein kinase RNA-like endoplasmic reticulum kinase (PERK) -eukaryotic initiation factor 2α (eIF2α) pathway. However, the role of ER stress in RH-induced aggravation of ischemic brain damage among treated diabetics is not known. Therefore, aim of the study was to evaluate post-cerebral ischemic ER stress in ITD rats exposed to RH. We determined levels of total and phospho-PERK, and C/EBP homologous protein (CHOP) (using western blot analysis) as markers of ER stress in Naïve (n=6), ITD (n=5), and ITD + RH (representing RH exposed treated diabetic) (n=8) groups. Rats were rendered diabetic by administration of streptozotocin and 2-3 weeks later, insulin pellet implantation was done to treat diabetic hyperglycemia. After 2-3 weeks, sub-cutaneous injection of insulin was given to induce hypoglycemia for 3 hours per day for 5 consecutive days. Overnight after last hypoglycemia exposure, global cerebral ischemia was induced by bilateral carotid artery occlusion with hypotension for eight minutes. We observed that pPERK to total PERK ratio in the ITD + RH group was higher by 57% ($P<0.05$), and 36% ($P<0.05$) as compared with naïve and ITD groups, respectively. We found that the level of CHOP in the ITD + RH group was higher by 30% ($P<0.05$), and 59% ($P<0.05$) as compared with naïve and ITD groups, respectively. Thus, we conclude that cerebral ischemia increases ER stress in RH-exposed ITD rats and may play a role in increased cerebral ischemic damage observed in RH exposed ITD rats. Confirming the role of ER stress in RH-induced aggravation of ischemic brain damage may help in developing new therapeutic options for diabetic stroke patients.

Title: Polymerase delta-interacting protein 2 regulates astrocyte activation in ischemic stroke

Authors: *M. S. HERNANDES[1], B. LASSÈGUE[1], L. L. HILENSKI[1], J. ADAMS[2], L. CHENG[3], M. YEPES[3], K. GRIENDLING[1]
[1]Cardiol., [2]Endocrinol., [3]Neurol., Emory Univ., Atlanta, GA

Abstract: Introduction: Polymerase delta-Interacting Protein 2 (Poldip2) is a multifunctional protein that regulates extracellular matrix via its ability to modify secretion of matrix components and alter matrix metalloproteinase activity. The blood-brain-barrier (BBB) is a dynamic structure assembled by endothelial cells, the basal lamina and perivascular astrocytes, raising the possibility that Poldip2 may be involved in maintaining its structure. **Objective:** Investigate the role of Poldip2 in the barrier function of the BBB in the ischemic brain. **Methods:** Transient middle cerebral artery occlusion (tMCAO) was induced in wild type (WT) and Poldip2$^{+/-}$ mice. The volume of the ischemic lesion was measured in TTC-stained sections. BBB breakdown was evaluated by Evans blue dye extravasation. Poldip2 protein expression was evaluated by immunofluorescence and western blotting. RT-PCR was used to measure mRNA levels of cytokines and MMPs. Cultured astrocytes were transfected with Poldip2 siRNA in culture and mRNA levels of cytokines were evaluated. **Results:** Micro-CT and electron microscopy were utilized to investigate the effect of Poldip2 depletion on the brain vasculature. No baseline difference between WT and Polidip2$^{+/-}$ mice was found in vascular volume, vessels per unit area, mean thickness, spacing between vessels, or in the ultrastructure of capillaries. An increase in connectivity (0.05±0.005 vs. 0.08±0.009) was observed (n=10). Poldip2$^{+/-}$ and WT mice displayed comparable infarct sizes following tMCAO (n=6). A decrease in Evans blue dye extravasation was observed in Poldip2$^{+/-}$ mice (25±3 *vs* 6±2µM/g) (n=7). Upregulation of cytokine mRNA following tMCAO was attenuated in Poldip2$^{+/-}$ mice (n=5): MCP-1(253±34 *vs* 83±23AU), IL-6 (134±38 *vs* 38±10AU) and TNFα (39±12 *vs* 12±3AU). MMP-2 (19±3 *vs* 10±1AU), MMP-9 (253±12 *vs* 13±3AU) and TIMP-1 (286±110 *vs* 61±15AU) expression induced by cerebral ischemia was abrogated in Poldip2$^{+/-}$ mice (n=5). Poldip2 protein expression increased in the ischemic brain of WT mice after tMCAO (69±4 *vs* 20±5AU) and was located in perivascular astrocytes (n=4). Poldip2 protein expression was also increased in cultured astrocytes following hypoxia (79±15 *vs* 27±5AU) (n=6), and Poldip2 siRNA prevented cytokine induction under these conditions. Significantly, the protective effect of Poldip2 depletion on increased permeability of the BBB permeability after ischemia was partially reversed by ip injection of TNF-α (5±1 *vs* 24±4µM/g) (n=5).**Conclusions:** Poldip2 contributes to BBB

breakdown after stroke. We propose that Poldip2 is an important regulator of the astrocyte-mediated inflammatory response in cerebral ischemia.

Title: Ginkgo biloba down-regulates pro-apoptotic gene expression in an *In vitro* stroke model

Authors: K. M. MCINTYRE[1], F. L. PRENDES[1], K. KARNAS[2], *A. J. ETTINGER[1]
[1]Biol. Sci. and Neurosci. Program, [2]Biol. Sci., Cedar Crest Col., Allentown, PA

Abstract: Ischemic stroke is a leading cause of death and disability in the United States, and current treatment options are limited and time-sensitive. In the brain, cellular apoptosis pathways are active for days following the initial insult and expand the area of damage. *Ginkgo biloba* leaf extract, an herbal remedy long used in traditional medicine, contains several components with antioxidant properties that could block the expansion of apoptosis to neighboring cells. Previous work has demonstrated that the purified extract of *Ginkgo biloba* (EGB761) has neuroprotective effects on cultured cells by blocking apoptosis. This study sought to extend those experiments by examining the effects of an over-the-counter *Ginkgo* supplement that people could easily access as either a prophylactic or an acute treatment. Primary brain and body cell isolates from *Gallus gallus* embryos served as a stroke model in which hydrogen peroxide was used to induce apoptosis, mirroring the cell death that occurs following the initial ischemic event; prophylactic *Ginkgo* treatment of these cell isolates was used to assess the protective properties of this herbal remedy. Cell viability assays using trypan blue exclusion at 0-24 hours post-treatment demonstrated that treated cells had improved survival compared to PBS-treated control cells. Apoptosis-associated gene expression differences were investigated via two independent PCR arrays; these assays showed up-regulation of several anti-apoptotic genes and down-regulation of several pro-apoptotic genes, such as caspases, that are components of the Fas death-inducing signaling complex (DISC), suggesting that *Ginkgo* is acting via this pathway. Western blots will directly examine the expression of some of the protein products of this pathway to determine whether protein level changes are consistent with gene expression changes. As dietary supplements, commercially available *Ginkgo* products are not regulated by the FDA. To test the potential biological activity of these supplements, a spectrophotometric assay was performed to

directly analyze the free-radical scavenging ability of separate containers of over-the-counter *Ginkgo biloba.* A dose-dependent effect of *Ginkgo* was measured, and samples from different lots showed similar radical scavenging. Together, these results merit further study of the use of a commercially available crude herbal supplement to convey protection from cellular apoptosis. Future work will include additional analysis of gene and protein expression and the direct inhibition or activation of the Fas death-inducing pathway to confirm its role in mediating the protective effects of *Ginkgo biloba* extract.

Title: Effect of resveratrol on expression of glucose transporters in astrocytes and neurons subjected to excitotoxicity

Authors: *G. F. GUTIÉRREZ-AGUILAR[1], P. AGUILERA HERNANDEZ[2]
[1]Patología Vascular Cerebral, Inst. Nacional De Neurología Y Neurocirugía, Ciudad DE Mexico, Mexico; [2]Patología Vascular Cerebral, Inst. Nacional De Neurología Y Neurocirugía, Mexico, DF, Mexico

Abstract: Stroke is characterized by a violent diminution of the blood circulation to the brain. Eighty percent of the strokes observed in clinical practice are of the ischemic type, whereas less than 15% are of the hemorrhagic type. Ischemia activates several mechanisms involved in neuronal damage such as excitotoxicity. N-methyl-D-aspartate (NMDA) glutamate receptors are highly permeable to Ca2+ ion channels whose over-activation induces death exclusively in neurons. The extracellular glutamate concentration is finely regulated through the astrocytic Na+-dependent glutamate transporter, the operation of which depends on the Na+/K+ gradient generated across the cell membrane by the Na+/K+ pump. Therefore, the preservation of the transmembrane Na+ gradient signifies an enormous energy cost for the astrocyte. Glucose transporters, GLUT-1 and GLUT-3, are the most abundant in the mammalian brain associated to the high level of expression in astrocytes and neurons, respectively. Under ischemic conditions brain cells regulate GLUT transporters expression in order to compensate its energetic deficiency. Objective. In this work we describe the effect of glutamate treatment on GLUT expression in neuronal and astrocytes cultures. Methods. Neurons were cultured from cerebral cortex of rat embryos (E17-18) an used after 10 DIV. Astrocytes were cultured from neonatal cortex (3 days) and used after 10 - 21 DIV. Cultures were stimulated with 100 μM glutamate for

10 minutes followed by different times recovery (from 1 to 24 h). GLUT expression was evaluated by western blot and immunofluorescence assays. Results and discussion. We observed that glutamate did not alter GLUT3 expression on neurons. On the contrary, astrocytes increase the expression of the “neuronal” glucose transporter (GLUT3), after glutamate neurotoxic stimulation. NMDA receptor activation was not involved on GLUT3 regulation which suggest that the glutamate transporter might be implicated. It has even been described that NF-κB pathway activation promotes transcription and translocation of GLUT3 to the membrane in conditions of oxygen and glucose deprivation which simulates ischemia, although the pathway has not been clearly described. Our results suggest that astrocytes over-express GLUT3 in order to support neuronal energetics under stress conditions such as cerebral ischemia.

Title: Transient focal ischemia significantly alters the temporal expression profiles of cerebral circular RNAome

Authors: *S. L. MEHTA, G. PANDI, R. VEMUGANTI
Neurolog. Surgery, Univ. of Wisconsin, Madison, WI

Abstract: Circular RNAs (circRNAs) are a novel class of non-coding RNAs (ncRNAs) formed from many protein-coding genes by backsplicing and covalent linking the 3′ end to the 5′ end. Their stability exceeds the linear RNAs due to the absence of well-defined ends. Although their physiologic functions are not yet completely defined, they are thought to control transcription, translation and miRNA levels. We investigated whether stroke changes the circRNAs expression profile in the mouse brain. Male C57BL/6J mice were subjected to transient middle cerebral artery occlusion (MCAO), and circRNA expression profile was evaluated in the penumbral cortex at 6h, 12h, and 24h of reperfusion using circRNA microarrays and real-time PCR. Bioinformatics analysis was performed to identify miRNA binding sites, transcription factor binding and gene ontology of circRNAs altered after focal ischemia. We found that 1,320 circRNAs were expressed at detectable levels mostly from exonic (1,064) regions of the genes in

the cerebral cortex of sham animals. Of those, 283 were altered (>2-fold) at least at one of the reperfusion time points, whereas 16 were altered at all 3-time points of reperfusion after transient MCAO studied compared to sham. Post-ischemic changes in circRNAs identified by microarray analysis were confirmed by real-time PCR. Bioinformatics analysis showed that these 16 circRNAs contain binding sites for many miRNAs. Promoter analysis revealed that the circRNAs altered after stroke might be controlled by a set of transcription factors. The major biological and molecular functions controlled by circRNAs altered after transient MCAO are biological regulation, metabolic process, cell communication, and binding to proteins, ions and nucleic acids. This is a first study that shows that stroke alters the temporal expression of circRNAs with possible functional implication to post-stroke secondary brain damage. Supported by Department of Neurological Surgery-University of Wisconsin, U.S. Department of Veterans Affairs and National Institute of Health.

Title: Putative stroke/vascular risk gene expression in blood of ischemic stroke patients is sexually dimorphic and cause-specific

Authors: *C. J. DYKSTRA-AIELLO, F. R. SHARP, G. C. JICKLING, H. HULL, F. HAMADE, N. SHROFF, X. ZHAN, D. LIU, B. P. ANDER, B. S. STAMOVA
Neurol., Univ. of California, Davis, Davis, CA

Abstract: **Background**. Few stroke/vascular risk factor loci have consistent association with stroke, raising questions about whether risk loci might be specific to stroke cause and/or sex. This study examined stroke/vascular risk factor gene expression in men and women with varying stroke etiologies. **Methods.** Male (n=122) and female (n=123) stroke and vascular risk factor control (VRFC) subjects were matched for race, age, time since stroke and vascular risk factors. Assessment of blood RNA expression for 72 stroke/vascular risk factor genes from whole

transcriptome arrays was completed at gene-, alternative splicing- and exon-levels. Expression of putative risk genes in blood of males and females was also evaluated following cardioembolic (CE), large vessel disease (LVD) and lacunar/small vessel disease (SVD) compared to Vascular Risk Factor Controls (VRFC). **Results**. Statistically significant differential expression (fold change >|1.2|, p-value<0.05, partial time correlation >|0.4|) and alternative splicing (FDR p<0.05) of putative risk genes was sexually dimorphic and stroke cause specific. Post-stroke exon-level expression changes were found in 71 of 72 genes studied, although very few genes were differentially expressed at gene level. These genes included ALDH2, ALOX5AP, F13A1, and IMPA2 in male ischemic stroke (all causes); ITGB3 in female CE; ADD1 in male LVD; F13A1, IMPA2 in male and WNK1 in female SVD. Alternative splicing of GP1BA and ITGA2B was significant in all stroke patients compared to controls in both sexes. Additionally, alternative splicing was found for six genes (ITGB3, LPA, LPAL2, NINJ2, PTGIS, ZFHX3) in males and five genes (F5, MTHFR, PON1, PRKCH, SMARCA4) in females when comparing all stroke to VRFC. Analyses of exon-level expression and differential alternative splicing showed association of many risk loci with a specific stroke cause in either sex. In all stroke patients, genes represented by differentially expressed exons included 24 that were associated with males and 2 (CDC5L/SUPT3H, PRKCH) that were female specific. Six represented genes (ACE, HDAC9, ITGB3, MTHFR, SMARCA4, SORT1) were common to both sexes. Six genes (ADD1, NINJ2, PCSK9, PEMT, SMARCA4, WNK1) in SVD patients were represented by 19 differentially expressed exons with decreased expression in males and increased expression in females. **Conclusion.** Results demonstrate that expression of most of the putative risk genes in blood of IS patients following stroke is both sexually dimorphic and, often, stroke cause specific. Both factors should be included in future stroke treatment trials and genetic association studies.

Title: Alteration of human neuronal kappa opioid receptor expression under hypoxic mimic condition

Authors: J. BABCOCK, A. HERRERA, G. CORICOR, C. KARCH, A. LIU, A. RIVERA-GINES, *J. L. KO
Dept. of Biol. Sci., Seton Hall Univ., South Orange, NJ

Abstract: Cellular adaptation to stressors, like hypoxia, is essential for neuronal survival. Some cells in a hypoxic environment developed adaptive changes allowing them to survive while others die as a result of the decrease in oxygen. Using human neuronal NMB cells treated with the hypoxic mimetic DFO, a hypoxic mimic cell model system was generated. A reduction of cell viability was detected. The cells surviving DFO exposure exhibited an increase in expression of the kappa-opioid receptor (KOR) and hypoxia inducible factor-1 alfa (HIF-1a). Therefore, the relationship between HIF-1a and KOR was investigated using RT-PCR, Western blot, luciferase reporter assay, mutagenesis, siRNA, and receptor-ligand binding assays. Neurons surviving DFO exposure exhibited an increase in HIF-1a expression overall, and its level in the nucleus was also increased. The surviving neurons also expressed an increase of KOR mRNA level in the time dependent manner as comparison to the control sample. While knockdown of HIF-1a by siRNA inhibited the increase of endogenous HIF-1a, it also reduced DFO-induced KOR expression. The HIF-1a siRNA treatment did not significantly affect the endogenous level of HIF-2a. To further examine the role HIF-1a in hKOR regulation, analysis of HREs of KOR gene was performed. Results revealed four potential HIF response elements (HIFA-D). Two of these HREs (HIFC and HIFD) synergistically mediated the DFO response using the reporter assay, also exhibiting a dose-dependent manner. Upon mutation of these two elements, DFO-induced effect was completely abolished. The CD1 plasmid, containing HIFC and HIFD with an 11 bp spacer, yielded a greater increase in promoter activity compared to that of CD17 plasmid (with a 17 bp spacer), suggesting that a head-tail arrangement of HREs synergistically enhanced promoter activity. Taken together, the alteration of human KOR expression under DFO treatment was mediated by HIF-1 in neuronal cells. Further studies are to determine the impacts of hKOR expression under hypoxic mimic condition.

Title: Multiscale computer modeling of penumbral zones in brain ischemia

Authors: *A. SEIDENSTEIN[1], A. NEWTON[2], R. A. MACDOUGAL[3], W. W. LYTTON[4]
[1]CBE, New York University- Tandon Sch. of Engin., Brooklyn, NY; [2]Neurosci., [3]Dept. of Neurosci., Yale Univ., New Haven, CT; [4]Dept. Physiol. & Pharmacol., SUNY Downstate Med. Ctr., Brooklyn, NY

Abstract: On a cellular level, molecular cascades produce damage that can lead to apoptosis, necrosis or necroptosis. Damage propagates due to a combination of extracellular diffusion and synaptic connectivity. Temporally, we are interested in aberrant spiking activity over milliseconds up to the progression of ischemia extending over a period of hours. Spatial scales range from subcellular changes in ion concentrations to large regions of brain tissue. Tissue affected by ischemic stroke is divided into three regions; 1. the core where cells suffer irreparable damage and death, 2. a penumbra where cells may recover with reperfusion, 3. a further region of edema where spontaneous recovery is expected.We extended the NEURON reaction-diffusion modules (NRxD) to include the extracellular space (ECS), providing a platform for modeling ischemia, with the penumbra cells and embedded in its extracellular environment. Here, we explored cellular failure initiated by ATP depletion at a central location. Ischemia impedes ATP production which results in a failure of the Na+/K+-ATPase pump and a rise in extracellular K+. Once extracellular K+ exceeds a threshold it will cause neurons to depolarize, further increasing extracellular K+. The cell network was created using NetPyNE in order to model the spreading depression seen in ischemic stroke by coupling a detailed biophysical model of cortical pyramidal neurons equipped with Na+/K+-ATPase pumps with reaction-diffusion of ions in the ECS.Multiscale modeling of ischemia combines the dynamics of rapid synaptic connectivity and slower extracellular diffusion of ions and toxic products of cell death, giving varying effects of core on the penumbra. Different penumbral subzones will produce differing intracellular dynamics biasing the cell to either cell death or potential recovery. The tools presented in this model allow for more efficacious experimentation and understanding of potential mechanisms to prevent permanent penumbra cell death.

Title: Identification the key sites of S2-S3 loop involved in TRPM2 gating mechanism

Authors: *Y. LUO, W. YANG
Inst. of Neurosci., Zhejiang province, China

Abstract: The melastatin-related transient receptor potential channel TRPM2 is a plasma membrane Ca^{2+}-permeable cation channel and it is mainly activated by intracellular adenosine diphosphoribose (ADPR) with the existence of Ca^{2+}. However, the mechanism of ADPR coordinated with calcium to activate TRPM2 channel remains unknown. By employing Rosetta software, we predicted the structure modeling of TRPM2 transmembrane domain based on TRPV1 structure. Interestingly, our model shows S2-S3 loop, the second longest loop between transmembrane segments, which contains α-helix and closes to the S4-S5 linker. By performing sequencing alignment across TRPM1-8 family, we found several amino acids are highly conserved including E842. In addition, several amino acids are conserved in TRPM2, TRPM4 and TRPM5, such as E843 and so on. It is well known that TRPM2, TRPM4 and TRPM5 are activated by calcium instead of other TRPM channels, which suggests there are some key sites to determine the calcium activated these channels. Here, we tested the hTRPM2 and its mutants currents in HEK293 cells by using 500μM ADPR, 50mM Ca^{2+},500μM ADPR+100μM Ca^{2+} conditions, respectively. Our results indicated that several amino residues (from L836 to P851) are critical for TRPM2 activation. Strikingly, E842A was no response to ADPR but had a small response to Ca^{2+}, while E843K was no response to Ca^{2+} but had a small response to ADPR, which suggests E842A and E843K separated the process of ADPR and Ca^{2+} activated TRPM2. Since E843 residue only exists in TRPM2/4/5 channels, our results strongly suggests that E843 is responsible for Ca^{2+} but not ADPR gating TRPM2 channel. In summary, our findings for first time identified key residues to separate the TRPM2 activation by ADPR or Ca^{2+}, which will be used to clarify the contribution of Ca^{2+} or ADPR alone in TRPM2 mediated neuron diseases such as ischemia injury and Alzheimer's disease.

Title: Netrin-5 is upregulated in the peri-infarct region after middle cerebral artery occlusion

Authors: *S. YAMAGISHI[1], M. TAKARADA[2], M. SAWADA[3], K. SAWAMOTO[3], O. HORI[2], K. SATO[1]
[1]Organ and Tissue Anat., Hamamatsu Univ. Sch. of Med., Hamamatsu-Shi, Japan; [2]Kanazawa Univ., Kanazawa, Japan; [3]Nagoya City Univ. Grad. Sch. of Med. Sci., Nagoya, Aichi, Japan

Abstract: Mammalian netrin family proteins are involved in targeting of axons, neuronal migration, and angiogenesis and act as repulsive and attractive guidance molecules. Netrin-5 is a new member of the netrin family with homology to the C345C domain of netrin-1. Strong netrin-5 expression was observed in the olfactory bulb (OB), rostral migrate stream (RMS), the subventricular zone (SVZ), and the subgranular zone (SGZ) of the dentate gyrus in the hippocampus, where neurogenesis occurs in the adult brain. In the SVZ and RMS, netrin-5 expression was observed in Mash1-positive transit-amplifying cells and in Doublecortin (DCX)-positive neuroblasts, but not in GFAP-positive astrocytes. In the OB, netrin-5 expression was maintained in neuroblasts, but its level was decreased in NeuN-positive mature neurons. In the hippocampal SGZ, netrin-5 was observed in Mash1-positive cells and in DCX-positive neuroblasts, but not in GFAP-positive astrocytes, suggesting that netrin-5 expression occurs from type 2a to type 3 cells. Next, we generated ischemia mouse model with middle cerebral artery occlusion. After 3 days from the stroke, netrin-5 was highly upregulated in the infarct region. Netrin-5 positive cells were expressing both NG2 and Iba1, suggesting they are BINCS (Brain Iba1+ /NG2+ Cells) derived from bone marrow and beneficial. These data suggest that netrin-5 is involved in neurogenesis and phagocytosis in the peri-infarct region of the cortex.

Title: Exploring the genome’s dark matter for novel therapeutic targets against ischemic stroke

Authors: *S. BHATTARAI, F. PONTARELLI, A. DHARAP
Neurosci. Inst., JFK Med. Ctr., Edison, NJ

Abstract: Long noncoding RNAs (lncRNAs) derived from the ‘dark matter’ of the genome play major roles in regulating gene expression in mammals, but their expression and functions after ischemic stroke are poorly understood. Using a mouse model of transient focal ischemia, we

applied RNA-sequencing to evaluate for the first time, the unbiased, genome-wide expression of lncRNAs as a function of reperfusion time in the cerebral cortex. After a 1h middle cerebral artery occlusion in adult male mice, ipsilateral cortices were harvested at 6, 12 or 24h of reperfusion. RNA was isolated and used for Illumina deep sequencing. The reads were mapped to the mouse genome (GRCm38), annotated and novel transcript isoforms were identified, and differential expression between the experimental groups was quantified. The data was validated using real-time PCR. Our results showed that while the baseline expression of lncRNAs in the healthy cortex was low, many of them were highly induced after stroke. In addition, hundreds of genomic loci that are not transcribed in the healthy cortex were robustly induced in the post-ischemic cortex, yielding ischemia-specific lncRNAs. Very few of the altered lncRNAs were previously annotated. We identified 259 transcript isoforms at 6h, 378 isoforms at 12h, and 217 isoforms at 24h of reperfusion that were differentially expressed versus sham controls. Of these, 212, 322 and 171 isoforms at 6, 12 and 24h of reperfusion, respectively, were novel lncRNAs. Overall, this work shows that transient focal ischemia induces widespread changes in the expression of lncRNAs in the mouse cortex with distinct reperfusion time-point-dependent expression characteristics that may underlie progression of the ischemic pathophysiology. The detection of hundreds of novel lncRNAs marks the discovery of new disease-related genomic regions in the adult post-stroke cortex.

Title: The selective antagonism of adenosine A_{2b} receptors prevents synaptic and neuronal damage induced by oxygen and glucose deprivation in CA1 rat hippocampus

Authors: F. UGOLINI, D. LANA, I. FUSCO, E. COPPI, I. DETTORI, L. GAVIANO, F. PEDATA, G. PEPEU, A. PUGLIESE, *M. GIOVANNINI
Univ., Firenze, Italy

Abstract: Cerebral ischemia results from severe reduction of cerebral blood flow after cardiac arrest, occlusion of vessels supplying nervous tissues, or prolonged systemic hypotension. Each year about 700,000 people suffer new or recurrent stroke, a major cause of long-term disability,

and the third most common cause of death in Western countries. The availability of drugs able to counteract stroke induced neurodegeneration is still an unmet need. Extracellular concentrations of adenosine significantly increase during ischemia reaching the μmolar range, activating all adenosine receptor subtypes: A_1, A_{2A}, A_{2B}, and A_3. No data on the involvement of A_{2B} receptor in cerebral ischemia are so far available. In this work we investigated the role of the A_{2B} receptor during oxygen and glucose deprivation (OGD, 7 min), a model of cerebral ischemia, in CA1 of rat hippocampus in vitro. A selective antagonist for A_{2B} receptor, PSB 603, was used to investigate the receptor putative involvement in the mechanisms of ischemic-mediated neuronal death. In order to better characterize the OGD-induced cell injury and pharmacological protection, if any, we conducted extracellular recordings of CA1 field excitatory post-synaptic potentials (fEPSPs); the extent of damage on neurons and glia was assessed by immunohistochemistry. OGD induced anoxic depolarization (AD), an unambiguous sign of neuronal damage, in all hippocampal slices tested (n=38), and completely abolished fEPSPs that did not recover after return to normoxic condition. The selective antagonist of A_{2B} receptor PSB 603 (50 nM, n=9) significantly delayed the appearance of AD and recovered fEPSPs amplitude. The extent of CA1 pyramidal neurons injury was assessed 1 hour after the end of OGD by immunofluorescence for NeuN. OGD caused substantial damage on CA1 pyramidal neurons, as determined by the significant increase of pyknotic nuclei (+696%, n=6), and of degenerating, anucleated neurons (+1400%, n=6). These effects were completely blocked by the antagonist PSB 603 (50 nM, n=5). OGD did not affect astrocytes or microglia, at least 1 h after the end of OGD. These results are the first to show that selective antagonism on the adenosine A_{2B} receptor delays the occurrence of AD and improves neuronal survival following severe OGD in the CA1 hippocampus, as demonstrated by the significant recovery of an otherwise disrupted neurotransmission and by the significant attenuation of neuronal damage induced by OGD. The selective antagonists for the A_{2B} adenosine receptor subtype may thus represent a new class of neuroprotective drugs.

Title: Cofilin-actin rod formation in brain ischemia

Authors: *S. WON[1], A. M. MINNELLA[1], C. EUN[1], E. ROME[1], P. S. HERSON[2], F. DABERTRAND[3], J. R. BAMBURG[4], R. A. SWANSON[1]
[1]Neurol, UCSF and SFVAMC, San Francisco, CA; [2]Anesthesiol., UC Denver, Aurora, CO; [3]Pharmacol., Univ. of Vermont, Burlington, VT; [4]Colorado State Univ., Fort Collins, CO

Abstract: Cofilin is a member of actin depolymerizing factor (ADF)/cofilin family, and plays a key role in the regulation of actin turnover (treadmilling). In neurons, actin turnover is involved in vesicle and organelle trafficking, and in the formation and maintenance of dendritic spines. Under stress conditions such as low ATP and oxidative stress, cofilin and actin form reversible rod-shaped aggregates. These may function to stop actin turnover and vesicular release, thereby preserving ATP consumed by these processes. However, the sustained presence of cofilin-actin rods may lead to spine collapse and degeneration of distal processes. It is unknown whether cofilin-actin rod formation contributes to stroke pathophysiology. As an initial step, we characterized cofilin-actin rod formation in cell culture and in five mouse models of brain ischemia. In 16-day old cortical neuron cultures, both glutamate exposure and oxygen glucose deprivation induced cofilin-actin rod formation in the neuronal processes. This was suppressed by inhibition of NADPH oxidase-2 (which produces superoxide). Cofilin-actin rod formation in vivo was assessed after transient forebrain ischemia, transient middle cerebral artery occlusion, cardiac arrest and cardiopulmonary resuscitation (CA/CPR), permanent photothrombotic ischemia, and in a mouse model of CADASIL (cerebral autosomal dominant arteriopathy with subcortical infarcts and leukoencephalopathy). We observed neuronal cofilin-actin rod formation in each of these models. Rod formation was most evident in and adjacent to the ischemic territories, and sometimes extended into neighboring white matter tracts. In the transient ischemia models, rod formation was most evident shortly after reperfusion, but was still evident 24 hours later. Ongoing studies are evaluating the effects of cofilin-actin rod formation on subsequent neurite survival.

Title: NAD^+ precursor protects against ischemic brain injury by promoting mitochondrial fusion

Authors: N. KLIMOVA[1], A. LONG[2], *T. KRISTIAN[3]
[1]Anesthesiol., Univ. of Maryland, Baltimore, Baltimore, MD; [2]Anesthesiol., Univ. of Maryland, Baltimore, MD; [3]Dept Anesthesiol, Univ. of Maryland Sch. of Med., Baltimore, MD

Abstract: Ischemic insult depletes pools of NAD^+, an essential factor in mitochondrial and cellular metabolism, leading to bioenergetics failure and cell death. NAD^+ levels can be replenished by the administration of nicotinamide mononucleotide (NMN), which serves as a biochemical precursor for NAD^+ synthesis. To assess the effect of NMN administration on ischemia-induced mitochondrial dynamics we used transgenic mouse model with mitochondria targeted expression of neuron specific enhanced yellow fluorescent protein (eYFP). The animals were subjected to transient forebrain ischemia and NMN was administered 30 minutes after the start of reperfusion at a dose of about 60 mg/kg. CA1 neuronal morphology was analyzed using cresyl violet staining at 6 days of recovery post ischemia. Alterations in mitochondrial fission and fusion dynamics were analyzed in post-ischemic animals treated with vehicle or NMN at 2, 4, and 24 hours of recovery. Fusion and fission protein levels were also determined by western blots. NMN treatment decreased neuronal death in the CA1 sector of the hippocampus and improved neurologic outcome. NMN reversed the excessive mitochondrial fragmentation in CA1 neurons that was permanent in vehicle-treated ischemic groups. Thus, NMN administration promoted normal mitochondrial morphology at 24 hours after the ischemic insult. Western blot analysis showed that NMN administration reversed ischemia-induced increase in P-Drp1(S616) to Drp1 ratio as well as normalized the increase in acetylation of mitochondrial proteins observed after ischemic insult. This effect could be mediated through increased activity of NAD^+ - dependent deacetylases, particularly the mitochondrial localized SIRT3, due to the replenished NAD^+ levels. Our data thus suggest that maintaining normal mitochondrial morphology is essential for cell bioenergetics metabolism and survival. Furthermore, the mechanisms of fission and fusion regulation could represent new therapeutic targets for neurobiological diseases.

Title: Matrilin-2: A pro-growth extracellular matrix protein in the post-stroke brain

Authors: *S. P. BRIDGES, M. MACHNICKI, S. T. CARMICHAEL
Dept. of Neurol., Univ. of California Los Angeles, Los Angeles, CA

Abstract: Ischemic brain injury causes many changes in the cells and environment of the central nervous system, leading to an incomplete recovery process and lasting disability due to failure to regenerate preexisting circuits. Changes in the extracellular matrix of the post-stroke brain have long been speculated as a primary cause for this halted recovery, with a great deal of focus being placed on a growth inhibitory environment following CNS insult. Transcriptional profiling of neurons that sprout after stroke shows upregulation of several extracellular matrix proteins that may be beneficial to the endogenous repair process; one such protein is matrilin-2. Matrilin-2 is a cartilage associated protein that is important in peripheral nerve regeneration following injury, but its function in the CNS is unknown. In our study, we assessed the pro-growth effect of matrilin-2, using cultured primary cortical neurons as well as in the CNS post stroke. Matrilin-2 was found to enhance axonal outgrowth in a dose dependent manner in post-natal day 3 cortical neurons, and was capable of overcoming a growth inhibitory environment *in vitro*. To assess the ability of matrilin-2 to promote enhanced axonal sprouting post-stroke, adult C57Bl/6 mice were subjected to photothrombotic motor cortex stroke and lentiviral overexpression of matrilin-2 in the peri-infarct region. Axonal sprouting relative to stroke location was assessed via BDA tracing of axons from the peri-infarct region. Our results begin to explore the pro-regenerative ECM environment in the post-stroke brain, and its role in functional recovery after stroke.

Title: Vitamin C and neuronal oxidative stress alter mitochondrial and cellular size, triggering neuronal death

Authors: *L. E. FERRADA[1], K. A. SALAZAR[3], F. J. NUALART[2]
[1]Univ. de Concepción, Concepcion, Chile; [2]Univ. de Concepción, Concepción, Chile; [3]Univ. De Concepción, Concepcion, Chile

Abstract: Vitamin C is the principal antioxidant in the central nervous system and is found in two states: reduced ascorbic acid (AA) and oxidized dehydroascorbic acid (DHA). In the presence of oxidative damage, AA acts as an antioxidant, oxidizing to DHA. Whereas AA is

incorporated by neurons through the sodium-dependent vitamin C transporter (SVCT2), DHA diffuses into nerves by glucose transporters (GLUTs). Our laboratory has shown that accumulation of DHA induces neuronal death in oxidative stress, but the cell death pathways are unknown. Here, we analyzed cellular and mitochondrial morphology, because morphological alterations and mitochondrial fission/fusion processes are associated with cell death. The Neuro2a cell line and rat cortical neurons were supplemented with AA and thereafter treated with H_2O_2. Cell viability was quantified using the XTT method. Cellular distribution of SVCT2 and GLUT1 were analyzed by SIM super-resolution microscopy. Mitochondrial and cellular size was analyzed using the Bounding-Box tool. Oxidation of vitamin C generates neuronal death in 50% of the cells. Prior to neuronal death, GLUT1 distribution was altered from the plasma membrane to the perinuclear zone and SVCT2 increased in the plasma membrane. Oxidation of vitamin C decreased mitochondrial size and volume on average by 0.3 µm and 0.2 μm^3, respectively. Furthermore, we noted a decrease in mitochondrial activity (MitoTracker, red) with 4D live cell experiments following permeabilization of the plasma membrane and incorporation of phalloidin (green). In conclusion, intracellular DHA generation induces neuronal death, which involves the redistribution of SVCT2 and GLUT1. Mitochondrial size, volume, and activity also decrease during vitamin C oxidation.

Title: Epigenetic regulation of ion channels in stroke, the acts of PcG and TrxG proteins

Authors: *A. ZHOU[1], L. HERNANDEZ[1], P. SHARMA[1], T. YANG[1], R. P. SIMON[2]
[1]Morehouse Sch. of Med., Atlanta, GA; [2]Morehouse Med. Sch., Atlanta, GA

Abstract: Ion channels play pivotal roles in the pathology of ischemic stroke. Little is known if and how different ion channels are synergistically regulated in brain ischemia. Polycomb group (PcG) and Trithorax group (TrxG) proteins are epigenetic gene repressors and activators,

respectively, that regulate the same genes via specific histone modifications. Previously, we reported increased levels of several PcG proteins in ischemic-tolerant mouse brains (Stapels et al., Sci Signal. 2010 Mar 2;3(111):ra15). We showed neuroprotective roles of PcG proteins against ischemic injury, as well as initial experimental evidence supporting a suppressive role of PcG proteins on whole cell potassium currents. Our recent, unpublished data (presented elsewhere) show that PcG proteins also down regulate sodium currents in neuronal cells. TrxG proteins, on the other hands, appear exert opposite effects on neuronal ischemic injury and ion channel activity. These implicate the play of a previously undescribed, PcG/TrxG protein-mediated epigenetic mechanism in the regulation of ion channels in neuronal ischemia.
The objective of this work was to characterize the expressional changes in ion channel genes in ischemia, with a primary focus on potassium and sodium channel genes, and to determine if their expression can be regulated by PcG or TrxG proteins. In mice in vivo, focal cerebral ischemia was induced by middle cerebral artery occlusion. In cultured neuronal cells in vitro, simulated ischemia was modeled by oxygen-glucose deprivation. Three ischemic conditions were included: injurious (prolonged ischemia), preconditioning (short ischemia to induce tolerance), and tolerant ("injurious" ischemia preceded by preconditioning ischemia), plus control. The effects of over- or under-expression of a PcG or TrxG protein on gene expression were examined in normoxic cell cultures. Expression levels of a panel of 84 neuronal ion channel genes (including 42 potassium and 9 sodium channel genes) were determined by qPCR mini-array, and compared across ischemic conditions, or between cells with or without PcG or TrxG manipulation. We found that levels of many potassium channel genes were decreased under ischemic-tolerant conditions, notably members of delayed rectifying and modifier subunit families. Knocking down a PcG protein or inhibiting its histone modification activity resulted in increased expression of a large number of potassium channel genes. Similar changes were also observed for several sodium channel genes. Overall, current results support a role of PcG proteins as broad-base regulators of ion channel genes. Ongoing experiments focus on the roles of TrxG proteins.

Title: Suppressive effect of hypothalamic orexin-A-mediated vagus nerve activation on the cerebral ischemia-induced elevation of hepatic inflammatory cytokines

Authors: *S. HARADA, S. TOKUYAMA
Kobe Gakuin Univ., Kobe, Japan

Abstract: We have previously found that the development of post-ischemic glucose intolerance is one of the triggers of ischemic neuronal damage. Orexin-A (a neuropeptide in the hypothalamus) plays an important role in many physiological functions, including the regulation of glucose metabolism. Activation of vagus nerve exerts orexin-A (OXA)-mediated suppression of post-ischemic glucose intolerance and cerebral ischemic neuronal damage. Cerebral ischemia induces hepatic inflammatory factors and contributes to the development of hepatic insulin resistance by activating sympathetic nerves. However, it is not enough to understand whether OXA regulates these phenomena through activation of vagus nerve. In this study, we demonstrated that the involvement of OXA-induced activation of vagus nerve in the induction of hepatic inflammatory factors by cerebral ischemia.
Male ddY mice were subjected to middle cerebral artery occlusion (MCAO) for 2 h. The hepatic vagotomy mice created to selectively transect at the hepatic branch vagus nerve. Neuronal damage was estimated by histological and behavioral analyses. Expression of each protein levels was analyzed by western blot and immunofluorescence staining.
Intrahypothalamic orexin-A (5 pmol/mouse) administration significantly suppressed the development of post-ischemic glucose intolerance and neuronal damage on day 1 and 3, respectively after MCAO. The MCAO-induced decrease in hepatic insulin receptors and increase in hepatic gluconeogenic enzymes were suppressed by OXA administration. These effects were canceled by *N*-butylscopolamine and hepatic vagotomy. MCAO-induced increases in hepatic tumor necrosis factor-α, and interleukin-1β on day 1 after MCAO were reversed by OXA administration. These effects were abolished by *N*-butylscopolamine or hepatic vagotomy. These results suggest that the orexin-A and vagus nerve may play an important role in the regulation of post-ischemic elevated hepatic inflammatory factors.

Title: Survival of pyramidal neurons within the ischemic core of 12-hour post-MCAo mice

Authors: *R. H. MEHDER, D. PETRIN, P. J. GAGOLEWICZ, B. M. BENNETT, A. Y. JIN, R. D. ANDREW
Biomed. & Mol. Sci., Queen`S Univ., Kingston, ON, Canada

Abstract: During the acute ischemia of focal stroke, neurons in the higher brain immediately depolarize, swell and lose synaptic input as their dendrites contort and form interconnected beads. At some point the neurons either partially recover or initiate necrosis but the time course is not well described. Here we examined neuronal morphology and electrophysiology at two time points following intraluminal left middle cerebral artery occlusion (MCAo) induced for 30 minutes in male C57/BL6 mice (20-25g). We not only gauged deterioration but also looked for surviving neurons within the ischemic core. The first time-point examined was immediately post-MCAo where there was ~10 minute reperfusion before immersion fixation of the brain. Golgi-Cox stained pyramidal neurons in the future core region were surprisingly unaltered based on morphometric analysis of dendritic branching, length and spine numbers (n=3 mice). Neuronal cell bodies were of comparable size and shape in both non-ischemic and ischemic hemispheres. This is in sharp contrast to the ischemic hemisphere 12h post-MCAo (n=3 mice) where most pyramidal and all striatal neurons were severely dysmorphic. Every principle cell in striatum was shrunken with retracted and beaded dendrites. The pyramidal cell response was more variable, displaying regions of uniformly swollen cell bodies but maintaining a pyramidal shape. Their dendrites lacked spines and were beaded, typical of ischemic neurons in the early phase of deterioration. More commonly, the remaining neocortical neurons were necrotic i.e., shrunken with retracted dendrites lacking spines. This contrasted with neocortical gray immediately outside the MCAo infarct region which appeared normal. Surprisingly, some core pyramidal neurons survived 12h post-MCAo, displaying spinous dendrites and normal cell body size/shape despite being surrounded by swollen or necrotic neurons. These rare cells could be visualized with contrast optics and recorded under whole-cell current clamp in live brain slices. The mean values for the fast afterhyperpolarization, whole cell input resistance, resting membrane potential, as well as action potential threshold, amplitude and width were not significantly different between these 12h `healthy` neurons in the ischemic hemisphere (n=5 cells) and unstressed neurons in the non-ischemic hemisphere (n=6). How long these resilient neurons continue to survive beyond 12h and how they selectively survive are two questions we are currently examining.

Title: Autophagy in diabetic retinal ischemia/reperfusion injury

Authors: *A. C. LO, L. H. C. TANG, A. K. W. LAI, F. K. C. FUNG
Dept. of Ophthalmology, The Univ. of Hong Kong, Hong Kong, Hong Kong

Abstract: Purpose
Retinal ischemia/reperfusion (I/R) injury is a common cause of retinal cell death. Despite increasing interest in autophagy modulation as a therapeutic strategy, the effect of retinal I/R injury on autophagy (up or downregulation) remains controversial. We investigated the effect of retinal I/R injury on autophagy using both an *in vivo* model and an *in vitro* model.
Methods
In vivo: A middle cerebral artery occlusion (MCAO) stroke model was used to induce unilateral retinal I/R injury in wild-type and Akita (type I diabetic) mice. Ischemia was maintained for two hours, followed by 2 or 22 hours of reperfusion. Autophagy markers, microtubule-associated light chain protein (LC3) and lysosomal associated membrane protein (LAMP1), were assessed via immunohistochemical staining on retinal sections.
In vitro: R28 cells (a retinal precursor cell line) were cultured in low glucose DMEM medium. One group of cells was incubated with additional glucose to mimic hyperglycemia. Hypoxia was chemically induced using cobalt (II) chloride for 24 hours. Cell viability and autophagy was assessed via the MTS assay and the detection of LC3 by immunoblotting, respectively.
Results
In vivo: After 2 hours of reperfusion, LC3 was significantly upregulated in the ganglion cell layer (GCL) in MCAO-injured Akita retinae as compared with sham-treated Akita retinae. After 22 hours of reperfusion, LAMP1 immunoreactivity was increased in the GCL and inner nuclear layer of MCAO-injured retinae as compared with their sham-treated counterparts.
In vitro: Hypoxic cells had lower cell viability than untreated cells. Hypoxia also resulted in significant LC3 upregulation.
Conclusion
Retinal I/R injury and $CoCl_2$-induced hypoxia induces autophagy activation in mouse retinae and R28 cells, respectively. Both our *in vivo* and *in vitro* results suggest that retinal I/R injury-induced autophagy may be exacerbated by elevated glucose levels.

Title: Targeting the vulnerable phase of SD with ketamine does not prevent plasticity mechanisms

Authors: *K. M. REINHART, R. J. OLIVER, G. PERALES, N. I. PERRONE-BIZZOZERO, C. W. SHUTTLEWORTH
Univ. of New Mexico HSC, Albuquerque, NM

Abstract: Spreading depolarizations (SD) are slowly propagating waves of neuronal and glial depolarization that occur in stroke brain. SD causes irrecoverable injury to metabolically compromised tissues by over-excitation of NMDA receptors. However, SD may also promote NMDA receptor-dependent synaptic plasticity and protective preconditioning in healthy tissues surrounding infarcts. We tested whether low concentrations of the NMDA receptor antagonist ketamine can prevent NMDA receptor-dependent injury, without preventing potential beneficial effects of SD. Acute cortico-hippocampal brain slices were prepared from C57Bl/6 mice. SD was initiated by KCl microinjection in CA1 and we monitored extracellular DC potential and evoked excitatory postsynaptic potentials (fEPSPs). BDNF mRNA was assessed by rt-qPCR. We first established a concentration of ketamine (30µM) that did not prevent SD initiation or propagation, but which protected tissues against deleterious effects of SD in vulnerable tissues. DC shifts of SD were reduced, recovery of intracellular Ca^{2+} was accelerated, and tissues recovered the ability to generate repetitive SDs. A post-hoc analysis of fEPSP amplitude revealed that fEPSP potentiation after recovery from SD was not prevented by ketamine ($P = 0.135$; n=11, 8, untreated and ketamine, respectively). In a subset of experiments, total BDNF (BDNF-Pan) and activity-dependent BDNF (BDNF-L) mRNA from hippocampus was assessed 15 minutes post SD. When SD was blocked with high concentrations of ketamine (300µM), both total BDNF and BDNF-L expression were reduced (by ~27% and ~50%, respectively), compared to SD in control conditions. In contrast, when SD propagated in the presence of ketamine (30µM) both BDNF-Pan and BDNF-L mRNA expression were elevated above control levels (by ~73% and ~52%, respectively). These findings suggest that low ketamine concentrations can protect against damaging effects of SD while permitting propagation into peri-infarct regions. Such SDs could potentially contribute to protective preconditioning and support recovery and repair.

Title: Pathologic roles of proteolytic enzymes associated with receptor processing

Authors: *M. YAMADA, H. HAYASHI, N. MATSUSHIMA, M. OHATA, B. YUAN, N. TAKAGI
Applied Biochem., Tokyo Univ. of Pharm. and Life Sci., Hachioji Tokyo, Japan

Abstract: Ischemic brain damage is associated with various causes such as glutamate excitotoxicity, oxidative stress and trophic factor deficiency. An excess amount of extracellular glutamate induced by ischemia is a major factor to induce intracellular Ca^{2+} overload via *N*-methyl-D-aspartate (NMDA) receptor and then causes neuronal cell death. Although it has been shown that several proteolytic enzymes are over-activated by high concentration of intracellular Ca^{2+}, roles of proteolytic enzymes associated with receptor-processing in NMDA-induced neuronal death are not fully understood. We investigated the effects of inhibition of proteolytic enzymes on NMDA-induced cell death. For analysis of cell viability, mitochondrial activity of primary rat cortical neurons was measured by XTT assay 24 hours after NMDA treatment with or without inhibitors of proteolytic enzymes. Inhibitors of matrix metalloproteinase, γ-secretase, protein convertase subtilisin / kexin type 9 and furin were examined whether they affect neuronal survival. Remarkable neuroprotective effect against NMDA-induced injury was observed in a dose-dependent manner by the furin inhibitor. Decreases in the amounts of NMDA receptor subunits and TrkB as well as intracellular signaling molecules Akt and glycogen synthase kinase 3 beta induced by NMDA treatment were suppressed by inhibitor of furin. Furthermore, the activation of calpain was significantly inhibited by the furin inhibitor. Thus, the activation of calpain would be involved in downstream of furin activation. These results indicated that the furin may be a therapeutic target for ischemic brain injuries.

