**Title:** A single calcium-binding domain is sufficient to mediate the Syt III's regulation of retinal waves

**Authors: *H.-Y. CHEN**[1], C.-T. WANG[1,2,3,4]
[1]Inst. of Mol. and Cell. Biol., [2]Dept. of Life Sci., [3]Neurobio. and Cognitive Sci. Ctr., Natl. Taiwan Univ., Taipei, Taiwan; [4]Genome and Systems Biol. Program, Natl. Taiwan Univ. and Academia Sinica, Taipei, Taiwan

**Abstract:** Patterned spontaneous activity in the developing vertebrate visual system, known as retinal waves, is important for the establishment of correct neural circuits. Particularly, stage II retinal waves are essential for refining retinal projection to central brain. The stage II waves during the first postnatal week is initiated by acetylcholine release from starburst amacrine cells (SACs) via calcium-regulated exocytosis, further propagating onto neighboring SACs and retinal ganglion cells (RGCs). We previously showed that a calcium sensor protein, Synaptotagmin I (Syt I), is consistently expressed in developing SACs and RGCs. Weakened calcium binding to either C2A or C2B domain of Syt I can abolish the Syt I's regulation of retinal waves from either SACs or RGCs, suggesting the importance of the C2AB domains of Syts in regulating the spatiotemporal properties of stage II retinal waves. In contrast to Syt I, Syt III is abruptly upregulated in developing RGCs during the stage II wave period, and has been shown important for regulating wave properties. However, it remains unknown which calcium-binding domain has a dominant effect on the Syt III-mediated regulation of stage II wave properties. To answer the question, RGCs were transfected with genes of interests, including Syt III and its two mutants (Syt III-C2A*, harboring D386N; Syt III-C2B*, harboring D520N), by using the RGC-specific promoter (pBrn3b). Live calcium imaging was further conducted to detect the changes in wave-associated calcium transients after transfection. We found that Syt III in neonatal RGCs enhanced the frequency but reduced the spatial correlation of retinal waves compared to control. In contrast, the spatiotemporal properties of wave-associated calcium transients remained unchanged by overexpressing Syt III-C2A* or Syt III-C2B* compared to Syt III. Thus, our results revealed that unlike Syt I, a single calcium-binding domain is sufficient to mediate the Syt III's regulation of retinal waves. Given that RGCs release glutamate, our results imply that Syt

III in RGCs may play an important role in mediating glutamate release from RGCs, through calcium binding to either C2A or C2B domain.

**Title:** Role of RNA Binding Proteins in the stress response: RNA metabolism and consequences in motor behavior in mice

**Authors: *C. M. FREIRE-COBO**, B. JORDAN
Albert Einstein Col. of Med., New York, NY

**Abstract:** How chronic stress unbalances synaptic protein homeostasis to exacerbate synaptopathies is unknown. Regulation of translational and transcriptional pathways constitutes part of the cell response to environmental stress. Sam68 (Src associated protein in mitosis, 68kD) and FMRP (Fragile X Mental Retardation Protein) are RBP RNA-binding proteins (RBPs) that mediate downstream signaling in response to neuronal activity and other internal/external stimuli. Sam68 and FMRP regulate the splicing, translation and transport of important synaptic mRNA cargoes in neurons and immune system components. The main effect caused by the lack FMRP is elevated protein synthesis and mGluR-dependent long-term depression (mGluR-LTD), a form of synaptic plasticity that requires protein translation. mGluR-LTD is dysfunctional in a number of neurodevelopmental disorders including Autism spectrum disorders (ASD). Our group has shown that mGluR-LTD expression is impaired in Sam68 KO mice. We hypothesize that maladaptive response to stress stimuli alter proteostasis through Sam68 function, and that this process regulates how stress aggravates behavioral phenotypes in Sam68 KO mice. We addressed how pharmacologically induced stress altered Sam68 and FMRP-dependent RNA metabolism in primary cultures, and in Sam68 and FMRP KO mice. We compared how stress impacts the ataxic phenotype observed in Sam68 and Fmr1 mutant mice at different developmental stages. Moreover, we analyzed how external stressors influence the availability and function of core elements that link translation to synaptic function. Finally, we compare how stress differentially affects Sam68 and FMRP cargo expression. Overall, our work provides insights into how stress affects the homeostatic control of neural networks. We propose that stress alters the expression of factors that affect brain plasticity, which ultimately aggravates synaptopathy-based diseases. The significant impact of environmental stressors on quality of life of ASD patients highlights the importance of further studies on how stress regulates symptoms that might be considered as diagnostic of disease progression.

**Title:** FGF22-IGF2 signaling regulates hippocampal synaptic stabilization and affective behaviors

**Authors: *A. TERAUCHI**[1], E. JOHNSON-VENKATESH[1], B. BULLOCK[1], M. LEHTINEN[2], H. UMEMORI[1]

**Abstract:** Neurons in the developing brain must build complex networks by forming appropriate synaptic connections with one another. Synaptic development can be separated into two critical stages. First, a new synapse is assembled, and then the synaptic contact is stabilized. Initial synapse assembly is a local event at the contact sites and requires the exchange of molecules between pre and postsynaptic sites, while subsequent synaptic stabilization requires transcriptional regulation and is regulated by neural activity. Previously, we found that fibroblast growth factor 22 (FGF22), released from postsynaptic hippocampal CA3 pyramidal neurons, is required for initial presynaptic assembly of glutamatergic synapses. However, much less is known about the signals that regulate the stabilization of synapses and the genes that are involved. Here, we asked whether retrograde FGF22 signaling regulates gene expression in presynaptic neurons to control the stabilization of presynaptic terminals. By using microarray analysis, we found that a gene encoding insulin-like growth factor 2 (IGF2) was less expressed in the dentate granule cells (DGCs), major presynaptic neurons of CA3 pyramidal neurons, in *Fgf22*KO mice compared to wild-type mice. Application of FGF22 on DGC axons induced IGF2 expression in the cell body of DGCs. IGF2 is then transported to DGC presynaptic terminals in an activity-dependent fashion to stabilize these structures. We further found that IGF2 is not required for initial assembly of DGC-CA3 synapses but is required for their stabilization both in vitro and in vivo. Interestingly, FGF22-IGF2 signaling is not involved in the stabilization of CA3-CA3 synapses. These results indicate that FGF22 controls both the assembly and

stabilization of synapses: FGF22 directly controls local synapse assembly, and then FGF22 via IGF2 expression regulates synapse stabilization in a pathway specific manner.
The hippocampus plays a key role in multiple behaviors such as mood, anxiety, and social cognition. We found that *Fgf22*KO (null) mice exhibit passive stress-coping behavior in the forced swim test and tail suspension test as well as anhedonia in the sucrose preference test without changes in other behavior tasks relevant to anxiety, social cognition, and motor phenotypes. *Igf2*KO mice also exhibit passive stress-coping behavior. These results suggest unique roles of FGF22-IGF2 signaling in affective behaviors. We are currently identifying specific neurons and developmental periods that are critical for FGF22-IGF2 signaling in regulating affective behaviors.

**Abstract:** During development, spontaneous waves of depolarizations sweep across the visual system, shaping connections into a refined network by strengthening useful synapses and weakening others. This activity also allows inputs to be organized along the dendritic branch, resulting in a system where co-active synapses are located close together. Modelling studies had predicted that such sub-cellular organization would greatly increase the computational ability of the cell. However, we do not yet know the exact function of these clusters in the visual system. They could separate inputs, segregating synapses that arise from different sources. Alternatively, they could act as integration centers that mix inputs from different sources, allowing the cluster to act as a coincidence detector. To test these options, the origins of synaptic inputs onto a single

cell must be identified. Here, we describe a method to image synaptic inputs *in vivo* and subsequently characterize the source of those same synapses using immunolabelling. First, we recorded individual synaptic inputs along the dendrite *in vivo* in mouse pups (P8-P13), by performing simultaneous whole-cell recordings and 2-photon calcium imaging of GCaMP6 and dsRed expressing pyramidal cells in primary visual cortex (V1) layer 2/3. Recording pipettes were coated in Alexa-594 for visualization in the brain and contained biocytin for post-hoc identification of imaged cells. Brains were then perfused and whole cortices were cleared using the SeeDB2 method. Synaptic inputs from the thalamus and cortex into V1 are mutually exclusive populations, and can be distinguished as such by immunohistochemistry for vesicular glutamate transporters (VGluT1), namely VGluT1 (cortical) and VGluT2 (thalamic) expressing inputs. Confocal z-stacks of the target (biocytin+) cells were acquired at high resolution, up to a depth of 240 µm. The confocal images were then deconvolved and rendered in 3D with Huygens software, allowing cortical and thalamic contacts to be identified. We have obtained reliable labeling, clearing and confocal imaging and we have been able to locate target cells and target dendrites.

**Title:** Non-hebbian activity-dependent synaptic refinement at the *Drosophila* nmj

**Authors: *F. J. VONHOFF**, H. S. KESHISHIAN
Molecular, Cellular, and Developmental Biol., Yale Univ., New Haven, CT

**Abstract:** The removal of off-target contacts is essential for establishing precise synaptic connectivity. In many systems Hebbian spike timing is involved, often associated with low frequency calcium and cyclic nucleotide oscillations. Here we describe a novel form of activity-dependent refinement at Drosophila neuromuscular junctions (NMJs) that may be non-Hebbian: silencing the presynaptic but not the postsynaptic side leads to extensive synaptic miswiring. Low frequency oscillatory presynaptic activity and calcium signaling regulate the motoneuron's

response to a muscle-derived chemorepellant, Sema2a, acting via the PlexinB receptor. Live imaging of intact embryos expressing the Ca indicator GCaMP reveals episodic calcium signals in motoneuron growth cones and filopodia. Ca transients are evident in both native and ectopic contacts, oscillating at 0.03Hz towards the end of embryogenesis. Genetic and RNAi knockdown tests show that the refinement depends on both the Ca(v)2.1 and Ca(v)3 channels. We are testing the effects of Ca dynamics on filopodial exploration and withdrawal at both correct and off-target muscles by manipulating Ca transients using the temperature-gated channel TrpA1 and the red-shifted channelrhodopsin Chrimson. Downstream of calcium, three Ca-dependent effectors act within a common signaling pathway to regulate refinement: the Ca-dependent adenylyl cyclase Rutabaga, the kinase CaMKII, and the phosphatase Calcineurin. Loss of function mutations in the corresponding genes disrupts normal refinement, leading to ectopic neuromuscular synapses on up to 30-40% of the examined muscle fibers. We have optogenetically activated the bPAC adenylyl cyclase and demonstrated that intracellular cAMP levels are required to be dynamically maintained within an optimal range for proper refinement. Downstream of cAMP, both PKA and protein phosphatase 1 (PP1) interact with CaMKII and Calcineurin to regulate the neuron's responsiveness to Sema2a-dependent chemorepulsion. Live imaging reveals that partial loss of Sema2a increases ectopic filopodial contacts onto off-target muscles. An off-target contact frequency of 0.85 filopodia/min was observed in Sema2a/+ heterozygotes compared to 0.35 filopodia/min observed in controls. We are currently testing the effects of manipulating the different molecular components of the pathway on filopodia dynamics on correct and incorrect muscle targets. These results reveal a novel mechanism for synaptic refinement, where the response of the innervating cell to retrograde chemorepulsion is regulated by oscillatory presynaptic Ca activity.

**Title:** Dendritic spine remodeling promoted by NrCAM in cortical pyramidal neurons during adolescence through the Semaphorin3F holoreceptor

**Authors: *P. F. MANESS**[1], V. MOHAN[1], C. SULLIVAN[1], J. GUO[2], S. WADE[1], S. MAJUMDER[1], A. AGARWAL[3], E. S. ANTON[2], B. TEMPLE[1]

**Abstract:** Dendritic spines of excitatory cortical pyramidal neurons are dynamic actin-rich protrusions that are overproduced postnatally, eliminated in substantial numbers during adolescence, then stabilized during synaptic maturation. Although much is known about spine morphogenesis, less is understood about mechanisms of adolescent spine pruning and maturation. Neuron-glial related cell adhesion molecule (NrCAM) is an Ig- class cell adhesion molecule that is required for limiting the density of populations of dendritic spines and excitatory synapses in mouse cerebral cortex. NrCAM is an obligate component of the receptor complex for Semaphorin 3F (Sema3F), a secreted ligand that induces spine elimination in cultured neurons through NrCAM, Neuropilin-2 (Npn2) and PlexinA3 (PlexA3). To determine if NrCAM functions in pyramidal neurons and to define its time course of action *in vivo*, we generated a novel NrCAM floxed mouse line and crossed it to Nex1Cre-ERT2 mice to inducibly delete NrCAM specifically from pyramidal neurons. By deleting NrCAM at different time windows, we determined that NrCAM constrains spine density of cortical pyramidal neurons in early adolescence, but deletion in adulthood had no effect. NrCAM regulated spine density on apical but not basal dendrites of pyramidal neurons in both visual (layer 4) and medial prefrontal cortex (layers 2,3). Re-expression of NrCAM by *in utero* electroporation of NrCAM-null embryos demonstrated that NrCAM regulates spine density *in vivo* in a cell autonomous manner, and requires the NrCAM PDZ binding motif. This motif (SFV) bound the synapse-associated scaffold protein SAP102, which localizes to nascent synapses.
Molecular modeling and mutagenesis identified an interface between the NrCAM Ig1 domain (TARNER) and Npn2 a1 domain (E56) that promoted clustering of Npn2 and PlexA3 in the dendritic membrane. Receptor oligomerization, in turn, activated PlexA3 Rap-GAP signaling essential for Sema3F-induced spine pruning in cortical cultures. Further structure-function analyses supported the conclusion that binding of NrCAM Ig1 to the Npn2 a1 interface, together with cytoplasmic PDZ scaffold protein interaction, stabilizes weaker Npn2-PlexA3 binding, so that Sema3F dimers can more efficiently form a signaling holoreceptor.
Temporal restriction of NrCAM function to adolescent rather than adult stages adds to evidence that neocortical mechanisms of juvenile and adult plasticity differ. Genetic linkage of NrCAM, Npn2, PlexA3, and Sema3F to autism spectrum disorders, in which increased spine density has been observed, may implicate the mechanisms identified here in neurodevelopmental disease pathology.

**Title:** Conditional deletion of all neurexins defines diversity of essential synaptic organizer functions for neurexins

**Authors: *L. Y. CHEN**, M. JIANG, B. ZHANG, O. GOCKE, T. C. SUDHOF
Stanford Inst. for Neuro-innovation & Translational Neurosciences, Stanford Univ., Stanford, CA

**Abstract:** Neurexins has been thought as the key organizers of synapses that are essential for normal brain function. To date, it remains unclear whether neurexins are fundamental building blocks of all synapses with similar overall functions, or context-dependent specifiers of synapse properties. To address this question, we produced triple conditional knockout mice that allow ablating all neurexin transcripts in mice. Using neuron-specific manipulations combined with immunocytochemistry, paired-recordings, and two-photon $Ca^{2+}$-imaging, we analyzed excitatory synapses formed by climbing fibers on Purkinje cells in cerebellum, and inhibitory synapses formed by parvalbumin- or by somatostatin-positive interneurons on pyramidal layer 5 neurons in the medial prefrontal cortex. After pan-neurexin deletions, we observed in these synapses severe but dramatically different phenotypes that ranged from major impairments in their distribution and function (climbing-fiber synapses) to large decreases in synapse numbers (parvalbumin-positive synapses) and severe alterations in action-potential-induced presynaptic $Ca^{2+}$-transients (somatostatin-positive synapses). Our results suggest that neurexins primarily function as context-dependent specifiers of synapses.

**Title:** The role of ipRGCs in mediating Synaptotagmin I's regulation of retinal waves during development

**Authors: Y.-W. LIN**[1], *C.-T. WANG[1,2,3,4]
[1]Inst. of Mol. and Cell. Biol., [2]Dept. of Life Sci., [3]Neurobio. and Cognitive Sci. Ctr., Natl. Taiwan Univ., Taipei, Taiwan; [4]Genome and Systems Biol. Program, Natl. Taiwan Univ. and Academia Sinica, Taipei, Taiwan

**Abstract:** The refinement of visual circuits requires the patterned spontaneous activity in developing retinas, named retinal waves. Particularly, stage II retinal waves are essential for retinal projection to central brain. During the first postnatal week in rodent, stage II retinal waves are initiated by neurotransmitter release from starburst amacrine cells (SACs), propagating through the neighboring SACs and retinal ganglion cells (RGCs). However, we previously found that manipulating a calcium sensor during exocytosis (synaptotagmin I, Syt I) in RGCs by using the Brn3b promoter can regulate the spatiotemporal properties of stage II retinal waves. The effects can be abolished by ionotropic glutamate receptor antagonists (RGCs release glutamate), suggesting that a retrograde circuit may exist between RGCs and SACs, further regulating wave properties. Previous studies showed that melanopsin-expressing intrinsically photosensitive retinal ganglion cells (ipRGCs) project axon collaterals to SACs, forming a retrograde circuit. However, it remains unknown whether ipRGCs may involve in Syt I's regulation of retinal waves during development. To answer this question, we determined whether Syt I's regulation of retinal waves can be attributed to ipRGCs. First, developing rat retinas were transfected with pBrn3b-HA-Syt I. Further, immunofluorescence staining was performed in whole-mount retinas to analyze the localization of ectopic Syt I expression. By immunostaining transfected RGCs with HA antibodies, ipRGCs with melanopsin antibodies, and SACs with ChAT antibodies, we found that 25% of HA-labeled cells demonstrated immunoreactivity against melanopsin and 85% of HA-labeled cells showed immunoreactivity against Brn3. By constrast, only ~5% of colocalization was found between HA-labeled cells and ChAT-labeled cells. Thus, our analysis indicated that the Brn3b promoter may drive ectopic Syt I expression in a population of ipRGCs, suggesting that ipRGCs may play a role in mediating Syt I's regulation of retinal waves during development.

**Abstract:** For many vertebrate animals, the nervous system undergoes a drastic rewiring between birth and adulthood. This process, known as synapse elimination, is essential to normal development, but little is understood about the mechanisms that make it work, especially in the central nervous system. To study the developmental changes that occur during the earliest phase of synaptic rewiring in the cerebellum, we have used high-throughput electron microscopy to trace out the synaptic connections between climbing fibers and Purkinje cells in mice at postnatal days 3 and 7. Our analysis shows that many more climbing fibers innervate developing Purkinje cells than previously estimated and that each climbing fiber innervates a group of nearby Purkinje cells. Throughout the first postnatal week these climbing fibers functionally differentiate by adding synapses, as opposed to changing the sizes of existing synapses or removing them. Specifically, climbing fibers preferentially add synapses onto Purkinje cells they already strongly innervate, so that by the end of the first postnatal week typically one or at most a few climbing fibers dominate each cell. As they add synapses onto some target cells, climbing fibers remain weakly connected with others. These results argue that the eventual dramatic phase of climbing fiber synapse elimination in the cerebellum does not occur until a dominant climbing fiber is designated for each Purkinje cell.

**Title:** Stromalin is a master regulator of synaptic vesicle biogenesis

**Authors: *A. PHAN**[1], C. I. THOMAS[3], M. CHAKRABORTY[2], J. A. BERRY[2], N. KAMASAWA[3], R. L. DAVIS, Prof[2]
[2]Neurosci., [1]The Scripps Res. Inst., Jupiter, FL; [3]Max Planck Florida Inst., Jupiter, FL

**Abstract:** The proper wiring of neural circuits during critical periods is necessary for proper adult cognitive function. However, the mechanisms required to orchestrate the precise wiring of memory systems remain unclear. Here we show that *stromalin*, a subunit of the cohesin complex known to be important for cell division, plays a role in *Drosophila* memory formation. We were surprised to find Stromalin knockdown (KD) in dopaminergic neurons (DAn) increased aversive olfactory memory acquisition. Strikingly, using a temperature-inducible RNAi expression system, we found that Stromalin KD in DAn during the 3$^{rd}$ instar larval stage was both necessary and sufficient to increase memory scores in adult flies. To elucidate how Stromalin affects DAn to enhance memory, we performed functional imaging experiments to examine DAn to mushroom body neuron (MBn) communication, which is important for the formation of olfactory aversive memory. Interestingly, we found Stromalin KD in DAn resulted in an increased cAMP signal generated in the MBn upon DAn stimulation, but that the DAn themselves did not have increased $Ca^{2+}$ responses to the stimulation. Thus, Stromalin KD in DAn strengthened the functional connection between DAn and MBn, which appears to underlie the enhanced memory acquisition seen in these flies. To probe the mechanisms behind this strengthened connection, we next examined whether Stromalin KD produced neuroanatomical effects in DAn. While the cohesin complex is known for its role in cell division, KD of Stromalin did not change DAn cell numbers, nor did it obviously affect their morphology. Stromalin KD did however increase levels of the presynaptic marker synaptotagmin:GFP (syt:GFP) in the DAn innervating the MB lobe. We showed, using super resolution structured illumination microscopy (SIM) of syt:GFP, that Stromalin KD did not affect the number or size of DAn synapses. We then turned to electron microscopy to image synaptic vesicles in DAn of the fly brain. Surprisingly, Stromalin KD DAn had 2-fold greater numbers of synaptic vesicles and dense core vesicles than control neurons. This appears to underlie the strengthened DAn to MBn connection. Remarkably, we report here that Stromalin KD does not affect the

neuroanatomy or network connectivity of DAn, but specifically increases the strength of otherwise normal connections by increasing synaptic vesicle numbers at the synapse. Our data demonstrate that the role of Stromalin is to developmentally suppress memory acquisition and synaptic strength by negatively regulating synaptic vesicle biogenesis. **Title:** Spontaneous activity and mitochondrial dynamics during synapse development

**Authors: *C. SILVA**[1], M. V. F. BUSCH[3], M. V. ZWIETEN[4], C. LOHMANN[2]
[1]Netherlands Inst. For Neurosci., Amsterdam Zuidoost, Netherlands; [2]Netherlands Inst. For Neurosci., Amsterdam, Netherlands; [3]Netherlands Inst. for Neurosci., Amsterdam Zuidoost, Netherlands; [4]Univ. of Amsterdam, Amsterdam, Netherlands

**Abstract:** Developing neurons constantly undergo functional and structural plasticity as they establish and eliminate synaptic contacts. Synapses are extremely energy demanding and mitochondria, the major ATP providers, are transported throughout axons and dendrites presumably to meet these high-energy demands at developing synapses. Furthermore, defects in mitochondrial motility can lead to impaired synaptic function and plasticity.
During development, spontaneously generated activity fine-tunes synaptic connectivity. Previous studies have shown that artificially enhancing activity arrests mitochondria at synapses. It is unknown, however, whether spontaneously occurring activity affects mitochondrial dynamics in the developing cortex, and, in turn, the formation of cortical networks. To address this question, we performed calcium imaging in organotypic slices and *in vivo* and investigated the relationship between spontaneously occurring calcium transients and mitochondrial motility during synapse development.
In organotypic slices obtained from P5 mice and kept in culture for 3 to 6 days (P5+DIV3-6), the average percentage of moving mitochondria, at a given moment, was 5.3% ± 3.6%. There were no differences in mitochondrial motility at different days *in vitro*. However, in slices obtained from older mice (P8+DIV3), mitochondrial motility was lower (1.5% ± 1.0%). *In vivo* (P8-11), the percentage of moving mitochondria was very low (0.1% ± 0.1%). Preliminary data showed

that at P5/6 *in vivo*, mitochondrial motility was 3.8% ± 0.9%. Together, this suggests a developmental decrease in mitochondrial motility *in vivo* that is not replicated in slice cultures. When we investigated the relationship between mitochondrial motility and spontaneously occurring calcium transients; neither *in vitro* nor *in vivo*, we found evidence that individual spontaneously occurring calcium transients could directly affect mitochondrial motility.
We observed, however, that stationary mitochondria seem to accumulate in stretches of dendrite with higher synaptic density.
We are currently further investigating the details of mitochondrial motility throughout synapse development, as well as the relationship between stationary mitochondria and synapses.

**Title:** Synergistic action of mAChR receptors,adenosine receptors and TrkB receptors in synapse elimination during neuromuscular junction development

**Authors: *N. GARCIA**, L. NADAL, E. HURTADO, A. SIMÓ, M. TOMÀS, V. CILLEROS, M. A. LANUZA, J. M. TOMÀS
Univ. Rovira i Virgili, Reus, Spain

**Abstract:** The development of the nervous system involves an initially exuberant production of neurons, which establish an excessive number of synaptic contacts, and the subsequent reduction in both neurons and synapses as maturation proceeds. Hebbian competition between axons with different activities leads to the loss of roughly half of the neurons initially produced so connectivity is refined and specificity gained. The skeletal muscle fibers in the newborn neuromuscular junction (NMJ) are polyinnervated by several motor axons but by the end of the axonal competition, two weeks later, the endplates are innervated by a single axon. This peripheral synapse has long been used as a convenient model for synapse development.We used quantitative confocal imaging of the autofluorescent axons from transgenic B6.Cg-Tg (Thy1-YFP)16 Jrs/J and C57BL/6J mices to investigate the possible cooperation of the muscarinic autoreceptors (mAChR, $M_1$-, $M_2$- and $M_4$-subtypes), adenosine receptors (AR, $A_1$- and $A_{2A}$-

subtypes) and the TrkB receptor in the control of axonal elimination after the mice *Levator auris longus* muscle (at P9) had been exposed to several selective antagonist of the corresponding receptor pathways *in vivo*. We investigated the effect of simultaneous incubation with two inhibitors (two antagonists of two different receptor subtypes) as a pharmacological tool for revealing the possible occlusive or additive crosstalk effects between the corresponding receptors.We found that a potent effect of the $M_2$ receptor is largely independent of the other receptors in favouring axonal competition and loss. However, the other receptors ($M_1$, $M_4$, $A_1$, $A_{2A}$ and TrkB)cooperate and add their respective individual effects to increase axonal elimination rate. Thus both, cooperative and non-cooperative signaling mechanisms contribute to developmental synapse elimination in the neuromuscular system.This work was supported by a grant from the Catalan Government (2014SGR344) and a grant from MINECO (SAF2015-67143-P).

**Title:** BMP signaling modulates presynaptic neurotransmitter release in *Drosophila* neuromuscular junction synapses

**Authors: S.-H. LEE**[1], Y.-J. KIM[2], *S.-Y. CHOI[2]
[1]Dent. Res. Inst., [2]Seoul Natl. Univ., Seoul, Korea, Republic of

**Abstract:** Regulation of synaptic structure and function via interaction between presynaptic and postsynaptic neurons is critical to neural functions. In particular, Bone morphogenic protein (BMP) is a secreted molecule mediating retrograde signaling that is involved in the formation and maintenance of synaptic structure throughout many animal species. However, how BMP signaling modulates presynaptic neurotransmitter release is not yet clear. We studied the function of BMP signaling factors in neurotransmitter release in Drosophila neuromuscular synapses using loss-of-function mutants in genes for BMP modulators, Wit, Mad, and Dad. Larvae with mutations in wit and mad commonly showed a decreased synaptic bouton number in neuromuscular synapses. Larvae with dad mutations showed an increased bouton number. The

amplitudes of miniature EJC (mEJC) were normal for these mutants. Wit and mad mutants showed decreased evoked EJC (eEJC) amplitude and increased paired pulse facilitation, implying impaired presynaptic neurotransmitter release. We found a reduction in readily releasable neurotransmitters pool sizes in wit and mad mutants. However, dad mutants showed a normal probability of neurotransmitter release and readily releasable pool sizes and normal eEJC amplitude even with clear abnormalities in synaptic structure. These results suggested that BMP signaling was critical for each step of presynaptic neurotransmission. The results also suggested that BMP signaling modulated both synaptic structure and function independently and specifically.

**Title:** ArhGAP22 is a new regulator of spines development and function

**Authors: *A. LONGATTI**[1,2], L. MURRU[1], L. PONZONI[3,4], E. MORETTO[1], M. SALA[1], M. PASSAFARO[1]
[1]CNR-IN, Milano, Italy; [2]DiSFeB, Univ. of Milan, Milan, Italy; [3]Biometra, Univ. of Milan, Milano, Italy; [4]Fondazione Umberto Veronesi, Fondazione Umberto Veronesi, Italy

**Abstract:** ArhGAP22 is a member of the RhoGTPase-activating protein (GAP) family. It is involved in many processes in eukaryotic cells including organization of cytoskeleton, regulation of cell polarity, gene transcription and vesicular trafficking. In particular, one of the main function of ArhGAP22 is the inhibition of Rac1, a protein involved in cytoskeleton remodeling and in dendritic spines morphology.
The main aim of this project is to define molecular and functional mechanisms underlying biological properties of ArhGAP22 in nervous system taking advantage of a mouse model knockout (KO) for ArhGAP22. In fact, although previous works demonstrated that ArhGAP22 is expressed in brain (cortex, cerebellum, hippocampus) and preferentially in the post-synaptic compartment of excitatory synapses, specific mechanism and functional consequences of its activity in neurons have not been demonstrated yet.
Since ArhGAP22 is a selective inhibitor of Rac1, we analyzed the levels of active Rac1 in adult mouse brain. Rac1-GTP levels are significantly increased in KO mice. Moreover, since Rac1 is a positive regulator of dendritic spine formation, we performed morphological analyses of excitatory synapses in hippocampus. KO mice showed an increase in dendritic spines density and an altered morphology.

In parallel, we analyzed the effect of ArhGAP22 knock down on the expression profile of several pre and post -synaptic markers in hippocampal synaptosomes deriving from WT and KO mice. Surprisingly, western blot experiments showed that KO mice had a significative reduction of AMPAR GluA1 and GluA2/3 subunits expression.
To explore the functional role of ArhGAP22, we studied electrophysiological properties of hippocampal neurons of WT and KO mice. Although there were no differences in CA3-CA1 synapses baseline function and release probability between the two genotypes, LTP induction at the CA3-CA1 synapse was strongly impaired in KO mice compared to WT. Furthermore, we tested ArhGAP22 KO mice in several behavioral tests. Significant alterations in anxiety and learning/memory profiles have been observed.
Overall, these data suggest that ArhGAP22 silencing in mice leads to marked deficits in hippocampal-dependent cognitive functions. These alterations could be explained by abnormal dendritic spines number and maturation together with altered AMPA receptors composition.

**Title:** Role of serotonin signaling on synaptic plasticity in tuberous sclerosis complex

**Authors: *W. FRANCESCONI**[1], R. KIRCHNER[2], F. BERTON[3], A. YOSHII[4]
[1]Dept. of Anat. and Cell Biol., Univ. of Illinois Chicago, Chicago, IL; [2]Biostatistics, Harvard Chan Sch. of Publ. Hlth., Boston, MA; [3]Anat. and Cell Biol., Univ. of Illinois at Chicago, Chicago, IL; [4]Dept of Anat. & Cell Biol., UIC, Chicago, IL

**Abstract:** Tuberous sclerosis complex (TSC) is an autosomal dominant genetic disorder caused by mutations in *TSC1* or *TSC2*. While it is a multi-organ disease, neurological symptoms are prominent and include epilepsy, intellectual disabilities and autistic behaviors. Dysregulated synapse formation and plasticity is likely to play a major role in pathophysiology of TSC. The TSC-1 and -2 proteins form a complex that downregulates the mammalian target of rapamycin (mTOR) pathway, and a gene mutation results in mTOR overactivation. mTOR is a critical regulator of protein synthesis as well as synaptic plasticity. Consequently, suppression of mTOR by rapamycin or its derivatives is one way to correct the pathophysiology of TSC. However, mTOR pathway has multiple roles and rapamycin neither specifically nor completely cures all

neurological symptoms. A greater understanding of dysregulated synaptic function will enable identification of specific therapeutic targets for epilepsy and cognitive disabilities in TSC. To identify the cause of these abnormal synaptic activities, we conducted an RNA-seq analysis and found an excess of transcripts associated with the serotonin signaling pathway. The amount of protein was also higher and its intracellular distibution was altered in pyramidal cells of the *TSC1*$^{-/-}$ cortex. We used calcium imaging and found that *TSC1*$^{-/-}$ cultured cortical neurons had frequent $Ca^{2+}$ bursts throughout the soma and dendrites that depended on a specific serotonin pathway while wildtype neurons showed random and scattered transients mostly within dendritic spines. Furthermore, daily injection of the sertonin pathway antagonist rescued the premature death of the mutant pups. Our results indicate synaptic dysregulation in TSC can be corrected by modulating serotonergic pathway and set the stage for developing a new therapeutic approach.

**Title:** Altered perineuronal net structure in Ptprz1 knockout mice

**Authors: *G. J. EILL**, *G. J. EILL, A. SINHA, R. T. MATTHEWS
Neurosci. and Physiol., Upstate Med. Univ., Syracuse, NY

**Abstract:** A unique lattice-like substructure of neural extracellular matrix (ECM), perineuronal nets (PNNs), are key regulators of plasticity in the mature central nervous system (CNS). PNNs are found on a subset of neurons in the CNS, for example, they are prominently surrounding parvalbumin interneurons in the cerebral cortex. Despite their limited distribution, they profoundly impact developmental plasticity in areas such as the visual cortex as well as plasticity in numerous brain regions in the adult. The prominent role in these processes has led to their implication in multiple neuropsychiatric disorders, neurodegenerative disease and recovery after injury. However, despite clear evidence for a role of PNNs in regulating neural function, their exact molecular composition and structure is not well understood, which, in turn, has made it difficult to determine precise molecular function of PNNs. From previous work, PNNs are composed of a hyaluronan backbone saturated with an array of hyaluronan-binding chondroitin sulfate proteoglycans (CSPGs), link proteins, and glycoproteins. Previous work has suggested that in addition to the hyaluronan-binding CSPGs (primarily members of the lectican family), the CSPG RPTPζ/phosphacan is localized in PNNs. Receptor-type protein tyrosine phosphatase zeta

(RPTPζ), and a secreted splice variant (phosphacan), are derived from the *Ptprz1* gene and have been implicated in a variety of developmental processes. RPTPζ/phosphacan is interesting among the CSPGs because not only can it serve typical ECM functions, but direct signaling functions as well. However, the contribution of RPTPζ/phosphacan to PNN structure and function is not well understood. Using *Ptprz1* KO mice we investigated PNN formation via immunohistochemistry and biochemical techniques. We found that in the cortex and hippocampus, PNNs were severely disrupted in the absence of RPTPζ/phosphacan. Further analysis using cell culture and biochemical techniques revealed that RPTPζ/phosphacan mediates key interactions between known components of the PNN and the cell surface of net-bearing neurons. Therefore, our work demonstrates that RPTPζ/phosphacan is a central player in the formation of PNNs. We further disected how membrane bound versus secreted splice-variants of *Ptprz1* contribute to the formation and structure of PNNs. Overall, this work sheds new light on the structure of PNNs and is an important step towards understanding PNN function.

**Title:** Synaptic pruning and phenylketonuria

**Authors: *G. M. RUNE**, G. SCHLEGEL
Univ. Hamburg, Hamburg, Germany

**Abstract:** High levels of phenylalanine in serum due to mutations of the gene coding for the enzyme phenylalanine hydroxylase are considered to account for mental retardation in Phenylketonuria. In the hippocampus, which is related to learning and memory, of corresponding mutants ($Pah^{enu2}$) with high levels of phenylalanine, we found delayed synaptic pruning thus higher synaptic density. Physiologically, synaptic pruning is aimed at elimination of weak synapses by microglia and required for rearrangement of synaptic connectivity after birth. The delay in synaptic pruning in the $Pah^{enu2}$ mouse was consistently associated with reduced neuronal activity and reduced C3 complement expression, which is essential for activation of microglia. In order to control whether these effects are actually caused by high concentrations of phenylalanine in serum of these mutants, we studied the effects of the amino acid on synaptic connectivity in hippocampal cultures, where microglia was either absent or unaffected by elevated levels of phenylalanine. Unlike in the $Pah^{enu2}$ mouse, synapse density and dendritic length were dramatically reduced in hippocampal slice cultures and dispersion cultures respectively, indicating strong neurotoxic capacity of high levels of phenylalanine. Changes in

the p-/n-cofilin ratio, which were rescued by increasing neuronal activity, and reduced activation of the small GTPase Rac1 likely underlie structural alterations. Since C3 complement expression, which is required for microglia recruitment, was reduced in the $Pah^{enu2}$ mouse but not in hippocampal slice cultures, our data strongly suggest a two-fold effect of mutations in the gene coding for phenylalanine hydroxylase: reduced C3 complement accounts for increased synapse density due to delayed synaptic pruning, while the supraphysiological levels of phenylalanine impair neuronal activity followed by synapse loss and reduced dendritic length.

**Title:** Mesoscale calcium imaging of neonatal cortical connectivity

**Authors: *C. CROSS**, J. AGULLO CAMPELLO, M. C. ASHBY
Univ. of Bristol, Bristol, United Kingdom

**Abstract:** Early postnatal life is a period of rapid neuron growth, migration and synaptogenesis. With these anatomical developments, come changes to the functional activity of neural networks, but it is not yet fully understood how and when these changes occur, or when the network reaches a mature state. Activity in the primary sensory cortex in response to peripheral stimuli is not always present at birth, with different sensory modalities emerging at different stages. Spontaneous neural activity occurs before sensory inputs shape the network, also contributing to network maturation, including modulating of axon guidance and synaptic plasticity. The developing patterns of activity in the neuronal network of the cortex in early postnatal life are the focus of this study, using recordings of both spontaneous activity, and responses to sensory stimuli. It is hypothesised that both types of network activity will change with age, converging towards a mature pattern of activity. To assess cortical activity with high temporal and spatial resolution in the neonatal mouse brain, we used imaging of the genetically-encoded calcium indicator, GCaMP6. Emx1-IRES-cre (Jax # 005628) and Ai95d (Jax # 024105) mice were crossed to obtain offspring expressing the calcium indicator protein GCaMP6f in excitatory cortical neurons. Following removal of the scalp and implantation of a miniature head-fixation post, the cortex of awake neonatal pups was imaged using a tandem lens fluorescence macroscope. Spontaneous and sensory stimulus-evoked cortical activity was imaged at 50Hz, alongside recording of body movements by mechanical and optical sensors. This approach

allows the measurement of activity across almost the entire cortical surface at a resolution of ~50μm$^2$. Using this, we assessed the development of cortical activity patterns across neonatal maturation. Cortical activity, both spontaneous and triggered by somatosensory stimulation, is present from postnatal day 1. During postnatal maturation patterns of spontaneous and evoked activity undergo significant changes, including an increase in the frequency of spontaneous events and alterations in the spatial organisation of activity that suggest maturation of inter-regional connectivity. As such, we have assessed the developmental profile of early cortical network activity. This approach is not only useful for informing of the mechanisms of ontogenetic development, it can also offer a template for comparison with animal models of disease, providing a new mode of investigating aberrant neural network development.

**Authors: *J. GRAF**[1], C. ZHANG[1], O. W. WITTE[1], C. A. HÜBNER[2], K. HOLTHOFF[1], K. KIRMSE[1]
[1]Hans-Berger Dept. of Neurol., [2]Inst. of Human Genet., Jena Univ. Hosp., Jena, Germany

**Abstract:** The developmental shift from depolarizing to hyperpolarizing GABAergic responses is a widely accepted developmental concept. The shift reflects a change in the intracellular chloride concentration in postsynaptic neurons which, in most cell types, is due to a differential expression of the chloride importer NKCC1 and the chloride exporter KCC2. Whereas the mechanisms of change in GABA signaling are well understood, the developmental impact on network maturation is still under debate. To address this issue, we here generated a mouse line with a conditional deletion of NKCC1 in cortical glutamatergic neurons. Electrophysiological recordings from CA3 pyramidal cells *in vitro* confirmed that NKCC1 deletion attenuated the depolarizing-excitatory effects of $GABA_A$ receptor-activation, whereas miniature IPSCs and EPSCs were found to be unaffected. Confocal $Ca^{2+}$ imaging revealed a strong reduction of highly synchronized network activity in hippocampal slices of conditional knock-out mice,

similarly to acute pharmacological inhibition of NKCC1. In addition, *in vivo* wide-field $Ca^{2+}$ imaging in the hippocampal CA1 region unveiled a minor reduction in the frequency of network events without significant effects on spatial extent, amplitude or kinetics. Conversely, local pharmacological block of $GABA_A$ receptors profoundly increased both frequency and amplitude of network events *in vivo*. In summary, our preliminary data support the view that in neonatal mice depolarizing GABAergic transmission can both facilitate and profoundly inhibit the generation of hippocampal network activity in a context dependent manner.

**Authors: *A. S. KHAKHALIN**[1], C. D. AIZENMAN[2]
[1]Biol., Bard Col., Annandale on Hudson, NY; [2]Dept Neurosci, Brown Univ., Providence, RI

**Abstract:** One of the important open questions in connectomics and neuroscience is whether feature detection in small networks relies more on specialized cells with highly selective input connections, or on distributed activation of sparse neural networks. In this study, we use in-vivo high acquisition rate calcium imaging to record network activation in the optic tectum of Xenopus tadpoles, while these networks respond to visual stimuli delivered to the tadpole eye. We first describe overall patterns of activity in tectal networks, and provide a classification of visually evoked responses in individual tectal cells. We then use several alternative computational methods (based on either coupled linear models or machine learning, and with different underlying assumptions) to reconstruct elements of tectal network topology from its activation data. While it is impossible to fully reconstruct network topology from a recording of a subset of its neurons in a situation of shared driving inputs, we attempted to correct for some of these complications using data-based modeling and hidden parameters sensitivity analysis, and report reliable differences between connectivity estimates for cells selective to either looming stimuli or full-field visual flashes. We then compare estimations of network topology and selectivity of individual tectal cells in older tadpoles to that in animals at earlier stages of development, to better describe the trajectory of functional network maturation and connectomic

reorganization. Finally, we propose a computational model of tectal network development that relies on spike-time-dependent plasticity, homeostatic plasticity, and reinforcement learning, to provide a general framework for the emergence of looming selectivity in visual sensory cells.

**Title:** Short-term plasticity and vesicle pool replenishment at inhibitory synapses of the auditory brainstem: Adaptations and refinements after hearing onset

**Authors: *D. J. WEINGARTEN**[1,2], N. MÜLLER[1], E. FRIAUF[1], H. VON GERSDORFF[2]
[1]Animal physiology group, TU Kaiserslautern, Kaiserslautern, Germany; [2]Vollum Inst., Oregon Hlth. & Sci. Univ., Portland, OR

**Abstract:** Mammals have evolved the ability to accurately pinpoint the location of high frequency sounds in the horizontal plane. This requires an auditory system that can distinguish sound signals that differ by minute amounts of intensity. Indeed, reliable synaptic transmission is a hallmark of the ascending auditory pathway where highly specialized excitatory synapses allow the processing of auditory information with exquisite temporal precision. However, less is know about how inhibitory synapses shape the processing of sound signals after hearing onset. Here we investigated the inhibitory synapses of the lateral superior olive (LSO) in the mouse auditory brainstem. A speeding of evoked excitatory and inhibitory postsynaptic currents (EPSCs & IPSCs) has been observed in the LSO during postnatal development. Yet, if changes occur in the presynaptic parameters remains unclear. Using whole-cell patch clamp recordings in acute brainstem slices we characterized inputs from the medial nucleus of the trapezoid body (MNTB) and the cochlear nucleus (CN) to principle neurons of the LSO (MNTB-LSO and CN-LSO synapses) via electrical stimulation of the respective axons. Recordings were done at 36±1°C from pre-hearing mice at postnatal day P10-12 and young adults at P28-34. Evoked IPSCs of MNTB-LSO synapses showed a 2-fold speeding of their kinetics from P10-12 to P28-34. In addition, IPSC onset latency was reduced from ~1 ms to below 500 µs (P10-12: n=9, P28-34: n=14). Miniature IPSCs (mIPSCs) showed a 2-fold speeding of their kinetics between both age groups. Furthermore, whereas mIPSC amplitudes remained unchanged around 25 pA, the

spontaneous mIPSC frequency doubled from 3 to 6 Hz. Via application of high-frequency stimulation trains (50 pulses of 50, 100, and 200 Hz) the readily releasable pool (RRP) and the delay and extent of vesicular replenishment in both ages were estimated. Surprisingly, a strong reduction of RRP vesicles from 600 to 200 vesicles was observed (P10-12: n=13, P28-34: n=7), whereas, the vesicular release probability tripled after hearing onset from 5 to 15%. To cope with this accelerated emptying of the RRP, MNTB-LSO synapses stimulated at 50 Hz showed a shorter onset of replenishment, which shifted from 150 ms to 100 ms (P10-12: n=13, P28-34: n=7). In both age groups this onset became shorter with higher stimulation frequencies, hinting at a $Ca^{2+}$-dependent mechanism. Introducing gaps of different lengths (10-5000 ms) in between stimulation trains revealed an increased $Ca^{2+}$-dependent RRP replenishment in P28-34. In summary, the mature MNTB-LSO synapse has remarkably fast and resilient presynaptic machinery for replenishing synaptic vesicles.

**Title:** Impaired topographic map refinement and synaptic strengthening of an inhibitory auditory microcircuit in Otoferlin knock-out mice

**Authors: *N. MÜLLER**[1], M. SONNTAG[2], E. FRIAUF[1]
[1]Animal Physiol. Group, TU Kaiserslautern, Kaiserslautern, Germany; [2]Paul Flechsig Inst. for Brain Res., Leipzig, Germany

**Abstract:** During development, sensory neural circuits are established broadly and become subsequently refined prior to sensory input in an activity-dependent manner involving spontaneous activity. In the auditory system, the impact of spontaneous activity on circuit refinement is much less described than in other sensory systems, especially for inhibitory projections. Spontaneous prehearing activity is generated in the cochlea, and the activity pattern is conserved in downstream nuclei. To analyze the isolated role of spontaneous activity on circuit refinement of the inhibitory projection from the medial nucleus of the trapezoid body (MNTB) to the lateral superior olive (LSO), we studied P11 Otoferlin$^{deaf5/deaf5}$ mice (Otof). Otoferlin is highly expressed in the inner ear, but not in MNTB and LSO. Otof mice show a strongly reduced vesicle exocytosis from inner hair cells. In line with this, *in vivo* recordings in the MNTB suggest

a lower number of active units. Furthermore, the frequency of residual MNTB activity was reduced and showed atypical patterns. Focal flash photolysis of caged glutamate in the MNTB while recording from LSO neurons in acute slices of Otof mice revealed a 2-fold broader mediolateral and dorsoventral input width. This strongly implies impaired synapse elimination, resulting in a distorted and imprecise topographic map. Besides synapse elimination, synaptic strengthening is a hallmark of circuit refinement. To assess this issue, we recorded from LSO neurons in acute slices while stimulating MNTB fibers with stepwise increasing stimulus intensities resulting in gradual recruitment of converging MNTB fibers. The number of MNTB fibers in Otof mice was increased by 50%, confirming the impaired elimination seen in the glutamate uncaging experiments. Furthermore, the single fiber strength was reduced by 40%, demonstrating impaired synaptic strengthening. To reveal its origin, we determined quantal parameters and found a 40% lower quantal content per MNTB fiber. We obtained further insight into the mechanism of strengthening via fluctuation analysis. The reduced quantal content was due to 40% fewer release sites per fiber, while the release probability and the number of vesicles released from a release site were normal. In conclusion, we demonstrate the requirement of spontaneous prehearing activity in topographic map refinement and strengthening of the inhibitory MNTB-LSO circuit. Our findings are novel in that they address effects of missing spontaneous activity restricted to the cochlea. This contrasts to other deafness models (VGlut3 and Cav1.3), in which relevant proteins are abolished both in the cochlea and the central auditory system.

**Abstract:** Spike Timing-Dependent Plasticity (STDP) is a strong candidate for a synaptic mechanism involved in development and in learning and memory. We have previously shown in the hippocampus that a post-before-pre pairing protocol (pairing postsynaptic action potentials with EPSCs at 0.2 Hz) produced robust input-specific t-LTD and that the induction of this form of LTD was completely blocked by D-AP5, by the broad spectrum mGluR antagonist MCPG, and that this form of t-LTD is present only until the third week of development. The goal of this work was to determine the mechanisms responsible for the closure of this plasticity window. We performed experiments in the CA1 region of hippocampal slices prepared from P13-P28 mice using the whole-cell configuration of the patch-clamp technique. To induce t-LTD, a post-pre pairing protocol (with the presynaptic activity occurring 18 ms after a postsynaptic action potential) was applied. We found that a post-before-pre pairing protocol was unable to induce a significant depression at P22-P28 (103 ± 6%, n = 7) in contrast to the t-LTD observed at P13-P18 (74 ± 6%, n = 8). The lack of t-LTD at P22-P28 was not due to an increase in GABAergic inhibition during development as in the presence of bicuculline or gabazine no t-LTD is observed at P22-P28 (98 ± 6%, n = 7). By contrast, in the presence of A1 adenosine receptor antagonists (as 8CPT), t-LTD is present at P22-P28 (76 ± 9%, n = 8), thus suggesting the involvement of A1R in the closure of the plasticity windows. These results suggest that spike timing-dependent depression disappears during the fourth week of development due, at least in part, to an increase of inhibition mediated by the activation of adenosine A1 receptors.

**Title:** A role for integrin beta 3 in dendritic spinogenesis and pruning in cerebral cortex

**Authors: K. M. BLAND**, Z. O. CASEY, C. J. HANDWERK, Z. L. HOLLEY, *G. S. VIDAL Biol., James Madison Univ., Harrisonburg, VA

**Abstract:** Dendritic spinogenesis and pruning in the cerebral cortex is a normal developmental process. Early in postnatal development, the cerebral cortex normally overproduces dendritic

spines, and then undergoes a period in which spines are pruned away, leaving behind spines that are postsynaptic sites of excitatory synapses important for neural function. Dysregulation of spine pruning in excitatory neurons of the cerebral cortex may lead to neurological disorders such as schizophrenia and autism spectrum disorder. Itgb3 is an autism susceptibility gene and integrin beta 3 KO in mice leads to decreases in callosal, striatal, and hippocampal volume. While it is known that integrin beta 3 forms heterodimers with integrin alpha V in neurons, it is unknown what functional role integrin beta 3 has in shaping cortical circuits early in life. To answer this, here we labeled layer II/III pyramidal neurons of mouse cerebral cortex via in utero electroporation and examined their dendritic spine density immediately before eye opening and 1-2 weeks later. Loss of function of integrin beta 3 was achieved by in utero electroporation of Cre recombinase to a mouse line with loxP sites flanking exon 1 of Itgb3. Results show that control but not Itgb3 KO neurons followed a timeline of increased dendritic spine density from P14 and P23 followed by decreased dendritic spine density between P23 and P30. Taken together, results from histological preparations suggest periods of dendritic spinogenesis and spine pruning in layer II/III of cortex that may be regulated by integrin beta 3.

**Title:** MicroRNA-218 regulates early postnatal synchronized activity to promote proper hippocampal network function

**Authors: *S. R. TAYLOR**[1], G. LIPPI[1], M. KOBAYASHI[2], J. J. FAK[2], C. GIRGISS[1], J. LIU[1], R. B. DARNELL[2], D. K. BERG[1]
[1]Neurobio. Section, Biol. Sci., UCSD, La Jolla, CA; [2]Lab. of Mol. Neuro-Oncology, The Rockefeller Univ., New York, NY

**Abstract:** The development of functional mature neural networks relies on coordinated genetic programs and neural activity that together establish and refine patterns of connectivity. In the early postnatal rodent hippocampus, synchronized activity is thought to be crucial for network

formation. During the second postnatal week, network activity transitions from early, immature patterns to more complex, mature patterns. MicroRNAs (miRs) are promising candidates for regulating such transitions, as each miR is capable of modulating up to hundreds of genes. We hypothesized that miR-218 regulates hippocampal development because it increases in expression in the first two postnatal weeks, is highly abundant in the adult, is down-regulated in some forms of epilepsy, and putatively targets many genes involved in neural development and activity. We tested the roles of miR-218 *in vivo* using a locked nucleic acid (LNA) antagonist followed by *ex vivo* slice calcium imaging and dendritic spine analysis. We find that transient inhibition of miR-218 *in vivo* alters synchronized activity in an age-dependent manner, causing long-lasting changes in hippocampal activity. Transient inhibition of miR-218 in the first three postnatal weeks increased both the number of spontaneously active cells and the spontaneous activity per cell in hippocampal area CA3 at postnatal day 40-45 (P40-45). Testing the effects of miR-218 inhibition on early patterns of activity revealed that blockade of miR-218 starting at P2 decreased the frequency of synchronized activity at P5, but increased synchronized event frequency at P8 in CA3. Acute blockade of $GABA_A$ receptors with picrotoxin similarly altered synchronized activity at P5 and P8. Additionally, early blockade of miR-218 resulted in a decrease in spine density in stratum radiatum of CA1 at P11. Hi-throughput RNA profiling using RNAseq revealed multiple activated genes upon miR-218 inhibition, including factors involved in synapse formation, neurite outgrowth, and neurotransmission. These results indicate that miR-218 is essential for fine-tuning early patterns of spontaneous activity that promote proper mature network function.

**Title:** A non-sensory activity based checkpoint for interneuron wiring in the olfactory system

**Authors: *B. THROESCH**, K. N. JAMES, K. K. BALDWIN
Mol. and Cell. Neurosci., TSRI, San Diego, CA

**Abstract:** The olfactory bulb (OB) is a dynamic system where newly born interneurons are integrated throughout the lifetime of an organism. The largest population of these interneurons are granule cells (GCs). While GCs are present at birth, additional precursors migrate into the OB where they mature and form reciprocal synapses with second-order projection neurons, mitral and tufted cells (MTs), continuously reshaping the OB circuit. Therefore, the olfactory system is an attractive model to identify signals that regulate the integration of neurons into a pre-existing neuronal circuit. To examine the impact of sensory vs non-sensory neuronal activity on OB circuit architecture, we selectively blocked neurotransmission from either olfactory sensory neurons or MTs using genetically encoded tetanus toxin. While the loss of sensory input has a modest effect, blocking MT signaling dramatically alters the structure of the OB. The increased disorganization is due to delayed maturation and increased cell death of most populations of inhibitory interneurons, including GCs. Single cell tracing analyses of GCs showed these neurons exhibit decreased dendritic branching as well as spine density, resembling immature GCs. Furthermore, this developmental blockade cannot be rescued by blocking apoptosis, uncovering a direct role for activity in regulating GC dendritic maturation. Transcriptome analyses of mature GCs and those stalled at activity-dependent developmental milestones identify gene regulatory networks that correlate with activity dependent maturation and functional integration. These studies establish a new role for non-sensory neuronal activity in regulating the development and integration of interneurons into adult circuits, which has implications for understanding olfactory coding and neurological disease.

**Abstract:** Cortical interneurons undergo extensive synaptogenesis and maturation of intrinsic properties during the first weeks after birth. In particular, parvalbumin (PV)-expressing interneurons go through a shift in their transcriptional profile during the second postnatal week, believed to be indispensable for their maturation. Because Sox6 is expressed in these cells throughout postnatal maturation, we investigated its role on late maturation and synaptic function and maintenance. For this, we utilized a conditional knockout strategy to specifically remove Sox6 in interneurons at different postnatal stages. Our results show loss of Sox6 in individual PV-cells (in otherwise wild type tissue) led to a robust decrease of size of PV interneuron axonal boutons contacting pyramidal neuron cell bodies, suggesting it to be a cell-autonomous effect. Furthermore, Sox6 was necessary for discrete aspects of cortical PV interneuron maturation independently of when it was removed (P7 or P21). By removing Sox6, although PV-expression was normal and their electrical properties mature, we observed a 30% decrease of PV-cells enwrapped by perineuronal nets (a hallmark for functional maturation). PV-cells lacking Sox6 also displayed reduced levels of TrkB-FL, which was sufficient to rescue the axonal phenotype when overexpressed in PV-cells lacking Sox6. Preliminary paired recordings of PV-cells and pyramidal neurons suggest that the decrease in bouton size leads to higher eIPSC failure rate. We are currently investigating if this role of Sox6 in PV-cells persists after adolescence.

**Title:** Developmentally specific expression and network function of cb1 receptors in the newborn rat cerebellum

**Authors: *J. L. BARNES**, D. J. ROSSI
Integrative Physiol. and Neurosci., Washington State Univ., Pullman, WA

**Abstract:** The type 1 cannabinoid receptor (CB1R) is widely expressed throughout the adult brain, especially the cerebellum, but while CB1Rs are also developmental neuromodulators, the

underlying mechanisms are not well understood. The cerebellum undergoes its most significant development during the third trimester of pregnancy, so *in utero* exposure to exogenous cannabinoids has the potential to alter cerebellar development. Thus, understanding how exogenous cannabinoids affect cerebellar developmental processes is important for providing usage guidelines for pregnant women, 3-6% of which consume cannabis during pregnancy, and for ascertaining potential therapeutic applications for neurodevelopmental disorders. Using immunohistochemistry, we find distinct CB1R expression in the third trimester-equivalent (PND 2-10) compared to adult (PND 30-35) cerebellar rat tissue: there is ubiquitous CB1R expression in all layers of the cerebellar cortex in developing tissue, whereas CB1R expression in adult tissue is more localized to the Purkinje and Molecular layers. CB1R staining was absent from all layers in CB1R knockout mice. In agreement with our immunohistochemistry studies, using whole-cell voltage-clamp recording in granule cells (GCs) of PND 2-14 rats, we found the CB1R agonist, WIN 55,212-2 (WIN; 5µM), reduces the frequency of both mossy fiber (MF) glutamatergic spontaneous EPSCs (sEPSCs) and Golgi cell GABAergic spontaneous IPSCs (sIPSCs). WIN also reduced the amplitude of the MF-evoked EPSC which was associated with an increase in the ratio of facilitation in paired pulse recordings. Lastly, WIN reduced the frequency of miniature EPSCs (recorded in TTX), which combined with the data above suggests that functional CB1Rs are expressed on MF axonal terminals. All actions of WIN were blocked by the CB1R antagonist SR141716A (2µM) and by germline genetic deletion of CB1R. In striking contrast to numerous studies in adult cerebellum, in voltage-clamped Purkinje cells (PCs), WIN did not affect sIPSC or sEPSC frequency. However, WIN did reduce MF-evoked disynaptic PC EPSC amplitude, suggesting cannabinoid effects on PCs stem from upstream activation of CB1Rs on granule cell synapses, despite apparent ubiquitous expression. In whole-cell voltage-clamp recordings from PND 30-35 GCs, WIN (5µM) did not affect sEPSCs, which combined with reduced immunostaining for CB1R in the adult GC layer, suggests that functional CB1Rs are only transiently expressed on incoming MF afferents during cerebellar development, but that their activation will also modify downstream output of developmental signals from GCs to developing PCs and possibly other developing neurons.

**Title:** Nicotine enhances depolarizing $GABA_AR$ synaptic currents and signal transmission through the developing cerebellar cortex

**Authors: *H. SHIINA**, D. J. ROSSI
Washington State Univ., Pullman, WA

**Abstract:** Cerebellar injury or exposure to exogenous toxicants during development causes neurodevelopmental disorders in the offspring, leading to long-term decrements in cognition, affect and motor coordination. The cholinergic system plays a critical role in cerebellar development, and perturbation of that system by perinatal exposure to nicotine, an exogenous agonist of the nicotinic acetylcholine receptor (nAChR), retards cerebellar development, and increases risk for several cerebellar associated neuropathologies. Unfortunately, 10% of pregnant women still smoke during pregnancy due to nicotine's addictive nature, and the recent advent and rapidly growing use of e-Cigarettes is causing a resurgence of nicotine use and addiction. Despite well-established deleterious impacts of nicotine, relatively little is known about the mechanisms by which nicotine affects cerebellar development. Here we determined how activation of nAChRs by clinically relevant concentrations of nicotine (100-700nM) affects synaptic physiology and signal transmission through the cerebellar cortex during a critical developmental period. We used patch-clamp recording of GABAergic and glutamatergic synaptic currents in migrating and post-migratory granule cells, as well as Purkinje cells (mig-, GCs and PCs, respectively) in cerebellar slices from newborn rats (PND 3-9, equivalent to the human third trimester of gestation), and bath-applied nicotine to simulate *in utero* exposure. In voltage-clamped GCs, nicotine significantly increased GABAergic transmission from Golgi cells to GCs. Using perforated patch to record from GCs with unperturbed $[Cl^-]_{in}$, we determined that the reversal potential of $GABA_ARs$ relative to resting membrane potential is positive, making GABA depolarizing at this age. Thus, the nicotine-induced increase in GABA release excited GCs, which in turn increased glutamatergic transmission to developing PCs and mig-GCs. Mig-GCs express NMDARs, which drives their migration, and the nicotine-induced increased glutamate release enhanced NMDAR-mediated single channel activity. In addition to nicotine tonically activating these nAChR driven cascades, concomitant desensitization of nAChRs also reduced responses to transient pulses of pressure ejected exogenous ACh, as presumably occurs *in vivo* from cholinergic afferents. Given that nicotinic, $GABA_A$ and NMDA receptors are heavily involved in neurodevelopmental processes, these data suggest that nicotine usurps several endogenous developmental signals, which likely alter cerebellar development and contributes to the known smoking-induced impacts on the cerebellum and related behaviors.

**Title:** Postnatal development of GABAergic-dependent brain oscillations during sevoflurane anesthesia in children 0 to 3 years old

**Authors: *L. CORNELISSEN**[1,2], S.-E. KIM[3], J. M. LEE[2], E. N. BROWN[3], P. L. PURDON[4], C. B. BERDE[2]
[1]Boston Children's Hosp. (EN311.1), Boston, MA; [2]Anesthesiology, Perioperative & Pain Med., Boston Children's Hosp. & Harvard Med. Sch., Boston, MA; [3]Brain & Cognitive Sci., MIT, Cambridge, MA; [4]Anesthesia, Critical Care, and Pain Mgmt., Massachusetts Gen. Hosp., Charlestown, MA

**Abstract: BACKGROUND**: GABAergic interneurons are thought to drive circuit development throughout childhood; disruptions of these processes underlie many developmental disorders. Trajectories for development of GABAergic brain circuits have been characterized in animal models, but are difficult to measure in humans. Translation of insights from animal models could be better informed with a more detailed understanding of how these circuits develop in humans. Anesthetic drugs act through a GABAergic mechanism, and induce GABA-dependent stereotyped oscillations that relate fundamentally to circuit architecture and function (mPFC, Thal). Preliminary studies suggest that the neurophysiologic response to anesthetic drugs changes as a function of age, particularly in the first year of life [1,2]. Each year millions of children are administered general anesthesia for surgery, providing an experiment of nature that makes it possible to characterize how the brain responds to a strong GABA stimulus as a function of age. We therefore analyzed in detail how sevoflurane-induced brain oscillations change across the first three years of life to inform the developmental trajectory of GABAergic inhibitory circuits.
**METHODS**: We used multichannel scalp electroencephalograph (EEG) recordings in 120 children undergoing sevoflurane general anesthesia for elective surgery, to determine transitions in EEG power spectra and coherence across early infancy (birth - 3 years) as a reflection of naturally shifting excitatory-inhibitory circuit balance. We mapped spatial power and coherence over frontal, central, parietal, temporal and occipital cortices. Coherence was estimated between frontal channels FP1-F7 and FP2-F8.
**RESULTS**: During a surgical state of anesthesia, EEG power spectral properties: (1) all children

had slow (0.1-1Hz) and delta (1 to 4Hz) oscillations across the entire scalp; (2) theta (4 to 7Hz) and alpha (8-12Hz) oscillations emerged around 3-4 months; (3) alpha oscillations increased in power with postnatal age; (4) frontal alpha power was significantly greater than occipital power from ~7 months onwards; (5) frontal slow and delta coherence was observed from birth until 3-4 months and (6) frontal alpha coherence was observed from 10 months onwards.
**CONCLUSIONS**: Our results reveal key developmental milestones in the assembly and maintenance of the GABAergic-thalamocortical circuits. These data help explain why EEG-based indices provide inaccurate measures of anesthetic states in children and potentially identify critical periods of plasticity.

**Title:** VIP interneurons mediate cortical phenotypes in a genetic model of schizophrenia

**Authors: *R. BATISTA-BRITO**[1], J. A. CARDIN[2]
[1]Neurobio., [2]Dept. of Neurobio., Yale Univ., New Haven, CT

**Abstract:** Schizophrenia is associated with altered cognitive and perceptual processing, as well as disruption of normal brain rhythms such as gamma oscillations (30-80Hz). Current evidence suggests that dysregulation of GABAergic interneurons contributes to neural and behavioral deficits in this disease. However, there are several major populations of interneurons and their respective roles in psychiatric disease remain poorly explored. Neuregulin 1 (*NRG1*) and its interneuron-specific tyrosine kinase receptor *ERBB4* are risk genes for schizophrenia. Using a conditional ErbB4 deletion model, we directly tested the role of vasoactive intestinal peptide (VIP)-expressing interneurons in schizophrenia-related deficits *in vivo*. ErbB4 removal from VIP interneurons during development leads to changes in their activity, along with severe dysregulation of the temporal organization and state-dependence of cortical activity. As a result of these neural circuit alterations, animals in which VIP interneurons lack ErbB4 exhibit reduced cortical responses to sensory stimuli and impaired sensory learning. Our data support roles for VIP interneurons in both normal cortical circuit development and the pathophysiology of

schizophrenia. These findings provide a new perspective on the role of GABAergic interneuron diversity in the disruption of cortical function in this complex psychiatric disease.

**Title:** Development of neuronal microcircuits in neocortex layer1

**Authors: *S. JIANG**[1], Y.-C. YU[2], X. YAO[2]
[2]Inst. of Brain Sci., [1]Fudan Univ., Shanghai City, China

**Abstract:** Layer 1 is the outermost layer of the cerebral cortex, which originated from the neocortical marginal zone (MZ). Many studies strongly implied that layer 1 neurons (L1-INs) play crucial roles in neocortical development, synaptic integration and information processing. However, the functional microcircuits of L1-INs remain incompletely quantified. Previously studies have shown that on the basis of their electrophysiological properties, L1-INs were classified into two subtypes, the burst spiking (BS) interneurons and the late spiking (LS) interneurons. In this study, combining whole-cell patch clamp recordings with immunohistochemistry and microelectrode dye filling technologies, we investigated the electrophysiological properties of different neuronal types and the development synaptic microcircuits in layer 1 of somatosensory cortex. We found that 79.7% of L1-INs are late spiking (LS), and 20.3% of them are burst spiking (BS). Moreover, we found that the electrical connections exhibit cell-type selectivity among neocortical L1-INs, the LS pairs have more proportions of electrically coupled than LS to BS and BS pairs, but the coupling coefficients between coupled pairs revealed no significant difference between interneuron subtypes. Furthermore, the unidirectional chemical synapses between LS-LS pairs was significantly higher than between LS-BS pairs and BS-BS pairs. The peak amplitude of unitary inhibitory postsynaptic current between LS pairs was significantly larger than that between LS-BS pairs and BS-BS pairs. The unidirectional chemical synapses between LS and BS pairs showed directional selectivity. The majority of unidirectional pairs formed connections from LS to BS,

whereas only small number of them formed connections from BS to LS. Overall, our results can provide new insights into the mechanism of fundamental cortical computation involved by the superficial layer of the neocortex.

**Title:** Investigating synaptic plasticity and the balance of protein palmitoylation-depalmitoylation in the pathogenesis of a pediatric neurodegenerative disorder

**Authors: *K. P. KOSTER**[1], W. FRANCESCONI[2], F. BERTON[2], A. YOSHII[2]
[1]Dept. of Anat. and Cell Biol., [2]Anat. and Cell Biol., Univ. of Illinois at Chicago, Chicago, IL

**Abstract:** The neuronal ceroid lipofuscinoses (NCLs) are a class of progressive pediatric neurodegenerative diseases. The infantile form, CLN1, causes visual failure, seizures, developmental regression and death by age 10. The cardinal neuropathological finding of all NCLs is the accumulation of proteolipid material, lipofuscin, which is readily visualized as autofluorescent lipopigment (AL) using fluorescence microscopy. Interestingly, AL is also identified in prominent neurodegenerative disorders, including Alzheimer's disease, suggesting conserved degenerative mechanisms. CLN1 is an autosomal recessive disorder caused by mutations in palmitoyl protein thioesterase 1 (PPT1), a depalmitoylating enzyme. Consequently, protein metabolism is dysregulated, leading to AL deposition. However, it remains unclear whether AL accumulation correlates with impaired synaptic functions in CLN1. Further, while the balance of palmitoylation-depalmitoylation is critical for synaptic protein function, the mechanisms by which mutations in PPT1 disrupt this balance and, thus, drive synaptic dysfunction in CLN1, are unknown. We first investigated the relationship between synaptic plasticity, protein palmitoylation and AL deposition in PPT1-knockout (KO) primary neuronal cultures and found: 1) ALs accumulate in PPT1-KO cells immediately following mature synapse formation, and 2) modulating neuronal activity or protein palmitoylation-depalmitoylation directly impacts this AL deposition. Next, we examined AL accumulation in the visual cortex (VC) of PPT1-KO mice as progressive visual failure is among the first clinical symptoms of CLN1. While AL deposition had previously been described only in adult PPT1-KO mice, we found the accumulation of AL immediately after eye opening at post-natal day (P) 14 in the PPT1-KO VC. Remarkably, AL accumulation appeared first in layer IV of the VC, the termination site of thalamocortical projections. Together, these results suggest that neuronal activity regulates the balance of protein palmitoylation-depalmitoylation and affects AL

accumulation. In the future, we aim to biochemically and electrophysiologically define key synaptic mechanisms underlying the relationship between neuronal activity, protein palmitoylation-depalmitoylation and the accumulation of AL, particularly as it pertains to the progressive synaptic dysfunction and cell death in CLN1. Importantly, novel therapeutic strategies for this monogenic disorder will have broader implications for adult-onset neurodegenerative diseases.

**Title:** Maternal regulation of pups' cortical activity: Role of serotonergic signaling

**Authors: E. COURTIOL**[1], D. A. WILSON[3], R. SHAH[1], R. M. SULLIVAN[3], *C. M. TEIXEIRA[2]
[2]EBI, [1]Nathan Kline Inst., Orangeburg, NY; [3]Child and Adolescent Psychiatry, New York Univ. Sch. of Med., New York, NY

**Abstract:** Neuronal activity during development shapes the new wiring and connectivity in the emergent brain. In this period of heightened plasticity the brain is shaped to adapt to the environment it will encounter. It is also a period of heightened vulnerability to factors that can derail adaptive brain development. Recently, pup cortical activity has been found to be influenced by maternal interactions, the major environmental input at this stage. It has been shown, using local-field-potential (LFP) recordings in behaving rat pups (P12-P19), that nipple attachment was related to an increase in low frequency neural activity while the absence of the mother from the nest was associated with decreased low frequency neural activity. The maternal interactions during early-life are thus a critical factor modulating pups neuronal activity. However, the mechanisms underlying these changes of neural activity are still not understood. Serotonin is a key neuromodulator involved in brain development. Postnatal life is a critical period when serotonergic activity can regulate the development of neuronal circuitry and specifically emotional neurocircuitry. For instance, increasing serotonergic signaling during postnatal days 2 to 11 (P2-P11) with a selective-serotonin-reuptake inhibitor (SSRI) has been shown to lead to emotional deficits in the adult. Furthermore, maternal tactile stimulation regulates glucocorticoid receptor expression via activation of the serotonergic system. Serotonin in the maternal brain is known to regulate maternal care. However, little is known on how maternal care regulates pups' brain activity. In our study, we found evidence suggesting that: (a) maternal presence increases LFP power in low-frequency bands in P11 rat pups; (b)

serotonergic signaling through 5-HT2 receptors is necessary for this modulation; and (c) enhancing serotonergic signaling, using a SSRI, in isolated P11 rat pups produces an enhancement in LFP power in low-frequency bands similar to the effect produced by maternal presence. Our results suggest a contribution of the serotonergic system in mediating changes of cortical activity in pups related to maternal care.

**Abstract:** The development of a functional nervous system is characterized by the generation and specification of a diverse array of neuronal subtypes that subsequently form an integrated system. This process is orchestrated by both intrinsic and extrinsic molecular signals. One of the key signals is calcium, a ubiquitous and essential messenger that plays an important role during various developmental processes from neural induction through synapse establishment. While a great deal is known regarding the role of calcium in the adult nervous system, far less is known regarding the widespread calcium activity prior to synapse establishment. Using *Xenopus laevis* primary neuronal cell culture, we show that at neurula stages neuronal progenitor cells exhibit frequent small amplitude spikes that span shorter duration and presumptive neurons fated to differentiate exhibit higher amplitude spikes spanning longer duration. However, the pattern, regularity, cellular molecular phenotype of calcium active cells and the underlying molecular mechanism(s) of this activity during early embryonic neural development remains unknown. Therefore, in this project we extend our investigation to an *in vivo* system and monitor calcium activity in *X. laevis* embryos during neural development using genetically encoded calcium markers and identify phenotype of the cells employing *in situ* hybridization and immunocytochemistry. We have developed a system to correlate molecular cellular phenotype of individual cells and their calcium dynamics that entails calcium imaging using GCaMP and

memRFP followed by in situ hybridization with genetic markers and immunocytochemistry against RFP. Preliminary closeness centrality analysis of *in vivo* calcium recordings revealed correlated clusters of cells as well as highly connected cells that may define important domains for early neurogenesis.

**Abstract:** Establishment of precise neuronal connectivity in the neocortex relies on activity-dependent circuit reorganization in postnatal development; however, the nature of cortical activity during these periods remains largely unknown. Using two-photon calcium imaging of the barrel cortex during the first postnatal week, here we found a “patchwork-type” spontaneous activity, which was confined to the barrel map. In the absence of whisker-stimulation, layer 4 (L4) neurons belonging to the same barrel fired together. By generating transgenic mice expressing GCaMP6s in the thalamocortical (TC) axons, we showed that TC axon termini also exhibited the patchwork activity. This activity was diminished by peripheral anesthesia but

mostly uncorrelated with whisker movements. In the second postnatal week, the patchwork pattern disappeared and L4 neurons even within the same barrel fired in a desynchronized manner. The patchwork-type spontaneous L4 activity has features that are suitable as the template for TC circuit refinement in the neonatal barrel cortex.

**Title:** Elucidating the organization and regulation of lipid nanodomains on neuronal plasma membrane

**Authors:** ***M. J. DEEPAK**, D. KUMARAN NAIR, V. CHAUHAN
Indian Inst. of Sci., Bengaluru, India

**Abstract:** Lipid rafts (LR) are sphingolipid-enriched nanodomains on the plasma membrane which act as organizing centres for the assembly of signaling molecules influencing membrane fluidity. Several studies indicate the crucial role of lipid rafts in diverse biological processes such as cell division, development, migration, and organogenesis. Unfortunately, the precise physiological role as well as nanoscale organization remains elusive due to their small size and dynamic character with lifetimes varying from milliseconds to seconds. Previous studies on lipid rafts have shown that they are highly mobile structures on the plasma membrane with their size ranging from 10-200 nm. Conventional microscopy techniques for imaging protein-lipid interactions at the cell membrane are limited by optical diffraction, which does not allow characterization of structures below 200 nm. This calls for recently developed single molecule based superresolution techniques such as PALM (Photoactivation Localization Microscopy) and SPT-PALM (single particle tracking-PALM), which allow resolving structures few tens of nanometres apart by controlling the fluorophore emission and activation. SPT-PALM (single particle tracking-PALM) allows to address in living cells in real-time the nanoscale regulation of the transient lipid nanodomains at a resolution multifold better than the conventional microscopy techniques. Here, we try to elucidate the organization and regulation of lipid nanodomains on neuronal plasma membrane using single molecule based superresolution imaging to understand its relevance in diverse biological processes.

**Title:** Mother-pup interactions and oxytocin during early brain development

**Authors:** ***P. P. MALDONADO**[1], A. NUNO-PEREZ[1], Y. HAN[2], M. CARRILLO[2], P. DE GOEDE[3], A. KALSBEEK[3], C. KEYSERS[2], C. LOHMANN[1]
[1]Synapse and Network Develop., [2]Social Brain Lab., Netherlands Inst. For Neurosci., Amsterdam, Netherlands; [3]Dept. of Endocrinol. and Metabolism, Academic Med. Ctr. (AMC), Amsterdam, Netherlands

**Abstract:** Spontaneous network activity occurs before birth and during early postnatal brain development. This type of activity regulates the establishment of synaptic connections and subcellular compartments in order to prepare the brain before it can fully experience the environment. Though the senses of vision and hearing and most motor abilities become functional around the second postnatal week in rodents, tactile and odor cues are already perceived at birth, playing a significant role during mother-pup interactions in the nest. Moreover, natural occurring differences in maternal care behaviors such as licking and grooming affect adult brain functions. How brain development process is affected by this type of early social experience has not yet been investigated. Associated with adult social behaviours and already expressed during prenatal development, the neuropeptide oxytocin (OT) and OT receptors (OTR), are good candidates to mediate the effects of mother-pup interactions on brain development. Thus, here we aim to address the role of OT on spontaneous neuronal activity of primary visual cortex (V1). As shown by *in vivo* 2-photon calcium imaging recordings in layer II/III of V1, OT decreases the frequency of spontaneous calcium network events. *In vitro*, OT increases the frequency of inhibitory postsynaptic currents (IPSCs) without affecting excitatory postsynaptic currents (EPSCs). This OT-mediated increase in inhibition is concomitant with an increase in the excitability of somatostatin interneurons upon OTR activation. Moreover, by performing large-field calcium imaging recordings we observed that OT-mediated inhibition is selective to V1, without affect somatosensory cortex (S1). Consistently with this observation, OT has a balanced effect in S1, increasing the frequency of both IPSCs and EPSCs, therefore leading to a zero net effect of OT on synaptic activity. Finally, we used primi- and multiparous mouse mothers as a model to study the effect of differential maternal interactions on OT and OTR levels in the neonatal mouse brain. Our preliminary data suggest that OT and OTR mRNA levels, as

obtained from the cortex and the hypothalamus of mouse pups, are differentially modulated depending on the degree of maternal experience. Together, our results reveal that OT exerts specific cellular and network effects in the developing V1, changing the inhibitory-excitatory balance towards inhibition. Moreover, these results give evidence for a role of maternal interactions on postnatal brain development.

**Abstract:** Autism spectrum disorder (ASD) is a highly prevalent neurodevelopmental disorder and the exact causal mechanism is unknown. Dysregulated allele-specific expression (ASE) has been identified in persons with ASD; however, a comprehensive analysis of ASE has not been conducted in a family quartet with ASD. To fill this knowledge gap, we analyzed ASE in a family quartet with ASD (one of the two offspring had been diagnosed with ASD) by using genomic DNA from both parents and offspring's and RNA from offspring's' postmortem prefrontal cortex (PFC). DNA- and RNA-sequencing revealed distinct ASE patterns from PFCs of both offspring. Noteworthy, only the PFC of the offspring with ASD exhibited a mono-to-biallelic switch for two autism susceptibility genes. We have also identified novel RNA-editing and monoallelically-expressed genes and miRNAs. These results demonstrate the prevalence of ASE in human PFC and ASE abnormalities in the PFC of a person with ASD and may provide mechanistic insights for the pathogenesis of ASD.

**Abstract:** Neurodevelopmental disorders (NDD), such as autism and schizophrenia have a diverse and multi-faceted etiology that is poorly understood, though epidemiological studies suggest that environmental risks such as prenatal infections or other gestational immune events correlate with increased NDD risk. It is also known that there is strong heritability of NDDs, providing evidence that genetic predisposition for such disorders exist. Innate immune responses are evoked by toll-like receptor (TLR)-dependent signaling pathways, and TLR4 selective (bacterial) mimetic-mediated maternal immune challenges have been shown to result in brain and behavioral changes (as reviewed by Meyer 2014). Previously, we demonstrated that a TLR4-selective insult at E12.5 has adverse effects on fetal and placental health, proliferation of radial glial cells, altered cortical laminar patterning in the adult and behavioral deficits (Carpentier et.

al 2013). Here, we aim to determine if heterozygous expression of autism susceptibility genes act synergistically with TLR4-selective insult during mid-gestation to impact the developing fetus. Placental pathology and pregnancy outcomes were evaluated by quantifying tissue necrosis and fetal survival, respectively. Neocortical alterations in the developing fetuses were examined via immunohistochemistry for markers of cell proliferation and neural progenitor cell populations. Finally, behavioral outcomes were measured using tasks that evaluate behaviors analogous to the symptoms of NDDs, including pup vocalizations, social approach and marble burying. Thus far, we have observed increased placental hemorrhage and decreased fetal viability when mice heterozygous for an autism risk gene were exposed to bacterial infection. Behavioral analysis is ongoing. Our results have implications for understanding how environmental insults may act synergistically with genetic susceptibilities to induce greater levels of affection in individuals.

**Title:** Differential methylation across multiple tissues as a means of determining causality in Autism Spectrum Disorder

**Authors: *E. L. BEARER**[1], B. S. MULLIGAN[2], J. M. STEPHEN[3]
[1]Dept. of Pathology, UNM Sch. of Med., Albuquerque, NM; [2]Pathology, Univ. of New Mexico Hlth. Sci. Ctr., Albuquerque, NM; [3]Mind Res. Network, Albuquerque, NM

**Abstract:** In 2016 the CDC announced that 1 in 68 Americans are diagnosed with Autism Spectrum Disorder (ASD), with an estimated $265 billion a year (2015) attributed to care. ASD often cannot be reliably diagnosed until age 2 because children present neurotypically until that point in development, but current practice standards are inexact: 57% of children identified with autism do not receive their diagnosis until after age 3, and white children are up to 1.6 times more likely to be diagnosed than minority children. In order to diagnose ASD earlier, improvements in objective testing are needed. Genetic differences have been identified for various subtypes of this disorder, such as Rhett syndrome, but no single unifying DNA alteration has yet been found. Hence we propose that a global epigenetic change, possibly affecting one

gene or across the genome, that impacts the development of the nervous system in a child who will develop ASD that would not happen in a neurotypical (NT) child, and will be identifiable across a comparison of multiple tissues. We predict that this change in epigenetic status will be detected earlier than the behavioral manifestations, and further that these changes are environmentally regulated and thus would be targets for therapy. To test this, we recruited children with ASD and not (NT) for interviews and sample collection. From these children, 11 individuals' saliva was sequenced with an Illumina HumanMethylation450 BeadChip, 6 NT and 5 ASD. NT and ASD brain samples from a separate study analyzed on the same platform were used for cross comparison between tissues. After initial processing yielded little variation between ASD and NT whole genome DNA methylation (DNAme) patterns, saliva cell composition was found to be somewhat different, 62.419%( +/- 6.585%) keratinocyte (K) in ASD saliva samples and 57.639% (+/- 9.135%) K in NT samples, with a total average composition of 59.478% (+/- 7.850%) K, with the remaining being whole blood. This difference was enough to believe that reference-based cell type deconvolution is needed. After correction, ASD-driven whole-genome variation is more detectable between ASD and NT in saliva samples. Similar corrections made in the brain samples, and then the two compared again. This yielded a single gene with evidence to suggest differential methylation had taken place in the gene's promoter region. This gene's role in neural development and maintenance proves interesting for future exploration into the mechanism by which developing brains become autistic.

**Title:** Histone binding protein, PHF21A, is required for rapid induction of cAMP-responsive immediate early genes

**Authors: *R. S. PORTER**[1], Y. MURATA-NAKAMURA[1], H. NAGASU[1], H.-G. KIM[2], S. IWASE[1]

[1]Human Genet., Univ. of Michigan, Ann Arbor, MI; [2]Obstetrics and Gynecology, Augusta Univ., Augusta, GA

**Abstract:** Given the prevalence of neurodevelopmental disorders (NDD) such as syndromes of intellectual disability (ID) and autism spectrum disorders (ASD), there has been a great effort to identify genetic causes of these early cognitive disorders. Recent studies have identified a number of transcriptional, synaptic, and interestingly many histone methylation regulating genes. Histone H3 lysine 4 methylation (H3K4me) is the most extensively regulated histone modification in eukaryotes. Out of the 13 known enzymes that place and remove H3K4me marks, eight have been implicated in NDDs, as well as multiple H3K4me reader proteins that recognize the mark and recruit effectors. One such is example is Potocki Shaffer Syndrome, a rare neurodevelopmental syndrome associated with microdeletion of a region of Chromosome 11p11.2. Genetic evidence has implicated haploinsufficiency of *PHF21A*, which encodes a histone-binding protein, as the likely cause of intellectual disability and craniofacial abnormalities in Potocki Shaffer Syndrome. Previous work, however, has not investigated the molecular consequences of reduced *PHF21A* expression and how it leads to a cognitive phenotype. In this study, we analyzed the transcriptomes of two patient-derived cell lines with heterozygous loss of *PHF21A* compared to unaffected individuals by RNA-Sequencing and identified 1,885 genes that were commonly misregulated. Despite using lymphoblastoid cells, pathway analyses of the misregulated genes showed significant enrichment of genes involved in neuronal development and synaptic plasticity. Specifically, cAMP-mediated signaling was among the top downregulated pathways. Through luciferase reporter assays, we found that *PHF21A* is required for full induction of a CRE-Luciferase reporter following stimulation by the cAMP analog, forskolin. Furthermore, patient cells stimulated with forskolin showed a delayed induction of immediate early genes (IEGs) compared to control cells. IEG induction, by pathways including cAMP-signaling, is a key initial step in learning and memory. Our results suggest that an inefficient transcriptional response to cAMP-signaling might be involved in the pathology of *PHF21A* deficiency. This study emphasizes the importance of dynamic chromatin regulation in the temporal response to external stimuli. Furthermore, this work sheds light on the molecular mechanism that underlies intellectual disability in Potocki Shaffer Syndrome and may extend to other syndromes of intellectual disability associated with disruption of chromatin regulating genes.

**Title:** Maturation of corticospinal tracts in children with congenital hemiplegia using diffusion tensor imaging

**Authors: *C. PAPADELIS**[1], M. RUBENSTEIN[1], H. L. KAYE[2], K. KAPUR[3], B. SNYDER[4], E. GRANT[6], A. ROTENBERG[5]
[1]Newborn Med., [2]Dept. of Neurology, Div. of Epilepsy and Clin. Neurophysiol., [3]Neurol., [4]Orthopedic Ctr., [5]Boston Children's Hosp., Boston, MA; [6]Div. of Newborn Med., Boston Childrens Hosp., Boston, MA

**Abstract: Objectives:** The corticospinal tracts (CSTs) are among the first white matter tracts to mature. During brain maturation, CSTs are susceptible to injury leading to neurological deficits, often resulting in the clinical presentation of cerebral palsy. Our objective is to describe changes in the developmental trajectory of CSTs maturation as a function of age in children with congenital hemiplegia and typically developing children. **Methods:** Diffusion tensor imaging (DTI) was performed in 13 children with congenital hemiplegia (7 females; 14.02 years ± 5.14; range: 6 to 17 years) and 16 age-matched typically developing children (9 females; 11.9 years ± 3.56; range: 7 to 18 years) with a 3-T MR scanner. The CSTs were reconstructed passing through brainstem and the pre-central gyrus using TrackVis software. The mean number of fibers, fractional anisotropy (FA), apparent diffusion coefficient (ADC), axial diffusivity (AD), and radial diffusivity (RD) of the CSTs were estimated for each participant and hemisphere. For each child with congenital hemiplegia, a pediatric radiologist identified a more affected (MA) and a less affected (LA) hemisphere. Each child in the typically developing group was assigned to have a MA hemisphere according to the matched congenital hemiplegia participant's side of damage. Analysis was performed using linear mixed-effects regression model with random intercept to account for within subject correlations for each diffusion measure. The fixed-effects in the model included age, injury side, group and all possible higher order interaction terms. The final model selection was performed using Akaike Information Criterion. **Results:** In the congenital hemiplegia group, AD, ADC, and RD increased linearly with age ($p<0.001$). This relationship was not present in the typically developing children in either hemisphere. For the congenital hemiplegia group, the linear relationship between the ADC and RD with respect to age was more pronounced for the MA compared to the LA hemisphere ($p<0.01$). In both groups, and in both hemispheres, the number of fibers and the FA did not change as a function of age. **Conclusions:** We identify for the first time that white matter injury in the brain of children with congenital hemiplegia slows the normal maturation of CSTs. These radiographic findings provide insight into both normal motor system development, and into the development of the motor system in the setting of early life brain injury.

**Abstract:** Autism spectrum disorder (ASD) is a developmental neuropsychiatric disorder characterized by a wide range of clinical manifestations and genetic heterogeneity. This complex genetic landscape poses a serious challenge for efforts to find a relationship between genotype and clinical phenotype. Therefore, the disorder remains poorly understand, and diagnostic and treatment tools are lacking. Though genetic overlap between patients is low, many mutations in autism likely affect stereotyped biological pathways, resulting in subgroups of autistic patients with similar functional mutation burden. The central hypothesis of this study is that patients with functionally similar mutations can be clustered together in order to reveal previously unidentified groups that share both molecular mechanisms and disease related cognitive traits.
This study describes the construction and application of a novel algorithm for genomic sub- type detection in ASD using graph clustering and a subject distance function that is based on gene ontology, a database that describes the functional relationship of genes. Using the Autism Speaks MSSNG Database, a large set of paired genetic sequencing and clinical data, it is shown that resulting subject clusters are defined by both unique and convergent involvement of genetic pathways, which provides insight into the variety of disease mechanisms that may be present in ASD. These potential mechanisms are validated at the cellular level by connecting the clustering algorithm with data from ASD patient derived neurons. Finally, cluster memberships are associated with differences in clinical and cognitive variables, validating the medical utility of the genomic subtypes. Genome clustering in autism is an important step towards defining both mechanistic and clinical subtypes in this complex disorder, and this study addresses a growing need for algorithmic tools that connect genotype to phenotype in the context of heritable mental illnesses.

**Abstract:** The general chromatin remodeling gene *CHD8* has received high levels of interest since emerging as a top candidate causal gene in Autism Spectrum Disorder (ASD) via patient sequencing studies. Studies of mouse and human iPSC models have validated the relevance of *CHD8* mutations to neurodevelopmental disorders (NDDs), yet specific mechanisms by which haploinsufficiency impacts gene regulation during brain development remain unknown. We generated a mouse line harboring a loss-of-function frameshift allele of *Chd8* and show that heterozygous mice exhibit macrocephaly and cognitive deficits but do not exhibit gross laminar or structural cortical defects. Differential gene expression and co-expression network analysis of $Chd8^{+/-}$ forebrain revealed perturbation to biological processes and pathways across developmental stages, from proliferation through neuronal migration and maturation to synaptogenesis. ChIP-seq performed on mouse forebrain showed that Chd8 interacts with many regulatory elements genome-wide, but is strongly enriched for promoter interaction of genes associated with RNA processing and chromatin organization. Many RNA processing and chromatin-associated genes directly targeted by Chd8 exhibit decreased expression in $Chd8^{+/-}$ brain, indicating regulatory activity of Chd8 is dosage-sensitive. Our findings suggest a model where Chd8 acts to set the epigenomic state of cells in the developing brain, with haploinsufficiency resulting in attenuation of cellular differentiation and identity. We verified increased neuronal proliferation and global perturbation of RNA splicing during brain development in $Chd8^{+/-}$ embryos. Alterations to chromatin structure and transcriptional regulation identified in $Chd8^{+/-}$ mice may represent generalizable mechanisms underlying NDD neuropathology produced by loss-of-function mutations to chromatin remodeling factors.

**Abstract:** The Simons VIP consortium spearheaded a genetics-first approach towards autism (Neuron, 2012). Here we explored the influence of copy number variation (CNV) of a recurrent ~600 kb (BP4-BP5) microdeletion of 16p11.2 using resting-state functional connectivity. Twenty-six 16p11.2 deletion carriers and 42 age-matched controls were included. A significant portion of carriers harbored language impairment (Phonological Processing Disorder 15/25; Language disorders 10/25), and social impairment (ADI 10/18; ADOS 7/25; Clinical ASD 5/25). The intrahemispheric correlation matrix of deletion carriers showed preservation of large-scale network architecture. Local and distant connectivity was estimated using prior methodology (Sepulcre et al., 2010). The degree of local and distant connectivity was computed for the number of links $r>0.25$ using a 16mm radius. The mean global sum of degree connections did not significantly differ for local ($t=-1.39$, $p=0.18$) or distant ($t=1.21$, $p=0.23$) connectivity between groups. The data did not support a uniform, global process consistent with the *theory of underconnectivity* in autism (Just et al., 2004). Nor did it support the more recent *dysconnectivity model* of decreased distant & increased local connectivity (Uddin et al., 2013; DeMartino et al., 2013). Regional differences in degree were observed at $p<0.05$, but no regions survived FDR correction. Next, we found differential links - or distinct connectivity between groups - to be non-uniformly distributed across the cortex. Local correlations significantly differed at the auditory cortex, insula, middle-posterior cingulate and the paracentral gyrus at $p<0.001$, FDR

corrected. In distant connectivity, the auditory cortex and insula were again present, but additionally the inferior parietal lobule, left middle frontal gyrus, right inferior frontal gyrus, posterior mid-cingulate & posterior cingulate sulcus, and dorsal & anterior medial prefrontal cortex were regions with the greatest differential links at $p<0.001$, FDR corrected. To visually demonstrate topographical displacement of connectivity a seed-based analysis was run as proof-of-principle. This analysis suggested functional connectivity differences between separate large-scale resting-state networks. These functional correlation differences are discussed in the context of other analyses of resting-state data.

**Abstract:** Epigenetic modifications confer stable transcriptional patterns in the brain, and both normal and abnormal brain function involve specialized brain regions, yet little is known about brain region-specific epigenetic differences. Here, we compared prefrontal cortex, anterior cingulate gyrus, hippocampus and nucleus accumbens from 6 individuals, performing whole genome bisulfite sequencing for DNA methylation. In addition, we have performed ATAC-seq for chromatin accessibility, and RNA-seq for gene expression in the nucleus accumbens and prefrontal cortex from 6 additional individuals. We found substantial neuron- and brain region-specific differences in both DNA methylation and chromatin accessibility which were largely non-overlapping, and were greatest between nucleus accumbens and the other regions. In contrast, glial methylation and chromatin were relatively homogeneous across brain regions, although neuron/glia ratios varied greatly, demonstrating the necessity for cellular fractionation.

Gene expression was also largely the same across glia from different brain regions and substantially different for neurons. Expression was correlated with methylation and accessibility across promoters and known enhancers. Several classes of transcription factor binding sites were enriched at regions of differential methylation and accessibility, including many that respond to synaptic activity. Finally, both regions of differential methylation and those of differential accessibility showed a surprising >10-fold enrichment of explained heritability associated with addictive behavior, as well as schizophrenia- and neuroticism-associated regions, suggesting that common psychiatric illness is mediated through brain region-specific epigenetic marks.

**Abstract:** Mutations of the gene encoding the chromatin remodelling factor CHD8 have been identified as one of the strongest autism risk factors to date. Autism is characterized by behavioural deficits, including impairments in social interaction and communication, as well as alterations in brain structure and connectivity. In addition to autism, *CHD8* haploinsufficiency is associated with macrocephaly and developmental delay. We developed several mouse lines to investigate the effects of *Chd8* deficiency on brain development and behaviour. *Chd8* heterozygous mice exhibited complex behavioural abnormalities including increased interest in social cues and hypo-activity. These anomalous behaviours were accompanied by a 2.7% increase in brain volume, with volumetric increases in autism-associated areas, including frontal cortex and hippocampus. Due to the unusual complement of abnormal behaviours identified in *Chd8* heterozygous mice, we explored whether these structural brain and behavioural phenotypes could be exacerbated by further decreasing *Chd8* expression to around 40% of wild-type levels. Indeed, $Chd8^{neo/neo}$ mice, homozygous for a hypomorphic $Chd8^{neo}$ allele, displayed more pronounced structural brain changes than *Chd8* heterozygous mice, with a 4.5% increase in total brain volume. Behavioural anomalies were largely similar to heterozygous mice, and included hypo-activity and an increased predisposition to anxiety but no social deficits or other autism-associated behaviours. To gain insight into altered neural circuitry that could underlie the anomalous behaviours we observed, we performed resting-state functional MRI (rs-fMRI) in *Chd8* heterozygous mice. The results from these studies will be presented. Overall, our work suggests that threshold differences may exist between mice and humans, where *Chd8* levels even below 50% are not sufficient for mice to develop autism-associated behaviours. Future work will aim to investigate atypical neural circuitry underlying observed behavioural phenotypes and to establish a causal association of such abnormalities with dysregulation of molecular developmental pathways arising from *Chd8* deficiency.

**Title:** Evaluating the effect of high-frequency beta oscillations on sleep and cognition in Dup15q syndrome

**Authors: *V. SARAVANAPANDIAN**[1], R. BHATT[2], J. T. LERNER[2], S. S. JESTE[3]
[1]Neurosci., [2]Pediatric Neurol., [3]Psychiatry and Biobehavioral Sci., UCLA, Los Angeles, CA

**Abstract:** Duplications of 15q11.2-13.1 (Dup15q Syndrome) is one of the most common copy number variations associated with autism spectrum disorders (ASD) and is characterized by global developmental delay, hypotonia, intellectual disability (Battaglia et al., 2010) and an increased risk for epilepsy (Conant et al., 2014). This 15q region harbors genes critical for brain development, including three $GABA_A$ receptor genes. Recent studies in our lab have identified that children with Dup15q syndrome show an electrophysiological biomarker characterized by increased resting state beta power, compared with non-syndromic ASD cohort and typically developing children, and this EEG signature strongly resembles that induced by allosteric modulation of $GABA_A$Rs suggesting the biomarker may reflect disruptions in GABAergic tone (Frohlich et al, 2016). Brain rhythms vary across different states and this neuromodulation supports learning and cognition. Our study aims to evaluate the stability of high beta oscillations across brain states and investigate its the functional consequences. Specifically, we hypothesize that: a) High beta oscillations seen during resting will persist during sleep in Dup15q; b) Persistent beta oscillations in the brain may inhibit brain-state-dependent modulation of neural activity, therefore disrupt sleep architecture, which can affect cognition. We have a cohort of 12 Dup15q children (average age: 6.8yrs) with overnight sleep recordings from UCLA hospitals. Preliminary qualitative assessments of 10mins of continuous sleep EEG from all participants revealed sustained beta oscillations in sleep. Using EEGLAB, sleep and wake (resting state before entering into sleep) data from one participant was processed and beta power computed across 9 scalp regions of interest to confirm the presence of beta oscillations in both brain states. Emerging evidence suggests that sleep plays a critical role in healthy cognitive function. Over the next few months we will quantify EEG beta power during sleep and characterize sleep in Dup15q behaviorally. We will determine if there is a relationship between beta power in sleep and standardized questionnaires of sleep quality as well as cognitive and developmental questionnaires. We hypothesize that increased beta power in sleep will correlate with poor sleep quality and potentially more cognitive impairment. Stability of beta power across different brain states would underscore the hypothesis that high beta EEG signature seen in Dup15q is related to the underlying genetic mechanisms and may be a true biomarker for the syndrome which may serve as an important target for clinical and pharmacologic intervention.

**Abstract:** The serine/threonine kinase Glycogen Synthase Kinase-3 (GSK3), part of the canonical WNT signaling pathway, has been implicated in multiple human diseases, including neurological and psychiatric disorders. Several converging lines of evidence make GSK3 an attractive target for the treatment of psychiatric disease. First, a growing number of direct genetic associations for WNT signaling have been established in bipolar disorder, schizophrenia, and autism. Secondly, the rapid anti-depressant effects of ketamine may depend on GSK3 signaling. There are two paralogs of GSK3, α and β, and while numerous dual GSK3α/β inhibitors have been reported, none possess paralog selectivity. This lack of selectivity has plagued their clinical development due to elevation of β-catenin levels, a known toxic consequences of dual inhibition. To circumvent this toxicity, we identified small molecule isoform selective inhibitors of GSK3α and GSK3β and used them to delineate the biological function of each paralog. We probed the contribution of the GSK3 paralogs to the pathophysiology of Fragile X syndrome (FXS) in *Fmr1*$^{-/y}$ mice and found that pharmacological inhibition of GSK3α, but not GSK3β, corrects excessive basal protein synthesis and susceptibility to audiogenic seizures. Inhibition of GSK3α additionally reversed other FXS-relevant phenotypes, including sensory cortical hyperexcitability and deficits in learning and memory, but does not induce the known liabilities of $mGlu_5$ inhibitors. We are currently pursuing phosphoproteomic analysis to understand the mechanisitic underpinning of the selective effect of GSK3α inhibition and its impact on FXS biochemical signaling. Our results indicates that GSK3α selective inhibitors may offer a new treatment of FXS and related disorders.

**Abstract:** Fragile X-associated tremor/ataxia syndrome (FXTAS) is a late onset neurodegenerative disorder caused by a premutation (PM) of the Fragile X Mental Retardation (*FMR1*) gene, which is a CGG trinucleotide expansion of 55-200 repeats in the 5'UTR. The clinical symptoms of FXTAS include intention tremor, gait ataxia, cognitive decline. This PM can alter *FMR1* transcription and translation, more importantly, it is susceptible to repeat-associated non-AUG (RAN) translation that produces a toxic peptide, FMRpolyG. In the brain, the cellular pathology of FXTAS is marked by cell loss, or brain atrophy, as well as the presence of ubiquitin-positive intranuclear inclusions. While most male PM carriers will not show the signs of FXTAS until after the age of 50, research in mouse models indicates that the disease process may actually begin much earlier in life. In fact, in a dox-inducible mouse model of the PM, only 8 wks of expressing an ectopic CGG repeat alone is sufficient to produce the FXTAS hallmark cellular pathology, ubiquitin-positive intranuclear inclusions. Here, we investigated cell type-specific contributions in FXTAS pathogenesis using a doxycycline (dox)-inducible transgenic mouse model that ectopically expresses a CGG(90) repeat selectively in neurons. By giving inducible mice different dox treatments, we are able to assess FXTAS disease progression (comparing 8 vs 20wk on) and the potential for disease reversibility (8wk on, followed by a 12wk off). To assess disease progression, inducible mice were screened using a battery of behavioral assays followed by a variety of histological studies to characterize cellular pathology.

The mice show mild behavioral changes associated with the symptoms of FXTAS patients. Histological analysis revealed that these inducible mice produce FMRpolyG and ubiquitin-positive intranuclear inclusions. By comparing different time points, we determined that the number and size of inclusions increases over time in the inducible PM mice. These mice also show significant cell loss in key brain regions. Unexpectedly, we also identified the presence of inclusions that did not appear to reside within neurons. We hypothesize that these inclusions could be remnants of dead neurons, inclusions in non-neuronal cells, or extracellular inclusions. Further analysis may identify a novel mechanism of disease progression and transmission which, in turn, would aid in the development of treatments. Collectively, these results indicate that ectopic CGG(90) expression in neurons is sufficient to produce FXTAS-associated pathology in mice and supports the hypothesis of a RAN-associated mechanism underlying FXTAS pathogenesis.

**Abstract:** Fragile X Syndrome (FXS) is a monogenic neurodevelopmental disorder attributed to the loss of the protein Fragile X Mental Retardation Protein 1 (FMRP). Promoter methylation triggered by the expansion of greater than 200 CGG trinucleotide repeats at the 5' UTR of the X-linked gene results in the epi-genetic silencing of *FMR1*. FMRP is a widely-expressed RNA-binding protein with particularly high expression in neurons and gonads. FMRP has been shown to be essential for regulated protein synthesis at developing synapses and for maintenance of normal synaptic plasticity. There is a lack of quantitative and sensitive assays for measurement of FMRP. Furthermore, the relationship between FMR1 mRNA and FMRP levels and neuronal function has not yet been established. While assays to detect and measure FMRP have previously been described, none is sufficiently sensitive, precise and accurate to properly characterize such relationships. We evaluated, optimized and compared various immunoassay technologies,

including Luminex, Quanterix Simoa and Meso Scale Detection. We have successfully developed a novel electro-chemiluminescence immunoassay capable of detecting attomolar ($10^{-18}$) levels of FMRP with a lower limit of detection of 142 aM. With this assay, FMRP levels were quantified in normal cultured human iPSC, neuronal precursor cells and NGN2-induced neurons. Furthermore, we have successfully determined FMRP levels in primary tissues and fluids from healthy individuals and compared them to FXS individuals. The assay is suitable for quantitative assessment of FMRP levels in disease states and for evaluation of novel therapies involving *FMR1* gene activation.

**Abstract:** Fragile X Syndrome (FXS) is a neurodevelopmental disorder caused by a CGG repeat expansion in the 5'-UTR of the Fragile X mental retardation gene, *FMR1*. Expansions of >200 repeats can lead to hypermethylation of the CGG repeats and CpG islands in the upstream promoter region, resulting in heterochromatin formation and silencing of the *FMR1* transcript thereby preventing FMRP protein production. FMRP is a RNA-binding protein highly expressed in neurons where it plays a key role in regulating local activity-dependent synaptic translation. Therefore, the absence of FMRP has been shown to affect both synaptic formation and maturation, as well as different forms of synaptic and homeostatic plasticity. In this study, we have taken advantage of patient-specific iPSC-derived neurons retaining the pathological repeat expansion, as well as CRISPR/Cas9 technology to create isogenic clones to better understand the relationship between *FMR1* and FMRP expression levels with a specific FXS functional phenotype. Using both MEA technology to record electrical activity, and FLIPR technology to

characterize evoked calcium responses, we have elucidated disease-relevant functional impairments that are dependent upon the level of FMRP expression. Therapies aimed at reactivating *FMR1* transcription in hopes of restoring FMRP levels are therefore an attractive approach for disease-modification in FXS.

**Abstract:** Fragile X syndrome (FXS) is a monogenetic neurodevelopmental disorder with an incidence of ~ 1/4,000 live male births. Patients with FXS display a broad spectrum of intellectual, cognitive, and social deficits. These deficits are attributed to the loss of the protein

FMRP as a consequence of heterochromatin formation, methylation, and silencing caused by CGG trinucleotide repeat expansions at the 5' UTR of the X-linked gene, *FMR1*. FMRP has been shown to be essential for regulated protein synthesis at the developing synapses and maintenance of normal synaptic plasticity. However, *in vivo* or *in vitro* quantitative correlations of the length and methylation status of the CGG repeat expansion and the levels of FMRP with the functional deficits have not been established. In this study, we used two distinct but complementary approaches to establish the genotype, epigenotype and phenotype relationship in iPSC-derived Fragile X neurons. First, we developed an mRNA titration approach in iPSC-derived NGN2 neurons from patients with FXS (FXS iPSC neurons). mRNAs for WT *FMR1* or *FMR1* with 450 CGG repeats in the 5' UTR were expressed in FXS iPSC neurons. The minimal level of FMRP, as measured by Meso Scale Discovery immunoassay, that was required to normalize both expression of FMRP responsive genes and neuronal spontaneous network activity was determined by RT-qPCR and multi-electrode array (MEA) analysis, respectively. In the second approach, CRISPR/Cas9 genome editing was applied to generate a panel of isogenic lines with diverse shortening of the CGG expansion from an FXS iPSC line. Systematic analyses of the repeat length, methylation status of the CGG expansion, *FMR1* mRNA and FMRP protein expression, along with the MEA functional analysis of the NGN2-induced neurons from these isogenic lines allowed us to establish a precise relationship among the genotype, epigenotype and phenotype of the FXS neurons *in vitro*. This study quantitatively assessed the minimal level of gene expression necessary to rescue the physiologic deficit of FXS neurons. It therefore provides quantitative molecular guidance for novel disease modifying therapeutic approaches that involves *FMR1* reactivation. Establishment of this correlation may also provide a useful predictor of FXS phenotypic severity.

**Abstract:** Fragile X Syndrome (FXS) is the most common form of heritable intellectual disabilities and a leading genetic cause of autism. An effective treatment for the cognitive deficits associated with Fragile X Syndrome remains an unmet medical need. Recent findings have revealed that mammalian target of rapamycin (mTOR) is overactivated in the hippocampus and is causally related to an overabundance of immature spines in hippocampal neurons of Fragile X mice, linking cognition defects in Fragile X to down-stream processes of mTORC1. Autophagy is a process of programmed degradation and recycling of cellular components *via* the lysosomal pathway. In neurons, mTORC1 is strategically positioned at pre- and postsynaptic sites where it serves as a brake on autophagy. In the present study, we show that autophagic flux, a functional readout of autophagy, and degradation of synaptic proteins *via* the lysosomal/autophagy pathway are impaired in hippocampal neurons of Fragile X mice. We further show that activation of autophagy rescues aberrant spine morphology, synaptic function, and cognition behaviors in Fragile X mice. These findings implicate a causal relation between impaired autophagy and cognitive defects in Fragile X, and identify autophagy as a novel therapeutic target for Fragile X syndrome.
**Key Words:** *Fragile X syndrome, Autophagy, mTOR, Cognition defect, Spine morphology*

**Abstract:** Fragile X syndrome is caused by loss of function of the gene encoding Fragile X mental retardation protein (FMRP), an RNA-binding protein. Loss of FMRP leads to abnormally elevated protein synthesis. It has been reported that loss of FMRP causes abnormally high survival rates in the brain leading to excessive numbers of neurons and insufficient neuronal pruning, associated with a significant elevation in levels of the anti-apoptotic mitochondrial protein Bcl-xL. Moreover, Bcl-xL and FMRP target to mitochondria and depletion of either Bcl-xL or FMRP disrupts mitochondrial membrane potential and decreases ATP content of neurons. We now show that FMRP associates with mitochondria, that absence of FMRP alters mitochondrial structure and function and that an FMRP-dependent relationship exists between ribosome-containing complexes and mitochondria. We also find that the elevated levels of protein translation in FMRP KO mouse neurons can be reduced by treatment with specific modulators of the ATP synthase, the function of which is to increase the efficiency of mitochondrial metabolism. These modulators also increase LTP in FMRP KO mouse hippocampal slice recordings. We suggest that FMRP is not only an mRNA binding protein but also enhances the normal relationship between the ribosome and the mitochondria. This relationship is crucial for normal synapse formation and function.

**Title:** Restoration of FMRP in the prefrontal cortex of adult Fragile X mice post-development rescues prefrontal-associated deficits

**Authors: *J. J. SIEGEL**, R. A. CHITWOOD, J. M. DING, R. GRAY, B. V. ZEMELMAN, D. JOHNSTON

**Abstract:** Fragile X Syndrome (FX) is an autism spectrum disorder and the most common heritable cause of mental disability, resulting from an inability to produce the protein FMRP. In neurons, FMRP regulates the transcription of hundreds of proteins related to development, synaptic plasticity, and numerous other cellular functions. The dysregulation of protein synthesis, particularly during development, is considered the primary cause of ongoing neural dysfunction in patients. A number of impairments in FX patients are associated specifically with prefrontal cortex (PFC) dysfunction, including attention deficits, hyper-responsiveness, impaired social inhibition, and working memory deficits. We have identified a behavioral task, trace eyeblink conditioning (TEC), which is particularly sensitive to PFC dysfunction in mice. Recently, we demonstrated that FX mice show an increased proportion of nonlearners and delayed acquisition in learners in TEC, which appears due to an excitation/inhibition (E/I) imbalance based on single-unit recordings. Interestingly, the PFC-associated deficits in TEC were fully recapitulated when FMRP was blocked in the PFC alone of adult (post-development) mice. The latter result suggested that 1) deficits are due to the absence of FMRP in the PFC alone, and 2) deficits cannot be the sole result of developmental dysregulation in the PFC. Here, we test whether restoration of the production of FMRP to the PFC post-development (at 10-15 weeks of age) may partially or fully rescue deficits in TEC. For these experiments, we injected an rAAV for the production of Cre into the PFC of adult conditional restoration (cON) mice. Control groups consisted of wild-type littermates receiving PFC Cre injections, and non-injected sham cON littermates. Although FMRP was absent in the rest of the brain, restoration of FMRP in the PFC of adult cON mice rescued both the proportion of observed nonlearners and the onset of learning to wild-type levels, and was significantly different than cON sham controls. The results suggest a dissociation between the roles of FMRP in ongoing neural function and in developmental dysregulation, at least for PFC, and that PFC function can be restored in the adult FX brain. Future experiments will use single-unit recordings in the PFC of Cre-injected cON mice to determine whether the post-development rescue restores E/I imbalance, or whether a different compensatory mechanism allows for rescued PFC function.

**Abstract:** Fragile X Syndrome (FXS) is the most common inherited cause of intellectual disability, and is the leading known single-gene cause of autism spectrum disorder. FXS patients display varied behavioral deficits ranging from mild to severe cognitive impairment, mood disorder to language problem. Current medications targeting specific FXS symptoms are limited and there is huge unmet need for developing cure for FXS. Minocycline, which can alleviate social behavioral deficit and improving verbal functioning in FXS patients, is currently the only prescribed and targeted treatment for FXS patients. Previously we have demonstrated dentate gyrus region-specific deficits in NMDA receptor-dependent synaptic plasticity in the hippocampus of Fmr1 knockout (KO) mice. Here we tested whether chronic treatment with minocycline improves deficits in hippocampal dentate gyrus (DG)-dependent cognitive learning and memory via promoting *N*-methyl-D-aspartate receptor (NMDAR)-dependent functional and structural plasticity in the DG. Our results showed that chronic minocycline treatment significantly reversed impairments in hippocampal-dependent cognitive tasks in FXS mice, including novel object recognition and categorical spatial tasks. The behavioral benefits were accompanied by significant enhancement in NMDA receptor function in the dentate granule cells and increases in synaptic contents of PSD-95 and NMDAR subunits NR2B and NR2A in synaptoneurosome fractions. Minocycline treatment also enhanced dendritic length and branching of dentate granule cells in the DG of FXS mice. These findings indicate that minocycline treatment could reverse deficits in hippocampal synaptic and structural plasticity, as well as learning and memory performance in FXS mice, providing important therapeutic basis of pro-cognitive effect of minocycline in FXS.

**Abstract:** During female embryogenesis, somatic cells epigenetically silence one of the two inherited X-chromosomes in a process known as random X-chromosome inactivation (XCI). XCI is vital for brain function and cognition, with many X-linked genetic mutations leading to mental retardation syndromes, such as fragile X syndrome (FXS). The cumulative XCI status amongst cells within defined brain regions has been proposed to influence the severity of X-linked disease phenotypes in heterozygous females, but this hypothesis has yet to be experimentally tested in an unbiased, brain-wide fashion. Here, we quantify XCI dynamics across the entire mouse brain at single-cell resolution, both in wild type mice and in the FXS mouse model. We use an X-linked knock-in allele (*MeCP2-GFP*) to fluorescently label active XC (XCa) cells with known maternal or paternal parent-of-origin and computationally quantify *MeCP2-GFP+* XCa densities through serial two-photon tomography. This analysis demonstrated a statistically significant ~12.5% higher paternal XC-inactivation (XCi) across hemispheres and all brain regions, though with a notable variability (ratio range = 25/75 – 75/25%) between individual brains. Next, we determined whether the same bias of higher paternal XCi persists in the FXS mouse model and whether this affects the penetrance of behavioral phenotypes in FXS heterozygous female mice. We show that the average maternal XCa/paternal XCi bias observed in wild-type mice persists in heterozygous mice carrying either the maternal and paternal *FMR1* knockout (KO) allele. Notably, the modest difference in the estimated whole-brain *FMR1* KO XCa cell density, ~60% in maternal *FMR1* KO inheritance and ~40% in paternal *FMR1* KO inheritance, resulted in the manifestation of behavioral phenotypes only in the maternal *FMR1* KO heterozygous mice, including modest alterations in exploratory behavior and spatial memory, and a more pronounced deficit in social behavior. Remarkably, we detected highly significant correlations between the healthy XCa cell densities per brain areas and the severity of behavioral phenotypes: high mutant FMR1 KO / healthy cell ratio in sensorimotor and arousal linked brain areas predicted the presence of deficits in the open field exploration, and high mutant FMR1 KO / healthy cell ratio in regions linked to a social-spatial encoding network predicted social behavior deficits. These data therefore suggest that similar regional changes in the distribution of affected / healthy XCa cells may account for the broad variability of behavioral manifestations in female heterozygous patients with X-linked diseases.

**Title:** Inhibiting mGluR5 activity by Mavoglurant rescues circuit specific long-range connectivity in Fmr1 knockout mice: A rs-fMRI study

**Authors: *V. ZERBI**[1], M. MARKICEVIC[1], M. RUDIN[2], N. WENDEROTH[1]

**Abstract: Motivation.** Previous work has demonstrated that neuroimaging biomarkers which capture functional connectivity of the brain can be used to define a specific and robust endophenotype in *Fmr1*$^{-/y}$ mice[1], a well-established animal model of human Fragile-X Syndrome. However, it is currently unknown whether this macroscopic measure of brain connectivity is sufficiently sensitive to detect changes caused at the molecular level. Here we inhibit the activity of the metabotropic glutamate receptor-5 (mGlutR5) via AFQ056/Mavoglurant, a drug that is assumed to normalize excitatory/inhibitory neural signaling imbalances in *Fmr1*$^{-/y}$ mice. In this experiment, we employ resting-state-fMRI (rs-fMRI) to test (2) whether Mavoglurant re-establishes brain connectivity -at least partly- within some of the affected circuits in *Fmr1*$^{-/y}$ mice and (2) whether connectivity within specific circuits correlates with social behavioral.
**Experimental setup.** Untreated and treated adult *Fmr1*$^{-/y}$ mice (18 mg/kg/day of Mavoglurant by food pellets for 3 weeks prior the testing) as well as treated and untreated wildtype mice were evaluated with a three-chambered test to assess sociability and social novelty preference. One week later, we performed MRI scanning to evaluate functional connectivity changes. The datasets are acquired on a 7T scanner equipped with a mouse brain cryogenic coil, using well-established protocols to sedate and monitor mice. Rs-fMRI is cleaned from artifacts and analyzed using several established methods, including independent component analysis, total correlations and BOLD dynamics[2,3].
**Preliminary results and impact.** Preliminary rs-fMRI data indicate the presence of abnormal connectivity in Fmr1$^{-/y}$ mice, specifically for circuits that are associated with sensorial processing; for some, but not all of these circuits Mavoglurant had an effect of restoring functional connectivity. In line with previous findings, we observed that Fmr1$^{-/y}$ mice exhibited altered social interaction. However, at the group level, Mavoglurant did not rescue abnormal social behavioral. Further analyses will identify candidate brain circuits that are associated with

alterations in social behavior. Data from our experiment show that rs-fMRI connectivity is sufficiently sensitive to pick up changes at the molecular level, specifically the pharmacological inhibition of mGluR5 activity. However, our results also show that the effects of Mavoglurant are anatomically specific suggesting that behavioral benefits might be restricted to narrow functional domains.

**Title:** Intranasal oxytocin fails to increase sociability in male offspring of fmr1 deficient dams

**Authors: *K. NEWHALL**[1], A. KOO[2], B. ZUPAN[3,1]
[1]Neurosci. and Behavior Program, [3]Dept. of Psychological Sci., [2]Vassar Col., Poughkeepsie, NY

**Abstract:** The *fmr1* knock-out (KO) mouse model of Fragile X syndrome (FXS) and autism exhibits a number of disorder-associated phenotypes including abnormal sociability. Previous data have shown that maternal *fmr1* genotype is a marker for male offspring social behavior, independent of their own *fmr1* genotype. Specifically, KO and wild-type (WT) adult male mice born to *fmr1* heterozygous (H) dams and *fmr1* WT sires on the FVB strain show increased sociability compared to WT mice born to WT dams. The neuropeptide oxytocin (OT) modulates affiliative social behaviors, and *fmr1* KO mice on the C57 strain, which exhibits reduced sociability, show reduced number of OT+ cells in the paraventricular nucleus (PVN) of the hypothalamus. In contrast, increased expression of OT in the PVN and supraoptic nuclei (SON) of the hypothalamus of valproic acid-treated rats, another rodent model of autism, were associated with increased sociability. We therefore asked whether maternal *fmr1* haploinsufficiency-dependent increase in offspring sociability in the FVB strain is associated with increased OT+ cells in the PVN as well as altered sensitivity to sociability-modulating effects of intranasal (IN) OT administration. We administered 0.3IU OT or saline 15 minutes

prior to sociability testing using a modified single chamber sociability task. Mice were grouped by offspring and maternal genotype, and tested on a within-subject counter-balanced design for drug treatment. We found that relative to saline, OT administration in WT mice from WT dams [WT(WT)] increased sociability, but had no effect or even reduced social interaction time in KO and WT mice from H dams, respectively. Furthermore, avoidant behavior was reduced following OT administration only in the WT(WT) group. Preliminary examination of immunolabeled OT+ cells in the PVN and SON regions has found no differences in cell number across groups, suggesting that lack of responsivity to exogenous OT in H dam offspring is not mediated by reduced OT cell numbers. Additionally, published data shows no evidence of activation of endogenous OT signalling prior to 30 minutes post-IN OT administration in mice, so it is unlikely that our data reflect altered signaling of PVN OTergic neurons. Rather, we hypothesize that the reduced responsivity to sociability-increasing effects of IN OT in offspring of *fmr1* deficient dams may reflect abnormal OT receptor expression and/or function.

**Abstract:** Fragile X Syndrome (FXS) is the leading monogenic cause of intellectual disability and autism spectrum disorder. It is caused by expansion of a trinucleotide repeat in the 5'UTR of the Fragile X Mental Retardation-1 (FMR1) gene. We recently reported that induced pluripotent stem cells (iPSCs) derived from FXS patients exhibit profound neurogenic defects early in development, accompanied by genome-wide changes in DNA methylation and gene expression (Boland, 2017). To understand how these early phenotypes affect neuronal function in FXS neurons, we performed single cell patch clamp and microelectrode array (MEA) recording in control and FXS neurons (day 80 of culture). Our patch clamp recording revealed that FXS and control neurons share similar intrinsic properties, but FXS neurons received much less synaptic input**.** We applied a novel analysis, Near-Field Electromagnetic Holography analysis (Kjeldsen, 2015), with our MEA recording which evaluate spike activity and patterns of directional

propagation which maps networks of activity in space and time. Complement to patch clamp result, we detected more energy flow but less efficient synaptic transmission in FXS neurons using MEA recording. Notably, our MEA recording also revealed an impaired ephaptic transmission, a form of neural communication that can influence the synchrony of electric waves in the brain and could contribute to epilepsy. We are currently incorporating neuronal subtype and morphology in our modeling algorithm. Additionally, we will integrate immunocytochemistry, transcriptome, methylome, and functional analysis to dissect the molecular pathways underlying the functional phenotypes in FXS neurons. Our aim is to predict the structural-functional properties of neurons in underlying networks and their variance as they are revealed by this new mapping technique. Our long-term goal is to leverage our results to develop a phenotypic assay that is amenable to high-throughput therapeutic drug screening.

**Abstract:** Down syndrome (DS) is the most frequent genetic cause of developmental abnormalities leading to intellectual disability. One notable phenomenon affecting the formation of nascent neural circuits during late developmental periods is the so called ‘developmental excitatory to inhibitory GABA switch’ (DEIGS). We examined DEIGS properties in DS using primary cultures and acute hippocampal slices from Ts65Dn mice, a genetic model of DS. Cultures of DIV3-DIV13 Ts65Dn and 2N (control) neurons were loaded with FURA-2AM, and polarity of GABA action was assessed using local applications of GABA. In 2N cultures, the number of GABA-activated cells dropped from ~100% to 20% between p3-p13 reflecting DEIGS. In Ts65Dn cultures, the timing of this switch was delayed by few days. Next,

microelectrode recordings of multi-unit activity (MUA) were performed in CA3 slices during bath application of the GABAA agonist isoguvacine. MUA frequency was increased in p8-p12 and reduced in p14-p22 slices reflecting the switch of GABA from excitatory to inhibitory mode. The timing of this switch was delayed in Ts65Dn by ~ 2 days. Furthermore, giant depolarizing potentials (GDPs), a form of primordial neural activity, were observed in p12-p14 Ts65Dn but not in 2N slices. Finally, levels of NKCC1 and KCC2 chloride transporters were measured in the hippocampus of p12 Ts65Dn and 2N pups. Levels of NKCC1 were unaltered, while levels of KCC2 were reduced in Ts65Dn. Thus, DEIGS timing is delayed in Ts65Dn mice. These changes may affect nascent neural circuits formation and contribute to the synaptic and neuronal abnormalities in DS.

**Title:** Characterization of brain region-specific Dyrk1a protein levels and kinase activity during development of Ts65Dn Down syndrome mice to guide pharmacotherapy by Dyrk1a inhibition

**Authors: M. STRINGER**[1], J. M. LACOMBE[2], *C. R. GOODLETT[3], R. J. ROPER[2]
[1]Psychology, [2]Biol., [3]IUPUI, Indianapolis, IN

**Abstract:** Down syndrome (DS) is caused by three copies of human chromosome 21 (Hsa21) and results in phenotypes including intellectual disability. Ts65Dn mice, the most extensively studied DS model, have three copies of ~50% of the genes on Hsa21 and display many phenotypes associated with DS, including cognitive deficits. *DYRK1A* is a dosage-sensitive gene found in three copies in humans with Trisomy 21 and in Ts65Dn mice, and is involved in CNS development. Overexpression of *DYRK1A* is hypothesized to cause many of the cognitive and developmental deficits observed in DS, and has been touted as a target for drug development in DS. Studies testing Epigallocatechin-3-gallate (EGCG), a putative inhibitor of Dyrk1a, have yielded inconclusive results and there is no direct evidence that EGCG itself produces any therapeutic outcomes via Dyrk1a inhibition. Definitive evidence that excessive expression/activity of Dyrk1a directly contributes to specific phenotypes in DS mouse models is

limited, and there is no direct evidence that pharmacological inhibition of Dyrk1a *in vivo* causes enduring improvement in DS cognitive phenotypes. In part, this reflects the remarkably limited knowledge of the temporal regulation of Dyrk1a expression and activity in different brain regions across development in DS mouse models. To establish the therapeutic potential of Dyrk1a inhibitors, it is first necessary to determine when and in what brain regions excessive Dyrk1a is evident and directly associated with enduring aberrant functional development. The goal of this study is to provide the first systematic quantification of Dyrk1a protein levels and kinase activity at key postnatal (P) ages (P12, P30, P42 and P65) in Ts65Dn mice, at ages of translational relevance to clinical applications in humans (birth, early adolescence, late adolescence, young adult). Contrary to expectation, Western blot analyses indicated a surprising reduction of Dyrk1a protein in cerebellum and no difference in cerebral cortex or hippocampus in young adult Ts65Dn as compared to euploid controls mice, and high performance liquid chromatography assays in the same tissue indicated kinase activity was not elevated in any of the three brain regions of trisomic mice. Ongoing studies continue to test the hypothesis that temporal differences in Dyrk1a protein and kinase activity will be evident in specific brain regions at earlier postnatal periods. Stages when excessive Dyrk1a is evident in one or more brain regions should identify candidate periods to test the therapeutic efficacy of Dyk1a inhibition in DS.

**Title:** Human iPSC-based organoid and chimeric mouse models reveal OLIG2-dependent abnormal production of GABAergic neurons in down syndrome

**Authors: *R. XU**, P. JIANG
UNMC, Omaha, NE

**Abstract:** Down syndrome (DS), characterized by the triplication of human chromosome 21 (HSA21), is the most common genetic cause of developmental delay and intellectual disability. Over-inhibition or overproduction of GABAergic neurons significantly contributes to the cognitive deficit of DS. However, deciphering the genotype-phenotype relationships in DS with mouse models is challenging, due to the incomplete trisomy of orthologous genes on HSA21 and

in some animal models, the overexpression of additional genes that are not syntenic to HSA21 genes. Previous studies have reported that *Olig1* and *Olig2*, which are triplicated in DS, play critical roles in regulating GABAergic neuron differentiation in mice. However, their functions in regulating differentiation of human GABAergic neurons are largely uncertain. Here, we established human induced pluripotent stem cell (iPSC)-derived 3-dimensional brain organoid and chimeric mouse brain models to recapitulate the differentiation of GABAergic neurons in humans. First, we generated human iPSC-derived brain organoids, containinga large population of OLIG2-expressing ventral forebrain neural progenitors. Using this model, we found increased expression of OLIG2 but not OLIG1 in DS forebrain organoids. Moreover, compared to the control organoids, these DS organoids overproduced GABAergic neurons, particularly the calretinin-expressing GABAergic neurons. Mechanistically, we found that the overexpression of OLIG2 upregulated the expression of transcription factors that were reported to regulate development and specification of GABAergic neurons, such as *LHX8*. The upregulated expression of *LHX8* could be corrected by *OLIG2* knockdown in DS organoids. Furthermore, we engrafted the DS hiPSC-derived ventral forebrain neural progenitors into the neonatal mouse brains and found similarly abnormal production of GABAergic neurons *in vivo*. These data demonstrate that OLIG2 plays a critical role in GABAergic overproduction in DS based on our established human iPSC-derived organoid and chimeric mouse brain models. These results suggest a potential therapy for DS by regulating the expression of OLIG2 to manipulate GABAergic neuron production.

**Abstract:** Down syndrome (DS) is a neurodevelopmental disorder that is caused by the presence of an extra copy of human chromosome 21 (Hsa21). Currently, DS is one of the most common genetic causes of intellectual disability in the clinical population. While health management has significantly improved the clinical prognosis and quality of life in the DS population, there are currently no available drug treatments to ameliorate the cognitive impairments associated with DS. In addition, recent findings have shown that people with DS develop symptoms consistent with early onset Alzheimer's disease (AD). Further, Both AD and DS have been associated with abnormal EEG activity and seizures. In DS, seizures seem to peak at two ages; the first peak occurs in the first two years of age, while the second peak occurs during adulthood. The second peak may be connected with the symptoms of AD. The goal of the present study was to test the hypothesis that the Dp(16)1Yey/+ mouse model of DS develops epilepsy during aging. Dp16 mice have a direct duplication of the entire Mmu16 region that is conserved in HSA21. In the current study, we examined the effects of pentylenetetrazol (PTZ), a $GABA_A$ antagonist on seizure activity and EEG spectral power in freely moving mice. Aged (12-16 months) Dp16 and WT control mice were surgically implanted with preamplifier headmounts containing two EEG and one EMG electrodes. PTZ was then administered via intraperitoneal (i.p.) injections every other day in increasing dosages and seizure activity was scored visually using the revised Racine scale. We found that Dp16 display phenotypic differences in both the response to PTZ and spectral power following PTZ administration. We expect that old Dp16 mice have increased power in beta and gamma frequencies due to excessive inhibition by the GABAergic circuit reported in DS model mice, while spiking frequency may be reduced. This work will be important to better understand circuit dysfunction during aging and its role in seizure activity in DS.

**Abstract:** Down syndrome (DS) is a genetic disorder caused by the presence of an extra copy of chromosome 21 and it is mainly characterized by a wide range of cognitive disabilities. Studies on DS mouse models have shown that learning and memory deficits are likely determined by neurodevelopmental alterations arising during brain development and extending into adulthood. Among the many abnormalities found in the brains of DS mice, altered GABAergic inhibition is believed to largely impinge on cognitive functions. Indeed, we have recently found that the expression of the chloride importer NKCC1 is increased in the brains of both the Ts65Dn mouse model of DS and individuals with DS. Accordingly, we have found that increased intracellular chloride concentration renders $GABA_A$-mediated currents depolarizing in the adult brain of Ts65Dn mice. Here, we show that NKCC1 upregulation is also replicated *in vitro* in primary neuronal cultures from Ts65Dn mice. As a consequence, we found that the GABA developmental excitatory-inhibitory shift -assessed by calcium-imaging experiments- is largely incomplete in trisomic neurons. Accordingly, patch-clamp recordings in mature trisomic cultures indicate the occurrence of a high percentage of neurons showing depolarizing GABA signaling. In agreement with a depolarizing action of GABA, multi-electrode array (MEA) experiments also show that neural response to GABAergic drugs are profoundly altered also at the network level in mature neuronal cultures. Interestingly, treatment of Ts65Dn neurons with the FDA-approved NKCC1 inhibitor Bumetanide rescues intracellular chloride accumulation in trisomic neurons and restores inhibitory GABA signaling at both the cellular and network levels. Finally, consistent with a depolarizing GABA action in Ts65Dn mice, the positive $GABA_A$ allosteric modulator Diazepam demonstrates a paradoxical anxiogenic effect in trisomic mice, which is reversed by Bumetanide. Our findings demonstrate that NKCC1 upregulation drives depolarizing $GABA_A$ signaling in trisomic neurons, leading to altered neuronal-network activity and behavioral abnormalities in DS mice.

**Abstract:** Down Syndrome (DS, trisomy 21) is a condition that entails an excess dosage of genes localized in chromosome 21, where genes mapped to the DS critical region are particularly relevant. Among those genes is the Regulator of Calcineurin 1 (RCAN1), whose overexpression disturbs neurotransmitter release, and impairs synaptic plasticity, learning and memory. The relative contribution of RCAN1 in a context where other genes of the DS critical region are also overexpressed has yet to be elucidated. In the present work, we aimed to explore the contribution of RCAN1 to exocytosis. We used the CTb cell line, derived from the brain cortex of a trisomy 16 mouse, a model for DS, to study the contribution of RCAN1 to exocytosis. Single exocytotic events were imaged at the evanescent field of cells expressing the vesicular acetylcholine transporter fused to the pH-sensitive green fluorescent protein pHluorin, and subsequently measuring the fluorescent signal with total internal reflection fluorescence microscopy. We found that, as compared with CNh cells (a cell line established from the cerebral cortex of a normal littermate), CTb cells not only overexpress RCAN1 but display alterations in Ca2+-induced exocytosis, manifested by a reduced number of exocytotic events and a slower time-dependent kinetics. CNh and CTb cells displayed respectively 34 ± 4.4 and 23 ± 1.9 exocytotic events during a period of 3 min of recording ($p<0.05$). Decay time values for such events were 2.4 ± 0.2 s and 3.4 ± 0.3 s for CNh and CTb cells, respectively, being significantly slower in the trisomic cells ($p<0.05$). We further demonstrated that RCAN1 knockdown restored this altered exocytosis to levels comparable to those of the euploid CNh line. Our data support the critical contribution of RCAN1 to neurotransmission dysfunction in the DS condition.

**Abstract:** The genes that drive different aspects of developmental defects in Down syndrome (DS) are largely unknown. A potential driver of neurodevelopmental defects is Down syndrome cell adhesion molecule (Dscam), which is located in the Down Syndrome critical region of chromosome 21. Our previous studies have demonstrated that increased levels of Dscam causes axon terminal overgrowth in *Drosophila*. Moreover, we found that Dscam requires Abelson tyrosine kinase (Abl) to promote this axon terminal overgrowth. Interestingly, Amyloid Precursor Protein (APP), which is often overexpressed in the brains of DS patients, has also been shown to promote axonal growth in *Drosophila*. This raises the possibility that overexpression of these two genes, as occurs in DS, exacerbates the developmental defects that are caused by overexpression of each gene alone. We used genetic and biochemical approaches to test this possibility. Our results suggest that Dscam and *Drosophila* homolog of APP (Appl) function in parallel pathways that interact with each other to promote axon terminal growth. This study elucidates how two genes function together to contribute the developmental defects in DS. (M.V. and G.S. contributed equally to this work.)

**Title:** Disrupted sleep architecture in a mouse model of Down syndrome

**Authors: *P. CAIN**[1], D. J. PETERSON[2], J. LEVENGA[2], C. A. HOEFFER[3]
[2]Inst. for Behavioral Genet., [1]Univ. of Colorado, Boulder, Boulder, CO; [3]Dept. of Integrative Physiol., Univ. of Colorado, Boulder, CO

**Abstract:** Down syndrome (DS) results from the triplication of the 250 or so genes on human chromosome 21 (HSA21). Sleep disruption is a well-documented phenotype in approximately 50% of Down syndrome individuals. These disruptions may appear as night terrors or sleep walking during slow-wave sleep or REM behavior disorders or nightmares during REM sleep. There are mouse models of DS, including Ts65Dn mice, which are trisomic for a segment of mouse chromosome 16 orthologous to a region containing over 150 genes of HSA21 along with genes found on a segment of mouse chromosome 17. The sleep disruption observed in Ts65Dn mice may be attributed to the additional copies of these non-orthologous genes. Dp(16)1Yu mice (Yu et al., 2010), derived on a C57BL/6J strain, duplicate only the portion of mouse chromosome 16 that is homologous to HSA21 and thus are more comparable to DS. Among observed phenotypes are heart defects, learning and memory deficits comparable to DS symptoms. Sleep disruption has not been investigated in Dp(16) mice.
In this study, old (16 mos) Dp16+/+ mice were surgically implanted with EEG and EMG electrodes and EEG activity recorded. Sleep and motor activity were recorded across two 24 hr periods with sleep states (Wake, NREM, REM) scored and activity confirmed via video recording. We observed disrupted sleep demonstrated by increased activity as compared to wild-type conspecifics. In addition, we found that compared to wild-type, Dp(16) mice display significant differences in the relative EEG power distributed among oscillation frequencies in both sleep and awake states. The results we see are consistent with sleep disturbances in DS. These differences in relative power reflect underlying differences in neuronal activity at the network level and thus are causative agents rather than merely symptoms.

**Abstract:** Down syndrome (DS) is one of the most common forms of intellectual disabilities and is due to the trisomic repeat of chromosome 21 (HSA21). Impaired cognitive ability is a hallmark of DS pathology, and there are currently no pharmacological treatments that have effectively ameliorated the memory deficits associated with DS. Long-term potentiation (LTP) is a major form of synaptic plasticity and a cellular model of memory and is impaired in DS model mice.
We have previously reported that the glucagon-like peptide-1 (GLP-1) cleavage product, GLP-1 (9-36) enhances LTP in wild-type mice and restores LTP in mouse models of Alzheimer's disease (AD). Here, we show that GLP-1 (9-36) rescues LTP deficits in DS model mice. We also show that GLP-1 (9-36) treatment decreases mitochondrial superoxide within hippocampal CA1 neurons. Together these data provide evidence that GLP-1 (9-36) may improve memory in DS model mice by decreasing oxidative stress within CA1 hippocampal neurons.
This study provides a potential mechanism through which GLP-1 (9-36) may improve memory

in DS model mice. In the future, we will further elucidate the molecular mechanisms through which GLP-1 (9-36) influences learning and memory in mouse models of DS.

**Title:** Upregulation of NKCC1 chloride importer impairs GABAAR-mediated inhibition and memory in Down syndrome

**Authors: *M. PARRINI**[1], S. NASKAR[1], M. ALBERTI[1], M. NANNI[1], G. RONZITTI[2], F. MINGOZZI[2], A. CONTESTABILE[1], L. CANCEDDA[1,3]
[1]FONDAZIONE ISTITUTO ITALIANO DI TECNOLOGIA, GENOVA, Italy; [2]Genethon, Evry, France; [3]Telethon Dulbecco Inst., Genova, Italy

**Abstract:** Down syndrome (DS) is caused by the triplication of human chromosome 21 and it represents the most frequent genetic cause of intellectual disability. The Ts65Dn mouse model of DS exhibits the main cognitive disabilities of the human syndrome and it is characterized by learning and memory deficits in several behavioral tasks. Previous studies have shown that altered GABAergic transmission through chloride-permeable $GABA_A$ receptors ($GABA_ARs$) largely contributes to cognitive impairment inTs65Dn mice. Specifically, we have recently found that intracellular chloride accumulation shifts the chloride reversal potential ($E_{Cl}$) toward more positive values and $GABA_AR$-mediated signaling from hyperpolarizing to depolarizing in the adult brain of Ts65Dn mice. Moreover, intracellular chloride accumulation is paralleled by increased expression of the chloride importer NKCC1 (Na-K-Cl cotransporter) in the brains of both trisomic mice and individuals with DS. Importantly, pharmacological inhibition of NKCC1 with the FDA-approved drug Bumetanide restores learning and memory in Ts65Dn mice. In order to validate NKCC1 as a molecular target for cognitive deficits in DS and open the possibility for a future gene-therapy approach to treat the disease, we have here investigated whether normalization of NKCC1 activity could rescue cognitive deficits in Ts65Dn mice. In particular, we have developed and optimized a RNA-interference approach to knockdown NKCC1 expression. Our results show that reducing the expression of NKCC1 restored intracellular chloride concentration and $GABA_AR$-mediated inhibition in trisomic neurons *in vitro*. Most importantly, AAV-mediated neuron-specific NKCC1 knockdown *in vivo* in the hippocampus of adult Ts65Dn animals rescued behavioral performance on different learning and memory tests at levels undistinguishable from those of WT mice. Since the developmental excitatory-inhibitory shift in GABA signaling is fundamental for proper adult brain physiology,

we are currently assessing long-term effects and possible adverse outcomes of NKCC1 downregulation in DS neonatal mice. These findings indicate that NKCC1 upregulation drives intracellular chloride accumulation and depolarizing $GABA_AR$-signaling in trisomic cells, leading to behavioral impairments in DS mice. Moreover, our study identifies a new molecular target for treatments aimed at rescuing cognitive disabilities in individuals with DS.

**Abstract:** Microtubules play essential roles during neuronal proliferation, migration and post-migrational organisation stages of cerebral cortex development. Microtubule polymers are composed of α and β tubulin heterodimers, forming the dynamic scaffold-like structure essential for cell motility and function. In recent years, a number of genetic variations in neuronal, developmentally-regulated tubulin genes (*TUBA1A, TUBB2B, TUBA8, TUBB4B, TUBB, TUBB2A* & *TUBB3*) have been associated with a spectrum of malformations of cortical development (MCDs) including microcephaly, lissencephaly (LIS) and polymicrogyria-like malformations (PMG). Individuals with LIS and PMG were screened for tubulin mutations by whole-exome sequencing and targeted gene screening. Three novel tubulin gene-variants were identified in *TUBA1A* including two missense changes and one predicted in-frame deletion. Novel missense mutations were also identified in *TUBB2A* (n=2), *TUBB2B* (n=1) and *TUBB* (n=1). The tubulin variants were functionally analysed using *in silico* predictive protein modelling, *in vitro* microtubule polymerisation assays, and confocal immunocytochemistry. Homology models of tubulin mutants predicted the protein conformation consequences of the amino acid residue substitutions. C-terminally FLAG-tagged tubulin expression constructs were generated and transfected into HEK293 cultured cells. Incorporation of tubulin variants into the microtubule network was observed in comparison to wild-type, with reduced microtubule incorporation or altered microtubule stability/dynamics. *In silico* and *in vitro* functional analysis

provides evidence of the potential damaging effects of these variants on microtubule assembly and gives further insight towards *in vivo* causality in MCDs.

**Abstract:** Chromosome 1q41-q42 deletions have recently been associated with a distinguishable neurodevelopmental disorder in early childhood (OMIM 612530). Features of this microdeletion syndrome vary moderately depending on the location and specific genes encompassed by the each deletion. Despite this, a predominant phenotype has emerged that includes developmental delay, intellectual disability, epilepsy and unique facial features including a depressed nasal bridge, gingival hyperplasia and widely-spaced teeth. It is also frequently accompanied with CT/MRI abnormalities, hypo/hypertonia, nail hypoplasia, digit abnormalities or contractures and less often congenital anomalies including diaphragmatic hernias and cardiac defects. To date, no definitive gene(s) have been directly attributed to the predominant 1q41-q42 microdeletion phenotype as even the smallest deletions encompass a minimum of 6 genes. Nevertheless recent reports have proposed DISP1, FBXO28 and TP53BP2 to play roles in 1q41-q42 pathogenesis through studies of smallest region of overlap and single gene murine models. Here we present the first report of a single-gene loss-of-function event in a 3 year-old female patient with global developmental delay, intellectual disability, seizures, distinct facial features and other traits highly reflective of the overriding 1q41-q42 microdeletion phenotype. Through Whole Exome Sequencing we identified a de novo, heterozygous c.972_973delACinsG (p.Arg325GlufsX3) 2 base pair genomic event in FBXO28 in the female proband. The resulting frameshift leading to a

premature stop codon three amino acids downstream has not been reported in any genomic reference database including ExAC and gnomAD. This frameshift variant is the first report of single-gene, base-pair level event causing the hallmark features of the predominant 1q41q42 deletion syndrome phenotype. Additionally, it establishes FBXO28 as a novel monogenic neurodevelopmental disease gene. In light of this new evidence we propose a more accurate name of FBXO28 Haploinsufficiency Syndrome in describing the phenotype displayed in our patient and others harboring FBXO28 deficiencies in the future.

**Abstract:** Angelman Syndrome (AS) is a monogenetic neurodevelopmental disorder that affects approximately 1 in 15,000 births. In addition to cognitive and motor deficits, epileptic seizures and abnormal EEG activity are commonly found in AS. Currently, there is no treatment for AS available, and the seizures associated with AS are resistant to most anti-epileptic drugs. The most common genetic cause of AS is the deletion or mutation in the maternally imprinted Ube3a gene, encoding ubiquitin ligase (Ube3a), leading to absence or dysfunction of the Ube3a protein. In our studies, we have investigated the effect of mouse strain background on the AS behavioral profile, electroencephalography (EEG) activity, and seizure threshold in a mouse model of AS (Ube3a gene maternal deletion). We found strain-dependent differences in the AS phenotypes. The AS C57Bl/6J mice displayed hypoactivity, impaired motor coordination, learning and memory deficits, and abnormal EEG activity. The AS 129 mice exhibited poor performance on the wire

hang and contextual learning and memory tests and lower threshold to audiogenic seizures. These findings indicate that the mouse genetic background modifies the behavioral, EEG, and seizure threshold phenotype in the AS mice. Using these strain-specific phenotypes for the AS mice we are screening novel therapeutics, including artificial transcription factors (ATF) to restore Ube3a brain levels and testing whether these manipulations reverse the behavioral, EEG, and seizure phenotypes in the AS mouse model. We have also begun work screening the effect of different neuroprotective compounds from Neuren Pharmaceuticals (NNZ-2566), Anavex (A2-73), and Mitochon (MP101) on AS phenotypes. Our initial data suggests different compounds selectively rescue specific phenotypes in the AS and wildtype littermate mice. These studies will serve as preclinical data for additional translational studies in larger mammals and ultimately humans with AS.

**Title:** The angelman syndrome protein Ube3a regulates the assembly of PP2A

**Authors: *J. WANG**, Q. Z. XIONG
Inst. of Neurosci., Shanghai, China

**Abstract:** Disruption or duplication of maternally inherited 15q11-13, the chromosomal location where UBE3A resides, results in neurodevelopmental diseases including Angelman syndrome(AS) or Autism. In most causes, AS is resulted from the deletion, disruption or mutation of the maternal UBE3A allele, which encodes a HECT domain ubiquitin E3 ligase and its deficiency. Although a few targets of Ube3a have been identified in brain, they could not

explain all the phenotypes of the syndrome. Several studies demonstrated that phosphorylation-level of several proteins is dysregulation in AS mice model. Recent studies indicated Ube3a can be phosprylated by PKA at residue T485 and inhibited its activity, of which a de novo autsim linked missense mutation leads to autism. These findings indicate that Ube3a are related to protein phosphorylation homeostatsis in brain.Reversible phosphorylation of proteins is tightly and precisely regulated by relative activities of protein kinases and phosphatases. Protein phosphatase 2A(PP2A) is one major of the Ser/Thr phosphatases, which is essential for different aspects of celluar progresses, including cell cycle, cell differentiation, cell fate determination and multiple signal pathways. The underlying basis of diversity functions is the PP2A complex structure and a plethora of regulations. PP2A holoenzymes are hetertrimers formed by a catalytic C subunit, a scaffolding A subunit and a variety of regulatory B subunits that are divided into four non-homologous families: PR55/B(B55), PR61/B'(B56), PR48/PR72/PR130/B'' and PR93/PR110/B'''.In brain, impaired funciton of PP2A is associated with several neuronal diseases. However, it remains largely unknown about how these regulating factors together affect the PP2A activity *in vivo*.Herein, we show, using coimmunoprecipitation and mass spectrum methods, that Ube3a specifically interacts with PP2A heterotrimers containing regulatory B subuint PPP2R2A/B55α, which belongs to PR55 family members. In Angelman syndrome model mice, the assembly of PP2A increased, thereby enhancing the activities of PP2A during postnatal three to six weeks. Furthermore, using SILAC mice technology, we show that PTPA, the protein phosphatase 2A(PP2A) activator, increased in AS model mice brain, which contribute to the assembly of PP2A holoenzymes. Downregulation of PTPA can partially prevent the motor learning deficiency in AS model mice.These findings descirbe a molecular regulation that contributes to some certain pathologic mechanisms behind the neurodevelopmental disease Angelman syndrome.

**Abstract:** Clinicians have qualitatively described rhythmic delta activity as a prominent EEG abnormality in individuals with Angelman syndrome, but this phenotype has yet to be rigorously quantified in the clinical population or validated in a preclinical model. Here we sought to quantitatively measure delta rhythmicity and evaluate its fidelity as a biomarker. We quantified delta oscillations in mouse and human using parallel spectral analysis methods and measured regional, state-specific, and developmental changes in delta rhythms in a patient population. Delta power was broadly increased and more dynamic in both the Angelman syndrome mouse model, relative to wildtype littermates, and in children with Angelman syndrome, relative to age-matched neurotypical controls. Enhanced delta oscillations in children with Angelman syndrome were present during wakefulness and sleep, were generalized across the neocortex, and were more pronounced at earlier ages. Delta rhythmicity phenotypes can thus serve as reliable biomarkers for Angelman syndrome in both preclinical and clinical settings.

**Abstract:** Epigenetic alterations, including DNA methylation, have been implicated in many psychiatric and neurodevelopmental disorders. Williams Syndrome (WS) is rare genetic neurodevelopmental disorder and characterized by multiple symptoms including hypersociability. WS is caused by a 7q11.23 heterozygous deletion containing 26-28 genes, which include genes associated with epigenetic regulation. In this study, we performed epigenome-wide association study (EWAS) to determine the contribution of DNA methylation to WS. We examined a total of 171 subjects, including a discovery set (34 WS and 34 controls) and an independent confirmation set (56 WS and 47 controls). We used the Social Responsiveness Scale-2 (SRS-2), the Hyperacusis Questionnaire (HQ), the revised Fear Survey Schedule for Children (FSSC-R) and the sensory profile (SP) to evaluate behavioral and neuropsychiatric symptoms in WS. DNA methylation profiles were obtained from whole blood samples from a discovery set using the Illumina HumanMethylation 450 K BeadChip. Validation analyses of the epigenome-wide findings performed in a confirmation set using site-specific methylation with pyrosequencing. After accounting for batch effects, the effects of leukocyte subsets and multiple testing, we have identified multiple differentially methylated positions (DMPs) and regions (DMRs) consistently associated with WS in a discovery set. Some of the identified genes with differential methylation (*ANKRD30B*) have previously been associated with WS and we replicate those findings in a confirmation set. Pathway analysis revealed significant enrichment of our DMPs in cardiac-adrenergic signaling and tRNA splicing. To our knowledge, this study is the largest EWAS performed in WS. Our findings provide insights into the molecular basis and pathophysiology of the various phenotypes of WS.

**Abstract:** Despite the known causality of copy number variations (CNVs) to human neurodevelopmental disorders, the mechanisms behind each genes' contribution to the constellation of neural phenotypes remains elusive. Here, we investigated the 7q11.23 CNV, associated with Williams syndrome and autism spectrum disorder, and reveal that Williams syndrome is mediated in part by mitochondrial dysfunction. Dysfunction is facilitated by the 7q11.23 protein DNAJC30, which interacts with ATP synthase. Removal of Dnajc30 in mice resulted in hypofunctional mitochondria, decreased ATP synthesis, and lowered K+ATP channel-mediated membrane potentials in neurons of the cerebral cortex. Dnajc30 knockout mice exhibited Williams syndrome-like features of altered social behavior and anxiety, as well as a smaller corpus callosum, reduced axonal caliber, pyramidal neuron size, and dendritic elaboration, similar to that seen in Williams syndrome patients. On the whole, we reveal a mechanism of how hypofunctional mitochondria stunt neural circuit development and cause several hallmarks of neurodevelopmental disorders.

**Title:** ATRX specifies stem cell identity during human brain development

**Authors: *T. SANOSAKA**, R. TOMOOKA, M. CHAI, I. KOYA, T. ANDO, H. OKANO, J. KOHYAMA
Kieo Univ. Sch. of Med., Tokyo, Japan

**Abstract:** The prevalence of human diseases caused by mutations in chromatin remodeling genes underpins the importance of chromatin structure in gene regulation. One such disease, Alpha-thalassemia X-linked intellectual disability (ATR-X) syndrome, is caused by mutations of *ATRX* gene. This syndrome is characterized by mental retardation with severe developmental delay, craniofacial and urogenital abnormalities, as well as mild anemia. Previous studies have reported the role of ATRX in α-thalassaemia and cancer; however, the function of ATRX during human brain development remains unknown. In addition, multiple organ defects observed in ATR-X syndrome patients, and the identification of *ATRX* mutation as the sole genetic cause of ATR-X syndrome has raised the question of how disruption of single factor can lead to multiple phenotypes. In the present study, we found that ATRX regulates stemness and neurogenic property of human neuroepithelial (NE) cells. Dysregulation of ATRX results in the loss of NE identity and the aberrant acquisition of neural crest properties. We also generated chromatin landscapes of ATRX-bound genomic regions and found that ATRX displayed correlation with repressive heterochromatin (H3K9me3), as reported previously. In addition to its well-established repressive role, we found that a small but significant fraction of ATRX-bound regions was associated with active histone marks. Such an association was undetectable in other somatic cells, indicating the dual function of ATRX is exclusive to neural lineage. Thus, the function of ATRX as a transcription activator in the regulation of cell identity during human brain development certainly warrant further study.

**Title:** Identifying mechanisms underlying intellectual disability linked to β-catenin disruptive mutations

**Authors: *R. WICKHAM**, J. ALEXANDER, A. PIRONE, L. EDEN, P. ZAMAN, S.-X. JIN, L. FEIG, M. JACOB
Neurosci., Tufts, Boston, MA

**Abstract:** Intellectual disability (ID, IQ<70) affects 2-3% of the United States population. Despite its prevalence, the underlying pathophysiology is poorly defined, so effective pharmacological treatments are lacking. Several ID-linked human gene mutations have been identified, including disruptive mutations in the *CTNNB1* gene, encoding the β-catenin protein. β-catenin, through its roles in synaptic adhesion complexes and as a mediator of Wnt-target gene expression, is required for proper brain development, synaptic function, and plasticity. Human and mouse genetic studies suggest that the period of peak synaptogenesis in the brain may be a critical window for pathophysiological changes that can lead to ID. However, the pathophysiological changes caused by β-catenin loss in the brain during this window are unknown; their identification is essential to advance the design of effective therapeutic interventions to ameliorate ID. To gain insights into the pathological consequences of β-catenin loss-of-function in the developing brain, we have generated a novel mouse model with β-catenin conditionally knocked-out (β-cat cKO) during peak synaptogenesis in glutamatergic neurons. Our preliminary studies show that β-cat cKO mice display memory impairments, compared with wild-type littermates. We have also found several novel molecular changes in the hippocampus, including reduced levels of two β-catenin binding partners critical for synaptic adhesion and stability, N-cadherin and α-catenin. Consistent with these changes, preliminary findings suggest decreases in synaptic spine density and maturity on hippocampal CA1 pyramidal neurons in the β-cat cKO. Moreover, preliminary data indicates hippocampal TBS-LTP is also reduced at CA3/CA1 synapses, suggesting reduced synaptic plasticity required for learning and memory. As an unanticipated change, the β-cat cKOs exhibit increases in γ-catenin, a homologue of β-catenin with partial overlapping function. γ-catenin's neural specific role is unknown, and normally γ-

catenin levels are very low in neurons. Our studies will elucidate γ-catenin's neural functions, with particular emphasis on the composition of the cadherin based synaptic adhesion complex and Wnt-target gene expression. Together, these studies are providing new insights into molecular changes that can lead to intellectual disabilities

**Title:** Mice lacking cyclin-dependent kinase-like 5 manifest autistic and ADHD-like behaviors

**Authors: *W.-L. LIAO**, C.-L. JHANG, W.-J. CHUANG
Inst. Neurosci., Nat'l Cheng-Chi Univ., Taipei, Taiwan

**Abstract:** Neurodevelopmental disorders frequently share common clinical features and appear high rate of comorbidity, such as those present in patients with attention-deficit hyperactivity disorder (ADHD) and autism spectrum disorders (ASD). While characterizing behavioral phenotypes in the mouse model of CDKL5 disorder, a neurodevelopmental disorder caused by mutations in the X-linked gene encoding cyclin-dependent kinase-like 5 (CDKL5), we found that these mice manifest behavioral phenotypes mimicking multiple key features of ASD, such as impaired social interaction and communication, and increased stereotypic digging behaviors. These mice also displayed hyper-locomotion, increased aggressiveness and impulsivity, as well as deficits in motor and associative learning, resembling primary symptoms of ADHD. Furthermore, through brain region-specific biochemical analysis, we uncovered that loss of CDKL5 disrupts dopamine synthesis and the expression of social communication-related key genes in the corticostriatal circuit. Thus, our findings suggest that CDKL5 dysfunction contributes to the comorbid features of ASD and ADHD, and therapeutic development targeting the dopamine pathway and the corticostriatal circuit may ameliorate shared symptoms in ASD and ADHD.

**Title:** Dasotraline is a monoamine reuptake inhibitor not a releasing agent as revealed by tetrodotoxin (TTX) sensitivity in microdialysis in the nucleus accumbens of freely-moving rats

**Authors: D. J. HEAL**[1], R. S. KULKARNI[1], L. PINDER[1], *H. L. ROWLEY[1], T. DEATS[2], S. C. HOPKINS[2], K. S. KOBLAN[2]
[1]Renasci Ltd, Nottingham, United Kingdom; [2]Sunovion Pharmaceuticals Inc, Marlborough, MA

**Abstract:** Dasotraline is a novel drug that has been shown in clinical trials to be effective in managing ADHD in adults (Koblan et al, 2015, Neuropsychopharm 40**:**2745; Hopkins et al, 2016, Clin Drug Invest 36**:**137). Dasotraline acts as a potent inhibitor of human DA transporters (DAT; dopamine uptake $IC_{50}$ 3 nM) and NE transporters (NET; norepinephrine uptake $IC_{50}$ 4 nM), and a weaker inhibitor of human serotonin transporters (SERT; serotonin uptake $IC_{50}$ 15 nM). We have used the sodium channel blocker, TTX, to investigate whether dasotraline evokes monoamine release in the CNS. d-Amphetamine was the reference comparator.
A single 2.0mm microdialysis probe was stereotaxically implanted into nucleus accumbens (ACB) (AP +2.2mm, ML ±1.5mm, DV -8.0mm relative to bregma) of isofluraneanaesthetised male, Sprague Dawley rats (300±50g). After ≥16hr recovery, 15min microdialysate samples (1.2µl/min artificial CSF (aCSF)) were taken from freelymoving rats for 2hr after administration of dasotraline, d-amphetamine or vehicle. TTX was reversedialysed via the probe starting 15min before drug or vehicle injection and was maintained throughout the experiment. Dopamine (DA), DOPAC and HVA were measured by ALEXYS$^{TM}$ hplc-ecd. All results are reported as mean±SE, n=7-9.
Basal DA efflux (6.11±0.29fmol/5µl; 0-2hr) in ACB was rapidly decreased by reverse dialysis of TTX (1µM) reaching a nadir of 85.6% vehicle control at 135min ($p<0.001$). TTX also markedly reduced extracellular DOPAC (≤57.9%; $p<0.001$) and HVA (≤28.5%; $p<0.001$). Under control conditions, dasotraline (10mg/kg ip) produced a gradual increase in DA efflux that peaked at 770±137% of baseline at 120min ($p<0.001$). Dasotraline produced a concomitant fall in DOPAC (nadir = 36.2% at 75min; $p<0.001$) but not HVA. dAmphetamine (3mg/kg ip) produced a rapid increase of DA efflux in ACB with a peak of 3015±634% of baseline at 30min ($p<0.001$). There were concomitant decreases in DOPAC and HVA ≤70.7% ($p<0.001$) and ≤36.2% ($p<0.001$), respectively. Under conditions of reversedialysis of TTX into ACB, dasotraline administration failed to significantly increase DA efflux above vehicle control values. In contrast, DA release by damphetamine was unaltered in the presence of TTX with a maximum increase of 2437±705% at 30min ($p<0.001$). Analysis of the data in 1hr time-bins confirmed no significant

differences between the damphetamineinduced DA efflux in the presence or absence of TTX. These findings lead to 3 important conclusions. Dasotraline is a DA reuptake inhibitor. Dasotraline is not a DA releasing agent. Dasotraline will be devoid of damphetamine-like stimulant properties.

**Abstract:** Despite the prevalence of Attention-Deficit/Hyperactivity Disorder (ADHD) in our society, and our readiness to dispense pharmaceutical interventions, much of the underlying etiology remains unknown. To help untangle the genetic underpinnings of ADHD, we bred mice from the same starting population either selectively for high home cage activity (High-Active), or randomly (Control). The High-Active mice also display motor impulsivity ameliorated by therapeutic doses of amphetamine, another core feature of ADHD. Previous work has implicated altered striatal function in ADHD, but the molecular mechanisms are not known. The goal of this study was to identify gene expression differences in the striatum of our High-Active line as compared to the Control line. RNA was extracted and sequenced from the entire striatum of 10 High-Active and 10 Control mice, then analyzed via statistical analysis and Weighted Gene Co-Expression Network Analysis (WGCNA). WGCNA uncovered a network of correlated genes involved in cell structure, monoamine regulation, and *Wnt* signaling that are differentially expressed between the High-Active and Control lines, as well as human ADHD-linked genes

such as latrophilin 3. Future work will first focus on quantifying differential gene expression by looking at protein expression and localization. Then, using this data, we will focus on identifying potential novel medications that can help ameliorate negative behavioral aspects of ADHD through targeted action at the molecular level.

**Title:** Dasotraline - Evaluation of its dopamine reuptake characteristics in comparison to stimulants and non-stimulants by microdialysis in the nucleus accumbens of freely-moving rats

**Authors: H. L. ROWLEY**[1], R. S. KULKARNI[1], L. PINDER[1], *D. J. HEAL[1], T. DEATS[2], S. C. HOPKINS[2], K. S. KOBLAN[2]
[1]RenaSci Ltd, Nottingham, United Kingdom; [2]Sunovion Pharmaceuticals Inc, Marlborough, MA

**Abstract:** Dasotraline is a novel DAT, NET and SERT uptake inhibitor that is being developed as a new treatment for ADHD. In cell-lines transfected with human transporters, dasotraline is a potent uptake inhibitor of dopamine (DA; $IC_{50}$ 3nM) and NE ($IC_{50}$ 4nM), and a weaker inhibitor of serotonin ($IC_{50}$ 15 nM). We have used microdialysis to compare dasotraline's effects on DA efflux against methylphenidate, d-amphetamine, phentermine and bupropion.
Microdialysis probes (2mm) were implanted into nucleus accumbens (ACB) (AP +2.2mm, ML ±1.5mm, DV -8.0mm relative to bregma) of isofluraneanaesthetised male, Sprague Dawley rats (300±50g). After ≥16hr recovery, 20min samples (1.2µl/min artificial CSF (aCSF)) were taken from freelymoving rats for 4hr after administration of dasotraline [1-10], methylphenidate [1-10], d-amphetamine [0.13], phentermine [1-9], bupropion [10-50] or vehicle. Doses in square brackets are [mg/kg ip]. DA, DOPAC and HVA were measured by ALEXYS™ hplc-ecd. All results are reported as mean±SE, n = 6-10.
Basal DA efflux was 5.29±0.22fmol/5µl (0-4hr). Dasotraline produced dose-dependent gradual increases in DA efflux peaking at 160-240min. Peak increases as % baseline: 144±21% [1], 204±38% [3] and 926±269% [10] (all $p<0.01$). Dasotraline produced concomitant falls in DOPAC (≤33.3%; $p<0.001$) but not HVA. The stimulants, damphetamine, phentermine and methylphenidate, dosedependently evoked rapid increases in DA efflux that peaked at 40min and declined rapidly thereafter. There was no dose-effect ceiling with the stimulants. Peak increases: damphetamine = 3393±399% [3], phentermine = 924±196% [9] and methylphenidate = 487±105% [10] (all $p<0.001$). dAmphetamine and phentermine decreased DOPAC (≤70.7%;

p<0.001 and ≤56.7%; p<0.001) and HVA (≤42.2%; p<0.001 and ≤27.2%; p<0.001). Methylphenidate reduced DOPAC (≤32.4%; p<0.001) but not HVA. The nonstimulant, weak dopamine reuptake inhibitor, bupropion, increased extracellular DA with maximum effects at 20-40min. Peak increases: 228±37% [10], 552±78% [30] and 441±104% [50] (all p<0.001). There was a clear dose-effect ceiling for bupropion. Bupropion produced concomitant falls in DOPAC (≤29.1%; p<0.01) but not HVA.
The stimulants produced rapid, large increases in DA efflux with no dose-effect ceiling. Bupropion rapidly increased DA efflux, but its effect was dose-limited. Dasotraline evoked slow increases in DA efflux in ACB. Dasotraline is clearly different from the DA stimulants and bupropion. The results indicate that at pharmacologically relevant doses (1-3mg/kg), dasotraline produces only relatively small increases in synaptic DA concentrations in vivo.

**Abstract:** Attention-deficit/hyperactivity disorder (ADHD) is a complex neurodevelopmental disorder characterized by inappropriate levels of hyperactivity, impulsivity, and inattention. Determining specific genetic risk variants for each symptom dimension of ADHD may aid in the identification of the biological risk factors of the disorder. In the present study, we explored the potential genetic underpinnings of the hyperactive phenotype of ADHD. To this end, we examined differentially expressed genes (DEGs) in the prefrontal cortex (PFC) of SHR/NCrl, an animal model of ADHD, compared with its genetic control, the Wistar Kyoto (WKY/NCrl) rat and the Wistar rat, strain used to represent the “normal” heterogeneous population. Relative to WKY/NCrl and Wistar controls, SHR/NCrl showed hyperactivity in the open-field test. Treatment with the ADHD drug, amphetamine (AMPH) reduced hyperactivity in SHR/NCrl. Meanwhile, AMPH increased locomotor activity in WKY/NCrl and Wistar rats. Gene expression analysis found 21 common upregulated and 36 downregulated genes in the PFC of drug-naïve SHR/NCrl when compared with WKY/NCrl and Wistar rats. Of these DEGs, expression levels of *Atxn7* which are involved in transcription, respectively, were downregulated following AMPH treatment in SHR/NCrl. qRT-PCR analyses verified expression patterns of these genes in the PFC of drug-naïve and AMPH-treated SHR/NCrl. We then proceeded in generating Atxn7 overexpressing transgenic (Atxn7 TG) mice to clarify whether changes in *Atxn7* gene expression in the brain correlate with hyperactive behavior. Behavioral screening results showed that the Atxn7 TG mice are hyperactive, with no alterations or impairment in other behaviors. qRT-PCR and immunofluorescence confirmed that *Atxn7* gene and ATXN7 protein is overexpressed in various brain areas of the Atxn7 TG mice. Furthermore, treatment with atomoxetine (ATO) reduced the hyperactive behavior in Atxn7 TG mice. Although further studies are warranted, our findings suggest that the *Atxn7* gene might play an important role in the pathophysiology of ADHD and that the Atxn7 TG mice can be used as a specific animal model of the hyperactive phenotype of this disorder.

**Abstract:** Newly developed molecularly targeted anti-cancer drugs target signaling pathways critical for normal brain development. While their use in the pediatric population is being considered, the age-dependent effects of these agents on the developing brain are unknown. The objective of this study was to define the cellular and behavioral effects of these targeted therapies when administered at different developmental stages. The agents chosen target pathways commonly altered in pediatric brain tumors and that are also crucial for cellular growth, proliferation, and migration during normal brain development: i) the receptor tyrosine kinase family, such as epidermal, vascular, and platelet-derived growth factor receptors; and ii) the downstream intracellular mechanistic target of rapamycin. In this study, naïve mice at different ages received a short-course of molecularly targeted drugs acting on these pathways: i) gefitinib, which inhibits the epidermal growth factor receptor; ii) sunitinib malate, which inhibits both the vascular and platelet-derived growth factor receptors; or iii) rapamycin, which inhibits the mTOR pathway. Cellular and behavioral characteristics involving the white matter and hippocampus were determined, as these regions undergo rapid development during childhood and are important for sensorimotor and cognitive function. We found that all three targeted therapeutic agents produced the greatest detrimental effects on the white matter and hippocampus when mice were treated at an early age (postnatal day [P]12 to P17), compared with administration at a later age (P17 to P22). Interestingly, there was no evidence of cellular or behavioral deficits when mice were treated with any of these drugs in adulthood. We then wanted to determine whether the detrimental effects of these agents could be reversed by an intervention known to promote plasticity - environmental enrichment. We chose the group

treated at an early age with these therapeutic agents (P12-17) and they underwent enrichment for 8-12 hours per day until P30. Behavioral tests of white matter and hippocampal function clearly demonstrated significant improvements in behavioral performance compared to treated mice that did not undergo enrichment. Interestingly, these improvements with a short course of enrichment were long-lasting and still evident at 2 months of age. Our findings that molecularly targeted drugs have age-dependent and reversible effects on the brain are of great significance, as these drugs are being tested in pediatric patients.

**Title:** Postnatal erythropoietin repairs executive function deficit detected with touchscreen in adult rats with CNS injury that mimics preterm birth

**Authors: L. L. JANTZIE**[1], A. OPPONG[2], F. CONTEH[2], *S. ROBINSON[2]
[1]Pediatrics, Univ. of New Mexico Dept. of Pediatrics, Albuquerque, NM; [2]Neurosurg., Johns Hopkins Univ., Baltimore, MD

**Abstract:** Children born preterm are prone to executive function deficits. A persistent challenge has been to develop highly translatable cognitive tests that accurately replicate human tests of executive function. Touchscreen operant chambers use the same testing paradigms as human of executive function tests, and thus have the potential to speed translation of effective interventions from preclinical models to clinical trials. Erythropoietin (EPO) is a promising, safe, neuroreparative agent for perinatal brain injury currently being tested in clinical trials. We hypothesized that touchscreen paradigms can test the ability of neonatal EPO to repair deficits in cognition, and executive function, including cognitive flexibility. We used an established model of prenatal injury that mimics chronic deficits of children born preterm, including impaired gait and social interaction in adult rats. On embryonic day 18 (E18), pregnant Sprague-Dawley rats underwent laparotomy and transient systemic hypoxia-ischemia (TSHI) via occlusion of uterine arteries. Shams had anesthesia with laparotomy only. On postnatal day 1 (P1), injured rats of both sexes were randomized to treatment with EPO (2000U/kg ip P1-P5) or vehicle. Rats were weaned on P21, and began mild food restriction on P28. On P35, rats commenced training for reward retrieval in touchscreen operant chambers, with one testing session per day. Rats that passed training then underwent visual discrimination (VD) testing, and if successful, continued on to a reversal (REV) learning task to test cognitive flexibility. Passing criteria was set *a priori*

at 80% for 2 consecutive days with 60 trials per day. Two-way ANOVA with Bonferroni correction was used to compare differences for parametric variables. Results show the majority of rats pass training (sham, n=16, 100%; TSHI-veh, n=22, 92%, TSHI-EPO, n=24, 100%), which shows that young rats with late gestation injury can be trained in touchscreen paradigms. The majority of sham (81%), TSHI-veh (59%) and TSHI-EPO (75%) rats also passed VD, demonstrating that rats with prenatal CNS injury can perform VD. However, on REV, TSHI-EPO (58%) rats passed, while only 45% of TSHI-veh rats passed (p=NS), compared to sham (63%). The number of trials correct was higher for TSHI-veh (133±15), compared to shams (83±11, p=0.03) or TSHI-EPO (87±10, p=0.03). Notably, when different learning stages during REV were assessed, it was clear that TSHI rats had a perseverative reversal deficit. No differences attributable to sex were apparent in early analyses. Together, these results show for the first time that touchscreen can detect repair of executive function in rats with perinatal brain injury.

**Title:** Desflurane-induced neuronal damage in infant monkey after prolonged exposure

**Authors: *F. LIU**[1,2], Q. YIN[1], S. LIU[1], C. M. FOGLE[1], T. A. PATTERSON[1], M. G. PAULE[1], J. P. HANIG[2], W. SLIKKER, Jr.[1], C. WANG[1]
[1]Natl. Ctr. for Toxicological Res., Jefferson, AR; [2]Ctr. for Drug Evaluation and Research/FDA, Silver Spring, MD

**Abstract:** It has been a public concern as to whether general anesthesia has any adverse effects on developing brain. Desflurane is frequently used to maintain general anesthesia for pediatric surgeries. In the present study, postnatal day (PND) 5 or 6 rhesus monkeys were randomly assigned to a control group (room-air; n=3) and a desflurane-exposure group which was exposed to 5.7% desflurane in medical grade air (n=3) for 8 hours. Four hours after completion of the exposure the animals were euthanized and brain tissue were collected for histochemical analyses, including Fluoro-Jade C staining and immunohistochemical staining of Bax and Iba1 (ionizing calcium-binding adaptor molecule 1). Fluoro-Jade C staining indicated an increased number of Fluoro-Jade C-positive cells in layers II, III, IV and V of the frontal cortex after an eight-hour exposure to desflurane. Higher expression of Bax, a pro-apoptotic protein, was observed in the

brain of exposed group, suggesting elevated apoptosis is one of the consequences of prolonged desflurane exposure in the developing monkey brain. In addition, increased Iba1 expression indicated the involvement of microglia activation in desflurane-exposed infant monkey brain. These findings suggest that an 8-hour exposure to a clinically-relevant concentration of desflurane could cause neuronal damage in infant monkey brain, which may at least be partially apoptotic in nature. The role of microglial activation in desflurane-induced neuronal degeneration merits further studies.

**Abstract:** Creatine (Cr) transporter (Crt) deficiency (CTD) is characterized by a lack of brain Cr, severe intellectual disability, and aphasia. To date there is no treatment for CTD. Unlike the other Creatine Deficiency Syndromes involving mutations in Cr synthesis enzymes, CTD involves a mutation in the Crt, preventing treatment by Cr supplementation. Faced with this barrier, there is a need for the development of novel and creative treatment strategies. Adeno-associated viral vector 9 (AAV9) has recently been shown to penetrate the blood-brain barrier via intravascular (IV) administration and efficiently targets cells of the central nervous system, making it a good candidate for diffuse gene delivery. The purpose of this study is to determine the efficacy of an AAV9 expressing a functional copy of the human Crt (AAV9-hCrT) in transducing cells from a knockout out mouse model of CTD (*Slc6a8*$^{-/y}$). In this study, the efficacy of AAV9-hCrT was tested both *in vitro* and *in vivo*. Cultured fibroblasts and primary hippocampal neurons from *Slc6a8*$^{-/y}$mice were treated with AAV9-hCrT. Cr uptake and SLC6A8 gene expression were increased in cells treated with AAV9-hCrt. *Slc6a8*$^{-/y}$mice were then treated with AAV9-hCrt via IV administration. Increases in SLC6A8 transcript and Cr levels were

observed in the brain of *Slc6a8*$^{-/y}$mice treated with AAV9-hCrt. These findings lay the foundation for the use of gene therapies for the treatment of CTD.

**Title:** Sex differences in the 20HETE induction and toxicity in primary cortical neurons after oxygen-glucose deprivation

**Authors: *N. E. MOHAMMED**[1], R. KOEHLER[2], Z. YANG[3]
[1]John Hopkins Sch. of Med., Baltimore, MD; [2]Anesthesiol. and critical care unite ACCU, John Hopkins Sch. of medicine, Baltimore, MD; [3]Anesthesiol. and critical care unite, John Hopkins school of medicine, Baltimore, MD

**Abstract:** 20-Hydroxyeicosatetraenoic acid 20HETE, an arachidonic acid metabolite from cytochrome P450 (CYP) 4A and 4F, contributes to ischemic brain injury in adults and the newborn. Our previous work has indicated that 20-HETE can be induced in oxygen-glucose deprivation (OGD) neurons and directly aggravate neuronal injury. In addition, mRNA of Cyp4a12a, a male-specific 20-HETE synthesis enzyme, exists in mixed-sex mouse primary cortical neurons. Thus, it is crucial to determine whether 20-HETE plays different roles in male or female neurons after OGD, an *in vitro* model of ischemia. Here, we tested the hypothesis that there are sex differences in the 20HETE production and toxicity in primary cortical neurons after OGD. The sex of E15 embryo or 1-day old pups of C57/bl6 mice were identified by their internal sex organs. Primary mouse cortical neurons or astrocytes were cultured from male or female embryo or 1-day old pups and further confirmed cells' sex stratification by PCR amplification of Jarid1c (X chromosome-specific) and Jarid1d (Y-chromosome-specific). Quantitative real-time PCR results showed that Cyp4a10 mRNA presented in both male and female neurons on 7 days *in vitro*. However, only Cyp4a12a mRNA could be found in male neurons. mRNA of Cyp4a12b and Cyp4a14 were not detected in neither male or female neurons. 1-h OGD increased levels of Cyp4a10 and Cyp4a12a mRNA at 1 and 3 h recovery. For astrocyte, Cyp4a10 mRNA was also existed in female and male cells. However, only Cyp4a12a was existed in males and Cyp4a12b was found in females. Cyp4a14 was not detected in both male and female astrocytes. 1-h OGD did not induce the level of astrocyte CYP4A mRNA. 20-HETE measurement with ELISA assay

on primary cortical neurons or astrocytes showed a significant increase in 20HETE release in culture medium of male neurons. However, no significant 20HETE induction could be found in female neurons or male or female astrocytes. CellTiter Blue (CTB) cell viability assay results indicated ~40% of neuronal death at 24 h after 1-h OGD. 10 µM of HET0016 protected OGD male neurons rather than female neurons, which is consistent with the effects of 20-HETE antagonist 20-6,15-HEDGE (50 µM). However, 20HETE analog 20-5,14HEDGE (10 µM) could not only reverse the protection of HET0016 in OGD male neurons, but lead to more severe injury in both male and female neurons. Moreover, CTB assay results suggested that 20-5,14HEDGE application could directly lead to neuronal injury without OGD in both sex. Therefore, we conclude that induced 20HETE in male neurons exerts detrimental effects after OGD.

**Title:** A novel preclinical model of chronic pain from cerebral palsy

**Authors: *A. Y. OPPONG**[1], T. R. YELLOWHAIR[2], J. KIM[1], L. L. JANTZIE[2], S. ROBINSON[1]
[1]Neurosurg., Johns Hopkins Univ., Baltimore, MD; [2]Departments of Pediatrics and Neurosci., Univ. of New Mexico Sch. of Med., Albuquerque, NM

**Abstract:** Children, adolescents and adults with cerebral palsy (CP) are prone to chronic pain. The most common cause of preterm birth in the USA is chorioamnionitis from varying combinations of bacterial inflammation and hypoxia-ischemia. The proportion of patients with CP who suffer chronic pain increases from adolescence to adulthood. The frequency and severity of chronic pain in patients with CP is disproportionate to the progression of musculoskeletal deformity, which suggests that patients with CP may have altered nociception. Discovery of more effective interventions for patients with CP plus chronic pain requires an adequate preclinical model to study the cellular and molecular mechanisms of pain, and their potential reversibility. Similar to other developing CNS circuits that are disrupted by perinatal injury, dorsal spinal cord nociceptive (DSCN) circuits undergo perinatal maturation, and are thus vulnerable to early CNS insults. We used an established rat model of CP from chorioamnionitis in which adult rats have impaired gait and cognition that mimics children born very preterm. We hypothesized adult rats that suffer a prenatal injury that mimics CNS injury from very preterm birth would exhibit a nociceptive phenotype as young adult rats. Using an established preclinical

model of CP, chorioamnionitis was induced on embryonic day 18. Rat pups were born at term (E22, ~30 weeks human gestation). Adult rats of both sexes were tested for mechanical (von Frey up-down) and thermal sensation (tail immersion and Hargreaves) from juveniles (P30) to adults (P90). Lumbar dorsal spinal cord was assayed with immunoblotting. Groups were compared with two-sided t test, with $p<0.05$ significant. Rats exposed to prenatal injury showed sustained hindpaw allodynia at P30, P40, P60 and P90 compared to shams (n=12-19, all $p<0.01$). Injured rats initially at P30 exhibited hyposensitivity to thermal tail immersion compared to shams ($p<0.01$), which normalized by P40. Notably, Hargreaves testing revealed injured rats were hypersensitive at P90 compared to shams ($p=0.005$), which suggests both thermal and mechanical hindpaw sensation are abnormal at P90 in rats with prenatal injury. The chemokine CXCL1 is implicated in calpain-mediated degradation of co-transporter KCC2 in neuropathic pain. Rats with prenatal injury had elevated serum CXCL1 and lumbar cord KCC2 degradation products compared to shams (both $p<0.01$). Together, these results for the first time present a preclinical model that replicates both the impaired gait and nociception of patients with CP. Multiple mechanisms contribute to deficits in patients with CP, and we predict these mechanisms alter DSCN circuits too.

**Abstract:** N-methyl D-aspartate receptors (NMDAR) play crucial role in normal brain function and pathogenesis of neurodegenerative and psychiatric disorders. Functional tetra-heteromeric

NMDAR contains two obligatory GluN1 subunits and two identical or different non-GluN1 subunits from among six different gene products; four GluN2 (A-D) and two GluN3 (A-B) subunits. Since NMDARs composed of different GluN2 subunits (GluN2A-D) confer varied physiological properties and have different distributions in the brain, pharmacological agents that target NMDARs with specific GluN2 subunits have significant potential for therapeutic applications. In the present work, by amino acid point mutations and electrophysiology techniques, we have studied the role of ligand binding domain (LBD) interactions in determining the effect of well-characterized pharmacological agents including agonists, competitive antagonists, channel blockers and allosteric modulators. Remarkably, memantine blocked the mutant GluN1/2A receptors with significantly higher potency than the wild type GluN1/2A receptors. In addition, similar changes were observed with GluN2B subunit-containing receptors. However, memantine potency remained unchanged with the mutant GluN1/2C or 2D subunit-containing receptors. These results indicate that GluN2A and GluN2B receptors are more sensitive to LBD interactions. Further, they readily translate any subtle LBD modifications all the way downstream to the extracellular vestibule of channel pore, where memantine binds, to adopt a conformation that locally resembles GluN2C or 2D subunit-containing NMDA receptors. Further studies on NMDA receptor LBD to transmembrane domain signal propagation mechanisms will help develop GluN2 subunit selective biomolecules that can be used for the treatment of neurological and psychiatric disorders.

**Abstract:** Decades of research has established that inhibitory interneurons, which coordinate circuit excitability and information processing in the brain, are amongst the most heterogeneous cell types in the nervous system. It is now clear that flawed interneuron development and

function precipitates neurological disorders such as epilepsy, schizophrenia and autism. Additionally, wealth of evidence points to the role of interneuron-specific NMDA-type ionotropic glutamate receptor (NMDAR) dysfunction recapitulate the phenotypes of several neurological disorders. In the present study we apply cell-type specific, next-generation RNA sequencing to examine the role of activity-dependent gene expression programs in interneurons. We perform this by selectively ablating GluN1 subunit of NMDARs in the medial ganglionic eminence (MGE)-derived, hippocampal interneurons, that gives rise to predominantly parvalbumin and somatostatin cohorts. We identify several classes of genes including transcription factors, cytoskeletal modifiers and regulators of neuronal excitability, differentially expressed in the MGE-derived interneurons lacking GluN1. We will use a combination of molecular, cellular and electrophysiological approaches to validate the consequence of abnormal gene regulation following the loss of GluN1, based on our sequencing data. Overall, our findings indicate NMDAR signaling as a critical regulator of excitation-transcription coupling in hippocampal interneurons, and allow us to design rational therapeutic strategies to rescue interneuron deficits underlying neurological disorders.

**Abstract:** NMDA receptors play critical roles in normal physiological function within the CNS and disruption of their function can have profound detrimental consequences on CNS function. For example, downregulated NMDA receptor function in anti-NMDA encephalitis provides further evidences about the determinant role of these receptors in psychiatric and neurological illness.
Development of novel molecules acting at the NMDA receptors necessitate the identification of pharmacologically active compounds at human NMDA receptors but also their characterization in different animal models that are used in preclinical efficacy and safety studies. Nowadays the availability of genomes from multiple organisms and the possibility of recombinant expression offer new possibilities to assess the characterization of a given receptor across different species.

In the present study we have examined the functional properties of NDMA receptors reconstituted by expression of the GluN1a and GluN2A subunits from human, dog, rat and mouse and compared their pharmacological properties and modulation by two synthetic oxysterol NMDA receptor allosteric modulators, SGE-301 and SGE-550.
Sequence alignments of the human, dog, rat and mouse GluN1 and GluN2A indicate that while some regions of the receptors are highly conserved notable differences can be observed in other segments of the proteins. To evaluate the possible importance of such variation on the receptor properties it is therefore critical to examine the functionality of the different receptors and to compare the pharmacology of compounds of interest.
Expression of NMDA receptors in *Xenopus* oocytes offered an efficient way to assess their functional properties using two electrode voltage clamp. Determination of the concentration activation curve to glutamate revealed the high similitude in sensitivity to the natural agonist and showed no major differences in the time course of Glutamate-evoked currents. However, determination of the pharmacological modulation by oxysterols revealed, differences in their potency across species. SGE-301 was approximately 50-fold more potent at the human receptor than the mouse. Rank order of potency for SGE-301 across species was human > rat > dog > mouse. SGE-550 displayed more modest differences in potency across species, with a maximum of a 5-fold difference between the rat and dog receptors.
Altogether, these data highlight the importance of fully characterizing the activity of novel NMDA receptor modulators across species that will be used in preclinical efficacy and safety models in order to better understand pharmacokinetic-pharmacodynamic relationships

**Abstract:** The NMDA receptors (NMDARs) are tetrameric assemblies of 2 GluN1 and 2 GluN2 subunits. The tetrahydroisoquinoline **(+)-CIQ** is a positive allosteric modulator (PAM) of GluN2C- and GluN2D-containing NMDARs, increasing the current response to maximally effective concentrations of agonist by 3-fold. Recently we identified a chiral analogue, **IPQ-2**, that is a non-selective PAM of NMDARs. This compound enhances saturated responses of GluN1/GluN2D NMDARs by 3-fold and can enhance the response of GluN1/GluN2B NMDARs by 2-fold. **IPQ-2** increases glutamate potency by 1.5-4 fold for all NMDARs (n=15-28). Separation of **IPQ-2** *R* and *S* enantiomers revealed that ***R*-(+)-IPQ-2** acts like **(+)-CIQ**, potentiating only GluN1/GluN2C and GluN1/GluN2D NMDARs, whereas ***S*-(-)-IPQ-2** can potentiate all NMDARs. In addition, ***S*-(-)-IPQ-2** slowed the current response deactivation time course following removal of glutamate for all NMDARs (n=5-16), in contrast to ***R*-(+)-IPQ-2**, which (like **CIQ**) only slowed the deactivation of GluN1/GluN2C (n=5-15 cells). We utilized scanning alanine mutagenesis to search for structural determinants of action that might explain the subunit selectivity of the enantiomers of **IPQ-2**. We focused on the M1 transmembrane helix as well as the pre-M1 helix, which lies parallel to the membrane and is in contact with the M3 transmembrane helix that forms the channel gate. We evaluated mutations at each position in these regions in GluN1, GluN2B, ad GluN2D. We identified 13 residues in the GluN1 subunit that perturbed **IPQ-2** potentiation of GluN1/GluN2B, including a stretch of 6 consecutive residues in the GluN1 pre-M1. By contrast, no mutations at GluN2B pre-M1 residues influenced **IPQ-2** potentiation, suggesting that structural determinants of the pan-potentiator actions of ***S*-(-)-IPQ-2** may reside in or near GluN1 pre-M1. We next evaluated whether GluN1 mutations also altered the actions of ***S*-(-)-IPQ-2** on GuN1/GluN2D NMDARs. We screened a large number of mutations with racemic **IPQ-2**, and selected a subset of residues at which to evaluate the two enantiomers. We found that 5/6 mutations in GluN1 perturbed the actions of ***S*-(-)-IPQ-2** on GluN1/GluN2D, compared to 2/6 mutations that influenced ***R*-(+)-IPQ-2**. By contrast, we found that 8/8 GluN2D pre-M1/M1 mutations perturbed ***R*-(+)-IPQ-2** effects, compared to 1/8 mutations that altered the actions of ***S*-(-)-IPQ-2**, consistent with structural determinants for ***S*-(-)-IPQ-2** residing in GluN1 and for ***R*-(+)-IPQ-2** residing in GluN2. These results suggest that two distinct allosteric modulatory sites reside in the GluN1 and GluN2 subunits, and show that selectivity among these sites can be tuned by subtle changes in the modulator structure.

**Abstract:** Objective: The most frequent autoimmune encephalitis syndrome is characterized by anti-NMDAR autoantibodies. Their pathogenic relevance has been implied by *in vitro* analysis and passive transfer of patients' cerebrospinal fluid (CSF) in mice *in vivo*. We aimed to analyze

the intrathecal plasma cell repertoire in anti-NMDAR encephalitis, identify autoantibody-producing clones, and characterize their antibody signatures in recombinant form *in vitro* and *in vivo*.
Methods: Treatment-naive patients were subjected to flow cytometry analysis of the peripheral and intrathecal immune response throughout the disease course. Recombinant human monoclonal antibodies (rhuMab) were cloned and expressed from matching immunoglobulin heavy (IgH) and light (IgL) chain amplicons of clonally expanded intrathecal plasma cells (cePc) and tested for their pathogenic relevance using *in vitro* assays and an *in vivo* mouse model of passive cerebroventricular antibody transfer.
Results: Intrathecal accumulation of B cells and plasma cells corresponded to the clinical course. The presence of cePc with hypermutated antigen-receptors indicated an antigen-driven intrathecal immune response. Consistently, a single recombinant human GluN1-specific monoclonal antibody, rebuilt from intrathecal cePc, was sufficient to reproduce NMDAR epitope specificity *in vitro*. After intraventricular infusion in mice, it accumulated in the hippocampus, decreased synaptic NMDAR density, and caused severe memory impairment *in vivo*.
Interpretation: A CNS-specific humoral immune response is present in anti-NMDAR encephalitis specifically targeting the GluN1 subunit of the NMDAR. Having recovered this defined intrathecal antibody signature in recombinant form proves its pathogenic relevance by passive transfer of disease symptoms from man to mouse and may contribute to understanding the role of the NMDAR in synaptic function, cognition and behavior.

**Abstract:** Major depressive disorder (MDD) is a devastating psychiatric disorder which afflicts 7% of the adults in the US (SAMSHA). MDD is commonly treated with selective serotonin/norepinephrine reuptake inhibitors (SS/NRIs), but these drugs are fully effective for only 2/3 of patients (Trivedi *et al., 2006*). Moreover, SS/NRIs often require several weeks of treatment to achieve efficacy which can increase the risk of suicide for some patients. Some NMDAR (N-methyl-d-aspartate receptor) antagonists elicit a rapid antidepressant response in humans and animal models. For example, the anesthetic drug, ketamine, is a rapid-acting antidepressant (Berman, *et al.* 2000) that can improve symptoms of depression in as quickly as 1 hr (Zarate, *et al.,* 2006). Ketamine blocks the ion channel pore of NMDA receptors (Orser *et al.*,1997), but the mechanism of rapid antidepression is unclear. 2R,6R, hydroxynorketamine (6-HNK) is a metabolite of ketamine that was recently shown to have rapid antidepressant action in rodent models (Zanos, *et al*., 2016). However, 6-HNK may not block NMDARs and the biochemical signals evoked by ketamine and 6-HNK are not fully distinguished. The rapid antidepressant action of ketamine activates mTOR (mammalian target of rapamycin); eEF2K/eEF2 (Eukaryotic Elongation Factor 2 kinase/ Eukaryotic Elongation Factor 2); and BDNF (brain-derived neurotrophic factor) signaling. In this study organotypic brain slices were obtained from rodents to evaluate the acute and prolonged biochemical actions of ketamine and 6-HNK in hippocampus and cortex. Brain slices were incubated in ketamine or 6-HNK, for 1h and tissue was harvested at 1h and 24h post-treatment. Protein lysates were obtained for each sample and evaluated by western blot. Our findings suggest ketamine and 6-HNK may activate similar biochemical pathways. These data suggest further research is required to more fully distinguish the actions of ketamine and its metabolites.

**Abstract:** NMDA receptors (NMDARs) are a class of ionotropic glutamate receptors present at most excitatory synapses in the brain. NMDARs are highly calcium permeable, and timely calcium influx through NMDARs initiates signaling cascades responsible for many forms of learning and memory. Aberrant activation of NMDARs can also occur, and is implicated in numerous pathologies. A variety of NMDAR inhibitors exist, including open-channel blockers, inhibitors that bind in the pore of NMDARs and impede ion flux. Open channel blockers are typically charged molecules and can only access their binding site in the presence of agonist, when the channel is open. Memantine, a drug approved to treat the symptoms of Alzheimer's disease, is mostly charged at physiological pH, but exists in equilibrium between its charged and uncharged forms. Memantine potently inhibits NMDARs through an open-channel block mechanism. However, a second form of inhibition by memantine has also been described, called second site inhibition (SSI). SSI involves memantine binding in the absence of agonist, and causing inhibition of NMDAR current upon subsequent agonist application. Because SSI was observed following memantine application in the absence of agonist, it was thought that SSI involved memantine binding outside the channel gate on NMDARs. However, our data suggest that SSI involves entry of the uncharged form of memantine into the plasma membrane, from where it can access the channel blocking site. We expressed NMDARs in tsA201 cells and used whole-cell patch clamp electrophysiology to further investigate SSI. By varying pH, and by using a permanently charged trimethyl derivative of memantine synthesized by extensive methylation of memantine, we examined access of uncharged memantine to the NMDAR pore through a hydrophobic pathway. The presence of a hydrophobic pathway through which drugs can pass has not been demonstrated in NMDARs, and reveals a new route of drug access to NMDAR channels.

**Abstract:** N-methyl-D-aspartate receptors (NMDARs) play a key role in excitatory synaptic transmission, and their dysfunction underlies some neurological and psychiatric disorders. Receptor hypofunction was implicated in autism, schizophrenia, and various forms of intellectual disability, and compounds with a positive allosteric effect at NMDARs may have a beneficial effect in these diseases. The aim of this study was to characterize the structure-activity relationship of newly synthesized structural analogues of pregnenolone sulfate (PES) - a naturally occurring neurosteroid that has a positive modulatory action at NMDARs.
We designed, synthesized, and electrophysiologically tested PES analogues, pregne-5-ene and androst-5-ene dicarboxylic acid esters, which differ in the length of the hemiester substituent at the C-3-position and have various structure modifications at C-17 and C-20. All newly synthesized steroids potentiate GluN1/GluN2B receptor currents from +8 to +539 % and most of them are more potent modulators of NMDARs than PES, which potentiates currents by +78 %. The structure-function analysis of synthetic steroids indicates the optimal length of the C-3 substituent (hemisuccinate to hemiazelate), depending on the C-17 substituent for the maximal positive modulatory effect at NMDARs.
The most potent modulator 20-oxo-pregnenolone hemiadipate (20-oxo-PE-hAdi) was further tested for activity at GluN1/GluN2A-D receptors. Dose-response analysis indicates significant differences in the degree of maximal potentiation ($E_{max}$) for 20-oxo-PE-hAdi modulation of GluN1/GluN2A (226.3 ± 36.2 %); GluN1/GluN2B (151.0 ± 15.6 %), GluN1/GluN2C (139.6 ± 39.8 %), and GluN1/GluN2D (114.8 ± 8.8 %) with no significant differences in $EC_{50}$ (9.8 to 13.0 µM).
The endogenously occurring neurosteroid PES (100 µM) and its analogue 20-oxo-PE-hAdi (30 µM) were evaluated for activity at native NMDA, AMPA, and GABA receptors. PES and 20-oxo-PE-hAdi potentiated responses mediated by native NMDAR (+55.8 ± 5.6 % and +138.3 ± 11.4 %, respectively), inhibited responses of native AMPA receptors (-32.2 ± 2.2 % and -6.8 ± 1.6 %, respectively), and GABA receptors (-89.2 ± 2.3 % and -82.8 ± 4.7 %, respectively).
We conclude that the newly synthesized hemiester analogues of PES are potent and selective positive modulators of NMDRs and may lead to the development of new therapeutics.

**Title:** Intracellular state affects NMDA receptor positive allosteric modulator activity

**Authors: *K. SAPKOTA**[1], D. E. JANE[2], D. T. MONAGHAN[1]
[1]Dept. of Pharmacol. and Exptl. Neurosci., Univ. of Nebraska Med. Ctr., Omaha, NE; [2]Ctr. for Synaptic Plasticity, Sch. of Physiol. and Pharmacology, Med. Sci. Building, Univ. of Bristol, Bristol, United Kingdom

**Abstract:** N-Methyl-D-aspartate (NMDA) receptor hypofunction is believed to contribute to the symptoms of schizophrenia and, perhaps, autism. Thus, NMDA receptor positive allosteric modulators (PAMs) are potential therapeutics for the treatment of these conditions. Our laboratories have previously reported the mechanism of action and properties of NMDA receptor PAMs based upon phenanthroic acid and naphthoic acid. In this study, we have identified the differential effect of GluN1- and GluN2-C terminals on potentiation by these PAMs. We also observed that the C-terminal is important for potentiation by other known PAMs. Intracellular $Ca^{+2}$ affected potentiation especially at GluN2A-containing NMDA receptors. Intracellular treatment with a $Ca^{+2}$ chelator diminished the potentiation by PAMs. Phosphorylation state of the receptor also appears to affect PAM activity. PKC activation enhanced the potentiation of PAMs, especially at GluN2B-containing NMDA receptors. These results suggest that the intracellular C-terminal segment of NMDA receptors regulates the activity of NMDAR PAMs and that PAM actions can be dependent upon intracellular factors. Thus, it may be possible to modulate NMDA receptors differentially in different phosphorylation states. These findings may help in the development of new therapeutics for neuropsychiatric disorders.

**Title:** A gating motif in NMDA receptors targeted by disease mutations

**Authors: *J. AMIN**[1,2,3], A. GOCHMAN[1], X. DONG[4], H.-X. ZHOU[4], L. P. WOLLMUTH[1]
[1]Neurobio. and Behavior, [2]Med. Scientist Training Program, [3]Mol. and Cell. Pharmacol., Stony Brook Univ., Stony Brook, NY; [4]Physics and Inst. of Mol. Biophysics, Florida State Univ., Tallahassee, FL

**Abstract:** NMDA receptors (NMDAR) are glutamate-gated ion channels that have a wide distribution in the nervous system. Recently a variety of *de novo* missense mutations in NMDAR subunits have been identified that are associated with severe neurological disorders, particularly epileptic encephalopathies. These disease mutations often target motifs critical to the process of glutamate-induced channel opening or gating. NMDARs are obligate heterotetramers typically composed of two GluN1 and two GluN2 subunits. The pore domain or central core of the ion channel, which is homologous to an inverted K+ channels, is formed by transmembrane segments M1 and M3 and an M2 pore loop. Eukaryotic iGluRs possess an additional transmembrane segment, the M4 segment. Surprisingly, a number of missense mutations are found in the GluN1, GluN2A and GluN2B M4 segments. Based on on-cell single channel recordings, many of these missense mutations have limited effects on gating but very dramatic effects, including in one instance halting gating, occurred for missense mutations at a highly conserved glycine, positioned at the extreme extracellular end of M4. Even alanine substitutions at this conserved glycine severely restricted channel opening, with these actions subunit dependent: for GluN1, any substitution at the conserved glycine equally restricted gating, whereas for GluN2A, the alanine substitution was severe but less dramatic. Interestingly, this glycine is part of a preserved structural motif in the extracellular M4, termed the NMGV motif. We show that the conserved glycine in GluN1 acts as a gating hinge which allows elements of this motif to interact with the pore lining helix of an adjacent subunit during channel opening. This action creates a bridge between the GluN2 M3 and GluN1 M4 transmembrane helices, stabilizing the open state. The NMGV motif in GluN2 also appears to participate in transmembrane interactions but the conserved glycine does not appear to function as a hinge. These results have strong implications for how such disorders are caused at the ion channel level and highlight an important role for the M4 in NMDA receptor gating.

**Title:** Biochemical characterization of glutamate receptors and associated proteins

**Authors: *S. WON**, K. W. ROCHE
NINDS, NIH, Bethesda, MD

**Abstract:** Glutamate receptors mediate the majority of excitatory synaptic transmission in the central nervous system. Ionotropic glutamate receptors (NMDA, AMPA, and kainate receptors) are widely expressed throughout the nervous system and responsible for a variety of processes in mammalian brain including neuronal development, excitatory neurotransmission, learning and memory, and synaptic plasticity. NMDARs assemble as heterotetramers containing two obligatory GluN1 and two GluN2 (A-D) or GluN3 (A-B) subunits to form functional receptors. Calcium influx through NMDARs is thought to be critical for induction of synaptic plasticity, a cellular mechanism for learning and memory. AMPARs are composed of four subunits (GluA1-4), which combine to form tetramers, mostly heterotetrameric. In addition, AMPARs conduct the majority of fast synaptic transmission throughout the CNS and their trafficking and synaptic expression is the critical mechanism that underlies much of the plasticity of excitatory transmission. At excitatory synapses, glutamate receptors assemble into multi-protein complexes including NMDARs, AMPARs and a variety of scaffolding proteins such as the membrane-associated guanylate kinases (MAGUKs). Indeed, the MAGUKs interact with many receptors, channels and neuronal adhesion molecules. Through the years, many studies have indicated that synaptic proteins have unique biochemical properties including distinct posttranslational modifications like phosphorylation and palmitoylation, as well as specific interacting proteins. Indeed, many high-profile studies have been aimed at understanding glutamate receptor ‘interactomes’ using mass spectrometry. However, these protein assemblies are entirely dependent on the solubility of the PSD proteins and antibodies used to immunoprecipitate the proteins of interest, and a systematic comparison of synaptic protein solubility has been lacking. We have now characterized the solubility of NMDARs, AMPARs, neuroligins, and MAGUKs in different tissue and culture conditions. We evaluate adult mouse hippocampus, cultured cortical neurons, and expression of synaptic proteins in heterologous cells. Interestingly, we find that NMDAR subunits and PSD-95 are highly insoluble in brain with mild detergent and are sensitive

to temperature and pH. In contrast AMPARs and neuroligins are much more soluble and don't vary much in different cell preparations. These results reveal the complication that various protein complexes containing NMDAR or PSD-95 in neuron exist in different assemblies, which will likely reveal different interactomes depending on preparation and detergent.

**Title:** Synaptically-induced slow inward currents mediated by pannexin-1 in CA3 pyramidal neurons

**Authors: *M. SOULA**[1], D. L. HUNT[4], E. SCEMES[2], P. E. CASTILLO[3]
[1]Neurosci., [2]Dept of Neurosci, [3]Albert Einstein Col. of Med., Bronx, NY; [4]Janelia Res. Campus, Ashburn, VA

**Abstract:** Pannexins are large pore ion channels widely expressed in the mammalian brain. While pannexins have been involved in a number of pathological conditions, including brain ischemia, inflammation, neurodegeneration and epilepsy, little is known about their physiological role. Remarkably, strong, non-physiological NMDA receptor (NMDAR) stimulation triggers a secondary pannexin-1 (Px1)-mediated inward current in neurons, which has been linked to excitotoxicity and epilepsy. Px1 is highly expressed in the hippocampus where it co-localizes with PSD-95, suggesting a synaptic role. Using pharmacological and genetic tools combined with brain slice electrophysiology in rodents, we found that synaptic activation of NMDARs elicits a Px1-mediated slow postsynaptic current (Px1 EPSC) in CA3 but not CA1 pyramidal neurons. Here, we further characterized these Px1 EPSCs in acute hippocampal slices. Px1 EPSCs were revealed at physiological temperature (35 °C), occurred probabilistically following NMDAR-EPSCs, and produced enough depolarization to elicit action potentials in CA3 pyramidal neurons. In addition, Px1 EPSCs were more robustly elicited by activating mossy fiber to CA3 pyramidal cell synapses than CA3-CA3 synapses. Intracellular loading of the calcium chelator BAPTA (10 mM) or bath application of the NMDAR open channel blocker MK-801 (50 µM) abolished Px1 EPSCs, strongly suggesting that calcium influx

via NMDARs is necessary to elicit these currents. Moreover, a low concentration of the group I metabotropic glutamate receptors (mGluR1/5) agonist DHPG (1 μM) strongly facilitated Px1 EPSCs, whereas mGluR5 antagonism (MPEP, 4 μM) or intracellular loading of the irreversible G protein inhibitory GDP-βS (2 mM) reduced these currents. Activation of other $G_q$ protein-coupled receptors, such as muscarinic receptors M1, facilitated Px1 EPSCs, whereas activation of the $G_s$ protein-coupled receptor A2A had no effect. Our findings indicate that Px1 EPSCs can be regulated by neuromodulators and provide a mechanism for signal amplification in the CA3 area that may be relevant to memory formation and temporal lobe epilepsy.

**Title:** Activity-Dependent postsynaptic signaling in hippocampal neurons is altered by transgenic expression of chimeric NMDA receptor GLuN2 subunits

**Authors: *J. P. FOTANG**[1], C. LEONG[2], F. BOURA[2], S. HUSSAIN[2], R. HOPWOOD[2]
[1]Neurosci., [2]George Mason Univ., Fairfax, VA

**Abstract:** N-methyl-D aspartate receptors (NMDARs) at excitatory synapses in the hippocampus are central players in the synaptic plasticity required for learning and memory. Two predominant signaling properties of NMDARs that have been independently linked to hippocampal plasticity are calcium conductance into the postsynaptic spine and direct intracellular protein signaling. These properties vary with the composition of the NMDAR such that, compared to NMDARs with GluN2A subunits, NMDARs with GluN2B subunits conduct calcium for a longer period after activation and display greater affinity for the obligatory synaptic plasticity protein, CaMKII. Thus, it is not possible to determine the separate influences of these NMDAR properties by switching the entire GluN2 subunit. To overcome this obstacle, we created GluN2 chimeras, one having the amino (A)-terminus and transmembrane domains (TMDs) of GluN2A fused to the carboxy (C)-terminus of GluN2B (termed ABc) and, vice versa, the other line having the A-terminus and TMDs of GluN2B fused to the C-terminus of GluN2A (termed BAc). These chimeric GluN2 subunits were expressed in transgenic mice using the tet-off expression system with tetracycline transactivator protein (tTA) expression under

transcriptional control of the CaMKII minimal promoter. tTA expression was seen in many forebrain regions, but predominantly in hippocampal pyramidal cells. This project used a three by two design in which half of the animals from each genotype (ABc, BAc, and Wildtype-WT) were exposed to a Y-maze in a novel environment to activate NMDARs in the hippocampus. Control animals were not exposed to the Y-maze. We quantified intracellular signaling through fluorescent puncta counts following immunohistochemistry for plasticity related proteins in the synaptic regions of hippocampal area CA1. Pairs of antibodies were applied (anti-pCaMKII and anti-CaMKII; anti-calmodulin and anti-PSD95). There were no genotype or maze exposure effects on number of puncta for pCaMKII, CaMKII or colocalization of these two proteins. Also, there was no effect of genotype or maze exposure on PSD95-positive puncta. However, the number of calmodulin puncta was reduced by maze exposure in WT and ABc, but not BAc mice and colocalization between PSD95 and calmodulin was reduced after maze exposure only in ABc mice. The pattern of results for calmodulin parallels alterations in learning and memory we observed in these mice when tested previously in the Morris water maze. The findings suggest that alterations in calmodulin, but not CaMKII, allow the NMDAR subunit mutations to impact cognition.

**Title:** NYX-2925 promotes GluN2B-PSD95 colocalization and LTP in rat hippocampal neurons

**Authors: *M. S. BOWERS**[1,2], P. K. STANTON[3], A. L. GROSS[1], R. M. MITCHELL[1], M. A. KHAN[1], R. A. KROES[1,2], J. R. MOSKAL[1,2]
[1]Aptinyx, Inc., Evanston, IL; [2]Falk Ctr. for Mol. Therapeut., McCormick Sch. of Engin., Northwestern Univ., Evanston, IL; [3]Cell Biol. & Anat., New York Med. Col., Valhalla, NY

**Abstract:** Aptinyx has developed a novel class of small molecule N-Methyl-D-Aspartate (NMDA) receptor modulators with broad applicability across neurologic and psychiatric disorders. NMDAR activation was measured using a [$^3$H]MK-801 potentiation assay in membrane extracts prepared from human NR2 subtype-expressing HEK cells. NYX-2925 in the presence of glutamate (50 μM) dose-dependently facilitated [$^3$H]MK-801 binding to all four NR2 subtypes. Moreover, NYX-2925 preferentially activated the NR2B subtype by several orders of magnitude. Given the pivotal role of synaptic NMDAR in mediating long-term potentiation (LTP), the effect of NYX-2925 on LTP was measured at Schaffer collateral CA1 synapses in

hippocampal slices prepared from young adult rats. NYX-2925 enhanced NMDAR-dependent LTP and increased NMDAR current. Therefore, the effect of NYX-2925 on surface expression of NR2B-containing NMDAR within PSD95-positive puncta was quantified using spinning disc confocal microscopy in primary rat hippocampal neurons. NYX-2925 increased colocalization of NR2B and PSD95 in a dose- and time-related manner. Moreover, this effect was dependent on both glutamate and glycine concentration. Increased colocalization was paralleled by NR2B and PSD-95 protein expression. Glutamate (50 μM) alone increased colocalization, but not protein expression. These data suggest that NYX-2925 facilitates synaptic plasticity in part by increasing synaptic NR2B. Thus, the biological effects of NYX-2925 result not only from direct receptor modulation, but also by regulating the trafficking of receptors into and out of the synapse.

**Title:** Coupling ligand binding to ion channel opening in NMDA receptors

**Authors: *A. GOCHMAN**, J. AMIN, K. CHAN, L. WOLLMUTH
Stony Brook Univ., Stony Brook, NY

**Abstract:** *N*-methyl-D-aspartate receptors (NMDARs) are glutamate-gated ion channels that are fundamental to brain function. Highlighting the central role of NMDARs is the recent identification of numerous *de novo* missense mutations in NMDAR subunits that are associated with severe neurological disorders. Many of these missense mutations disrupt NMDAR channel gating, the process of converting glutamate binding to opening of its associated $Ca^{2+}$-permeable ion channel, but fundamental features of the gating process in NMDARs remain unknown. In all glutamate-gated ion channels, the M3 transmembrane segment lines the pore and contains elements of the activation gate. Opening of the ion channel is driven by tight mechanical coupling between glutamate-induced conformational changes in the ligand-binding domain (LBD) and displacement of the M3 helices. Surrounding the M3 helices are additional transmembrane helices, M1 and M4. These outer helices must be displaced for efficient pore opening to occur, but whether they are displaced actively by conformational changes in the LBD or passively through movement of the M3 helices remains unknown. To address the displacement of the outer structures, we inserted glycines into the linkers coupling M1 and M4 to the LBD, the S1-M1 and S2-M4 linkers, respectively, and assayed the effect of these manipulations on NMDAR gating using on-cell single channel recordings. Like comparable insertions in the M3-S2 linker, insertions in S1-M1 dramatically attenuated gating, suggesting that like M3-S2 this region is mechanically coupled to the LBD. In contrast, glycine insertions in the S2-M4 linker strongly potentiated NMDAR gating, suggesting a distinct role for the M4/S2-M4 complex in NMDAR gating. To elucidate segment-specific roles in the gating machinery, we combined potentiating S2-M4 glycine insertions with attenuating M3-S2 glycine insertions. These combination insertions have a higher equilibrium open probability ($P_{open}$) than the M3-S2 glycine insertions alone. Interestingly, the relative degree of potentiation for the combination insertions was much greater than the independent effect of S2-M4 insertions in the wild-type background, suggesting that the M4/S2-M4 complex does not act independently as a potentiator of gating, but rather acts synergistically with other transmembrane segments including M3/M3-S2. Hence, the M4/S2-M4 region appears not to exert its effect on gating independently of the active movement of the core gating elements M1 and M3. Our results have implications for how disease causing missense mutations in the outer structures might impact receptor function.

**Abstract:** N-methyl-D-aspartate receptors (NMDARs) are ligand-gated ion channels that are tetrameric complexes of two GluN1 and two GluN2 subunits, of which there are four subtypes (GluN2A-D). A large proportion of NMDARs in adult brain contain two different GluN2 subunits, and are referred to as triheteromeric receptors because they comprise three unique subunits (e.g. GluN1/GluN2A/GluN2C). We have utilized a strategy to enrich cell surface triheteromeric receptors by harnessing the interactions of coiled-coil domains fused to the intracellular domains of different GluN2 subunits to mask a C-terminal endoplasmic reticulum retention signal. We assessed the degree of subunit escape for of this system in Xenopus oocytes, and found that about 90% of the current observed in oocytes coinjected with GluN1 and the modified GluN2A/GluN2C cRNAs arose from triheterimeric GluN1/GluN2A/GluN2C receptors. We subsequently transfected HEK cells with GluN1/GluN2A, GluN1/GluN2C, or GluN1/GluN2A/GluN2C. We excised outside-out patches and recorded the unitary currents activated by maximally effective concentrations of glycine (100 μM) and glutamate (1 mM). In patches where double openings were not observed, we were able to statistically verify that the unitary currents arose from a single channel. The unitary currents were idealized by fitting a filtered step response function to each potential open-closed transition, and we analyzed histograms of the duration and amplitude of all fitted unitary currents, as well as the duration of all closed periods by maximum likelihood fitting. The properties of channels from patches obtained from cells expressing modified GluN1/GluN2A (n=3, mean open time 2.83 ms, mean chord conductance 75, 64 pS) or GluN1/GluN2C (n=7, mean open time 0.70 ms, mean chord conductance 48, 30 pS) were similar to those previously published. We also recorded from 7

patches from GluN1/GluN2A/GluN2C-transfected cells that showed both high and low conductance levels (75, 59, 40 chord conductance) with direct transitions among the three observed levels. We concluded that these patches contained a single triheteromeric GluN1/GluN2A/GluN2C receptor, which opened in bursts like GluN1/GluN2A, but had a low open probability (0.02) and mean open time (0.84 ms) similar to GluN1/GluN2C. The properties of the triheteromeric GluN1/GluN2A/GluN2C receptors may allow synaptic signaling to proceed with a reduced charge transfer. Similar work will be required to understand the properties of other triheteromeric receptors in the adult CNS.

**Abstract:** N-methyl-D-aspartate receptors (NMDARs) are major excitatory receptors that play distinct roles in the central nervous system. Over the past decades, most studies on NMDARs have focused on diheteromeric receptors that contain two GluN1 and two identical GluN2 subunits. However, four genes encoding GluN2 subunits (GluN2A-D) have been identified, and multiple GluN2 subunits are expressed in almost all neurons. Many native NMDARs are triheteromeric assemblies of two GluN1 and two different GluN2 subunits (e.g. GluN1/GluN2A/GluN2C). Thus, there is a lack of information about the properties of physiologically-relevant triheteromeric NMDARs. In this study, we have adapted a strategy that utilizes the masking of engineered endoplasmic reticulum retention signals to selectively express GluN1/GluN2A/GluN2C receptors, allowing an evaluation of triheteromeric receptor properties. Our data suggest that triheteromeric GluN1/GluN2A/GluN2C receptors have a distinct pharmacological profile compared to GluN1/GluN2A and GluN1/GluN2C with respect to altered EC50 and IC50 values for agonists, endogenous ions, and allosteric modulators. Since receptors that contain both GluN2A and GluN2C are known to be expressed in the cerebellum, we used cerebellar granule cells as a model to study native GluN2C-containing NMDAR. The positive allosteric modulator 1616-19 is highly selective for GluN2C-containing NMDARs and potentiates only diheteromeric receptors that contain two GluN2C subunits; 1616-19 has no effect on triheteromeric receptors that include only one copy of GluN2C. We used 1616-19 to test for the presence of triheteromeric GluN1/GluN2A/GluN2C receptors in granule cells in cerebellar slices. Our data suggest that the GluN2C/D-selective modulator CIQ, which can potentiate triheteromeric GluN1/GluN2A/GluN2C receptors, enhanced the response to pressure-applied NMDA in granule cells (n=6), consistent with surface expression of GluN2C. By contrast, 1616-19 had no effect on granule cell NMDAR responses in slice preparations (n=8), suggesting cell surface GluN2C was mostly in the form of triheteromeric NMDARs rather than diheteromeric GluN1/GluN2C receptors. This study advances our understanding of the NMDAR identity in cerebellar neurons, and raises the idea that the GluN2C subunit preferentially associates with GluN2A, suggesting that there may be very little diheteromeric GluN1/GluN2C receptors in some neurons.

**Title:** Region-and activity- dependent regulation of transporter-mediated glutamate uptake

**Authors: *N. F. PINKY**[1], C. M. WILKIE[2], M. P. PARSONS[3]
[1]Biomed. Sci., Mem. Univ. of Newfoundland, St. Johns, NL, Canada; [2]Biomed. Sci., Mem. Univ. of Newfoundland, St. John's, NL, Canada; [3]Biomed. Sci., Mem. Univ., St John's, NL, Canada

**Abstract:** Glutamate is the major excitatory neurotransmitter in the central nervous system and is essential for neuronal survival and rapid cellular communication. However, too much glutamate can have a damaging effect on cell health through a process known as excitotoxicity. Once released into the extracellular space, glutamate must be cleared rapidly in order to prevent excitotoxic damage; this is accomplished through glutamate transporters which are located in high concentrations on astrocyte membranes adjacent to synaptic sites. As excitotoxic cell death is associated with many neurodegenerative diseases, it is important to understand the mechanisms by which the healthy brain efficiently clears extracellular glutamate during neurotransmission. While different types of glutamate transporter exist, it is thought that GLT-1 is responsible for over 90% of total glutamate uptake activity. However, prior work relied heavily on biochemical assays from synaptosome preparations which have recently been shown to overemphasize neuronal glutamate uptake at the expense of astrocytic glutamate uptake. Here, we used a novel optogenetic sensor of extracellular glutamate termed iGluSnFR (intensity based glutamate sensing fluorescence reporter) to visualize, in real-time and on a millisecond timescale, how glutamate clearance dynamics are affected by neural activity in different brain regions *in situ*. By electrically stimulating neural activity in acute brain slices from C57Bl/6 mice, we find that the hippocampus is much more efficient at clearing glutamate compared to the cortex and striatum, particularly during prolonged high-frequency trains of synaptic stimulation. Using a pharmacological approach to quantify the relative contribution of different transporters to total glutamate uptake, our estimates show that while GLT-1 indeed plays an important role in glutamate uptake, approximately 75% of total uptake capacity can be maintained even at high levels of neural activity when GLT-1 is inhibited by a saturating concentration of the GLT-1 blocker DHK. These data suggest a much more important role of non-GLT-1 transporters than previously thought. In all, our data demonstrate that the transporter-mediated regulation of extracellular glutamate dynamics is dependent on both the region being studied and the amount

of neural activity, and therefore highlights the importance of studying glutamate dynamics in real-time *in situ*.

**Title:** Mapping the spatial extent of climbing fiber-mediated spillover to cerebellar interneurons

**Authors: *K. ABIRAMAN**, A. NIETZ, L. CODDINGTON, L. OVERSTREET-WADICHE, J. I. WADICHE
Univ. of Alabama At Birmingham, Birmingham, AL

**Abstract:** Excitatory synaptic transmission in the nervous system is mediated by glutamate, and is traditionally considered to occur exclusively at synapses. Under conditions of high activity or when released at a high concentration, glutamate spills out of synapses to activate extrasynaptic receptors. While extrasynaptic signaling is thought to augment synaptic transmission in several brain regions, we and others have shown that communication between climbing fibers (CFs) and molecular layer interneurons (MLI) in the cerebellar cortex occurs exclusively via glutamate spillover in the absence of anatomically-defined synapses. Glutamate released at the CF-Purkinje cell (PC) synapse spills out to activate AMPA- and NMDA-type receptors on surrounding MLIs. The actions of extrasynaptic glutamate are controlled by excitatory amino acid transporters (EAATs) that remove glutamate from the extracellular space. Although the cerebellar cortex exhibits highly stereotyped anatomical connectivity and astrocytic transporter expression, it is divided into zones based on differential expression of several proteins including the PC-specific glutamate transporter, EAAT4. We performed simultaneous whole cell voltage clamp recordings and confocal imaging of PCs and MLIs to monitor CF activation and assess spillover responses from a single CF. Post-hoc neuronal reconstruction show that the degree of dendritic overlap between the PC-MLI pairs correlates with the magnitude of spillover current in MLIs. Ongoing experiments seek to understand the spatial spread of spillover mediated MLI activation in zones of high and low EAAT4 expression. Together these results help define the anatomical and molecular factors governing spillover transmission at the CF-MLI synapse.

**Title:** Release/uptake mismatch in corticostriatal synaptic connections due to astrocyte dysfunction in mice suffering from Huntington's disease (HD)

**Authors: A. DVORZHAK**[1], A. WÓJTOWICZ[2], *R. GRANTYN[2]
[2]Exptl. Neurol., [1]Univ. Med. Charité, Berlin, Germany

**Abstract:** Previous studies in mouse models of HD reported reduced spine densities in striatal projection neurons (SPNs) as well as decreased expression of the astrocytic glutamate transporter EAAT2 in striatal tissue. To what extent both changes are linked to each other has remained unclear. It is possible that the loss of glutamatergic synapses initiates an adaptive response of astrocytes resulting in smaller/fewer glutamate transporter clusters. Alternatively, insufficient clearance of synaptically released glutamate may lead to alterations in corticostriatal or thalamostriatal synaptic transmission up to the loss of overstimulated contacts. We addressed these possibilities by comparing 1 year old wildtype (WT) and symptomatic HD mice (Q175 hom). Quantification of EAAT2 immunofluorescence (IF) revealed a significant decrease in the integral EAAT2-IF localized next to vGluT1+ but not vGluT2+ terminals in HD, suggesting the existence of a disease-related mismatch between glutamate release and glutamate uptake at the level of individual corticostriatal synapses. In line with this finding, sulphorhodamine-labelled astrocytes in slices from HD mice exhibited smaller glutamate-induced sodium transients as recorded after loading SBFI-AM. They also showed a slower decay of glutamate transporter currents (GTCs) and decreased single-cell GTC maxima in response to increasing concentrations of photolytically applied glutamate. The idea of a glutamate release-uptake mismatch was further confirmed by the analysis of unitary corticostriatal responses. Corticostriatal afferents were visualized by YFP fluorescence after stereotaxic injection of a variety of adenoviral constructs. Individual axons were submitted to optogenetic or electrical microstimulation. The AMPAR- and NMDAR-mediated components of the corticostriatal unitary EPSCs (uEPSCs) were separated by setting the holding potential to - 70 or +40 mV or by using respective receptor blockers. In line with the observed reduction in the density of corticostriatal glutamate release sites, uEPSC

maxima were found to be smaller in HD. At the same time the average release probability was significantly higher, likely as a consequence of increased presynaptic excitability. On the postsynaptic side, the most prominent disease-related alterations were the slowing of the uEPSC decay and the increase in the ratio of NMDA/AMPA components in the postsynaptic response. Together, these results support the hypothesis of an HD-related release/uptake mismatch in the corticostriatal pathway. Whether this is also a cause of synapse pruning remains to be determined.

Univ. At Albany, Albany, NY

**Abstract:** The neuronal glutamate transporter EAAC1 is abundantly expressed in the basal ganglia nucleus of the striatum, yet its role in regulating the functional properties in this brain region remain largely unknown. The striatum plays a crucial role in regulating the execution of stereotyped motor behaviors and reward. In humans, mutations in the gene encoding EAAC1 are associated with the onset of neuropsychiatric disorders like obsessive compulsive disorders. Here we ask how EAAC1 controls glutamatergic signaling in the striatum. Mice that do not express EAAC1 display increased anxiety and abnormal motor behaviors controlled by striatal circuits. This general phenotype suggests that EAAC1 might be involved in regulating excitatory synaptic transmission onto D1 and D2 dopamine receptor expressing medium spiny neurons, which together represent more than 95% of all neurons within the striatum. Consistent with this hypothesis, electrophysiology recordings indicate that EAAC1 limits activation of group I metabotropoic glutamate receptors (mGluRI) and controls D1 dopamine receptor expression. Conversely, blocking mGluRIs rescues D1 dopamine receptor expression. These results indicate that EAAC1 can powerfully regulate excitatory transmission in the striatum and identify new

molecular mechanisms by which loss of EAAC1 might contribute to the onset of OCD-like behaviors.

**Title:** Modulatory effects of Ampicillin-Sulbactam on glial glutamate transporters and metabotropic glutamate receptor 1 as well as reinstatement to cocaine seeking behavior

**Authors: A. M. HAMMAD**, F. ALASMARI, Y. ALTHOBAITI, *Y. SARI
Pharmacol., Univ. of Toledo Col. of Pharm. and Pharmaceut. Sci., Toledo, OH

**Abstract:** The glutamatergic system has an important role in drug dependence including cocaine. Studies reported that chronic exposure to cocaine dysregulates the glutamatergic system. Previous findings revealed that glial glutamate transporter-1 (GLT-1), cystine/glutamate exchanger (xCT) and metabotropic glutamate receptors 1 (mGluR1) in the central reward brain regions mediate cocaine reinstatement. Moreover, treatment with ceftriaxone, a β-lactam antibiotic, known to upregulate GLT-1 reduced cocaine cue-induced reinstatement seeking. In this study, we investigated the reinstatement behavior to cocaine (20 mg/kg, i.p) seeking using a conditioned place preference (CPP) paradigm in male alcohol-preferring (P) rats. We further investigated the effects of Ampicillin/Sulbactam (AMP/SUL) (200 mg/kg, i.p), a β-lactam antibiotic, on cocaine-induced reinstatement. We studied also the expression of glial glutamate transporters GLT-1, xCT and glutamate/aspartate transporter (GLAST) as well as mGluR1 expression in nucleus accumbens (NAc) core and shell and dorsomedial prefrontal cortex (dmPFC). We found that AMP/SUL treatment reduced reinstatement to cocaine seeking. This effect was associated with the decrease in locomotor activity. Moreover, GLT-1 and xCT were downregulated in NAc core and shell but not in the dmPFC following cocaine-primed reinstatement. However, cocaine upregulated mGluR1 expression in the NAc core but not NAc shell or dmPFC. Importantly, AMP/SUL treatments normalized GLT-1 and xCT expression in the NAc core and shell; however, the drug normalized mGluR1 expression in the NAc core only. Additionally, AMP/SUL upregulated GLT-1 and xCT in the dmPFC as compared to water naïve group. These findings demonstrated that glial glutamate transporters and mGluR 1 in the

mesocorticolimbic brain regions could be potential therapeutic targets for cocaine-seeking behavior

**Abstract:** Introduction
The aim of this study is to increase the amount of intracellular glutamate by activating the target eAAT2 receptor and thus to establish a new therapeutic approach to cancer.
Methods
Glioblastoma multiforme cell lines exposured with EAAT1, EAAT2, EAAT3 blockers and ceftriaxone. With Real-Time PCR Slc1a1, Slc1a2 and Slc1a3 gene expressions had been analyzed. MTT test had been done. Statistical Analyses were done.

**Results and Discussion**

Taken together, this study suggest that Ceftriaxone, or rationally designed and pharmacologically enhanced drugs that act in a similar way as glutamate transporter inducer, may serve as a therapeutic drug for ameliorating and potentially annihilating the cancer cells via inducing EAAT2.

**Abstract:** Glutamate is the major excitatory neurotransmitter in the brain. Clearance of glutamate after synaptic release is achieved primarily by the transporters GLT-1 and GLAST that are highly expressed in astrocytes. However, GLT-1 is also expressed in axon terminals. Using a conditional GLT-1 knockout in which GLT-1 is deleted in neurons using synapsin-Cre (synGLT-1 KO), we recently demonstrated significant glutamate uptake mediated by neuronal GLT-1 in crude synaptosomes from the whole forebrain [Petr et al. *J Neurosci* (2015) 35: 5187]. In the present study, we found reduced glutamate uptake into synaptosomes isolated from the cortex (50±7%, n=6; $p<0.05$), hippocampus (16±4%, n=3; $p<0.05$), and striatum (45±3%, n=3; $p<0.01$) of synGLT-1 KO mice compared to controls. Our goal here was to investigate by NMR spectroscopy, HPLC, and GC-mass spectrometry the importance of GLT-1 expressed in neurons for synaptic energy metabolism and glutamate homeostasis.
SynGLT-1 KO and control littermates were subjected to three types of experiments to assess

energy metabolism at a cellular (1), mitochondrial (2) and synaptic (3) level: (1) *in vivo* metabolic $^{13}$C-labeling with [1-$^{13}$C]glucose and [1,2-$^{13}$C]acetate to prime neuronal and astrocytic metabolism, respectively; (2) measurement of oxygen consumption and ATP production in isolated mitochondria to assess energy metabolism; and (3) metabolic $^{13}$C-labeling of purified synaptosomes with [U-$^{13}$C]glucose and [U-$^{13}$C]glutamate to characterize synaptic neuronal energy metabolism. In addition, we performed an electron microscopic assessment of mitochondria in the neocortex of synGLT-1 KO and control littermates.
The key significant findings in cerebral cortex include: (1) reduction in aspartate level (57%; p=0.04) paralleled by an increased glutamate level (6%; p=0.03) in the synGLT-1 KO, and absence of change in neuronal and astrocytic metabolism based on products of [1-$^{13}$C]glucose and [1,2-$^{13}$C]acetate metabolism, respectively; (2) unchanged oxygen consumption, but increased ATP production (77%; p=0.01) measured in isolated synGLT-1 KO mitochondria; (3) changes in synaptosomal $^{13}$C-labeling of TCA cycle intermediates following metabolism of [U-$^{13}$C]glucose and [U-$^{13}$C]glutamate. Ultrastructural analysis indicated that the occurrence of mitochondria within astrocyte processes immediately adjacent to and within 5 micrometer from excitatory synapses was doubled in tissue of synGLT-1 KO cortex, relative to controls ($p<0.05$; n=3). These results collectively suggest important roles for neuronal GLT-1 in synaptic glutamate homeostasis and energy metabolism.

**Title:** Modulation of the excitatory amino acid transporter 2 by spider venoms

**Authors: *A. TORA**, M.-L. RIVES, A. D. WICKENDEN
Discovery Sci. - Mol. and Cell. Pharmacol., Janssen R&D Johnson&Johnson, San Diego, CA

**Abstract:** The excitatory amino acid transporter 2 (EAAT2) or sodium-dependent glutamate transporter 2 (SLC1A2) plays an essential role in glutamate clearance from the synaptic cleft, therefore regulating glutamatergic neurotransmission. Numerous neurological diseases, such as mood disorders, addiction, Huntington's disease and amyotrophic lateral sclerosis (ALS) have been linked to impairments of glutamate transporter function and/or expression, making this transporter an emerging therapeutic target. Spider venoms represent an incredible source of biologically active compounds, notably due to diversity within the Araneae order, which

comprises more than 46,000 species. Spider toxins, like argiotoxins from Araneus *gemma* and the joro spider toxin from the Nephilia *clavata* have been shown to block the activity of ionotropic glutamate receptors. Regarding glutamate transporters, previous studies have indicated that EAAT2 function can be enhanced by Parawixin-1, a substance present in the venom of the Brazilian spider Parawixia *bistriata* (Fontana et al., Br J Pharmacol. 2003; 139:1297-309). In this study, we evaluated the EAAT2 modulatory effects of a focused library of spider venom fractions. Using functional assays (fluorescence-based membrane potential measurements, glutamate uptake assays and electrophysiology), we screened a venom library containing 207 fractions derived from 12 different species of orb weaving spiders (VenomTech, UK). Our results showed that venoms from Eresidae, Ctenidae, Lycosidae and Sparassidae families exhibit modulatory activity on EAAT2. These findings may provide insights to the development of new pharmacological tools as well as compounds of therapeutic interest targeting the glutamate transporter family.

**Title:** Subcellular distribution of astroglial receptors monitored with super-resolution microscopy

**Authors: *J. P. HELLER**[1,2], K. ZHENG[2], D. A. RUSAKOV[2]
[1]Clin. and Exptl. Epilepsy, Univ. Col. London, London, United Kingdom; [2]UCL Inst. of Neurol., London, United Kingdom

**Abstract:** Astrocytes play an active role in shaping and maintaining neuronal circuits. In addition to their long-established role in extracellular potassium buffering and glutamate uptake,

these cells can also regulate the activity of local synaptic circuits through secretion and clearance of neurotransmitters. Whilst the molecular signal exchange between astroglia and synapses occurs in a highly heterogeneous microenvironment on the nanoscale, the spatial subcellular distribution of the underlying molecular machineries remains poorly understood.
We have therefore employed super-resolution microscopy techniques such as dSTORM (direct stochastical optical reconstruction microscopy) to visualise the 3D positions of neurotransmitter receptors and transporters in astrocytes. This imaging technique relies on the sequential activation, imaging and bleaching of a sparse subset of fluorescent molecules. Thus, images can be obtained with sub-diffraction resolution by localising individual activated molecules in each frame. Using dSTORM, we were able to localise cytoskeletal proteins as well as clusters of receptors and transporters in astrocytic and neuronal membranes in fixed cultured cells and in brain slices. Moreover, through multi-colour imaging, the positional relationship between synapses and astroglial receptors and transporters can be assessed. We are currently attempting to determine whether the astroglial coverage of excitatory as well as inhibitory synapses is altered in different conditions compatible with long-term synaptic potentiation or depression.

**Abstract:** Evidence shows a high rate of co-abuse of methamphetamine (METH) and ethanol. In this study, we investigated the reinstatement to METH using conditioned place preference (CPP) in alcohol-preferring (P) rats as an animal model of alcoholism. Among other neurotransmitters, glutamate is implicated in mediating relapse to several drugs of abuse. Glutamate homeostasis is maintained by number of glutamate transporters, such as glutamate transporter type 1 (GLT-1), cystine/glutamate transporter (xCT), and glutamate aspartate transporter (GLAST). In addition,

group II metabotropic glutamate receptors (mGluR2/3) were found to be implicated in relapse to different drugs of abuse. Ceftriaxone, β-lactam antibiotic, has been previously shown to be effective in improving glutamate homeostasis and preventing relapse to drugs of abuse. Here, we tested the effect of clavulanic acid (CA), a non-antibiotic β-lactam compound, on reinstatement to METH seeking, ethanol intake, the expression of glial glutamate transporters, and mGluR2/3 in the nucleus accumbens (NAc) shell and core as well as the dorsomedial prefrontal cortex (dmPFC). Chronic exposure to ethanol decreased the expression of GLT-1 and xCT in the NAc shell, but not the NAc core or dmPFC. CA treatment attenuated the reinstatement to METH seeking, decreased ethanol intake and restored the expression of GLT-1 and xCT in the NAc shell. CA treatment increased the expression of mGluR2/3 in the NAc shell and dmPFC. These findings suggest that CA has the potential to modulate the expression of glial glutamate transporters and mGluR2/3 receptors, which consequently attenuate reinstatement to METH seeking and decrease ethanol intake.

**Title:** Characterization and functional relevance of SLC38 (SNAT) homologues in D. Melanogaster

**Authors: *T. AGGARWAL**, M. M. ERIKSSON, R. FREDRIKSSON
Dept of Pharm Biosciences, Uppsala Univ., Uppsala, Sweden

**Abstract:** Glutamine, glutamate and GABA are important amino acids for our body which are regulated by an important mechanism known as Glutamate/GABA-glutamine cycle working between neurons and astrocytes. This is controlled by several members of membrane bound transporter proteins known as solute carriers (SLCs) which are vital for transport and cellular homeostasis. Imbalance and dysregulation in the cycle and transport can result in cellular stress, cell death and hence neurodegeneration.
SLC38 is one the transporter family also referred to as sodium-coupled neutral amino acid transporters (SNATs). In *D. Melanogaster*, there are two SNATs, one possible orthologous to

SLC38A10 (SNAT10) and one that are ancestral to SLC38 (SNAT 1-6,7,8,11). SLC38 family in *D. Melanogaster* is unexplored, and here we investigate the functional characterization and functional relevance of SLC38 transporters in cellular metabolism and bioenergetics. We have used UAS/Gal4 system to check for expression and we observed that SLC38A10 is expressed in brain and salivary gland and SLC38 only in salivary gland. To characterize the role of SLC38 transporter, we are using RNAi lines for ubiquitous knockdown to be compared to controls. We performed qPCR to check for gene expression, sugar assay to measure important sugars, DAMS (drosophila activity monitoring system) to analyze starvation resistance, circadian rhythm, locomotion activity, survival assay, and tissue staining to check for neuronal loss. We are analyzing the neurotransmitter levels in the brain to check for any upregulation or downregulation of specific neurotransmitter. We have observed significant changes in SLC38 knockdowns compared to controls. This will help us to functionally characterize and further explore any links between the role of SLC38, Glutamate/GABA-glutamine cycle and any neurodegenerative phenotype.

**Title:** Modulation of anion channel gating in Excitatory Amino Acid Transporters by c-terminal domains

**Authors: A. M. KARA**[1], A. D. GONZALEZ[2], J. GARCIA-OLIVARES[1], *D. TORRES-SALAZAR[1], S. G. AMARA[1]
[1]Natl. Inst. of Hlth., Bethesda, MD; [2]Yale Univ., New Haven, CT

**Abstract:** Excitatory Amino Acid Transporters (EAATs) are responsible for clearing glutamate following its synaptic release, and thus they facilitate the precise transmission of excitatory signals within the CNS. Failure to maintain tight control of extracellular glutamate concentrations can lead to overstimulation of glutamate receptors and neuronal cell death due to excitotoxicity. EAATs serve two functions: they couple the transport of glutamate to the inward movement of sodium ions and they also allow chloride permeation through a substrate-gated anion selective channel. In recent years, our understanding of the substrate transport mechanism has significantly advanced. However, the mechanism and molecular determinants for channel gating and anion permeation are only now emerging. Studies combining molecular dynamics (MD) simulations and electrophysiological techniques have provided evidence for a structural coupling controlling the equilibrium between the transport cycle and anion channel opening, the

latter occurring “outside” the transport cycle in intermediate conformations. We have constructed a computational model of EAAT4 including the C-terminus, which suggests that interactions between the C-terminus and a conserved region of transmembrane domain 3 (TM3) influence the structural coupling between transport and anion channel activity. We tested this hypothesis using electrophysiological recordings in *Xenopus* oocytes expressing different point mutations in TM3 (K119D, R123D, and R127D) and in the C-terminus (E523, E528, and E530) or using transporters with different C-terminal truncations. Our preliminary results indicate that truncation of the full C-terminus (Q521X) disrupts anion channel gating and significantly reduces glutamate transport, indicating that the C-terminal domain and its potential interaction with TM3, may play a critical role in modulating the structural coupling that control the equilibrium between substrate transport and anion channel opening. Our results provide additional insight into the complexity of structural conformations that link substrate binding and the anion channel gating.

**Title:** Astroglial glutamate transporters and reversed-mode $Na^+/Ca^{2+}$-exchange contribute to neurovascular coupling

**Authors: *J. G. JACKSON**[1], H. TAKANO[2], D. A. COULTER[3], M. B. ROBINSON[4]
[1]Neurosci., [2]Neurol., [3]Pediatrics Div. of Neurol., Children's Hosp. of Philadelphia, Philadelphia, PA; [4]Neurosci. Res., Children's Hospital/Univ Pennsylvania, Philadelphia, PA

**Abstract:** Cerebral blood flow is increased to match energetic demands imposed by neuronal activation. This process, termed neurovascular coupling, provides the basis for the signal detected with functional MRI. Although the mechanism (s) underlying neurovascular coupling have been studied for two decades, the field is still highly controversial. Astrocytes have fine processes that contact synapses and endfeet that ensheath the vasculature, making them ideal anatomic mediators of this effect. Some have shown that increases in astrocytic $Ca^{2+}$ are

sufficient to increase blood flow and observed $Ca^{2+}$ increases that precede the increase in arteriole diameter, while others have not observed $Ca^{2+}$ responses with the appropriate temporal characteristics. Most excitatory activity is mediated by glutamate and most glutamate is cleared into astrocytes by $Na^{+}$-dependent transporters. A decade ago three groups demonstrated that blocking glutamate uptake attenuates the neurovascular response (Gurden et al 2006; Petzold et al 2008; Schummers et al 2008), but the effects of glutamate transporter substrates have not been examined and the mechanisms underlying transporter-mediated increases in blood flow have not been explored. We hypothesized that glutamate uptake-mediated arteriole dilation might depend on the $Na^{+}/Ca^{2+}$ exchanger. To test this hypothesis, we used two-photon *in vivo* microscopy to measure arteriole diameter in anesthetized mice, of either sex. As others have reported, either electrical stimulation or focal application of glutamate transiently increased arteriole diameter. Focal application of a glutamate transporter substrate (L-(-)-threo-3-hydroxyaspartic acid; THA), at a concentration (100 µM) that does not activate ionotropic glutamate receptors (Erreger et al 2007), increased arteriole diameter to 113 ± 2% of control (n=6 mice). In preliminary experiments, the increases in arteriole diameter induced by either electrical stimulation or THA were blocked by an inhibitor of reversed-mode $Na^{+}/Ca^{2+}$-exchange (1 µM; YM244769). These results suggest that activation of glutamate transporters is sufficient to evoke arteriole dilation *in vivo* and suggest a mechanism by which transporter-mediated dilation may occur.

**Abstract:** Glutamate (Glu), a major excitatory neurotransmitter, is taken up by normal brain astrocytes whereas brain tumor cells release more Glu or fail to take it up, causing a positive

feedback loop which can injure neurons. We hypothesized that secretion of Glu or failure of uptake by brain tumor cells can be inhibited by delivering anti-cancer drugs to remove this dysfunctional component of the normally homeostatic system. To verify this, we measured Glu uptake by normal brain astrocytes and brain tumor cells (CRL-2303) from American Type Culture Collection (ATCC) using EnzyChrom$^{TM}$ Glutamate Assay kit and spectrophotometric measurements. Preincubation of cells with Glu for 5 hours at 37°C and 5% $CO_2$ showed uptake in normal brain astrocytes but not by brain tumor cells. Glu (100 uM) was taken up by astrocytes in a cell density-dependent manner, whereas glioma cell cultures lacked such relationship. For 200,000, 100,000, and 50,000 cells per mL, astrocytes showed Glu uptake of 67.7, 41.7, and 15.9% respectively. In contrast, under the same conditions, glioma cells showed 10.1, 8.2 and 2.5% respectively. Our data indicated that this type of brain tumor cells have minimum or no Glu clearing capacity from the extracellular environment compared to normal brain astrocytes. These dynamics could be important for measuring functional effects of potential anti-cancer drugs. For example, camptothecin (CPT), an apoptotic anti-cancer drug, but poorly soluble, was encapsulated here in the lumen of halloysite nanotubes (HNTs) by using their saturated solutions in organic solvents and delivered to the tumor cells. In comparison to free CPT, HNTs-loaded with CPT at submaximal killing concentrations (1 ug/mL), sustained suppression of glioma cell growth *in vitro* after the initial burst of inhibition. In contrast, normal brain astrocytes treated with submaximal apoptotic treatments demonstrated much less recovery after release from the apoptotic stimulus. After determining recovery from apoptosis for the two cell culture types separately, feasibility of mixed glioma/astrocyte cultures was demonstrated using beta-galactosidase staining, which is specific for the glioma cells (modified to carry the expression marker). Mixed cultures of glioma cells and astroctyes better mimic the *in vivo* environment which is heterogeneous, and is anticipated to also reflect altered Glu uptake regulation both before and after anti-cancer drug treatments. Thus, cell killing effects and regulation of Glu uptake together may give added insight to long-term efficacy of potential apoptotic applications for healthy and diseased brain cell systems.

**Title:** Targeting glial glutamate transporters for the treatment of cannabinoids dependence in rat model

**Authors: *A. Y. HAKAMI**, F. S. ALSHEHRI, Y. S. ALTHOBAITI, Y. SARI
Univ. of Toledo, Toledo, OH

**Abstract:** Several studies have reported the involvement of CB1 receptors in mediating the effect of many drugs of abuse based on pharmacological manipulations of CB1 receptors. Previous studies on cannabinoids, using conditioned place preference (CPP) paradigm, have reported conflicting results regarding their rewarding effects involving certain neurotransmitter systems. However, less is known about the role of glutamate neurotransmission on cannabinoid dependence. Glutamate homeostasis is maintained by several glial glutamate transporters, such as glutamate transporter 1 (GLT-1), cystine/glutamate transporter (xCT) and glutamate aspartate transporter (GLAST). Studies from our laboratory demonstrated that β-lactam compounds can restore glutamate homeostasis in alcohol-preferring rats, in part, through upregulation of GLT-1 and xCT expression. In this study, we tested the effects of chronic treatment with CP 55940 (20 μg/kg) on the CPP paradigm and glial glutamate transporters. Moreover, we investigated the effect of Ampicillin/Sulbactam (AMP/SUL), β-lactam compounds, on the reinstatement to CP 55940; we also determined the effects of these β-lactams on glial glutamate transporters. We found that our established CPP paradigm showed reinstatement to CP 55940 and this effect was associated, in part, with downregulation of xCT expression in the brain reward regions. Importantly, AMP/SUL treatment attenuated reinstatement to CP 55940 and restored the expression of xCT in the brain reward regions. These findings demonstrated that AMP/SUL attenuated reinstatement to CP 55940 through upregulation of xCT. This study suggests that AMP/SUL may be potentially used for the treatment of cannabinoid dependence.

**Title:** Characterization and modelling of a putative glycine transporter in *Drosophila melanogaster*

**Authors: *A. B. LOPEZ**[1], F. FRATEV[2], A. SILVA[3], S. SIRIMULLA[2], M. MIRANDA[3]

**Abstract:** Glycine is the simplest amino acid, but also serves as a major inhibitory neurotransmitter in the vertebrate central nervous system. Although glycine transporters (GlyT1 and GlyT2) and receptors have been established as critical components of inhibitory neurotransmission in mammals, they are poorly studied in invertebrate models such as *Drosophila melanogaster*. Published work by other groups, using sequence alignments of mammalian transporters against the fly genome, predicts the presence of a single glycine transporter. In this work, we used protein modelling and biochemical assays to characterize this putative glycine transporter (Dmel GlyT2). Based in dynamic simulations, we build a 3D model and localized the possible binding cage for glycine and sodium ions, providing evidence that this is a glycine transporter with equivalent organization to the mammalian GlyT2. To obtain additional biochemical evidence of a glycine transporter, we will express this protein in mammalian cells and analyze for substrate specificity and kinetic parameters. The results should provide strong evidence of the presence of glycinergic components in invertebrates.

**Abstract:** Glycine is an important inhibitory neurotransmitter in the CNS of vertebrates. The neuronal glycine transporter 2 (GlyT2) is localized in presynaptic terminals and mediates glycine

uptake from the synaptic cleft, thus contributing to glycine homeostasis. GlyT2 is considered a potential target for treatment of pain and hyperekplexia. As GlyT2 activity can be regulated by protein-protein interactions, it is essential to investigate the interactome of GlyT2. To do so, we performed coimmunoprecipitations (co-IPs) of GlyT2 with hindbrain lysate and subsequent mass spectrometry (in triplicate). Forty-five putative GlyT2-interacting proteins were exclusively identified in GlyT2 co-IPs of wildtype animals. Among these, the calcium-dependent secretion activator 1 (CAPS1) was identified with 7, 14 and 5 exclusive unique peptides. Co-IPs with endogenous protein followed by immunoblotting verified the binding of CAPS1 to GlyT2. Moreover, GlyT2 efficiently bound to CAPS1 in reverse co-IPs, suggesting a physical interaction of GlyT2 and CAPS1 *in vivo*. The protein-protein binding site was assessed via a peptide spot array. To this end, peptides corresponding to the mouse GlyT2 amino-terminus, carboxy-terminus and parts of CAPS1 were spotted onto a membrane and incubated with hindbrain lysate, followed by antibody labeling. We found binding of CAPS1 to the conserved GlyT2 carboxy-terminus. Immunocytochemistry and immunoblotting of HEK293 cells revealed higher GlyT2 expression when CAPS1 is co-expressed, suggesting a positive regulation. Interestingly, GlyT2 appears to be localized more intracellularly in the presence of CAPS1. Indeed, biotinylation of surface proteins in HEK293 cells indicated a lower relative amount of biotinylated GlyT2 when co-expressed with CAPS1. Demonstration of a functional interaction between GlyT2 and CAPS1 was that glycine uptake was reduced in HEK293 cells co-expressing GlyT2 and CAPS1. The substrate affinity of GlyT2 was unchanged by CAPS1. In contrast, the maximal glycine transport velocity was reduced, confirming a decreased surface expression of GlyT2, which suggests reduced trafficking of the transporter to the plasma membrane or enhanced endocytosis. Taken together, our data provide evidence that CAPS1 interacts with GlyT2 and reduces glycine uptake by decreasing its surface expression. This is in line with the knowledge that CAPS1 is essential for vesicle trafficking, neurotransmitter exocytosis, and the modulation of monoamine uptake and storage by vesicular monoamine transporters.

**Title:** PADI4/PADI6 gene variations are associated with common forms of human generalized epilepsy

**Authors: *R. J. BUONO**[1], T. N. FERRARO[1], J. P. BRADFIELD[2], H. HAKONARSON[2]
[1]Biomed. Sci., Cooper Med. Sch. of Rowan Univ., Camden, NJ; [2]Ctr. for Applied Genomics, The Children's Hosp. of Philadelphia, Philadelphia, PA

**Abstract:** Epilepsy is a complex heterogenous disorder with strong heritability. We performed a genome wide association study (GWAS) using single nucleotide polymorphism (SNP) arrays (Illumina HumanHap 550, 610 Quad and OMNIExpress) to identify genetic variants associated with common forms of idiopathic generalized epilepsy (GE) and focal epilepsy (FE). The Philadelphia Cohort contains 2617 patients with common forms of GE or FE of unknown cause. Association tests were performed separately for all epilepsy, GE and FE compared to 8070 controls. All SNPs were tested with a logistic regression using the top 3 eigenvectors and sex as covariates for the 3 phenotypes. SNPtest was used for the association analysis. The cohorts, separated by ancestry, were meta-analyzed using METAL applying an inverse variance-based algorithm. A SNP in the ancestry specific meta-analysis was considered to be genome wide significant with a P-value <= $5x10^{-8}$. Ancestry level meta-analysis statistics were then combined using MANTRA in a trans-ethnic meta-analysis. The number of samples in each analysis was calculated as the effective sample size $N_{eff} = 4/(1/N_{cases}+1/N_{ctrls})$. A SNP in the trans-ethnic meta-analysis was considered to be genome wide significant with a log10(Bayes Factor) >= 6.
No SNPs reached genome wide significance when comparing all cases to controls. Positive association was found in GE patients with four SNPs reaching genome wide significance ($P < 5 \times 10^{-8}$) across the PADI4/PADI6 locus. Four additional SNP markers in this region reached p-values of between $5.3 \times 10^{-8}$ and $8.1 \times 10^{-8}$. Five of these SNPs reached genome wide statistical significance via MANTRA analysis as well. The associated SNPs reside within intronic regions of *PADI4* and *PADI6* with one synonymous
SNP (rs35240185, P424P) and one 3' untranslated region SNP in *PADI4*. Several SNPs reached genome wide significance in the focal cohort including one marker in the ASS1 gene, two markers in the RANBP3 gene and three markers in PIK3C3 with an additional 8 markers in PIK3C3 reaching suggestive significance (Bayes Factor scores 5.65 – 5.88).
Our results demonstrate that genetic variation at 1p36.13 in the *PADI4-PADI6* gene region is associated with GE. These genes are related to processes that regulate early development, cause epigenetic modification of histones and are also implicated in the generation of autoantibodies. FE genes of interest included ASS1 (in the same enzymatic pathway as PADI4/PADI6) RANBP3 and PIK3C3. Further study of these genes may help elucidate causes of epileptogenesis and lead to potential therapeutic targets for common forms of human epilepsy.