Title: *In vivo* studies of neuronal activity in the primary motor cortex after transient ischemic attack

Authors: *H. ZHOU[1], H. A. RIINA[2], J. ARD[1], A. ROSENBERG[1], G. YANG[1]

Abstract: A transient ischemic attack (TIA) is a brief, reversible episode of neurological dysfunction caused by focal ischemia without acute infarction. Evidence indicates that a transient interruption in cerebral blood flow may impair sensation, motor function and cognition. However, the effect of focal cerebral ischemia on brain activity at the cellular and subcellular level remains unclear. In this study, we mimicked TIA by producing a targeted ischemic attack in the primary motor cortex using photothrombosis. Using in vivo two-photon microscopy, we monitored the cortical activity before and after focal ischemia induction in real time by recording the Ca^{2+} activity of cortical pyramidal neurons that express genetically encoded Ca^{2+} sensor (GCaMP6s). Under normal conditions, pyramidal neurons in the motor cortex show increased somatic and dendritic Ca^{2+} activity when the animals are running on a treadmill. Following targeted focal ischemia in the superficial layer of the motor cortex, we observed a marked reduction of neuronal activity in both layer 2/3 and layer 5 pyramidal cells. This reduction of neuronal activity persists for at least 24 hours after the focal ischemia has been resolved. These results suggest that a transient interruption of cerebral blood flow may have long-lasting effect on neuron activity in local cortical circuitry. Currently, we are screening compounds that have the potential to mitigate the deleterious effects of focal ischemia on neuronal activity and motor function.

Title: Targeting the liver acute phase response following traumatic brain injury reduces brain inflammation

Authors: E. WICKER[1], L. BENTON[2], S. ALAIYED[1], W. MUALEM[3], M. P. BURNS[3], *S. VILLAPOL[4]
[1]Pharmacol. and Physiol., [2]Dept. of Biochem. and Mol. Biol., [3]Dept. of Neurosci., Georgetown Univ., Washington, DC; [4]Departament of Neurosci., Georgetown Univ. Med. Ctr., Washington, DC

Abstract: Traumatic brain injury (TBI) triggers a loss of tissue followed by a strong and acute inflammatory response. Serum amyloid A1 (SAA1) is an acute phase protein that is mainly produced in the liver in response to inflammatory events such as TBI. SAA1 is released into the bloodstream, establishing a channel of communication between the liver and extra-hepatic organs. To date, no *in vivo* studies have investigated the role of SAA1 release in the central inflammatory response after TBI. We performed a mild and moderate/severe controlled cortical impact (CCI) injury in male C57BL/6J mice. One week before CCI, we injected antisense oligonucleotides (ASOs) (25 mg/kg/week by i.p.) to suppress mRNA SAA1 production. We wanted to explore the potential application of ASOs by modifying the inflammatory response. Western blot and ELISA analysis were used to quantify the expression of SAA1 in the serum and liver at several time points after CCI; immunohistological analysis was performed to identify macrophages/microglial and inflammatory cells binding SAA1 in the brain, *in situ* hybridization to detect mRNA SAA1 expression in the brain, and motor behavioral test were performed. Our results revealed that the highest grade of TBI severity was correlated with high levels of SAA1 in plasma at 1 dpi, and with a larger lesion volume and inflammation. We also found that SAA1 colocalizes with activated macrophages/microglial cells in the injured cortex and hippocampus; blocking SAA1 production reduced microglia activation and macrophage infiltration into the brain. Finally, we demonstrated that ASOs reduced SAA1 levels by 60-80% in plasma at 1 and 3 days after brain injury. ASO-treated mice displayed better motor skills on the rotarod 1 day after injury. Collectively, our findings demonstrate that SAA1 levels in plasma after brain damage depend on damage severity, acting as a potential biomarker. Also, we found that SAA1 binds to macrophages/microglial cells in the injured brain, and that ASO treatment reduces the

inflammatory response in the damaged brain. Altogether, this suggests that blocking SAA1 production could provide an advantageous environment for repair and functional recovery after brain trauma.

Title: Effects of Apyrase in a rat model of cerebral contusion injury

Authors: *Y. FURUKAWA, M. KOBAYASHI, T. KUMAGAWA, K. SHIJO, N. MORO, M. FUKUSHIMA, T. MAEDA, A. YOSHINO

Abstract: We have shown that gliotransmittion is activated immediately after traumatic brain injury. Gliotransmitter ATP is released into the extracellular space from injury stimulated astrocyte that will activate nearby microglia to initiate inflammatory response. In the previous study, we have shown that blockade of major receptor in gliotransmittion will suppress the activation of microglia and reduce the release of several cytokines in the extracellular space. In the present study we used Apyrase, an enzyme that catalyses the hydrolysis of ATP, to shut down the gliotransmittion and observed if it can suppress inflammatory response. Cerebral contusion injury was made in a rat and osmotic pump was implanted to deliver Apyrase or saline directly into the injured tissue. Rats were sacrificed at day 1, 3 and 7 following injury and analyzed. On day 1 and 3 after injury, increased level of activated microglia was observed by both histological staining and western blotting of Galectin-3. In the Apyrase injected group the activation was suppressed compared to the saline group in tissue near the contusion site. Few cytokine levels were suppressed by Apyrase injection in a mRNA level. Suppression of gliotransmittion by Apyrase have an effect to reduce inflammatory response after experimental cerebral contusion injury.

Title: Early reduction of large layer V corticospinal motor neurons precedes the inflammatory response and upregulation of phosphorylated-tau following repetitive mild TBI

Authors: *M. ALKASLASI, N. CHO, N. DHILLON, P. HARO-LOPEZ, O. SHELEST, G. BARMPARAS, E. LEY, G. M. THOMSEN
Cedars-Sinai Med. Ctr., West Hollywood, CA

Abstract: Objectives: Chronic traumatic encephalopathy (CTE) is a neurodegenerative disease linked to repeated head injury. The absence of stringent diagnostic tools together with variable disease progression limit our understanding of the disease. There are currently few experimental models that attempt to recapitulate the progressive brain atrophy and tau pathology that characterize the human condition. Using a recently described novel rat model of CTE, we examined temporal changes in layer V cortical neurons, the inflammatory response, and hyper-phosphorylated tau (P-tau) following repeat mild TBI.
Methods: Mild, bilateral, closed-skull TBI was administered once per week for 5 weeks, to rats at post-natal day (p) 60 once weekly for either 2 or 5 weeks. Sham and TBI rats were euthanized at acute (p90), short (p144) or long (p235) time points. TBI rats were classified as having “mild” or “severe” injuries based on rotorod performance following the last injury. Brain tissue was collected for stereological analysis to quantify layer V corticospinal motor neurons (CTIP2+ cells, large >300um), inflammatory cells (Iba1), and P-tau (AT8) over time.
Results: TBI rats exhibiting only mild rotorod deficits did not demonstrate a significant loss of large layer V corticospinal motor neurons at any time point following injury. Conversely, those with severe rotorod deficits exhibited a significant loss of large corticospinal motor neurons at the acute time point that persisted over time. Although there is an evident reduction of large corticospinal motor neurons in layer V, the total number of CTIP2+ cells in this region remained constant between sham and TBI groups at both the acute and long time points and between both mild and severe symptom groups. This would suggest that motor neurons are not dying but are perhaps unhealthy and shrinking due to injury. This apparent shrinkage of motor neurons preceded both the microglial inflammatory response and the upregulation of P-tau that was evident in both severity groups at the short and long time points, but not at the acute time point.
Conclusions: Following repeat mild TBI, rats that display severe motor deficits and progressive CTE-like brain pathology exhibit a significant reduction in large layer V corticospinal motor neurons that precedes the microglia response and upregulation of P-tau. This suggests that early targeting of neuronal cell damage could be beneficial to altering the progression of CTE caused

by repetitive head injury. By continuing to elucidate the underlying mechanisms of this disease, appropriate treatment strategies can be developed and applied.

Title: Investigating the inflammatory response to midline and lateral fluid percussion injury

Authors: *O. KOKIKO-COCHRAN[1], K. WITCHER[1], D. EIFERMAN[2], J. GODBOUT[1]
[1]Neurosci., [2]Critical Care, Trauma, & Burn, Ohio State Univ., Columbus, OH

Abstract: Animal modeling studies have become essential in identifying molecular mechanisms driving post-traumatic brain injury (TBI) pathology as well as potential therapeutic targets to improve recovery. Fluid percussion-induced TBI is one of the most popular experimental models available. Typically, fluid percussion injury (FPI) is applied at midline or parasagittal to midline in rodents. Midline FPI is broadly defined as a diffuse model of TBI in which both hemispheres are equally injured. Lateral FPI is a mixed model of TBI in which the ipsilateral hemisphere receives a focal injury resulting in diffuse damage to subcortical structures. The present study sought to investigate the acute and sub-acute inflammatory response to midline and lateral fluid percussion injury (FPI), with specific emphasis on leukocyte recruitment and cytokine expression within the brain at acute and sub-acute time points. We hypothesized that the acute inflammatory response to TBI would be enhanced following lateral FPI compared to midline FPI resulting in hippocampal-dependent functional decline at sub-acute time points. To test this hypothesis, lateral or midline FPI or sham injury was administered to equal numbers of male and female C57BL6 mice at two months of age. By four hours post-injury, flow cytometric analysis revealed a TBI-induced increase in circulating neutrophils following midline and lateral FPI. Unexpectedly, sham injured mice receiving a midline or lateral craniectomy displayed a higher percentage of patrolling monocytes compared to TBI mice. Furthermore, both sham and TBI mice in the lateral FPI group displayed a higher percentage of circulating inflammatory monocytes. Brain neutrophils and inflammatory monocytes increased following midline and lateral FPI and occurred in conjunction with an increase in inflammatory cytokines IL1-β, TNF-α, and CCL2 at 4 hours post-injury. By 72 hours post-injury, the percentage of circulating neutrophils and monocytes declined in midline and lateral TBI mice. Similarly, brain leukocytes and inflammatory cytokine expression decreased by 72 hours post-injury, although CCL2 expression remained increased in the ipsilateral hemisphere following lateral FPI. Taken

together, these data indicate that the acute inflammatory response to midline and lateral FPI is quite similar with regard to leukocyte recruitment and cytokine expression soon after injury. Further studies are underway to determine differences in behavior and leukocyte recruitment at sub-acute time points.

Abstract: Every year in the US, 2.4 million people experience traumatic brain injury (TBI). Post-mortem human pathological studies have shown chronic inflammation and ongoing white matter degeneration after a single TBI. Moreover, a single moderate-to-severe TBI has been identified as a risk factor for Parkinson's disease (PD), Alzheimer's disease (AD), and other neurodegenerative dementias. The current study sought to examine chronic neuropathological changes after a single mild TBI in swine. Using a closed-head, rotation-acceleration injury model, swine were injured and survived for various time points out to 1 year post-injury. Pathological examinations included the entire brain, but focused on areas known to be at risk in TBI, such as the corpus callosum, periventricular white matter, and hippocampus. Sections of porcine tissue were stained for the amyloid precursor protein (APP), a marker for axonal pathology, GFAP (astrocytes), Iba-1 (microglia/macrophages), and Syn303 (α-Synuclein). Initial semi-quantitative assessments found subtle pathology in discrete anatomical regions. At one month post-injury, specimens had significant reactive microglia and astrocytes in the hippocampus, subcortical white matter, and periventricular white matter. Additionally, one-month injured specimens had occasional APP+ dystrophic neurites in the periventricular white matter and corpus callosum. α-Synuclein (α-Syn) also appeared to be upregulated in several regions of the thalamus, which was reflected by increased somatodendritic Syn303 staining in

some cells and the emergence of α-Syn over-expression in a subset of white matter tracts. In the one-year cohort, time-matched shams exhibited reactive microglia in the hippocampus and periventricular white matter, but not in subcortical white matter; astrocytes exhibited normal phenotypes in these regions. There was no noticeable APP or α-Syn pathology in one-year sham specimens. In contrast, one year post-injury specimens had significant reactive microglia and astrocytes in the hippocampus, subcortical white matter, and periventricular white matter; however the amount of reactive microglia in the white matter was noticeably less than at 1 month post-injury. There was no noticeable APP pathology at one year post-injury, although thalamic α-Syn over-expression appeared to increase in presence and intensity. These results suggest that persistent inflammation and alterations in α-Syn expression may occur after a single TBI. These findings provide insight to neurodegenerative disease as a sequela to TBI, particularly as neuroinflammation is increasingly linked to the development of AD and PD.

Title: Neurofilament light concentrations in serum following experimental rotational traumatic brain injury in rats

Authors: *M. G. RISLING[1], M. ANGÉRIA[2], H. ZETTERBERG[3], K. BLENNOW[3], J. DAVIDSSON[4]
[1]Karolinska Inst., Stockholm S-171 77, Sweden; [2]Neurosci., Karolinska Institutet, Stockholm, Sweden; [3]Clin. Neurochemistry Lab., Sahlgrenska Univ. Hosp., Mölndal, Sweden; [4]Dept. of Mechanics and Maritime Sci., Chalmers Univ. of Technol., Göteborg, Sweden

Abstract: The protein neurofilament light (NFL) is predominantly expressed in the long myelinated subcortical axons. Measurement of NFL in serum of athletes after head trauma have been shown to correlate with the severity of brain injury. However, experimental models that allow for studies of NFL in serum in combination with studies of structural brain injuries are limited. Therefore, the aim of this study was to measure NFL in serum from rats following experimental sagittal plane rotation trauma and to compare these measurements to data on accumulation of Amyloid Precursor Protein (APP) in the white matter following similar type and severity trauma. Spray Dawley rats (n=65) were exposed to rapid sagittal plane rotational

acceleration head trauma (maximum rotational acceleration 1.40 ± 0.32 (mean ± SD, n=29). Serum samples were collected just prior to termination at 2.5, 24, 72, 120, 168 and 672 hours post trauma. The NFL serum concentration was studied using NFL immunoassay on the single molecule array (Simoa) platform. The trauma caused subdural bleedings in most animals. Staining brain tissue with APP antibodies and FD Neurosilver revealed wide spread axonal injuries in the corpus callosum, the border between the corpus callosum and cortex and in tracts in the brain stem. Only limited signs of contusion injuries were observed following trauma. Macrophage invasions, glial fibrillary acidic protein redistribution or hypertrophy, and blood brain barrier (BBB) changes were unusual. Traumatized animals exhibited increased NFL concentrations compared to sham exposed animals for all survival times; for survival times 24 h the increase was 8 times (exposed 666 pg/mL (range 327 to 1421 pg/mL) sham 83 pg/mL (range 40 to 114 pg/mL). The shorter and longer survival times resulted in lesser increase. At 2.5 hours and 28 days post trauma the NL serum concentration increase were approximately 2.5 times. The measured NFL leakage to the blood system appear to occur despite the absence of obvious BBB injuries. Serum NFL concentration appear to correlate with APP level in the white matter for all time points studied. In conclusion NFL serum concentrations in experimental trauma was more prominent than those reported following sports-related concussion and when using the same immunoassay technique. This study supports the hypothesis that mild rotational trauma is associated with acute axonal injury and serum NFL may offer diagnostic utility for such trauma. NFL serum level increased following trauma despite no apparent BBB injury.

Title: Divergent glial response following CCI versus blast injury in the gyrencephalic ferret brain

Authors: *S. C. SCHWERIN[1], M. CHATTERJEE[1], E. B. HUTCHINSON[2], K. RADOMSKI[4], A. IMAM-FULANI[1], J. T. MCCABE[5], C. PIERPAOLI[3], S. L. JULIANO[1]
[1]Anatomy, Physiol. and Genet., Uniformed Services Univ., Bethesda, MD; [3]Quantitative Med. Imaging Section, NIBIB, [2]NIH, Bethesda, MD; [4]Ctr. for Neurosci. and Regenerative Med., Henry M. Jackson Fndn., Bethesda, MD; [5]Dept. of Anatomy, Physiol. & Genetics, Uniformed Services Univ., Bethesda, MD

Abstract: The ferret brain is gyrencephalic, has a high white to gray matter ratio, and the placement of the hippocampus is in a ventral location similar to humans. The pathological mechanisms occurring after TBI in the ferret may therefore be more similar to humans than previously reported findings in rodents. In this study we investigated markers of injury after two different types of TBI: controlled cortical impact (CCI) and blast. Adult male ferrets either received a mild CCI (velocity = 5 m/s, depth = 2 mm, impactor diameter = 3mm, dwell time = 100 ms) in the somatosensory cortex, a single mild blast (15-17 psi) or a quick succession of 4 mild blasts (15-17 psi each, occurring within 30 minutes) and survived for various times after injury. We evaluated pathological markers of brain injury using immunohistochemistry (IBA-1: microglia; GFAP: astrocytes; CP13: phosphorylated Tau) and behavior (open field, novel object recognition, Tmaze, gait). RESULTS. A focal increase in astrocytes occurred in the region of CCI injury - both in the cortex and immediate underlying white matter. In the animals receiving a blast, however, there was a global upregulation of astrocytes just beneath the pia, in the sulcal depths, and around blood vessels in the neocortex, as well as a displaying a strong pattern of astrogliosis in the white matter. There was little to no change in microglial morphology or density in the brain after blast. In the CCI animals, however, microglia were found in clusters in the white matter extending several millimeters away from the center of the injury. Markers for phosphorylated tau were increased within the brain after blast injury but were relatively unchanged after CCI. Motor behavior was subtly affected after mild CCI, but not at all after 4X blast. Cognitive skills such as memory began to decline at 4 weeks after injury in both CCI and blast animals. In summary, two types of brain injury were studied in a gyrencephalic animal model which expressed different spatial/temporal pathological responses across glial subtypes. The astrocyte response appeared similar to that observed in humans and supports the use of the ferret in studying traumatic brain injury.

Title: Comprehensive dose-response study of progesterone in a preclinical model of penetrating ballistic-like brain injury

Authors: *C. M. GROEBER TRAVIS, S. L. OKADA-RISING, R. C. PEDERSEN, J. A. SUN, K. E. DEDOMINICIS, D. A. SHEAR
BTNN, Walter Reed Army Inst. of Res., Silver Spring, MD

Abstract: Progesterone has shown great promise in preclinical studies as a potent anti-edemic and neuroprotective therapy for traumatic brain injury (TBI). However, a recent Phase III clinical trial for progesterone as a treatment for TBI was recently stopped for futility. While there are a number of reasons why success achieved at the preclinical level with progesterone failed to translate to the clinical level, it may be partly due to the dosing regimen. In the current study, we tested 4 dose concentrations (1, 5, 10 and 20 mg/kg) for neurobehavioral outcomes in a rodent model of penetrating ballistic-like brain injury (PBBI). Unilateral frontal PBBI (10%) was induced in the right hemisphere of isoflurane anesthetized rats. Progesterone (22.5% 2-hydroxylpropyl-B-cyclodextrin) was administered as 10 minute intravenous infusions delivered at 30 min and 6 hours post-PBBI and then every 24 hours for 5 consecutive days. Results showed that 5 mg/kg was effective in reducing cognitive deficits in the Morris water maze (MWM) but was not effective in reducing motor impairment on the rotarod task. Conversely, 10 mg/kg improved motor outcome but did not ameliorate cognitive deficits. Additional experiments assessed the effects of progesterone (5 mg/kg) on reducing brain edema (wet/dry weights) at 24, 48, and 72 hours post-PBBI. Overall, progesterone failed to mitigate brain edema following PBBI. However, in brain regions distal from the lesion core, progesterone did appear to be improving recovery from edema at 48h post-injury. Additional post-injury time points are being evaluated and will be presented at the meeting. Collectively, the current results support the preclinical literature indicating that progesterone is effective in ameliorating behavioral decrements in a model of severe penetrating TBI but dosing regimens may need to be tailored more specifically to injury severity.

Title: Transcriptional alterations following traumatic brain injury in mOHSC model

Authors: *D. ZHOU[1], H. YAO[1], I. HARTLEY[1], J. WANG[1], W. WU[1], O. POULSEN[1], J. XUE[1], G. G. HADDAD[1,2,3]
[1]Pediatrics, UCSD, La Jolla, CA; [2]Neurosciences, Univ. of California San Diego, La Jolla, CA; [3]The Rady Children's Hosp., San Diego, CA

Abstract: Traumatic brain injury (TBI) may occur at any time and age. It is the leading cause of disability and death in children and adolescents in the US. The nature of the injury and its consequences vary and the course of recovery is very difficult to predict. Even though early diagnosis and ongoing therapeutic intervention may decrease the severity of symptoms, TBI, and subsequent secondary brain injuries (SBI), may still lead to long lasting impairments in one or more brain functions (such as cognitive function, physical abilities, communication and/or social/behavioral aspects). It may also trigger or predispose subjects to a variety of neuronal disorders. Therefore, a better understanding of the molecular mechanisms underlying TBI injury is essential for identifying potential targets for novel therapeutic strategies. To do so, we developed a mouse organotypic hippocampal slice culture injury model (mOHSC) in which a specified stretch for a specified duration was introduced to hippocampal slices grown on silastic membranes of the Bioflex plate to mimic the stretch impact in TBI. The level of injury was measured using PI staining of the dead cells to monitor the level of injury following stretch. Using RNA-seq, we investigated gene expression 2 hours after the introduction of the stretch. We detected a total of 265 genes with significant alteration in expression (77 were up- and 188 were down-regulated). These alterations demonstrated the presence of various pathological changes, including apoptosis, necrosis, brain edema, leakage of blood-brain barrier, severe astrocytosis, development of glial scar, leukocyte migration and tauopathy. Furthermore, these transcriptional changes also suggest potential predispositions for a variety of neuronal disorders following TBI injury, including neurodegeneration and Alzheimer disease. The current study demonstrated that mOSHC is a convenient and powerful model to study the mechanisms underlying immediate as well as consequential molecular responses to traumatic brain injury.

Title: Temporal changes in mast cell release following a mild traumatic brain injury in rats

Authors: *H. O. AWWAD[1], M. R. LERNER[2], M. BAIER[3]
[1]Pharmaceut. Sciences, Col. of Pharm., [2]Surgery, Univ. of Oklahoma Hlth. Sci. Ctr., Oklahoma City, OK; [3]Pharmaceut. Sciences, Col. of Pharm., Univ. of Oklahoma Hlth. Sci. Ctr., Oklahoma city, OK

Abstract: Following a TBI, shear force and stress to brain tissue releases a plethora of neurotoxic factors in addition to glutamate that contribute to TBI pathology and a worse prognosis, if left untreated. However, histamine release in cerebral ischemia alleviates neuronal apoptosis and improves neurological function and histamine receptors are implicated in neuronal disorders to modulate memory, pain and sleep. The specific objective of this study was to quantify the release of histamine and to correlate these changes with pain and vestibulomotor deficits following a mild TBI (mTBI) in Sprague-Dawley male rats compared to sham rats. Brains were extracted from rats euthanized on day 1 or day 8 post-TBI using the controlled cortical impact model. Levels of injury proteins and mast cells were quantified in the ipsilateral (left) and contralateral (right) sensory cortex (SC) using immunoblotting analysis and immunofluorescence microscopy. Rotarod performance, tactile allodynia and thermal hyperalgesia were assessed up to day 8 post-injury/sham. mTBI-induced vestibulomotor deficits were transient and rats showed complete recovery within 7 days of injury, whereas the same animals did not recover from mTBI-induced neurological deficits, tactile allodynia and thermal hyperalgesia during that same post-injury period. Reactive astrogliosis and degranulated mast cells were detected in mTBI rats at day 1 post-injury using immunohistochemistry. In conclusion, changes in histamine levels seem to correlate with the histopathology of reactive astrogliosis and neuroinflammation as well as increased pain sensitivity following a mild TBI.

Title: Synaptic formation of alpha synuclein aggregates acutely following experimental traumatic brain injury

Authors: *C. DIXON, Y. LI, J. HENCHIR, X. MA, S. W. CARLSON
Neurosurg., Univ. of Pittsburgh, Pittsburgh, PA

Abstract: Traumatic brain injury (TBI) has been identified as a risk factor for the development of chronic neurodegenerative diseases, including Parkinson's disease. Pathological protein misfolding is associated with disrupted cellular function and can contribute to subsequent neuronal loss. Current hypotheses suggest that synaptic dysfunction precedes neuronal loss in the pathological progression of neurodegenerative disease. Alpha synuclein (α-synuclein) has been well described for its role in contributing to the pathogenesis of Parkinson's disease. Pathological forms of α-synuclein have been observed at chronic time points following TBI. Emerging evidence highlights a central role for α-synuclein in the formation of the soluble N-ethylmaleimide-sensitive factor attachment protein receptor (SNARE) complex responsible for neurotransmitter release. We recently reported that TBI results in an acute reduction in monomeric α-synuclein. We hypothesized that TBI results in acute formation of α-synuclein aggregates in synapses. To this end, male Sprague Dawley rats were subjected to sham or controlled cortical impact (CCI) injury (2.7 mm, 4 m/s, 150 msec) and sacrificed at 2, 7, or 14 days post-injury. High molecular weight α-synuclein aggregates, confirmed using two antibodies, were detected in hippocampal whole cell and synaptosomal-enriched lysates at all time points assessed. Immunohistochemical staining revealed aggregated α-synuclein immunoreactivity in pericontusional gray and white matter and the dentate gyrus of the hippocampus at 2 weeks following CCI injury. These findings provide novel evidence for acute α-synuclein aggregates in the injured synapse that may contribute to impaired synaptic and neurobehavioral function after TBI.

Title: Neuroinflammation and Neuronal damage in neurocysticercosis using animal model

Authors: *M. R. VERASTEGUI[1], R. P. CARMEN[1], R. H. GILMAN[3], D. G. DÁVILA[1], G. CASTILLO[1], J. D. MORALES[1], N. CHILE[1], E. G. BERNAL[1], B. J. CONDORI[1], A. D. DELGADO[1], L. E. BAQUEDANO[1], C. CYSTICERCOSIS-WORKING-GROUP[2]
[1]Infectious Dis. Lab. Research-LID, [2]Univ. Peruana Cayetano Heredia, Lima, Peru; [3]Bloomberg Sch. of Hyg. and Publ. Hlth., Johns Hopkins Univ., Baltimore, MD

Abstract: Human neurocysticercosis (NCC) is a parasitic disease caused by larvae of the cestode *Taenia solium* (cysticercus), when invade central nervous system (CNS). Human NCC is one of the most significant parasitic diseases of the CNS. It is an important contributor to neurological morbidity in developing countries, and is the major cause of acquired epilepsy in the developing world. We developed a NCC animal model using rats, which is useful tool to investigate NCC pathology. The following study describes the neuronal damage in rats infected with activated oncospheres of *T. solium* via two routes of infections: direct intracranial injection and oral feeding. At 4-5 months after infection where the larvae is mature, infected brains present extensive axonal spheroids immunoreactive to neurofilament and amyloid precursor protein. We did not observe difference in the frequency nor the average number of axonal spheroids in both routes of infection. This pathology is observed in conjunction with perivascular inflammatory cuffing (PIC), edema and gliosis in the tissue adjacent to the parasite as well as extending beyond this area into otherwise appearing normal brain tissue. Gliosis (positive to GFAP and Iba-1) were similar in both routes but PIC and inflammatory cells (heterophils and plasmocytes) were significantly higher in the intracranial route. Taken together, our data provides the first evidence that neuronal lesion may contribute to the pathogenesis in experimental NCC. Additionally, our findings may represent an interesting avenue for future study in this parasitic brain disease for their potential as a common crossroad between neuroinfectious diseases such as NCC and neurodegenerative diseases, which classically exhibit neuronal damage.

Title: Sex modulates the impact of inflammation on brain development after cranial irradiation

Authors: *E. DE GUZMAN[1,2], M. AHMED[1], S. PERRIER[1], B. NIEMAN[1,2,3]
[1]Mouse Imaging Ctr., Hosp. For Sick Children, Toronto, ON, Canada; [2]Dept. of Med. Biophysics, Univ. of Toronto, Toronto, ON, Canada; [3]Ontario Inst. for Cancer Res., Toronto, ON, Canada

Abstract: Introduction: Cranial radiation therapy (CRT) is one of the main contributing factors to long term neurocognitive deficits in survivors of pediatric cancers. The risk for and severity of these deficits are greater in female patients. CRT also induces neuroanatomical changes detectable as volume deficits with magnetic resonance imaging (MRI). These are likewise more pronounced in females, both in humans [1] and, to a lesser extent, in mice [2]. While the direct cellular cause of these deficits remains to be elucidated, it has been hypothesized that changes to the cellular environment post-irradiation alter neural progenitor cell fate, and may inhibit recovery [3]. Irradiation induces a chronic inflammatory response that may be responsible [4]. With strong evidence suggesting sex is an important factor in immune response [5], the goal of this study was to determine how irradiation induced changes in neuroanatomical development depend on inflammatory response, and whether or not that response is dependent on sex.
Methods: C-C chemokine ligand 2 (CCL2; previously called monocyte chemoattractant protein, MCP-1) has been shown to play a critical role in neuroinflammation [6]. Knockout of its receptor, CCR2, recovers neurogenesis in the irradiated adult mouse brain and is associated with recovery of hippocampal dependent behaviour [7]. As a result, we chose to irradiate CCL2-deficient and CCL2-wild-type mice with a whole brain dose of either 0 or 7 Gy during infancy. In vivo MRI was used to track brain development for 3 months following irradiation, and deformation-based morphometry was used to identify volume differences across development.
Results: Irradiation of wild type mice results in a deficit in neuroanatomical growth that is subtly more pronounced in females. Male CCL2-deficient mice are significantly protected from this damage, while female CCL2-deficient mice are not. The development of unirradiated CCL2-deficient mice is also different from wild type mice, confounding the response to irradiation. Our conclusions are two-fold: 1) immune response plays an important role in the development of irradiation induced neuroanatomical deficits, and 2) sex modulates the role of the immune response to radiation and is critical to consider in development of treatment strategies.

Title: Optic tract degeneration and neuroinflammation in a closed head adolescent mouse model of traumatic brain injury

Authors: *N. K. EVANSON, F. GUILHAUME-CORREA
Div. of Pediatric Rehabil. Med., Cincinnati Children's Hosp. Med. Ctr., Cincinnati, OH

Abstract: Objective: To determine the nature of injury in adolescent mice after experimental closed head weight drop traumatic brain injury (TBI).
Methods: 6 week old male C57BL/6J mice were subjected to weight drop using a 400g rod and drop height of 1.5 cm under isoflurane anesthesia, or to anesthesia only. Separate cohorts of mice (n=8 per experimental group) were perfused either 24 hours or 7 days after injury, and brain was examined using histologic staining (NeuroSilver or FluoroJade degeneration stains, or Nissl Stain), or by immunohistochemistry to markers for neurons (NeuN), astrocytes (Glial Fibrillary Acidic Protein), microglia/macrophages (Iba-1), or a marker of axonal damage (amyloid precursor protein, APP). Other animals (n=16 per group) were subjected to experimental TBI, then underwent behavioral analysis including visual cliff, open field, and novel object recognition tests. The effect of coronal load on the skull was analyzed by MicroCT imaging. Planned experiments will test the effect of chronic variable stress on behavioral outcomes after experimental TBI.
Results: Gross pathology and Nissl stain did not reveal evidence of gross neurologic damage, and there was no widespread neuronal loss by NeuN staining. Fluoro Jade and NeuroSilver stains revealed evidence of axonal degeneration that was most evident in the bilateral optic tracts, the lateral geniculate nucleus of the thalamus, and superior colliculus. This was accompanied by astrocytic gliosis in these areas, and neuroinflammation as revealed by morphologic activation of microglia. MicroCT analysis of the mouse skull under dorsal-ventral load revealed partial collapse of the optic canal. Behavioral differences between TBI and sham animals were relatively subtle, and did not appear to demonstrate severe visual deficits.
Conclusions: Experimental closed head TBI in adolescent mice leads to reproducible damage to the optic tracts and proximal target regions, which is associated with astrocytosis and neuroinflammation. This damage appears to be caused by an optic nerve contusion due to collapse of the optic canal during TBI.

Title: The effect of repetitive mild traumatic brain injury on tau pathology

Authors: *G. EDWARDS, III, N. MENDEZ DINAMARCA, C. SOTO, I. MORENO-GONZALEZ
Neurol., Univ. of Texas Hlth. Sci. Center-Houston, Houston, TX

Abstract: Mild traumatic brain injury is the most common form of concussion and is prevalent among contact sports athletes and military personnel. Repetitive mild traumatic brain injury (rmTBI) can trigger the activation of several molecular cascades that lead to neuropathological consequences in the brain. Moreover, rmTBI has been correlated to neurodegenerative diseases such as chronic traumatic encephalopathy (CTE). CTE is a slow, progressive tauopathy that exhibits neurofibrillary tangles (NFTs) accompanied by psychiatric and cognitive manifestations. NFTs are intracellular aggregates formed from the misfolding and aggregation of tau protein. A vast majority of individuals following a TBI event demonstrate early tau accumulation, independent of age, suggesting a potential pathological link between TBI and tauopathies. The role of tau aggregation in brain and in subsequent clinical symptoms following rmTBI remain to be elucidated. Moreover, effective diagnostic methods for TBI and tau pathology are lacking. The goal of the current study is to assess the generation of tau aggregates and brain pathology following rmTBI induction in mice. Thus, transgenic (Tg) tau mice were subjected to rmTBI events, which mimic multiple sub-concussive impacts in athletes, over various time-points. Tg tau mice subjected to rmTBI demonstrated neurobehavioral changes as well as early misfolded tau deposition and elevated tau levels in brain. These results indicate that rmTBI could be a trigger for early aggregated tau formation; in addition, misfolded tau can play a role in the psychiatric and cognitive behaviors affiliated to TBI and disease. Overall, this work will shed light to understanding the effect of rmTBI in relation to tau pathology and behavioral impairment and will potentially provide a potent diagnostic tool to detect tauopathy onset and monitor TBI-induced brain damage in the future.

Title: Pial arteriolar hyper-responsiveness after blast was related with changes in endothelin-1 and endothelin receptors expression

Authors: *S. H.-E.-R. MULLAH[1], R. ABUTARBOUSH[1], Y. CHEN[1], M. LASHOFF-SULLIVAN[1], F. ARNAUD[1,2], U. KAWOOS[1], R. MCCARRON[1,2], S. T. AHLERS[1]
[1]Naval Med. Res. Ctr., Silver Spring, MD; [2]Uniformed Services Univ. of Hlth. Sci., Bethesda, MD

Abstract: Background: Traumatic brain injury (TBI) resulting from exposure to blast overpressure (BOP) component of improvised explosive devices (IEDs) is a prevalent injury in recent conflicts. Changes in cerebral vasculature, such as delayed presentation of cerebral vasospasm and blood-brain barrier dysfunction, have been reported following blast-induced TBI that present challenges to neurosurgical care and to the recovery of the patient. We previously reported functional changes in cerebrovascular responses within 24 hours after different BOP intensities using a cranial window technique in rodents. In this study, we examined vascular responsiveness over a longer timeframe after the blast exposure than our previous study and further explored potential underlying role of endothelin-related pathways after BOP exposure as a possible mechanism underlying BOP-induced cerebrovascular changes. **Methods:** Anesthetized male Long Evans rats were exposed to single blasts of either 0 (sham control), 37, 75 or 140 kPa while located inside a shock tube apparatus and then allowed to recover fully. At 2h, 1, 3, 14 or 28 days, rats were re-anesthetized, ventilated and a cranial window was made in the parietal bone to expose the surface of the cerebral cortex. Pial arteriolar diameters were measured in real time using intravital microscopy before and after hypercapnia (7.5% CO_2), and topical application of barium chloride (5% $BaCl_2$,) and serotonin (5-hydroxytryptamine, 5HT). The expression of endothelin-1 (ET-1), ETA and ETB receptors was examined in the frontal cortex at 1 and 3 days post-blast. **Results:** After blast, increases in vasoconstriction by $BaCl_2$ ($P < 0.01$), and vasodilatation by CO_2 were seen at all intensities of BOP. While control animals showed vasoconstriction by 5-HT, BOP-exposed animals showed vasodilation. The changes in pial arteriolar reactivity varied with blast intensity and time after blast. The increase in the

arteriolar response in BOP-exposed rats in the 37 kPa group appeared to normalize to baseline levels by 28 days. In the 140 kPa group increased responsiveness persisted until at least 28 days post-BOP. Preliminary RT-PCR data showed an increase in mRNA expression for ET-1 one day following low intensity blast. Western blot analysis indicated significantly lower levels of ETA receptor in the 140 kPa group and significantly lower levels of ETB receptor in 75 and 140 kPa groups at 3 days post-blast. **Conclusion:** Cerebral pial arteriolar hyper-responsiveness may correlate with BOP intensity. Changes in expression of ET-1, ETA and ETB receptors indicate a possible association with BOP-induced changes to cerebrovascular function.

Title: Nogo receptor-1 regulates balance, cognition and emotion after mild traumatic brain injury in mice

Authors: *J.-H. LAI, ESQ[1], K.-Y. CHEN[2], J. C.-C. WU[3], C.-Z. CHI-ZONG HUANG[3], Y.-H. CHEN[3], L. OLSON[4], Y.-H. CHIANG[3]
[1]Ph.D. Program for Neural Regenerative Med., [2]Grad. Inst. of Neural Regenerative Medicine, Col. of Med. Sci. and Technol., [3]Dept. of Surgery, Col. of Med., Taipei Med. Univ., Taipei, Taiwan; [4]Karolinska Inst., Stockholm, Sweden

Abstract: Background: Traumatic brain injury (TBI) is a major public health issue of the lesioned central nervous system. Among all the TBI, Mild TBI (mTB) has 75~90% of the TBI and can cause the various physical, cognitive, emotional, and psychological-related symptoms. Nogo receptor 1 (NgR1) is a glycosylphosphatidylinositol (GPI)-anchored protein on the cell surface and involved in the central nervous system (CNS) axonal plasticity, development, and recovery from injury. But the role of the NgR1 in behavior after mTBI is still unknown. The study focusses on investigating the role of NgR1 in the balance, cognition and emotion after mTBI in mice
Methods: NgR1-Tg mice were obtained from the Olson Laboratory in Karolinska Institute Stockholm, Sweden. NgR1-Tg mice were generated by CamKII-tTA mating with pTRE-NgR1 to obtain NgR1 overexpressing mice. Doxycycline (Sigma-Aldrich) dissolved in drinking water

(100 μg/mL) was giving to turn off transgene expression to mice carrying both the CamKII-tTA and the pTRE-NgR transgenes. Animal study were approved by the Institutional Animal Care and Use Committee (IACUC) of the Taipei Medical University and National Defense Medical Center. mTBI was induced by weight drop impact. Mice were anesthetized with isoflurane and then brain was placed soft platform and impacted with a rod-shaped 25-g metal dropped trough the guide tube (diameter 13 mm × length 80 cm).
Results: To determine the role NgR1 on behavior after mTBI, we tested NgR1-Tg mice by the four groups after non mTBI and mTBI with doxycycline or not. We found the NgR1-Tg mice with doxycycline were better than the NgR1-Tg mice without doxycycline after mTBI on balance, learning memory, cognition and anxiety. The behaviors after mTBI were recovery on the second week.
Conclusions: These results were shown that NgR1-Tg mice have the long-term memory, cognitive and emotional problems on non-mTBI mice but not in balance. The NgR1-Tg mice after mTBI were worse than these mice with doxycycline on balance, the long-term memory, cognitive and emotional. NgR1 could play an important role in physical, cognitive, and psychological-related behavior. Key words: mTBI, NgR1, behavior

Title: Blast-induced traumatic brain injury displays a unique pattern of spatial neuropathology

Authors: *N. CHANDRA[1], R. R. KAKULAVARAPU, 07102-1982[2], D. Y. YOUNGER, 07102-1982[2], A. A. ARAVIND, 07102-1982[2], B. P. PFISTER, 07102-1982[2], M. KURIAKOSE[2], M. SKOTAK[2]
[1]Biomed. Engin., New Jersey Inst. of Technol., Morris Plains, NJ; [2]Biomed. Engin., New Jersey Inst. of Technol., Newar, NJ

Abstract: Blast-induced Traumatic brain injury (bTBI) is a leading cause of morbidity and mortality in soldiers in the combat and in training sites and is becoming an important public health issue. The bTBI simultaneously causes primary (shockwave), secondary (penetrating), and tertiary (blunt-accelerative forces) injuries causing different loading modalities and pathological outcomes compared to pure blunt injury. The brain injury patterns resulting from primary

shockwave propagation across different brain structures has not been carefully investigated. We hypothesize that bTBI has a unique histopatholgy and pathophysiology different from blunt TBI. In bTBI all the regions of brain from prefrontal cortex to hippocampus to cerebellum to brain stem are all simultaneously biomechanically loaded as the shock wave propagates unimpeded across the brain. This is different from the blunt TBI, where the injuries are mostly confined to the site of injury and nearby areas, the extent of which is dictated by the severity of blunt loading. Since oxidative stress has been implicated as a major pathogenic factor in TBI, here we examined the brain spatial resolution and cellular distribution of changes in superoxide producing enzyme NADPH oxidase1 (NOX1) as well as neurodegeneration paradigm during the early phase (4h) of moderate blast TBI (180 Kpa) and compared these data with that of moderate blunt TBI (FPI). Immunofluorescence analysis displayed that NOX1 was upregulated in different brain regions and showed a differential vulnerability with the highest increase found in hippocampus and thalamus followed by frontal cortex and cerebellum. Among different cells, neurons exhibit highest amount of basal NOX1 and its increase was higher in hippocampal and cerebellar regions compared to astrocytes and microglia. Interestingly, blunt injury induced in the cortical region did not display any change in NOX1 expression in cerebellum suggesting that the spread of the injury in blunt TBI is localized. Blast did not display neurodegeneration in any region, while blunt TBI showed focal neurodegeneration in the cortical and hippocampus areas only in ipsilateral side. These studies indicate that the injury pattern and pathological changes in blast TBI are unique and spread across the entire brain compared to blunt injuries.

Abstract: Mild traumatic brain injury (mTBI) is the predominant type of brain injury in young adults and is a risk factor for developing chronic traumatic encephalopathy and other neurodegenerative diseases. Our previous studies have demonstrated that elevation of endocannabinoids 2-arachidononyl glycerol and anandamide by inhibition of α/β-hydrolase domain 6 and fatty acid amide hydrolase reduces neuroinflammation and attenuates neuronal injury in the controlled cortical impact mouse model. Here, we investigate the therapeutic efficacy of MJN110, a novel monoacylglycerol Lipase (MAGL) inhibitor in a repetitive mild closed head injury (rmCHI) mouse model. rmCHI procedure was performed in 8-10 week old, male C57BL/6 mice once a day for 3 days. MJN110 (2.5 mg/kg, i.p.) was administered at 30 min after each impact and then once a day for 5 days. To evaluate fine motor movement and motor coordination, beam walk and rotarod tests were conducted at 4, 6 and 10 days after first impact. Our results showed that treatment with MJN110 significantly reduced foot-faults in beam walk and rendered longer latency to fall in the rotarod test. Learning and memory defects in TBI mouse were observed at day 13 by Y maze and Days 24-28 by Morris water maze, and these deficits were significantly reversed in the drug treated animals. Treatment with MJN110 significantly attenuated the expression of proinflammatory cytokines including IL-6, TNF-α, iNOS and ATF-3 (a stress inducible transcription factor) in ipsilateral cortex and suppressed the accumulation of astrocytes and microglia/macrophages in hippocampus. The increased expression of phosphorylated Tau (p-Tau) in ipsilateral hippocampal dentate gyrus was dramatically reduced. Western blot analysis revealed that MJN110 significantly reduced the increased expressions of amyloid precursor protein (APP), p-Tau and iNOS in the cerebral cortex of TBI mouse brain. MJN110 treatment also restored the expression of the glutamate receptor subunits, GluR1, NMDAR2A and 2B, which showed a significant decrease in the rmCHI mouse cortex and hippocampus. We speculate that the reduced inflammatory response and restored glutamate receptor expression might contribute to the improved motor function, learning and memory in MJN110 treated animals. The therapeutic mechanisms afforded by MJN110 is currently under investigation.

Abstract: Worldwide, the incidence of traumatic brain injury (TBI) approximates 0.5% per year and the frequency is much higher among service personnel and athletes. The majority of TBIs are mild and these can result in deleterious cognitive effects for which there is currently no effective treatment. Moreover, repetitive mild head injuries, common in military and athletic activities, have produced more severe consequences. We have demonstrated improved outcomes in both *in vitro* and *in vivo* models of brain injury following treatment with tert-butylhydroquinone (tBHQ) by activation of the inflammatory responsive transcription factor, Nrf2, and downstream neuroprotective factors. Additionally, the PPAR-γ agonist, pioglitazone, has been shown to have neuroprotective effects in models of neurodegenerative disease and TBI. In an effort to better understand the underlying mechanisms we tested mice receiving closed head injuries once per week for 5 weeks along with potentially synergistic treatment by tBHQ plus pioglitazone. At acute and chronic times we evaluated gene expression, cognitive changes, and immunohistochemistry for microglial changes (Iba1) and lipid peroxidation (4-hydroxynonenal). mRNA samples from the ipsilateral hippocampi one day post-injury were evaluated with Affymetrix GeneChip Arrays. Our initial examination (4 groups, n=6 per group) indicated that genes displayed a variety of expression patterns. For example, dysregulations after injuries alone included upregulation of G-protein coupled receptor 3 (Gpr3) and downregulation of aminolevulinic acid synthase (Alas2). After injuries, the transcription factor modulation caused elevation of cysteine-rich secretory protein LCCL domain containing 2 (Crispld2) and lowering of erythroid differentiation regulator 1 (Erdr1) expression. Some genes that were decreased by the injury were increased by the treatment, e.g., SRY (sex determining region Y)-box 3 (Sox3), and certain genes, like ankyrin repeat and SOCS box-containing 6 (Asb6), were induced by the injury and reduced by the treatment. Through these approaches, we hope to better define inflammatory responsive transcription factor signaling pathways and identify factors that could be targeted to produce neuroprotection and improve outcomes for our veterans and others that have received TBIs.

Title: Phenserine mitigates neurodegeneration and neuroinflammation in a mouse mild traumatic brain injury model

Authors: D. LECCA[1], M. BADER[2], D. TWEEDIE[1], R. BECKER[3], C. PICK[2], *N. H. GREIG[1], *N. H. GREIG[1], *N. H. GREIG[1]

Abstract: Mild traumatic brain injury (mTBI), as a single or repeated event, is a common cause of a large spectrum of symptoms, including headache, depression, anxiety, and impaired cognitive function. Associated with neuronal dysfunction and loss, mTBI may promote later development of neurodegenerative disorders. No pharmacological treatment has been approved for TBI. Herein, we evaluated the neuroprotective and anti-inflammatory potential of phenserine (Phen), a reversible anticholinesterase with a broad range of non-cholinergic actions originally developed and clinically tested for Alzheimer's disease, in a mouse mTBI (30 g weight drop) model. By immunohistochemical techniques, we evaluated Phen at 2 clinically translatable doses (2.5 & 5.0 mg/kg BID post mTBI) in hippocampus and lateral parietal cortex (LPC) of mTBI-challenged vs. control (unchallenged) mice at 72 hr (time of peak apoptosis). mTBI induced neuronal loss within all analyzed brain regions, as evaluated by counting Fluorojade C positive (+) cells, which Phen (5.0 mg/kg) fully mitigated. Neuroinflammatory changes were appraised by quantitative evaluation of microglial activation (IBA1) and pro-inflammatory cytokine TNFα immunoreactivity (IR) levels. Following mTBI, IBA1 IR was elevated vs. controls, across all analyzed brain regions. Treatment with Phen (5.0 mg/kg) inhibited microglial activation in CA3 and dentate gyrus (DG) of hippocampus, and in LPC. Consistent with this, IR for the pro-inflammatory cytokine TNFα was elevated in IBA1+ cells in mTBI-challenged vs. control mice across brain areas. Phen (2.5 & 5.0 mg/kg) reduced levels IBA1/TNFα IR colocalization volume in CA3 and DG for hippocampus, and in LPC. These data indicate that Phen ameliorated the neurodegeneration and neuroinflammation mediated by mTBI, consistent with these same doses mitigating cognitive impairments in mice at 7 days (Tweedie et al., PLoS One, 2016); offering a therapeutic approach for this pathological condition.