**Abstract:** Epileptic encephalopathies (EE) (MIM 308350) are severe childhood brain disorders characterized by a variety of severe epilepsy syndromes that differ by age of onset and seizure type. Until recently, the cause of many epileptic encephalopathies was unknown. Whole exome or whole genome sequencing has led to the identification of several causal genes in individuals with epileptic encephalopathy, and the list of genes has now expanded greatly. Studies in our Center for Rare Childhood Disorders and by others have defined de novo missense mutations in the Dynamin 1 gene (*DNM1*, OMIM: 602377) in several patients with early infantile epileptic encephalopathy (OMIM: # 616346). Early onset epileptic encephalopathy, intractable seizures, intellectual disability, developmental delay, and hypotonia are the common neurological deficit described in patients with DNM1. Dynamin 1 (DNM1), with a molecular mass of ~100 kd, functions in GTPase mediated endocytosis, synaptic transmission, and activation of signaling mediated by PKC. DNM1 is highly expressed in neurons, but not widely expressed in other tissues. We describe the phenotypic and genetic spectrum in a cohort of patients (n=5) with early infantile epileptic encephalopathy caused by the DNM1 mutation. Past research has provided insights into dynamin-1 structure and function; however it is still unclear how the de novo missense mutation in DNM1, a core component of postsynaptic endocytosis machinery leads to early epileptic encephalopathy. To understand the pathogenesis of DNM1 epileptic encephalopathy we studied the patient-derived fibroblasts and have developed a zebrafish model of DNM1 mutations. Our results from the zebrafish model with morpholino knockdown and chemical inhibition of DNM1 protein revealed the presence of smaller head (microcephaly) and body size. We detected a hyperactive phenotype and whole body convulsion in zebrafish embryos at 72 hrs. We have also observed mitochondrial dysfunction in the fibroblast cells

derived from a patient. The mitochondrial dysfunction was characterized by decreased ATP generation and reduced store capacity. We also observed an impaired endocytosis mechanism revealed through transferrin uptake assay. Our studies demonstrate a DNM1-specific phenotype in patient-derived fibroblasts and in the zebrafish model. Use of such cellular and simple animal models may lead to a better understanding of DNM1-related neurological disease mechanisms and may lead to the identification of novel therapies.

**Title:** Loss-of-function mutations in the epileptic encephalopathy candidate gene TRIO impair the pre- and post-natal development of cortical GABAergic interneurons

**Authors: *L. EID**, F. CHARRON-LIGEZ, P. RAJU, F. HANSSON, M. LACHANCE, E. ROSSIGNOL
Ctr. De Recherche Du CHU Sainte-Justine, Montreal, QC, Canada

**Abstract:** Epileptic encephalopathies (EEs) are neurodevelopmental diseases characterized by early-onset epilepsy with cognitive deficits. EE remain of unknown etiology in up to 50% of patients. However, recent data suggest that a subset of genetically determined epilepsies result from defects in the development of inhibitory interneurons (INs) leading to aberrant enhancement of cortical excitability. Recessive mutations in the *TRIO* gene have been recently identified through whole-exome sequencing in patients with EE or isolated intellectual deficiency by our lab and others. *Trio* encodes a guanine nucleotide exchange factor (GEF) that activates the Rho GTPases Rac1, RhoG and RhoA, implicated in fundamental aspects of neuronal development, including cell cycle regulation, neurite outgrowth, nucleokinesis and caudal neurite retraction. However, the roles of *Trio* in the development of INs are unknown. Considering the proposed involvement of *Trio* in neuronal development and the implication of IN disorders in the pathophysiology of EE, we stipulate that *Trio* might be a central regulator of the development and connectivity of cortical INs. To assess this hypothesis, we performed a

targeted repression of *Trio* in migrating INs through *ex-vivo* electroporation of a *Dlx5/6::shRNA-tdTomato* plasmid in the medial ganglionic eminences of e13.5 embryonic mice and cultured organotypic cortical slice that were imaged after 48h using confocal and time-lapse imaging. We show that the targeted repression of *Trio* impairs the morphological development and migratory dynamics of cortical INs. These morphological defects were partly rescued after co-electroporation with a shRNA-resistant version of the full-length *Trio* cDNA, reflecting the requirement for specific TRIO isoforms. Furthermore, the morphological defects can be partially rescued by co-electroporation of the *Trio* shRNA with a constitutively active form of RhoA. To assess the role of *Trio* in the post-natal development of cortical INs, we transfected a *10kb-GAD67::shRNA-tdTomato* plasmid, specific to parvalbumin (PV)-INs, in post-natal cortical organotypic cultures. We show that the post-natal repression of *Trio* decreases the complexity of the dendritic field and reduces the extent of the innervation field of PV-INs on pyramidal cells. Altogether, our data suggest that *TRIO*-associated EE might be due to a defect in cortical INs development, both pre- and post-natally, presumably resulting in cortical hyperexcitability. We will validate these findings *in vivo* using a *Trio* conditional knockout mouse and further assess the contribution of specific Rho GTPAses to the cellular pathological phenotypes observed.

**Abstract:** The ketogenic diet (KD) is an effective therapy for pediatric epilepsy patients that are refractory to conventional anti-seizure drugs, a condition in which people with seizures do not

achieve adequate seizure control with medication. Recently, we have identified the nutritionally-regulated transcription factor PPARγ2 as an important contributor to the anti-seizure effects of the KD. PPARγ2 regulates hundreds of genes involved in adipogenesis, insulin sensitivity, anti-inflammation, antioxidation and mitochondrial function. We performed a RT-qPCR array experiment on a small set of known PPARγ-regulated genes on hippocampal tissue from wild-type (WT) and epileptic Kcna1-null mice. We found that half the genes were regulated by the KD in both genotypes. As oxidative stress has been implicated in the pathology of epilepsy, we focused on one of the genes identified, the antioxidant catalase. We hypothesized that the KD regulates catalase via PPARγ2. Using qPCR and Western blot techniques, we found that the KD regulates mRNA and protein levels of catalase in WT and Kcna1-null hippocampus, but not Pparγ2-null hippocampus. However, catalase activity assays did not reveal any significant differences between mice fed a standard diet or KD. Ongoing experiments will determine the effects of a catalase inhibitor on the KD antiseizure efficacy. In conclusion, as a dietary therapy the KD has wide ranging effects on gene expression. However, the mechanisms contributing to the antiseizure effects are not completely understood. Our results here suggest that KD regulation of catalase is dependent on PPARγ2.

**Title:** The role of T-cell intracellular antigen-1 in epileptogenesis

**Authors: *Y. GONG**[1,2], J. A. HEWETT[1]
[1]Dept. of Biology, Syracuse Univ., Syracuse, NY; [2]Interdisciplinary Neurosci. Grad. Program, Syracuse Univ., Syracuse, NY

**Abstract:** T-cell intracellular antigen-1 (TIA-1) is an RNA binding protein that contributes to post-transcriptional control of gene expression by silencing translation of target mRNAs. Under conditions of cellular stress, TIA-1 arrests translation by sequestering target mRNAs in stress granules (SGs). It may also serve functions other than mRNA translational regulation via protein-protein interactions. TIA-1 has recently been implicated in several acute and chronic neurodegenerative conditions, including cerebral ischemia and Alzheimer's disease. Because brain damage is an important risk factor for development of epilepsy, a chronic disorder that is

characterized by spontaneous seizures, the purpose of this study was to examine the possibility that TIA-1 functions in epileptogenesis, the process by which the normal brain becomes prone to spontaneous seizures. Although TIA-1 is known to be expressed in the central nervous system, this has not been characterized systematically in the normal brain. Thus, we first examined the constitutive expression profile of TIA-1 mRNA and protein. In comparison to other tissues, brain exhibited the highest level of TIA-1 mRNA expression and this was particularly high in the hippocampal formation and cortex. Protein was concentrated in the nuclei of glutamatergic neurons in all layers of the cortex and dentate gyrus, CA3, and CA1 regions of the hippocampus. Astrocytes express TIA-1 as well albeit at a lower level than neurons. To assess the role of TIA-1 in epileptogenesis, we examined the effect of *TIA1* gene deletion (-/-) on pentylenetetrazole (PTZ)-induced kindling. Mutant mice lacking TIA-1 exhibited accelerated kindling progression and significantly higher kindling incidence relative to their wild-type littermates (+/+). Moreover, a higher mortality rate was associated with convulsions during kindling acquisition in -/- mice relative to +/+. These effects could not be explained by a reduction in the acute seizure threshold as the incidence of acute PTZ-induced convulsions and mortality were not different between +/+ and -/-. Interestingly, whereas a lower kindling dose of PTZ yielded similar kindling incidences, enhanced mortality was still detected in mutant vs. wild-type mice. Together, these results suggest that TIA-1 functions to antagonize the progressive changes in neuroplasticity associated with kindling development. The extent to which this is due to post-transcriptional regulation or via protein-protein interaction is currently under investigation.

**Title:** PTEN deletion from a subset of hippocampal granule cells produces seizures and hippocampal cell loss

**Authors: *S. KHADEMI**[1], C. L. LASARGE[1], I. V. A. LIMA[2], B. E. HOSFORD[1], A. C. P. DE OLIVEIRA[2], S. C. DANZER[1]
[1]Cincinnati Children's Hosp., Cincinnati, OH; [2]Dept. of Pharmacol., Univ. Federal de Minas Gerais, Belo Horizonte, Brazil

**Abstract:** Abnormal hippocampal dentate granule cells appear in significant numbers in animal models of temporal lobe epilepsy, as well as in patients with the disease. These cells mediate the

formation of recurrent excitatory circuits, and are hypothesized to promote epileptogenesis. Abnormal granule cells can be produced experimentally in mice by deleting phosphatase and tensin homologue (PTEN), an inhibitor of the mammalian target of rapamycin (mTOR) pathway. Indeed, hyperactivation of the mTOR pathway is also implicated in epileptogenesis. Previous studies have shown that PTEN deletion from as little as ≈10% of granule cell population is sufficient to produce epilepsy, but exactly how these cells produce the disease is unclear. Here, we explored whether granule cell-specific PTEN deletion leads to the loss of hippocampal mossy cells and interneurons. Experiments were conducted in animals with low (<10%) and high (>10%) percentages of PTEN knockout (KO) cells, to determine whether abnormal granule cell "load" impacted the phenotype. We found that PTEN KO mice on a C57BL/6 background, age (2.3 m – 3.7 m), with a high load of knockout cells develop spontaneous cortical seizures and exhibit loss of hippocampal mossy cells and neuropeptide Y-expressing interneurons. By contrast, animals with relatively few knockout cells did not exhibit seizures or cell loss. Together, these data reveal that selective deletion of PTEN from a subset of hippocampal granule cells can reproduce a pattern of cell loss common in temporal lobe epilepsy. These findings are consistent with the hypothesis that abnormal granule cells can be a driving force in epileptogenesis.

**Abstract:** Epilepsy is one of the most studied neuropathologies in neuroscience, however the basic mechanisms for the development of the seizures are not completely understood. The use of animal models is yet a valuable strategy because of the maintenance of the central nervous system complexity concerning the neuroanatomical/neurochemical substrate underlying the epileptic activity. Endogenously epilepsy-prone animals present advantages in comparison to chemically or electrically induced models due to, again, the maintenance of complexity. In this study we aimed to verify differences between naïve Wistar Audiogenic Rat (WAR), an inbred strain derived from susceptible Wistar rats, and resistant Wistars on the expression of genes that undergo epigenetic influences. We selected genes with monoallelic expression: (a) imprinted genes (Igf2, Peg1, Peg3, and Zac1), (b) a gene with monoallelic stochastic expression (Lgi1), and (c) an X-linked gene (Pgk1). RNA was extracted from the hypothalamus and frontal cortex from two adult females of each strain, placenta and brain from three pups of their respective litters. The cDNA was analyzed by real-time PCR. Zac1 and Peg3 showed higher levels of expression in the adult hypothalamus than in the cortex. In the offspring, Igf2 and Zac1 showed higher expression levels in placenta, and Lgi1 and Pgk1 showed higher expression levels in brain tissue. Adult WARs presented higher expression levels of the Igf2, Peg3, Peg1, Lgi1, and Zac1 genes. Only Pgk1 was highly expressed in adult Wistar. In pups, only Peg1 showed higher expression levels in WAR. Zac1 correlated positively with Igf2, Peg1, and Peg3 genes. Our data suggest that Igf2, Zac1 and Pgk1 genes may have significant roles in epilepsy susceptibility observed in the WAR strain, and strengthen the idea of a net of epigenetically regulated genes in epilepsy.

**Title:** Cell-type-specific Rbfox3 (NeuN) deletion causes spontaneous seizures through excitation/inhibition imbalance

**Authors: *D.-F. HUANG**[1], R.-N. WU[1], C.-C. LIEN[2], H.-S. HUANG[1]
[1]Grad. Inst. of Brain and Mind Sci., Col. of Medicine, Natl. Taiwan Univ., Taipei, Taiwan; [2]Inst. of Neurosci., Natl. Yang-Ming Univ., Taipei, Taiwan

**Abstract:** Neuronal nuclei (NeuN), a neuronal nuclear antigen, is widely used to label neurons for over 20 years. Previous study has identified that NeuN corresponds to a RNA binding protein known as RBFOX3 (RNA binding protein fox-1 homolog 3), one of the FOX family proteins. It is an alternative splicing regulator, which is able to enhance or repress the exon usage. In recent studies, the roles of other FOX family members, RBFOX1 and RBFOX2, in the brain have already been investigated. Previous research also found that RBFOX3 mutations were linked to human epilepsy, cognitive impairment, speech disorder, developmental delay, long sleep latency and some autistic features. Although NeuN has been identified as RBFOX3, it is still unclear what physiological roles it plays in the brain. Therefore, we used *Rbfox3* knockout mice model to investigate the roles of RBFOX3 in the brain. The previous findings in our lab indicated that conventional *Rbfox3*$^{-/-}$ mice had increased seizure susceptibility and abnormal synaptic transmission in the dentate gyrus (Wang, H.Y., et. al.. ***Scientific Reports*** (2015)). We also found that RBFOX3 played an important role in adult hippocampal neurogenesis and synaptogenesis (Lin, Y.S., et. al., ***PLOS ONE*** (2016)). The dentate gyrus granule cells of *Rbfox3*$^{-/-}$ mice exhibited increased spine density, excitatory synapse number, and dendritic complexity. Furthermore, to investigate the roles of RBFOX3 in specific type of neurons, we set up the cell type-specific conditional *Rbfox3* knockout mouse. This approach has allowed us to perform a genetic dissection of *Rbfox3*. Cell-type-specific deletion of *Rbfox3* caused spontaneous seizure, premature death, and circuitry hyper-excitability. RBFOX3 in presynaptic and postsynaptic neurons of the dentate gyrus circuitry played different roles in the normal function of synaptic transmission and hippocampal circuit balance. This study can help us more understand the roles of RBFOX3 in hippocampal circuitry, seizure pathogenesis of defects in *Rbfox3*, as well as how the splicing regulators such as RBFOX3 operate in the brain and different types of neurons.

**Abstract:** The *Cacng2* gene encodes a brain-specific synaptic protein, one member of the transmembrane AMPA receptor regulatory family (TARP gamma-2; aka Stargazin). While the role of this protein in synaptic function has been extensively investigated, comparatively little is known about the transcriptional regulation of the *Cacng2* gene, which is surprising given evidence of altered expression in pathophysiological states. We have now cloned the *Cacng2* promoter region from rat genomic DNA, and investigated transcriptional regulatory activity in a series of transient transfection studies, comparing activity to the widely used *Synapsin I* (*SynI*) neuronal gene promoter. In two cell lines (rat PC12 pheochromocytoma; mouse HT22 hippocampal), the rat *SynI* promoter had significantly greater transcriptional activity compared with *Cacng2* sequences. Within the *Cacng2* promoter region, we identified three repressive sub-regions: (i) sequences downstream from the TSS; (ii) a distal upstream region that contains a calcium-response factor (CaRF) binding site previously documented as repressive in a genome-wide screen (Pfenning et al [2010] PLos One 5:e10870), and (iii), a more proximal upstream region containing multiple REST/NRSF sites. Deletion of all three repressive regions enhanced promoter activity in both cell lines, but the refined *Cacng2* promoter construct remained weaker than the *SynI* construct. Further analysis of the *Cacng2* locus revealed a bi-directional promoter organization in which the TARP gamma-2-encoding transcript is paired with a long non-coding RNA (lncRNA) transcribed in the opposite direction. RT-PCR analysis demonstrated brain-specific expression of lncRNA transcripts in adult rat, but absence of expression in undifferentiated PC12 and HT22 cells. RNAseq expression data from GTEx (Genotype-Tissue Expression project, NCBI, V6p; 53 tissues) indicates highly correlated neuronal expression between human *Cacng2* mRNA and an annotated upstream lncRNA (ENST00000 430281.1). Differentiation of HT22 cells in serum-free media & dibutyryl cAMP results in detectable expression of both *Cacng2* mRNA and the associated lncRNA transcripts, providing further evidence of co-regulation. However, in this differentiation paradigm, activity of the *Cacng2* promoter constructs was not enhanced. These experiments reveal significant repressive control of *Cacng2*, located within a proximal regulatory region that contains multiple distinct molecular features, each with potential for independent modulation of expression. Co-regulation of *Cacng2* with an associated lncRNA may subserve another level of genetic control.

**Abstract:** Advances in genomic technologies, such as exome sequencing, have led to an exponential growth in the discovery of genes associated with epilepsy. While these initial associations are important, it is critical to confirm which genes truly play a role in epilepsy through functional validation. As a result, in this study we performed a phenotype-based screen to validate candidate epilepsy genes. We employed the zebrafish as our model, an excellent vertebrate model amenable to high-throughput whole-organism phenotype-based screening. Moreover, zebrafish are an established model for epilepsy with sensitivity to convulsants and anticonvulsants with robust and stereotypical behavioral and electrographic seizures. In the first part of this project, we generated a master list of all epilepsy-associated genes based on an extensive review of all available information from both research and clinical diagnostic domains. This list was carefully analysed and filtered to only include candidate genes with high likelihood of true association with epilepsy. Next, we optimized our CRISPR/Cas9 genome editing protocol to generate biallelic mutations in the F0 generation. By using synthetic gRNAs, carefully titrating the gRNAs and Cas9 protein, injecting into the 1-cell zygote, and performing deep sequencing, we established a robust protocol for generating F0 zebrafish with null-like phenotypes. We are employing this protocol to knock out over 20 genes from our master list in zebrafish embryos. Injected and control embryos are reared to 5dpf, at which time they undergo automated epilepsy-related phenotyping. Acknowledging that not every animal system will show positive seizure-like results with every gene, we anticipate based on past experiments that at least 1 in 3 candidate epilepsy genes would show a seizure-related phenotype.

**Title:** Movement disorder in GNAO1 encephalopathy associated with GOF mutations

**Authors: *H. FENG**, B. SJÖGREN, Y. YUAN, R. R. NEUBIG
Michigan State Univ., East Lansing, MI

**Abstract: Rationale:** The heterotrimeric protein $G_o$, whose α subunit is encoded by *GNAO1*, regulates ion channel function, neurotransmitter release, and neurite outgrowth. Mutations in *GNAO1* have been identified in children with either epileptic encephalopathy (EIEE17) or a severe choreoathetotic movement disorder. The mechanism underlying the complex clinical spectrum of these *GNAO1* encephalopathies poorly understood. A *Gnao1* gain-of-function (GOF) knock-in mutant (*Gnao1*$^{G184S/+}$) causes a mild seizure phenotype in C57Bl/6J mice. In the current study, we did a biochemical analysis of 15 human *GNAO1* mutations to correlate function with clinical phenotype. Moreover, we examined electrophysiology and gait in *Gnao1* mutant mouse models with both GOF and loss-of-function (LOF) mutations to validate the genotype-phenotype correlation identified from patient mutations.
**Methods:** Wild-type and mutant $G\alpha_o$ were expressed in HEK293T cells and protein levels tested by western blot (WB). Function was assessed by co-expression with the $\alpha_{2A}$ adrenergic receptor. Concentration response curves for inhibition of cAMP levels by the $\alpha_2$ receptor agonist UK14,304 were determined. *Gnao1*$^{G184S/+}$ (GOF) and *Gnao1*$^{-/+}$ (hetKO) animals of both sexes (age - 8 to 14 weeks) were analyzed by slice electrophysiology for IPSCs and EPSCs in hippocampus and cortex and gait was assessed using a DigiGait Imaging System.
**Results:** In contrast to previous reports, we observed both GOF (3 mutants) and LOF (9 mutants) for cAMP regulation by pathogenic human *GNAO1* mutations. Three distinct mutant alleles in Arg$^{209}$ had relatively normal function (NF) despite obvious pathogenicity. All LOF mutants had low $G\alpha_o$ protein expression as a potential contributor to their reduced function. Intriguingly, *GNAO1* GOF mutations are associated with movement disorder with or without mild seizures while the LOF mutations are associated with severe epilepsy. The *Gnao1*$^{G184S/+}$ GOF mutant mouse followed a similar pattern. We previously reported that it had a mild seizure phenotype (sensitization to pentylenetetrazole kindling but few spontaneous seizures). Hippocampal and cortical slices from these GOF mutant mice showed reduced spontaneous IPSCs but normal EPSCs. Digigait® analysis showed a striking reduction in stride length and increased paw angle variability in GOF mutant mice but not in *Gnao1* hetKO mice.
**Conclusions:** *De novo GNAO1* mutations have both GOF and LOF biochemical function with the former associated with seizures and the latter with movement disorder. This is phenocopied by a GOF mutant mouse. Further studies of human *GNAO1* mutant alleles in mice are warranted.

**Abstract:** Mutations in the gene encoding N-Methyl-D-aspartate receptors (NMDAR) subunit *GRIN2A*/GluN2A have been identified in individuals with various neurological disorders, such as epilepsy, intellectual disability, autism spectrum disorder, and schizophrenia. Indeed, pathogenic *GRIN2A* variants are known to present with different clinical phenotypes, which makes precision medicine a necessity and a goal to improve outcome. In order to study potential therapeutic solutions, we modeled the *de novo* mutation GRIN2A S644G, based on a child with epileptic encephalopathy, including seizures refractory to conventional anti-epileptic medications. *In vitro* heterologous expression showed that the S644G mutation increases glutamate and glycine potency by 10-fold, and strongly enhances channel open probability by 5-fold, indicating a strong gain-of-function effect. S644G knockin mice generated by CRISPR/Cas9 and examined for seizure susceptibility *in vivo* and for abnormal neuronal network features in primary cortical neuron cultures using the microelectrode array (MEA) platform. While video-EEG of heterozygotes did not reveal obvious spontaneous seizures (5 mice recorded for 48 hours each), electroconvulsive threshold (ECT) testing showed significant and intriguing

differences. As expected, heterozygotes were more susceptible to minimal and maximal high frequency ECT, a test that models generalized seizures. Counterintuitively, however, heterozygotes also showed a significantly elevated threshold (i.e. seizure resistance) in the 6 Hz ECT test, designed to model partial or "psychomotor" seizures. In preliminary studies on the MEA platform, S644G heterozygous cortical neurons show increased firing and more network spikes in network bursts compared to wildtype neurons. Although homozygous S644G mice have not yet been examined, and while we expand the phenotyping to morphological analyses and synaptic studies, we are encouraged by these early findings and the prospects of combined *in vivo* and cellular mouse model platforms to reveal interesting and relevant preclinical features suitable for therapy screening.

**Title:** Modeling of an epilepsy-related neurodevelopmental disorder caused by de novo GNB1 missense mutations and identification of targeted treatments

**Authors: *S. COLOMBO**[1], M. J. BOLAND[2], W. N. FRANKEL[3], D. B. GOLDSTEIN[3]
[1]Inst. for Genomic Med., [2]Inst. for Genomic Medicine, Dept. of Neurol., [3]Inst. for Genomic Medicine, Dept. of Genet. and Develop., Columbia Univ., New York, NY

**Abstract:** Heterozygous *de novo* missense mutations in *GNB1*, a beta subunit of GTPases heterotrimeric G proteins (Gα,β,γ) were recently implicated as the cause of a new syndrome that includes neurodevelopmental disability, hypotonia and seizures (Petrovski S. et al., 2016, PMID 27108799). While G proteins are known to mediate G protein-coupled receptor signaling and regulate a variety of downstream effectors, such as $Ca^{2+}$ and $K^{+}$ channels, or PI3K and MAPK

pathways, it is unclear how mutations in ubiquitously expressed *GNB1*, result in a predominantly neurological disorder. In an effort to unravel the specific neuronal functions of *GNB1* affected by the mutations and to find appropriate treatments, we chose both *in vitro* and *in vivo* approaches. As the mutations tend to cluster in a region important for Gβ interaction with Gα and downstream effectors, we first introduced *GNB1* variants in HEK cells to evaluate interactions of mutant proteins with partners, and the activation of downstream pathways in response to GPCR activity, using techniques such as Bioluminescence Resonance Energy Transfer (BRET), co-immunoprecipitation (co-IP) and phosphoprotein assays. While BRET demonstrated that most variants affect interaction of Gβ with Gα, co-IP confirmed that the Gβ-K78R variant affects interaction with several Gα and also revealed a reduced interaction with a GIRK channel. In order to model the human disease, we used CRISPR/Cas9 to knock-in disease variants, beginning with K78R, in mice and in human induced pluripotent stem cells (iPSC) to be differentiated into neurons. Using microelectrode arrays (MEA) to detect extracellular field potentials (a surrogate for action potentials) of neuronal networks, we observed that heterozygous (het) K78R neurons present a bursting defect compared to wild-type. Moreover, K78R het pups present with developmental delay as shown by a significantly smaller size and delay in reaching developmental milestones compared to wild-type littermates. Preliminary tests reveal that K78R het mice have low seizure threshold. We are presently evaluating the presence of spontaneous seizures (video-EEG) as well as neuronal development, morphology and activity. The MEA platform will be used to perform an initial screen of FDA-approved drugs, and top candidates will be tested in mice to assess efficacy and toxicity. Our work will help to understand *GNB1* functions in neurodevelopment and identify appropriate therapies.

**Title:** Characterization and therapeutic screening of a gain of function mutation in KCNT1 utilizing multielectrode arrays

**Authors: *C. D. BOSTICK**[1,2], S. COLOMBO[2], M. J. BOLAND[2,3], V. A. LETTS[2], W. N. FRANKEL[2], D. B. GOLDSTEIN[2]
[1]Dept. of Developmental Genet., [2]Inst. for Genomic Med., Columbia Univ. Med. Ctr., New York, NY; [3]Neurol., Columbia Univ., New York, NY

**Abstract:** *De novo* mutations in the C-terminal domain of the KCNT1 sodium activated potassium channel have been implicated in multiple early-onset epileptic encephalopathies including Malignant Migrating Partial Seizures of Infancy (MMPSI) and Autosomal Dominant Nocturnal Frontal Lobe Epilepsy (ADNFLE). KCNT1 channels are known to contribute to a late afterhyperpolarization after repetitive stimulation and regulation of neuronal excitability and adaptation. While studies utilizing heterologous expression systems have demonstrated a gain of function underlies the mechanism of these *de novo* mutations, there still remain many questions about the resulting hyperexcitability pathology seen *in vivo*. To this end we have characterized mouse models including a knock-in (ki) gain of function *Kcnt1* mutation (Y777H) generated by CRISPR/Cas9 in the JAX Center for Precision Genetics based on an individual with moderate ADNFLE. Homozygous ki mice exhibit spontaneous generalized tonic-clonic seizures in video-EEG, as well as a modestly lower seizure threshold. In addition, *in vitro* studies have been conducted on mouse primary cortical neurons utilizing Multielectrode Arrays (MEA). MEA allows noninvasive measurement of neuronal activity, and has recently been adopted to study aberrant neuronal network activity associated with genetic variants. The multi-well format yields the ability for medium throughput screening for therapeutics in the treatment of various neuronal pathologies. Studies on the spontaneous activity of homozygous ki primary cortical neurons demonstrate increased firing and bursting during neuronal network maturation in homozygous neurons as well as increased neuronal activity during burst and network events post network maturation. In addition, preliminary work has demonstrated that Y777H homozygotes have greater evoked responses to electrical stimulation compared to wildtype control. Utilizing this platform, we will screen candidate therapies from an FDA approved library searching for effective targeted treatments to further assess *in vivo*.

**Title:** Developmental trajectory of interneuron dysfunction in a mouse model of Dravet syndrome

**Authors: *M. FAVERO**[1], E. LOPEZ[2], N. P. SOTUYO[1,3], E. M. GOLDBERG[1,3,4]
[1]Pediatrics, The Children's Hosp. of Philadelphia, Philadelphia, PA; [2]Sch. of Arts and Sci., [3]Neurosci., [4]Neurol., Univ. of Pennsylvania, Philadelphia, PA

**Abstract:** Dravet syndrome (DS) is a neurodevelopmental disorder characterized by childhood onset, treatment-resistant, temperature-sensitive epilepsy, accompanied by intellectual disability and autistic traits, hyperactivity, and ataxia, with markedly increased mortality from status epilepticus and sudden unexplained death (SUDEP). DS is due to a dominant *de novo* heterozygous mutation in the gene *SCN1A* encoding the type 1 neuronal voltage-gated sodium (Na+) channel alpha subunit ($Na_V1.1$). Electrophysiological data indicates that $Na_V1.1$ mutations underlying DS lead to loss of channel function. The effect of $Na_V1.1$ mutation has also been studied in various transgenic mouse models of DS (Scn1a+/- mice), and the phenotype largely replicates the human condition. *In vitro* evidence suggests that preferential dependence upon this channel by inhibitory GABAergic interneurons (INs) leads to reduced IN excitability, particularly in parvalbumin (PV) positive (PV+) INs, while it does not appreciably influence the activity of excitatory pyramidal neurons. Thus, the net effect of *Scn1a* mutation on brain networks overall is considered to be disinhibition due to dysfunction of INs relative to excitatory cells. Here, we performed targeted electrophysiological recordings of PV+ and non-PV+ INs as well as excitatory principal cells in acute brain slices of primary somatosensory cortex prepared from $Scn1a^{+/-}$ mice and age-matched wild-type (WT) littermate controls at various ages to determine the developmental trajectory of cell type-specific dysfunction; $Scn1a^{+/-}$ mice were crossed to IN-specific Cre driver lines to label discrete IN subtypes. At post-natal day (P) 18-21 (within days of epilepsy onset) PV+ INs and, to a lesser extent, SST+ INs, in $Scn1a^{+/-}$ mice, exhibit profound impairments relative to WT, with failure of action potential generation and markedly decreased maximal firing frequency. However, at P35-49 (established epilepsy), these defects had partially, albeit incompletely, recovered, despite ongoing seizures in $Scn1a^{+/-}$ mice at this age. Our results indicate that the prominent effect of *Scn1a* mutation on the firing properties of INs may be only transient, restricted to a delimited time window during development. The mechanism of partial normalization during the established phase of epilepsy may be due to compensatory up-regulation of other Na+ channel subtype(s). Such data suggests that other cellular- and circuit-level mechanisms may contribute to the maintenance of chronic epilepsy and epilepsy-associated developmental disability in Dravet syndrome.

**Title:** Heterogeneity of gene associated with retinoid-interferon-induced mortality-19 (GRIM-19) expression in the adult mouse brain

**Authors: S.-N. HWANG**[1], J.-C. KIM[2], *S. KIM[3,2]
[1]Dept. of Pharmacology, Catholic Neurosci. Inst., The Catholic Univ. of Korea Col. of Med., Seocho-gu, Korea, Republic of; [2]Dept. of Pharmacology, Catholic Neurosci. Inst., The Catholic Univ. of Korea Col. of Med., Seoul, Korea, Republic of; [3]The Catholic Univ. of Korea, Seoul, Korea, Republic of

**Abstract:** Gene associated with retinoid-interferon-induced mortality-19 (GRIM-19) has been identified as a gene inducing apoptosis of various cancer cells such as thyroid, renal and liver cancer cells and as a subunit of the mitochondrial respiratory chain complex I that has a significant effect on ATP production. The brain, unlike the heart or the kidney, is particularly susceptible to ATP deficiency due to its limited energy storage capability and its high rate of oxygen consumption. The possibility is raised that GRIM-19 plays important roles in regulating ATP level and/or cell death caused by neurological disorders. Although there has been a few efforts to examine the expression changes of GRIM-19 under several pathological conditions such as brain ischemia and Parkinson's disease the thorough investigation of the neuroanatomic distribution of GRIM-19 in the normal brain is still needed to understand the physiological and pathophysiological roles of GRIM-19. Thus, the present study investigated the distribution patterns of GRIM-19 in the adult C57BL/6 mouse brain using immunohistochemistry and analyzed the comparison of GRIM-19 immunoreactivity with the density of neuronal cells which was reported in Allen Brain Atlas (www.mouse.brain-map.org). GRIM-19 was ubiquitously expressed throughout the whole brain as our expectation since GRIM-19 is the composition of the mitochondria. In most regions of the brain, the stronger the GRIM-19 immunoreactivity, the denser the NeuN-positive cells and Nissl substance were shown. However, there were a few exceptions. The regions showing the intensive immunoreactivity of GRIM-19 but weak NeuN immunoreactivity as well as weak Nissl staining included the outer plexiform layer of the main olfactory bulb, the molecular layer of the piriform cortex, the nucleus of the lateral lemniscus, the molecular layer of the cerebellum, etc. On the other hand, the granule layer of the main olfactory bulb showed the opposite pattern. Interestingly, the immunoreactivity of GRIM-19 was relatively prominent in the hippocampal CA3 pyramidal layer compared with that of the

hippocampal CA1 pyramidal layer and the dentate granule cell layer. This is the first report showing immunohistochemical distribution of GRIM-19 throughout the whole adult mouse brain and we expect that the findings obtained in this study can provide a clue to study the pathophysiological mechanisms responsible for various mitochondrial dysfunction-related neurological disorders, including brain ischemia.

**Title:** Cx3cr1 inhibition modulates synaptic integration of adult born hippocampal neurons following an epileptogenic insult in the rat brain

**Authors: *U. AVDIC**[1], I. ALI[2], C. EKDAHL[2]
[2]Clin. Sci., [1]Lund Univ., Lund, Sweden

**Abstract:** The fractalkine-CX3CR1 pathway has been shown to regulate neurogenesis in the dentate gyrus (DG). Neuronal proliferation in the hippocampus is frequently described in temporal lobe epilepsy and microglia activation is associated with an impaired survival of new adult born neurons. If a reduced inflammatory environment, by CX3CR1 inhibition will alter the synaptic integration of these neurons remains to be studied. These mechanisms might be central in driving network hyperexcitability after epileptogenic injuries and may be targeted for therapeutic intervention. Thus, we studied the expression of synaptic proteins in neurons born in an acute epileptic environment with an altered neuroinflammatory milieu. Adult male rats were implanted with electrodes in the right hippocampus and a brain infusion cannula in the lateral ventricles. Following 1w of recovery temporal status epilepticus (SE) was electrically induced in

the hippocampus. Rats were subsequently injected with retroviral vector expressing GFP. Immediately after, brain infusion cannulas were connected with osmotic pumps carrying either anti-CX3CR1 antibody (ab) or vehicle. Morphological evaluations, 7w following SE, revealed subtle changes in dendritic morphology with reduced medial dendrites in SE-CX3CR1 rats. Seizure-induced microglia activation was also reduced in the hilus in SE-CX3CR1 animals. No changes in the expression of scaffolding proteins (gephyrin) and adhesion molecules (NL-2) were detected at inhibitory synapses. Instead, there was a strong reduction of scaffolding proteins at excitatory synapses in treated rats. PSD-95 cluster density was decreased in the molecular layer of the DG. No changes were observed in the excitatory adhesion molecule NL-1. Here we show that the fractalkine-CX3CR1 pathway mediates neuroinflammation on synaptic integration of new neurons born in an epileptic environment, confirmed by altered morphological profiles and altered expression of excitatory synaptic scaffolding proteins. Future studies need to determine whether an altered neuroinflammatory environment during chronic epilepsy leads to a changes in chronic seizure burden in these animals.

**Authors: *H. O'LEARY**, A. M. CASTANO, L. VANDERLINDEN, L. M. SABA, T. A. BENKE
Univ. of Colorado, Denver, Aurora, CO

**Abstract:** RNA sequencing was used to investigate gene expression in a rat model of early life seizures. We aimed to characterize the functional pathways that are up and down regulated following an early life seizure. Rat hippocampal CA1 mRNA was isolated and profiled one week following a single early life seizure, corresponding to a critical developmental period in which AMPA receptor desensitization is decreased. Isoform level results revealed significant differences in the expression of only 7 genes after adjustments for all genes analyzed. Ingenuity pathway analysis revealed an upregulation of the Long term potentiation pathway, thus confirming previous findings at this developmental time point following seizure. Additionally, editing and splice variants were analyzed with a particular interest in ADAR2 editing sites in the

brain. No differences were observed in the editing of GluA subunits, suggesting another mechanism for alteration in AMPA receptor desensitization in this time period.

**Title:** Time course and isoform specificity of JNK activation during epileptogenesis

**Authors: A. N. PARIKH**, F. A. CONCEPCION, R. D. BOEHM, *N. P. POOLOS
Univ. of Washington, Seattle, WA

**Abstract:** c-Jun N-terminal kinases (JNK1-3) are members of the stress-activated kinase family that are encoded by three genes, *Mapk8-10*. Abnormal JNK activation has been implicated in neurodegenerative disorders such as Alzheimer's and Parkinson's diseases. We recently discovered that JNK is hyperactivated in an animal model of chronic epilepsy, and that pharmacological inhibition of JNK exerts an antiepileptic effect (Tai TY et al, *Neuroscience*, 2017). Currently, we do not know the role JNK plays during the development of chronic epilepsy; thus, this project aims to understand the timeline of JNK activation. We measured both activated (phosphorylated; pJNK) and total JNK (tJNK) levels by immunoblotting hippocampal tissue homogenates both from chronically epileptic rats induced via status epilepticus (SE) and from age-matched controls. We measured JNK levels at four time points after SE onset: one hr, when animals are in SE; one day, when animals are seizure-free; one wk, when animals begin to have spontaneous seizures; and 6 wks, when animals are chronically epileptic. Collectively, the JNK isoforms separate into two electrophoretic bands: 54 kDa and 46 kDa. In both bands, we discovered significant increases in pJNK levels at the chronic epilepsy stage (54 kDa: 160 ± 26% of naive levels, $p<0.05$; 46 kDa: 125 ± 17%, $p<0.05$), while there were no significant changes in pJNK levels at the other three earlier time points. We saw no significant changes in the levels of total JNK for either band at all time points. We also measured changes in the fractional activation of JNK by quantifying pJNK/tJNK. In the 54 kDa band, we discovered significant increases in pJNK/tJNK at one hr and one day, no change at one wk, and a significant increase in chronic epilepsy. In the 46 kDa band, there was no change in pJNK/tJNK at one hr, but significant increases were observed at all later timepoints. We then asked how JNK isoforms segregated into the 54 and 46 kDa bands. We determined that JNK1 segregates primarily in the

46 kDa band, JNK2 is present nearly equally in both bands, and JNK3 (which is brain-specific) is predominately in the 54 kDa band. We conclude that in chronic epilepsy there are substantial increases in activated JNK present in the 54 kDa (containing JNK3 and JNK2) and 46 kDa (containing JNK1 and JNK2) bands, consistent with our previous studies. The increase in fractional activation of JNK (pJNK/tJNK) during epileptogenesis suggests upregulation of upstream signaling mechanisms. Further experiments are underway to quantify the activation of JNK isoforms in chronic epilepsy and their alterations during the development of chronic epilepsy.

**Title:** Pattern of expression of proinflammatory cytokines on a model of acute seizures under time-restricted feeding

**Authors: *J. SANTILLAN-CIGALES**, J. LANDGRAVE-GÓMEZ, V. S. ARRIAGA-ÁVILA, O. F. MERCADO-GOMEZ, S. GONZALEZ-REYES, R. GUEVARA-GUZMAN

**Abstract:** Introduction: In recent years, experimental research has demonstrated an important role of pro-inflammatory molecules to develop epileptogenic and ictogenic processes. Recently, our research group reported that time-restricted feeding (TRF) has an anticonvulsant effect; however, the precise mechanism that could be involved is still unknown. Objective: To investigate whether TRF is able to exert its beneficial effect by modifying the expression pattern of pro-inflammatory molecules and therefore, has a neuroprotective role after induction of seizures. Methodology: Briefly, TRF consisted of allowing rats to feed for two hours daily during their luminous phase for 20 days; whereas the control group (AL) had free access to food and water 24 hours a day. After the diet period, status epilepticus (SE) was induced by pre-treatment with lithium chloride (LiCl 3 mEq/kg i.p.). 18 h after LiCl, animals were injected with scopolamine (1 mg/Kg s.c.) and 30 min later. animals received a pilocarpine injection (60 mg/kg s.c.) to induce SE for 90 minutes immediately attenuated with diazepam injection (5 mg/Kg). The mRNA expression of pro-inflammatory molecules such as interleukin 1 beta (IL-β), tumor necrosis factor alpha (TNF- α) and interleukin 6 (IL-6) in hippocampus of each group were

quantified at 3 h, 12 h and 24 h after SE. In addition, coronal sections of brains were obtained to label Iba-1 and TUNEL to evidence changes of activated microglia and apoptosis, respectively. Results: Our preliminary data show that the group with TRF had a decrease of mRNA levels of pro-inflammatory molecules (IL- β, TNF- α, IL-6) compared to that of AL group, after seizure induction. Likewise, changes in the levels of activated microglia were observed in the hippocampus as well as fewer TUNEL-positive cells after SE. Conclusion: Our data demonstrated that TRF exerts a neuroprotective effect by modifying the mRNA expression pattern of pro-inflammatory molecules after induction of seizures.

**Title:** Time-restricted feeding confers an anti-oxidative effect in rat hippocampus on pilocarpine seizure model

**Authors: *O. F. MERCADO-GOMEZ**[1], V. S. ARRIAGA-ÁVILA[2], J. J. SANTILLAN-CIGALES[2], M. ÁLVAREZ-HERRERA[2], R. GUEVARA-GUZMAN[2]
[2]Physiol., [1]Natl. Autonomous Univ. of Mexico, Mexico City, Mexico

**Abstract: Introduction:** Several reports on experimental models and epilepsy patients have demonstrated that oxidative stress has a crucial role in epilepsy because it contributes to the etiophatogenesis of seizures. On the other hand, metabolic-based diets such as ketogenic diet (KD) and calorie restriction (CR) have shown to have an anti-oxidative effect on several models of neurological disease. We recently described that time-restricted feeding (TRF) has an anticonvulsant effect that is mediated by metabolic and epigenetic changes. **Objective:** To investigate whether TRF could have an anti-oxidative effect in *status epilepticus* (SE)-induced hippocampus. **Methodology:** Male Wistar rats weighing 220 g were divided into four groups (Control, TRF, SE, and TRF plus SE). Control animals had free access to food and water. TRF schedule consisted of allowing rats to feed only for two hours daily for 21 days with free access to water. The pilocarpine seizure model consisted of a pre-treatment of lithium chloride (3mEq/kg i.p.). Eighteen hours after LiCl injection, animals were injected with scopolamine (1 mg/kg s.c.) and 30 min later, animals received a pilocarpine injection (60 mg/kg s.c.) to induce SE for 90 minutes and immediately attenuated with diazepam injection (5 mg/kg). Control

animals followed the same procedure without pilocarpine injection. All animals were sacrificed during an acute time-course (3, 8 and 24 h) and their hippocampi were used to measure malondialdehyde (MDA) levels. Moreover, frozen brain slices were obtained to measure superoxide ion in CA1, CA3 and dentate gyrus of hippocampus by fluorescent microscopy using dihydroethidium (DHE) on rats 24 h after pilocarpine injection. **Results:** Preliminary results showed that pilocarpine-injected rats had significant high levels of MDA compared with those of control animals or TRF-treated animals throughout the time-course. Interestingly, rats subjected to TRF and SE-induced showed a slight decrease of MDA levels during the time points of 3 and 8 hours. However, after 24 h post-SE, MDA levels were statistically reduced compared with those of SE-induced rats. Furthermore, animals subjected to TRF and SE had a reduction of fluorescence of DHE in all regions of hippocampus compared with that of pilocarpine-injected rats. **Conclusion:** Our results suggest that TRF has an anti-oxidative effect on pilocarpine seizure model by reducing MDA levels and superoxide ion presence in the hippocampus. Even though we do not know the precise mechanisms which TRF exert this effect, it is important to note that TRF has similar effects that other diets such as KD o CR whereby could be used as a new alternative therapy.

**Title:** Early life seizures chronically alter the requirement of L-type voltage gated calcium channels to induce mGluR dependent long term depression

**Authors: *P. B. BERNARD**, A. M. CASTANO, T. A. BENKE
Univ. of Colorado, Anschutz Med. Campus, Aurora, CO

**Abstract:** We have reported that adult rats have chronically enhanced mGluR-mediated long-term depression (mLTD) following a single episode of early life seizures (ELS). Herein we explored the role of calcium influx and release in the expression of mLTD and specifically how ELS impacts the role of calcium signaling in mLTD. We hypothesized that calcium flux through L-type voltage gated calcium channels (LTCCs) is necessary for the induction of mLTD and that these and related processes are chronically altered following ELS.
ELS were induced in Sprague Dawley rats at P7 with kainate (2 mg/kg, s.c.). Hippocampal slices were prepared for electrophysiological recording at P60+. Induction paradigms designed to isolate mLTD were utilized in area CA1 of the hippocampus and LTD was measured using field

excitatory postsynaptic potentials. Isradipine (10 μM), BayK (1 μM), PKI (300 nM) and cyclopiazonic acid (CPA)(30 μM) were used to probe the dependence on mLTD on calcium-related signaling.
Blocking voltage gated calcium channels with isradipine completely blocked mLTD in controls and normalized enhanced mLTD following ELS. BayK, an agonist of voltage gated calcium channels, increased mLTD in controls only; no further increase in mLTD was observed following ELS. CPA, which inhibits the release of calcium from intracellular stores, normalized mLTD following ELS and had no effect on mLTD in controls. In contrast, PKI, which regulates the activity of voltage gated calcium channels, normalized mLTD following ELS, while also reducing mLTD in controls.
Our results indicate that calcium flux through LTCCs is necessary for mLTD under normal conditions. ELS results in chronic alterations in the role of LTCCs in mLTD and related signaling, including release from intracellular stores. Following ELS, chronically enhanced mLTD can be rescued using pharmacological methods to limit intracellular calcium, either via reducing LTCC activity or reducing the availability of intracellular stores. We have previously linked enhanced mLTD with several behavioral deficits later in life, including deficits in social behavior, learning and memory. Future investigations will determine if normalizing calcium signaling in vivo also normalizes behavior.

**Abstract:** Epilepsy is a chronic disorder characterized by abnormal brain cell activity leading to recurrent, unprovoked seizures. Pharmacological therapies are commonly used for the treatment

of epilepsy, although nearly 30% of patients do not respond to current medications. This highlights the need for new drug targets and treatments. Many recent studies have centered on the use of cannabidiol (CBD) to treat epilepsy. Early use of CBD, a non-psychotropic component of *Cannabis sativa*, is reported to lessen the severity of experimentally induced seizures in animals and to suppress neuroinflammation in culture. Although CBD has been shown to increase intracellular levels of anandamide, an endogenous cannabinoid, its complete mechanism of action is still poorly understood. Our previous studies have shown that microglia, the immune cells of the central nervous system (CNS), are important mediators of seizure severity. Microglial ability to modulate seizures has been linked to the activation of Toll-like receptors (TLRs). TLRs play important roles in pathogen recognition and inflammation. Microglia also act as modulators of neurogenesis and synaptogenesis, contributing to the refinement of functional neuronal circuits. We postulate that CBD modulates the activation of microglial cells to exert beneficial effects in the brain. In this study, we evaluate the effects of CBD on cell death and inflammation in the hippocampus during recovery. Microglial engulfment of newborn cells and the effect of CBD on TLR expression was also studied.

**Title:** Changes in the expression of gene associated with retinoid-interferon induced mortality-19 (GRIM-19) after pilocarpine-induced status epilepticus in the mouse hippocampus

**Authors: J.-C. KIM**[1], S.-N. HWANG[1], *I.-B. KIM[2], S. KIM[1]
[1]Dept. of Pharmacol., The Catholic Univ. of Korea, Seoul, Korea, Republic of; [2]Col. of Medicine, the Catholic Univ. of Korea, Seoul, Korea, Republic of

**Abstract:** Gene associated with retinoid-interferon induced mortality-19 (GRIM-19) is a multifunctional gene involved in cell death, mitochondrial metabolism and growth regulation. Recently, it has been also reported that GRIM-19 is closely related to inflammation by regulating the expression of pro-inflammatory cytokines such as IL-1β, IL-6, tumor necrosis factor-α and IL-17. Meanwhile, the common pathological features of status epilepticus (SE) include hippocampal neuronal cell death and glial cell activation of which the mechanisms are related to the action of pro-inflammatory cytokines. However, to date, it is not reported about the role of

GRIM-19 in the pathogenesis of SE. Thus, the present study investigated the expression pattern of GRIM-19 and identified cell types expressing GRIM-19 in the mice hippocampus after pilocarpine-induced SE. Male C57BL/6 mice (22-26 g) were treated with pilocarpine (280 mg/kg, intraperitoneally) and monitored to evaluate seizure stage based on Racine scale. After 2 hours of SE, which was defined as a continuous motor seizure of stage 5 (rearing and falling), diazepam was administered to terminate seizure. The mice which received saline instead of pilocarpine served as control. Pilocarpine- or saline-injected animals were perfused at 1, 4, 7 and 14 days after SE onset. To identify the cell types expressing GRIM-19, double immunofluorescence staining using NeuN (a neuronal cell marker), GFAP (an astrocyte marker) and Iba-1 (a microglia marker) antibody was performed. In saline-treated control animals, GRIM-19-positive cells were mainly observed in both pyramidal neurons and dentate granule cells. Four days after SE, neuronal cell death was observed in certain hippocampal areas including CA1 and CA3 regions whereas astrocytes and microglial cells were activated in the entire hippocampus. At that time, compared with control animals, GRIM-19 immunoreactivity was markedly reduced in pyramidal cell layer where neuronal cell death occurs. Furthermore, GRIM-19-expressing cells induced by SE were turned out to be mainly reactive astrocytes in the stratum radiatum of the hippocampus. These results suggest that GRIM-19 may play a role, at least in part, in the reactive astrocytosis following SE, probably through the action of pro-inflammatory cytokines.

**Abstract:** Epileptic patients suffer from several disorders associated to this illness, including sexual disorders; though it has been difficult to distinguish how epilepsy affects directly on them

rather than the well-known side-effects of antiepileptic drugs. Recent studies in adult rats have demonstrated that *status epilepticus* (SE) affects sexual performance; nevertheless, SE is more common in childhood. To that end, in this study we assessed the effect of SE in infant male rats on their sexual behavior during adulthood. To do this, thirteen-days-old male rat pups (P13) were given an intraperitoneal injection of lithium chloride (3mEq/kg) and SE was induced 20 h later at P14 by a subcutaneous injection of pilocarpine hydrochloride (100mg/kg); control rats were injected with an equal volume of saline (NaCl 0.9%). Rats were weaned at P21 and at P90 sexual behavior was evaluated during five trials (every four days) lasting one hour. After de fifth trial, serum corticosterone levels were measured using an ELISA kit. Data were analyzed by a Fisher test, a two-way ANOVA for repeated measures, or a Student t test. The results show that in the SE group a lower proportion of males ejaculated in comparison with the control group (2/7 and 6/8, respectively; $p< 0.0001$), effect that was observed in session 3 (1/9 and 6/8, respectively; $p= 0.0134$), 4 (1/9 and 6/8, respectively; $p= 0.0134$) and 5 (2/9 and 6/8 $p= 0.0445$). Frequency of mounts ($p= 0.0009$) and intromissions ($p= 0.0077$) was lower in SE rats than in control rats. Latency to mount attempts ($p= 0.016$), mounts ($p= 0.001$), intromissions ($p= 0.008$) and ejaculations ($p= 0.007$) was increased in SE rats when compared with control rats. Serum corticosterone levels show no difference between SE and control groups ($p= 0.46$). In conclusion, one event of SE in infancy disrupts sexual performance during adulthood in male rats without altering the baseline levels of corticosterone.

**Title:** Antiseizure actions of a ketone body and its analog in a chronic seizure model

**Authors: *N. SADA**[1,2], A. KADOWAKI[1], T. INOUE[1]
[1]Okayama Univ., Okayama, Japan; [2]Kawasaki Med. Sch., Kurashiki, Japan

**Abstract:** A ketogenic diet has been used to treat a drug-resistant epilepsy. The diet treatment increases a ketone bodies (acetoacetate and β-hydroxybutyrate) in the brain. In addition, ketone bodies have inhibitory actions on the central nervous system, but its molecular mechanisms are not understood. Here, we studied effects of acetoacetate on voltage-dependent Ca2+ channels (VDCCs) and excitatory postsynaptic currents (EPSCs) in hippocampal CA1 pyramidal neurons using patch-clamp recordings. We found that acetoacetate inhibited VDCCs and reduced EPSCs

in hippocampal pyramidal cells. More potent EPSC inhibitors were then explored by modifying the chemical structure of acetoacetate, and 2-phenylbutyrate was identified as an acetoacetate analog that inhibited VDCCs and EPSCs more potently. We further found that 2-phenylbutyrate markedly suppressed hippocampal seizures in vivo and its antiseizure effect was stronger than acetoacetate using a chronic seizure model induced by intrahippocampal injection of kainate. In addition, intraperitoneally-injected 2-phenylbutyrate was delivered to the brain and suppressed seizures in vivo, and its brain concentration reached the level enough to reduce EPSCs in brain slices. In conclusion, 2-phenylbutyrate is an acetoacetate analog that inhibits VDCCs and EPSCs in pyramidal cells, suppresses hippocampal seizures in vivo, and has a brain penetration ability. Thus, 2-phenylbutyrate provides a useful chemical structure as a seed compound to develop new antiepileptic drugs originating from ketone bodies.

**Title:** Dynamic modulation of intrinsic excitability and sensory inputs processing in cortical neurons during absence seizures

**Authors: *M. WILLIAMS**[1,2], S. LECAS[1,2], S. MAHON[1,2], S. CHARPIER[1,2]
[1]ICM, Brain and Spine Inst., Paris, France; [2]UPMC, Pierre and Marie Curie université - Paris 6, Paris, France

**Abstract:** Epileptic seizures result from aberrant cellular and/or synaptic properties that may alter the capacity of neurons to process ongoing information. For instance, during absence seizures spike-and-wave discharges (SWDs) likely interfere with incoming sensory inputs, participating in the looseness of conscious experience. However, the mechanisms by which SWDs alter conscious sensory perception remain unclear. Using the Genetic Absence Epilepsy Rat from Strasbourg (GAERS), a validated animal model of absence epilepsy, we identified the cellular correlates subtending the negative interactions between epileptic discharges and sensory processing. By combining *in vivo* electrocorticographic and intracellular recordings from the somatosensory cortex of GAERS, we found that the intrinsic excitability of cortical neurons was dynamically altered during seizures, alternating periods of increased and decreased cell responsiveness. To investigate how this time-dependent change in cortical excitability affected sensory processing during absence seizures, we examined the whisker-evoked sensory responses in the related thalamo-cortical system in the course of SWDs. Consistent with the fluctuating neuronal excitability, sensory stimuli were still processed in primary sensory cortices and

thalamic nuclei during SWDs but with a severe time-to-time instability. This lack of consistent sensory responses in the somatosensory thalamo-cortical network could, at least partly, explain the interruption of conscious perception during absence seizures.

**Title:** Autonomic dysfunction and increased arrhythmogenic potential in mice following status epilepticus

**Authors: *A. LEVINE**[1], A. DAO[2], A. E. ANDERSON[3]
[1]BAYLOR COLLEGE OF MEDICINE, Houston, TX; [3]Pediatrics, Neurology, Neurosci., [2]Baylor Col. of Med., Houston, TX

**Abstract:** Status epilepticus (SE) is a prevalent disorder, which is associated with significant morbidity, including the development of epilepsy and mortality. Studies indicate that lethal cardiac arrhythmias contribute to death following SE as well as sudden unexpected death in epilepsy (SUDEP). A range of potentially lethal cardiac arrhythmias (i.e. tachycardia, bradycardia, and asystole) are observed in epilepsy and are indicative of underlying autonomic nervous system (ANS) dysfunction. Tachycardia is the most commonly reported seizure-related to arrhythmia but asystole and bradycardia have been observed and may occur ictally in people with temporal lobe epilepsy (TLE). Studies have described ANS imbalance during ictal and postictal periods but less is understood about ANS function during interictal periods. We sought to understand ANS changes following SE by monitoring cardiac electrical activity in a chemoconvulsant mouse model of TLE. To simultaneously investigate alterations in electrocardiography (EKG) and video synchronized electroencephalographic (vEEG) signals following SE. Recordings showed ictal bradycardia and post-ictal tachycardia, which had been described in other mouse models of SE, as well as humans. Interictally, no changes were seen in heart rate, RR interval, QTc interval, and PR interval between saline and kainate treated animals. However, SE animals exhibited decreased interictal beat-to-beat variability of the QTc and decreased PR intervals for the two weeks of monitoring after SE or until a death event. Sinus pause with a junctional escape beat, premature ventricular contractions, and accelerated ventricular rhythm were observed interictally following SE during sleep. Additionally, death events were captured and showed seizure-related increases in beat-to-beat variability in the RR, QTc, and PR intervals preceding death. Our mouse model recapitulates changes that are observed in human TLE. Although average values for heart rate, R-R interval, QTc interval, and

PR interval showed no difference interictally between saline and kainate treated animals, the potentially lethal arrhythmias observed and beat-to-beat variations indicate ANS dysfunction. Interestingly, the arrhythmias were observed commonly during sleep and more than half of all cases of SUDEP are reported to occur during sleep. Further research into the mechanisms of ANS dysfunction following SE may be fruitful in providing greater understanding as well as treatments to prevent future cases of SUDEP.

**Title:** Faster flux of neurotransmitter glutamate during seizure --- *In vivo* evidence from $^{13}C$-enrichment of extracellular glutamate in the hippocampus of the kainate rat model of temporal lobe epilepsy

**Authors: *K. KANAMORI**[1,2]
[1]Neurosci. Res., Lab. Launch, Monrovia, CA; [2]Epilepsy Dept., Huntington Med. Res. Inst., Pasadena, CA

**Abstract: Aim**: Examine how the flux of neurotransmitter glutamate from neurons to the extracellular fluid, as measured by the rate of $^{13}C$ enrichment of extracellular glutamate ($GLU_{ECF}$), changes in response to seizures in the kainate (KA)-induced rat model of temporal-lobe epilepsy.
**Method:** Following intrahippocampal KA injection, $GLU_{ECF}$ was collected by microdialysis from the CA1/CA3 region of awake rats, in combination with EEG recording of chronic-phase recurrent seizures and intravenous infusion of [2,5-$^{13}C$]glucose. Progressive $^{13}C$ enrichment of $GLU_{ECF}$ C5 at ~ 10 picomol level was analyzed by gas-chromatography mass-spectrometry (GCMS), by measuring the increase in the peak area of m/z 331 vs m/z 330 ion (Fig. 1).
**Results**: The $^{13}C$ enrichment of $GLU_{ECF}$ C5 increased much faster in a rat with frequent seizures (shown by arrows) than in controls (Fig. 2A). The mean enrichment rate (the increase in fractional enrichment/min for $t$ = 0-120 min) was 0.0029 ± 0.0001 in frequently-seizing (10 ± 0.7 seizures/3 h) rats ($n$ = 4), vs controls, 0.00167 ± 0.0001/min ($n$ = 6) ($p < 0.01$) (Fig. 2B).
**Significance**: The *flux* of the excitatory neurotransmitter GLU, as measured for the first time in

vivo by $^{13}C$ enrichment analyses, is significantly enhanced by seizures, in addition to the previously-reported rise in $GLU_{ECF}$ *concentration.*

**Clinical potential**: To examine seizure-induced change in GLU flux, the time-resolution can be improved >10-fold in the human brain, where a 70-mm (instead of 2-mm) probe can sample more GLU per unit time.

**Abstract: Background**: Exercise is a known for its modulatory and beneficial effect on brain function. The development of epilepsy often includes a primary insult i.e genetic changes or a head trauma that initiates an epileptogenic phase that will lead to epilepsy and spontaneous seizures. We therefore set out to study if exercise by running could be a modulator of the epileptogenesis in a genetic mouse model of epilepsy notably the synapsin 2 knockout (KO), which will develop handling induced seizures from 2.5-3 months of age.
**Method**: Seizures were induced with handling by lifting the mice into another cage. Synapsin 2 KO mice (n=98) were housed with or without free access to a running wheel. All the handling and provocations of animals were done systematically for 8 weeks; first 3 times a week for 5 weeks and then once a week for additionally 3 weeks. Wheels were introduced at different time points in different groups, both before and after seizure onset. All seizures were recorded, and seizure onset, frequency and seizure severity was compared between running and control animals. Corticosterone levels and social ability of animals were also investigated before and after wheel inset.
**Results:** Animals that had wheels introduced before the development of seizures had a significantly later seizure onset compared to controls. The majority of these running animals did remarkably not develop any seizures. Running before seizure onset had a huge effect on seizure development even when the mice were not running during the provocation period. However, when wheels were introduced after seizure onset the effect of supressing seizures failed. In the groups that had a strong positive correlation between exercise and suppression of seizure onset, no change in seizure severity could be found. In addition, there was a decrease of corticosterone levels from 1 month to 2 months of age in both experimental groups. Furthermore, only running animals increased their social interaction time compared to non-runners.
**Conclusion**: These are the first results showing that exercise modulates epileptogenesis and seizure development in mice. These results may be of significance for the prevention and disease modifying strategies in the treatment of epilepsy.

**Abstract:** Epilepsy and Autism spectrum disorder (ASD) have a high comorbidity rate, with the co-occurrence of having both disorders being approximately 30% in children with either disorder. Researchers have begun to investigate this relationship by examining how early life seizures can lead to the development of autistic-like behavior in rodent epilepsy models. However, utilization of different seizure induction methods and background strain of mouse used has shown variable results, and thus it is critical we continue to investigate this relationship to determine the most optimal model to study the comorbidity. In this study, we used the inhalant flurothyl to induce seizures in male and female 129SvEvTac and C57BL/6 mice on postnatal days 7 to 11. Each mouse received 3 seizures per day, each approximately 2 hours apart (15 seizures total). All mice went through behavioral testing 3 months later in adulthood to examine how flurothyl seizures in early developmental periods effected the behavioral phenotype. We examined activity levels, social behavior, anxiety, repetitive behavior, learning/memory, and sensory gating abilities in all mice. The 129SvEvTac mice did not exhibit the typical ASD-like behavior we would have expected. Rather, the 129SvEvTac seizure mice exhibited significantly decreased repetitive behavior in the nose poke task compared to controls ($p < .05$). Results from 129SvEvTac mice will be compared to the behavioral phenotype of a more active mouse strain, C57BL/6 mice. Understanding mechanistically how early life seizures can contribute to the development of autistic-like behavior will be critical for elucidation of new therapeutic approaches for both disorders.

**Abstract:** Epilepsy is a neurodevelopmental disorder that is highly prevalent during the first year of life. Early life seizures are known to cause deficits in a variety of behavioral domains and have been shown to contribute to the development of autistic-like behaviors. Previous data from our lab using Ultravox equipment has demonstrated that a single acute early life seizure results in male-specific suppression of 50kHz ultrasonic vocalizations (USVs) in 129 SvEvTac mice. However, the impact of other types of seizure inductions have not been studied. For our studies, we evaluated the impact of seizures on vocalization development in 129 SvEvTac male and female mice across two different seizure paradigms, a single bout of continuous seizures on postnatal day (PD) 10 and multiple flurothyl seizures across PD 7-11. For the first paradigm, we administered kainic acid to mice on PD 10 to induce status epilepticus. On PD 12, pups were separated from their mothers and quantitative and spectrographic analysis was conducted to analyze USVs using Avisoft equipment and software. Results indicated that a single acute seizure suppressed USV quantity and duration, $p < 0.05$, as well as altered call-type utilization, $p < 0.05$. For the second paradigm, we administered flurothyl to mice on PD 7 to PD 11. The animals received 3 flurothyl-induced seizures per day, with 2 hours between each seizure, through PD 11. Similar to the first paradigm, on PD 12, pups were separated from dams and USV production was recorded for 2 minutes. These results indicate that call-type utilization was significantly impacted by seizures, $p < 0.05$, with an increased utilization of complex calls and a decreased use of chevron and upward call types. This study provides evidence that the suppression of USVs by seizures is not limited to a particular type of seizure induction, as call-type utilization was significantly impacted in both models. These are also the first results to examine the impact of a multiple seizure paradigm using flurothyl on vocalization development in mice.

**Abstract:** Conventionally, epileptic seizures are detected and characterized in zebrafish either as behavioral alterations or by means of direct electrographic recordings. To overcome the limitations of these conventional approaches (namely limited sensitivity of behavioural assays and lack of spatial resolution of electrographic recordings), we implemented the real time optical mapping of neuronal activity during the onset and propagation of epileptic seizures. We employed a transgenic zebrafish line with pan-neuronal expression of the genetically encoded calcium indicator GCaMP6s to measure neuronal activity in zebrafish larvae during seizures induced by pentylenetetrazole (PTZ). With this approach, we simultaneously measured neuronal activity in different regions of the larva brain together with tail locomotor activity, showing the high sensitivity of this method to detect different levels of alteration, as induced by increasing PTZ concentrations and treatments with various drugs. Moreover, we applied this optical method to the development of a high-throughput drug-screening assay able to simultaneously record brain and locomotor activity, demonstrating that GCaMP measurements can be more sensitive than behavioral assays for the detection of subclinical epileptic seizures. The methodological approach described here could provide a deeper comprehension of the mechanisms underlying epilepsy, enabling investigations on hypomorphic human mutations, and could improve the development of new anticonvulsant drugs. Furthermore, this method can also be easily applied to the study of other human neuropathologies modelled in zebrafish, allowing a simple and yet detailed investigation of brain activity alterations associated with the pathological phenotype.

**Abstract:** Focal cortical dysplasia (FCD) is a major cause of intractable focal epilepsies and has been clearly linked to abnormal MTOR signaling pathway. Recently, genetic mutations in this pathway have been increasingly identified in familial and sporadic focal epilepsies. However, there is no animal model that concordantly recapitulates pathological and electrophysiological changes observed in resected human tissues. Therefore, it has been challenging to develop new effective medical or surgical therapies. Here, we use CRISPR genomic editing tools to establish a novel FCD animal model that shows cortical dyslamination, ctyomegaly and increased intrinsic excitability. Everolimus is able to reverse the increased soma size and ameliorate the seizure burden. We also use genetically engineered human stem cells for in vitro study with hopes to develop a cell-based transplant therapy and a medium-throughput drug-screen platform.

**Abstract:** The dentate gyrus plays a central role in regulating activity in the extended hippocampal network and is thus critical for its normal functioning regarding cognition but also with regard to pathological conditions such as epilepsy, in which dentate granule cells (DGCs) are hyperactive. In order to better understand how altered dentate function affects downstream processing we decided to look at how cellular activity in areas such as the CA1 hippocampal region is affected when normal dentate function is perturbed, either through injury or through pharmacogenetic manipulations. For this purpose, we implemented an in vivo approach and performed two-photon calcium imaging in the CA1 of awake, behaving, mice traversing a virtual reality environment. CA1 is characterized by the presence of cells that encode spatial information (“place cells”). Our experimental setup allowed us to monitor the activity of CA1 pyramidal cells and assess their spatial tuning with regard to the animal's position within the virtual environment. Our preliminary data suggests that, compared to control animals, CA1 cells in animals that had experienced pilocarpine-induced status epilepticus (SE), which is devastating to DGCs, had a lower spatial specificity. Following SE, DGCs exhibit hyperactivity which persists permanently, so the reduction of spatial tuning specificity in CA1 cells could be attributed to a downstream flood of propagated activity.
Interestingly enough however, when animals expressing CaMKIIa.hM3D in their dentate were treated with clozapine-N-oxide (CNO), thus hyperexciting DGCs (mimicking the conditions seen in SE animals), there was no disruption of spatial tuning specificity in CA1 cells, nor was there any effect on their overall activity levels. In fact, CNO administration tended to increase spatial specificity in these cells, but not in a statistically significant manner. These diametrically opposite effects on CA1 cells following dentate hyperexcitability suggest that a complex pattern of interactions between the two structures may be at play.

**Title:** Neuron Restrictive Silencing Factor mediates long term learning and memory deficits provoked by developmental long febrile seizures

**Authors: *M. M. CURRAN**[1], K. P. PATTERSON[2], J. M. BARRY[3], A. SINGH-TAYLOR[4], G. P. BRENNAN[5], N. RISMANCHI[6], M. PAGE[3], Y. NOAM[7], G. M. HOLMES[3], T. Z. BARAM[1]
[1]Univ. of California Irvine, Irvine, CA; [2]Anat. and Neurobio., Univ. of California- Irvine, Irvine, CA; [3]Univ. of Vermont, Burlington, VT; [4]Anatomy/Neurobiology, Pediatrics, Neurol., Univ. of California Irvine Dept. of Anat. and Neurobio., Irvine, CA; [5]Physiol. and Med. Physics, Royal Col. of Surgeons Ireland, Dublin, Ireland; [6]Anat. & Neurobio., UC Irvine, Irvine, CA; [7]Univ. of California, Irvine, Irvine, CA

**Abstract: Rationale**: In a subset of children experiencing prolonged febrile seizures (FSs), the most common type of childhood seizures, cognitive outcomes are compromised. Similarly, our lab has identified significant, enduring spatial memory problems in rats following experimental prolonged FS (febrile status epilepticus; eFSE). The underlying mechanisms of these cognitive changes are unknown. Our lab has discovered Neuron Restrictive Silencing Factor (NRSF, also known as REST), a transcriptional repressor, as one of the mechanisms underlying the development of spontaneous seizures following status epilepticus in adult rats[1]. NRSF is known to contribute to neuronal differentiation during development and to programmed gene expression in mature neurons. Thus, we aim to determine if dysregulation of NRSF contributes to long term learning and memory deficits following eFSE.
**Methods:** Experimental FSE is induced in 10-11 day old Sprague Dawley rats as previously described.[2] To determine the role of NRSF following eFSE, we administer decoy oligodeoxynucleotides (ODNs) to acutely block NRSF function after eFSE. The first cohort consists of all male rats. At adulthood, we test their learning and memory function via the active avoidance spatial memory task, and then use golgi staining to analyze structural changes within

the hippocampus. To better understand how exposure to eFSE affects the developing brain, we use the novel object location task in a second cohort of male and female rats.
**Results:** Spatial memory, measured as the avoidance of the shock zone in the active avoidance task, is reduced after eFSE. Remarkably, these deficits are abolished by transient, post hoc interference with the chromatin binding of NRSF. Additionally, eFSE provokes region-specific dendritic loss in the hippocampus and aberrant generation of excitatory synapses in dentate gyrus granule cells. NRSF prevents the granule cell changes, but does not prevent dendritic loss in the CA1. The novel object location tasks in both males and females are ongoing.
**Conclusions:** Together, these studies provide novel insights into developing networks that underlie memory, the mechanisms by which early-life seizures influence them, and the means to abrogate the ensuing cognitive problems. We show that NRSF-based transcriptional repression is required for the development of long term memory deficits as tested in the active avoidance task and we will determine if that extends to other tests and to females as well.

**Title:** Online classification of behavior using miniature motion sensors during electrical recordings in freely moving rodents

**Authors: *H. POLDER**[1], N. ZIEGENSPECK[2], P. ZHAO[2], B. KLEINER[2], J. PLANCK[1], M. WESKAMP[1], A. DRAGUHN[3], M. BOTH[3], J. BRANKAčK[3]
[1]npi electronic GMBH, Tamm, Germany; [2]Fraunhofer-Institute for Manufacturing Engin. and Automation, Stuttgart, Germany; [3]Neuro- and Sensory Physiol., Ruprecht-Karls-University, Heidelberg, Germany

**Abstract:** Correlation of neuronal activity and behavior is a substantial goal of modern neuroscience research. For the investigation of pathological states (e.g. epilepsy, sleep disorders, drug addiction) the examination of the interconnection between behavioral patterns and electrophysiological data is of great importance. However, synchronous acquisition and

combined analysis of electrophysiological and quantitative behavioral data is still a challenging task. Currently, video tracking systems are the standard for behavioral monitoring. However these systems require a considerable amount of hardware, computing power and manual work for offline analysis.
We developed a method for automatic classification of behavioral states based on tracking and analyzing the motion of rodents using a set of miniature motion tracking sensors. Our approach is based on synchronization of multiple motion sensor data with local field potentials (EEG, LFP) in freely moving rodents for automatic classification of behavioral states. Classification of behavior is based on a learning algorithm working on a hierarchy of behavior states.
The headstage on the rodent consists of a miniature inertial measurement unit (IMU) with nine degrees of freedom (DOF), multiple channel recording of electric signal patterns (EEG, LFP) and a LED marker set for motion capturing. A stereo camera system placed above the recording cage tracks the LED signals and synchronizes them with the IMU data for estimation of the movement trajectory with 6 DOF and an accuracy of 2 cm. The camera system can be used to define behavioral states in the algorithm for automatic classification and is not used by the algorithm any more once the behavioral states are defined.
Compared to previously used approaches, this method yields lower false positive rates and a better association of motion features with behavioral state. For every layer of hierarchy, we identified the most informative feature components. For example, exploratory behavior was identified by the correlation between location, head orientation and acceleration signals. Among the classifiers tested, Neuronal Network, Gradient Boosted Trees and Random Forest achieved the best results. With these methods, first results show a classification accuracy of 99 % for immobility vs. movement and 96 % for detection of REM-sleep. Further behavioral states like classification of locomotion, exploration, or other behaviors can be flexibly added using appropriate training data.
The method is suited to correlate multi-dimensional physiological data (e.g., EEG) and behavioral states in a semi-automatic, highly reliable and reproducible manner.

**Title:** Does atomoxetine, a norepinephrine reuptake inhibitor, reduce seizure-induced respiratory arrest by modulating cardiorespiratory function?

**Authors: *H.-J. FENG**[1], H. ZHAO[1,2], J. COTTEN[1], X. LONG[2]
[1]Massachusetts Gen. Hosp., Boston, MA; [2]Central South Univ., Changsha, China

**Abstract: Background:** Sudden unexpected death in epilepsy (SUDEP) is a significant public health burden. The mechanisms of SUDEP are elusive, although cardiorespiratory dysfunction is a likely contributor. Clinical and animal studies indicate that seizure-induced respiratory arrest (S-IRA) is the primary event leading to death in many SUDEP cases. Our prior studies demonstrated that intraperitoneal (IP) injection of atomoxetine, a norepinephrine reuptake inhibitor (NRI), suppresses S-IRA in DBA/1 mice. In the current study, we injected atomoxetine intracerebroventricularly (ICV) and measured its effect on S-IRA in DBA/1 mice to determine its central effects. Additionally, we tested our hypothesis that atomoxetine reduces S-IRA via altering cardiorespiratory function.
**Methods:** DBA/1 mice were primed by daily subjecting to acoustic stimulation for 3-4 days to establish consistent susceptibility to audiogenic seizures (AGSz) and S-IRA. Atomoxetine was applied ICV using microinjection in behaving DBA/1 mice. We examined the effect of atomoxetine on respiratory and cardiac function using non-invasive plethysmography and ECG in anesthetized DBA/1 mice. Blood pressure and heart rate were measured using a tail-cuff system in conscious DBA/1 mice.
**Results:** The incidence of S-IRA was significantly reduced 2 hr after ICV administration of atomoxetine at 200 (40%, $n = 10$; $p < 0.01$) and 250 nmol (0%, $n = 6$; $p < 0.001$) as compared with vehicle control (100%, $n = 12$). Although atomoxetine suppressed tonic AGSz in 33.3% of mice in both dosages, it did not block susceptibility of DBA/1 mice to AGSz. IP atomoxetine administration at a dosage (15 mg/kg) that reduces S-IRA slightly increased basal ventilation (116.4% of vehicle control, $n = 7$; $p < 0.01$) as compared with vehicle control ($n = 7$), but exerted no effect on heart rate in anesthetized DBA/1 mice. IP injection of atomoxetine produced no effect on the heart rate and blood pressures in conscious mice.
**Conclusions:** Our data indicate that atomoxetine reduces S-IRA through direct effects on the CNS and potentially through modest effect on lung ventilation in DBA/1 mice. Atomoxetine, at a dosage that inhibits S-IRA, produced no detectable effects on the cardiovascular system. As a medication widely used for treatment of attention deficit hyperactivity disorder, atomoxetine is potentially useful to prevent SUDEP.

**Abstract:** Na/K-ATPase dysfunction, primary (mutation) or secondary (energy crisis, neurodegenerative disease) increases neuronal excitability in the brain. The mechanisms underlying this increased excitability remain to be fully understood. To evaluate increased excitability we performed extracellular as well as whole cell patch clamp recordings from the brain slices. We also performed immunohistochemistry to count the hippocampal cells. Here we demonstrate in the CA1 region of knock-in mice carrying the D801N $\alpha_3$ subunit mutation the following as compared to wild type. 1) Increased polyspiking evoked by electrical stimulation of Schaffer collaterals. 2) Equalization by bicuculline of the number of polyspikes induced by Schaffer collaterals stimulation. 3) Reduced miniature, spontaneous, and evoked, inhibitory postsynaptic currents, but no change in excitatory postsynaptic currents. 4) Robust action potential frequency adaptation in response to depolarizing current injection in stratum oriens fast-spiking/parvalbumin and quasi fast-spiking/somatostatin/neuropeptide Y interneurons. 5) No change in number of neuropeptide Y, somatostatin or pyramidal cells, but reduced number of parvalbumin positive interneurons. Our data indicate that, in our model, parvalbumin and somatostatin GABAergic interneuron dysfunction is a major contributor to Na/K-ATPase related increased excitability.

**Title:** Capnotaxis in the African naked mole-rat regulates GABA efficacy

**Authors: *M. ZIONS**[1], D. P. MCCLOSKEY[2]
[1]CUNY CSI, Staten Island, NY; [2]Dept of Psychology and Program in Developmental Neurosci., City Univ. of New York, Staten Island, NY

**Abstract:** Rationale: The African naked mole-rat (H. glaber), a species with a broad tolerance for low oxygen and high carbon dioxide, presents a unique opportunity to study how the mammalian brain accommodates environmental conditions. We have demonstrated that this species displays spontaneous seizure behavior and activity in vivo and in vitro under normal environmental conditions, which are exacerbated under conditions which lower inhaled carbon dioxide (hyperthermia, hyperventilation, hypocapnia).
Here we explored a mechanism that may explain both the environmental tolerance and the vulnerability to seizure: carbon dioxide regulation of GABAergic tone.
Methods: Adult naked mole-rats were injected with diazepam (5 mg/kg ip) and recorded with video and/or EEG. All animals exhibited seizures within 10 minutes. Treatment with 5% carbon dioxide allowed a second dose of diazepam to stop the seizure. Behavioral analysis using RFID tracking in the housing colony showed a strong preference of all colony members for the nest chamber, which contained the highest levels of carbon dioxide. When exogenous carbon dioxide (11%) was infused into the colony, animals spent more time away from the nest chamber and near the gas source.Conclusions: Diazepam typically suppresses seizure by promoting binding of GABA at its receptors, increasing chloride influx down its gradient. In naked mole-rats diazepam induces seizures in normal environmental conditions, but blocks seizures in hypercapnic conditions, indicating a chloride gradient which is tightly coupled to availability of carbon dioxide. Naked mole-rats demonstrate capnotaxis toward carbon dioxide sources, indicating not just a tolerance but a preference for hypercapnic environments. We therefore propose that naked mole-rats experience an anxiolytic effect through the enhanced efficacy of GABA when in the presence of their carbon dioxide exhaled by colony mates, a physiological adaptation which may be linked to the emergence of eusociality in this species.

**Abstract:** Febrile seizure (FS) is the most common seizure type in infants and young children. FS may induce functional changes in the hippocampal circuitries. Abnormality of excitatory and inhibitory neurotransmissions was previously related to wide-spread seizure attack in the hippocampus following recurrent seizure onset. To clarify the involvement of expressional changes and functional alterations of hippocampal interneurons with epileptogenesis following FS, we investigated long-term effects following recurrent seizure in a hyperthermia-induced seizure animal model. At 12 weeks following FS, the recurrent seizure time period, local field potentials (LFP) revealed high amplitude potential and a sharp wave characteristic of epilepsy. Mossy fiber reorganization in the hippocampus was also detected as abnormal synaptic connection at 8 weeks. Calretinin (CR) -positive interneurons were transiently enhanced during epileptogenic period at 7-9 weeks after FS in the CA1 and DG region and it is double labeled with VGLUT-1. However, although GABAA-α1 immunoreactivities were un-changed as similar to control hippocampus at 7-9 weeks after seizure onset, its expression was significantly enhanced at 4 weeks and 12 weeks and it is colocalized with GABA. Furthermore, the field excitatory postsynaptic potential (fEPSP) and the paired-pulse responses including population spike (PS) latency, excitability ratio and PS2/PS1 ratio were markedly altered in the CA1 and DG region at 12 weeks after FS. Therefore, our findings in present study indicate that these time-dependent changes may be based on the persistent alterations of hippocampal neuronal circuits in balance between excitatory and inhibitory responses, and may lead to the epileptogenesis and spread of seizure activity following FS.

**Title:** Synaptic balance of adult-generated dentate granule cells in the rat pilocarpine temporal lobe epilepsy model

**Authors: *K. M. GLANOWSKA**, G. G. MURPHY, J. M. PARENT
Univ. of Michigan, Ann Arbor, MI

**Abstract:** Excessive excitatory or altered inhibitory signaling is proposed to underlie the abnormal synchrony of hippocampal neuronal networks which are thought to contribute to seizures in human and experimental temporal lobe epilepsy (TLE). Increased dentate granule cell (DGC) neurogenesis is implicated in these epileptogenic mechanisms, as DGCs born around or shortly after the time of epileptogenic insult, especially hilar-ectopic DGCs, show abnormal integration into pre-existing circuits. However, specific alterations in both glutamatergic and GABAergic innervation of individual, birthdated DGCs during epileptogenesis has not been studied before. We investigated changes in excitatory and inhibitory synaptic inputs onto individual DGCs born during epileptogenesis using retroviral DGC labelling and whole cell voltage clamp techniques in the rat pilocarpine model of TLE. We compared neurons born shortly after induction of status epilepticus (SE) in adult male rats with DGCs born neonatally in age-matched controls after SHAM treatment. Additionally, ongoing studies are investigating synaptic balance in adult-born DGCs from SHAM animals. Birthdating of DGCs was achieved using retrovirus expressing GFP or mCherry driven by a synapsin promoter. All electrophysiological recordings were performed 8 to 10 weeks after SE or SHAM. We recorded both glutamatergic and GABAergic spontaneous synaptic activity in normal mature DGCs and those born during epileptogenesis. We calculated ratios of frequencies and amplitudes of excitatory to inhibitory postsynaptic currents (PSCs) to compare the synaptic balance index for individual neurons. This allowed us to identify candidate hub neurons exhibiting a disproportionately high contribution of one type of synaptic inputs over another. The vast majority of adult-born DGCs in the epileptic brain did not differ from normal controls; however, a small fraction, approximately one in 15 cells, showed a substantial increase in the ratio of glumatergic to GABAergic PSCs frequencies. We speculate that those cells serve as network hubs facilitating seizure development after an epileptogenic insult. An understanding of DGC integration into pre-existing networks may be crucial for the development of antiepileptogenic therapies.

**Title:** Immediate hippocampal granule cell epileptogenesis in experimental temporal lobe epilepsy

**Authors: A. V. BUMANGLAG**, *R. S. SLOVITER
MOREHOUSE SCHOOL OF MEDICINE, Atlanta, GA

**Abstract:** Acquired temporal lobe epilepsy with hippocampal sclerosis is a common neurological disorder defined, in part, by hippocampal formation neuron loss. It has been hypothesized that normally quiescent dentate granule cells generate spontaneous epileptiform discharges, either immediately, as a possible consequence of neuron loss, or after a seizure-free “latent period” when a secondary epileptogenic process gradually develops. Here we sought to determine whether and when granule cell epileptogenesis occurs after hippocampal injury, and whether the “latent period” is a clinically subtle epileptic state or a seizure-free “pre-epileptic” state. Perforant path stimulation-induced nonconvulsive status epilepticus for 24 hrs in urethane-sedated rats (n=16) caused selective injury to the hippocampus and entorhinal cortex. Continuous granule cell layer recording at 10 KHz in awake rats (n=16) revealed immediate and spontaneous granule cell population spikes and epileptiform discharges in all animals. These high-amplitude granule cell layer events were not identified by parallel surface EEG recording. Video data revealed spontaneous granule cell layer discharges lasting <10 sec had no detectable behavioral correlate, whereas discharges lasting ~15-40 sec reliably triggered subtle focal seizures (behavioral arrest, facial automatisms, and “wet-dog” shakes). Only granule cell layer discharges lasting ~40-130 sec caused clinically obvious seizures (behavioral arrest, facial automatisms, and forepaw clonus, with or without rearing), which ended the "latent period" 2-4 wks post-injury. Prolonged hippocampal excitation at 2 Hz for 24 hrs caused no obvious neuron loss and no spontaneous epileptiform discharges during the 1-month observation period (n=4). These results indicate that post-injury granule cell "epileptogenesis" occurs without delay, and that focal hippocampal discharges associated with non-convulsive seizures are shorter than those associated with convulsive seizures. The "latent period" is therefore a subtle epileptic state in gradual transition to a clinically obvious epileptic state, and not a seizure-free “gestational" state

when an unidentified epileptogenic mechanism gradually develops. Surface EEG recording appears to be an insensitive method that fails to detect focal hippocampal seizures readily detected by granule cell layer recording. Thus, even continuous EEG recording has a high probability of yielding the false negative conclusion that seizures do not occur during the latent period, which probably explains why the latent period has long been incorrectly assumed to be a seizure-free, pre-epileptic state.

**Abstract:** The use of electrical stimulation therapy for epilepsy is currently being studied in preclinical and clinical protocols. We have reported that the high-frequency stimulation (HFS) in the thalamic reticular nucleus (TRN) induced an anti-epileptogenic effect. The goal of the present study was to evaluate the effects of TRN electrical stimulation on the expression of pentylenetetrazole-induced (PTZ) seizures. Experiments were performed using Wistar male rats, with electrodes stereotaxically implanted in the left TRN (AP -1.4mm, L 1.6mm, H 6.2mm). Epidural EEG recording screws were implanted in the prefrontal cortex for EEG recording. The rats were classified as follows: Control, received only PTZ injection; HFS 10 min, treated with HFS for 10 min; LFS 10 min, subjected to LFS 10 min; HFS 60 min, HFS application for 60 min; LFS 60 min, received LFS for 60 min. EEG recordings were obtained from the cortex and were evaluated to assess ictal behavior over 30 min. The electrical stimulation of TRN induced a

significant decrease in seizure severity. DBS in the TRN induced a significant decrease in seizure severity and duration of TCGCs. Additionally, increased in latency of TCGCs and protected against death as a consequence of *status epilepticus*. These data support the benefical effects of TRN in mediating the expression of experimental seizures. In the future, the thalamic reticular nucleus may be a hopeful target for electrical stimulation to treat intractable seizures in humans.

**Title:** Loss of parvalbumin-immunoreactive interneurons in epileptic California sea lions

**Authors: *S. CAMERON**[1], R. GLABMAN[3], E. ABRAMS[1], S. JOHNSON[4], F. GULLAND[4], P. BUCKMASTER[2]
[1]Comparative Med., [2]Dept Comparative Med., Stanford Univ., Stanford, CA; [3]Univ. of Pennsylvania, Philadelphia, PA; [4]Marine Mammal Ctr., Sausalito, CA

**Abstract:** Temporal lobe epilepsy is common in humans. Seizures typically originate in the hippocampus, but the cause is unknown. The hippocampal dentate gyrus of human patients displays neuropathological abnormalities, including the loss of parvalbumin-immunoreactive interneurons. Normally, parvalbumin interneurons strongly inhibit excitatory neurons. Loss of parvalbumin interneurons in temporal lobe epilepsy might cause seizures. Rodent models of temporal lobe epilepsy do not perfectly replicate the parvalbumin interneuron loss found in human patients, so better animal models are needed. California sea lions (*Zalophus californianus*) develop temporal lobe epilepsy after exposure to the excitatory neurotoxin domoic acid, which enters the marine food chain during harmful algal blooms. We hypothesized that epileptic sea lions would display significant loss of parvalbumin interneurons in the dentate gyrus. To test this hypothesis, sea lions were intracardially perfused with formaldehyde immediately upon euthanasia because of failed response to treatment and poor prognosis. Brains were sectioned (40 μm) coronally. Nissl staining revealed obvious hippocampal neuron loss

(sclerosis) unilaterally in 22 sea lions and bilaterally in 15. Control sea lions (n=14), that were euthanized because of other conditions (e.g., septicemia and severe malnutrition) with a poor prognosis and failure to respond to treatment, displayed no obvious loss of hippocampal neurons. Stereology and a Neurolucida system are being used to estimate the number of parvalbumin-positive interneurons per dentate gyrus. Preliminary data suggest control sea lions have 14,200 ± 1600 parvalbumin interneurons per dentate gyrus. The average number of parvalbumin interneurons per dentate gyrus is reduced to only 6% of controls in sclerotic hippocampi of epileptic sea lions, similar to reports for human patients with temporal lobe epilepsy. If confirmed, these findings would suggest that epileptic sea lions can be used as a large animal model of human temporal lobe epilepsy and as candidates to test novel anti-epileptogenic treatments before human clinical trials.

**Abstract:** Neonatal seizures are associated with long-term cognitive and behavioral deficits, including autism and intellectual disability. We have found that pentylenetetrazol (PTZ)-induced seizures early in life prematurely unsilence thalamocortical (TC) synapses to disrupt tonotopic plasticity in the primary auditory cortex (A1; Sun et al, in review). Here, we examine whether early-life PTZ seizures may further disrupt E-I balance by altering the postnatal maturational profile of parvalbumin (PV+) cells across A1. Notably, this particular inhibitory circuitry is underdeveloped at birth and matures postnatally, signaling both the onset of critical period plasticity and its closure as they become tightly enwrapped by perineuronal nets (PNN).
We induced acute seizures in male C57BL6 mice by PTZ injection (60mg/kg daily i.p.) from P9-

11. Both mRNA and protein expression for PV and PNN were evaluated across the A1 critical period (P12-15) and beyond (P20, P40). By *in situ* hybridization, PTZ-mice at P13 had reduced PV transcripts strongly correlated with PNN gene expression. Immunohistochemistry revealed no differences in the number of PV+ cells with PNN in A1 across development. However, a significant decrease in cells only positive for PV+ (without PNNs) emerged in P20 PTZ mice (n=10) relative to that of saline-treated controls (n=8) within layer IV (respectively, 71.11±7.9% vs 100±10.45%; p=0.039) and layer V (78.88±7.32% vs 100±4.95%; p=0.038).
Across the tonotopic axis, TC responses in A1 mature at differential rates with earlier strengthening in rostral, high frequency regions (Barkat et al., 2011), as confirmed by vGluT2 labeling before and after the critical period. Because PV+ cells receive stronger TC innervation (Cruikshank et al., 2007), and impact the horizontal spread of TC driven activity, we further examined functional sensitivity to PTZ treatment across the tonotopic axis using voltage-sensitive dye imaging in an acute TC slice preparation. We compared naive (no tone-rearing) mice that were injected either with PTZ or saline from P9-11 and imaged at P15 upon stimulating the central thalamic (MGBv) sites for alignment and plotting the ΔF/F signal decay across layers. Surprisingly, the PTZ-injected mice displayed greater spread of activity only in the caudal direction and restricted to thalamo-recipient layers I and IV.
Taken together, our results suggest that in addition to unsilencing auditory synapses, PTZ-induced seizures may also impact PV circuit maturation which may contribute to biased spread of excitability toward late maturing portions of the caudal tonotopic map.

**Title:** Long-term seizure suppression and rescue of behavioral comorbidities in epileptic mice with hippocampal transplantation of GABA progenitors from the medial ganglionic eminence

**Authors: *M. L. CASALIA**[1], M. A. HOWARD[2], S. C. BARABAN[3]
[2]Neurolog. Surgery, [1]Univ. of California San Francisco, San Francisco, CA; [3]Dept Neurolog Surgery, Univ. California San Francisco, San Francisco, CA

**Abstract:** Epilepsy is a neurological disorder characterized by unprovoked seizures, behavioral and cognitive comorbidities. We recently showed that adult intra-hippocampal transplantation of

interneuron progenitors from the embryonic medial ganglionic eminence (MGE) dramatically reduce spontaneous electrographic seizures and rescue comorbidities observed in a mouse model of acquired epilepsy (Hunt et al. 2013). Whether the therapeutic benefits of transplanted interneuron progenitors are long-lasting or whether other types of ganglionic eminence derived interneurons are also therapeutic is not known. Here adult male CD1 mice (n = 134) were administered pilocarpine to elicit status epilepticus (SE). Only mice that survived acute SE and subsequently exhibit at least two unprovoked tonic-clonic seizures were designated as “epileptic” (n = 63; 90%) and became candidates for intra-hippocampal progenitor cell transplantation. In the open field (OF) test, epileptic mice showed progressive impairments compared to controls that were rescued 60 days after bilateral MGE transplantation (n = 26). In ‘epileptic+MGE’ mice continuous 14-day video-electroencephalographic (vEEG) monitoring at 180 days after transplant (DAT) showed an 84% reduction in mean seizure frequency and an 88% reduction in the total number of seizures. *Post hoc* immunohistochemistry at 210 and 360 DAT showed that MGE cells co-express neuronal (Tuj1 and GAD67) and interneuron markers (PV, SOM and nNOS), as expected. Slice electrophysiology studies at 270 DAT showed that inhibitory postsynaptic current frequency was reduced in epileptic mice (n = 7) but restored to naïve levels in ‘epileptic+MGE’ mice (n = 6). In a separate group of naïve mice, intra-hippocampal transplantation of CGE progenitors resulted in mice that exhibited “interictal” bursts at 30 DAT (n = 3) and seizure-like events with high-frequency, high-voltage, rhythmic activity with clear onset, progression and termination at 90 DAT (n = 3). Although CGE progenitors integrated as vasoactive intestinal protein- and reelin-positive interneurons in ‘epileptic+CGE’ mice, the pattern and frequency of electrographic seizure activity did not diminish during the 14 days of continuous vEEG monitoring (n = 5). Taken together, we demonstrate that MGE (but not CGE) progenitors enhance functional GABA-mediated inhibition, dramatically reduce spontaneous seizure frequency and rescue behavioral deficits in epileptic mice more than six months after treatment. We conclude that MGE progenitor cell transplantation exerts a long-term therapeutic effect in pre-clinical epilepsy models.

**Title:** Slow $Cl^-$ extrusion promotes the spread of activity among reticular thalamic neurons

**Authors: *P. M. KLEIN**[1], A. LU[2], M. P. BEENHAKKER[3]
[2]Med. Scientist Training Program, [3]Pharmacol., [1]Univ. of Virginia, Charlottesville, VA

**Abstract:** Inhibitory GABAergic signaling among reticular thalamic (RT) neurons is thought to form an important choke point that prevents the occurrence of seizures. We have previously demonstrated that despite diminished expression of the $Cl^-$ cotransporter KCC2 in the RT nucleus, RT neurons still maintain a sufficiently hyperpolarized reversal potential for GABA-induced currents ($E_{GABA}$) to promote inhibition. However, our previous $E_{GABA}$ measurements only reflect the ability of RT neurons to maintain low intracellular $Cl^-$ concentrations ($[Cl^-]_i$) during short periods of mild GABAergic signaling. We predict that low KCC2 expression leaves RT neurons susceptible to activity-dependent increases in $[Cl^-]_i$, allowing prolonged stimulation to render GABAergic signaling among RT neurons excitatory and to then promote spreading activation within the RT nucleus. Using a paradigm of repeated GABAergic activation in neurons voltage-clamped at depolarized potentials, we determined that $Cl^-$ accumulates more rapidly in RT neurons than in neurons of the ventrobasal (VB) thalamic nuclei in P10-20 Sprague Dawley rats. The time constant for recovery from $Cl^-$ loading ($\tau_{rec}$) in RT neurons (30.3±3.7 sec, n=11) was also much slower than in VB neurons (18.3±2.3 sec, n=15, p=0.008). The KCC2 antagonist VU0463271 slowed $\tau_{rec}$ in VB neurons (baseline: 16.4±3.6 sec; 10 minutes post-VU: 28.2±4.0 sec, n=8, p=0.045), but had no impact on $\tau_{rec}$ in RT neurons (baseline: 25.5±3.3 sec; 10 minutes post-VU: 27.2±3.1 sec, n=6, p=0.47). VU0463271 may not alter the $\tau_{rec}$ of RT neurons because KCC2 expression is already sufficiently low, such that further reductions have little impact in this experimental paradigm. Based on our experimental findings, we produced a computational model of the RT nucleus, with 100 RT neurons arranged in a linear array and each cell projecting GABAergic synapses to the eight nearest neurons. When RT neurons were assigned a slow $\tau_{rec}$ reflecting our experimental data (~30 sec), stimulation of neurons within our network provoked GABA-mediated action potentials more rapidly, and in a greater number of neurons, than with faster $\tau_{rec}$ values. Less frequent stimulation also produced a greater spread of activation within our network when slower $\tau_{rec}$ values were modeled. Our results indicate that the reduced $Cl^-$ extrusion capability of RT neurons leaves the RT nucleus more susceptible to undergoing an activity-dependent switch to excitatory GABAergic signaling. The loss of inhibitory GABAergic signaling among RT neurons breaks open this important seizure choke point and implicates upregulating $Cl^-$ extrusion in RT neurons as a therapeutic strategy for treating absence epilepsy.

**Abstract:** There is a great demand for therapeutic advancements with respect to mood disorders and a significant link between stress and major depressive disorder (MDD) exists. Maternal separation in rodents is a widely used animal model used to induce early-life stress. This model has reliably demonstrated an increased risk of depressive-like behavior later in life. Existing research also supports that individuals with MDD have learning and memory deficits. Two regions of the hippocampus, the dorsal and the ventral regions, are suggested to be functionally different while the dorsal hippocampus is involved in cognitive function and the ventral hippocampus is involved in emotion and stress. Additionally, microglia activity is associated with causing the atrophy and pathology of these brain regions and may be implicated in MDD. The proliferation and stability of microglia across the development into adulthood differs. We aimed to examine the expression of dorsal and ventral hippocampal microglia in adolescent rats that experience postnatal maternal separation during early development. In the present study, Sprague Dawley male pups were separated from the dam from PND 2 to PND 14 for three hours a day. A control condition of non-separated pups was maintained. First, we examined behavioral tasks during adolescence and found separated offspring spent more time in closed arms of an elevated plus maze. Second, we found epigenetic markers correlating with anxious behavior in the elevated plus maze. Also, we found decreased Iba1 protein expression and increased Rel A protein expression in both hippocampal compartments. Further, we found increased CD11b protein in only the ventral portion of the hippocampus. Decreased levels of histone deacetylase 4 were found in the ventral hippocampus but not dorsal hippocampus. There were no changes in glutamatergic transporters in neurons or astrocytes. To understand the functional connectivity of our findings, we used immunohistochemistry to examine the alterations in dorsal and ventral hippocampal input and output regions. Microglia were quantified in the nucleus accumbens, prelimbic and orbital cortex and based on morphology of Iba1 expressing cells. Our data may provide insight as to the molecular mechanisms responsible for MDD vulnerability, pathogenesis and possible therapeutic remedies.

**Title:** Molecular evolution of adeno-associated virus for targeting of microglia

**Authors: *A. O. GEZER**[1], S. MISHRA[1], F. P. MANFREDSSON[2]
[2]Translational Sci. & Mol. Med., [1]Michigan State Univ., Grand Rapids, MI

**Abstract:** Adeno-associated virus (AAV) is a small virus that causes very mild immune response and no disease. Lack of pathogenicity makes AAV an attractive and powerful gene therapy tool. The AAV genome contains two open reading frames named rep and cap. The cap gene encodes the proteins that form the capsid. A plethora of various AAV serotypes have been identified, all differing in the capsid gene, which dictates cellular receptor binding and thus the tropism of that particular serotype. However, although AAV transduces a variety of cell types with high efficiency, microglia remains remarkably refractory to transduction. The purpose with this project was to utilize molecular evolution to engineer novel AAV capsid mutants that efficiently transduce microglia, thereby creating a novel tool to aid investigations in to the role of microglia in disease. We chose microglia because ongoing research by us and others demonstrate that neuroinflammation plays an important role in the pathophysiology of Parkinson's disease (PD) and other neurodegenerative disorders. Neuroinflammation in PD involves an activated microglia response along with an increase in inflammatory markers. Targeting microglia by AAV opens the door for modulating neuroinflammation, potentially interfering with the disease process in PD, and providing a new tool to study PD etiology.
We utilized 2 different methods to generate diverse libraries of AAV cap mutants 1) Random DNA shuffling of naturally occurring mutant capsids in combination with rationally engineered mutant capsids. With this approach various cap genes were digested and randomly reassembled to generate chimeric capsids. 2) Insertion of peptide libraries in to the AAV cap. Introduction of short peptides in to certain motifs of the AAV capsids can alter the tropism of the virus by mediating capsid attachment to non-canonical receptors that are specifically expressed on the surface of the target cell, in our case the microglia. In our study, we utilized a random peptide library as well as a library based on CD11b, an integrin family member expressed on surface of the microglia. AAV was thereafter generated and injected in to the CNS (striatum) of adult rats. Ongoing work is aimed at 1) Determining the diversity of our viral library, and 2) Isolate and sequence chimeric cap genes contained within microglia. Identified capsids will thereafter be subject to additional rounds of evolution in order to further improve the efficacy of microglial transduction. Although this work is focused on microglia per se, it is important to note the power

of this approach, as it can be applied to a variety of cell types to facilitate research in to a variety of pathologies.

**Abstract:** The enzyme glutamine synthetase (a.k.a. glutamate ammonia ligase, Glul) is enriched in astrocytes and serves as the primary pathway for synaptic glutamate clearance and brain ammonia detoxification. Loss of astrocytic Glul has been implicated in several CNS disorders, such as epilepsy; however, the mechanism by which Glul deficiency might cause disease is not understood. Here we selectively deleted Glul in the hippocampus and neocortex of mice to study the consequences of Glul deficiency. This resulted in a viable mouse model which allows detailed studies of the pathological progress leading to epilepsy and neurodegeneration. At two weeks of age, the brain cytoarchitecture and behavior of Glul deficient mice were largely unremarkable; however, the brain chemistry, microglial cells and blood vessels were altered. At four weeks of age, other changes became apparent, such as slowed brain growth, altered functional connectivity, reduced cerebrovascular reactivity, behavioral abnormalities, epileptic seizures and progressive neuron loss. Conclusions: Lack of Glul is in itself sufficient to cause epilepsy and neurodegeneration. However, Glul deficiency does not immediately cause seizures,

but rather triggers a pathological process involving early changes to microglia and blood vessels, as well as astrocytes, before culminating in epileptic seizures and progressive neuron loss.

**Abstract:** In typically developing individuals, dendritic spine density peaks between 12 and 36 months after birth and is then pruned during maturation. Autism spectrum disorder (ASD) appears to lack this normal pruning process and spine density remains high up to adulthood. Microglia are resident immune cells of the brain that are involved in synaptic pruning during development. It is possible that there is a change in phagocytic microglia in ASD that leads to a decrease in synaptic pruning. To address this, we used an unbiased stereological approach to quantify phagocytic cups and phagocytic microglia in postmortem human temporal cortex immunocytochemically labeled with Iba1. We observed and report for the first time, phagocytic cups and phagocytic microglia in the tissue sample we analyzed. The total density of all microglia phenotypes and phagocytic microglia did not differ between ASD donors (n=10, 14.6 yrs, range 2.8-29 yrs) and typically developing individual donors (controls, n=9, 14.9 yrs, 1.8-32 yrs). However, the phagocytic capacity of microglia was significantly higher in ASD compared to controls, which suggests increased phagocytosis of either apoptotic or proliferating cells. There was a significant negative correlation with the density of ramified microglia and a significant positive correlation with the density of amoeboid/rod/dystrophic microglia in ASD. It may be that these phagocytic microglia are not associated with synaptic pruning, but with increased inflammatory responses or cell death. Further investigations of phagocytosis by microglia using different functional markers (e.g., CD68 or CD11b, PSD-95) may be a step forward in understanding its significance in synaptic pruning and neuroinflammation in ASD.

**Abstract:** ***Introduction;*** Anorexia nervosa (AN) is a unique psychiatric disorder characterized by the persistent restriction of energy intake that leads to significantly low body weight, a tremendous fear of gaining weight, and disturbances in normal perception of a body shape. Previous studies showed significant increases in inflammatory cytokines (i.e. TNF-α, IL-1β, IL-6) and immunoreactive protein (i.e. corticotropin release hormone) in AN patients. Although it is reported that changes of these cytokines in the peripheral blood are linked with activation of microglia in various diseases, no study exists on microglial activation in the AN brain. Here, we aim to clarify that microglial activation is present in the active state of AN and that the level of microglial activation is associated with clinical scores of the AN severity using PET with [$^{11}$C]DPA713.
***Methods;*** Twenty female AN patients (mean age±SD, 25.0±6.2 years old, mean BMI±SD, 14.1±1.3) and 20 healthy female subjects (22.9±3.7years old, BMI 20.6±2.4) underwent [$^{11}$C]DPA713 PET measurements and neurocognitive tasks. $BP_{ND}$ of [$^{11}$C]DPA713 was estimated with a simplified reference tissue model. We examined the whole brain using a voxel-wise analysis, SPM8 (Wellcome Department of Cognitive Neurology, London, UK).
***Results;*** The levels of [$^{11}$C]DPA $BP_{ND}$ in AN patients were significantly higher in the broad brain regions except for the parietal cortex compared to healthy subjects. General cognitive abilities evaluated with Raven colored progressive matrices (visual and spatial cognition), Stroop test (frontal lobe function), and Iowa Gambling Task (decision making) did not differ between AN patients and healthy subjects. No significant correlation was found between [$^{11}$C]DPA $BP_{ND}$

values and these clinical parameters.
***Discussion;*** Our results showed a significant increase in microglial activation in the extensive brain areas but the parietal cortex in the active state of AN. The heterogeneous activation of microglia in the brain and no correlation between microglial activation and clinical scores unlike evidence reported in mild cognitive impairment or dementias suggest that the microglial activation depicted during the aggravated period may be reversible in the AN brain.

**Title:** Microglial activation regulates cognitive deficit in young offspring of maternal immune activation

**Authors: *Q. ZHAO**[1], Z. YOU[2]
[1]Sch. of Life Sci. and Technol., Univ. of Electronic Sci. and Technol. of, SICHUAN, China; [2]Sch. of Life Sci. and Technology, Ctr. for Informational Biol., Univ. of Electronic Sci. and Technol. of China, SICHUAN, China

**Abstract: Introduction:** Maternal immune activation (MIA) during pregnancy increases the risk of psychiatric disorders such as schizophrenia, autism-spectrum disorder and depression in offspring. But the underlying mechanism of MIA-induced neurodevelopmental and behavioral abnormality in prepuberty offspring has not yet elaborated. The present study was intended to investigate the effects of MIA on cognitive behavior in young offspring and its potential neuroinflammatory pathway. **Methods:** Animal model of MIA was induced by injection of pregnant Wistar rats with polyinosinic-polycytidylic acid (Poly(I:C)), a synthetic analogue of the viral double-stranded RNA. The male prepuberty offspring (21 days old) were used in this experiment. Cognitive behavior was estimated by the Morris Water Maze. Inflammatory

cytokines and microglial activated phenotype (classical activated microglia: M1 phenotype; alternative activated microglia: M2 phenotype) were confirmed by Real-Time PCR, ELISA and IHC. The offspring were injected with different dose of pioglitazone by intraperitoneal administration for 7 days. **Results:** The young offspring with MIA showed impaired spatial learning and memory in Morris Water Maze task, increased expression of pro-inflammatory cytokines (IL-1β, IL-6, TNFα, iNOS), and decreased expression of anti-inflammatory mediators (IL-4, IL-10). Microglial M1 activation was observed in MIA offspring. Pioglitazone administration inhibited M1 activation, promoted M2 polarization, improved spatial learning and memory and the balance of pro- and anti-inflammatory cytokines in offspring rats. **Conclusion:** MIA-induced cognitive deficit was modulated by microglia-dependent inflammatory response in the prepuberty offspring rats.

**Title:** Microglia are more active in schizophrenia as evidenced by gene expression signatures

**Authors: *C. L. SAVONEN**, M. A. REIMERS
Neurosci., Michigan State Univ., East Lansing, MI

**Abstract:** The pathological mechanisms of schizophrenia (SCZ) are still unknown. This has left drug treatments essentially the same as they were four decades ago despite that these drugs have considerable side effects and do not address all the symptoms. Recent findings show genetic and environmental risk for SCZ is associated with a number of immune response factors. Microglia, the principal immune effectors in the brain, play a critical role in synaptic pruning and increase their rate of pruning in response to inflammation. This suggests that microglia could be responsible for the synaptic loss observed postmortem in SCZ. We hypothesize that a type of microglial activation similar to their inflammatory responses play a key role in the synaptic loss in SCZ. Using Affymetrix microarray data from Martinez et al (*J. Immunol.*, 2006), we identified a gene expression signature indicative of microglial activation. From the initial 19,530 genes in the dataset, the bottom 10% least abundant probes were eliminated from the analysis. MANOVA

with Hotelling-Lawley statistic identified 1723 genes that were differentially expressed in response to LPS and IFN-γ treatment (to induce what is known traditionally as an 'M1' state) using FDR of 0.05, and subsequent fold change cutoff of 1.2. Of these 426 genes, 305 were eliminated because they were expressed more highly in other brain cell types than in microglia, based on Zhang et al data (*J. Neurosci.*, 2014). These 121 genes were used to investigate microglial activity within SCZ RNA-Seq dataset from Zhao et al (*Mol. Psychiatry*, 2015). Using principal components analysis as a dimension reduction technique, overall expression scores for genes indicative of microglial activation and overall expression scores for genes indicative of synaptic density were obtained for both SCZ and controls samples. SCZ samples showed overall higher levels of microglial activation gene expression ($t= -4.10$, $p<0.001$) and lower synaptic gene expression ($t= 4.9446$, $p<0.001$). Overall, synaptic density and microglia activation estimated in this manner were negatively correlated to each other ($R= -0.52$, $p<0.001$). Overall, these data show the plausibility of our microglia-centered disease model of SCZ.

**Title:** The agonists of $PGE_2$ EP1 receptor potentiate microglial CD36 recycling without affecting migration

**Authors: *B. MA**[1,2], K. GOODWIN[1], S. DORÉ[3,2]
[1]Dept. of Anesthesiol., Univ. of Florida Col. of Med., Gainesville, FL; [2]Ctr. for Translational Res. in Neurodegenerative Dis., Gainesville, FL; [3]Dept. of Anesthesiology, Neurology, Psychiatry, Neurosci., Univ. of Florida, Gainesville, FL

**Abstract:** We previously documented that the deletion of the prostaglandin E2 (PGE2) EP1 receptor undermined microglial phagocytosis in vivo. However, the related mechanism still remains unknown. CD36 is a type II scavenger receptor that mediates microglial phagocytosis, which contributes to hematoma clearance after intracerebral hemorrhage (ICH). In this study, we sought to identify the effects of two EP1 receptor agonists on CD36 receptor recycling and cell migration using primary microglial cultures.
The EP1 agonists 17-pt-PGE2 and ONO-DI-004 were used in our study as the treatment.

Fluorescent latex beads and CFSE-labeled red blood cells (CFSE-RBCs) were added to microglial cells independently at a concentration of 10 beads or CFSE-RBCs per cell for live-cell imaging. Immunocytochemistry was performed with the antibody against ionized calcium-binding adapter molecule 1 (Iba1, a microglial marker). We analyzed microglial CD36 receptor recycling by using an established receptor recycling assay. As migration also affects microglial phagocytosis, we used the DUNN chamber to monitor microglial chemotaxis.
We found that 10μM 17-pt-PGE2 significantly increased the number of attached beads to microglial cells from 40 to 120min of incubation ($p<0.01$). Furthermore, we analyzed CD36 receptor recycling using an established receptor recycling assay, and the quantitative results showed that a 10μM 17-pt-PGE2 treatment markedly increased the positive staining area of recycled CD36 receptor in microglial cells ($p<0.05$). We then treated primary microglial cells with another EP1 agonist, ONO-DI-004, for 120min at concentrations of 5 and 10μM. The fluorescent area of CFSE-RBCs after ice-cold PBS washing was markedly increased with the 10μM ONO-DI-004 treatment ($p<0.05$). In the live-cell imaging experiment, a 10μM ONO-DI-004 treatment also significantly increased the number of attached CFSE-RBCs to microglial cells from 25 to 60min of incubation ($p<0.01$). However, the DUNN chamber results indicated that neither EP1 agonist had an effect on microglial travelling distance or velocity.
This study demonstrates that the PGE2 EP1 agonists 17-pt-PGE2 and ONO-DI-004 can potentiate microglial phagocytosis in vitro through enhanced CD36 receptor recycling.

**Authors: *A. SEPULVEDA RODRIGUEZ**[1,2], C. A. CARLONE[1], S. VICINI[1,2,3], P. A. FORCELLI[1,2,3]

[1]Dept. of Pharmacol. and Physiol., [2]Interdisciplinary Program in Neurosci., [3]Dept. of Neurosci., Georgetown Univ. Med. Ctr., Washington, DC

**Abstract:** Microglia, the resident macrophages of the CNS, play a central role in the neuroinflammatory response that characteristic of many brain disorders. A specific pattern of changes in microglial physiology, motility and morphology have been described in the mouse hippocampus after severe seizures (Sz) known as *Status Epilepticus* (SE) (Avignone et al. J Neuro 28(37):9133 2008). SE creates two potent and distinct activators of microglial activation (neuronal hyperactivity and neurodegeneration) and results in the development of spontaneous Sz reminiscent of Temporal Lobe Epilepsy (TLE).

This study aims to further characterize the microglial response to abnormal neuronal hyperactivity using Sz induced by a range of *in vivo* transcorneal Electroconvulsive Shock (ECS) regimens on transgenic reporter mice. Unlike chemoconvulsants, ECS yields reproducible Sz of varying severity without neuronal damage or disruption of endogenous neurotransmission. We employ a well-established in-slice functional assay of microglial responsive motility to monitor the physiological state of the microglia. P28-P35 female and male CX3CR1$^{eGFP/+}$ mice (with and without P2rx4-tdTomato) were randomized to treatment and control groups, then subjected to one of the following ECS regimens: 1 minimal (clonic) Sz, 3 minimal Sz in 1d, 3d with 3 minimal Sz each, or 1 maximal (tonic-clonic) Sz. Horizontal slices of hippocampus were prepared 24h after the last Sz, following standard protocols. Confocal fluorescence z-stacks were taken every 30s to capture the response of microglial processes in CA1 towards a patch pipette with 3mM ATP. Extent and velocity of responsive motility was quantified using Manual Tracking (ImageJ). Microglial expression of P2RX4 was evaluated by tdTomato fluorescence intensity.

None of our minimal ECS regimens affected microglial responsive motility, while a single exposure to maximal ECS significantly enhanced the velocity of the response. The correlation of these changes with microglial P2RX4 expression will be reported.

Our data suggest that unlike minimal Sz, maximal Sz recruit microglial activation pathways reminiscent of the response to SE. In sharp contrast to SE, such Sz are not thought to cause hippocampal degeneration nor result in TLE-like spontaneous Sz. In conclusion, our data suggest that at least part of the SE-induced microglial response can be recapitulated with much less severe Sz. These results could reveal novel biomarkers and therapeutic targets for hippocampal sclerosis, neuroinflammation and epileptogenesis.

**Title:** Activation of microglia and loss of synapse in the developing hippocampus of mice prenatally treated by valproate

**Authors: *T. HONDA**[1], Y. ISHIHARA[1,2], A. ISHIDA[1], T. YAMAZAKI[1]
[1]Integrated Arts and Sci., Graduated Sch. of Hiroshima Univ., Higashi-Hiroshima City Hiroshima, Japan; [2]Ctr. of Hlth. and the Envrn., Univ. of California, Davis, CA

**Abstract:** Valproate (VPA) is the first choice drug for treatment of generalized epilepsy, but taking VPA in pregnant increases the risk of autism spectrum disorder (ASD). Recently, it is reported that the anatomical and morphological characteristics as well as the number of microglia are abnormal in ASD patients, suggesting that microglia are involved in ASD pathology. The purpose of this study is to unravel the mechanism of abnormal behavior induced by VPA, focusing on microglial activation. Pregnant ICR mice were orally administered with pure water or VPA at 800mg/kg dosage on gestational day 11 (GD11). Behaviors in male pups were examined using open field test in 4-week old to evaluate locomotor activity and Y-maze test, social interaction test and marble burying test in 5-week old to evaluate cognitive function, social preference and repetitive behavior, respectively. On postnatal day 10 (P10), neuroinflammation was investigated by proinflammatory cytokine expression using real-time PCR. Microglial activity was evaluated by ionized calcium-binding adopter molecule 1 (Iba1) and cluster of differentiation 68 (CD68) staining, and synaptic formation was assessed by postsynaptic density protein 95 (PSD95) staining on P10 and in 6 week-old. There was no change in locomotor activity between VPA-treated group and vehicle-treated group, but VPA-treated mice showed deficit in alternation, decreases in contact with a novel mouse and increment of burying behavior as compared to vehicle-treated mice, suggesting that VPA induces impairment of working memory, abnormal social behavior and symptom of repetitive behavior, respectively. VPA up-regulated expression of interleukin 1β (IL-1β) in the hippocampus. There was no change in the number of microglia between VPA-treated murine brain and vehicle-treated murine brain, but VPA enlarged microglial cell body and up-regulated CD68 expression in hippocampal CA1 region on P10 but not in 6 week-old. These results clearly show that exposure to VPA during fetal stage activates microglia accompanied with increased phagocytic activity in the hippocampus. VPA reduced the number of PSD95 puncta in the CA1 hippocampus, but the alteration of PSD95 expression disappeared in 6-week old mice. Therefore, VPA could transiently induce synaptic loss in developing brain. Taken together, the present study has demonstrated that fetal exposure to VPA elevates microglial activity and decreases the number of synapse in hippocampus during developmental period. Impairment of developmental synapse pruning by activated microglia might elicit abnormal behaviors accompanied with prenatal VPA exposure.

**Abstract:** Major depressive disorder (MDD) is a mood disorder of multifactorial origin and a significant contributor to the global burden of disease. The effective antidepressant treatments are insufficient as result of the considerable heterogeneity of depression and a lack of defined etiology. Growing body evidence from human postmortem and animal researches suggests that the change in structure and function of microglia contributes to the physiopathology of major depression disorders and associated deficits in neuroplasticity and neurogenesis. Recent studies reported that groups of individuals with depression demonstrated significantly changes in the levels of a variety of inflammatory biomarkers in central nervous system. However, the relationship between microglia-mediated neuroinflammation and hippocampal neurogenesis remain poorly understood. In this study, we provided an underlying mechanism by which microglial phenotype transformed by stress from resting state to M1 state suppresses hippocampal neurogenesis and results in depressive-like behavior. The animal model of depression was established by chronic mild stress. Base on the data from behavioral test, the mice were divided in two group, including high-susceptible to stress (HS) and low-susceptible to stress (LS). The neurogenesis and microglial morphology was examined by immunohistochemistry. And the microglial phenotype was assessed by qRT-PCR. The results showed the microglia polarized to M1 state in HS group. And microglial M1 polarization and depressive-like behavior were positively correlated. Hippocampal neurogenesis was decreased in HS group, and associated with depressive-like behavior. In a separate in vitro experiment, IFN-γ-induced M1 primary microglia suppressed neural stem cell proliferation, differentiation, and survival. These results suggested that the phenotypic polarization of microglia contribute to neuroinflammation, hippocampal neurogenesis and stress-induced depressive symptomatology.

**Title:** A potential role for class IIa HDACs in mediating neuroinflammation following traumatic brain injury

**Authors: *D. P. CROCKETT**[1], R. PATEL[2], M. PAUL[2], A. WACH[2], R. GRAZIANO[3], L. P. BERNARD[1], V. L. DIBONA[1], H. ZHANG[1]
[1]Dept Neurosci. and Cell Biol., Rutgers Robert Wood Johnson Med. Sch., Piscataway, NJ; [2]Rutgers Univ., Piscataway, NJ; [3]GSBS, Robert Wood Johnson Med. Sch., Piscataway, NJ

**Abstract:** Each year millions of Americans will suffer either a traumatic injury to the brain or the spinal cord. At present, there is no effective cure. One major factor preventing recovery within the central nervous system is ongoing neuroinflammation triggered by the injury. Prolonged inflammation can lead to continued loss of neurons and consequently loss of function. A major player in the inflammatory response is microglia, the brain's resident immune cells. Microglia are highly ramified at "rest" but change into rounded phagocytic cells following injury. The mechanism associated with this activation and morphological change is poorly understood.
To better understand the molecular mechanisms that might be responsible for control of microglial activation, we have focused our attention on class IIa zinc dependent histone deacetylases (HDACs). Many members of this class (e.g., HDAC4, 5 and 7) are expressed in macrophages and microglia and seem to play an important role in innate immune responses. Classically HDACs were recognized as enzymes that deacetylated the lysine residues of histones within the chromatin, regulating gene expression. They are balanced by other enzymes termed histone acetyl transferases. The class IIa HDACs are unique in that they possess minimal enzymatic activity and their actions depend on forming complexes with class I HDACs and transcription factors. Further, their function is dependent on their cellular location which is determined by their phosphorylation state. When phosphorylated they are sequestered in the

cytoplasm. When dephosphorylated they enter the nucleus to regulate gene expression. In mice subjected to traumatic brain injury (TBI), we observed intense immunoreactivity for HDAC7 within activated microglia and reactive astrocytes. Sham-operates and naive controls showed minimal staining for HDAC7 in microglia and astrocytes. In-vitro studies using activated, immortalized microglia (BV2 cells) and primary cultures of astrocytes confirmed cellular expression of HDAC7. Our results indicate that increased HDAC7 expression may mediate the inflammatory response after neural injuries.

**Abstract:** Parkinson’s Disease (PD) is a progressive neurodegenerative disease characterized by the pronounced loss of dopaminergic neurons. In recent years, mitochondria dependent oxidative stress and inflammation have been implicated in the mechanism of dopaminergic neurodegeneration. In this context, the activation of innate immune response is becoming a pivotal component of neurodegeneration. Here we investigated the mechanisms by which minimally toxic concentration of LPS and rotenone (ROT) elicited microglial activation response via NOD-like receptor containing a pyrin domain 3 (NLRP3) inflammasome using mouse microglial BV2 cells and primary microglia. Upon sequential treatment of BV2 cells with ROT and LPS, a marked time-dependent increase in ROS generation, mitochondrial membrane potential (MMP) collapse was found to accompany an impaired autophagolysosomal system (ALS). Moreover, a concomitant increase in the activation of cathepsin B (cath B), a lysosomal protease, and NLRP3 inflammasome as evidenced by a marked increase in NLRP3 expression

and secretion of IL-1β and caspase-1 were also evidenced in these cells. Additionally, ROT/LPS exposure also lead to the extracellular release of high-mobility group box 1 (HMGB1) protein, further enhancing microglial activation. Intriguingly, blocking cath B activation by RNAi or pharmacological blockade using CA074 attenuated NLRP3 inflammasome activation, ROS generation and mitochondrial dysfunction, as was well as accumulation of autophagic vacuoles (AVs) and lysosomal destabilization in ROT/LPS treated microglial cells. Conversely, cath B overexpression accentuated the levels of NLRP3 inflammasome markers and p62, an autophagy adaptor protein in ROT and LPS treated cells indicative of impaired autophagic flux mechanisms. Our results indicate that low non-cytotoxic concentrations of ROT and LPS, amplifies NLRP3-dependent inflammatory response via enhanced lysosomal membrane permeabilization (LMP) and subsequent release of cath B into the cytosol by controlling the activation of the autophagy mechanism.