Title: Hyperbaric oxygen therapy as a treatment for traumatic brain injury

Authors: *C. G. PICK[1], S. TOUSSIA- COHEN[2], R. BARATZ- GOLDSTEIN[2], A. ELPAZ[2], V. RUBOVITCH[2]
[2]Anat., [1]Tel Aviv Univ., Tel Aviv, Israel

Abstract: Traumatic brain injury is the most common cause of death and chronic disability among people under 35-years-old and without an effective pharmacological treatment currently existing. Hyperbaric oxygen therapy (HBOT) is defined as the inhalation of pure oxygen in a hyperbaric chamber that is pressurized greater than 1 atmosphere. HBOT offers physiological and mechanical effects by inducing a state of increased pressure and hyperoxia. HBOT has been proposed as an effective treatment for mTBI, yet the exact therapeutic window and mechanism that underlies this effect is not completely under stood. HBOT was administrated for 4 consecutive days, post a mouse closed head weight drop mild TBI (mTBI) in 2 different time lines: immediate initiated 3 hours post injury and a delayed treatment initiated 7 days post injury. Behavioral cognitive tests and biochemical changes were assessed. The results were similar for both the immediate and the delayed treatments. mTBI mice exhibited impairment in learning abilities, whereas mTBI mice treated with HBO dis played significant improvement compared with the mTBI group, performing similar to the sham groups. mTBI mice had a decline in the myelin basic protein, an increase in neuronal loss (NeuN staining), and an increase in the number of reactive astrocytes (GFAP). The HBO treated mice in both groups did not exhibit these changes and remained similar to the sham group. The delay HBOT has a potential to serve as a neuro protective treatment for mTBI with along therapeutic window.

Inst. of Hlth., Baltimore, MD; [3]Dept. of Chemistry, Indiana Univ., Bloomington, IN; [4]Dept. of Neurol., UCLA, Los Angeles, CA

Abstract: Traumatic brain injury (TBI) is a commonly occurring injury in victims of sports, motor vehicle accidents and falls. TBI has become a pressing public health concern with no specific therapeutic treatment. Mild TBI (mTBI), which accounts for approximately 90% of all TBI cases, is frequently underestimated, as the immediate physical symptoms decrease rapidly and patients do not show clear structural brain defects. However, they frequently suffer from long-lasting cognitive, behavioral and emotional impairments. The incretins glucagon-like peptide-1 (GLP-1) and glucose-dependent insulinotropic polypeptide (GIP) are gastrointestinal hormones. These peptides induce glucose-dependent insulin secretion, promote β-cell proliferation and enhance resistance to apoptosis. GLP-1 mimetics are on the market as treatments for type II diabetes and are well tolerated. Both GLP-1 and GIP mimetics have shown neuroprotective properties in animal models of Parkinson's and Alzheimer's disease. The aim of this study is to evaluate the potential benefit of enhancing the incretin activity in the brain following mTBI by using two different drugs; liraglutide (GLP-1 analogue) and twincretin (dual GLP-1/GIP receptor agonist). To do that, we subjected mice to mTBI using a weight-drop device and administered twincretin or liraglutide in a 7-day regimen of subcutaneous injection starting 30 min after the injury. Subsequently, we investigated the effects of these drugs on cognitive impairments, neuronal degeneration and neuroinflammation following mTBI over several times. Both liraglutide and twincretin ameliorated mTBI-induced visual memory impairments as assessed by the novel object recognition paradigm, with twincretin showing superiority. Both drugs similarly mitigated mTBI-induced spatial memory deficits in the Y-maze test. These effects were observed at both 7 and 30 days post-mTBI. No differences between groups were evident in anxiety-like behavior assessed by the elevated plus maze demonstrating that efficacy in the preceding paradigms were not confounded by anxiety differences among the groups. Neuronal loss was quantified immunohistochemically using Fluoro-Jade B and anti-NeuN antibodies in the cortex. Both treatments significantly mitigated mTBI-induced neuronal

degeneration. Neuroinflammation was evaluated by the anti-GFAP antibody. mTBI resulted in elevated astrocytes count. No treatment affected this elevation. These findings offer a new potential therapeutic approach to treat mTBI. Further studies will continue to investigate the neuroprotective effects and mechanism of action of incretin-based therapies within the brain.

Title: The GLP-1R agonist, exendin-4, ameliorates open-field blast brain injury-induced learning and memory deficits, neuronal degeneration and altered synaptophysin staining in mouse

Authors: *L. RACHMANY RABER[1], D. TWEEDIE[2], V. RUBOVITCH[1], B. J. HOFFER[3], N. H. GREIG[2], C. G. PICK[1]
[1]Dep.Of Anat. and Anthropology, Sackler Sch. of Medicine, Tel-Aviv Univ., Tel-Aviv, Israel; [2]Intramural Res. Program, Natl. Inst. on Aging, NIH, Baltimore, MD; [3]Case Western Reserve Univ. Sch. of Med., Cleveland, OH

Abstract: Blast Traumatic Brain Injury (B-TBI) is a significant cause of disability and death worldwide, particularly among military forces serving in modern combat operations and civilians. A blast detonation of an explosive device causes changes in the atmospheric pressure, and as a result, organs and tissues of different densities are accelerated at different relative rates, resulting in displacement, stretching and shearing forces. Presently there is no FDA approved medication for the treatment of B-TBI. We investigated the benefits of a FDA approved medicine, Exendin-4 (Exenatide, Ex-4) a long acting glucagon-like peptide 1 receptor agonist, with known neuroprotective/neurotrophic/anti-inflammatory properties in an open field B-TBI model. B-TBI induced long-lasting cognitive and memory impairments. These deficits were associated with B-TBI-dependent diffuse neuronal degenerative process and reductions in the levels of synaptophysin protein staining in cortical and hippocampal tissues. Treatment of animals with a clinically translatable dose of Ex-4 delivered by subcutaneous micro-osmotic pumps to maintain steady-state drug levels for 7 days starting either 48 hours prior to or 2 hours immediately following B-TBI prevented the induction of cognitive and memory deficits as demonstrated in Novel Object Recognition and Y-maze behaviors and the Injury-induced neuronal degeneration and changes in synaptophysin staining. Even very mild exposure to blast wave might cause brain injury. This kind of injury strikes mostly military personnel but also

civilians encountering acts of terrorism and its consequences might be prolonged. Therefore, finding medical solutions to treat the injury is critical and essential. Currently, there is no clinical treatment for blast injury preventing future damage, probably due to the complexity of the brain injury. These data indicate that treatment with the clinically approved drug, Ex-4, represents a viable option for the management of secondary events triggered by blast-induced, mild traumatic brain injury that is commonly observed in militarized areas. Current studies are optimizing Ex-4 administration to support rapid clinical translation.

Title: Loss of blood-brain barrier integrity in the corticostriatal pathway following experimental traumatic brain injury and subsequent susceptibility to the rewarding effects of a sub-threshold dose of cocaine

Authors: *L. CANNELLA[1], M. MAYNARD[1], S. F. MERKEL[1], E. M. LUTTON[1], R. RAZMPOUR[1], R. G. AZER[1], A. M. ANDREWS[3], S. M. RAWLS[2], S. H. RAMIREZ[1]
[1]Pathology and Lab. Med., [2]Ctr. for Substance Abuse Res., Temple Univ. Lewis Katz Sch. of Med., Philadelphia, PA; [3]Pathology and Lab. Med., Temple Univ. L, Philadelphia, PA

Abstract: Substance use disorders are a common de novo psychiatric diagnosis seen in traumatic brain injury (TBI) patients. Previously we found that moderate experimental TBI increased the susceptibility to the rewarding effects of a sub-threshold dose (2.5 mg/kg) of cocaine in adolescent mice two weeks post injury. Interestingly, we did not see this effect if injury occurred during young adulthood or if tested four weeks post injury. Consistent with known secondary mechanisms of injury following TBI, we observed loss of blood-brain-barrier (BBB) integrity and augmented inflammatory profiles, although distal from the area of impact, in brain regions associated with motivation, saliency and reward perception. Specifically, we detected disrupted BBB properties in vessels isolated from the cortex, prefrontal cortex (PFC), and nucleus

accumbens (NAc) of TBI animals measured by decreased expression of tight junction proteins. We also report marked changes in immune response-associated gene expression and increased BBB permeability in these nuclei. Thus, we hypothesize that the BBB changes post brain injury, as a component of neuroinflammation, affect how the rewarding effects of cocaine may shift as a consequence of TBI. An important question that has yet to be answered is whether TBI selectively alters the sensitivity to rewarding effects of psychostimulants or alters responses to their pharmacodynamics, such as induced locomotion. To investigate this we used a controlled cortical impactor set to produce a moderate or mild TBI in 6-week-old male C57BL/6 mice. Locomotor activity was assessed following a single administration of vehicle, 2.5, or 10 mg/kg cocaine in un-injured, sham, mild, or moderate TBI mice two weeks post injury. Ambulation, stereotypy, and total activity were recorded for 60 minutes following acute cocaine exposure. Moderate TBI did not affect locomotor activity produced by cocaine administration. In combination with recent data implying altered expression of dopamine-associated genes in the NAc, our studies suggest that TBI during adolescence may increase the abuse liability of cocaine, as indicated by increased drug-seeking behavior, by altering dopamine neurotransmission in the reward pathway, without increasing cocaine's locomotor activating properties.

Title: Differential changes in tight junction protein expression at areas of blood-brain barrier hyperpermeability following experimental traumatic brain injury

Authors: *M. MAYNARD[1], A. M. ANDREWS[2], E. M. LUTTON[2], R. RAZMPOUR[2], M. SEASOCK[2], W. R. KUNG[2], S. H. RAMIREZ[3]

[1]The Lewis Katz Sch. of Med. at Temple Univer, Philadelphia, PA; [2]Pathology & Lab. Med., [3]Pathology and Lab. Med., The Lewis Katz Sch. of Med. at Temple Univ., Philadelphia, PA

Abstract: Traumatic brain injury (TBI) is an important public health problem in the US. Primary injury from TBI results in physical damage to the neurovascular unit. The secondary phase of injury is triggered by oxidative stress, inflammatory responses and changes in cerebral blood flow. Additionally, it has been well established that dysfunction of the blood-brain barrier (BBB) is a key contributor to the pathology of TBI. However, a biochemical characterization of how tight junction proteins (TJPs), which are essential for BBB integrity, are affected following TBI has not been previously reported. Therefore, using the controlled cortical impact mouse model of TBI (CCI-TBI), vessels were isolated from the site of injury at various time points and across TBI severities. First, visual assessment of BBB permeability was performed using a sodium fluorescein (NaF) in vivo permeability assay. Results demonstrated hyperpermeability to NaF following CCI-TBI, as indicated by increased fluorescent signal in the brain parenchyma of animals that received mild or moderate CCI-TBI at 8, 24 and 72 hrs. Vessels isolated from cortical regions ipsilateral to the impact site were immunostained for the following TJPs: occludin, tricellulin, claudin-5 and ZO-1. Next, vessels were counterstained for endothelial markers PECAM-1 or Glut-1. Image analysis was performed and intensity measurements were calculated as a function of area and vessel caliber. Results demonstrated lower TJP expression following CCI-TBI in the moderate injury groups when compared to sham surgery controls, with distinct protein-specific rates of decreased expression. Morphological changes were also evident, in that some TJPs (i.e. occludin) seemed to be absent from the injured vessels in contrast to others which had a more punctate or cytosolic redistribution. Mild CCI-TBI had a similar profile to moderate for occludin but differed in magnitude. Therefore, our results suggest that various TJPs at the BBB are affected differently by neurotrauma and that ongoing dynamic changes in their expression may offer an explanation to the increased vascular permeability that is observed following TBI.

Title: Intraventricular *In utero*-electroporation BRAFV600E-induced tumors in mice resemble ganglioglioma key features

Authors: *S. CASES-CUNILLERA[1], B. K. ROBENS[2], S. SCHOCH[3], A. J. BECKER[4]
[1]Inst. für Neuropathologie, Universitäts Klinikum Bonn, Bonn, Germany; [2]Univ. Bonn Med. Ctr., Bonn, Germany; [3]Bonn Univ. Med. Sch., Bonn, Germany; [4]Neuropathology; Univ. Bonn Med. Ctr., Bonn, Germany

Abstract: Gangliogliomas (GGs) are generally benign glioneuronal tumors strongly associated with focal epilepsy emerging in younger aged patients. The histological hallmark is an admixture of dysplastic, sometimes bi-nuclear neurons with neoplastic astroglia. Recently, $BRAF^{V600E}$ has been found in approximately 20-60% of human GGs in both, neuronal and astroglial tumor cell components. These data have prompted the concept that GGs can develop by only a 'single mutational' hit to a neural precursor cell population during brain development. To test this hypothesis, we applied intraventricular *in utero* electroporation (IUE) with the piggyBac transposon system to drive genomic integration of transgenes into progenitor cells. We IU-electroporated a piggyBac vector containing the sequence encoding $BRAF^{V600E}$ under control of the ubiquitous (CAG-) promoter at the embryonic day 14 (E14) in CD1/C57BL6 mice (n=5). We observed highly differentiated glioneuronal tumors in all mice subjected to IUE with CAG-$BRAF^{V600E}$ (n=5) vs. no tumors in mice IU-electroporated with CAG-GFP (n=4). Respective tumors are composed of irregularly oriented ganglionic neurons and sparse, isomorphic glial cells with astrocytic differentiation, strongly resembling human GGs. Immunolabeling revealed 48.4% percent of cells within the tumor to be positive for the glial marker Olig2 and 23.4% were positive for the neuronal marker NeuN. These neoplasms showed a low-grade biological behavior with 80% of animals surviving until P110 and, accordingly, antibodies against the proliferation-associated antigen Ki-67 were only detected in less than 5% of cellular nuclei in the area of the tumor. Our data suggest, that the distinct astroglial and dysplastic neuronal components of GGs can develop from a unique mutational hit of neural precursors and that thus, both components can be targeted by a BRAF-inhibitory pharmacological approach.Our work is supported by the Deutsche Forschungsgemeinschaft (SFB 1089), Fritz Thyssen Foundation, the EraNet DeCipher (BMBF) and local funding (BONFOR). We thank Dr. David Jones for providing the DNA encoding $BRAF^{V600E}$.

Title: Long-term effects of blast exposure: A functional study in rats using an advanced blast simulator

Authors: *P. ARUN, D. M. WILDER, M. A. BENTON, C. M. CHRISTOFOROU, W. DRIWECH, R. T. URIOSTE, O. D. EKEN, V. SAJJA, S. A. VAN ALBERT, Y. WANG, I. D. GIST, J. B. LONG
Ctr. for Military Psychiatry and Neurosci., Walter Reed Army Inst. of Res., Silver Spring, MD

Abstract: Anecdotal observations of blast victims indicate that significant neuropathological and neurobehavioral defects develop at later stages of life. In this study, we have examined the neurobehavioral changes in rats up to 9 months after exposure to single and tightly coupled repeated blasts using an advanced blast simulator. Neurobehavioral changes were monitored at acute (1-15 days), sub-acute (16-30 days) and chronic (1-9 months) time points up to 9 months using elevated plus maze, Y-maze, water maze, open field exploration, rotary pole, rotarod and novel object recognition tests. Single and closely coupled repeated blast exposures resulted in significant functional deficits at both acute and chronic time points. In most functional tests, rats exposed to repeated blasts performed more poorly than rats exposed to single blast. Rotating pole and rotarod tests to assess the neuromotor/balance functions revealed significant deficits at acute and sub-acute time points after blast exposures, and all experimental subjects, including sham controls, had difficulties with these tests at chronic time points. Interestingly, several functional deficits were more pronounced in blast exposed rats at 6 months and beyond. The most substantial changes in blast-exposed rats were observed in the center time and margin time legacies in the open field exploration test at 6 and 9 months after blast exposures. Notably, these two outcome measures were minimally altered acutely, fully recovered during sub-acute stages, and were pronounced during the chronic stages after blast exposures. Significant neuromotor impairment occurred at early stages after blast exposure and the severity increased with number of exposures. Water maze test for spatial learning and memory revealed short-term memory impairments at chronic stages, but not at early time points. The pronounced changes in center time and margin time legacies in the open field exploration test after 6 months post-blast implicate development of depressive-like behavior.

Abstract: Chronic degenerative brain disease in diabetes, known as ‘diabetic encephalopathy’, is a recognized complication that can occur due to long-standing diabetes in patients. The hippocampus appears vulnerable in diabetic subjects that have a higher risk of stroke, dementia, and cognitive decline. Although the decreased neurogenesis in the dentate gyrus was found streptozotocin (STZ)-induced diabetic mice, the effects of ω3-polyunsaturated fatty acids (PUFA) in diabetics have not been studied yet. Here, we report that high ω3-PUFA could ameliorate the hippocampal degeneration in STZ model, using fat-1 transgenic mouse. When STZ was administrated to wild-type mice in order to induce diabetes, hyperglycemia was well induced after 14 days but not in STZ-treated Fat-1 mice. To examine whether omega-3 could protect from the pyramidal cell loss in the dentate gyrus of hippocampus caused by STZ treatment, we immunostained with Ki67- or DCX antibodies. The number of Ki67- or DCX-reactive cells from STZ-treated wild-type mice was decreased, but not in the STZ-treated fat-1 mice. In addition, the level of expression of Brain-derived neurotrophic factor (BDNF) from hippocampal homogenates in STZ-treated wild-type mice was significantly decreased compared to untreated-wild-type mice. However, BDNF expression in STZ-treated fat-1 mice was comparable to STZ-treated wild-type mice. In conclusion, these findings indicate that PUFA may reduce the loss of proliferation and neuronal progenitors in the dentate gyrus of hippocampus in Type-2 diabetes by STZ.

Title: Administrations of mesenchymal stem/stromal cells (MSCs) produced beneficial effects in models of traumatic brain injury via prevention of blood brain barrier leakage

Authors: *J. WATANABE, H. OHTAKI, K. YAGURA, K. HONDA, S. ARATA
Showa Univ., Tokyo, Japan

Abstract: Traumatic brain injury (TBI) causes multiple long-term defects including a loss of working memory that is frequently incapacitating. Administrations of mesenchymal stem/stromal cells (MSCs) previously produced beneficial effects in models of TBI as well as other disease models. Intravenous human MSCs decreased neutrophil extravasation, expression of matrix metalloproteinase 9 by endothelial cells and neutrophils, and the subsequent blood brain barrier leakage. In this time, the expression of GFAP was significantly increased. When MSCs were co-cultured with scratch wounded astrocytes in vitro, the wound was disclosed much earlier than control. The data suggested that administration of MSCs may activate astrocytes, and be an effective therapy for TBI via prevention of blood brain barrier leakage.

Title: Focal brain lesions induced by ultraviolet irradiation

Authors: *M. NAKATA[1,2], K. NAGASAKA[1,2,3], I. TAKASHIMA[1,3], S. YAMAMOTO[1]
[1]AIST, Tsukuba, Japan; [2]JSPS Res. fellow, Tokyo, Japan; [3]Univ. of Tsukuba, Tsukuba, Japan

Abstract: Animal models of focal brain lesions are produced using electric current, heat, or drugs, including ibotenic acid. Focal brain injury can also be induced by mechanical impact (e.g., fluid percussion). However, breaks in the dura mater can occur at injection or impact sites, inducing cerebrospinal fluid leakage and increasing the risk of infection during long-term experimental periods. Furthermore, these manipulations may also induce cell death in untargeted brain regions due to the propagation of excess excitation from neuronal cell death within the targeted site (excitotoxicity). To avoid these artifacts, we developed a new method to induce focal brain lesions using irradiation with an ultraviolet (UV) ray over intact dura mater. Adult Wistar rats were anesthetized with isoflurane and the skull was removed. UV irradiation was conducted through an optical fiber connected to a UV (UV-A; wavelength 365 nm, about 1.1 mWh) LED light source. A fiber tip (flat circle, 400 μm in diameter) was stereotaxically placed on the targeted brain site (anterior parietal cortex; Bregma -3.7 mm, 2.0 mm from the midline) and contacted the dura mater. Five days after the irradiation, the animals were perfused for histological analysis. Nissl staining revealed that the UV ray injured the cortical surface of the irradiated site. The absence of neuronal marker (NeuN)-immunopositive cells within the lesion core indicated UV-induced depletion of neuronal cells. After 120 min of irradiation with an about 0.55-mW UV ray, we observed a column-shaped lesion core of approximately 600 μm in diameter and 700 μm in depth. In contrast, irradiation with reduced light intensity produced a relatively superficial lesion. Taken together, we succeeded in developing a novel method to create focal brain lesions using UV irradiation. Moreover, our results suggest that this UV-lesion method enables the control of the lesion depth using the light intensity while keeping the dura mater intact.

Title: Assessing dendritic identity and protein trafficking in regenerated dendrites in adult *Drosophila*

Authors: *S. IZABEL[1,2], Y. JAN[3], L. JAN[3], L. DEVAULT[4]
[1]Anat. and Neurobio., Richmond, VA; [2]Physiol., [3]Physiology, Biochem., [4]Neurosci., Univ. of California San Francisco, San Francisco, CA

Abstract: Neurons exchange information through synaptic signals or sensory inputs received by the dendrites, which may generate action potentials that can propagate along the axon. This exchange can be interrupted when axons or dendrites are damaged. Axonal regeneration has been widely studied, but dendritic regeneration has not received the same attention. For that reason we have focused this study on assessing injury recovery in Drosophila dendrites. The model used has several desirable features: neurons that are easily imaged, a tractable genetic system, and the potential to build a framework for future studies. Previous research has assessed dendritic growth in response to acute injury using Drosophila larvae. We aim to evaluate such growth in adult animals. Drosophila larvae are still developing. We aim to understand how stable adult dendritic arbors respond to injury. When injuring the animals, we utilize lasers from a two-photon microscope to severe all dendrites at the first branch point by laser ablation, leaving a bald neuron. In assessing injury response, we image animals and perform immunohistochemistry staining. The staining assesses the injured neuron's maintenance of neuronal identity, ability to correctly traffic somatodendritic proteins and integrity of cytoskeletal structure. We stained these neurons using the antibody against PPK-26, a neuronal type specific marker, to assess the identity of injured neurons. We also stain for PPK-26 in a non-permealized condition to attest that these proteins are located at the surface of the neuron, as in uninjured neurons. Finally, we test for stabilized microtubules, by staining for Futsch, the Drosophila MAP1B homolog. Preliminary results indicate the presence of PPK-26 in regenerated neurons suggesting that the dendrites present morphological similarities to those of fully functioning healthy neurons. We have also located presence of Futsch marker in regrown dendrites. Although certainty is only reached after quantitative analyses, we hope to find that these dendrites also contain microtubules in its regenerated expansions. Ultimately, we aspire to expand our knowledge of the cytoskeletal structure of regenerated dendrites and compare with findings of the larvae model, which have established that regrown dendrites maintain some but not all of the characteristics of uninjured dendrites.

Title: Acamprosate reduces traumatic brain injury-induced neuronal death in rats

Authors: *B. CHOI[1], S. LEE[1], S. MIN[2], T. CHUNG[2], H. CHOI[3], S. SUH[1]
[1]Dept. of Physiol., Hallym University, Col. of Med., Chuncheon, Korea, Republic of; [2]Dept. of Emergency Med., CHA Bundang Med. Center, CHA University, Sch. of Med., Seongnam, Korea, Republic of; [3]Dept. of Neurol., Hallym University, Collge of Med., Chuncheon, Korea, Republic of

Abstract: Acamprosate, or N-acetyl homotaurine, is a N-methyl-D-aspartate (NMDA) receptor antagonist that is used as a pharmacological means of treatment for chronic alcohol dependence. Although the exact mechanism of acamprosate has not been clearly established, it appears to work by promoting a balance between the excitatory and inhibitory neurotransmitters, glutamate and gamma-aminobutyric acid (GABA), respectively. Several studies have demonstrated that acamprosate provides neuroprotection against cerebral ischemia-induced brain injury. However, there are no studies investigting the role of acamprosate on traumatic brain injury (TBI)-induced neuronal death. In the present study, we sought to analyze the therapeutic potential of acamprosate to protect against neuronal death and other underlying pathogenic mechanisms that arise following TBI. Rats were given acamprosate (200 mg/kg) orally once per day for two weeks. Two week later, rats were subjected to a controlled cortical impact (CCI; 5 m/sec, 500-msec duration, 5-mm deformation) injury over the right parietal cortex. Histological analysis was performed at 3 or 24 hours, or 7 days after TBI. We found that acamprosate treatment for 2 weeks reduces levels of vesicular glutamate and zinc in the hippocampus. Consequently, this reduced vesicular glutamate and zinc level resulted in reduction of ROS production at 3 hours after TBI. When evaluated at 24 hours after TBI, acamprosate administration reduced the number of degenerating neurons, blood-brain barrier (BBB) disruption, leukocyte infiltration and dendritic loss. Acamprosate also reduced glial activation and neuronal loss at 7 days after TBI. The present study demonstrates that acamprosate attenuates TBI-induced brain damage by depletion of vesicular glutamate and zinc levels. Therefore, the present study suggests that acamprosate may have a high therapeutic potential for prevention of TBI-induced neuronal death.

Title: Protective effects of dichloroacetic acid on traumatic brain injury induced neuronal death

Authors: *S. LEE, B. CHOI, S. SUH
Dept. of physiology, Col. of Med., Chunchen, Korea, Republic of

Abstract: Traumatic brain injury (TBI) is defined as damage to the brain resulting from external mechanical force, such as rapid acceleration or deceleration, impact, blast waves, or penetration by a projectile. A penetrating or open head injury occurs when an object pierces the skull and breaches the dura mater, the outermost membrane surrounding the brain. Neuronal death occurs in the hippocampus due to this traumatic brain injury. Dichloroacetic acid (DCA) is a small molecule that has multiple effects on intermediary metabolism. Biochemically, DCA inhibits gluconeogenesis, lipogenesis and cholesterol synthesis and stimulates peripheral glucose and lactate utilization. DCA has also been studied as a potential drug due to its ability to inhibit the enzyme pyruvate dehydrogenase kinase. The present study aimed to evaluate the therapeutic potential of DCA on TBI-induced neuronal death. Traumatic brain injury was performed using a weight drop model in rat. DCA (100mg/kg) was injected into the intraperitoneal space immediately after TBI. Neuronal death was evaluated with Fluoro Jade-B (FJB) staining 24h after TBI. DCA reduces the number of degenerating neurons in CA3 and DG of hippocampus after TBI. Oxidative injury was detected by 4-hydroxy-2-nonenal (4HNE) and microglia activation was detected by CD11b immunohistochemistry in the hippocampus after TBI. DCA treatment decreased the intensity of 4HNE fluorescence and microglia activation in the hippocampus compared to the saline-treated group after TBI. Therefore, the present study suggests that DCA may have protective effects on traumatic brain injury-induced hippocampal neuronal death. Title: Effects of combined treatment of dichloroacetic acid (DCA) with pyruvate on global cerebral ischemia-induced hippocampal neuronal death

Authors: *D. HONG[1], A. KHO[1], S. SUH[1], M. CHOI[2], O. RYU[2], M. SOHN[3]
[2]Endocrinol. and Metabolism, [1]Hallym Univ., Chuncheon, Korea, Republic of; [3]Nursing, Inha Univ., Incheon, Korea, Republic of

Abstract: Global cerebral ischemia (GCI) occurs when blood flow toward the brain is blocked or dramatically reduced. In this condition, oxygen and glucose provide into the brain was decreased. GCI induces vesicular zinc release, oxidative injury, neuronal death and cognitive impairment. Dichloroacetic acid (DCA) inhibits pyruvate dehydrogenase kinase (PDK), which increases the uptake of pyruvate into the mitochondria and promotes glucose oxidation during glycolysis through enhancement of pyruvate dehydrogenase (PDH) activity. Here, we tested our hypothesis that DCA can prevent neuronal damage after GCI by inhibition of PDK activity since DCA increases the rate of pyruvate converted to ATP. Global cerebral ischemia (GCI) was induced by occlusion of both common carotid arteries (CCAO) and blood was withdrawn through the femoral artery to induce a 7 minute isoelectric period, evaluated by monitoring EEG changes. Eight week old male Sprague-Dawley rats were used and neuronal death was evaluated with Fluoro Jade-B (FJB) staining at 7 days after GCI. To test the therapeutic potential of DCA, rats were given an intraperitoneal injection of DCA (100mg/kg) once per day for 2 days after ischemia. However, there was no difference in the number of FJB + neurons between vehicle and DCA administrated groups after ischemia. Additionally, 50mg/kg of pyruvate was also not neuroprotective after ischemia. Thus, we administrated DCA with pyruvate once per day for 2 days after ischemia. The present study found that administration of DCA with pyruvate significantly decreased neuronal death, oxidative stress, microglia activation, zinc accumulation after GCI. These findings suggest that co-treatment with DCA and pyruvate may increase the regenerative capacity of the hippocampus after stroke or myocardial infarction. Keywords : Global cerebral ischemia, Dichloroacetic acid, Pyruvate, Neuronal death

Title: Effects of sodium dichloroacetate (DCA) on hypoglycemia-induced hippocampal neuronal death

Authors: *A. KHO[1], B. CHOI[1], S. SUH[1], H. CHOI[2], M.-G. CHOI[3], O. RYU[3], T. CHUNG[4]
[1]Dept. of physiology, [2]Neurol., [3]Endocrinol. and Metabolism, Hallym Univ., Chuncheon, Korea, Republic of; [4]Dept. of Emergency Med., CHA Univ. Sch. of Med., Seongnam-si, Gyeonggi-Do, Korea, Republic of

Abstract: Type 1 diabetic patients who are treated with insulin for tight control of blood glucose levels frequently experience severe hypoglycemia when plasma glucose level falls below ~3.5 mM (~63mg/dL), which can lead to seizures and loss of consciousness. Our lab has shown that neuronal cell death caused by hypoglycemia is not only a result of reduced glucose supply to the brain but also proceeds via a cell death process that is initiated by the reperfusion of glucose after a sustained period of glucose deprivation. Severe and prolonged hypoglycemia causes zinc release, oxidative stress, neuronal death and cognitive impairment. Zinc release contributes to neuronal death under severe disease conditions, such as prolonged seizure, ischemia and brain trauma. In addition, zinc can inhibit the key glycolytic enzyme glyceraldehyde-3-phosphate dehydrogenase (GAPDH), making glycolysis not to work properly, which compromised neuronal cells eventually. Sodium dichloroacetate (DCA) is a pyruvate dehydrogenase kinase (PDHK) inhibitor and thus activates pyruvate dehydrogenase (PDH), the gatekeeper of glucose oxidation. The principal site of action of DCA is the pyruvate dehydrogenase (PDH) complex inhibiting PDHK, keeping PDH in the unphosphorylated catalytically active form and replacing pyruvate with acetyl-CoA production, which enhances glucose oxidation in cells, leading to increased levels of ATP. Additionally, DCA has been shown to prevent ROS generation. We hypothesized that DCA treatment can reduce neuronal cell death through improvement of glycolysis and prevention of ROS production after hypoglycemia. To test this, we used an animal model of insulin-induced hypoglycemia and injected DCA (100mg/kg, *i.v*, 2 days) following hypoglycemic insult. Brain sections were stained with Fluoro Jade-B (FJB) to detect degenerating neurons in the hippocampus at 1 week after hypoglycemia. As a result, DCA treatment after hypoglycemia reduced the number of FJB (+) cells compared to hypoglycemia-

vehicle group. Brain sections were also evaluated for oxidative injury using 4-hydroxy-2-nonenal (4HNE) and for microglia activation using CD11b antibody. DCA treatment also significantly reduced hypoglycemia-induced oxidative injury and microglial activation. Therefore, the present study suggests that DCA may have high therapeutic potential to reduce hippocampal neuronal death after hypoglycemia. **Key word**: Hypoglycemia, Sodium dicholoroacetate (DCA), PDH, PDHK inhibitor, Pyruvate, Glycolysis, Oxidative stress, Neuron death

Title: The effects of alcohol and traumatic brain injury on neural stem cell responses

Authors: *S. T. TON[1], S.-Y. TSAI[2], H. M. FLINK[2], J. Y.-T. WU[2], J. J. HSU[2], I. C. VAAGENES[2], G. L. KARTJE[2]
[1]Neurosci., Loyola, Maywood, IL; [2]Edward Hines Junior VA Hosp., Hines, IL

Abstract: Our laboratory has previously found that a repeated dose of binge alcohol prior to TBI leads to worse recovery on a sensitive test of skilled forelimb function (Vaagenes et al. 2015). Mobilization of endogenous neural stem cells might be one mechanism that contributes to the functional compensation after TBI. We therefore sought to determine the effect of binge alcohol at the time of TBI on subventricular zone (SVZ) neural stem cell responses. Male rats (2 month old Sprague Dawley) underwent binge alcohol (3g/kg/day) by gastric gavage for 2 days prior to TBI. On the day of TBI, rats were given alcohol 1 hour prior to injury using the controlled cortical impact (CCI) method directed to the forelimb sensorimotor cortical area. We assessed the SVZ neural stem cell response after binge alcohol and TBI by utilizing the proliferation marker 5-bromo-2'-deoxyuridine (BrdU) along with other markers for neurogenesis such as Doublecortin. We found that binge alcohol did not affect short and long term lesion size (as measured at 24 hours, 7 days and 6 weeks post TBI). As expected, TBI alone significantly increased SVZ proliferation bilaterally 24 hours post injury. Surprisingly, binge alcohol alone also significantly increased proliferation bilaterally in the SVZ at the 24 hour time point. A

combined binge alcohol and TBI regimen resulted in decreased SVZ proliferation bilaterally at 24 hours and 7 days post-TBI. Furthermore, when assessed at 6 weeks after TBI, binge alcohol significantly decreased SVZ neuronal differentiation. While we observed that TBI alone increased migration toward the rostral migratory stream (RMS), binge alcohol did not affect either RMS or perilesional migration post-TBI. Taken together, these results suggest that TBI combined with binge alcohol decreases short-term neural stem cell proliferative responses as well as long-term neuronal differentiation of these cells in the SVZ, thereby negatively impacting functional recovery. We are currently examining the possible functional implications of the stimulatory effect of binge alcohol alone on SVZ neurogenesis, specifically its connection to olfactory bulb function.

Title: Evaluating the protective effect of etazolate on anxiety- and depression- like behavior and cognitive impairment induced by post traumatic stress disorder

Authors: *K. H. ALZOUBI[1], Z. AL SUBEH[2], O. F. KHABOUR[2]
[1]Jordan Univ. of Sci. & Technol., Irbid, Jordan; [2]Jordan Univ. of Sci. and Technol., Irbid, Jordan

Abstract: Post-traumatic stress disorder (PTSD) occurs after experiencing traumatic events. PTSD symptoms usually include intrusive recollections of traumatic event, avoidance of event reminders, and hyperarousal. The absence of optimal treatment along with low response rate make the investigation for novel pharmacological therapy highly required. Etazolate (ETZ), on the other hand, is a selective PDE-4 inhibitor that is proven to be of particular importance in neuropharmacology. In this study, we aimed to evaluate the possible beneficial effects of etazolate in preventing and reversing stress induced anxiety, depression, and cognitive impairment. Single prolonged stress (SPS) is an animal model of PTSD that can effectively manifests its characteristic symptoms of anxiety, depression, and memory impairment. Current results revealed that ETZ significantly reduce anxiety, depression-like behavior, and memory

impairment induced by PTSD. It also restored oxidative stress biomarkers, and reduced BDNF level, which are suggested as possible molecular targets of ETZ protective effect during PTSD.

Title: Positive allosteric modulation of cholinergic receptors improves spatial learning and memory following brain trauma in mice

Authors: *D. P. HOLSCHNEIDER[1], Y. GUO[1], O. U. SCREMIN[2], Z. WANG[1]
[1]Psychiatry & the Behavioral Sci., USC, Los Angeles, CA; [2]Greater Los Angeles VA Healthcare Syst., Los Angeles, CA

Abstract: AIM: There are currently no clinically efficacious drug therapies to treat neuronal damage following traumatic brain injury. This study examines the potential of a novel cholinergic treatment on improving memory and motor dysfunction with a lower incidence of undesirable side effects that have limited prior pharmacotherapies. **METHODS:** Adult mice received unilateral cortex contusion injury (CCI) or sham injury. Two days thereafter, they were administered benzyl quinolone carboxylic acid (BQCA, 5, 10, 20 mg/kg, i.p.), a M1 muscarinic positive allosteric modulator or vehicle, with dosing twice per day over 3 ½ weeks, and the 1st daily dose given 30 minutes prior to behavioral testing. One week following CCI, mice were evaluated weekly for 3 weeks with a battery of motor tests, as well as with daily evaluation of spatial learning and memory using the Morris Water Maze. **RESULTS:** Unilateral CCI resulted in a significant, persistent, asymmetric postural reflex on tail suspension. Motor testing revealed significant deficits on the accelerating rotarod, increased footslips on grid walking and decreased grip strength and stride length ($p<0.05$), as well as progressive hyperactivity that was significant 3 weeks after CCI ($p<0.05$). Compared to sham-vehicle controls, CCI-vehicle mice demonstrated significantly delayed spatial learning at 2 and 3 weeks post-CCI during exposure to a reverse learning task in which the platform position was moved ($p<0.05$). In CCI mice, BQCA resulted in significantly improved spatial learning and recall at weeks 2 and 3. Effects of BQCA on motor outcomes were minimal. There was a trend toward the highest dose of BQCA attenuating the locomotor hyperactivity seen in CCI animals. BQCA at 20 mg/kg had no significant effect on general motor activity, body weight or acute motor, secretory, or respiratory symptoms.

CONCLUSION: BQCA in CCI mice elicited improved hippocampal-dependent learning with repeated daily exposure to visual cues in a spatial navigation task. Improvements were noted in the absence of significant cholinergic side effects. No significant drug effect was noted on motor outcomes. These results suggest that BQCA is a candidate compound to improve learning and memory function following brain trauma, and may not suffer the associated CNS side effects typically associated with even modest doses of other cholinergic enhancers. Ongoing work is applying functional brain mapping to examine functional reorganization of disrupted neuronal networks in this rodent model of focal brain trauma. **Acknowledgements**: This work was supported by a grant from NINDS 5R21NS096554. Abstract: Traumatic brain injury (TBI) remains one of the major causes of death and disability. Due to the heterogeneity of its causes, the events that occur after TBI can be quite varied and are not well understood. Regardless of cause, deformation of brain tissue can lead to neuronal, glial and endothelial cell death as well as other cellular and molecular responses including changes in blood-brain barrier (BBB) permeability. Understanding the events that occur after TBI is important for the development of therapeutic approaches. The aim of this study is to characterize

the effects of mild and moderate TBI on the BBB in mice using a weight drop method. Mice were anesthetized using isoflurane and placed on a soft foam pad. An acrylic tube was placed directly above the head of the mouse and a 50 gram weight was dropped onto the mouse head from either a 30cm (mild) or 120cm (moderate) height within the tube. 24 hours after a single such TBI episode BBB permeability was evaluated using the Evans blue method and by quantifying the plasma concentrations of the glial-specific protein S100β. The expression of the tight junction proteins zonula occludens-1 (ZO-1) and occludin was evaluated using western blot. Mild TBI did not affect Evans blue extravasation or S100β concentration and did not change the expression of the tight junction proteins; however, moderate TBI significantly increased Evans blue extravasation and the plasma concentrations of S100β, indicating an increase in BBB permeability. This effect was related to a decrease in the expression of ZO-1 and occludin. In summary, we demonstrated using a weight drop model that moderate TBI increases BBB permeability that is likely due to a decrease in the expression of tight junction proteins. This model can be used as a tool to test potential treatments that can protect the BBB after TBI.

Abstract: Object : There are many studies that demonstrate correlation between traumatic brain injury (TBI) and Alzheimer's disease (AD). Several large epidemiological examinations have revealed that TBI is an epigenetic risk factor for developing AD. But it is not known how TBI contributes to the onset or progression of this late life dementia. To investigate this question, we studied neuropathological and behavioral consequences of TBI in a triple transgenic AD-model mouse (3×Tg mice) that harboring $PS1_{M146V}$, APP_{SWE}, and tau_{P301L} transgenes. Here, we report that weight drop method TBI in 3×Tg mice demonstrated Aβ deposition and APP accumulation at 7days or 4 weeks after TBI. **Material and method :** Five to seven-month-old 3×Tg mice and wild type mice were subjected to TBI (n = 7-10) or sham treatment (n = 7-8). At 7 days and 4weeks after treatment, we assessed Aβ deposition and APP accumulation in the hippocampus of these mice. And a subset of mice also was studied behaviorally at 7 days and 4 weeks after injury. **Result :** Compared to sham-treatment wild type mice, brain-injured wild type mice exhibited significant deficits in spatial learning ability as measured using the Morris water maze over the first 7 days ($p = 0.018$), but not after 4 weeks post-injury. On the other hand, compared to sham-treatment 3xTg mice, TBI-treated 3×Tg mice demonstrated significant deficits in spatial learning ($p = 0.048$) and slower acquisition of delay eyeblink conditioning ($p = 0.023$) after 4 weeks post-injury accompanied increased Aβ deposition in the hippocampus ($p = 0.018$). **Conclusion :** This is the experimental evidence linking TBI to mechanism of AD by showing that TBI accelerates brain Aβ deposition and cognitive impairment. These data suggested that despite recovery from acute cognitive deficits, concussive brain trauma leads to axonal damage with APP accumulation and increased Aβ disposition induced cognitive impairment after brain injury.

Title: Molecular basis for amyloid precursor protein mediated neuroprotection in brain injury

Authors: *C. L. INAMPUDI[1], L. Q. LAM[2], B. ROBERTS[3], S. PLUMMER[4], F. CORRIGAN[4], G. D. CICCOTOSTO[1], P. J. CRACK[2], C. VAN DEN HEUVEL[4], R. CAPPAI[1]

Sci., The Univ. of Adelaide, Adelaide, Australia

Abstract: Amyloid precursor protein (APP) is neuroprotective in traumatic brain injury (TBI). Treatment with soluble amyloid precursor protein (sAPP) can rescue motor and cognitive deficits following TBI in mouse and rat models (Corrigan, Vink et al. 2012). The neuroprotective active site in sAPP is located in residues 96 to 100 (APP96-110) (Corrigan 2014). We hypothesize that APP96-110 interacts with specific molecule(s) to trigger its neuroprotective response in TBI. To identify protein(s) interacting with APP96-110 peptide, a biotin-streptavidin affinity capture method followed by mass spectrometry was utilised. Among the proteins identified the Amyloid Precursor-like Protein 2 (APLP2) was found to be a robust interacting target with APP96-110. Previous reports showed APLP2 binds to region in APP which includes 96-110 (Soba, Eggert et al. 2005). To test the neuroprotective interaction between APP and APLP2, APLP2 wild type (APLP2 WT) and APLP2 knockout (APLP2 KO) mice (male and female) have been subjected to TBI and gait parameters assessed by Digigait. Preliminary data shows that APLP2 KO mice are more susceptible to TBI than APLP2 WT mice after 24h of injury. This indicates that the APLP2 expression modulates the rate of brain injury following TBI. The role of APLP2 in mediating APP96-110 neuroprotection is currently being investigated.

Title: Circulating miR-124 as a predictive biomarker for characterizing post-TBI cortical lesion endophenotypes

Authors: *S. DAS GUPTA, N. VUOKILA, N. PUHAKKA, A. PITKÄNEN
Neurobio., Univ. of Eastern Finland/AIVI, Kuopio, Finland

Abstract: Traumatic brain injury (TBI) encompasses primary brain damage inflicted immediately at the time of impact, and secondary damage involving cellular and molecular alterations progressing over a prolonged time post-trauma. Early diagnosis is thus crucial to identify patients at risk of developing the long-term comorbidities. In this study, we hypothesize that level of the brain-enriched microRNA-124 (miR-124) in circulation may serve as a TBI biomarker, and can predict the chronic cortical lesion endophenotype developing in response to TBI.

For this, we first assessed miR-124 level from plasma, in rats receiving the experimental lateral fluid-percussion injury. Analysis was done with droplet digital PCR (ddPCR). Next, from a cohort of 22 TBI rats with T2-w MRI imaging available at 2mo post-TBI, we characterized the post-TBI cortical lesion endophenotypes. Based on Nissl staining, we also grouped the ddPCR cohort to the different endophenotypes, and combined them with the MRI animals. Finally, we measured plasma miR-124 level in the combined cohort with reverse transcriptase quantitative PCR (RT-qPCR), and checked if animals with the different lesion endophenotypes also varied in their plasma miR-124 content.

Droplet digital PCR indicated elevation in plasma miR-124 level at 2d post-TBI [~39% more miR-124 copies in TBI animals than controls ($p<0.05$)]. MRI revealed 41% of the 22 rats to possess a “cavity forming” (TBI_{CF}) endophenotype, with larger cortical tissue loss, and an inflammatory rim covering 4% of the ipsilateral cortex. Remaining 59% presented a “chronic inflammatory” (TBI_{CI}) endophenotype, with inflammatory rim covering 11% of the ipsilateral

cortex. Plasma miR-124 analysis from the combined cohort revealed TBI_{CF} to have higher plasma miR-124 at 2d in comparison to both controls (FC=2.09, $p<0.01$) and TBI_{CI} (FC=1.66, $p<0.05$). ROC curve distinguished TBI_{CF} from TBI_{CI} with AUC=0.735 ($p<0.05$), and TBI_{CF} from controls with AUC=0.824 ($p<0.01$). TBI_{CI} did not differ from controls.
Our data indicate that plasma miR-124 is an early biomarker for TBI, and that rats developing the "cavity forming" endophenotype at chronic post-TBI time already present higher plasma miR-124 at 2d post-injury, in comparison to the "chronic inflammatory" group.

Title: Decreased hippocampal N-Acetylaspartate in rodent models of preterm brain injury is due to mitochondrial dysfunction

Authors: *B. M. TALBOT[1], S. LIN[4], N. NIFORATOS-ANDESCAVAGE, 20010[2], P. WANG[4], S. SCAFIDI[5], J. SCAFIDI[3]

Abstract: Long-term cognitive dysfunctions occur in half of children born very premature. Imaging studies in adolescents demonstrate structural dysmaturity and consistent decreased N-acetylaspartate (NAA) - a neurometabolite synthesized specifically by neuronal mitochondria. The cause of decreased NAA, and subsequently the impact of changes in NAA, in the injured developing brain is poorly understood. The objective of this study is to characterize cellular and metabolic alterations that result in decreased NAA in the hippocampus in different rodent models of preterm brain injury. C57BL6/J mice were randomly assigned to hypoxic rearing in a hypoxia chamber (10.5% oxygen) or normal rearing conditions from postnatal day (P) 3-11. At one month of life mice were subjected to a battery of hippocampal-dependent behavioral tests to confirm cognition changes consistent with premature infant cognitive dysfunctions. We

performed ^{1}H-magnetic resonance spectroscopy (^{1}H-MRS) in the hippocampus to quantify neurometabolites, including NAA, using LC-Model. We conducted immunohistochemistry on fixed tissue in that region to compare cell density of post-mitotic neurons between groups. We also assessed group differences in mitochondria by comparing mitochondrial copy number to nuclear DNA. We utilized Western blots to analyze protein expression of mitochondrial-specific proteins and NAA synthesis and degradation enzymes. We are currently looking at differences in precursors to NAA using gas chromatography mass spectrometry, and evaluating NAA synthesis rates with 13C-nuclear MR. Hypoxic mice performed significantly worse in all behavioral tests compared to controls. ^{1}H-MRS revealed significantly decreased NAA levels and NAA/choline ratios in hypoxic mice compared to controls. Together, these results confirm the hypoxia model is appropriate for understanding metabolic and cellular changes due to preterm brain injury. There were no differences in neuronal density, expression of mitochondrial-specific proteins, mitochondrial copy number, or expression of NAA synthesis or degradation enzymes between groups. This data strongly suggest that decreased NAA after hypoxic-induced injury results from altered mitochondrial function. We are further verifying our findings in other models of preterm brain injury, such as the moderate systemic inflammation model using interleukin-1-beta injections. Understanding how NAA production after preterm brain injury relates to mitochondria function can help us develop therapies that target the mitochondria and improve their efficiency.

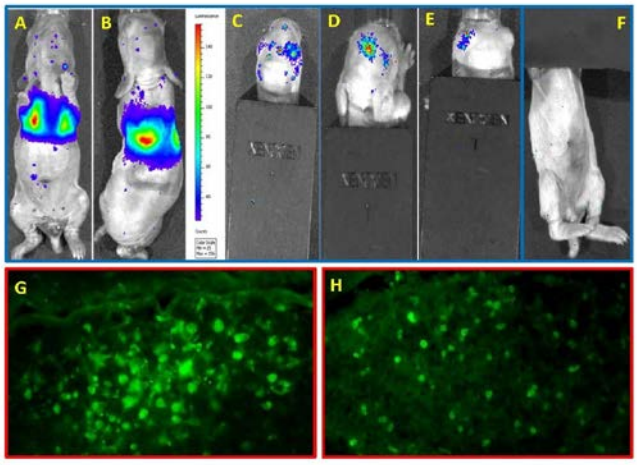
Newborn Med., Maria Fareri Children's Hospital-New York Med. Col., Valhalla, NY; [6]Dir Regional Neonatal Ctr., Maria Fareri Children's Hosp., Valhalla, NY

Abstract: Germinal matrix-intraventricular hemorrhage (GMH-IVH) is a severe complication of preterm births, which results in acute inflammation and white matter injury leading to cerebral palsy and mental retardation. There is no treatment for IVH or its collateral damage. Stem cells from different sources offer great promise in the treatment of brain disorders. We have isolated novel unrestricted somatic stem cells (USSCs) from human cord blood, with multi-lineage differentiation and regenerative properties. Here we tested if intravenously (i.v.) infused USSC stem cells will: a) survive and migrate in different regions of IVH brain and b) improve neurobehavioral performance in a rabbit model of GMH-IVH. Premature rabbit pups were delivered by Cesarean-section & pups were injected i.p. glycerol (6.5g/kg) to induce hemorrhage. The IVH pups were then infused $1X10^6$ USSC through the jugular vein after confirming IVH by head ultra sound. The USSCs labeled with luciferase reporter gene were monitored for bioluminescence imaging (BLI) on postnatal days 1-3, 7&14. The BLI shows USSCs first appeared in the lung after a few hours of injection & persisted by > 5d in the lung (Fig. A-B). Later the USSCs migrated to the brain starting from day 3 to day 7 (Fig.C-E) to the site of injury. No BLI signals were found in other organs of the body (Fig.F). The migration of USSCs was further confirmed by immunohistochemical staining (IHC) using anti-hNuc antibody specific for USSC stem cells. The immunofluorescence studies of coronal brain section demonstrated the persistence of USSCs at days 7 & 14 forebrain (Fig. G-H). Importantly the motor function and overall neurobehavioral scores were significantly improved in the pups with IVH-USSCs stem cell engrafted intravenously compared with IVH-saline pups at day14 (N=5 in each group ($P<0.05$). These pre-clinical results support the development of a novel stem cell therapeutic strategy for treatment of GMH-IVH human premature infants.



Representative of Bioluminescence imaging & Immunostaining: A-E) BLI-live images for intravenous jugular (i.v.) USSCs infusion demonstrating transient migration via Lung day 3 (A-B) to the brain days 3,5 & 7 (C-E), No USSC in other parts of body (F). G-H) IHC staining using nuclear nuclei specific antibody for USSC stem cells for day7(G) & day17 (H).

Title: Attenuation of axonal degeneration relative to myelin pathology after mild traumatic brain injury in mice lacking Sarm1

Authors: *C. M. MARION[1,2], K. L. RADOMSKI[2,3], R. C. ARMSTRONG[2,3]
[1]Neurosci. Dept., Uniformed Services Univ., Bethesda, MD; [2]Ctr. for Neurosci. and Regenerative Med., [3]Dept. of Anatomy, Physiol. and Genet., Uniformed Services Univ. of the Hlth. Sci., Bethesda, MD

Abstract: Traumatic brain injury (TBI) results in traumatic axonal injury (TAI) in white matter tracts. Myelin pathology may contribute to deficits experienced after TBI. Myelin pathology may be due to secondary effects along degenerating axons or may occur as primary pathology of white matter injury. The current studies investigate the relationship between axonal degeneration and myelin pathology. Sarm1 is essential for execution of the conserved axon death pathway in injured axons. *Sarm1*-/- mice exhibit suppressed Wallerian degeneration and long-term survival of injured axons. Using a mild TBI (mTBI) model that results in TAI in the corpus callosum, we assessed axon degeneration and myelin pathology in *Sarm1*-/- and wild type mice. The corpus callosum was sampled using electron microscopy 3 days post-mTBI or sham procedure. In wild type mice, TBI increased axon degeneration and produced two forms of myelin pathology - demyelination of intact axons and excessive myelin extending out from axons. In *Sarm1*-/- mice, axon degeneration and demyelination were both suppressed after TBI. However, formation of excessive myelin figures after mTBI was similar in wild type and *Sarm1*-/- mice. We generated myelin reporter mice to label membranes with green fluorescent protein (GFP) to visualize these excessive myelin figures by confocal microscopy. *PLPcreER^{T2};mTmG* mice were given a single low-dose of tamoxifen prior to mTBI/sham procedure, to induce recombination in sparse oligodendrocytes. At 3 days post-injury, aberrant myelin formations were observed along GFP-labeled internodes in mTBI animals as compared to sham controls. These myelin abnormalities may represent dynamic myelin remodeling in a compromised axon-myelin unit. These results indicate that Sarm1 may be an important therapeutic target to interrupt processes that produce axon degeneration and demyelination after mTBI. In addition, mTBI also produces excessive myelin that was not mitigated by suppressing axon degeneration. Funded by the Center for Neuroscience and Regenerative Medicine.

Title: Platelet Activating Factor receptor inhibition improves neurological outcome following pediatric traumatic brain injury

Authors: *J. L. ROSSI, T. TODD, N. G. BAZAN
Dept. of Neurosci., Louisiana State Univ. Neurosci. Ctr. of Excellence, New Orleans, LA

Abstract: Introduction: TBI is known to result in intravascular microthombosis. Children with brain injury had a greater prevalence of disseminated intravascular coagulation compared to non-TBI trauma patients. VWF and ADAMT13 (**a d**isintegrin **a**nd **m**etalloproteinase with a **t**hrombospondin type 1 motif, member **13**) are two proteins known to be involved in the clotting cascade. Platelet activating factor (PAF) is known to contribute to clot formation and this study is to look at the relationship of PAF to VWF and ADAMT13 and how it translates to neurological outcomes following pediatric traumatic brain injury (pTBI). **Methods:** Male PND24 C57bl6 or male platelet activating receptor knockout (PAFrKO) PND24 mice were anesthetized with avertin, mechanically ventilated, physiologically regulated, and subjected to lateral closed-skull injury model with impact depth of 2.00mm, 2.25 mm (bregma level - 0.10mm) or sham. Saline 10ul/g or LAU 901 (a PAF receptor antagonist) - 5mg/kg of LAU901 was injected IP at 12h after impact i.p. Mice were sacrificed at 24h 72h and 7D. Brains were processed with RIPA. Elisa's were then performed on the brain lysates per manufacture's protocols. 2 object novel recognition was performed at 7D before sacrifice to test memory. PAFr KO mice at PND24 7D performed be memory test. **Results: ELISA** *In PND24 saline* injected mice: PAF was statistically elevated at the 72h time point only in the 2mm depths compared to sham and the 2mm was statistically higher than the 2.25mm depth (sham: 6.167 vs. 2mm: 14. 67 vs. 2.25mm: 7.667). VWF was statistically higher in both 2mm and 2.25mm depth compared to sham (Sham: 4.667 vs. 2mm: 11.50 vs. 2.25mm: 12.33) at 72h. ADAMTS13 showed significant elevation in only the 2.25mm compared to sham (Sham: 4.667 vs. 2mm: 9.667 vs. 2.25mm: 14.17) at 72h. *In PND24 LAU* injected mice: PAF was significantly elevated over sham at 24h and 72h in 2.25mm compared to sham (Sham: 4.667 vs 2.25mm: 10.83 and Sham 4.38 vs

2.25mm:11.17) respectively. VWF was only significantly elevated at 72h in the 2.25mm (Sham: 8.167 vs 2.25mm: 14.17) and ADAMTs13 was not elevated at any timepoint or depth. **Behavior** PND24 saline injected sham mice showed preference in the new object vs the old object $p<0.0073$ but the saline TBI mice did not prefer one over the other $p<0.1499$. In the LAU injected PND24 mice the shams and the TBI both showed preference in new vs old objects $p<0.0155$ and $p<0.0036$ respectively. PAFrKO mice also showed preference for the new compared to the old object in both sham $p<0.0001$ and TBI $p<0.0045$. **Conclusion:** Inhibition of PAFr shows changes in proteins related to the clotting pathway are in part dependent upon the PAF receptor and preserves neurological function following pTBI.

Title: CHIMERA repetitive mild traumatic brain injury induces long-term pathological and behavioral changes in APP/PS1 mice

Authors: *W. CHENG[1], K. M. MARTENS[1], S. STUKAS[1], E. B. BUTTON[1], A. WILKINSON[1], A. BASHIR[1], C. J. BARRON[1], P. A. CRIPTON[2], C. L. WELLINGTON[1]
[1]Dept. of Pathology and Lab. Med., [2]Dept. of Mechanical Engineering, Intl. Collaboration on Repair Discoveries, Univ. of British Columbia, Vancouver, BC, Canada

Abstract: The annual incidence of traumatic brain injury (TBI) is over 2.5 million in the US, with over 3-5 million people living with residual problems. Moderate and severe TBI survivors have high rates of long-term disability and increased risk of neurodegenerative disease. On the other hand, the symptoms of mild TBI (mTBI, the most common form of TBI) usually resolve within weeks of injury. However, some patients may still present symptoms in long-term, which is known as the "Post-concussive syndrome". In addition, repetitive exposure to mTBI has been linked to a neurodegenerative condition called chronic traumatic encephalopathy, which is characterized by tau deposits at sulcal depths and around cerebral vessels, and can exhibit amyloid deposition (50%). Recently, we reported the acute outcomes (6 hr -14 d) of two mTBI (0.5J, 24 hr apart) in the APP/PS1 amyloidogenic mouse model (6-mo or 13-mo), using the

Closed-Head Injury Model of Engineered Rotational Acceleration (CHIMERA). We observed that age at injury, in addition to genetic predisposition to AD, is crucial in determining acute outcomes: TBI induced cognitive deficits and Aβ deposition of APP/PS1 mice in an age-dependent manner; and post-TBI neuroinflammation was exacerbated in 6-mo APP/PS1 but blunted in 13-mo APP/PS1. In the current study, we used the same mTBI paradigm to injure APP/PS1 mice and their wildtype littermates at 6-mo, and assessed the long-term behavioral, histological, and biochemical outcomes of mTBI up to 8-mo post-injury. We found that mice with mTBI had prolonged white matter microgliosis (Iba1) up to 8-mo, and they showed reduced anxiety-like behavior (Elevated plus maze). These two injury outcomes were not different between APP/PS1-TBI and WT-TBI mice. However, long-term fear memory (passive avoidance) was only chronically intensified in APP/PS1-TBI mice. In addition, spatial learning (Barnes maze) was most impaired in APP/PS1-TBI mice, and reversal spatial learning was only impaired in APP/PS1-TBI mice. Neither Aβ nor tau levels in brain homogenates were changed by TBI 8-mo post-injury. These findings suggest that two mild TBI are sufficient to induce long-term neuropathological changes up to 8-mo post-injury without chronic effects on Aβ or tau. Nevertheless, TBI may exacerbate chronic cognitive deficits to a greater extent in mice capable of amyloid deposition.

Title: A novel mouse model of repeat mild TBI that leads to long-lasting motor deficits and CTE-like brain pathology

Authors: *N. CHO, N. DHILLON, M. ALKASLASI, P. HARO-LOPEZ, O. SHELEST, G. BARMPARAS, E. LEY, G. M. THOMSEN
Cedars-Sinai Med. Ctr., West Hollywood, CA

Abstract: Objectives: Repetitive mild traumatic brain injury (mTBI) has been a suggested risk factor for various neurodegenerative diseases including chronic traumatic encephalopathy (CTE), amyotrophic lateral sclerosis (ALS), and Alzheimer's disease (AD). The use of rodent models to study recurrent mild TBI can provide mechanistic insights into the long-term consequences and help establish a connection between this type of injury and the development of

neurodegenerative disease. We recently developed a novel model of repeat TBI in rats that results in motor deficits sustained out to at least 25 weeks as well as significant brain atrophy and tauopathy consistent with the TBI-linked neurological disease CTE. These sustained deficits and pathology have not been observed in other rodent TBI models that deliver one-time, or repeat, *unilateral* insults. Here, we describe a novel mouse model whereby we delivered a once-weekly, bilateral, closed-skull, controlled cortical impact (CCI) injury over five weeks to reproduce the behavioral and pathological phenotype observed in our rat model, and to recapitulate the human CTE condition.
Methods: We tested various bilateral, closed-skull, CCI injury paradigms, administered once per week for five weeks to C57BL/6J (WT) mice, by varying tip diameter, impact depth and impact velocity. Rotorod testing was performed to assess injury-induced impairments at various time points following injury. Tissue was collected and brain atrophy, as measured by cortical and corpus callosum thinning and tau pathology (AT8) was assessed.
Results: One paradigm tested lead to sustained significant rotorod deficits that persisted for at least 11 weeks post-first injury. Brain tissue collected from a subset of mice euthanized at this time point showed significant brain atrophy (cortical and corpus callosum thinning) and elevated tau pathology that was most extreme in the corpus callosum.
Conclusions: Although motor function deficits are not a prominent feature of acute mild TBI, difficulties in motor coordination are commonly associated with CTE, suggesting that repetitive mild TBI has long-term detrimental effects on the motor system. Here we have provided a unique mouse model of repeat mild TBI that leads to long-term motor impairment with associated CTE-like brain pathology. As we have previously described a similar rat model, the ability to now implement this injury paradigm in transgenic mice will be useful to study repeat mild TBI as a risk factor for a large number of neurodegenerative diseases that are currently modeled in mice but not in rats.

Title: P2X4 and P2X7 receptor blocker in a rat model of cerebral contusion injury

Authors: *M. KOBAYASHI, Y. FURUKAWA, T. KUMAGAWA, K. SHIJO, N. MORO, M. FUKUSHIMA, T. MAEDA, A. YOSHINO
Neurosurg., Nihon Univ. Sch. of Med., Tokyo, Japan

Abstract: Massive release of gliotransmitter ATP is observed immediately after traumatic brain injury. ATP is known to activate nearby microglia which will initiate inflammatory response. P2X4 and P2X7 receptor are the major receptor on microglia to receive ATP signal in vitro that will activate ramified microglia to amoeboid microglia. In the present study, 5-BDBD a selective P2X4 receptor blocker and AZ11645373 a selective P2X7 receptor blocker were used in a in vivo rat cerebral contusion model to observe the magnitude of inflammatory response. Rat cerebral contusion injury was used as a traumatic brain injury model. Control, 5-BDBD, AZ11645373 or both was directly injected into the contused tissue by implanted osmotic pump. Three days after injury, rat was sacrificed and brain was extracted for analysis. Iba-1 antibody positive and Galectin-3 antibody positive amoeboid microglia increased in the surrounding cortical tissue but not in the contralateral hemisphere. Activated microglia was also seen in the ipsilateral hippocampus. Western blotting of Galectin-3 showed significant increase of activated microglia by injury, but this increase was partially suppressed by 5-BDBD and AZ11645373 administration. Some but not all inflammation related cytokines were suppressed by 5-BDBD and AZ11645373 administration. Blockade of microglial activation by P2X4 and P2X7 receptor blocker have an effect to suppress inflammatory response in an in vivo model of traumatic brain injury.

Title: Function study of knockout brain-specific mitochondrial apoptosis-inducing factor gene (AIF2) in normal and pathological state

Authors: *J. I. RODRIGUEZ[1], Y. ZHANG[1], T. LI[1], Y. SUN[1], C. XIE[1], K. BLOMGREN[2], C. ZHU[1]
[1]Ctr. for Brain Repair and Rehabil., Inst. of Neurosci. and Physiology, Sahlgren, Goeteborg, Sweden; [2]Karolinska Inst., Stockholm, Sweden

Abstract: Perinatal complications such as asphyxia and preterm birth can cause perinatal brain injuries that are often associated with subsequent neurological deficits, such as cerebral palsy. Mitochondria-mediated apoptosis-inducing factor (AIF) dependent neuronal cell death is the central process in perinatal brain injury.
Without an apoptotic stimulus, AIF has a vital role in oxidative phosphorylation and detoxification of reactive oxygen species. However, under apoptotic stimulus, AIF translocate to the nucleus and induce DNA fragmentation and chromatin condensation.
Recently, it has been discovered a brain-specific AIF isoform (AIF2). Numerous functional studies have been performed on AIF1, the most abundant and ubiquitous AIF isoform, whereas, AIF2 has not been further characterized. AIF1 and AIF2 only differ in a short stretch of their amino acid sequence in the N-terminal region that is removed from the mature protein as it translocates to the nucleus. The aim of this study is to assess the functional and regulatory profiling of AIF2 in normal state and after hypoxia-ischemia (HI) insult. For this purpose, we generated AIF2-flox mice and produced AIF2 flox/flox.pgk-cre knockout (KO) mice.
KO AIF2 did not affect the expression of proteins such us Cytc, mia40, OPA1 or SOD2 in neonatal brain mice (9-days old) in physiological state. However, the relative expression of AIF1 in AIF2 KO mice is higher in adult (60-days old) mice, compare to wilt-type litter-mates. KO AIF2 did not affect the fertility of female mice, either caspase-3 activity or the survival and proliferation of neural progenitors in P9 and P60 mice brain. However, KO AIF2 increased brain injury in HI neonatal mice, as showed via immunohistochemistry staining for markers of gray matter (MAP2) at 72 h after HI.
All in all, these data suggest that there is a compensation in the expression level of AIF1 when AIF2 is KO, and this change in the AIF1/AIF2 ratio would lead to an increased brain injury after HI insult.
In summary, we believe that an in-depth understanding of this process will lead to the development of effective treatments during the early stages of perinatal brain injury.

Title: Heterozygous cysteine-string protein alpha knock-out mice exhibit reduced SNARE protein abundance following traumatic brain injury

Authors: *S. W. CARLSON, C. DIXON
Neurosurg. and VA Pittsburgh Healthcare Syst., Univ. of Pittsburgh, Pittsburgh, PA

Abstract: Traumatic brain injury (TBI) disrupts cognitive function up to 1 year post-injury as reported by patients and observed in preclinical models. Published studies implicate deficits in neurotransmission as contributing to neurobehavioral dysfunction after TBI, but additional work is needed to understand the mechanisms underlying this pathological response. In the synapse, formation of the soluble N-ethylmaleimide-sensitive factor attachment protein receptor (SNARE) complex is an important step facilitating vesicular docking and fusion for neurotransmitter release into the synaptic cleft. Cysteine string protein alpha (CSPα) is a critical chaperone that promotes formation of the SNARE complex. We previously showed CSPα abundance is reduced in the days following TBI. To test the effect of reduced CSPα on neurobehavioral function, we utilized CSPα heterozygous (CSPα HET) mice previously shown to have reduced CSPα protein. Naïve male CSPα HET and wild-type (WT) mice subjected to motor and cognitive testing, performed similarly in the beam balance task. CSPα HET mice exhibited an increase in Morris Water maze spatial acquisition latency on day 3 of testing, compared to WT mice (interaction effect, post-hoc $p<0.05$). We hypothesized CSPα HET mice would exhibit reduced SNARE complex formation and exacerbated neurobehavioral dysfunction after TBI, as compared to WT mice. To test this, CSPα HET and WT mice were subjected to controlled cortical impact (CCI) injury (1.8 mm, 6 m/s, 150 msec dwell) or sham control surgery. Assessment of beam balance performance revealed no differences between groups on days 1-5 post-injury. Assessment of spatial acquisition on days 9-13 post-injury revealed a significant injury effect ($p<0.05$), independent of genotype, compared to sham injury. Evaluation of spatial memory and visible platform performance at 14 days post-injury revealed no difference between groups. Immunoblotting revealed a significant reduction in CSPα abundance in the hippocampus of sham and CCI-injured CSPα HET mice compared to sham and CCI-injured WT mice ($p<0.01$) at 2 weeks post-injury. Assessment of SNARE complex syntaxin-1-immunoreactivity revealed sham and CCI-injured CSPα HET mice had reduced complex formation ($p<0.05$), compared to sham WT mice, at 2 weeks post-injury. While these findings show limited exacerbation of CCI-associated neurobehavioral deficits in CSPα HET mice, future work will investigate compensatory mechanisms capable of promoting SNARE complex formation in the context of reduced CSPα abundance. These data provide novel findings for the effect of TBI on CSPα HET mice and synaptic SNARE protein abundance post-injury.

Title: The effect of the angiotensin receptor blocker candesartan after repeated unilateral closed head injury in mice

Authors: M. RUSNAK[1], *A. J. SYMES[2]
[1]USUHS-Henry M. Jackson Fndn., Bethesda, MD; [2]Pharmacol., USUHS, Bethesda, MD

Abstract: The brain renin-angiotensin system (RAS) is an important mediator of inflammation and oxidative stress after CNS injury. Our laboratory and others have shown that treatment with FDA approved angiotensin receptor blockers (ARBs) are effective in ameliorating inflammation and glial reactivity and improving morphological and cognitive recovery after controlled cortical impact injury in mice. As different models of traumatic brain injury (TBI) have distinct neuropathologic features, we wanted to determine whether the ARBs could be effective in a repetitive closed head injury model (rCHI).
In the present study we investigated the effect of the ARB candesartan on behavioral and histopathological outcome after repeated closed head injury. Mice were injured with an electromagnetic impactor on the skin four times, at 24-hour intervals. rCHI produced strong activation of astrocytes and microglia as well as significant loss of neurons in the cerebral cortex in the impacted area compared to the contralateral side 5 days after the last injury. Significant, but less pronounced astrocyte and microglial activation was also observed in the ipsilateral dorsal striatum and corpus callosum. Treatment with candesartan (0.5mg/kg daily) reduced ipsilateral neuronal loss at 5 days post injury but had no effect on astrocyte or microglial activation.
The brain RAS is also involved in the response to stress partially through activation of angiotensin II receptor I (AT1R) in the hypothalamic paraventricular nucleus (PVN). AT1R is co-expressed with corticotropin-releasing hormone (CRH) in the majority of parvocellular neurons of the PVN. We therefore wanted to determine whether candesartan altered the response to restraint stress in rCHI injured mice. rCHI injured mice were subjected to 20 min restraint stress 5 days after the last injury, and sacrificed 2 hours after initiation of the stress. Candesartan treatment reduced CRH mRNA expression in the PVN after 20 min restraint stress compared to vehicle treated mice, but neither the stress nor the candesartan treatment altered AT1R mRNA expression. In behavioral experiments rCHI injured mice showed hyperactivity as compared to

sham animals in open field test. Paradoxically, in the zero maze assay, the injured mice spent more time in the open zones compared to sham animals suggesting a decreased inhibition in an aversive environment, perhaps due to the increased mobility. Candesartan treatment reduced this effect. Thus, in addition to its positive effects improving recovery after controlled cortical impact model, the ARB candesartan has potential benefit in treating closed head injury.

Title: Soccer heading-related memory deficit in players with the apolipoprotein ε4 allele

Authors: *L. E. HUNTER[1], *L. E. HUNTER[1], M. L. LIPTON[2]
[1]Albert Einstein Col. of Med., Bronx, NY; [2]Dept Radiology, Albert Einstein Col. Med., Bronx, NY

Abstract: Aim: We aimed to determine the extent to which presence of the Apolipoprotein ε4 allele modifies the association between 12-month total number of headers and verbal learning and memory.
Methods: We examined 248 soccer players enrolled the Einstein Soccer Study, a longitudinal study of amateur soccer players in the New York City area. At each visit, players underwent verbal learning and verbal memory testing using Cogstate™ (International Shopping List (ISL) and International Shopping List Recall (ISRL) tasks), respectively. Players also completed Head-Count, a validated, web-based questionnaire that ascertained the total number of headers in the past year. Repeated measures multivariable linear regressions were employed to test for effect modification of ε4 allele status on the association between 12 month total heads and verbal learning and verbal memory.
Results: 24.6 % of the players examined were carriers of at least one copy of the ε4 allele. We found a significant effect modification ($p= 0.007$) of ε4 allele status on the relationship of total headers in the past year and verbal memory (by number of items (1-12) correctly recalled at 20 minutes). Compared to ε4- players with fewest headers of (lowest quartile; 0-130 headers), ε4+ players with most headers (highest quartile; 1044-22838 headers) recalled fewer items = -.99; $p <0.001$). There was a borderline significant effect modification ($p= 0.06$) of ε4 allele status on

the association of heading and immediate recall (i.e., verbal learning).
Conclusions: Soccer players that carry an ε4 allele are more vulnerable than players without the ε4 allele to adverse effects of high levels of heading on memory. These findings suggest that ε4+ players might be targeted in efforts to minimize excessive heading to mitigate potential for adverse impact on memory function.

Title: Gradient echo plural contrast imaging detects mtbi related brain tissue damage in areas without evident anatomical changes on clinical mri

Authors: S. V. ASTAFIEV[1], J. WEN[2], D. L. BRODY[3], A. H. CROSS[3], A. P. ANOKHIN[1], K. L. ZINN[3], M. CORBETTA[3], *D. A. YABLONSKIY[4]
[1]Psychiatry, [2]Radiology, [3]Neurol., Washington Univ. in St. Louis, St. Louis, MO; [4]Mallinckrodt Inst. Radiol, Saint Louis, MO

Abstract: Background. It is widely accepted that symptoms in chronic mild traumatic brain injury (mTBI) are caused by injury to the white matter (WM), but the role of grey matter (GM) damage in TBI-related symptomatology is less clear. While WM damage can be detected by DTI, there is currently no accepted technique to detect mTBI-related GM damage. In this study we demonstrate that an advanced implementation of quantitative MRI-based high-resolution 3D Gradient Echo Plural Contrast Imaging (GEPCI) technique(1) sensitive to cellular loss(2,3) allows mTBI-related evaluation of GM tissue abnormalities complementary to DTI.
Methods. We tested 26 healthy controls and 14 mTBI patients with isolated mTBI. GEPCI data

were reconstructed using previously developed algorithms that allow separation of cellular-specific part of relaxation rate constant (R2t*) from global R2* affected by BOLD effect and background gradients. As demonstrated previously, both cell loss in GM and demyelination of WM lead to reduced R2t* values that can be detected by GEPCI.
Results. Single subject voxel-wise analysis (comparing each mTBI patient to 26 control subjects by using a one-sample t-test and selecting voxels with significantly ($p<0.05$) lower R2t* values in mTBI patients) revealed distributed GM abnormalities, not detectable on standard MRI images (T1w, T2w, FLAIR and SWI), in multiple GM regions, especially frontal and temporal, that are frequently damaged after mTBI. We identified 243 clusters of voxels with low R2t* (cluster size: $\geq 27mm^3$, average $634mm^3$) that showed spatial overlap in ≥2 mTBI patients.
To test for random noise, we conducted a similar voxel-wise analysis for control subjects and did not identify any such clusters. Abnormal tissue with the highest degree of overlap across mTBI patients (>45% of overlap) was located in cerebellum, superior temporal gyrus, insula, inferior occipital gyrus, precuneus and inferior temporal gyrus.
Conclusion. We demonstrated that the GEPCI-derived tissue specific R2t* metric is sensitive to GM tissue damage in subjects with mTBI. The ability of GEPCI imaging to detect compromised GM cellular integrity makes it an important diagnostic tool that can complement the information about WM damage provided by the DTI.

Title: Multimodal tasks can cause more difficulty compared to simple tasks in concussed athletes indicating a dysfunction of the sensorimotor integration mechanisms

Authors: A. B. BIALUNSKA[1], *A. P. SALVATORE[2]
[1]Rehabil. Sci., Univ. of Texas At El Paso, El Paso, TX; [2]U. of Texas At El Paso, El Paso, TX

Abstract: Clinical characteristics of concussion (mild traumatic brain injury, mTBI), include neurological signs and symptoms, as well as cognitive dysfunction which are linked to microstructural injury to neural tissue after biomechanical force to the brain. Such an injury leads to axonal dysfunctions, white matter damage, impaired neurotransmission and potential for neural disconnection (Giza & Hovda, 2014). Cognitive functioning is a complex phenomenon requiring coherent communication across distributed networks of cortical and sub-cortical brain regions. The fine-scale temporal coordination of these regions is critically dependent on white matter tracts that allow effective transmission of information across the brain. Therefore, perturbations following mTBI result in cognitive deficits, but in our opinion particularly in the impairment of multisensory integration. Neurocognitive post-concussion tests were used for assessing verbal and visual memory, attention, and motor processing. However the sensitivity of an instrument for assessing a concussion is a challenge. Sport-related concussion (SRC) is purported to have a relatively short recovery time, 7 to 14 days after injury (DAI) based on an assessment using the ImPACT test. This tool consists of simple, yet not easy tasks. To test whether more complex task which measure multisensory (auditory-visual-verbal-motor) processing could lead to a different evaluation of concussed athletes, we analyzed how the results obtained from two different tests, the ImPACT and Computerized-Revised Token Test (C-RTT), a test of auditory comprehension, change over time following SRC. Using case study method we found that patients showed cognitive dysfunctions both on the ImPACT and C-RTT. Performance was assessed on these instruments in repeated sessions over time. Performance showed a gradual improvement over time. However cognitive performance on ImPACT measures of efficiency and response time were, in some cases, faster than those variables assessed by the C-RTT. The C-RTT measures the accuracy of following spoken sentences and the timing of moving visual objects on a computer screen in response to the spoken sentence. Reaction time performance on the C-RTT was more disrupted and improved much slower than on the ImPACT, about 43 - 60 DAI. Our findings indicate that the more complex task requirements of the C-RTT which required integration of information from different modalities and domains produced poorer performances across time compared to the ImPACT. We hypothesize that the cognitive dysfunction characteristic of SRC is a result of general purpose mechanism (e.g. timing) rather than domain specific.

Title: Neurocognitive, neuroimaging and biomolecular findings in concussed adolescents: An investigation of working memory, math fluency, functional near Infrared spectroscopy (fNIRS), and micro-RNA (miRNA)

Authors: N. SIDEMAN[1,2], H. AYAZ[5], C. J. HAMMOND[2,3], A. SARGENT[5], D. M. APPELT[4,2], S. L. ALLEN[2,1], *B. J. BALIN[4,2]
[1]Psychology, [2]Ctr. for Chronic Disorders of Aging, [3]Div. of Res., [4]Bio-Medical Sci., Philadelphia Col. of Osteo. Med., Philadelphia, PA; [5]Sch. of Biomed. Engineering, Sci. & Hlth. Systems, Drexel Univ., Philadelphia, PA

Abstract: OBJECTIVES: Methods used to make concussion diagnoses, namely neurocognitive testing and symptom reporting/observation, can be unreliable and lack sensitivity. For adolescents, an especially susceptible age group, decisions regarding returning to activities typically rely on these methods. The imprecision of these measures can therefore unnecessarily subject children to further injury and prolonged recovery trajectories. While current methods can help inform some decisions, much of the underlying physiological changes attributed to concussion cannot be gleaned from these standard practices. The current study aimed to evaluate underlying physiological changes that occur in concussions in order to better understand and validate potential bio-marker candidates. **METHODS:** Concussed adolescents (n=10) ages 14-17 within 4 weeks of concussion were compared to matched control subjects (n=10). Subjects completed two tasks (N-back, Math Fluency) while wearing the fNIRS. Each task consisted of three conditions (N-back: N-back1, N-back2, and N-back3; Math Fluency: Addition, Subtraction, and Multiplication). Subjects also provided a saliva sample for miRNA analysis. Groups were compared across neurocognitive, neuroimaging, and biomolecular dimensions. **RESULTS**: Subjects did not differ significantly in age, gender, education, handedness, or hours of sleep. Average age of all participants was 16.1 years (SD=1.33) and mean time since injury was 18.3 days (SD= 6.7). Correlational analyses revealed significant correlations within the response time (RT) and accuracy (ACC) measures of each task. There were significant main effects for the math (p&lt01) and n-back conditions (p&lt01) on RT and ACC across groups. No behavioral differences between groups were seen. Pre-frontal cortex (PFC) brain activation was significantly higher for the mTBI group (p=.049) on the math fluency task. The mTBI group also showed stronger right PFC activation (p=.016) compared to the left PFC. Control subjects did

not show this difference. miRNA responsible for neuro-inflammatory gene expression were regulated differently between groups. **CONCLUSIONS:** This study helps to elucidate the fact that neurocognitive findings often do not vary between individuals with mTBI and their healthy peers. Despite these similar neurocognitive findings between groups, fNIRS and miRNA findings reveal significant underlying physiological differences. These findings support the efficaciousness of neuroimaging and biomolecular analyses in the diagnosis and remediation of concussions. Further work will need to be conducted to analyze the sensitivity and specificity of these methods.

Title: Exploring the links between traumatic brain injuries and crime: A 24-year longitudinal study of Canadian males

Authors: *G. GUBERMAN[1,3], M.-P. ROBITAILLE[4,5], A. PTITO[1,2], S. HODGINS[4,5]
[1]Neurol. & Neurosurg., [2]Psychology, McGill Univ., Montreal, QC, Canada; [3]Inst. Universitaire en Santé Mentale de Montréal, Montréal, QC, Canada; [4]Inst. Universitaire en Santé Mentale de Montréal, Montreal, QC, Canada; [5]Psychiatry, Univ. of Montreal, Montreal, QC, Canada

Abstract: Traumatic brain injuries (TBIs) are the leading cause of death and disability in children and young adults around the world (WHO, 2006). Although incidence rates vary across studies, TBIs are estimated to affect approximately 0.6% of Canadians and 1-2% of the US population. Several studies conducted in different countries confirm that the prevalence of TBIs is higher among criminal offenders than in age and sex matched general population samples. However, presently, it is not known whether TBIs precede or follow criminal behavior, hence if they predict criminality. Further, robust evidence from longitudinal investigations shows that from childhood onwards, most offenders display a pattern of conduct problems including impulsive and reckless behaviors. We hypothesized that such behaviors would also increase the risk of TBIs. The present study aimed to determine whether TBIs preceded and predicted criminal offending, and whether the well-known childhood predictors of offending also predicted

TBIs. The study examined 724 males followed from age 6 to 30 in Quebec (Canada), using health records from age 6 to 24 and official criminal records from age 12 to 24. Information was also available on two known criminality-related measures: the mother's age at participants' birth and socioeconomic deprivation of the childhood neighborhood. At age 6, 10, and 12, classroom teachers rated participants' conduct problems, inattention, hyperactivity, hurtful and uncaring behaviors. Our results confirmed previous findings showing that proportionately more offenders than non-offenders had suffered at least one TBI. However, similar proportions of offenders committed their first crime before and after their first TBI. In a logistic regression model that excluded participants with TBIs prior to age 10, experiencing a TBI after 10 was predicted by conduct problems at age 6 (OR 1.07, 95% CI 1.02-1.13), hyperactivity at age 10 (OR 1.28, 95% CI 1.10-1.48), and deprived neighborhood (OR 1.70, 95% CI 1.08-2.68). In models predicting criminal offending, after taking account of childhood behaviors, maternal age, and neighborhood deprivation, sustaining a TBI did not predict subsequent offending. Thus, among males, behaviors observed by classroom teachers at age 6 and 10 and deprivation of the childhood neighborhood predicted subsequent TBIs showing that not all boys are at similar risk for a TBI. Future research is needed to develop more precise measures of childhood behaviors as a first step to establishing programs to prevent TBIs.

Abstract: Conventional patient neuroimaging often fails to provide sensitive and accurate assessment of brain injury severity or classification. Thus, minimally invasive biomarkers can supplement imaging for patients by identifying prognostic genomic markers specific to brain injury type. We hypothesized that two broad types of traumatic brain injury (TBI), focal or

diffuse, can be distinguished with unique signatures of circulating microRNAs (miRNAs). As a first step, computed tomography (CT) imaging distinguished TBI patients with focal or diffuse injury and later was correlated with serum miRNA levels. RNA was isolated from TBI and non-TBI patient serum, reverse-transcribed, pre-amplified and run on PCR arrays containing 84 common biofluid miRNAs. Fold changes were calculated by comparing TBI to non-TBI controls. One-way ANOVA followed by Benjamin-Hochberg and Tukey's test for multiple comparisons was used to assess statistical significance. Preliminary analysis shows several miRNAs are differentially expressed in human serum between control and injury groups, and one differently expressed miRNA distinguishes between focal and diffuse injury. In parallel animal studies, brain tissue and serum miRNA expression were examined after fluid percussion injury (FPI) and controlled cortical impact (CCI), which produce diffuse and focal injuries, respectively. We hypothesized that unique differential regulation of miRNA in various brain regions would be injury-type specific and that these changes are reflected in serum. Rats were anesthetized and subjected to either severe FPI or CCI and naïve controls remained uninjured. Four hours after TBI, blood was collected, serum was isolated, and rats were sacrificed. Fresh frozen brains were prepared for laser capture microdissection of hippocampus, frontal cortex, and nucleus accumbens. Serum and tissue miRNA were isolated, reverse-transcribed, pre-amplified and run on arrays populated with 84 common disease associated miRNAs. Our analysis shows distinct miRNAs differentially expressed in a brain region dependent manner, between focal or diffuse injuries. Ingenuity Pathway Analysis of differentially expressed miRNA suggests their involvement in potential pathophysiologic processes after TBI. Serum miRNA expression revealed significant differences among FPI and CCI comparisons and to naïve controls. Minimally invasive miRNA biomarkers will improve clinical decision making for TBI patients by supplementing conventional neuroimaging.

Title: Reaction time deficits in asymptomatic adolescents during the subacute period following mild traumatic brain injury

Authors: *K. SPIEGLER[1], J. D. HANDY[2], M. M. CRIPPEN[3], S. KOMARAVOLU[3], K. C. H. PANG[1,4], C. A. MAZZOLA[5], R. J. SERVATIUS[1,2,4,6]

Sch., Newark, NJ; [5]Div. of Pediatric Neurolog. Surgery, Goryeb Children's Hosp. of Morristown Med. Ctr., Morristown, NJ; [6]Dept. of Psychiatry, SUNY Upstate Med. Univ., Syracuse, NY

Abstract: Adolescents are at high risk for mild traumatic brain injury (mTBI). Thus, practical and accurate diagnostic tools to evaluate concussive symptoms in this population are of great importance. There is considerable controversy regarding the sensitivity of neurocognitive tests to assess dysfunction in the aftermath of mTBI. Therefore, we examined the performance of adolescents who recently experienced mTBI on the commonly used Immediate Post-Concussion Assessment and Cognitive Testing (ImPACT) and the Defense Automated Neurobehavioral Assessment (DANA), a test used by the military for assessing mTBI. Adolescents ages 11-17 years old with a recent mTBI diagnosis (8 males and 7 females, 9-69 days after concussion) were recruited and compared to non-concussed (NC) volunteers in the same age range (11 males, 3 females). Adolescents completed the online version of the ImPACT battery and completed the DANA battery on a handheld device. There were no differences in self-reported symptoms on the Post-Concussion Symptom Scale comparing mTBI and NC adolescents (Wilks $\lambda = .863$, F (4, 24) = 0.96, $p = .449$, partial $\eta^2 = .137$). With regard to ImPACT performance, the multivariate effect of injury group was not significant (Wilks $\lambda = .821$, F (4, 20) = 1.09, $p = .389$, partial $\eta^2 = .179$). In contrast, there was a significant between-groups multivariate effect for the DANA assessment battery (Wilks $\lambda = .531$, F (3, 20) = 5.88, $p = .005$, partial $\eta^2 = .469$). Follow-up univariate ANOVA revealed significantly lower throughput scores for Simple Reaction Time (F (1, 22) = 13.30, $p = .001$, partial $\eta^2 = .377$) and GoNoGo (F (1, 22) = 7.87, $p = .01$, partial $\eta^2 = .263$) tasks in the mTBI group compared to the NC group. These results suggest reaction time deficits after adolescent mTBI that persist despite the resolution of other symptomatology according to self-report and ImPACT measures. The DANA battery has promise as a tool to determine cognitive dysfunction in the subacute period after mTBI in adolescents.

Title: Sex divergence of white matter microstructural change associated with soccer heading

Authors: *T. G. RUBIN[1], E. CATENACCIO[2], R. FLEYSHER[1], L. E. HUNTER[1], N. LUBIN[1], M. E. WAGSHUL[1], W. F. STEWART[3], M. KIM[1], R. B. LIPTON[1], M. L. LIPTON[1]
[1]Albert Einstein Col. of Med., Bronx, NY; [2]Johns Hopkins Univ., Baltimore, MD; [3]Sutter Hlth., Walnut Creek, CA

Abstract: Head impacts in soccer are common. Although men may be exposed to a greater number and greater force of impacts, women report more symptoms which take longer to resolve. These findings suggest that women may be more vulnerable to the effects of heading than men. In a small sample of men and women we previously showed that heading is associated with damage to white matter tract integrity as assessed by lower fractional anisotropy (FA) on diffusion tensor imaging MRI (DTI). In that study of 37 amateur athletes, biological sex was treated as a nuisance covariate. The present study explicitly characterizes the role of sex in the association of heading with microstructural changes (FA) in a cohort of 49 male and 49 female soccer players matched for age and prior 12-month heading. Subjects underwent 3.0T DTI imaging. FA was analyzed with a voxelwise linear model to assess where the association of heading with FA was significant for men, for women, and for significant differences between men and women. We found 3 regions with negative association of heading with FA for men (i.e. decreased FA with heading), and 8 regions with negative association of heading with FA for women. The volume of each region was summed to find 2,121mm^3 of white matter exhibiting lower FA associated with more heading in women, but only 408mm^3 in men. These findings provide evidence that, at the level of brain tissue microstructure, women are more sensitive to the effects of heading than men, supporting the sex differences in symptom frequency and persistence.

Title: Decreased head movement variability after unilateral vestibular correlates with dizziness: A locomotion study on vestibular schwannoma patients

Authors: *O. ZOBEIRI[1], S. KING[2], R. F. LEWIS[3], K. E. CULLEN[4]
[1]Dept. of Physiol., McGill Univ., Montreal, QC, Canada; [2]Jenks Vestibular Physiol. Lab., Massachusetts Eye and Ear Infirmary, Boston, MA; [3]Otolayngology & Neurol., Harvard Med. Sch., Boston, MA; [4]Johns Hopkins Univ., Baltimore, MD

Abstract: A wide range of functions, from basic reflexes to high-level behaviors, depend on the vestibular system. By sensing head motion and then generating the appropriate reflexes, the vestibular system is vital for maintaining balance and stabilizing gaze. In turn, it has been shown that immediately following unilateral vestibular loss, patients experience impaired balance, postural, and gaze control during clinical tests. However, to date, much less is known about the effects of vestibular loss on voluntary behavior. Here, to assess how unilateral vestibular loss alters voluntary behaviour, we analyzed locomotive behavior in a group of patients with a diagnosis of vestibular schwannoma (VS) who had undergone a primary surgical resection of their tumor via suboccipital craniotomy and retrosigmoid approach with sectioning of the vestibular nerve. Head movements were recorded in healthy volunteers, and patients before the surgery, as well as two and six weeks after surgery using an inertial measurement unit (IMU), which records 3-axis linear acceleration and 3-axis angular velocity. Patients and healthy controls were asked to complete the Functional Gait Assessment, and we focused our analysis on short, 15-to-30-second long normal waling task. We then compared the data that are collected from healthy subjects, as well as patients before and after surgery, to determine if and how patients' movements were altered. Our results confirmed that walking trajectories of patients were more asymmetric than those of control subjects, but were comparable that observed for patients before their surgeries. Patients' gait speed was reduced as compared that observed either before surgery or relative to age matched controls. Specifically, the number of steps generated per second decreased as did the magnitude of forward and vertical acceleration. Surprisingly, two and six weeks after vestibular loss, patients demonstrated a marked reduction movement variability across cycles in both the linear and rotational axes of motion following surgery. Interestingly, our results further showed that patients that demonstrated less variability during walking were actually more impaired; patients that perceived themselves as more dizzy (measured via the Dizziness Handicap Inventory (DHI)) actually demonstrated less reduced variability in their gain during walking. Taken together, our results suggest a positive role for variability in sensori-motor compensation and suggest that movement variability achieved during the early stages of vestibular compensation is an important indicator of how well patients ultimately recover.

Title: Near-infrared spectroscopy measures of prefrontal cortex oxygenation following mild traumatic brain injury

Authors: *T. SUSA[1], K. J. KANGAS[3], M. MOORE[4], J. M. CARLSON[2]
[1]Psychology/Neuroscience, [2]Psychology, Northern Michigan Univ., Marquette, MI; [3]Northern Michigan Univ. Psychology, Marquette, MI; [4]Northern Michigan Univ. Hlth. and Human Performance, Marquette, MI

Abstract: Concussions, or mild traumatic brain injuries, are common in many contact sports. Yet, little is known about the neural consequences of a concussion. Research on the effects of concussions has spiked since 2010. This relatively recent interest has led to an improved understanding of mild traumatic brain injury and how it affects behavior. However, only a small proportion of concussion studies, include a neuroimaging component and in particular, very few studies have assessed the effects of mild traumatic brain injury using functional neuroimaging. This study aimed to fill this knowledge gap by examining prefrontal cortex oxygenation levels during a non-task (i.e., resting) state after mild traumatic brain injury using near-infrared spectroscopy (NIRS). Participants were split into two groups: (1) the experimental group consisted of volunteers who recently suffered a concussion and were then cleared to resume play and (2) the control group consisted of volunteers who were matched based on age, gender, and sport. We recorded using a 16 channel array that was placed over the participant's prefrontal cortex during a five minute rest session. Differences in brain activity were observed across the mild traumatic brain injury and control groups. In general, NIRS activity decreased in the mild traumatic brain injury group across the prefrontal cortex. The results are consistent with previous meta-analytic evidence indicating that the prefrontal cortex is particularly susceptible to concussion. This suggests that NIRS could be used as a portable and cost-effective method of measuring the effects of mild traumatic brain injury on prefrontal cortex activity.

Title: An assessment of frontal lobe activity during an attentional bias task following concussion in collegiate athletes: A near-infrared spectroscopy study

Authors: *K. J. KANGAS[1], J. ADAY[2], M. T. MOORE[3], J. M. CARLSON[2]
[2]Psychology, [3]Sch. of Hlth. and Human Performance, [1]Northern Michigan Univ., Marquette, MI

Abstract: Impacts to the head, that are associated with sports related injuries, can result in a mild traumatic brain injury (mTBI) also known as a concussion. Emotional and attentional impairments often result from concussions; yet, these dimensions of mTBI and their relation to prefrontal cortex (PFC) activity are not well understood. The PFC is involved in increased attentional control during threat-related distractors, and the PFC is particularly susceptible to the effects of mTBI. There is limited research comparing attention-related PFC activation between athletes with and without mTBI in tandem with neuroimaging techniques. To fill this knowledge gap, this study utilized a neuroimaging technique that is inexpensive, non-invasive, and portable to measure PFC activity post-concussion. In particular, near-infrared spectroscopy (NIRS) was used to measure activity during the dot-probe task of affective attentional bias. There were three trial types: baseline (two neutral faces), congruent (dot appears behind the fearful face), and incongruent (dot appears behind the neutral face). This task appears to engage the PFC in past studies. We found significant interactions for trial type and group (mTBI vs Control) as well as time and group. Athletes with mTBI were referred to study personnel, and the control group were matched based on age, gender, and sport. In the control group, the dot-probe task elicited an initial event-related decrease in oxygenated hemoglobin (HbO) in the PFC, which then stabilized and returned to baseline. However, for athletes with mTBI, PFC HbO levels did not dip in response to the task and thus displayed task-insensitivity. At the behavioral level, the mTBI (relative to the control) group showed delayed response times in the dot-probe task. Together, these results allow us to better understand concussions across behavioral and neuroimaging techniques—suggesting the PFC shows an insensitivity to affective stimuli in the dot-probe task of attentional bias after a mTBI.