**Title:** Microglia priming through maternal immune stress influences brain function and behavior

**Authors: *L. N. HAYES**[1], K. AN[2], M. KIM[2], R. NARODU[3], A. J. CHANG[3], G. DOLEN[3], A. SAWA[2,3]

**Abstract:** Genomic and molecular studies suggest a role for immune dysfunction in psychiatric conditions. Furthermore, prenatal infections in mothers lead to an increased risk for psychiatric disorders in the offspring. However, the mechanisms in the pathological trajectory are unclear. We hypothesize that early immune activation permanently alters microglia (MG) function, which effects neural circuit development, immune responsiveness, and adult behavior. We can test this by using the maternal immune activation (MIA) model that delivers polyinosinic:polycytidylic acid to pregnant dams at embryonic day 9.5. In the MIA offspring, we observed several behavioral alterations relevant to psychiatric conditions, including psychostimulant hypersensitivity and dysfunctional social behaviors. We measured MG activation in response to lipopolysaccharide (LPS) *in vitro* and found that both embryonic and adult MG, especially from

the striatum, showed reduced TNFα and IL-6 suggesting a blunted MG responsiveness. Furthermore, MIA animals showed increased MG activation and survival factors at baseline as measured by CD68, IL-34, and TNFα in the striatum. We stimulated the mice with LPS *in vivo* and observed induction of IL-6 in the striatum and IL-4 in the cortex only in MIA mice. However, surprisingly, we found increased variability in the expression of major proinflammatory cytokines, TNFα and IL1β in MIA animals. The correlation of TNFα and IL-1β expressions in both cortex and striatum, only in MIA, suggests the program of transcriptional response maybe dysregulated after MIA. We now evaluate MG specific RNA sequencing results to discover other transcriptional programs that are desynchronized by the early immune stress. We evaluated the MG maturation because MG play a critical role in neural circuit development. We found an increase in MG density in the dorsal striatum at postnatal day (P)3 that was unsustained resulting in a decreased MG density and activation in the dorsal and ventral striatum by P30. We quantified the spine density of medium spiny neurons in the striatum to determine if the decreased MG density influenced spine formation, but we observed a normal spine density. Now we extend our studies to evaluate other physiosiological properties. Altogether, we argue that early maternal immune stress constitutes a priming stimulus for microglia in the offspring. These primed microglia show a disrupted developmental trajectory, immune responsiveness, and gene expression program. We are now investigating how dysfunctional microglia impact neural circuitry and whether together these are causal to the observed behavioral deficits.

Support Center, Lab. of Electron Microscopy, Col. of Medicine, The Catholic Univ. of Korea, Seoul, Korea, Republic of

**Abstract:** NG2 glia, which are characterized by expression of chondroitin sulfate proteoglycan, have been recognized as a distinct class of glial cells in the mammalian central nervous system (CNS). Recently, it has been reported that NG2 glia can be activated in response to a variety of CNS insults, and their activation is closely related to astroglial and microglial reactions. In this study, we examined the spatiotemporal distribution profiles and detailed morphological characteristics of resting and reactive NG2 glia in the striatum of rats treated with a mitochondrial toxin 3-nitropropionic acid (3-NP), which induces pan-necrosis of all cell types in the lesion core and reactive astrogliosis in the perilesional area. In the striatum of saline-treated control rats, weak NG2 immunoreactivity was restricted to small stellate-shaped cell, typical NG2 glia. However, prominent NG2 expression was also noted on vasculature-associated cells including pericytes and smooth muscle cells and activated microglia/macrophages in the lesion core after 3-NP injection. The lesion core was initially characterized by the absence of microglia and astrocytes due to cell death, but was infiltrated with activated microglia/macrophages, most of which revealed NG2 immunoreactivity, over a 7-day period post-injection. In parallel with microglial infiltration, resting NG2 glia began to change into the reactive phenotype including larger cell bodies and thicker processes. The activation and proliferation of NG2 glia were first observed at the edge of the lesion core and were gradually found within the epicenter, eventually in all areas of the lesion core at 7 days post-lesion, which was both spatially and temporally correlated with the infiltrating microglia/macrophages. Reactive NG2 glia revealed progressively more complicated processes-bearing morphology during the experimental period until 28 days, when they formed the structures surrounding the cystic cavities by linking to each other, being devoid of glial fibrillary acidic protein-positive astrocytes. Immunoelectron microscopic findings demonstrated that NG2 glia were characterized by large euchromatic nuclei with prominent nucleoli and well-developed Golgi-complex. Thus, our data provide the evidence that the activation of NG2 glia could be attributed to the possible interaction with infiltrating microglia/macrophages. In addition, the distribution pattern of reactive NG2 glia forming the complex network in the lesion core and particularly the walls of the cystic cavities suggest that NG2 glia participate in fibrotic scar formation and tissue remodeling after brain insults.

**Abstract:** We have previously shown that mice injected with a single dose of LPS (5 mg/kg; ip) displayed a progressive loss of dopaminergic neurons in the substantia nigra pars compacta (SNpc) and PD-like motor dysfunction within 10 months. Since the well-known anti-inflammatory property of norepinephrine (NE) and its important role in regulating non-motor behaviors, we hypothesized that prior damage of locus coeruleus (LC) noradrenergic neurons in this inflammatory mouse model may render neurons in upper brain regions more vulnerable to inflammation-mediated degeneration and accelerate the appearance of non-motor and motor symptoms. For this purpose, male mice received a single systemic injection of DSP-4, a selective noradrenergic neurotoxin one week before LPS dosing. We found that DSP-4 intoxication potentiated LPS-induced sequential neurodegeneration in SNpc, hippocampus, and cortex. Mechanistic study revealed that DSP-4 enhanced LPS-induced microglial activation and subsequently elevated neuronal oxidative stress in different brain regions through a sequential ascending pattern. To further demonstrate the effects of DSP-4 on non-motor and motor symptoms in LPS model, the related functional behavior tests were performed at different time points after treatment. Consistent with the enhanced neurodegeneration, DSP-4 intoxication accelerated the progressive deficits of non-motor symptoms including hyposmia, constipation, anxiety, sociability, exaggerated startle response and memory loss, and motor symptoms including decreased rotarod activity, grip strength, and gait disturbance in LPS-injected mice. In summary, our studies not only provided an excellent model that recapitulates the features of sequential neuron loss and the progression of motor/non-motor symptoms of PD, but also revealed the critical role of early LC noradrenergic neuron damage in the pathogenesis of PD.

**Title:** Brain-derived neurotrophic factor-TrkB receptor signaling negatively regulates the pro-inflammatory response of microglia to lipopolysaccharide

**Authors: *A. M. GARRISON**[1], J. M. PARROTT[2], L. REDUS[3], J. C. O'CONNOR[4]
[1]Pharmacol., Univ. of Texas Hlth. Sci. Ctr. at San Antonio, San Antonio, TX; [2]Psychiatry and Behavioral Sci., Univ. of California Davis Sch. of Med., Sacramento, CA; [3]UT Hlth. San Antonio, San Antonio, TX; [4]Pharmacol., UTHSCSA, San Antonio, TX

**Abstract:** Peripheral inflammation concurrently increases microglial pro-inflammatory cytokine expression and reduces expression of brain-derived neurotrophic factor (BDNF) in the brain. Both neuroinflammation and reduced BDNF have been implicated as contributing factors in the pathogenesis of anxiety and depression, but the interaction between these factors has not been thoroughly investigated. We have previously observed that BDNF deficient ($BDNF^{+/-}$) mice exhibit an exaggerated neuroinflammatory and depressive-like behavioral response to peripheral lipopolysaccharide (LPS), suggesting that endogenous BDNF could have an important negative regulatory role in the neuroinflammatory process. Therefore, we utilized the BV-2 mouse microglial cell line to investigate directly whether BDNF regulates the pro-inflammatory response to LPS challenge. BV-2 microglia were treated with vehicle or LPS (100 ng/ml) in the presence or absence of BDNF (0, 1, 10, 100 ng/ml). After 6h, tumor necrosis factor-α (TNFα), interleukin-1β (IL-1β), IL-10, and ionized calcium-binding adapter molecule-1 (IBA1) mRNA transcripts were increased in response to LPS along with extracellular nitrite. Interestingly, co-treatment with BDNF significantly reduced the induction of pro-inflammatory factors, while significantly increasing expression of the anti-inflammatory cytokine IL-10. To confirm whether the effect of BDNF is mediated via activation of the high affinity TrkB receptor, BV-2 cells were challenged with LPS in the presence or absence of 7,8-dihydroxyflavone (0.1, 1, 10, 100 μM). Activation of TrkB receptor using the selective agonist completely replicated the modulatory effect of BDNF at 10 and 100 μM. These data suggest that BDNF can modulate the inflammatory responses of microglia, which may be involved in conferring vulnerability/resilience to stress- or inflammation-induced psychiatric disorders.

**Title:** Microglia mediate early loss of specific synaptic connections in Huntington's disease

**Authors: *D. WILTON**[1], M. HELLER[1], A. DAGGETT[2], A. KIM[1], A. FROUIN[1], M. ESZES[3], R. L. FAULL[3], X. W. YANG[2], B. A. STEVENS[1]

**Abstract:** Synaptic dysfunction is becoming increasingly recognized as one of the earliest pathological events in many neurodegenerative diseases, including Huntington's disease (HD). Despite HD being a monogentic disease with a well characterized pathology, the molecular mechanisms underlying synaptic dysfunction remain poorly understood. In this study, we show that loss of specific synaptic connections can be observed as early as 3 months in multiple slow progressive Huntington's disease mouse models prior to the onset of motor or cognitive impairment and that microglia contribute to this via a complement-dependent mechanism. During development, synapse loss as a result of pruning is a normal and highly regulated process required for the correct wiring of the brain. Microglia together with complement proteins, a key component of the innate immune system, play a key role in regulating this process (Stevens et al, 2007; Schafer et al., 2012; Paolicelli et al., 2011). Here we provide evidence that aspects of this developmental mechanism are aberrantly reactivated in Huntington's disease mouse models leading to the loss of specific synaptic inputs. Using super resolution imaging, genetic ablation and viral-mediated labeling, we demonstrate that complement proteins selectively target cortico-striatal connections for engulfment by microglia and that this process requires mutant huntingtin expression in both striatal and cortical neurons. Moreover, blocking this process at multiple levels through both genetic and antibody mediated approaches is able to prevent synaptic pathology. Notably, we find that aspects of this mechanism may also be conserved in human disease, as post-mortem tissue from Huntington's disease patients reveals evidence of synapse loss, complement deposition at synapses and phagocytic microglia. Together these findings demonstrate that elements of the innate immune system previously only thought to be involved

in late stage inflammation mediate the loss of specific synaptic connections early in Huntington's disease pathology.

**Abstract:** Gliomas are malignant brain tumors that show complex heterogeneity at the cellular and molecular level. In addition to the neoplastic cells in a glioma, microglia form a significant portion of the tumor mass and secrete soluble factors that aid in the tumorigenesis. The Transforming Growth Factor β (TGFβ) is a pleiotropic cytokine that exerts both tumor suppressive and tumor promoting effects, depending on a cellular and gene specific context. TGFβ is known to be enriched in higher-grade glioma tumors sand glioma-associated microglia; however, the role of its signaling pathway in glioma progression is poorly understood. This study investigates the role of SMAD4, a key mediator of the TGFβ signaling pathway, found in glioma associated microglia on tumorigenesis. *In vitro* analysis showed that SMAD4 expression levels were increased in microglia upon glioma conditioned medium (GCM) treatment. On the other hand, miR-146a which is predicted to target SMAD4 was found to be downregulated in microglia upon GCM treatment. Using loss- and gain-of function studies and luciferase assay, SMAD4 was confirmed to be a direct target of miR-146a in microglia. Overexpression of miR-146a in microglia suppressed the expression of tumor supportive factors, VEGFa and MMP9 in microglia, and conversely, miR-146a inhibition, resulted in an increase in the expression of these factors. Stable knockdown of SMAD4 in microglia revealed a decrease in the expression level of MMP9 as compared to control microglia, indicating a crucial role for SMAD4 in regulating tumor supportive genes in microglia. Taken together, this study shows that miR-146a targets

SMAD4, which mediates the regulation of tumor supportive genes in glioma-associated microglia. Further studies are needed to evaluate therapeutic potential of miR-146a in suppressing microglia specific tumor supportive gene expression in gliomas.

**Title:** Nicotine increases limbic microglial expression and cocaine self-administration in the adolescent rat by a D2 receptor mechanism

**Authors: *K. LINKER**[1], M. A. WOOD[3], P. TAWADROUS[2], F. M. LESLIE[4]
[1]Anat. and Neurobio., [2]Univ. of California, Irvine, Irvine, CA; [3]Neurobiol & Behavior, Univ. of California Irvine, Irvine, CA; [4]Dept Pharmacol, UC Irvine, Irvine, CA

**Abstract:** Epidemiological studies indicate that the vast majority of smokers begin tobacco use during adolescence, and rodent studies demonstrate that adolescent nicotine exposure has unique effects on brain and behavior. It is well established that adolescent nicotine exposure increases subsequent cocaine-associated behaviors. Specifically, our lab has demonstrated that brief (4-day), low dose (60μg/kg/day) nicotine pretreatment during early adolescence, but not adulthood, increases subsequent cocaine-self administration in rats. This nicotine pretreatment also induces age-specific changes in D2 receptor sensitivity. To assess if D2 receptors are necessary for the nicotine-induced increase in cocaine reinforcement, the D2 antagonist, raclopride (.5mg/kg/day), was administered during nicotine pretreatment. We have shown that this D2 receptor antagonism blocks adolescent nicotine-induced increases in cocaine self-administration. This finding aligns with literature demonstrating that adolescent nicotine exposure uniquely alters dopaminergic and limbic function. While multiple studies have elucidated age-specific changes in neurons after nicotine exposure, few have looked at microglia. However, microglia are in constant communication with neurons, are important during brain development and express D2 receptors. Whereas many drugs of abuse activate microglia, we have confirmed that nicotine suppresses microglia in the adult brain. We now show, however, that brief low dose early adolescent nicotine exposure increases microglia marker (IBA1) expression and microglia cell number. These increases in microglia are specific to the nucleus accumbens (NAc) and basolateral amygdala (BLA), two regions that are associated with reward and are actively maturing during

adolescence. Both these regions also have dopamine innervation and express D2 receptors. In alignment with our behavioral data, administering the D2 antagonist, raclopride, during the nicotine pretreatment blocks increased microglial expression in the NAc and BLA. Together, these studies demonstrate that D2 receptors are necessary for nicotine-induced increases in microglia and cocaine self-administration in early adolescent rats.

**Title:** Acetaminophen rescues microglial defects and cognitive impairment in the DP16 murine model of Down syndrome

**Authors: *B. PINTO**[1,2], A. PETRETTO[3], M. BARTOLUCCI[3], L. PERLINI[1], L. CANCEDDA[1]
[1]NBT, Inst. Italiano Di Tecnologia, Genova, Italy; [2]Neurosci., Scuola Normale Superiore, Pisa, Italy; [3]Lab. of Mass Spectrometry, Core Facility, Inst. Giannina Gaslini, Genova, Italy

**Abstract:** Down syndrome (DS) is caused by the presence of a supernumerary chromosome 21 (Chr21), and it represents the most frequent cause of genetic intellectual disability. Interestingly, some of the genes located on Chr21 are essential for the correct function of the immune system, and DS individuals often suffer from immunological disorders. Microglia are the main immune cells of the brain and play important roles in its development and mechanisms essential for cognitive functions. However, it is not known whether microglial defects are involved in the cognitive deficits associated with DS. Here, we investigated the presence of microglial alterations and their possible implication in cognitive impairment in the DP16 murine model of DS. At postnatal day (P22), we found microglial morphological defects both in the hippocampus and somatosensory cortex of DP16 mice. The trisomic microglia showed enlarged cell body and decreased ramifications, morphological alterations typically associated with increased microglial phagocytic activity. Interestingly, administration of acetaminophen, a commonly used non-steroidal anti-inflammatory drug, restored the cell-body size to the WT level, with no significant effect on ramifications. Remarkably, this treatment had a paradoxical effect on WT microglia: it caused an enlargement of the cell body and a significant decrease of the ramification. The morphological alterations of microglia correlated with cognitive performance of the mice in the novel object recognition test: DP16 mice showed cognitive impairment, and the acetaminophen treatment improved their cognitive performance to untreated WT littermate levels; WT mice showed cognitive impairment upon acetaminophen treatment. JAK1/2 are important signaling kinases downstream to many pro-inflammatory cytokines including Inferon Gamma (IFNγ),

which is dysregulated in DS and strongly expressed in microglia. Remarkably, the administration of Ruxolitinib (a JAK1/2 inhibitor) recovered microglial morphology in the DP16 mice, without causing a cognitive impairment in the WT littermates. Altogether, our data suggest a possible involvement of microglia in the cognitive defects observed in adult DS animals. Thus, microglia may be a potential target for interventional therapies for the treatment of cognitive impairment in DS individuals and acetaminophen, a widely used, safe and over-the-counter drug, could be a potential treatment for cognitive defects in DS.

**Title:** Microglia isolated from offspring of dams with allergic asthma exhibit methylation and transcriptional alterations to genes dysregulated in autism

**Authors: *A. VOGEL CIERNIA**, M. CAREAGA, J. LASALLE, P. ASHWOOD
Univ. of California Davis, Davis, CA

**Abstract:** Dysregulation in immune responses during pregnancy increase the risk of a having a child with an autism spectrum disorder (ASD). Asthma is one of the most common chronic diseases among pregnant women, and symptoms often worsen during pregnancy. We recently developed a mouse model of maternal allergic asthma (MAA) that induces alterations in behavioral outcomes of the offspring including changes in sociability, repetitive and perseverative behaviors. Since epigenetic changes help a static genome adapt to the maternal

environment, activation of the immune system may epigenetically alter fetal microglia, which are the brain's resident immune cells. We therefore sought to test the hypothesis that transcriptional and DNA methylation alterations to microglia may be involved in the long-lived behavioral alterations in offspring exposed to gestational MAA. Here we used the genome-wide approaches of whole genome bisulfite sequencing to examine DNA methylation combined with RNA sequencing to examine gene expression in microglia from juvenile MAA offspring. Differential expression analysis revealed significant alterations in the epigenome of microglia from MAA compared to PBS treated control offspring and identified genes involved in controlling microglial sensitivity to the environment and shaping both synaptic and long-range neuronal connections in the developing brain. Differentially methylated regions (DMRs) in MAA microglia were enriched for immune signaling pathways and important microglial developmental transcription factor binding motifs. Differentially expressed and DMR associated genes significantly overlapped genes with altered expression in human ASD cortex, supporting a role for microglia in the pathogenesis of ASD.

**Abstract:** ITI-214 is a a potent and specific inhibitor of PDE1 that has important beneficial effects in mice, rats, and dogs (Li, et al., 2016, J. Med. Chem. 59:1149; Snyder et al., 2016, Psychopharm. 233:3113). In humans, this compound has been well-tolerated across a broad range of doses in multiple Phase I studies. It is currently in development for the treatment of

CNS and non-CNS diseases. Enzymes of the PDE1 family hydrolyze both cAMP and cGMP and are activated by calcium. PDE1 is expressed in microglia, and isofoms of PDE1 may be involved in the regulation of inflammatory responses by modulating microglial intracellular cyclic nucleotide pools. Inhibition of PDE1 activity in microglia, therefore, may provide a promising avenue for therapeutic intervention in CNS disorders in which inflammation is a prominent feature. Increasing intracellular cGMP by either stimulating production or inhibiting hydrolysis has been shown to attenuate lipopolysaccharide (LPS)-induced responses in microglia (Baltrons et al., 2008, Neurochem Res 33:2427; Pifarre et al., 2010, J Neurochem 112:807; Zhao et al, 2011, Intl Immunopharm 11:468). Additionally, cGMP has been shown to play a role in LPS-induced motility of microglia (Scheiblich et al., 2014, Brain Res 1564:9). Cyclic adenosine monophosphate (cAMP) is also a key regulator of inflammatory responses. We tested the effects of ITI-214 in LPS-stimulated immortalized murine microglial cells, BV2 cells, by measuring changes in cytokine release using ELISA and in gene expression using RT-qPCR. PDE1 inhibition with ITI-214 prevented LPS-induced increases in TNFalpha release from BV2 cells. Similarly, LPS-induced increases in TNFalpha, IL-1beta, and Ccl2 mRNA expression were reduced by greater than 50 percent both in BV2 cells and in mice (p is less than 0.01) upon PDE1 inhibition. Transcriptome analysis has shown that ITI-214 triggers changes in a unique, signature pattern of genes under LPS-induced and basal conditions in BV2 cells. Our data support the importance of ITI-214 in regulating microglial responses and its use in treating neuroinflammation associated with neurodegenerative and neuropsychiatric disease.

**Abstract:** Emerging evidence demonstrates a close link between neuroinflammation and drug addiction. The CX3CL1/CX3CR1 axis plays critical roles in both neuron- microglia communication and in maintaining microglial quiescence. Previous studies have reported increased inflammatory responses, as well as increased LPS-mediated neurotoxicity in the CX3CR1-GFP mice (CX3CR1 deficiency). The detailed signaling mechanism(s) underlying such exaggerated immune responses and what if any, effect CX3CR1 deficiency has on other CNS cells types such as the astrocytes and neurons, however, remains unexplored. In the current study, we demonstrate increased basal glial (microglia and astrocytes) activation in CX3CR1-GFP mice compared to the wild type controls. CX3CR1-GFP mice exhibited increased expression of the inflammasome marker NLRP3 in microglia, astrocytes and neurons. Intriguingly, in response to phsychotimulant such as cocaine, there was an even more increased inflammatory response. These findings were complemented with behavioral assays, wherein the CX3CR1-GFP mice showed increased cocaine-mediated locomotor activity and condition place preference compared with the controls. Taken together our findings suggest a link between the NLRP3 inflammasome signaling, neuroinflammation the development of drug addiction in the context of CX3CR1 deficiency. Modulation of the NLRP3 pathway could thus be targeted and developed as an alternative approach for the treatment of drug addiction.

**Abstract:** Carbenoxolone (CBX) is a glycyrrhetinic acid derivative that is well known to inhibit endogenous glucocorticoids by potently inhibiting 11b-hydroxysteroid dehydrogenase, and it is also known in cellular physiology as an effective and water-soluble gap junction blocker. There are many reports of the neural modulating effects of CBX. However, given the drug's multiple sites of action, it has been difficult to pinpoint the exact mechanism of action. Here we found that CBX reduced intracellular glutamate levels, indicating it may directly affect glutamate metabolism, and more specifically on glutaminolysis, a metabolic process that converts glutamine to glutamate. Glutaminase is the mitochondrial enzyme that catalyzes the first step of glutaminolysis. Two genes encode at least four isoforms of glutaminase in humans. GLS1 gene encodes isoforms kidney-type glutaminase (KGA) and glutaminase C (GAC) through alternative splicing, whereas GLS2 gene encodes liver-type glutaminase isoforms. Using our established glutaminase activity assay based on rat brain mitochondrial lysates, we demonstrated that CBX inhibited glutaminase activity in a dose dependent manner. To eliminate any irrelevant components of the enzyme reaction, we generated recombinant KGA and GAC proteins and CBX inhibited glutaminase activity in these proteins in a dose dependent manner. Pharmacological analyses of CBX-mediated inhibition of glutaminase suggest it is more potent and efficient than the commercially available 6-diazo-5-oxo-L-norleucine. Based on two recently published models of the structure basis for GLS1 inhibition, we applied the Glide docking of CBX to the GLS1 and identified that CBX binds to the interface of a tetramer of the GLS1. After confirming that CBX is an effective glutaminase inhibitor, we applied it to a macrophage-tropic HIV-1 infected primary microglia culture system that is known to have excess glutamate production and neurotoxicity. As expected, CBX potently reduced intracellular and extracellular glutamate levels and completely abolished neurotoxicity in HIV-1-infected microglia. While CBX is known as a hemichannel blocker that blocks glutamate release, we found that hemichannel blocking only modestly reduced glutamate levels, suggesting that CBX blocked the neurotoxicity of HIV-1-infected microglia through inhibition of glutaminase. This novel mechanism of action for CBX via the inhibition of mitochondrial glutaminase will have broad implications for neuroscience studies that apply CBX.

**Title:** Microglial activation of the nuclear GAPDH cascade mediates cognitive inflexibility in an inflammatory mouse model

**Authors: *A. RAMOS**[1], F. E. DOMINGUEZ[2], N. J. ELKINS[3], K. MAULDING[4], K. ISHIZUKA[5], A. SAWA[6]
[1]Psychiatry and Behavioral Sci., Johns Hopkins Univ. Sch. of Med., Baltimore, MD; [2]Johns Hokins Sch. of Med., Baltimore, MD; [3]Psychiatry, Johns Hopkins Univ. Dept. of Psychiatry and Behavioral Sci., Baltimore, MD; [4]Johns Hokins Univ. Sch. of Med., Baltimore, MD; [5]Dept Psychiatry, [6]Dept. of Psychiatry, Johns Hopkins Univ., Baltimore, MD

**Abstract:** Behavioral flexibility is one of the most important behavioral constructs that is required for adaptability. This behavior is affected under stress conditions, and its disturbance is involved in many neuropsychiatric disorders, in particular schizophrenia. Nonetheless, molecular and cellular mediators for this behavior are unclear. Also, it has been proposed that neuroinflammation and excess oxidative stress may play a role in the pathology of neuropsychiatric disorders. Therefore we wanted to study how these stressors can mediate deficits in behavioral flexibility. For that, we have specifically focused on the nuclear GAPDH (Glyceraldehyde-3-phospate Dehydrogenase) cascade since GAPDH can act as a sensor of oxidative stress: our group has reported that under stress condition, a small fraction of GAPDH is posttranslationally modified and translocated to the nuclei to mediate stress signaling (which we call the “nuclear GAPDH cascade”).
In this study, we used LPS (Lipopolysaccharide)-treated mice. We found these mice displayed behavioral inflexibility in a paradigm using rule shifting. Interestingly, the behavioral deficits were ameliorated by a compound, (1R,3R)-1,3-dymethyl-2-propargyl-1,2,3,4tetrahidrosiquinoline (called RR) that is a blocker of the nuclear GAPDH cascade (Hara *et al*. Nat Cell Biol. 2005). Therefore, we next validated whether the nuclear GAPDH cascade was indeed activated in the LPS-treated mice. We found that this cascade was selectively activated in microglia in the cortex, but not in the striatum. This region specificity is consistent with preclinical and clinical findings that the prefrontal cortex is involved in controlling behavioral flexibility. To understand how the activation of nuclear GAPDH cascade in microglia leads to neural circuitry dysfunction, we conducted molecular profiling of *in vivo* microglia by CHIP-Seq and RNA-Seq. Finally, we have introduced the conditional K225A-GAPDH$^{f/f}$ mouse model in

which lysine (K) 225 of GAPDH is replaced by alanine (A), preventing GAPDH from nuclear translocation. Using this model we genetically target microglia and corroborate the activation of the nuclear GAPDH cascade in these cells is sufficient to cause behavioral inflexibility. Taken together, we now propose that the transcriptional regulation mediated by nuclear GAPDH cascade in cortical microglia is a key molecular and cellular mediator for behavioral flexibility. Note, the potential utility of the nuclear GAPDH cascade as a clinically-available high throughput biomarker for cognitive deficits in major mental disorders is demonstrated by Dominguez *et al* in this meeting.

**Authors: *A. A. ADAMS**[1], B. J. PFISTER[2], H. A. KIM[1]
[1]Rutgers Univ., Newark, NJ; [2]Dept Biomed Engin., New Jersey Inst. Technol., Newark, NJ

**Abstract:** Traumatic brain injury (TBI) is one of the leading causes of hospitalization and death in the United States. The effects of TBI on myelin structures in the brain have not been characterized until fairly recently, given the assumption that myelin loss occurs as a secondary effect after axonal degeneration. Recent animal studies indicate that mild TBI (mTBI) induces primary demyelination. Importantly, myelin loss in the brain has been shown to leave previously myelinated axons more vulnerable to degeneration after a second mild injury. Appropriate axo-glial signaling is essential for the maintenance of myelin homeostasis. Axons are known to release aberrant levels of glutamate following injury induced increases in excitatory neurotransmission. Our recent study demonstrates that neurons distal to the site of injury remain hyperexcitable for up to one hour after *in vitro* injury. Previous studies have suggested that NMDAR mediated calcium entry in oligodendrocytes (OL) may play a role in myelin damage after CNS injury. We hypothesize that glutamate release from hyperexcited axons activates glutamate mediated calcium dependent signaling in OLs that disrupts myelin homeostasis. Using an *in vitro* stretch-injury device combined with a neuron-OL co-culture system, we show that injury to neurons results in intracellular calcium increases in non-injured neighboring OLs, suggesting the occurrence of an injury induced neuron to OL signaling event. Further, NMDA

treatment in mature OL monoculture induces downregulation of myelin basic protein expression in the absence of cell death. The effect of NMDA was attenuated upon inhibition of the ERK pathway. I*n vivo*, we show that mild fluid percussion type injury in rodents increases ERK activity in CC1+ cells within white matter tracts. Our findings suggest that neuronal hyperexcitability and aberrant glutamate release may initiate calcium mediated ERK activation in the OL that results in loss of myelin.

**Abstract:** Oligodendrocyte precursor cells (OPCs) act as a reservoir of new oligodendrocytes (OLs) in homeostatic and pathological conditions. OPCs are activated in response to traumatic neural injury such as spinal cord injury (SCI), to generate myelinating OLs. This OPC activation is the first step in the process of remyelination, and proper control of OPC activation is important for tissue repair following SCI. However, the molecular mechanisms underlying OPC activation, especially its epigenetic regulation, remain mostly unknown. Here we demonstrate that Chromodomain helicase DNA binding protein 7 (Chd7), which is a member of the Chd family of chromatin remodelers, regulates the proliferation and identity maintenance of OPCs following SCI. Chd7 was expressed in OPCs in the intact adult spinal cord, and its expression level was upregulated with a concomitant increase in Sox2 expression at 3 days post injury (dpi) in a mouse model of SCI. OPC-specific deletion of *Chd7* (*PDGFRα-CreER*;*Chd7*$^{flox/flox}$;*CAG-CAT-EGFP* mice, *Chd7* cKO) in the injured spinal cord lead to reduced OPC proliferation and the loss of OPC identity, but did not affect the survival of OPCs at 3 dpi. Furthermore, *Chd7* cKO attenuated OPC differentiation and remyelination at 42 dpi. Behavioral assessment using the Basso Mouse Scale showed that *Chd7* cKO mice performed significantly worse than control mice at 28, 35, and 42 dpi. Knockdown of Chd7 or Sox2 in cultured OPCs showed similar phenotypes to those observed in *Chd7* cKO mice. Co-immunoprecipitation experiments revealed that Chd7 and Sox2 formed a complex in cultured OPCs. We performed microarray analysis of OPCs following Chd7 knockdown and found that regulator of cell cycle (Rgcc) and protein

kinase Cθ (PKCθ) are novel target genes of Chd7 for OPC activation. Knockdown of Sox2 also reduced the expression of Rgcc and PKCθ. Chromatin immunoprecipitation analysis showed that Chd7 and Sox2 bound to the regulatory regions of Rgcc and PKCθ genes to induce their expression. Knockdown of either Rgcc or PKCθ decreased OPC proliferation and identity maintenance. Conversely, overexpression of Rgcc or PKCθ promoted OPC proliferation. Furthermore, the Chd7 knockdown phenotypes were fully restored by overexpression of both Rgcc and PKCθ. In conclusion, Chd7 is a key regulator of OPC activation, in which it cooperates with Sox2, and acts through direct induction of Rgcc and PKCθ expression after SCI.

**Abstract:** Oligodendrocyte (OL) progenitor cells (OPCs) are widely distributed throughout the brain, both in gray and white matter. Whereas BrdU labeling studies have revealed that the cell cycle time of OPCs increased from early postnatal to adult, the production of mature OLs decreases steadily during adulthood, suggesting that adult OPCs might play a more important role in the maintenance of as-yet-unknown physical conditions than in the production of mature OLs. The lack of technique to purify and culture OPCs from adult brain is one major disadvantage of studying of their functions. We have recently established a novel method to isolate and culture OPCs from adult rat brains. In the present study, we report a progress of our OPC culture system in more detail with a finding of a novel OPC subtype. To isolate OPCs from other CSF cells, we used a step gradient composed of the 4 different buoyant densities with Optiprep™. After centrifugation, a major thick layer was apparently formed on the top of the layers containing microglia and neuronal stem cells. After this thick layer was put on the culture dishes more than for 30min, the supernatants including non-adherent cells and the debris were removed. After these purification procedures, adherent cells on the culture dishes were our

culture OPCs from adult rat brains (aOPCs-culture). aOPCs-culture effectively continued to proliferate in response to basic fibroblast growth factor (FGF2) instead of platelet-derived growth factor (PDGF). FGF2 withdrawal from aOPCs-culture increased the proportion of plexin-B3-expressing cells. Immunohistochemical studies revealed that plexin-B3 is expressed in olig2$^{+}$ aOPC-like glia cells distributed throughout the adult rat brain (plexin-B3$^{+}$ aOPCs). They could be clearly distinguished from neurons, astrocytes, microglia, OLs and strongly NG-expressing OPCs. Furthermore, cortical spreading depression (CSD), a self-propagating wave of cellular depolarization that has been implicated as a fundamental common mechanism of progressive cortical injury seen in stroke and head trauma, significantly increased densities of plexin-B3$^{+}$ aOPCs in the remote ipsilateral in compared with contralateral cortex. These data suggest that brain injuries induce unique delayed cortical oligodendro(gliosis) of plexin-B3$^{+}$ aOPCs. Taken together, our data is highly suggestive that aOPC-culture is a novel system for investigating the physiological mechanisms of OPCs in the adult brain.

**Title:** RyR3-mediated ER calcium release is dynamically regulated and crucial for oligodendroglial differentiation RyR3-mediated ER calcium release is dynamically regulated and crucial for oligodendroglial differentiation

**Authors: *L. XIAO**, T. LI
Dept. of Histology and Embryology, Third Military Med. Univ., Chongqing, China

**Abstract:** It has been known that dynamical intercellular calcium ($Ca^{2+}$) increase in oligodendrocyte progenitor cells (OPCs) is important to initiate differentiation,while the intracellular calcium-release channel involved in this process remains unclear. As one of the intracellular calcium channels which mediate ER calcium-release, the role of Ryanodine receptors (RyRs) in oligodendroglial development is understudied. In this study, we demonstrated that: (1) Among RyRs, RyR3 is specifically expressed in oligodendroglial lineage cells but down-regulated following OPC differentiation. The strong RyR3 positive reactions were distributed all over the cytoplasm and processes in OPCs and/or immature oligodendrocytes (imOLs), while it gradually decreased and located around the perinuclear region in mature OLs. (2) RyR3 mediated intercellular $Ca^{2+}$ waves following caffeine stimulation were correlated with their expression pattern, in which high flat $Ca^{2+}$ fluctuations and spontaneous oscillatory $Ca^{2+}$

waves were more frequently recorded in OPCs and/or imOLs. (3) RyR antagonist ryanodine pretreatment can neutralize the increase of intracellular $Ca^{2+}$ induced by OPC differentiation, and reduced the number of mature OLs. Finally (4) Knockdown RyR3 in OPCs resulted in inhibition of OPC differentiation. Taking together, our results indicated that RyR3-mediated ER $Ca^{2+}$ release is dynamically regulated and crucial for oligodendroglial differentiation.

Organization of Sci. and Technol., Ritsumeikan Univ., Kusatsu, Shiga, Japan; [5]Dept. of Anat. and Cell Biol., Temple Univ. Sch. of Med., Philadelphia, PA

**Abstract:** Oligodendrocytes (OLs) form myelin sheaths that are critical for rapid axonal conduction and metabolic support of axons in the CNS. These cells are highly vulnerable to injury, and OL loss and hypomyelination are frequently observed in numerous brain injuries. Earlier studies have suggested that NMDA receptor (NMDAR) or AMPA receptor (AMPAR)-mediated glutamate excitotoxicity is the major mechanism leading to OL damage in response to CNS insults, such as hypoxic ischemia (H/I). However, supporting *in vivo* evidence has been limited to outcomes of systemic administrations of NMDAR or AMPAR-targeted reagents, which are not cell-specific and likely impact neurons and other glia, including oligodendrocyte progenitor cells (OPCs) that express glutamate receptors and form synapses with neurons. To define the impact of glutamate receptor-dependent $Ca^{2+}$ signaling within oligodendroglia, we employed cell-specific, *in vivo* genetic approaches to selectively block NMDAR- (by deleting *Grin1,* an essential NMDAR subunit) or AMPAR-mediated $Ca^{2+}$ influx (by

overexpressing EGFP-fused *Gria2*, a $Ca^{2+}$-impermeable AMPAR subunit) into OL lineage cells in a mouse model of neonatal H/I brain injury. Removal of *Grin1* from OPCs or all oligodendroglia did not significantly change OL development, in accordance with previous results, or attenuate OL loss in response to the H/I injury. Although abolishment of AMPAR $Ca^{2+}$ signaling also did not affect the rate of normal OL development or OL loss following H/I injury, this manipulation accelerated OL lineage transition in the injured brain, promoting the formation of new OLs. These results suggest that neither NMDAR- nor AMPAR-mediated $Ca^{2+}$ influx is a major cytotoxic contributor to H/I-induced OL loss, but that AMPAR-mediated $Ca^{2+}$ signaling in OPCs or immature OLs inhibits post-injury regeneration of myelin.

**Abstract:** Myelination is a complex biological process and the extracellular factors responsible for inducing myelination in the central nervous system (CNS) remain incompletely understood. We have previously identified brain-derived neurotrophic factor (BDNF) as a key player in promoting CNS myelination during development, as BDNF heterozygous mice exhibit a severe hypomyelinating phenotype during early postnatal weeks. However, it remains controversial whether BDNF exerts an influence upon oligodendroglial cell numbers and lineage progression during CNS development *in vivo.*
To investigate this, BDNF heterozygous (HET) and BDNF wild type (WT) littermate control mice were sacrificed at P6, P9, P15 and P30. Both white and grey matter of the brain and lumbar spinal cord were immunohistochemically analysed for total density of oligodendroglial (Olig2+) cells. Further analysis of oligodendroglial development identified sub-populations of these cells at early and late stages of lineage progression; immature oligodendrocyte precursor cells (PDGFRa+) and mature oligodendrocytes (CC1+).

We found significantly fewer oligodendroglial lineage cells (Olig2+) in the dorsal white matter tracts and grey matter of the spinal cord of HET mice compared to WT controls. Whilst overall there were lower numbers of both immature and mature oligodendroglial sub-populations, proportions of these cells relative to the total oligodendroglial density remained not significantly different, indicating BDNF is likely influencing oligodendroglial proliferation and/or survival, but not differentiation and lineage progression during CNS development *in vivo*.
Interestingly, we found a significantly higher proportion of mature oligodendrocytes in both spinal cord and cortical grey matter of HET mice compared to WT controls at P6, indicating BDNF may temporally influence oligodendroglial differentiation during early postnatal development.
Together, this study reveals an important role of BDNF signalling in regulating oligodendroglial populations in different CNS regions during early postnatal development, providing a new insight into understanding the cellular and molecular signalling pathways that govern CNS myelination.

**Title:** Motor neuron sonic hedgehog specifies the first wave of oligodendrogenesis in the vertebrate spinal cord

**Authors: *L. STARIKOV**[1,2,3], A. SAJAN[1], A. H. KOTTMANN[1,2,3]
[1]Ctr. for Discovery and Innovation, CUNY City Col., New York, NY; [2]Molecular, Cellular, and Developmental Biol., CUNY The Grad. Ctr., New York, NY; [3]Molecular, Cellular, and Biomed. Sci., CUNY Sch. of Med., New York, NY

**Abstract:** Oligodendrocytes are a heterogeneous group of myelin forming cells which ensheath axons to increase electrical conductance of action potentials and provide trophic support to neurons. In the spinal cord, oligodendrocytes are produced from two domains that are spatially and temporally distinct and give rise to oligodendrocyte populations that react differently to injury. The first born lineage produces ventral oligodendrocyte precursors (vOPs) from the Olig2 precursor domain in the ventricular zone. This lineage provides 80% of all mature oligodendrocytes, and is developmentally dependent on the signaling protein Sonic hedgehog (Shh). A second group of oligodendrocyte precursors, dOPs, arises two days later from the dorsally located Msx3 domain in a Shh independent manner. The mechanisms of cell lineage

specification in these two precursor domains and whether oligodendrocytes derived from them can functionally compensate for each other is not fully investigated. It is widely assumed that the relevant source of the Shh signal needed for specification of vOPs emanates from the midline, i.e. notochord and floorplate. However, due to the lack of selectivity of currently available Cre expression alleles, extra midline sources of Shh cannot be excluded. Curiously, post mitotic motor neurons (MNs) begin to express Shh when they settle in their lateral positions in the spinal cord, coinciding with a switch from MN to vOP production by the ventricular Olig2 precursor domain. By analyzing an allelic series of selective ablation of Shh expression by Olig2cre in MNs, we observe a Shh gene dose-dependent reduction in the specification and migration of vOPs from the Olig2 precursor domain without alteration in the qualitative or quantitative outcome of neurogenesis from either more ventral or more dorsal located precursor domains of the ventricular zone. The ablation of Shh from MNs mediated by ChATcre, which is expressed around the same time as Shh in MNs has no effect on vOP production. Together our results define a narrow temporal window during which Shh expression specifically from nascent MNs is essential for the production of vOPs. Our data attributes a so far unappreciated morphogenic signaling function to MNs and points to a neuronal based mechanism by which morphogenic activity can impact select precursor domains once the advanced size of the germinal niche prohibits the formation of instructive gradients.

**Abstract:** Traumatic brain injury (TBI) is caused by mechanical force to the brain, and it is associated with the disability of cognition or neuronal behavior. It has been shown that oligodendrocyte (OL) pathology following TBI that is associated with demyelination and OL

death. Since myelin is crucial for neuronal function and survival, loss of myelin is likely to impair axonal integrity, resulting in axonal degeneration. Balances in cellular signaling pathways are important for maintenance of myelin homeostasis. Disruption of calcium homeostasis or activation of MAPK following stretch injury has been shown in previous research in neurons and glial cells, leading to cell death. While axon pathology associated with TBI has been actively studied, the molecular mechanisms how myelin and OL respond to stretch injury are not fully understood.
In this study, we tested whether TBI induces changes in calcium homeostasis and Erk1/2 MAPK activity in mature OLs that may contribute to TBI-induced myelin damage. TBI-induced Erk1/2 activation and loss of myelin basic protein (MBP) were observed in mature OL within white matter tracts, such as the corpus callosum and external capsules, of the brain. To elucidate OL autonomous response to TBI, we have developed OL monocultures on deformable silicone membranes, which are later rapidly stretched to induce a mechanical stretch injury to OLs *in vitro*. The stretch injury induced efflux of calcium in mature OLs. Also, stretch injury-induced Erk1/2 activation and MBP loss were detected in mature OLs without cell death, and inhibition of Erk1/2 activation restored the MBP loss following injury. In addition, increasing intracellular calcium with a calcium ionophore was sufficient to activate Erk1/2 that results in MBP loss, while chelating intracellular calcium during the injury reduced Erk1/2 activation following injury. Altogether, we found a molecular mechanism of OL pathology that is associated with TBI: the stretch injury induces calcium-dependent Erk1/2 activation in mature OL, resulting in MBP loss.

**Abstract:** Myelination by oligodendrocytes is essential for the rapid propagation of action potential and the maintenance of axons in the central nervous system (CNS). Cell-cell interactions between oligodendrocytes and neuronal axons or other glia cells play a role in the myelin formation. Therefore, defects in the cell-cell adhesions impair oligodendrocyte differentiation/maturation and myelination, which results in neuological disorders, such as tremors. Previously, we reported that Teneurin-4 (Ten-4), a type II tramsmembrane protein, is required for oligodendrocyte differentiation and myelination of small diameter axons in the CNS and Ten-4-deficient mice develop tremors. However, cellular and molecular functions of Ten-4 in oligodendrocytes and myelination have not been fully elucidated yet. In this study, we first found that the defects in Ten-4-deficient mice appear at the early postnatal stage, when oligodendrocyte precursor cells (OPCs) attach axons and start to differentiate into oligodendrocytes. We then investigated whether Ten-4 possesses cell adhesion activity and found that Ten-4-overexpressing cells formed larger cell aggregations, compared with control cells. Furthermore, the recombinant extracellular domain of Ten-4 (rTen-4ECD) exerted OPC attachment activity. Oligodendrocytes formed lamellar-type morphology on the rTen-4ECD-coated culture slides and myelin-like structure surrounding the rTen-4ECD-coated nanofibers. In addition, we screened Ten-4 binding proteins and found that they formed a molecular complex with a couple of intracellular proteins that contain SH3 domains and are critically involved in cell-cell adhesion and cytoskeletal organization. These results revealed that Ten-4 is a key regulator of cell adhesion and cytoskeletal organization in oligodendrocytes for CNS myelination.

**Title:** Expression of Rictor in oligodendrocyte precursor cells is required for proper maturation and myelination

**Authors: *H. A. HATHAWAY**, W. B. MACKLIN
Cell and Developmental Biol., Univ. of Colorado Anschutz Med. Campus, Aurora, CO

**Abstract:** Mammalian target of rapamycin (mTOR) is a protein kinase that regulates a variety of cellular processes, from protein translation to cytoskeletal organization. One such process is the

differentiation of oligodendrocyte precursor cells (OPCs) into mature, myelinating oligodendrocytes. The substrate specificity of mTOR is determined through the formation of complexes with adaptor proteins. Many studies have investigated the role of Raptor-containing mTOR complex 1 (mTORC1) in oligodendrocyte development, and suggest that mTORC1 plays a role in myelination within the CNS. However, few studies support a similar role for Rictor-containing mTORC2. Here, we present the first report of Rictor playing an important role in CNS myelination. Rictor was deleted specifically from platelet-derived growth factor receptor α (PDGFRα)-expressing OPCs. These Rictor knockout mice exhibited a decrease in myelinated axons, reduced expression of myelin proteins, and fewer mature oligodendrocytes relative to wildtype littermates. Additionally, Rictor knockout mice had reduced expression of proteins involved in cytoskeletal regulation. Together, these data suggest that Rictor is required for proper oligodendrocyte maturation and myelination and that this pathway may involve cytoskeletal reorganization. These studies supported by NIH NS080223.

**Abstract:** Glial cells of the central nervous system (CNS) express a number of different connexins. These connexins are integral membrane proteins that form gap junction channels and provide a low resistance pathway for the diffusion of small molecules and ions between coupled cells. Diseases like X-linked Charcot-Marie-Tooth disease (CMT1X) and Pelizaeus-Merzbacher-Like disease 1 (PMLD1), caused by mutations in connexin 32 (Cx32), and connexin 47 (Cx47) respectively, provide evidence that oligodendrocytes rely on connexins to effectively function in the CNS. Recent data suggests that connexins may also have a role in the regulation of cell growth and resistance to apoptotic and necrotic cell death. In this experiment, we investigated the effect disrupting Cx32 and Cx47 has on the oligodendrocytes' overall capacity for proliferation and survival. Utilizing immunolabeling we examined cell proliferation, and apoptotic cell death in the different cell populations from the mixed glial cultures of Cx32KO, Cx47KO, T55I mice

when compared to wild-type controls. Total $O4^+$and $GFAP^+$ cell counts were performed. The results continue to support and highlight the critical role connexins play in oligodendrocyte and CNS myelin, and implicates further investigation into therapeutic targets.

**Abstract:** Multiple sclerosis (MS) is a neurologic disease characterized by widespread demyelination with subsequent degeneration of axons. Remyelination of these axons has been widely proposed as a key therapeutic target to reverse clinical disability associated with disease progression. However, there is a large unmet need for FDA-approved remyelinating therapeutics for patients with MS. Utilizing a high-throughput screening platform, we identified a cluster of small molecules that enhance oligodendrocyte precursor cell (OPC) differentiation: Selective Estrogen Receptor Modulators (SERMs). While several SERMs have previously been implicated, most are not well-tolerated in patients. However, we have identified one attractive candidate FDA-approved SERM that has previously proven very tolerable in clinical trials for menopausal symptoms: Bazedoxifene (BZA). Using mouse as well as human OPCs *in vitro*, we

validated BZA's potent, cell-autonomous effects on OPC differentiation and myelination. When tested in an *in vivo* focal demyelination model, BZA showed significantly enhanced and accelerated remyelination. Lastly, we sought to validate BZA's mechanism of action through Estrogen Receptor using OPCs isolated from total ERα, ERβ and double ER knockout animals. Instead, our results indicate that BZA elicits its robust OPC differentiation and remyelination results in an ER-independent manner, in contrast to previous reports for other SERMs. Further bioinformatics profiling has led to the implication of several attractive target candidates for a variety of FDA-approved SERMs that present exciting opportunities for future drug development of remyelinating therapeutics. Our results implicate bazedoxifene as a potent regulator of remyelination that could be available at an accelerated timeline to patients, and its off-target effect has indicated a previously unknown mechanism of action through a novel receptor hit by a plethora of SERMs.

**Title:** Gli1 fate-labeling during postnatal development identifies sonic hedgehog (Shh) responsive cells that give rise to oligodendrocyte lineage cells during myelination and in adulthood contribute to remyelination

**Authors: *M. A. SANCHEZ**, R. C. ARMSTRONG
Anat. Physiol. and Genet., Uniformed Services Univ. of the Hlth. Scienc, Bethesda, MD

**Abstract:** The forebrain oligodendrocyte population undergoes dramatic amplification to accomplish extensive myelination during postnatal development. This increased generation of oligodendrocytes correlates with sonic hedgehog (Shh) signaling in the dorsal subventricular zone (SVZ) beneath the corpus callosum (CC) (CK Tong et al., 2015, Stem Cell Reports). We examined Shh signaling relative to this wave of forebrain oligodendrogenesis to determine whether postnatal Shh-responsive cells contribute to myelination in development and to remyelination in adults. Transgenic mouse lines were generated for induced genetic fate-labeling of cells actively transcribing *Shh* or *Gli1*. *Gli1* transcription is an effective readout for canonical Shh signaling. $Shh^{CreERT2}$ mice and $Gli1^{CreERT2}$ mice were each crossed to reporter lines, either $R26^{tdTomato}$ mice to label cells with red fluorescence, or, $R26^{IAP}$ mice to label cell membranes with

alkaline phosphatase. When tamoxifen (TMX) was given i.p. on postnatal days 6-9 (P6-9), Shh ligand synthesis was prevalent in neurons of *Shh*$^{CreERT2}$ mice. In *Gli1*$^{CreERT2}$ mice, TMX at P6-9 detected Gli1 expression in cells that populated the CC, with the vast majority localized laterally. This lateral distribution was maintained through adulthood, which contrasted with the pattern of myelination that progressed from lateral to medial in the CC between P14-56. Delaying TMX to P14-17, after the peak of oligodendrogenesis, significantly reduced labeling of Shh synthesizing neurons and Gli1 expressing cells in the CC. Subsequent studies used TMX from P6-9 in *Gli1*$^{CreERT2}$ mice to label Gli1 expressing cells and examine their fate in the adult CC. Gli1 fate-labeled cells gave rise to astrocytes and oligodendrocyte lineage cells, including cycling oligodendrocyte progenitor cells identified by EdU incorporation and NG2 immunolabeling. The SVZ also contained Gli1 fate-labeled cells, including neural stem cells immunolabeled for GFAP. Finally, the cuprizone model of demyelination was used to examine the potential for Gli1 fate-labeled cells to contribute to oligodendrocyte repopulation during remyelination. Gli1 fate-labeled cells incorporated EdU in response to chronic demyelination. In addition, Gli1 fate-labeled cells were immunolabeled by NG2 early during remyelination and formed myelin-like membranes after longer periods for remyelination to progress. These studies reveal a population of cells with active Shh signaling during postnatal development that contributes to the generation of oligodendrocytes during CC myelination and gives rise to cells that continue to proliferate in adulthood and contribute to CC remyelination.

**Abstract:** The ability to regenerate oligodendrocytes depends on the availability of neural progenitors called oligodendrocyte precursor cells (OPCs). They are present throughout the adult

brain and spinal cord and can replace oligodendrocytes lost due to injury, aging or disease such as Multiple Sclerosis (MS). OPCs are massively recruited to the site of injury in damaged myelinate axons, but in MS patients remyelination is often ineffective. The factors that promote the initiation of OPC differentiation and overcome the block for successful remyelination in demyelinating diseases are poorly defined. Different pathways may contribute to ameliorate/impair remyelination in MS lesions, including adenosine and sphingosine kinase/sphingosine 1-phosphate (SphK/S1P) signaling axis. At all maturational stages OPCs express all four adenosine receptor subtypes ($A_1$, $A_{2A}$, $A_{2B}$ and $A_3$). S1P, produced by the action of SphK (two isoforms: SphK1 and SphK2), is a bioactive lipid that regulates remyelination and cell injury. An unexpected finding is that FTY720 (Fingolimod), approved as orally active drug for relapsing MS, modulates S1P receptors. Here, by electrophysiological recordings combined with Real-time PCR and Western Blot analysis, we studied the effects of adenosine $A_{2B}$ receptors and SphK/S1P signaling on membrane currents and differentiation of purified primary OPCs isolated from the rat cortex.
Selective stimulation of adenosine $A_{2B}$ receptors by 2-[[6-Amino-3,5-dicyano-4-[4-(cyclopropylmethoxy)phenyl]-2-pyridinyl]thio]-acetamide (BAY60-6583, 0.1-30 µM, n=43), an adenosine $A_{2B}$ receptor agonist, inhibited $K^+$ outward currents elicited by a voltage ramp protocol. This effect was prevented by the selective adenosine $A_{2B}$ receptor antagonist *N*-(4-Acetylphenyl)-2-[4-(2,3,6,7-tetrahydro-2,6-dioxo-1,3-dipropyl-1*H*-purin-8-yl)phenoxy]acetamide (MRS 1706, 10 µM, n=5) and was reduced by VPC96047 (500 nM, n= 4), a pan-SphK inhibitor. Similarly, FTY720 phosphate (1 µM, n=4), the active metabolite of FTY720, mimicked and partially occluded the effect of 10 µM BAY60-6583 on ramp-evoked current. In cultured OPCs, SphK1 phosphorylation was enhanced after acute (10 minutes) application of 10 µM BAY60-6583 in the medium cultures, demonstrating an interaction between SphK/S1P pathway and $A_{2B}$ activation. Finally, chronic $A_{2B}$ stimulation (by 10 µM BAY60-6583 for 6 days in the medium cultures) reduced the expression of mature oligodendrocyte markers, as determined by Real-time PCR analysis.
Our findings reveal that activation of adenosine $A_{2B}$ receptors and the SphK/S1P pathway are involved in the maturation of OPCs. Support: PRIN 2015 (2015E8EMCM_002).

**Title:** RNA methylation plays a critical role in CNS myelination

**Authors: *H. XU**[1], R. B. KUNJAMMA[1], X. ZHUANG[2], Q. FEI[3], C. HE[3], B. J. POPKO[1]
[1]Neurol., Univ. of Chicago, Chicago, IL; [2]Dept Neurobiol, Univ. of Chicago Dept. of Neurobio., Chicago, IL; [3]Dept. of Chem. and Inst. for Biophysical Dynamics, Chicago, IL

**Abstract:** Recent evidence has shown that RNA modification is a dynamic and reversible process that adds a new layer of epigenetic regulation in biological processes. N6-methyladenosine ($m^6A$), the most abundant internal modification site in eukaryotic messenger RNA (mRNA), is the first example of reversible RNA methylation. The conservative enrichment of $m^6A$ in stop codons, 3'-untranslated regions and long internal exons in mouse and human suggests its fundamental importance in RNA biology. Discoveries of $m^6A$ methyltransferase protein "writers", demethylase protein "erasers" and functional recognizer "reader" proteins suggest their dynamic regulatory roles in reversible RNA modification. A number of in vitro and in vivo studies have shown that reversible methylation of $m^6A$ is essential to cell survival and development. Nevertheless, the role of reversible RNA epigenetic modification in specialized cells, including myelinating cells, remains unknown. In our study, we used a Cre-loxP genetic approach to examine the role of RNA methylation in different developmental stages of myelinating cells. Methyltransferase like (METTL) 3 and 14 are active enzymatic components of the $m^6A$ "writer", and the knockdown of either component leads to substantially decreased $m^6A$-containing mRNA levels in the cells. We used mice containing a floxed *Mettl14* allele, which were crossed with mice that express Cre in oligodendrocytes in the CNS, to examine the role of $m^6A$ RNA methylation in CNS myelination. The Cre lines used were 2′,3′-cyclic nucleotide 3′-phosphodiesterase (CNP)-Cre mice and oligodendrocyte transcription factor 2(Olig2)-Cre mice, which expresses Cre in mature oligodendrocytes and oligodendrocyte lineage cells respectively. *Mettl14* floxed mice lacking the Cre-expressing loci were used as controls. Molecular, biochemical, histological, and behavioral approaches were used to examine the role of RNA methylation in oligodendrocyte lineage cells. The CNP-Cre $Mettl14^{fl/fl}$ mice and the Olig2-Cre $Mettl14^{fl/fl}$ mice appear phenotypically normal until four to six months of age when they begin to display clinical symptoms that include tremor and ataxia, which are typical symptoms for CNS myelin abnormalities. The clinical symptoms displayed by the mutant mice correlate with reduced oligodendrocyte numbers and severe myelin abnormalities. These results indicate that $m^6A$ RNA methylation plays an essential role in oligodendrocyte function and myelin maintenance.

**Authors: C.-Y. WANG**[1], C.-H. HO[1], *S.-F. TZENG[2]
[1]Dept. of Life Sci., Natl. Cheng Kung Univ., Tainan, Taiwan; [2]Natl. Cheng Kung Univ., Tainan City, Taiwan

**Abstract:** Oligodendrocytes (OLGs) produce myelin to wrap axons and promote action potential propagation in the central nervous system (CNS). BRCA1/BRCA2-containing complex subunit 3 (BRCC3), a lys63-specific deubiquitinase, was originally discovered to participate in DNA repair complex against double strand break. In addition, BRCC3 has been reported to regulate the activation of inflammasome by deubiquitinating NLRP3. Our previous study has shown that BRCC3 gene knockdown (KD) can increase the sensitization of glioma cells to alkylated agents. Recently, we also found that the reduction of BRCC3 expression in OLG precursor cells (OPCs) by lentivirus-mediated delivery of shRNA against BRCC3 (BRCC3-KD) suppressed OPC cell growth and sphere formation of OPCs. Moreover, suppression of BRCC3 led to the downregulation of DNA repair genes, such as BRCA1 and Rad51. Through the measurement of the OLG process complexity and myelin basic protein (MBP) production, BRCC3-KD increased OLG maturation when OPCs were maintained in the differentiation medium. The expression of genes (e.g. Sox10, Myrf, and MBP) that are responsible for OLG maturation was upregulated in BRCC3-KD cultures compared to that detected in the scrambled control cultures. The observations from neuron-OLG co-culture also showed that BRCC3-KD increased the maturation of OLGs derived from OPCs. The molecular mechanism underlying BRCC3-mediated OLG maturation is under investigation.

**Title:** Oligodendrocyte contact induces presynaptic specialization in axons

**Authors: *A. N. HUGHES**[1], B. APPEL[2]
[1]Neurosci. Grad. Program, [2]Pediatrics, Univ. of Colorado Anschutz Med. Campus, Denver, CO

**Abstract:** Many neural circuits depend on the coincident arrival of neural impulses at common targets. However, action potentials travel along axons of unequal lengths and conduction velocities. One mechanism by which the timing of impulses can be tuned is by regulating the amount of myelin membrane that ensheathes axons. To craft the temporal precision demanded by circuits, oligodendrocytes (OLs), the myelinating cell type of the CNS, must determine which axons should be myelinated and how much myelin to deliver to selected axons. What informs an OL of which axons should be myelinated? Our group and others found that preventing vesicular release in neurons reduces the number of stable myelin sheaths that form on axons. However, we know little about how neuronal vesicular release serves myelination. Previous work from our lab indicates that a major synaptic vesicle protein, synaptophysin, clusters under myelin sheaths that form on *phox2b+* reticulospinal axons, raising the possibility that vesicles are released directly onto apposing myelin sheath. Other groups have performed proteomic analysis of purified myelin to reveal several factors, including neuroligin1, CaMKII, and synCAM3 and -4, known to function at postsynaptic terminals. Drawing on these data, we hypothesized that OL contact induces the formation of a synapse-like structure by inducing presynaptic specialization in the axon. To test this, we use zebrafish as a model system to combine genetic and pharmacological tests of gene function with direct observation of axon ensheathment using time-lapse imaging. Our preliminary data indicate that neurons respond to OL contact with local calcium transients, reminiscent of those that occur in motor neurons upon contact with target muscle cells during neuromuscular junction formation. Additionally, we show that the presynaptic terminal protein, synaptophysin, is recruited to nascent sheaths. Together, these data support a role for OL contact in inducing presynaptic differentiation in neurons.

**Abstract:** Myelination and the localization of voltage-gated ion channels to nodes of Ranvier enables axons to conduct signals in an efficient and timely manner. While the traditional model of myelination assumes a uniform distribution of myelin sheaths along the length of the axon, the recent discovery of diverse myelin profiles in the cortex—termed intermittent myelination—reveals the necessity for a greater understanding of the structure and function of these diverse myelination profiles in the adult brain. Here, we evaluated the localization of ion channels on cortical axons with intermittent myelination using immunohistochemical analysis to characterize the distribution of sodium channels at paranodes in superficial layers of cortex from 1.5 to 10 months of age. A differential distribution of sodium channels was found adjacent to nodal and heminodal paranodes and a large proportion of heminodes showed no sodium channel immunoreactivity. Furthermore, paranodes of terminal myelin sheaths showed a greater propensity for clustering sodium channels than paranodes of isolated myelin sheaths. Nav1.6, the predominant sodium channel isoform at nodes of Ranvier, was absent from the majority of heminodes even in 10 month old mice. Together, these data indicate that the differential targeting and clustering of sodium channel isoforms to nodes and heminodes in the superficial cortex is related to the distribution of myelin. This varied distribution of voltage-gated ion channels may suggest additional roles for myelin beyond regulating conduction velocity in axons with intermittent myelination.

**Abstract:** Extracellular vesicles (EVs) describe a broad family of cell-secreted, membrane-containing nanoparticles of varying cellular origins capable of diverse biological function, diagnostic potential and therapeutic applications. The relatively small size of these EVs (~50nm - 1μm) has mainly required the use of bulk analyses, making more nuanced biological investigations into cell of origin or population heterogeneity difficult. Here we describe a new technique for single EV analysis (SEA) that provides a multiplexable and sensitive method to probe proteomic information with single vesicle resolution. We used this method to profile glioblastoma EVs and found high variation in both pan-EV and tumor cell markers. This initial investigation provides some of the first evidence of heterogeneity among biomarker profiles across tumor EVs. The data demonstrates the capacity of the SEA technology to be used in an array of clinical applications and to address key questions in EV biology moving forward.

**Abstract:** Glioblastoma (GBM) is the most common and deadly primary brain tumor of the adult CNS. GBM cells remodel their local extracellular matrix (ECM) to create a tumor microenvironment, which in turn supports the tumor progression. Collagen I, which is not usually expressed in the normal adult brain, is over-expressed within the tumor core relative to the peritumor region in patients with short survival times. Collagen-based 3D culture models show that altering the collagen I density and in turn the elastic modulus of the matrix, alters the migration mode and rate of GBM cells. Little is known, however, regarding the elastic modulus within the native GBM tumor microenvironment and whether there is a potentially instructive mechanical gradient from tumor to the native brain. Literature provides a wide range of estimated elastic moduli of normal brain as result of varying tissue preparation methods, temperature conditions, testing methods, and post mortem time. To address these issues, we aim to measure the mechanical properties in the tumor and peritumor tissue from canine patients with spontaneous glioma and attempt to match these properties in a 3D brain mimic culture model. We measure elastic moduli by Atomic Force Microscopy (AFM), using a Bruker Bioscope Catalyst with Nanoscope V Controller mounted on an Olympus inverted microscope, using a cantilever with a nominal spring constant (k) of 0.12 N/m. To delineate the effects of preservation methods, brain tumor and brain samples will be flash frozen within 3 hrs post mortem, while other brain tumor and brain samples will be incubated ($37^o$, 5% $CO_2$) within 3 hrs post mortem. These results will determine how tissue preservation affects the mechanical properties, and will be the baseline to adjust the mechanical properties of the 3D tunable culture. We expect that matching the brain environment in culture will encourage a typical genetic tumor expression profile and help create a more representative pathophysiological model to study GBMs.

**Title:** Pharmacological modulation of calcium signaling to overcome acquired cisplatin resistance in neuroblastoma cells

**Authors: *A. M. FLOREA**[1], J. MCCALLUM[2], E. VARGHESE[2], G. REIFENBERGER[1], D. BÜSSELBERG[2]
[1]Heinrich Heine Univ. Düsseldorf, Uniklinikum, Düsseldorf, Germany; [2]Weill Cornell Med. in Qatar, Qatar Foundation-Education City, Doha, Qatar

**Abstract:** High-risk neuroblastoma (NB) patients are treated with chemotherapy protocols including e.g. cisplatin (CDDP) and topotecan (TOPO) that is successful in only 30-40% of cases due to acquired chemotherapy resistance, thus improved therapies are urgent. Relapsed or metastatic NB tumors are difficult to treat as the molecular mechanisms leading to drug resistance are not understood. Since alterations of intracellular calcium homeostasis induced by anticancer drugs have been demonstrated in NB before it is suggested that manipulation of key modulators of calcium signaling associated with apoptosis may provide novel treatment strategies in NB. In this study, we assessed whether calcium signaling modulators enhanced the effects of CDDP and TOPO in parental SH-SY5Y and cisplatin (CDDP) resistant SH-SY5Y_R cells. In vitro cellular cytotoxicity was utilized as an endpoint. Treatment schemes included untreated control cells (72h), cells treated with a calcium modulator alone (72h), cells treated with CDDP or TOPO (72h), and cells treated with a combination of a calcium modulator and CDDP or TOPO. In the combinatory treatment, the cells were first exposed to the calcium modulator for 30min. followed by CDDP or TOPO for 72h. We tested the following compounds: thapsigargin (THAPS), 2-aminoethoxydiphenylborane (2-APB), cylopiazonic acid (CPZ), dantrolene (DANTR), ryanodine (RYA), verapamil (VERA), nifedipine (NIFE), cyclosporine A (CYCLA), 1,2-Bis(2-aminophenoxy) ethane-N,N,N',N'-tetraacetic acid known as BAPTA/BAPTA-AM, the $Na^+/Ca^{2+}$ exchange inhibitor YM58483, reversan (REV), as well as the calmodulin (CaM) kinase inhibitors STO-609 acetate and PD 150606 cell permeable calpain inhibitor. Treatment of SH-SY5Y and SH-SY5Y_R with modulators of calcium signaling revealed THAPS, CPZ, as well as 2APB and CYCLA as potentially active compounds in CDDP resistant NB cells since their combination with CDDP or TOPO showed significant additive effects, revealing the potential role of the regulation of sarco/endoplasmic reticulum $Ca^{2+}$ ATPase (SERCA) pump, IP3 receptors and mitochondrial calcium flux in enhancement of chemotherapy. The other calcium modulators did not cause increased cytotoxity in SH-SY5Y_R cells, with STO-609 acetate and PD 150606 demonstrating additive effects with CDDP or TOPO only in the parental SH-SY5Y cells. Additional research is required to experimentally validate these findings in independent NB models with acquired resistance to chemotherapy as well as the functional roles of modified calcium signaling in CDDP-resistance and characterize their potential relevance for in vivo treatment of chemotherapy-resistant NB.

**Abstract:** Neuroblastoma (NB) is a childhood tumor that is often treated with cisplatin (CDDP) as a first line chemotherapy. Secondary effects resulting chemotherapy is the acquired drug resistance that leads to poor patient survival that still represents major challenges towards effective chemotherapy. Intracellular calcium ($[Ca^{2+}]_i$) is a universal second messenger that regulates many cellular processes including apoptosis. Several chemotherapeutic agents including CDDP have shown to modulate $[Ca^{2+}]_i$ and apoptosis in neuroblastoma. Here we analyze gene expression and specific functional characteristics of resistant NB cells associated with $[Ca^{2+}]_i$ handling in sensitive and CDDP-resistant subline of NB cells (SH-SY5Y).
The trypan blue cell viability test showed that in CDDP-resistant SH-SY5Y, the CDDP exposure resulted lower cytotoxicity as compared to the parental CDDP sensitive cells ($\leq$1μM; $p<0.01$). The mRNA expression of a selected genes related to drug transport ABCB1, ABCC1, ABCG2, ATP-7a and LRP were analyzed. LRP demonstrated a highly significant 3-fold increase in basal CDDP-resistance ($p<0.001$). A scratch-wound healing assay reveled that CDDP exposure could not block migratory capacity of CDDP-resistant cells, as with CDDP-sensitive migratory capacity ($P<0.01$). Furthermore, plasma membrane drug transporter function was measured via a Hoechst dye exclusion assay, determined by verapamil inhibition. Verapamil could not inhibit ABC efflux transporter function in CDDP-resistant SH-SY5Y cells treated with CDDP. Finally, single cell $[Ca^{2+}]_i$ was measured using the calcium sensitive fluorescent dye Fluo-4AM, over 3h. A more pronounced increase of was observed in CDDP-resistant cells, compared to sensitive SH-SY5Y cells. Thapsigargin, a SERCA blocker and verapamil an L-type channel blocker were used to monitor calcium influx to ER stores or from an extracellular source. Results indicate that CDDP-resistant cells cisplatin mediated increases in $[Ca^{2+}]_i$ were most compromised following depletion and block of ER calcium stores.
Together, results characterize a chemoresistant NB phenotype that has improved capacity for survival, cell motility and drug efflux. Future investigations will assess if disruption of intracellular calcium storage, initially induced following CDDP exposure, might compromise chemotherapy resistant NB cell viability.

**Abstract:** Glioblastoma multiforme (GBM) is a stage four astrocytoma comprising a majority of primary malignant brain tumor diagnoses in adults in the U.S. Conventional therapies are ineffective, leading to patient death within 15 months of diagnosis. Chondroitin sulfate proteoglycans (CSPGs) and their glycosaminoglycan (GAG) side chains are key components of brain extracellular matrix (ECM) implicated in promoting tumor invasion. We hypothesize that glioma invasion is triggered by selective expression of oversulfated CS-GAGs in tumor microenvironment, and preventing glioma cell signaling with extracellular CS-GAGs will restrict invasion. Microfluidics devices were used to present mono- and oversulfated CS-GAG matrices to F98 rat glioblastoma cells and cell infiltration *in vitro* was quantified. Cell infiltration was compared across unsulfated (HA), 4,6-sulfated CS-GAG (CS-E) matrices, and media only controls. The small molecule GAG-antagonist (surfen) was introduced to inhibit GAG signaling. Focal adhesion protein colocalization was quantified within antagonist-containing and control hydrogels to determine the influence of CS-GAGs on cell invasion. *In vivo* tumor inductions in rats were performed stereotactically to induce frontal lobe tumors to mimick human GBM. F98 cells in media only or containing surfen were inoculated to evaluate effects of surfen on glioma invasion over 21 days. MR imaging was used to track progress of tumor volume and angiogenesis.
Our results demonstrated enhanced preferential cell invasion into hydrogel matrices containing disulfated CS-E compared to unsulfated hydrogels ($p<0.05$). F98 cells invading into CS-E hydrogels displayed enhanced colocalization ($p<0.05$) of focal adhesion proteins compared to cells within unsulfated hydrogels. This effect was significantly reduced in cells within CS-E

hydrogels containing surfen ($p<0.05$). Rats inoculated with F98 cells developed diffusely invasive tumors 14 days post-induction when compared to surfen treated rats, which developed smaller tumors with more defined margins ($p<0.05$). These results suggest that sulfated CS-GAGs may directly induce tumor invasion, and that this signaling mechanism can be disrupted by surfen. Our results also suggest that heightened presence of extracellular CS-E induced enhanced cellular migration in a GAG sulfation-dependent manner, and that perturbing cellular interactions with CS-E significantly reduced tumor invasion. Identification of the role of CS-GAGs in glioma behavior would advance our understanding of glioma invasion, and contribute to development of novel therapeutic interventions for this intractable form of brain cancer.

**Title:** Tspo deficiency promotes glioma development

**Authors: *D. WANG**, Y. FU, H. WANG, H. CHEN, Y. HU, J. ZHANG
Peking Union Med. Col., Beijing City, China

**Abstract:** Glioma is the most common type of primary tumor in brain with a high morbidity and mortality. Previous studies indicated that the 18 kDa translocator protein (TSPO) was highly expressed in glioma tissue, especially in the malignant glioma tissues. However, the roles of TSPO in glioma development are unclear. In this study we investigated the functions of TSPO in glioma development by using in vivo mouse model by intracranial xenograft glioma in TSPO knockout mice. The results showed that TSPO deficiency promoted the growth of glioma. The volume of glioma with TSPO deletion grew bigger than that of WT glioma. In addition, the expression of CD31 and other angiogenic factors was increased in the TSPO-KO glioma, indicating an enhanced angiogenesis in TSPO KO glioma. We also found more $P2Y12^{+}$ microglia/macrophages infiltrated in TSPO-KO glioma compared to WT glioma. Our findings

demonstrate that TSPO deficiency promotes glioma progression, and TSPO may be a novel target for glioma therapy.

**Title:** The N - alkyl carbazole derivative 4OHCARB6BSAL induces neuroblastoma cell death by promoting p53 protein translocation into the nucleus

**Authors: *S. L. NORI**[1], A. SANTORO[1], M. ZANETTI[2], V. NICOLIN[2]
[1]UNIVERSITY OF SALERNO, Baronissi, Italy; [2]Clin. Dept. of Medical, Surgical and Hlth. Sci., Univ. of Trieste, Trieste, Italy

**Abstract:** Neuroblastoma (NB) is a childhood tumor of neural crest origin presenting along the sympathetic chain especially in the adrenal medulla or paraspinal ganglia. More than half of children diagnosed with high-risk NB either do not respond to conventional therapies or relapse after treatment, and nowadays chemotherapy has not yet made a significant effect on the survival of high-risk NB children. An attractive feature of NB is that the p53 protein, whose alterations are well known to play a crucial role in malignant transformation, is rarely mutated at the time of diagnosis and it appears that p53 dysfunction can result mostly from a nonfunctional conformation or cytoplasmic sequestration of the wild-type protein. Therefore, pharmacological approaches aimed at targeting the p53 protein by promoting its translocation into the nucleus could improve NB therapeutic strategies. In this study, we investigated the cytotoxicity of a new N-alkyl carbazole derivative named 4OHCARB6BSAL (Saturnino et al., Eur J Med Chem. 2013, 60:112-119) in NB SK-N-AS cells using DAPI staining and explored its potential mechanism of action by analyzing cell morphology and p53 distribution by immunofluorescence microscopy during the treatment. Results show that the compound is able to significantly inhibit the number of SK-N-AS cells in a concentration range from 10 to 50 µM and a time treatment of 48 h. Particularly it reduces cell survival of about 25 % at 10 µM, whereas at 50 µM only about a 3% of cells were viable. The cytotoxic activity of the carbazole derivative was associated to a change of cell shape and cytoskeletal organization, as revealed by β-tubulin staining, compared to untreated (control) cells. On the other hand, we also observed a change in cell distribution of the phosphorylated (Ser15) p53 protein that appeared concentrated in the nucleus of the cells as a consequence of the treatment. Interestingly, the distribution pattern of p53 protein was comparable to that induced by the MDM2 antagonist Nutlin-3 (Van Maerken et al., Mol Cancer

Ther. 2011, 10:983-993) used as positive control. Moreover, to provide further insights we also detected STAT3 expression and distribution in NB cells. Results show a general low expression of this protein even though an increase in immunofluorescence intensity in the nucleus has been detected. Altogether, these data suggest that 4OHCARB6BSAL can induce cell death by targeting p53 protein and might be involved in the activation of differentiation pathways by modulating STAT3 protein expression.

**Title:** Plasticity of cognitive functions after resection of glioma: new evidence from voxel-based lesion symptom mapping

**Authors: *C. NIKI**[1], T. KUMADA[2], T. MARUYAMA[1], M. TAMURA[1], Y. MURAGAKI[1]
[1]Tokyo Women's Med. Univ., Tokyo, Japan; [2]Kyoto Univ., Kyoto, Japan

**Abstract: Background and aims:** The aim of this study was to evaluate changes of cognitive function of glioma patients from pre-operation to 6 months after surgery and identify brain regions that are related to recovery of cognitive function or continuous impairments after resection of glioma. **Method:** We recruited 25 patients with glioma in the left hemisphere (15 male, 10 female, mean age=41.2, SD=10.4, all right-handed). Cognitive test battery composed of six cognitive tasks such as memory, attention was administered at pre-operative stage, 1 month and 6 months after a resective surgery. A factor analysis was performed to their pre-operative cognitive performance to extract cognitive factors common to the six cognitive tasks, then examined the neural correlates for the extracted factors using voxel-based lesion-symptom mapping(VLSM) method. To reveal differences of brain regions related to impairments of cognitive performance between 1 month and 6 months after surgery, VLSM were performed twice, for performance of 1 month and that of 6 months later. **Results:** Four main cognitive factors were extracted by a factor analysis. VLSM analyses revealed that the first component affected verbal memory and verbal fluency tasks and corresponded with anterior parts of middle temporal (MTG) and superior temporal gyri (STG) at 1 month later. Lesions to MTG found at 1 month later was disappeared at 6 months later, whereas those to STG were revealed at both 1 month and 6 months later. The second component, affecting letter-digit substitution and digits

forward and backward tasks, revealed around the posterior STG, including Wernicke's area, the middle STG, the supramarginal and the angular gyri at both 1 month and 6 months later. The third and the fourth components affected each task, concept of shifting and Stroop color-word tasks. For the third component, cognitive performance was improved from 1 month to 6 months later and STG found at 1 month disappeared at 6 months later, whereas regions around the supramarginal and the angular gyri were found only at 6 months later. Cognitive performance of the fourth component also improved from 1 month to 6 months later and the inferior frontal lobe found in analyses at 1 month disappeared at 6 months later, although the middle frontal regions were found only at 6 months later. **Discussion:** Results showed that brain regions associated with cognitive impairments in the early stages recovered 6 months later, suggesting plasticity of higher cognitive function after resection of glioma. Results also suggests that some brain regions might be amenable to recovery of cognitive function following resection of glioma than others.

**Title:** Implications of the inhibitors of HuR multimerization in glioma treatment

**Authors: *N. FILIPPOVA**, X. YANG, L. B. NABORS
Univ. of Alabama At Birmingham, Birmingham, AL

**Abstract:** The mRNA binding protein HuR expression is consistently elevated in tumor tissue and promotes HuR cytoplasmic localization essential for HuR dependent oncogenic transformations. In our previous report, we performed a detailed analysis of HuR multimerization in samples of primary brain tumors, patient-derived xenolines (PDGx), and the established glioma U251 cell line. We found a significant increase in HuR multimerization with the enhancement of tumor grade.
In our current work, by utilizing the HuR/split Firefly luciferase assay in U251 cells, we discovered several new compounds inhibiting HuR multimerization. The tanshinone group compound 15,16 dihydrotanshinone-I (DHTS), the compound #5 and the JSI-124 are among on them. The HuR specific regulator MS-444 has been utilized as the control. The $IC_{50}$ for the inhibition of HuR-dimerization are: 20$\pm$6 uM (n=4), 1.5h of treatment for DHTS; 21$\pm$6 uM (n=4), 6h of treatment for compound #5 and 0.9$\pm$0.1 uM (n=4), 6h of treatment for JSI-124. We

found that the exposure of the established glioma cell lines and human derived PDGx to the above compounds leads to the ultimate reduction of tumor cell survival and proliferation. The most pronounced effect on the decrease of cancer cell survival and proliferation was observed with the JSI-124, the main mechanisms of action of which consist of the inhibition of HuR dimerization and the inhibition of JAK/STAT3 pathways. The JSI-124 effectively inhibits TMZ resistant and non resistant cancer cell growth and works well in combination with the irradiation cell treatment. In the cytotoxicity assay the JSI-124 $IC_{50}$ for the stem cell population isolated from PDGx cell lines was in 0.05-0.1 uM range. The JSI-124 growth inhibitory effect depends from the cell density and declines with the increase of cell density. The mouse GL261 cells with the HuR knockdown exhibit higher sensitivity to the JSI-124 compared to the sh-control cells, the difference increases with an increase in cell density. Several glioma cell lines with high levels of HuR and PDL1 expression exhibit significant reduction of HuR and PDL1 levels following the JSI-124 treatment. In the glioma mouse immunocompetent model the evaluation of the source and the concentration of the PDL1 and the cytokine profile in the tumor micro environment and CSF prior and after the disruption of the HuR function is in progress. Overall, our work confirmed that the inhibition of HuR dimerization in the glioma cell lines decreases cell proliferation, enhances cancer cell sensitivity to the chemotherapeutics and may affect cancer cell immune defense axes through the regulation of PDL1 expression and the cytokines profile.

**Title:** Bradykinin induces cell migration and interleukin-8 production through the bradykinin B1 receptor in glioblastoma

**Authors: *Y.-S. LIU**[1,2], C.-F. TSAI[3], D.-Y. LU[1,4]
[1]Dept. of Pharmacology, Sch. of Med., [2]Grad. Inst. of Basic Med. Sci., China Med. Univ., Taichung, Taiwan; [3]Dept. of Biotech., [4]Dept. of Photonics and Communication Engin., Asia Univ., Taichung, Taiwan

**Abstract:** Glioblastoma (GBM) is the most aggressive brain tumor, with a poor prognosis because of the ease with which tumor cells migrate to surrounding normal brain. Recent studies have shown that bradykinin is involved in progressions of various types of cancer. However, the molecular mechanisms and pathologic roles underlying bradykinin-induced GBM migration remain unclear. In this study, we found that bradykinin induced GBM migration in a dose-

dependent manner. Analysis of cytokine array showed that bradykinin increased production of interleukin-8 (IL-8) in GBM. Moreover, bradykinin induced IL-8 mRNA and protein expression were observed in GBM as well. Knockdown of IL-8 attenuated bradykinin-induced migration in GBM. Bradykinin-induced IL-8 protein expression was repressed by the administration of a bradykinin B1 receptor (B1R) antagonist, but not the bradykinin B2 receptor (B2R) antagonist. Activations of FAK and STAT3 were observed time-dependently after stimulation by bradykinin. In addition, inhibition of B1R by desBK effectively antagonized the bradykinin-induced phosphorylation of FAK. Moreover, treatment with FAK or STAT3 inhibitor reduced the bradykinin-induced IL-8 protein expression. Taken together, these results indicate that bradykinin-induced IL-8 expression through B1R, FAK and STAT3 resulting in contributing to promote GBM migration.

**Title:** Sirtuins mediated metabolic stress in HIV associated brain lymphoma

**Authors: *D. PATEL**[1], P. R. GUDA[1], S. RAY[1], R. SUBEDI[1], M. GHOSH[1], G. ASEMU[2], T. K. MAKAR[1], J. L. BRYANT[2]
[1]Neurol., Univ. of Maryland, Baltimore, MD; [2]Inst. of Human Virology, Baltimore, MD

**Abstract:** Inhibition of histone deacetylases (HDACi) is one of the treatments of many types of cancer, including brain lymphoma. Among the HDACs, Class III HDACs, also known as sirtuins (SIRTs), are unique in that their function is directly related to the cell's metabolic state through their dependency on the co-factor NAD(+).The role of SIRTs in cancer is extremely complex, with different functions. Mammalian SIRTs (SIRT1-7) differ according to cellular localization and biologic functions. Among these, SIRT -3, -4, and -5 are located in the mitochondria and the rest are cytosolic. Mitochondrial Sirt3 regulates multiple cellular and physiologic processes, including cell cycle, gene expression, cell viability, stress response, metabolism, and energy homeostasis. Recent research suggests that Sirt3 influences tumors by regulating the metabolic state of the cell. So far nothing is known about the role of sirtuins in the regulation of HIV-associated brain B cell lymphoma. In this study, we examined the relation between SIRTs and the hippocampal changes of HIV-associated brain B cell lymphoma. Recently we developed the HIV-1 Tg26 mouse model of brain B cell lymphoma similar to what is seen in human HIV primary central nervous system lymphoma (PCNSL) which is a malignant diffuse large B cell lymphoma that occurs in 3-5 % of HIV patients. The hippocampus plays a crucial role in

cognitive function. Memory deficits are characteristic of HIV-associated neurocognitive disorders and involved with hippocampal pathology in the hippocampus region of these mice, NAMPT (NAD(+) biosynthesizing enzyme), SIRT1 (The NAD(+)-dependent deacetylase), SIRT3 (mitochondrial deacetylase) and PGC1α (a key enzyme involved in mitochondrial biogenesis and function) expressing cells were increased, Our finding suggests NAMPT/SIRT1/SIRT3/PGC1α signaling is activated in the hippocampus of PCNSL in the HIV-1 TG26 mouse model. The identification of metabolic changes in the hippocampus of these mice may provide novel insight into the basic mechanisms underlying key cognitive deficit associated with the disease

Autónoma de Baja California, Ensenada, Mexico; [7]Cinvestav-IPN, Mexico City, Mexico

**Abstract:** Gliomas are malignant and infiltrative brain tumors, which treatment generally includes surgery, radiation, and chemotherapy. However, brain tumor’s treatment commonly is difficult to achieve and drugs are non-selective, causing side effects and chemotherapy tolerance. Seaweeds are used since ancient times to treat several kinds of tumors, and it has been described

that seaweeds are rich in natural products with several biological activities, including anti-cancer activity. Egregia menziesii is a brown seaweed that belongs to the Lessoniaceae family and it is distributed in the north Pacific coast of Mexico, which biological activity has not been investigated yet. Since, some Lessoniaceae family members are showed anti-proliferative activity, the aim of this work was to evaluate the anti-cancer activity of Egregia menziesii extracts against cell lines of nervous system lineage. Specimens of this brown seaweed were collected in Campo 5 Punta Banda, Baja California, Mexico, and hexanic, chloroformic, and methanolic extracts were obtained by maceration. MTT proliferation assay was used to evaluate cell viability in C6, N1E-115, MIO-M1, U737 cell lines, and the non-cancerous Bergmann glia primary culture; after 4, 24, and 48h exposure. Our results showed that the hexanic and chloroformic extracts have a potent anti-proliferative capacity in C6 glioblastoma cells (IC50= 2.3 y 2.0 µg/ml, at 24h exposure) respectively, without affecting the Bergmann glia cell's viability. In conclusion, these results show the first approach to evaluate the anti-cancer activity of the Mexican algae E. menziesii.

**Title:** Does dual pharmacological inhibition of aquaporin-1 water and ion channel activity inhibit glioma cell migration?

**Authors: *M. DE IESO**[1], J. PEI[1], M. KOURGHI[1], S. NOURMOHAMMADI[1], J. E. HARDINGHAM[2], A. J. YOOL[1]
[1]Dept. of Physiol., Univ. of Adelaide, Adelaide, Australia; [2]Oncology Dept., The Basil Hetzel Inst., Adelaide, Australia

**Abstract:** Cancer is a leading cause of death, primarily due to metastasis. Aquaporin-1 (AQP1) is one of fifteen classes of water channels in mammals and is well known for roles in fluid absorption and secretion in the kidney, brain, and vascular system. AQP1 has also been shown to act as a cGMP-gated ion channel, essential for cerebrospinal fluid production. AQP1 is

upregulated in a subset of aggressive cancers including many gliomas, and some colorectal cancers, and expression has been shown to increase with the grade of the neurological malignancy. Interestingly, when AQP1 is transfected into an AQP1-null glioma cell line in vitro, cell migration is potentiated compared to wild type. This potentiation of cell migration cannot be replicated with the transfection of other mammalian aquaporins, suggesting a unique migration-enhancing property of AQP1. These findings imply that AQP1 may play an important role in facilitating cell migration and motility in glioma cells. Moreover, upregulation of AQP1 in glioma tumours may also contribute to vasogenic brain oedema, and the acidification of the extracellular space – likely contributing factors to the invasive potential of these cancer cells. Our research group recently discovered two novel inhibitors (AqB011 and bacopaside II) that selectively block the AQP1 ion and water channels respectively, and applied individually were found to inhibit cell migration in HT29 colon cancer cells highly expressing AQP1, without evidence of cytotoxicity at effective doses. Cell migration was quantified using a circular wound closure assay and live cell tracking. Dual treatment produced a block of 81%, which was significantly greater than the block produced by AqB011 (38%) or bacopaside II (44%) alone. Additionally after AQP1 was knocked down via short interfering RNA, the effects of both AqB011 and bacopaside II on cell migration were nullified, suggesting specific action on the AQP1 channel. These results were the first to suggest that the AQP1 water and ion conductance may exhibit a coordinated role in facilitating cell migration in AQP1-dependent cancer cell lines. Work here tests the idea that blocking both AQP1 water and ion channels in glioma cell line U87-MG will inhibit cell migration and invasion in an in vitro model, consistent with previous results from the HT29 cell line. Western blot analysis for AQP1 expression in U87-MG cell line showed levels of AQP1 similar to that of HT29, thus a reasonable candidate to test the AQP1 inhibitors. More work needs to be conducted to test specificity of the AQP1 inhibitors, and to test how AQP1 water and ion conductance may exhibit a cooperative role in facilitating cancer cell migration and invasion.

**Title:** Pericyte dysfunction in radiation induced brain injury

**Authors: *Y. TANG**[1], J. CHENG[2], Y. GUAN[2], Y. LI[2], J. CAI[2], X. WANG[2]
[1]Sun Yat-Sen Mem. Hospital, Sun Yat-Sen Univ., Guangdong, China; [2]Sun Yat-Sen Mem. Hosp., Guangzhou, China

**Abstract:** Radiation-induced brain injury (RI) is a severe complication of radiotherapy for head and neck tumor. However, the pathogenesis of RI remains unclear.
We found that after radiation, there is severe Blood brain barrier (BBB) disruption, which is in line with literatures. It has been known that pericytes play key role in maintaining the integrity of BBB. Therefore, we detect the expression of soluble platelet-derived growth factor receptor-β (PDGFR-β), a hallmark of pericytes, in the cerebrospinal fluid of patients after radiotherapy, and discover that expression of PDGFR-β is significantly higher among patients with RI than those without RI ($P < 0.05$).The level of PDGFR-β is positively correlated with the area of edema and severity of brain injury (measured by SOMA score), suggesting involvement of pericytes.
Further we aim to elucidate how pericytes function in RI through animal model. We find that after whole brain radiation of 30Gy, fluorescent dye exudation increases significantly using two-photon microscopy imaging, suggesting increase of BBB permeability and BBB disruption after radiation. In addition, we also found that blood flow slows down, diameter of microvessels narrows and density of microvessels decreases in cortex and hippocampus. Moreover, decrease of pericytes' density, coverage rate and its detachment from endothelial cells are significant. Expression of PDGFR-β in cortex and hippocampus is reduced. Nevertheless, detailed signaling pathway needs further investigation. Our previous work confirmed that microglia activate and secrete large amounts of inflammatory mediators such as TNF-α, IL-6 and IL-1β after radiation. And it has been reported in vitro that pericytes transform to "harmful cells" in respond to inflammatory mediators such as TNF-α or IL-6. Thus we speculate that there might be direct crosstalk between pericytes and microglia after radiation.
Next we will try to clarify the mechanism of vascular injury after radiation and the signaling pathway, and verify the scientific hypothesis that there is crosstalk between pericytes and microglia.

**Title:** Oral administration of a novel histone deacetylase 6 inhibitor MPTOB291 reduces glioblastoma volume and changes gene expression in tumor surrounding stromal tissue in orthotopic xenograft mouse model

**Authors: *B. BATSAIKHAN**[1], K.-S. HUNG[2], J.-Y. WANG[1,2]
[1]Grad. Inst. of Med. Sci., Taipei Med. Univ., Taipei, Taiwan; [2]Dept. of Neurosurg., Wan Fang Hospital, Taipei Med. Univ., Taipei, Taiwan

**Abstract:** Histone deacetylase (HDAC) inhibitors have emerged as a new class of anti-tumor agents for various types of tumors, including glioblastoma. We have recently found that a novel HDAC 6 inhibitor MPTOB291 has anti-tumor effects on glioma cell death, cell cycle arrest, migration *in vitro* and on tumor growth, angiogenesis *in vivo*. To futher examine anti-tumor effects of this novel drug on tumor microenvironment, we examined the expression of mRNAs and lncRNAs in orthotopic xenografts in mice by using cDNA microarray. MRI and bioluminescence imaging analyze show that tumor growth in animals was inhibited by MPTOB291 and that tumor volume determined by MRI and bioluminescence signal determined by *in vivo* imaging system (IVIS-200) were highly correlated ($R=0.839$, $p<0.05$). Our microarray data showed that a number of mRNAs and lncRNAs were up- and down-regulated by MPTOB291 compared to those in sham xenograft and xenograft treated with vehicle drug. Gene Ontology (GO) enrichment analysis and KEGG pathway analysis suggest that treatment of MPTOB291 promotes protective processes which are related to glioma pathoway and protective pathways in tumor surrounding tissue (TSST) such as MAPK signaling pathway ($p<0.05$). To evaluate a role of interaction between mRNAs and lncRNAs on glioma microenvironment, we found physical and functional relationships of top 10 up- and down- regulated mRNAs and lncRNAs. Data show that nearby located-mRNAs of top ten up- and down-regulated lncRNAs were expressed similarly with those expression-changed lncRNAs. Highly correlated ($p<0.05$) lncRNAs with top ten up- and down-regulated mRNAs were also expressed similarly with those coding transcripts. Our study have shown that lncRNA and mRNA interaction plays a role in tumor microenvironment; and the novel HDAC inhibitor, MPTOB291 may decrease tumor growth *in vivo* by changing gene expression in tumor surrounding stromal tissue.

**Title:** Caffeine modulates the hypoxic/angiogenic pathway in glioblastoma cells

**Authors: *G. MAUGERI**[1], A. D'AMICO[2], D. RASÀ[1], S. CAVALLARO[3], V. D'AGATA[1]
[1]BIOMETEC, Univ. of Catania, Catania, Italy; [2]San Raffaele Open Univ. of Rome, Rome, Italy; [3]Italian Natl. Res. Council, Catania, Italy

**Abstract:** Glioblastoma multiforme (GBM) represents the most aggressive primary brain tumor in adults including extensive hypoxic areas. The latter is one of the hallmarks of this cancer. It triggers hypoxia-inducible factors (HIFs) expression leading to accumulation of pro-angiogenic factors such as vascular endothelial growth factor (VEGF). Previous papers have shown that the most common ingested psychoactive drug in the world, caffeine, reduces proliferation of GBM, by inducing apoptotic cell death. In the present study, it has been investigated whether caffeine effect is mediated through the modulation of HIFs and VEGF expression. Results have shown that caffeine significant reduced HIF-1α and VEGF expression in GBM cells exposed to hypoxia. Its role is mediated by inhibition of PI3K/Akt and MAPK/ERK signaling pathways, which are implied in HIFs regulation. These data give new insight into the antitumor activity of caffeine, counteracting hypoxia event in GBM.

**Title:** TAK1 inhibitor 5Z-7-oxozeaenol sensitizes glioma to chemotherapy

**Authors: *E. ESPOSITO**, M. CAMPOLO, M. LANZA, G. CASILI, I. PATERNITI, A. FILIPPONE, S. CUZZOCREA
Univ. of Messina, Messina, Italy

**Abstract:** Gliomas are the most common primary brain tumors of the central nervous system. Despite relevant progress in conventional treatments, the prognosis of such tumors remains almost invariably dismal. NF-κB activation is one of the resistance mechanisms for cancer cells to escape from chemotherapy-induced cell-death. TAK1 is an essential component in genotoxic stresses-induced NF-κB activation; however, the role of TAK1 in the development of chemoresistance in glioma remains unknown. Using a panel of glioma cell lines, U138 and A172, we found that TAK1 inhibitor 5Z-7-oxozeaenol significantly augmented the cytotoxic effects of temozolomide (TMZ) on glioma cell lines. TAK1 inhibition also enhanced the inhibitory effect of TMZ on anchorage independent growth. Treatment of glioma cells with 5Z-7-oxozeaenol blocked TMZ- induced NF-κB activation, reduced cytokines expression and

enhanced TMZ-induced apoptosis in both cell lines.
Together, our results provide a proof-of-concept that TAK1 inhibition significantly increases the sensitivity of glioma cells to chemotherapy-induced cell-death and can serve as an effective adjunct to current chemotherapeutic regimens for high risk diseases.

**Abstract:** When primary glioma cell lines derived from patients are implanted in the brain of animal laboratories, a multitude of extremely long (up to .500 μm) and very thin (1-2 μm thick) membrane protrusions are observed (Osswald et al 2015). These protrusions are referred to as tumor microtubes (TMs) and are thought to be a major player of the malignancy of brain tumors. We found that similar structures can be seen in vitro when glioma cell lines are cultured and stained with the fluorescent dye membrane marker Vybrant DiI. Indeed, live cell imaging of U87 cell lines (Fig.1) shows the presence of very thin processes connecting different glioma cells at distances varying from 10 to 500 μm. These thin processes are not visible with usual bright field illumination and presumably for this reason were not seen before. These processes are very similar to the TMs previously described (Osswald et al 2015) and will be referred to in the same way. In our experiments a fluorescent image was acquired every minute, so that we could observe the dynamics of these TMs over time. In vitro TMs provide connections between distant glioma cells which remain stable for several hours even when the cells move and proliferate. TMs appear to be formed when glioma U87 cells divide. Similar structures are also observed in cultures of astrocytes, but in this case these thin and long structures are not stable and disappear in less than 10 minutes. Cultures of glioma U87 and of U251 cell lines exhibit also large and slow calcium transients during which the relative change of fluorescence ΔF/F could be 100 %. When glioma cells form tumorspheres, these calcium waves become less evident.
Osswald M et al. (2015) Brain tumour cells interconnect to a functional and resistant network. Nature. 528(7580):93-98.

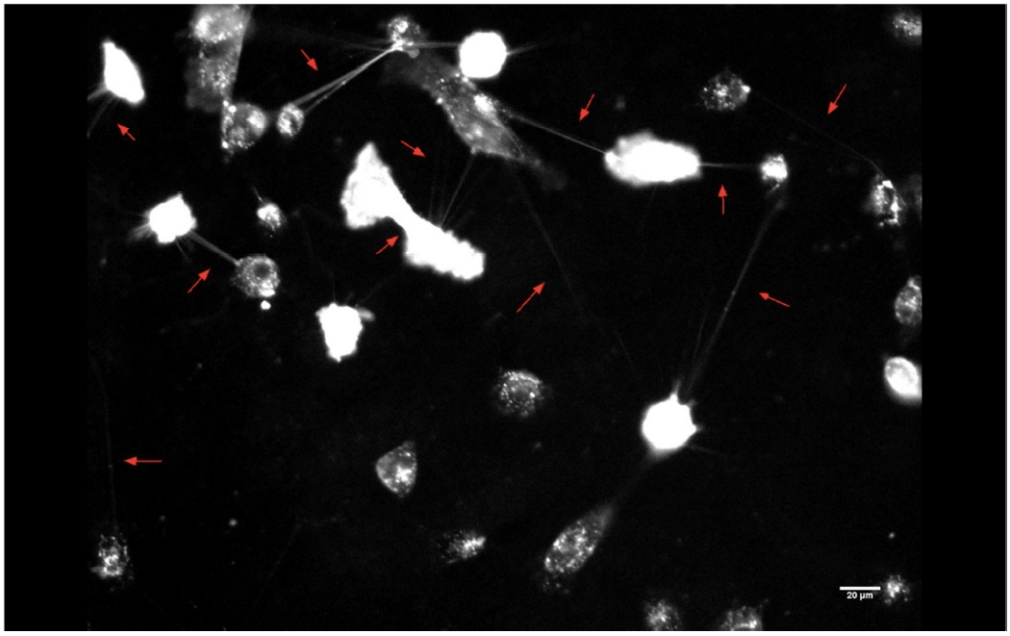

*Fig.1: A fluorescence image of a glioma U87 culture, stained with the membrane marker Vybrant DiI. Red arrows indicate TMs providing stable links between glioma cells. TMs are stable structures observed for several hours.*

**Title:** Inhibition of prostaglandin E2 receptor EP2 suppresses malignant gliomas

**Authors: J. QIU**[1,2], Q. LI[1], K. BELL[1], E. ZHANG[3], J. YU[3], Z. SHI[2], *J. JIANG[1]
[1]James L. Winkle Col. of Pharm., Univ. of Cincinnati, Cincinnati, OH; [2]Dept. of Cell Biol. and Inst. of Biomedicine, Jinan Univ. Col. of Life Sci. and Technol., Guangzhou, China; [3]Dept. of Intrnl. Med., Univ. of Cincinnati Col. of Med., Cincinnati, OH

**Abstract:** Glioma constitutes about 80% of all primary malignant brain tumors in humans, and 82% of these cases are classified as the WHO grade IV tumor - glioblastoma multiforme (GBM). Despite current combined treatment engaging surgical resection, chemotherapy and radiation therapy, the median survival of GBM patients is only about one year, with less than 3-5% of

patients surviving over five years. Malignant gliomas grow relentlessly and impinge on vital neural structures, leading to profound neurological impairments. As such, over 80% of glioma patients experience seizures during the course of their illness. Developing new therapeutics with adequate efficacy for this devastating brain condition and the associated comorbidity is an urgent unmet need. Cyclooxygenase-2 (COX-2) is commonly induced in gliomas, and its expression level is highly positively correlated with the tumor grade and mortality of human patients. Mounting evidence from animal and human studies suggests that the elevated COX-2 is a key driving force for glioma growth. However, COX-2 inhibitors in malignant glioma treatment has been limited due to their well-documented vascular toxicity and recent inconsistent outcomes from a number of population studies. It thus has been proposed that targeting the downstream prostanoid receptors might provide more specificity than blocking the entire COX cascade. As a major enzymatic product of COX-2, prostaglandin E2 ($PGE_2$) directly mediates inflammatory reactions during the pathogenesis of tumors and other chronic conditions, and facilitates the disease progression via its four G protein-coupled receptors (GPCRs) - EP1, EP2, EP3 and EP4. However, which type of EP receptor is involved in COX-2/$PGE_2$-mediated glioma growth remains largely unknown. Using a combination of pharmacological and genetic strategies, we show that the $PGE_2$ receptor EP2 is a dominant Gαs-coupled receptor that mediates COX-2/$PGE_2$-initiated cAMP signal pathways in human malignant glioma cells, such as LN229 and SF767, and is essentially involved in the proliferation, migration and invasion of these brain tumor cells *in vitro, in vivo* and *in situ*. Our results together suggest that $PGE_2$ signaling via EP2 receptor increases the malignant potential of human glioma cells and might represent a novel molecular target for malignant gliomas.

**Title:** Effects of serum-free media on the growth of astrocytoma in hydrogel and monolayer environments

**Authors: *M. P. JOGALEKAR**[1], E. E. SERRANO[2]
[1]Mol. Biol., [2]Biol., New Mexico State Univ., Las Cruces, NM

**Abstract:** Grade IV astrocytoma is a type of invasive primary malignant tumor. Preliminary work from our laboratory has shown that astrocytoma cells form distinct morphologies when cultured in different microenvironments - monolayer or hydrogel - in media supplemented with serum. This pilot study was designed to evaluate the growth of astrocytoma in serum-free conditions. To this end, we established the grade IV astrocytoma cell line, CCF-STTG1, in monolayer and in hydrogel (Geltrex$^{TM}$) using media containing either fetal calf serum, or serum-free media with growth factors. Phase contrast and epifluorescence microscopy of monolayer cultures showed that astrocytoma cells appeared dispersed and flattened in presence of serum, while the cells aggregated when cultured in serum-free media. In contrast, astrocytoma grown in hydrogel culture, with or without serum, formed compact cell clusters interconnected by strands of extended cells. Preliminary analysis suggests cell proliferation is augmented in serum-free medium as compared to cultures where media contain serum. These findings suggest that the combination of hydrogel and serum-free media with growth factors can provide a unique model for examining cancer progression in vitro. Future studies will continue to investigate different hydrogels for their potential to support astrocytoma cell growth in serum-free conditions.

**Title:** Reciprocal facilitation of proliferation and migration between Schwann cells and cancer cells through Adenosine A2B receptor

**Authors: *Y. YE**[1], E. SALVO[2]
[2]Bluestone Ctr. for Clin. Res., [1]New York Univ., New York, NY

**Abstract:** Neural invasion (NI) occurs in 85% of head and neck squamous cell carcinoma (HNSCC) cases. NI contributes to cancer pain and is a route for metastasis dissemination. Schwann cells have been recently shown to play an active role in facilitating neural invasion by cancer cells. Cancer microenvironment contains high levels of adenosine which is accumulated during cancer induced hypoxia, inflammation, and ischemia. Adenosine and its pro-inflammatory receptor A2B in cancer contribute to cancer growth and metastasis. We hypothesize that cancer derived adenosine stimulates Schwann cells to proliferate and migrate towards cancer through A2B receptor, and controlling A2B receptor on both cancer and

Schwann cells will inhibit cancer progression (*i.e.*, cancer growth and NI). Using an *in vitro* co-culture system, we demonstrate that Schwann cells (RSC96) and oral cancer cells (HSC-3) can reciprocally promote proliferation, migration, and invasion, which are critical cellular events that lead to NI. A2B receptors are expressed on both HSC-3 and RSC96 cells and treatment with the A2B receptor antagonist PSB603 significantly reduced RSC96 and HSC-3 cell proliferation and migration towards each other, whereas the A2B receptor agonist BAY60-6583 promoted cell proliferation in both cell lines. Together, these results suggest an important role of A2B receptors in Schwann cell interaction with oral cancer. Whether A2B receptor holds the key for NI *in vivo* needs to be determined.

**Authors: *A. G. DANIEL**[1], J. L. ROLAND[2], J. S. SHIMONY[3], E. C. LEUTHARDT[2,1]
[1]Biomed. Engin., Washington Univ. In St. Louis, Saint Louis, MO; [2]Neurolog. Surgery, [3]Mallinckrodt Inst. of Radiology, Washington Univ. Sch. of Med., Saint Louis, MO

**Abstract:** Despite advancements in neuro-oncology, glioblastoma, the most common primary brain tumor, has a median survival of 15 months with optimal surgical and medical treatment. This is related to the observation that microscopic tumor cells extend beyond the borders defined by gadolinium enhancement. The diffuse tumor extent leads to debate regarding the amount of tissue that should be resected to limit recurrence. Tissue that when resected leads to an overt deficit, termed eloquent, is a well-accepted limit. However, non-eloquent tissue beyond gadolinium enhanced borders may have variable tumor involvement. In addition, tumor infiltration may also be heterogeneous within these borders. Resting-state functional magnetic resonance imaging (rs-fMRI) can be used to identify language, sensory and motor cortex yet limited studies have evaluated rs-fMRI to assess tumor involvement. In this study, we evaluated the effects of glioblastoma on standard rs-fMRI connectivity measures between tumor and peri-tumor regions to distant areas in 6 patients. Distinct patterns emerged within these regions and their contralateral homologues. Inter-hemispheric correlations suggested persistence of functional connectivity despite tumor infiltration. These results indicate a potential role for rs-

fMRI to improve the delineation of areas associated with glioblastoma and functional tissue, which may better inform preoperative planning.

**Title:** BPM 31510, a clinical stage metabolic modulator, alters mitochondrial bioenergetics and resensitizes Temozolomide resistant glioma lines to TMZ induced cell death

**Authors: T. DADALI**, P. AWATE, S. MOGRE, A. DIERS, S. GESTA, V. K. VISHNUDAS, *K. THAPA, N. NARAIN, R. SARANGARAJAN
Berg, LLC, Framingham, MA

**Abstract:** Glioblastoma multiforme (GBM) is an aggressive malignancy with limited treatment options and high probability of acquiring chemoresistance. Upon acquisition of Temozolomide (TMZ) chemoresistance, glioma undergo mitochondrial electron transport chain (ETC) remodeling, correlating chemoresistance and alterations in metabolism at the mitochondrial level. BPM31510, a metabolic modulating agent in clinical trials for solid tumors and GBM, selectively targets and reprograms cancer cells to execute mitochondrial-dependent apoptosis. Here, we sought to investigate the mechanism of action of BPM31510 in TMZ chemo-sensitive and resistant glioma models. BPM31510 demonstrated anti-cancer activity in human GBM cell lines in vitro (U251-MG, U87-MG), and long-term survival was achieved in ~20% of BPM31510-treated rats bearing orthotopically implanted C6 glioma allografts, indicating efficacy in the chemo-sensitive/naïve setting. A model of acquired TMZ chemoresistance (TMZ-R) was then generated by progressive adaptation of parental U251-MG and U87-MG cells to incremental doses of TMZ. Treatment with BPM31510 decreased viability in TMZ-R U-251 and U-87 MG cell lines. In addition, combinational treatment with BPM31510 sensitized parental cells to TMZ, and importantly, resensitized TMZ-R cells to TMZ (250-1000 μM), indicating BPM31510 retains anti-cancer activity in a TMZ chemoresistant setting. Given the critical role of ETC remodeling in TMZ chemoresistance, we next examined the impact of BPM31510 treatment on mitochondrial respiration. As expected, alterations in mitochondrial respiration characterized by an increase in succinate (Complex II) and glycerol-3-phosphate (Complex III)-fueled respiration were observed in TMZ-R cells compared to parental controls. BPM31510 exposure (EC50) did not impact pyruvate/malate (Complex I) driven respiration in either parental of TMZ-R U251-MG. In contrast, BPM31510 consistently decreased succinate- and

glycerol-3-phosphate driven respiration in both parental and TMZ-R U251-MG, indicating that BPM31510 disrupts ETC Complex function dependent on a functional Q-pool and that TMZ-dependent ETC remodeling remains sensitive to BPM31510. Together this data demonstrate that BPM31510, by altering Q-pool dependent mitochondrial function, may provide a potential therapeutic strategy to treat GBM in both chemosensitive and resistant settings.

**Abstract:** Some of the most potent treatments for cancers have been antibodies to cell surface proteins that cause tumor cell proliferation. Examples are cetuximab (antigen: EGFR) approved for colorectal cancer and Trastuzumab (ERBB2) for breast cancer. These antibodies have more than one effect on the cancer cell, but one of the most important is that, upon binding to the cell surface antigen, the complex is internalized by so-called antibody mediated internalization. As such, the mitogenic cell surface protein no longer plays a role in cancer cell division. Despite the blood brain barrier challenging systemic treatment for brain tumors, intracerebroventricular injection can produce similar results. For example, Gholamin *et al*., (Sci Transl Med 9:381, 2017) and Kang *et al.* (Sci Rep 6:34922, 2016) reported down-regulation of brain tumor mitogenic agents through antibody-mediated endocytosis. The quick and efficient screening of antibodies that internalize effectively is vital for determining suitability of an antibody as a therapeutic targeting agent. Here we describe a method for the efficient determination of internalization of cell surface molecules by antibodies using a pH-dependent fluorescent reporter cross-linked to a secondary antibody in a plate-based assay with visualization of internalization in hours. This conjugate is comprised of an affinity-purified monovalent secondary antibody against both the heavy and light chain of human or mouse IgG and is conjugated to a pH - dependent fluorescent reporter. The fluorescence from this reporter increases intensity as the pH of its surroundings becomes more acidic, as evident when exposed to the environment inside a cell (thereby providing evidence of internalization). A successful assay protocol has been developed to provide an $EC_{50}$ by way of a fluorescence-detecting plate reader, which could be used to explore antibody candidates as therapeutics in a quick and reproducible manner.

**Abstract:** Most known for their essential roles in the development and maintenance of the nervous system, the neurotrophins consist of nerve growth factor (NGF), brain derived neurotrophic factor (BDNF), NT-3, NT-4 and their respective tropomyosin receptor kinases (Trks) TrkA, TrkB, and TrkC along with the low affinity nerve growth factor receptor, p75. In addition to their roles in neuronal survival, proliferation, differentiation, and apoptosis, Trks exert diverse effects on cellular outcomes through their interactions with ion channels, G-protein coupled receptors (GPCRs), and activation of downstream signaling cascades such as extracellular related kinase (ERK) and phosphatidylinositol-3 kinase (PI3K). Prior to Trks' established roles in neurobiology, oncogenic Trk was discovered as tropomyosin 3 (TPM3)-TrkA fusion and as a result, oncological studies of the neurotrophin family have since embarked on the quest for identifying additional Trk fusions. Putative oncogenic Trk fusions have been observed in various cancer types, but their clinical significance remains unclear and these fusions tend to occur at very low frequencies below 1-2%. The low incidence of these fusions combined with significant overexpression of various Trks in a multitude of cancers raises the complex possibility that another aspect of Trk biology, aside from kinase-domain fusions, may be at play. Basic scientific and clinical investigation surrounding Trks' role in cancer has been hindered due to the nonspecific nature of antibodies and kinase inhibitors, combined with a lack of precise exon-specific expression data from patient populations. Alterations in RNA splicing are being appreciated for their contributions to cancer, and as TRK genes have multiple splice variants, we sought to investigate exon-specific expression of neurotrophin receptors in human gliomas via RNA-Seq data obtained from The Cancer Genome Atlas (TCGA). We have created an antibody specific to an alternatively spliced NTRK2 variant and have used it to detect protein expression in human gliomas. Forced expression of this neurotrophic receptor splice variant in mouse models contributes to the formation of gliomas and other tumors, within and outside the central nervous system, highlighting the potential role for alternative splicing of neurotrophin receptors in oncogenesis.

**Abstract:** Glioblastoma mutiforme (GBM) is the most prevalent, aggressive brain cancer, characterized by necrosis surrounding the brain area. Current palliative therapies available are surgical treatment, radiation therapy, and chemotherapy, but these treatments are unable to stop completely the progression of this disease, so alternative therapies are needed. Curcumin (Cur), a natural polyphenol, has potent anti-cancer effects against several cancers. It is a potent inhibitor for tumor growth and possesses promising pro-apoptotic activities. Unfortunately, its poor solubility and rapid degradation make it less attractive for GBM therapy. Recently, we have shown that solid lipid curcumin particles (SLCPs) have greater bioavailability and brain tissue penetration than observed with administration of dietary Cur. The present study characterizes the comparative cell viability, cell death, and DNA fragmentation in culture human GBM cells (U87MG) after treatment with different dose and duration of either dietary Cur or SLCPs. We have investigated cell viability by MTT assay, mode of cell death by annexin-V staining, DNA fragmentation by TUNEL staining, and single cell gel electrophoresis (Comet assay), and also nuclear morphology by propidium iodide following administration of 25 μM dietary Cur or SLCPs for 24-, 48-, and 72-h. We observed that SLCPs showed significantly less cell viability, greater cell death, and DNA fragmentation in comparison to dietary Cur. Further, our comet analysis revealed longer DNA tails and more number of fragmented nuclear lobes when SLCP was used, in comparison to dietary Cur. Taken together, our *in vitro* work suggests that use of SLCPs may be a promising strategy for reversing or preventing GBM growth and differentiation, as compared to using dietary Cur *in vitro*. **Keywords:** Glioblastoma mutiforme, curucmin, apoptosis, DNA fragmentation, comet assay, TUNEL staining, cell death

**Title:** Enhanced peritumoral hyperexcitability in a pediatric glioma model: The role of KCC2

**Authors: *S. L. CAMPBELL**[1], A. NYITRAY[3], L. CHAUNSALI[2], H. SONTHEIMER[4]
[1]Virginia Tech. Carilion Res. Inst., [2]Virginia Tech. Carilion Res. Inst., Roanoke, VA; [3]Virginia Tech. Carilion Sch. of Med., Roanoke, VA; [4]Sch. of Med. and Res. Inst., Virginia Tech. Sch. of Neurosci., Roanoke, VA

**Abstract:** Pediatric high-grade gliomas are highly aggressive brain tumors with high mortality and morbidity. High-grade gliomas are less frequent in children and widely understudied. When gliomas occur in the cortex of pediatric patients, they often present with seizures, called tumor-associated seizures. We previously showed that in vivo implantation of adult patient-derived tumors with high expression of cystine/glutamate transporter system xc (-) (SXC) induced seizures and displayed peritumoral hyperexcitability in adult animals. In addition we found that GABAergic disinhibition contributed to the disease pathophysiology where peritumoral neurons exhibited elevated intracellular Cl(-) concentration and consequently depolarizing, excitatory gamma-aminobutyric acid (GABA) responses. In these adult neurons, the plasmalemmal expression of KCC2- a potassium-chloride transporter, which establishes the low Cl(-) concentration required for GABA receptor-mediated inhibition, was significantly decreased. KCC2 expression is developmentally regulated and causes Cl(-) to be depolarizing early in development. It is unknown whether the expression of KCC2 is altered in pediatric glioma and contributes to peritumoral hyperexcitability. Changes in Cl(-) homeostasis in the developing brain could affect therapeutic strategies to treat tumor-associated seizures in younger patients. The objective of this study is to determine if glioma induces changes in KCC2 expression early in development and if those changes affect peritumoral hyperexcitability. Electrophysiological recordings from pups implanted with pediatric glioma cells revealed that peritumoral neurons are hyperexcitability. Pediatric peritumoral neurons displayed spontaneous epileptiform events and decreased action potential (AP) threshold. Compared to sham controls, peritumoral neurons also fired more action potentials and displayed a depolarization block in response to small current

injections. The mRNA (SLC7A11) and protein level of SXC was lower in our pediatric glioma cells compared to adults. There was also a decrease in KCC2 expression in the pediatric peritumoral cortex compared to sham controls. Together our data suggest that a high expression of SXC on pediatric glioma cells is not required for pediatric peritumoral hyperexcitability. Furthermore, the effect of the decrease in KCC2 expression is dependent on the excitatory state of GABA, inhibitory or excitatory, therefore more studies are warranted to determine the contribution of KCC2 to pediatric peritumoral hyperexcitability.

**Title:** VEGFR1 and VEGFR2 in Alzheimer’s disease and vascular dementia

**Authors: *R. HARRIS**, S. MINERS, S. ALLEN, S. LOVE
Univ. of Bristol, Bristol, United Kingdom

**Abstract:** Brain ischaemia is the defining pathological process in vascular dementia (VaD); however, cerebral blood flow is also reduced in Alzheimer’s disease (AD) and there is evidence that the hypoperfusion contributes to tissue damage. Vascular endothelial growth factor-A (VEGF) is a pro-angiogenic factor expressed in response to tissue hypoxia. VEGF receptor 2 (VEGFR2) mediates the actions of VEGF on endothelial cells leading to the formation of blood vessels. VEGF receptor 1 (VEGFR1) has limited kinase activity and its soluble form (sVEGFR1) acts as a negative regulator of VEGF. We previously reported that increased VEGF protein in AD was not associated with an increase in microvessel density. Aβ42 was shown to bind to VEGFR2 and block signalling in vitro providing a possible mechanism for reduced angiogenesis; however, there are no studies of VEGFR1 or VEGFR2 in AD brain. We have investigated the expression of these receptor proteins in parietal cortex and white matter in AD, VaD and controls, and related this to VEGF, microvessel density and Aβ levels.Samples of medial parietal cortex and white matter were dissected from 49 AD, 19 VaD and 37 control brains from the South West Dementia Brain Bank, UK. Total VEGFR1 was measured by dot blot. VEGFR1 subtypes were measured by western blot. Total VEGFR2, VEGF and von Willebrand factor

(VWF, a marker of microvessel density) were measured by ELISA. Aβ40 and Aβ42 had previously been measured in parietal cortex from the same brains. Human brain microvascular endothelial cells (HBMECs) were used to investigate VEGFR signalling. Total VEGFR1 levels were reduced in AD compared to control though an increase in the level of sVEGFR1 was observed in AD. VEGFR2 level was similar in the three groups, as was VWF level, in agreement with previous data. VEGFR2 level positively correlated with both VEGF and VWF. It also correlated positively with soluble Aβ40 but not Aβ42. Elevated VEGF fails to increase microvessel density in AD despite normal VEGFR2 level. This suggests that VEGFR2 signalling is defective in AD. In combination with an increased proportion of a negative regulator of VEGF, this may contribute to reduced angiogenesis observed in AD. Further research using is needed to elucidate the underlying mechanisms.

**Title:** Role of Unc5c, an Alzheimer’s risk gene in late-onset Alzheimer’s Disease in a novel mouse model

**Authors: *D. KARUNAKARAN**[1], R. J. VASSAR[1], R. J. WATTS[2,3], J. K. ATWAL[2]
[1]Northwestern Univ., Chicago, IL; [2]Dept. of Neurosci., Genentech, South San Francisco, CA; [3]Denali Therapeut. Inc., South San Francisco, CA

**Abstract:** Alzheimer’s disease (AD) is characterized by amyloid plaques, neurofibrillary tangles, and synaptic and neuronal loss. Recently, a rare autosomal dominant coding mutation, T835M, was discovered in the Un-coordinated 5c (*UNC5C*) netrin receptor gene that segregated with late-onset AD (LOAD). T835M alters a conserved amino acid in the hinge region of the UNC5C death domain, suggesting the mutation may increase apoptosis. Interestingly, *UNC5C* rare coding mutations near amino acid 835 (T837K, S843G, Q860H) have also been found associated with AD, suggesting that this region of UNC5C is critical for AD risk and pathogenesis. Indeed, in primary hippocampal neurons, overexpression of UNC5C T835M increased cell death in response to neurotoxic stimuli including beta-amyloid (Aβ). These results suggest a mechanism by which UNC5C T835M may confer increased risk of LOAD, however the effects of this mutation in an AD animal model have not yet been explored. Toward this end, we generated a mouse knock-in (KI) model of Unc5c T835M and crossed it with the 5XFAD mouse model of

amyloid pathology and neuron loss. Our preliminary results in mice suggest that UNC5C T835M promotes neuron loss in the presence of Aβ pathology. We hypothesize that the UNC5C T835M mutation predisposes to LOAD by exacerbating neuronal death, as observed in the 5XFAD brain, via increased sensitivity to Aβ-induced neurotoxicity and UNC5C death domain activation. We are further investigating mechanisms of cell death and distal phenotypes in 5XFAD; Unc5c T835M KI mice by biochemical, cellular, and behavioral approaches. Although neuron loss is a cardinal feature of AD, the molecular mechanism of cell death in AD is still unclear. We expect our results to provide valuable insight into the role of UNC5C T835M mutation in Aβ- and Tau-associated cell death, and thereby identify novel therapeutic targets to prevent neuron loss in AD.

**Title:** Dysregulation of protein prenylation in aging and Alzheimer’s Disease

**Authors: *A. JEONG**[1], M. DISTEFANO[2], D. A. BENNETT[4], G. WOOD[3], L. LI[1]
[1]Exptl. and Clin. Pharmacol., [2]Chem., [3]Pharmacol., Univ. of Minnesota-Twin Cities, Minneapolis, MN; [4]Rush Alzheimer's Dis. Center, Rush Univ., Chicago, IL

**Abstract:** Alzheimer’s disease (AD) is the leading cause of age-related dementia, and the 6th leading cause of death in the U.S. Despite its prevalence, the pathogenesis of AD is not fully understood. Emerging evidence suggests that protein prenylation, an important posttranslational modification, may be dysregulated in aging, contributing to the development of AD. Many proteins, including the Ras superfamily of small GTPases, undergo prenylation catalyzed by farnesyl transferase (FT) and geranylgeranyl transferases (GGT-1 and GGT-2). These small GTPases are involved in regulating diverse cellular processes. Recent findings have shown that the levels of isoprenoids are increased in the brain of AD patients. Animal studies also showed elevated isoprenoids in aged mouse brains. In addition, genetic downregulation of protein

prenylation reduces amyloid pathology and neuroinflammation in a transgenic mouse model of AD. This study aims to determine the dynamic changes of prenylated proteins in human brains and their association with aging and AD pathology. For the aging study, postmortem frozen frontal cortical tissues (BA46/BA9) from cognitively normal individuals across the lifespan were obtained via the NIH NeuroBioBank. For the AD study, postmortem frozen tissues from the dorsolateral prefrontal cortex were obtained from the Religious Orders Study, which included age- and sex-matched human subjects with a spectrum of cognitive function from individuals with no cognitive impairment (NCI), mild cognitive impairment (MCI), to AD dementia. The brain tissue samples were subjected to subcellular fractionation and immunoblotting analysis. We found that compared to the young age group (20-29 years), the levels of FT were increased in both the middle age group (50-59 years) and the old age group (74-91 years), whereas the levels of GGT-1 were only increased in the old age group. In the brain of individuals with AD dementia, only the levels of FT, but not GGT-1, were increased. Consistent with the upregulation of FT in AD dementia, we found a significant increase in membrane-associated (farnesylated) H-Ras in the brains from individuals with MCI and AD dementia compared to age- and sex-matched individuals with NCI. Further, the levels of farnesylated H-Ras correlate with the tangle pathology in the brain. These findings suggest that protein prenylation is upregulated in the brain during aging, and in particular, abnormal upregulation in protein farnesylation may contribute to the pathogenic process of AD dementia.