Title: Lingering dynamic balance decrements in mild traumatic brain injured vs controls in collegiate athletes

Authors: *M. T. MOORE[1], J. M. CARLSON[2], K. J. KANGAS[2], J. P. YOUNG[1], J. J. HAMACHEK[1]
[1]Sch. of Hlth. and Human Performance, [2]Psychology, Northern Michigan Univ., Marquette, MI

Abstract: Balance is a complex process involving visual, vestibular and neuromuscular control. The Biodex Balance System SD is a reliable method to measure dynamic balance. Functional near infrared spectrometry (fNIRS) examines hemodynamic activity in the prefrontal cortex during testing. Little research has examined this low cost approach to testing in mTBI compared to controls after the individual has completed a graduated return to play protocol. Lingering effects after the acute phase could put the individual who is returning to full contact sport at risk for re-injury. The purpose of this research is to examine the differences between mTBI and controls dynamic balance and hemodynamic activity measured by fNIRS 14-42 days after injury and full return to play. Eleven controls matched for age, gender and sport with 11 mTBI (age 18-29) completed dual limb support testing on the Biodex Balance System SD. Limits of Stability (LOS) testing at moderate skill level (75%) involved center of gravity control within their base of support. The clinical test of sensory integration and balance tested stability and sway indexes within four conditions (eyes open/closed on firm vs foam surface) for 30 second intervals. An independent t test revealed significant differences (t(20) p=.033) between controls (M=2.104, SD=.395), and mTBI (M=2.695, SD=.395)] in a dynamic sway balance on a foam surface with the eyes closed. These differences appear to be linked to prefrontal cortex fNIRS activity during dynamic balance tasks. Lingering effects of mTBI beyond the acute phase cause individuals to exhibit difficulty with center of gravity shifts during dynamic settings. Once LOS is exceeded a fall, stumble or step will ensue. This suggests lingering decrements in proprioception and sensory pathways.

Title: The long-term outcomes of concussion: Alterations in emotional status and executive function

Authors: *V. SICARD[1], *V. SICARD[1], J.-C. LORTIE[1], R. D. MOORE[2], D. ELLEMBERG[1]
[1]Kinesiology, Neurodev Lab. - Univ. of Montreal, Montreal, QC, Canada; [2]Arnold Sch. of Publ. Hlth., Univ. of South Carolina, Columbia, SC

Abstract: Concussions may produce long-term alterations in psycho-affective state, mood and cognition. Moreover, studies suggest that concussion may be associated with self-reported symptoms of executive dysfunction. However, few studies used both subjective and objective measures to assess the long-term outcomes of concussion. Thus, the current study sought to determine whether the cognitive alterations would relate to day-to-day problems in emotional status and behavior. Accordingly, 64 university athletes (32 with a history of concussion (HOC); 32 controls) completed the Beck Depression Inventory II (BDI-II), Beck Anxiety Inventory (BAI), Profile of Mood States (POMS), Behavioral Rating Inventory of Executive Functions for Adults (BRIEF-A), and an experimental task-switching paradigm, which is thought to be a measure of executive functioning. Athletes with a HOC were 6+ months from their last injury, and controls were teammates matched on various factors. Athletes with a HOC reported significantly increased depressive symptoms on the BDI-II (ps < .05) and more problems on the Emotional Control and Self-monitor scales of the BRIEF-A relative to controls (ps < .01). Moreover, they significantly differed on total mood disturbance and all sub-categories except for vigor on the POMS (ps < .05). Athletes with a HOC took significantly longer to respond to respond on the task-switching paradigm (ps < .01). Significant variables were not correlated with the age at which they sustained a concussion, the number of concussions, or time since last injury. The current results suggest that beyond acute and sub-acute phase of injury, not only do athletes with a HOC report greater depressive symptoms and total mood disturbance, but they also exhibit longer reaction times compared to their control teammates. Moreover, they suggest that athletes with a HOC may exhibit more problems in their everyday live such as regulating their emotions and monitoring their behaviors. These alterations may carry negative implications for academic and vocational success and overall well-being.

Title: Altered dynamics of the thalamo-cortical system following mild traumatic brain injury: A combined experimental and theoretical study

Authors: *R. ZUCCA[1], X. ARAKAKI[2], S. C. LOW[1], R. T. GOLDWEBER[3], M. G. HARRINGTON[2], P. F. M. J. VERSCHURE[1,4]
[1]SPECS Univ. Pompeu Fabra, Barcelona, Spain; [2]HMRI, Pasadena, CA; [3]Huntington Mem. Hosp., Pasadena, CA; [4]ICREA, Barcelona, Spain

Abstract: Mild traumatic brain injury (mTBI) is one of the most common neurological disorders and one of the most difficult to diagnose. The initial trauma can lead to a cascade of delayed neurodegenerative events, e.g. diffuse axonal injury and/or excitotoxic neuroinflammation, affecting distal brain areas and causing a variety of adverse sensory, motor, cognitive and affective outcomes which can persist for weeks or even months and lead to severe disability due to cumulative damage (Sharp, 2014; Arakaki, 2016). Because of its diffuse nature, mTBI is difficult to diagnose and no clear biomarkers exist. Electrophysiological methods and computational modelling may shed light on the disruptions in large-scale neural networks involved in the functional deficits following mTBI. Indeed, we have recently shown that stroke-related cortical lesions induce pathological alterations to the thalamo-cortical system, or thalamocortical dysrhythmia (TCD). This arises by attenuating the cortical drive onto the thalamus, switching the latter into a low bursting regime, which further propagates to the neocortex through divergent intra-thalamic circuits (van Wijngaarden, 2016). TCD low-frequency dynamics can account for a variety of non-specific symptoms that are dissociated from the lesion site itself. Here we investigate whether such a network mechanism is implied in mTBI. We investigated brain activation profiles in 10 mTBI patients using resting state EEG after 7, 14 and 31 days following injury, as well as a group of age-matched trauma control patients. Our results show a pattern of increased delta activation in the frontal electrodes, consistent with published results (Lianyang, 2015; Huang, 2009), and attenuation in the beta-band power relative to trauma controls in the acute phase, which gradually recovers after four weeks. At the individual level, the spectral power distributions show high heterogeneity that depends on the lesion site and distribution, suggesting that diagnostically relevant EEG patterns could be revealed taking into account those specific individualized features. To explain the origins of these alterations, we developed a detailed spiking model of the thalamo-cortical circuits to identify the cellular and network mechanisms by which different thalamo-cortical pathways are entrained by means of propagating low-frequency oscillations beyond the restricted region of the diffuse mTBI lesions, giving rise to the associated symptoms.

Title: Traumatic photalgia changes in the human brainstem: Tensor-based morphometry

Authors: *L. T. LIKOVA, C. W. TYLER
Smith-Kettlewell Eye Res. Inst., San Francisco, CA

Abstract: Introduction. A well-known consequence of mild, or diffuse, traumatic brain injury (dTBI) is the development of debilitating light-induced pain, or 'photalgia'. The mechanism of the sensitization to light, however, remains unresolved. One hypothesis is that the tissue edema (swelling), which is a common feature of dTBI, might sensitize the trigeminal nucleus to signals from ocular mechanisms activated by bright light.
Methods. To assess this hypothesis, we ran high-resolution Magnetic Resonance Imaging of the brainstem of dTBI participants with mild and severe photalgia, without photalgia, and of healthy controls. The configuration of the brainstem was determined for each participant by Tensor-Based Morphometry (TBM) and compared across the participant groups. The TBM was based on a T1-weighted structural sequence acquired with 0.8 x 0.8 x 0.8 mm voxels. The T1 volume was processed with the FIRST tools from FSL, which provided an affine registration to a standard brain metric (the MNI152), and generated a triangular mesh representation of the brainstem. Data were visualized as a rendering of the surface of the control group colored by the magnitude of the average difference tensor at each vertex, for each of the dTBI groups.
Results and Conclusions. The TBM revealed significant deviations in the brainstem morphology of all dTBI groups. In particular, there was a pronounced difference between the patterns of average swelling and shrinkage between the non-photalgic and photalgic dTBI groups. dTBI without photalgia showed bilateral expansion at the pontine/medulla junction. dTBI with photalgia showed a band of mid-pontine shrinkage, more pronounced in severe photalgia, consistent with deterioration of the trigeminal complex. These results suggest that this shrinkage represents the morphological substrate of the photalgic sensitization of the trigeminal pathway.

Title: Neuroimaging of diffuse axonal and vascular injury in chronic traumatic brain injury

Authors: *M. HABER[1], F. AMYOT[2,4], K. FLESHER[3], K. KENNEY[2,4], C. MOORE[4], E. SILVERMAN[1], Y.-Y. CHOU[5], D. PHAM[5], E. M. WASSERMANN[5], R. R. DIAZ-ARRASTIA[1]
[1]Neurol., Univ. of Pennsylvania, Philadelphia, PA; [2]Neurol., [3]Uniformed Services Univ. of the Hlth. Sci., Bethesda, MD; [4]Ctr. for Neurosci. and Regenerative Med., The Henry M. Jackson Fndn. for the Advancement of Military Med., Bethesda, MD; [5]NINDS, NIH, Bethesda, MD

Abstract: Traumatic Brain Injury (TBI) results in diffuse axonal injury (DAI) and diffuse vascular injury (DVI). Both DAI and DVI result from inertial shearing forces, and the two terms are often used interchangeably, the spatial relationships between DAI and DVI have not been carefully studied. Multimodal magnetic resonance imaging (MRI) can help to distinguish these injury mencahisms: diffusion tensor imaging (DTI) provides information about axonal integrity, while arterial spin labeling (ASL) and functional Blood Oxygen Level Dependent imaging (BOLD) with hypercapnia challenge, reflect cerebral blood flow (CBF) and cerebrovascular reactivity (CVR) respectively. Chronic TBI participants (n=27) and age- and education-matched healthy controls (n=15) underwent multimodality MRI. The Freesurfer image analysis suite (MGH, Harvard, MA) was used to segment each MP-RAGE image into regions of interest (ROIs). Mean values of mean diffusivity (MD), fractional anisotropy (FA), CBF, and CVR were extracted for each ROI. Additionally, maps were normalized into a common space (MNI Atlas) and z-score maps were generated based on a pool of healthy controls. Normality of an ROI/voxel was determined based on z-score (abnormal MD: z-score>2.5; abnormal FA, CBF, and CVR: z-score<-2.5). Abnormal ROIs in one modality were not predictive of abnormalities in another modality. Approximately 8-10% of abnormal voxels for CVR and CBF also show an abnormal voxel value for MD, while only 1% of abnormal CVR and CBF voxels show a concomitant abnormal FA value. These data indicate that chronic TBI patients display two distinct endophenotypes: microstructural tissue/axonal injury and vascular injury that are spatially independent.

Title: Derivation of a clinical decision support tool for traumatic brain injury

Authors: *J. E. OLSON[1], M. H. YACYSHYN[1], M. L. WHITMILL[2], M. C. MCCARTHY[2]
[1]Dept Emergency Med., [2]Dept Surgery, Wright State Univ. Boonshoft Sch. Med., Dayton, OH

Abstract: Traumatic brain injury (TBI) is commonly seen in emergency departments and represents a significant burden for health care systems, both during the initial hospital visit and during the recovery period. Numerous clinical models which focus on moderate and severe TBI have been developed to predict long-term outcome following TBI. Because some patients with mild TBI proceed to an unfavorable in-hospital outcome, we previously developed a clinical prediction model for in-hospital mortality which encompasses the entire range of TBI severity. Multiple logistic regression analysis was performed on a derivation data set consisting of 23 clinical parameters retrospectively obtained from 6571 TBI patients presenting to a level 1 trauma center. The analysis yielded eight parameters that are significantly associated with mortality; brain edema, brain contusion, heart rate, systolic blood pressure, age, Glasgow Coma Score, Injury Severity Score, and mode of transportation to the hospital. We are now using the results of this analysis to (1) derive a clinical decision support tool to identify patients likely to have a poor in-hospital outcome and (2) predict patient disposition at discharge. The regression model with beta coefficients calculated from the derivation data set has a receiver operating curve (ROC) with the area under the curve (AUC) of 0.93 and sensitivity of 95% with specificity of 72%. To simplify this model for clinical utility we removed four clinical parameters with the least impact on patient outcome. The ROC of the resulting model has an AUC of 0.90 and a specificity of 53% at a sensitivity of 95%. To test the validity of this model for predicting in-hospital mortality, we collected a validation data set of all eight clinical parameters from patients presenting with TBI to the same level 1 trauma center in 2017. In addition we evaluated the model's ability to predict patient disposition from the hospital using a five-point ordinal scale; 1 = Home, 2 = Rehabilitation facility, 3 = Nursing home, 4 = Hospice care, and 5 = Coroner. With this validation data set, the probability of mortality calculated with our model was higher for patients who died in the hospital. In addition, a more favorable patient disposition was associated with a lower calculated probability of in-hospital mortality ($r^2 = 0.457$, $p < 0.0005$). We conclude

that this model can be used as a clinical decision support tool to identify patients likely to progress to a poor in-hospital outcome and may be useful to predict patient disposition from the hospital. This will aid the allocation of hospital resources and alert physician to patients which may need early interventions.

Abstract: Traumatic brain injury (TBI) is often accompanied by hypoxia and inflammation of brain tissue. The cascade of harmful changes in neurons and glial cells followed by an excess concentration of glutamate in synaptic gap, glutamate receptors overstimulation, increased influx to neurons Ca^{2+} and Na^{+}, oxidative stress and the development of autoimmune response may be responsible for a second impact brain injury. The aim of this study was to evaluate the diagnostic and prognostic significance of different brain markers in blood of children with TBI within 24-48 hours after trauma. The severity of TBI was evaluated according to the Glasgow Coma Scale. Based on the clinical examination children following TBI were divided into 2 groups: (1) mild TBI (35 children with concussion; GCS=15); and (2) moderate and severe TBI (25 children; GCS=8-12). TBI markers such as S100b, autoantibodies (aAB) to NMDA and AMPA receptors (NMDARc and AMPARc), 3-nitrotyrosine were measured in blood serum; NMDARc and AMPARc peptides were measured in plasma using ELISA methods. The levels of $NO^{\cdot}$ metabolites were measured with assay kit from Calbiochem. Results: 1) Mild TBI was characterized by high heterogeneity of changes in S100b than might be due to trophic or

adaptation features of some elevation of S100b. The elevated levels of S100b in the first days after TBI in patients from second group were not strictly correlated with severity of TBI and fell to normal levels after 2-3 days; 2) The increased level of aAB to NMDARc observed on the 1st day after TBI in children with concussion. At the same time in patients from second group the level of aAB to NMDARc was decreased; 3) The normal level of NMDARc peptide was detected in all observed children; 4) The increased concentration of AMPARc peptide was revealed only in children with concussion. The level of this peptide in children from the 2nd group was the same as in healthy children. It should be noted that the level of antibodies to AMPARc in all examined children was in the range of normal values. The observed increase in the levels of AMPA peptide and autoantibodies to NMDA receptors in children with concussion should be considered in terms of the risk of future neurological complications. 5) The levels of NO˙ metabolites and 3-nitrotyrosine were significantly increased in all children with TBI especially in patients with severe TBI. Thus, our studies of chosen parameters allowed to form a panel of biomarkers for the diagnosis and prognosis of TBI in children. The revealed changes are also important for clarifying the mechanisms of brain damage in children with TBI. This work was supported with grant of Russian Scientific Found N 17-15-01487.

Title: Command following assessment and communication with vibro-tactile p300 and motor imagery brain-computer interface tools in complete locked-in and locked-in patients

Authors: *C. GUGER[1], R. SPATARO[2], B. ALLISON[1], A. HEILINGER[1], R. ORTNER[3], W. CHO[3], V. LABELLA[2]
[1]Guger Technologies OG, Graz, Austria; [2]Univ. of Palermo, Palermo, Italy; [3]g.tec medical engineering GmbH, Schiedlberg, Austria

Abstract: Many patients with locked-in syndrome (LIS) or complete locked-in syndrome (CLIS) also need brain-computer interface (BCI) platforms that do not rely on visual stimuli and are easy to use. We investigate command following and communication functions of mindBEAGLE with 9 LIS, 3 CLIS patients and three healthy controls. This tests were done with vibro-tactile stimulation with 2 or 3 stimulators (VT2 and VT3 mode) and with motor imagery (MI) paradigms. In VT2 the stimulators are fixed on the left and right wrist and the participant has the task to count the stimuli on the target hand in order to elicit a P300 response. In VT3 mode an additional stimulator is placed as a distractor on the shoulder and the participant is counting stimuli either on the right or left hand. In motor imagery mode the participant is instructed to imagine left or right hand movement. VT3 and MI also allow the participant to answer yes and no questions. Healthy controls achieved a mean assessment accuracy of 100% in VT2, 93% in VT3, and 73% in MI modes. They were able to communicate with VT3 (86.7%) and MI (83.3%) after 2 training runs. The patients achieved a mean accuracy of 76.6% in VT2, 63.1% in VT3, and 58.2% in MI modes after 1-2 training runs. 9 out of 12 LIS patients could communicate by using the vibro-tactile P300 paradigms (answered on average 8 out of 10 questions correctly) and 3 out of 12 could communicate with the motor imagery paradigm (answered correctly 4,7 out of 5 questions). 2 out of the 3 CLIS patients could use the system to communicate with VT3 (90 and 70% accuracy). The results show that paradigms based on non-visual evoked potentials and motor imagery can be effective for these users. It is also the first study that showed EEG-based BCI communication with CLIS patients and was able to bring 9 out of 12 patients to communicate with higher accuracies than reported before. More importantly this was achieved within less than 15-20 min.

Title: Clinical severity in the acute phase and brainstem volume reduction in the chronic phase in diffuse axonal injury

Authors: *G. FUJIMOTO[1], S. UBUKATA[2], N. OISHI[3], T. ASO[3], G. SUGIHARA[2], T. MURAI[2], K. UEDA[2]
[1]Psychiatry, Kyoto Univ. Grad. Sch. of Med., Kyoto-Shi, Japan; [2]Psychiatry, Kyoto Univ. Grad. Sch. of Med., Kyoto, Japan; [3]Human Brain Res. Center, Kyoto Univ., Kyoto, Japan

Abstract: Diffuse axonal injury (DAI), one of the major forms of traumatic brain injury, is characterized by diffuse white matter disruption caused by shearing forces on the brain. Loss of consciousness is present in the acute phase, and some behavioral disorders or psychiatric symptoms are often apparent in the chronic phase. One of the significant image findings in the chronic phase is atrophy of brainstem and cerebrum, which is thought to reflect acute severity, but there are few reports that focused on the correlation between chronic reduction in volume of brainstem or cerebrum and acute severity. The aim of this study is to investigate the normal volume of each brain part based on healthy subjects' data, and to assess the correlation between the estimated reduction in volume of each part and acute severity in DAI. Twenty patients with DAI and sixty age- and gender-matched healthy controls underwent T1-weighted three-dimensional magnetization-prepared rapid gradient-echo (3D-MPRAGE). 3D-MPRAGE data were processed by Freesurfer to determine individual volumes of interest. First, we performed group comparison, and identified the statistically significant difference in the volume of brainstem and cerebrum between healthy subjects and DAI patients. Second, we performed correlation analysis on healthy subjects' data between each individual's intracranial volume (ICV) and volume of cerebrum, midbrain, pons, and medulla. Every volume of these brain parts above was significantly correlated with ICV, but the more distal the brain part was, the smaller its coefficient of correlation value was. Third we calculated the estimated atrophy rate in each brain part in DAI individuals by comparing the measured values of volume with the estimated preinjury volume which we got based on multiple-regression analysis on healthy subjects' data. The estimated atrophy rate was significantly larger in brainstem than in cerebrum, and the atrophy rate of brainstem showed a significantly positive correlation to an acute severity, the duration of post-traumatic amnesia. These results suggest that chronic atrophy rate of brainstem can be a marker for estimating the acute severity, and that acute severity may be a marker for predicting chronic atrophy of brainstem.

Title: Alterations in perivascular Aquaporin-4 distribution in chronic traumatic encephalopathy

Authors: *B. R. HUBER[1], V. VENTRANO[2], B. KNAPP[2], J. D. CHERRY[3], V. ALVAREZ[1], T. STEIN[2], A. C. MCKEE[4]
[1]VA Boston Healthcare, Boston, MA; [2]Boston Univ. Med. Sch., Boston, MA; [3]Neurol., Boston Unviersity, Allston, MA; [4]Boston Univ., Boston, MA

Abstract: Chronic traumatic encephalopathy (CTE) is a neurodegenerative disease associated with repetitive exposure to traumatic brain injury (TBI). It is characterized by perivascular hyperphosphorylated tau (ptau) neurofibrillary tangles, and astrocytic ptau deposits at the sulcal depths. The glial lymphatic (glymphatic) system is a waste clearance system that facilitates perivascular fluid flux through aquaporin-4 (Aqp4) channels. Most normal vessels in the brain have perivascular astrocytes with processes that ensheathe vessels with astrocytic end-feet. Recent studies suggest that end-feet regulate fluid flow and are part of the glymphatic system. Animal models have demonstrated that aquaporin-4 redistributes from astrocyte end-feet to cell body after traumatic brain injury (TBI). The perivascular distribution of aggregated tau and involvement of astrocytes in CTE suggests that astrocytes in the glymphatic system may be altered in CTE. To address this hypothesis, we examined the distribution of glial fibrillary acidic protein (GFAP) and Aqp4 in individuals with CTE neuropathology. We found that Aqp4 positive astrocytes were depleted in the perivascular space. The remaining perivascular astrocytes expressed increased GFAP indicative of reactive astrocytosis. Moreover, Aqp4 positive end-feet were depleted around vessels with aggregated tau. These findings demonstrate alteration of the glymphatic system within CTE lesions. We also found an increase in activated perivascular microglia and reactive astrocytes in the perivascular space suggesting an ongoing inflammatory process. These findings demonstrate alterations of the glymphatic system within the perivascular tau lesions considered pathognomonic for CTE.

Title: Concussion and a single season of contact sport participation affect performance on a test of high memory interference

Authors: *M. D. MCCRADDEN[1], S. BECKER[2], P. I. ROSEBUSH[3], M. F. MAZUREK[4]
[1]Neurol., [2]Psychology Neurosci. and Behaviour, [3]Dept Psych & Behav Neuro, McMaster Univ., Hamilton, ON, Canada; [4]Dept Med. & Neurosci, McMaster Univ. Med. Ctr., Hamilton, ON, Canada

Abstract: Introduction:
Sport-related concussion is one of the most impactful injuries sustained by youth and varsity athletes. Recent attention has also been paid to the effects of contact sport participation in the absence of concussion, and the potential cognitive effects of repeated 'subconcussive' head injuries.
The hippocampus is known to be vulnerable to head injury. A test involving a high memory interference component, known as the mnemonic similarity test (MST), may be able to detect deficits of hippocampal neurogenesis. The goal of this project was to utilize the MST to investigate cognitive changes in: 1) concussed athletes and 2) contact athletes sustaining subconcussive impacts over a single rugby season.
Methods:
A total of N = 160 McMaster athletes participated between September 2014-January 2016. During the preseason, all individuals completed sport psychology questionnaires and a semi-structured psychiatric interview. We then administered the MST, which tests recognition of images that are new, old, or very similar previously presented images. Two subgroups were studied: 1) *Concussion*: 11 athletes in the original cohort supplemented by 6 others referred to our neurology clinic were matched using a 1:2 ratio with athlete controls and were tested while symptomatic (~2-4 weeks postinjury) and again upon recovery; 2) *Contact athletes*: in addition to the preseason assessment, 13 rugby players also completed midseason and postseason testing.
Results:
1) In the *concussion* subgroup, we found impaired identification of similar stimuli during the symptomatic phase, which had significantly improved upon full concussion recovery. The identification of old stimuli was also mildly impaired while symptomatic, and also improved. Using a regression model we
found that concussion was significantly predictive of the degree of impairment in the identification of similar stimuli.

2) In the *contact athlete* subgroup, we found a significant impairment of their ability to identify similar stimuli during the midseason, but in the postseason this resolved and surpassed preseason performance.
Significance: This study is the first to utilize the MST in concussion and contact sport samples. We found that the ability to discriminate between highly similar stimuli is impaired following concussion, and with contact sport participation - in both subgroups, test performance improved after a reprieve from sport participation. This study contributes to the growing body of evidence indicating subconcussive head impacts may affect cognition in the absence of an overt concussion. These results may reflect a head- injury-induced impairment of hippocampal neurogenesis.

Title: Predicting military-related mild traumatic brain injury disease - a multimodal neuroimaging study with machine learning

Authors: P.-H. YEH, C. G. KOAY, J. GRANER, *S. RAJAMONI NADAR, W. LIU, T. OAKES, G. RIEDY, G. BONAVIA, J. OLLINGER
Natl. Intrepid Ctr. of Excellence, Walter Reed Natl. Military Med. Ctr., Bethesda, MD

Abstract: Purpose:
Machine learning methods using neuroimaging data for the diagnosis of neurodegenerative and psychiatric disorders have been the subject of extensive research in recent years. The goal of this study is to demonstrate the feasibility of applying machine learning techniques that can be useful in diagnosing service members with mild traumatic brain injury (mTBI).
Materials and Methods:
Participants included 130 male active service members diagnosed with mTBI (age 34.7±7.8

years old) and 53 non-TBI male controls (age 31.9±8.3 years old) who underwent neuroimaging exams on a 3T MRI scanner. Several metrics derived from neuroimaging modalities, including diffusion tensor imaging (DTI), dynamic susceptibility contrast perfusion MRI and resting state fMRI, were used as predictors. After regressing out age effect, the accuracy of identifying mTBI patients using multimodal neuroimaging metrics was predicted using several machine learning techniques, including linear logistic regression, random forest, Gaussian Naïve Bayesian classifier, support vector machine (SVM) followed by feature transform and feature selection (k highest scoring features), and cross validation. Machine learning algorithms from Scikit-Learn package (http://scikit-learn.org) were used for post-processing classification.

Results:

The accuracy of identifying mTBI patients varied from 67% to 82% with relative consistency of accuracy of around 73% ± 4 % using the method of SVM followed by feature transform and feature selection, and cross validation; however, the accuracy of identifying mTBI using the metrics derived from a single neuroimaging modality varied among different modalities. The important features in identifying mTBI include clusters of DTI metrics and relative cerebral blood flow over the internal / external capsule, thalamus, corpus callosum, cerebral peduncles, cingulum bundle, corona radiata; and the clusters of functional networks, including the posterior / anterior default networks, bilateral frontoparietal networks, salience network, and the central executive network.

Discussion and conclusions:

These preliminary results suggest machine learning techniques might be useful in identifying mTBI with acceptable accuracy. Our results support disrupted neurocircuitry in mTBI, particularly involving the cortico-thalamo-striatal networks interconnecting frontal cortex, parietal cortex and thalamostriatal system. Future work, including adding additional neuroimaging metrics, neurobehavioral data, and using more advanced techniques such as deep learning techniques with a larger sample size for cross validation has been under way.

Title: Minocycline plus N-acetylcysteine targets synaptic plasticity and restores cognition when first dosed three days after closed head injury

Authors: *K. WHITNEY, E. NIKULINA, L. BUITRAGO-SOTO, P. J. BERGOLD
Dept. of Physiol. and Pharmacol., State Univ. of New York Downstate Med. Ctr., Brooklyn, NY

Abstract: Traumatic brain injury (TBI) produces long-lasting cognitive and behavioral deficits. Patients often wait days to seek treatment, only when their symptoms do not abate. Therefore, an effective drug to treat TBI must retain potency when dosed days after an injury. We tested the potency of minocycline (MINO) plus N-acetylcysteine (NAC) when first dosed 72 hours in the mouse closed head injury (CHI) model. CHI produces many of the same outcomes as TBI, including heterogeneous severity, cognitive and behavioral deficits, and gray and white matter damage both ipsilateral and contralateral to the impact site. The hippocampus is particularly susceptible to both TBI and CHI. CHI damages the ipsilateral and contralateral hippocampi. Both hippocampi display neuronal loss, decreased expression of synaptic markers, decreased dendritic density and altered spine morphology. Fourteen days after CHI, the contralateral hippocampus has decreased expression of neuronal marker NeuN, the pre-synaptic marker synaptophysin, and post-synaptic markers PKMζ and MAP2 in areas CA1 and CA3. Injured mice are impaired in acquisition of Barnes maze, a spatial memory task that requires one intact hippocampus. LTP is impaired in Schaffer collateral-CA1 synapses in slices isolated from both the ipsilateral and contralateral hippocampus. MINO plus NAC treatment beginning at 72 hours after CHI improved performance on Barnes maze and prevented neuronal loss in both hemispheres, suggesting the drugs are acting both at and distal to the impact site. Treatment maintained hippocampal dendritic structure, spine density and morphology, and preserved expression of pre- and post-synaptic markers. MINO plus NAC also restored Schaffer collateral LTP in the contralateral hippocampus. These data suggest that: (1) CHI induces gray matter injury leading to long-term changes to neuronal structure and synaptic connections; (2) these long-term changes result in impairments in synaptic plasticity and hippocampus-dependent behavior; and (3) MINO plus NAC first dosed 72 hours after injury limits these impairments. Our results identify dendritic morphology and synaptic plasticity as potential targets for drugs that can be dosed at clinically useful windows to improve functional outcome after CHI. Both MINO and NAC are FDA-approved drugs suggesting that this combination could be used to limit cognitive and behavioral deficits after clinical TBI.

Title: Therapeutic benefit of galantamine in hyperoxic brain injury in neonatal mice

Authors: *N. ZAGHLOUL[1,2], N. COHEN[2], K. AYYASOLA[2], V. PAVLOV[3], M. N. AHMED[2]
[1]Pediatrics, Cohen's Children Med. Ctr., Manhasset, NY; [2]Neonatal-Perinatal Med., [3]Ctr. for Biomed. Sci., Feinstein Inst. for Med. research, Manhasset, NY

Abstract: Background: Brain growth and development in premature infants is affected by hyperoxic environments. Hyperoxia leads to excess free radical production with subsequent inflammation, astrogliosis, microgliosis and apoptosis. Galantamine, an acetylcholinesterase inhibitor, has been studied previously for its role in reducing hypoxic brain injury through its anti-inflammatory effects. **Objective:** To explore the role of galantamine in reducing hyperoxic brain injury in neonatal mice. **Design/Methods:** Wild type mouse pups were placed in a hyperoxia chamber (FiO2 95%) for 7 days. Half the group was injected daily with intraperitoneal galantamine (5mg/kg/dose) and the other half was injected with normal saline. After exposure, mice were sacrificed and brain tissue was studied. To study cholinergic neurons and glia, we performed immunflorescent (IF) staining for choline acetyl transferase (ChAT), NeuN, Iba-1, CD68, CNPase and GFAP. Inflammatory markers; IL-1β, IL-6, TNF-α; were measured by Elisa and NF-κB activity (phosphorylated P65) was assessed by western blot. Acetylcholinesterase activity was assayed. Caspase 3 activity, a marker of apoptosis, and reactive oxygen species were assessed fluorometrically. All results were compared to control group housed in room air. **Results:** There was a statistically significant increase in ChAT (IF and WB) and a decrease in acetylcholinesterase activity in the hyperoxia groups treated with galantamine compared to those treated with saline ($P<0.05$). The preservation of ChAT neurons in the galantamine-treated hyperoxic group was associated with a significant decrease in microgliosis, astrogliosis and NF-kB activation. In the galantamine treated hyperoxia group, oligodendrocytes were preserved and therefore myelination. Both ROS and studied inflammatory cytokines; IL-1β, IL-6, and TNF-α; were statistically decreased in the galantamine treated hyperoxia group when compared to the saline treated hyperoxia group ($P<0.05$). **Conclusion(s):** Galantamine has potent anti-inflammatory and antioxidant short-term effects in hyperoxia-induced brain injured neonatal mice. Galantamine attenuates the inflammatory response by decreasing brain cytokine levels, microgliosis, NF-kB activation, and oxidative stress induced by hyperoxia. Galantamine decreases oligodendrocyte loss thus preserving myelination. This data suggests a potential role for galantamine in attenuating hyperoxia-induced brain injury.

Title: Altered cognition, anxiety, and neuroinflammation in mouse model of comorbid traumatic brain injury and post traumatic stress disorder

Authors: *K. ST. LAURENT-ARIOT[1], A. FESHARAKI[2], J. MIYAUCHI[3], S.-A. E. TSIRKA[4], P. J. BERGOLD[5]
[1]SUNY Downstate COM, Brooklyn, NY; [2]Yale Univ. Sch. of Med., New Haven, CT; [3]Dept. of Pharmacol., Stony Brook Univ., Stony Brook, NY; [4]Stony Brook Univ. Med. Ctr., Stony Brook, NY; [5]SUNY-Downstate Med. Cen., Brooklyn, NY

Abstract: Comorbid traumatic brain injury (TBI) and post-traumatic stress disorder (PTSD) have been understudied despite increasing evidence that it produces greater psychological and neurological deficits than TBI or PTSD alone. TBI or PTSD produce long-lasting neuroinflammation. A key question is: Does TBI, PTSD or co-morbid TBI and PTSD produce differing levels of neuroinflammation. C57Bl/6mice (28g) received either closed head injury (CHI), a model of TBI; chronic variable stress (CVS), a model of PTSD; CHI followed by CVS (CHI→CVS), or CVS followed by CHI (CVS→CHI), both models of co-morbid TBI/PTSD. CHI is produced by a single strike to the skull over the parietal lobe. CVS is four days of chronic variable stress consisting of cold-water swim, transient restraint, cage tilt, wet cage, and food deprivation. Barnes Maze and active place avoidance assayed cognition and memory. Elevated plus maze evaluated basal anxiety and acoustic startle response assayed fear-potentiated anxiety. Mice in the CHI, CVS, and CHI→CVS groups had similar acquisition of Barnes maze and active place avoidance as the sham-CHI and CVS groups, suggesting no deficits in cognition. However, CVS→CHI mice did not acquire active place avoidance suggesting a deficit in cognition. On elevated plus maze, the CVS group had significantly higher basal anxiety. All groups, except for CHI→CVS, did not differ in the frequency of freezing as intensity increased from 90dB to 105dB. Neuroinflammation was assessed in mice sacrificed 12 days after the onset of CHI or CVS. Expression of glial acidic fibrillary protein (GFAP) assayed astrocyte activation, Iba-1 assessed microglial activation, and the mitochondrial transporter TSPO assessed overall changes in inflammation. All experimental groups increased GFAP expression in the amygdala. In contrast, Iba-1 expression was only significantly higher in the dentate gyrus, CA3 and CA1 regions of the CVS→CHI group. The hippocampus of the CVS→CHI group had significantly higher expression of the M2 marker Arg-1^{hi} as well as increased TSPO expression. These data suggest an increased inflammatory response in the CVS→CHI group. The CVS→CHI group was treated with the TSPO agonist AC5216 to test for a potential anti-inflammatory or anxiolytic role of TSPO. Preliminary data suggests AC5216 lowered anxiety, but had no effect on cognition in the CVS→CHI group. Neuroinflammation is being assessed in the CVS→CHI AC5216-treated mice. Taken together, these data suggest that increased neuroinflammation in CVS→CHI mice underlie their impaired cognition and increased anxiety.

Title: Post-treatment with melatonin prevents cerebral myelin and memory deficits in male rats exposed to repeated hypoxia during the equivalent of extreme prematurity

Authors: *D. E. OORSCHOT, S. NARAYANAN, L. GODDARD
Anat., Univ. Otago Sch. Biomed Sci., Dunedin, New Zealand

Abstract: The birth of an extremely premature baby (≤28 weeks of gestation) is costly to health systems. Children born extremely prematurely can experience repeated hypoxic injury to the brain and can develop memory and myelin deficits. In a new Sprague-Dawley rat model of repeated hypoxic brain injury during the equivalent of extreme prematurity, decreased O4-positive pre-oligodendroglia, decreased cerebral myelin and memory deficits were observed (Oorschot et al., 2013, *Journal of Neuroscience* 33:11863-11877). Yet, treatment with melatonin, which is safe in clinical neonatology and a known antagonist of the proposed biological mechanisms that generate a lower number of O4-positive pre-oligodendroglia, has not been investigated in terms of rescuing cerebral myelin or preventing memory deficits. Hence, the aim of this study was to investigate whether treatment with melatonin rescues memory and cerebral myelin. Postnatal day (PN) 1-3 Sprague-Dawley male rats were exposed to repeated hypoxia and divided into treatment groups of repeated hypoxia diluent-treated and repeated hypoxia melatonin-treated. The treatment commenced after the second repeated hypoxic exposure. A first cohort of rats (n = 4 pairs) were perfuse-fixed at PN14/15, and the left cerebral hemisphere was serially sectioned and then immunohistochemically stained with an antibody to myelin basic protein. The absolute surface area of myelin was then measured using stereological methods. After treatment with melatonin, there was a significant increase in the absolute surface area of myelin in the anterior commissure and the subcortical white matter (paired two-tailed Student's *t*-test, $p = 0.044$ and $p = 0.039$, respectively). There was also an increase in the absolute surface area of myelin in the corpus callosum after treatment with melatonin, but this increase was not statistically significant (paired two-tailed Student's *t*-test, $p = 0.124$). A second cohort of rats were tested for memory on the radial maze from PN35-45 (n = 10 melatonin-treated, n = 9 diluent-treated, n = 3 uninjured controls). The percentage of rats per day that achieved 100% success over 11 days on the radial arm maze was significantly different between the three groups (one-way ANOVA, $p = 0.006$). Post-hoc comparisons revealed a significant increase in the repeated hypoxia melatonin-treated rats and the control uninjured rats compared to the repeated

hypoxia diluent-treated rats ($p < 0.01$ and $p < 0.05$, respectively, Tukey's test, corrected for multiple comparisons). Thus, post-treatment with melatonin prevents cerebral myelin and memory deficits in male rats exposed to repeated hypoxia during the equivalent of extreme prematurity.

Abstract: Traumatic Brain Injury (TBI) is a major cause of death and disability worldwide with 1.5 million people inflicted yearly. TBI is associated with severe post-TBI symptoms such as sensorymotor deficits. Several neurotherapeutic interventions have been proposed including drug administration as well as cellular therapy including neural stem cell (NSC)-based treatment. Among the proposed drugs utilized is docosahexaenoic acid (DHA), a poly-unsaturated fatty acid, exhibiting neuroprotective properties. In this study, we propose to combine an innovative intervention of neonatal NSCs transplantation in combination with DHA injections in order to ameliorate brain damage and promote functional recovery. Thus, NSCs derived from the subventricular zone of neonatal pups, cultured into neurospheres, were transplanted in an experimental controlled cortical impact mouse model of TBI. Effect of NSC transplantation was assessed alone and in combination with DHA administration. Motor deficits were evaluated using pole climbing and rotarod tests. Using immunohistochemistry, the effect of transplanted NSCs and DHA treatment was assessed by quantification of doublecortin (DCX), glial fibrillary acid protein (GFAP), ionized calcium binding adaptor molecule (IBA-1), and tyrosine hydroxylase (TH) markers. Combined NSC transplantation and DHA injections significantly attenuated TBI-induced motor function deficits (pole climbing tests), promoted neurogenesis coupled with an increase in glial reactivity at the cortical site of injury, and interestingly, with a marked increase in the number of dopaminergic neurons in the ventral tegmental area and the

substantia nigra. These data demonstrate that prior treatment with DHA may be a desirable strategy to improve therapeutic efficacy of NSC transplantation in TBI.

Title: Functional brain network reveals enhanced rehabilitative potential by combining pharmacology and exercise after traumatic brain injury

Authors: *G. KRISHNA[1], Z. YING[1], A. PAYDAR[2], N. G. HARRIS[2], F. GOMEZ-PINILLA[1,2]
[1]Dept. of Integrative Biol. & Physiology, UCLA, Los Angeles, CA; [2]Dept. of Neurosurg., UCLA Brain Injury Res. Ctr., Los Angeles, CA

Abstract: Traumatic brain injury (TBI) often progresses to persistent disability accompanied with cognitive and psychiatric pathology. Although exercise has a rehabilitative value, its action on brain functional connectivity (fc) is poorly understood, which might limit efficacy. Brain fc is crucial for processing of information but it is disrupted by TBI therefore reducing outcome. Therefore, here we investigate how the concurrent application of exercise and pharmacology provided by 7,8-dihydroxyflavone (7,8-DHF, a neurotrophin receptor agonist) can stimulate rehabilitative training efficacy provided by exercise. Here we describe how 7,8-DHF and exercise influence resting-state functional MRI (rsfMRI) after TBI to characterize functional network properties. Adult male Sprague-Dawley rats (n= 5-6/group) were subjected to moderate fluid percussion injury (FPI) and received treatment with 7,8-DHF (5 mg/kg, i.p.), and half of them had access to voluntary wheel running for 2 consecutive weeks. rsfMRI was performed using a 7Tesla MRI scanner using a single-shot, echo-planar, gradient-echo sequence to measure BOLD contrast at 2h following the final treatment. We show that 7,8-DHF and exercise improved spatial memory responses, and activated TrkB signalling and cell metabolism post-injury. Initial assessment of global fc revealed that TBI decreased inter-hemispheric fc among hippocampus, sensory (S1), motor (M1), cingulate (Cg) regions of the cortex and caudate putamen (CP). The altered fc among these regions likely lead to inefficient spatial memory functioning among FPI animals. 7,8-DHF treatment and exercise increased fc ($P < 0.05$, uncorrected) in some of the same regions that were functionally disconnected after FPI. These preliminary findings highlight the efficacy of interventions to promote reorganization of

functional pathways, particularly, in networks located in regions implicated in cognitive and sensorimotor processing. Enhancement in fc may be an important biomarker after to predict success of the rehabilitative potential of exercise and 7,8-DHF interventions, and this would ultimately have important clinical implications.

Title: Role of chloride homeostasis in post-traumatic depression

Authors: *E. GOUBERT[1,2], I. KHALILOV[1,2], M. ALTVATER[3], M. SCHAEFER[3], C. RIVERA[1,2,4], C. PELLEGRINO[1,2]

Abstract: Traumatic brain injury is one of leading cause of major depressive disorders, which represents a major public health concern. The identification of early neurological changes and whether they have later consequences on the depression onset represent critical issues. We have established and validate the controlled cortical impact rodent model of traumatic brain injury. Our current data suggest that there is early chloride homeostasis impairment leading to depressive-like behavior at later stages. Interestingly, an early treatment aiming at restoring chloride homeostasis during the first post-traumatic week significantly ameliorates the depression-like behavior at chronic stages. We will present result from experiments aiming to dissect out the mechanism of chloride homeostasis impairment and the settling up of depression. We highlight that post-traumatic dentate gyrus adult neurogenesis and GABAergic neurotransmission are key events in those processes. This will provide new insights on the early mechanisms underlying the onset of post-traumatic depressive disorders.

Title: IL-1RI blockade results in decreased cytokine expression and improved learning following TBI

Authors: ***B. TODD**, J. MAHONEY, P. FERGUSON, A. G. BASSUK, E. A. NEWELL
Univ. of Iowa, Iowa City, IA

Abstract: Neurologic injury from traumatic brain injury (TBI) is due to primary and secondary injury mechanisms. Neuroinflammation is one secondary injury mechanism felt to contribute to ongoing cell death following TBI. Interleukin-1 (IL-1) is a key regulator of neuroinflammation; IL-1α and IL-1β are the best-characterized cytokines of this family and signal through type I IL-1 receptor (IL-1RI). We aim to isolate the role of IL-1RI in TBI pathogenesis and evaluate the therapeutic potential of pharmacologic IL-1RI blockade using anakinra, recombinant IL-1RI antagonist. We use lateral fluid percussion injury model adapted to mice targeting moderate-severe TBI. C57BL/6J and global IL-1RI KO male mice (on C57BL/6J background) were used. In pharmacologic studies, systemic anakinra via IP injection was compared to saline control. Gene expression was evaluated by qPCR. Barnes maze testing was used to evaluate cognitive function 2 weeks post-FPI. Immunohistochemistry staining for IgG was used to evaluate blood brain barrier (BBB) breakdown. FPI resulted in a diffuse inflammatory cytokine response, with increased IL-1α, IL-1β, TNF and IL-6 expression in both focal (left parietal cortex, hippocampus) and remote regions (brainstem, cerebellum). IL-1RI ablation resulted in decreased IL-1β and IL-6 expression in remote regions (brainstem, cerebellum) 6 hours post injury, and decreased IL-1β and IL-6 expression in both focal (parietal cortex) and remote (brainstem) regions at 24 hours. Mice treated with anakinra, did not show altered inflammatory cytokine expression at 6 hours, but did show decreased IL-1β expression in the parietal cortex at 24 hours. Significant IgG immunoreactivity was present at 24hrs post-FPI and was maximal in peri-lesional cortex. Following FPI, anakinra treated mice showed improved learning in the Barnes maze compared to saline treated mice. Conclusions: FPI results in a diffuse inflammatory cytokine response, with increased expression of pro-inflammatory cytokines in focal and remote regions. Genetic IL-1RI ablation decreased the spread and hastened resolution of CNS inflammatory cytokine expression following FPI. Pharmacologic IL-1RI blockade did not

prevent the spread of inflammatory cytokine expression, but did hasten the resolution of IL-1β in the parietal cortex. This focal pharmacologic effect may be due to regional differences in CNS drug penetration as cytokine modulation mirrored area of maximal BBB breakdown. Pharmacologic IL-1RI blockade following TBI is a potential therapeutic strategy but dosing and delivery methods need to be optimized for maximal beneficial effect. Support: K12 HD27748-11

Title: Antibody fragment phage display as a biomarker discovery tool for traumatic brain injury

Authors: *B. I. MARTINEZ, G. MOUSA, S. STABENFELDT
Arizona State Univ., Tempe, AZ

Abstract: Introduction: Traumatic brain injury (TBI) affects 1.7 million people in the United States each year, costing billions of dollars in medical care expenses. The temporal nature of the secondary injury that progresses after the initial insult contributes to a complex pathology that confounds efforts to develop TBI diagnostic and therapeutic modalities. Therefore, it is critical to identify unique neural injury biomarkers at distinct injury phases to improve prognosis and intervention efforts. Here, we combined antibody fragment phage display with the potency of next generation sequencing (NGS) analysis as a biomarker discovery tool for TBI at the acute and subacute post-injury phases. We postulated that unique sets of antibody fragments that recognize neuropathology at each phase following injury would be uncovered. **Methods:** Animal studies were conducted in accordance to protocols approved by ASU IACUC. Adult C57Bl/6 mice were anesthetized and subjected to either unilateral controlled cortical impact (CCI) injury or a sham surgery (n=3 per group/timepoint). Animals were randomly assigned to either the acute (1 day) or subacute (7 days) post-injury/sham group and intravenously injected with 100 µL of human domain antibody (dAb) phage library at a concentration of 10^9-10^{12} phage. Bound phage were eluted from the brain and control tissue pools and quantified with titers. Phage eluted from injured ipsilateral brain tissue were amplified for the second biopanning round. Phage amplified from recovered tissues and control libraries were sequenced using Illumina's MiSeq

2x300 module. Analysis was completed using the FASTAptamer Toolkit package and Bioconductor for R. **Results:** NGS analysis revealed that each tissue and control library sample yielded 7000-12,000 antibody fragment sequences. Looking specifically at sequences from the injured ipsilateral brain tissue, there were 109 identical sequences in both the acute and subacute injured brain tissue. 64 of 109 sequences appeared more frequently in the subacute group than the acute group. A similar comparison between sham and injury groups of ipsilateral tissue yielded less than 90 shared sequences, the majority of which occurred with markedly decreased frequency within injury groups. **Discussion:** Our *in vivo* phage display biopanning process is sensitive to the robust temporal effects of neural injury, thus demonstrating its efficacy as a biomarker discovery tool for TBI. Further studies will isolate unique candidate biomarkers for each timepoint and further characterize their specificity to distinct phases of neural injury.