**Title:** Neurons are not postmitotic: DNA replication, mitotic entry and initiation of cell division amidst canonical mitotic checkpoint regulation

**Authors: *C. C. WALTON**, I. PATIÑO-PARRADO, E. BARRIO-ALONSO, J. M. FRADE
Cajal Institute, CSIC, Madrid, Spain

**Abstract:** Neurons are the paradigmatic postmitotic cell. Indeed, after several years of work, we have never found any trace of cell cycle activity in cultured NeuN+/MAP2+ neurons. However, there is evidence of cell-cycle re-entry in Alzheimer’s disease. Here we show that the canonic cell cycle checkpoints are active in NeuN+/MAP2+ neurons and that their suppression results in a functional cell-cycle. Ectopic expression of endogenous cell cycle regulators in mouse hippocampal neurons maintained in culture for 16-17 days (i.e. at postsynaptogenesis stages of

development) induced BrdU incorporation in 48%, 58%, and 33% of neurons at, respectively, 24, 36, and 48 hours post transfection (hpt). The decline of BrdU incorporation observed at 48 hpt coincided with cell death, likely triggered by the mitotic DNA damage response (DDR) since widespread DNA double strand breaks (DBS) were present in transfected neurons, as assessed by Histone H2AX phosphorylation. Indeed, inhibition of the apoptotic DBS branch with a dominant-negative form of p53 dramatically reduced the proportion of active caspase-3-positive neurons. After apoptosis rescue, 41%, 59% and 61% of neurons incorporated BrdU at 24, 48, and 72 hpt respectively, and neurons progressed into G2 phase (G2). At 36 hpt, 46% of neurons were in late G2, as evidenced by the presence of phosphoHistone H3 (pH3) specific foci, suggesting the G2/M checkpoint prevents M-phase (M) entry of neurons with DNA damage. Abrogation of this checkpoint with MK1775, a Wee1 inhibitor, increased neurons in M from 2% to 31% as assessed by nuclear pH3 staining. Based on chromatin morphology and pH3 staining, 23% of transfected neurons were in prophase, 4% in prometaphase and 4% in metaphase. Prometaphase onset was further confirmed by anillin staining, which shifts from the nucleus to the cell cortex in this stage. The spindle assembly checkpoint (SAC), which arrests cells at metaphase and prevents anaphase and cytokinesis onset (cell division), appears to be also present in neurons. By overcoming the SAC with the Mps1 inhibitor AZ3146 we found neurons attempting division joined by a nucleoplasmic bridge with chromatin stretching between two nuclei. Midbody formation, the last stage of cytokinesis before abscission, was confirmed with anillin staining. In corollary, insofar it affords efficient mitotic checkpoints, we propose that the proper assembly of mitotic machinery is what renders neurons apparently postmitotic, a status that may be applicable to other postmitotic cells. Finally, to the degree in which mitotic machinery can be efficiently manipulated, one may consider the possibility of postmitotic tissue regeneration.

**Title:** Fus1 KO mice as new model for sAD: Dysfunction of the electron transport chain and compensatory enhanced blood volume responses in the olfactory bulb

**Authors: *G. CORONAS-SAMANO**[1], K. L. BAKER[1,2], A. GUMASTE[1,2], W. J. T. TAN[3], A. V. IVANOVA[3], J. V. VERHAGEN[1,2]
[1]The John B. Pierce Lab., New Haven, CT; [2]Neurosci., [3]Surgery, Yale Sch. of Med., New Haven, CT

**Abstract:** Aging is a complex biological process in humans characterized by a progressive impairment of sensory function, motor skills and cognition over time. Mitochondrial dysfunction has been proposed to play a critical role in the aging process via oxidative stress, energy deficiency and calcium dysregulation. Mitochondrial dysfunction also has been implicated in age-related neurodegenerative diseases such as sporadic Alzheimer's disease (sAD). Fus1/Tusc2 is a mitochondrial tumor suppressor protein regulating numerous mitochondrial activities. Knockout of Fus1 in mice (Fus1 KO) results in mitochondrial dysfunction, chronic inflammation, and premature aging. Our *in silico* analysis showed that Fus1 levels are significantly decreased in aging brains and further decreased in the brains of AD patients, thus strongly suggesting a link between Fus1 and sAD. Genes co-expressed with Fus1 are involved in mitochondrial respiration and neurodegenerative diseases including AD. Our analysis of mitochondrial respiration in WT and Fus1 KO embryonic fibroblasts and epithelial cells using high resolution respirometry (Oxygraph-2k) showed significantly lower respiratory reserve capacities in both types of KO cells suggesting an intrinsic defect in the ability of their mitochondria to produce additional ATP in response to increased energy demands. Our recent RNA microarray analysis of hippocampi and olfactory bulbs (OB) from 7 m.o. Fus1 KO mice showed significant alterations in Alzheimer's-associated processes and pathways. We have previously demonstrated that 4 months old Fus1 KO female mice have increased oxidative stress, disrupted metabolic homeostasis, autophagy, PKC and calcium signaling in the hippocampus and/or OB. Behaviorally they performed poorly in the hidden cookie task and the Morris water maze. Given that loss of odor identification is an early marker for sAD and that we found deficits in odor-guided behavior in Fus1 KO mice, we performed intrinsic optical imaging of odor-induced blood volume responses at hemoglobin's isosbestic wavelength (565nm). We found a ~76% increase in peak blood volume response in KO mice over WT ($P<0.001$) in large and small dorsal blood vessels. These findings support the hypothesis that mitochondrial dysfunction in Fus1 KO mice negatively affects energy homeostasis, the physiology and function of the olfactory bulb, and other functions that parallels sAD. Thus, the Fus1 KO mouse is a useful model for studying aging and aging-associated disorders such as sAD characterized by learning and memory decline and impaired mitochondrial activities.

**Abstract:** Delta-secretase, a lysosomal asparagine endopeptidase (AEP), simultaneously cleaves both APP and Tau, controlling the onset of pathogenesis of Alzheimer’s disease (AD). However, how this protease is post-translationally regulated remains unclear. Here we report that Serine-arginine protein kinase 2 (SRPK2), a kinase phosphorylating serine/arginine (SR) domain-containing proteins involved in pre-mRNA splicing machinery, phosphorylates delta-secretase and enhances its enzymatic activity. SRPK2 phosphorylates the serine 226 residue on delta-secretase and accelerates its autocatalytic cleavage, leading to its cytoplasmic translocation and escalation of enzymatic activities. Delta-secretase is highly phosphorylated in human AD brains, tightly correlated with strong SRPK2 activity. Overexpression of phosphorylation mimetic (S226D) in young 3XTg mice strongly promoted APP and Tau fragmentation, and facilitated amyloid plaque deposits and neurofibrillary tangles (NFT) formation, resulting in cognitive impairment. Conversely, viral injection of the non-phosphorylatable mutant (S226A) into 5XFAD mice, an aggressive model of AD, resulted in decreased APP and Tau proteolytic cleavage and attenuated AD pathologies, and a reversal of cognitive defects. Our findings support that delta-secretase phosphorylation by SRPK2 plays a critical role in regulating this crucial protease, aggravating AD pathogenesis.

**Title:** Amyloid beta-induced alterations in basal forebrain cholinergic intrinsic excitability are sub-region specific

**Authors: *A. A. GEORGE**[1], H. A. BIMONTE-NELSON[3], R. J. LUKAS[4], P. WHITEAKER[2]
[1]Neurobio., [2]Div. Neurobiol, Barrow Neurolog. Inst., Phoenix, AZ; [3]Arizona State Univ., Tempe, AZ; [4]Barrow Neurol Inst., Phoenix, AZ

**Abstract:** Alzheimer's disease (AD), a progressive neurodegenerative disorder, is one of the most common causes of mental deterioration in the elderly. Hallmarks of AD pathology include alterations in brain regions associated with higher cognitive functions. Several studies have correlated the severity of cognitive decline in AD with a loss of basal forebrain cholinergic neurons (BFCNs). Mechanisms underlying cholinergic neurodegeneration and subsequent memory impairments remain unknown. However, interactions between amyloid-β (Aβ), a suspected etiopathogenic agent in AD, with a nicotinic acetylcholine receptor subtype containing α7 subunits (α7*-nAChR) trigger hippocampal pyramidal neuronal homeostatic instability. Recently, a nAChR subtype containing α7 and β2 subunits has been identified on BFCNs. These heteromeric α7β2-nAChRs have different pharmacological properties from those of homomeric α7-nAChRs and are highly sensitive to functional inhibition by Aβ. Toward understanding the roles played by α7β2-nAChRs in BFCN function we used organotypic basal forebrain slice cultures and whole-cell patch clamp electrophysiology to investigate Aβ-induced alterations in BFCN intrinsic excitability. Whole-cell current clamp recordings were taken from cholinergic neurons within the medial septal-diagonal band (MSDB), the horizontal diagonal band (HDB), and the nucleus basalis (NB). We demonstrate that chronic incubation (9 days) with oligomeric or fibrillar forms of $A\beta_{1\text{-}42}$ increases MSDB and HDB cholinergic action potential firing rates (mean increase of 64 ± 8% and 25 ± 3.5%, respectively). Additionally, the magnitude of the medium afterhyperpolarization (mAHP) phase following spike generation (mean reduction of 44 ± 6.5% and 15 ± 2.5%, respectively) was lower when compared to control conditions (scrambled version of $A\beta_{1\text{-}42}$). No significant changes in action potential firing rates or mAHP magnitudes were observed in cholinergic neurons within the NB following chronic Aβ administration. Using nAChR β2 subunit knockout mice, we demonstrate normalization of Aβ-induced alterations in firing rate and mAHP of BFCNs within the MSDB. These preliminary findings suggest that

specific forms of $A\beta_{1-42}$ alter cholinergic intrinsic excitability by interacting with β2-containing nAChR subtypes. These interactions may be uniquely specific to certain cholinergic circuits within the basal forebrain and suggest novel and potentially productive therapeutic strategies to combat neurodegeneration in a brain region affected early in AD. This work was supported by the Arizona Biomedical Research Commission (AAG) and the Barrow Neurological Foundation (AAG).

**Abstract:** Despite the presence of Lewy bodies in more than half of Alzheimer's disease (AD) cases, the functional role of α-synuclein (αSyn) in AD remains unclear. Here we report that genetic regulation of wild-type αSyn expression modulates several key components of the phenotype displayed by APP transgenic mice, including survival, pathology and cognitive deficits. Overexpression of human αSyn had no bearing on premature mortality and led to a marked reduction in amyloid deposition. Counter-intuitively, deficits in spatial memory were exacerbated in young bigenic animals. By contrast, ablating *SNCA* in APP mice abolished early mortality, increased plaque burden and improved memory retention. To demonstrate the translational impact of these results, we will lower αSyn expression using antisense oligonucleotides in APP mice and determine whether cognitive deficits are alleviated. Altogether, this complementary, bidirectional genetic evidence suggests that αSyn may be an intrinsic component of AD and a novel therapeutic target.

**Title:** Allosteric BACE inhibition by Deformable Nanovesicle-delivered sAPPα *In vitro* and *In vivo*

**Authors: *J. J. CAMPAGNA**, A. IVANOVA, P. SPILMAN, H. GALLO, D. BAI, V. JOHN
Neurol., UCLA, Los Angeles, CA

**Abstract: Background.** A hallmark of Alzheimer's disease (AD) brain tissue is the presence of plaques largely composed of amyloid-β (Aβ) peptide. Aβ is derived by BACE1 cleavage of amyloid precursor protein (APP) to generate soluble APPβ (sAPPβ) and the β C-terminal fragment (βCTF), followed by cleavage of βCTF by γ-secretase to produce Aβ. Alternatively, APP is cleaved by ADAM10 to produce soluble APPα (sAPPα) and the α C-terminal fragment (αCTF). We recently reported that sAPPα acts an as endogenous inhibitor of BACE activity and that the mechanism is likely allosteric, that is, sAPPα interacts with an 'exosite' site remote from the catalytic dyad to exert its effect (Libeu et. al., JAD, 2015). BACE inhibition as a target for new AD therapeutic development is still of interest, and allosteric inhibition is appealing since it has the potential to be both substrate- (APP) and enzyme- (BACE) selective. Therefore, sAPPα - or a small molecule mimetic - may be a potential therapeutic for AD that has a lower risk of undesirable off-target effects due to its selectivity. Since sAPPα is a large protein and subject to proteolysis, we encapsulated it in deformable nanovesicles (DNVs) to increase the likelihood of brain delivery. This gave us an opportunity to perform proof-of-concept *in vivo* studies of allosteric BACE inhibition and to ascertain sAPPα's potential as a therapeutic.
**Methods.** Recombinant human sAPPα (hsAPPα) was encapsulated in DNVs (DNV-hsAPPα) using a microfluidic reactor-based method we recently developed (Subbiah et. al., J. of Drug Delivery 2017). DNV-hsAPPα ability to lower sAPPβ and Aβ levels was first assessed *in vitro* in Chinese Hamster Ovary cells stably transfected with huAPP (CHO-7W). We next treated human iPSC-derived neurons with DNV-hsAPPα to determine dendritic outgrowth and sAPPβ levels; used a Caco-2 cell permeability assay of both free- and DNV-hsAPPα to predict BBB penetrance; and then confirmed brain permeability in a pharmacokinetic (PK) study by injecting wildtype mice and rats with DNV-hsAPPα intravenously (IV). AlphaLISAs (Perkin-Elmer) specific for human sAPPα, sAPPβ, and Aβ were used for all studies.
**Results.** DNV-hsAPPα reduced sAPPβ and Aβ in both CHO-7W cells and human iPSC-derived neurons. Compared to free hsAPPα, DNV-hsAPPα showed greater Caco-2 cell permeability, and

we were able to detect husAPPα in rodent brain after IV DNV-hsAPPα delivery.
**Conclusions.** Encapsulation of hsAPPα in DNVs is an efficient way to deliver hsAPPα in rodent AD models and to conduct proof-of-concept testing of allosteric inhibition of BACE *in vivo*. These studies could enable development of DNV-hsAPPα as a potential promising new therapeutic approach for AD.

**Title:** Neurofilament light chain is increased in induced pluripotent stem cell-derived three dimensional neurons from Alzheimer patients

**Authors: W. XIA**[1], M. CHEN[2], *T. D. STEIN[3]
[1]Dept. of Pharmacol. & Exptl. Therapeut., Boston Univ. Sch. of Med., Boston, MA; [2]Geriatric Res. Educ. and Clin. Ctr. (GRECC), ENR Mem. Veterans Hospital, Bedford, MA, Bedford, MA; [3]Boston VA Med. Ctr., Boston, MA

**Abstract:** Mass Spectrometry (MS)-based analysis of human tissue from peripheral and central nervous system has contributed to our current understanding of the relationship between blood and brain proteins in Alzheimer disease (AD) patients. We have collected peripheral blood mononuclear cells (PBMC) from AD patients and control subjects, converted PBMC to induced pluripotent stem cell (iPSC) lines, and further differentiated iPSC into human three-dimensional (3D) neurons. At autopsy, postmortem brain tissue specimens from AD subjects were collected. Liquid chromatography/MS was used to analyze 3D neurons labelled with isobaric mass tags for relative protein quantification. Our study revealed a group of differentially expressed proteins that are associated with AD, including those proteins involved in modulating γ-secretase activity for Aβ generation. Importantly, our unbiased proteomic profiling showed a specific increase of neurofilament light chain in 3D neurons derived from AD subjects compared to controls. Previous reports from others have shown that neurofilament light chain was increased in cerebrospinal fluid (CSF) and blood of patients with AD, dementia with Lewy bodies, idiopathic Parkinson’s disease, multiple system atrophy, progressive supranuclear palsy, or corticobasal

syndrome. Exploration of tauopathy was carried out in 3D neurons by quantification of total tau and phosphorylated tau at residue 181 and 231 using phosphor-tau specific ELISAs. We found that phosphorylation of tau protein was altered among those iPSC-derived 3D neurons from AD patients. In conclusion, our 3D neuronal culture provides an in vitro platform to mimic the brain environment. Similar to findings in human blood and CSF, the detection of neurofilament light chain increased in AD neurons illustrates its physiological relevance in AD pathogenesis.

**Title:** Proteolytic cleavage modulates TREM2 function and regulates gene expression for microglia lineage

**Authors: *J. SIMA**
NIA/NIH, Baltimore, MD

**Abstract:** Triggering receptor expressed on myeloid cells-2 (TREM2) variants have been shown to be linked to late onset Alzheimer disease (AD) and its proteolytic cleavage is also implicated for its function in AD. However, the molecular features of TREM2 cleavage in microglia remain unclear. Here, found that the c- terminal fraction (CTF) of TREM2 had two isoforms and each sequence was determined by Edman sequencing. Furthermore, we found that a small fraction of TREM2 CTF entered into nucleus. Overexpression of TREM CTF affected the morphology both in primary mouse microglia and in microglia cell lines. Next, we found several genes involved in cell lineage determination were regulated by TREM2 CTF in cell culture. Currently, we are analyzing the mechanism of nuclear TREM2 on the gene regulation and microglia morphogenesis. Overall, our findings imply a new function of TREM2 on gene regulation in microglia.

**Abstract:** Epigenetic proteins including histone deacetylases (HDACs) and sirtuins (SIRTs) are dysregulated in the entorhinal and parietal cortices in Alzheimer’s disease (AD). Whether alterations in HDAC and SIRT protein levels occur in the frontal cortex and are associated with pathological and cognitive changes during AD progression remains unknown. Here we performed quantitative western blotting to examine alterations in HDACs 1-4, 6, and SIRT1 in frozen frontal cortex tissue obtained from subjects who died with a premortem clinical diagnosis of no cognitive impairment (NCI, n=14), mild cognitive impairment (MCI, n=13), mild/moderate AD (mAD, n=13) and severe AD (n=8, sAD) from the Rush Religious Orders Study (RROS) and the Rush ADC, respectively. Groups were matched by age, gender, and postmortem interval. Western blot analysis revealed a significant increase in levels of HDAC1 and HDAC3 proteins in the frontal cortex of MCI (HDAC1, $p<0.001$; HDAC3, $p=0.02$) and mAD (HDAC1, $p<0.001$), with a decrease in HDAC1 ($p=0.05$) and HDAC3 ($p=0.04$) in sAD compared to NCI subjects. HDAC2 levels remained stable ($p=0.62$) across clinical groups. HDAC4 levels were significantly increased in MCI ($p<0.001$) and mAD ($p=0.04$) compared to NCI, and did not change significantly in sAD compared to control levels. HDAC6 levels increased across disease progression (NCI<MCI, $p=0.01$; NCI, mAD<sAD, $p<0.001$), while SIRT1 decreased significantly in MCI ($p=0.03$), mAD ($p<0.001$), and sAD ($p<0.001$) compared to NCI subjects. HDAC1 was negatively correlated with perceptual speed ($r=-0.45$, $p<0.05$), while levels of SIRT1 were positively correlated with perceptual speed ($r=0.61$, $p<0.001$), episodic memory ($r=0.36$, $p<0.05$), global cognitive score ($r=0.40$, $p<0.05$), and mini-mental state examination ($r=0.37$, $p<0.05$). There was a positive correlation between frontal cortex neurofibrillary tangle (NFT) counts and HDAC1 ($r= 0.37$, $p=0.02$), while SIRT1 levels were negatively correlated (r=-

0.31, p=0.05) with these lesions. These results indicate that specific HDAC protein levels are altered in the frontal cortex of prodromal AD and may contribute to cortical genomic and cellular instability during disease progression.

**Title:** Fluorogenic probes to monitor cytosolic phospholipase $A_2$ activity

**Authors: *C.-M. LOW**[1], C. NG[3], T. KWOK[3], F. TAN[2], Y. LAM[3]
[2]Anaesthesia, [1]Yong Loo Lin Sch. of Med., Singapore, Singapore; [3]Chem., Natl. Univ. of Singapore, Singapore, Singapore

**Abstract:** Arachidonic acid (AA) is a precursor of a family of lipid mediators, including prostaglandins, that regulates a wide variety of physiological responses and disease pathogenesis. The biosynthesis of AA occurs mainly through the activation of phospholipase A2 (PLA2) which catalyzes the hydrolysis of the sn-2 ester bond of glycerophospholipids to release AA. Mammalian cells have diverse forms of PLA2 including the secreted small molecular weight sPLA2, the larger cytosolic Ca2+-dependent cPLA2 and Ca2+-independent iPLA2. Although sPLA2 could participate in the release of arachidonate during injury, the main gatekeeper for the enzymatic conversion of arachidonate is cPLA2. Given that cPLA2 is an ubiquitous enzyme which is highly selective for glycerophospholipids containing AA, there has been much interest to design and identify cPLA2 inhibitors to better understand the molecular mechanism regulating this enzyme and to develop efficacious therapeutics for the treatment of cPLA2-upregulated diseases such as neuroinflammation and Alzheimer's disease. To this end, we are interested to identify novel chemical tools, particularly fluorescent probes which could provide a means to monitor cPLA2 activity. Arachidonyl trifluoromethyl ketone (AACOCF3) is a potent inhibitor of cPLA2 which served as the template for modifications in this study. Arachidonic acid derivatives equipped with either one or two fluorescent groups attached to the tip of the alkyl chains were synthesized and shown to function as inhibitor and substrate probes of cPLA2. The inhibitor probe 7OHCou-AACF3 has an IC50 of 12.5 +- 1.0 uM which is comparable with AACOCF3. It

is able to quench iNOS production via its role as an inhibitor and is capable of imaging the increase in cPLA2 protein levels. We have also developed another probe Flu7OHCou as a cPLA2-selective fluorogenic substrate and demonstrated its use for inhibitor screening assays. Taken together, we report two novel fluorogenic probes capable for determining cPLA2 activity as well as cellular imaging.

**Title:** Analysis of physicochemical interaction GM1 ganglioside cluster containing lipid membrane with amyloid beta peptides: Alzheimer's related protein

**Authors: *M. VAHED**[1], T. HOSHINO[1], S. NEYA[1], M. VAHED[2], M. KATSUMI[3]
[1]Grad. Sch. and Fac. of Pharmaceut. Sciences,, [2]Med. Mycology Res. Center,, Chiba Univ., Chiba, Japan; [3]Grad. Sch. and Fac. of Pharmaceut. Sciences,, Kyoto Univ., Chiba, Japan

**Abstract:** The Cluster of GM1-ganglioside lipid membrane play an important role to interaction with amyloid beta (Aβ) in the initial stages of Alzheimer's disease pathology. In this work, molecular dynamics (MD) simulations for five Aβ42 were performed to investigate the behaviors of Aβ42 on GM1-ganglioside-containing lipid membrane. As far the computational model, the initial atom coordinate of Aβ42 were extracted from one of the conformations which had been determined by solution nuclear magnetic resonance (NMR) spectroscopy (PDB accession code: 1Z0Q/1IYT). A computational model for mixed membrane was composed of 48 monosialotetrahexosylganglioside (GM1), 96 sphingomyelin (SM) and 96 cholesterol (CHL). A 1000ns simulation was executed with NAMD 2.9 programs to analyze the probability of the Aβ binding to the mixed lipid membrane. The hydrogen bond occupancy was calculated using visual molecular dynamics (VMD) software. The results showed that binding affinity of Aβs were increases with GM1 in lipid membrane, suggesting the involvement of OH−π and CH-π interaction between the aromatic side chains of sugar carbohydrate moieties of GM1 with aromatic rings of Aβs. The secondary structures of five Aβ42 through MD simulations were examined, which indicated that the most frequently structure was helix. Cluster dendrogram analysis of structure Aβ42 represents the conformation changes during interaction with lipid membrane.

**Title:** Dramatic changes in mitochondria and calcium homeostasis during differentiation of induced pluripotent stem cells

**Authors:** ***A. THAKKAR**[1], H. CHEN[1], X. HUI[1], D. PAULL[2], H. ZHOU[2], A. LI[2], S. NOGGLE[2], G. GIBSON[1]
[1]Weill Cornell Medicine,Burke Med. Res. Inst., White Plains, NY; [2]New York Stem Cell Fndn. Res. Inst., New York, NY

**Abstract:** Reduction in glucose metabolism and changes in calcium are the hallmarks of neurodegenerative diseases like Alzheimer’s disease (AD). Internal calcium stores are exaggerated in fibroblasts from patients with AD and in multiple models of AD. Activities of the alpha-ketoglutarate dehydrogenase complex (KGDHC), a rate-limiting enzyme of the

tricarboxylic acid cycle, are diminished in AD brain and in models of plaques and tangles. Reducing KGDHC increases the internal calcium stores similarly to cells from AD patients. Assessing the importance of the abnormalities in the disease process and their therapeutic importance has not been possible because it is unknown if they occur in human neurons, and how the calcium and mitochondria interact in human neurons. The emergence of research with fibroblast derived induced pluripotent stem cells (iPSCs) from humans will allow questions to be answered that have always eluded the field. Research on mitochondria (e.g., KGDHC) or internal calcium homeostasis in iPSCs and their interactions in iPSCs or iPSC derived cells is surprisingly limited.

The goal of these studies is to provide a foundation for subsequent research on calcium and mitochondria in AD. iPSCs that were generated from fibroblasts derived from a 75-year-old healthy male were positive for the pluripotent markers Oct4 and SSEA4. These cells were differentiated to neural stem cells (NSCs) that were positive for nestin, SOX2 and SOX1. The activities of KGDHC in iPSCs were approximately equal to those in fibroblasts and about 50% lower than in a standard mouse neuroblastoma cell line (N2a). The activity declined about 50% upon differentiation to NSCs. In-situ measurement of KGDHC activity showed a reduction of 45-75% upon differentiation of iPSCs to NSCs. The subunit proteins of the complex (E1k, E2k and E3) in iPSCs were also diminished by differentiation to NSCs. Calcium regulation in iPSCs and NSCs was studied by measuring cytosolic free calcium in response to depolarization with KCl (50 mM) and by measuring internal calcium stores in the endoplasmic reticulum that are sensitive to bradykinin (BRCS). Depolarization did not increase calcium in either iPSC or NSC. In iPSCs, BRCS increased in a dose-dependent manner in response to bradykinin. BRCS declined by 50% from one to two days in culture. BRCS was six times higher in iPSCs than NSCs under similar conditions.

The data demonstrate that KGDHC and BRCS change dramatically upon differentiation of iPSCs to NSCs. Productive use of iPSCs and iPSC-derived NSCs and neurons for studies of neurodegeneration require a deeper understanding of how mitochondria and energy metabolism change with differentiation.

**Title:** Exploring the role of BRCA1 in neurodegenerative disease

**Authors: *N. M. SHANBHAG**, M. D. EVANS, L. MUCKE
Gladstone Inst. of Neurolog. Dis., San Francisco, CA

**Abstract:** The accumulation of DNA damage is emerging as a driving force behind normal aging as well as neuronal degeneration. As a testament to this, mutations in DNA repair proteins underlie diseases that can manifest neurodegenerative phenotypes, such as ataxia telangiectasia and xeroderma pigmentosum. It is therefore possible that acquired deficits in DNA repair could contribute to late onset neurodegenerative disorders such as Alzheimer's disease (AD). Suberbielle et al. (Nat. Commun. 2015) recently demonstrated reduced cerebral levels of the DNA repair factor BRCA1 in a mouse model of AD and in postmortem brain tissue from humans with AD. Experimental depletion of BRCA1 in neurons of the dentate gyrus in wildtype mice increased levels of neuronal DNA double strand breaks and caused deficits in spatial learning and memory. These data suggest that BRCA1 may be critical for DNA integrity in the adult brain, and that BRCA1 depletion in AD may impact cognitive performance.
To further explore the role of BRCA1 in the adult central nervous system, we developed several lines of transgenic mice with alterations in BRCA1 levels or function. These include mice with constitutive and inducible cell type-specific reductions in BRCA1, overexpressing BRCA1, or carrying mutations in distinct functional domains of BRCA1. Our preliminary data suggest that 50% reduction of BRCA1 in the brain can lead to deficits in spatial learning and memory in mice. Ongoing studies aim to clarify the roles of BRCA1 and other DNA repair factors in the adult brain and in AD, how BRCA1 depletion leads to cognitive deficits, and whether these deficits can be prevented or reversed by increasing BRCA1 expression.

**Abstract:** Sleep deprivation is a common problem in our society resulting in deleterious consequences, including impaired memory and cognitive performance. Long term memory consolidation and late-phase long-term potentiation (L-LTP) requires active protein synthesis in the hippocampus. The kinase complex mammalian target of rapamycin complex 1 (mTORC1) regulates protein synthesis by phosphorylating and inhibiting the eukaryotic translation initiation factor 4E-binding protein (4EBP) and activation of the ribosomal protein S6 kinase (S6K), resulting in the binding of the eukaryotic initiation factor 4E (eIF4E) to elF4G to initiate translation. Sleep deprivation impairs L-LTP and mTORC1-dependet protein translation in the hippocampus. We showed the dietary supplementation with a standardized bioactive dietary polyphenol preparation (BDPP) rescued hippocampal-dependent long term memory impairment in a mouse model of sleep deprivation. Based on this evidence we investigated the role of BDPP in mTORC1 pathways in the molecular mechanisms mediating the cognitive resilience to sleep deprivation. We found BDPP treatment prevented the SD-induced down regulation of eIF4E expression and up regulated the interaction between eIF4E and eIF4G, an important step towards translation initiation. In addition we identified the specific brain bioavailable bioactive phenolic metabolites derived from BDPP; Quercetin-glucuronide and 3-hydroxybenzoic acids to increase eIF4G expression and down regulate 4EPB expression in embryonic primary cortico-hippocampal neurons. We also found treatment with Quercetin-glucuronide attenuates SD-induced impairment in protein synthesis-dependent L-LTP. Collectively, these findings demonstrate that BDPP regulation of mRNA and protein translation is a critical mediator of resilience against the memory deficits caused by sleep deprivation.

Sapienza Univ. of Rome, Rome, Italy; [4]IRCCS San Raffaele Pisana, Roma, Italy; [5]Inst. of Translational Pharmacol., Natl. Res. Council, Rome, Italy

**Abstract:** Several evidence support the role of oxidative stress in Alzheimer disease (AD) pathophysiology. In particular, many redox proteomics studies on AD cerebral tissues led to the identification of oxidatively modified proteins that were consistent with biochemical or pathological alterations of the disease (Nunomura et al, 2001; Zhu et al, 2004; Smith et al, 2007; Droge et al, 2007). Interestingly, HSV-1, a neurotropic virus able to establish a lifelong latent infection in trigeminal ganglion followed by periodic reactivations, has been reportedly linked both to AD (Piacentini et al, 2015) and to oxidative stress conditions (Nucci et al, 2000; Palamara et al, 1995). Herein we design *in vivo* studies to investigate whether multiple HSV-1 reactivations induced in the brain the accumulation of oxidative stress hallmarks, particularly those correlated to AD. To this aim, BALB/c mice were inoculated via snout abrasion with HSV-1, virus reactivation was periodically induced by thermal stress, and virus replication in the brain was analyzed through PCR and RT-PCR analysis of viral TK gene and ICP4 mRNA. Oxidative stress marker levels, i.e. 4-hydroxynonenal (HNE, marker of lipid peroxidation), 3-nitrotyrosine (3NT, marker of protein nytrosylation) and carbonylated proteins, were measured in brains of mice undergone multiple HSV-1 reactivations by western blotting. In addition, redox proteomic was used to identify those HNE-modified proteins mostly modulated by recurrent HSV-1 reactivations into the brain. Following several cycle of viral reactivation, we found in mouse brains: 1) viral TK and ICP4 genes in cortex and hippocampal tissues, indicating that HSV-1 is able to reach and replicate in those brain regions mostly affected during AD; 2) increased levels of HNE, 3-NT, and protein carbonylation, indicating generalized conditions of oxidative stress; 3) thirteen HNE-modified proteins whose levels were significantly modulated in the cortex of HSV-1 infected mice compared to control mice. Interestingly, all these proteins are involved in important cellular processes, such as energy metabolism, protein folding, cell structure, and signal transduction, suggesting that their oxidative modification may affect brain physiology. Some of these proteins are reported to be significantly HNE-modified in AD brains compared to matched controls. In addition, these mice showed several signs of neurodegeneration (De Chiara et al, SfN abstract 2017). Overall, these data support the hypothesis that repeated HSV-1 reactivation into the brain may concur to neurodegeneration also inducing oxidative damages.

**Title:** Progranulin is proteolytically cleaved into stable, lysosomal granulins that are haploinsufficient in frontotemporal dementia with GRN mutations

**Authors: *C. J. HOLLER**[1], G. TAYLOR[1], Q. DENG[2], T. L. KUKAR[1]
[1]Dept. of Pharmacol., [2]Dept. of Biochem., Emory Univ., Atlanta, GA

**Abstract:** Frontotemporal dementia (FTD) is the second most common neurodegenerative disease in people <65 years old. Heterozygous mutations in the progranulin gene (*GRN*) leading to progranulin (PGRN) haploinsufficiency are a major cause of familial and sporadic FTD. It is currently unknown how loss of PGRN leads to neurodegeneration, but mounting evidence suggests PGRN plays a critical role in maintaining proper lysosome function in the brain. This concept is supported by several lines of evidence. First, homozygous *GRN* mutations in humans leads to a complete loss of PGRN protein and manifests as a lysosomal storage disease called neuronal ceroid lipofuscinosis (NCL), characterized by lysosome dysfunction and neurodegeneration. Second, FTD patients with *GRN* mutations as well as *Grn*-deficient mice also display lysosomal storage disease phenotypes. Third, two receptors - sortilin and the prosaposin/cation-independent mannose 6-phosphate receptor/low density lipoprotein receptor-related protein complex - have been demonstrated to bind and traffic PGRN to lysosomes. Finally, variants in *TMEM106B*, which encodes a lysosomal trafficking protein, are a significant risk factor for FTD-*GRN*. PGRN is a secreted glycoprotein that can be cleaved into seven ~6 kDa proteins called granulins (GRNs), however little is known about the production of GRNs or their levels in disease due to lack of specific tools. To overcome this gap, we have identified and validated antibody-based tools for the detection of endogenous human GRNs which have previously never been reported. Using these tools, we find that endocytosed PGRN is rapidly processed into stable GRNs within lysosomes. Processing of PGRN into GRNs is conserved between humans and mice and is dependent on cysteine proteases. Further, alkalizing agents or expression of TMEM106B in cells cause lysosome dysfunction and inhibit processing of PGRN into GRNs. Finally, multiple GRNs are haploinsufficient in FTD-*GRN* patient derived cells and brain tissue. Our findings suggest that GRNs may be the functional units of PGRN responsible for maintaining lysosome homeostasis, and their deficiency may underlie development of lysosomal storage disease and neurodegeneration. Future experiments will determine if

individual GRNs can rescue lysosomal dysfunction phenotypes in cellular and animal models of PGRN deficiency.

**Abstract:** High degree of Aβ heterogeneity - going far beyond the classic Aβ40/Aβ42 dichotomy and particularly associated with a plethora of C-terminal truncations - is a consistent finding in proteomic analysis of CSF collected from healthy controls as well as from AD individuals and transgenic mouse models. Biochemical analysis of parenchymal brain deposits largely expands the Aβ heterogeneity, revealing numerous post-translational modifications and multiple truncations at both N- and C-terminal ends of the molecule likely reflecting local action of resident enzymes. Notably, the relevance of these N- and C-terminal truncated species for the mechanism of AD pathogenesis remains largely understudied. Utilizing specifically designed differential tissue extraction protocols, synthetic homologues of intact and truncated Aβ peptides as well as novel antibodies recognizing specific truncations we compared their solubility properties, self-oligomerization propensity, predisposition for fibrillization, topographic localization, and *in vivo* brain clearance characteristics. The findings clearly indicate that in AD and transgenic mouse brain specimens N- and C-terminal Aβ truncated forms exhibit differential fractionation characteristics. Water-soluble brain extracts were largely enriched in C-terminal fragments - closely resembling the heterogeneity of the CSF Aβ peptidome - whereas N-terminal truncated fragments in brain homogenates primarily required formic acid for solubilization in line with their preferential topographic association with amyloid plaque cores. Biophysical

studies using synthetic homologues confirmed the differences in solubility and contrasting oligomerization/ fibrillization characteristics of the various Aβ truncated derivatives whereas intracerebral injections of monomeric and oligomeric radiolabeled homologues revealed striking differences in their brain clearance characteristics. While soluble derivatives exhibited a fast brain removal, oligomerization largely increased brain retention, a characteristic particularly evident in fragments truncated at Phe4, topographically abundant in fibrillar, thioflavin positive plaque cores. Taken together, our data indicate that Aβ degradation at its C-terminal-end generates highly soluble fragments associated to catabolic/clearance mechanisms whereas truncations at the N-terminus favor oligomerization and brain retention, with the potential to exacerbate the process of amyloid formation and self-perpetuate the amyloidogenic loop.

**Title:** AnkyrinG disruption and axon initial segment breakdown lead to neuronal polarity loss in Alzheimer's disease transgenic mouse models

**Authors: *F. MA**[1], K. HERRUP[2]
[1]Hong Kong Univ. of Sci. and Technol., Hong Kong, Hong Kong; [2]Hong Kong Univ. of Sci. & Technol., Kowloon, Hong Kong

**Abstract:** Mature neurons are highly polarized cells that typically have multiple dendrites and a single axon. The axon and dendrites have different sets of characteristic resident proteins. This asymmetric distribution of the cellular components is defined as neuronal polarity. Nearly every aspect of neuronal development, neuronal signaling and neuronal plasticity depends on the accurate localization of these proteins. Therefore, polarity is critical for neurons to form a functional network. In the past decade, the mechanisms that underlie the development of neuronal polarity have received a lot of attention, but the maintenance of such polarity is often overlooked. It is known now that the axon initial segment (AIS) serves as a critical physical barrier at the junction of the axon with the cell body for maintaining the polarity. The AIS itself has a number of specialized proteins, one of which is a unique scaffold protein Ankyrin G (AnkG) that governs the assembly and stabilizes the initial segment. However, neuronal polarity is not immutable. Under certain pathological conditions, neurons fail to maintain their polarity

and immunocytochemistry reveals the mis-localization of some normally polarized proteins. In the two different transgenic mouse models of Alzheimer's disease, APP K670/M671 (R1.40) mice and APP K670/M671 /PS1 dE9 (PAB) mice, we observed a portion of neurons in the cortex undergoes a loss of polarity as the brains age. The length of AnkG-labeled AIS in the neocortex of these mice as well as the levels of AnkG protein throughout the life span of both wildtype and the AD models were also examined. AnkG levels in the neocortex of R1.40 mice were significantly different from wildtype beginning at six months of age. This is consistent with the hypothesis that the loss of polarity is associated with the pathogenic process of Alzheimer's disease. Using ß-amyloid peptide and lipopolysaccharide to mimic AD chemistry *in vitro* mimicked these findings and lead to the collapse of neuronal polarity. Together, these results suggest that the loss of neuronal polarity is correlated with Alzheimer's disease and may be an important factor in the neurodegeneration process.

**Abstract:** Oxidative stress and cerebrovascular damage have been implicated in Alzheimer's disease (AD). Reduced brain levels of protein kinase C epsilon (PKCε) have been found in autopsy samples from AD victims. In the present study, reciprocal interactions among Aβ, oxidative stress, and PKCε were studied in microvascular endothelium and pyramidal neurons in the hippocampus. PKCε and mitochondrial manganese-superoxide dismutase (MnSOD) were depressed in microvascular endothelium of CA1 areas of autopsy-confirmed AD hippocampus. Microvascular density was correlated with PKCε level. Increases in Aβ and decreases in PKCε, MnSOD, and brain-derived neurotrophic factor (BDNF) levels were found in pyramidal neurons. In cultured human primary hippocampal neurons, oxidative stress, induced with t-butyl hydroperoxide, reduced neuron density and the levels of MnSOD and BDNF. These changes were reversed with the PKCε activators bryostatin and DCPLA-ME, indicating that MnSOD and BDNF expression are PKCε-dependent. Oxidative stress reduced levels of amyloid precursor protein (APP) but increased Aβ; both were prevented by PKCε activators, suggesting activation of the amyloidogenic pathway (normally inhibited by PKCε) and/or a decrease in Aβ

degradation (normally activated by PKCε). In cultured neurons, siRNA suppression of PKCε produced effects similar to oxidative stress. PKCε, MnSOD, and vascular endothelial growth factor (VEGF) levels were also reduced in hippocampal neurons and microvascular endothelium, as well as microvascular loss, in 5–6 month old Tg2576 AD transgenic mice. These changes were prevented by PKCε activators. These results suggest that a decrease in PKCε suppresses MnSOD, VEGF, and BDNF expression. An imbalance among PKCε, Aβ, and ROS may contribute to vascular dysfunction in AD.

**Abstract:** Animal models of AD represent an invaluable tool to evaluate potential therapeutic compounds and to study mechanisms underlying the pathogenesis of the disease. 3xTgAD mice are a widely used animal model of AD. As reported in 2003, these mice are characterized by the accumulation of plaques, tangles, and cognitive decline. Currently, 3xTg-AD mice are being used by more than 100 investigators throughout the world. Such widespread use has led to the generation of multiple independent colonies. Converging evidence indicates that the phenotype of 3xTg-AD mice has shifted over the years, and contradicting reports about onset of pathology and cognitive deficits are apparent in the literature. Given the widespread use of these mice, it is imperative to re-define the progression of AD-like pathology. We employed a cross-sectional approach using 3-, 6-, 12-, 16-, and 20-month-old 3xTg-AD and wildtype mice (n = 15/age group/genotype). Per each age-group, we tested mice in a battery of cognitive and non-cognitive tasks, including the Morris water maze, open field, novel object recognition, contextual fear conditioning, and Rotarod. We will present a comprehensive, age-dependent assessment of the cognitive changes of 3xTg-AD mice and the associated neuropathological phenotype, including soluble and insoluble Aβ and tau levels in different brain regions. The data presented here will

serve as a benchmark for investigators in the field using these mice. In addition, our results will facilitate the design of preclinical studies in which these mice are used to test new therapeutic approaches.

**Title:** Acute knockdown of tau in the adult hippocampus impairs spatial learning and memory

**Authors: *R. VELAZQUEZ, JR**[1], E. FERREIRA[1], A. TRAN[1], O. SALVATORE[1,2]
[1]Neurodegenerative Res. Ctr., Biodesign Inst. At Arizona State Univ., Tempe, AZ; [2]Sch. of Life Sci., Arizona State Univ., Tempe, AZ

**Abstract:** Misfolded and hyperphosphorylated tau accumulates in several neurodegenerative disorders collectively known as tauopathies. Evidence indicates that tau-mediated neuropathology may occur by both toxic gain-of-function and by loss-of-function. While a wealth of data is available on the role of tau in the formation of toxic inclusions, less is known about its function in the otherwise healthy adult brain. Furthermore, being that anti-tau therapies are quickly approaching clinical trials, fully understanding the involvement of tau in the healthy brain remains an important question. To date, it has been difficult to elucidate the role of tau in learning and memory during adulthood as data obtained from tau knockout mice are confounded by robust developmental compensation of other microtubule-binding proteins such as microtubule-associated protein 1A. Thus, to fully understand tau's role in learning and memory, manipulations need to be done solely in adult mice to remove any developmental compensations. Here, we generated an adeno-associated virus (AAV) expressing a doxycycline (doxy)-inducible short-hairpin (Sh) RNA targeted to tau, herein referred to as AAV-shRNAtau. We stereotaxically and bilaterally injected 8-month-old C57x129 mice with either the AAV-shRNAtau or an AAV expressing a scramble shRNA sequence (AAV-shRNA-CTL; n =17/group). During the surgeries, mice were kept off doxy to keep the expression of the tau shRNA off. Seven days after the injections, all animals were put on doxy, to induce expression of the tau and control shRNAs. One month after the start of the doxy administration, we tested all mice in the rotarod and Morris water maze, to assess motor coordination, and spatial learning and memory, respectively. Following testing, we harvested tissue from mice to assess spine density, microtubule assembly

and axon morphology. Our results show that reducing tau in the adult hippocampus produces significant impairments in motor coordination, endurance and spatial memory. Collectively, these findings illustrate the importance of the tau protein in both non-cognitive and cognitive functions. These results may have a major impact on tauopathies and associated therapies as we have directly addressed important questions regarding the role of tau in adult brains.

Medicine, Mitchell Ctr. for Neurodegenerative Dis., Univ. of Texas Med. Br. at Galveston (UTMB), Galveston, TX; [4]Sch. of Life Sci., Arizona State Univ., Tempe, AZ

**Abstract:** Type 2 diabetes (T2D) is one of the most prevalent risk factors that contributes to Alzheimer’s disease (AD). Brain and peripheral insulin dysregulation have been demonstrated in subjects with both mild cognitive impairment (MCI) and early AD. However, it is not certain whether changes in brain insulin signaling occur before or after the onset of peripheral insulin resistance. Here, we examined peripheral glucose metabolism and brain insulin signaling in the Tg2576 and 3xTg-AD mouse models of AD at ages with different degree of AD-like pathology. We first assessed peripheral insulin resistance via a glucose tolerance test in 10- and 16-month-old 3xTg-AD and age-matched wildtype (WT) mice. Our results show that fasting glucose levels and the ability to restore elevated glucose levels were significantly different between WT and 3xTg-AD mice at 16 months of age, but non-significantly different at 10 months of age. In contrast, as previously reported, peripheral insulin resistance in Tg2576 is first detected at 9 months of age. Immunoblot results of brain homogenates show reductions in IRS-1 and PI3K levels in the older age groups of 3xTg-AD (16-month old) and Tg2576 (9-month old), illustrating dysregulated brain insulin signaling. Additionally, downstream target PDK1 was dysregulated in both 5-month-old Tg2576 and 10-month-old 3xTg-AD mice, prior to peripheral

insulin resistance. Notably, 10-month-old 3xTg-AD mice show decreased activity of IRS-1 and PI3K, while Tg2576 mice show dysregulation of these two markers only after the onset of peripheral insulin resistance. This finding may be attributed to the 3xTg-AD mice developing both Aβ and tau pathology while Tg2576 mice only develop Aβ plaques. AKT, an integral component of the insulin signaling pathway was dysregulated in both mouse models after the onset of peripheral insulin resistance. Lastly, GSK-3β, a convergent target of the PDK1/AKT pathways and a key negative regulator of IRS-1, was upregulated consecutively with peripheral insulin resistance. Collectively, our data show evidence that various brain insulin signaling abnormalities are evident months before peripheral insulin resistance in two mouse models of AD. Furthermore, these brain insulin dysregulations are more apparent in 3xTg-AD mice which features both hallmark pathologies of AD. This work suggests that early AD may reflect engagement of different signaling networks that influence brain metabolism, which in-turn alters peripheral insulin signaling.

**Abstract:** Neuronal loss is a major pathological feature of Alzheimer’s disease (AD). Nevertheless, the mechanisms underlying this key event in the disease pathogenesis are not clear. Necroptosis, a programmed form of necrosis, is performed by the mixed lineage kinase domain-like (MLKL) protein, which is activated by receptor-interactive protein kinases (RIPK) 1 and 3. Necroptosis is activated in various neurodegenerative disorders including multiple sclerosis and amyotrophic lateral sclerosis. However, it remains to be determined whether necroptosis plays a role in AD. Here we show that necroptosis is activated in human AD brains and its activation

correlates with brain weight and cognitive scores. We also show that necroptosis is also activated in 5xFAD mice, which are characterized by marked neuronal loss. Using complementary in vitro and in vivo approaches, we found that reducing necroptosis activation rescues AD-related neuronal loss. Overall, these data provide the first direct evidence that necroptosis is a mechanism involved in neurodegeneration in AD.

**Abstract:** Axonal degeneration and synapse loss are key traits of Alzheimer’s disease, with several lines of evidence suggesting these may be the earliest degenerative events. Additionally, growing evidence suggests tau’s functional capabilities are more diverse than previously thought, and may include regulation of signaling pathways. Our group previously showed that the N-terminus of tau can activate a pathway involving protein phosphatase-1 (PP1) that causes axonal transport deficits, but it remains unclear whether tau directly or indirectly interacts with and activates PP1. Here, we tested the hypothesis that tau activates PP1 through a direct interaction. Tau constructs used include full-length wild-type (hT40), pseudophosphorylated-AT8 (psAT8), and hTt40 and psAT8 tau with amino acids 2-18 deleted (Δ2-18), as well as the three PP1 isoforms (α, β and γ isoforms). HEK293T cells were transfected with plasmids coding HaloTag-PP1 and NanoLuciferase-tau for use in pulldown and NanoBRET experiments. PP1 activity was measured using recombinant PP1 and tau proteins and in an *in vitro* PP1 activity assay. NanoBRET results show that each of the tau constructs tested interact with all three PP1 isoforms. Pulldown experiments confirmed that tau directly interacts with each PP1 isoform, and

each tau construct increased the activity of all PP1 isoforms. Interestingly, tau showed a stronger interaction and activation of PP1α and PP1γ compared to PP1β. These results indicate that tau and PP1 can directly interact, and that this interaction increases PP1 activity. Future studies will further characterize this interaction in the context of tau-mediated toxicity in neurons.

**Title:** Regulation of tau sumoylation by SUMO ligases and proteases

**Authors: H. WADA**, *T. NIIKURA
Sophia Univ., Tokyo, Japan

**Abstract:** The microtubule-associated protein tau is mainly expressed in the axon and associated in neurodegenerative disorders including Alzheimer's disease (AD). AD is neuropathologically characterized by intraneuronal neurofibrillary tangles (NFT), which are formed by the abnormal hyperphosphorylated tau that is aggregated and accumulated in the soma. In addition to phosphorylation, other post-translational modifications were found in tau, including ubiquitination, acetylation, methylation, and glycosylation. However, functional effects of these are largely unknown. Sumoylation is a process in which, Small Ubiquitin-like Modifier (SUMO) is conjugated to lysine residues of target proteins, and is mediated by enzymes: E1, E2, and E3. PIAS (protein inhibitor of activated STAT) protein family, with four PIAS genes in mammals, function as SUMO E3 ligase. Additionally, six SENP (sentrin-specific protease) family proteins have been identified as desumoylation enzymes. The balance of activities between sumoylation and desumoylation enzymes influences the rate of sumoylation. It has been previously shown that sumoylation and phosphorylation in tau have positive correlation, but it is still unclear how it is regulated. In this study, we identified enzymes that regulate sumoylation and desumoylation of tau. We found that PIAS2 functioned as tau specific sumoylation enzyme, and SENP1 and 2 functioned as tau specific desumoylation enzyme. Consistently, we verified that tau colocalized with SENP1 or PIAS2 in HEK293 cells. Further, we identified at least one new sumoylation site in tau protein. Our findings suggest that these sumoylation-regulating proteins can be new targets to understand the pathogenesis of the tau-related neurodegenerative disorders.

**Title:** Modulation of hyperphosphorylated tau accumulation by chaperone proteins in a neuroblastoma cell culture model of Alzheimer's disease

**Authors: *S. MAY**[1], N. H. ZAWIA[2], J. L. CAMBERG[3]

**Abstract:** Alzheimer's disease is characterized by intracellular and extracellular aggregates of impaired, misfolded proteins, including tau and amyloid-beta. To prevent aggregate accumulation, healthy cells have a robust, extensive network of molecular chaperone proteins that maintain protein homeostasis. Molecular chaperone proteins assist in the folding of nascent polypeptides, refolding and reactivation of misfolded or partially unfolded proteins, and targeting of irreversibly misfolded proteins for degradation. Here, we investigated the role of chaperone proteins Hsp70, Hsp90, and Hsp110 in tau neuroblastoma SH-SY5Y cells treated with the phosphatase inhibitor okadaic acid. Accumulation of hyperphosphorylated tau was monitored over time in undifferentiated and differentiated cells. Initially, we observed that Hsp70 expression levels increase after administration of okadaic acid to cells. Additional experiments to knockdown and overexpress chaperone proteins will determine if changes in the molecular chaperone landscape lead to changes in the rate of tau accumulation. These studies investigate the involvement of molecular chaperone proteins in the pathogenesis of Alzheimer's disease and may provide insight into new therapies for targeting tau protein misfolding and aggregation.

**Title:** Quantitative live cell imaging reveals critical influence of a highly conserved pseudorepeat region on tau's interaction with neuronal microtubules

**Authors: *R. BRANDT**, B. NIEWIDOK, M. IGAEV, F. SUENDERMANN
Univ. of Osnabrueck, Osnabrueck, Germany

**Abstract:** The tau proteins are generated by alternative splicing from a single gene and are the major microtubule-associated proteins in neuronal axons. In healthy brains, tau remains enriched in the axon however the distribution changes during Alzheimer's disease and other tauopathies, where tau localizes to the somatodendritic compartment. Tau's redistribution is associated with hyperphosphorylation, reduced binding to microtubules (MTs) and aggregation into filaments. Tau's MT interaction is thought to be mediated by the microtubule-binding region (MBR), which contains three or four repeat regions. Regions flanking the MBR may modulate tau's interaction with MTs. The functional organization of tau has been mainly studied *in vitro* or in non-neuronal cells. Although, it has become evident that tau shows an unexpectedly high dynamic interaction with MTs - a feature that has been termed "kiss and hop" behavior - at conditions of high MT density that prevail in the axon [1]. It is unclear, how "kiss and hop" is regulated and what is the effect of flanking regions in authentic axons. To scrutinize the functional organization of tau's MT interaction in axon-like processes, we employed a refined fluorescence decay after photoactivation (FDAP) approach [2]. Tau was N-terminally tagged with a photoactivatable variant of GFP and a panel of C-terminal tau deletion constructs was expressed in neuronally differentiated PC12 cells [3]. A defined region of interest within a process was activated and the fluorescence intensity distribution as a function of time monitored. The decay transient was fitted by a mathematical model to yield mobility and binding properties of the tagged protein. Our findings show that - in contrast to previous *in vitro* data - tau isoform variation had only a minor influence on MT binding. Notably, the presence of a conserved pseudorepeat region (PRR) in tau's C-terminus robustly enhanced MT binding by a greater-than-sixfold decrease of the dissociation rate. Bioinformatic analysis showed that the PRR is highly conserved across vertebrates, is also present in MAP2 and the non-neuronal MAP4, and constitutes a separate group in nearest-neighborhood cluster analysis. Our data indicate that under conditions of high MT density in the axon, tau's MT binding and localization are crucially affected by the presence of the PRR and indicate that conditions that affect the integrity of the PRR could have a critical role in triggering the redistribution of tau during tauopathies. **Abstract:** Alzheimer’s disease (AD) and frontotemporal lobar dementia with tau pathology (FTLD-tau) are the most prevalent forms of dementia with tauopathy. They are characterised by the presence of neurofibrillary tangles (NFTs) consisting of hyperphosphorylated tau, as well as neuronal dysfunction that is partially due to defective neuronal metabolism. Liver kinase B1 (LKB1) is a crucial regulator in neuronal energy homeostasis via activating AMP-activated protein kinase (AMPK). During neuronal development, LKB1 plays a vital role in regulating neuronal polarity via specific phosphorylation of tau. However, whether this pathway is involved in neuronal dysfunction in tau pathology remains unknown. Our experiments show that LKB1 function is seen to be impaired when naturally occurring tau phosphorylation is dysregulated. This in turn has downstream effects on brain metabolism and cognition. Hence, we propose that site specific phosphorylated tau is able to inhibit LKB1-mediated AMPK activation in neurons. Furthermore, the LKB1-tau pathway may serve as a future therapeutic target in tau-related neurodegeneration.

**Abstract:** Exposure to chronic stress and high glucocorticoid (GC) levels leads to cognitive decline and neuronal atrophy. Previously, GC were shown to induce Alzheimer's disease (AD)-related pathomechanisms, including the intracellular accumulation of hyperphosphorylated Tau protein, suggesting that dysregulation of Tau proteostasis is a major causative factor for stress-induced brain pathology. However, the mechanisms underlying Tau turnover and degradation are still poorly understood. Here, we have identified a novel molecular pathway that mediates the degradation of Tau in hippocampal neurons. This pathway comprises the small GTPase Rab35 and the endosomal sorting complex required for transport (ESCRT) machinery, which catalyzes the biogenesis of multivesivular bodies (MVBs) for delivery of cargo to lysosomes. Interestingly, we find that the Rab35/ESCRT pathway is negatively regulated by GC, which are known to impair Tau degradation and lead to Tau accumulation, hyperphosphorylation, and synaptic missorting. Furthermore, we show that stimulating this pathway via Rab35 overexpression can rescue GC-induced Tau accumulation, thus supporting the relevance of the Rab35/ESCRT pathway for Tau pathomechanisms, and identifying a promising therapeutic target for the treatment of stress-related cognitive decline and other tauopathies, such as AD.

**Title:** P53 and Tau in Alzheimer's Disease

**Authors: *K. FARMER**[1], P. SARKAR[2], R. KAYED[2]
[2]Neurol., [1]Univ. of Texas Med. Br., Galveston, TX

**Abstract:** The homotetrameric tumor suppressor, p53, acts as a master regulator of cell cycle control, apoptosis, and DNA repair. DNA damage is one of the earliest pathological changes in Alzheimer's disease (AD) and a reduction in the DNA damage response significantly increases neurodegeneration. P53 has been shown to play a neuroprotective role in tauopathies. Previous studies have also implicated the microtubule-associated protein tau as a factor in DNA damage in neurodegenerative diseases. Depending on phosphorylation state, nuclear tau has been proposed to play a protective role against DNA damage. In addition, tau has been shown to induce chromatin relaxation, which subsequently leads to DNA damage and global changes in transcription. As p53 becomes activated due to DNA damage, it may be possible that an interaction between tau and p53 occurs in the early stages of AD. In addition, tau oligomers have been found to develop toxic gain of function and are one of the major contributors to neuron death in AD. Tau oligomers have also been found to sequester and/or cause the aggregation of other proteins. Thus, we hypothesize that p53 may be sequestered by tau oligomers, inhibiting its function. Neurons in Alzheimer's disease (AD) have also been shown to re-express factors that promote cell cycle progression and undergo cell cycle re-entry just before massive neuronal death in AD. This would suggest a reactivation of the cell cycle—in which p53 is critically involved—in the process of neurodegeneration. We evaluated total p53, functional phospho-p53, and tau aggregation status in AD patients and Tg2576 mice by immunohistochemistry using both commercial and novel antibodies with conformational epitopes common to oligomers of aggregated proteins. We found that phospho-p53 levels are decreased in human AD brain in comparison to control brain. We also found that phospho-p53 colocalizes with tau oligomers in human AD brain, highlighting a potential overlap between DNA damage response and AD. Our findings suggest that tau oligomers may be interacting with p53 and causing a down regulation of functional p53 in AD. This may suggest that tau may be interacting in DNA damage response signaling and therefore affecting cell death. These results may have implications for a number of other neurodegenerative disorders. Therefore, further research is needed to understand the underlying signaling pathways of tau and p53 interaction.

**Abstract:** Background Recently, diet habit changes to high fatty food, obesity, diabetes and lifestyle diseases are increasing in Japan. There was reported that development of Alzheimer's disease is high risk in diabetes mellitus patients compare to normal person. However, the clear mechanism of Alzheimer's onset has not been elucidated. The present study was investigated the seaweed of Japanese traditional diet to effect on prevention and onset of Alzheimer's disease. We have already obtained data showing the prevention and improvement effect of diabetes by improving glucose metabolism abnormality by seaweed ingestion. Material and Method The mice were divided into four groups as high fat diet, normal diet, high fat diet with 1% seaweed, and normal diet with 1% seaweed. In addition, all groups were fed ad libitum for 6 months. Phosphorylation of tau protein in mouse olfactory bulb and cerebral cortex part was analyzed by western blotting method. Results and Discussion It was found that phosphorylation of tau was suppressed in both of high fat diet and normal diet with seaweed. This result suggested that feeding of seaweed suppresses tau phosphorylation and it might be related to reduce the onset of Alzheimer's disease. Furthermore, seaweed components related to inhibition of phosphorylation of tau are identified while focusing on signal systems such as AKT and GSK-3β, used cultured cell HEK293 overexpression of tau.

**Abstract:** Alzheimer Disease and other tauopathies show abnormal aggregation of tau protein into paired helical filaments (PHFs) and neurofibrillary tangles. Initially small, but soluble oligomers turn subsequently into insoluble PHFs. It is hypothesized that small molecules, such as leucomethylthioninium bismethanesulfonate salt (LMTM), are able to prevent aggregation. The present study aimed at monitoring tau oligomer formation after acute treatment with LMTM. Two complementary techniques, Western blot (WB) and mass spectrometry (MS), were compared, analysing samples from wild-type (WT) and tau transgenic mice (P301S). LMTM was administered subcutaneously (10 mg/kg) to 9 months old WT (n=9) and P301S (B6:C3-Tg(Prnp-MAPT*P301S)PS19Vle/J, n=9) mice. Animals were sacrificed 1 hour after treatment and brains dissected. Brain samples were homogenized and proteins separated using denaturing or semi-native polyacrylamide gel electrophoresis (PAGE) for visualization of tau monomers or oligomers, respectively. For MS, gel bands were excised (according to molecular weight standards), crushed, trypsin digested and heavy peptides added for quantitation. Light and heavy peptides were screened in LC-SRM mode using a triple quadrupole mass spectrometer. Initially, optimal brain structure and age was determined. Total tau was detected in decreasing amounts in: hippocampus ≥ frontal cortex > brain stem ≥ spinal cord in P301S and WT mice, though to a lower extent. Starting at 9 months (P301S), a doublet band (~65 kDa) appears in denaturing PAGE, likely reflecting a different conformation of tau. This observation matches with temporal changes in phosphorylation and behavioural status. Similar levels of Mono-, di-, and trimers were quantified using semi-native PAGE in both strains, with or without LMTM treatment. However, quantification by MS of LMTM samples revealed a 2-fold increase in the ratio monomer/oligomer in WT mice. No change in ratio was observed in treated P301S mice that typically express high levels of tau, suggesting the acute LMTM dosing was too low to prevent tau oligomerization. Absolute quantification with MS is able to reveal changes in amounts of tau oligomers *vs* monomers after LMTM treatment, whereas WB is not sensitive enough to reveal such changes.

**Abstract:** Tau-containing neurofibrillary tangles are a neuropathological hallmark of Alzheimer's disease, progressive supranuclear palsy and other forms of frontotemporal dementia. Tau is a multi-domain protein, comprising an amino terminal proline-rich projection domain, followed by 3 or 4 microtubule-binding repeats and a carboxyl terminal tail region (CTTR). In disease, tau becomes phosphorylated at both physiological and 'pathological' sites, resulting in a state referred to as hyper-phosphorylated. Several of the 'pathological' phosphorylation sites that have been associated with advanced disease are located within the protein's CTTR. However, little is known about the functional relevance of the CTTR. To obtain insight into the role of the CTTR, we asked if there are specific interaction partners of the CTTR and how hyper-phosphorylation might impact on such interactions. Therefore, we substituted the serine residues of human tau at the position 396,404,409 and 422 by aspartic acid to mimic phosphorylation (PM tau) and used this variant as a bait for yeast-two-hybrid screening compared to the non-mutant tau (WT tau) sequence of the CTTR. We identified 21 candidates that interacted preferentially with PM tau, 18 candidates that interacted preferentially with WT tau and 7 that interacted with both tau variants. Differential cluster analysis of interaction candidates identified two major clusters, namely molecular chaperones and members of the ubiquitin proteasome system. Using co-immunoprecitation (CoIP), we confirmed interaction of several E3 ubiquitin ligases and molecular chaperones with full-length tau. Then we used differential extraction with buffers of increasing stringencies to determine the effects of the identified E3 ubiquitin ligases and chaperones on tau solubility. We found that differential interaction mediated by phosphorylation of sites in the CTTR accelerated formation of insoluble tau aggregates in transfect cells. Taken together, we found that phosphorylation of tau in the CTTR contributes to the protein's quality control and possibly its deposition in disease.

**Abstract:** The mechanism of tau induced neurotoxicity is unknown. Nucleocytoplasmic transport (NCT), an essential process for cell survival, is impaired in cells with cytoplasmic protein aggregates such as mutant huntingtin and TDP-43 due to impairment of nuclear pore complexes (NPCs). We tested the hypothesis that soluble, high molecular weight bioactive tau disrupts neuronal NCT. The effect of cytoplasmic tau on NPCs was tested in wild type (WT) and tau P301S overexpressing (PS19) neurons in vitro and in vivo, and in human control and Alzheimer autopsy samples. Five lines of evidence support the idea that tau correlates with disruption of NCT. NCT was evaluated in the presence of different tau species using a fluorescence-based nuclear pore integrity reporter, the nuclear: cytoplasmic ratio of endogenous RanGTP, and a dextran exclusion assay. In cells having tau aggregates or high molecular weight soluble tau, we observe abnormal distribution of NPCs and disrupted NCT. Both spectral FRET and FLIM demonstrated close proximity of aggregated tau and NPCs, suggesting a direct protein-protein interaction of tau with NPC constituents. Nuclei from affected areas in AD brain have abnormal dextran exclusion, and altered RAN GTP nuclear/cytoplasmic distribution. The extent of aberrant nuclear pore morphology and nuclear membrane leakiness correlate with Braak staging in AD brains. We suggest that abnormal cytoplasmic soluble or aggregated tau disrupts NCT, likely through direct interactions of tau with NPCs. We believe that tau-induced impairment of nuclear transport may contribute to tau-related neurotoxicity.

**Title:** Regulation of microtubule dynamics by Tau

**Authors: *R. ALI**[1], C. L. BERGER[2]
[1]Neurosci. Grad. Program, [2]Mol. Physiol. and Biophysics, Neurosci. Grad. Program, Univ. of Vermont, Burlington, VT

**Abstract:** The microtubule associated protein, Tau, is implicated in a class of neurodegenerative diseases known as “Tauopathies”. One of the common feature of these disease states is misregulation of axonal transport. Thus to better understand the pathology of these diseases it is important to understand the role that Tau plays in regulation of axonal transport. Tau is known to regulate microtubule dynamics *in vitro*, which is thought to be an important function in stabilizing the microtubule tracks required for efficient axonal transport; however the mechanisms by which Tau regulates microtubule dynamics are not well understood. Moreover, six isoforms of Tau are expressed in adult human brain, and the isoform specificity of Tau’s function is also not completely clear. To address these issues, we use total internal reflection fluorescence (TIRF) microscopy to examine the dynamics of individual microtubules in the absence and presence of different isoforms of Tau. We are currently working with 3RS-, 3RL- and 4RL isoforms of Tau. 3RS- and 3RL-Tau contain three microtubule-binding repeats in the C-terminal microtubule-binding domain, but differ in the number of N-terminal acidic inserts that they contain (0 and 2, respectively) in the N-terminal projection domain. 4RL-Tau contains four microtubule-binding repeats and 2 N-terminal acidic inserts in the N-terminal projection domain. Our findings show that 3RS- and 3RL tau isoforms reduce microtubule catastrophe frequencies but have no effect on microtubule rescue frequencies, whereas, 4RL-Tau increases microtubule rescue frequency but has no effect on microtubule catastrophe frequency. 3RL-Tau and 4RL-Tau increase microtubule growth velocity and 3RL-Tau has no effect on it. We further demonstrate that Tau reduces the rate at which microtubule tip structure evolves while it is growing, such that the microtubule tip becomes tapered at a slower rate in the presence of Tau compared to the no Tau control. This is a previously unknown mechanism by which Tau can alter microtubule catastrophe frequency. Currently, work is on-going with other isoforms of Tau. In summary, we are elucidating in detail the role of Tau in regulation of microtubule dynamics in an isoform specific manner, leading to new insight as to how misregulation of Tau’s function affects microtubule dynamics and in turn axonal transport during the disease process.

**Authors: *L. WEINSTOCK**[1], L. WOOD[2]
[1]Dept. of Biomed. Engin. and Inst. for Bioengineering and Biosci, [2]Mechanical Engin. and Inst. for Bioengineering and Biosci., Georgia Inst. of Technol., Atlanta, GA

**Abstract:** Postmortem Alzheimer's disease (AD) brain tissues exhibit extensive vascular changes including loss of blood-brain barrier (BBB) function. Moreover, increased hippocampal vascular permeability has been reported in patients with mild cognitive impairment, suggesting that vascular dysfunction may play a pathogenic role. Yet, the mechanisms promoting vascular dysfunction remain poorly understood. Cerebral pericytes encircle the vascular endothelial layer on the parenchymal side and are responsible for regulating blood-brain barrier function. In this work, we hypothesized that pericytes become dysfunctional in response to the AD microenvironment and in turn promote loss of barrier function. Pericytes give structural support to the endothelial layer in the microvasculature, help maintain vascular coupling, and are immunoactive. Pericyte dysfunction has also been correlated with AD onset and in AD comorbidities, e.g. diabetes and traumatic brain injury**.** Our data indicate that amyloid beta, key inflammatory cytokines (e.g., TNF-α), and high insulin/glucose do not affect cerebral pericyte viability or migration in 2D and 3D cell cultures. However, TNF-α and high glucose, but not Aβ alone, stimulated broad up-regulation of pericyte-expressed inflammatory cytokines. The cytokines that correlated most strongly with pro-inflammatory and diabetic conditions include MCP-3, G-CSF, IL-8, and RANTES, which are known to promote immune cell chemotaxis and angiogenesis. Pericyte-conditioned culture medium reduced expression of endothelial adherens junction proteins VE-Cadherin and PECAM in TNF-α and high glucose/insulin conditions significantly more than when the conditions were directly applied to endothelial cells. These data suggest that pericyte response to the AD microenvironment may promote leakiness of the blood-brain barrier. Given the chemotactic nature of the cytokines secreted by pericytes in these

conditions, our data further suggest that pericyte signaling may play an important role in regulating activation and recruitment of neural glia and extravasation of circulating immune cells at the blood-brain barrier.

**Abstract:** It is widely accepted that there exists a profound role for inflammation in the pathogenesis of Alzheimer’s disease (AD). This inflammatory component can play a dichotomous role in modifying the various hallmarks of AD, including the deposition of amyloid beta (Aβ) and microtubule associated protein tau (MAPT; Tau). Acute inflammation can be beneficial to pathology by increasing the clearance and processing of toxic misfolded proteins, but left chronically unchecked can be detrimental to other aspects of disease including oxidative stress, and exacerbating hyperphosphorylation and aggregation of intracellular tau. Further nuancing the inflammatory contribution to disease are the non-redundant roles for distinct myeloid cell populations in the brain which remain poorly understood. It has been shown throughout the course of numerous CNS diseases including multiple sclerosis and AD, that pathogenesis can involve the recruitment of several populations of peripheral immune cells which can uniquely shape pathology. Until now, little has been known regarding the presence or role of peripheral inflammatory cell populations throughout tauopathy. Here, using a variety of transgenic mouse models including *Cx3cr1*$^{GFP/+}$*;Ccr2*$^{RFP/+}$ mice, along with bone-marrow chimerism studies, we demonstrate a significant region-specific increase in infiltrating

inflammatory cells in the brains of hTau mice compared to B6 controls beginning at 6-months and persisting through 18-months of age. This phenomenon is abrogated upon deletion of myeloid CCR2 which results in choroid plexus cell accumulation, but not entry of peripheral cell populations into the diseased parenchyma. This results in heightened tau pathology which is most notable in white matter regions. These results demonstrate a clear role for peripheral immune cell populations in the pathogenesis of AD related tauopathy, and represents a unique therapeutic target which is accessible without the need access the brain through the blood brain barrier.

**Abstract:** Tau vaccination and systemic administration of anti-tau antibodies prevent pathology and cognitive impairment in mouse models of tauopathy, suggesting that therapies which increase anti-tau antibodies might slow development and/or progression of Alzheimer’s disease (AD). The extent to which individuals with no cognitive impairment (NCI) possess serum anti-tau antibodies, and whether their concentrations of these antibodies differ from the anti-tau antibody levels found in persons with mild cognitive impairment (MCI) or AD, are unclear. We developed an ELISA to measure serum anti-tau antibody levels; this ELISA accounted for antibody polyvalent binding and for the possibility that antibody binding to phosphorylated tau peptides could be due to binding to non-phosphorylated epitopes on those peptides. Specific IgG

and IgM binding to phosphorylated ("pTau;" phosphorylated at Serine-199 and Serine-202) and non-phosphorylated ("non-pTau") tau 196-207 was measured in serum samples from subjects with NCI, MCI, or AD (n = 10/group). RESULTS: Specific pTau and non-pTau IgG antibodies were detected in most subjects. Mean pTau IgG increased in MCI subjects by 53% and 70% vs. AD and NCI subjects respectively (both $p < 0.05$), while no statistically significant differences were found between groups for non-pTau IgG ($p = 0.052$), pTau IgM, or non-pTau IgM antibody levels. Non-pTau IgG levels were negatively associated with global cognition (Spearman rho = -0.50). These findings suggest that serum IgG and IgM to both phosphorylated and non-phosphorylated tau are likely to be present in older persons regardless of their cognitive status. Further, serum concentrations of anti-phospho-tau IgG may be increased in individuals with MCI.

**Authors: *B. CASALI**, E. G. REED-GEAGHAN, G. E. LANDRETH
Dept. of Neurosciences, Case Western Reserve Univ., Cleveland, OH

**Abstract:** Treatment of Alzheimer's disease (AD), a neurodegenerative disorder characterized by pathological hallmarks of beta-amyloid (Aβ) plaque deposits, inflammation, and cognitive decline, remains a clinical obstacle in part due to lack of targeted therapeutics. Our lab established that prolonged treatment with nuclear-receptor agonist bexarotene reversed cognitive deficits in a murine model of AD without notable modification of plaque burden. These conclusions suggest that nuclear receptor agonists exert salutary effects on cognition through alternative mechanisms not fully dependent on plaque burden changes. To elucidate alternative mechanisms, we treated one-year old APP/PS1 mice with bexarotene for two-weeks and then we discontinued bexarotene treatment for two weeks. In both groups of mice, we administered the novel-object recognition test to monitor cognitive improvements, and we analyzed amyloid pathology at the conclusion of the study. Similar to previous findings, bexarotene enhanced cognition; strikingly, we observed sustained improvements in cognition in mice discontinued

from bexarotene. Cognitive improvement in both treatment groups was independent of changes in plaque burden and insoluble Aβ species. Following bexarotene treatment and its discontinuation, we observed significant reductions in microglial reactivity exclusively in the hippocampus of APP/PS1-treated mice. Our findings demonstrate that bexarotene may selectively modify neuroinflammation in a regional-specific manner to reverse hippocampal-dependent cognitive deficits in AD mice, and they may lend insight to inform future studies involving nuclear receptor agonists.

**Title:** Resolution of inflammation - Relation to Alzheimer neuropathology

**Authors: C. EMRE**[1], E. HJORTH[1], A.-C. GRANHOLM[2], *M. SCHULTZBERG[1]
[1]Karolinska Institutet, Huddinge, Sweden; [2]Denver Univ., Denver, CO

**Abstract:** In Alzheimer’s disease (AD) an inflammatory response occurs as a reaction to the primary pathology, and may also be a part of it. The ensuing glial proliferation and activation contributes to the neurodegeneration by increased levels of harmful inflammatory mediators. In general, upon successful removal of the pathogenic insult inflammation is down-regulated together with restoration of the site of insult by the resolution of inflammation, which is actively induced by derivatives of omega-3 and -6 fatty acids named specialized pro-resolving mediators (SPMs). We have previously shown reduced levels of SPMs in *post mortem* brain tissue from AD patients together with alterations in proteins involved in resolution, a negative influence on resolution by the AD pathogen β-amyloid$_{42}$, and that stimulation with SPMs is neuroprotective, anti-inflammatory and increases phagocytosis of Aβ.
We are now further investigating the relationship between the pathology of AD and resolution in different brain regions including the basal forebrain, BA46, cerebellum, cingulate gyrus and

hippocampus. *Post mortem* brain tissue from AD patients and healthy controls are analysed with regard to markers for the resolution of inflammation including receptors and enzymes involved in SPM signalling and synthesis, markers of inflammation, as well as the pathology of AD using immunohistochemistry and western blotting. Data on disease stage according to the ABC scoring system are also available. Our preliminary results show that the levels of ChemR23, receptor for the SPM resolvin E1, were significantly higher in the basal forebrain and in the cingulate gyrus in AD cases compared to controls. These data correlate with neuropathology scores as well as the levels of the microglial marker HLA-DR. This suggests that the resolution of inflammation is related to the neuroinflammation in AD brains, and is supportive of a disturbance in the resolution pathway in AD. Together with our previously published data showing beneficial effects of SPMs, we suggest that stimulation of pro-resolving activities represents a potential treatment for AD and other neurodegenerative disorders.

**Title:** Relationship between BRCA1 and neuroinflammation mediated by PGJ2: Relationship to Alzheimer's disease and cancer-related cognitive impairment

**Authors: *J. DINE**[1], T. JEAN-LOUIS[2], M. E. FIGUEIREDO-PEREIRA[3]
[1]PhD Nursing Program, The Grad. Ctr. of the City Univ. of New, New York, NY; [2]Biol. Sci., [3]Hunter Col., New York, NY

**Abstract:** Alzheimer’s disease (AD) affects approximately 5 million people in the United States and is the leading cause of dementia in older adults. Interestingly, AD shares several genotypic and phenotypic features with cancer-related cognitive impairment (CRCI), which presents in an estimated 75% during and 35% months to years after treatment, most notably in breast and ovarian cancer survivors. Both AD and CRCI are strongly associated with aging, cognitive dysfunction, inflammation, and DNA damage response changes. Decreased expression of

BRCA1, an E3 ubiquitin ligase responsible for DNA double-strand break repair and mediating apoptotic signaling, has been identified in the neurons of individuals with mild cognitive impairment and AD. Deleterious BRCA1 variants that result in loss of functional activity are also associated with breast and ovarian cancer development, among other conditions, due to impaired DNA quality control mechanisms. Thus, BRCA1 loss may be a shared feature of AD and CRCI and warrants investigation, particularly in the context of the neurotoxic prostaglandin J2 (PGJ2). PGJ2 is an endogenous product of inflammation and is considered to be one of the most toxic prostaglandins that is produced downstream from cyclooxygenase-2 (COX-2) activation. COX-2 is highly expressed in AD brains and its activity correlates with the severity of AD. Our *in vitro* studies with human neuroblastoma SY5Y cells overexpressing APP695 (APP695-SY5Y), showed that PGJ2 recapitulates pathological events relevant to AD, including neurotoxicity, caspase-3 activation, tau aggregation, and the accumulation/aggregation of ubiquitinated proteins. We determined the effect of PGJ2 on BRCA1 expression in APP695-SY5Y cells. Upon PGJ2-treatment, the levels of BRCA1 were decreased in a concentration-dependent manner, assessed by western blot analysis. Our findings indicate that BRCA1 expression is attenuated in the presence of PGJ2. This study establishes a potential relationship between BRCA1 and PGJ2 in human neuronal cells for what we believe to be the first time. Further study is needed to investigate PGJ2, as well other the other neuroinflammatory prostaglandins PGD2 and PGE2, and BRCA1 signaling interactions. Such work may lead to the identification of potentially novel therapeutic targets for the treatment of AD and CRCI.

**Title:** Assessing the effects of various fractalkine cleavage products on microglial activation

**Authors: *D. J. FINNERAN**[1], S. KAMATH[2], D. G. MORGAN[4], K. R. NASH[3]
[2]Byrd Alzheimer's Inst., [3]Mol. Pharmacol. and Physiol., [1]Univ. of South Florida, Tampa, FL; [4]Byrd Alzheimer Inst., Byrd Alzheimer's Inst., Tampa, FL

**Abstract:** Fractalkine (CX3CL1; FKN) is an endogenous chemokine expressed throughout the body. It is a type 1 transmembrane protein containing the chemokine domain, a long mucin-like stalk domain, and small transmembrane and intracellular domains. FKN can be cleaved by several proteases (ADAM10, ADAM17, and cathepsin S) to signal as a soluble peptide. The putative ADAM10/17 cleavage site yields a soluble peptide consisting of the chemokine domain and the mucin-like stalk domain. It is thought that cathepsin S cleavage occurs further in the

mucin-like stalk, yielding a shorter peptide than the ADAM10/17 cleavage product. In the CNS, FKN is expressed solely by neurons and binds its unique receptor, CX3CR1, which is expressed only on microglia. FKN signaling leads to decreased expression of pro-inflammatory cytokines such as IL-1β and TNF-α. Recent studies have shown AAV-mediated overexpression of a soluble FKN in Tg4510 mice inhibited microglial activation, reduced tau pathology, and ameliorated neuron loss. However, FKN has also been implicated in neuropathic pain. Rodent spinal injury models show FKN staining near the lesion and inhibition of the lysosomal protease cathepsin S can prevent hyperalgesia. Furthermore, infusion of recombinant chemokine domain caused hyperalgesia while full-length soluble FKN did not. Our study investigates this duality of FKN signaling; full-length soluble is anti-inflammatory while the chemokine domain is implicated in neuropathic pain and microglial activation. Here, we generated conditioned media of human FKN: chemokine domain (ckFKN), full-length soluble FKN (sFKN), and a secreted mucin-like stalk of FKN (mucFKN). We assessed the ability of these constructs to reduce TNF-α secretion from both immortalized rat microglia and primary rat microglia activated by LPS treatment.

**Authors: *S. CHOMPOOPONG**[1], F. PADUNGRAKSART[2], T. NAOWASIRI[2], N. PAKAPROT[3], T. RUNGRUANG[2], T. TAECHOWISAN[4], P. SOBHON[5]
[1]Fac. of Med. Siriraj Hospital, Mahidol Univ., Bangkok Noi, Thailand; [2]Anat., [3]Physiol., Fac. of Med. Siriraj Hospital, Mahidol Univ., Bangkok, Thailand; [4]Microbiology, Fac. of Science, Silpakorn Univ., Nakhon Pathom, Thailand; [5]Anat., Fac. of Science, Mahidol Univ., Bangkok, Thailand

**Abstract:** Sea Cucumber (*Holothuria scabra*) extracts or HsE is a valuable source of several kinds of substances that can serve as natural health products, contain saponins or triterpene glycosides. Pharmacological studies indicate anti-inflammatory and anticancer properties of the sea cucumber saponins that it may enhance learning and memory and promote brain functions. To determine therapeutic potential of HsE as an alternative treatment for vascular dementia,

cerebral hypoperfusion was induced by modified common carotid artery occlusion in 60 ICR mice. After arterial occlusion, HsE was injected intraperitoneally for ten days in HsE treated group, then Morris water maze and voice-cued fear conditioning test were performed. At the end of experiment, eye balls and brains of sacrificed mice were removed for histopathological study of retinal layer, white mater (WM) damage in corpus callosum, pyramidal cell death in hippocampal CA1 and level of TNF-α and IL-1β in serum and brain. Expression of TNF-α and IL-1β in serum and brain were decreased in HsE treated group significantly when compared to occlusion group. HsE improved memory retention significantly at $p<0.05$, treated group swam up to platform with less escape latency time (14.69±2.12 sec) than occlusion group (21.54±3.22 sec). Percent thickness of outer plexiform layer and WM damage indicated by myelin index were enhanced and improved significantly by HsE. The memory retention with increased freezing behavior was also increased from 12.96% ± 4.91 to 49.53% ± 9.72%, significantly at $p<0.001$. HsE showed therapeutic effects against cerebral hypoperfusion and attenuated memory deficits. The decreased pyramidal cell death in hippocampal CA1 area, improved retina and WM damages related to decrease in TNF-α and IL-1β level in serum and brain, therefore, role of HsE may be described by its anti-inflammatory effect.

**Title:** Neurodegeneration and cognitive deficits in aged CIZ1 knock-out mice

**Authors: *M. KHAN**, J. XIAO, D. PATEL, J. TIAN, M. LEDOUX
Neurol., Univ. of Tennessee Hlth. Sci. Ctr., Memphis, TN

**Abstract:** Preserving DNA integrity is vital for normal cellular functioning. Defective DNA repair leads to genomic instability and promotes neurodegeneration and cognitive decline. In this regards, a substantial body of work suggests that mutations in genes that encode proteins involved in cell-cycle and DNA repair have been linked to several age-related neurodegenerative diseases including Alzheimer disease (AD). CDKN1A interacting zinc finger protein 1 (CIZ1), a nuclear protein, plays an important role in DNA repairs pathway and cell-cycle progression at the G1/S checkpoint. Recently, we have shown that germline knock-out (KO) of *Ciz1* is associated with motor, and hematological abnormalities in young adult mice. However, it

remains obscure whether CIZ1 deficiency is involved in age-related neurodegenerative diseases especially in AD. To test our hypothesis that deficiency of CIZ1 has a pathogenic role in AD, we have treated primary neuronal cultures of WT and CIZ1KO mice with $A\beta_{1-42}$ (5 μM) for 24 h. We observed degenerated MAP2-positive neuronal cells along with increased DNA breaks in cultures from CIZ1KO mice compare to barely detectable degeneration in WT cells after $A\beta_{1-42}$ treatment. Interestingly, we observed that 17β-estradiol (E2) treatment confers neuroprotection against $A\beta_{1-42}$ treatment in the CIZ1KO neuronal cells, suggesting neurons derived from CIZ1KO mice were more susceptible *to* $A\beta_{1-42}$ toxicity than neurons derived from their WT littermates. Furthermore, aged CIZ1KO mice exhibited cognitive decline, increased neuronal DNA breaks, vascular dysfunction, upregulation of NF-kB and neurodegeneration in the hippocampus when compared to WT littermates. Our findings suggest that the deleterious effects of CIZ1 deficiency become more pronounced with aging and failure of CIZ1 function may contribute the cognitive decline and neuronal death in the aged brain. Moreover, Identification of the downstream signaling pathways by which CIZ1 promotes neuroprotection may open novel therapeutic avenues to treat neurodegenerative diseases and age-related cognitive deficits

**Title:** Diazoxide as a protective therapeutic against the neurotoxic effects of neuroinflammation induced by the cyclooxygenase product prostaglandin J2: Relevance to Alzheimer’s disease

**Authors: *A. LEVINE**[1], J. SEPULVEDA[1], L. XIE[2,3], P. ROCKWELL[1,4], M. E. FIGUEIREDO-PEREIRA[1,4]
[1]Biol. Sci., [2]Computer Sci., Hunter Col., New York, NY; [3]Computer Sci., [4]Biol. and Biochem., CUNY Grad. Ctr., New York, NY

**Abstract:** Chronic neuroinflammation is a major factor initiating/exacerbating neurodegeneration in Alzheimer’s disease (AD). The pro-inflammatory enzyme cyclooxygenase-2 (COX-2) is highly expressed in AD brains and its activity correlates with the severity of AD.

COX-2 catalyzes the synthesis of prostaglandins, some of which are neuroprotective while others are neurotoxic. Anti-inflammatory drugs that target COX-2 can prevent/inhibit inflammation. However, this anti-inflammatory strategy can produce adverse side effects, including renal failure, heart attack and stroke, as well as preventing the synthesis of neuroprotective prostaglandins. Therefore, to prevent the effects of neurotoxic prostaglandins without interfering with the neuroprotective ones, would offer a significant *therapeutic benefit* to the *treatment* of *AD*. Prostaglandin J2 (PGJ2) is an endogenous product of inflammation and is considered to be one of the most toxic prostaglandins that is produced downstream from COX-2 activation. Our *in vitro* studies with human neuroblastoma SY5Y cells overexpressing APP695 (APP695-SY5Y), showed that PGJ2 recapitulates pathological events relevant to AD, including neurotoxicity, caspase-3 activation, and the accumulation/aggregation of ubiquitinated proteins. We investigated the therapeutic potential of Diazoxide (DZ) against the neurotoxic effects induced by PGJ2 in APP695-SY5Y cells. DZ is a well-known potassium channel activator, is safe, is an FDA-approved drug for hypertension, and was also shown to positively modulate glutamate receptors indicating that it has potential to enhance cognition. Our *in silico* studies predicted that DZ binds to multiple kinases that are responsible for the pathology of AD. Our *in vitro* studies established that DZ significantly reduces the accumulation of ubiquitinated proteins and caspase-3 activation in the SY-APP695 cells. Our data support that DZ protects the neuronal cultures from PGJ2-induced neurodamage. The deeper study of DZ will provide insights for a therapeutic approach to overcome the neurotoxic effects of neuroinflammation and for enhancing neuronal survival in AD. NOTE: *Alec Levine and Jordy Sepulveda contributed equally to these studies.

**Title:** Frontal cortex chitinase 3-like protein 1 (CH13L1) and complement component C1q protein levels during the progression of Alzheimer’s disease

**Authors: *M. NADEEM**, S. PEREZ, E. J. MUFSON
Dept Neurol, Barrow Neurolog. Inst., Phoenix, AZ

**Abstract:** Chitinase 3-like protein 1 (CH13L1 or YKL-40) and C1q are involved in immune regulation in several inflammatory conditions and neurodegenerative diseases, including Alzheimer's disease (AD). In brain, CH13L1 and C1q are secreted mainly by innate immune cellular elements, astrocytes and microglia, which are involved in anti-inflammatory responses. Astrocytes and microglia are increased in areas of the brain displaying amyloid beta (Aβ) and tau pathology in AD, suggesting the involvement of CH13L1 and C1q in the pathogenesis of AD. While a few studies have shown an upregulation of CH13L1 and C1q in cerebral spinal fluid and temporal cortex in AD, virtually nothing is known about the evolution of these inflammatory markers in the frontal cortex during the progression of AD. In the present study, we examined CH13L1 and C1q protein levels in frozen frontal cortex obtained from subjects who died with an antemortem clinical diagnosis of no cognitive impairment (NCI, n=14), mild cognitive impairment (MCI, n=13), mild/moderate AD (mAD, n=12) and severe AD (sAD, n=11,) from the Rush Religious Orders Study (RROS) and the Rush ADC, respectively, using quantitative immunoblotting. Levels of CH13L1 and C1q were correlated with the microglia markers triggering receptor expressed on myeloid cells (TREM2) and Iba1 values, which are known to regulate inflammation and phagocytosis. Western blot analysis revealed no significant differences in CH13L1 ($p=0.097$) and C1q ($p=0.072$) protein levels among the clinical groups. However, there was a trend towards an increase CH13L1 and C1q in MCI and mAD, which were correlated with each other in both clinical groups ($r=0.6$, $p<0.0004$). In addition, we found that C1q levels were positively associated with Iba1 values ($p=0.7$, $p<0.00009$), but not with TREM2, in MCI and mAD. Conversely, cortical CH13L1 levels did not show a correlation with Iba1 in the early stages of the disease, and only a negative correlation was observed with TREM2 in the MCI group ($r=-0.7$, $p=0.01$). These data suggest that increases in CH13L1 and C1q protein levels in the frontal cortex are indicative of an active gliosis process associated with an anti-inflammatory response early in the disease.

**Abstract:** Microglial cells are the resident phagocytes of the central nervous system (CNS) and represent a key cell type implicated in the CNS inflammatory response. Mutations and/or differential expression of microglial cell surface molecules such as TREM2, CD33 and CR3 have been associated with altered relative risk(s) for developing Alzheimer's disease (AD). TYROBP (also known as DAP12) is a microglial adaptor protein that acts as a key driver of a microglial activation network underlying AD. TYROBP binds TREM2, CD33, and/or CR3 and is increased in the brains of humans and mouse models of AD (Zhang et al., 2013; Readhead et al. 2015).
We crossed Tyrobp-deficient mice with either APP/PSEN1 or MAPT P301S mouse models in order to determine the effect of loss of TYROBP function on amyloid and/or tauopathy features of these mice. We will present the effects of Tyrobp deficiency on the microglial inflammatory response and AD pathology, and, in turn, on the behavior and electrophysiology. One unexpected feature of Tyrobp-/- x APP/PSEN1 or MAPT P301S mice was a reduction in brain levels of complement initiating protein C1q, a molecule known to modulate synaptic sculpting (Hong et al. 2016). Thus, one potential consequence of the excess TYROBP observed in the AD brain might be to play a role in complement-related synaptic pruning (and synaptic loss) by microglia.

**Abstract:** Alzheimer's disease (AD) is the most common cause of dementia in the elderly. The main symptoms and signs of the AD are a progressive loss of cognitive functions and the presence of extracellular plaques of aggregated β-Amyloid and intracellular deposits of hyperphosphorylated tau protein. These features cause a prominent neuroinflammation, with interleukin-6 being one of the critical cytokines. For signalling, IL-6 binds to a membrane receptor (mIL-6R) and the complex of IL-6 and mIL-6R associates with gp130, which dimerizes and activates the intracellular signalling. The expression of mIL-6R is restricted to a few tissues. A soluble form of IL-6R (sIL-6R) exists naturally, and it is demonstrated that this form can activate gp130 in the presence of IL-6. This procedure has been called trans-signalling. Due to the ubiquitous expression of gp130, every cell in the body can be stimulated by this process. IL-6 trans-signalling is specifically inhibited by the soluble form of gp130, sgp130.
To study the role of IL-6 trans-signalling in AD, we generated a mouse model of AD, Tg2576, which expresses the human $APP_{695}$ harbouring the Swedish K670N/M671L mutation and simultaneously secretes the specific inhibitor of IL-6 trans-signalling, human sgp130-Fc, from astrocytes.
We are characterizing the model behaviourally and neuropathologically at different stages of the disease. Herewith we show body weight gain, survival and behavioural characterization before the formation of β-amyloid plaques (5-6 months of age), using Open-field, Hole-board, Novel Object Recognition Test, Elevated-plus Maze and Morris Water Maze. Additionally, preliminary neuropathological analysis (APP precursor protein, $A\beta_{40}$ and CTF-β) were carried out in animals of 10-11 months of age.
The main aim of this study is to clarify the function of IL-6 trans-signalling in the AD. At this moment, we do not observe major effects of the inhibition of the trans-signalling on the disease. Whether or not a significant effect will be observed upon amyloid plaques formation remains to be established.

**Title:** MicroRNAsmiR-155 and miR-146a modulate neuroinflammation in Alzheimer’s disease

**Authors: *M. S. ALOI**[1], K. E. PRATER[2], S. DAVIDSON[2], B. WATHEN[1], S. JAYADEV[2], G. A. GARDEN[2]
[2]Neurol., [1]Univ. of Washington, Seattle, WA

**Abstract:** Alzheimer’s Disease (AD) is a progressive age-related neurodegenerative disorder. AD is characterized by the accumulation of extracellular amyloid beta (A$\beta$) as well as CNS and systemic inflammation. Innate immune cells like CNS resident microglia and circulating monocytes use microRNAs to rapidly respond to inflammatory signals, such as A$\beta$ exposure. AD patient microRNA (miRNA) profiles are altered in tissue, circulating monocytes, and serum. miR-146a and miR-155 are two miRNAs that modulate the phasic inflammatory responses of innate immune cells. Previous studies show that miR-146a is upregulated in PS2 knock-out microglia. Deletion of miR-146a leads to an accelerated aging phenotype and multi-organ inflammatory infiltration, which is abrogated by conditional deletion of miR-155. miR-155 and miR-146a modulate transitions between inflammatory phases, however their precise roles in modulating inflammation in AD remains unknown. We hypothesize that miR-155 and miR-146a participate in AD pathology by modulating A$\beta$ equilibrium by influencing the functions of inflammatory cells. Using cultured neonatal microglia, we observed that modulation of miR-155 and miR-146a impact the internalization and degradation fibrilized A$\beta$. We generated trigenic mouse models to acutely or continuously induce CX3CR1 driven Cre-mediated deletion of floxed miR-155 or miR-146a alleles in either microglia alone, or microglia and circulating monocytes in the APP/PS1 mouse model. After *ex-vivo* percoll gradient selection of microglia, cells were isolated by FACS and miR-155 or miR-146a deletion was detected by PCR. Changes in inflammatory gene and miRNA expression in microglia 3 and 6 months post-acute and -chronic miR-155 deletion were assessed by qPCR. Cortical and hippocampal soluble and insoluble A$\beta$ levels were assessed by ELISA 3 and 6 months following miRNA-155 and miR-

146a deletion. Conditional miR-155 and mIR-146a deletion was detected in FACS isolated microglia at 3 and 6. In addition, we observed changes in inflammatory gene expression in microglia. Our results thus far support the hypothesis that acute and continuous miR-155 deletion in microglia and monocytes alters innate immune gene expression and Aβ equilibrium, further elucidating the molecular pathways regulating neuroinflammation in AD.

Inst., Roper St. Francis Healthcare Syst., Charleston, SC

**Abstract:** Current research efforts have begun to explore functional brain network alterations in mild cognitive impairment (MCI) and Alzheimer’s Disease (AD). However, the clinical significance of different network measures is not yet clear. Here, we present a framework in which different network properties constitute different hypotheses of network configuration and information organization, which may be related to different aspects of cognitive impairment and decline in AD. The framework is tested using graph-theory measures of intrinsic connectivity from resting state fMRI (rsfMRI). Data collected as part of ADNI and ADNI-DOD included fifteen AD patients and 14 age-matched healthy controls. After data preprocessing, fully-connected and weighted connectivity matrices were constructed using partial correlation and a shrinkage operation. Clustering coefficient and eigenvector centrality were computed for each of 264 brain regions (nodes) for each subject. The 264 node measures were reduced to 12 components and factor scores served as predictors (using linear modeling) of either cognitive impairment (the MMSE score at the time of scanning, which was at least 6 months after the

baseline visit) or cognitive decline (the change in MMSE score from baseline to the time of scanning). Clustering coefficient marginally predicted MMSE score at the time of scanning (Accuracy = 41.8%, p = .062). Lower MMSE was associated with higher clustering coefficient in a number of different nodes in frontal, parietal and occipital cortex. Eigenvector centrality (EC) significantly predicted change in MMSE score from baseline (Accuracy = 66.2%; p = .023). A more restricted set of brain regions predicted change in MMSE, with greater cognitive decline associated with higher EC in the right superior occipital and right inferior frontal cortex and with lower EC in the right cuneus. The prediction of MMSE from eigenvector centrality persisted even when age and sex were added as predictors (Accuracy = 59.4%; p = .042). Although preliminary, these initial findings indicate that different graph-theory measures of functional network connectivity are associated with cognitive impairment versus cognitive decline, indicating that models of network degradation and compensation in AD should consider the different information properties of graph-theory measures.

**Title:** Posttranslational-modification impacts on the mechanism by which oligomeric Aβ triggers synaptic dysfunction

**Authors: *P. YUANXIANG**, K. GROCHOWSKA, M. KREUTZ
Leibniz Inst. for Neurobio., Magdeburg, Germany

**Abstract:** It is generally believed that soluble oligomeric amyloid beta (Aβo) disrupts synaptic plasticity and memory at an early stage of Alzheimer's disease (AD). Various posttranslational-modified Aβo have been identified, and the most abundant types are N-terminally truncated forms. It is not clear, however, whether modified forms can induce synaptic dysfunction on their own. Here, we show that the D1/D5R agonist SKF38393 protects LTP of hippocampal CA1 synapses from the deleterious action of oligomeric amyloid beta 1-42 (Aβ 1-42). Moreover, we found that inhibition of Src-family tyrosine kinases completely abolished the protective effects of D1R/D5R stimulation. In addition, we show that a prominent isoform, pyroglutamated Aβ3(pE)-42, induces synaptic dysfunction to a similar extent like Aβ1-42 but by clearly different mechanisms. In contrast to Aβ1-42, Aβ3(pE)-42 does not directly associate with synaptic membranes or the Prion protein but is instead taken up by astrocytes and potently induces glial release of the pro-inflammatory cytokine TNFα. Moreover, Aβ3(pE)-42 induced synaptic dysfunction is not related to NMDAR signalling and Aβ3(pE)-42 induced impairment of synaptic plasticity cannot be rescued by D1R/D5R-agonists. Collectively the data point to a scenario where neuroinflammatory processes together with direct synaptotoxic effects are caused by posttranslational modification of soluble oligomeric Aβ and contribute synergistically to the onset of synaptic dysfunction in AD.

**Title:** Heterogeneity in local hippocampal connectivity as measured by functional magnetic resonance imaging increases with Alzheimer's disease progression

**Authors: *K. SHATTUCK**[1], S. ASHBURN[2], W. HORTON[3], J. H. HOWARD, Jr.[4], G. W. REBECK[2], R. S. TURNER[3], X. JIANG[2]
[2]Neurosci., [3]Neurol., [1]Georgetown Univ., Washington, DC; [4]Psychology, Catholic Univ. of America, Washington, DC

**Abstract:** Early detection of Alzheimer's disease (AD) symptoms enables treatment strategies based on slowing disease progression. However, despite recent efforts and significant progress, reliable detection of pre-symptomatic and prodromal AD remains a major challenge. Synaptic dysfunction precedes neurodegeneration in early stages of AD, but is difficult to detect and quantify. Functional magnetic resonance imaging (fMRI), with its ability to measure neuronal

function, has the potential to non-invasively identify systems-level connectivity impairments associated with cognitive decline prior to identifiable structural changes. Using a previously validated analysis technique (Hcorr) that estimates the heterogeneity of functionally localized connectivity, we report that local hippocampal activity shows marked differences between patients diagnosed with AD or mild cognitive impairment (MCI) and healthy control subjects. Methods: Fifteen individuals with AD, 12 with MCI, 24 high-risk control subjects (with a family history of AD and/or APOE-4 genetic status), and 27 low-risk control subjects (all subjects: 56-85 years old, 43 females) underwent a T1-weighted structural MRI scan as well as six 6-minute fMRI scans. The fMRI scans comprised two runs each of a 1-back face-detection task, a modified serial reaction time task, and resting scans. Hcorr was calculated within left and right hippocampus for each MRI scan using a revised algorithm to improve robustness. ROI localization was based on a publicly available brain atlas and customized within each subject to voxels estimated via structural scan segmentation to contain at least 50% grey matter volume. Results: Mean bilateral hippocampal Hcorr for each of the three scanning tasks was greater in patients than control subjects (2-way *t*-tests, all $p < .001$) as well as greater for MCI patients than high-risk control subjects (2-way *t*-tests, all $p < .01$). Across all subjects, bilateral hippocampal Hcorr for each of the three scanning tasks correlated with performance on tests of general cognition (MMSE and ADAS) as well as scores of immediate and delayed memory (Hopkins Verbal Learning Test; all $p < 0.01$). Conclusion: Local hippocampal functional heterogeneity as measured by Hcorr is informative to disease state even between high-risk healthy individuals and MCI patients, and measurement is robust to the task performed during functional scan acquisition. Further research and technique refinement is warranted to improve applicability in clinical settings.

**Title:** AβO-mediated calcium disruption connects excitotoxicity to cell cycle re-entry and subsequent neuron death in Alzheimer's disease

**Authors: *E. J. KODIS**[1], S. CHOI[2], G. S. BLOOM[3]
[1]Biol., [2]Biochem., [3]Univ. of Virginia, Charlottesville, VA

**Abstract:** Excitotoxic neuron death caused by excess calcium influx is initiated by amyloid-β oligomers (AβOs) in Alzheimer's disease (AD), but the downstream signaling that results in neuron death remains less well understood. Ectopic neuronal cell cycle re-entry (CCR) is an early symptom of neuron dysfunction, ultimately leading to neuron death, rather than replication of neurons, accounting for substantial neuron death in AD. The present study tests the idea that excitotoxicity and the resulting synaptic dysfunction, in addition to being toxic in their own right, also contribute to the CCR pathway of neuron death. To test this, we first asked whether AβO-mediated calcium influx is necessary for CCR *in vitro* using primary cortical neurons. Pharmacologically blocking N-methyl-D-aspartate receptor (NMDAR) activity with memantine or MK-801, or knocking down the NMDAR subunit, NR1, blocks CCR. Furthermore, NMDAR inhibition by these same methods prevents AβO-stimulated activation of calcium-calmodulin-dependent protein kinase II (CaMKII), which mediates excitotoxicity and is necessary for CCR. Next, we tested whether treating neurons with a canonical excitotoxic insult would induce CCR. Exposing primary neuron cultures to a 30 second shock of 10 μM NMDA induces CCR in a manner similar to AβOs. Next, we wanted to recapitulate our *in vitro* results using the Tg2576 mouse model of AD. To test the role of AβO-mediated calcium influx *in vivo*, Tg2576 mice were treated with memantine, an FDA approved drug for the treatment of AD that gates the NMDA receptor. Memantine treatment in these mice blocks CCR compared to the untreated Tg2576 mice and WT controls. Together, these data imply a functional connection between NMDAR excitotoxicity and the CCR pathway in AD.

**Authors: J. T. GLADMAN**[1], S. JEON[1], D. BABCOCK[1], M. EMR[1], A. K. GUBITZ, Ph.D.[1], C. MOY[1], P. A. SCOTT[1], B.-A. SIEBER[1], M. SUTHERLAND[1], C. TORBORG[1], W. J. KOROSHETZ[2], *R. A. CORRIVEAU[1]
[1]NINDS/NIH, Rockville, MD; [2]NINDS/NIH, Bethesda, MD

**Abstract:** Goal 1 of the National Plan to Address Alzheimer's Disease is to prevent and effectively treat Alzheimer's disease and Alzheimer's disease-related dementias (AD/ADRD) by

2025. To inform the research agenda toward achieving this goal, the National Institute of Neurological Disorders and Stroke (NINDS) hosts periodic Summits that set and refine relevant research priorities for multiple etiology dementias, Lewy body dementia, frontotemporal degeneration, vascular contributions to cognitive impairment and dementia, collectively referred to as the Alzheimer's Disease-Related Dementias (ADRD). Here we introduce and outline several major new NINDS-led ADRD research programs supported by additional funds that first became available for AD/ADRD research during fiscal year 2016. Each of these programs represents a top research priority based on scientific progress and broad stakeholder input provided at the ADRD Summit 2016. The Center without Walls for the Identification and Validation of Molecular Mechanisms Contributing to Tau Pathogenesis (RFA-NS-16-023) is made up of interdisciplinary, multi-institute research that will lead to the identification and validation of molecular mechanisms that are relevant to human biology that contribute to tau toxicity associated with Frontotemporal Degeneration. The Lewy Body Dementias Biomarker initiative (RFA-NS-16-022) supports hypothesis-driven clinical research to discover biomarkers to improve the efficiency and outcome of clinical trials. Mechanistic Basis of Diffuse White Matter Disease in Vascular Contributions to Cognitive Impairment and Dementia (VCID) research (RFA-NS-16-021) will elucidate cellular and molecular mechanisms that underlie diffuse white matter disease of vascular origin that contribute to cognitive impairment and dementia. Finally, MarkVCID (RFA-NS-16-019; RFA-NS-16-020) is a consortium of US academic medical centers whose mission is to identify and validate biomarkers for the small vessel diseases of the brain that produce VCID. As additional resources become available, the NINDS will implement other top recommendations.

**Title:** The impacts of family history of Alzheimer's disease and education on white matter integrity

**Authors: *N. J. GALLEGOS**[1], A. STICKEL[1], L. RYAN[2]
[1]Psychology, [2]Evelyn F. McKnight Brain Inst., Univ. of Arizona, Tucson, AZ

**Abstract:** A family history of Alzheimer's disease (AD) has been shown to increase risk for the disorder beyond known genetic risk factors such as e4 status. Other factors, such as higher education, may decrease risk or delay the onset of AD. Our study investigated the effects of family history on white matter microstructure. Greater deterioration of white matter with age may serve as an indicator of AD-related pathology in preclinical stages of AD. Diffusion magnetic resonance imaging scans were obtained from 28 cognitively normal older adults with a family history of AD and 29 older adults without family history. Groups were matched on age, education, gender, and apolipoprotein e4 status. Fractional anisotropy (FA) measurements were computed using DTI-tk (http://dti-tk.sourceforge.net) in the uncinate fasciculus and the inferior longitudinal fasciculus (ILF) bilaterally, two regions susceptible to damage in the early development of AD (Smith et al., 2010). General linear models controlling for age, education, and gender found no differences in FA between the two groups. However, this relationship was moderated by education. Participants were split into two groups, high education (>14 years) and moderate-to-low education (≤14 years). Controlling for age and gender, individuals with a family history and moderate-to-low education had significantly lower FA values in both the uncinate fasciculus and ILF compared to those with family history and high education and those with no family history. These results suggest that education may protect white matter against the negative impact of risk factors for AD such as family history. Future analyses will investigate whether the interaction between family history and education is protective across the entire brain or in specific tracts (e.g., the uncinate and ILF), and whether other known risk factors such as cardiovascular health may also be moderated by education.

**Title:** Altered resting-state brain complexity in alzheimer's disease: A multiscale entropy analysis

**Authors: *P. REN**[1], F. LIN[2]
[1]Univ. of Rochester, Rochester, NY; [2]Univ. of Rochester Med. Ctr., Rochester, NY

**Abstract: Objective:** Reduced complexity in multiple physiological systems is considered an aging sign. Alzheimer's disease (AD) is a progressive neurodegenerative disorder with aging. Using multiscale entropy (MSE) analysis, which measures brain complexity in different time scales, we examined change of brain complexity in AD associated neurodegeneration. **Methods:** Resting-state fMRI data and neuropsychological assessments from 62 HC, 81 amnestic mild cognitive impairment (aMCI), and 25 AD participants from the Alzheimer's Disease Neuroimaging initiative were used. A three-group comparison of 90 ROI from the Automated Anatomical Labeling (AAL) atlas was conducted to determine the optimal parameters for calculating MSE. Group comparison on whole brain voxel-wise MSE and correlations between MSE and neuropsychological assessments were then conducted. **Results:** We found two opposite MSE patterns in small (scale=1 and 2) and large time scales (scale=3 and 4) between groups. Applying the optimal parameters of MSE analysis (m=1, r=0.35, scale=2), significant changes of entropy was found in four brain regions, including hippocampus, precentral gyrus, intraparietal lobe, and superior frontal gyrus. Post-hoc analysis showed significant lower MSE in all the four regions in AD than HC, and significant lower MSE in hippocampus and precentral gyrus in MCI than HC. In addition, MSE in the four regions were positively correlated with Montreal Cognitive Assessment (MoCA), memory and executive function. **Conclusions:** The study revealed altered patterns of brain complexity in AD compared to normal aging, which depend on different time scales.

**Title:** The effects of SDC3 and FGFRL1 on neurodegeneration in AD and PD

**Authors: *J. WANG**, W. SONG
UBC, Vancouver, BC, Canada

**Abstract:** Neuritic plaque, the pathological hallmark of Alzheimer's Disease (AD), is formed by extracellular deposits of amyloid β protein (Aβ) cleaved from amyloid β precursor protein (APP). Parkinson's Disease (PD) is featured by intracellular Lewy bodies (LBs), primarily consisted of aggregated alpha-synuclein protein (αSyn), encoded by SNCA gene. Both AD and PD are characterized by extensive neuronal loss within selected brain regions exemplified by

basal forebrain cholinergic dystrophy in AD and nigrostrital dopaminergic deficient in PD. In this study, we stably overexpressed human wildtype/ mutant APP and SNCA in the cholinergic SN56 cells and dopaminergic MN9D cells. The total RNA was extracted from eight stable cell lines and performed gene expression profiling by Illumina platform. Differential gene expression was analysed in APP-related stable cells and SNCA-related stable cells, separately. The microarray results showed that SDC3 gene was differentially expressed in SN56-$APP_{SWE}$ and MN9D-$APP_{SWE}$ cells, while FGFRL1 gene was differentially expressed in SN56-$SNCA_{A53T}$ and MN9D-$SNCA_{A53T}$. By conducting qt-PCR and immunoblotting, the results were consistent with the findings observed in microarray. In the $APP_{SWE}$ knock-in mice ($APP^{NL/NL}$) developed by Saito's group, the expression of SDC3 protein was significantly increased in medium septal (MS) with comparison to substantial nigra(SN) by immunoblotting. Knockdown of SDC3 gene showed protective effects in SN56-$APP_{SWE}$ cells under hydrogen peroxide-induced oxidative stress, but not in MN9D-APPSWE cells. Meanwhile, the expression of FGFRL1 protein was upregulated the in dopaminergic neurons instead of cholinergic neurons in the Prnp-$SNCA_{A53T}$ transgenic mice, which was detected by immunofluorescent staining. By knocking down of FGFRL1 gene in the SNCA-related stable cells, it only rescued cell death in MN9D-$SNCA_{A53T}$ cells under hydrogen peroxide treatment, but not in SN56-$SNCA_{A53T}$ cells. Taken together, differential expression of SDC3 and FGFRL1 in the cholinergic and dopaminergic neuron may mediate the selective neurodegeneration in $APP_{SWE}$-associated AD and $SNCA_{A53T}$-associated PD.

**Abstract:** The purpose of our research was to understand the role of comorbidity of depression in Alzheimer's disease (AD). Neurotransmitter, serotonin plays an important role in regulating

midbrain pathology in AD. However, molecular links between serotonin regulation and AD progression are not completely understood. To achieve our objective, we stably transfected rat serotonergic (5HT) cell lines RN46A and B14, and non-serotonergic IMR32 and SHSY5Y cells with mutant APP (Swiss) and WT APP and mutant Tau (P308L) and WT Tau cDNAs. Stably transfected and un-transfected cells were studied for mitochondrial biogenergetics, apoptosis, cell viability and mRNA and protein levels of mitochondrial, AD, serotonin, and synaptic genes. Using immunocytochemistry, we studied localization of synaptic and mitochondrial proteins and mechanism of serotonin in AD pathology. Using sandwich ELISA, we measured amyloid beta (Aβ) 40 and 42, Serotonin, beta and alpha secretase levels in transfected and un-transfected cells. Using transmission electron microscopy, we also studied ultra-structural changes. Preliminary results of our study revealed that significantly increased cell apoptosis, reduced cell viability in stably transfected cells with mutant APP and mutant Tau cDNAs relative to un-transfected cells. Serotonin neurons have never been studied under the effect of APP/Tau pathology so this will be first studies in *in vitro* mid brain neurons. Based on these observations, we conclude that RN46A, B14 and non-serotonergic cell lines IMR32 and SHSY5Y are unique cell models to study mechanisms involving the serotoninergic system in AD pathology. These stable cell lines will be useful for drug screening in AD.

**Abstract:** Primary progressive aphasia (PPA) is a neurological disorder that typically presents with a progressive loss of language capabilities. Approximately 30-40% of PPA cases present with Alzheimer's disease pathology (PPA-AD), with an asymmetric distribution favoring the cortical language network in the dominant hemisphere (usually left). The typical amnestic variant of AD is characterized by significant loss of basal forebrain cholinergic neurons (BFCN). However, the status of BFCN in PPA is unknown. The purpose of this study was to determine the presence, extent and hemispheric asymmetry of BFCN loss in PPA-AD. Tissue from five PPA-AD and three normal control participants were used in this experiment. Sections from basal forebrain containing BFCNs were stained immunohistochemically for low affinity neurotrophin receptor (p75), which is specifically enhanced in BFCN. Unbiased stereological counting was used to estimate changes in the number of p75-positive BFCN in PPA-AD. The number of BFCN in the language-dominant hemisphere of PPA-AD participants was 35% lower when compared with the right hemisphere ($p<0.008$). The left hemisphere of the PPA-AD brains also contained 73% fewer BFCN than the left hemisphere of control brains ($p<0.02$). Examination of Nissl stained material corroborated loss of magnocellular, hyperchromic BFCN in PPA-AD participants. Qualitatively, BFCNs in PPA-AD participants contained substantial densities of tangles and pre-tangles as revealed by thioflavin-S staining and abnormally phosphorylated tau (AT8) immunostaining. These findings indicate that, like typical amnestic AD, PPA-AD is characterized by substantial degeneration of basal forebrain cholinergic neurons. They also suggest that cholinesterase inhibitors used as therapeutic agents in AD are likely to also be effective in PPA-AD.

**Abstract:** The gut microbiome consists of trillions of microorganisms that include bacteria, archaea, viruses and eukaryotes. Previous studies have shown that this diverse community communicates with the central nervous system (CNS) via a bidirectional pathway termed the gut-brain axis. Recent research concerning the gut-brain axis has implicated microbiome dysregulation in a variety of pathological states, including neurodegenerative disorders such as Alzheimer's disease (AD). So far, research has shown characteristic pathological dysbiosis (microbial imbalance), but probiotic treatment as a therapy has not been thoroughly explored. In our study, we sought to correct the dysbiosis with a probiotic diet in an AD mouse model, with the hope of exploring the potential benefits of an easily accessible therapeutic. Transgenic APPSWE-Tau301 mice were fed a probiotic diet (*Lactobacillus plantarum KY1032* and *Lactobacillus curvatus HY7601*) for 12 weeks, during which cognitive functions were evaluated via the Barnes Maze during the final 5 weeks of the study. Our data show that AD mice on probiotics performed comparably to wild-type controls, while AD mice on a regular diet showed deficiencies. To determine if the improved cognitive functions were reflective of decreased tissue damage, brains were collected from all animals at the end of the probiotic treatment, and several CNS cell populations were analyzed using immunohistochemistry. Number of total cells ($DAPI^+$), neurons ($NeuN^+$) and astrocytes ($GFAP^+$) were assessed first in the cortex. Preliminary data show that AD mice on control diet have an approximate 50% decrease in total cell numbers and an increased percentage of $GFAP^+$ cells. These changes are mitigated in the AD probiotic treatment group, returning cell numbers close to wild-type controls' level. Ongoing studies are assessing these cell populations in other brain regions, as well as determining the CNS inflammatory state in these animals via analysis of astrocytic and microglial reactivity. Our results suggest that an alteration of the microbiome could be effective in delaying or mitigating neurodegeneration and improving cognitive abilities in this AD animal model. It is vital to explore new possibilities for palliative care of Alzheimer's disease, and a supplementary probiotic diet could provide an inexpensive and easily implemented clinical treatment.

**Abstract:** Worldwide, every year there is an increase in the number of people exposed to inorganic arsenic (iAs) via drinking water. Human populations present impaired cognitive function as a result of prenatal and childhood iAs exposure, while studies in animal models in similar conditions demonstrate neurobehavioral deficits accompanied by protein and enzyme alterations associated to Alzheimer´s disease (AD). In primary cultures of Tg2576 mouse brain, iAs promotes the production of βA and decreases the activity of α -secretase. In order to determine whether arsenic promotes the pathophysiological progress of AD, we used the 3xTg-AD mouse model since it mimics the development of amyloid plaques, neurofibrillary tangles and behavioral dysfunction. Male and female 3xTg-AD mice (25-30 g) were divided into 2 groups (n=7): 1) control without arsenic; and 2) exposed to 3 ppm sodium arsenite in drinking water. Animals received the treatment from gestation until 6 months. We investigated the behavior phenotype on a test battery including locomotor behavior, Morris water maze (MWM) and contextual fear conditioning. Immunohystochemical studies were performed to detect AD markers. 3xTg-AD mice exposed to iAs presented alterations in their circadian rhythm, specifically, males showed higher locomotor activity during the day and shorter free running periods prior to the onset of AD-pathology. Females had a slightly decrease in activity levels during their typical active phase compared to controls. Longer escape latencies and higher number of failures to reach the platform were found in the iAs group than in the control group in the MWM. Short term memory was assessed by means of contextual fear conditioning. Exposed animals exhibited a significant difference in freezing time compared to the control group. Immunopositivity to amyloid and tau markers in sections of hippocampus and frontal cortex resulted in meaningful effects of the treatment in both regions. Significantly higher inmunoreactivity to amyloid isoforms particularly in the cortex and CA3, as well as desestabilized microtubules in CA1-hippocampus at the 6$^{th}$ month of age were found in the iAs group as compared to the control group. In summary, iAs prenatal and life-long exposure results in contextual and spatial memory decline. Furthermore, arsenic enhances the development of amyloid pathology. With less significant effect on tau pathology. These results are consistent with classical pathway of amyloid cascade hypothesis. These findings confirm that iAs exposure induces cognitive deficits and degenerative markers in the central nervous system that are characteristic of AD.

**Abstract:** Alzheimer’s disease (AD) causes progressive deficits in memory and cognitive function, and it has emerged as a major health and socio-economic concern in the US and worldwide. In order to develop more effective therapeutic treatments, we need to further understand neural mechanisms underlying Alzheimer’s disease. Toward this goal, we study large-scale hippocampal CA1 neuronal network activation and memory behavior deficits in a well-established model for AD, the 3xTg-AD mouse model which presents amyloid plaques and neurofibrillary pathology. Stereotaxic injection of AAV-Camk2a-GCaMP6f is used to selectively express GCaMP6 in CA1 excitatory neurons in AD and control mice. A new object-location based task to assess learning and memory updating is coupled with simultaneous *in vivo* GCaMP6-based calcium imaging of hippocampal CA1 neuronal populations using miniature microscopes placed on freely moving mice. Compared with control mice, our preliminary data analysis indicates that AD mice of 4 months and older appear to have major deficits in memory updating, as reflected by discrimination measurements. We are able to track the activation of more than one hundred of the same CA1 neurons in each mouse across days of behavior training and testing using *in vivo* microscopic Ca2+ imaging. In marked difference from control mice, CA1 neuronal responses in the AD mice are far more heterogeneous in calcium response dynamics and signal pattern. Based on these initial results, we conclude that differential neuronal activity patterns in AD and control mice are associated with their memory behavior outcomes, and that hippocampal CA1 networks in AD mice have alterations in organizing spatially correlated activities likely due to AD histopathology.

**Title:** Oxidative stress and antioxidant response in frontal cortex of demented and non-demented individuals with Alzheimer's neuropathology

**Authors: *A. FRACASSI**[1], S. MORENO[2], G. TAGLIALATELA[1]
[1]Mitchell Ctr. for Neurodegenerative Diseases, Dept. of Neurol., Univ. of Texas Med. Br., Galveston, TX; [2]Dept of Science-LIME, Univ. Roma Tre, Rome, Italy

**Abstract:** Alzheimer’s disease (AD) is the most common form of dementia characterized by progressive neurodegeneration affecting specific brain areas, particularly frontal cortex. Histopathological features include extracellular senile plaques, composed of amyloid β (Aβ) polymers, and intracellular neurofibrillary tangles, formed by hyperphosphorylated Tau protein. Several mechanisms have been put forward to explain the pathogenic events occurring in AD, among which the so-called amyloid cascade, involving a critical role of Aβ peptide. However, the accepted correlation between Aβ and dementia has recently been challenged by the emergence of a group of individuals, referred to as "Non-Demented with Alzheimer’s Neuropathology" (NDAN), showing severe neuropathological signs, though remaining cognitively intact. The existence of these individuals suggests that some unknown mechanisms are triggered to resist the detrimental events, normally leading to cognitive impairment in AD. Such mechanisms would not impede Aβ overproduction or aggregation, but possibly prevent neurotoxic effects of the peptide. Noteworthy, Aβ accumulation affects mitochondrial redox balance increasing oxidative stress status, which has long been recognized as a major trait of the disease and been proposed as a primary culprit in AD pathogenesis. To clarify the relationship linking Aβ, oxidative stress and cognitive impairment, we performed a comparative immunofluorescence study on AD, NDAN and normally aged human *post-mortem* frontal cortices. To assess the precise localization of oxidative damage at a cellular level, we evaluated the occurrence of 8-oxo-dG marker in neuronal and astroglial cells. We also investigated the expression of SOD2, PGC1α and PPARα as key factors in antioxidant response and energy metabolism. This study allowed us to confirm the crucial role of redox imbalance in AD pathogenesis, at least due to an impairment of antioxidant defences. By the contrast, the analysis

of NDAN individuals proved especially enlightening, in clarifying the role of regulators of antioxidant response pathways. Indeed, in NDAN subjects, the low oxidative damage, correlated with the high content of scavenging systems, suggests the ability to activate an efficient PGC1α-dependent "safety mechanism" to cope with oxidative imbalance, thus preventing Aβ-mediated detrimental effects. The analyses conducted in a comparative manner in neurons and astrocytes further highlighted cell-specific mechanisms to counteract redox imbalance. These emerging concepts may help envisioning neuroprotective therapies aimed at ameliorating defects in antioxidant response in AD patients.

**Abstract:** Military personnel are often exposed to high environmental temperature in desert areas during combat operations. Since traumatic brain injury (TBI) is quite common in combat operation, a possibility exists that hot environment (HE) could affect pathophysiology of TBI. However, effects of HE on TBI are not well known. Previous reports show that hyperthermia duirng TBI could worsen the pathological outcome. However, TBI induced pathophysiological outcome following HE still require further investigation. TBI induces increase in amyloid beta peptide (AbP) and tau protein in the brain and in the cerebrospinal fluid (CSF). AbP and tau are responsible for neuronal, glial and microvascular damages leading to breakdown of the blood-brain barrier (BBB) and vasogenic edema formation. However, effects of HE on AbP and tau are unknown. In present investigation we examined whether TBI could induce an increased production of AbP and tau in HE. Furthermore to understand the role of tau in neuropathology we infused tau antibodies [Anti-Tau antibody [E178, ab32057) together with cerebrolysin (a known neuroprotective agent) in the CSF after TBI with HE. TBI was inflicted by dropping a weight of 114.6 g from 20 cm height on the exposed parietal skull bone in Equithesin anaesthetized rats acclimatized at 21±1°C (room temperature) or exposed to 34°C for 4 h per day for 2 weeks in biological oxygen demand incubator (BOD, relative humidity 45-47 %, wind speed 20-25 cm/sec). Exposure to HE alone did not result in BBB breakdown, edema formation or changes in AbP or tau levels. However, TBI in HE animals resulted in about 2-to 3-fold higher breakdown of the BBB to Evans blue albumin and radioiodine ($^{[131]}$-I) and neuronal, glial and axonal damage as compared to TBI in rats at room temperature after 24 trauma. The AbP and tau levels in TBI group after heat exposure increased by e- to 6-fold in the CSF (control AbP ng/ml 0.23±0.04; TBI 0.82±0.05; TBI+HS 2.34±0.12; Control tau pg/ml 20±2; TBI 34±6; TBI+HS 76±8). Treatment with H-290/51 (100 mg/kg, i.p.) together with 50 µl 1:20 tau antibodies i.c.v. 4 h after injury resulted in reduction of tau and AbP levels and brain pathology in TBI but failed to induce neuroprotection in HE group. However, when TiO2-nanowried H-290/51 was co-administered with nanowired tau antibodies in identical conditions pronounced neuroprotection was observed in HE group with TBI. Also the tau and AbP levels were considerably reduced (AbP ng/ml 0.43±0.08; tau pg/ml 28±7) in the CSF of HE rats after TBI. This indicates that both AbP and tau levels are somehow responsible for enhanced brain pathology in TBI following HE, not reported earlier.