Title: Improving outcomes: An emerging role for zinc chelation and pH in traumatic brain injury

Authors: *Z. WANG[1], R. TIAN[2]
[1]Biomed. Sci., Ohio Univ. Dept. of Biomed. Sci., Athens, OH; [2]Neurosurg., Beijing Tiantan Hospital, Capital Med. University, Beijing Neurosurgical Inst., beijing, China

Abstract: Traumatic brain injury (TBI) occurs when an external mechanical force blows the brain, resulting in brain dysfunction. Mild traumatic brain injury may cause temporary dysfunction of brain cells. More serious traumatic brain injury can result in bruising, torn tissues, bleeding and other physical damage to the brain that can result in long-term complications or death. According to the data from CDC, the number of reported TBI cases is over 2 million in 2010 in the United States, which becomes a major cause of death and disability, especially in children and young adults. The major causes of TBI are falls, motor vehicle traffic injuries, and strikes. Numerous of previous works demonstrated that TBI-induced excessive zinc release from neurons, resulting in neuronal death and damage. This damage might be caused by the formation of zinc accumulation. Furthermore, some researchers indicate that following an acute brain injury, cerebral blood flow and cerebral metabolism of patients will be disturbed, resulting in brain pH decrease in the beginning, followed by latterly pH increasing. Decreased pH in the brain will lead to zinc release from loosely bound proteins, and later pH increase will promote the production of zinc precipitate. In the present study, we investigated the effect of zinc chelation on TBI-induced brain infraction and edema in a mice model. We proposed a strategy to

improve TBI outcomes through reducing the formation of zinc precipitate. Both acidic solution (pH~4) and zinc chelator, Ca-EDTA, was directly applied to the brain damage region. TTC staining was used to measure brain infarction and edema levels. Results showed that both acidic solution and zinc chelator showed a benefit effect on TBI outcomes. Both acidic condition and zinc chelation exhibited a neuroprotective effect on TBI-induced brain damage through reducing brain infarct volumes and edema areas. Zinc chelation and acidic solution showed a more neuroprotective effect on decreasing infarct volume than that of edema levels. Furthermore, the treatment with zinc chelator presented more powerful effect than that of the acidic solution on anti-infarct volume but anti-edema formation after TBI.

Title: NYX-2925 regulates tau dynamics in rat cortical tissues

Authors: *L. P. CACHEAUX[1], K. LEADERBRAND[1], M. SCHMIDT[1], E. COLECHIO[1], J. S. BURGDORF[1,2], R. A. KROES[1,2], J. R. MOSKAL[1,2]
[1]Aptinyx Inc., Evanston, IL; [2]Falk Ctr. for Mol. Therapeutics, McCormick Sch. of Engin., Northwestern Univ., Evanston, IL

Abstract: Aptinyx has developed a novel class of small molecule N-Methyl-D-Aspartate (NMDA) receptor modulators with broad applicability across neurologic and psychiatric disorders. It is a robust cognitive enhancer that binds with high affinity to all four NR2 subtypes and rapidly enhances synaptic plasticity processes associated with learning and memory. Oral administration of NYX-2925 (1 mg/kg, 1-24 hr post-injury) ameliorates learning deficits in a rat model of traumatic brain injury (TBI). In both humans and rodent models, TBI has been shown to result in both cognitive deficits and altered tau phosphorylation. Because NMDAR activation regulates phosphorylation of endogenous tau, the effects of NYX-2925 on tau expression and phosphorylation were investigated as a putative mechanism underlying its therapeutic efficacy in TBI. Naïve rats were treated with either vehicle (0.5% CMC in saline; 1 ml/kg, PO) or NYX-2925 (1 mg/kg, PO), and medial prefrontal cortex (mPFC) proteins were isolated at 15, 30, 60 min, and 24 hr post-dosing. Both total and phosphopeptides enriched by HILIC fractionation were analyzed using nano-LC MS/MS analysis. This unbiased proteomic approach identified significant time-dependent changes in total tau and tau phosphorylation at 16 sites, primarily serine and threonine residues. These changes were confirmed via Western blot analysis in rat primary cortical cultures treated with NYX-2925. This work provides evidence that targeting

NMDAR-associated modulation of tau phospho-dynamics is a promising therapeutic strategy for TBI.

Title: Modulation of single-neuron and network activity in motor cortex by clinically realistic transcranial direct current stimulation in non-human primates

Authors: *A. R. BOGAARD[1,2], H. M. BOYD[2], A. MORSE[2], S. ZANOS[3], E. E. FETZ[2]
[1]Med. Scientist Training Program, [2]Physiol. and Biophysics, Univ. of Washington, Seattle, WA; [3]Feinstein Inst. for Med. Res., Manhasset, NY

Abstract: Transcranial direct current stimulation (tDCS) is a popular brain stimulation technique used in human trials because it is noninvasive and simple to implement. Despite its popularity, tDCS is controversial because results are variable and the mechanism of action is not well understood. The reason for this is twofold: animal models of tDCS do not resemble that used with patients, and studies with humans generally use secondary outcomes to infer physiological effects. In the present study, we set out to test the prevailing theories underlying tDCS by directly measuring effects on brain activity in a non-human primate model of tDCS which closely matches that used in humans. Recordings of single unit activity (SUA) and local field potentials (LFP) were obtained from two macaca nemestrina monkeys by 96 channel microelectrode arrays implanted over the forelimb area of left motor cortex (MC). tDCS was delivered to the scalp by saline soaked sponge electrodes in a unilateral montage to target anodal or cathodal polarization to the area of MC being recorded, and intensity ranged from low in human studies (0.027 mA/cm^2), to higher than that used in humans (0.5 mA/cm^2). Each monkey was trained in a visuomotor target tracking task in which the position of a cursor was controlled by a 2-axis manipulandum that registered isometric wrist torques. During each trial, the monkey was cued to move the cursor to one of eight targets by contracting his forearm muscles. Each trial was followed by a period of quiet sitting (0.5-2 sec) to compare effects of tDCS on active and resting cortex. First, we looked for evidence that anodal and cathodal tDCS have opposite modulatory effects on SUA. We recorded over 3000 neurons from 90 experiments (29 anodal, 28 cathodal and 33 control), and found a modest but significant increase in median firing rate during anodal tDCS. This increase in firing was positively correlated with current intensity and was significant only for currents over 0.13 mA/cm^2, and persisted after tDCS was turned off. Interestingly, cathodal tDCS produced no significant change in firing at any current intensity. Second, we looked for changes in the baseline LFP beta power during quiet sitting. We observed a significant increase in beta power during cathodal tDCS, and a smaller, but significant, decrease in beta power during anodal tDCS. Lastly, we found no evidence that tDCS affected the shape of motor directional tuning or spike-field coherence. As far as we know, this is the first direct demonstration of how clinical-type tDCS modulates neuron firing and network activity.

Title: Pre-treatment with the macrolide antibiotic azithromycin increases tissue sparing after cortical contusion brain injury in rats

Authors: *K. B. HUBER, D. HOPKINS, J. R. PAULY
Pharmaceut. Sci. PhD program, Univ. of Kentucky, Lexington, KY

Abstract: Traumatic brain injury involves a mechanical injury followed by secondary biochemical cascades that propagate further damage including production of reactive oxygen species, and release of pro-inflammatory factors from resident innate immune cells. No pharmacological therapeutics have translated from preclinical models to clinical trials, highlighting the need for further research. Neuroinflammation has gained prominence as an important mediator of secondary damage after injury. Azithromycin (AZM) treatment has been shown to increase M2 polarization and decrease lesion volumes/motor deficits in models of spinal cord injury and stroke (Zhang et al., 2015; Amantea et al., 2016). The purpose of this study was to determine if AZM pretreatment would promote neuroprotection and enhance behavioral recovery following experimental cortical contusion brain injury. Adult male Sprague-Dawley rats were administered 160mg/kg of AZM daily, via oral gavage, for once daily three days prior to cortical contusion injury (2.0mm depth, 3.5m/s, 2.5mm tip diameter, 500ms dwell time) and once 15 minutes post-injury. Morris Water Maze (MWM) testing was conducted for 4 days (4 trials per day) starting on day 4 post-injury to assess spatial memory. There was no significant difference in performance between AZM and vehicle treated animals in the MWM. Following behavioral testing, animals were euthanized and the brains were prepared for a cortical tissue sparing analysis, and assessment of neuroinflammation using [^{3}H]-PK-11195, which binds to the translocator protein 18kDa (TSPO). In spite of the lack of effects on cognitive behavior, AZM treatment was associated with significant cortical tissue sparing (89.0 ± 4.8 percent spared) compared to vehicle treated animals (78.4 ± 4.8 percent spared; $p<0.0001$). Neuroinflammation, as assessed by PK-11195 binding, was significantly increased in all animals with head injuries, but there were no robust differences between animals treated with vehicle and AZM. We conclude that AZM exhibited significant neuroprotection against overt tissue loss, but more studies will need to be conducted to elucidate the nature of its effect on cognitive deficits and inflammatory signaling post-injury.

Title: L-DOPA induces reversibility of dopamine presynaptic deficit in minimally conscious state patients following traumatic brain injury

Authors: *E. A. FRIDMAN[1], J. R. OSBORNE[2], N. D. SCHIFF[1]
[1]Weill Cornell Med., New York, NY; [2]Mem. Sloan Kettering Cancer Ctr., New York, NY

Abstract: Minimally conscious states (MCS) following severe TBI express evidence of conscious awareness or goal-directed behaviors. Pharmacological stimulation can markedly improve some MCS patients. We previously demonstrated the use of [^{11}C]raclopride-PET a novel biomarker to identify a presynaptic dopamine deficit affecting the mesolimbic and mesothalamic pathways in MCS (Fridman et al. SfN 2015). However, no studies have provided direct measurements to test the reversibility of a presynaptic dopaminergic deficit in MCS. Here, we compared the availability of dopamine D2-like receptors in five MCS patients at a baseline, induced after prior dopamine reuptake blockade with dextroamphetamine (AMPH), and after a single dose of 375mg of $_{L}$-DOPA. We manually defined in high-resolution MRI the following structures: the ventral striatum (VST), associative striatum (AST) and sensorimotor striatum (SMST); and, the central thalamus (c-TH). We analyzed the signal using the kinetic SRTM2 with cerebellum as reference tissue to extract binding potential nondisplaceable (BP_{nd}) from ROIs. The mean delta % change (Δ BP_{nd}) between pre- and post-AMPH and between pre- and post-$_{L}$-DOPA were calculated and analyzed using ANOVA (Δ BP_{nd} as dependent variables and condition as independent variable in each ROI). Results showed that despite persistent deficit in the presynaptic dopaminergic neurons after administration of AMPH, 4 out of 5 MCS patients could increase dopamine release and reverse the deficit after a single dose of $_{L}$-DOPA. Specifically, when comparing the mean Δ BP_{nd} in MCS post-AMPH to those obtained post-$_{L}$-DOPA we identified a significant reduction in AST, SMST and c-TH [AST: AMPH =-9.9 ± 2.9, $_{L}$-DOPA =-23.0 ± 3.7; F= 7.9, p =0.01; SMST: AMPH =-7.0 ± 3.5, $_{L}$-DOPA =-20.9 ± 3.9; F= 6.4, p= 0.02; c-TH: AMPH =-0.1 ± 6.1, $_{L}$-DOPA =-23.7 ± 7.6; F= 6.1, p= 0.03]. We interpret findings as demonstrating that administration of exogenous $_{L}$-DOPA restores dopamine biosynthesis via bypassing the first step of the process; thus, our observations suggest that a deficiency of the enzyme tyrosine hydroxylase is present in post-TBI MCS, accounting for the inability of blocking the dopamine transporter reuptake alone to increase dopamine availability.

Title: The enhancement of neuroscience educational tools for subjects with traumatic brain injury

Authors: J. ORTIZ[1], F. BERLIN[1], *G. LEWIS[2]
[2]Col. of Sci., [1]George Mason Univ., Fairfax, VA

Abstract: The knowledge divide that separates non-scientists, health-care professionals, and research investigators has led to inadequate patient education within the medical field. Often, the only materials patients receive are relatively complex medical packets that are difficult for non-medical professionals to understand. This problem is made worse for patients who suffer Traumatic Brain Injuries (TBIs). These patients often suffer cognitive deficits and have difficulties with reading comprehension. Here we investigate the efficacy of a novel program for patient education in TBI subjects. In this study, TBI patients participated in a series of 3 engaging lesson plans that were delivered in a one-on-one format. Lesson plans topics focused on 1) the central and peripheral nervous system, 2) the regenerative properties of the nervous system, and 3) the biological properties of Traumatic Brain Injury. Lesson plans were delivered by a personal tutor in a one-on-one setting, where patients had the opportunity to ask questions and were free to interact with the tutor. Visual aids were provided in the form of white-board drawings and a 1-page learning map, which clearly summarized the important concepts of each lesson on a single page. Pre and post lesson quizzes and surveys were conducted to assess learning and confidence. Pre and post study interviews were conducted to determine the perceived value of the lessons to participants and to collect qualitative data about participant's injuries and experiences. Our data suggests this educational program improved patient's knowledge and confidence in understanding basic neuroscience and TBI concepts. Improvements in patient knowledge and confidence could increase the quality of communication between patients, doctors and caregivers. This may ultimately aid in decisions regarding the care, treatment, and life-management of individuals who have suffered TBI.

Title: Evidence of mitochondrial energy dysfunction following penetrating ballistic-like brain injury

Authors: *J. D. PANDYA, Y. DENG-BRYANT, X. YANG, L. Y. LEUNG, D. A. SHEAR
Brain Trauma Neuroprotection and Neurorestoration (BTNN), Walter Reed Army Inst. of Res. (WRAIR), Silver Spring, MD

Abstract: Mitochondria play a pivotal role in the development of secondary pathophysiology and subsequent neuronal cell death following traumatic brain injury (TBI). Under normal circumstances, brain consumes glucose as the preferred energy source for adenosine triphosphate (ATP) production over ketones. However, the bioenergetics profile of glucose intermediate metabolites and ketones have not been individually compared following TBI. We evaluated the injury-induced alterations in brain mitochondrial bioenergetics, enzyme activities and coenzyme contents in the penetrating ballistic-like brain injury (PBBI) model of TBI. Adult male rats were subjected to either 10% unilateral PBBI or Sham craniotomy (n=5 per group). At 24 hours post-injury, mitochondria were isolated from pooled brain regions (i.e. frontal cortex and striatum) of the ipsilateral hemisphere. Mitochondrial bioenergetics parameters were measured in the presence of metabolic substrates pyruvate+malate (PM), glutamate+malate (GM), succinate (Succ) and β-hydroxybutyrate+malate (BHBM). Mitochondrial electron transport chain (ETC) complex enzyme activity i.e. NADH dehydrogenase (Complex I), succinate dehydrogenase (Complex II) and cytochrome c oxidase (Complex IV) were evaluated in isolated mitochondria of the Sham and PBBI groups. Additionally, the tricarboxylic acid (TCA) cycle dehydrogenases enzyme activity i.e. pyruvate dehydrogenase complex (PDHC), alpha-ketoglutarate dehydrogenase complex (α-KGDHC), glutamate dehydrogenase (GDH); and mitochondrial coenzyme contents were quantitated. Significant reductions in ATP synthesis were detected in PBBI group with PM (-43%), Succ (-50%) and BHBM (-44%) as respiratory substrates Vs Sham. When compared ATP synthesis rates of four substrates within Sham or PBBI group; the PBBI group had a distinct substrate utilization pattern for ATP synthesis. In the PBBI group, mitochondrial Complex I (-50%) and Complex IV (-80%) enzyme activity were significantly reduced; whereas Complex II activity was comparable to Sham. The PDHC (-45%) and GDH (-50%) activity were significantly reduced in the PBBI group as compared to Sham; whereas no significant differences were noted in α-KGDHC activity between two groups. Additionally, mitochondrial coenzyme contents (i.e. FAD and NAD) were significantly decreased (-25% to -35%) in PBBI Vs Sham group. Collectively, PBBI leads to an overall reduction and shift in the metabolic activity that may be caused by significant reductions in brain mitochondrial ETC and TCA cycle enzyme activities. These results provide a strong basis for the use of “alternative biofuels” following brain trauma.

Title: Magnetic resonance spectroscopy detects early, regional glutathione decrease and restoration by N-acetylcysteine following traumatic brain injury in rats

Authors: *R. M. GUERRIERO[1,2], M. HAMEED[2], N. W. HODGSON[2], B. ROWLAND[3], P. L. PEARL[2], B. E. KOSOFSKY[4], T. K. HENSCH[5], A. LIN[3], A. ROTENBERG[2]
[1]Neurol., Washington Univ. Sch. of Med., Saint Louis, MO; [2]Boston Children's Hosp., Boston, MA; [3]Brigham And Women's Hosp., Boston, MA; [4]Ped Neurol. Div., Weill Cornell Med. Col., New York, NY; [5]Boston Children's Hosp. & Harvard Univ., Boston, MA

Abstract: Objective: To evaluate magnetic resonance spectroscopy (MRS) as an *in vivo* tool to detect early biomarkers of injury in a rat traumatic brain injury (TBI) model. **Background**: TBI leads to glutamate excitotoxicity and oxidative stress, which lead to neuronal injury and death. Rising extracellular glutamate levels inhibit the transport of cystine into astrocytes via the glutamate/cystine antitransporter. This inhibition decreases the amount of cystine available for conversion to cysteine, the rate-limiting precursor for glutathione (GSH) synthesis. A high reduced:oxidized GSH ratio is essential for maintaining the neuronal redox state and mitigating oxidative stress after TBI. In the days after injury, parvalbumin-positive inhibitory interneurons are injured preferentially in the post-traumatic cortex, as they are highly metabolically active and particularly sensitive to oxidative stress. An *in vivo* tool to serially measure regional GSH remains an unmet need. **Methods:** Adult male rats underwent a rapid fluid percussion injury. One group of rats was treated with N-acetylcystine (NAC) for the first week post-injury. The three groups were: sham, TBI/NAC (T/N), and TBI/vehicle (T/V). Animals were studied by MRS on a 7T Bruker rodent MRI 7 days after injury with 2 x 2 x 2 mm voxels using PointRESolved Spectroscopy (PRESS) localization, water suppression, Fast Automatic Shimming Technique by Mapping Along Projections (FASTMAP) with 256 repetitions and regions of interest over lesional and contralesional cortex. MRS data was analyzed using linear combinations model (LCmodel, Provencher). Metabolite measures with Cramer-Rao lower bound of less than 20% standard deviation were analyzed. Rats were sacrificed 7 days after TBI for tissue processing for high performance liquid chromatography (HPLC) to measure GSH and its metabolites. **Results**: MRS on day 7 following injury showed that both N-Acetylaspartic acid (NAA), a marker of neuronal health and GSH levels were significantly ($p < 0.05$) decreased in T/V animals (N=8) compared to sham (N=4). Both NAA and GSH levels were restored to

normal levels following NAC treatment (N = 13) compared to the T/V group ($p< 0.01$) and were not different from the sham group. These data corresponded to a decrease in the ratio of reduced GSH to its oxidized form in lesional cortex at Day 7 ($p < 0.01$) and restored GSH levels in T/N treated animals ($p < 0.05$) as measured by HPLC. **Conclusion**: Serial MRS measures detect pathologic alterations in GSH homeostasis from time of TBI through the first week following injury, which corresponds to neuronal loss. NAC treatment restores GSH levels as measured by MRS and HPLC and appears to be neuroprotective.

Title: Small molecule inhibition of p38α-mediated neuroinflammatory response to traumatic brain injury

Authors: *J. M. MORGANTI[1], D. M. WATTERSON[2], L. J. VAN ELDIK[1]
[1]Univ. of Kentucky, Lexington, KY; [2]Northwestern Univ., Chicago, IL

Abstract: Traumatic brain injury (TBI) initiates a multitude of cellular responses in the brain following the primary injury. Aberrant neuroinflammatory signaling cascades are one of these hallmark responses. Consistently, dysregulation of neuroinflammation has been linked with propagating neurodegenerative sequelae following TBI. Of principal interest is the role of p38α mitogen activated protein kinase (MAPK) in regulating inflammatory-linked responses to TBI. In the current study, we examined the brain's acute and subacute inflammatory response to TBI after treatment of mice with a novel, brain-penetrant, small molecule p38α inhibitor, MW150. Focal TBI was reproduced using the controlled cortical impact method. Three post-injury time points were examined; 1 day, 3 day, and 7 day. For each time point, three groups were examined; sham-vehicle (saline), TBI-vehicle, and TBI-MW150 (5mg/kg). Saline or MW150 was administered at 3 and 6 hours after injury and daily (3 and 7 day groups only) thereafter. At the prescribed interval, animals were euthanized for tissue collection to examine gene expression via NanoString. Current results suggest that the post-injury timing of p38α inhibition is critical for remediating injury-induced inflammatory sequelae.

Title: Neuroprotective strategies following severe controlled cortical impact traumatic brain injury: Lipid peroxidation-derived neurotoxic aldehyde scavenging and inhibition of mitochondrial permeability transition

Authors: *J. R. KULBE, ***J. R. KULBE**, I. N. SINGH, J. A. WANG, E. D. HALL
Spinal Cord and Brain Injury Res. Ctr., Univ. of Kentucky, Lexington, KY

Abstract: There are currently no FDA-approved pharmacotherapies able to prevent the devastating neurological deficits caused by traumatic brain injury (TBI). Following injury mitochondria buffer increases in intracellular Ca^{++}. However, an increase in intra-mitochondrial Ca^{++} leads to mitochondrial generation of reactive oxygen and nitrogen species (ROS/RNS), which initiate lipid peroxidation (LP) of cellular and organelle membranes, particularly mitochondrial membranes. LP is terminated upon formation of LP-derived neurotoxic aldehydes, which covalently bind cellular and mitochondrial proteins, exacerbating mitochondrial dysfunction and enhancing Ca^{++} induced opening of the mitochondrial permeability pore (mPTP), resulting in loss of ATP production and extrusion of Ca^{++} back into the cytosol where it can initiate a downstream cascade of calpain activation, cytoskeletal spectrin degradation, neurodegeneration and neurologic impairment. Therefore, mitochondria are promising therapeutic targets following TBI. Promising strategies of mitochondrial protection include scavenging of LP-derived neurotoxic aldehydes and inhibition of mPTP. Therefore, combining aldehyde scavenging with mPTP inhibition may enhance neuroprotection. Phenelzine (PZ), an FDA-approved monoamine oxidase (MAO) inhibitor used clinically as an anti-depressant, is capable of scavenging neurotoxic aldehydes. Cyclosporine A (CsA), an FDA-approved immunosuppressant, is capable of inhibiting mPTP. This is the first study to evaluate the neuroprotective effects of a continuous 72h subcutaneous infusion, representative of peak LP and mitochondrial dysfunction, of PZ, CsA, or PZ+CSA following a severe controlled cortical impact injury in rats. Results for the first dosing paradigm evaluated (PZ: 10mg/kg s.c. 15min

post-injury + 10mg/kg/day/72h; CsA: 20mg/kg i.p. 15min post-injury + 10mg/kg/day/72h) indicate that while PZ is able to maintain respiratory control ratio, a general measure of mitochondrial health, compared to sham, neither CsA nor PZ+CsA is able to improve mitochondrial respiratory function. However, PZ and CsA, but not the combination PZ+CSA, were able to attenuate modification of mitochondrial proteins by LP-derived neurotoxic aldehydes. However, it is premature to abandon the combination of aldehyde scavenging and inhibition of mPTP for neuroprotection following TBI. Therefore, additional outcome measures, including spectrin degradation and attenuation of cellular oxidative damage will be evaluated. Furthermore, the effects of MAO inhibition on mitochondrial function following TBI will need to be assessed.

Title: Therapeutic hypothermia promotes cerebral blood flow recovery and brain homeostasis after resuscitation from cardiac arrest in a rat model

Authors: *Q. WANG, P. MIAO, H. MODI, S. GARIKAPATI, R. KOEHLER, N. THAKOR
Johns Hopkins Univ., Baltimore, MD

Abstract: ***Aim***: Laboratory and clinical studies has demonstrated that therapeutic hypothermia (TH), when applied as soon as possible after resuscitation from cardiac arrest (CA), results in better neurological outcome. This study aimed to test hypothesis that TH would promote cortical cerebral blood flow (CBF) restoration and maintenance after return of spontaneous circulation (ROSC) from CA.
Methods: Twelve Wistar rats resuscitated from 7 minutes of asphyxial CA were randomized into two groups: hypothermia group (7H, n=6), treated with mild TH (33~34°C) immediately after ROSC; and normothermia group (7N, n=6, 37.0±0.5°C). We recorded multiple parameters including mean arterial pressure, CBF via laser speckle contrast imager and neural activities via electroencephalogram (EEG). The neurological outcomes were evaluated using Information quantity (IQ) entropy of EEG and neurological deficit scale (NDS).
Results: TH promoted consistently stable CBF near baseline in 7H group compared to that of the 7N group (the average CBF during first 30-minute post ROSC of two groups was 7H vs 7N as 91.4% ± 0.45 % vs 76.7% ± 0.6 %, $p<0.01$). Rats in the 7H group showed significantly better IQ

scores by 10 minutes after ROSC and better NDS scores at 4 and 24 hours (55.0 ± 1.83 in 7H vs 49.3 ± 1.9 in 7N at 4h, $p<0.05$; 70.0 ± 2.62 in 7H vs 60.0 ± 2.65 in 7N at 24h, $p<0.05$; best score=80).
Conclusion: TH facilitates restoration of CBF back to baseline levels after asphyxial CA and is associated with the restoration of brain electrical activity and improved outcome.

Title: Peripheral neurotrophic factor signaling with chronic mild traumatic brain injury

Authors: *M. W. MCNERNEY, V. DARCY, L.-L. WU, D. WALTZMAN, G. SWAMINATH, M. YUTSIS, O. HARRIS, J. ASHFORD, J. YESAVAGE, A. SALEHI, M. ADAMSON
VA, Palo Alto, CA

Abstract: An estimated 15.2% to 22.8% of returning service members suffer from mild traumatic brain injury (mTBI), with many experiencing chronic post-concussive symptoms. Common symptoms include memory problems or cognitive impairments, fatigue, headache, and loss of emotional regulation. Immediately following injury, there is a release of numerous neurotransmitters and signaling factors that may also play an important role in chronic mTBI etiology. Brain-derived neurotrophic factor (BDNF) is one of these molecules, and is thought to be involved in neuronal recovery and regrowth following injury. However, research on its role in chronic mTBI is limited. Here, we measured plasma BDNF levels in 47 Veterans (mean age 44.5 years, SD = 13.03) with and without a history of mTBI. We found that even years following injury, there is a significant positive correlation between injury severity and circulating BDNF levels. Neither BDNF levels nor injury severity were related to overall hippocampal volume, but there was a relationship with the BDNF precursor, proBDNF, and the val66met single nucleotide polymorphism. Mechanisms for this increase in BDNF in terms of injury severity and recovery and genotype will be discussed.

Title: Patient-derived glioblastoma cells are susceptible to intratumoral modulation therapy both in 2D and neurosphere culture

Authors: *A. DEWEYERT[1], A. DI SEBASTIANO[1], H. XU[2], C. DE OLIVEIRA[1], E. WONG[3], S. SCHMID[1], M. HEBB[2,1]
[1]Anat. and Cell Biol., [2]Clin. Neurosci., [3]Med. Biophysics, Univ. of Western Ontario, London, ON, Canada

Abstract: Introduction: Glioblastoma (GBM) is the most common and aggressive primary brain tumor in adults. Advances in electrotherapy offer new promise for GBM but the potential of this putative treatment modality has not yet been realized. Our group has been pioneering an innovative strategy called Intratumoral Modulation Therapy (IMT) which delivers pulsed electric current or fields directly into GBM tissues. IMT produces caspase-dependent apoptosis of GBM cells without significant impact on post-mitotic neurons. The goal of this work was to characterize the anti-tumor impact of a spectrum of IMT parameters and to define the resultant IMT treatment fields using in vitro and in vivo GBM models. **Materials and Methods:** Patient-derived and immortalized GBM cells were treated with IMT using an established in vitro model (Xu et al 2016). We have also established a syngeneic rodent GBM model for in vivo evaluation of IMT. Waveform generators were used to deliver sinusoidal or square waves pulses with varying frequency (100 Hz- 200 kHz) and amplitudes (4-10 V) directly to GBM cells or tumors. Pilot studies with various cancer cell lines known to cause brain metastases were also screened for susceptibility to IMT. Cell viability was assessed with activated caspase-3 labeling, 3-(4,5-

dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide (MTT) viability assay and flow cytometry with Annexin V and propidium iodide detection. Image-based computer modeling was performed using COMSOL software to predict field strength and dimensions, and to reconstruct IMT treatment fields using various electrode configurations and stimulation parameters. **Results:** The MTT assay revealed a significant loss of metabolic viability in patient derived and rat GBM cells, as well as other cancer cell lines treated with various electrical permutations of IMT compared to the respective sham conditions *in vitro*. Activated caspase-3 was elevated and consistent with flow cytometry that demonstrated increased expression of apoptotic markers in treated GBM cells. To date *in vitro* measurements within our IMT model have corroborated early mathematical predictions of field intensity and dimensions generated by COMSOL. These in vitro methods have been translated successfully to the GBM animal model. **Discussion and Conclusions:** This data supports further studies to reveal the potential of IMT as a putative new treatment strategy for GBM and possibly other forms of brain tumors. Advances in field prediction mapping and optimization of IMT hardware and stimulation parameters are needed.

Title: Long-term viability of optogenetically transfected neurons and implantable electrodes in the motor cortex of mice

Authors: *C. GORINI[1], B. KOO[1], C. ALTIMUS[1], E. F. CIVILLICO[2]
[1]Food and Drug Administration/CDRH/OSEL/DBP, Silver Spring, MD; [2]OD/OSC, NIH, Rockville, MD

Abstract: Optogenetics has become a critical part of the neural circuit research toolbox; however, its utility for chronic studies, which is directly related to its therapeutic promise, has yet to be proven. Few studies have utilized optogenetics for chronic applications, and there is a paucity of knowledge regarding the stability of opsin expression or the neuronal network response to repeated stimulation over time. In order to contribute to the understanding of the long-term viability of optogenetic gene therapy in combination with implanted intracortical

devices, we performed bilateral injections of an adeno-associated virus (AAV5:hSyn:ChR2:EYFP) to transfect the excitatory opsin, channelrhodopsin-2(ChR2), into the mouse motor cortex. We then unilaterally implanted a 16 channel shank recording optrode (A16-177-OCM16, NeuroNexus) into one of the previously injected cortical hemispheres of each mouse. Following recovery from surgery, spontaneous cortical activity was recorded in freely moving mice. During weekly recording sessions, the cortex was illuminated with pulsed 473nm laser light (Laserglow Technologies) for 10ms, 20ms, 50ms, and 100ms, at 1Hz to excite ChR2+ motor neurons. Responses to light pulses were quantified to determine changes in neuron spike amplitude or firing frequency over time. After collection of data for 8-12 months, animals were sacrificed and tissue analyzed for changes in microglia response, neuroinflammation, and morphology. Viral injection sites with and without devices were compared to examine the interaction between the viral transfection and the foreign body response to the implant. Preliminary results do not indicate any significant changes in morphology or immune response when compared to the contralateral, unactivated hemisphere. In ongoing analysis, we are characterizing the dynamics of the cortical response to this multimodal intervention. **Disclaimer**: The mention of commercial products, their sources, or their use in connection with material reported herein is not to be construed as either an actual or implied endorsement of such products by the Department of Health and Human Services.

Title: Safety of intrathecally administered baclofen in rats

Authors: *T. TAKENAMI[1], Y. NARA[2], R. ISONAKA[3], K. SUGIMURA[2], Y. SUZUKI[2], H. OKAMOTO[2]
[1]Kitasato Univ., Sagamihara, Japan; [3]Dept. of PhysiologyDepartment of Physiol., [2]Kitasato Univ. Sch. of Med., Sagamihara, Japan

Abstract: Background: Intrathecal infusion of baclofen (ITB) therapy for spasticity was approved application of insuarance in Japan at 2006. Recently, ITB is reported to be analgesic effect for chronic pain [1], central pain [2], or CRPS [3] regardless of spasticity. However, there is only little information on baclofen-related neurotoxicity. Therefore, we examined intrathecal baclofen neurotoxicity by histological and neurofunctional analyses. Methods: Thirty-three rats were each randomly injected intrathecally with 0.12μl/g body weight of either of 400 (400B), 800 (800B), 2000 (2000B), 3000 (3000B), 4000 (4000B), or 8000 (8000B) μg/ml of baclofen dissolved in

saline. Control rats received saline alone. Seven days after the injection, the L2 spinal cord with the anterior and posterior roots, dorsal ganglion, and cauda equina were extracted for microscopy. The hind limbs were evaluated neurologically by walking behavior. Results: Neurohistopathological examination showed no evidence of neurotoxic damage in all groups. Immediately after intrathecal baclofen injection, all rats displayed lower limbs weakness, and couldn't keep normal posture. However, all rats of each group could walk normally within 0.25, 0.25, 1, 1, 4, and 4h after injection in 400B, 800B, 2000B, 3000B, 4000B, and 8000B groups, respectively. None of the rats showed irreversible palsy or required tracheal intubation, even at 8000B. The sensory threshold was no significant difference among the baclofen and control groups at 7 days post-injection. Discussion and Conclusion: Intrathecal baclofen produced no histological or neurofunctional neurotoxicity even at 8000B. Our previous studies on 4% bupivacaine neurotoxicity using the same experimental protocol showed nerve damage in rats, and posterior nerve lesions at concentrations approximately 8 times higher than the clinically-used concentration [4], while 8000B is approximately 50 times higher concentration than clinical concentration. These results indicate that intrathecal baclofen is a safe treatment option for chronic intractable pain. However, further investigation is necessary to determine the effects of continuous long-term infusion of baclofen. [1]Univ. of Campinas, Campinas, Brazil; [2]Unicamp, Campinas, Brazil; [3]Inst. for Drug Research, Med. Faculty, Hebrew Univ., Jerusalem, Israel; [4]Sch. Med. Ribeirao Preto-Usp, Ribeirao Preto, Brazil; [5]Univ. of Campinas - Lab. of Nerve Regeneration, Campinas, Brazil

Abstract: Lesion to the immature peripheral nervous system, such as the transection of a peripheral nerve, results in extensive degeneration of motoneurons and dorsal root ganglia (DRG) sensory neurons, mostly by apoptotic events. In turn, the axotomy of the sciatic nerve in the neonate has become a golden standard experimental approach to test new neuroprotective molecules and therapies. We have previously shown that cannabidiol (CBD), the most abundant non-psychotropic molecule present in Cannabis sativa leaves, exhibits neuroprotective action, reducing spinal motoneuron loss by 20% and dorsal root ganglia degeneration by 10% when daily administered at a dose of 15mg/Kg. The present work shows that the use of 4'-fluoro-cannabidiol, HUF-101, a fluorinated synthetic version of CBD, significantly improves neuronal survival by 2 to 3-fold with only one-third of the dose. Furthermore, we show that HUF-101 administration significantly upregulates anti-apoptotic genes and block pro-apoptotic nuclear factors expression. Thus, 2-day-old Wistar rats were subjected to a unilateral section of the sciatic nerve and daily treated with HUF-101 (1, 2.5, 5 mg/Kg/day, i.p.) or vehicle solution for five days. The results were evaluated by Nissl staining, immunohistochemistry, and qRT-PCR. Neuronal counting revealed 40 % rescue of spinal motoneurons and 20% improved preservation of DRG neurons (HUF-101, 5mg/Kg) when compared to the vehicle treatment. Such survival was associated with complete depletion of p53 and an elevation of 60-fold of BCL2 like 1 gene expression. Also, peroxisome proliferator-activated receptor gamma (PPAR-gamma) gene expression was downregulated by 80%. Neuronal preservation was coupled with a reduction in astroglial reaction, studied by glial fibrillary acidic protein (GFAP) immunolabeling, which shown a 50% reduction when the integrated density of pixels was evaluated nearby spinal motoneurons, present in the ventral horn of the lumbar intumescence. Overall, the current data strongly indicates the HUF-101 has potent neuroprotective effects, significantly superior to native CBD. Such properties are particularly related to anti-apoptotic protection and reduction of astrogliosis.

Title: Inhibition of HDAC6 reverses cisplatin-induced neurotoxicity

Authors: *J. MA[1], K. KRUKOWSKI[1], O. GOLONZHKA[2], G. LAUMET[1], T. GUTTI[1], J. VAN DUZER[2], R. MAZITSCHEK[3], M. JARPE[2], C. J. HEIJNEN[1], A. KAVELAARS[1]

Abstract: Chemotherapy-induced neurotoxicity is among the most common dose-limiting side-effects of cancer treatment, which not only hampers effective cancer therapy, but also greatly reduces the quality of life for cancer survivors. Currently, there is no FDA-approved treatment available. Histone deacetylase 6 (HDAC6) is a microtubule-associated deacetylase whose function includes regulation of α-tubulin-dependent intracellular mitochondrial transport. Inhibition of HDAC6 has been shown protective in several neurological disorders. Here we examined the effect of HDAC6 inhibition on established cisplatin-induced peripheral neuropathy and cisplatin-induced cognitive impairments in mice. We used a novel HDAC6 inhibitor ACY-1083, which readily crosses the blood-brain barrier and shows 260-fold selectivity towards HDAC6 versus other HDACs. The HDAC6 inhibitor was injected intraperitoneally for 2 weeks after termination of cisplatin treatment. Our results demonstrate that HDAC6 inhibition completely reversed already existing cisplatin-induced mechanical allodynia, spontaneous pain, numbness, and cognitive deficits. It also restored the loss of intra-epidermal nerve fiber density in cisplatin-treated mice. Mechanistically, treatment with the HDAC6 inhibitor increased α-tubulin acetylation. In addition, HDAC6 inhibition restored the cisplatin-induced reduction in mitochondrial bioenergetics and mitochondrial content in the tibial nerve, indicating increased mitochondrial transport. At a later time point, dorsal root ganglion mitochondrial bioenergetics also improved. Cisplatin-induced changes in mitochondrial morphology and bioenergetics in the brain synaptosomes were also restored by the HDAC6 inhibitor. Our results demonstrate that pharmacological inhibition of HDAC6 completely reverses established cisplatin-induced peripheral neuropathy and cognitive impairments, and the protective effects were associated with normalization of mitochondrial function. These results are especially promising because HDAC6 inhibitors are currently used in clinical trials as an add-on cancer therapy, highlighting the potential for clinical translation of our findings.

Title: Neuroprotective effects of novel oxyindole compounds against oxytosis, feroptosis and ER stress

Authors: *Y. HIRATA[1], C. YAMADA[1], Y. ITO[1], S. YAMAMOTO[1], H. NAGASE[1], K. OH-HASHI[1], K. KIUCHI[1], H. SUZUKI[2], M. SAWADA[2], K. FURUTA[1]
[1]Gifu Univ., Gifu, Japan; [2]Nagoya Univ., Nagoya, Japan

Abstract: Current medical and surgical therapies for neurodegenerative diseases such as Alzheimer's disease and Parkinson's disease offer symptomatic relief but do not provide a cure. Small synthetic compounds that protect neuronal cells from degeneration are critically needed to prevent and treat the aforementioned diseases. Both oxidative stress and endoplasmic reticulum (ER) stress have been implicated in the pathophysiological conditions of those neurodegenerative diseases. In search of neuroprotective agents against oxidative stress and/or ER stress using the murine hippocampal HT22 cell line, we found a novel oxindole compound, GIF-0726-r. The structure is comprised of an indane-type skeleton and an electron-rich unsaturated side-chain attached at C-1 of the ring system. It is effective in preventing limited types of cell death involved in neurodegenerative disorders, such as Alzheimer's and Parkinson's diseases. GIF-0726-r prevented oxidative stress, including glutamate-induced oxytosis and erastin-induced ferroptosis, and tunicamycin-induced ER stress, but did not affect apoptosis induced by staurosporine, camptothecin, and etoposide. GIF-0726-r was capable of inhibiting reactive oxygen species generation and Ca^{2+} influx, a presumed executor in cell death, and activating the antioxidant response element (ARE), a *cis*-acting regulatory element in promoter regions of several genes encoding phase II detoxification enzymes and antioxidant proteins. In addition, GIF-0726-r reduced ER stress-induced gene expression of GADD153 and Grp78 and

XBP1 mRNA splicing for the key downstream targets of ER stress sensors. These results suggest that GIF-0726-r is a low molecular weight compound that prevents neuronal cell death through the attenuation of oxidative and ER stress pathways, and could be a useful therapeutic, as well as a pharmacological tool to manipulate the cellular stress response. We prepared over two hundred oxindoles and related compounds by the modification of GIF-0726-r structure and screened those according to the ARE activity. GIF-2651X-G1 was the most potent ARE activator and successfully showed neuroprotective activity *in vivo* in a model of Parkinson's disease. Further studies are needed to assess the efficacy of GIF-2651X-G1 using various animal models of Parkinson's and Alzheimer's diseases.

Title: Pioglitazone attenuates lipopolysaccharide- induced neuroinflammation and depressive-like behaviour via suppressing the NFκB/Nrf-2 and MAPK signalling pathways

Authors: *S. AHMED[1], M. KWATRA[1], A. AHMED[2], V. NAIDU[1], M. LAHKAR[1], B. BEZBARUAH[3]
[1]Pharmacol. and toxicology, NIPER, Guwahati, India; [2]Pathology, Rajarajeshwari Med. Col., Bangalore, India; [3]Gauhati Med. Col., Guwahati, India

Abstract: Depression is generally described as a low mood state and repugnance to physical activity provoking for suicidal tendencies. According to WHO report, nearly 450 million people suffer from mental disorders of which nearly 10-20 million commit suicide every year. Despite having several medications the disease is still a challenging with approximately a large number of populations do not respond to their first line medication. Hence there exists a necessity to explore new targeted drugs. Lipopolysaccharide (LPS) is an endotoxin obtain from gram negative bacteria which, when injected into experimental mice produces depressive-like behaviour by activating the microglia cells. Upon activation, microglia releases a plethora of mediators including cytokines, chemokines, reactive oxygen species (ROS) and reactive nitrogen species (RNS) which may alter the serotoninergic and glutamatergic neurotransmission. Pioglitazone belongs to peroxisome proliferator-activated receptor gamma (PPAR-γ) agonist class regulates lipid metabolism, exerts potent central and peripheral anti-neuroinflammatory action and possesses neuroprotective effect. However, the mechanisms through which PPAR's

exert these effects have yet to be fully elucidated. In this study, we have explored the neuroprotective nature of pioglitazone in attenuating these insults via inhibiting the activation of multiple transcription factors such as NF-κB, Nrf-2 and MAPKs. Pioglitazone at a dose of 30mg/kg body weight for 14 days was sufficient to show neuroprotective activity by inhibiting the oxido-nitrosative stress and other inflammatory cytokine markers. Taken together our study concludes the neuroprotective potential of pioglitazone in psychiatric disorders associated with inflammation and oxidative stress.

Title: Restoring the impaired cholesterol accumulation and autophagy by graphene enhances neuronal differentiation and prolongs survival in Niemann pick type C disease

Authors: *K.-S. KANG
Vet. medicine, Seoul Natl. Univ., Seoul, Korea, Republic of

Abstract: Niemann-Pick type C (NPC) disease is an inherited lipid storage disorder, characterized by neurodegeneration. Mutation in NPC1 causes accumulation of unesterified cholesterol and dysregulation of autophagy. Here, we report NPC1 mutant mice given graphene show improved clinical outcomes through improved neuronal survival, especially Purkinje cells. In survived Purkinje neurons, cholesterol accumulation was significantly decreased. Interestingly, this therapeutic effect was also found in generated human induced neural stem cells from NPC patient-derived fibroblasts (NPC-iNSC). NPC-iNSC treated with graphene showed restored cholesterol accumulation and improved neuronal differentiation. Additionally, we were able to observe that dysfunctional autophagic flux in NPC-iNSC was restored by graphene. Taken together, graphene can rescue of homeostatic regulation of cholesterol storage and autophagy in NPC disease and provide a potential therapeutic treatment option for neurodegenerative diseases.

Title: Insulin containing PLGA nanoparticles may restore myelin to axon area and proprioceptor function in diabetic rat

Authors: *V. K. HAFTEL, C. BOWE, A. NWANCHA, A. OLADIMEJI, R. MCREYNOLDS, T. GYLES
Dept of Biol., Morehouse Col., Atlanta, GA

Abstract: Diabetic neuropathy is a complication that can arise from diabetes that commonly causes nerve degeneration in the peripheral regions of the body. As a result, a person can experience a number of symptoms such as pain, numbness, a loss of reflexes and a general loss of sensation, which can result in serious infections. It has been suggested that insulin can bind to receptors on the nerves to encourage growth, therefore, may be possible to prevent or counteract this degeneration by delivering insulin directly to the degenerating nerves. One possible method of delivering this insulin to the nerves is through the use of nanoparticles (InsNP). Using the biodegradable NPs will allow the insulin to be primarily deposited at the site of interest with

little to no consequence. In our experiments, the effects of diabetic neuropathy were observed using the ratio of the area of the myelin sheath to the area of the axon (m:a), along with electrophysiological measures of individual proprioceptor responses to muscle stretch from sciatic nerve of rats of various treatment groups. Data from untreated, short-term diabetic rats (3wk, 6wk) and diabetic rats with InsNP injected in triceps surae muscles was reanalyzed and sham-injected control groups were added. It has been observed that diabetes does have an effect on the m:a and that nanoparticle injections of insulin bring the ratio towards the non-diabetic control ratios. In order to ensure that the effects were a result of the InsNP injections, and not the injection into muscle, itself, a control group was added: diabetic rats with triceps surae injections of phosphate buffer solution (PBS). These controls are tested because it is possible that the perceived recovery of the m:a and electrophysiological measurements following InsNP injection may be a result of a reaction to the injection or the PBS in which NPs are suspended. In fact, the data show that m:a was much reduced in the 3wk diabetic + sham injected rats (3.6 +/- 0.05 vs. 5.3 +/- 0.12 for 3wk diabetic, $p = 0.00002$; 8.9 +/- 0.07 untreated, $p = 0.00002$; 5.7+/- 0.09 for 3wk diabetic + 1 wk InsNP, $p = 0.89$, ANOVA, post hoc unequal N HSD), therefore, not explaining the recovery toward untreated values of m:a in the InsNP injected rats. In future experiments we aim to examine the time course of InsNP treatment more closely, test various formulations of NPs to possibly increase the stability of insulin release, and to determine whether or not insulin growth factor (IGF1) is more effective than insulin in the prevention or treatment of diabetic neuropathy.

Title: Exposure to low doses of helium particles disrupts neuronal function and cognitive performance

Authors: *B. M. RABIN[1], S. M. POULOSE[2], M. G. MILLER[2], D. F. BIELINSKI[2], K. L. CARRIHILL-KNOLL[1], E. M. HAWKINS[1], R. C. HENG[1], A. LARSEN[1], C. SPADAFORA[1], N. N. ZOLNEROWICH[1], R. PATEL[1], B. SHUKITT-HALE[2]
[1]Univ. Maryland Baltimore County, Baltimore, MD; [2]Neurosci., HNRCA At Tufts Univ., Boston, MA

Abstract: On exploratory class missions, such as a mission to Mars, astronauts will be exposed to types of radiation (cosmic rays) that are not experienced in low earth orbit where the space shuttle and International Space Station operate. A significant portion of this radiation will be composed of low linear energy transfer (LET) helium (^{4}He) particles, which produce less damage to neuronal tissue as they pass through the brain. Sprague-Dawley rats weighing between 200-225 g were given either head-only or whole-body exposures to ^{4}He particles (1000 MeV/n) at doses ranging from 0.01 to 0.5 cGy. Following exposure, the brains were removed from a subset of the rats for analysis of oxidative stress by measuring NADPH oxidase (NOX2) expression. Measurements were also made of phosphorylated-cyclic AMP (cAMP)-responsive element-binding protein (CREB) and nuclear factor E2-related factor 2 (Nrf2). The remaining rats (n = 10/dose) were shipped to UMBC for behavioral testing, including elevated plus maze (baseline anxiety); novel object and novel spatial recognition (learning and memory); and operant responding on an ascending fixed-ratio schedule (motivation to work for reward). The results indicated that changes in behavioral endpoints could be observed following exposures to ^{4}He particles at doses as low as 0.01 to 0.025 cGy. Differences in neurochemical endpoints were observed following exposure to doses as low as 0.05 cGy (the lowest dose tested). There were no significant differences between head-only and whole-body exposures on behavioral performance. Preliminary analyses of the neurochemical data suggest that whole body exposures may not have been as effective in producing changes in neuronal functioning as were head-only exposures. Because ^{4}He particles will constitute a significant fraction of the radiation dose to which astronauts will be exposed, the present results suggest the possibility that astronauts on exploratory class missions may be at a greater risk for HZE-induced cognitive deficits than anticipated.