Hosp., Boston, MA; [10]Pathology, Univ. of Maryland, Baltimore, MD

**Abstract:** Military personnel are often prone to traumatic brain injury (TBI) that enhances the possibility of Alzheimer’s disease (AD) at a later stage. Since TBI leads to breakdown of the blood-brain barrier (BBB) and extravasation of serum proteins into the brain fluid compartment, it is quite likely that plasma amyloid beta protein (AbP) may enter into the brain after TBI leading to development of AD. Thus, there is a need to understand the role of TBI in AD. AD like brain pathology was induced by intracerebroventricular (i.c.v.) administration of soluble form of AbP 200 ng/30 µl per day into the left lateral ventricle for 4 weeks in a rat model. This treatment resulted in AD like pathology e.g., deposit of AbP in the brain as well as BBB breakdown, edema formation and neuronal, glial and axonal injuries. In order to find out role of TBI in AD development, rats were subjected to mild concussive head injury (CHI) by dropping a weight of 114.6 g over the exposed parietal skull bone from a 20 cm height through a guide tube. This adjustment resulted in an impact of 0.224 N over the skull surface. In these CHI inflicted animals AbP was infused in identical conditions starting from 1 week after injury for 4 weeks.

Our observations show that AbP infusion in CHI rats exacerbated BBB breakdown to serum proteins by 2-4 fold, edema formation by 1.5 to 2 fold and marked increase in neuronal, glial or axonal injuries as compared to AbP treatment in normal animals. Immunohistochemical examination revealed enhanced deposits of AbP in the brain in CHI group after AbP infusion. The glial reactions and myelin damages were also much more aggravated. Extravasation fo albumin was also increased in several brain regions in CHI group after AbP infusion as compared to normal animals. Administration of mesenchymal stem cells (MSCs, ca. 1 million, i.c.v.) 1 week after AbP infusion resulted in marked neuroprotection as seen by reduced BBB leakage, AbP deposits and brain pathology in normal animals. Likewise i.c.v. administration of 50 µl cerebrolysin daily for 3 weeks starting from 1 week after AbP infusion was neuroprotective in normal animals. However, in CHI group these treatments either alone or in combination were ineffective. Interestingly when TiO2 nanowired MSCs and cerebrolysin administered together in identical conations, significant neuroprotection was achieved in AD cases in CHI group. Taken together, our observations are the first to point out that co-administration of MSCs and cerebrolysin using nanowired delivery has far more superior neuroprotective effects in AD model in CHI, not reported earlier.

**Title:** Hypusinated eIF5A governs TDP-43 accumulation in the cytoplasm and stress granules

**Authors: *M.-L. B. SELENICA**[1], C. OSORNO CRUZ[2], S. SMELTZER[2], F. ZAMUDIO[2], Z. QUADRI[2], M.-L. B. SELENICA[2]
[2]Pharmaceut. Sci., [1]Col. of Pharmacy, Byrd Alzheimer Institute, USF, Tampa, FL

**Abstract:** TDP-43 pathology is involved in impairment of motor neuron function and cognitive dysfunction in a spectrum of disorders. The hallmark of TDP-43 proteinopathy is loss of nuclear function and accumulation as cytoplasmic inclusions. Recent evidence suggests for unique accumulation of TDP-43 in stress granules as disease progress. Hypusination of eIF5A (eIF5AhypK50) denotes its activation and cytoplasmic localization where it also binds various RNA binding proteins. Its overall cellular function is translational elongation but translation inhibition in stress granules (SG) might also occur. The localization of eIF5AhypK50 in SG lead to further accumulation of TDP-43 and translation of aberrant truncated forms causing TDP-43

seeding and aggregation once SGs are dissolved. Our data demonstrate increases in the eIF5AhypK50 levels and expression levels of enzymes involved in hypusination pathway in AD brain tissue as well as in TDP-43 animal models, suggesting implication to the disease progression. We show that both pharmacological inhibition and siRNA approaches targeting hypusination pathway reduce cytoplasmic accumulation of total TDP-43 and its phosphorylation in various cellular models. The same inhibitor effectively reduces TDP-43 accumulation in SG as demonstrated by immunocytochemical assays. We hypothesize that eIF5AhypK50 orchestrates the fate of TDP-43 and determines the biological signature of SGs. As the exact mechanism by which eIF5AhypK50 interacts with TDP-43 is unknown our data strongly suggests for protein-protein binding properties between both proteins, hence promoting TDP-43 cytoplasmic accumulation. However, eIF5AhypK50 could regulate TDP-43 fate via several other potential mechanisms, including translational regulation. Utilizing SUnSET assay (surface sensing of translation), we demonstrate that eIF5A inactivation reduces the overall protein synthesis rate in cells, whether this has a direct impact on TDP-43 proteinopathy remains to be investigated. Overall, we demonstrate that inhibition of hypusination either by reducing eIF5A levels or specific enzymes reduce TDP-43 burden and provide the foundation for detailed understanding of eIF5A role in neurological diseases and viable therapeutic approaches.

**Abstract:** Military personnel in combat operation often inflicted with brain and/or spinal cord injury (SCI) causing lifetime disability. Thus, exploration of novel treatment strategies and factors affecting the functional or pathological outcome after SCI require further investigations. Recently, gold nanoparticles (AuNPs) are used for the treatment of neurodegenerative diseases. However, AuNPs induced neurotoxicity is not well known. Our previous studies show that AuNPs depending on the size and route of administration induces neurotoxicity in normal rats. Thus, AuNPs for therapeutic strategies needs further investigation in vivo models. Several reports suggest that trauma to the brain results in upregulation of amyloid beta peptide (AbP) and tau proetins responsible for neuronal, glial and axonal injuries. However, increased AbP and tau following SCI is not well known. Few reports indicate that AuNPs therapy reduce AbP and tau protein accumulation in Alzheimer's disease (AD) however, the matter is still controversial. We examined SCI induced changes in cerebrospinal fluid (CSF) concentrations of AbP and tau and their modification with AuNPs in a rat model. In addition, we also investigated the influence of nanodelivery of cerebrolysin (CBL)- a multimodal neuroprotective drug in SCI. SCI was inflicted in Equithesin anaesthetized rats by making a longitudinal lesion on the right dorsal horn of the T10-11 segments (2 mm deep and 4 mm long) in normal animals or in rats intoxicated with AuNPs (50-60 nm, 50 mg/kg, i.p. once daily for 7 days). Laminectomized animals served as controls. A sample of CSF (30 µl) was withdrawn in all groups after cisterna magna puncture 24 h after injury and analyzed for AbP and tau using commercial ELISA protocol. Blood-spinal cord barrier (BSCB) breakdown to Evans blue albumin and neuronal injuries were assessed in T9 and T12 segments. SCI in AuNPs intoxicated group exhibited about 180 to 230 % increase in AbP and 220 to 256 % elevation of tau as compared to saline treated SCI rats. The BSCB breakdown and cord pathology was also 2-to 3-fold increased in AuNPs group from saline treated injured group. Intrathecal administration of CBL (50 µl) 4 and 8 h after SCI significantly reduced AbP and tau increase and cord pathology in saline treated group. However, TiO2-nanowired delivery of CBL is needed to reduce AbP, tau and cell injuries in AuNPs treated injured group. These observations are the first to show that AuNPs aggravate AbP and tau production after SCI and cord pathology. TiO2-nanowired delivery of CBL is capable to induce neuroprotection by reducing these peptides following SCI, not reported earlier.

Hosp., Boston, MA; [7]Div. of Cardiology, Dept. of Med., Karolinska Institutet, Karolinska Univ. Hosp., Stockholm, Sweden

**Abstract:** Military personnel are often exposed to high altitude (HA) for combat operations. Staying at HA alone causes neurological dysfunctions. We showed that traumatic brain injury (TBI) at HA (ca. 4500 to 5000 m) aggravates brain pathology. People living at HA often consume methamphetamine (METH) or cocaine to cope HA stress. METH alone at HA induces neuronal, glial and axonal damages. Thus, METH exposure could aggravate TBI induced brain pathology. We explored the effects of METH exposure on TBI at HA on brain pathology in a rat

model. Animals exposed to HA in a hypobaric chamber equivalent to 5000 m (53.8 kPa) for 1 week. TBI was inflicted under Equithesin anesthesia by dropping a weight of 114.6 g from 20 cm height on right parietal skull (impact of 0.224 N). Control animals received identical TBI at sea level (200m). Another group of rats received 9 mg/kg, s.c. METH and TBI was inflicted 4 h after either at HA or at sea level. After 8, 12 and 24 h after TBI in METH or saline group, blood-brain barrier (BBB) breakdown, edema formation and neuronal, glial and myelin injuries were examined. Our results showed that TBI at HA in METH group induced about 2- to 3-fold higher BBB breakdown to Evans blue albumin (EBA) and radioiodine ([131]-I) as compared to identical TBI in saline treated animals. Interestingly, TBI at sea level induced only 0.5-to 1.5-fold greater BBB damage in METH group as compared to saline controls. This indicates that METH exposure at HA is more dangerous for TBI than at sea level. Reductions in cerebral blood flow (CBF) were 70 to 90 % greater in METH exposed group after TBI at HA as compared to saline controls after TBI. Brain edema formation was 4 to 6 % higher in METH exposed HA rats after TBI than the saline treated traumatized animals. On the other hand, METH exposed TBI group at sea level showed only 40 to 60 % higher reduction in the CBF and 2 to 3 % greater brain edema formation as compared to saline treated TBI group. Neuronal, glial and myelin damages were also exacerbated in HA rats in METH exposed group after TBI as compared to identical TBI in METH exposed rats at sea level. In general, the magnitude and intensity of TBI in METH or saline treated rats at HA or sea levels were progressive in nature. Treatment with antioxidant H-290/51 (100 to 150 mg/kg, i.p.) was able to thwart brain pathology in TBI either at HA or sea levels. However, TiO2-nanowired delivery of H-290/51 (150 mg/kg, i.p.) is needed to reduce brain pathology in METH exposed rats after TBI at HA or sea level. Taken together our observations are the first to point out that METH exposure in TBI is exacerbated at HA probably due to greater production of oxidative stress as compared to sea level, not reported earlier.

Engin., Indian Inst. of Technology,Banaras Hindu Univ., Varanasi, India; [8]Drug Develop. & Discovery, Ever NeuroPharma, Mondsee, Austria

**Abstract:** Military personnel are often subjected to traumatic brain injury (TBI) during combat operations. There are evidences that TBI is one of the predisposing factors in causing development of Parkinson's disease (PD) at a later stage. This is largely due to the fact that mild or moderate TBI induces rapid production of tau protein and alpha synuclein (ASNC) that could be seen in various brain areas as well as in the cerebrospinal fluid (CSF). Enhanced tau-phosphorylation and associated ASNC leads to profound cellular stress and alter molecular machinery of the brain leading to brain pathology. Recent evidences show that upregulation of constitutive isoform of hemeoxygenase (HO-2) is elevated in patients of PD that correlates well with the brain pathology. Thus, it would be interesting to examine whether TBI could exacerbate PD pathology in relation to tau, ASNC and HO-2 expression. Since trophic factors and stem cells are known to reduce brain pathology in stroke and trauma, we examined the role of mesenchymal stem cells (MSCs) and cerebrolysin (CBL), a well-balanced composition of several neurotrophic factors and active peptide fragments on brain pathology in PD model after TBI. PD like symptoms were produced in mice by administration of 1-metyl-4-fenyl-1,2,3,6-tetrahydropyridin (MPTP, 20 mg/kg, i.p.) daily within 2-h intervals for 5 in normal animals or following TBI. Mild TBI was induced by dropping a weight of 28.6 g from 20 cm height on the right parietal skull bone (impact 0.056 N). On the $8^{th}$ day after MPTP administration brain pathology was examined. Our observations showed a 2-4-fold greater increase in the blood-brain barrier (BBB) breakdown to Evans blue albumin and radioiodine ([131]-I) in several brain areas in PD group after TBI. Immunohistochemical studies showed marked higher upregulation of HO-2 in the PD brain after TBI in areas exhibiting neuronal and glial cell injuries than PD group alone. Biochemical measurement of tau protein and ASNC also showed greater accumulation in the brain and CSF samples of TBI cases in PD group. Treatment with MSCs ($10^6$ cells and CBL 2.5 ml/kg, i.v.) 5 days after MPTP administration resulted in marked neuroprotection in normal

PD group and reduced HO-2 expression, tau protein and ASNC levels. However, TiO2-nanowired delivery of MSCs and CBL in identical doses is needed to reduce brain pathology and biochemical changes in PD group after TBI. These observations are the first to show that TBI exacerbates PD pathology and nanowired delivery of co-administration of MSCs and CBL has superior neuroprotective effects as compared to either agent alone, not reported earlier.

**Title:** Astrocyte-produced lipoxins protect retinal neurons from acute and chronic stress

**Authors: *I. LIVNE-BAR**[1], J. WEI[4], H.-H. LIU[5], S. ALQAWLAQ[2], K. GRONERT[4], J. G. FLANAGAN[6], J. M. SIVAK[3]

**Abstract:** Astrocytes and related Müller glia play critical homeostatic roles in the inner retina and become activated upon retinal disease or injury. However, astrocytes' role in protecting retinal neurons under stress remains unclear. We previously published that resting retinal astrocytes promote retinal ganglion cells (RGC) survival following acute injury *in vivo*, and that inducing stress in retinal astrocytes curtails RGC survival. Here, we report that intravitreal injection of astrocyte conditioned media (ACM), but not control media, promoted RGC survival following acute insult. Size fractionation of the ACM indicated that a small-molecule component contained prominent protective activity. We analyzed the ACM by LS-MS/MS based lipidomics and detected high enrichment of the lipoxins $LXA_4$ and $LXB_4$. Lipoxins are part of a family of potent specialized pro-resolving lipid mediators (SPMs). The protective activity of these lipoxins was tested by intravitreal injection prior to induction of retinal insult. RGC survival was quantified by immunofluorescence microscopy. We found that lipoxin injection reduced RGC loss from acute injury with $LXB_4$ being more protective than $LXA_4$. Furthermore, inhibition of

the key enzyme for lipoxin biosynthesis compromised RGC survival while an antagonist against the $LXA_4$ receptor also reduced survival. Finally, therapeutic $LXB_4$ treatment in a chronic RGC-degeneration model significantly rescued RGC function and promoted their survival. In summary, we have established that astrocyte produced lipoxins protect retinal neurons from acute and chronic injury.

**Abstract:** Military personnel are often victims of spinal cord injury (SCI) for which there is no suitable treatment available. Thus, exploring new therapeutic avenues using select combination

of novel neuroprotective agents is the need of the hour to improve the quality of life of SCI patients. Previous experiments from our laboratory show that a focal SCI inflicted in rat by making an incision of the right dorsal horn of the T10-11 segment resulted in pronounced functional disability on Tarlov Scale, inclined plane angle test and walking on a mesh grid in a progressive manner after 12 and 24 h trauma. This behavioral dysfunction correlated well with breakdown of the blood-spinal cord barrier (BSCB), edema formation and cell injuries seen in both the rostral and caudal segments after SCI in a progressive manner. Recording of spinal cord evoked potentials using epidural electrodes at rostral and caudal to lesion segments exhibited significant increase in latency and amplitude changes indicating loss of spinal cord conduction. Several lines of evidences suggest that intraspinal administration of mesenchymal stem cells (MSCs) improves functional outcome and enhance spinal cord conduction. However, MSCs induced restoration of BSCB and reduction in edema formation is not well known. In present investigation we examined the role of MSCs alone or in combination with cerebrolysin (CBL)- a multimodal drug on SCI induced restoration of cellular and behavioural functions in a rat model. SCI was inflicted in Equithesin anesthetized rats over the right dorsal horn of the T10-11 segments (2 mm deep and 4 mm long) and the animals were allowed to survive 12 or 24 h after trauma. In separate groups of SCI rats MSCs ($10^6$ cells) and CBL (50 µl) were administered into the rostral and caudal spinal cord around the lesion site after 3 h injury using a 100 µl Hamilton syringe connected to a constant infusion pump (10 µl/min). Since nanodelivery of MSCs or CBL has superior neuroprotective effects in CNS injury, we also examined TiO2 nanodelivery of MSCs and CBL in SCI. Our observations showed that co-administration of MSCs and CBL significantly reduced BSCB breakdown, edema formation and cell injuries at 12 h but not at 24 h after SCI. In this group significant improvement on behavioral function was seen after 12 h SCI. However, when TiO2-nanodelivery of MSCs and CBL was done in identical conditions, these treatment strategies significantly attenuated cord pathology and improved behavioral dysfunctions after 24 SCI. These observations are the first to show that intraspinal administration of nanowired MSCs and CBL have superior neuroprotective effects in SCI, not reported earlier.

**Abstract:** Previous reports from our laboratory showed neuroprotective effects of melanocortin (MC) receptor 4 agonist on the pathophysiology of spinal cord cell and tissue injury as well as on the functional outcome. Topical application of MC compounds 1 µg to 10 µg over the traumatized cord after 5 to 10 min results in significant improvement in Tarlov scale up to 3 h. Nanodelivery of these compounds with or without dexamethasone applied topically did not induce any further functional improvement beyond 3 h. High doses of dexamethasone (100 µg) together with MC-4 agonist (20 µg) shows some late beneficial effects on Tarlov scale at 10 to 12 h SCI. This suggests that MC receptor agonists are neuroprotective and potentiate the ability of dexamethasone. In present investigation we applied MC-4 agonist or antagonist or MC1 receptor antagonist with partial agonist of MC3 and MC5 receptors in SCI on cord pathology and functional outcome. In addition we also co-administered TiO2 nanowired H-290/51 systemically (50 mg/kg, i.p.) and examined any potentiation of MC compounds on the outcome following SCI. SCI was inflicted in Equithesin anesthetized rats by making a longitudinal incision of the right dorsal horn of the T10-11 segments. Melanocortin $MC_4$ receptor antagonist ML 00253764 or potent and selective $MC_4$ receptor agonists PG931 or THIQ or potent $MC_1$ receptor antagonist with $MC_3$ and $MC_5$ partial agonist MSG 606 were used in this study. MC compounds were applied 5 or 10 µg over the traumatized cord 5 min after injury with or without H-290/61 (50 mg/kg, i.p.) 30 min after SCI. MC 4 receptor agonists and MC 3 and MC 5 receptor agonist with

MC1 antagonist were the most effective in neuroprotection and improved Tarlov scale up to 5 h afire SCI. When given in combination with H-290/51 functional improvement was extended beyond 8 h and neuroprotection was seen up to 12 h after injury. However TiO2 nanowired delivery of PG931 or THIQ and MSG606 together with H-290/51 in SCI resulted in functional improvement up to 12 h and reduced cord pathology at 24 h. MC4 receptor antagonist did not induce neuroprotection or improved functional parameters either given alone or together with H-290/51 in SCI. These observations provide new evidences on MC 4 receptor agonists and MC3 and 5-receptor agonist with MC1 antagonist are powerful in inducing neuroprotection in SCI that was further potentiated by antioxidant H-290/51. Moreover TiO2-nanodelivery of these MC 4 agonist compounds together with H-290/51 has prolonged superior effects on functional outcome and neuroprotective capability in SCI, not reported earlier.

**Title:** Stabilizing neuronal cytoskeleton facilitates neurite development and repair

**Authors: *Y. SONG**[1,2,3], T. J. MITCHISON, 02115[1]
[1]Systems Biol., [2]Systems Pharmacol., Harvard Med. Sch., Boston, MA; [3]MassGeneral Inst. for Neurodegenerative Dis., Mass Gen. Hosp., Boston, MA

**Abstract:** Microtubules (MTs) are structural components vital for important neuronal functions such as neurite outgrowth and maintenance, as well as for axonal trafficking and synaptic remodeling. Neuronal MTs are particularly stable compared with those in other cell types and often exist for years before they get degraded and recycled. They are mostly synthesized in the somatodendritic compartment and have to be transported along axons as much as a meter or more in humans to reach the terminals where synaptic proteins are delivered and synaptic

transmission occurs. A significant portion of neuronal MTs stay polymerized when challenged with cold temperature, Ca2+ and antimitotic drugs (e.g. Nocodazole), all of which destabilize MTs effectively in test tubes and various non-neuronal cell lines, suggesting that baseline MT stability is high in neurons. Such stability increases during development and maturation, but decreases with axonal injury and neurodegeneration. This leads to an intriguing question: can stabilizing MTs facilitate neurite outgrowth during early development or restore axonal integrity and function upon injury? To address these questions, we have characterized a group of MT stabilizing drugs regarding their binding affinity to MTs in vitro using biochemical assays and fluorescent live imaging; and evaluated their effects on neurite growth during normal differentiation and regrowth after axotomy. Dose and time dependent drug treatments were performed on ReNcell VM cells (an immortalized human neural progenitor cell line), and differentiated VM cells that exhibit neuronal morphology and electrophysiology, followed by high-content live-cell imaging and automated imaging analysis. We found that these drugs showed bimodal effects on initial neurite extension and regeneration after injury. To understand the molecular mechanisms underlying regulation of MT stability by these drugs and their biological effects, we have used multiplex proteomics to study dose-dependent changes in signaling pathway components and MAPs over time. These results may provide useful information for understanding not only neuronal MT dynamics and stability in health and disease, but also for determining the therapeutic value of MT stabilizers in axonal injury and neurodegeneration where loss of neuronal MT integrity may exacerbate disease pathology.

**Title:** Neuroprotective and behavioral effects of weak static magnetic fields in the rat

**Authors: *R. UZAN**, Y. LOBODA, L. SCHACHTER, J. FINBERG
Technion-Israel Inst. of Technol., Haifa, Israel

**Abstract:** Magnetic field’s (MF's) beneficial effect was documented over 4000 years ago, especially for analgesia. In the modern era, the use of MF as a medical treatment gained momentum in the mid-eighties with the development of transcranial magnetic stimulation (TMS), which is an accepted treatment for major depression. Accordingly many studies address MF’s effect on biological tissues as a non-invasive and innovative medical treatment for different disease conditions.
In a previous study from our lab, (Ben-Yakir Blumkin et al. 2014), it was found that exposure of

primary cortical neurons to static magnetic field (SMF) causes a reduction in etoposide-induced apoptosis. Accordingly we explored SMF’s neuroprotective effect on the neurodegenerative effect of 6-hydroxydopamine (6OHDA) in vivo, by implanting a small (3mm X 0.5mm) titanium-coated magnetic disc on the cranium above bregma. In addition, since TMS is commonly used for the treatment of depression, and alterations in memory and increased anxiety are observed in ageing, we studied SMF's age related and time course related, effects on rat behavior, using young (2 month) , middle age (12 month) and aged rats (24 month). Using proteomic analysis (mass spectrometry) we studied SMF's effect on protein expression in the rats' hippocampus.
Our study demonstrated that 1 week of SMF exposure, (but not 3 or 5 weeks), caused an anxiolytic effect in elderly rats, and improved recognition and spatial memory in young rats. We also found that exposure to SMF protected the dopaminergic cells in substantia nigra pars compacta (SNc) from 6OHDA-induced neurodegeneration preserving cell number at normal levels. In the mechanistic study, we found that SMF exposure affected proteins related to cell energy and metabolism, calcium channels and myelination processes.
The results indicate that 1 week of SMF exposure exerts age dependent effects on anxiety and memory related parameters, and a neuroprotective effect on dopaminergic neurons of SNc. Alterations in cell metabolism, myelin related and calcium channel proteins observed in SMF-exposed brains can partly explain SMF’s mechanism of action. In general, the study indicates a possibility of using SMF for treatment of neurodegeneration and anxiety in humans.

**Abstract:** Blast brain injury (bBI), a combination of pressure, rotation, penetration of sharp objects and chemical exposure is prevalent in military personnel during combat operations causing laceration, perforation and tissue loss in the brain. Since combat stress could induce wide variety of cardiovascular and endocrine deregulation, it is unclear whether bBI could exacerbate brain pathology in diabetes. Thus, in present investigation influence of diabetes on bBI was investigated in a rat model. bBI was produced using a shock tube blast devise in which compressed air-and compressed helium-driven membrane rupture induces pressure waves to simulate some aspects of bBI. The rats were anesthetized with Equithesin (3 ml/kg, i.p.) and their head was exposed to overpressure blast (100, 150 or 200 kPa) in the shock-tube with a shockwave velocity of ca. 400 to 450 m/sec). After the bBI the animals were allowed to survive 8 and 12 h after trauma. Identical procedures were applied for bBI in diabetic rats that were produced by streptozotocine (50 mg/kg, i.p.) administration once daily for 3 days. The animals develop clinical diabetes after 4 to 6 weeks (blood glucose level 220-25 mM/L, control 5-6 mM/L). In both normal and diabetic rats blood-brain barrier breakdown to Evans blue albumin and radioiodine ($^{[131]}$-I), brain edema formation and neuronal, glial and axonal injuries were evaluated. In addition, regional cerebral blood flow (rCBF) was also examined using standard procedures.
A progressive increase in the BBB permeability to EBA and radioiodine in the cerebral cortex, hippocampus, cerebellum, thalamus, hypothalamus and brain stem was seen that correlates well with the blast overpressure strength. In these brain areas rCBF was reduced by -30 to -58 %. Brain edema formation as measured using water content exhibited a 2- to 4 % increase (ca. 8 to 16 % volume swelling). Expansion of neuropil, sponginess and neuronal, glial and myelin damages are quite frequent. These pathophysiological changes were 2-to 5-fold exacerbated in diabetic animals after bBI. Treatment with cerebrolysin (a multimodal drug comprising neurotrophic factors and active peptide fragments) 30 min to 1 h after bBI (5 to 10 ml/kg, i.v.) significantly reduced brain pathology in normal animals. However, TiO2 nanodelivery of cerebrolysin (5 ml/kg, i.v.) is needed to induce neuroprotection in bBI in diabetic animals. These observations are the first to show that (i) bBI is exacerbated in diabetes, (ii) cerebrolysin has the potential to reduce brain pathology in bBI in healthy animals, whereas, TiO2-nanowired

cerebrolysin is needed to induce neuroprotection in diabetic animals after bBI, not reported earlier.

**Abstract:** Sleep deprivation (SD) is common in military personnel engaged in combat operations. Our previous reports show that 12 h SD alone induces brain pathology and continued until 72 h in a progressive manner. However, these military personnel with SD are also prone to traumatic brain injury (TBI). Thus, a possibility exists that TBI could further exacerbate SD induced brain pathology. Several lines of evidences suggest that both in TBI and in SD a decrease in alpha-melanocyte stimulating hormone (MSH) and brain derived neurotrophic factor (BDNF) levels occur in plasma as well as in the brain. This could be one of the leading causes of brain pathology in SD or in TBI. Thus, exogenous supplement of alpha-MSH and/or BDNF could induce neuroprotection in SD or TBI. In present investigation effect of concussive head injury (CHI) in SD induced brain pathology and effects of alpha-MSH and neurotrophic factors treatment leading to neuroprotection in a rat model was examined. SD was induced in rats using the inverted flowerpot methods surrounded by water level 1 cm below the platform (6.5 cm in diameter) that allow free movement but continuously sleep leads to fell down in water disturbing the sleep process. SD was induced in healthy rats as well as in rats that were subjected to CHI by dropping a weight of 114.6 g over the skull causing an impact of 0.224 N on the brain without skull fracture. Rats subjected to 48 h SD in CHI (24 h after insult) exhibited greater brain pathology e.g., higher leakage of Evans blue albumin and radioiodine ([131]-I) by 3-to 4 fold as compared to naïve rats subjected to identical SD. Neuronal, glial and axonal damages using histopathological techniques were also exacerbated by several fold in CHI after SD. Plasma alpha-MSH and BDNF level shows significant reduction (alpha-MSH 8.34±0.23 vs. Control 20.34±0.12 pg/ml; BDNF 8.23±0.11 vs. control 22.34±0.21 pg/ml) in SD group after CHI as compared to SD group alone (alpha-MSH 15.13±0.12 pg/ml; BDNF 14.23±0.08 pg/ml). Intravenous administration of alpha-MSH (100 µg/kg) together with cerebrolysin (a balanced composition of several neurotrophic factors and active peptide fragments 5 ml/kg) significantly induced neuroprotection in CHI or SD groups alone. However, TiO2 nanowired delivery of alpha-MSH and cerebrolysin is needed to induce neuroprotection in SD rats after CHI. The levels of alpha-MSH and BDNF were also retired by this treatment in SD rats after CHI (alpha MSH 22.34±0.12 pg/ml; BDNF 23.34±0.17 pg/ml). Taken together our results are the first to point out that TiO2 nanowired administration of alpha-MSH and cerebrolysin induces superior neuroprotective effects following SD in CHI, not reported earlier.

**Abstract:** Military personnel lead very stressful life during combat situations. Stress alone induces breakdown of the blood-brain barrier (BBB) and neuronal damages. Long-term stress is related to the development of Alzheimer’s disease (AD) as compared to their stress free counterparts. In present investigation we explored whether AD induced brain pathology caused by amyloid beta peptide (AbP) infusion is exacerbated in rats after repeated emotional stress enough to open the BBB to large molecules e.g., proetins.
AD like brain pathology was induced by administered intraventricularly (i.c.v.) of AbP (1-40) in the left lateral ventricle (250 ng/10 µl) of rats (250-300 g body weight) once daily for 4 weeks in naïve animals as well as in rats that were subjected to repeated immobilization stress 2 h daily for 1 week. Control rats received identical dose of saline instead of AbP. In these control and AbP infused rats BBB breakdown, edema formation, neuronal, glial injuries and AbP deposits in the brain was examined in a blinded fashion by at least 3 independent workers.
Our observations showed that repeated 2 h stress for 1 week induced marked BBB breakdown to Evans blue albumin and radioiodine tracers in the cerebrla cortex (55 to 78 %), hippocampus (89 to 98 %), thalamus (34 to 46 %), hypothalamus (35 to 50 %), caudate nucleus (78 to 97 %), cerebellum (80 to 134 %) and brainstem (23 to 35 %) from the naive rats. Infusion of AbP in

these stressed rats further enhanced the BBB breakdown to protein tracers by 3- to 5-fold and resulted in pronounced neuronal damages (+400 %), astrocytic activation (+350 %) and brain swelling (+10 %) compared to identical AbP infusion in naive rats. The number of AbP positive cells increased by 3- to 6-fold in these brain areas in stressed group as compared to naive rats. Administration of PLGA nanoparticles (NPs) loaded cerebrolysin (2.5 ml/kg, i.v. /day from 2nd week of AbP infusion for 2 weeks) induced profound neuroprotection in stressed rats, whereas 5 ml normal cerebrolysin is needed to attenuate brain pathology after AbP infusion in these rats. Taken together our observations are the first to demonstrate that repeated stress exacerbates AD pathology in brain and nanodelivery of cerebrolysin has superior neuroprotective effects in AD.

**Abstract:** Military personnel deployed to combat operations are highly susceptible to develop Parkinson's disease (PD) or Alzheimer's disease (AD) particularly after sustaining traumatic brain injury (TBI). TBI causes increased amyloid beta peptide, alpha synuclein (ASNC) or tau protein in the brain or cerebrospinal fluid (CSF) leading to neuropathology. Although, PD involves dopaminergic pathways, recent evidences suggest that histaminergic system is also involved in the pathophysiology of PD. Increased histaminergic nerve fibers in substantia niagra pars Compacta (SNpc), striatum (STr) and caudate putamen (CP) occurs in human brain postmortem study associated with increase in Histamine H3 receptors and decrease in H4 receptors in these areas. This indicates involvement of histaminergic transmission in PD. Thus, a possibility exists that modulation of histamine H3 and H4 receptors as well as histaminergic transmission could reduce PD brain pathology. Previously, we showed that a potent histaminergic H3 receptor inverse agonist BF-2549 and clobenpropit a partial histamine H4 agonist with H3 receptor antagonistic activity induced profound neuroprotection in amyloid beta peptide infusion induced AD in a rat model. In present investigation we examined the role of histamine H3 and H4 receptor in a mouse model of PD. In addition we also evaluated intracerebroventricular (i.c.v.) administration of monoclonal ant-histamine-antibodies on PD induced brain pathology with or without histaminergic drug treatments. PD like symptoms was produced by administration of 1-metyl-4-fenyl-1,2,3,6-tetrahydropyridin (MPTP, 20 mg/kg, i.p.) daily within 2-h intervals for 5 days in mice. On the 8$^{th}$ day, marked decrease in the number of tyrosine hydroxylase (TH) positive cells in the SNpc and STr as well as decrease in dopamine (DA) and its metabolites 3,4-Dihydroxyphenylacetic acid (DOPAC) and homovanillic acid (HVA) occurred associated with increased ASNC and tau proetins in the CSF. Mice treated with BF 2649 (1 mg/kg, i.p.) or Clobenpropit (1 mg/kg, i.p.) once daily for 1 week accompanied with normal or TiO2 nanowired histamine antibodies (25 µl, MAB0021, Clone HYHIS1, Abnova, USA) resulted in significant reduction in ASNC and tau protein in the CSF as well as restoration of DA and DOPAC in SNpc, STr. These neuroprotective effects were most marked when histamine antibodies were administered through nanowired technique in combination with clobenpropit as compared to BF-2649. These observations strongly indicate an involvement of histamine and opens up new avenues in drug development for PD using modulation of histamine H3 and H4, not reported earlier.

**Title:** Which factor has a stronger effect on cerebral $^{18}$F-FDG distribution in cognitively normal older subjects, plasma glucose level or insulin resistance?

**Authors: K. ISHIBASHI**, A. ONISHI, Y. FUJIWARA, K. ISHIWATA, *K. ISHII
Tokyo Metro Inst. Gerontology, Tokyo, Japan

**Abstract: Background:** Increasing plasma glucose level and insulin resistance can alter the distribution pattern of fluorine-18-labeled fluorodeoxyglucose ($^{18}$F-FDG) in the brain and relatively reduce $^{18}$F-FDG uptake in Alzheimer's disease (AD)-related hypometabolic regions, leading to the appearance of an AD-like pattern (1,2). However, of the two parameters, it is unclear which factor is more responsible for the distributional change of $^{18}$F-FDG followed by the appearance of the AD-like pattern. **Methods:** Fifty-nine cognitively normal older subjects (age = 75.7 ± 6.4 years) who were free of diabetes underwent $^{18}$F-FDG positron emission tomography along with measurement of plasma glucose and insulin levels. As an index of insulin resistance, the Homeostasis model assessment of Insulin Resistance (HOMA-IR) was calculated. To normalize regional $^{18}$F-FDG uptake in the brain, the global brain was used as a reference region. **Results:** Whole-brain voxelwise analysis showed a negative correlation of $^{18}$F-FDG uptake with plasma glucose level in the precuneus and lateral parietotemporal regions (cluster-corrected $p < 0.05$), and no correlation with HOMA-IR. In the significant cluster, $^{18}$F-FDG uptake decreased by approximately 5-6% when plasma glucose level increased by 20 mg/dL. In the precuneus region, volume-of-interest analysis confirmed a negative correlation of $^{18}$F-FDG uptake with plasma glucose level ($r = -0.603$, $p < 0.001$), and no correlation with HOMA-IR. **Conclusion:** This study showed that plasma glucose level has a negative correlation with $^{18}$F-FDG uptake in the precuneus and lateral parietotemporal regions which are the main component of AD-related hypometabolic areas, and confirmed that increasing plasma glucose level can induce the appearance of the AD-like pattern in $^{18}$F-FDG images. However, there was no significant negative correlation of $^{18}$F-FDG uptake with insulin resistance. Thus, increasing plasma glucose level has a stronger effect on the appearance of the AD-like pattern in $^{18}$F-FDG images than increasing insulin resistance does. **References:** 1) Ishibashi K, et al. **Abstract:** Altered glutamatergic neurotransmission after traumatic brain injury (TBI) results in excitotoxic cell damage and death, and may contribute to an increased risk for developing Alzheimer's disease (AD) pathology. Suppression of such changes in the aftermath of TBI is a desirable therapy goal. Memantine (3,5-dimethyl-1-adamantanamine) is a voltage-dependent open channel blocking NMDA receptor antagonist. A previous study reported neuroprotective effects of memantine in rats evaluated acutely after severe controlled cortical impact (CCI) injury. Our pilot study showed that 3-week long daily treatment of humanized Amyloid-Beta (hAβ) mice with memantine (5mg/kg, intraperitoneal, i.p.) lowered injury-induced elevations in brain Aβ peptides concentration and blunted behavioral deficits at 21 days after CCI. The current chronic (3-months) study explored further the effects of daily administration of memantine (5mg/kg daily i.p.), or vehicle, on behavioral outcomes in adult hAβ mice exposed to severe CCI injury (depth=1.6 mm; velocity=5.82 m/s), sham surgery (craniotomy), or no surgery (naïve). Additional groups received simvastatin (daily, 3mg/kg by oral gavage) or a combination of memantine and simvastatin. Mice were evaluated for vestibulomotor (VM) function (days 1-5 and 71-75) and memory acquisition/retention (Morris water maze, MWM, days 14-21 and 83-90). On VM tests, all CCI groups performed worse than non-CCI groups, but did not differ from one another (both time points). MWM test results also separated CCI and non-CCI groups and, additionally, CCI groups treated with simvastatin, memantine, or the two drugs combined performed better than the vehicle-treated group at the first MWM testing trial (days 14-21). Remotely after injury (days 83-90) MWM testing showed persistent effects of CCI injury in the CCI/vehicle group, but not in CCI/treatment groups. In summary, daily memantine treatment improved behavioral recovery (spatial memory acquisition/retention) at acute and chronic time

points after severe CCI injury in hAβ mice. Simvastatin also improved behavioral outcomes and there was evidence of beneficial effects of combined treatment. We are currently assessing brain Aβ concentrations and histological outcomes to relate to these behavioral results. These preclinical data warrant further investigations of the effects of memantine and simvastatin in other brain injury models, such as blast and repetitive mild TBI.

**Title:** A novel immunregulatory action of alpha-synuclein on human natural killer cells

**Authors: *R. H. EARLS**[1], J. CHUNG[2], J.-K. LEE[2]
[1]Neurosci., [2]Physiol. and Pharmacol., Univ. of Georgia, Athens, GA

**Abstract:** Alpha-synuclein (α-Syn) species (monomer, oligomer and fibril) are present in human plasma and cerebrospinal fluid in Parkinson's disease (PD) patients. In PD patients, natural killer (NK) cell numbers are increased in blood and their activity level is associated with disease severity. NK cells as part of the innate immune system exhibit the highest cytotoxic capacity as a first-line of defense and modulate adaptive immune response. Despite of their potential involvement in PD pathogenesis, its role in PD has hardly been explored. We aim to investigate if NK cell functions are modulated by monomer and pathologic forms (oligomers or fibrils) of α-Syn. Our study, for the first time, demonstrated that pathologic forms of α-Syn significantly attenuate NK cell cytotoxicity against K562 leukemia target cells while monomeric α-Syn has no effect on cytotoxicity. In addition, both monomeric and pathologic forms of α-Syn attenuate the production of interferon-γ (IFN-γ), a major cytokine produced by NK cells, which promotes Th1 differentiation and myeloid cell activation. Based on our findings, using flow cytometry analysis, we are in the process of testing whether monomer and/or pathologic forms (oligomers or fibrils) of α-Syn change NK cell receptor expressions including NKG2D (activating) and NKG2A (inhibitory). Both of these receptors are reported as having altered expressions on NK cells in PD patients. We are also conducting *in vivo* study to investigate the involvement of NK cells in PD pathogenesis. Collectively, our studies will provide us critical, novel information about the immunoregulatory role of α-Syn on NK cells and the role of NK cells in the context of PD.

**Abstract:** Human studies and preclinical models of Parkinson's disease (PD) implicate the involvement of both the innate and adaptive immune systems in disease progression. PD affected brain regions show high levels of activated microglia, increased pro-inflammatory cytokine expression, and infiltration of peripheral leukocytes. Additionally, these pro-inflammatory markers are highly enriched near neurons containing pathological forms of alpha synuclein (α-syn), and α-syn overexpression recapitulates these neuroinflammatory changes in models of PD. These data suggest that α-syn may initiate a pathological inflammatory response. However, the mechanism by which α-syn initiates neuroinflammation is poorly understood. Silencing endogenous α-syn results in a similar pattern of nigral degeneration observed following α-syn overexpression. Here we aimed to test the hypothesis that loss of α-syn function within mature nigrostriatal neurons results in neuronal dysfunction, which subsequently stimulates neuroinflammation. Adeno-associated virus (AAV) expressing an shRNA targeting endogenous rat α-syn was unilaterally injected into the substantia nigra pars compacta (SNc) of adult rats, after which nigrostriatal pathology and indices of neuroinflammation were examined. Silencing endogenous α-syn below 50% of basal levels within nigrostriatal neurons resulted in a rapid (10 days), cell autonomous up-regulation of the major histocompatibility complex class 1 (MHC-1) within transduced nigral neurons. Nigral MHC-1 expression occurred prior to any overt cell death and resulted in the recruitment of microglia and peripheral T-cells to affected neurons. Recruited microglia were in a reactive state and made physical contact with MHC-1 expressing neurons, indicative of microglial phagocytosis of live neurons. Concomitantly, α-syn knockdown resulted in a progressive loss of tyrosine hydroxylase expression prior to the occurrence of overt neuronal death. Within 3 weeks of injection, α-syn knockdown resulted in a 50% loss of nigrostriatal soma in the SNc and a corresponding loss of nigrostriatal terminals and dopamine concentrations within the striatum. Silencing α-syn within glutamatergic neurons of the

cerebellum did not elicit inflammation or cell death, suggesting that inflammation and toxicity initiated by α-syn silencing is specific to dopamine neurons. These data provide compelling evidence that loss of normal α-syn function within nigrostriatal neurons initiates a neuronal-mediated neuroinflammatory cascade, involving both the innate and adaptive immune systems, which ultimately results in the death of affected neurons.

**Abstract:** The protein alpha-synuclein (α-syn) is implicated as causative in both sporadic and familial forms of Parkinson's disease (PD). Consequently, targeting α-syn has been proposed as a therapeutic strategy for PD. However, α-syn is one the most abundant proteins in the nervous system, and its endogenous function is not fully understood. Indeed, removal of α-syn from mature dopamine (DA) neurons of mice, rats, and nonhuman primates result in dosedependent and progressive neurodegeneration. In contrast, non-DAergic brain regions are resistant to α-syn silencing. These results demonstrate that α-syn is essential for the survival of mature DA neurons. Moreover, removing α-syn from non-DA neurons offers the opportunity to study the effect of α-syn removal without the complication of neurotoxicity. In this study we aimed to determine the consequences of postnatal α-syn silencing in areas such as the hippocampus and cerebellum; areas which express high levels of α-syn, but which do not display the selective vulnerability observed in PD. To better study the consequences following α-syn removal from mature neurons *in vivo* we generated a conditional knockout mouse engineered to have exons 1-2 of the α-syn gene flanked by loxP sites. Adeno-associated virus (AAV) expressing CRE recombinase (iCRE) was bilaterally injected into the lateral ventricles of neonate α-syn-floxed mice. This novel approach allows us to efficiently target these areas with one injection so that we can assess changes in neuronal physiology at the behavioral and cellular level. With this method

we achieved robust, widespread, and persistent transduction throughout the brain. Expression of iCRE successfully excised the floxed genomic region, eliminating α-syn gene and protein expression. Monthly behavioral tests are being performed to assess motor, balance, gait, and memory phenotypes. Animals will be sacrificed 3 months post surgery and histological analyses will be performed to determine physiological changes that are occurring. Once validated, this new model will provide a foundation for investigations into the physiological function of α-syn without the potential confounds that may occur due to removal of α-syn prior to neuronal development (e.g. germline compensation) or toxicity. This model will also be valuable when investigating the role of α-syn in PD etiology and its role in dopaminergic neurodegeneration.

Med., Philadelphia, PA; [6]Dept of Pathology and Lab. Med., Univ. Pennsylvania, Philadelphia, PA

**Abstract:** Cytoplasmic inclusions of the pre-synaptic protein α-synuclein (α-syn) known as Lewy pathology and neurodegeneration of select neuronal subpopulations define the synucleinopathies, a group of disorders that include Parkinson's disease (PD), Multiple System Atrophy, and Dementia with Lewy Bodies. It is increasingly appreciated that α-syn aggregates spread in a trans-neuronal fashion between vulnerable brain regions. Although point mutations, multiplications, and polymorphisms in the α-syn gene either cause or influence the risk of developing PD, determining the relationship between α-syn and neurodegeneration has proven

difficult as few model systems concurrently recapitulate key aspects of PD, including α-syn pathology, selective neuron loss, and trans-neuronal spread of pathology. We explored the relationship between α-syn and selective neurodegeneration using pre-formed α-syn fibrils (PFFs) to induce the conversion of endogenous α-syn into Lewy-like inclusions both in primary hippocampal cultures and *in vivo*. Using immunostaining for neuronal markers (NeuN and Neurofilament light chain) to determine neuronal viability after PFF-treatment, we found that PFFs cause toxicity in dose and time dependent manner. Toxicity is also pathology dependent since more pathogenic PFFs show increased toxicity whereas toxicity is not observed in PFF-treated $Snca^{-/-}$ neurons. Interestingly, we observed that toxicity was limited to only a subset of neurons, even after extensive periods of PFF treatment. In particular, glutamatergic Math2-positive neurons derived from the CA region were vulnerable to PFF-induced toxicity. In contrast Prox1-expressing glutamatergic neurons derived from the dentate gyrus (DG) and GABAergic neurons were relatively resistant both *in vitro* and *in vivo*. Vulnerability correlated with relative α-syn expression as $Math2^{+}$ neurons expressed higher levels compared to $Prox1^{+}$ neurons. Neuron loss was partially rescued by the antioxidant N-acetyl cysteine indicating that toxicity is oxidative stress-dependent. Our ongoing experiments will seek to determine the mechanisms linking α-syn aggregation to toxicity.

**Abstract:** Accumulating evidence suggests that many individuals with Parkinson's disease (PD) exhibit abnormalities in systemic energy metabolism prior to motor symptom onset, but the relationships between such abnormalities and the characteristic alpha-synuclein pathology are unclear. We previously reported that a high fat diet exacerbates, and alternate day intermittent fasting (IF) reverses, autonomic nervous system dysfunction in presymptomatic mice overexpressing a familial PD alpha-synuclein mutation (A53T) in neurons (Griffioen et al., 2013), and that this same PD mouse model exhibits a marked reduction in adipose tissue (Rothman et al., 2014). We further interrogated the metabolic status of cohorts of wild type (WT)

and PD mice maintained on control or alternate day IF diets for two months beginning at 10 weeks of age. MRI analysis data revealed that the PD mice have less adipose tissue, especially visceral fat, compared with WT mice when maintained on a standard ad libitum diet, and that IF accentuates fat loss. Measurements of metabolic parameters indicated reduced energy expenditure (EE) in PD mice compared to WT mice fed ad libitum, but not when maintained on IF. WT and PD mice exhibited increased spontaneous activity when on the IF diet compared to the control diet. As expected, the respiratory exchange ratio was reduced on fasting days in both the WT and PD mice. PD mice consumed less oxygen than WT mice when on the ad libitum diet, but not when on IF. Motor performance was significantly impaired in PD mice on both diets compared to WT mice, and mortality was hastened in PD mice on IF compared to those fed ad libitum, suggesting the contribution of a presymptomatic "wasting" phenotype to disease progression and death in this PD mouse model. This research was supported by the Intramural Research Program of the National Institute on Aging.

**Abstract:** α-Synuclein is a 17-kDa protein that is highly expressed in neurons. Although the exact function of α-synuclein is unclear, it is thought to play a role in vesicle transport. α-Synuclein is at the center of focus in understanding a group of neurodegenerative diseases called α-synucleinopathies, including Parkinson's disease and multiple system atrophy, where it is proposed to be passed between cells with advancing disease. Structurally, α-synuclein is similar to lipid-binding apolipoproteins, which are known extracellular lipid acceptors. The function of extracellular α-synuclein as a lipid acceptor is unknown, and therefore we asked the question whether extracellular α-synuclein mediates cholesterol efflux for neurons. We treated cholesterol-loaded SK-N-SH neuronal cells with extracellular α-synuclein and performed

cholesterol efflux assays. Extracellular α-synuclein potently stimulated cholesterol efflux from neurons to a similar extent as the positive control apolipoprotein E. The process was dose dependent and was saturated at an α-synuclein concentration of 1.0 μg/ml. The process was also time dependent. Here, we established, for the first time, a function for extracellular α-synuclein as a mediator of cholesterol efflux from neurons. This novel data provides a new facet to the role of α-synuclein in the brain and reveals new leads to understanding the pathomechanisms of α-synucleinopathies.

**Title:** Pum2-dependent translational regulation of alpha-synuclein mRNA on mitochondrial outer surface

**Authors: *Y.-S. KIM**, S. GUHATHAKURTA, S. BASU, G. JE
Biomed. Sci., Burnett Sch. of Biomed. Sci., Orlando, FL

**Abstract:** Alpha-synuclein (α-SYN) is a central molecule in the pathogenesis of Parkinson's disease (PD). α-SYN and mitochondrial functions are intimately entwined but the molecular mechanisms are incompletely understood. Here, we show that α-SYN mRNA is associated with the outer surface of mitochondria, where mitochondrial reactive oxygen species (ROS) caused by inhibition of respiratory complex I triggers local translation of α-SYN protein. The 3'-UTR of α-SYN mRNA is indispensable in the regulation of α-SYN translation on the surface of mitochondria. Next, we identified that the RNA-binding protein, Pum2, binds to its cognate binding site in the α-SYN 3'-UTR that is highly conserved across species. While knockdown of Pum2 significantly increased mitochondrial α-SYN, Pum2 overexpression lowered α-SYN levels, indicating that α-SYN translation is repressed by Pum2 until mitochondrial ROS derepress it. To investigate the role of Pum2-mediated translational regulation of α-SYN in mitochondrial functions, mutagenesis of a Pum2-binding motif in the 3'-UTR was achieved using CRISPR/Cas9-based genome editing in the mammalian cells. Homozygous mutation of a Pum2 binding motif resulted in changes in mitochondrial morphology, and reductions in cellular oxygen consumption and ATP synthesis. Altogether, we report a novel mechanism that Pum2-

dependent translational regulation of a pool of α-SYN mRNA pre-associated with mitochondrial surface contributes to the fine-tuning of mitochondrial respiratory functions. The results suggest that dysregulation of these mechanisms could contribute to mitochondrial impairment, leading to PD pathogenesis.

**Abstract:** Alpha synuclein (aSyn) is involved in synaptic vesicle trafficking and synaptic transmission, but is also strongly linked to Parkinson's disease (PD) and other neurodegenerative disorders. In diseases where aSyn aggregates, or synucleinopathies, it accumulates in and spreads to different brain areas and peripheral organs. Although increased aSyn levels likely underlie familial PD with SNCA mutations thus implicating the protein in disease initiation, most synucleinopathies arise sporadically indicating that the expression of normal levels of wild type aSyn is sufficient for the development of disease. In spite of our increasing knowledge in the field, the physiological function of aSyn and its precise role in disease remain enigmatic urging the development of new tools for further investigations. Here, we report the development and characterization of a new mouse model expressing a GFP-aSyn fusion protein under the control of the endogenous Snca promoter. We describe the expression pattern of the fusion protein in the brain and peripheral organs and characterized its subcellular localization and trafficking in the brain. Primary neurons expressing GFP-aSyn were also successfully derived from this line. In addition, intracerebral injection of aSyn pre-formed fibrils induced formation of GFP-positive inclusions with a similar distribution pattern to that observed in wild type mice. We anticipate that this new mouse model will facilitate in vitro and in vivo studies that incorporate live imaging and detection of endogenous alpha synuclein, therefore providing new insights into aSyn function in health and disease.

**Abstract:** Glucocerebrosidase (GCase) is a lysosomal enzyme encoded by the GBA1 gene. Mutations in GBA1 gene lead to Gaucher's disease (GD), the most prevalent lysosomal storage disorder. GBA1 mutations reduce GCase activity, therefore promoting the aggregation of alpha-synuclein, a common neuropathological finding underlying Parkinson's disease (PD) and dementia with Lewy bodies. Bearing in mind that a number of strategies increasing GCase expression for the treatment of PD are currently under development, here we sought to analyze the baseline expression of GCase in the brain of *Macaca fascicularis*, which has often been considered as the gold-standard animal model of PD. Although as with other lysosomal enzymes, GCase is expected to be ubiquitously expressed, here a number of regional variations have been consistently found, together with several specific neurochemical phenotypes expressing very high levels of GCase. In this regard, the most enriched expression of GCase was constantly found in cholinergic neurons from the nucleus basalis of Meynert, dopaminergic cells in the substantia nigra pars compacta, serotoninergic neurons from the raphe nuclei, as well as in noradrenergic neurons located in the locus ceruleus. Moreover, it is also worth noting that high levels of expression were also found in a number of areas within the paleocortex and archicortex, such as the entorhinal cortex and the hippocampal formation, respectively.

**Abstract:** Parkinson’s disease (PD) is the second most frequent progressive neurodegenerative disorder of aging characterized by apoptosis and neuro-inflammation, which subsequently leads to the deterioration of nigrostriatal dopaminergic (DA) neurons. This study was designed to investigate the neuroprotective effects of osmotin against MPTP/$MPP^+$-induced in mice and SH-SY5Y human neuroblastoma cell lines respectively. Osmotin is a tobacco plant-derived protein associated to pathogenesis-related proteins of family 5. Being a structural and functional homolog of the mammalian adiponectin, osmotin is believed to have similar biological and physiological effects as adiponectin, and so has been implicated as anti-inflammatory and anti-apoptotic agent in different experimental settings. Osmotin administration to MPTP-induced models of PD led to improvement of motor impairment. Furthermore, Osmotin was able to enhance the expression of tyrosine hydroxylase (TH) protein and increase TH-positive neurons in SNpc and Striatum. Osmotin attenuated MPTP/$MPP^+$-induced DA neuronal cell death in SNpc through regulation of anti/pro-apoptotic markers as Bcl-2, Bax, caspase-3 and Cytochrome c. In addition, our data demonstrated that osmotin suppressed JNK phosphorylation and promoted ERK activation in PD model. To the best of our knowledge, this research was the very first investigation confirmed that novel osmotin is the best candidate which can ameliorate neurological deteriorations associated with PD.

**Title:** Copaifera reticulata Ducke oil-resin reduces apomorphine-induced rotations in the striatal 6-OHDA mouse model of Parkinson's disease

**Authors: *A. VALENTE**[1], R. D. M. GOMES[1], S. M. G. SERRÃO[1], E. T. COSTA[1], D. C. F. LOPES[1], V. S. L. CARDOSO[1], W. GOMES-LEAL[2], E. S. YAMADA[1]
[1]Exptl. Neuropathology Lab., Univ. Hosp. João De Barros Barreto, UFPA, Belém, Brazil; [2]Lab. of Exptl. Neuroprotection and Neuroregeneration, Inst. of Biol. Sciences, UFPA, Belém, Brazil

**Abstract:** Parkinson's disease (PD) is traditionally classified as a motor disorder characterized by resting tremor, muscular rigity, postural instability and bradykinesia, which result from dopaminergic neuronal death in the substantia nigra pars compacta (SNpc) and consequent depletion of dopamine in the striatum. The exact trigger of the neuronal cell death in PD remains unknown, but oxidative stress and neuroinflammation are involved in the mechanism underlying the dopaminergic neurodegeneration. The 6-OHDA mouse models of PD are useful tools for the study of the biological processes involved in the pathophysiology of PD, as well as to investigate neuroprotection strategies. In this way, the Amazonian biome represents a great source of natural resources for compounds with neuroprotective potential. *Copaifera reticulata* Ducke (Copaíba) is among the most used plants in folk medicine and its oil-resin has several sesquiterpenes with anti-inflammatory and antioxidant properties. Thus, the aim of this study was to evaluate a neuroprotective effect of the Copaíba oil-resin in the striatal 6-OHDA mouse model of PD. Forty-Eight male Swiss mice were used, divided in 4 groups: Vehicle/Vehicle (N = 8), Vehicle/Copaíba (N = 8), 6-OHDA/Vehicle (N = 15) and 6-OHDA/Copaíba (N = 17). Stereotaxic surgeries were performed in all animals; vehicle or 10 µg 6-OHDA solution was infused into the striatum. Copaíba oil-resin treatment (50 mg/kg) was performed for 7 days after stereotaxic surgeries and the survival time was 28 days. Open field test, apomorphine-induced rotational test and immunostaining for tyrosine-hydroxylase (TH) were performed. The analyses from the open field test showed that 6-OHDA/Vehicle and 6-OHDA/Copaíba was reduced on the $14^{th}$ (59%) and $28^{th}$ day (56%) in relation to day 0, suggesting that Copaíba oil-resin treatment did not improve the motor performance at this test. Additionally, 6-OHDA/Vehicle and 6-OHDA/Copaíba groups remained less time in the peripheral zone in open field test in relation to Vehicle/Vehicle and Vehicle/Copaíba groups, which did not display thigmotaxis behavior. The apomorphine-induced rotational test on the $14^{th}$ day showed that 6-OHDA/Vehicle group

presented significant decrease of 54% in relation to 6-OHDA/Vehicle group, but this difference did not remain on the 28th day. Histological analyses showed that the Copaíba oil-resin treatment was associated with less degeneration of TH+ neurons in the nigrostriatal pathway. Hence, the Copaíba oil-resin treatment has a potential neuroprotective effect in this mouse model of PD, which deserves to be better characterized for translational application.

**Title:** Cerebral dopamine neurotrophic factor (CDNF) attenuates endoplasmic reticulum stress-induced apoptosis

**Authors: *D. A. ARANCIBIA**[1], P. ZAMORANO[2], M. E. ANDRES[3]
[1]Pontificia Univ. Católica De Chile, Santiago, Chile; [2]Univ. de Antofagasta, Antofagasta, Chile; [3]Pontificia Univ. Catolica De Chile, Santiago, Chile

**Abstract:** The endoplasmic reticulum (ER) is an organelle that maintains the equilibrium between synthesis, folding and degradation of proteins. Many stressors can induce failing the adaptive capacity of ER producing the accumulation of misfolded proteins in the ER lumen and triggering the unfolded protein response (UPR). Failure to maintain the proteostasis at the ER in neurons has been associated with many neurodegenerative diseases, such as Parkinson, Alzheimer and Huntington's disease among others. CDNF is a non-conventional neurotrophic factor that has been reported to exert a neuroprotective and neurorestorative effect in animal models of Parkinson disease. Although the molecular mechanisms of the protective role of CDNF are still unclear, a participation of the UPR has been observed, suggesting a modulating role in ER stress. CDNF is constitutively secreted to the extracellular medium, but is also an ER-resident protein. In this study, we investigated whether CDNF expressed intracellularly inhibited ER stress and apoptosis in HEK-293 cells upon exposure to thapsigargin (TG), an ER stress inductor, to determine its effects on cell viability and the UPR response. Our results show that

intracellular overexpression of CDNF improved cell viability in cells exposed to TG. In addition, CDNF increased GRP78 and decreased ATF6 and XBP-1 protein levels. Furthermore, the ER stress-induced apoptosis response proteins CHOP, pJNK and cleaved caspase-3 are decreased with CDNF overexpression. Collectively, our results suggest that protective effect of CDNF are related to the inhibition of ER stress-induced apoptosis by increasing GRP78 expression, a principal regulator of UPR. Thus, here we show a role of CDNF in ER proteostasis and suggest a role for CDNF in the context of neuroprotection.

**Title:** Pakinson's disease provokes oxidative stress and movement disorders: Neuroprotective potential of purple grape juice

**Authors: *C. S. FUNCHAL**[1], M. ROCHA FRUSCIANTE[1], A. SOUTO FERREIRA[1], J. PEREIRA MARINHO[1,2], A. QUINCOZES DOS SANTOS[2], D. POCHMANN[1], C. DANI[1]
[1]Methodist Univ. Ctr. - IPA, Porto Alegre, Brazil; [2]UFRGS, Porto Alegre-RS, Brazil

**Abstract:** Parkinson’s Disease (PD) is a chronic degenerative disease of the central nervous system. The aim of this study was to evaluate the effect of purple grape juice on the movement disorders and oxidative parameters in hippocampus of reserpine-treated rat model of PD. Adult Wistar rats were treated with water or purple grape juice (gavage) for 14 days (7 μL/g) and on the 15$^{th}$ day the animals received a subcutaneous single dose of reserpine (1.0 mg/mL/kg) for induction of DP. After 1, 6 and 24 h induction of PD model some motor and behavioral parameters were observed by a trained evaluator: head, jaw and vibrissae movements, and changes in curvature and tail rigidity. After 24 h of PD induction, the hippocampus was dissected for analysis of the parameters of oxidative stress: lipid peroxidation (TBARS), carbonyl, sulfhydryl (SH), reduced glutathione (GSH) and the activity of the antioxidant enzymes, catalase (CAT), superoxide dismutase (SOD) and glutathione peroxidase (GPx) (CEUA IPA-15/2015).

Rats treated with reserpine presented changes in curvature and tail stiffness, repeated jaw, head and vibrissae movements after1, 6 and 24 h of PD induction. Purple grape juice prevented most of these changes. Reserpine increased the levels of carbonyl, reduced GSH and the activity of CAT and SOD in hippocampus. Purple grape juice was effective in preventing all damages. The levels of TBARS and GH were not modified. Therefore, purple grape juice revealed a possible antioxidant and neuroprotective effect and might be used as a therapeutic adjuvant in PD patients.

**Title:** Silymarin corrects chaperon-mediated autophagy and contributes to neuroprotection in MPTP-induced Parkinsonism

**Authors: *M. K. TRIPATHI**, M. S. U. RASHEED, A. K. MISHRA, M. P. SINGH
TOXICOGENOMICS AND PREDICTIVE TOXICOLOGY DIVISION, CSIR-INDIAN INSTITUTE OF TOXICOLOGY RESEARCH, LUCKNOW, India

**Abstract:** 1-Methyl-4-phenyl-1, 2, 3, 6-tetrahydropyridine (MPTP) induces α-synuclein aggregation and impairs lysosomal function. Abnormal α-synuclein is eliminated from the nigrostriatal dopaminergic neurons primarily via the chaperon-mediated autophagy (CMA). Impaired CMA leads to an accumulation of aggregated α-synuclein leading to Parkinson’s disease in humans and Parkinsonism in intoxicated experimental animals. Silymarin, an antioxidant, anti-inflammatory and anti-apoptotic agent, is found to encounter MPTP-induced oxidative stress and neuronal apoptosis. The present study aimed to investigate the effect of silymarin on MPTP-induced changes in CMA and Parkinsonism. Male Swiss albino mice (20-25 g) were treated intraperitoneally with silymarin (40 mg/kg, daily) for 15 days along with vehicle controls. Subsets of animals were also treated with MPTP on the day 7 (20 mg/kg intraperitoneally; 4 times at 2 h interval). Mice were sacrificed, brain was dissected out and western blot analysis of α-synuclein, heat shock cognate-70 (Hsc-70) and lysosome-associated

membrane protein-2A (LAMP-2A) was performed. Besides, immunofluroscence employing lysotracker and dansylcadaverine dye was also performed to ensure the autophagosome formation and lysosomal quality. Silymarin significantly encountered MPTP-induced changes in the expression of LAMP- 2A and Hsc-70 proteins in the nigrostriatal tissue. Silymarin attenuated the level of aggregated α-synuclein accumulation and increased the autophagosome formation in the substantia nigra of MPTP-treated mice. The results obtained thus suggest that silymarin corrects CMA and contributes to neuroprotection in MPTP-induced Parkinsonism. **Keywords:** Parkinson's disease; Antioxidants; Autophagy

**Abstract:** *Centella asiatica* extract exhibits various pharmacological activities *in vitro* and *in vivo*. In this study, the neuroprotective effects and underlying mechanisms of the standardized extract of *Centella asiatica* ECa233 were investigated in rotenone model of Parkinson's disease. Male Wistar rats were divided into three experimental groups (n=10/group) which were control, PD and PD+ECa233. Rats in control and PD groups received 0.5% CMC (1 mL/kg p.o.) while rats in PD+ECa233 received ECa233 (30mg/kg p.o.) for 14 days. On day 15-20, rats in the control group received 2% DMSO (1 mL/kg i.p.) with 0.5% CMC while PD and PD+ECa233 rats received rotenone (2.5 mg/kg i.p.) with 0.5% CMC and ECa233 respectively . Rats were performed locomotor activity test on day 1, 14 and 20. Brains were collected and determined tyrosine hydroxylase (TH)-positive cells and malondialdehyde (MDA) levels. The results showed that locomotor activity of rats in PD+ECa233 group was significantly higher than that of

rats in the PD group on day 20 ($p<0.05$). In addition, ECa233 protected against rotenone-induced dopaminergic neuronal loss in the substantia nigra as the TH-positive cells of rats in PD+ECa233 group were significantly higher than that of PD rats ($p<0.05$). ECa233 tended to decrease brain MDA levels in rotenone-treated rats, but this effect did not significantly different from PD rats. The present study showed that ECa233 can protect against rotenone-induced neurotoxicity via ameliorating lipid peroxidation. As rotenone is a mitochondria complex I inhibitor, the mitochondria protection effect of ECa233 should be further investigated.

**Title:** NADPH oxidase (NOX1) mediates testosterone-induced neurodegeneration

**Authors: *M. A. TENKORANG**[1], R. L. CUNNINGHAM[2]
[1]Ctr. for Alzheimer’s and Neurodegenerative Dis. Res., Univ. of North Texas Hlth. Sci. Ctr., Fort Worth, TX; [2]Pharmacol. & Neurosci., Univ. North Texas Hlth. Sci. Ctr., Fort Worth, TX

**Abstract:** One of the primary characteristics of Parkinson’s disease (PD) is oxidative stress (OS). Men have a higher risk for PD than women. Testosterone, a primary male sex hormone has been implicated in PD, and is a known oxidative stressor. Previous studies in our lab have shown that testosterone exacerbates OS damage in dopaminergic neurons. However, the mechanism by which testosterone increases OS is unknown. We hypothesize that in dopaminergic cells, testosterone increases OS by activating NOX 1, a major OS generator in cells. To test our hypothesis, we used a dopaminergic cell line (N27 cells). For an oxidative stressor, we used tert-butyl-hydrogen peroxide ($H_2O_2$) to induce 20% cell loss prior to testosterone (100nm) administration. NOX1 inhibitors (Apocynin, Diphenyleneiodonium-DPI) were administered before $H_2O_2$ exposure. Cell viability and Oxidative stress were quantified using the MTT and Reduced Thiols assays respectively.
Testosterone is only damaging in the presence of OS. DPI, alone, was damaging to N27 cells, hence this was no longer used as a NOX1 inhbitor. Unlike DPI, Apocynin had no effect on cell viability and oxidative stress. Further, Apocynin alone, did not alter $H_2O_2$-induced cell loss, indicating that $H_2O_2$ increases OS via a non-NOX1 mechanism. However, Apocynin blocked testosterone’s induced cell loss and oxidative stress generation. Testosterone-induced cell loss is

mediated by NOX1, indicating that NOX1 is involved in testosterone induced OS generation. By understanding testosterone's mechanism of action, potential therapeutic targets for Parkinson's disease can be explored.

**Title:** Physical activity alone is not enough in Parkinsonism; but significantly protective when combined with an antioxidant

**Authors: *A.-L. GIL-MARTÍNEZ**, L. CUENCA, C. ESTRADA, E. FERNÁNDEZ, M. HERRERO
Clin. and Exptl. Neurosci., Univ. of Murcia, Murcia, Spain

**Abstract:** Neuroprotection is becoming relevant to slow down dopaminergic cell death and inflammatory processes related to progressive degeneration in Parkinson's Disease (PD). Interestingly, among others, physical exercise and anti-oxidant treatments (such as *N*-acetyl-L-cysteine, NAC) are common therapeutic strategies. Therefore, this study aims to analyze the synergistic effect of physical activity and NAC treatment on inflammatory activation and dopaminergic degeneration in a Parkinsonism -induced 1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine (MPTP) model. To ascertain this possibility, 48 eight-weeks-old mice (C57BL/6 strain) were used. 24 of them were individually placed in cages where voluntary physical exercise was monitored during four weeks and divided into groups: i) control; ii) NAC treatment; iii) MPTP and iv) MPTP+NAC. The other 24 mice were divided into the same four groups, described above, without physical exercise. Post-mortem studies with midbrain cells (substantia nigra, SNpc) and striatum show a significant decrease of the cell death in all treated groups compare with MPTP group but especially significant in NAC+exercise group. Moreover, it was observed a significant decrease of GFAP and Iba-1 expression in NAC groups and a very

significant in NAC+exercise groups. These results suggest that physical exercise, on its own, does not have an improvement effect on neuronal death and inflammation activity, it is necessary to combine it with an anti-oxidant (as NAC) so that these effects are significant. In conclusion, the combination of physical exercise with an anti-oxidant drug has a synergistic effect improving motor condition as well as reducing inflammatory processes that protects dopaminergic neurons against neurodegeneration.

**Abstract:** Experimental and clinical evidence suggests that inflammatory factors, controlled by glial cells may play an important role in the development of neurodegenerative processes associated with Parkinson's disease. Even though PD is an aging-related disorder, only few studies have been performed in old animals. Otherwise, it has been demonstrated that c-Jun N-terminal kinase (JNK), an important kinase member of the MAPK family, is implicated in 1-

methyl-4-phenyl-1,2,3,6-tetrahydropyridine (MPTP) neurotoxic mechanisms. Therefore, the inhibition of JNK could prevent or delay the dopaminergic injury of MPTP intoxication and the secondary inflammatory response. In this study, we analyzed two different agents which mechanisms of action are related to JNK pathway: i) the *N*-acetyl-L-cysteine (NAC), a glutathione precursor, and ii) HA-1077, a ROCKinase inhibitor and microglia polarizer. Additionally, we evaluated the combination of both treatments (NAC+HA-1077). 75 twenty-weeks-old C57BL/6 mice were used in this study; 33 of them were control groups and the other 42 animals were acutely intoxicated with MPTP and divided into 4 groups: i) MPTP; ii) MPTP+NAC; iii) MPTP+HA1077; iv) MPTP+NAC+HA1077. Postmortem quantitative analysis showed a significant decrease of TH expression in the SNpc and in the striatum as well as significant increased Iba-1 and GFAP levels in all MPTP-animals comparing with control groups. However, old-Parkinsonian mice treated with NAC had TH+ cells and fibers, GFAP and Iba-1 expression similar to control animals. Surprisingly, microglial and astroglial cells were significantly incremented in MPTP-intoxicated animals treated with both drugs (NAC+HA1077) compared with all the other MPTP groups. Unfortunately, these unexpected results discard the use of the combined treatment (HA1077+NAC) in old mice. However, NAC treatment does have neuroprotective effects in old Parkinsonian mice probably due to its anti-oxidant properties (associated to JNK inhibition).

**Title:** Neuroprotection induced by HDAC inhibitor in Parkinson's disease model

**Authors: *S. SONG**, T. KIM, J. KIM, H. NOH, S. KANG, H. SEO
Hanyang Univ., Ansan, Korea, Republic of

**Abstract:** Parkinson’s disease (PD) is one of the progressive neurodegenerative diseases with dopaminergic neuronal loss and Lewy body deposit in substantia nigra pars compacta. We hypothesized that histone hypoacetylation is associated with progressive pathology of PD. In this study, we aimed to understand target of HDAC inhibition for PD. We determined the effects of pan HDAC inhibitor as well as selective HDAC inhibitor such as valproic acid (VPA), sodium butyrate (SB), MS-275, and tubacin, in dopaminergic SHSY-5Y cells. We also administered VPA in PD model LRRK2 R1441G mice. VPA significantly decreased cytokine expression levels and PD pathological markers in midbrain region of LRRK2 R1441G mice. VPA also significantly increased the number of TH positive neurons in substantia nigra of LRRK2R1441G mice. VPA increased latency to fall in rota-rod test and decreased number of rearing counts in open-field test in LRRK2R1441G mice. These data suggest that histone deacetylation may be a promising therapeutic target for PD.

**Abstract:** Parkinson’s disease (PD) is a common neurodegenerative disorder characterized by the loss of dopamine (DA) neurons in the substantia nigra pars compacta and the accumulation and aggregation α-synuclein (α-syn). Misfolded fibrillar forms of α-syn are thought to spread via cell-to-cell communication contributing to the progression and neurodegeneration in PD. However, the underlying molecular mechanisms by which α-syn causes cell death and neurodegeneration in PD is not known. Here, we show that the PAAN mediates α-syn-induced degeneration in A53T transgenic mice. Conditional expression of the familial associated A53T α-syn mutant in DA neurons of transgenic mice leads to loss of DA neurons and behavioral deficits that is significantly reduced in the absence of the PAAN. Further, we developed an endonuclease assay and screened a novel hybrid macrocyclic rapafucin library (~11,248 compoinds) to find PAAN inhibitors. Novel PAAN antagonists can inhibit DNA cleavage and

prevent α-syn induced degeneration. Thus, targeting PAAN activity may provide an important therapeutic opportunity in Parkinson's disease.

**Abstract:** Activation of microglia leads to the conversion of resting astrocytes to toxic A1 type astrocytes in a variety of neurodegenerative diseases. Development of agents that could inhibit the formation of A1 type astrocytes have profound therapeutic potential since they could be used to treat a variety of neurologic disorders for which there currently are no disease modifying therapies. The glucagon-like peptide-1 receptor (GLP1-R) agonist have shown some efficacy in providing a reduction in inflammation, augmentation in mitochondrial function and neuroprotection, however, the mechanism of how GLP1-R agonism elicits these actions, especially in Parkinson's disease (PD), is not known. Here we show that a potent, brain penetrant pegylated long acting GLP1-R agonist NLY01, has neuroprotective effect in PD models via direct actions on microglial mediated conversion to neurotoxic A1 astrocytes. NLY01 reduced pathological phosphorylation of α-synuclein, dopaminergic (DA) neuronal loss, and behavioral deficits in the α-synuclein preformed fibril (α-syn PFF) model of sporadic PD. In addition, NLY01 significantly prolongs the lifespan and reduces neuropathology of human A53T α-syn (hA53T) transgenic mice, a model of familial α-synucleinopathy. NLY01 protective effects are independent of its potential action on neurons, but appear to primarily involve inhibition of microglia. We show that α-syn PFF induced microglial activation is blocked by NLY01 both in vitro and in vivo. The inhibitory effect of NLY01 on microglial activation also prevents the conversion of resting astrocytes into toxic A1 astrocytes, which contributes to the demise of DA neurons in the α-syn PFF mouse model and in human DA neuronal cultures. Taken together these findings strongly suggest that NLY01 has broad neuroprotective properties in a variety of

neurodegenerative disorders including PD characterized and involving A1 astrocyte activation. In addition, due to its significantly increased half-life and bioavailability it offers greatly improved therapeutic opportunities for the treatment of chronic neurologic diseases.

**Title:** Neuroprotective effect of MHY908, a PPAR α/γ dual agonist, on the MPTP-induced Parkinson’s disease model

**Authors:** ***Y. LEE**, S. LEE, W. LEE, J. LEE
Pharm., Pusan Natl. Univ., Busan, Korea, Republic of

**Abstract:** Parkinson’s disease (PD) is a progressive neurodegenerative disease, and induced by a selective loss of dopaminergic neurons in the nigrostriatal pathway. Previous studies demonstrated that several peroxisome proliferator-activated receptor (PPAR) agonists were protective against various neurodegenerative diseases including PD. MHY908, developed as PPAR α/γ dual agonist, has been shown to have multiple effects, such as anti-diabetic, anti-inflammatory, and anti-melanogenic effects. In the present study, we evaluated neuroprotective effects of MHY908 on the PD mouse model. Pretreatment of MHY908 attenuated MPTP-induced dopaminergic neuronal loss and motor deficit. MPTP-induced glial activations were alleviated by MHY908 in nigrostriatal pathway. MHY908 was also effective to prevent $MPP^+$-induced neuronal cell death and ROS production in SH-SY5Y cells. Further study revealed that MHY908 inhibited $MPP^+$-induced astroglial activation via suppressing NF-κB signaling in primary astrocytes. Taken together, the present study suggests that PPAR α/γ dual agonist could be useful agent for therapeutic candidates for PD and other neurodegenerative diseases associated with neuroinflammation.

**Title:** Melatonin protects from aberrant mitochondrial dynamics in cypermethrin model of Parkinson’s disease

**Authors: *A. K. MISHRA**, M. K. TRIPATHI, M. P. SINGH
Toxicogenomics and Predictive Toxicology Lab., Csir-Indian Inst. of Toxicology Res., Lucknow, India

**Abstract:** The study aimed to investigate the effect of melatonin on the mitochondrial dynamics in a cypermethrin model of Parkinsonism. Male pups were treated with cypermethrin during the postnatal days 5-19 (1.5 mg/kg; twice a week) along with vehicles. Animals were re-challenged with cypermethrin during adulthood for 12 weeks (15 mg/kg, twice a week). Subsets of animals were also treated with melatonin (10 mg/kg, daily), during adulthood, 2 h prior to cypermethrin. Indicators of the mitochondrial dynamics were measured in the nigrostriatal tissue of control and cypermethrin-treated rats. Animals were sacrificed and nigrostriatal tissue was dissected out from the decapitated brain. Cypermethrin increased the expression of dynamin-related protein-1 (Drp-1) and Parkin as compared with control. Cypermethrin also increased the ubiquitination of the mitochondrial proteins. Melatonin reduced the expression of the mitochondrial Drp-1 and Parkin and ameliorated the ubiquitination of the mitochondrial proteins in cypermethrin-treated rats. Moreover, cypermethrin induced the translocation of optic atrophy-1 protein from the mitochondria to the cytosol, which was considerably normalized in melatonin co-treated rats. The results of the study indicate that melatonin resists the impairment of the mitochondrial dynamics in cypermethrin-induced Parkinsonism.

**Abstract:** Parkinson's disease (PD) is common among the elderly. Physical exercise, in turn, is described by its beneficial effects. The purpose of this study was to analyze treadmill exercise, may promote plasticity in the motor cortex, area with altered excitability in PD. Wistar rats were submitted to the unilateral PD model induced by striatal 6-OHDA, and a treadmill exercise protocol (3x / week for 40 minutes). Groups control received saline injection only. The animals were divided into 4 groups (n = 5 animals / group). Before induction of the model and 10 days later, the animals were submitted for 5 minutes to the cylinder test for motor behavior analysis. The plasticity in the motor cortex was determined by the expression of synaptic proteins (synapsin; synaptophysin) and structural (neurofilaments; MAP-2) 10 days after the induction of the model. In addition, immunohistochemical data were compared with data obtained on positron emission tomography labeled with [18F] FDG radiopharmaceutical. The results showed a neuroprotection of the dopaminergic neurons in the pars compacta in the exercised+6-OHDA animals compared to the sedentary animals+6-OHDA (27%, $p < 0.05$, SED + 6-OHDA 72 ± 5, EX + 6 -OHDA 99 ± 3). In addition, dopaminergic depletion in the striatum is also reduced in the exercised animals (15%, $p < 0.05$, SED + 6-OHDA 0.73 ± 0.05, EX + 6-OHDA 0, 88 ± 0.04). In the cylinder test, the SED + 6-OHDA group revealed asymmetry in the use of the paws, which was not observed in the exercised group (16%, $p < 0.05$, SED + 6-OHDA 69 ± 7.4, EX + 6 -OHDA 53 ± 0.8, EX 50 ± 0.7), suggesting an improvement in motor behavior. Besides that, there was an increase in MAP-2 expression in the motor cortex (primary motor cortex 133%, $p < 0.0001$, SED + 6-OHDA 1.82 ± 0.15, EX + 6-OHDA 0.50 ± 0 , EX 1.08 ± 0.02, secondary motor cortex 78%, $p < 0.0001$, SED + 6-OHDA 1.77 ± 0.41 EX + 6-OHDA 1.85 ± 0.85 EX 0 , 94 ± 0.06), and decreased neurofilaments in the primary motor cortex of the SED + 6-OHDA group (ca. 50%, $p < 0.05$, SED + 6-OHDA 0.55 ± 0.17, EX + 6-OHDA 1.10 ± 0.197, EX 1.20 ± 0.125). The expression of synaptophysin showed an increase in the primary motor cortex of SED + 6-OHDA animals (36%, $p < 0.01$, SED + 6-OHDA 1.36 ± 0.24, EX + 6-OHDA 1.03 ± 0.04 ; EX 0.99 ± 0.03). Therefore, we can suggest that this model promotes alteration of cortical

excitability, which seems to be reversed by the exercise protocol. Data from [18F] FDG in the striatum corroborate immunohistochemical data with decreased uptake (10%, $p < 0.001$) in SED + 6-OHDA animals, suggesting lower dopaminergic activity. Thus, this study suggests that this exercise protocol may be able to normalize cortical excitability and improve motor behavior that occurs in the early stage of the disease.

**Abstract:** Recombinant Hc-TeTx fragment has been successfully assayed as a neuroprotector in Parkinson's disease (PD) models. While levodopa has been the gold standard in the therapeutic treatment of PD, unfortunately almost all patients develop dyskinesia or abnormal involuntary movements (AIMs). The aim of this study was to evaluate the effect of post-lesion or pre-lesion treatment with Hc-TeTx on levodopa-induced dyskinesia in rats. AIMs were induced with low, mid and high levodopa doses (6, 10 and 25 mg/kg respectively) and examined for 22 days. Also all rats were monitored the motor activity in closed-field box or cylinder test. Finally, tyrosine hydroxylase-positive (TH) neurons in the *substantia nigra pars compacta* (SNpc) and FosB/ΔFosB expression in the striatum were examined. Hc-TeTx (20 µg/kg i.m.) co-administrated with levodopa (6 or 10 mg/kg) did not reduce the severity of the AIMs, while the

group treated with Hc-TeTx plus levodopa (25 mg/kg) presented a temporary attenuation of dyskinetic limb and orolingual movements. However the restorative effects of Hc-TeTx on motor behavior and dopaminergic neuronal death in the SNpc were not observed. There was a significant post-treatment increase in FosB/ΔFosB expression in the dorsolateral and ventral striatum of animals treated with Hc-TeTx. When Hc-TeTx was administrated prior to dopaminergic lesion and levodopa administration (10 mg/kg), there was a slight recovery of motor asymmetry, one week post-lesion. Moreover, while the Hc-TeTx slightly reduced the AIMs score in the first days of levodopa treatment, it was not effective by the end of the experiment. Also, the loss of TH neurons in the SNpc revealed that Hc-TeTx did not induce effective neuroprotection. It is worth noting that a reduction of FosB/ΔFosB expression in the dorsolateral striatum was observed. In summary, Hc-TeTx treatment did not effectively reduce the induction of AIMs by levodopa in hemiparkinsonian rats, although the pre-treatment administration of Hc-TeTx causes minor FosB expression in the dorsolateral striatum.

**Abstract:** Object
In clinical practice, deep brain stimulation (DBS) is effective for the treatment of motor symptoms in Parkinson’s disease (PD). However, the mechanisms have not been understood completely. There are some reports that electrical stimulation exerts neuroprotective effects on the central nervous system disorders including cerebral ischemia, head trauma, epilepsy and PD. Meanwhile, there are only few reports on neuroprotective effects of spinal cord stimulation (SCS). In the present study, we investigated neuroprotective effects of SCS on PD model of rats.
Methods
Adult female Sprague-Dawley rats received hour-long SCS (2, 50 or 200Hz) with an epidural electrode at C1-2 level for 16 consecutive days. At 2 days after initial SCS, 6-hydroxydopamine (6-OHDA), a neurotoxin of dopaminergic neurons, was injected into the right striatum of rats.

Behavioral evaluations of PD symptoms, including cylinder test and amphetamine-induced rotation test, were performed at 1-2 weeks after 6-OHDA injection. Animals were subsequently euthanized for immunohistochemical investigations. In order to explore neurotrophic and growth factor upregulation induced by SCS, another cohort of rats that received 50Hz SCS was euthanized at 1 and 2 weeks after lesion for protein assays.
Results and Discussion
Behavioral tests revealed that the number of amphetamine-induced rotations decreased in SCS groups. Immunohistochemically, tyrosine hydroxylase (TH)-positive fibers in the striatum were significantly preserved in SCS groups. TH-positive neurons in the substantia nigra pars compacta were significantly preserved in 50Hz SCS group. The level of vascular endothelial growth factor (VEGF) was upregulated by SCS at 1 week after the lesion. These results suggest that SCS exerts neuroprotection in PD model of rats, at least partially by upregulation of VEGF. SCS is supposed to suppress or delay Parkinson's disease progression and might become a less invasive therapeutic option for PD patients. Although neuroprotective effect was observed by hour-long SCS paradigm for 16 consecutive days in the present study, longer continuous stimulation might exert greater effect. We are currently investigating this possibility.

**Abstract:** Parkinson's Disease (PD) is a neurodegenerative disorder characterized by the presence of inclusions in dopaminergic neurons from substantia nigra, known as Lewy bodies, and the progressive loss of these neurons. The protein α-Synuclein (α-syn) constitutes one of the main components of the Lewy bodies in sporadic cases of PD. Animal models overexpressing α-

syn exhibit neuronal degeneration and abundant α-syn-positive inclusions, which recapitulates essential neuropathological features of PD. On the other hand, chronic Spinal Cord Stimulation (SCS), a neuromodulation technique consisting in the epidural delivery of electrical pulses in the dorsal portion of the spinal cord, has emerged as a potential treatment of PD. SCS showed to be very effective alleviatingparkinsonian motor symptoms both in animal models and patients. Evidence collected in both the classical 6-OHDA neurotoxin and the α-syn animal models of PD, suggest that SCS could have long-term effects associated to neuroprotection. Neurotrophic factors, i.e. the Vascular Endothelial Growth Factor (VEGF), have been shown to support the survival of many neuronal populations both in culture and pre-clinical models of PD. Our research focuses in the study of the neuroprotective mechanisms that could be involved in the improvement of the motor performance of an α-syn animal model of PD submitted to chronic spinal cord stimulation. We used an α-syn animal model corresponding to Sprague Dawley male rats injected unilaterally in the substantia nigra with adenovirus AAV6-α-syn. Four weeks after the viral injection, rats were treated with high-frequency (300 Hz) SCS during five weeks, two sessions/week. Assays of immunohistochemistry showed that chronic SCS modulates the expression of vascular endothelial growth factor (VEGF) in the nigro-striatal pathway. This suggests that chronic SCS might exert neuroprotective effects through the regulation of VEGF, which is known for angiogenic and pro-survival functions.

**Abstract:** Cardiac dysautonomia is a common nonmotor symptom of Parkinson's disease associated with loss of sympathetic innervation to the heart and decreased plasma catecholamines. Disease-modifying strategies are not available, and biomarkers are lacking. Systemic administration of the catecholaminergic neurotoxin 6-hydroxydopmaine (6-OHDA) recapitulates this loss of cardiac sympathetic innervation and circulating catecholamines. We recently used positron emission tomography (PET) imaging in 10 6-OHDA-treated (50mg/kg; iv) adult, male rhesus to visualize and quantify cardiac sympathetic neurodegeneration and increased inflammation and oxidative stress following neurotoxin, which were attenuated in pioglitazone treated rhesus (n=5; 5mg/kg) compared to placebo (n=5). Here we report post mortem characterization of heart and adrenal tissue in these animals compared to age and gender matched normal controls (n=5). Tissues were collected following PFA perfusion, blocked in paraffin, sectioned at 5µm, immunostained, and immunoreactivity (-ir) quantified as area above threshold (%AAT) in NIH ImageJ. In the heart, immunohistochemistry was performed for sympathetic innervation (tyrosine hydroxylase; TH) and inflammation (HLA-DR) in 3 base to apex layers and 4 regions (septal, anterior, lateral, inferior) of the left ventricle. Average TH-ir in all left ventricle nerve fascicles was significantly lower in pioglitazone (48.2%) and placebo (46.9%) groups than in healthy controls (65.6%; ANOVA $p<0.001$). Placebo vs pioglitazone groups showed a difference in combination with cardiac layer and region (ANOVA $p=0.039$). No group differences were observed for HLA-DR. Adrenal tissue was analyzed in the medulla for catecholamine production capability by TH-ir and aromatic amino acid decarboxylase (AADC)-ir. TH-ir revealed significant 6-OHDA associated loss (control 90.5%; placebo 53.6%; ANOVA $p<0.0001$), and preservation in the pioglitazone group compared to placebo (pioglitazone 78.9%; $p<0.01$). AADC-ir confirmed these findings, with a significant difference between control (86.7%) and placebo (50.0%) animals (ANOVA $p<0.01$), but not between control and pioglitazone (69.0%). HPLC for plasma norepinephrine (NE) showed dramatic %loss from baseline to 1wk post-6-OHDA in placebo (69.1%) and pioglitazone (57.4%) groups, which was significantly higher in placebo animals compared to pioglitazone (Mann Whitney $p=0.016$). Overall, these results validate in vivo findings of 6-OHDA associated cardiac sympathetic denervation and demonstrate the ability of pioglitazone to preserve enzymes critical for catecholamine production in the adrenal medulla.

**Abstract:** Numerous studies have demonstrated that neuroinflammation accompanies and may promote progression of alpha-synuclein (Asyn)-induced nigral dopaminergic degeneration as found in Parkinson’s disease (PD). During degenerative processes, peripheral immune cells cross the BBB and can exert actions on the brain, yet it remains unclear how their brain activity affects PD progression. Modulating the activation state of microglia or infiltrating cells can largely alter the local environment via cytokine signaling, and in turn impact neuronal survival. The cannabionoid type 2 receptor (CB2) is highly expressed on activated microglia and circulating monocytes, upregulated in the nigra of PD patients and when modulated protects against rotenone-induced nigral degeneration. Studies conducted by collaborator Bob Moore using a novel CB2 inverse agonist SMM-189 demonstrated immunomodulatory effects that improve acute neuronal injury and behavioral outcomes potentially explained by a mechanism that suppresses pro-inflammatory markers and increases anti-inflammatory effects. Here we report the peripheral and central immunomodulatory effect of SMM-189 treatment in an AAV2/5-hAsyn rat model of PD. We hypothesize that targeting CB2 will benefit the local central inflammatory environment by inhibiting activation of central and peripheral immune cells and promoting phagocytosis and clearance of Asyn to protect against PD-like pathology. Spraque-Dawley rats (n=28) were unilaterally injected in the nigra with AAV2/5-hAsyn and followed for 8 weeks. One week later, animals were randomly selected to receive daily systemic SMM-189 (6 mg/kg, n=14) or vehicle (n=14). At sacrifice, peripheral blood mononuclear cells (PBMCs) were isolated, animals were transcardially perfused, and midbrain post-fixated for immunohistochemistry. Our preliminary results indicate, rats treated with SMM-189 demonstrate

a decreased size of IBA1+ cells ($p<0.0001$) compared to vehicle-treated, suggesting that targeting CB2 ameliorates persistent microgliosis from Asyn overexpression. Additionally, SMM-189 decreased gene expression of pro-inflammatory marker TNF ($p=0.0084$) while promoting anti-inflammatory behavior with increased TGFβ ($p=0.0204$) in PBMCs, suggesting that SMM-189 skews the peripheral immune phenotype towards an alternatively activated state. We are currently completing analysis of MHCII to establish the microglial activation state, toxic Asyn to determine the effect on Asyn aggregate clearance, and PBMC frequencies and cell surface markers by flow cytometry to elucidate changes in circulating immune populations following SMM-189 treatment.

**Abstract:** Parkinson’s disease (PD) is a progressive and continuous neurodegenerative disorder. Transplantation of human embryonic dopaminergic progenitors within the striata of PD patients has given the field encouraging results, but ethical concerns and tissue availability limit this approach. The use of mesenchymal stem cells (MSCs) as an alternative cell source for transplantation circumvents the ethical issues, and provides a readily available source of cells, as they are derived from adult tissue. In this study, we transplanted MSCs that were semi-differentiated into dopamine like cells (DA). MSCs were cultured with a DA gene expressing adenovirus, to initiate differentiation. We transplanted these semi-differentiated DA-like cells

into the striatum of rats who were given unilateral 6-hydroxydopamine (6-OHDA) lesions. The unilateral 6-OHDA lesion was assessed utilizing the cylinder test and by assessing the asymmetry of amphetamine-induced rotations. The induced DA-like cells were transplanted into the dorsal striatum of rats at 4 weeks, following verification of the 6-OHDA lesion. After transplantation, rats were divided into two groups, with one group sacrificed at 8 weeks post transplantation and the second group at 24 weeks post transplantation. There was a significant improvement in the cylinder test observed for both groups. In addition to a significant improvement in amphetamine-induced rotational asymmetry was observed for both groups. These results are suggestive of a potential clinical utility for this method.

**Title:** ANAVEX 2-73, a clinical Alzheimer drug candidate, induces neurorestoration in experimental parkinsonism

**Authors: *V. FRANCARDO**[1], F. BEZ[1], J. S. SPROUSE[2], C. MISSLING[2], A. CENCI[1]
[1]Lund Univ., Lund, Sweden; [2]Anavex Life Sci., New York, NY

**Abstract:** Background: Sigma-1 receptor (Sig-1R) is an endoplasmic reticulum-chaperone protein promoting mechanisms that protect cells under stress. We have previously shown that a selective agonist of the Sig-1R promotes recovery of motor functions and activates neuroplasticity mechanisms in a mouse model of nigrostriatal dopaminergic degeneration (Francardo et al Brain 2014).
Aim: Using the same animal model as in our previous study, we set out to evaluate the potential neurorestorative effects of ANAVEX 2-73 (ANA 2-73), a ligand at both Sig-1 and muscarinic receptors currently being tested in Alzheimer´s disease patients.
Methods: Mice sustained intrastriatal 6-OHDA lesions and were treated with ANA 2-73 (doses 0.3, 1 and 3 mg/kg/day) for 5 weeks, starting on the day of the lesion. Tests of forelimb hypokinesia and spontaneous rotation were carried out at the end of each week. After this period, brains were processed for tyrosine hydroxylase (TH) immunohistochemistry.

Results: After 5 weeks of treatment, the two lower doses of ANA 2-73 induced a significant behavioral improvement in all the behavioral tests. The highest dose of ANA 2-73 (3 mg/kg) significantly improved animals' forelimb use in the cylinder test (dependent on a dopaminergic activity in the dorsolateral striatum) but did not have effects on the spontaneous rotations (depending mostly on dopamine stimulation in the substantia nigra, SN). Immunohistochemical analysis of TH immunoreactivity revealed a massive TH+ fibers innervation in the dorsolateral striatum of mice treated with ANA 2-73, regardless of the dose. These fibers were positive for GAP43, a marker of axonal regeneration. In the SN, only the two lower doses of ANA 2-73 significantly protected nigral dopaminergic neurons, whereas the dose of 3 mg/kg did not have neuroprotective effects.
Conclusion: Our results reveal that ANA 2-73 ameliorates motor deficits in tests assessing spontaneous rotational activity and forelimb use asymmetry, and exerts noticeable neurorestorative effects on the damaged nigrostriatal dopamine system. Further experiments are now ongoing to elucidate the mechanisms underlying these effects.

**Abstract:** The tetracycline-derivative doxycycline (α-6 deoxy-5-hydroxytetracycline) has been shown to be neuroprotective in *in vitro* and *in vivo* models of neurodegenerative diseases. The proven reliability and safety of the medication suggests its potential as an effective and inexpensive treatment to protect or at least mitigate the central nervous system from neurodegenerative diseases such as Parkinson's disease. It has been suggested that the

modulation of astrocyte and microglial activation could prevent neuronal demise and thus the progression of neurodegeneration. We hypothesize that doxycline could exert a neuroprotective effect by suppressing astrocyte and microglial activation induced by the neurotoxin 6-hydroxydopamine (6-OHDA), a preparation with similarities to Parkinson's disease. **Methods:** We investigated in striatal 6-OHDA lesioned mice the effects of a doxycycline given chronically either orally or subcutaneously at sub-antibiotic concentrations. To assess the protective mechanism conveyed by doxycycline we quantified using immunoreactive labeling tyrosine hydroxylase (neurons), glial fibrillary acid protein for astrocytes and cell surface marker macrophage antigen complex-1 for microglial cells. Brain regions containing cell bodies and fibers of dopamine in the nigrostriatal pathway were evaluated. Neuroinflammation indicators were sampled by Western blot analysis of metalloproteinase-3, cycloxygenase-2 and caspase-3 from the striatum. **Results:** Chronic treatment with doxycycline, either administered orally or injected subcutaneously at sub-antibiotic concentrations, mitigates the loss of dopaminergic neurons in the substantia nigra compacta and nerve terminals in the striatum. This protective effect was associated with: (1) a reduction of microglia in normal mice as a result of doxycycline administration *per se*; (2) a decrease in the astrocyte and microglia response to the neurotoxin 6-OHDA in the globus pallidus and substantia nigra compacta, and (3) decrease of the astrocyte reaction in the striatum. **Conclusion**: Our results suggest that doxycycline blocks 6-OHDA neurotoxicity *in vivo* by inhibiting microglial and astrocyte expression. This action of doxycycline in nigrostriatal dopaminergic neuron protection is consistent with a role of glial cells in Parkinson's disease neurodegeneration.

**Title:** Ectonucleotidase CD73-mediated adenosine signaling regulates neuroinflammation in a Parkinson's disease model

**Authors: *F. MENG**, Z. GAO
Inst. of Neurosci., Zhejiang, China

**Abstract:** The ecto-5' -nucleotidase (CD73) is one of the major ectonucleotidases that dephosphorylate extracellular AMP into adenosine in the brain. Recent studies have shown that CD73 is abundantly expressed in the striatum and physically associated with adenosine $A_{2A}$ receptors ($A_{2A}$Rs). Interestingly, suppression of $A_{2A}$Rs signaling has been shown to be beneficial for Parkinson's disease (PD). While studies have focused on the adenosine-mediated downstream signaling, little is known how extracellular adenosine production is regulated. Using enzyme histochemistry and HPLC analysis, we found that CD73 was the prominent ectonucleotides that generates adenosine in the striatum. Removal of CD73 significantly reduced the rate of microglia process retraction and enhanced acute injury- triggered striatal microglial movement. Moreover, CD73 deletion suppressed pro-inflammatory responses in LPS-primed microglia via suppressed $A_{2A}$R signaling pathway. Microglial activation and inflammation were attenuated in $CD73^{-/-}$ PD model (Mice were injected with 1-Methyl-4-phenyl-1,2,3,6-tetrahydropyridine hydrochloride, namely MPTP, 25 mg/kg/day, i.p., for 5 days.). Deficiency of CD73 protected MPTP-induced neurotoxicity of dopaminergic neurons in the SNc (Substantia Nigra pars compacta) and behavioural impairment.
Together, our results reveal the neuroprotective role of blocking adenosine signaling in neuroinflammation, which may provide a new perspective to neurological disorders.

**Title:** The catalyzed assembly hypothesis: Novel drug-like small molecules that modulate assembly and toxicity of alpha-synuclein in a cell culture model of Parkinson´s disease

**Authors: *A. MUELLER-SCHIFFMANN**[1], K. PAULVANNAN[2], V. ASUNDI[2], S. SELVARAJAH[2], V. LINGAPPA[2], C. KORTH[1]
[1]Heinrich Heine Univ. of Duesseldorf, Duesseldorf, Germany; [2]Prosetta Biosciences, Inc, San Francisco, CA

**Abstract: Background**
The toxic effects of α-synuclein (αSYN) pre-fibrillar aggregates on dopaminergic neurons are believed to be central to the pathogenesis of Parkinson´s Disease (PD). So far, therapeutics targeting these toxic αSYN forms have not been successful. PD patients generally receive L-DOPA substitution therapy, although there is evidence that L-DOPA actually promotes degeneration of dopaminergic neurons and may accelerate PD progression. According to the catalyzed assembly hypothesis, protein complexes don't form spontaneously. Rather, their

formation is catalyzed by transient multi-protein complexes termed assembly machines. We have successfully identified cellular assembly machines for virus capsid formation and have generated a library of compounds with anti-viral activity by virtue of targeting allosteric sites governing composition of assembly machines essential for viruses.

**Objectives**

To screen for efficacy against αSYN aggregation our "Hit-finder" collection of 300 drug-like chemotypes active against aberrant forms of host assembly machines essential for viruses. This approach has been successfully used for ALS and Alzheimer's Disease.

**Methods**

We generated cellular models for robust αSYN aggregation in αSYN-transfected SH-SY5Y and performed toxicity assays in differentiated dopaminergic LUHMES cells. We applied the "Hit-finder" collection to these cells and monitored effects of assembly machine modulation on αSYN aggregation and toxicity.

**Results**

Two different assembly subcellular states of αSYN were observed, manifesting either as small aggregates or ring-like structures. These rings were αSYN associated with lipid droplets (LDs). The "Hit-finder" library contained subsets of chemotypes that were active in enhancing either the formation or dissolution of αSYN aggregates vs rings in a dose-dependent manner. Interestingly, the most potent ring-inducing compound showed the least degree of aggregated αSYN and was protective against rotenone and dopamine induced toxicity in differentiated LUHMES cells. Western Blots showed that the total αSYN load was slightly reduced. Early structure-activity relationship (SAR) optimization of a ring-inducing chemotype generated a lead compound with an $EC_{50}$ below 200 nM.

**Conclusion**

The compounds identified here prevent αSYN-mediated cell death of dopaminergic neurons via a novel molecular mechanism, namely, the increased association of toxic αSYN aggregates with LDs, thereby facilitating degradation of αSYN. With respect to L-DOPA substitution therapy, these compounds may be able to reduce neurotoxic side effects to allow enhanced, safer, and prolonged use of L-DOPA.

**Abstract:** Current Parkinson’s disease (PD) therapies, including the gold-standard, L-DOPA, treat patient’s symptoms but do not provide protection against the loss of dopaminergic cells in the substantia nigra (SN). One potential neuroprotective agent of interest is vascular endothelial growth factor B (VEGF-B). We have previously shown that the PD-inducing toxin, rotenone, upregulates endogenous VEGF-B in the dopaminergic cells of a rat midbrain culture model. In addition, exogenous VEGF-B provides neuroprotective support *in vitro.* VEGF-B is also neuroprotective *in vivo*. In the unilateral 6-hydroxydopamine (6-OHDA) rat model of PD, an injection of VEGF-B into the striatum reduces the loss of motor function and reduces both the loss of dopaminergic cells in the SN and terminals in the striatum. Here we investigate the neuroprotective effects of VEGF-B in a PTEN-induced putative kinase 1 (PINK1) knockout rat model, a genetic model of PD. The PINK1 gene is thought to play a role in protecting cells from stress-induced mitochondrial dysfunction. PINK1 mutations are also linked to some cases of human familial PD.
In a pilot study, male, PINK1 KO rats, at 5-months of age were injected unilaterally with an adeno-associated virus expressing human VEGF-B (AAV2/1-hVEGF-B). AAV2/1-hVEGF-B overexpression is driven by a CAG promoter. The AAV2/1-hVEGF-B vector was injected at two sites in the striatum (AP +1.0, ML +3.0, DV -5.0; AP -0.6, ML +3.5, DV -5.0) and a single site in the SN (AP -5.0, ML +2.0, DV -7.2). AAV2/1-hVEGF-B treated PINK1 KO, PINK1 KO and wild type (WT) rats were tested monthly, up to 12-months of age, for changes in motor function with the tapered balance beam test (TBB). Unilateral AAV2/1-hVEGF-B treatment resulted in a significant improvement, as compared to untreated PINK1 KO rats, in the number of cumulative

(5-11 months) foot slip errors during TBB (One-way ANOVAs, Tukey post-hoc tests; n=5-6). These effects were seen bilaterally in both the forelimbs (ipsilateral, *p<0.05; contralateral, **p<0.01), and hind limbs (ipsilateral, **p<0.01; contralateral, *p<0.05).
Following behavioral testing, striatal tissue was analyzed via HPLC-EC to quantify changes in dopamine (DA). Striatal DA content was reduced by 25-30% in the PINK1 KO rats compared to WT, and restored to wild-type levels in the hemisphere of PINK1 KO rats injected with AAV2/1-hVEGFB (One-way ANOVAs; p<0.05; n=3-5). To delineate other potential mechanisms, we harvested striatal protein, and in a pilot analysis (n=2-4) found an increase in pigment epithelium derived factor (ELISA) and fatty acid transport protein 4 (semi-quantitative western blot) on the injected side.

**Abstract:** Recent studies have shown that Korean Red Ginseng (KRG) suppresses dopaminergic neuronal death in the brain of a Parkinson’s disease (PD) mouse model, but the mechanism is still elusive. Using a 2-dimensional electrophoresis technique, we investigated whether KRG can restore the changes in protein expressions in the striatum (ST) of 1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine (MPTP)-injected mice. Male C57BL/6 mice (9 weeks old) were injected with 20 mg/kg MPTP intraperitoneally four times at 2-h intervals. KRG (100 mg/kg) was orally administered once a day for 3 days from one hour after the first MPTP injection. Two hours after the third KRG administration a pole test was performed to evaluate motor function, after which the brains were immediately harvested. Survival of dopaminergic neurons in the nigrostriatal pathway and protein expression in the ST were measured by immunohistochemistry and 2-

dimensional electrophoresis. KRG suppressed MPTP-induced behavioral dysfunction and neuronal death in the nigrostriatal pathway. Moreover, 30 proteins changed by MPTP and KRG in the ST were identified and shown to be related to glycolysis/gluconeogenesis and neurodegenerative diseases including Alzheimer's disease and PD. KRG has neuroprotective effects against MPTP toxicity and alleviates protein expression profiles related to enhancing energy metabolism in the ST of MPTP-treated mice.

**Title:** PK-PD analysis identifies similar high amantadine plasma concentrations needed to reduce L-DOPA-induced dyskinesia across multiple species

**Authors: *B. BRIGHAM**[1], T. H. JOHNSTON[2], C. BROWN[1], J. D. S. HOLT[1], S. H. FOX[3], M. P. HILL[2], P. A. HOWSON[2], J. BROTCHIE[2], J. T. NGUYEN[1]

**Abstract:** Dopamine replacement therapy with the dopamine precursor, L-DOPA, remains the most effective symptomatic treatment for Parkinson's disease. However, long term treatment invariably leads to the development of motor complications that include L-DOPA-induced dyskinesia (LID). There are currently no approved pharmacological therapies for LID in Parkinson's disease. Amantadine, an uncompetitive NMDA receptor antagonist, has been shown to reduce LID in rodent and non-human primate (NHP) models of LID, and in small clinical studies. While animal studies have consistently demonstrated that higher doses of amantadine resulted in greater efficacy, none of the studies determined the plasma concentrations associated with therapeutic effects.
Our objective was to evaluate the pharmacokinetic-pharmacodynamic (PK-PD) relationship between amantadine plasma concentrations and anti-dyskinetic efficacy across species to define optimal therapeutic dosing.
The single-dose pharmacokinetics of amantadine was determined in mice, rats, and cynomolgus monkeys, and PK modeling was conducted to estimate the plasma concentration at different doses. Efficacy data was generated from the 6-OHDA rat model and the MPTP NHP model of LID. These data, along with published anti-dyskinetic efficacy data in mice, rats, and NHPs, were used to establish the PK-PD relationship using a direct effect $E_{max}$ model. The model was then used to determine the effective plasma concentrations ($EC_{50}$) required for anti-dyskinetic

efficacy across animal species.
The PK-PD model demonstrated that the plasma concentrations required for the reduction of LID was highly consistent across species, with the $EC_{50}$ ranging from approximately 1100 ng/mL to 1600 ng/mL (mean ~1400 ng/mL). These results are consistent with a clinical study conducted with ADS-5102 (amantadine) extended release capsules, in which doses that provided reduction in LID were associated with mean plasma concentrations approximating 1400 ng/mL (Pahwa 2015).
In conclusion, amantadine plasma concentrations of ~1400 ng/mL are required to reduce LID across species from rodents to primates. These results provide target plasma concentrations for the reduction of LID in PD patients, which were confirmed in a clinical study with ADS-5102.

**Title:** Antiparkinsonian-like effects of Nigella sativa-oil and latent targets for microglia regulation

**Authors: *T. MALIK**[1,2]
[1]Basic Sci. Dept., Natl. Univ. of Hlth. Sciences, Basic Scie, Lombard, IL; [2]Neurochemistry and Biochem. Neuropharm. Unit, Dept. of Biochem., Karachi Univ., Karachi, Pakistan

**Abstract:** The symptoms of Parkinsonism and oral dyskinesia are associated in the chronic inflammation in the basal ganglia which mediated by microglial activation and dopaminergic neuronal mortality. Pathogenic analogy has been observed while neuroleptics induce generation of *Extrapyramidal symptoms*. In this study, we investigate whether *Nigella sativa*-oil (NS) (black cumin seeds) - a traditional medicine used for the seizure treatment in eastern country- may reduce the haloperidol (HAL) - induced extrapyramidal symptoms (EPS) - like behavior in rats. After combine treatment with HAL (1mg/kg) on NS (0.2ml/rat), rats displayed a significant decreased EPS-like behavior including movement disorders and oral dyskinesia as compared to controls. Immuno-histochemical analysis indicates that NS reduced astrogliosis in caudate and accumbens nuclei. Activation of microglia together with reactive changes in astroglial morphology combating movement deficits. These results suggest that NS may consider as an adjunct to antipsychotics to reduce the EPS-like side effect. The prospective lab concerns are to understand how NS reduces pro-inflammatory responses, what are the latent therapeutic targets of microglial cells, and crosstalk of astrocytes and microglia, worth investigating to recognize the effective treatments for Parkinsonism and other inflammatory diseases of the CNS.

**Abstract:** Parkinson's disease (PD) is characterized by the progressive degeneration of dopaminergic (DAergic) neurons in the substantia nigra pars compacta (SNpc) leading to motor dysfunctions. REV-ERBα is a transcription factor that functions not only as a repressor in the molecular clockwork but also as a repressor of tyrosine hydroxylase (*TH*) gene transcription in midbrain DAergic neurons. However, the role of REV-ERBα on DAergic neuronal cell death according to the pathophysiological process of PD is still unknown. Here, we addressed the question of whether *Rev-erbα* may play a role in the progression of DAergic neuronal cell death and pathological phenotypes in the mouse model of PD. We unilaterally injected the neurotoxin 6-hydroxydoapmine (6-OHDA) to left striatum to induce PD mouse model in both wild type (WT) and *Rev-erbα* knockout (KO) mice. We found that *Rev-erbα* KO mice began to die at 7 days after 6-OHDA injection accompanied with a sudden decline of body weight. Furthermore, REV-ERBα deficiency induced more severe motor impairment after 6-OHDA injection, suggesting accelerated PD progress in *Rev-erbα* KO. To explain the behavioral severity of 6-OHDA-treated *Rev-erbα* KO mice, we observed the progressive DAergic neuronal cell death, as a main pathological hallmark of PD, in the SNpc and the ventral tegmental area (VTA) after 6-OHDA injection. Histological results showed that DAergic neuronal loss in *Rev-erbα* KO mice was exacerbated and accelerated in both the SNpc and VTA at 2 weeks after 6-OHDA treatment compared with WT mice. To elucidate the pathogenetic mechanisms of exacerbated neurodegeneration induced by absence of REV-ERBα in PD, we analyzed the ventral midbrain transcriptome of WT and KO following 6-OHDA treatment. Notably, expression levels of genes encoding mitochondrial respiratory chain and mitochondrial transcription factors were lower in 6-OHDA-injected *Rev-erbα* KO mice than 6-OHDA-injected WT mice, indicating mitochondrial dysfunction in exacerbated neurodegeneration induced by REV-ERBα deficiency. Therefore, these findings suggest that REV-ERBα may play a neuroprotective role to pathological process of PD.

**Title:** MLR1019 reduces dyskinesias and subthalamic neuron bursting in rat 6OHDA Parkinsons disease model

**Authors: *J. A. GRUNER**, J. R. CIALLELLA, A. G. REAUME, J. WANG, E. ZUVICH, K. JONES
Melior Discovery, Exton, PA

**Abstract:** Treatment of Parkinson's disease (PD) is currently limited to surgery or dopaminergic agonist medications such as L-DOPA. Drug treatments have significant limitations including reduced efficacy and appearance of side effects such as dyskinesias after several years. In order to better regulate brain levels of dopamine (DA), dopamine transport (DAT) inhibitors have been evaluated in combination with DA agonists, but with little success. MLR-1019, a repositioned molecule under development by Melior Discovery, is a uniquely potent DAT inhibitor having negligible serotonin and norepinephrine transport activity. In the rat unilateral 6-hydroxydopamine (6-OHDA) lesion model, chronic L-DOPA treatment (12 mg/kg) induced abnormal involuntary movements (AIMs), the rodent equivalent to Parkinsonian levodopa-induced dyskinesia (LID). Co-administration of L-DOPA with MLR-1019 significantly attenuated AIMs and enhanced the effects of L-DOPA on motor deficits, as measured by the forelimb adjusting step (FAS) test. MLR-1019 was also examined for effects on burst-firing in subthalamic nucleus (STN) neurons in unilateral 6-OHDA-lesioned rats. STN bursting is a well-established consequence of loss of dopaminergic innervation seen both clinically and in animal models. Single-unit recordings were obtained from STN neurons before and 1 – 3 h after administration of MLR-1019 (10 mg/kg IP). Data from 91 neurons recorded 5 min each in 12 rats showed no effect on firing frequency, interspike interval, or spike waveform shape. In contrast, the number of bursts, percentage of spikes in bursts, and number of spikes within bursts were reduced by 58%, 61%, and 9% respectively ($P < 0.001$, ANOVA). These results indicate that MLR-1019 could represent a new PD therapeutic that significantly reduces the side effects and enhances the antiparkinsonian activity of L-DOPA treatment, as well as reduces STN bursting in lesioned brain. Efforts are underway to initiate a clinical trial to test MLR-1019 in PD patients.

**Abstract:** The L-type Ca2+ voltage (CaV) gated channel antagonist, isradipine (israd) administered continuously via subcutaneous pellets can dose-dependently dampen the severity of dyskinetic behaviors in parkinsonian rats in response to subchronic (2wks), low dose (6 mg/kg) levodopa (LD) (Schuster et al., 2009, Biol Psych 65:518). However, two questions related to the potential clinical utility of CaV (i.e.: CaV1.3) channel antagonism for LD-induced dyskinesias (LIDs) remain: 1) Can the same antidyskinetic effect, albeit modest (~25-40%), be achieved with non-continuous israd mimicking dosing in PD patients? 2) Is the modest degree of benefit linked to the pharmacological limitations of israd or the CaV1.3 target *per se*? To determine whether 2x daily israd has utility in preventing LIDs, male Sprague Dawley rats were unilaterally lesioned with 6OHDA. 24 hrs post-lesion, rats began 2x daily injections of vehicle or israd (0.2mg/kg) for remainder of the study. This israd dose is analogous to dosing tested in neuroprotection clinical trials (NCT02168842) and shown to be modestly antidyskinetic in preclinical studies. Two wks post-6OHDA, rats began daily LD (6mg/kg) for 10 days (d). In a 2nd study, to provide unequivocal target validation evidence, rats received intrastriatal injections of rAAV-CaV1.3-shRNA (CaV1.3) to provide continuous, high level silencing of CaV1.3 channels, or a rAAV-Scr-shRNA (Scr) control. One wk post-vector delivery, rats were unilaterally lesioned with 6OHDA and 2 wks post-lesion began daily treatment with escalating doses of LD (6, 9, 12, & 18mg/kg; 10 d/dose). We found that 2x daily israd provided partial protection at d5 (Peak Dose LID: Veh+LD=6.8$\pm$1.6; Israd+LD=4.3$\pm$1.9; mean$\pm$SEM; 37% reduction) against low dose LD (6mg/kg), but the effect was lost by d10. Studies aimed at enhancing israd protection (i.e.:

israd±quinpirole) have been examined and will be reported. Our rAAV-mediated CaV1.3 silencing studies are ongoing, but data thus far confirm that vectored silencing can provide near complete prevention of LID induction following 10d low dose LD (6mg/kg; Peak Dose LID Day 10: Scr=12.6±3.0; CaV1.3=2.7±0.7; $p<0.001$) and 10d moderate dose LD (9mg/kg; Peak Dose LID Severity Day 6: Scr=15.2±2.9; CaV1.3=2.4±0.9; 85% reduction; $p<0.001$).

**Abstract:** Mutations in the *LRRK2* gene represent a major genetic risk factor for both sporadic and familial Parkinson’s disease (PD). However, the mechanistic link between LRRK2 variants and PD-related neurodegeneration remains unclear. We have previously disclosed the application of Berg’s proprietary Interrogative Biology® methodology to compare primary skin fibroblasts from PD patients harboring the $LRRK2^{G2019S}$ mutation, idiopathic PD patients, and their matched mutation-negative controls. This study led to identification of the quinone oxidoreductase, PIG3, as a novel candidate for mechanistically linking $LRRK2^{G2019S}$ to PD pathology. Fibroblasts from LRRK2-PD patients demonstrated elevated steady-state PIG3 protein expression that correlated with upregulation of MKK3/6 activity, p38 MAPK phosphorylation, and accumulation of p53. We have previously shown that human dopaminergic SH-SY5Y cells treated with rotenone and 6-hydroxydopamine (6-OHDA) exhibited an increase in PIG3 mRNA and protein expression that correlated with apoptosis. siRNA directed against *PIG3* significantly reduced rotenone- and 6-OHDA- induced cell death in SH-SY5Y cells. We have also shown that inhibition of p38 MAPK, by SB203580, reduced apoptosis in these models and was associated with attenuated induction of PIG3 expression. Here we demonstrate that inhibition of LRRK2 kinase activity, by

LRRK2-IN-1, similarly reduces neurotoxin-induced PIG3 expression and apoptosis induction. Furthermore, we demonstrate that PIG3 siRNA reduces reactive oxygen species (ROS) production in SH-SY5Y cells. To further examine the role of PIG3 in human PD models *in vitro*, we have successfully reprogrammed fibroblasts from our discovery cohort to generate patient-specific iPS cells. Indeed, the resulting IPSCs express the appropriate pluripotency markers (ie. SOX2, OCT4 and NANOG). These models enable us to assess the potential role of genetic predisposition on PIG3 modulation and apoptosis in response to PD neurotoxins. This study also addresses the effects of attenuated PIG3 expression on neurotoxin susceptibility using patient-specific, iPSC-derived neurons from LRRK2 and alpha-synuclein mutant donors. Taken together, our findings demonstrate that PIG3 contributes to apoptosis in neuronal models of PD and may advance our understanding of the mechanism behind $LRRK2^{G2019S}$ and hypersensitivity to environmental neurotoxins.

**Title:** Inhibition of brain-derived neurotrophic factor signaling prevents effects of vagus nerve stimulation in a preclinical model of Parkinson's disease

**Authors: *A. FARRAND**[1], R. GREGORY[2], M. GOOZ[3], D. TOWNSEND[3], V. HINSON[4], K. HELKE[5], H. BOGER[1]
[1]Neurosciences, [2]Comparative Med., [3]Drug Discovery and Biomed. Sci., [4]Neurol., [5]Comparative Med. and Pathology, Med. Univ. of South Carolina, Charleston, SC

**Abstract:** Vagus nerve stimulation (VNS) is currently FDA-approved for the treatment of drug-resistant epilepsy and depression. Previous studies have shown that VNS has beneficial effects on noradrenergic (NE) neurons in the locus coeruleus (LC) and its innervation of target regions. This makes VNS an innovative treatment strategy for Parkinson’s disease (PD) since LC-NE

degeneration typically occurs prior to the dopaminergic (DA) loss in the substantia nigra (SN). Studies from our lab show that VNS can attenuate the loss of tyrosine hydroxylase-positive neurons in the LC and SN observed in a rat lesion model of PD, and can improve locomotor activity. Additionally, previous studies show that VNS increases activation of signaling proteins downstream of BDNF-TrkB activation, suggesting BDNF-TrkB signaling as a potential mechanism of action. Therefore, our hypothesis is that by blocking BDNF signaling via daily administration of a TrkB antagonist (ANA-12), we can reduce the beneficial effects of VNS in a progressive preclinical model of PD. To create the model, we administered DSP-4 (50 mg/kg, i.p.) to rats to lesion the LC-NE system, followed one week later by bilateral intrastriatal 6-OHDA (5 µg/µL) to lesion the SN-DA system. At this time, a subset of rats also had vagus cuffs implanted around the isolated vagus nerve that connect to a headcap to later receive VNS. After eleven days to allow lesion development, rats received two thirty-minute sessions of VNS per day using precise bursts at a set amplitude and rate for ten days, and locomotor activity was measured during the afternoon session each day. Rats received either ANA-12 (0.5 mg/kg, i.p.) or vehicle daily prior to the afternoon VNS session. Immediately following the final session, rats were euthanized, and the SN and LC were dissected out for immunohistochemical assessment of neuronal populations. The right dorsal striatum and frontal cortex were dissected for detection of BDNF, protein thiols, and redox enzyme levels. Lesion + VNS rats had increased levels of BDNF in target regions of LC (frontal cortex) and SN (dorsal striatum), as well as reduced thiol levels and alterations in redox enzymes indicative of decreased oxidative stress, compared to lesion control rats. Additionally, daily administration of ANA-12 prevented improvements of VNS on locomotor activity for lesion rats. Studies are ongoing to determine whether blocking BDNF-TrkB signaling can also prevent the improvements observed after VNS on neuronal populations and oxidative stress. Collectively, these data indicate that VNS works through a BDNF signaling mechanism to attenuate PD-like deficits observed in this preclinical model.

**Abstract:** [Objective]
The main pathology of Parkinson's disease (PD) is a loss of dopamine neurons in the substantia nigra pars compacta (SNc), but underlying mechanism has not been fully understood. Recently, neuroinflammation in the pathogenesis of PD has been documented. High mobility group box-1 (HMGB1) exists as a structural nuclear protein in the normal state, but displays an inflammatory cytokine-like activity in the extracellular space under pathological condition. In this study, we investigated the involvement of HMGB1 in the pathology and the neuroprotective effects of anti-HMGB1 monoclonal antibody (mAb) on rat model of PD by focusing on their role in the plasma and brain tissue.
[Material and Method]
Adult female Sprague-Dawley rats were injected with 6-hydroxydopmaine (6-OHDA, 20 μg/4 μl) into the right striatum, then anti-HMGB1 mAb (1 mg/kg), or control mAb was intravenously administered immediately, at 6 and 24 h after 6-OHDA injection. Enzyme-linked immunosorbent assay (ELISA) of HMGB1 in plasma and Western immunoblotting in the striatum and SNc were performed at days 1 ,4 and 7 to measure the expression of HMGB1. Fluorescent immunostaining for HMGB1, Iba1 as a microglia marker, MAP2 as a neuron marker and GFAP as an astrocyte marker were performed at 24 hours, day7 and 14 for histological evaluation. Fluorescent immunostaining for albumin was conducted to assess blood-brain barrier leakage at day1. Polymerase chain reaction (PCR) was performed to assess expression of inflammatory cytokines in the striatum and SNc at day1 and 4.
[Result and Discussion]
The treatment with anti-HMGB1 mAb significantly suppresses the increase of HMGB1 in the plasma and brain tissue compared to the control mAb-treated group. Iba1-positive cells were decreased at day7 and 14 after 6-OHDA injection in anti-HMGB1 groups, whereas HMGB1 translocation was observed in neurons at day1 and astrocytes at day7 in the control mAb-treated group. Anti-HMGB1 mAb inhibited the activation of microglia, blood-brain barrier leakage and the expression of inflammation cytokines such as IL-1β and IL-6. These results suggested that HMGB1 released from neurons and astrocytes was at least partly involved in the mechanism and pathway of degeneration of dopaminergic neurons induced by 6-OHDA exposure.
[Conclusion]
Intravenous administration of anti-HMGB1 mAb suppresses neuroinflammation and attenuates disruption of blood-brain barrier in a rat model of PD.

**Abstract:** Previous studies have reported the antioxidant and anti-inflammatory effects of oxyresveratrol *in vitro*. The neuroprotective effect of oxyresveratrol has also been demonstrated in animal model of cerebral ischemia. This study aimed to investigate effects of oxyresveratrol in rotenone model of parkinson's disease in rats. Male Wistar rats were assigned randomly into three groups; control, parkinsonism and oxyresveratrol groups. Oxyresveratrol (300 mg/kg p.o.) was given to rats in oxyresveratrol group for 20 days while rats in control and parkinsonism groups received 1% CMC. To induce parkinsonism behaviors, rotenone (3 mg/kg i.p.) was given to rats in parkinsonism and oxyresveratrol groups on day 15, 16, 18 and 20 while control rats received 2% DMSO. Rotarod test was performed on day 1, 16 and 20. At the end of experiment, brains were collected. The malondialdehyde (MDA) levels and trolox equivalent antioxidant capacity (TEAC) were determined in brain tissue. It was shown that rotenone treatment significantly decreased latency to fall of rats in parkinsonism group compared to controls on day 16 and 20 ($p<0.0001$ and $p<0.05$, respectively). On day 16, oxyresveratrol-treated rats had higher latency to fall than that of rats in parkinsonism group ($p<0.01$). However, rotarod performance of rats in oxyresveratrol and parkinsonism groups significantly decreased from controls on day 20 ($p<0.05$). Brain MDA levels of rats in parkinsonism group were higher than that of controls ($p<0.05$) while oxyresveratrol significantly decreased MDA levels compared to parkinsonism rats ($p<0.05$). Oxyresveratrol tended to increase brain TEAC but this result was not significantly different from parkinsonism rats. Overall, the results indicated that oxyresveratrol prevented rotenone-induced parkinsonism behaviors and revealed an antioxidative effect. The protective effects of oxyresveratrol on dopaminergic neurons in the nigrostriatal pathway will be further investigated.

**Abstract:** Synucleinopathies are neurological disorders, characterized by neuronal and glial deposition of alpha-synuclein aggregates. Cell-to-cell transmission of these aggregates are thought to be the underlying mechanism of aggregate spreading in patients' brain and perhaps of clinical progression. Interfering with the aggregate transmission can thus be a potential strategy for halting the disease progression. Here, we verify the pathological role of TLR2 in alpha-synucleinopathies. Overexpression of TLR2 aggravates alpha-synuclein neuropathology in alpha-synuclein transgenic mice. Thereby, administration of TLR2 neutralizing antibody alleviates synucleinopathy lesions and neuroinflammation in synucleinopathies animal model. In addition, we demonstrate that TLR2 plays an important role in cell-to-cell transmission of alpha-synuclein aggregates, regulating both secretion and uptake of the aggregates. Therefore, we propose the anti-TLR2 treatment as a therapeutic strategy for Parkinson's disease and related synucleinopathies.

**Abstract:** Parkinson's disease (PD) is a neurodegenerative disease characterized by degeneration of dopaminergic neurons. The canonical symptoms of this disease are: resting tremor, rigidity and hypokinesia. Aging is considered the major risk factor for generating idiopathic PD. Recently, several studies have focused the neuroprotective effects of Palmitoylethanolamide (PEA) alone or in combination with antioxidants, in an experimental model of PD after 1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine (MPTP) induction. The aim of this study was to evaluate the pre-treatment effect of micronized PEA formulation (PEAm), on the neuroinflammation process and on the neuronal death on in vivo model of PD on aged mice. The old animals were pre-treated orally for 60 days with PEAm at dose of 10mg/kg. After pre-treatment, they received four injections of the dopaminergic neurotoxin MPTP and were sacrificed 7 days after induction. On the 8th days, brains were processed for histological and immunohistochemical analysis. Pre-treatment with PEAm significantly ameliorated behavioral deficits, reduced the expression of specific markers of PD such as tyrosine hydroxylase (TH), dopamine transporter (DAT), as well as decreased the upregulation of α–synuclein and β3-tubulin in the substantia nigra after MPTP induction. Moreover PEAm reduced proinflammatory cytokines expression and showed a pro-neurogenic effect in hippocampus. Thus, this strategy could prevent neurodegenerative diseases associated to the old age.

**Abstract:** Parkinson's disease (PD) is a progressively debilitating neurodegenerative disorder that characterized the massive loss of dopominergic (DA) neurons, particularly in substantia nigra pars compacta (SNpc), and can be experimentally established by the most useful neurotoxin 1-methyl-4-phenyl-1, 2, 3, 6-tetrahydropyridine (MPTP). Subsequently there was accompanied by bradykinesia, resting tremor, and postural instability. The drug treatments have many limitations in terms of side effects and incapability to protect the neurodegeneration. The oxidative stress and neuro-inflammatory maker, Ionized binding adaptor molecule-1 (Iba-1) have been strongly implicated in pathogenesis of PD. Recently, novel treatments associated to natural anti-inflammation and marine products/molecules with neuroprotectant effect are being exploited for therapy, Astaxanthin extract from white shrimp shell to investigate the neuroprotective effect of Astaxanthin and possible mechanisms related to antioxidant and neuroinflammatory marker in models of PD. Thirty-five adult C56BL/6 mice orally received pretreatment with Astaxanthin extracts for 3 weeks and then were divided into seven groups: control group, MPTP treatment (i.p., 15 mg/kg BW in saline, four times for 1 consecutive day at 2-h intervals), MPTP combined with oral administrations of vitamin C (100 mg/kg BW), Tidomet plus (L-dopa+carbidopa 5 mg/kg BW) and Astaxanthin extracts (30, 60, and 100 mg/kg BW) respectively. After 1, 3, and 7 days of MPTP treatment, all mice were subjected to rotarod test and resting tremor score in order to determine motor, coordination, and severity of PD. Moreover, oxidative stress parameters of malondialdehyde (MDA) level, glutathione peroxidase (GPx) activity, and % inhibition of $O_2^{-\cdot}$ and immunohistochemistry of Iba-1 were also examined. Treatment with Astaxanthin extract 60 mg/kg for 7 days significantly improved retention time and resting tremor score compared to untreated-mice and tidomet plus-treated group ($p<0.05$). In addition, Astaxanthin 60 mg/kg exhibited decrease of MDA level while increase of both GPx activity and % inhibition of $O_2^{-\cdot}$ and suppress of Iba-1 expression compared to MPTP-treated group in striatum areas ($p<0.05$). The result of our study proposed that Astaxanthin at dose of 60 mg/kg BW ameliorated behavioral tests by mediating its neuroprotection against MPTP induced-PD via its antioxidant activities and anti-inflammatory effect.

**Abstract:** Parkinson’s disease (PD) is a neurodegenerative disorder characterized by reduced mitochondrial complex I activity, free radicals' overproduction and reduced antioxidant defenses in the substantia nigra pars compacta (SNpc). Intrastriatal injection of 1-methyl-4-phenylpyridinium (MPP+) is considered a model to reproduce some biochemical alterations observed in PD patients. Copper (Cu) plays an important role in the metabolism and antioxidative responses through its participation as a cofactor in the cytochrome c oxidase (COX), Cu/Zn-superoxide dismutase (Cu/Zn-SOD), and metallothioneins (MTs). We tested the effect of copper sulfate (CuSO4) pretreatment on the mitochondrial electron transport chain (METC) in the striatum after MPP+ toxicity in rats. The results showed that the MPP+ intrastriatal injection reduced mitochondrial complex I, II, IV and V activities, while 10 µmol of CuSO4 pretreatment counteracted this damage. Activities of complexes I, II and IV, were coincident with ATP recovery. Moreover, Cu/Zn-SOD activity was reduced as a consequence of MPP+; however, copper pre-treatment kept the striatal Cu/Zn-SOD activity unchanged in MPP+-damaged animals. We observed that MPP+ also reduced the metallothionein content and that CuSO4 pretreatment maintained baseline values. CuSO4 pretreatment also reduced the striatal caspase-3 and caspase-9 activities that were increased three days after MPP+-induced damage. The present study provided evidence that copper pretreatment reduced MPP+-induced apoptotic damage, probably through direct action on copper-dependent proteins or indirectly on proteins in the apoptotic pathway.

**Title:** GW5074, Raf 1 kinase inhibitor induced neuroprotection and motor improvement in LRRK2 G2019S PD model

**Authors:** ***Y. PARK**, J. KIM, T. KIM, H. SEO
Hanyang Univ., Ansan, Korea, Republic of

**Abstract:** Dopaminergic neurons in substantia nigra are selectively vulnerable under high risk environments with genetic or external cause of Parkinson's disease (PD). LRRK2G2019S mutation has been reported to increase kinase activity inducing neurodegeneration associated with PD. We hypothesized that LRRK2 kinase inhibition by GW5074 [5-Iodo-3-[(3,5-dibromo-4-hydroxyphenyl) methylene]-2-indolinone], synthetic drug that inhibits Raf 1 activity induces neuroprotection in *in vitro* and *in vivo* PD models with LRRK2G2019S mutation. In this study, we found that MPP+ induced cell death of dopaminergic neuron was blocked by GW5074 which activated the neuroprotective signaling pathway. Treatment with GW5074 protects dopaminergic neurons against the neurotoxic effects of MPP+ and glutathione depletion-induced oxidative stress. GW5074 prevented neurodegeneration and improved motor functions in LRRK2G2019S model of PD. Given its neuroprotective effects, in response to neurotoxic stimuli, and in LRRK2G2019S model of PD, GW5074 could be used to study therapeutic mechanism against neurodegenerative pathologies of PD by LRRK2G2019S mutation.

**Title:** Synphilin-1 has neuroprotective effect on Parkinson’s disease-model cells by inhibiting apoptosis

**Authors: *Y. NAGANO**, T. SHISHIDO, M. ARAKI, T. TAKAHASHI, H. MARUYAMA
Hiroshima Univ., Hiroshima, Japan

**Abstract:** [Background] Synphilin-1 represents a cytoplasmic protein that interacts with α-synuclein in neuron and labels the central core of Lewy bodies which is the pathological hallmark of Parkinson’s disease (PD). The interaction of synphilin-1 with α-synuclein indicates that synphilin-1 may also play a central role in PD pathogenesis. However, the biological functions of synphilin-1 are not fully understood. [Objective] In this study, we investigated whether synphilin-1 would have neuroprotective effects on both *in vitro* and *in vivo* PD-models using $MPP^+$ or MPTP which preferentially cause dopaminergic cell death. [Materials and Methods] *In vitro* study, we established SH-SY5Y cells stably overexpressing synphilin-1. The cells treated with $MPP^+$ were evaluated to check the cell viability, apoptosis and ROS production using immunoblotting and immunostaining methods.
*In vivo* study, we generated transgenic mice overexpressing synphilin-1. To investigate the function of synphilin-1 against MPTP toxicity, synphilin-1 transgenic and non-transgenic mice were treated chronically with MPTP/probenecid. We analyzed the number of dopaminergic neurons in substantia nigra pathologically and immunoreactive bands of tyrosine hydroxylase in midbrain using immunoblotting. [Results] Trypan blue exclusion assay showed that synphilin-1 significantly inhibited neuronal cell death induced by $MPP^+$. Confocal study showed that synphilin-1 partially restored nuclear condensation and fragmentation caused by $MPP^+$. Furthermore, immunoblotting studies indicated that the protein expression levels of cleaved-PARP and cleaved-caspase3 were decreased in synphilin-1 expressing cells compared to control cells. *In vivo* studies showed that synphilin-1 tended to inhibit dopaminergic neuronal death induced by MPTP, however the differences weren't significant. [Conclusion] These data suggested that synphilin-1 could have neuroprotective function in the molecular mechanism of PD.

**Abstract:** The beta-lactam antibiotic, ceftriaxone, attenuates tyrosine hydroxylase(TH) loss in striatum in rodent Parkinson's disease (PD) models when given early after nigrostriatal lesion. This protection may be related to the well-known properties of ceftriaxone to increase expression of the glutamate transporter, GLT-1, which increases glutamate uptake. However, it is unknown if ceftriaxone could partially restore striatal TH loss, concomitant with decreased motor impairment, when administered at a time post-lesion when motor function is impaired. The ability of ceftriaxone to decrease motor impairment was evaluated after evidence of motor impairment was observed in 3 tests; forepaw adjustment steps, open-field locomotor activity, and amphetamine-induced rotation. Ceftriaxone (200 mg/kg, i.p.) was given intermittently on days 7-13, 21-27, and 35-38 post-lesion. The FAS test and amphetamine-rotation tests established evidence of motor impairment 7 days after lesion induction. There was a significant increase in FAS taken, with an overall 45% increase in mean FAS of the 3 days evaluated 19,25, and 35 days post-lesion. Amphetamine-induced rotation was reduced by 63% between day 7 and day 14 after lesion. Locomotor activity increased at the end of the study (38 days post-lesion) against the day 7 baseline following ceftriaxone. Expression of striatal TH protein revealed no significant difference in loss between rats receiving ceftriaxone or saline injections in the intermittent injection regimen. Taken together, these preliminary data suggest the possibility that ceftriaxone-mediated increases in locomotor activity following nigrostriatal lesion may be independent of any preservation or possible restoration of striatal TH. Given previous evidence of protection against striatal TH loss when ceftriaxone is given early after lesion, the results also indicate that progression of striatal TH loss is affected by excitotoxic mechanisms.

**Abstract:** Induced pluripotent stem cells (iPSCs) are a renewable source of dopamine neurons and as such are a good candidate for cell replacement therapy in Parkinson's disease (PD). Previously we showed that commercially available cryopreserved iPSC-derived midbrain dopamine (iPSC-mDA) neurons (iCell DopaNeurons) survive and reverse 6-hydroxydopamine (6-OHDA)-induced motor asymmetry in the cyclosporine-immunosuppressed Sprague Dawley rat (Wakeman et al., 2017). In the present study we compared the efficacy of additional iPSC-mDA differentiation protocol variations, including an earlier cryopreservation date (iPSC-mDA-early), omission of FGF-8 (iPSC-mDA-noFGF-8), and alternative purification strategies (iPSC-mDA-purified) in the athymic nude rat. Rats received 6-OHDA injections in the right medial forebrain bundle. Nude rats with unilateral lesions confirmed by ipsilateral amphetamine-induced rotations were then transplanted with $4.5x10^5$ ($1.5x10^5$ cells/µl; 3µl) viable iPSC-mDA neurons in the right striatum. Motor asymmetry was assessed by amphetamine- and apomorphine-induced rotations. Animals were sacrificed at 9 months post-transplantation and brains were processed for immunohistochemistry. Here we show that striatal injections of cryopreserved mDA neurons survived and integrated with the host tissue over a period of 9 months. Robust grafts and fiber integration were seen in all animals that received iPSC-mDA injections. Transplanted cells maintained their dopaminergic phenotype, as indicated by the presence of tyrosine hydroxylase-immunoreactive fibers and cell bodies localized to the striatum. Importantly, we saw little evidence of proliferation indicative of teratoma formation or neural outgrowth in grafted animals. Amphetamine-induced rotations were completely reversed in animals receiving iCell DopaNeurons, iPSC-mDA-purified, or iPSC-mDA-early and partially reversed in animals injected with iPSC-mDA-noFGF-8 compared to vehicle control. Partial reversal in apomorphine-induced rotations was seen for iCell DopaNeurons and iPSC-mDA-

purified. These data support the application of cryopreserved iPSC-mDA neurons as a cell replacement therapy in PD. Further long-term studies with cells made using a fully cGMP-compliant process are currently underway.

**Title:** TRPC3 mediates ROS-dependent regulation and dysregulation of spontaneous firing activity in the midbrain dopamine neurons

**Authors: *S. KIM**, Y. LEE, M. PARK, H. KIM
SKKU Sch. of Med., Suwon, Korea, Republic of

**Abstract:** Midbrain dopamine neurons are pacemakers generating spontaneous firing activity, which triggers dopamine release. Thus, they are continuously exposed to oxidative stress conditions due to dopamine metabolism. Parkinson’s disease (PD)-related risk factors exacerbate mitochondrial dysfunction leading to more reactive oxygen species (ROS) formation. Although oxidative stress is implicated in dopaminergic neurotoxicity in PD, the molecular mechanisms underlying the loss of dopamine neurons are still elusive. We recently found that TRPC3 drives pacemaking and regulates basal firing rate in the midbrain dopamine neurons. Since TRPC3 is a ROS-sensitive channel, we hypothesized that the spontaneous firing activity of the midbrain dopamine neurons may be regulated by intracellular ROS levels via TRPC3. ROS generators including PD-related neurotoxins increased, while ROS blockers decreased the basal firing rate of the acutely isolated midbrain dopamine neurons. Importantly, the effects by ROS generators were totally abolished by pretreatment of a selective inhibitor of TRPC3, implying that TRPC3 may be involved in dopaminergic neurotoxicity. In a PD model using human dopaminergic neuronal cell line LUHMES, knock-down of TRPC3 greatly increased neuronal survival in response to PD-neurotoxin, 1-methyl-4-phenylpyridinium. Immunocytochemistry experiments

confirmed that TRPC3 is present in both isolated midbrain dopamine neurons and differentiated LUHMES cells. Taken together, these results suggest that disruption of spontaneous firing activity through TRPC3 activation by ROS is a possible mechanism for dopaminergic neurotoxicity and TRPC3 may be a therapeutic target for PD.

**Title:** Role of gut microbiota-derived metabolites in neurodegenerative disorders involving protein misfolding and C9orf72 expansion

**Authors: *L. HO**[1,2,3], K. RUAN[4], K. ONO[5], T. LLOYD[4], G. M. PASINETTI[1,2,3]
[1]Dept Neurol., The Icahn Sch. of Med. At Mount Sinai, New York, NY; [2]Geriatric Research, Educ. and Clin. Ctr., James J. Peters Veterans Affairs Med. Ctr., Bronx, NY; [3]Dietary Supplement Res. Ctr., The Icahn Sch. of Med. at Mount Sinai, New York, NY; [4]Dept. of Neurosci., Johns Hopkins Sch. of Med., Baltimore, MD; [5]Dept. Neurol., Showa Univ. Sch. of Med., Tokyo, Japan

**Abstract:** There is growing evidence that in many neurodegenerative disorders, cell-to-cell transmission of a pathological, misfolded protein, such as misfolding of α-synuclein (α-syn) in Parkinson's disease (PD), may be a vehicle for the spreading of pathology throughout the brain. This misfolded protein, or seed, further induces misfolding of native proteins within the cell. Pathological misfolded proteins may exist in diverse conformations with distinct cellular and biochemical properties. We investigate whether microbiota-derived metabolites may help to attenuate the misfolding of α-syn and thereby promote resilience against PD phenotypes. We identified 6 biologically available, gut microbiota-derived compounds (GMP10, GMP11,

GMP26, GMP28, GMP39, and GMP44) for investigation. Using independent *in vitro* protein aggregation assays (e.g., photo-induced cross-linking of unmodified proteins assay, thioflavin-T, fluorescence assay, and electron microscopy) we demonstrated that three of the compounds (GMP26, GMP44, GMP28) potently inhibit aggregations of monomeric α-syn (or monomeric β-amyloid peptides) into neurotoxic protein aggregates, *in vitro*. Based on evidence linking the c9orf72 gene with expansions of GGGGCC hexanucleotide repeats and PD, as well as amyotrophic lateral sclerosis (ALS) and frontotemporal dementia (FTD), we continue to test the neuroprotective ability of our compounds *in vivo* using a Drosophila model with overexpression of GGGGCC hexanucleotide repeats. Overexpression of 30 GGGGCC repeats in the Drosophila eye causes age-dependent photoreceptor neurodegeneration (Zhang K. et al, Nature 2015; 525:56). We treated Drosophila by mixing individual test compounds into the food and found all six compounds significantly suppressed eye degeneration at 10 μM, with compounds GMP26 and GMP11 almost completely suppressing the eye phenotype. The comparative efficacy of the six compounds are GMP26 = GMP11 > GMP39 > GMP10 > GMP44 > GMP28. Outcomes from our studies link gut microbiota with mechanisms underlying PD and suggest the feasibility of developing GMP26 as a means to simultaneously target both α-syn misfolding and C9orf72 expansion to increase the likelihood of therapeutic efficacy in PD, ALS, FTD patients with C9orf72 expansion.

**Title:** Bioluminescent optogenetics activation of transplanted neural precursor cells improves motor deficits in a Parkinson disease mouse model

**Authors: B. L. PALMATEER**, N. DORKA, L.-M. WAGNER, E. D. PETERSEN, M. PRAKASH, *U. HOCHGESCHWENDER
Neurosci., Central Michigan Univ., Mt Pleasant, MI

**Abstract:** The need to develop efficient therapies for neurodegenerative diseases is urgent, especially given the increasing percentages of the population living longer, with increasing chances of being afflicted with conditions like Parkinson's Disease (PD). A promising curative approach towards PD and other neurodegenerative diseases is the transplantation of stem cells to halt and potentially reverse neuronal degeneration. However, stem cell therapy suffers from problems with graft efficiency that can lead to adverse side effects and reduced improvement for patients. By using remote stimulation to optogenetically activate cells we attempted to increase graft efficiency. We generated a neuronal precursor cell line expressing luminopsin 3 (LMO3), a luciferase-channelrhodopsin fusion protein, which responds to the luciferase substrate coelenterazine (CTZ) with emission of blue light that in turn activates the opsin. Neuronal precursor cells were injected bilaterally into the striatum of homozygous aphakia mice, which carry a spontaneous mutation leading to lack of dopaminergic neurons and symptoms of PD. Following transplantation, the cells were stimulated over a period of 10 days by intraventricular injections of CTZ. Mice receiving CTZ demonstrated significantly improved motor skills in a rotarod test compared to mice receiving vehicle. Thus, bioluminescent optogenetic stimulation of transplanted neuronal precursor cells shows promising effects in improving graft efficiency in the aphakia PD mouse model and encourages further studies to elucidate the mechanisms and long-term outcomes of the beneficial effects.

**Abstract:** Mitochondrial fragmentation and bioenergetic failure manifest in Huntington's disease (HD), a fatal neurodegenerative disease. Hyperactivation of Dynamin-related protein 1 (Drp1), a primary fission protein, causes mitochondrial fragmentation and dysfunction in various HD models. Crucial questions such as how Drp1 hyper-activation mediates mitochondrial

dysregulation, especially those damages that occur inside the mitochondria, and how these processes are linked to neurodegeneration, however, remain to be answered. The factors that couple mitochondrial fusion/fission with bioenergetics and their impacts on neurodegeneration also remain poorly understood. In this study, we use unbiased proteomics analysis for Drp1-interacting proteins in HD patient neuronal cells derived from patient induced pluripotent stem cells (HD-iPS cells), and identify mitochondrial protein ATAD3A (ATPase family AAA-domain containing protein 3A) as an interactor of fission protein Drp1 in HD. ATAD3A is a nuclear-encoded mitochondrial protein and belongs to a family of AAA-ATPase proteins. ATAD3A has a unique structure; its C-terminus containing the conserved ATPase domain which is located in the mitochondrial matrix, whereas its N-terminus has been reported to either expose to the cytosol or associate with mitochondrial outer membrane. Here we document an enhanced interaction between Drp1 and ATAD3A and ATAD3A oligomerization in various HD models, which are required for Drp1-mediated mitochondrial fragmentation. Moreover, disturbance of ATAD3A steady state impairs mtDNA maintenance by disrupting TFAM/mtDNA binding. Blocking Drp1/ATAD3A interaction with a peptide, DA1, abolishes Drp1 hyperactivation and ATAD3A oligomerization, suppresses mitochondrial fragmentation and mtDNA lesion, and reduces bioenergetics deficits and cell death in HD mouse- and patient-derived cells. Treatment with DA1 reduces behavioral and neuropathological phenotypes of HD in HD transgenic mice. Our findings provide novel insights
into the pathogenesis of HD, present evidence for ATAD3A function on maintaining mitochondrial integrity and neuronal survival, demonstrate a key role of ATAD3A in neurodegeneration by bridging Drp1-induced mitochondrial fragmentation with mtDNA defect, and highlight a promising therapeutic strategy for HD and other neurodegenerative disorders featured with mitochondrial dysfunction.

**Title:** Striatal projection neurons require Huntingtin for synaptic connectivity

**Authors: *C. BURRUS**, S. U. MCKINSTRY, N. KIM, H. YIN, C. EROGLU
Duke Univ., Durham, NC

**Abstract:** Huntington's Disease (HD) is a fatal, inherited disease caused by an autosomal dominant polyglutamine expansion mutation in the N-terminus of Huntingtin (Htt) protein. Patients with HD suffer from progressive motor, cognitive, and psychiatric impairments, along with significant degeneration of the striatal projection neurons (SPNs) of the striatum. The dominant nature of the Htt mutation has led to the widely-accepted hypothesis that HD is caused by a toxic gain-of-function of mutant Htt protein. However, recent findings suggest that loss of function of Htt due to dominant-negative effects of the mutant protein also play important roles in HD. Previously, we have shown that wildtype Htt plays a critical role in regulating the dendrite formation and excitatory synaptic connectivity of cortical pyramidal neurons. However, the role of Htt in synaptic development and connectivity within the striatum is not yet known, leaving critical aspects of HD pathology unexplored. In the current study, we conditionally deleted Htt from specific subpopulations of striatal projection neurons (SPNs) using the Cre-Lox system and have determined that SPNs require Htt for synaptic development and longevity, as well as coordinated motor function. Our findings show that Htt is necessary for proper striatal synaptic connectivity and motor function, indicating that loss of Htt function likely plays a critical role in HD pathogenesis.

**Abstract:** Huntington's disease (HD) is a fatal and progressive condition with severe debilitating motor defects. While classically recognized as a neurodegenerative disorder, there is increasing evidence of cell autonomous toxicity in skeletal muscle. Recently, our laboratory demonstrated that, despite being fully innervated, the membrane properties of skeletal muscle are hyperexcitable in HD. In this study, we examined the relationship between neuromuscular transmission and skeletal muscle hyperexcitability using an ex-vivo preparation of the levator auris longus (LAL) muscle from late-stage R6/2 HD model mice and age-matched wild-type controls. Spontaneous miniature endplate currents (mEPCs) and nerve-evoked endplate currents (eEPCs) were recorded under voltage clamp, which, unlike current clamp records, were independent of the changes in muscle membrane properties. There was a reduction in the number of vesicles released per action potential (quantal content) in R6/2 muscle, which binomial statics suggest is caused by a reduction in the number of vesicle release sites (*n*) rather than a change in the probability of release (*p*). To assess endplate morphology, we performed a combination of immunohistochemistry with confocal microscopy. There was no evidence of denervation, but neuromuscular junctions were not only smaller, they were less dense, which would result in fewer vesicle release sites. The depressed neuromuscular transmission in R6/2 muscle may help compensate for the muscle hyperexcitability and contribute to motor impersistence.

**Title:** The moonlighting role of $NAD^+$ salvage pathway proteins in huntingtin proteotoxicity protection

**Authors: *A. RUETENIK**[1], A. OCAMPO[2], A. BARRIENTOS[3]
[1]Neurosci. Program, Univ. of Miami Sch. of Med., Miami, FL; [2]The Salk Inst., La Jolla, CA; [3]Univ. of Miami, Miami, FL

**Abstract:** Huntington's disease is caused by a single genetic abnormality in which the number of trinucleotide repeats encoding polyglutamine in exon 1 of the huntingtin gene expands to or past a threshold number of repeats to cause disease. This abnormally high number of glutamine repeats cause dysfunction and oligomerization of the resulting huntingtin protein. Neurodegeneration is the main hallmark of the disease, effecting mainly the striatum and cortex,

and patients usually die within 15-20 years of the first noticeable symptoms. As no current treatments exist to prolong lifespan for this terrible disease, we are interested in better understanding the disease mechanism complexities, as well as exploring possible routes for therapeutic targets. Previously, our lab discovered that several proteins that form the $NAD^+$ salvage pathway in yeast protected against deleterious effects caused by the overexpression of human huntingtin exon 1 with a 103 repeat polyglutamine (103Q) track in a yeast model of Huntington's disease. We further found that 103Q oligomers were being degraded in these cells, while 103Q oligomers in cells without overexpression of the $NAD^+$ salvage pathway proteins were stable. Importantly, we also showed that an intact $NAD^+$ salvage pathway was unnecessary for the protection seen by the salvage pathway proteins. Together, this suggests that $NAD^+$ salvage pathway proteins may have an alternative function in the cell, additional to their catalytic role in the $NAD^+$ salvage pathway Here, we have continued the investigation into the mechanisms and ability of $NAD^+$ salvage pathway proteins to confer protection, with the hypothesis that they may have a moonlighting chaperone function. In addition to continuing our studies in our yeast model of Huntington's disease, we have expanded our studies to include *in-vitro* assays and human cells derived from Huntington's disease patients to aid in our research. Preliminary studies *in-vitro* support our hypothesis that at least some of the $NAD^+$ salvage pathways proteins may have intrinsic chaperone function. Additionally, preliminary studies of catalytically inactive $NAD^+$ salvage pathway proteins in our yeast model of Huntington's disease in a variety supports previous findings that the catalytic function within the $NAD^+$ salvage pathway is non-essential for their protective function. These preliminary results suggest that proteins of the $NAD^+$ salvage pathway may have previously unknown functions within the cell, and suggests that these proteins may be possible targets for therapeutic intervention in Huntington's disease and other diseases of protein misfolding.

**Title:** Mutant huntingtin is secreted via a late endosomal/lysosomal unconventional secretory pathway

**Authors: *K. TRAJKOVIC**, H. JEONG, D. KRAINC
Neurol., Northwestern University, Feinberg Sch. of Medici, Chicago, IL

**Abstract:** Huntington's disease (HD) is an autosomal dominant neurodegenerative disorder caused by the expansion of a CAG triplet in the gene encoding for huntingtin. The resulting mutant protein huntingtin (mHtt) with extended polyglutamine (polyQ) sequence at the N-terminus leads to neuronal degeneration both in cell-autonomous and non-cell-autonomous manners. Recent studies identified mHtt in the extracellular environment and suggested that its spreading contributes to toxicity, but the mechanism of mHtt release from the cell of origin remains unknown. In this study, we performed a comprehensive, unbiased analysis of secretory pathways and identified an unconventional lysosomal pathway as an important mechanism for mHtt secretion in mouse neuroblastoma cell line. Mutant Htt secretion was dependent on synaptotagmin 7, a regulator of lysosomal secretion, and inhibited by chemical ablation of late endosomes/lysosomes, suggesting a lysosomal secretory pattern. Moreover, mHtt was preferentially targeted to the late endosomes/lysosomes compared to wild-type Htt. Importantly, we found that late endosomal/lysosomal targeting and secretion of mHtt could be efficiently inhibited by the phosphatidylinositol 3-kinase (PI3-kinase) and neutral sphingomyelinase (NS) chemical inhibitors, Ly294002 and GW4869, respectively. Together, our data suggest a lysosomal mechanism of mHtt secretion and offer potential strategies for pharmacological inhibition of neuronal secretion of mHtt.

**Title:** The autophagy receptor p62/SQSTM1 is palmitoylated and significantly decreased in brains of Huntington disease patients

**Authors: *D. D. MARTIN**[1], S. S. SANDERS[1], N. S. CARON[1], Y. T. NYUGEN[1], D. J. KLIONSKY[2], M. R. HAYDEN[1]
[1]Med. Genet., Univ. of British Columbia, Vancouver, BC, Canada; [2]Univ. of Michigan, Ann Arbor, MI

**Abstract:** Autophagy is essential for the removal of damaged proteins and organelles by delivering them to the lysosome for degradation and recycling. Induction of autophagy requires quick relocalization of many proteins from the cytosol to organellar membranes. A potential mechanism mediating this shift is lipidation. However, lipidation of many autophagy proteins has been overlooked. We recently constructed a compendium of palmitoylated proteins from

proteomic studies and performed enrichment analysis to determine the pathways and diseases that are enriched for palmitoylation. Similar to phosphorylation, palmitoylation involves the dynamic and reversible addition of the fatty acid palmitate to cysteine residues. Schizophrenia, HD and ALS were among the top diseases predicted to be enriched in palmitoylation. A new comparison between all known palmitoylated genes and the autophagy regulatory network shows significant enrichment of palmitoylation in the regulation of autophagy (~50%). Consequently, dynamic and reversible palmitoylation may be crucial for regulating autophagy and allowing the rapid relocalization of its regulators. Subsequently, by focusing on points of convergence within the autophagy pathway, we confirmed that an essential autophagy receptor, sequestosome-1 (SQSTM1, also known as p62), is palmitoylated. p62 is required for the removal of aggregated proteins and damaged mitochondria. Consequently, mutations in *SQSTM1* are associated with neurodegeneration, including frontotemporal dementia and amyotrophic lateral sclerosis (ALS). Dysfunctional p62 cargo loading is also associated with the neurodegenerative disease Huntington disease (HD). We show that palmitoylated p62 is degraded by the lysosome, signifying that palmitoylated p62 is the "active" form of p62. Subsequently, we confirmed that palmitoylation of p62 is significantly decreased in the brains of an HD mouse model and in the cortex of human HD patients. Strikingly, we demonstrate that p62 palmitoylation can be altered in mouse brains by 2 different fasting regimes, thereby demonstrating that palmitoylation can be dynamically regulated in the brain through fasting. **Appeal:** This is study suggests that palmitoylation may have a greater role in regulating autophagy. This is also the first demonstration that palmitoylation can be regulated by diet, suggesting that diseases with dysregulated palmitoylation, like Schizophrenia or HD, may be normalised through diet or fasting. We clearly show that p62 is palmitoylated and significantly decreased in human HD brains suggesting that the deficiency in cargo loading in HD may be related to decreased palmitoylation of p62.

**Title:** Mitochondrial iron dysregulation in mouse and human Huntington's disease brain

**Authors: S. AGRAWAL**, J. A. FOX, *J. H. FOX
Vet. Sci., Univ. of Wyoming, Laramie, WY

**Abstract:** Huntington's disease (HD) is an autosomal dominant disorder caused by a CAG repeat expansion in the huntingtin gene. Mitochondria have an important role in HD pathogenesis and are also a major site of iron utilization for heme and iron-sulfur cluster protein synthesis. Brain iron dysregulation is involved in the pathogenesis of HD. We investigated a role for mitochondrial iron dysregulation in disease pathogenesis. Using brain regional sub-cellular fractionation and ICP-MS measurements for total iron, in R6/2 and YAC128 HD models, we demonstrate that brain iron accumulation is present in mitochondrial, but not cytoplasmic fractions. To investigate potential mechanisms of mitochondrial iron accumulation in HD models we completed Western blot analyses of the mitochondrial iron homeostatic proteins mitoferrin 2, ABCB8 and frataxin in R6/2 mice and in human HD brain. Levels of the iron-uptake protein mitoferrin 2 were increased in R6/2 striatum and cortex and in human HD BA9 and BA17 neocortical regions. Levels of the mitochondrial iron export ABCB8 protein were unaltered in R6/2 mice. Levels of frataxin, a protein involved in iron-sulfur cluster synthesis, were decreased in R6/2 striatum and cortex and human HD BA4 and BA9 neocortical regions. We further demonstrate that oxidative stress markers in brain mitochondrial membrane fractions are increased. Specifically, there are significant elevations of mitochondrial lipid peroxidation products and oxidized glutathione in R6/2 mouse striatum and cortex. Findings support a role of dysregulated mitochondrial iron in the pathogenesis of HD as studied in genetic mouse models.

**Title:** Gene therapy based on SMaRT for Huntington's disease: Fluorescent screening to assess trans-splicing RNA molecule activity

**Authors: *S. C. MAIRE**[1,2], M.-C. GAILLARD[1,2], A. BERGER[3], N. DUFOUR[1,2], C. JOSÉPHINE[1,2], P. HANTRAYE[1,2], E. BROUILLET[1,2], A.-P. BEMELMANS[1,2]

**Abstract:** Huntington's disease (HD) is an autosomal dominant genetic disorder caused by a CAG repeat expansion mutation located in the first exon of the Huntingtin gene (*HTT*). We use spliceosome mediated RNA *trans*-splicing (SMaRT) to develop an innovative strategy of gene therapy that will significantly reduce or eliminate the expression of the mutant protein while

restoring a physiological level of normal *HTT*. This process is achieved using an artificial RNA, termed pre-*trans*-splicing molecule (PTM), which has the capacity to exchange the mutant exon with a mutation-free exon. In the case of a dominant mutation, therapeutic benefits can only result from high rates of correction. Therefore, our goal is to achieve the most efficient *trans*-splicing (TS) reaction possible by implementing different strategies of PTMs screening in order to select *HTT*-targeting PTMs efficient enough to exhibit therapeutic benefit in affected neuronal population.
Our screening strategy is based on an artificial fluorescent reporter system which results in the production of two fluorescent proteins: (i) a chimeric fluorescent protein (XFP) (ii) a mTurquoise2 protein. XFP sequence is basically composed of YFP sequence in 5' and mTurquoise2 sequence in 3'. Since these two proteins are derived from GFP, the combination of these sequences results in chimeric fluorescent compound at protein level. The innovative strategy with this construction is to insert between these two sequences an *HTT* target intron, exhibiting splicing activity. In case of *cis*-splicing, XFP is produced with varying fluorescence emission levels, dependent on XFP expression driven by the strength of the *HTT* target intron introduced (MaxEnt analysis, Yeo et al, 2003). We constructed PTMs libraries for each *HTT* intron targeted with 5' mTurquoise2 sequence as exchanging exon. When TS occurs with those PTMs, it is supposed to produce the native mTurquoise2 protein with distinct excitation and emission spectra, allowing detection and quantification. PTM libraries were tested to assess their TS activity in HEK293T cells using epi-fluorescence microscopy and flow cytometry. We first screened hundreds of PTMs and assessed their individual TS activity but this strategy has not been successful. Then we combined PTMs with different targets supposing to act in synergy in inhibiting *cis*-splicing process. This new strategy gave us promising results with fluorescence emission significantly ($p=0.007$, T-test, $n=3$) higher than negative control, suggesting a TS activity. We will next adapt PTM constructs to the *HTT* context and validate their potential therapeutic benefits in relevant cellular models such as HD patient-derived iPS cells.

**Abstract:** Huntington's disease (HD) is caused by a polyglutamine-repeat expansion in exon 1 of *huntingtin (HTT).* The mutation confers gain of function phenotypes on the HTT protein, as well as on transcripts arising from the *HTT* locus. Additionally, recent analyses show differential gene expression and alternative splicing in HD brain, with RNA-binding proteins as candidate mediators of that misregulation. Here, we show in neurons *in vivo* and in culture, that the presence of mutant huntingtin (mHTT) alters the transcript and protein levels of the RNA binding proteins Muscleblind-like Splicing regulator 1 (MBNL1) and CUGBP/Elav-Like Family Member 1 (CELF1), with CELF1 more stable and abundant in HD tissues, and MBNL1 levels reduced. Moreover, the MBNL1 that is present has partitioned to a less soluble species that co-localizes with mHTT transcripts. CELF1s stability in HD cells results from a combination of a MBNL1-dependent switch in poly(A) site preference on the transcript, and a PKR- and PKC-dependent hyperphosphorylation of the protein. Intriguingly, the extent of CELF1-MBNL1 regulatory loop disruption is correlative with the CAG-repeat length. Knockdown of m*HTT* rescues the misregulation of the CELF1-MBNL regulatory loop, providing further support for a gain-of-function role for m*HTT* transcripts.

**Abstract:** Huntington's disease (HD) is caused by an expanded CAG repeat in the Huntingtin (HTT) gene. The mechanism(s) by which mutant HTT (mHTT) causes disease is unclear. Nucleocytoplasmic transport, the trafficking of macromolecules between the nucleus and cytoplasm, is tightly regulated by nuclear pore complexes (NPCs) made up of nucleoporins (NUPs). Previous studies offered clues that mHTT may disrupt nucleocytoplasmic transport and a mutation of an NUP can cause HD-like pathology. Therefore, we evaluated the NPC and nucleocytoplasmic transport in multiple models of HD, including mouse and fly models, neurons transfected with mHTT, HD iPSC-derived neurons, and human HD brain regions. These studies revealed severe mislocalization and aggregation of NUPs and defective nucleocytoplasmic transport. HD repeat-associated non-ATG (RAN) translation proteins also disrupted nucleocytoplasmic transport. Additionally, overexpression of NUPs and treatment with drugs that prevent aberrant NUP biology also mitigated this transport defect and neurotoxicity, providing future novel therapy targets.

**Title:** Changes in PT and IT corticostriatal projections in the Q175 mouse model of Huntington's disease

**Authors: *T. PANCANI**, J. KONDAPALLI, J. SURMEIER
Dept. of Physiol., Northwestern Univ. Feinberg Sch. of Medicin, Chicago, IL

**Abstract:** Huntington's disease (HD) is a neurodegenerative disease characterized by severe motor alterations. The neuropathological occurrences underlying behavioral changes are extensive and include significant loss of striatal and cortical parenchyma. Direct communication between cortex and striatum is ensured by glutamatergic corticostriatal (CTX-STR) fibers which play a pivotal role in shaping motor behavior. Not surprisingly, a growing body of evidence is revealing significant alterations of these fibers in several mouse models of HD. CTX-STR axons are mainly originating from two distinct classes of cortical neurons: intratelencephalic (IT) and pyramidal tract (PT) neurons. IT neurons project within the telencephalon ipsi- and contralaterally to cortex and striatum forming the main component of the callosal commissure. Conversely, PTs project only ipsilaterally to extratelencephalic regions such as thalamus or brainstem forming also *en passant* synapses in striatum. The severe and progressive reduction of corpus callosum fibers seen in HD clearly suggest that CTX-STR IT projections are altered in HD. Moreover, the loss and/or alteration of SMI32-immunopositive long-projecting pyramidal neurons, seen in M1 cortex, suggests that PT projections are also affected in HD. However, alterations of corticostriatal fibers originating from specific cortical neuronal subpopulations has not been studied in the context of HD. Using the Q175 mice and IT and PT - Cre expressing mouse lines, together with optogenetics and electrophysiology techniques, we found that IT CTX-STR glutamatergic transmission onto both direct and indirect pathway SPNs is surprisingly increased in 7-8 - month-old Q175 mice while the opposite trend is seen at PT - SPNs synapses. At IT synapses, we also found that the amplitude of $Sr^{2+}$-mEPSCs is unaltered in SPNs from HD mice compared to control, suggesting increased glutamate release sites rather than increased neurotransmitter's release probability. To address this issue, we used sCRACM and mGRASP to determine specific topological alterations of CTX-STR IT (and also PT) synapses onto SPNs. Furthermore, it is well established that mAChRs can potently modulate CTX-STR glutamatergic transmission and a recent report show that this effect is altered in HD. Interestingly, we also found that muscarinic receptors (mAChR) activation has a differential modulatory influence on CTX-STR IT versus PT synapses and this effect is altered in Q175 symptomatic mice.

**Title:** Targeting Gpr52 lowers mutant huntingtin levels and rescues huntington's disease-associated phenotypes

**Authors:** *B. LU[1], ***B. LU**[1], X. XIE[2], H. SONG[1]
[1]Fudan Univ., Shanghai, China; [2]CAS Key Lab. of Receptor Research, Natl. Ctr. for Drug Screening, Shanghai, China

**Abstract:** Lowering the levels of disease-causing proteins is an attractive treatment strategy for neurodegenerative disorders, among which Huntington's disease (HD) is an appealing model to test this strategy because of its monogenetic nature, allowing early diagnosis/treatment and establishment of reliable genetic disease models. HD is mainly caused by cytotoxicity of the mutant huntingtin protein (mHtt) with an expanded polyglutamine repeat (polyQ). Lowering mHtt is a promising HD treatment strategy, but this is hard to be achieved by small molecule drugs due to a lack of effective drug targets. Here we demonstrate that knocking-out an orphan G protein-coupled receptor (GPCR), Gpr52, significantly reduces mHtt levels in the striatum and rescues HD-associated behavioral phenotypes in a knock-in HD mouse model. Importantly, a novel Gpr52 antagonist E7 also reduces mHtt levels and rescues HD phenotypes in cellular and mouse models. Our study provides a proof-of-concept in treating HD by targeting GPR52 with small molecule drugs aiming at lowering the mHtt level.

**Abstract:** A variety of huntingtin (HTT) lowering strategies have shown preclinical promise for the treatment of Huntington disease (HD), and the first HTT lowering clinical trial is now underway. Based on our previous work demonstrating that CNS-wide suppression of HTT in mice results in correlative reduction of cerebrospinal fluid (CSF) mtHTT, CSF mtHTT is being used as a marker of target engagement. However, there is very little known about CSF mtHTT; where it comes from, how it enters CSF. Thus, interpretation of treatment-induced changes, or lack thereof is not currently possible. We are using our ultrasensitive immunoprecipitation and flow cytometry (IP-FCM) mtHTT detection assay to address these questions and enable substantive use of CSF mtHTT as an HD biomarker. Unlike mice, HTT lowering in man is not expected to be CNS-wide. The agent under trial is expected to be predominantly active in the cortex, but partial cortical reduction may be insufficient to result in measureable CSF reduction. This could erroneously indicate failure to suppress HTT in the cortex. The same applies to agents delivered by viral vector that may only be active in the basal ganglia or in specific cell types. Thus, we are interrogating the source of CSF mtHTT protein using BACHD HD model mice (floxed mtHTT exon 1) crossed to brain region and cell type-specific cre mice. These crosses generate mice with selective KO of mtHTT and enable evaluation of the contribution of the region or cell type at study to the pool of CSF mtHTT protein. Additionally, we do not know how mtHTT enters CSF. If it is mostly released passively from dying cells, any neuroprotective therapy would be expected to reduce CSF mtHTT, but if it is actively cleared from the brain, only HTT lowering therapeutics targeting regions or cells that substantially contribute to CSF mtHTT would be expected to reduce it. Furthermore, therapeutics that increase brain HTT clearance could even increase CSF mtHTT. We have previously shown that mtHTT is not detected in CSF of all premanifest HD mutation carriers and that acute brain injury causes a transient increase in CSF mtHTT. This suggests that HTT is passively released to CSF from dying cells. However, we have detected high concentrations of mtHTT in the CSF of a mouse that lacks neurodegeneration, suggesting that there may be both passive release and active clearance mechanisms at play. We are ectopically delivering intracellular and extracellular mtHTT to investigate the kinetics and mechanism of mtHTT clearance to CSF. Delineating the source and mechanism of entry of CSF mtHTT protein will greatly enhance the utility of this measure as an HD biomarker.

**Abstract:** Neuronal loss in HD striatum is preceded by as yet unexplained changes in dendritic morphology including the marked loss of spines, onto which most synaptic contacts occur. The small GTPase Rac1 regulates Actin-dependent morphology changes including changes in dendritic spines, growth cone shape and motility. Striatum of HD knock-in mice (Q140/Q140) had significantly higher levels of Rac1 activity at 6 weeks followed by a significant decrease at 4.5 months compared to age matched wild-type controls. Furthermore, human neural stem cells (NSCs) derived from induced pluripotent stem cells (IPSCs) with 42Q, 50Q, and 72Q in Huntingtin had increased basal Rac1 activation compared to controls and correction of the 72Q repeat to 21Q by homologous recombination reduced Rac1 activation levels in NSCs. Human neuronal cultures from HD IPSCs differentiated towards medium spiny neurons with 50Q showed increased Rac1 activation compared to wild-type cultures derived from two independent control lines. Morphology driven processes such as motility and growth cone development which are regulated by Rac1 were also changed in HD cells compared to controls. At a molecular level, immunoprecipitation of endogenous wild-type and mutant Huntingtin co-precipitated the p85α regulatory subunit of PI 3-kinase, Rac1 and Alpha-actinins. Alpha-actinins can crosslink and bundle Actin filaments, regulate spine shape, and can be regulated by Rac1 during cell adhesion. In control human fibroblasts where the microfilament cytoskeleton is easily observed, we show localization of Huntingtin to Actin stress fibers, Vinculin-positive adhesion contacts, and co-localization with Alpha-actinin-1 at membrane ruffles and lamellapodia. Depletion of Huntingtin

by small interfering RNA (siRNA) altered cell morphology and increased basal Rac activation. Finally, reducing Huntingtin protein using siRNA in fibroblasts altered the stimulation dependent localization of Alpha-actinin-1 at the plasma membrane. All together, these data provide evidence that Rac activation is changed in mouse and human HD models resulting in diverse phenotypic changes and that normal Huntingtin is important for Rac1 regulation and localization of Alpha-actinins necessary for cell morphology.

**Title:** A novel automated home-cage system to assess learning and performance of a skilled motor task in a mouse model of Huntington’s disease

**Authors: *C. L. WOODARD**, F. BOLAÑOS, J. D. BOYD, G. SILASI, T. H. MURPHY, L. A. RAYMOND
Univ. of British Columbia, Vancouver, BC, Canada

**Abstract:** Behavioural testing is a critical step in assessing the validity of rodent models of neurodegenerative disease, as well as evaluating the efficacy of pharmacological interventions. In models of Huntington’s disease (HD), a gradual progression of impairments is observed across ages, increasing the need for sensitive, high-throughput and longitudinal assessments. Recently, a number of automated systems have been developed to perform behavioural profiling of animals within their own home-cage, allowing for 24-hour monitoring and minimizing experimenter interaction. However as of yet, few of these have had functionality for the assessment of skilled motor learning, a potentially relevant behaviour for movement disorders such as HD. To address this, we have adapted a novel paradigm that incorporates a lever positioning task into the mouse home-cage. Animals first learn a simple version of the task, before moving to a second phase where they must learn to hold the lever for progressively longer in a rewarded position range. Testing with this paradigm has revealed the presence of distinct phenotypes in the YAC128 mouse model of HD at 2 months, 4 months and 6 months of age. YAC128 mice at 2 months, but not older, displayed a decreased ability to adapt to changes in

task demands when shifting to a more difficult task. In contrast, 4 and 6 month-old YAC128 mice exhibited circadian abnormalities and alterations on several kinematic measures, suggesting an impairment in motor control. This paradigm holds promise for facilitating high throughput behavioural assessment of HD mouse models for preclinical therapeutic screening.

**Abstract:** Huntington’s disease (HD) is an autosomal dominant neurodegenerative disorder characterized by the presence of a misfolded mutant *Huntingtin* (muHTT) protein. Strategies aimed towards reducing expression of muHTT through gene silencing may prove to be an effective strategies towards attenuating disease progression. We have previously shown allele-specific silencing of the muHTT transcript in patient-derived fibroblasts via transcriptional

activator-like effectors (TALE) by targeting a single nucleotide polymorphisms (SNP) that is highly associated with the mutant allele. Furthermore, we have demonstrated robust distribution following unilateral striatal injection of our lipid nanoparticle-encapsulated TALE (LNP-TALE) across the ipsilateral striatum, sub-ventricular zone, corpus collosum, and cerebral cortex as well as presence of LNP-TALE in the contralateral striatum and cortex. Molecular analysis of those regions demonstrated a significant reduction of the muHTT and an observable reduction of the muHTT protein 48 hrs following injection.
In this study we examine LNPs and adeno-associated virus (AAV) as putative delivery vehicles for our therapeutic TALE transgene in our novel NOD-SCID gamma YAC128 (YAC128xNSG) transgenic HD mouse model. Both delivery platforms have been explored in human clinical settings and offer multiple avenues in successfully delivering therapeutic transgenes *in-vivo*. In addition, the YAC128xNSG provides a model for future toxicity studies of potential humanized immune responses towards our novel therapeutics. We have executed a longitudinal study evaluating an optimized LNP-TALE formulation and AAV9-TALE for distribution of the TALE, duration of transgene expression over the course of 3 months, duration of mutant allele silencing, and attenuation of HD-related neuropathology and behavioral phenotypes. Identification of a potent, widespread delivery vehicle and assessment of the long-term duration of expression and effect of our therapeutic transgene will be vital in the evaluation of our TALE as a viable therapeutic for HD.

**Abstract:** Dopamine, a neurotransmitter, plays an important role in the mediation of movement, cognition, and emotion. Dopamine receptors are involved in the pathophysiology of neuropsychiatric diseases, such as Huntington's disease, Parkinson's disease, Alzheimer's disease, and schizophrenia. $^{18}$F-Fallypride is a selective, high-affinity antagonist of D2/3R's, which has been used to study receptor occupancy and density in neuropsychiatric disorders and aging in humans. In this study, comparison of $^{18}$F-fallypride binding between heterozygous (HET, n=12) and wild-type (WT, n=12) Q175DN Huntington's mice was performed. Mice were studied at the age of 9 and 12 months. Prior the experiment, bile acid concentration (indication of liver shunt) was confirmed from plasma samples. Also, minimum of 2 weeks prior the PET scan, the males were housed with single females to minimize stress of the animals. Based on published material in rodents, primates and humans, stress and dominant behavior can affect $^{18}$F-fallypride PET imaging outcome. The least stressful housing for male mice is together with females, i.e. one male with one female (Prof. Koolhaas laboratory, University of Groningen). $^{18}$F-Fallypride was synthetized with high specific activity (SA, 298 - 360 GBq/µmol EOS) and excellent radiochemical purity (>99.8%). For the PET scan, animals were anesthetized using isoflurane, cannulated and put in the scanner. PET scan was started and $^{18}$F-fallypride (10 - 15 MBq) was administrated as a bolus. List mode PET scan over 90 min was performed, after which a CT scan was performed. For the PET analysis, 3D OSEM reconstruction was performed. To calculate $BP_{ND}$ for each individual, simplified reference tissue modeling was applied (PMOD 3.7). VOI delineation was preformed using in-house generated MRI images from HET and WT mice.Small variation in binding potential ($BP_{ND}$) was seen within genotypes and no mass effect was observed when SA of $^{18}$F-fallypride was >100 GBq/µmol at the time of injection. HET showed 30.2% decrease in $BP_{ND}$ ($p<0.0001$) when compared to WT at 9 mo and 51.6 % decrease ($p<0.0001$) at 12 mo. Further, 23.6 % decrease ($p<0.05$) was analyzed during aging in HET mice. As a summery, significant decrease in D2R/D3R availability in striatum of HET mice was observed compared to WT in 9 and 12 mo. PET imaging provides a powerful and translational research tool in Huntington's disease allowing comprehensive evaluation of disease progression and treatment interventions for in vivo studies.

**Abstract:** zQ175 knock-in (KI) mice have been considered a valuable mouse model for Huntington's disease (HD) research. Especially mice heterozygous for the KI of an expanded CAG tract in exon 1 of the mouse huntingtin (Htt) gene mimic well the human mutation causing HD. Recently, a modified zQ175 KI mouse line was introduced. In these mice, a neomycin resistance cassette in the Htt gene locus was removed resulting in increase in the amount of mutated Htt in the mice. In this study, we aimed to characterize the behavioral phenotype, brain volumetric changes and concentrations of striatal metabolites in the newly developed zQ175 KI delta neo (DN) mice. We also wanted to compare the results to those previously obtained in zQ175 KI with existing neomycin cassette. Total of 40 female wild-type and heterozygote (HET) zQ175 KI DN mice were used. The motor behavioral tests including fine motor kinematic analysis, open field, rotarod, tapered beam balance and grip strength tests were performed at 2, 6, 9, 12 and 15 months of age. At the same age points MRI measurements of whole brain, striatum and cortical volumes, and the 1H-MR spectroscopy measurements of the striatal metabolites, including, amongst others, glutamine, myo-inositol, taurine and choline, were performed. The HET zQ175 KI DN mice had decreased body weight starting from 30 weeks of age in females and 25 weeks of age in males. Beam balance performance started to decline at 6 months and rotarod performance from 9 months onwards. Fine motor kinematic revealed genotype differences already at 2 months of age, showing clear and progressive deficits starting from 6 months of age. MRI volumetric and striatal metabolic changes were similarly progressive starting from 6 months of age. Taken together, in HET zQ175 KI DN mice the age of onset of HD-like symptoms appeared to be earlier and occurring with a more rapid progression than previously observed in KI mice of HD. These changes were most clear in the fine motor capabilities and gait.

**Title:** Deficient object location/paired associates learning in Q175KI mouse model of Huntington's disease

**Authors: *M. KOPANITSA**, T. O. PIIPONNIEMI, T. PARKKARI, A. J. NURMI
Charles River Discovery, Kuopio, Finland

**Abstract:** Huntington's disease (HD) is a fatal neurodegenerative disorder characterized by uncontrolled movements, psychiatric disturbances and cognitive impairment. Numerous mouse models of HD have been developed, but cognitive performance of such mutants is often based on approaches that are not easily translatable to clinical setting.
We examined performance of 10-12-month-old Q175 knock-in (Q175 KI) mice, expressing human mHTT allele with expanded CAG repeat (~179 repeats) within the native mouse huntingtin gene, and their age-matched wild-type (WT) counterparts in a highly translational task of object location/paired associates learning (OL/PAL). This touchscreen-based task is similar to Paired Associates Learning (PAL) test of CANTAB panel of human touchscreen tasks. Impaired performance of HD patients in the human version of PAL task has been previously reported.
During basic operant pretraining for OL/PAL task, Q175 KI and WT mice exhibited similar performance during "Initial touch", "Must touch", and "Must initiate" tasks, whereas during the last "Punish Incorrect" pretraining task, mutants achieved the criterion ~3-fold slower. This impairment stemmed from low selectivity of touches (target vs. blank) and lower number of trials attempted by Q175 KI mice. In addition, during "Punish Incorrect" pretraining task, mutant mice were slower to poke both into the image (target touch) and into the blank area of the screen (blank touch). These alterations were unlikely due to locomotor disturbances because Q175 KI and WT mice made a similar number of beam breaks and chamber traversals during the first exposure to touchscreen chamber.
During 50 36-trial OL/PAL sessions, WT mice demonstrated clear learning of the task, improving their performance from initial chance level (50%) to over 80% correct response rate during the last five sessions. In contrast, Q175 KI mice showed very little learning of the task as their performance, even at later stages, was only slightly higher than chance level (57.1 ± 1.6%). As was during the "Punish Incorrect" pretraining stage, Q175 KI also required much more days to complete the required number of trials.
We conclude that impaired learning of OL/PAL touchscreen task by Q175 KI mice parallels deficient performance of individuals diagnosed with Huntington's disease in human PAL task. Lower responding rate of Q175 mice may be an indication of an apathic phenotype. Because apathy is an important symptom in HD, assessment of Q175 KI mice in more specific tests of motivational behavior and reward-related decision making, such as progressive ratio or effort-related choice, is warranted.

**Title:** Use of CRISPR/Cas9 to alter huntingtin expression in Huntington's disease mice

**Authors: *H. YANG**, S. YANG, R. CHANG, S.-H. LI, X.-J. LI
Dept. of Human Genet., Sch. of Medicine, Emory Univ., Atlanta, GA

**Abstract:** Huntington’s disease (HD) is a genetically inherited autosomal dominant neurodegenerative disease characterized by motor impairments, cognitive disorders and psychiatric symptoms. Expanded polyglutamine repeats (> 35) in the N-terminal region of huntingtin (mHtt) lead to the neuropathology and symptoms in HD. It is well known that N-terminal region of mHtt is responsible for the gain-of-function and that loss of Htt can cause embryonic lethality in mice. However, how N-terminal region of mHtt contributes to the neuronal survival and pathology in HD remains to be elucidated. Also, current HD mouse models that express N-terminal mutant Htt were generated by expressing exogenous Htt via the transgenic approach. Adeno-associated virus (AAV) mediated delivery of CRISPR/Cas9 *in vivo* has been used to modify endogenous genes in adult neurons in the mouse brain, which would allow us to examine the effects of altered expression of endogenous mHtt. We used AAV-CRISPR/Cas9 to remove the exon1 of mutant Htt in HD 140Q KI mouse brains. We found that permanent suppression of the endogenous expression of mHtt via CRISPR/Cas9 in the striatum of HD140Q knock-in mice can effectively deplete Htt aggregates and early neuropathology. The reduction of Htt expression in striatal neuronal cells in the adult HD140Q KI mice does not affect their viability, but alleviates their motor deficits. These findings suggest that CRISPR/Cas9 can be used to efficiently remove N-terminal region of mHtt to mitigate the neuropathology and symptoms. To further address the role of N-terminal mHtt in the mouse brain, we have also performed injection of CRISPR/Cas9 into HD KI mice to generate new HD mice that express truncated Htt with an expanded polyQ repeat at the endogenous level. We will characterize these HD mice to examine their phenotypes that are caused by endogenous N-terminal mHtt.

**Abstract:** PPAR beta/delta is a Peroxisome Proliferator-Activated Receptor (PPARs) member of the nuclear receptor superfamily that can be activated by endogenous (fatty acids) or exogenous (thiazolidinediones and fibrates) ligands. From the three isoforms of PPARs (alpha, beta/delta and gamma), PPAR beta/delta is highly expressed in the CNS and their activation has been related to a neuroprotector effect. Our aim was to explore the PPARs-induced mechanism and to evaluate the therapeutic effect of PPAR beta/delta ligand preventing the damage into HD models, induced by quinolinic acid (QUIN, NMDAR agonist) and R6/1 transgenic, both in mice. (I)Male C57 black mice (25-30 g) were divided into 3 groups (n=12): 1. Vehicle-treated, administered with the striatal saline solution (SS). 2. Vehicle-treated, administered intrastriatal with QUIN to induce injury 3. L165041 (a PPAR-beta/delta selective ligand) (10 mg/kg), administered with striatal QUIN. Three days after injury, apomorphine was administered and circling behavior was evaluated. Oxidative stress was evaluated in striatum homogenate, 2 hours after QUIN injection, (reactive oxygen species and lipid peroxidation). (II) Mice R6/1 and Wild-type of 11 and 24 weeks were administrated icv a specific agonist L 165041 (120µg) and they were divided into 6 groups(n=8-10). 1. Wild Type-untreated, 2. HTT-untreated, 3.Wild Type-vehicle treated, 3. HTT-vehicle treated, 4. Wild Type-L 165041 treated, 5. HTT- L 165041 treated. Spontaneous activity and rotarod test were performed. Oxidative parameters were also measured. Our data in the QUIN-model shows that a pre-treatment with L165041 was able to reduce circling behavior and oxidative stress. Mice pre-treated recovered QUIN-induced lowered GABA levels, promoting a neuroprotector effect in QUIN-induced injured mice and exerting a higher antioxidant effect also in the transgenic model. These effects were reflected improving the response in the motor behavior to 24 weeks. In conclusion, our results suggest that the

stimulation of PPARbeta/delta by L165041 in experimental models could be a therapeutic resource to limit the progression of HD. Supported by Grant Conacyt 241911 to FPS.

**Title:** Striatal projection neuron pathology in heterozygous Q175 knock-in Huntington's disease mice

**Authors: *Y. DENG**, H. WANG, M. JONI, A. REINER
Univ. of Tennessee Hlth. Sci. Ctr., Memphis, TN

**Abstract:** Progressive basal ganglia neurodegeneration is a well-known feature of Huntington's disease (HD). The Q175 knock-in mouse is a slowly progressing HD model, but its basal ganglia pathology is not well characterized. Our previous studies have reported that in 18 month-old Q175 mice, although total striatal neuron numbers and striatal volumes were not significantly changed, significantly fewer striatal projection neurons were positive for DARPP32. As enkephalin (ENK) message in indirect pathway striatal projection neurons (iSPNs) was also significantly decreased, but substance P (SP) message in direct pathway striatal projection neurons (dSPNs) was unchanged, the DARPP32 perikaryal reduction appears to be preferential for ENK iSPNs. Consistent with this, we found reduction in DARPP32 in the striatal terminals in globus pallidus externus (GPe) but not in striatal terminals in globus pallidus internus (GPi) or substantia nigra pars reticulata (SNr). Despite the reduced ENK message and unaltered SP message in striatum, ENK was increased in striato-GPe terminals and SP was increased in striatal terminals in GPi and SN in 18 month-old Q175 mice. In the present study, we examined striatal projection neuron pathology in 6 and 12 month-old heterozygous Q175 mice. We found again that fewer striatal projection neurons immunolabeled for DARPP32 at 12 months, ENK message in iSPNs was significantly reduced, but SP message in dSPNs was not. Increased ENK+ striato-GPe terminals and SP+ striato- GPi and striato-SN terminals were also observed in both 6 and 12 month Q175 mice, reflecting either early occurring striatal neuron dysfunction or a

developmental abnormality. Of note, the DARPP32 reductions in striatal projection neurons and striato-GPe fibers, and the increased ENK+ and SP+ terminals in striatal target areas were all correlated with motor abnormalities such as reduced time on rotarod, and/or shorter distance traveled, slowed speed, and increased turning (a sign of chorea) in open field. Our results suggest that striatal projection neuron abnormalities are present early in Q175 knock-in mice

**Abstract:** Huntington's disease (HD) is a neurodegenerative disease caused by an autosomal dominant mutation resulting from a variable expansion of a CAG repeat encoding polyglutamine. It is an inherited disorder principally characterized by neuroinflammmation and neurodegeneration in the striatum. In this study, we used yeast artificial chromosome (YAC) mouse model of HD which expresses human huntington's gene containing 128 CAG repeats (YAC128). We have previously reported that TNF-α contributes to homeostatic plasticity and differentially regulates α-amino-3-hydroxy-5-methyl-4-isoxazolepropionic acid (AMPA) receptor trafficking. Here, we investigated whether TNF-α signaling altered striatal synaptic function in medium spiny neurons (MSNs) in HD mouse model. We performed whole-cell voltage-clamp recording on MSNs in acute dorsal striatal slices from adult (8-10 week old) mice. The strength of direct pathway cortico-striatal glutamatergic input was measured by targeting fluorescent dopamine D1 receptor (D1+) expressing neurons and recording the ratio of AMPAR to N-methyl-D-aspartate receptors (NMDAR) mediated excitatory post-synaptic currents (EPSCs) both in wild type and HD mice. We found YAC128 mice showed significantly higher AMPA/NMDA ratio, higher AMPA rectification and a substantial increase in the AMPA input-output curve, as compared with WT littermates. In contrast, no change in AMPA/NMDA ratio

was found in YAC128 on a TNF-α -/- background and was indistinguishable from TNF-α -/- alone. Pharmacological blockade of TNF-α signaling similarly restored normal AMPA/NMDA ratios on D1-MSNs. However, there were no significant changes in AMPA/NMDA ratios in dopamine D2 receptor expressing MSNs in any condition. Furthermore, while exogenous incubation of striatal slices with a moderate concentration (100ng/ml; 1-2hr) results in AMPAR endocytosis, we find that a high concentration of TNF-α (1mg/ml, 1-2 hr) significantly increased AMPA/NMDA ratio. This suggests that YAC128 mice have high endogenous levels of TNF-α. Collectively, our findings suggest that TNF-α regulates striatal synapses and alters corticostriatal glutamatergic inputs to MSNs during Huntington's disease.

**Title:** Microstructural alterations of corpus callosum in developing brains of macaques with Huntington's disease

**Authors: *Y. MENG**[1], J. BACHEVALIER[4,2], A. W. CHAN[5,3], X. ZHANG[1,3]
[1]Yerkes Imaging Ctr., [2]Div. of Developmental and Cognitive Neurosci., [3]Div. of Neuropharm. and Neurologic Dis., Yerkes Natl. Primate Res. Ctr., Atlanta, GA; [4]Dept. of Psychology, [5]Dept. of Human Genet., Emory Univ. Sch. of Med., Atlanta, GA

**Abstract:** It is poorly understood when corpus callosum (CC) changes emerge during development with Huntington's disease (HD). HD rhesus monkeys (male, n=3) were generated using lentiviral-mediated transgenesis (Yang et al., Nature, 2008) and four age-matched wild-type non-transgenic rhesus macaques (2 males and 2 females) were used as controls. Animals were anesthetized with 1.0% isoflurane mixed with 100% $O_2$. Diffusion tensor imaging (DTI) was conducted on a Siemens 3T Trio with parallel echo planar imaging (EPI) sequence with isotropic voxel size 1.3 mm and a single b-value of 1000 s/mm$^2$ with 30 gradient directions. $T_1$-weighted images acquired were used for structural identification and template construction. FA maps were nonlinearly registered to a population-specific template and then skeletonised with

TBSS toolbox (FMRIB, Oxford). FA in the skeleton was averaged for each of the seven CC segments (from CC1 to CC7: rostrum, genu, rostral body, anterior mid-body, posterior mid-body, isthmus, and splenium) (Witelson et al., Brain, 1989). A multivariate analysis of variance (MANOVA) was performed to examine group difference in FA of each CC segments with significant level 0.05. No significant group differences in FA were noted in any CC segments before 18 months ($p>0.2$) (Fig. 1). Group differences were shown in rostrum from 18 months ($p<0.02$) and in genu from 30 months ($p<0.05$). From 36 months, splenium began showing group differences. At 48 months, most CC segments of the HD monkeys ($p<0.05$) except anterior mid-body ($p=0.22$) had FA values significantly different from controls. Altered rostrum and genu connect inter-hemispheric prefrontal cortical areas, paralleling the impairment in motor planning skills reported previously in the same HD animals at 36 months (Chan et al., PLOS One, 2015). CC alterations were observed as early as at 18 months and became more severe with ages. They parallel the findings in patients with progressive HD stages (Rosas et al., Neuroimage, 2010). The results suggest that DTI may provide valuable early neural markers for the pre-diagnosis of HD.

**Title:** Measuring glutamate transmission in Huntington disease using iGluSnFr, an optogenetic probe

**Authors: *E. KOCH**, C. WOODARD, M. SEPERS, L. A. RAYMOND
Psychiatry, Univ. of British Columbia, Vancouver, BC, Canada

**Abstract:** Huntington disease (HD) is a progressive neurodegenerative disorder caused by an autosomal dominant genetic mutation, and characterized by motor dysfunction, psychiatric disturbances and cognitive deficits. Degeneration of striatal medium spiny neurons is a key feature of the disease, along with cortical atrophy. Glutamate is an important excitatory neurotransmitter and dysfunction in its signalling is associated with HD. The YAC128 transgenic mouse model of HD was previously demonstrated to exhibit increased glutamate release at 1 month of age and decreased release at 12 months, and glutamate receptor signalling is altered in HD. However, little is known about alterations in mechanisms or modulation of cortical glutamate release onto striatal neurons in HD. An optogenetic probe, the iGluSnFr, is a genetically-encoded reporter that allows for sensitive, real-time measurement of glutamate dynamics. We exposed brain slices to conditions that are known to decrease cortical-striatal glutamate release, including low calcium and pharmacological activation of autoreceptors. Our results showed that the iGluSnFr signal decreases under these conditions, verifying this probe as an accurate measure of glutamate release. We are now testing the effects of pharmacological manipulation of presynaptic receptors, particularly glutamatergic NMDA receptors and cannabinoid receptor type 1, on glutamate release at corticostriatal synapses in YAC128 HD and wild-type mouse brain slices. The iGluSnFr provides a new approach to measuring glutamate release that can help us understand HD pathology and contribute to the development of treatments.

**Abstract:** Huntington's disease is a neurodegenerative disorder of genetic etiology in which the basal ganglia suffers profound degeneration. Of late, the corticostriatal pathway has emerged as a key site of early disease-induced change. Previously we examined changes in the density of axonal terminals arising from several corticostriatal pathways, including primary and secondary motor cortex. This was accomplished by injections of anterograde axonal tracers into the cortex, followed by quantification of the axonal terminal fields in the caudoputamen, in 2, 6, and 12 month old zQ175 heterozygous male mice. We found selective alterations, with some pathways showing reductions in terminal density, others increases, and others no change. Yet in addition to the striatum, the cortex provides axonal input to other parts of the basal ganglia. We have therefore quantified axonal terminal densities arising from these injections and terminating in the subthalamic nucleus, i.e., the so-called hyperdirect pathway, a key component of the cortico-basal ganglia-thalamic circuit. An overview of the concerted changes in connectivity within this circuit will provide a roadmap illustrating the pathological and compensatory effects that occur in the progression of Huntington's disease.

**Abstract:** Parkinson's disease (PD) is a neurodegenerative disorder characterized by motor and non-motor symptoms, including, rigidity, difficulty of movement, and impaired with walking and gait. The main pathological feature of PD is the cell death of dopaminergic neurons located in the substantia nigra pars compacta (SNc) and substantial loss of dopamine (DA) and its

metabolites, and reduced dopamine active transport (DAT) activity. Imaging technologies have been used to monitor the progression of PD as well is supporting criteria for Parkinson's diagnosis. DA plays an important role in the mediation of movement, cognition and emotion. Loss of DA-containing neurons in striatum, results in a loss of DA transporters (DAT) in the presynaptic nerve terminals and hence the reduction of DAT density is inversely correlated with the severity of motor dysfunction. In this work we have used various imaging tools in mouse model of systemic administration of MPTP by using T2-MRI, 1H-MRS and PET imaging (DAT and glucose consumption). MPTP was administered intraperitoneally (i.p.) or subcutaneously (s.c.) at different doses (20 mg/kg) two times a day with 3h-interval on two consecutive days. On week 2 and 5 MPTP treated mice showed small but non-significant trend towards anatomical atrophy in various brain structures. In addition, on same time points MPTP mice showed significant changes in cellular metabolites in striatum when compared to vehicle treated mice. PET imaging of $^{18}$F-FE-P2I was performed on week 5, clear and significant decrease in DAT activity was seen in MPTP mice. Furthermore, and supporting the 1H-MRS findings we observed that glucose consumption by FDG-PET was significantly decreased at week 6 after the MPTP challenge when compared to healthy mice. Taken together, MPTP challenge creates a permanent and long term phenotype which can be evaluated by various imaging techniques, in addition to conventional biochemical and histological and immunohistochemical means.

**Title:** Identification of chemical compounds that interfere with Supt4h/Supt5h complex formation and suppress mutant HTT gene expression

**Authors: *Y.-Y. WU**[1,2]
[1]Natl. Yang-Ming Univ. / Molecule Med., Taipei, Taiwan; [2]Inst. of Biochem. and Mol. Biol., Taipei, Taiwan

**Abstract:** Huntington's disease (HD) is an autosomal dominant neurodegenerative disorder resulting from expression of mutant huntingtin (*HTT*) allele that carries an expanded CAG tri-nucleotide repeat in the exon 1 of coding sequence. HD afflicted individuals suffer from progressive motor, cognitive, and psychiatric impairments, and usually die 10 to 15 years after the onset of disease. Lowering the level of toxic mutant HTT alleviates the behavior symptoms and pathological features of HD. However, since normal HTT is required for neuronal

development and functions, it is desirable to develop a therapeutic intervention that preferentially suppresses mutant HTT for countermeasures against HD.
Supt4h and Supt5h form a protein complex that aids RNA polymerase II moving persistently along the chromatin template during transcription elongation. Our earlier studies demonstrated that interference of Supt4h/Supt5h complex formation by lowering Supt4h results in a substantial decrease of transcript production from mutant HTT allele while having a marginal effect on the wild-type allele. Moreover, the motor function deficits and lifespan shortening of HD mice are ameliorated by genetic knockout of Supt4h, suggesting targeting Supt4h or Supt4h/Supt5h complex formation is a feasible approach to suppress mutant HTT and likely against HD.
Here, we employ bimolecular fluorescence complementation assay to design a novel screening system that enables us to identify reagents preventing the formation of Supt4h/Supt5h protein complex. We have identified and validated multiple hits with the capability of lowering mutant HTT expression in mouse striatal neural cells or lymphoblastoid cells derived from HD patients. These chemical compounds also show a rescue effect on rough eye and declined eclosion rate that are caused by expression of mutant HTT in Drosophila HD models, supportive of their potential use in HD.

**Abstract:** Complex cognitive deficits significantly affect the daily lives of people living with Huntington’s disease (HD) even before the characteristic motor symptoms of the disease emerge. In HD mutation carriers, the prevalence and severity of cognitive symptoms increases with age; however, few studies have examined the time course of these deficits in mouse models of the disorder. Our research examines cognitive function in the $Htt^{Q111/+}$ knock-in mouse model (n=17) and wildtype mice (n=14) at 9 months and 18 months of age. Cognitive function was assessed using a 5-choice serial reaction time task (5-CSRTT) in which mice were trained to perform a

nosepoke response to a brief, random illumination of one of five apertures. Correct responses were rewarded with delivery of a food pellet. Our findings indicate that there is a greater age-related decline in cognitive function in $Htt^{Q111/+}$ than wildtype mice. For example, performance deficits in $Htt^{Q111/+}$ mice in the 5-CSRTT under baseline conditions [1.6 s stimulus duration (SD)] were most apparent at 18 months. At 9 months, $Htt^{Q111/+}$ accuracy was ~5% lower and omissions were ~8% higher than that of age-matched wildtype mice ($Htt^{Q111/+}$: 85±1 & 27±3; wildtype: 89±1 & 25±4; all data are presented as mean percent accuracy or omissions ± SEM). When the mice were retested at 18 months, $Htt^{Q111/+}$ accuracy was ~10% lower and omissions were ~25% higher than that of wildtype ($Htt^{Q111/+}$: 77±3 & 39±4; wildtype: 85±2 & 31±4). Correct response latency was ~25% longer in $Htt^{Q111/+}$ mice than wildtype mice at both 9 and 18 months of age (9 months: 1.5±0.1 & 1.2±0.1 sec; 18 months: 1.4±0.1 & 1.1±0.1 sec). We examined whether increasing cognitive demand exacerbated performance deficits in $Htt^{Q111/+}$ mice by testing under conditions of reduced SD, variable intertrial intervals, and reduced stimulus intensity. Again, performance deficits in $Htt^{Q111/+}$ mice were most apparent at 18 months. When mice were tested at 9 months of age under reduced SD (0.4, 0.8, 1.2, & 1.6 sec), $Htt^{Q111/+}$ accuracy was ~2% lower and omissions were ~12% higher than that of wildtype mice ($Htt^{Q111/+}$: 80±2 & 36±3; wildtype: 81±3 & 32±4). When the mice were retested at 18 months, $Htt^{Q111/+}$accuracy was ~15% lower and omissions were ~28% higher than that of wildtype ($Htt^{Q111/+}$: 68±3 & 46±4; wildtype: 80±4 & 36±5 omissions). Our results suggest that, like human HD mutation carriers, $Htt^{Q111/+}$ mice experience progressive impairments in attention and impulsivity. Results of the present study differ from those of a recent publication in which Yhnell and colleagues reported that cognitive deficits in the $Htt^{Q111/+}$ mouse model of HD are not progressive [PLoS ONE. 2016, 11(10):e0164072].

**Abstract:** Huntington's disease (HD) is a neurodegenerative disorder caused by a mutation in the gene encoding the Huntingtin protein (HTT) resulting in a poly-glutamate (polyQ) expansion at the N-terminus of the protein. Due to this increased number of glutamate repeats (> 36) the HTT protein becomes unstable and neurotoxic. We optimized the conditions for *in vivo* microdialysis and sample collection to enable quantitation of polyQ HTT in striatal extracellular fluid (ECF) of Q175 mice. All samples were analysed by Charles River (the Netherlands). We found that polyQ HTT levels in the Q175 mice were increasing with age and that levels in homozygotes were higher than in age-matched heterozygotes, indicating increased levels of polyQ HTT aggregation in these mice. Additionally, we compared of the levels in striatal ECF, CSF and brain tissue, which showed that the polyQ HTT levels in ECF have a correlation with the disease progress, while levels in CSF and brain tissue show an inverse correlation.

MUNOZ-SANJUAN[3] [1]Discovery, Charles River, Leiden, Netherlands; [2]Discovery, Charles River, Saffron Walden, United Kingdom; [3]CHDI Fndn., Los Angeles, CA

**Abstract:** Huntington's disease (HD) is a severe neurodegenerative disorder characterized by motor, cognitive and psychiatric effects. HD is an autosomal dominant, inherited disease that is caused by an unstable trinucleotide repeat expansion (CAG repeats) in the *huntingtin (HTT)* gene. To better understand HD pathogenesis in a relevant cellular context, we developed a primary neuronal cortico-striatal co-culture platform derived from one of well-characterized

knock-in models, zQ175, further engineered to remove a neomycin cassette for genomic integrity. In particular, a robust HTT quantification assay was established in the co-cultures to study the effect of candidate therapeutics on endogenous soluble HTT levels. First, Homogeneous Time Resolved Fluorescence (HTRF) genotyping was performed, allowing for rapid and reliable identification of the knock-in mice in mixed genotype litters. Cortical and striatal neurons were harvested and subsequently subjected to electroporation separately with different fluorescent-tagged reporters and plating on top of a rat astrocyte feeder layer. Different treatment set-ups related to compound addition and readout time points were tested to obtain the most optimal assay set-up. Soluble mutant HTT levels were quantified using a Meso Scale Discovery (MSD) platform. Cell survival and toxicity were measured using high content assays for different reporters and viability. Treatments using previously characterized reference compounds showed that the best window of lowering soluble HTT over toxicity occurred at the later time points. Our results demonstrate that primary neuronal cortico-striatal co-cultures derived from the knock-in mice can be utilized as a robust model system, in particular, for the study of different candidate therapeutics for HTT lowering. In order to further develop physiologically relevant primary neuronal co-cultures, current efforts are focused on assessing the survival of the co-cultured cells using a mouse astrocyte feeder layer. Moreover, additional MSD assays for the quantification of total and mutant Htt levels, *e.g.* in an aggregated form, are also under development.

**Title:** Calcium regulation of dorsal root ganglion neurons after peripheral nerve injury

**Authors: *M. WALTERS**, D. R. LADLE, M. J. SONNER
Neuroscience, Cell Biol. and Physiol., Wright State Univ., Dayton, OH

**Abstract:** Peripheral nerve injuries (PNIs) occur when a nerve is damaged often as a result of motor vehicle accidents, falls, sport events, and other types of movement-related traumas. The failure to effectively treat PNIs means patients are often left with disability, neuropathic pain, social and economic hardships, and a decreased quality of life. Full functional recovery is dependent on the recovery of spinal reflexes whose feedback fine-tunes our movements. After PNI, reflexes remain abnormal, limiting motor coordination and functional improvement. The goal of this study is to better characterize the mechanisms responsible for these reflex-abnormalities with hopes that this knowledge will translate to better outcomes for patients who have suffered PNIs. Research has shown that neurons of the peripheral nervous system, whose cell bodies reside in dorsal root ganglia (DRGs), become hyperexcitable after injury due to changes in calcium and potassium currents. However, the majority of these studies have been *in vitro* , limiting their applicability to living animals. By employing less invasive methods than previous studies via calcium imaging, we are able to examine the functional properties of DRG neurons in an intact reflex system, using an *ex vivo* preparation of an adult animal. This study utilizes transgenic mice in which proprioceptive neurons express a fluorescent marker of neuronal activity (GCaMP6s). Calcium plays an essential role in neurons as it is responsible for regulating metabolic activity through activation of receptors, channels, and second messenger pathways. Therefore, determining the calcium signature of neurons in response to physiologically relevant stimuli provides an indirect means of assessing the function and activity of a cell . The functional properties of DRG neurons will be explored via calcium imaging at three time points after sciatic crush injury: during inflammation at 48 hours, during regeneration at two weeks, and after regeneration is complete at three months. Comparing the calcium signatures of animals that underwent surgery to sham-surgery controls at these key time points will reveal how calcium metabolism changes over the course of regeneration to achieve a final, hyperexcitable state in DRG neurons. These experiments will test the hypothesis that abnormal calcium regulation contributes to spinal reflex dysfunction after PNI and regeneration. This central hypothesis puts forth a novel mechanism to explain why spinal reflexes fail to recover after nerve injury. Identifying the mechanism underlying reflex failures will be beneficial in providing direction for research targeted at treatment.

**Abstract:** Frontotemporal lobar degeneration (FTLD) is a leading cause of dementia, similar in prevalence to Alzheimer's disease in patients younger than 65. FTLD has heterogeneous clinical features of dementia that encompass progressive behavioral, language, and motor dysfunctions. FTLD also typically involves specific protein abnormalities in the brain, or proteinopathies. The main two proteinopathies that characterize FTLD entail the accumulation of either TAU or TDP-43 proteins. These proteinopathies have different progressions and patterns of degeneration in the brain and thus are ideally associated with different courses of treatment. In many cases, however, such tailored treatments cannot be used because these proteinopathies can often only be distinguished from each other post mortem, at autopsy. One striking finding from these post-mortem studies is that FTLD-Tau involves severe neurodegeneration in the brainstem nucleus locus coeruleus (LC), whereas FTLD-TDP involves mild LC deficits that occur only in advanced-stage cases. The goal of this study is to investigate if and how indirect measures of LC activation, including changes in pupil diameter and certain event-related potentials (ERPs) can be used to assess LC function in FTLD patients and potentially as a biomarker to distinguish FTLD-TAU from FTLD-TDP.
We are using three complementary approaches. First, we are extending ongoing studies in awake monkeys of relationships between spiking activity of individual LC neurons and pupil diameter to include ERP measurements (including the P3 response and spectral components), which show LC-related modulations under both passive conditions and in response to surprising sounds. Second, we are testing how pupil diameter and ERPs are modulated under a broad range of conditions in healthy young human subjects, to establish a baseline for measurements in FTLD patients. In particular, we are using an auditory oddball task in which preliminary data indicate that manipulations of motor responses, distractors, and the discriminability of the oddball and standard stimuli all have different effects on these indirect measures of LC function. Third, we will use the task conditions and physiological measurements that we develop in the monkey and healthy human studies to develop effective, non-invasive approaches to assess LC function in healthy and FTLD-afflicted older adults. This study thus may culminate in a novel, non-invasive method to providing ante mortem diagnosis of FTLD-Tau to improve clinical trials.

**Title:** Transmission of scrapie into sheep after passage through white-tailed deer results in a phenotype change

**Authors: *R. KOKEMULLER**[1], S. J. MOORE[2], M. H. W. GREENLEE[1], J. J. GREENLEE[2]
[1]Biomed. Sci., Iowa State Univ., Des Moines, IA; [2]United States Dept. of Agr., Ames, IA

**Abstract:** Transmissible spongiform encephalopathies (TSE's) are neurodegenerative diseases that result in misfolding of the prion protein from the normal cellular form ($PrP^{C}$) to the diseased form ($PrP^{Sc}$). TSE's affect sheep (scrapie), deer (chronic wasting disease; CWD), cattle (bovine spongiform encephalopathy), and humans (Creutzfeldt-Jakob disease). TSE agents can have strain variations that influence disease phenotype (eg. incubation time, location of $PrP^{Sc}$ deposition, etc.) and may affect susceptibility in animals with different prion protein gene (*PRNP*) sequences. Susceptibility of sheep to disease is associated with 3 specific polymorphisms in *PRNP*; 136 valine (V), 154 arginine (R), and 171 glutamine (Q) (VRQ). Sheep resistant to scrapie are known to have the genotype 136 alanine (A), 154 histidine (H), and 171 arginine (R) (AHR). The most influential codon being 171 where QQ171 is susceptible and RR171 is resistant. Inter-species transmission of TSE's causes genetic and phenotypic variability, which may affect sampling and eradication of prion-infected animals. Since deer and sheep may use the same grazing land, it is important to understand the potential transmission of TSEs between these species. The US scrapie isolate (No.13-7) has a 100% attack rate in white-tailed deer (WTD) after oronasal challenge. The purpose of this study was to determine if sheep are susceptible to oronasal challenge with the scrapie agent from WTD. Suffolk lambs of *PRNP* genotype $VV_{136}RR_{154}QQ_{171}$, $AA_{136}RR_{154}QQ_{171}$, and $AV_{136}RR_{154}QQ_{171}$ were challenged by the oronasal route with a 10% brain homogenate from scrapie-affected WTD. Upon development of clinical signs, sheep were euthanized and necropsied. Tissues were tested for $PrP^{Sc}$ by enzyme immunoassay (EIA), western blot (WB), and immunohistochemistry (IHC). The first sheep to develop clinical signs at approximately 29 MPI had the VRQ/VRQ genotype. Sheep of the ARQ/ARQ genotype also developed clinical signs, but at a mean of 52 MPI. This is in contrast to the original No.13-7 inoculum that has a faster incubation period in sheep with the ARQ/ARQ genotype (20 MPI). This work is intriguing because the original No. 13-7 scrapie isolate had a faster incubation time in ARQ/ARQ sheep, but after being passaged through deer, the incubation time was much shorter in VRQ/VRQ sheep indicating a phenotype change. This is significant because it raises the concern that scrapie infected deer could transmit disease to sheep and potentially promote the propagation of a new strain of scrapie.

**Title:** Wallerian degeneration: Is it regulated by NAD, NMN or both?

**Authors: *M. P. COLEMAN**[1], A. LORETO[1], M. DI STEFANO[3], C. ANGELETTI[4], J. GILLEY[1], C. HUNG[2], N. RAFFAELLI[4], G. ORSOMANDO[4], L. CONFORTI[5]
[1]Dept of Clin. Neurosciences, [2]Gurdon Inst., Univ. of Cambridge, Cambridge, United Kingdom; [3]Univ. Col. London, London, United Kingdom; [4]Polytechnic Univ. of Marche, Ancona, Italy; [5]Univ. of Nottingham, Nottingham, United Kingdom

**Abstract:** The degeneration of transected axons (Wallerian degeneration) can be slowed tenfold by overexpression of a variety of NAD-synthesizing enzymes, such as isoforms of NMNAT or the related mutant fusion protein, $WLD^S$. Wallerian degeneration is also delayed by deletion of TLR adapter protein SARM1, a protein recently reported to promote NAD degradation. It is important to understand fully the mechanism of Wallerian degeneration because related mechanisms contribute to axon loss in a number of disease models, including models of peripheral neuropathies, Parkinson's disease, multiple sclerosis and glaucoma. We will also present new data implicating a role in hereditary spastic paraplegia.
While depletion of NAD is an attractive hypothesis for the mechanism of Wallerian degeneration, especially as NAD can be increased by dietary methods, it cannot explain a number of key observations. FK866, an inhibitor of NAMPT, blocks the NAD salvage pathway and strongly depletes NAD, including within axons. However, instead of killing axons as the NAD hypothesis would predict, it does precisely the opposite: it phenocopies the protective effect of $WLD^S$. Moreover, ectopic expression of the bacterial enzyme NMN deamidase, a protein absent in mammals, protects injured axons both in transgenic mice and in primary neuronal cultures, but it has no effect on NAD levels either under basal conditions or in degenerating nerves. These observations fit better with a proposed toxic role for the NAD synthesis intermediate NMN, a model that can also explain the protective effect of $WLD^S$. This poster will discuss the strengths and limitations of each hypothesis, including new data, and explore models to explain the changes in both NMN and NAD.

**Title:** Structural plasticity in rat cortical neuron induced by Pentacalia nitida

**Authors:** ***S. L. ALBARRACIN**, D. M. RAMIREZ, R. VERA, J. J. SUTACHAN
Pontificia Univ. Javeriana, Bogota. D.C., Colombia

**Abstract:** Processes of formation, growth and branching of the dendritic tree are fundamental in learning and memory. In addition, it has been found that a reduction in the complexity of the dendritic tree is a common feature share by neurodegenerative diseases, suggesting that the maintenance of the dendritic arborization is critical for the normal function of the nervous system. Therefore, the search for molecules that can modulate structural plasticity in these diseases has recently gain interest, especially for those non-traditional molecules derived from medicinal plants. *Pentacalia nitida* is a plant of the asteraceae family that is commonly used for the regulation of signaling pathways that regulate inflammation. Although, the prospective use of this plant, there are not studies evaluating the potential of *Pentacalia nitida* extracts in regulating structural plasticity in neurons. In the present work, extracts from leaves of *Pentacalia nitida* were obtained by hydro-alcoholic solution and by a solid-liquid phase using solvents with different polarities and evaluated for their capacity to regulate the dendritic branching of rat cortical neurons *in vitro*. Toxicity assays showed that the methanol extract did not affect the viability of cortical neurons. In addition, methanol extracts at concentrations of 25 µM and 2.5 µM increased the complexity of the dendritic tree and the levels of MAP2. These effects were inhibited by the use of the LY294002 y PD98059 inhibitors, suggesting that extracts achieves its stimulatory effect by regulating the $PI_3$ and MAP kinase pathways. The obtained results suggest that *Pentacalia nítida* have molecules that can regulate the neuronal dendritic tree and may have therapeutic potential.

**Title:** Thalamic proteome changes and behavioral impairments in thiamine deficient rats

**Authors: *A. M. RIBEIRO**, P. T. NUNES, D. P. GOMEZ-MENDOZA, C. P. REZENDE, H. C. P. FIGUEIREDO
Univ. Federal De Minas Gerais, Belo Horizonte, Brazil

**Abstract:** Thiamine deficiency (TD) has been used as an experimental model in rodents to study the molecular mechanisms of neurodegeneration process. The aims of the present study were to investigate: (i) the spatial cognitive performance of pyrithiamine-induced thiamine deficiency (PTD) in adult rats using the Morris Water Maze task (MWM) and (ii) the thalamic proteome alterations occurred by a TD episode, using a combination of liquid chromatograph with mass spectrometry (LC-MS/MS) analysis. After the onset of the last neurological signs, the TD was interrupted and after two weeks of recovery, spatial cognitive tasks in MWM were performed. One day after the behavioral test, the animals were killed and the thalami were dissected. The PTD rats exhibited deficits during the learning process, which was reverted by repeated training. The neuroproteomic analysis, using label-free quantification, revealed deregulation of 183 proteins, among the 1440 detected by LC-MS/MS. From the 183 proteins, 153 and 30 were down and up-regulated, respectively. Using bioinformatics tools, the deregulated proteins were categorized according to the Gene Ontology **(**GO) functional annotation and metabolic pathways. TD affects proteins involved in different biological processes, such as oxidative stress, neuroplasticity and neurotransmission release, including several proteins involved in the synaptic vesicle cycle function, such as complexin 2, dynamin 3, AP2 adaptor complex, V-ATPase. In addition, one of the proteins up-regulated by TD is the leucine-rich repeat kinase 2 (gene: Lrrk2 - accession: F1LNJ1-LRRK2), that is also involved with synaptic processes. Mutations in this protein have been found in hereditary and sporadic form of Parkinson’s Disease pathogenesis. One important conclusion from these data is that not only thiamine-dependent enzymes are affected by TD, indicating that thiamine and its phosphate forms might have relevant roles in central nervous system distinct from those well-known co-enzymatic functions. The observed deregulation of antioxidant thalamic proteins and anti-inflammatory cytokines represents a disruption of inflammatory response induced by TD. In addition, proteins that are components of different metabolic pathways, such as fatty acid and glycolysis were deregulated in thalamus of

the PTD rats. Some of these targets are indirectly involved in the glutamate and GABA syntheses. Finally, the present data highlight some relevant molecular targets for future studies focusing on neurodegenerative process and/or on the neurobiological mechanisms related to the spatial cognitive deficits induced by TD.

**Abstract:** Our lab recently reported that the A1R agonist $N^6$cyclopentyladenosine (CPA) or focal cortical ischemia caused hippocampal neurodegeneration, which was prevented by A1R antagonist dipropylcyclopentylxanthine (DPCPX). We hypothesized that aging-related elevation of adenosine leads to changes in adenosine receptors and increased neurodegeneration in Parkinson's disease (PD). The anti-diabetic drug metformin has also been reported to slow the progression of PD. Therefore, we determined whether metformin exhibits its neuroprotective effect by altering the adenosine signalling pathways. Male Sprague-Dawley rats received intraperitoneal injections of CPA (3mg/kg, daily for 7 days) or vehicle control, and some rats also received metformin 30min prior to CPA. Rats treated with metformin for 7 days showed a dose-dependent reduction in the CPA-induced hippocampal neurodegeneration (5 and 10 mg/kg metformin prevented, but 2 mg/kg metformin did not) as shown by propidium iodide uptake and increased FluoroJadeB staining. Consistent with hippocampal neuronal loss, CPA caused significant hippocampal-dependent learning and memory deficits (Y-maze test), increased depressive behaviour (by forced swim test) as well as enhanced anxiety behaviour (by open field

test). Metformin at 10mg/kg improved all behavioural deficits. Electrophysiological fEPSP recordings from acute 400μm hippocampal slices revealed that 1-30μM metformin increased baseline synaptic transmission, which was accompanied by increased paired pulse depression. Metformin (5μM) reduced the synaptic depression produced by CPA (100nM). Taken together, metformin protects hippocampal neuronal damage and learning deficits by preventing the adenosine A1 receptor-mediated neurotoxicity enhancing signalling pathways.

**Title:** Role of CAMKK2-AMPK stress response pathway in chemotherapy induced peripheral neuropathy

**Authors: *A. SAHASRABUDHE**[1], F. BARTOLINI[2], F. POLLEUX[1]
[1]Neurosci., [2]Columbia Univ., New York, NY

**Abstract:** Chemotherapy Induced Peripheral Neuropathy (CIPN) is a serious side effect of many drugs using for chemotherapy including paclitaxel-based (Taxol) cancer treatments and is frequently the main reason for reduction or discontinuation of the therapytreatment. General clinical signs of CIPN involve numbness, paresthesia, dysesthaesia and tingling often aggravated by neuropathic pain. The supposed pathogenesis of CIPN is thought to be the onset of axonopathy through dying back axonal damage, however the exact molecular events underying these cellular damages are largely unknown. We recently identified the CAMKK2-AMPK kinase pathway as a critical stress response pathway in early stages of neurodegenerative conditions such as Alzheimer's disease (Mairet-Coello et al. *Neuron* 2013). We decided to explore if this pathway is involved in CIPN.
Using cultured adult Dorsal Root Ganglia (DRG) neurons, we show found that there is a marked upregulation of AMPK phosphorylation upon taxol treatment. This upregulation over-activation is transient, lasting for about 12 hours followed by a steep decrease in the pAMPK levels and subsequent increased mTOR activation up to 72 hours. Morphological analysis of DRG axons in culture at 72 hours post- taxol treatment leads to formation of retraction bulbs at the tip of the axons, morphologiically mimicking the dying back mechanism of the axon described for CIPN.

Genetic analysis using AMPK$^{-/-}$ DRG neurons showed that the axon morphology defects described above can be significantly reversed prevented using AMPK-null mouse DRG neurons to an extent suggesting a role for AMPK in the process of axon fragmentation degeneration up induced on by taxol treatment. To delineate identify the upstream regulators of AMPK, we used LKB1-null$^{-/-}$ neurons and or an pharmacological inhibitionor for CAMKK2 (STO609). While CAMKK2 inhibition partially reversed the axon phenotypes described above to an extent, removal genetic ablation of LKB1 did not have any effect on the formation of retraction bulbs. Our preliminary results are suggestivesupport of a role for $Ca^{2+}$-CAMKK2-AMPK pathway in the process of taxol CIPN and in particular taxol-mediated induced axonal damagedegeneration. Following up on these lines weWe are currently testing the activation of calpainsif Calpain activation is a downstream target of taxol-induced CAMKK2-AMPK overactivation and also determining the source of $Ca^{2+}$ that might leads to the activation of CAMKK2.

**Abstract:** Ischemic tolerance is an endogenous cytoprotection mechanism that allows a cell, previously exposed to a sub-lethal ischemic event, survive a lethal one. In the heart it has been shown that a series of brief ischemia/reperfusion cycles limit the extent of the cardiac infarct generated in a subsequent prolonged ischemic event. The experimental protocols of ischemia/reperfusion, designed to activate ischemic tolerance, are termed ischemic preconditioning (IPC) and although in the last decades the understanding of the cellular mechanisms involved in this cytoprotection in the heart has increased, there is still a lot to learn

about ischemic tolerance in other organs, like the brain. Evidence about the participation of the post-translational protein modification of O-GlcNAcylation in cytoprotective mechanisms has been increasing in different tissues. O-GlcNAcylation is a dynamic and ubiquitous protein modification much like phosphorylation and, for many proteins, it has been demonstrated that phosphorylation and O-GlcNAcylation are reciprocal modifications that regulate protein function. In multiple forms of cellular stress, including ischemic stress, an acute increase of O-GlcNAc levels on proteins is an endogenous response to the stress and strategies that augment O-GlcNAcylation have been shown to be pro-survival. Here we evaluate a protocol of IPC as a protective strategy against cerebral ischemic injury in the rat Middle Cerebral Artery Occlusion (MCAO) model. We have found that the IPC protocol reduces the size of the infarct and increases the level of protein O-GlcNAcylation suggesting a possible participation of this protein modification in the neuroprotection generated. We have also investigated how IPC affects the expression of a protein kinase known as Akt or PKB which is a crucial component of cellular survival pathways that can block apoptosis. Our results indicate that the IPC protocol generates a significant increase in Akt phosphorylation at residues necessary for the kinase activity, providing additional insight into the probable cellular pathways involved in the cytoprotection elicited by ischemic preconditioning in the brain.

**Title:** Multiple target of hAmylin on rat primary hippocampal neurons

**Authors: *W. ZHANG**
Insitute of Chinese Integrative Medicine, Hebei Med. Univ., Hebei, China

**Abstract:** Alzheimer’s disease (AD) and type II diabetes mellitus (DM2) are the most common aging-related diseases, characterized by β-amyloid and amylin accumulation, respectively. Multiple studies have indicated a strong correlation between these two diseases. Amylin oligomerization in the brain appears to be a novel risk factor for developing AD. Although amylin aggregation has been shown to induce cytotoxicity in the neurons via altering $Ca^{2+}$ homeostasis, the underlying mechanisms have not been fully explored. Here, we investigated the effects of amylin on the rat hippocampal neurons using calcium imaging and whole-cell patch

clamp recordings.. We showed that $Ca^{2+}$response induced by low concentration of hAmylin was abolished by Amylin receptor antagonist AC187. However $Ca^{2+}$response induced by higher concentration of human amylin (hAmylin) was independent with amylin receptor. This effect relied on extracellular $Ca^{2+}$. Additionally, blockade of L-type $Ca^{2+}$ channels partially reduced hAmylin-induced $Ca^{2+}$ response. In whole-cell recordings, hAmylin depolarized membrane potential. Moreover, application of transient receptor potential (TRP) channel antagonist ruthenium red (RR) attenuated hAmylin-induced $Ca^{2+}$ increase. Single-cell RT-PCR showed that transient receptor potential vanilloid 4 (TRPV4) mRNA expressed in most of hAmylin-responsive neurons. Meanwhile, selective knockdown TRPV4 channel inhibited hAmylin-evoked $Ca^{2+}$ response. These results indicated that different concentration of human amylin (hAmylin) act via different pathways. Amylin receptor mediates the excitatory effects of low concentration of hAmylin. While for the high concentration of hAmylin, hAmylin aggregation precipitated on the neuron membrane activated TRPV4 channels and then triggered membrane voltage-gated calcium channel opening followed by membrane depolarization. Hence, out data suggest that TRPV4 is a key molecular mediator for the cytotoxic effect of hAmylin on hippocampal neurons.

**Abstract:** *Neuroscience: Neurotoxicology*
Combinational toxicity is the aggregate effect of multiple environmental contaminants, including metals, insecticides, and pesticides, on living systems. Many recent studies have demonstrated that metals cause degeneration of the central nervous system, however, the mechanisms underlying toxicity resulting from the effect of multiple metal types, or metals in conjunction

with other classes of environmental contaminants, has yet to be identified. The purpose of this study is to understand the threat of combinational toxicity, in addition to identifying the molecular basis of neurotoxicity as a result of cross exposure to two environmental contaminants, Lead (Pb) and Tellurium (Te). We hypothesized that Te would exacerbate Pb induced neurotoxicity. To test this hypothesis, we 1) quantified the production of reactive oxidative species (ROS) in differentiated human neuroblastoma (SH-SY5Y) cells after exposure to Pb and Te, 2) assessed the effects of Pb and Te on mitochondrial function/cell viability, and 3) determined the presence of cell death cascades through immunohistochemistry assays using cleaved caspase-3 antibody. The results show that Pb significantly increased ROS levels after 24 hours; Te also increased ROS levels after this time period. Pb at 1uM and 10 uM significantly decreased mitochondrial function/cell viability after 48hrs. The reduction in mitochondrial function/cell viability was associated with increased labeling of caspase-3 in SH-SY5Y cells, further demonstrating the cytotoxic effects of Pb. In addition, 10 uM Te caused labeling of caspase-3 in SH-SY5Y cells, suggesting that this dose caused injury/cytotoxicity. Combined effects on mitochondrial functioning/cell viability and caspase-3 labeling was also assessed. Taken together, the findings from the present study suggest that the presence of trace elements such as Te may exacerbate Pb induced neurotoxicity.

**Title:** Methamphetamine produces deficits in egocentric and allocentric learning and memory and in brain monoamines after a single dose in rats

**Authors: *A. GUTIERREZ**[1], M. T. WILLIAMS[2], C. V. VORHEES[3]
[1]Neurosci. Grad. Program, Cincinnati Children's Hosp. Med. Ctr., Cincinnati, OH; [2]Div. Neurol (MLC 7044), Cincinnati Children's Res. Found, Cincinnati, OH; [3]Div. of Neurol., Cincinnati Children's Hosp & Univ. of Cincinnati, Cincinnati, OH

**Abstract:** Chronic methamphetamine (MA) abuse results in long-term problems in cognitive function, including in working, declarative, and procedural memory. Neurochemical alterations include depletion of dopamine and serotonin in the striatum (STR) and hippocampus (HIPP). Rodent models produce similar neurochemical alterations, and we demonstrated that a 4 x 10 mg/kg MA regimen at 2 h intervals produced deficits in egocentric learning and memory in the

Cincinnati Water Maze (CWM) and in allocentric spatial learning and memory in a large Morris water maze (MWM). The purpose of the present study was to examine the effects of a single 40 mg/kg MA dose on egocentric and allocentric learning and memory rather than multiple distributed doses. We were also interested in differences in navigational strategy after MA, therefore, we assessed navigational preference using an 8-arm Star water maze (SWM). Monoamines were assessed by high performance liquid chromatography with electrochemical detection in STR, nucleus accumbens (NAcc), and HIPP, regions important for the aforementioned navigational strategies in naïve and behaviorally tested rats. Beginning 2 weeks after MA, Sprague-Dawley rats were tested in the CWM for 18 days, 2 trials/day, in the SWM for 20 days, 2 trials/day with a probe trial every 5 days, and finally in 3 phases of the MWM (acquisition, reversal, and shift) with 6 platform days and one probe trial on day 7. In the CWM, MA-treated rats were impaired for latency and errors. In the SWM, a preference for egocentric navigation was seen in saline-treated rats while MA-treated rats had no preference in the day 5 probe. In the MWM, impairments in the MA-treated rats were seen on acquisition and shift but not on reversal, although there was an effect on the reversal probe trial. Dopamine and serotonin levels in the STR were reduced in MA-treated rats 2 weeks post-treatment in groups of behaviorally untested animals and at the end of behavioral testing compared with controls. Monoamines in the NAcc and HIPP are being analyzed. The data show that deficits in both types of navigation are induced by MA, and MA reduces the inherent egocentric preference when rats can choose a strategy to use. MA-induced monoamine depletions in the STR persisted and showed no recovery even after behavioral testing. These findings provide a simpler, 1 dose model for further examination of interventions that may permit determination of the neurochemical effects that are critical for the induction of MA-associated cognitive deficits.

**Title:** Investigation of the autophagic process in the hippocampal neurons response to anhydroecgonine methyl ester exposure, a cocaine pyrolysis product

**Authors: *S. D. PRATES**
Dep Clin. and Toxicological Analysis, Univ. of São Paulo, São Paulo, Brazil

**Abstract: Background**: Cocaine is worldwide used as a recreational drug and can be found as hydrochloride form (taken by intranasal aspiration) and as cocaine freebase (crack cocaine) that is smoked. Crack is a thermo stable substance that vaporizes at temperatures above 93°C and 50-80% of cocaine is converted into
anhydroecgonine methyl ester (AEME) during the heat, which is inhaled with volatilized cocaine. There are evidences that cocaine can induce necrosis and/or apoptosis at several encephalic areas, however little is known about the mechanism underlying AEME neurotoxicity. Previous studies of our lab described that AEME is a neurotoxic compound with an additive effect when associated with cocaine after 24h of exposure and the mechanism of its neurotoxicity may involve apoptosis. **Aims**: To investigate the autophagic process involvement of cocaine (C), AEME (A) and the association of both substances (CA) in a primary hippocampus culture. **Methods**: Primary hippocampus neurons (E18) were exposed to 2 mM of C, 1 mM of A and 2 mMC+1 mM A (CA) for 3, 6 or 12h. For the flow cytometry analysis (Accure BD) it was used $5x10^5$ cells and after the exposure, the supernatant was discarded and was incubated with acridine orange (1µg/mL) during 15min. Then, the cells were washed once with PBS and collected by tripsinazation. We analyzed green versus red fluorescence and considerate the percentage of double marked cells. For LC3 evaluation by Western blotting, we used 40 µg of total protein in a 17% acrylamide gel and a PVDF membrane. **Results and conclusion**: At 3h (n=12) we observed an increase in the percentage of cells with acid vesicles when exposed to A ($p<0.05$) and CA ($p<0.01$) compared to the control group. C group showed lower acid vesicles when compared to A and CA (both $p<0.001$). No statistical differences were observed in 6h (n=5). After 12h (n=12) of exposure, only A showed more cells with acid vesicle than C group ($p<0.05$). Western blotting analysis showed at 3h that all treatment presented LC3 I and II fraction, but LC3 II was more evident at CA group.
At 6h and 12h, LC3 II was more evident at C group. Our results show that 3h is a critical point for neurons protective response to A and CA, and at posterior periods other mechanisms than autophagy can be triggered. **Acknowledges**: FAPESP, CAPES

**Title:** Phthalates affect synaptic growth and stability at the *Drosophila* nmj

**Authors: *K. M. DE LEON**[1], B. MARIE[2]
[2]Anat. & Neurobio., [1]Inst. of Neurobio., San Juan, PR

**Abstract:** Dibutyl phthalate (DBP) is a commonly used plasticizer in everyday products. Phthalates are not chemically bound to their polymer matrix and can leach out into the environment. Little is known about the effects of DBP on the nervous system. Studies have shown that DBP acts as a teratogen and as an endocrine disruptor. In addition, recent studies have linked DBP to apoptosis and neurotoxicity in mouse and rat models. In the present study, we address the effect of DBP at the neuromuscular junction (NMJ). We characterized a variety of synaptic markers: the vesicle marker synapsin, the microtubule associated protein Futsch (MAP1B homolog), the active zone associated structural protein Bruchpilot (CAST homolog), the postsynaptic marker discs large (Dlg; PSD-95 homolog), and the presynaptic membrane marker HRP. The animals were reared with a milieu containing environmentally relevant low concentrations of DBP (0.02, 0.2, 2 or 20 ppm). Animal reared in the contaminated milieu presented a reduction in synaptic growth. Indeed, synapses from animals reared in milieu at different concentrations of DBP showed a growth that was 80% of the control synapses. In addition, the animals reared in milieu with DBP showed synaptic retractions. These retractions are defined by the presence of postsynaptic markers and the absence of a subset of presynaptic markers. We found that the frequency of retraction to be dose dependent, where up to 30% of the synapses observed, showed synaptic retractions phenotype at 20 ppm. We observed that the animals exposed to DBP have boutons deficient in MAP1B and CAST. We also noted that when there is a synaptic retraction, neighboring boutons show abnormal accumulation of presynaptic proteins such as CAST, MAP1B and synapsin. We expanded our research to determine if different phthalates had similar effects on the synapse. Indeed, when exposed to di-2-ethylhexyl phthalate (DEHP) animals showed a reduction in synaptic growth and 41% retraction frequency. In contrast, exposing animals to benzylbutyl phthalate (BBP), diisononyl phthalate (DINP) and diisodecyl phthalate (DIDP) had no effect on synapse growth nor retraction frequency. These results correlate with the literature describing higher chained phthalates safer than shorter chained. This study shows that specific phthalates, such as DBP and DEHP can affect synaptic growth and stability. We are now focusing on the consequences of DBP exposure on glutamate receptor clustering and synaptic release.

**Abstract:** Diabetic retinopathy (DR) is one of the common complications associated with diabetes mellitus (DM) and the leading cause of blindness worldwide. Recent research has demonstrated that DR is not only a microvascular disease but may be a result of neurodegenerative processes and that glucose-induced neuron and glial cell damage may occur shortly after the onset of diabetes making the disease hard to diagnose at early stages. SIRT6, a NAD-dependent sirtuin deacylase, modulates aging, energy metabolism and neurodegeneration. In previous studies we showed that SIRT6 deficiency causes major retinal neurotransmission defects, changes in expression of glycolytic genes and elevated levels of apoptosis. Given the importance of glucose availability for retinal function and the critical role for SIRT6 in modulating glycolysis, we aim to analyze SIRT6 involvement in early neurodegenerative events during the development of experimental DR. Using non-obese diabetic mice (NOD/ShiLtJ), we determined by Western blot that two weeks after the onset of the disease high glucose concentrations (>250 mg/dl) induced retinal increased of a neovascularization promoting factor (VEGF, $p<0,01$) and loss of a neuroprotective factor (BDNF, $p<0,01$). At this stage, no evident vascular abnormalities were observed. Notably, reduced levels of SIRT6 ($p<0,05$) and increased acetylation levels of its substrates (H3K9 and H3K56, $p<0,01$) were observed suggesting a deregulation of key neural factors at early stages of the disease. Noteworthy, retinas from Central Nervous System (CNS) conditionally deleted SIRT6 mice (C57BL6/J, Nes-Cre-SIRT6$^{-/-}$) showed a resemblance to diabetic retinas exhibiting lower levels of BDNF and increased levels of VEGF. Moreover, cultured Müller glial cells subjected to high glucose concentrations (25mM) exhibited decreased levels of SIRT6 and increased levels of H3K56 acetylation ($p<0,05$). Our findings suggest that neurodegenerative events regulated epigenetically may occur early during diabetes preceding proliferative and vascular changes observed later in a diabetic retina.

**Title:** Gestational and chronicexposure to inorganic As (iAs) generates up regulation of Xc- system with changes in the hippocampus glutamatergic neurotransmission

**Authors: *J. NELSON-MORA**, M. GONSEBATT, L. MASSIEU-TRIGO, M. L. ESCOBAR, T. MONTIEL, L. RODRÍGUEZ-DURÁN, V. RODRÍGUEZ
Univ. Nacional Autonoma De México, Mexico, Mexico

**Abstract:** More than 200 million people in the world are estimated to be exposed to iAs levels above the security standards suggested by the World Health Organization. Polluted water is the main exposition way. iAs exposure is associated with different types neurological disorders that can also cause memory and learning impairment in children. Our lab has developed a murine model of iAs gestational exposure, in order to seek for the physiological, biochemical and molecular mechanism underlying the cognitive disorders seen in iAs exposure. It has been shown that iAs can induce ROS elevation. Moreover, glutathione (GSH) the main antioxidant molecule in the nervous system participates in iAs metabolism, consequentlty iAs exposure can deplete GSH. The aminoacid cysteine is a limiting resource in GSH synthesis which enters the cell via the Xc- antiporter importing one cystine molecule and exporting one glutamate molecule. We have previously observed and increased expression of Xc- in male hippocampus. This higher Xc- system activity could be associated to elevated extracellular glutamate that can lead to exitotoxicity, and to glutamatergic synapse alterations in hippocampus. CD1 animals were exposed to 20 ppm in drinking water, during gestation and then until three months of age. Extracellular glutamate concentrations were measured by *in-vivo* microdialysis while GSH/GSSG concentrations were determined with the fluorescence probe o-phthalaldehyde (OPA). The glutamatergic transmission status was assessed measuring changes in GluA1 and GluA2 AMPA subunits expression of glutamate receptors by Western Blott in cortex and hippocampus. Also, induction of LTP phenomena in hippocampal dentate gyrus in anesthetized animals, and Morris water maze were used to evaluate the impact of iAs exposure in memory and learning.. Our results show that GSH and GSSG levels were increased suggesting Xc- system activation. Also, extracellular glutamate levels were higher in iAs exposed mice. Both AMPA subunits were down-regulated and an impairment in LTP induction was observed.

**Title:** Recombinant human erythropoietin protects hippocampal neurons against excitotoxic damage through expression change of mediators signaling

**Authors:** ***S. F. CORNELIO-MARTINEZ**[1], C. BEAS ZARATE[2], A. FERIA-VELASCO[3], M. RIVERA CERVANTES[4]
[1]Neurobiología Celular, Ctr. Universitario De Ciencias Biológicas Y Agro, Zapopan, Mexico; [2]Biologia Celular y Mol., Univ. de Guadalajara, GUADALAJARA, Mexico; [3]Univ.Guadalajara, Jalisco Mexico, Mexico; [4]Univ. De Guadalajara, Zapopan, Jalisco, Mexico, Mexico

**Abstract:** Erythropoietin (EPO) is a cytokine required for proliferation, differentiation and maturation of red cells. However, it has been reported EPO acts as a pleiotropic cytokine beyond hematopoietic system, in other tissues including the brain, reproductive tract, in myoblasts and in kidney. In central nervous system EPO, performs neuroprotective functions against neuronal damage in various neurodegenerative disorders. It has anti-inflammatory, anti-oxidant, anti-apoptotic, neurotrophic, neurogenic, angiogenic and anti-excitotoxic effects essential for tissue repair. The signaling pathways involved in these responses have not been fully clarified but are known to involve the erythropoietin receptor (EPOR), moreover beta common receptor (βcR) a subunit. The main purpose of this work was to evaluate the neuroprotective effect of recombinant human EPO (rh-EPO) and determine the change expression of EPO, EPOR and βcR mRNAs in the hippocampus of neonate rats, under excitotoxic conditions, with monosodium glutamate (MSG). First we administered (4 mg/g bw) of MSG at 1, 3, 5 and 7 postnatal day (PD) to induce excitotoxic damage, then administered three different doses of rh-EPO (250UI/kg body weight (bw), 500UI/kg bw and 1,000UI/kg bw) intravenously at 8 PD, and we evaluated the cellular damage at 14 PD using Nissl technique, because it has been found that hippocampus present greater damage at this age in treated animals with MSG. Finally, we determine the change of EPO, EPOR and βcR gene expression at 2, 6 and 24 h after the administration of rh-EPO. Results of this work demonstrated that after administration of EPO, cell damage in hippocampal CA1 region decrease compare with those animals that were administered with MSG only and the most effective dose of EPO was 1,000 UI/kg bw. We also demonstrate that EPO gene expression increase at 2 h after the administration of rh-EPO, meanwhile, EPOR gene increase at 6h and βcR gene increase at 2h then decrease at 6h and increase at 24h again. Our

findings demonstrate that rh-EPO has a neuroprotective role against excitotoxic damage induce by MSG. therefore, EPO may acts through its binding to EPOR and βcR to activate its signaling pathway as a cellular response to excitotoxic injury to prevent damage and cellular lost and it can be used for the treatment of neurodegenerative diseases

**Title:** MicroRNA-200b attenuates increases in cytosolic calcium and improves survival from oxidative stress in neuronal N2a cells

**Authors: J. D. BELL**[1], X. SUN[2], *C. STARY[2], R. G. GIFFARD[2]

**Abstract:** Oxidative stress mediated by reactive oxygen species (ROS) is an important common pathway in cerebral ischemia, traumatic brain injury and neurodegenerative disease. Excessive production of ROS leads to disruption in intracellular calcium handling and induction of cell death pathways. Modulation of the cellular response to ROS therefore has widespread implication for neuroprotection across modalities. MicroRNAs (miRs) are short non-coding RNA molecules which bind to the 3' untranslated region (UTR) and inhibit the translation of mRNA strands to protein. MiR-200b has been shown to target protein kinase C alpha (PKCα), a known mediator of transient receptor potential cation channel-M2 (TRPM2)-mediated calcium influx in response to oxidative stress. Here we examined the effects of miR-200b mimic on alterations in cytosolic calcium and neuroprotection against oxidative injury in neuronal cells. N2a cells were grown in low serum and low density to induce a neuronal phenotype, characterized by extensive neuritic processes. Cells were transfected with miR-200b mimic or vehicle control and gene changes were verified with RT-qPCR. Oxidative stress was induced by 400 υM $H_2O_2$ plus serum deprivation, and cell death was assayed via propidium iodide after 24 hr. Fura-2 fluorescence was used to examine changes in cytosolic calcium. PKCα protein levels were assessed by immunoblot, and colocalization with TRPM2 was verified with

immunofluorescence. A one-way ANOVA with post-hoc multiple comparisons was used in all analyses to assess significant ($p<0.05$) differences. Oxidative injury induced an increase in cytosolic calcium and PKCα, which was attenuated in cells treated with miR-200b mimic. In N2a cells miR-200b mimic afforded significant protection 24 hr following oxidative stress, however, in separate experiments, miR-200b did not protect primary astrocyte cultures from oxidative injury. Notably, astrocytes do not express TRPM2 channels, validating the specificity of the effect of miR-200b on ROS-induced injury. These results describe a novel method of cellular neuroprotection against ROS-induced calcium influx and subsequent injury, with potential implication for other models of brain injury and disease.

**Abstract:** Neuroinflammation and oxidative stress are key pathogenic factors in the etiology and progression of many neurological disorders. Mechanistically, however, the link between these processes is unclear. Research has shown that modulation of cellular redox status can influence inflammatory processes in different diseases. Hence, we hypothesized that the modulation of intracellular levels of glutathione (GSH) would decrease oxidative stress and reduce neuroinflammation *in vitro*. We previously identified several thiol compounds with sulfhydryl side groups which could increase cellular glutathione (GSH) levels by a novel mechanism: post-translational activation of glutamate cysteine ligase (GCL), the rate-limiting enzyme in GSH biosynthesis. Of the compounds tested, 2,3-dimercapto-1-propanol (DMP) was most potent in increasing GSH ($p<0.001$ versus (vs) vehicle control) and decreasing pro-inflammatory cytokine production ($p<0.0001$ vs vehicle control; $p<0.001$ vs lipopolysaccharide (LPS)) in different cell types (JBC: Vol.292, No.13, pp5532-5545, 2017). Based on this, we hypothesized that an FDA approved drug used as a systemic protective agent against chemotherapy, 2-mercaptoethane

sulfonate (MESNA) having a thiol group would increase intracellular GSH levels thereby ameliorating oxidative stress and neuroinflammation *in vitro*. Non-cytotoxic doses of MESNA were chosen based on its ability to release lactate dehydrogenase. At 24h, MESNA (10μM) increased intracellular GSH levels in a rat dopaminergic neuronal cell line (N27) (57% increase over control) as well in mixed rat primary cortical cultures (20.3% increase over control). Next, we determined if treatment with MESNA impacted the generation of reactive oxygen species induced by Antimycin A (mitochondrial respiratory chain complex III inhibitor) in mixed rat primary cortical cultures. To visualize and quantify the oxidative stress response in these cells, we utilized a highly sensitive and selective fluorescent probe that could detect endogenous superoxide levels. Co-treatment with MESNA decreased Antimycin A-induced superoxide levels to control values. The data suggest that MESNA increases cellular GSH and decreases superoxide levels. Furthermore, the data suggest that thiol-containing compounds could inhibit neuroinflammation by modulation of cellular GSH levels.

**Abstract:** Hydrogen peroxide ($H_2O_2$), whose role in the complex environment of the brain is not well understood, has been implicated in the slow destruction of dopaminergic neurons in Parkinson's disease (PD). This neurodegenerative disease affects more than one million people in America, creating a critical need to identify the mechanisms through which $H_2O_2$ interacts with dopaminergic neurons. Real-time in vivo detection of this analyte has recently been described using fast-scan cyclic voltammetry at carbon-fiber electrodes. However, selectively identifying hydrogen peroxide from interferents such as adenosine and pH shifts remains a challenge. Additionally, some chemical agents used to pharmacologically verify the presence of hydrogen peroxide, such as mercaptosuccinic acid (MCS), oxidize at a potential close to that of the target analyte, further convoluting the characterization of $H_2O_2$ dynamics in the brain. We have addressed these problems by fabricating a mechanically robust $H_2O_2$-selective electrode.

1,3-phenylenediamine (mPD) was electrodeposited onto the surface of a carbon-fiber electrode to render it sensitive to small molecules such as $H_2O_2$ fluctuations and pH shifts, but not other analytes. Since pH changes generate a well-characterized and distinct voltammogram, they can easily be removed from the signal using principal component regression to reveal an electrochemical signal due solely to the oxidation of $H_2O_2$. This technology was fully characterized, and the work will facilitate the selective detection of $H_2O_2$ in a variety of preparations, opening the door for further elucidation of the neurodegenerative role it plays in PD, as well as other neuropathies involving oxidative stress.

**Abstract:** Epilepsy is an important pathological conditions characterized by recurrent seizures and it affects approximately 1% of the population. Adenosinergic system and oxidant-antioxidant mechanisms are thought to be involved in the pathogenesis of many neurological diseases such as epilepsy. Adenosine is an ATP metabolite, has a number of important roles in physiologic processes in the body. Adenosine contributes to cytoprotection depending on its receptor types. Caffeine has anti-oxidant property against oxidative stress originated from various toxic drugs. The aim of this study is to investigate the effect of adenosine and caffeine on oxidant parameters in convulsive seizure induced by pentylenetetrazol (PTZ). Male Wistar-albino rats were used for the study. Convulsive seizures were generated by injecting PTZ intraperitoneally (ip). Rats were divided into three groups randomly; PTZ (60 mg/kg/i.p., n = 8), Adenosine + PTZ Group (500 mg/kg ip adenosine administered 15 minute prior to PTZ injection, n = 8), Caffeine + PTZ group (5 mg/kg/ip caffeine administered 30 minute prior to PTZ injection, n = 8). Seizure activity was scored by observing seizure behavior and onset time. Rats were anesthesized with ether, blood samples were collected from heart. Brain tissues samples obtained and homogenized. Blood

samples were centrifuged to collect serum samples. Total protein amounts of the cortex tissue and serum samples were determined by using Lowry Method. MDA and GSH levels have been measured both in cortex tissue and serum samples. PTZ + caffeine administration reduced MDA and GSH levels in cortex tissue and enhanced the same parameters in serum compared to PTZ group. In addition, PTZ+adenosine administration decreased MDA and GSH levels in cortex, but there was not any change in serum levels of these parameters compared to PTZ group. Adenosine and caffeine caused a significant decline in cortex MDA level in PTZ induced seizure group ($p<0,05$). But changes in GSH levels have not been found significant. According to results; adenosine and caffeine reduced MDA level in cortex at oxidative stress conditions induced by PTZ. Adenozinergic modulation by adenosine and caffeine might protective effect on lipit peroxidation in oxidative stres process.