Abstract: Apocynin, known as acetovanillone, is a natural organic compound structurally related to vanillin. Apocynin also known as an inhibitor of NADPH oxidase activity and thus is effective in preventing the production of superoxide. Apocynin has been studied to determine its application in several brain injuries, such as stroke, traumatic brain injury (TBI) and epilepsy. Previously, our lab demonstrated that TBI or seizure-induced oxidative injury and neuronal death were reduced by apocynin treatment. Several studies have demonstrated that neuroblast production is increased in the hippocampus after seizure. Here we confirmed the hypothesis that long-term treatment with apocynin may enhance newly generated hippocampal neuron survival by reduction of superoxide production after seizure. Seizure was induced by pilocarpine (25mg/kg i.p.) injection. Apocynin was continuously injected for 4 weeks after seizure (once per day) into the intra intraperitoneal space (i.p.). We evaluated NeuN, BrdU and doublecortin (DCX) immunostaining to determine whether treatment of apocynin increased neuronal survival and neurogenesis in the hippocampus after seizure. The present study indicates that long-term treatment of apocynin increased the number of NeuN (+) and DCX (+) cells in the hippocampus after seizure. Therefore this study suggests that apocynin treatment increased neuronal survival and neuroblast production by reduction of hippocampal oxidative injury after seizure.

Title: Effects of donepezil, an acetylcholinesterase inhibitor, in hippocampal neurogenesis after pilocarpine-induced seizure

Authors: *J. JEONG[1], B. CHOI[1], S. SUH[1], H. CHOI[2], H. SONG[2]
[1]Dept. of Physiol., [2]Dept. of Neurol., Hallym Univ., Chuncheon, Korea, Republic of

Abstract: Epileptic seizures are short episodes of abnormal brain electrical activity and the presence of recurrent and unprovoked seizures is known as epilepsy. Primary symptoms of epileptic seizure may include tonic-clonic movement or convulsions, accompanied by a loss of memory that may be short or sustained. Many survivors of severe epilepsy display delayed neuronal death and permanent cognitive impairment. It is well known that seizure increases the rate of adult neurogenesis in the subgranular zone of the dentate gyrus of the hippocampus. Severe seizures rapidly induce an increase in the proliferation of neural progenitor cells. However, the exact mechanism by which seizures regulate progenitor cell proliferation and neurogenesis is not well known. Donepezil, also called Aricept, is an acetylcholinesterase inhibitor. Donepezil is an effective treatment agent for Alzheimer's disease, dementia and in ischemic or hypoxic settings. However, the role of donepezil on seizure-induced neurogenesis remains untested. Thus, the present study sought to evaluate the therapeutic potential of donepezil treatment on seizure-induced neural injury. Temporal lobe epilepsy (TLE) was induced by intraperitoneal (*i.p*) injection of pilocarpine (25 mg/kg) in male rats. Behavioral testing confirmed the presence of seizure. Donepezil (2.5 mg/kg/day) was injected by gavage for one week after seizure to see the effect of short-term administration. In addition, donepezil was injected for 3 weeks from 3 weeks after seizure to observe the effects of long-term administration. One or six weeks after seizure, BrdU staining and DCX staining were performed to evaluate the effect of donepezil on neurogenesis. There was no difference in the number of BrdU and DCX positive cells when donepezil was administered for one week after seizure. However, the number of BrdU and DCX positive cells was increased in the donepezil-treated group, compared to the vehicle-injected group, when evaluated at six weeks after seizure. In conclusion, donepezil was not effective in the short time period after seizure but was effective in promoting neurogenesis when administered for longer timeframes after seizure. Keywords: Epilepsy, pilocarpine, neurogenesis, donepezil

Title: Acute and sustained excitoxicity differentially influence riluzole’s neuroprotective effect

Authors: *S. WAGNER, E. ANDRIAMBELOSON, C. NEVEU
NEUROFIT, ILLKIRCH, France

Abstract: Excitotoxicity is caused by overstimulation of glutamate receptors. This pathological process that results from excessive release glutamate leads to neuronal injury or death in various

neurological disease conditions. An acute elevation of glutamate is thought to induce neuronal injury in conditions such as stroke, epilepsy and brain trauma injury. More chronic and sustained exposure to milder elevations of glutamate is believed to mediate excitotoxicity in neurodegenerative diseases such as Amyotrophic lateral sclerosis (ALS).The aim of the present study was to compare the excitotoxic effect of acute (10 - 60 min) and sustained (24 h) exposure to glutamate by cultures of cortical neurons. The neuroprotective effect of riluzole (the unique FDA-approved drug ALS drug) was comparatively assessed under the two glutamate exposure conditions. Two biochemical measurements were used to evaluate glutamate-induced neuronal damage 1 day after the initiation of excitotoxicity: *i)* measure of the increase in the amount of lactate dehydrogenase (LDH) released in the cell culture supernatant and *ii)* measure of the decrease in the ATP level in the cell culture.Acute exposure of cortical neurons to glutamate (3, 10, 20 and 75 µM) produced a concentration-dependent increase in extracellular LDH (up to 2-fold increase as compared to the control). When the exposure was extended to 24 h, the amount of extracellular LDH became even more elevated (up to 4-fold increase). Whilst riluzole treatment did not prevent the increase in LDH observed after acute glutamate exposure, it fully abolished the further increase in LDH induced by the sustained exposure. These results suggest that sustained exposure to glutamate induces an additional mechanism of death which is sensitive to riluzole, unlike the one caused by acute exposure. A similar pattern of results was observed when using the decrease of ATP level as a measure of neuronal damage.The above results suggest that acute and sustained exposure to glutamate induce differential mechanisms of neuronal death and this finding is supportive of the beneficial effect of riluzole in neurodegenerative diseases such as amyotrophic lateral sclerosis where more chronic exposure to glutamate is hypothesized.

Title: Neuroprotective effects of lipid emulsion in the acute phase of kainic acid-induced injury in the rat hippocampus

Authors: *M. TANIOKA[1,2], S. UM[1,2], K. KIM[1,2], B. LEE[1,2]
[1]Yonsei University, Grad. Sch. Dept. of Med. Sci., Seoul, Korea, Republic of; [2]Brain Korea 21 PLUS Project for Med. Sci., Yonsei University, Seoul, Korea, Republic of

Abstract: Numerous anti-epileptic drugs (AEDs) have been successful in attenuating seizures. However, neuroprotective methods for the neural injuries that occur after seizures are still in jeopardy due to the lack of specificity in targeting protective markers. Excitotoxic substances such as kainic-acid (KA) and pilocarpine are widely used to induce status epileptus (SE) in animal models causing permanent impairments in the brain. In recent research, lipid emulsion (LE), a well-known parental nutrition has attenuated excitotoxic cell death caused by local anesthetics in myocardial cells. Intravenous LE was reported to provide cytoprotection via various mechanisms involving fatty acid interactions at molecular levels. In our study, we tested the cytoprotective effect of LE on excitotoxic injury in the brain and investigated its protective mechanisms. This study used male Sprague Dawley rats which were divided into 4 groups: vehicle, KA+vehicle, KA+LE 0.01%, and KA+LE 1%. The experimental animals underwent guide cannulae implantation surgeries under pentobarbital anesthesia. Bilateral intrahippocampal injections of KA and LE were given to the experimental groups. Protective effects were observed for both LE-pretreated animals, and animals that were treated with LE after the induction of acute seizures. After the treatment of the experimental groups, the elevated plus maze and passive avoidance behavioral tests were performed and analyzed. After the behavioral tests, brains were perfused and stained with cresyl violet to measure morphological changes. As a result, LE with the concentration of 1% increased the survival of neurons in the pyramidal tract of the hippocampus. Behavioral analysis also displayed less impairment of cognition in the passive avoidance test and decreased the level of anxiety in the elevated plus maze compared to the control group. Wnt1 was up-regulated as a potent protective biomarker at molecular levels which may be due to the palmitate bonding provided by LE. As a result, the canonical Wnt signaling pathway can be a potential target for neuroprotection via fatty acid interaction. Our data suggest that the nutritional aspects of phytochemicals may provide neuroprotection. Further studies that accompany phytochemicals with existing AEDs may lead to new treatments and possibly aid patients suffering from cognitive deficits caused by neurodegenerative diseases.

Title: Pharmacological agents for enhancing cognitive functions

Authors: *G. B. PATRUDU
Andhra Med. Col. & King George Hosp., Visakhapatnam, India

Abstract: Research on the use of drugs for cognitive enhancement has been on the rise. Several classes of drugs can positively influence cognitive functions. This review classifies the various classes of drugs that have been used in cognitive enhancement research based on their mechanism of action.The classes of drugs that have been used in studies include Psychostimulants (amphetamine, methylphenidate, modafinil, caffiene, nicotine etc); Drugs increasing availability of various neurotransmitters in the brain like Acetylcholinesterase inhibitors (donepezil, galantamine, rivastigmine), sources of choline (citicholine), noradrenaline reuptake inhibitors (reboxetine and atomoxetine), MAO inhibitors, Tricyclic antidepressants, serotonin noradrenaline reuptake inhibitors (duloxetine) ,Selective seratonin reuptake inhibitors (Fluoxetine),Central dopamine increasing agents (levodopa); central vasodilators (Nimodepine); drugs acting on Glutamate receptors (riluzole); NMDA partial antagonists (memantine); Drugs acting on AMPA receptor (Ampkines, Racetams); Drugs increasing cAMP in the brain such as PDE4 inhibitors(roflumilast); drugs enhancing BDNF production such as Histone deactylase (HDAC) inhibitors (valproate); drugs enhancing metabolism in the brain mitochondria (Methylene blue); Growth factors involved in neurogenesis (Insulin like growth factor (IGF), Brain derived Neurotrophic factor(BDNF) etc); Drugs activating CREB (Lithium) and opiate receptor antagonists(naloxone, substance P).

Title: A clinically relevant, low-dose activated protein C (APC) protects the brain against ischemic stroke in mice

Authors: *K. YAMATO[1], Y. NAKAJO[1,4], H. YAMAMOTO-IMOTO[2], K. KOKAME[2], T. MIYATA[2], H. KATAOKA[3], J. C. TAKAHASHI[3], H. YANAMOTO[1,5]
[1]Lab. of Neurol. and Neurosurg., [2]Dept. of Mol. Pathogenesis, [3]Dept. of Neurosurg., Natl. Cerebral and Cardiovasc. Ctr., Suita, Japan; [4]Res. Lab., Rakuwa–kai Otowa Hosp., Kyoto, Japan; [5]Dept. of Cardiovasc. Science, Div. of Surgical Med., Osaka Univ. Grad. Sch. of Med., Suita, Japan

Abstract: Plasma levels of protein C (PC) are inversely associated with the incidence of ischemic stroke, according to a large prospective study, suggesting that the serine protease:

activated PC (APC), an intrinsic anticoagulant, may have a role in protecting the brain against ischemic stroke. Previously, we demonstrated that 2 mg/kg APC (i.v.) in the acute phase, rather than higher doses, suppresses the development of cerebral infarction after temporary focal ischemia, with some cases of hemorrhagic transformation. Here, we examined the effect of < 2 mg/kg APC, using the same three-vessel occlusion (3-VO) model (Yang *et al.*, 2014). The effect of the potent anticoagulant, heparin, or a protease-activated receptor (PAR)-1 antagonist, SCH79797, was also investigated in this model. Male C57BL/6J mice, received either human APC (Kaketsuken) - 0.25, 0.5, 1 or 2 mg/kg, heparin - 600 U/kg, or saline (i.v.), at 5 min and 3 h (twice for the acute phase analysis), or at 5 min, 3, 24, 48, and 72 h (five times for the chronic phase analysis), after the induction of ischemia. The regional cerebral blood flow (rCBF) was monitored using laser Doppler flowmetry. Infarcted lesion sizes and neurological deficits were analyzed at day 1 or 7. The suppression in the infarcted lesion sizes was most prominent in the 0.5 mg/kg APC group, in which the rCBF during ischemia was not affected, neurological deficits were less severe compared to the control, and no hemorrhagic transformation occurred. The treatment with heparin did not suppress the lesion volume, and the pretreatment with SCH79797 at 1 mg/kg (i.p.), 1 h before the induction of ischemia, abolished the efficacy of the 0.5 mg/kg APC. It has been reported that 2 mg/kg APC, or 600 U/kg heparin, but not < 2 mg/kg APC, was effective in suppressing the development of cerebral infarction in the intra-luminal thread-insertion (ITI) model used for assessing neuroprotective properties, indicating that APC or heparin prevents the thread (foreign body)-induced blood coagulation, prevents reduction in the rCBF and improves the outcome. However, the determined efficacy of heparin in the present study confirmed that the coagulation system does not play a role in inducing ischemia in our 3-VO model and that APC acts as a pure neuroprotectant, i.e., protects the brain without improving rCBF. As the pretreatment with the PAR-1 antagonist canceled the efficacy of APC, PAR-1-signaling is needed for the APC-derived neuroprotection. The clinically relevant low-dose APC, never demonstrated effective in the ITI model, was found to protect the brain against ischemic stroke, without causing hemorrhagic transformation.

Title: Hypoxia induces bidirectional plasticity in retinocollicular synapses

Authors: *H. DUMANSKA[1], N. VESELOVSKY[2]
[1]Dept. of Neuronal Networks Physiol., Bogomoletz Inst. of Physiology, Natl. Acade, Kyiv, Ukraine; [2]Dept. of Neuronal Networks Physiol., Bogomoletz Inst. of Physiology, Natl. Acad. of Sci. of Ukraine, Kyiv, Ukraine

Abstract: In this study we investigated effects of short-term hypoxia on synaptic transmission in the first visual (retinocollicular) synapses in coculture. Coculture was developed as adequate in vitro model of retinocollicular pathway with easily identified synaptic couples of retinal ganglion cell (RGC) - SC neuron. Method of fast local superfusion was used for short-term (5 minutes) application of hypoxic solution on synaptically connected neurons. Pharmacologically isolated evoked NMDA receptor (NMDAR)- and $GABA_AR$-mediated postsynaptic currents (PSCs) were and recorded from SC neurons by generation an action potential in presynaptic RGCs. Application of hypoxic magnesium-free solution resulted in a long-term potentiation (LTP) of NMDAR-mediated transmission. Furthermore, application hypoxic standard solution (2 mM Mg^{2+}) resulted in reduction in the ability of Mg^{2+} to induce a normal voltage-dependent blockade of the evoked NMDA response. Analysis of the oxygen deprivation effect on spontaneous and miniature postsynaptic currents (sPSCs and mPSCs) revealed an increase in occurrence frequency and the second peak appearance in the mPSCs histogram. Obtained estimates for quantal and binomial parameters reflected the presynaptic changes during the potentiation and can be caused by increasing in the average number of release sites and reducing of Mg^{2+} blockade. $GABA_AR$-mediated synaptic transmission responded to hypoxia by a long-term depression (LTD). Analysis of sPSCs and mPSCs showed significant decrease in the occurrence frequency and in the amplitude of mPSC (quantal size) during oxygen deficiency. Estimation changes in quantal and binomial parameters showed complex of presynaptic (independent of the release probability) and postsynaptic (decrease in sensitivity of postsynaptic receptors) mechanisms during hypoxia induced LTD. Physiological role of GABAergic retinocollicular projections is in regulation of activation and plasticity of excitatory NMDAR-mediated transmission. Thus, hypoxia induced LTD of GABAergic transmission could enhance pathological effect of LTP of NMDAR- mediated transmission in retinocollicular synapses and possibly is an additional injury which can be caused by hypoxia on transmission from the retina to subcortical visual center.

Title: Striatal neuronal death is attenuated in a swine model of pediatric hypoxic-asphyxic cardiac arrest with delayed hypothermia but off-target neurodegeneration is possible

Authors: *C. O'BRIEN[1], E. KULIKOWICZ[1], M. REYES[1], P. SANTOS[1], S. KANNAN[1], R. C. KOEHER[1], L. J. MARTIN[2], J. K. LEE[1]
[1]Anesthesiol. and Critical Care Med., [2]Pathology, Johns Hopkins Univ., Baltimore, MD

Abstract: Therapeutic hypothermia (HT) induced 4.9-5.9 h after resuscitation from cardiac arrest did not improve neurological outcomes in pediatric patients, in contrast to its benefit in perinatal hypoxia-ischemia. Whereas HT reduces necrotic cell death, it can promote apoptosis in cortical neurons and white matter after hypoxic-asphyxic (HA) cardiac arrest in piglets. Here, we tested the hypothesis that in putamen, a region vulnerable to necrotic cell death after HA, HT would decrease necrotic neuronal death but increase apoptotic cell death. We randomized 3-5 day old, male piglets to sham surgery or HA cardiac arrest followed by sustained overnight HT (34°C induced at 2 h), 20 h HT+8 h rewarming at 0.5°C/h, or normothermia. Viable, ischemic necrotic, and apoptotic profiles were counted in putamen. Sham normothermic (n=8) and naïve, unanesthetized (n=5) pigs had similar viable and ischemic neuron counts ($p>0.05$), but naïve pigs had more apoptosis than shams ($p=0.019$). Therefore, the anesthetic did not increase putamenal neuronal death. Sustained HT (n=7) and HT+rewarming (n=8) after HA preserved viable neuron counts to levels exceeding that of normothermia after HA (n=6; $p<0.001$ for both). Sustained HT and HT+rewarming after HA also reduced the number of ischemic necrotic neurons compared to normothermia ($p=0.007$ and $p=0.037$, respectively). After HA, the number of apoptotic profiles was similar among HT, HT+rewarming, and normothermic groups ($p>0.05$). However, among shams, sustained HT (n=7) increased apoptosis above that in normothermic (n=8) or HT+rewarmed (n=7) shams ($p=0.002$ for both). Interestingly, both sustained HT and HT+rewarming shams had decreased viable neuron counts relative to normothermic shams ($p<0.001$ and $p=0.019$, respectively). We conclude that HT with 2 h delayed induction protects putamenal neurons after HA cardiac arrest and, in contrast to cortical neurons, does not promote apoptosis. Insufficient neuroprotection from HT in clinical trials may be related to the 4.9-5.9 h delay in HT induction. Unexpectedly, HT independent of HA injury promoted putamenal apoptosis with loss of total viable neurons. Potential deleterious effects of HT in the developing brain warrants further study because cooling children with only mild hypoxic brain injuries may be detrimental.

Title: Insufficient proteasome function: A possible cause of white matter injury during hypothermia for neonatal hypoxic-ischemic encephalopathy

Authors: *P. SANTOS
ACCM, Johns Hopkins Univ., Hanover, MD

Abstract: White matter injury occurs in neonatal encephalopathy despite the use of therapeutic hypothermia (1). White matter apoptosis is also triggered by whole-body mild hypothermia and rewarming after global hypoxia-ischemia (HI) in our neonatal piglet model of HIE (2). Because HI may interrupt the unfolded protein response (UPR) to hypothermia and rewarming (3), we theorized that incomplete activation of the endoplasmic reticulum associated degradation (ERAD) pathway could cause proteasome insufficiency and white matter injury. We randomized neonatal piglets to HI or sham surgery followed by overnight hypothermia (induced at 2 h), hypothermia + rewarming (0.5°C/h), or normothermia. Piglets recovered for 2, 6, 20, or 29 h. The number of subcortical white matter glial cells immunopositive for endoplasmic reticulum to nucleus signaling-1 (ERN1) at 2 h exceeded that of 29 h after HI and hypothermia ($p<0.05$; n=6-8). By western blotting, heat shock protein 70 (HSP70) levels at 6 h also exceeded that of 29 h after HI ($p<0.05$; n=4). However, the UPR markers p-PERK, p-ERN1, ATF6, and GADD34 remained similar to shams through 29 h after HI ($p>0.1$ for all comparisons; n=4). This response indicates an attenuated UPR after HI with incomplete ERAD. A consequence of impaired ERAD is failure to activate proteasomes that clear oxidized and damaged proteins after HI. We randomized separate piglets to HI or sham surgery followed by overnight hypothermia, hypothermia + rewarming (0.5°C/h), or normothermia. Immunoblotting revealed that proteasome 20S levels peaked at 20 h and then declined 29 h after HI, hypothermia, and rewarming ($p<0.05$; n=4). Carbonylated protein levels were higher at 29 h than at 20 h after HI and hypothermia ($p<0.05$; n=4). Ubiquitinated proteins levels were also higher 29 h after HI and hypothermia than those at 6 and 20 h after HI and hypothermia or normothermia ($p<0.05$ for each comparison; n=4). These data suggest that an attenuated UPR with incomplete ERAD leads to insufficient proteasome function after HI and hypothermia. Proteasome insufficiency is consistent with the accumulation of carbonylated and ubiquitinated proteins that are likely to be dysfunctional, potentially cytotoxic, and may cause white matter injury with oligodendrocyte apoptosis. Thus, proteasome activation has potential as an adjunct to hypothermia to mitigate white matter injury

in HIE.

Title: Added value of interleukin-1 blockade to hypothermia in neonatal encephalopathy due to inflammatory-sensitized hypoxia-ischemia: A preclinical study

Authors: *M. CHEVIN[1], G. SEBIRE[2]
[1]Pediatrics Dept., McGill Univ., Montreal, QC, Canada; [2]Pediatrics, MUHC, Montreal, QC, Canada

Abstract: Background: Neonatal encephalopathy (NE) and subsequent cerebral palsy (CP) resulting from hypoxia-ischemia (HI) or inflammatory-sensitized HI remain very prevalent and lead to significant mortality and morbidity. Few neuroprotective treatments are available against NE: they are limited to symptomatic care and hypothermia (HT), leaving about 50% of patients with neurological sequelae. HT is effective in alleviating NE in some, but not all, human term newborns. It has been reported that these newborns exposed to inflammatory-sensitized HI might have less therapeutic benefit from HT than those exposed to HI alone. Our work and others uncovered that interleukin-1 (IL-1) is at the apex of the inflammatory cascade generating brain injury, and that HT fails to counteract the IL-1 system in NE (Chevin *et al*., Int J Dev Neurosci,

2016). This supports a potential neuroprotective benefit of IL-1 receptor antagonist (IL-1Ra) as targeted add-on therapy to HT. Objective: We tested the added value of IL-1Ra administration to the neuroprotective effect of HT in NE. Methods: We used a rat model of lipopolysaccharide (LPS)+HI-induced NE at postnatal (P) day 12. Inflammation was induced by injecting intraperitoneally (ip) 50 µg/kg of LPS from *E.coli*. Four hours (h) later, the right common carotid artery was ligated, then hypoxia was induced (8% O_2, 1 h 30 min). Pups were submitted (or not) to HT (32° ± 0.5°C, 4 h). IL-1Ra (12.5 - 200 mg/kg q12 h) *vs* saline was injected ip from P12 to P14. Results: HT alleviated brain injury in the ischemic penumbra (neocortex and hippocampus), but not core injury, of LPS+HI-exposed pups. This neuroprotective effect did not result from a down-regulation of the neuroinflammatory response mediated by IL-1β or TNF-α. IL-1Ra treatment (50 mg/kg) was well tolerated. It reduced core injuries and mortality of LPS+HI+HT-exposed pups. Conclusion: Our results demonstrate that IL-1Ra (50mg/kg) has an added value to the neuroprotective effect of HT in LPS+HI-induced NE. This project could open new therapeutic avenues to prevent CP.

Title: Effects of dexmedetomidine on brain ischemia

Authors: *S. MAEDA[1], R. ONISHI[2], Y. HONDA-WAKASUGI[2], A. YABUKI-KAWASE[3], H. HIGUCHI[1], T. MIYAWAKI[2]
[1]Dept. of Dent. Anesthesiol. Okayama Univ.Hosp., Okayama-Shi, Japan; [2]Dept. of Dent. Anesthesiol. and Special Care Dent., [3]Ctr. for Promotion of Dent. Educ. and Intl. Collaboration, Okayama Univ. Grad. Sch. of Medicine, Dent. and Pharmaceut. Sci., Okayama, Japan

Abstract: Background: The number of anesthetic managements of elderly patients has increased along with progresses of anesthetics and monitoring of patients. One of the major problems in anesthetic management of elderly patients is post-operative cognitive impairment (POCI). Although direct causes for the POCI remain unclear, unstable hemodynamics and brain inflammation are likely to associated with the POCI. Dexmedetomidine, a selective agonist on alpha 2 adrenaline receptor, can pass through blood brain barrier and act on the receptor in the CNS, and it has been established to have an anti-inflammatory effect in periphery. Therefore, it

is thought to be a possible treatment to control the POCI. And in this study, effects of dexmedetomidine against an ischemia and an inflammation in the mouse brain were evaluated. Material and Methods: As the first experiment, the effects of dexmedetomidine was evaluated against mouse ischemia/reperfusion model, which is brought by selective occlusion of middle cerebral artery with modified monofilament through internal carotid artery. The effect was assessed by comparing infarct areas in brain section stained with triphenyltetrazolium chloride. In the second experiment, we made mouse model of brain ischemia with inflammation by a temporally occlusion of bilateral common carotid arteries and an injection of low dose lipopolysaccharide, and effects of dexmedetomidine was examined with immunostaining and realtime RT-PCR for items related with apotosis, inflammation and oxidative reaction. Results: In the first experiment, brain infarction was brought in the mouse model of brain ischemia/reperfusion. But, dexmedetomidine did not decrease the infarction area in the model although sedative effect of dexmedetomidine was shown clearly. Conclusion: Dexmedetomidine did not reduce the infarct area. However, it is likely effective against reaction in brain brought by hemodynamic changes and inflammation.

Title: The effects of Ginkgo biloba standardized extract in the serotonergic, glutamatergic and gabaergic receptors modulation in the dorsal hippocampal formation (dHF) of rats submitted to acquisition of conditioned suppression

Authors: *M. TILGER, C. R. ZAMBERLAM, S. M. CERUTTI
Univ. Federal De São Paulo, Diadema, Brazil

Abstract: Recent studies from our lab have shown that EGb is able of modulating conditioned suppression by inducing differential expression of genes and proteins in the dHF of rats. Further, we have analyzed of gene expression in the dHF after conditioned suppression and treatment with flavonoidic fraction from Erythrina falcata and showed that NMDAR-GluN2B and 5-HT1ARs, $GABA_AR$ α1 and $GABA_AR$ α5 play an important role in synaptic plasticity and therefore contribute to the acquisition of fear memory. Furthermore, to better understand the effects of EGb and the contributions of these receptors as well as their interactions in the dHF

(CA3, CA1 and DG) were assessed for the first time by administering agonists, antagonists of receptors for GABA, glutamate (NMDA) and 5-HT or one these antagonists before EGb prior the conditioning session. Male adults Wistar rats (CEUA nº0268/12) were randomly assigned to the control (vehicle, Tween 80 12%) and EGb-treated groups (0.25, 0.5 ou 1 $g.Kg^{-1}$). After completing the behavioral tests the animals were deeply anesthetized and transcardially perfused with formalin 4% (n=3 per group). The encephalon was extracted and frozen at -80ºC. Coronal sections (20µm) were made with cryostat microtome. The slides contained the sections of dHF, were submitted to imunnohistochemical procedure for estimation of total GluN2B, 5-HT1ARs, $GABA_AR$ α1 and α5 and GFAP immuno-positive cells in the both side of the dHF and to imunnofluorescence of double labeling to colocalization of one these receptors with astrocytes (GFAP) or gabaergic interneurons (GAD-67). The images were acquired in AxioImagerA2 microscope with Zen 2 software, the imunnoreactive cells (IR) were quantified in four fields/region/hemisphere with ImageJ software, the statistical analyzes were made with one-way ANOVA and Tuckey post-hoc in the GraphPad Prism 6.0 software. We found that the treatment with EGb at doses 0.5 and 1.0 $g.Kg^{-1}$ increased the number of GluN2BR-IR cells and $GABA_AR$ α1-IR in the CA1, CA3 and DG of dHF. In addition, the treatment with 0.25 $g.Kg^{-1}$ EGb increases $5HT_{1A}R_{-IR}$ cells in the CA3 and DG ($p<0.05$) and treatment with 0.25 and 0.5 $g.Kg^{-1}$ EGb increased $GABA_AR$ α5-IR cells in the CA1 at the three doses after EGb in the CA3 and DG ($p<0.05$) in relation to control group. Furthermore, we found that all receptors, except $GABA_AR$ α1, were colocalizated with GAD-67 and GFAP except. Together, our data suggest that EGb modulates these receptors in a dose-dependent and region-specific manner and confirm our hypothesis that the hippocampus may be involved in suppressing the licking response and thereby be one of the targets of drug action in the modulation of conditioned suppression.

Abstract: The peripheral nervous system has remarkable regenerative capability. Regeneration in the peripheral nervous system depends upon the abilities of Schwann cells; de-differentiation, remyelination, and interaction with axon. Schwann cells-neuron interaction is known to be modulated via neuregulin/ErbB2 signaling but the underlying molecular mediators remain less well understood. Here, we introduced ERM binding protein 50 (EBP50) protein as a novel regulator of ErbB2-mediated Schwann cell functions. EBP50 is highly expressed at the tip of Schwann cells and the nodes of Ranvier, where the projections of the Schwann cells are perpendicular to. EBP50 expression in sciatic nerve significantly increased after crush injury, suggesting its functional role during injury-induced nerve degeneration/regeneration process. Knockdown of EBP50 in Schwann cells reduced the length of cell projections and cell motility. We further showed that EBP50 regulated the expression and localization of ErbB2 and the NRG-induced AKT activation in Schwann cells. In addition, the heterozygous knockout mice (EBP50+/-) have abnormal myelination and decreased motor function, showing some features of peripheral neuropathy. Finally, EBP50 heterozygote mutations were found in the patients with Charcot-Marie-Tooth neuropathy. Together, our results proposed that EBP50 is a key regulator of ErbB2-mediated peripheral nerve degeneration/regeneration.

Title: Obesity-induced neuroinflammation is decreased by omega-3 supplementation

Authors: *R. P. GUEDES[1], A. ANDRADE[1], B. PRAETZEL[1], M. PORAWSKI[1], L. S. DE FRAGA[2], M. GIOVENARDI[1]
[1]Fed. Univ. of Hlth. Sci. of Porto Alegre, Porto Alegre, Brazil; [2]Federal Univ. of Rio Grande Do Sul - UFRGS, Porto Alegre, Brazil

Abstract: Obesity is characterized by a systemic inflammatory status that affects multiple organs and body systems, including the central nervous system (SNC). Obesity induced-neuroinflammation generates deleterious effects in the SNC, including increased susceptibility to neurodegenerative diseases and cognitive impairment. Omega-fatty acids are well known for their anti-inflammatory and neuroprotective role. However, it is not known whether their supplementation can revert neuroinflammation. The present study aimed to evaluate the impact of omega-3 supplementation on neuroinflammatory markers of rats fed a high-fat diet. Male Wistar rats received standard diet (SD) or high fat diet (HFD) for 20 weeks. Omega-3 supplementation or vehicle administration started at 16th week. Omega-3 supplementation did not modify the total weight gain, but it lowered the visceral adiposity following HFD. We also found an improvement in insulin sensitivity following HFD plus omega-3. We also demonstrated that omega-3 supplementation decrease astrogliosis after HFD in the cerebral cortex through GFAP immunostaining. HFD increased gene expression of interleukin-6 and tumor necrosis factor-α in the cerebral cortex and omega-3 treatment decreased gene expression of these proinflammatory cytokines. Thus, our results demonstrate that omega-3 provides a beneficial metabolic role and a reduction of the neuroinflammatory profile following HFD, reinforcing the anti-inflammatory role of this family of fatty acids.

Abstract: Purpose: Inflammatory responses after ischemic stroke contribute to worsening of ischemic brain injury. Calcium release-activated calcium (CRAC) channels are known to be involved in the activation of immune responses in microglia, and have been studied indirectly through non-specific calcineurin inhibitors such as cyclosporine and FK506. Since these compounds have many off-target effects and unacceptable side effects, we studied a novel

CRAC channel inhibitor which is specific to the CRAC channel and appears safe in preclinical studies in anticipation of human clinical trials for other indications. We explored whether this inhibitor might improve outcome in experimental stroke by inhibiting microglial activation.
Subjects and Methods: 2-3 month old C57/BL6 male mice, were exposed to transient middle cerebral artery occlusion (tMCAO, filament model) for 2h followed by reperfusion. Some were treated with the CRAC channel inhibitor (CM-EX-137, 5mg/kg IP; tMCAO-CM) or vehicle control (tMCAO) daily beginning immediately after stroke onset. Brains were collected 3d post-stroke. Neurological function was evaluated using a Bederson score, elevated body swing test, adhesive removal test, and corner test at baseline, at 3, 24 and 72 h. Relative cerebral blood flow (rCBF) was studied in some mice using laser Doppler flowmetry. Ischemic lesion size was evaluated by 2,3,5-triphenyl tetrazolium chloride (TTC) staining. Microglial/monocyte activation was assessed by isolectin B4 histochemistry.
Results: A total of 18 mice were studied (tMCAO-CM: 8; tMCAO: 8, sham:2). 3 mice exposed to tMCAO (1 tMCAO-CM; 2 tMCAO) died before study completion (differences in mortality N.S). rCBF was no different between experimental groups, and is consistent with the notion that the compound should not alter blood flow. Neurological function at 1 & 3d after ischemia was significantly improved in
tMCAO-CM group compared to tMCAO ($p<0.001$). The CM compound also significantly reduced infarct volume by ~60% ($p<0.05$). Isolectin B4 staining was markedly reduced in the tMCAO-CM group compared to tMCAO 3d post ischemia ($p<0.01$).
Conclusion: CRAC channel inhibition protects against experimental stroke by decreasing lesion size, improving neurological outcomes and decreasing microglial activation.

Title: Delineating mechanisms underlying panic pathophysiology

Authors: *A. WINTER[1], R. AHLBRAND[1], L. VOLLMER[1], N. QUAN[2], E. G. KRAUSE[3], R. SAH[1]

[1]Psychiatry, Univ. of Cincinnati, Cincinnati, OH; [2]Dept Biosci., Ohio State Univ., Columbus, OH; [3]Dept Pharmacodynamics, Univ. of Florida, Gainesville, FL

Abstract: Panic disorder (PD) is a prevalent, complex anxiety disorder afflicting about 3% of U.S. adults. The hallmark of PD is recurring panic attacks; episodes of debilitating fear concurrent with intense physical symptoms. Existing treatments for PD are limited, and many patients are unresponsive. This highlights the need for improved mechanistic understanding of the biological triggers of panic attacks to identify novel targets of intervention. Panic attacks can occur spontaneously without external threats, suggesting internal homeostatic disturbances as likely triggers. Accordingly, PD patients are very sensitive to challenges producing pH imbalances, specifically acidosis. Carbon dioxide (CO_2) inhalation induces acidosis and reliably elicits panic attacks in PD patients. Thus, analysis of acid-sensing mechanisms and downstream effectors are crucial to understanding panic pathophysiology. Consistent with the negative valence construct within NIMH's Research Domain Criteria initiative, our lab employs CO_2 inhalation in mice to simulate an acute, interoceptive threat producing defensive behaviors representative of fear. Recently, we reported contributions of microglial acid-sensing to CO_2-evoked fear (Vollmer, 2016), however specific sites and neuronal effector mechanisms remain unclear. The current study a) confirms the brain site orchestrating acidosis-evoked behavior and b) identifies a potential neuronal coupling system in CO_2 responses: the renin angiotensin system (RAS). Site directed infusion of acidified aCSF into a homeostatic regulatory region, the subfornical organ (SFO), evoked significant freezing in mice dependent on the presence of the acid sensor. This suggests the SFO plays a pivotal role in regulating PD-relevant behavioral responses to acidosis. The SFO is also a known modulator of systemic homeostasis via RAS. To investigate the role of RAS in our CO_2 inhalation model, Angiotensin II-type I receptor antagonist, losartan, was delivered intracerebroventricularly near the SFO. Significant attenuation of CO_2-evoked freezing was observed in losartan treated mice, identifying RAS as a potential neuronal effector downstream of microglial acid sensing. Ongoing studies are characterizing microglial-neuronal coupling at functional and cellular levels using transgenic mice and DREADDs. Preliminary evidence suggests microglia-blood vessel-neuronal interactions, outlining a novel tripartite mechanism in CO_2-evoked adaptive fear responses relevant to PD. Our studies help delineate mechanisms by which homeostatic triggers may lead to panic attacks, and will identify targets for future therapeutic intervention.

Title: GABAergic depolarization in C-fiber axons is modulated directly and indirectly by allopregnanolone via PKC_e

Authors: V. BONALUME[1], L. CAFFINO[1], R. W. CARR[2], L. F. CASTELNOVO[1], D. COLLEONI[1], S. MELFI[1], F. FUMAGALLI[1], *M. SCHMELZ[2], V. MAGNAGHI[1]
[1]Dept. of Pharmacol. and Biomolecular Sci., Milan Univ., Milano, Italy; [2]Heidelberg Univ., Mannheim, Germany

Abstract: Schwann cells (SC) are specialized glial cells of the peripheral nervous system (PNS) some of which forming the myelin sheath and interacting functionally with neurons under basal and pathophysiological conditions. Schwann cells express ionotropic GABA-A and metabotropic GABA-B receptors and are able to synthetize both GABA and the neuroactive steroid allopregnanolone (ALLO), a progesterone metabolite known to bind selectively to GABA-A receptors.
It is well established that ALLO and GABA-A activation can regulate SC in the PNS in terms of differentiation, myelination and regeneration. However, the function of GABA-A receptors in peripheral axons and their role in SC-neuron cross-talk is still unclear.
To this end, we performed an electrophysiological characterization of GABA-A receptors on unmyelinated C-fibers in mouse sural nerve. GABA is commonly associated with inhibitory, hyperpolarizing effects in the central nervous system. However, GABA-A receptor activation resulted in axonal depolarization and increased excitability in peripheral C-fibres. This effect was blocked by bicuculline, mimicked by muscimol and enhanced by benzodiazepines and ALLO (1 μM) which produced a leftward shift of the dose-response curve. In addition to this rapid modulation of C-fibres, ALLO can also control intracellular pathways in neurons via SCs. Indeed, we observed that neurons exposed to conditioned medium of SCs treated with ALLO (1 μM) exhibit an upregulation of the ε isoform of protein kinase C (PKCε), an intracellular pathway known to be involved in the pathogenesis and maintenance of neuropathic pain conditions. The mediator responsible for this neuronal-glia modulation might be Brain-Derived Neurotrophic Factor via TrkB. Treatment of SCs with ALLO, indeed, results in the production and release of BDNF. In neurons, conditioned medium mediated up-regulation of PKCε was mimicked by recombinant BDNF and blocked by a TrkB inhibitor.
In conclusion, we suggest that SC and peripheral neurons interact in two ways: SC-derived ALLO can acutely sensitize GABA-A receptors modulating axonal excitability and SC-derived BDNF can lead to long-term upregulation of neuronal PKCε.

Title: Roles of autophagy in palmitate-induced ER stress and apoptosis in hypothalamic neuronal cells

Authors: *Y. LIM, E.-K. KIM
DGIST, Daegu, Korea, Republic of

Abstract: Autophagy is a cellular process that degrades damaged organelles and aggregated proteins. Hypothalamic autophagy is important for regulation of food intake and energy expenditure. High-fat diet induces hypothalamic injury through endoplasmic reticulum (ER) stress and apoptosis in rodents. We demonstrate here that autophagy plays a role in protecting hypothalamic neuronal cells from ER stress-induced apoptosis. Treatment of palmitate induces ER stress and autophagy in hypothalamic neuronal cells, N41. However, prolonged treatment of palmitate impairs autophagy and increases apoptosis. When palmitate-induced autophagy is enhanced by rapamycin, an autophagy inducer, ER stress and apoptosis are decreased. On the other hand, treatment of bafilomycin, an autophagy inhibitor, increases ER stress and apoptosis. In addition, pretreatment of ER stress reducer to palmitate decreases both autophagy and apoptosis. Taken together, our results indicate that autophagy has a protective role in cellular homeostasis by regulating ER stress. Our study suggests that modulation of autophagy is a possible therapeutic strategy for metabolic disorders such as obesity and diabetes.

Title: Peroxiredoxin 5 decreases beta-amyloid-mediated cyclin-dependent kinase 5 activation through regulation of Ca^{2+}-mediated calpain activation

Authors: *J. SEONG[1], *H. J. LEE[2], D.-S. LEE[1]
[1]BK21 Plus KNU Creative Bioresearch Group, Kyungpook National University, Daegu, Korea, Republic of; [2]Chung-Ang Univ. Hosp., Biomed. Res. Inst., Seoul, Korea, Republic of

Abstract: AIMS:Aberrant Cdk5 (cyclin-dependent kinase 5) and oxidative stress are crucial components of diverse neurodegenerative disorders, including Alzheimer's disease (AD). We previously reported that a change in peroxiredoxin (Prx) expression is associated with protection from neuronal death. The aim of the current study was to analyze the role of Prx in regulating Cdk5 activation in AD.RESULTS:We found that of the six Prx subtypes, Prx5 was increased the most in cellular (N2a-APPswe cells) model of AD. Prx5 in the brain of APP (amyloid precursor protein) transgenic mouse (Tg2576) was more increased than a nontransgenic mouse. We evaluated Prx5 function by using overexpression (Prx5-WT), a mutation in the catalytic residue (Prx5-C48S), and knockdown. Increased neuronal death and Cdk5 activation by amyloid beta oligomer (AβO) were rescued by Prx5-WT expression, but not by Prx5-C48S or Prx5 knockdown. Prx5 plays a role in Cdk5 regulation by inhibiting the conversion of p35 to p25, which is increased by AβO accumulation. Prx5 is also upregulated in both the cytosol and mitochondria and it protects cells from AβO-mediated oxidative stress by eliminating intracellular and mitochondrial reactive oxygen species. Moreover, Prx5 regulates Ca2+ and Ca2+-mediated calpain activation, which are key regulators of p35 cleavage to p25. Innovation and Conclusion: Our study represents the first demonstration that Prx5 induction is a key factor in the suppression of Cdk5-related neuronal death in AD and we show that it functions via regulation of Ca2+-mediated calpain activation.

Title: Influence of pulmonary inflammation on behavior in wistar rats exposed to cigarette smoke

Authors: *M. T. CHÍRICO, S. I. S. R. NORONHA, G. S. V. CAMPOS, P. M. A. LIMA, M. R. GUEDES, A. B. F. SOUZA, F. C. S. SILVA, A. B. FIGUEIREDO, L. C. C. AFONSO, S. D. CANGUSSÚ, D. A. CHIANCA-JR, F. S. BEZERRA, R. C. A. MENEZES
Univ. Federal De Ouro Preto, Ouro Preto, Brazil

Abstract: Background - Cigarette smoke (CS) is a complex combination that contains more than 7,000 chemicals substances, which can promote oxidative damage to the lung parenchyma and induce inflammatory process. Pulmonary inflammation leads to neurons activation in the central nervous system, however, the neural mechanisms implicit and the relationship between lung inflammation and behavioral assessment are not clear. Our aim in this study was to evaluate inflammation the anxiety behavior of animals exposed to cigarette smoke with and without tobacco. Methods - Twenty-four male Wistar rats were divided into three groups: control group (CG); common cigarette (CC) and paper cigarette (CP), without tobacco. The animals were exposed to twelve cigarettes per day in three periods (morning, afternoon and night) for eight consecutive days. In addition to CS exposure, the animals were submitted to behavioral tests: Elevated T-maze (ETM) and open field (OF). The animals were euthanized for removal of bronchoalveolar lavage (BAL), blood and lung. LBA was used for total count, cell differential and for the measurement of pro-inflammatory cytokines; Blood plasma was analyzed for cytokine dosing; And the lung was used for dosage of the total Proteins, Glutathione system, antioxidant enzymes: SOD and CAT, TBARS and carbonylated protein. Results - Exposure to CC smoke reduced anxiety and panick-like behaviors. On the other hand, CP induced panic and anxiety behaviors. Animals exposed to common and paper CS showed an increase on the influx of inflammatory cells (CC: 170 ± 3.162 x 103/ml and CP: 180 ± 6.547 x 103/ml vs. CG: 118 ± 6.665 x 103/ml); (CC: 34.86 ± 1.855 U/mg prot and CP: 40.65 ± 3.444 U/mg prot vs. CG: 25.73 ± 1.092 U/mg prot) and CAT (CC : 0.96 ± 0.06 U/mg prot and CP: 0.94 ± 0.10 U/mg prot vs. CG: 0.68 ± 0.10 U/mg prot). The exposure also generated lung damage as demonstrated by increased TBARS levels (CC: 1.39 ± 0.15 nM/mg prot and CP: 1.54 ± 0.10 nM/mg prot vs. GC: 1.02 ± 0.05 nM/mg prot) and reduction of the ratio GSH/GSSG (CC: 4.016 ± 0.5503 μM and CP: 3.316 ± 0.8901 μM vs. GC: 7.283 ± 0.6019 μM). In addition to the stereological analysis of the lung sections, which also showed alteration of histoarchitecture by increasing the volume of the alveolar space (CC: 57.46 ± 1.92%/mm² and CP: 53.40 ± 1.83%/mm² Vs. GC: 43.36 ± 3.46%/mm²) and alveolar septal volume reduction (CC: 41.60 ± 1.95%/mm² and CP: 46.21 ± 1.85%/mm² vs. GC: 55.28 ± 3.52%/mm²) in the exposed animals. Conclusions - Exposure to common cigarette smoke as well as paper cigarettes (without tobacco) led to an inflammatory process and lung damage. Importantly exposure to smoke from CP led to a increase in panic and anxiety behaviors.

Title: HTR2B in sensory neurons mediates pruritus to SSRI antidepressants

Authors: *S. LEE[1], P. CHO[2], J. JANG[3], D. P. ROBERSON[4], R. TONELLO[1], S. HWANG[5], S. HWANG[6], R. H. LAMOTTE[7], C. PARK[8], S. JUNG[9], T. BERTA[1]

Abstract: Acute and chronic pruritus is frequently associated with skin, liver and kidney diseases, as well as viral infection and drug treatment. Antidepressants called selective serotonin reuptake inhibitors (SSRIs) are among the most common drugs prescribed in U.S. today and are well-known to elicit skin adverse reactions such as rashes, urticaria and pruritus, often leading to non-compliance and interruption of otherwise successful therapies. We found that functional serotonin receptor 2B (HTR2B), a G protein-coupled receptors, was expressed in pruriceptive primary sensory neurons and specifically mediated pruritus to various SSRI antidepressants, but not other common pruritogen including histamine or the anti-malaria drug chloroquine. Notably, mice injected with sertraline (Zoloft®) or fluoxetine (Prozac®) or citalopram (Celexa®) scratched immediately and intensively for 10 minutes, a scratching that is significantly attenuated by the specific HTR2B antagonist RS127445. Although HTR2B is expressed and functional in a particular subpopulation of TRPV1-expressing neurons that innervate the skin and are linked to itch, HTR2B induced neuronal activity and itch through the transient receptor potential channel 4 (TRPC4) and not through the most common and well-studied TRPV1, TRPV4 or TRPA1. Finally, sertraline-evoked itch was significantly attenuated by the specific TRPC4 blocker ML204, as well as in *Trpc4-/-* mice. Our data clearly demonstrates that HTR2B and TRPC4 expressed in pruriceptive neurons mediate itch to SSRI antidepressants revealing previously

unknown itch signaling and suggesting new avenues for preventing cutaneous side effects to SSRI antidepressants.

Title: Fc-epsilon receptor I in primary nociceptors as a Fc-epsilon receptor I in primary nociceptors as a sensor of IgE-immune complex may contribute to allergic ocular pruritus

Authors: ***F. LIU**[1,2], T. WANG[1], B. YUAN[1], C. MA[1]
[1]Dept. of Anatomy, Histology and Embryology, Inst. of Basic Med. Sciences, Chinese Acade, Beijing, China; [2]Dept. of Anatomy, Histology and Embryology, Sch. of Basic Medicine, Peking Union Med. Col., Beijing, China

Abstract: Ocular pruritus is the major symptoms of allergic conjunctivitis, which usually accompanied with an elevated serum level of antigen-specific IgE. Fc-epsilon receptor I (FcεRI),typically expressed on the immune cells and bind to the Fc region of antigen-specific immunoglobulin E (IgE), is the only high-affinity activating cell-surface receptor that plays a key role in allergic responses. Fc receptors such as high-affinity IgG receptor (FcγRI) and FcεRI were recently discovered on neurons of dorsal root ganglion (DRG) and trigeminal ganglion (TG). Previous studies demonstrated that IgG-immune complex (IgG-IC) can directly activate primary nociceptor of DRG. In this study, we investigated the potential role of neuronal FcεRI in ocular pruritus. We first established that the mouse demonstrated a remarkable wiping toward the eye with the forelimb when the algogen capsaicin was dropped to the eye, but showed a remarkable scratching toward the eye with hindlimb when a pruritogen Bam8-22 was applied to

the eye. Next, we induced a mouse model of ocular pruritus via topical application of antigen to the eyes in the mice sensitized with the allergen (oval albumin, OVA) together with the adjuvant (aluminum hydroxide). Challenging with OVA (0.1%-5%, 5μL dropped to the eye) induced dose-dependent scratching behavior, which cannot be fully blocked by pre-treatment of mast cell stabilizer (cromolyn sodium) or histamine I receptor antagonist (terfenadine). However, pre-treatment of FcεRI blocking antibody almost completely abolished the OVA-evoked ocular scratching. Futhermore, we found that all three subunits (FcεRIα, β and γ) are expressed on TG neurons that co-expressed with itch-specific neuronal makers such as MrgprA3 or MrgprD. The expression levels of FcεRIα and β subunits were found upregulated in the TG of sensitized mice. In acutely dissociated TG neurons, IgE-IC produced an increase in the intracellular calcium level and induced hyperexcitability in small-sized nociceptive TG neurons. The IgE-IC induced calcium increase could be knocked down with a specific FcεRIα siRNA in dissociated TG neurons. These results indicate that primary nociceptive neurons express functional FcεRI and could be directly activated by IgE-IC. Neuronal FcεRI may serve as the sensor to IgE immune complex and play an important role in allergic ocular pruritus.

Abstract: The somatosensory system provides animals with the ability to detect, distinguish and respond to diverse thermal, mechanical and irritating stimuli. While there has been progress in defining classes of neurons underlying temperature sensation and gentle touch, less is known about the neurons specific for mechanical pain. Here, we use in vivo functional imaging to identify a class of cutaneous sensory neurons that are selectively activated by high threshold mechanical stimulation (HTMRs). We show that their optogenetic excitation evokes rapid protective and avoidance behaviors. Unlike other nociceptors, these HTMRs are fast conducting Aδ-fibers. Notably, we find that Aδ-HTMRs innervate unique but overlapping fields and can be activated by stimuli as precise as the pulling of a single hair. Together the distinctive features of this class of Aδ-HTMRs appear optimized for accurate and rapid localization of mechanical pain.

Title: The MrgprD agonist β-alanine and bovine adrenal medullary protein 8-22, an MrgprX1 agonist, preferentially activate subtypes of polymodal nociceptive C-fibers in pigtail monkeys

Authors: A. H. KLEIN[1,2], M. WOOTEN[2], T. V. HARTKE[2], G. WU[2], *M. RINGKAMP[3]
[1]Pharm. Practice and Pharmaceut. Sci., Univ. of Minnesota Duluth, Duluth, MN; [2]Dept of Neurosurg., Johns Hopkins Univ., Baltimore, MD; [3]Dept Neurosurg., Johns Hopkins Univ. Dept. of Neurol. and Neurosurg., Baltimore, MD

Abstract: In mouse DRG, the expression of mas-related G protein-coupled receptors (Mrgprs) differentiates classes of polymodal nociceptive C-fiber neurons, that have been proposed to mediate distinct behaviors. MrgprD neurons have been shown to be involved in paw withdrawal to mechanical stimuli and scratching behavior induced by β-alanine, and MrgprA3 neurons have been proposed to represent a labeled line for itch. In primate, orthologous genes for some Mrgs exist (MrgD-G), whereas others, designated as MrgX1-4, cannot be clearly assigned to any of the MrgA-C subfamilies described in mice. Currently, it is unclear whether functionally distinct subclasses of cutaneous nociceptive C- fiber neurons expressing different Mrgprs can be differentiated in primate. Two types of heat responses are observed in cutaneous polymodal nociceptive C-fibers when their receptive fields (RF) are exposed to a stepped heat stimulus (49°C, 3s): a quick response (QCs) or a slow response (SCs). We have previously shown that QCs are preferentially activated by the MrgprD agonist β-alanine (ALA). Whether QCs and SCs also differ in their responses to bovine adrenal medullary protein 8-22 (BAM8-22), an Mrgpr agonist that activates murine MrgprC11 and human MrgprX1, is not known. Using standard teased-fiber techniques, neuronal activity of unmyelinated C fibers innervating the hairy skin was recorded in anaesthetized nonhuman male primates (Macaca nemestrina). After locating the mechanical RF of the fiber under study, sensitivity to noxious heat was tested using a contact free, temperature-controlled CO_2 laser system. Two blocks of intradermal injections (each 10 µl)

were then administered at the RF: one block consisted of extracellular fluid (ECF, the solvent) followed by ALA (90 µg) and another block of BAM8-18 (the inactive truncated peptide, 1 µg) followed by BAM8-22 (1 µg). The order of the blocks was randomized. Following each injection, neuronal activity was recorded for at least 5 minutes. A total of 45 C fibers was tested. Of 24 QCs, 23 responded to ALA and 17 responded to both, ALA and BAM8-22. QC- responses to ALA were about 2-fold larger than responses to BAM8-22. All 21 SCs responded to BAM8-22, but only 4 also responded to ALA. SC responses to BAM8-22 were about 20-fold higher than those induced by ALA. ALA responses in QCs were about 10-fold larger than in SCs, whereas BAM8-22 responses were about 3-fold larger in SCs than QCs. These results show that QCs and SCs are preferentially activated by ALA and BAM8-22, respectively, and suggest that QCs may represent neurons that preferentially express MrgprD whereas SCs may represent MrgprX1 expressing neurons.

Abstract: The chronic pain syndrome erythromelalgia (IEM) is attributed to mutations in the voltage-gated sodium channel (Nav) 1.7. Here, we differentiated induced pluripotent stem cells (iPSC) from IEM patients with the Nav1.7/I848T mutation into nociceptors. Action potentials in these IEM nociceptors displayed a decreased firing threshold, an enhanced upstroke and a stronger hyperpolarization, all of which can explain the increased pain experienced by patients. Furthermore, IEM nociceptors showed a hyperpolarized Nav activation compared to unmutated controls. Application of the Nav1.7 inhibitor ProTx-II resulted in a loss of the mutation-induced shift of activation and revealed a hyperpolarized Nav activation in unmutated neurons. We conclude that Nav1.7 is not active during subthreshold depolarizations. Instead, its activity defines the action potential threshold and contributes significantly to the action potential upstroke. Thus, our findings may change our current understanding of the role of human Navs in the generation of action potentials and open new avenues for pharmacological intervention in pain syndromes.

Title: The role of Nav1.9 in somatosensory perception

Authors: *J. SALVATIERRA[1], X. DONG[2], F. BOSMANS[1]
[1]Physiol., [2]Neurosci., Johns Hopkins Univ. Sch. of Med., Baltimore, MD

Abstract: The somatosensory nervous system perceives and transfers sensory modalities such as pain, itch, touch, and temperature from the periphery to the central nervous system. Voltage-gated sodium (Na_v) channels are vital for action potential generation, and are key players in this

signal transmission process. Out of the nine Na_v channel subtypes, $Na_v1.7$, $Na_v1.8$, and $Na_v1.9$ are particularly important for the transmission of sensory modalities due to their strategic expression in the somatosensory nervous system. Although $Na_v1.7$ and $Na_v1.8$ have been extensively studied with respect to specific modalities, the role of $Na_v1.9$ remains unclear. However, accumulating evidence suggests a prominent role for this channel subtype in nociception. Challenges in expressing this channel in a heterologous system and a poor understanding of its tissue distribution complicate the formation of a hypothesis about the role of $Na_v1.9$ in transmitting sensory modalities. To overcome these obstacles, we developed a $Na_v1.9$ stable cell line and generated an EGFP-tagged $Na_v1.9$ mouse line, which allows us to refine tissue distribution and function of this channel in particular cells. For example, we took advantage of our EGFP-tagged $Na_v1.9$ mice by performing fluorescent activated cell sorting (FACS) of dorsal root ganglion (DRG) neurons. Fluorescent cells were subjected to transcriptional profiling which revealed a multitude of genes that were differentially expressed in $Na_v1.9$-expressing neurons, including several G-protein coupled receptors (GPCRs) implicated in somatosensory perception. We are currently using known ligands and mouse lines for these GPCRs to investigate their link with $Na_v1.9$. Our goal is to determine how modulation of $Na_v1.9$ via these GPCRs alters somatosensory perception.

Title: Proton-sensing GPCRs, G2A and OGR1, participate in establishing hyperalgesic priming

Authors: C.-W. LEE, *W.-H. SUN
Natl. Central Univ., Jhongli, Taoyuan, Taiwan

Abstract: High local concentration of protons was found in kinds of lesions and injury, such as fibromyalgia, immune disease or arthritis, accounted for part of chronic pain. Tissue acidosis triggers a signal switch (2-4hr after acid injection) from Gs-protein kinase A (PKA) to Gi-protein kinase Cε (PKCε) and the PKA-to-PKCε signal switch is associated with development of hyperalgesic priming. Proton-sensing G-protein-coupled receptors including OGR1, G2A, TDAG8, and GPR4, could be major candidates to mediate the PKA-to-PKCε signal switch. We have previously found hat T-cell death-associated gene 8 (TDAG8) mediates acidosis signals and couples to Gs protein to activate PKA pathway, initiating hyperalgesia. TDAG8-Gs-PKA

pathway also participates in the establishment of hyperalgesic priming. However, the mechanism underlying the PKA-to-PKCε signal switch remains unclear. In this study, we used shRNA knockdown technique to explore the transition from acute to chronic pain. In the dual acid injection model (acid [pH5.0] injected twice, 5 days apart), co-injection of G2A- and OGR1-shRNA plasmids significantly inhibited the prolonged phase (after 4hr) of the first hyperalgesia and shortened the duration of the second hyperalgesia, which corresponds to the action time of the Gi-PKCε signaling. Given that a heteromer of G2A and OGR1 mediates Gi-signaling, G2A and OGR1 may participate in the establishment of hyperalgesic priming through regulation of the Gi-PKCε signaling.

Title: Pyrethroids inhibit K_{2P} channels and activate sensory neurons: Basis of insecticide-induced paresthesias

Authors: A. CASTELLANOS[1,2], A. ANDRES[1], L. BERNAL[3], G. CALLEJO[1], N. COMES[1], D. SOTO[1,2], A. GUAL[1,2], J. P. GIBLIN[1], C. ROZA[3], *X. GASULL[1,2]
[1]Univ. De Barcelona, Barcelona, Spain; [2]IDIBAPS, Barcelona, Spain; [3]Dpto. Biología de Sistemas, Univ. de Alcala, Alcala de Henares, Madrid, Spain

Abstract: Pyrethroid insecticides such as permethrin, deltamethrin or tetramethrin are widely used for pest control, in agriculture and in human public health commonly as a topical treatment for scabies and head lice. Exposure to pyrethroids causes sensory alterations such as transient pain, burning, stinging sensations and paresthesias. Despite their well-known effects on sodium channels, their toxic effects on mammals can’t be fully explained by the modulation of these channels and the contribution of other channels that control sensory neuron excitability is less

studied. Given the role of two-pore domain potassium (K_{2P}) channels in modulating sensory neuron excitability and firing, both in physiological and pathological conditions, we pursued the possibility that pyrethroids modulate K_{2P} channels mainly expressed in sensory neurons. By combining electrophysiological and calcium imaging experiments, we show that a high percentage of tetramethrin-activated neurons were nociceptors, which were also activated by TRPA1 and/or TRPV1 agonists. This pyrethroid produced a significant inhibition of native TRESK, TRAAK, TREK-1 and TREK-2 currents from sensory neurons. Similar effects were found in transfected HEK293 cells expressing the different channels and challenged with pyrethroids. In addition, tetramethrin activated and enhanced the excitability of peripheral saphenous nerve fibers. At the behavioral level, intradermal tetramethrin injection in the mouse paw produced abundant nocifensive responses and caused mechanical allodynia, demonstrating that the effects seen on nociceptors in culture lead to pain-associated behaviors *in vivo*. In TRESK knockout mice, pain-associated behaviors elicited by tetramethrin were enhanced, providing further evidence for a role of this channel in preventing excessive neuronal activation. Our results indicate that inhibition of K_{2P} channels facilitates sensory neuron activation and increases their excitability. These effects contribute to the generation of paresthesias and pain after pyrethroid exposure and point out K_{2P} channels as possible targets of algesic substances.

Title: A microneurography inter-species study comparing the relative distribution of C-nociceptor types and parameters of activity-dependent slowing (ADS) of conduction velocity reflecting different axonal membrane properties in mice, rat, non-human primate and healthy subjects

Authors: *E. GARCIA-PEREZ[1], P. S. PALL[2], R. SOLA[1], M. SUMALLA[1], A. HOUGHTON[2], J. SERRA[1]
[1]Neurosci. Technologies, Barcelona, Spain; [2]Pharmacol., Merck Res. Labs., West Point, PA

Abstract: Objectives: To compare the different proportions of peripheral C-nociceptors in different mammalian species commonly used in preclinical drug development for neuropathic pain in humans.
Methods: Microneurographic recordings were obtained from the common sciatic nerve trunk of

naïve (Mus) mice (n=8), Sprague-Dawley rats (n=8) and from the superficial peroneal nerve of rhesus monkeys (n=8) and healthy human volunteers (n=24) using insulated tungsten microelectrodes. Relative proportions of C-nociceptors and several measures of ADS were compared between species.

Results: Total number of C-fibers recorded in mice, rats, monkeys and humans were 70, 132, 92 and 242, respectively. Relative proportions of C-nociceptors among all recorded C-fibers were 69% in mice, 71% in rats, 47% in monkeys and 79% in humans. Among C-nociceptors, the relative distribution between Type 1A mechano-sensitive and Type 1B mechano-insensitive nociceptors was mice (T1A 58%, T1B 19%), rats (T1A 46%, T1B 47%), monkeys (T1A 40%, T1B 40%) and human (T1A 47%, T1B 43%). A 15±8% of the nociceptors had features that prevented a clear-cut classification to one group or the other and remained as unclassified type C-nociceptors. Baseline conduction velocity (m/s) was: mice (T1A 0.70±0.02, T1B 0.88±0.09), rats (T1A 0.74± 0.03, T1B 0.68± 0.03), monkeys (T1A 0.83±0.03,T1B 0.86±0.16) and humans (T1A 0.73±0.03, T1B 0.48±0.04). Unpaired t-test was statistically significant for mice vs monkeys ($p=0.0041$) for type 1A fibers and for mice vs rats ($p=0.007$) and for mice vs rats ($p=0.007$), mice vs humans ($p=0.0005$), rats vs humans ($p=0.0002$) and monkeys vs humans ($p=0.0005$) for type 1B nociceptors. Percentage of CV slowing at 0.25Hz stimulation was: mice (T1A 0.004±0.15%, T1B 2.93±0.32%), rats (T1A 0.58±0.09%, T1B 3.4±0.25%), monkeys (data unavailable) and human (T1A 0.42±0.18%, T1B 3.87±0.21%). Differences for type 1A fibers were found for mice vs rats ($p=0.0006$) and mice vs humans ($p=0.0021$). Percentage of CV slowing after a 3 min 2Hz stimulation tetanus was mice (T1A 29.71±1.7%, T1B 31.41±3.8%), rats (T1A 31.3±1.58%, T1B 38.5±1.34%), monkeys (T1A 27.39±1.68, T1B 49.6±2.03) and humans (T1A 30.74±1.48%, T1B 34.56±1.9%). Differences were found between mice and rats ($p=0.04$), mice vs monkeys ($p<0.0001$) and monkeys vs humans ($p=0.0005$) only for type 1B fibers.

Conclusions: Although there are minor differences, peripheral C-nociceptor types exhibit remarkable similarity between species in terms of distribution of CV and different measures of ADS. The information obtained in this study is highly relevant when planning preclinical in-vivo studies for peripherally-acting neuropathic pain analgesics.

Title: Effect of eugenol on slow ventral root potentials in neonatal rats

Authors: *S. YAGURA, H. ONIMARU, M. IZUMIZAKI
Dept. of Physiol., Showa Univ. Sch. of Med., Tokyo, Japan

Abstract: Eugenol is contained in several plants including clove and is used as an analgesic drug. In peripheral and central nervous system, this compound modulates neuronal activity through action on voltage-gated ionic channels and on transient receptor potential channels. It has been established that slow ventral root potential induced by ipsilateral dorsal root stimulation in the isolated (typically lumbar) spinal cord of newborn rats reflects the nociceptive response. This *in vitro* experimental model is useful for assessing the actions of analgesics. However, there is no report regarding the effects of eugenol in the *in vitro* experimental model. Therefore, we examined the effects of extracellularly applied eugenol on the spinal reflex response in spinal cord preparations from newborn rats. Spinal cord preparations (Th10 - L5) were isolated from Wistar rats (postnatal day 0-3) under deep isoflurane anesthesia. Preparations were superfused continuously at 2.5-3 ml/min in a 2 ml chamber with artificial cerebrospinal fluid (ACSF) composed of (in mM) 124 NaCl, 5.0 KCl, 1.2 KH_2PO_4, 2.4 $CaCl_2$, 1.3 $MgCl_2$, 26 $NaHCO_3$, and 30 glucose and equilibrated with 95% O_2 and 5% CO_2 at a pH of 7.4. The preparations were maintained at a temperature of 25-26°C. To evaluate the effects of eugenol on putative nociceptive responses, the ipsilateral dorsal root of L5 was stimulated using a glass suction electrode, and the induced reflex response was recorded from the L5 and Th12 ventral roots through a 0.5 Hz high-pass filter. The dorsal root was stimulated every 60 s with a 5-20 V, 200 μs square pulse. We measured the peak amplitude and area of the slow ventral root potentials. The preparations were superfused with ACSF for at least 15-30 min until the spinal reflex response became stable. We found that eugenol (0.25-1 mM) caused dose-dependent attenuation of the reflex response. Eugenol also depressed spontaneous ventral root activity. Our report further provides the basic neuronal mechanisms to support the clinical use of eugenol that seems to be potentially expected for analgesic treatment.

Title: Sympathetic modulation of TNFalpha-induced nociception in the presence of oral squamous cell carcinoma

Authors: *N. SCHEFF[1], A. K. SHARMA[2], E. DOWSE[2], B. L. SCHMIDT[3]
[2]Col. of Dent., [3]Bluestone Ctr. for Clin. Res., [1]New York Univ., New York, NY

Abstract: Oral cancer patients report severe pain during function. Oral cancer pain is hypothesized to be due to tumor proliferation, perineural invasion, secretion of pro-nociceptive mediators, and infiltration of immune cells into the cancer microenvironment. Norepinephrine (NE), a key neurotransmitter released by sympathetic nerve fibers, is thought to modulate the immune system and pain in the presence of injury. NE also dysregulates cytokines and growth factors involved in cancer progression. We recently demonstrated that the pro-inflammatory cytokine, tumor necrosis factor alpha (TNFα), mediates oral cancer-associated inflammation and nociception. We sought to test the hypothesis that NE increases TNFα secreted by oral cancer. Using a retrograde tracer, we identified sympathetic postganglionic neurons in the superior cervical ganglia that innervate the tongue. We also showed that TNFα receptors, TNFR1 and TNFR2, are expressed on trigeminal primary afferent neurons innervating the tongue. Membrane β2-adrenergic receptors were expressed on oral cancer cell lines (SCC4, HSC3) and a dysplastic oral keratinocyte cell line (DOK). We measured NE-induced changes in TNFα expression in the cell lines and TNFα protein concentration in the supernatant of each cell line. A 24-hour exposure to 1μM NE did not change TNFα expression or protein concentration. Treatment with 10μM NE, however, elevated TNFα mRNA expression in SCC4 and HSC3 (1.5-fold and 2.3-fold, respectively) and resulted in an increase in TNFα protein in the cell line supernatants of SCC4 and HSC3 (130.9 ± 25.3 and 142.2 ± 12.5% respectively). Furthermore, 10μM NE treatment did not affect mRNA expression in DOK and only resulted in 33.8 ± 1.9% increase in TNFα protein in the DOK supernatant. Pre-treatment with the nonspecific β antagonist, propranolol, blocked the NE-induced increase in TNFα in all cell lines. Together these data suggest that sympathetic neurons in the oral cancer microenvironment potentially release NE that activates oral cancer cells to increase secretion of TNFα. The NE-induced TNFα might activate associated receptors on nociceptive neurons that innervate the cancer microenvironment and cause pain. Ongoing studies in oral cancer animal models are testing the therapeutic effect of β antagonists on cancer pain and inflammation through disruption of TNFα signaling.

Title: Translational profiling reveals widespread changes in translation resulting from chemotherapy induced painful neuropathy

Authors: *A. WANGZHOU[1], S. MEGAT[2], T.-F. LOU[3], P. BARRAGAN-IGLESIAS[4], J. K. MOY[4], M. N. ASIEDU[4], P. R. RAY[1], M. D. BURTON[4], G. DUSSOR[4], Z. CAMPBELL[3], T. J. PRICE[4]
[1]Behavioral and Brain Sci., Univ. of Texas At Dallas, Richardson, TX; [2]Behavioral and Brain Sci., [3]Biol., [4]Sch. of Behavioral and Brain Sci., Univ. of Texas at Dallas, Richardson, TX

Abstract: Next-generation sequencing technologies provide unbiased, high throughput snapshots of genomic, transcriptional and nascent translational profiles in cells or tissues. RNA-seq has been used to uncover transcriptional profiles underlying pathologies that could potentially lead to identification of therapeutic targets. However, transcriptomic-based approaches fail to accurately capture how disease states influence the landscape of nascent protein synthesis. We overcome this problem by coupling RNA-seq with Translating Ribosome Affinity Purification (TRAP) technology. We coupled RNA-seq to TRAP (eGFP-tagged ribosomal protein L10a (Rpl10a)) methodology, driven by the nociceptor-specific promoter of Scn10a (Nav1.8), to evaluate mRNA translational efficiency in the mouse dorsal root ganglia (mDRG). We used paclitaxel-induced neuropathic pain model to elucidate changes to the nascent translatome in mDRG neurons for chemotherapy-induced painful neuropathy (CIPN). The Scn10a promoter-driven eGFP-RPl10a was specifically expressed in nociceptors as indicated by co-staining with Prph and CGRP while only a small fraction of large diameter neurons expressed eGFP. Immunoprecipitation (IP) of eGFP from mDRG extracts successfully recovered polyribosome-associated mRNAs from the eGFP-Rpl10a reporter line, with little RNA recovered from mice without the transgene. mRNAs purified by eGFP IP from sensory neurons remained intact and were enriched for nociceptor-specific genes, including Scn10a and Calca/Calcb(CGRP). Traditional transcriptome analysis in the mDRG revealed small differences between naive and CIPN mice, with approximately 200 and 60 genes being up or down regulated, respectively, under paclitaxel treatment compared to naive mice. However, drastic changes were observed in nascent translatome with about 1000 and 900 genes being up or down regulated respectively, indicating pervasive changes in gene expression at the nascent

translatome level. Gene families of Cacn, Calc, Camk, Cox, Eif, Kcn, Ngf, and P2r (among others) are highly translated in CIPN. TRAP-based sequencing provides a novel method for discovering nociceptor-specific mRNAs that are translated in the setting of neuropathic pain. Our CIPN findings clearly demonstrate genome wide changes in translation that cannot be accounted for by transcriptional changes alone. We propose that transcriptional and translational changes are mostly decoupled in nociceptor plasticity, promoting neuropathic pain.

Title: PD-L1 inhibits acute and chronic pain by suppressing nociceptive neuron activity via PD-1

Authors: *Y. KIM[1,2], G. CHEN[1,3], H. LUO[1], D. LIU[1], Z. ZHANG[1], M. LAY[1], W. CHANG[1], R.-R. JI[1]
[1]Dept. of Anesthesiol. and Neurobio., Duke Univ. Med. Ctr., Durham, NC; [2]Dept. of Physiology, Col. of Med., Gachon Univ., Incheon, Korea, Republic of; [3]Nantong Univ., Nantong, China

Abstract: Programmed cell death ligand-1 (PD-L1) is typically produced by cancer cells and suppresses immunity through the receptor PD-1 expressed on T cells. However, the role of PD-L1 and PD-1 in regulating pain and neuronal function is unclear. Here we report that both melanoma and normal neural tissues including dorsal root ganglion (DRG) produce PD-L1 that can potently inhibit acute and chronic pain. Intraplantar injection of PD-L1 evoked analgesia in naive mice via PD-1, whereas PD-L1 neutralization or PD-1 blockade induced mechanical allodynia. Mice lacking *Pd1* (*Pdcd1*) exhibited thermal and mechanical hypersensitivity. PD-1 activation in DRG nociceptive neurons by PD-L1 induced phosphorylation of the tyrosine phosphatase SHP-1, inhibited sodium channels and caused hyperpolarization through activation of TREK2 K^+ channels. PD-L1 also potently suppressed nociceptive neuron excitability in human DRGs. Notably, blocking PD-L1 or PD-1 elicited spontaneous pain and allodynia in

melanoma-bearing mice. Our findings identify a previously unrecognized role of PD-L1 as an endogenous pain inhibitor and a neuromodulator.

Title: Visualization of P2Y1 reporters in peripheral tissues and sensory neurons and changes in response to injury

Authors: C. ESANCY, S. SANNAJUST, T. E. KING, *D. C. MOLLIVER
Biomed. Sci., Univ. of New England, Biddeford, ME

Abstract: P2Y1 is a Gq-coupled receptor for extracellular adenine nucleotides, with highest affinity for adenosine diphosphate (ADP). Functional effects of P2Y1 have been reported in diverse tissues. In peripheral sensory neurons of the dorsal root ganglion (DRG), P2Y1 is one of the most highly expressed P2Y family members and has been implicated in mechanical transduction. P2Y1 null mutant mice show deficits in heat and cold transduction, but the broad non-neuronal expression of P2Y1 poses a challenge for interpretation of behavioral experiments in these animals. Furthermore, it has been difficult to characterize the distribution of P2Y1 in functionally defined subsets of DRG neurons due to a lack of antibodies validated for immunohistochemistry. Here, we used mice with an IRES-Cre recombinase cassette downstream of the P2Y1 stop codon to generate 2 lines of P2Y1 reporter mice: a line expressing td-tomato in all CRE-expressing tissues, to visualize expression in non-neuronal cells of the DRG and peripheral tissues, and a neuron-specific line expressing myristylated GFP to visualize expression in DRG neuron subtypes, as well as their axon projections in peripheral tissues and spinal cord. The results were compared to the distribution of P2Y1 mRNA expression in published RNA-seq datasets. Retrogradely labeled DRG neurons were examined for changes in P2Y1 distribution evoked by hindpaw inflammatory insult or nerve injury. Tissue-specific expression was also examined in skin, colon, bladder and cornea. Finally, behavioral approaches to analyzing function of low threshold afferents expressing P2Y1 were explored in wild type and P2Y1-/- mice. Preliminary results suggest the intriguing possibility that complex social behaviors might be altered in response to deficits in peripheral sensory transduction. However, critical assessment of the challenges inherent in devising behavioral assays for low threshold sensory processing is essential to rigorous interpretation of the results and will be addressed.

Abstract: Serotonin (5-HT) is known to mediate both pain and itch in the peripheral nervous system. Our aim was to identify the specific 5-HT receptor subtypes expressed in the rat dorsal root (DRG) and trigeminal (TG) ganglion neurons.
We used calcium microfluorimetry, the patch clamp technique and pharmacological tools to investigate the action of 5-HT in primary cultures of rat sensory neurons.
Dorsal root and trigeminal ganglia were dissected out from adult male Wistar rats and dissociated neurons were cultured on glass coverslips. After 24 h, the cells were loaded with Calcium Green-1 AM and imaged while being chemically stimulated using a fast-exchange superfusion system.
The calcium responses to 5-HT (50 μM) were classified as transient and sustained according to their kinetics. The selective 5-HT3 antagonist granisetron (1 μM) completely inhibited the transient responses while the 5-HT3 agonist SR 57227 (1 – 10 μM) elicited similar responses in the same neurons.
The non-selective agonist 5-Carboxamidotryptamine (5-CT, 50 μM) induced only sustained responses, solely in the neurons that were sensitive to 5-HT. The same kinds of responses were elicited by the 5-HT1A and 5-HT7 agonist 8-OH-DPAT (10 μM) but were not inhibited by the 5-HT5A antagonist SB-699551-A (1 – 10 μM) or the 5-HT7 antagonist SB269970 (1 – 10 μM).
The 5-HT1A receptor antagonist WAY-100,635 (100 nM) was able to irreversibly inhibit the sustained responses evoked by 5-HT.
Given that the 5-HT1A is metabotropic receptor, we investigated the intracellular mechanisms that led to the sustained calcium influx. The broad-spectrum Transient Receptor Potential (TRP) channel blocker Ruthenium Red did not inhibit the sustained responses. Nor did the more selective antagonists: CIM 0216 (1 μM), A967079 (5 – 10 μM) and HC-067047 (0.5 μM) for

TRPM3, TRPA1 and TRPV4 respectively.
The adenylyl cyclase activator forskolin (10 μM) or the cAMP analog, 8-Br-cAMP (10 μM) did not affect the sustained responses to 5-HT.
Recently reported activators or inhibitors of 5-HT1F, 5-HT2 and 5-HT7 receptors from mouse DRG neurons, had no effects on rat neurons. Voltage clamp experiments were carried out in 5-HT-sensitive DRG neurons pre-selected with calcium imaging, and revealed only transient currents (5-HT3-like) at a holding potential of -80 mV. These currents were inhibited by granisetron (1 μM).
In conclusion, our results suggest that the transient responses are mediated by the 5-HT3 ion channel while the sustained responses are likely mediated by the 5-HT1A metabotropic receptor. This is supported by the inhibitory effect of WAY-100,635 and by the calcium influx elicited by 8-OH-DPAT and 5-CT.

Title: Sex differences in axonal membrane properties of peripheral C-nociceptors in humans and rats detected by microneurography

Authors: *R. SOLA, M. SUMALLA, J. SERRA
Neurosci. Technologies SLP, Barcelona, Spain

Abstract: Background: Pain perception studies have shown that healthy women perceive noxious stimuli as more painful than men. Furthermore female rodents are also more sensitive than males to noxious stimuli. Nevertheless there are no consistent electrophysiological studies showing such differences in the physiology of peripheral nociceptors.
Objective: To study if there exist any basic axonal membrane property difference between sexes in human and rodent peripheral C-nociceptors.
Methods: Microneurographic recordings of C-fibers were obtained from the peroneal superficial nerve of 22 healthy subjects, 12 females (38.9±3.3 yo) and 10 males (37.7±3.7 yo) and from the sciatic nerve of 52 naïve Sprague-Dawley rats, 25 females and 27 males We analyzed different parameters of activity-depending slowing of conduction velocity (ADS) and conduction velocity.
Results: A total of 141 C-nociceptors (75 mechano-heat-responsive [CMH] and 66 mechano-insensitive afferents [MIA])
among all measured ADS parameters only but striking difference in C fibers conduction velocity

has been identified. There is a statistically significant higher CV for human male's C fibers (0,70 ± 0,18) than for female's C fibers (0,51 ± 0,25), (P<0.001), as well for CMH (P<0.024) but no for MIA afferents (p<0.06). In rats, , have been studied in a similar manner recording a total of 87 C nociceptors (42 CMH and 45 MIA). CV of CMH units is higher as well (p<0.046). It is important to highlight a clear different C fiber CV distribution, being the coefficient of variation much higher for human females (45.4%) than for males (15.5%)
Discussion: this study has shown different CV in C-nociceptors, especially in CMH units, according to sex both in humans and rats. CMH units are responsive to mechanical and heat noxious stimuli. Our study suggests that the combination of lower CV and higher range of CV distribution for CMH units could modulate the temporal code of peripheral noxious input in such a way that results in increased pain perception in females and thus could partly explain gender differences in pain perception.
Conclusion: Peripheral C-nociceptor conduction velocity is lower in females than in males. This electrophysiological feature could explain differences in pain perception between sexes in humans and rodents.
fig 1. significant higher CV for human male's C fibers (0,70 ± 0,18) than for female's C fibers (0,51 ± 0,25), (P<0.001), as well for CMH (P<0.024)

Title: Assessment of Nav1.7-dependent electrical excitability of DRG neurons using a high-capacity calcium influx assay

Authors: L. DENG[1], K. STARK[1], S. LARDELL[2], P. KARILA[2], *D. H. HACKOS[1]
[1]Neurosci., Genentech Inc, South San Francisco, CA; [2]Cellectricon AB, Molndal, Sweden

Abstract: The sodium channel Nav1.7 is an attractive pain target based on human genetic evidence. Gain-of-function mutations in Nav1.7 are associated with inherited severe pain conditions, such as inherited erythromelalgia (IEM) or paroxysmal extreme pain disorder (PEPD), whereas individuals carrying loss-of-function mutations are congenitally insensitive to pain (CIP). Voltage-clamp recordings reveal that Nav1.7 makes up >80% of TTX-sensitive Nav current in small-diameter DRG neurons in culture. Current clamp recordings further demonstrate

that action potential generation in small-diameter DRG neurons is dependent on Nav1.7 as long as the resting membrane potential is adjusted to -70mV or more negative (where Nav1.7 is not fully inactivated). However, such electrophysiological recordings are time-consuming not well suited for testing the effects of Nav1.7-selective inhibitors. Here we demonstrate a medium-throughput assay that allows measurements of calcium influx following field electrical stimulation of DRG neurons in culture. By comparing WT vs Nav1.7 KO DRG neurons, we find that Nav1.7 is absolutely required for the observed electrical excitability and calcium influx. Furthermore, we demonstrate the use of high-content imaging to examine the excitability of individual subtypes of DRG neurons and their dependence on Nav1.7. Finally, we examine the effects of Nav1.7-selective inhibitors on DRG excitability.

Title: Role of nociceptors in driving B cell antibody class switching in allergic inflammation

Authors: *S. MATHUR[1,2], S. FOSTER[2], C. SEEHUS[2], S. TALBOT[2], C. J. WOOLF[2]
[1]Harvard Univ., Cambridge, MA; [2]Neurobio., Children's Hosp. Boston, Boston, MA

Abstract: During allergic inflammation, B-cells secrete antibodies that induce deleterious immune responses, including recruitment of immune cells to the site of the allergen exposure and smooth muscle contraction, potentially with deadly consequences in the airway in particular. In response to allergens, antibody genes re-arrange in a highly coordinated manner within B cells, a phenomenon termed immunoglobin class switching, allowing B cells to produce antibodies of different subtypes to modulate the immune response. The antibody IgE is released in an allergic response and directly activates mast cells, which then cause the release of inflammatory mediators, which can initiate bronchoconstriction, hyperperistalsis, and sensitize the pain pathway. Recent evidence has shown that nociceptors, high-threshold sensory neurons that detect noxious stimuli and elicit the sensation of pain, interact with immune cells to modulate their response during inflammatory disease. However, little is known about the interaction of B cells with nociceptors. We previously found that in animal models of allergic airway inflammation, genetic ablation and pharmacologic silencing of nociceptors results in decreased T helper type-2 cell (Th2) effector cytokine function, which potentially could impact the recruitment and

activation of B-cells in germinal centers. Here, we wanted to determine the role of nociceptors if any in modulating B cell class switching to IgE. Interestingly, we found that in the absence of nociceptors, mice sensitized to two different allergens had significantly less serum IgE than wild-type (WT) sensitized mice. In addition, we found that *in vitro* stimulation of B cells from nociceptor ablated mice produced similar levels of serum IgE as WT, implying that the decrease in IgE may not be an intrinsic developmental defect in B cells. Furthermore, co-culture of WT B cells with nociceptors in the absence of additional stimulation led to production of IgE. Our results suggest that nociceptors produce molecules that regulate the B cell class switch pathway. Studying these interactions may provide novel treatment strategies for allergic asthma and other debilitating autoinflammatory diseases.

Title: Characterization of the loss of primary cilia in nociceptive dorsal root ganglion neurons and its affect on acute pain processing

Authors: *K. L. LINDROS[1], E. J. BILSKY[3], K. L. TUCKER[2]
[2]Dept. of Biomed. Sci., [1]Univ. of New England, Biddeford, ME; [3]Admin., Pacific Northwest Univ. of Hlth. Sci., Yakima, WA

Abstract: In sensory DRG neurons, robust primary cilia appear at the soma shortly after elaboration of axons in embryonic development as early as embryonic day E12.5 and persist throughout postnatal stages of maturation. Primary cilia can be functionally eliminated through inducible inactivation of genes that encode proteins essential for the maintenance of primary cilia, such as the intraflagellar transport protein *Ift88.* To this end, knocking out the maintenance gene in the specific area of interest, nociceptive neurons in DRGs, constructs a working model for lack of cilia in sensory areas that largely control pain processing. We have chosen to focus on eliminating cilia from two different nociceptive neuronal subtypes, using an inducible knockout allele of *Ift88* crossed to transgenic mice expressing Cre-recombinase under the control of either the TrpV1 or $Na_V1.8$ promoter. Examination of E15.5 embryos that are Cre-recombinase positive and homozygous for the *Ift88* floxed allele revealed a loss of primary cilia in DRG neurons. This was made easier by the introduction of the lineage tracker Ai14 to the Cre driver, marking all

Cre-expressing TrpV1 neurons with a fluorescent tdTomato reporter. Subsequently, a variety of standard behavioral phenotyping including locomotor activity assays, gait and performance assays, as well as thermal and mechanical withdrawal assays, were conducted. Nociceptive testing assays following injection of Complete Freud's Adjuvant and Capsaicin were also completed for indications of initial deficits in sensory/pain processing. Finally, exploration of the role that primary cilia play in the development and maintenance of nociceptors was carried out to develop a hypothesis for the potential clinical applications of primary cilia in acute and chronic pain states.

Title: The evolutionary history of human dorsal root ganglia - enriched genes: Regulatory and coding sequence evolution as windows into functional turnover

Authors: *P. R. RAY[1], ***P. R. RAY**[1], T. J. PRICE[2]
[1]Behavioral and Brain Sci., The Univ. of Texas at Dallas, Richardson, TX; [2]Behavioral and Brain Sci., UTD, Richardson, TX

Abstract: Problem: Human dorsal root ganglia (DRG) and trigeminal ganglia are known to express many tissue-restricted genes, although the evolutionary history of these genes have not been well characterized except in the context of specific species like the vampire bat or star-nosed mole. As a result, it is difficult to predict if the molecular and functional roles of gene products are altered due to positive selection in the coding sequence, or whether programs controlling transcription or translation have changed due to regulatory evolution. We analyze evolutionary conservation of gene expression patterns and sequence to analyze this. **Approach and Results:** We identify DRG-enriched genes with potentially conserved transcription regulatory programs between humans and mouse by finding conserved tissue specificity of gene expression, avoiding explicit evolutionary analysis of regulatory sequences due to challenges of identifying distal regulatory regions. The set of genes with conserved DRG-enriched expression across species include many well-known DRG-related genes (PRDM12, TRPV1, SCN10A) but also have several notable omissions (TRPM8, TRPA1) which show regulatory divergence.

Analysis of gene families in the set of genes with conserved DRG enrichment shows two main groups of genes with Most Recent Common Ancestors that can be traced back to Vertebrata or Bilateria clades, suggesting that some of these genes co-evolved with nerve chords or dorsal root ganglia in animals. Identification of gene families with large numbers of duplication events show a signature of duplication followed by diversification of gene expression [Lynch and Conery, Science 2000], like members of the MRGPR family. Analysis of gene sequences yields several genes with evidence of recent selection in human populations, including glutamate receptors like GRIA2 and GRIK1 (with weaker enrichment but known expression and functional roles in DRG) [Schrider and Kern, Biorxiv 2017]. **Discussion:** Unlike olfactory, taste or vision receptors, somatosensory genes are less prone to adaptive sequence evolution, though a subset of them show divergent expression between human and mouse, suggesting turnover of regulatory function. Comprehensive analysis can reveal a blueprint of mammalian evolution for genes related to somatosensation, similar to in-depth evolutionary studies performed on olfactory receptors [Niimura and Nei, PNAS 2003]. Additionally, high rates of translational failure in preclinical therapeutic models [Van der Worp *et al*, PLoS Medicine 2014] could potentially be lowered by informed choice of both drug targets (gene products), and model systems based on evolutionary analysis.

Title: Genome-wide nonparametric tests of exon expression identify differentially expressed transcripts in human dorsal root ganglia and tibial nerves with sexual dimorphism

Authors: *J. KHAN[1], C. RAO[2], T. J. PRICE[3], P. R. RAY[3]
[1]Sch. of Natural Sci. and Mathematics, Univ. of Texas At Dallas, Richardson, TX; [2]Erik Jonsson Sch. of Engin. and Computer Sci., Univ. of Texas at Dallas, Richardson, TX; [3]Sch. of Behavioral and Brain Sci., UTD, Richardson, TX

Abstract: Problem: Tests for differential gene expression in *in vivo*, high throughput transcriptome profiling assays for human datasets typically rely on parametric statistics, due to small sample sizes resulting from regulatory and financial constraints in sourcing tissue from

large donor cohorts. Recently, the GTEx consortium [GTEx *et al*, Science 2015] and several laboratories have performed RNA-seq on a wide range of human tissues at unprecedented scale, allowing systematic analysis for *in vivo* human gene expression using nonparametric tests [Li and Tibshirani, SMMR 2013]. We developed a tool for performing nonparametric tests on distribution or sample statistics for mRNA expression at the resolution of individual exons in subsets of human transcriptome profiles defined by biological (tissue or cell type, sex, pathology), or clinical variables and used it to investigate sexual dimorphism in the tibial nerve. We sequenced dorsal root ganglia (DRG) from 6 human donors, and integrated our datasets with 304 tibial nerve samples from GTEx for analysis.
Results: We used 199 male and 105 female tibial nerve samples to identify exons or exon-exon junction boundaries that are differentially expressed between males and females in the tibial nerve. After removing sex linked genes, our tool identified genes that are consistently differentially expressed between males and females, including several related to neuronal function or neuropathies. COMP was found to be upregulated 2 fold in males and is part of the thrombospondin family known to be involved in synaptogenesis, although the role of COMP remains to be elucidated. GSTM1 and HSD11B1, both involved in glucocorticoid signaling, were upregulated 2-fold or more in females and are known to play a role in diabetic neuropathy and inflammation response respectively. MMP3 (Matrix Metallopeptidase 3) plays a role in mammalian inflammation models and pain processing, and is significantly increased in males.
Discussion: Multiple molecular mechanisms of pain and pain inhibition are known to possess sex differences, which is often overlooked in preclinical models that control for sex [Mogil, Nature 2016], increasing the potential for translational failure. Thus, our genome wide mRNA profile of sexual dimorphism in human peripheral nerves is relevant from a biological and pharmacogenomics perspective. Our computational framework opens up the possibility of performing differential whole gene, transcription start site or splicing analysis for other sensory tissues like the trigeminal ganglia, while making fewer assumptions about potentially diverse clinical samples due to use of nonparametric tests.

Title: Distinct classes of primary nociceptors show electrophysiological specializations for driving ongoing and evoked pain

Authors: *M. A. ODEM, R. M. CASSIDY, A. BAVENCOFFE, E. LOPEZ, J. TIAN, Z. WU, C. W. DESSAUER, E. T. WALTERS
Integrative Biol. and Pharmacol., McGovern Med. Sch. At UTHealth, Houston, TX

Abstract: Persistent ongoing pain, hyperalgesia, and allodynia following spinal cord injury (SCI) in rats requires continuing activity in nociceptors (Yang et al., *J Neurosci*, 34:10765, 2014). For months after SCI, many nociceptors generate spontaneous activity (SA) in their somata, both *in vivo* and after dissociation (Bedi et al., *J Neurosci*, 30:14870, 2010; Wu et al., *Pain*, 154:2130, 2013; Bavencoffe et al., *J Neurosci*, 36:1660, 2016). We have found that small (15-30 µm soma) DRG neurons dissociated from naïve rats and tested 20 h later fall into 2 distinct classes. **RF neurons** show non-accommodating **repetitive firing** during prolonged depolarization. **Ac neurons** show strong **AP accommodation** without repetitive firing at any level of depolarization. Both classes are primarily nociceptors, with ~70% excited by 1 µM capsaicin, and 40-60% also binding isolectin B4. RF neurons have smaller AP amplitudes and slower rise times, as well as longer afterhyperpolarizations that limit firing frequency during ongoing activity. RMP does not differ between the classes. In principle, SA might be generated by 1) tonic depolarization of resting membrane potential (RMP), 2) decreased action potential (AP) threshold, and/or 3) increased amplitude of depolarizing, spontaneous fluctuations (DSFs) of MP. We found that SCI induces chronic SA by all three effects, but only in RF neurons (~60% with SA, versus 0% of Ac neurons). After SCI only RF neurons showed persistently depolarized RMP. AP voltage thresholds are normally lower in RF neurons, and showed further lowering by SCI. Both RF and Ac neurons had lower rheobase after SCI. In A-fibre sensory neurons, sinusoidal, subthreshold oscillations drive SA after nerve injury (Amir et al., *J Neurosci*, 19:8589, 1999). In contrast, RF and Ac neurons generate irregular DSFs that are non-sinusoidal. Large DSFs (5-25 mV), which normally almost never occur in either class, increased dramatically in RF but not Ac neurons after SCI. Large-DSF frequency after SCI was nearly identical to the SA firing rate. Thus, the combination of depolarized RMP, reduced AP threshold, and enhanced DSFs accounts for the chronic generation of SA in RF nociceptors, and likely represents a set of mechanisms specialized to generate irregular, low-frequency firing in RF somata and peripheral terminals that can drive ongoing pain. Ac nociceptors may be specialized for rapid, transient, peripheral activation at the onset of noxious stimuli. Lowering of rheobase in Ac and RF nociceptors, if it also occurs in peripheral terminals, should contribute to hyperalgesia. Supported by Zilkha Family Discovery Fellowship, NIH (R01 NS091759), and US Army Medical Research (W81XWH-15-1-0702).

Title: Inhibition of Poly(A)-binding proteins reveals a key role in behavioral responses to inflammatory pain

Authors: *Z. CAMPBELL[1], P. BARRAGAN-IGLESIAS[2], T.-F. LOU[2], B. J. BLACK[5], V. BHAT[2], J. PANCRAZIO[3], T. J. PRICE[4]
[1]Biol., UT Dallas, Richardson, TX; [2]UT-Dallas, Dallas, TX; [4]Sch. of Behavioral and Brain Sci., [3]UT-Dallas, Richardson, TX; [5]The Univ. of Texas At Dallas, Irving, TX

Abstract: Post-transcriptional gene control is a dominant theme in neuronal plasticity. Endogenous cytokines that promote pain plasticity *in vivo* stimulate cap-dependent translation via eukaryotic initiation factor 4 (eIF4) proteins in nociceptors. Far less is known regarding regulatory events that occur on the 3' end. Regulated cytoplasmic polyadenylation serves crucial roles in development and in the nervous system. The direct consequence of poly(A) extension is increased binding of poly(A) binding proteins (PABPs) which stimulate translation initiation through simultaneous associations with the poly(A) tail and eIF4 proteins. PABPs are difficult to study; multiple paralogs produce functional redundancy and there is a paucity of pharmacological reagents. As a novel means of competitively inhibiting PABP function, we conducted an unbiased assessment of PABP specificity. These results were used to develop a specificity derived competitive inhibitor oligonucleotide (SPOT-ON). SPOT-ON RNAs are chemically modified to resist nuclease degradation and display 10 fold greater stability than an unmodified counterpart. The Poly(A) SPOT-ON binds with high affinity and selectivity to PABP. Our inhibitor confirms that PABP functions at the initiation phase of translation. We demonstrate that PABP is required for nascent protein synthesis in primary afferent neurons and their axons. PABP is broadly expressed in soma of cultured DRG sensory neurons and their axons, spinal dorsal horn, the dorsal root ganglia, and sciatic nerve. Mechanical nociceptive plasticity induced by inflammation is blocked by PABP inhibition. Collectively, these results suggest that PABP is integral for nociceptive plasticity.