**Title:** Increased striatal vulnerability to 3-nitroproponic acid in male mice lacking interleukin-1r1

**Authors: *M. ALLEN**, S. J. HEWETT
Dept. of Biology, Program in Neurosci., Syracuse Univ., Syracuse, NY

**Abstract:** Huntington's disease (HD) mice bred onto an IL-1R1 null background demonstrate less Huntingtin aggregation in brain, and reduced severity of motor symptoms, indicating a potential protective role for IL-1β (Molecular Brain 3:33, 2010). In HD, mutant Huntingtin aggregates adversely affect mitochondrial dynamics and function, leading to oxidative stress. Previous work from our lab demonstrated that IL-1β protects neural cells against oxidant injury *in vitro* (Glia 63: 1568-1580, 2016). This led us to the question whether IL-1β might protect against the cascade of processes leading to cell death in HD *in vivo* as incurred by the systemic treatment of mice with the phyto/fungal mitochondrial toxin, 3-nitropropionic acid (3-NP). Toward this end, we compared the extent of behavioral and histological injury between mice wild type (WT) and null for the IL-1β signaling receptor, IL-1R1. Both male and female mice (16-18 wks.) were treated with 3-NP intraperitoneally twice per day, over a twelve-day period for a total cumulative dose of 920mg/kg. Analysis of behavioral and striatal lesion pathology

were performed by an investigator blind to the animal's genotype. Motor symptomology — including reduced general locomotor activity, hind limb and truncal dystonia, and postural instability —increased progressively with increasing days of dosage with 3-NP, in both sexes regardless of genotype. Despite this, histological analysis of the striatum, measured over seven slices ranging from +1.22 to -0.18 from bregma, revealed that IL-1R1 null male, but not female, mice had a greater incidence of striatal lesions that were also larger in size as compared to their WT littermate controls. Our results indicate that endogenous IL-1β signaling mitigates 3-NP induced structural but not functional striatal injury in male but not female mice. This study was supported by NIH/NINDS R01 NS051445-09.

**Title:** DLK/Wnd MAP kinase signaling promotes synapse loss in mutants defective for axonal transport

**Authors: *E. ASGHARI ADIB**[1], J. LI[2], Y. V. ZHANG[4], T. M. RASSE[4], C. A. COLLINS[3]
[1]Molecular, Cellular, and Developmental Biol., [2]MCDB, [3]Mol. Cell. and Developmental Biol., Univ. of Michigan, Ann Arbor, MI; [4]Hertie-Institute for Clin. Brain Res., Tübingen, Germany

**Abstract:** The Dual Lucine Zipper Kinase DLK, known as Wallenda (Wnd) in Drosophila, controls a highly conserved signaling pathway that becomes activated in damaged axons, and is required for multiple responses of neurons to axonal damage. In some damage models, including NGF withdrawal, glaucoma, and excitotoxicity, Wnd/DLK signaling mediates cell death. However, for neurons of peripheral nervous system (PNS) that can regenerate axons, Wnd/DLK is required for the initiation of new axonal growth. A unifying feature of these different injury models is the activation of signaling by Wnd/DLK, which raises the question of how Wnd becomes activated to 'sense' axonal damage. We report here our findings in Drosophila motoneurons that Wnd is restrained by the kinesin 3 motor protein unc-104/imac/KIF1A. Unc-104 mutants show elevated levels of Wnd signaling, and phenocopy wnd gain-of-function mutations in many respects: they have overgrown axon terminals and a more robust axonal regeneration response to injury. We also found that previously described defects in synapse assembly in unc-104 mutants, which include impaired assembly of presynaptic active zones (AZ), reduced mini frequency and EJPs, and altered bouton morphology, are due to over-active

Wnd signaling, as they are rescued in unc-104/wnd double mutants and phenocopied in wnd gain-of-function mutants.
Synapse development and maintenance requires the synthesis and assembly of synaptic machinery at specific locations in neurons. A kinesin-3 family member, Unc-104/Imac/KIF1A, is required for the localization of many pre-synaptic components to nascent synapses. We found that the synaptic defects of Drosophila unc-104 mutants could be rescued by inhibiting the Wallenda (Wnd)/DLK MAP kinase signaling pathway, which was previously identified as a regulator of axonal damage signaling. Wnd/DLK signaling becomes activated when Unc-104's function is reduced, and inhibits synapse structure and function independently of Unc-104's transport functions by inhibiting the expression level of active zone (AZ) and synaptic vesicle (SV) components. Wnd signaling also becomes activated when presynaptic proteins are ectopically over-expressed. These findings suggest a model that the Wnd pathway functions within a stress response pathway to fine-tune the expression level of presynaptic proteins, whose localization requires an intact axon and functional axonal transport machinery.

**Title:** Reperfusion reoxygenation brain injury following rabbit fetal hypoxia-ischemia increases reactive nitrogen species

**Authors: A. SHARMA, 48201**[1], Z. SHI[1], M. MAHASETH[1], K. LUO[1], G. NATARAJAN[1], J. VASQUEZ-VIVAR[2], *S. TAN[1], M. BAJAJ[1]
[1]Pediatrics, Wayne State Univ., Detroit, MI; [2]Med. Col. of Wisconsin, Milwaukee, WI

**Abstract: Introduction**: We have shown previously production of reactive nitrogen species (RNS) in fetal brains following antenatal hypoxia-ischemia (HI). We have identified a specific type of injury due to oxidative stress using MRI during HI that occurs in the reperfusion-reoxygenation period (RepReOx injury). Previous attempts at identifying biomarkers of RNS in parts of the brain using nitrotyrosine Western Blot have not been successful.
**Hypothesis:** Biomarker detection of RNS production is found in RepReOx injury in fetal brains following antenatal HI.
**Methods:** In vivo global HI of fetuses was induced in pregnant New Zealand White rabbits with

uterine ischemia, in a 3T magnet. MRI delineated 4 groups of HI fetuses including No injury group, without drop in brain ADC and RepReOx injury group, with ADC continuing to drop after end of HI. The presence of RepReOx predicts postnatal hypertonia. Fetal brains were extirpated 20 min after the end of HI. Using automated Western blot (WES, Protein Simple), nitration of tyrosine was measured using an antibody to nitrotyrosine (Abcam, ab7048), and suitable controls were run.
**Results:** In RepReOx, peaks on the chromatogram showed significantly increasing areas with increasing antibody with automatic Western Blot. Specificity of immunodetection was determined by positive control of using a pretreated antibody to nitrotyrosine confirming that positive peaks that are detecting tyrosine nitration.
**Conclusions:** There is evidence of increased production of RNS during RepReOx in fetal brains following HI. Quantification and differentiating non-specific binding of antibody with true nitrotyrosine production has become easier using Automatic Western Blot methods.

**Title:** Regulation of activity-dependent synaptic plasticity and synaptic expression of glutamate receptors by the neurosteroid pregnenolone sulfate: Implications for learning and memory

**Authors: *V. KUMARESAN**, *V. KUMARESAN, M. H. RATNER, K. SUGUNAN, S. DOWNING, A. CASARELLA, N. LI, A. JOYAL, D. H. FARB
Lab. of Mol. Neurobiology, Dept. of Pharmacol., Boston Univ. Sch. of Med., Boston, MA

**Abstract:** Neurosteroids and synthetic analogs may be the basis for the development of adjunctive treatments for multiple CNS disorders ranging from super-refractory status epilepticus to neurodevelopmental disorders such as schizophrenia. Clinical trials suggest that the endogenous neurosteroids pregnenolone (PREG) with its immediate metabolite pregnenolone sulfate (PregS) show promise in the treatment of cognitive disorders (Marx et al., 2014, Psychopharm. 231 (17):3647). For example, therapeutic approaches aimed at restoring steroidogenesis in patients with PCDH-19 female limited epilepsy have recently been reported (Trivisano et al., Epilepsia,1-5, 2017). 110xC19 steroids and PregS might serve as clinically useful biomarkers of disease control in 21-hydroxylase deficiency (Turcu et al., 2017 J. Clin. Endocrinol Metab. 2016-3989). We recently reported that low nanomolar concentration of PregS, induced a delayed onset increase of the neuronal response to NMDA and trafficking of

NMDAR to the cell surface through an intracellular calcium ([Ca2+]i) dependent mechanism (Kostakis et al., 2013, Mol. Pharm. 84:261). Moreover we have shown that low picomolar PregS increases [Ca2+]i and CREB phosphorylation and the frequency of spontaneous excitatory postsynaptic currents (Smith et al., 2014, Mol. Pharm. 86:390)
Here we report that picomolar PregS stimulates synaptic expression of GluA1-containing AMPA receptor puncta on proximal spines of hippocampal neurons in culture in a synaptic GluN2B- and L-Type voltage gated $Ca^{++}$ channel-dependent manner. cAMP-dependent PKA and casein kinase 2 are mechanistically involved in this process. Recent reports show that repeated injections of the neurosteroid PregS, in rats have resulted in enhanced memory, spatial orientation and object discrimination (Plescia et al., 2014, Behav. Brain Res. 258 :193). To ask whether PREG and/or PregS might modulate spatial memory, we examined the effect of escalating doses of PregS and Preg (0.1, 1.0 and 10.0 mg/kg s.c.) on place cell dynamics. PregS but not PREG induced a dose dependent increase in spatial information content during repeated foraging-based exploration of a familiar environment. These findings suggest that spatial specificity of place cell firing is increased by PregS but not PREG.

**Title:** Inhibition of Src-PSD-95 interaction may enhance NMDA receptor function in schizophrenia

**Authors: *A. BANERJEE**[1], M. HELLER[1], A. SENGAR[2], M. SALTER[2], S. SIEGEL[3], K. E. BORGMANN-WINTER[4], C.-G. HAHN[1]
[1]Dept. of Psychiatry, Univ. Pennsylvania, Philadelphia, PA; [2]Neurosci. and Mental health, The Hosp. for Sick Children, Toronto, ON, Canada; [3]Psyciatry and Behavioral Sci., USC, LosAngeles, CA; [4]Dept. of Psychiatry, Univ. Pennsylvania and The Children Hosp. of Philadelphia, Philadelphia, PA

**Abstract:** Previously, we have reported that NMDA receptor hypoactivity in schizophrenia is partly mediated by reduced Src kinase activity (Banerjee et al. 2015) resulting from altered protein interactions of Src with its binding partners, including PSD-95, ErbB4, Dysbindin, rPTPa. Of these, PSD-95 is of particular interest as it inhibits Src kinase (Kalia et al. 2006) and

its association with synaptic NMDA receptors is increased in schizophrenia. We hypothesized that inhibiting protein interactions between Src and PSD-95 may increase Src activity and rescue NMDA signaling deficit in the illness. SAPIP (Src activating PSDS-95 inhibitory peptide) is a peptide that competes with PSD-95 for its binding domain and overcomes inhibition of Src activity by PSD-95 specifically in synaptic membrane. We first examined whether SAPIP increase Src activity in synaptic membranes of human postmortem and rodent cortex. When 20 ugs of synaptic membranes of human and rodent cortices were incubated with 200 ng of SAPIP, Src activity was increased by about 20% ($P<0.05$ for human and mouse). To increase the membrane permeability of the peptide for in vivo administration, Tat- SAPIP construct was designed and recombinant proteins were purified using nickel affinity chromatography. Tat-SAPIP was then tested for its binding with Src -PSD-95 complex in synaptic membrane fractions derived from mice cortex. To test its membrane permeability, cultured rat cortical neurons (DIV 5 or 12) were incubated with SAPIP (0, 1.3 or 6.5 ng/ul) for 45 min. Tat-SAPIP decreased interaction between PSD-95 and Src on membrane fractions while no effect was observed on the cytosol. We also observed a concomitant increase in src pY416 phosphorylation on the membrane correlated with increase in src activity. The results of this study demonstrate that Tat-SAPIP is membrane permeable, and perturb protein interactions between Src and PSD-95, thereby increasing Src activity. We thus propose Tat-SAPIP be considered a potential therapeutic strategy targeting Src mediated NMDA signaling deficit in schizophrenia.

Essen BioScience Inc, Ann Arbor, MI

**Abstract:** The ability to culture, monitor and analyze cells that accurately reflect disease phenotypes of human nervous system disorders has been a major limitation in neuroscience research. The introduction of human induced pluripotent stem cell (hiPSC)-derived neurons has provided a promising new approach aimed at modeling human neurological diseases. However, hiPSC-derived neurons are not well characterized, and the capacity to monitor neuronal

morphology and cell health is critical for the evaluation of these novel model systems in long-term culture. Traditional approaches rely on endpoint assays and imaging techniques that require immunochemical staining, yet they provide limited real-time kinetic information. In this study, we present data outlining optimal culture conditions for cell viability and neurite outgrowth in hiPSC-derived neurons from Cellular Dynamic International (CDI, iCell Neurons). We also evaluated neurite outgrowth and cellular viability in iCell Gluta Neurons from CDI using a quantitative, live-cell imaging approach with the IncuCyte S3® over days/weeks in culture. Testing multiple culture and plate coating conditions, we find iCell Neurons respond best with a combination of BrainPhys media (Stem Cell Technologies) and iCell DOPA Neuron Supplement/iCell Nervous System Supplement (CDI) combined with a plate coating of polyethyleneimine and laminin. To demonstrate a real-time imaging approach using hiPSC-derived neurons, we evaluated glutamate- and kainate-induced excitotoxicity using the IncuCyte S3® phase/fluorescent NeuroTrack applications multiplexed with Annexin V reagents in iCell Gluta Neurons. Glutamate and kainate produced a concentration- and time-dependent decrease in neurite length with a concomitant increase in red or green object count (indicating cell death) over 72 hours. Glutamate and kainate produced a similar effect when measured by IncuCyte™ Cytotox Red, IncuCyte™ Cytotox Green and caspase 3/7 reagents. Treatment with the NMDA receptor antagonist MK-801 and the AMPA receptor antagonist NBQX reduced the glutamate- and kainate-induced effects on neurite length and cell death. These data highlight optimal culture conditions for iCell Neurons and exemplify the ability of the IncuCyte S3® approach for real-time, long-term quantitative analysis of iPSC-derived neuronal cell health.

**Abstract: INTRODUCTION:** The interest in exosomes biology has grown dramatically over the past few years, specifically with their role in cell-to-cell communication and as potential biomarkers for staging neurodegenerative diseases. We previously reported the pathogenic potential of neuronally-derived exosomes (NDEs) as carriers of phosphorylated tau (p-tau) species and other AD-related proteins. Here, we utilize an *intro model* to investigate the role that secreted exosomes play in AD pathogenesis. **METHODS:** Exosomes secreted into the cell culture media were isolated from neuronally - differentiated, human induced pluripotent stem cells that express the tau repeat domain with the with P301L and V337M mutations (NiPSCEs - tau(LM)). Exosome preparations were characterized by size (Nanosight) and extracted protein cargo were quantified by Western blot (WB). NiPSCEs - tau(LM) suspensions was injected into normal mice CNS and pathological changes were characterized by IHC at one and two months' post injection. Following NiPSCEs - tau(LM) injection and animal sacrifice, mouse plasma exosomes were extracted, precipitated and enriched for neuronal source by anti-L1CAM antibody absorption and extracted protein cargo were quantified by WB. **RESULTS:** Size distribution for non-tau transduced hiPSCs exosome preparations (NiPSCEs) fluctuated significantly while NiPSCE - tau(LM) were uniform and smaller in size as demonstrated by Nanosight. KJ9A, a pan-human tau antibody recognized endogenous human tau only in NiPSCEs-tau(LM) samples as demonstrated by WB. KJ9A immunoreactivty was visualized in the CA1 region of the hippocampus while PHF-1 was visualized in the hippocampus, entorhinal cortex, and subcortical thalamic regions at one and two months post - injection. MAP2 staining revealed laminar disorganization and neuronal cell loss in the hippocampus and cortex of injected mice at both time points. Lastly, plasmas NDEs isolated from injected mice contained tau species suggesting the trafficking of exosome cargo proteins from the CNS to the periphery. **CONCLUSIONS:** We report secreted exosomes isolated from our *in vivo model* of hiPSCs propagate human tau and p-tau in mouse CNS with high pathogenic potential. Additionally, we report that NiPSCE - tau(LM) cargo traffic AD-related proteins from the CNS to the periphery by being encapsulated in NDEs isolated from mice plasma.

**Abstract:** Virus infection during perinatal period induces aberrant neuronal development and increases the vulnerability for neuropsychiatric disorders. Clinical studies suggest that serious viral infection in the central nervous system during the postnatal stage is involved in the etiology of psychiatric disorders. However, little is known about the neurodevelopmental mechanism underlying the association between perinatal virus infection and brain dysfunction in later life. Previously, we reported that treatment of polyriboioinic-polyribocytidylic acid (poly I:C), a synthetic double strand RNA which induces natural immune reaction, in neonatal mice lead to schizophrenia-like behavioral abnormality including increased anxiety, memory impairment, and social behavior deficit in adulthood. We also showed interferon-induced transmembrane protein 3 (Ifitm3) in astrocytes is the key molecule in poly I:C-induced behavioral alteration. However, the molecular mechanism underlying roles of Ifitm3 in CNS remains unknown. To understand how Ifitm3 causes developmental abnormalities in CNS, we screened novel Ifitm3-interacting proteins by combining immunoprecipitation and liquid chromatography-tandem mass spectrometry (LC-MS/MS). As a result, we identified Rab GDP dissociation inhibitor (RabGDI) as a novel Ifitm3-interactig protein. Interaction of Ifitm3 with RabGDI was confirmed by pull down assay in HEK293 cells. Ifitm3 was partially co-localized with RabGDI in cultured astrocyte. Expression of Ifitm3 increased size of EEA1-positive endosome and level of active Rab5. These results suggest that Ifitm3 regulates Rab5 activity through interacting with RabGDI, and promotes early endosome fusion.

**Title:** The neuropeptide substance P elicits cortical spreading depolarization (CSD) in adult rats via activation of the NK1-receptor - could this be important in brain pathophysiology?

**Authors: F. RICHTER**[1], J. LEUCHTWEIS[1], A. EITNER[1], *A. LEHMENKUHLER[2], H.-G. SCHAIBLE[1]
[1]Univ. Hosp. Jena, Jena, Germany; [2]Pain Inst., Dusseldorf, Germany

**Abstract:** It is known that substance P (SP) acts as a vasodilator, induces vasogenic edema, and is able to increase neuronal membrane excitability. Topical application of $10^{-5}$ M substance P (SP) to the surface of rat dura mater induced a significant plasma extravasation [1]. Such processes could contribute to brain damage if large enough amounts of SP are released, e.g. after brain injury or stroke. The particular pathophysiological processes through which SP induces secondary damage have not been clarified yet. In this study we tested, whether SP is able to induce CSD in the healthy brain, and whether this effect is specific to the action of this neuropeptide on its receptor. In spontaneously breathing anesthetized adult rats (sodium thiopentone, 100 mg/kg, i.p.) CSD were recorded in cerebral cortex with two pairs of glass micropipettes (distance 5-6 mm) at depths of 400 and 1200 µm in two areas of the cortex, separated by a wall. In one area, CSD was elicited by a microinjection of 1 M KCl (tip diameter 5 µm, 100 kPa, 300 ms-1 s) into the grey matter at intervals of 30 min. In the remote area 100 µl of SP at concentrations from $10^{-8}$ M to $10^{-5}$ M were applied topically and left there. To test for specificity, the remote area was pretreated in some experiments with 250 nM of the NK-1 receptor antagonist L703.606 and SP was applied afterwards. Plasma extravasation into the brain was visualized by evans blue. In all rats tested, a pulse of KCl elicited a single propagating CSD. The topical application of SP to the brain surface induced a series of self-regenerating CSD (3-7 within the first 30 min of application) that originated in the SP-treated area, and 87 % of the CSD propagated into the untreated cortical area. Microinjection of KCl to elicit CSD usually halted the self-regenerating waves. In the treated area, amplitudes of CSD elicited by KCl increased significantly (400 µm depth: control 21.3±3.0 mV, after two hours 23.2±4.8 mV; 1200 µm depth: control 21.7±1.4 mV, after two hours 27.4±4.0 mV). CSD elicited by KCl propagated faster after SP (control 2.4±0.1 cm/min, after two hours 2.8±0.7 cm/min). Plasma extravasation was seen in the superficial cortical layers. The NK-1 receptor antagonist prevented the occurrence of self-regenerating CSD by SP. However, it did not prevent the increase in CSD amplitudes and the faster propagation of the CSD waves after KCl microinjection. Our results confirm that SP is a candidate to elicit CSD via the NK-1 receptor independently from other depolarizing agents. Therefore SP-induced CSD might contribute to secondary brain damage besides the other pathophysiological effects of SP. [1] Ebersberger et al., Ann Neurol. 2001;49(1):7-13.

**Title:** Plasticity-related gene protein type 3 modulates neurite outgrowth inhibition through the RHOA-ROCK pathway

**Authors: *C. AGBAEGBU**
Georgetown University/Nih, Bethesda, MD

**Abstract:** Axonal outgrowth is severely limited after injury to the Central Nervous System (CNS) and the mechanisms through which both intrinsic and extrinsic factors regulate plasticity after injury is not completely understood. Here we report that PRG-3, an intrinsic factor, attenuates CSPG induced neurite outgrowth inhibition. Additionally, overexpression of PRG-3 abrogated lysophosphatidic acid (LPA) induced neurite retraction. PRG-3 is a member of the Plasticity-related gene (PRG) proteins, a subclass of the lipid phosphate phosphatase (LPP) superfamily. They are integral membrane proteins characterized by six transmembrane domains. There are five members, PRG1 - 5 that are sequence and structurally similarity to the lipid phosphate phosphatases, LPPs, however, they do not exhibit any phosphatase activity that characterizes the LPPs. Overexpression of PRG-3 has been shown to dramatically change the morphological phenotype of neuroblastoma cells by inducing membrane protrusions. Furthermore, cells overexpressing PRG-3 show a decrease in myosin light chain II phosphorylation after LPA treatment, indicating that PRG-3 modulates the RhoA-ROCK pathway. Although CSPG and LPA act on different receptors, these extrinsic factors converge upon the RhoA-ROCK signaling pathway. In summary, our data indicates that PRG-3 protein modulates neuronal response to CSPGs and LPA, both inhibitory molecules to axonal outgrowth, via the RhoA-ROCK pathway, and therefore may mediate neuronal plasticity, providing a target for investigation to improve therapeutic strategies after injury to the CNS.

**Title:** Long-term evaluation of vascular remodeling after traumatic brain injury in mice

**Authors: *M. R. MCCRARY**[1], J. Y. ZHANG[2], P. SETHAPUTRA[2], K. K. JESSON[2], X. GU[2], L. WEI[2], S. YU[2]

**Abstract:** Traumatic brain injury (TBI) is a leading cause of mortality and morbidity and contributes to about 30% of all injury deaths in the US. Vascular regeneration entails a series of complex events including angiogenesis, arteriogenesis, and pericyte recruitment. In the brain, these events are intimately tied to neurovascular and gliovascular unit regeneration and functional recovery. While vascular remodeling has been intensively studied after ischemic stroke, the timeline of neovascularization is less characterized in TBI, particularly in the chronic phases of tissue recovery. In the present investigation, we studied long-term vascular regeneration events in transgenic mice expressing the smooth muscle actin α-SMA-GFP. Adult mice were subjected to a controlled cortical impact stereotactically directed to the sensorimotor cortex. The proliferation marker BrdU was administered daily after injury, and peri-contusion blood flow was measured weekly using laser Doppler. Images of stained slides were analyzed using ImageJ under double-blind conditions. Brain tissues were isolated from the peri-contusion region and the contralateral cortex. Western blot analyses of tissue collected from early time points (1, 3, 7, and 14 days) after injury suggest VEGF rather than EPO is a major factor controlling vascular regeneration after TBI. Laser Doppler readings showed that local blood flow in the peri-contusion region decreased within 1 week after injury, then steadily recovered to pre-injury levels after ~5 weeks. TBI animals were sacrificed 2, 5, and 8 weeks after injury for histologic examination of macro- and micro-vessels. Low power images of macrovessels in the per-contusion and core zones were acquired of the whole brain. The complexity and density of both macrovessels and microvessels, as well as pericytes recovery over time were analyzed. Despite normalization of blood flow by 5 weeks, neovascularization events were noted weeks later. Taken together, these data suggest that vascular regeneration occurs over the course of months after traumatic brain injury and may have ramifications on our approach to the treatment of this disease. Future studies will elucidate the complexities of neovascularization and its implication for tissue regeneration after brain injury.

**Title:** Acute and chronic behavioral outcomes following closed head injury in adolescent mice are dependent on sex

**Authors: *L. PLYLER**, M. ZEMEL, M. BRANHAM, R. RAGHUPATHI
Neurobio. and Anat., Drexel Univ. Col. of Med., Philadelphia, PA

**Abstract:** Nearly 5.3 million Americans are currently living with disabilities resulting from traumatic brain injury (TBI) of which almost 80% are a consequence of mild TBI. Moreover, mild TBI is a significant health-related issue in adolescents and young adults engaged in contact sports. Girls who sustain mild TBI often exhibit different symptoms compared to their male counterparts and also take longer to recover from these symptoms. To better understand the cellular basis for these sex differences, a mouse model of closed head injury was developed in adolescent (35-42-day-old) male and female C57Bl/6 mice. Anesthetized mice received an impact to the intact skull along the midline suture halfway between bregma and lamba; sham-injured mice underwent an identical procedure without impact. On days 1-3 following injury, both male and female mice displayed deficits in spatial learning/acquisition, but not recall, tested in the Morris water maze. In week 4 after injury, an increase in open arm time, suggestive of impulsive behaviors, was observed in male brain-injured mice compared to their sham-injured counterparts in the elevated plus maze. In contrast, no differences in open arm times were observed between brain- and sham-injured female mice. Closed head injury did not induce a depression-like phenotype measured using the forced swim test in either male or female mice. At 5 weeks post-injury, male brain-injured mice demonstrated an increased periorbital sensitivity to Von Frey filaments compared to the sham-injured group, suggestive of a headache phenotype. Interestingly, brain-injured female mice exhibited hyposensitivity to the filaments suggestive of a decrease in sensory function. These data add to the ongoing characterization of the long-term functional deficits following closed head injury, and provide the basis for differential evaluation of post-traumatic effects in men and women.

**Title:** Short-term fructose ingestion disrupts peripheral and central metabolism and aggravates the outcome of brain trauma

**Authors: *Z. YING**[1], L. ROYES[1], A. JIMÉNEZ MALDONADO[1], S. REGE[1], G. KRISHNA[1], F. GOMEZ-PINILLA[1,2]
[1]Dept of Integrative Biol. and Physiol., [2]Dept. Neurosurg., UCLA, Los Angeles, CA

**Abstract:** Traumatic brain injury (TBI) results in high rates of morbidity and mortality in sports, military and domestic environments. The fact that TBI per se disrupts brain cell metabolism suggests that TBI pathology is highly susceptible to metabolic perturbations. Fructose is abundant in the Western diet and a major cause of metabolic syndrome (MetS), diabetes, and obesity. Chronic exposure to fructose has been associated with protracted brain plasticity and function, assumingly secondary to MetS. We wanted to evaluate the impact of short-term fructose ingestion (prior establishment of MetS) on the response of the brain to a traumatic lesion. A moderate fluid percussion injury (FPI, 2.7 atm) decreased glucose tolerance ($p<0.05$) as short as after 1 week postlesion. Intact animals exposed to fructose consumption for 3 weeks (15% w/v, 3wks) before FPI onset, showed no alterations in peripheral metabolism. However, fructose consumption potentiated an increase in plasma insulin ($p<0.01$) and a decrease in glucose tolerance ($p<0.05$) in animals exposed to FPI. These results indicate that fructose exacerbates the disruptive action of TBI on peripheral glucose regulation. The short-term fructose consumption increased escape latency in the Barnes maze test ($p<0.01$) in animals exposed to FPI, but fructose by itself was not sufficient to alter latency in intact animals. Fructose consumption reduced hippocampal dry weight which was accompanied by a reduction in the neuronal NeuN and Myelin Protein (MBP). Fructose also reduced levels of the peroxisome proliferator activated receptor gamma, coactivator 1 alpha (PGC-1α) and Cytochrome c oxidase subunit II (COX2), suggesting compromised mitochondrial function. We have previously shown that 6 weeks of fructose consumption significantly disrupts memory performance in the Barnes maze in intact rats (Agrawal et al., J Neurophysiol, 2012), and aggravates memory dysfunction after TBI (Agrawal et al, JCBFM, 2016). Our new results show that a short period of fructose consumption poses a risk for the outcome of TBI, compromising metabolic homeostasis in the brain and periphery, with subsequent effects on the progress of the pathophysiology of TBI.

These studies are particularly significant on the light of recent studies showing the pervasive effects of fructose and TBI on many genes associated with important neurological and psychiatric disorders (Meng et al., eBiomedicine, 2016, 2017).

**Title:** Differential regulation of Sirt1 and Sirt2 in white matter after neonatal hypoxia

**Authors: *B. JABLONSKA**, L.-J. CHEW, V. GALLO
Ctr. for Neurosci. Res., Children's Natl. Med. Ctr., Washington, DC

**Abstract:** Diffuse white matter injury (DWMI) is a major form of brain injury, which results in chronic neurological and behavioral disabilities in prematurely born infants, including a broad spectrum of cognitive and learning disabilities until young adulthood. To understand the mechanisms underlying white matter dysmaturation caused by injury, we have used a mouse model of neonatal hypoxia (Hx) that reproduces all the landmarks of brain injury observed in premature infants, including DWMI. In this model, we have previously demonstrated that Hx causes hypomyelination one week after injury (P18). This is due to delayed oligodendrocyte (OL) maturation and increased proliferative response of oligodendrocyte progenitor cells (OPCs) through Sirt1-activated Cdk2 signalling. Hx increases the expression of Sirt1 in white matter lysate, and elevates the number of $NG2^+Sirt1^+$ progenitors, whereas the number of mature $CC1^+$ oligodendrocytes expressing Sirt1 is unchanged. Since Sirt2 is implicated in OL maturation, here, we determined whether neonatal Hx altered Sirt2 expression and function in white matter. We found that Hx reduced Sirt2 expression and the number of $Sirt2^+$ cells in white matter. The number of $Sirt2^+Olig2^+$ cells decreased after Hx but $NG2^+Sirt2^+$ cells remained unchanged, indicating that Hx may affect primarily mature OLs. Indeed, we observed a significant reduction of Sirt2 expression in mature $CC1^+$ and $CNP^+$ oligodendrocytes after Hx. A role in differentiation was supported by Sirt2 loss-of function experiments, in which siRNA-mediated knockdown of Sirt2 in normoxic and Hx cultured cells was performed. In normoxic cultures,

knockdown of Sirt2 caused a significant reduction in the percentages of $Olig2^+$, $GalC^+$ and $O4^+$ cells, as compared to scrambled control cultures. In scrambled controls, Hx caused a reduction in the number of mature oligodendrocytes. This effect was more pronounced after Sirt2 siRNA treatment. These findings demonstrate reciprocal regulation of Sirt1 and Sirt2 consistent with their respective roles in proliferation and differentiation after white matter damage caused by Hx.

**Title:** Identification of genes that promote axonal regeneration of injured cortical neurons

**Authors: *C.-Y. CHANG**, L. CHEN
Inst. of Mol. Med., Hsinchu, Taiwan

**Abstract:** Neurons receive and propagate signals to coordinate behavior. Upon brain injury, one would suffer from impaired sensory, motor or cognitive functions. However, unlike the peripheral nervous system, the central nervous system exhibits poor recovery due to the non-permissive extrinsic environment as well as the low intrinsic regenerative capacity. Evidence shows that diminishing extrinsic inhibitor molecules confers limited neurite sprouting and is insufficient for improving distal axonal regeneration. We thus set out to explore the intrinsic growth capacity within brain neurons. In response to injury, a number of regeneration-associated genes have been identified and show promising potential for facilitating axonal regeneration of cortical and hippocampal neurons. This work is supported by National Health Research Institutes, Taiwan (NHRI-EX106- EX105-10206NI).

Ctr., Baltimore, MD

**Abstract:** Traumatic brain injury (TBI) remains a major public health problem, effecting more than 1.7 million people in the United States. In 2010, the center for disease control estimated the direct and indirect costs of TBI were $76.5 billion. Patients with TBI have impaired cognition, learning and memory deficits are also observed in animal models of TBI. In addition to direct, immediate primary injury, delayed molecular and cellular changes contribute to cell death and neurological dysfunction caused by TBI. A key secondary injury mechanism in experimental TBI is cell cycle activation (CCA). TBI induced CCA results in apoptosis of post-mitotic cells such as neurons and oligodendroglial cells as well as microglia proliferation, causing neuroinflammation and secondary neurotoxicity. Pharmacological inhibition of CCA with selective cyclin-dependent kinase (CDK) inhibitors prevents activation of microglia and astrocytes and improves cognitive function. We further investigated the beneficial effects of CDK inhibitors in a neuronal cell death model *in vitro.* After 6h of etoposide treatment, basal mitochondrial function of primary rat cortical neurons (RCN) is not affected, however, the ability of the neurons to respond to maximal energetic demand is impaired. Treatment of RCN with CDK inhibitors prevents impairments in the ability of the neurons to respond to maximal energetic demand on the mitochondria. Additionally, RCN treatment with CDK inhibitors prior to etoposide prevents induction of pro-apoptotic BCL2 family member's expression downstream of p53 phosphorylation/activation. CDK inhibitors prevent induction in Bim and Cdkn1a (p21), as well as cleavage of Caspase-3, Fodrin, Parp-1. Thus, our data indicate the robust protective effect of CDK inhibitors in response to neuronal injury is due to attenuation of p53 dependent apoptosis.

**Abstract:** Traumatic brain injury (TBI) is a leading cause of death and disability in army personnel and general population. Apolipoprotein E (APOE) is the major cholesterol carrier and lipid transporter in the CNS. Recent studies suggest a role for APOE in determining outcome severity following TBI, with inheritance of the APOE4 allele conferring worse outcome. APOE lipidation and stability is modulated by ATP-binding cassette transporter A1 (ABCA1), a transmembrane protein that transports lipids and cholesterol onto APOE. It is unknown how deficiency of ABCA1 would influence outcome following TBI. We hypothesized that inheritance of APOE4 combined with a deficiency of ABCA1 would lead to worse cognitive outcome and gene expression changes following TBI. This study uses mice expressing human APOE3 and APOE4 isoforms that are haplodeficient for the *Abca1* gene (APOE3/*Abca1*$^{+/-}$; APOE4/*Abca1*$^{+/-}$). Young adult, 3 month old mice received either a controlled cortical impact (CCI) brain injury or a craniotomy in the left hemisphere. *Abca1*$^{+/-}$ TBI mice had increased risk-taking behavior demonstrated by significantly more time in the open arms of the Elevated plus maze compared to sham ($p$<0.01). Additionally, *Abca1*$^{+/-}$ TBI mice performed worse than their sham counterparts ($p$<0.001) in Morris Water Maze (MWM), regardless of APOE isoform. To investigate the molecular mechanisms underlying this effect, we performed mRNA-seq using samples from cortices and hippocampi followed by genome-wide differential gene expression analysis. The transcriptomic profiles were compared to our published results for APOE mice

expressing both functional copies of *Abca1*. Using Network Analysis, we identified co-expressed-networks correlated to TBI, APOE isoform and Abca1 expression. We have identifiifed gene networks specific to each phenotype demonstrating roles for injury, APOE isoform and ABCA1 in modulating gene expression in the brain and after TBI.

**Abstract:** Despite the growing prevalence of traumatic brain injury (TBI) in athletics and combat, we still know very little about the pathophysiological changes that occur in the brain following injury. Mild, closed-skull forms of injury are the most common form of TBI, but remain particularly poorly understood. To probe the cellular and synaptic changes in cortical circuits arising from mild TBI, we used a closed-skull weight-drop model in mice and assessed affected areas using histology and cellular electrophysiology. We found that 2 days after repetitive injury, there was strong microglial activation in entorhinal and piriform cortices, indicated by altered morphology visualized with Iba-1 immunostaining. Focusing on piriform cortex, we used whole cell patch clamp recordings in acute brain slices to test for changes in both excitatory and inhibitory synaptic inputs onto superficial pyramidal cells. Injury tended to increase the frequency of spontaneous excitatory input without affecting amplitude, while inhibitory inputs were largely unaffected. Direct comparison of excitatory and inhibitory components of electrically evoked synaptic responses also indicated a shift towards greater excitation. These data are consistent with findings in other TBI paradigms, but identify piriform cortex as a potential locus of sensitivity to mild injury. Piriform and associated regions are also susceptible to damage in epilepsy and are strongly involved in propagating temporal lobe seizures, suggesting that injury-induced hyperexcitability in these areas may contribute to the established links between TBI and post-traumatic epilepsy.

**Title:** Effect of treadmill exercise on cognitive and behavioral outcomes following repeated mild traumatic brain injury

**Authors: M. ZEMEL**, M. BRANHAM, L. PLYLER, *R. RAGHUPATHI
Drexel Univ. Col. of Med., Philadelphia, PA

**Abstract:** Youth and young adults participating in contact sports such as football, hockey, lacrosse and soccer are apt to sustain multiple concussions (mild traumatic brain injury, mTBI) throughout their playing career. The long-term consequences of these repetitive injuries include altered cognitive function, increased incidence of headaches, and development of depression, anxiety and impulsivity. A number of preclinical models of repetitive mTBI have been developed in both rats and mice but few, if any, have addressed whether physical exercise, either prior to or after the injury, has the ability to influence the development of post-injury behavioral deficits. In the present study, anesthetized male mice (6-7 weeks of age) were subjected to 3 impacts (one every 48 hours) to the intact skull on the midline centered between bregma and lambda; sham-injured mice were anesthetized and surgically prepared but did not receive impacts. Repetitive mTBI resulted in a spatial learning deficit when mice were tested in the Morris water maze on days 1-3 following injury, an increase in open arm time in the elevated plus maze (EPM) at 4 weeks (suggestive of impulsivity) and increased facial allodynia at 5 weeks post-injury (suggestive of post-traumatic headache); there was no change in immobility time in forced swim test for depression. When mice were subjected to treadmill exercise (10m/min) for an hour each day for 3 weeks prior to repetitive TBI, the spatial learning deficit observed on the first 3 days after the last injury was significantly ameliorated. Pre-injury exercise did not affect injury-induced increases in open arm time but appeared to reduce the incidence of facial allodynia. Current guidelines for the treatment of concussed athletes are divided between a period of rest and continued physical activity prior to return to play. To test this concept, a subset of mice that received exercise prior to injury were subjected to treadmill exercise beginning on day 5 following the last injury and lasting for 4 weeks. When tested in the EPM, post-injury exercise decreased the open arm time of brain-injured mice when compared to non-exercised or

pre-injury exercised mice. However, the incidence of facial allodynia was similar in unexercised mice and in mice that received exercise post-injury suggesting that continued exercise may reverse the effect of pre-injury exercise. Together, these data establish a clinically-relevant model of repetitive mTBI in young adult mice and underscore the complexity in the ongoing characterization of the long-term functional deficits following multiple concussions.

**Title:** Insulin-like growth factor-1 overexpression enhances neurogenesis and activates the mTOR pathway after moderate TBI

**Authors:** ***E. LITTLEJOHN**, D. SCOTT, A. DESANA, J. JURAS, K. SAATMAN
Univ. of Kentucky, Lexington, KY

**Abstract:** Nearly 5 million people in the United States are living with TBI related disabilities, in part because of the brain's limited capacity to replace lost and damaged neurons. Immature neurons in the hippocampus are highly vulnerable to trauma, but can be replaced through proliferation and differentiation of neural stem cells in the subgranular zone. The extent of injury-induced neurogenesis, however, may be injury severity dependent. Insulin-like Growth Factor 1 (IGF1) modulates basal and injury-induced hippocampal neurogenesis. Using a transgenic mouse model with IGF1 overexpression restricted to astrocytes (IGF Tg) to raise brain levels of IGF1 by means of injury-induced astrogliosis, we previously showed that IGF1 enhances recovery of the immature neuron population and morphology after severe TBI. Mammalian target of rapamycin (mTOR), a signaling molecule downstream of IGF1, has been identified as a potential target for TBI interventions because of its regulatory role in plasticity and cell survival. We hypothesized that increased IGF1 would stimulate mTOR activity

following moderate injury, resulting in improved neurogenesis. To this end three cohorts of IGF Tg and wild-type (WT) mice received moderate controlled cortical impact (CCI, n=8-11/genotype) and survived 1, 3 or 10d or received sham injury (n= 3/genotype; 72h survival) At 1 and 3d following moderate injury, immunohistochemical labeling of pS6, a well characterized downstream effector of mTOR, was quantified in the granule cell layer, molecular layer, and the hilus of the dentate gyrus. Analysis of pS6 at the injury epicenter suggests that IGF1 stimulates activity of the mTOR pathway following moderate TBI in a region-specific manner. At 10d after moderate injury, IGF1 overexpression enhances recovery of immature neurons.

**Title:** Adolescent binge alcohol consumption affects hippocampal function through the impairment of mitochondrial dynamics and bioenergetics in the adulthood

**Authors: *C. TAPIA-ROJAS**[1], A. TORRES[1], F. CARVAJAL[2], R. MIRA[2], C. ARCE[2], W. CERPA[2], R. QUINTANILLA[1]
[1]Univ. Autonoma De Chile, Santiago, Chile; [2]Pontificia Univ. Católica de Chile, Santiago, Chile

**Abstract:** In the adolescent population, “binge drinking” is a common pattern of alcohol consumption, which is characterized by a short period of heavy alcohol use followed by a period of abstinence. Adolescents are highly susceptible to alcohol and their immature brains are more vulnerable to the effects of binge drinking. However, relatively little is known about the effects of adolescent binge drinking on mitochondrial structure and their effects on brain function. Male Sprague-Dawley rats, postnatal day 25 (PND25), were exposed to binge-like ethanol protocol; rats were treated by i.p. injections of ethanol (3,0g/Kg, 25% v/v) or saline solution during two consecutive days, with gaps of 2 days without injections, during 2 weeks. Then 1, 3 or 7 weeks after treatment rats were exposed to cognitive and social test. Finally, the animals were euthanized and the hippocampus tissue was analyzed through electrophysiological, biochemical and histochemical assays.
Our results show that binge-like alcohol consumption alters the levels of key proteins involved in mitochondrial dynamics such as Drp1, Fis1, Mfn1, Mfn2 and Opa1, disrupting the balance between fission and fusion events. Ethanol treated rats also showed changes in oxidative stress,

impaired synaptic plasticity and recognition and social memory loss. Some of these effects were compensated possibly through a mechanism that involves the activation of the Nrf-2 signaling pathway. The alterations in the regulation of mitochondrial dynamics continue overtime and importantly a delayed inflammatory response appearin the adult hippocampus. Additionally, we observed changes associated with mitochondrial dysfunction that persist until adulthood as is indicated by a deficient ATP production, reduced expression of mitochondrial respiratory complexes, increased ROS generation, decreased mitochondrial membrane potential, and increased mitochondrial calcium. Altogether, these results suggest that adolescent binge-like alcohol consumption, negatively affects mitochondrial dynamics regulation inducing mitochondria-mediated oxidative stress and triggering synaptic, cognitive and mitochondrial function defects that persist in the adult brain.

**Abstract:** Sensory activity is instructive for the development and refinement of sensory circuits, such as the visual circuit of the optic tectum in Xenopus laevis, which receives information from the retina and sends projections to motor regions. However, how sensory activity might exert an effect in a circuit following a traumatic brain injury is unknown. We have previously developed a penetrative brain injury model and shown that injury to the Xenopus tectum results in loss of visual avoidance behavior. Recovery of behavior is dependent on cell proliferation, and takes 4-7 days. Here, we test whether increased sensory activity can increase the speed with which the animal recovers from injury. We determined sensory activity significantly increased the ability of the animal to perform our behavior assay at two days following injury (behavior index, with activity: 0.57 +/- 0.03 vs ambient control: 0.38 +/- 0.05). Animals which received additional sensory activity also reached baseline levels of behavior more quickly. This behavioral recovery was correlated with changes in the frequency of spontaneous events recorded in neurons born post-injury, and with the frequency with which these neurons received barrages of organized

circuit activity, suggesting behavioral recovery is correlated with the successful incorporation of new neurons into the existing tectal circuit. Behavioral recovery was impeded by pharmacological blockade of the GluN2B subunit of the NMDA receptor. Loss of GluN2B subunit also decreased activity, as measured electrophysiologically. In conclusion, these data show enhanced sensory activity as mediated by NMDA receptors contributes to the repair of the post-injury tectal circuit. This work was supported by EY011261 to HTC.

**Abstract:** X-linked adrenoleukodystrophy (ALD) is a debilitating neurological disorder caused by mutations in the peroxisomal half transporter, *ABCD1*. Blood brain barrier (BBB) disruption with migration of leukocytes to the brain, as indicated by histopathology has for a long time been implicated in the cerebral inflammatory form of the disease. To assess how *ABCD1* alters brain endothelial barrier function we performed a gene expression analysis by direct RNA sequencing in human brain microvascular endothelial cells(HBMECs). Bioinformatic analyses identified upregulation of 1527 and downregulation of 1706 genes upon *ABCD1* silencing. Preliminary pathway analysis on these data showed that TGF-β pathway is upregualted while NF-κβ, cell cycle and extracellular matrix pathways are significantly downregulated in HBMECs lacking *ABCD1*. These molecular changes also correspond with our experimental findings demonstrating that lack of *ABCD1* in brain microvascular endothelium increases their permeability to monocytes and alters angiogenesis by upregulation of the TGFBeta1 pathway. Our analysis provides novel insights on molecular mechanisms and potential therapeutic targets for cerebral ALD.

**Abstract:** Advances in the gene editing arena, specifically with CRISPR-Cas9, has pushed the demand for efficiently delivering payloads even further. Of the tools available, developments in the field of lipid nanoparticles (LNPs) has allowed for the reliable and efficient delivery of CRISPR components, both in research and clinical settings. Here, we bridge that gap by describing the development of an LNP delivery system for CRISPR components, robustly manufactured with clinical-grade materials using microfluidic technology at scales for *in vitro* applications, with the potential to move into animal models. We describe the use of lipid-based nanoparticles for highly efficient encapsulation and delivery of payloads, such as siRNA, mRNA and plasmid. We show that representative small RNAs, mRNAs and plasmids can be successfully delivered to primary neurons. LNPs manufactured to encapsulate various nucleic acids can do so with high efficiency, encapulating more than 95% of the payload, minimizing payload loss. Transfection efficiency of the LNPs is variable based on payload. The biological endpoint assays used to determine the accessibility of the payloads delivered varies for siRNA, mRNA and plasmid. Using doses of 1μg per mL of media, we achieved >90% knockdown with siRNA delivery, >90% of the primary neurons are GFP+ with GFP mRNA delivery and 60% of the primary neurons are GFP+ with GFP plasmid delivery. The LNPs are well tolerated, such that 5x the required doses have no observable cytoxicity. We can deliver gRNAs to Cas9-expressing cells to achieve up to 80% editing. We also can co-deliver Cas9 mRNA and gRNAs in separate nanoparticles to achieve editing in wildtype cells. We show that the LNPs can also be used to deliver payloads into various regions of the animal brain. These validation studies provide suitable insights in establishing strategies for efficiently delivering CRISPR components into primary cultures.

**Abstract:** Severe traumatic brain injury (TBI) is a risk factor for neurodegenerative diseases, such as Alzheimer's disease (AD), yet mechanistic links remain elusive. Micro (mi) RNAs, small stable RNAs that regulate translational degradation or gene repression, are proposed to be central to both TBI and AD progression. Therefore, this study determined miRNA gene expression patterns, mRNA transcript levels, and resulting protein/peptide levels in brain tissue after 10% penetrating ballistic-like brain injury (PBBI) compared to sham (craniotomy) controls. Microarray analysis was conducted using ipsilateral coronal brain tissues collected 1, 3, or 7d post-injury. Differentially expressed miRNAs (PBBI vs. sham fold change) were mapped to the APP processing pathway defined by Pathway Studio Gene Set Enrichment Analysis. Messenger (m) RNA of select targets was determined with quantitative (Q) PCR Taqman Assays. APP content was confirmed with western blotting and amyloid beta (Aβ) peptide measurements were conducted using electrochemilluminescent ELISAs. Eight (5 up / 3 down), 7 (2 up / 5 down), and 46 (31 up / 12 down) miRNAs were differentially abundant 1, 3, and 7d, respectively, after PBBI. Suppression of miR-135A at 1d (0.59-fold), miR-328 at 3d (0.63-fold) and 7d (0.83-fold), as well as mir-29 at 7d (0.91-fold) displayed inhibitory relationships with BACE1. MiR-21, also negatively associated with BACE-1, was upregulated (1.5-fold) after 7d. BACE-1 mRNA increased at 1d (2.7-fold), peaked at 3d (5.3-fold), and returned to near sham levels at 7d following PBBI. APP mRNA also increased at 1d (1.7-fold) and 3d (3.9-fold). Western blots indicated that full-length APP levels progressively decreased at 3d (0.13-fold) and 7d (0.05-

fold). However, neither Aβ-40 nor -42 peptide quantities were significantly greater after PBBI compared to sham controls. The relationship between select miRNAs, BACE-1 and APP transcript upregulation, coupled to post-translational APP loss may be key indicators of AD-like mechanisms in brain tissues during TBI progression. These relationships imply that PBBI leads to APP loss due to the reduced miRNA suppressive regulation of BACE-1. Interestingly, the lack Aβ peptide upregulation may indicate that APP is degradation is not dependent upon further proteolytic cleavage. The regulatory role of select miRNAs upon APP cleaving enzymes and generation of toxic peptides in TBI mediated neurodegeneration warrants further investigation.

**Title:** Critical role of acid sphingomyelinase in mitochondrial dysfunction due to glutamate/cystine antiporter-dependent ferroptosis in oligodendrocytes

**Authors: S. A. NOVGORODOV**[1], J. A. VOLTIN[1], M. A. GOOZ[2], J. J. LEMASTERS[2], *T. I. GUDZ[1]
[1]Dept Neurosci., [2]Dept Drug Discovery, Med. Univ. South Carolina, Charleston, SC

**Abstract:** The glutamate/cystine antiporter system $x_c^-$ plays an important role in regulating the extracellular glutamate levels and in maintaining the intracellular cysteine/glutathione (GSH)-dependent antioxidant defense mechanisms in the brain. In tumor cells, blocking system $x_c^-$ triggers a novel form of programmed necrosis, ferroptosis, which is characterized by increased ROS generation and lipid peroxidation. Therefore, drugs that can inhibit system $x_c^-$ are considered as potential treatments for cancer. Yet, the mechanisms of system $x_c^-$-dependent ferroptosis in the neural cells remain unexplored. Primary oligodendrocytes (OLs) were treated with glutamate to provoke the system $x_c^-$-mediated cell death. Pharmacological analysis revealed ferroptosis as a major contributing factor to glutamate-initiated OL death. Although RIP1 kinase inhibitor necrostatin-1 slightly protected OLs from glutamate toxicity, there was no activation of the RIP1 and/or RIP3 kinase-mediated necroptosis signaling pathway, suggesting an off-target effect of necrostatin-1. Quantitative lipidomics analysis showed a significant elevation of sphingolipids (ceramide and sphingosine) that was prevented by inhibitors of acid sphingomyelinase (ASM). Notably, blocking ASM activity or knocking down ASM protected

OLs against glutamate toxicity suggesting the critical role of ASM in OL death. Glutamate-induced ASM activation seems to involve post-transcriptional mechanisms and is associated with decreased GSH levels. Further investigation of the mechanisms of OL response to glutamate revealed enhanced mitochondrial ROS production, augmented lipid peroxidation and dissipation of the mitochondrial transmembrane potential that was attenuated by hindering ASM. The results of these studies highlight a novel mechanism of ASM involvement in governing mitochondrial ROS production and suggest an important role of ASM in system $x_c^-$- dependent ferroptosis in the brain. Supported by NIH grant NS083544.

**Title:** Alternate strategies for ablation of microglia during brain injury in adult zebrafish

**Authors: *K. SKAGGS**
Biol., Univ. of Findlay, Findlay, OH

**Abstract:** Zebrafish are increasingly used for the study of neurogenesis following injury to the central nervous system in vertebrates because, unlike mammals, they regenerate damaged neurons. After stab lesioning, initial cell death is followed by a robust inflammatory response 1-2 days post-injury, a marked increase in proliferation of radial glia-like progenitors that peaks 3-4 days post-injury, and ultimately the generation of new neurons that migrate to the site of lesion and seem to repair the damage. In order to study the role of the early inflammatory response on neurogenesis, we ablated microglia that responded to injury by injection of Clodronate-containing liposomes at the time of stab lesion. In the absence of microglia, proliferation and neurogenesis were markedly reduced, resulting in incomplete repair of damage in Clodronate-treated lesioned brains. These results suggested that the early inflammatory response may be an important signaling event that stimulates neurogenesis and repair after brain injury in adult zebrafish. A significant limitation of Clodronate treatment is that the critical time period during which microglia crucially affect regeneration cannot be determined. Therefore, we employed a small molecule inhibitor of colony-stimulating factor receptor 1 (CSFR1) to determine the effects of non-invasive microglial ablation on regeneration following brain injury and to further determine with increased precision the time period during which microglia are required to stimulate the neurogenic response following injury. The small molecule can be administered in

fish water, allowing us to investigate how differential timing of microglial ablation affects regeneration following injury.

**Authors: *C. LIU**[1], R.-S. DUAN[1], G.-B. TANG[1], H.-Z. DU[1], Y.-W. HU[2], R.-Y. WANG[2], Z.-Q. TENG[1]
[1]The State Key Lab. of Stem cell and Reproductive Biol., Inst. of Zoology, Chinese Acad. of Sci., Beijing, China; [2]Dept. of Orthopaedic Surgery, Affiliated Hosp. of Guilin Med. Univ., Guilin, China

**Abstract:** Neurons in the central nervous system (CNS) lose their intrinsic ability and fail to regenerate, but the underlying mechanisms are largely unknown. Polycomb group (PcG) proteins, which include PRC1 and PRC2 complexes, function as gene repressors and are involved in the regulation of many biological processes. Here we report that one of PRC1 components polycomb chromobox (Cbx) 2, 7 and 8 are novel regulators of axon growth and regeneration. Especially, Knockdown of Cbx7 in embryonic cortical neurons and adult dorsal root ganglion neurons enhances their axon growth ability. GATA4 and SOX11 are functional downstream targets of Cbx7 in adult sensory neurons for controlling axon regeneration. Moreover, knockdown of GATA4 or SOX11 in cultured DRG neurons prevents axon regeneration. Finally, downregulation of GATA4 and SOX11 could rescue the phenotype in the Cbx7 lacking DRG neurons. Taken together, these data suggest that Cbx7 is a key intrinsic regulator of axon growth and regeneration.

**Abstract:** In addition to alterations in motor function, traumatic spinal cord injury (SCI) may also cause changes in sensory, autonomic and other organ systems. These changes lead to medical consequences of SCI, such as pain and thermoregulatory dysfunction (Handrakis et al 2016, Bryce et al 2000). Unfortunately, pain symptoms are often refractory to treatment and along with pain medications, negatively impact quality of life (Finnerup et al 2012). Thermoregulatory dysfunction is less well studied, but is more common after higher level injuries and has also been shown to negatively impact abilities to perform activities of daily living (Handrakis et al 2016). Here, we characterized symptoms of pain and thermoregulatory dysfunction in adults with chronic SCI (≥ 1 year from initial injury), using the recently developed ISCoS/NINDS International SCI Pain Basic Data Set and Skin and Thermoregulation Function Basic Data Set (Widerstrom-Noga et al, Spinal Cord 2014, Karlsson et al, Spinal Cord 2012). To understand symptom variability in chronic SCI, data was obtained at 2 study visits at 6 months apart. Participants (N=31, 81% males) had an average time from SCI of 15.7±2.3 years (mean±SEM). Most injuries were above the T3 level (65%) and were AIS grade A. Participants' age was 55.0±2.8 (mean±SEM). Most participants reported pain symptoms within 7 days prior to a study visit (62% & 76%, visit 1 & 2). The most common pain subtypes were nociceptive (32%) and neuropathic (25%) (visit 1). Most participants (60%) received pharmacological pain management: Gabapentin and Pregabalin (43%), acetaminophen (28%), NSAIDS (20%) and opioids (9%). Most participants reported no interference of pain in daily activities, sleep or mood. Participants who described their worst pain problem as neuropathic reported significantly higher pain intensity. Most participants reported symptoms of altered thermoregulatory function within 3 months prior to a study visit, including sudomotor (64%) and hypo- or hyper-thermia (36%). A lower oral temperature obtained at the study visit was recorded for participants who

reported symptoms of altered thermoregulation function. In the future, these data will be used to explore potential correlations between thermosensory symptoms and biochemical changes.

**Abstract:** The harsh microenvironment generated after traumatic spinal cord injury (SCI) results in significant early necrotic and apoptotic cell death. Oligodendrocytes are particularly susceptible to the death after injury and are one of the first cell types which die resulting in widespread demyelination of both injured and spared axons. Cell replacement therapy with neural progenitor cells (NPCs) represents a promising therapeutic potential for SCI, however, the proportion of NPCs differentiated to oligodendrocytes after transplantation is very low. This is more dramatic for human cells. We have developed a unique method to bias the differentiation potential of tripotent human NPCs towards more oligodendrogenic fate (oligodendrogenic NPCs; oNPCs) while preserving their potential to generate neurons and astrocytes. In clinically-relevant models of rodent cervical and thoracic clip-contusion SCI, we studied the effects of these novel cells on lesional area, graft-host integration, and functional recovery. Transplanted oNPCs migrated rostrocaudally along spinal cord and differentiated into $NeuN^+$/$Tuj1^+$ neurons and $GFAP^+$ astrocytes as well as $Olig2^+$ immature and GST-$pi^+$ mature oligodendrocytes. Mature human oligodendrocytes also expressed MBP and integrated with rodent NF $200^+$ neuronal axons, indicating the potential of transplanted oNPCs to remyelinate host axons in both the cervical and thoracic spinal cord. Furthermore, oNPC transplanted rats demonstrated

significantly reduced lesion volumes and enhanced tissue preservation, white matter sparing and motor functional recovery. This work provides evidence that partially biasing NPCs towards an oligodendrogenic fate can improve recovery via remyelination and highlights oNPCs as a promising cell-based approach for CNS-repair.

**Abstract:** Axon regeneration following spinal cord injury (SCI) is critical to restore lost motor function. Axon regeneration is prevented both by cell-extrinsic cues, and by a cell-intrinsic failure of many injured neurons to express key pro-regenerative genes. To address neuron-intrinsic constraints, we have shown previously that forced overexpression of pro-regenerative transcription factors (TFs), including KLF6, promotes regeneration of the corticospinal tract (CST). However, KLF6-stimulated axons regenerate only through spared tissue and avoid lesion sites, suggesting that environmental cues continue to constrain successful regrowth. Hence, an integrated approach to simultaneously boost intrinsic capacity along with negating inhibitory extrinsic cues could be a promising strategy going forward. To address this, we adopted a system of stem cell grafting shown recently to provide a permissive environment for CST regeneration. Here we tested the ability of KLF6-stimulated axons to regenerate through the stem cells matrix and used an optogenetics-based approach to assess their ability to form functional synapses. Adult mice received midline cervical (C4-C5) 1mm deep wire-knife transections followed by transplantation of embryonic neural progenitor cells (NPCs) expressing Td-tomato. Cortical neurons were transduced with AAV-KLF6 or AAV-EBFP control, along with AAV-Channelrhodopsin (rAAV9/CamKII-ChR2-EYFP). Consistent with prior reports, by 8-10 weeks CST axons extended into the stem cell transplants. KLF6 expression significantly increased the

number and distance of CST axon growth into the graft and, importantly, into host tissue beyond the graft. Optical stimulation of CST axons evoked clear post synaptic responses in spinal neurons above the injury site in both controls and KLF6-treated animals. More than half of KLF6 animals, but no controls, also showed light-evoked responses as far as 1mm below the injury site, indicating successful synapse formation by regenerated CST axons. However, KLF6-treated animals showed no improvements over control in a horizontal ladder task, hinting that axon growth remained insufficient or potentially mistargeted. Ongoing experiments are testing additional genetic manipulations and alternative retrograde gene deliveries to further improve axon growth. Overall our results show that an integrated approach of elevating intrinsic growth capacity of injured CST axons, while also providing cut axons with growth-permissive stem cell grafts, is a promising approach to maximize axon regeneration after SCI.

**Abstract:** Spinal cord injury (SCI) disrupts axonal pathways, leading to permanent motor, sensory, and autonomic dysfunction, as well as chronic pain, respiratory impairment, and loss of bowel or bladder control. Several complex pathophysiological mechanisms limit spontaneous recovery following SCI. The ultimate goal of our work is to develop cationic, amphiphilic polymeric nanoparticles for simultaneous delivery of drugs and therapeutic nucleic acids (TNAs) to promote axonal regeneration and plasticity. We recently reported the synthesis and characterization of poly (lactide-co-glycolide)-graft-polyethylenimine (PgP) and its ability to efficiently transfect TNAs in various neural cell lines and primary chick forebrain neurons *in vitro,* as well as in the normal rat spinal cord [1]. We have also shown that PgP can deliver

siRNA targeting RhoA, a critical signaling pathway activated by multiple extracellular inhibitors of axonal regeneration, to the injured spinal cord and maintain RhoA knockdown for up to 4 weeks post-injection, reduce astrogliosis and cavitation, and increase axonal regeneration [2]. In this study, we investigated the ability of amphiphilic copolymers (PgP) carrying rolipram (Rm) to restore cAMP level and reduce secondary injury following SCI. Rm was loaded in the PgP solution by solvent evaporation method and the amount of Rm loaded in PgP was measured by HPLC. Compression injuries were created by application of a micro vascular clip (70 gm pressure, Roboz Surgical Store) for 10 minutes at the T9 spinal cord in rats. To evaluate Rm loaded PgP (Rm-PgP) effect on cAMP level, 10 µl Rm-PgP (10 µg Rm) was injected at the injury lesion immediately after SCI. At 1, 2, 3, and 7 days post-injury, rats were sacrificed and cAMP level was evaluated using ELISA Assay. TUNEL and ED1 staining was also performed to evaluate Rm-PgP effect on apoptosis and inflammatory response. We found that single injection of Rm-PgP (10 µg Rm) in rat spinal cord lesion site restores cAMP levels to sham animal level up to 2 days and reduces apoptosis and the inflammatory response in rat SCI compression injury. In conclusion, we demonstrated that cationic amphiphilic polymeric nanoparticle, PgP is a promising carrier for Rm to for the SCI repair. In the future, we will assess the expression of key inflammatory cytokines and also the functional recovery after Rm-PgP treatment in rat SCI model.

**Abstract:** Regenerative failure is responsible for lack of functional recovery following spinal cord injury (SCI). To date, there are no effective treatments that overcome regenerative failure after SCI. Clarification of the molecular mechanisms underlying regenerative failure therefore remains a priority. In contrast to central nervous system axons, axons in the peripheral nervous system are able to mount a regenerative response. A key model to assess differences in this regenerative capacity are the L4-L6 dorsal root ganglia (DRG). These neurons extend one axonal branch towards the periphery that regenerates after injury and one branch towards the dorsal columns of the spinal cord that does not. In contrast to central branch injury, following injury to the peripheral branch, the neuron cell body is able to mount a profound transcriptional response that drives the expression of key genes that direct axonal outgrowth and regeneration. Given that histone acetylation facilitates gene expression, we hypothesised that injury-induced signalling converges on the epigenome to enhance histone acetylation and regenerative gene expression after sciatic nerve but not central branch injury. To address this hypothesis, we performed a systematic investigation, integrating RNA and ChIPseq for H3K9ac and H3K27ac after sciatic nerve (SNA) vs dorsal column axotomy (DCA). We identified that *(i)* increased histone acetylation is associated with an enhanced expression of key transcriptional and signalling dependent networks after SNA, which are not found following DCA. *(ii)* Bioinformatics analysis revealed that central to several signalling networks, is Cited2, an interacting transactivator of the histone acetyltransferases p300 and CBP. We found that Cited2 recruitment enhances the activation of p300 and CBP to promote increased H3K27ac and H3K9ac whilst also bridging upstream regenerative signalling through recruiting various transcription factors to the acetylated promoters. Next, (iii) we investigated FDA approved compounds that would trigger the expression of Cited2, histone acetylation and the Cited2 signalling network as a means to exploit the regenerative translational potential of Cited2 network modulation. We identified the FDA approved HDAC inhibitor Panobinostat, which we found enhances H3K27ac and H3K9ac after SCI, driving the expression of Cited2 and a number of members of the Cited2 associated transcriptional/signalling dependent networks. Lastly, we demonstrated that systemic administration of Panobinostat can promote axonal regeneration, sprouting and functional recovery following a thoracic spinal cord dorsal hemisection.

**Abstract:** [Introduction]Traumatic spinal cord injury (SCI) interrupts sensory and motor tracts resulting in severe, lifelong functional impairments for patients. Despite the need, one of the greatest challenges in developing an effective therapy for chronic SCI has been the inhibitory microenvironment of the injured spinal cord. Aspects of chronic spinal cord injury (SCI) environment such as formation of glial scars and Chondroitin sulfate proteoglycans (CSPGs) act as barrier to repair and regeneration. To address this environment Chondroitinase ABC (ChABC) is used to breakdown CSPGs and facilitate a permissive environment for the transplantation neural stem cells (NSCs) derived from induced pluripotent stem (iPS) cell in cervical SCI mouse model. [Materials and Methods]Six weeks after cervical SCI we had continuously injected ChABC into subarachnoid space for a week using an osmotic pump. After which NSCs derived from iPS cells (iPSC-NSC) are intraspinally transplanted rostral and caudal to the injury site. We examined neurobehavioral tests in BMS score, grip strength meter, inclining test and CatWalk analysis. In addition 8 weeks after transplantation, we performed histological and electrophysiological analysis. [Results]The administration of ChABC reduces elements of the glial scar and result in greater iPSC-NSC survival and engraftment. Fig.1 is the Schematic representation of experimental design. The combinatory treatment of iPSC-NSCs and ChABC significantly promoted forelimbs neurobehavioral recovery in grip strength meter and CatWalk analysis. The iPSC-NSCs integrate into the chronically injured spinal cord (Fig.2) and differentiated into neurons, astrocyte and oligodendrocyte without evidence of tumorigenesis. There is evidence that exogenous cells that differentiate to oligodendrocytes contributing for remyelination, while other exogenous cells become motor neurons. These motor neuron make new functional synaptic connections between host and grafted neurons via glutamate and acetylcholine receptors in patch clump analysis and electron microscope. [Conclusion]By altering the glial scar in cervical SCI prior to delivering iPSC-NSC, we demonstrate that even the chronic injury environment remained therapeutic relevant for iPSC-based treatments. This is the first report that we obtained the functional recovery in chronic SCI with solid scientific evidence. This results suggested that we can expect a good results in clinical trials in the patients with chronic SCI.

**Abstract:** Traumatic spinal cord injury (SCI) provokes dramatic disability and dysfunction in the motor, sensory and autonomic systems. The potent inflammatory reaction that occurs after SCI is strongly associated with further tissue damage. As such, immunomodulatory strategies have been developed aiming at reducing inflammation but also at shaping the immune response in order to protect spared neural tissue, to repair and to promote regeneration. One of those promising strategies is the intraspinal administration of the cytokine IL-4 that was shown to promote a phenotype on specific immune cells associated with neuroprotection and repair.
In this work we evaluated if a systemic delivery of IL-4 for a 7-days period was also capable to

promote neuroprotection after SCI by analyzing different neural cells populations and motor recovery.
IL-4 treatment promoted an elevation of the anti-inflammatory cytokine IL-10 in the serum both at 24h and 7 days after injury. Locally, treatment with IL-4 led to a reduction on cells expressing markers associated with inflammation CD11b/c and iNOS. Importantly, IL-4 treatment increased the neuronal markers βIII-tubulin and NeuN, and the oligodendrocyte marker O4, suggesting a neuroprotective effect.
Moreover, 100% of the animals treated with IL-4 were able to recovery a clinically relevant feature of locomotion (weight support) against only 33% of saline treated animals.
Overall, these results show that systemic administration of IL-4 positively impacts different aspects of spinal cord injury, creating a more favorable environment for recovery to take place.

**Abstract:** Recently, our lab demonstrated robust regeneration of corticospinal tract (CST) axons into neural progenitor cell (NPC) grafts placed in mid-cervical spinal cord injury (SCI) sites (Kadoya et al., Nat Med 2016). We hypothesized that forelimb and hindlimb CST axons regenerate into NPC grafts placed in the mid-cervical SCI sites, since both systems are axotomized. To test this hypothesis, we grafted rat embryonic day 14 spinal cord-derived NPCs expressing green florescent protein (GFP) into a C3 dorsal column lesion site, and then injected AAV-expressing red florescent protein (RFP) into only the forelimb or hindlimb regions of the motor cortex. To our surprise, we found that few forelimb CST axons regenerate into NPC grafts

one month later, whereas hindlimb CST axons robustly regenerate into these grafts at C3. To verify this unexpected result, we utilized highly specific, Cre-mediated tracing of CST axons projecting to either C6 or L3. We first injected AAV9 viral vectors expressing Cre-dependent Td-tomato into forelimb and hindlimb motor cortex, and then injected AAV8-Cre (which undergoes retrograde transport) into C6 (N=4 animals) or L3 (N=4 different animals), respectively. This approach specifically enabled Td-tomato expression exclusively in forelimb- or hindlimb-projecting CST axons. Preliminary studies confirm rare regeneration of forelimb CST axons into NPC grafts, whereas regeneration of hindlimb CST axons is robust. An examination of mechanisms underlying this selective regeneration is underway, and will contribute to efforts to optimize corticospinal regeneration after SCI.

**Abstract:** Spinal cord injury (SCI) is a devastating trauma that seriously impacts a patient's physical as well as psychological health. Elucidation of the dynamic process of degeneration of injured axons is very important for the development of therapeutic strategies for the treatment and investigating the therapeutic time window. In past, the pathological changes after SCI were mostly exanimated in isolated tissue by immunohistochemistry and anterograde tracing which provide information about the pathology at the given time points in different animals. We used a method for time-lapse observation of injured axons in living mice. This approach enables optical imaging of the dorsal spinal cord for a prolonged period of time up to several months without the

need of repeated surgical procedures. Briefly, we expose the vertebrae T11-L1 and construct custom-made chamber around exposed vertebral column using cyanoacrylate. A laminectomy of Th12 vertebra was carried out with dental drill and compression spinal cord injury was performed. Then a thin layer of silicone elastomer was applied to the surface of spinal cord and 3 mm round coverslip was positioned over the centre of the imaging window. Cyanoacrylate was used to seal the chamber. We investigated the role of endogenous individual cell types (neurons, reactive astrocytes, microglial cells and oligodendrocytes) in secondary injury processes using several transgenic mice, which express fluorescence in different cells. The morphological changes of cells were explored by two-photon microscopy which can observe deep structures of tissues including spinal cord axons. We observed fragmentation of axons and tracked retraction and degeneration of injured axons. We saw infiltration of microglial cells which exhibit changes in morphology, motility and phagocytic activity. This method may help clarification of pathophysiology of SCI and development of therapeutic modules for the treatment.

**Abstract:** The glial scar formed after a spinal cord injury acts as a physical and chemical barrier to nerve regeneration and functional recovery. The scar is composed of chondroitin sulfate proteoglycans (CSPGs), which strongly inhibit axonal regrowth. Previous work by Osterhout and

Siebert suggests that CSPGs may also inhibit remyelination, by influencing the behavior of endogenous oligodendrocyte progenitor cells (OPCs) near the injury. Migration and differentiation of OPCs is inhibited the presence of CSPGs. When OPCs come in contact with CSPG deposits, their processes retract and turn away. Treatment with chondroitinase ABC (cABC), which removes the glycosaminoglycan (GAG) side chains from CSPGs, creates a permissive environment for both axonal sprouting and OPC migration *in vivo*. Moreover, *in vitro* screening of neurotrophins that stimulate axonal growth revealed that several of these factors can also promote OPC migration and differentiation in the presence of CSPGs. Using a nanoparticle delivery system, we examined the effects of neurotrophins GDNF and NT3 on endogenous OPCs *in vivo* after spinal contusion injury. The total number of OPCs surrounding the lesion site was significantly increased after growth factor treatments as compared to control. This is due to enhanced migration of OPCs and is evident at early times post injury in the presence of growth factors. However, the OPCs accumulated at the immediate edges of the lesion and did not readily move into the lesion center. Axonal sprouting is also evident at earlier times with neurotrophin treatment, as compared to control. Collectively, these data demonstrate that nanospheres can effectively deliver neurotrophins to a spinal cord lesion, which stimulates early axonal sprouting as well as rapid OPC migration to the lesion site. This treatment may not only speed axonal regeneration, but stimulate remyelination and maximize recovery of function after SCI.

**Abstract:** Traumatic cerebrovascular injury (TCVI) is common after TBI is responsible for a significant portion of TBI-related disability. Development of therapies targeting TCVI will require reliable and inexpensive biomarkers to measure vascular dysfunction and document

target engagement. Cerebrovascular reactivity (CVR) is impaired following TBI and methods which reliably and non-invasively measure CVR are available, making CVR an attractive candidate predictive and pharmacodynamic biomarker for TCVI-directed therapies. This study was designed to assess CVR longitudinally after TBI in humans using functional Near Infrared Spectroscopy (fNIRS) from the acute to the subacute and chronic stages. We also studied the effect of treatment with a phosphodiesterase 5 inhibitor, sildenafil citrate, in order to assess the utility of fNIRS as a pharmacodynamic biomarker in future clinical trials. 7 participants with complicated mild TBI were studied in the acute (within 72 after injury) and subacute (14 days after injury) stages, in addition to 4 age- matched healthy controls (HC), who were studied once. CVR was assessed by measuring the changes in oxygenated hemoglobin (ΔHbO) and deoxygenated hemoglobin (ΔHbR) concentration produced by mild hypercapnia (5% $CO_2$). The change in CVR before and one hour after the administration of single dose of sildenafil citrate (60 mg orally) was also assessed. Mean (± SEM) CVR was lower in TBI patients compared to HC (HC: 0.100 ± 0.028%/mmHg; and TBI: CVR 0.057 ± 0.011%/mmHg, p=0.22). Sildenafil administration did not result in an increase in CVR in HC (t=0.1463 df=3, p=.89) whereas TBI patients show a clear potentiation of the CVR response (p<.08). These findings support the hypothesis that vascular injury represents a distinct endophenotype following TBI and PDE5 inhibition as a potential therapy for TCVI.

**Abstract:** In adult mammals the repair capacities of the central nervous system (CNS) white matter are poor. It follows that patients with spinal cord injury (SCI) usually evolve toward permanent disability. This can be partly explained by the action of components of the extracellular matrix (ECM). NX210 is a peptide derived from SCO-spondin, a protein of the ECM early expressed during the development of vertebrate CNS. SCO-spondin is a multi-domain protein containing several consensus domains, especially domains called thrombospondin type 1 repeats (TSRs), which are potential sites of protein-protein interactions. These TSR domains are shared by developmental proteins of the CNS and involved in crucial biological functions including axonal growth and pathfinding, and synaptogenesis. NX210 properties to increase neuronal survival, neurite outgrowth and fasciculation, and to inhibit oxidative stress and cell death have suggested its potential interest as a neuroprotective agent after SCI. The mechanism of its multi-functional activity was previously demonstrated to be partly related the cell surface receptor β1 integrin. We firstly assessed regenerative properties of NX210 in a rat model of SCI using a section of dorsal funiculi. Ten days after injury a sharp fiber regrowth in 4/5 NX210-treated rats *versus* a minor regrowth in 1/5 control rats were observed using neurofilament immunostaining. We secondly assessed functional recovery after treatment with NX210 in a contusion model of rat SCI using the NYU impactor and using the BBB score and reflex testing. Single intrathecal injection of NX210 (100 and 30 µg/kg) determined functional recovery with a dose-dependent effect as compared to the vehicle. BBB score was significantly higher in the NX210-group from D14 to the end of the study (D28); 60% (6/8) and 25% (2/8) of rats had a BBB score≥14 with a 100µg/kg and 30µg/kg of NX210 respectively compared to 17% (1/6) with vehicle. Reflex testing included paw placement and toe-spread reflexes. At D28 post-injury normal response was observed in 50% (4/8) and 38% (3/8) of rats to paw placement testing, and in 100% (8/8) and 50% (4/8) of rats to toe-spread reflex after 100µg/kg and 30µg/kg NX210 treatment, respectively. By contrast normal response was observed in only 33% (2/6) of rats to both reflex testing in the vehicle group. NX210 safety has been subsequently demonstrated in rats and dogs. A first-in man clinical trial on acute SCI is expected to start soon.

**Title:** TLR4 activation restores window of opportunity for rehabilitative training in rats with chronic cervical spinal cord injury

**Authors: *A. TORRES ESPÍN**[1], J. FORERO[2], K. K. FENRICH[2], A. M. LUCAS-OSMA[2], E. SCHMIDT[2], D. J. BENNETT[2], P. G. POPOVICH[3], K. FOUAD[2]

**Abstract:** Rehabilitative training is currently one of the most successful therapies to promote recovery after spinal cord injury (SCI). A significant challenge for rehabilitative training following SCI is the timing of the training onset. Starting training in the early stages following injury is much more effective in promoting recovery than starting it weeks thereafter. The challenge is that SCIs are often accompanied by multiple traumas, making rehabilitative training of motor tasks early after injury difficult. Here we investigated the possibility to reopen the window of opportunity for effective motor training in rats with chronic SCI by reintroducing inflammation with systemic lipopolysaccaride (LPS), administration. 8 weeks after a cervical spinal cord injury, animals were trained in a grasping task for 2 months in combination with LPS or Saline injection. 3 different experiments were performed using 3 training intensities. We found that rehabilitative training efficacy in a single pellet reaching and grasping task can be increased by systemic LPS administration. A loss-of-function experiment using a TLR4 antagonist prevented the LPS-increased training efficacy, suggesting that this effect is mediated by TLR4 activation. However, a beneficial effect was achieved only when high-intensive training was provided. Importantly, in contrast to training alone, the combination of systemic LPS and high-intensive training promoted functional improvement by increasing reparative rather than compensatory mechanisms, which was observed in functional and anatomical outcome measures. Thus, we propose that neuroinflammation plays a key role in determining the window of opportunity for rehabilitative training and reparative neuroplasticity after SCI. Modulation of post SCI neuroinflammation could thus become an approach to reopen the window for effective rehabilitative training even weeks after SCI.

**Title:** Effects of activity-based training on upper and lower urinary tract function following spinal cord injury

**Authors: *L. R. MONTGOMERY**, C. YANG, J. E. ARMSTRONG, C. H. HUBSCHER
Dept. of Anatom. Sci. and Neurobio., Univ. of Louisville, Louisville, KY

**Abstract:** Urinary complications are common following spinal cord injury (SCI) which severely impacts quality of life. Improving urinary function is one of the top priorities identified by SCI individuals. Our group has previously shown that activity-based training in human SCI research participants as well as in a rodent SCI model leads to improvements in urinary function, although the mechanisms are unknown. We have shown using metabolic cages in our animal studies that SCI-induced polyuria (increase in urine output) benefits from both locomotor training (LT; quadrupedal stepping on a treadmill with all limbs) as well as forelimb training (FT; non-weight-bearing exercise on a treadmill without hind-limb engagement). In this study, a cohort of adult male Wistar rats was given a T8 spinal contusion (215 kD) and randomly assigned to trained (daily for one hour/seven days a week beginning two weeks post-SCI) and non-trained groups. To elucidate possible mechanisms that may be driving the training effect on polyuria, vasopressin (AVP) levels were periodically measured. Terminal study assessments after two months of training targeted both the lower (terminal cystometrogram with external urethral sphincter EMG) and upper (Western blot analysis of kidney tissue) urinary tract. As we have shown previously, 24 hour urine output increased after SCI, with non-trained animal groups being higher by the end of training. AVP levels in all animals were decreased post-SCI and decreased further with training. Western blot analysis of kidney tissue however, showed differences in vasopressin (V2) receptor numbers between the groups, with LT/FT animals showing similar receptor levels to sham controls and non-trained animals showing significantly decreased receptor levels. Kidney aquaporin 2 (AQ2) receptor numbers were also significantly decreased in non-trained animals compared to sham and LT/FT animals. All animals exhibited a decrease in the inter-burst period during voids compared to sham, although the inter-burst duration was shorter for the non-trained compared to LT/FT animals, indicating increased sphincter activity in the non-trained SCI animals. Thus, activity-based training has a positive effect on urinary tract function in SCI animals. The decreased urine output is thought to occur in part to the ability of training to limit the SCI-induced loss of V2 and AQ2 receptors in the kidney. In addition, training appears to have a beneficial effect on external urethral sphincter activity allowing for longer inter-burst intervals during voiding compared to non-trained animals.

**Title:** Locomotor training alters penile reflex responses in a rat model of spinal cord injury

**Authors: *C. J. STEADMAN**, R. F. HOEY, L. R. MONTGOMERY, C. H. HUBSCHER
Univ. of Louisville, Louisville, KY

**Abstract:** Sexual dysfunction is rated by the spinal cord injury (SCI) population as a top priority issue that significantly impacts quality of life. In SCI males, erectile function, ejaculation, and fertility are severely impaired. The current examination of erectile function in a clinically relevant male rat contusion model was prompted by a recent report showing improvements in sexual function by male SCI research participants undergoing 60-minute daily sessions of locomotor training (LT) on a treadmill (harnessed with weight support). The present study utilized a behavioral reflex measure of penile dorsiflexion and terminal electromyography (EMG) assessments of the bulbospongiosus muscle (BSM) in an *in vivo* anesthetized preparation using uni- and bi-lateral electrical stimulation of the dorsal nerve of the penis (DNP) to examine any potential effects of daily one-hour LT (quadrupedal-trained) on erectile function. Other animal groups examined included a non-weight bearing exercise SCI group (forelimb-trained), a non-trained SCI control group harnessed for an equivalent one-hour time frame, and a home-cage injured control group that received limited handling. By the end of 8 weeks of daily task-specific training, latency to reach dorsiflexion reflex in the LT rats was shifted closer toward normal from pre-training values which was not found for the SCI groups that received either no training or forelimb-only daily training. Maximum and average amplitude of BSM response to DNP stimulation was significantly higher in LT animals as compared with forelimb-only trained animals and non-trained controls, and BSM response latency in LT animals was significantly decreased compared to non-trained controls. Initial histological examination of the lesion epicenter revealed no correlates associated with any of the changes in penile responses. Initial decreases in latency of dorsiflexion reflex after SCI is likely due to disruption of bilateral, descending reticulo-spinal projections in the spinal cord. Increases in dorsiflexion reflex latency after LT may indicate the strengthening of some residual connections through the lesion as the small but significant change could be indicative of a partial return of supra-spinal depression of this DNP-pudendal motoneuron reflex. An alteration in BSM response latency and amplitude after LT indicates an increase in the excitability of the circuitry below the level of the lesion. A

lack of effect with exercise alone suggests that sensory input through task-specific stepping and/or hind-limb loading may increase the excitability of the lumbosacral cord.

**Title:** Task-specific training effects on at-level allodynia in a rat model of spinal cord injury

**Authors: *J. GUMBEL**, J. D. FELL, C. H. HUBSCHER
Anatom. sciences and Neurobio., Univ. of Louisville, Louisville, KY

**Abstract:** At-level allodynia is a common complaint among the spinal cord injury (SCI) population as a quality of life issue. This type of hypersensitivity to touching the dermatomal zone just rostral to the level of injury also develops in male rats receiving a severe T8 spinal cord contusion (C.H. Hubscher and R.D. Johnson, J Neurotrauma, 16(6):533-541, 1999). Locomotor training (LT) after SCI is used as a rehabilitative therapy to improve quality of life factors such as bladder, bowel, and sexual function, but also has benefits of reducing SCI-related pain (P.J. Ward et al., J Neurotrauma, 31:819-833, 2014). In the present study, contusion injuries were made to test for the efficacy of activity-based training without hind-limb engagement, as such training was found to improve urinary tract function in addition to LT (Hubscher et al., AJP Renal, 310:F1258-F1269,2016). Using Semmes-Weinstein monofilaments at the level of injury, rats were scored weekly post-SCI using a 10-point scale for allodynia based upon pain-like behavioral responses previously defined (B.J. Hall et al., J Pain, 11(9):864-876, 2010). Rats in the current study underwent 60 minutes of activity-based training on a treadmill daily for eight weeks beginning at two-week's post-injury. Both the quadrupedal LT-trained and forelimb-only trained (non-weight bearing) groups scored significantly lower (indicative of reduced sensitivity) than the non-trained/home-cage group, starting around four weeks after the initiation of activity-based training. This result suggests that multiple forms of exercise/rehabilitative therapies, including LT, could benefit the SCI population with SCI-related pain. Mechanisms underlying these effects are currently unknown but likely include multiple factors that modulate interactions amongst neuronal, endocrine and immune systems.

**Title:** AAV vector mediated delivery of NG2 function neutralizing antibody and neurotrophin NT-3 improves synaptic transmission, locomotion and urinary tract function after mild spinal cord injury (SCI) but not in severe injury model of adult rats

**Authors: *H. A. PETROSYAN**[1,2], M. LENZI[2], S. GUMUDAVELLI[1], R. MUFFALETTO[1], K. LASEK[1], V. ALESSI[1], N. PHAGU[1], J. LEVINE[1], W. COLLINS[1], V. ARVANIAN[1,2]
[1]Neurobio. and Behavior, Stony Brook Univ., Stony Brook, NY; [2]Northport VA Med. Ctr., Northport, NY

**Abstract:** The role of NG2 proteoglycan in the function of spinal circuitry is dual. NG2 is considered one of the key inhibitory factors restricting axonal growth and blocking axonal conduction following SCI. Some studies, however, indicate the importance of NG2 in formation of synaptic contacts. We hypothesized that the optimal treatment would be neutralization of inhibitory function of NG2 without its physical removal. For prolonged delivery of NG2 function neutralizing antibody we (together with Dr. Levine) developed a novel gene therapy tool: an AAV construct expressing recombinant single chain variable fragment (scFv) anti-NG2 antibody (AAV-NG2Ab). We examined effects of AAV-NG2Ab alone or in combination with AAV-NT3 in adult rats with thoracic T10 contusion injuries. Single cell electrophysiology was used to evaluate synaptic function. Bladder function was assessed during the survival period and terminal cystometry with simultaneous acquisition of external urethral sphincter EMG activity. Battery of behavioral tests was used to evaluate sensory and motor function recovery. AAV-NG2Ab treated groups demonstrated significant improvements in synaptic transmission, locomotor and bladder function in mild contusion injury model. The best recovery was observed in the group that received AAV-NG2Ab combined with AAV-NT3. In severe spinal cord injury model, however, AAV-NG2Ab did not induce significant improvements of function. We hypothesize that AAV-NG2Ab mediated attenuation of the NG2-induced block of axonal conduction in spared fibers spanning the injury epicenter maybe a critical mechanism underlying

beneficial effects of AAV-NG2Ab in the mild contusion model. In the case of severe injuries, however, the portion of the anatomically intact fibers spanning injury epicenter is limited and improvement of conduction through these few fibers, if any, cannot mediate better recovery. In order to understand better how NG2 may block axonal conduction and how AAV-NG2Ab may attenuate this inhibitory action of NG2 in the model of mild contusion, we have also examined the presence of NG2 in the vicinity of the nodes of Ranvier. Comparison of sections double stained for Caspr (to identify the nodes) and NG2 revealed a significantly higher number of nodes with close contacts with NG2-positive processes in injured animals. Examination of sections from AAV-NG2Ab treated animals is on-going, with results to be analyzed. The results will demonstrate if treatment with AAV-NG2-Ab will result in a decreased number of nodes with close proximity to NG2 positive processes or will attenuate NG2 function to block conduction without physically removing NG2 processes from the nodes.

**Abstract:** Current methods used to treat spinal cord injury with stimulation include transcutaneous electrical stimulation at the muscle and intrathecal electrical stimulation. Both of these methods can offer quality of life improvements for patients but are not entirely effective at restoring function. Optogenetic stimulation provides a method of stimulation that can be done at the neuronal level and does not result in the rapid fatigue which occurs as a result of electrical

stimulation at the neuronal level. The current drawback of traditional optogenetic stimulation is the invasiveness, as this approach requires an implanted light source. Here we describe a method for the activation of optogenetic constructs in a spinal cord injury model where genetically expressed opsins are activated by a light-producing luciferase that is fused to the opsin (luminopsin). Using this approach, cells expressing the construct are activated by the injection of the luciferase substrate allowing for light to be produced by the luciferase. The light sensitive opsin then opens, allowing for non-selective cation flow, exciting the neuron. We found activation of neurons below the level of injury to significantly improve locomotor recovery following spinal cord injury. This new approach can be applied to distinct populations of endogenous neurons. This is the first example of non-invasive activation of an optogenetic component as a potential therapy following spinal cord injury. This approach can likely be applied to other neurological conditions and may prove to be a useful tool in future therapies for patients.

**Title:** Ketogenic diet improves mitochondrial function and reduces inflammation after spinal cord injury in rodents

**Authors: *W. TETZLAFF**[1], K. KOLEHMAINEN[2], O. SEIRA[1], W. PLUNET[1], R. BOUSHEL[3]
[1]Univ. of British Columbia, ICORD, Vancouver, BC, Canada; [2]ICORD and Dept of Biochem. and Mol. Biol., Univ. of British Columbia, University of British Columiba, BC, Canada; [3]Univ. of British Columbia, Sch. of Kinesiology, Vancouver, BC, Canada

**Abstract:** Introduction: Recent findings in our lab demonstrated that the ketogenic diet (KD) may be a promising SCI treatment as rats fed with KD acutely after cervical SCI showed behavioural improvement in forelimb function. KD is a high fat, low carbohydrate diet and is clinically used in drug-resistant epilepsy in children. Here we tested the hypothesis that KD improves recovery by reducing inflammation and improving mitochondrial function. Methods:

Male Sprague-Dawley rats had a C5 hemicontusion injury and were subsequently fed with a standard diet (SD) or KD beginning 4 hours after injury. Spinal cords were then extracted and assayed for cytokine levels and mitochondrial function. At 48 hours post-injury, pro-inflammatory (TNFα, IL-6, and IL-1β) and anti-inflammatory (IL-10 and IL-4) cytokine production was assessed using the MesoScale Diagnostics (MSD) multi-spot assay system. At 7 days post-injury, mitochondrial function was assayed using the Oroboros Oxygraph-2K high-resolution respirometry system. Results: Pro-inflammatory cytokine production was upregulated after SCI while anti-inflammatory cytokine production was reduced. Although KD did not change pro-inflammatory cytokine levels at the 48hr time point, it did significantly increase the anti-inflammatory cytokine IL-10 suggesting that KD does have anti-inflammatory effects. Mitochondrial function was reduced after SCI. However, administration of KD partially rescued function of Complex II after SCI and showed an overall improvement in mitochondrial function that approached non-injury levels. Conclusions: KD can improve recovery from spinal cord injury, in part by promoting production of anti-inflammatory cytokines and rescuing mitochondrial function.

**Title:** Retrograde AAV delivery of pro-regenerative genes for spinal cord injury

**Authors: *Z. WANG**, B. MAUNZE, M. BLACKMORE
Dept. of Biomed. Sci., Marquette Univ., Milwaukee, WI

**Abstract:** Axon regeneration in the central nervous system is limited in part by neuron-intrinsic patterns of gene expression that preclude effective axon extension. Thus, some form of gene manipulation in injured neurons may be needed to restore connectivity after CNS injury. Indeed, we and others have achieved improvements in axon regeneration by using viral vectors to manipulate gene expression in injured neurons after spinal injury. The current practice of direct injection to brain targets is likely impractical for clinical translation, however, due to the size and wide distribution of relevant supraspinal populations, and concerns about unwanted growth in off-target neurons. A potential solution is retrograde delivery of viral vectors. In principle, focal injection of retrograde vectors to the spinal cord could transduce broadly distributed cell bodies

that project axons to the vicinity of the injury, while avoiding transduction of non-supraspinal populations. Prior retrograde vectors have shown insufficient transduction efficiency, however, particularly in corticospinal tract (CST) neurons. A newly developed vector, termed rAAV-Retro, (Tervo et al., 2016) shows promising retrograde properties. Here we tested the timecourse and efficiency of rAAV-Retro in a mouse model of spinal cord injury. rAAV2-Retro-tdTomato was co-injected with retrograde tracer CTB-488 to C4/5 cervical spinal cord of adult mice in the presence or absence of cervical hemisection injury. Retrogradely transduced neurons were detected in diverse supraspinal populations including reticulopsinal, rubrospinal, and corticospinal neurons as early as three days post-injection. Expression was robust by one week post-injection, and unaffected by injury. Remarkably, transduction efficiency, as quantified by CTB-488/tdTomato co-expression, exceeded 90%. Transduction is likely synapse-independent, because spinal injection of rAAV at early postnatal timepoints, prior to the onset of widespread synaptogenesis, produced similarly efficient retrograde CST transduction. In contrast, retrograde transduction was minimal in ascending sensory neurons. Ongoing work is testing retrograde delivery of pro-regenerative genes including KLF6 and STAT3. Overall these data indicate that rAAV offers a simple and highly effective tool for widespread retrograde transduction of descending motor systems.

**Abstract:** Propriospinal neurons can relay functional information past incomplete spinal cord injuries (SCI) and are good candidates to target for restoring neural connectivity across anatomically complete SCI. Propriospinal neurons do not regrow spontaneously across complete SCI lesions and the molecular requirements to stimulate or improve such regrowth are not characterized. In this study we are examining, individually and in combination, various mechanisms with the potential to stimulate or improve propriospinal axon regrowth, including (i) biomaterial depots that locally deliver axon-specific chemoattraction in the form of glial cell-derived growth factor (GDNF) that has previously been reported to stimulate propriospinal axon growth after SCI; (ii) inducing growth supportive extracellular matrix by increasing the local expression of laminin; and (iii) activating propriospinal neuron intrinsic growth programs by using adeno-associated viral vectors (AAV) to deliver manipulations previously reported to activate intrinsic growth programs of other central nervous system neurons. **Title:** Self-deliverable siRNA compounds to evaluate PTEN as a therapeutic target to promote axon regeneration after central nervous system injury

**Authors: *J. RUSCHEL**[1], T. SHMUSHKOVICH[2], M. D. ABBINANTI[1], L. GUO[1], F. YANG[1], E. NIEDERST[1], M. BETANCUR-BOISSEL[2], A. WOLFSON[2], K. M. ROSEN[1], L. J. MCKERRACHER[1]
[1]BioAxone BioSciences, Inc., Cambridge, MA; [2]Advirna LLC., Cambridge, MA

**Abstract:** Phosphatase and tensin homologue (PTEN) is a critical neuron-intrinsic suppressor of axon regeneration in the injured central nervous system (CNS). Neuron-specific PTEN gene silencing, for instance by Cre-Lox recombination or by viral introduction of PTEN shRNA sequences, increases axon regeneration after optic nerve and spinal cord injury in rodents. While these approaches validated neuronal PTEN as a potent target to augment regeneration of injured mammalian CNS axons, drugs that target PTEN gene expression in a therapeutically relevant fashion have not been developed. Therefore, we created self-deliverable small interfering RNAs (sdRNAs) against PTEN sequences conserved in rat and human to evaluate PTEN gene silencing as a therapeutic strategy to promote axon regeneration after CNS trauma. sdRNAs are a novel class of chemically modified small interfering RNAs (siRNAs), which are suitable for therapeutic use due to their high gene silencing efficacy, nuclease resistance and cell penetration without specific delivery vehicles or formulations. We screened a library of multiple in silico-predicted PTEN sdRNA sequences for their mRNA-targeting efficacy using a luciferase reporter assay, which revealed a lead candidate sdRNA, termed BA-434. BA-434 strongly reduced PTEN mRNA levels in both rat PC12 and human HeLa cells and furthermore, induced long-lasting, yet reversible PTEN protein knockdown in rat primary neurons. After intravitreal injection of BA-434 in the eye of adult rats, PTEN protein levels were significantly reduced in the retina for at least 2 weeks as revealed by immunoblotting and immunohistochemistry. Strikingly, PTEN reduction in the retina was accompanied by increased activity of the phosphatidylinositol 3-kinase (PI3-K) signaling axis as demonstrated by increased phosphorylation of AKT and its downstream effectors glycogen synthase kinase (GSK) 3β and ribosomal subunit S6. Finally, we demonstrated that BA-434 promotes neurite outgrowth in cultured PC12 cells and enhances axon regeneration after optic nerve crush in adult rats when delivered intravitreally at post-injury time points. These results suggest, that PTEN gene silencing by the self-deliverable siRNA BA-434 is a promising therapeutic strategy to foster CNS repair after injury.

**Title:** Complement proteins and receptor are required for optic nerve regeneration induced by several pro-regenerative treatments

**Authors: *S. L. PETERSON**, Y. LI, T. KURIMOTO, K. YUKI, B. STEVENS, L. BENOWITZ
Boston Children's Hosp., Boston, MA

**Abstract:** The failure of axons to regenerate in the mature central nervous system (CNS) underlies the permanent functional deficit observed after clinical CNS damage such as spinal cord injury, traumatic brain injury, and optic nerve injury, as well as diseases such as Alzheimer’s and glaucoma. Several recent, promising strategies for improving CNS axon regrowth have been discovered using the optic nerve crush model, including inflammatory zymosan[1], the growth factor oncomodulin[2], PTEN deletion[3], combinatorial treatments[4], and chelation of free zinc using TPEN[5]. The inflammatory response to optic nerve crush, similar to other CNS injuries and diseases, involves the complement cascade, which normally functions in response to pathogen threat by recruiting inflammatory cells, marking pathogens for removal, and directly initiating cell lysis. While the role for complement proteins and their receptors in inflammatory host defense to pathogens is well characterized, recent findings have also suggested various non-traditional roles for complement proteins in CNS development, injury, and disease, including myelin clearance, neuroprotection, neurotoxicity, neuronal migration, synaptic engulfment, and axon guidance[6]. However, the potential involvement of complement in axon regeneration after optic nerve injury has not been investigated. We report that genetic removal of complement proteins C1q or C3 or complement receptor CR3 blocked treatment-induced RGC axon regeneration following optic nerve injury in mice. The number of GAP43-

labeled, regenerating axons beyond the crush site following treatment with zymosan plus cAMP, AAV2-shPTEN plus oncomodulin plus cAMP, or TPEN was significantly reduced in several lines of complement knockout mice in comparison to wild-type littermates 14 days post-injury. However, neither C1q, C3, nor CR3 knockout consistently affected RGC survival. These data suggest that the complement system is required for axon growth in the mature central nervous system, adding to the mounting evidence for non-traditional roles for inflammatory complement proteins in the nervous system.

**Abstract:** Known challenges to promoting functional axon regeneration across the injury site after a severe spinal cord injury (SCI) are: 1) the limited growth potential of adult neurons, 2) the growth inhibitory factors in the injury site, and 3) and the formation of functional circuits. We tested a combination of two promising therapies for SCI that theoretically act through different mechanisms. We asked if transplantation of olfactory ensheathing cells (OECs) combined with epidural stimulation (ES) and voluntary climb training would improve functional and anatomical recovery in a long-term model of severe rodent SCI. Because our previous study found that

transplanted OECs died between 4 and 8 weeks post-injury in outbred Sprague-Dawley rats, this study used an inbred Fischer 344 rat model to prevent transplant rejection. Fischer rats received a severe SCI at T8-T9 followed by a 2-week delayed transplantation of either OECs or media. One month post-injury the spinal rats received ES while climbing on a grid 3 times a week, 20 min/day for 5 months. Rats were tested and videotaped monthly on the climbing apparatus and perfused 5.5 months post-injury. Initially, we found that all of the OEC-transplanted rats had cell survival in both the lesion core and spinal stumps out to 5 months post-transplantation and 50% of them had OEC bridges spanning the lesion. Additional analyses of the injury site showed that OEC-transplanted rats had a greater volume of spared tissue compared to controls. We also assessed regeneration of descending serotonergic axons and neuron survival near the injury site. Lastly, we compared recovery of spinal rat climbing behavior between 2 and 5 months post-injury using a qualitative assessment of hindlimb locomotor features typical of pre-injury climbing. These findings show that OEC transplantation, combined with ES and climb training, can facilitate recovery when compared to media-transplanted controls that received the same treatment.

**Title:** Effect of adelmidrol, a palmitoylethanolamide analogue, on overactive urinary bladder syndrome induced by SCI in mice

**Authors: *S. CUZZOCREA**[1], M. CAMPOLO[2], R. SIRACUSA[2], E. ESPOSITO[1]
[2]department of chemical,biological, pharmaceutical and environmental science, [1]Univ. of Messina, Messina, Italy

**Abstract:** The disruption of coordinated control between the brain, spinal cord and peripheral nervous system caused by spinal cord injury (SCI) leads to several secondary pathological conditions, including lower urinary tract dysfunctions. In fact, a life-threatening disability after SCI is urinary dysfunction, which could be attributable to lack of neuroregeneration of supraspinal pathways that control the bladder function. As a consequence, individuals develop overactive urinary bladder (OAB), a syndrome characterized by exacerbated contractions of the urinary bladder during the filling phase, associated with detrusor sphincter dyssynergia (DSD) and inefficient voiding. The goal of the current study was to explore the effects of adelmidrol, an

analogue of the anti-inflammatory fatty acid amide signaling molecule palmitoylethanolamide, in OAB after SCI in mice. SCI was induced by an application of a vascular clip to the spinal cord dura at T5-T8 to provoke injury. Mice were treated with adelmidrol (10 mg/kg, intraperitoneally) daily for 48 h and 7 days after SCI. SCI was associated with a marked inflammatory response and functional changes in the urinary bladder. Adelmidrol reduced significantly mast cells degranulation and down regulated NFκB pathway in the bladder after SCI both at 48h and 7days. Moreover adelmidrol was able to reduce NGF expression, usually correlate with intravescical pressure caused by OAB, suggesting an association between neurotrophins and bladder pressure. Seven days after SCI, bladder was characterized by a considerable bacterial infection and proteinuria; surprisingly adelmidrol reduced significantly these two parameters. Therefore, taken together, these data show the protective roles of adelmidrol in OAB following SCI in mice, highlighting a potential therapeutic target for controlling OAB, making a significant impact on improving the function, wellness, and overall quality of life.

**Abstract:** Genetic engineering of mesenchymal stem cells (MSCs) and neuronal stem cells (NSCs) has been used to treat spinal cord injuries (SCI). As a mechanism of therapy, MSCs secrete high amounts of anti-inflammatory cytokines and trophic factors, while NSCs can

differentiate into neuronal lineages and aid in tissue replacement. Additionally, the forced overexpression of secreted proteins can enhance the secretome of transplanted cells, which can increase therapeutic efficacy. This project was broken up into two studies that first utilized a combinational treatment strategy that forced the overexpression of the chemokine stromal-derived factor-1 (SDF-1) from MSCs (SDF-1-MSCs), to treat a rat model of SCI. The next study further expanded on these findings by performing a co-transplantation of these SDF-1-MSCs with NSCs using the same transplantation parameters. Transplants occurred at 9-days post-injury, and motor functions were evaluated for 7-weeks post-injury. The first study evaluated the effects of MSCs and SDF-1-MSCs on axonal growth and cavitation in longitudinally cut sections, while the next study evaluated white matter sparing and axon densities surrounding the lesions in cross-sections. Findings from these studies demonstrate that overexpressing SDF-1 from MSCs can reduce cavitation and enhance axonal growth into the lesion site, while co-transplanting SDF-1-MSCs with NSCs can improve motor functions and enhance axon densities surrounding the lesion. However, no white matter sparing was found in either study, but some tumors were observed in rats given co-transplantations with either SDF-1-MSCs and NSCs or unmodified-MSCs and NSCs. Collectively, these studies offer evidence that overexpressing SDF-1 from MSCs can improve the efficacy of stem-cell-based therapies for SCI, but ways to avoid tumors need to be developed.

**Abstract: Introduction**
Human induced pluripotent stem cell-derived neural stem cell (hiPS-NSC) are an exciting therapeutic strategy for traumatic spinal cord injury (SCI) with the capacity to replace lost neural circuits, remyelinate denuded axons and provide trophic support. Unfortunately, most affected individuals are in the chronic phase of their injuries where dense deposition of perilesional chondroitin sulfate proteoglycan (CSPG) scar significantly hinders regenerative cell migration and neurite outgrowth. Scar-modifying enzymes have been shown to mitigate this effect, however, nonspecific delivery via intrathecal catheters risks off-target CNS effects. We aimed to generate a unique, genetically-engineered line of hiPS-NSCs, termed Spinal Microenvironment Modifying and Regenerative Therapeutic (SMaRT) cells, capable of locally expressing a scar-degrading enzyme to enhance functional recovery without the risks of untargeted administration.
**Materials/Methods**
Using non-viral techniques, a proprietary scar-degrading enzyme was genetically integrated into hiPS-NSCs under a human promoter and a monoclonal line was generated by FACS. Enzyme expression and activity was extensively characterized *in vitro* by biochemical assays, immunoblotting, and functional cell culture assay. To assess *in vivo* efficacy, T-cell deficient rats (N=60) with chronic (8 week) C6-7 clip-contusion SCIs were randomized to receive (1) human iPS-NSCs, (2) SMaRT Cells, (3) vehicle control, or (4) sham surgery. Behavioural assessments are ongoing; asynchronous rehabilitation will begin at 20 weeks post-injury with a study endpoint of 32 weeks. Graft survival, cell differentiation, extracellular matrix changes, and graft-host connectivity (trans-synaptic tracing/optogenetic stimulation) will be key outcome metrics in addition to sensorimotor recovery.
**Results**
The scar-degrading ENZYME is robustly expressed by the transgenic SMaRT cells. Importantly, SMaRT cells retain critical human NSC characteristics. The expressed ENZYME appropriately degrades human CSPGs and allows neurons to extend into CSPG-rich regions *in vitro.* Conditioned SMaRT cell media also degrades rodent CSPGs in *ex vivo* serial injured cord cryosections. While blinded behavioural assessments are ongoing, an interim histologic analysis of several animals shows that grafted human cells are extending remarkably long (>20,000um) axons along rodent white matter tracts.
**Conclusion**
This work provides exciting proof-of-concept data that genetically-engineered SMaRT cells can degrade CSPGs *in vitro* and that human NSC grafts can form long axonal processes in the chronic cervical SCI niche.

**Abstract:** We are testing a novel strategy to promote both regeneration of damaged descending bulbospinal respiratory axons and reinnervation of phrenic motor neurons (PhMN) after cervical spinal cord injury (SCI) in rats. More than half of all SCI cases occur in the cervical region, leading to respiratory dysfunction due to damage to respiratory-related neuronal soma and/or their axons. The C3-C6 mid-cervical spinal cord levels house the PhMNs, which are responsible for activation of the diaphragm via muscle innervation by the phrenic nerve. These PhMNs are predominately mono-synaptically innervated by supraspinal respiratory neurons located in a brainstem nucleus called the rostral Ventral Respiratory Group (rVRG). Our goal is to promote diaphragm recovery, and hence inspiratory breathing, by restoring respiratory neural circuitry after cervical SCI. To this end, we are selectively expressing the axon guidance molecule, brain-derived neurotrophic factor (BDNF), at the location of PhMNs to direct regenerating rVRG axons toward PhMN targets. In C2 hemisection rats, we intraspinally inject adeno-associated virus serotype 2 (AAV2)-BDNF specifically into the C3-C6 ventral horn at the location of the PhMN pool. AAV2 vector delivery results in efficient and selective neuronal transduction, as well as significantly increased BDNF expression in ventral horn of the C3-C6 spinal cord. In preliminary findings, AAV2-BDNF injection promotes partial recovery of ipsilateral hemi-diaphragm function (compared to AAV2-GFP control), as assessed by *in vivo* recording of electromyography amplitudes. We are currently elucidating the neuroanatomical mechanisms underlying this functional recovery by selectively labeling various descending rVRG axon populations after treatment. By combining retrograde CTB labeling of PhMNs from the diaphragm with stereotaxic injections of the anterograde/trans-synaptic tracer, AAV2-mCherry/wheat germ agglutinin (WGA), into either the ipsilateral or contralateral rVRG, we are assessing possible contribution of regrowth of damaged rVRG axons and sprouting of spared contralateral fibers, respectively.

**Title:** Direct osmotherapy for the reduction of edema following spinal cord injury

**Authors: *J. M. YONAN**[1], C. HALE[2], V. G. J. RODGERS[2], D. K. BINDER[1]
[1]Div. of Biomed. Sci., [2]Biomed. Engin., Univ. of California Riverside, Riverside, CA

**Abstract:** Spinal cord injury (SCI) is characterized by an initial injury due to trauma, which is followed by a cascade of cellular events, resulting in a greater degree of secondary damage. One of these secondary events is the accumulation of edema at the injury site, leading to expansion of the cord tissue within the spinal column. Current decompressive strategies do nothing to address this issue, leaving the expanding tissue to become compressed against the surrounding dura mater. This results in increased intraspinal pressure, reduced spinal perfusion and eventual tissue infarction. Our lab has developed an Osmotic Transport Device (OTD) to perform Direct Osmotherapy (DOT) following injury. This device is placed directly on the surface of the tissue and utilizes the creation of an osmotic gradient to actively remove water from the spinal cord after injury. We hypothesize that DOT following SCI will effectively remove water from the spinal cord and improve functional outcome. In this study, we first characterized the time course of edema following severe contusion SCI at thoracic level 8 in rats. At varying time points post injury, between 1 hour and 28 days, 15mm of spinal cord encompassing the lesion epicenter were freshly dissected. This tissue was further divided into 5mm segments at the lesion epicenter, as well as rostral and caudal to the lesion and analyzed for percent tissue water content. Results revealed increased water content at the lesion epicenter beginning at 1 hour after injury, which continued to increase until a peak was reached at 72hrs post injury. Water content levels decreased after this point, but remained significantly elevated compared to sham controls for at least 4 weeks post injury. While increases in water content were delayed in the rostral and caudal segments compared to the epicenter, they too peaked at 72 hours post injury and returned to control levels there after. This data provides insight into a critical period for treatment. Preliminary application of the device is underway to determine proper device parameters for effective removal of edema. Thus, DOT may prove to be a novel and minimally invasive method to effectively reduce edema formation following spinal cord injury.

**Title:** Targeting towards early vascular responses following contusive SCI

**Authors: *C. CHEN**[1,2], X.-M. XU[1]
[1]Indiana Univ. Dept. of Neurolog. Surg, Indianapolis, IN; [2]Program in Med. Neuroscience, Paul and Carole Stark Neurosciences Res. Institute, Indiana Univ. Sch. of Med., Indianapolis, IN

**Abstract:** In spinal cord injury (SCI), the initial mechanical damage immediately leads to two categories of effects: vascular effects and biochemical cellular alteration including excitotoxicity. In a conventional hypothesis, both vascular disruption and excitotoxicity-caused neuronal death, necrotic form of other cell death start to occur only in the injury epicenter, interacting with each other and push the boundary toward the adjacent area, so-called “transitional zone”, thus gradually expand the size of the lesion. However, in this study, we have observed vascular disruption in the “transitional zone” as early as 30 minutes after SCI, which was unexpected in the conventional hypothesis. In this “transitional zone”, our two-photon *in vivo* imaging data has indicated that vascular velocity, diameter and permeability were all affected by an acute SCI. Within the same “transitional zone”, histological evidence has also shown significantly increased number of leaked vessels at ventral gray matter. Meanwhile, the number of neurons and glial cells has been maintained in the acute phase of contusive SCI. These data suggest an alternative hypothesis that simultaneously with what happened in the epicenter, vascular damage has also occurred in the “transitional zone” while the cells have not responded to the injury yet. The data also indicates a time window between vascular disruption and neuronal loss at the transitional zone. In addition, targeting towards these early vascular responses and protecting vascular

integrity at an early phase of SCI could provide early neuronal protection and delay the expansion of damaged tissue in the spinal cord.

**Title:** Investigating the effect of stress and exercise in models of elicited headache pain in mice

**Authors: *O. ELLER-SMITH**, X. YANG, J. A. CHRISTIANSON
Univ. of Kansas Med. Ctr., Kansas City, KS

**Abstract:** Experiencing stressful events during the formative years is associated with an increased risk of developing comorbid chronic pain and mood disorders in adulthood. These include interstitial cystitis, chronic prostatitis, vulvodynia, migraine, fibromyalgia, and depression. The exact mechanism underlying the development of these disorders remains unknown, but it likely involves altered functioning of the hypothalamic-pituitary-adrenal (HPA) axis. The HPA axis regulates the stress response and alters one’s perception of pain. To study the consequences of early life stress, we utilize a mouse model of neonatal maternal separation (NMS)). In our model, NMS mice are separated from the dam for 3 hours/day beginning on postnatal (P) 1 through P21. Naïve mice remain undisturbed in their home cage until weaning on P22. Previously, we have shown that NMS mice display evidence of dysfunctional limbic regulation of the HPA axis as well as increased urogenital sensitivity. We are now expanding our studies into peripheral tissues involved in other chronic pain disorders and investigating if NMS mice display behavioral and molecular evidence of susceptibility to headache and fibromyalgia. We are also interested in researching the influence of exercise on chronic pain. At 4 weeks of age, NMS and naïve mice were divided into exercised (Ex) or sedentary (Sed) groups. Ex mice

were pair housed and received access to a running wheel in their home cage, while Sed mice did not receive running wheels. 8-12 weeks later, experiments were carried out. Different methods were used to elicit a migraine episode, including application of noxious solutions (inflammatory soup (IS) or 5% mustard oil (MO)) onto the dura mater via a modified cannula injection through the lambdoidal suture, or intraperitoneal injection of nitroglycerin (NG). Mice were subsequently evaluated for behaviors indicative of headache and widespread allodynia, including mouse grimace score (MGS), rearing episodes, evoked facial grooming, and forepaw or hind paw mechanical withdrawal threshold. Results indicate a significant impact of IS application on forepaw allodynia and MO application or NG injection on hind paw allodynia. We also see an impact of exercise on MGS in our mice. Finally, we found that NMS Sed mice weigh significantly more compared to NMS Ex mice and naïve mice. In summary, our results support the evidence of widespread allodynia experienced by individuals during a migraine attack, indicate that voluntary wheel running can influence the painful behaviors mice display during elicited migraine attacks, and suggest that NMS could have an influence on metabolic regulation that is attenuated by exercise.

**Title:** Vascular contributions of peripheral CGRP in migraine-like photophobia

**Authors: *B. N. MASON**[1], A. KUBURAS[2], W. J. KUTSCHKE[3], M. W. CHAPLEAU[4], A. F. RUSSO[2]
[2]Mol. Physiol. and Biophysics, [3]Anesthiology, [1]Univ. of Iowa, Iowa City, IA; [4]Intrnl. Med., Univ. of Uiowa, Iowa City, IA

**Abstract:** The neuropeptide calcitonin gene-related peptide (CGRP) is a key player in migraine. While migraine can be induced by peripherally administered CGRP (intravenous) and can be treated using CGRP antagonists that act peripherally, the relevant sites of CGRP action remain unknown. To address the role of CGRP both within and outside the central nervous system, we used a mouse model of photophobia. Photophobia is abnormal discomfort to non-noxious levels of light and is experienced by approximately 90% of migraine patients. We have previously shown that peripheral (intraperitoneal, IP) injection of CGRP resulted in light aversive behavior in wild-type CD1 mice similar to aversion previously seen following central (intracerebroventricular, ICV) injection. Importantly, two clinically effective migraine drugs, the 5-$HT_{1B/D}$ agonist sumatriptan and a CGRP-blocking monoclonal antibody, attenuated the peripheral CGRP-induced light aversion and motility behaviors. Our goal for this study, is to identify the mechanism of action of peripheral CGRP using light aversion. Previously we showed that ICV CGRP, but not IP CGRP, in nestin/hRAMP1 mice, mice that overexpress CGRP receptors in the nervous system, causes enhanced light aversion. We have now used transgenic CGRP-sensitized mice that have globally elevated levels of hRAMP1 (global *hRAMP1*) in all tissues. Interestingly, our preliminary data show sensitivity to low light after IP CGRP in these mice. This suggests that CGRP actions in the periphery play an important role in the induction of light aversion in this model. We have now begun investigating the role of the vasculature in peripheral CGRP-induced light aversion by using two approaches (1) genetic overexpression of the CGRP receptor in the vasculature (2) injection of phenylephrine to minimize vasodilation induced by CGRP. Our preliminary data show that IP CGRP in Tagln (SM22)/hRAMP1 mice, mice that overexpress RAMP1 on smooth muscle, display enhanced light aversion. These results suggest that CGRP can act in both the periphery and the brain by distinct, but possibly overlapping, mechanisms. This also suggests that peripheral CGRP actions may be transmitted to the CNS via indirect sensitization of peripheral nerves and likely not on CGRP receptors in the nervous system to cause migraine-like photophobia.

**Abstract:** Veterans returning from active duty are at an increased risk for post-traumatic headache (PTH) and migraine. Migraine alone affects 10% of men and 25% of women, with the lifetime risk increasing to 18% and 43% respectively. Sensory abnormalities are present in individuals with PTH and migraine including extreme light and sound sensitivity. Light sensitivity in patients with PTH or migraine can be debilitating and treatments are lacking. One reason interventions and treatments continue to fall short is a poor understanding of the relevant neuroanatomical correlates that underlie sensory changes in headache. Calcitonin gene-related peptide (CGRP) is a critical neuropeptide involved in pain signaling and has recently come to the forefront of migraine research where it contributes to headache and associated sensory abnormalities. In this study we attempt to identify anatomical regions where CGRP could act to induce light-aversive behavior in migraine and PTH. The posterior thalamus (Po), periaqueductal grey (PAG), and amygdala have been suggested to be regions that could contribute to light-aversive behavior. We hypothesized that CGRP could act as a neuromodulator in these regions to induce light aversive behavior. To test this hypothesis, we used targeted approaches to probe these areas of the brain thought to be important in the development of photophobia. The first approach was direct CGRP injection. The second was optical stimulation using channelrhodopsin driven by the CaMKII promoter. We found that CGRP injection and optical stimulation of the Po and the PAG resulted in different types of light-aversive behavior. These results may begin to shed light on the complex circuitry of light-aversive behaviors in mice.

**Title:** Neural basis for chronic headache and photophobia after mild traumatic brain injury

**Authors: *A. TASHIRO**, H. OHTA
Natl. Def. Med. Col., Tokorozawa, Saitama, Japan

**Abstract:** Mild traumatic brain injury (mTBI) accounts for the majority of head injuries, and posttraumatic headache (PTH) is the most common adverse effect. The most PTH has migraine-like phenotype (Hyperalgesia, Photophobia, Throbbing pain) and is difficult to resolve.

Headache pain is thought to require sensitization of the ophthalmic branch of the trigeminal nerve leading to long-term changes in the activity of neurons in the trigeminal brainstem nuclear complex (TBNC) and higher brain centers. Although the triggers that lead to sensitization of dural-responsive TBNC neurons are not well defined, considerable evidence suggests spatial summation from extradural inputs onto dural-responsive neurons in the brain plays an important role. Luminance-induced TBNC activity is directly relevant to headache pain since heightened light sensitivity is a recognized diagnostic feature of migraine. Neurovascular coupling within the eye likely mediates the discomfort and pain in photophobia that could trigger or exacerbate headache pain. Previously, we reported that the blight light-evoked increases in trigeminal subnucleus caudalis (Vc) neural activity depended on neurovascular link. This study used a rat model to examine the effects of laser-induced shock wave on the Vc neural activity. The parietal region of male rats was irradiated with laser-induced shock wave (diameter 3mm, 4J/cm$^2$) under barbiturate anesthesia. In awake male rats, ocular surface application of hypertonic saline (2.5 M NaCl; 40µl) evoked eye wipe behavior that was enhanced 3-14 days after shock wave irradiation (SWR). In separate rats, under isoflurane anesthesia, single cornea/dura responsive neurons were recorded at the Vc. Hypertonic saline (0.15-5M) and blight light (irradiance=50, 300, 500 W/m$^2$) selectively activated ocular surface and intraocular (neurovascular system), respectively. In SWR rats (seven-ten days after SWR), Vc units had enhanced responses to hypertonic saline and blight light compared to naïve rats. To determine if SWR caused bright light evoked intracranial blood flow increases, blood flow was monitored in arteries of the exposed cranial dura mater and the parietal cortex in naive and SWR rats. In SWR rat, bright light enhanced the magnitude of blood flow but not naive rat, and this blood flow increases evoked dura -responsive Vc units activities. It is concluded that mTBI produces a chronic state of hyperalgesia and light evoked vessels dilation that is reflected in the sensitization of trigeminal -parasympathetic circuit. This model may be suitable for future studies of migraine.

**Title:** Neck muscle inflammation induces trigeminal central sensitization: a risk factor for episodic migraine

**Authors: *P. L. DURHAM**[1], J. L. HAWKINS[2], B. BLANKENSHIP[3]
[1]JVIC-CBLS, [2]JVIC/CBLS, [3]Missouri State Univ., Springfield, MO

**Abstract: Objective:** The goal of this study was to understand the cellular changes associated with neck muscle inflammation, a reported co-morbid condition with migraine, that promote a sensitized state of trigeminal nociceptors. **Background:** Many migraine patients report stress, which can manifest as tension/tenderness and inflammation in neck muscles, as a major risk factor. Projections from neurons emanating from neck muscles converge with primary sensory trigeminal ganglion (TG) neurons in the spinal trigeminal nucleus (STN). Although neck muscle inflammation is implicated in migraine pathology, the cellular mechanisms that mediate an enhanced state of trigeminal sensitization is not well understood. **Methods:** To induce muscle inflammation in adult male Sprague Dawley rats, complete Freund's adjuvant (CFA) was injected at ten different sites of the trapezius. TG and STN tissues collected from naïve animals, and on days 1, 4, and 8 post CFA injection were used for immunohistochemical analysis of Calcitonin Gene-Related Peptide (CGRP) and Protein Kinase A (PKA), GFAP and Iba1, and P-ERK. Nociception to mechanical stimuli of V1 (eyebrow) nociceptors was determined on days 0, 1, 4, and 8 post CFA injection utilizing von Frey filaments and Durham animal holder. To act as an odorant trigger, some animals were exposed to an extracted oil from leaves of the California Bay tree 8 days post CFA injection and nociception assessed 2 hours post exposure. **Results:** Immunoreactive levels of CGRP were transiently upregulated in STN tissues 1 day post CFA as compared to naïve levels, while PKA expression exhibited a temporal increase, reaching significance by day 8 post CFA. Elevated levels of GFAP in the STN were detected at day 1 post CFA, but decreased to naïve levels by day 4. However, Iba1 expression was significantly elevated at days 1, 4, and 8 post CFA. No significant temporal changes in TG levels of CGRP, PKA, or P-ERK levels were detected in CFA alone treated animals. In agreement, mechanical nocifensive sensitivity was not different from naïve at any timepoint post CFA. However, animals with ongoing neck muscle inflammation exposed to the odorant trigger exhibited significantly higher levels of nociception as compared to control animals. **Conclusion:** Results from our study provide evidence that neck muscle inflammation promotes development of central sensitization via upregulation of the CGRP/PKA pathways, acute activation of astrocytes, and sustained microglial activation. We propose that neck muscle inflammation functions as a migraine risk factor by lowering the activation threshold of trigeminal nociceptors to a pungent odor reported as a migraine trigger.

**Title:** Intrinsic brain network abnormalities in chronic migraine are reversed following Onabotulinum toxin-A

**Authors: *A. K. KANUNGO**[1], D. TURCOTTE[2], J. KORNELSON[2], T. KOLESAR[2], B. MANSOURI[1]
[1]Neurol., [2]Univ. of Manitoba, Winnipeg, MB, Canada

**Abstract:** *Objective:* The objective of this study was to compare functional connectivity patterns across cortical brain regions utilizing resting state functional magnetic resonance imaging (rsfMRI) in patients with chronic migraine (CM) before and after treatment with onabotulinun toxin-A (BoNT-A).
*Methods:* An open-label, prospective interventional pilot study was conducted involving a total of 12 patients with confirmed CM. Patients followed a structured timeline consisting of follow-up with headache logbooks, well-validated migraine significance assessments and psychological inventories along with two cycles of BoNT-A injections on Day 0 and 84. Patients underwent rsfMRI scanning protocol at baseline and on Days 56, and 140 to monitor for differences in brain activity. Psychological and pain changes were analyzed by ANOVA, and rsfMRI data via independent component analysis.
*Results:* After the first treatment of BoTN-A, a change in brain connectivity was observed in the default mode network (DFN), right central executive network (RCEN) and salience network (SN), that most prominently involved the left superior parietal gyrus and the bilateral extrastriate gyri, which correspond to components of the lateral pain system and the visual association areas, respectively. Changes to the pattern of functional connectivity within these brain regions was correlated with clinical improvement of migraine frequency and severity (i.e. transformation of CM into episodic migraine (EM)), as well as associated anxiety. Additionally, we observed at baseline and following BoTN-A administration, no significant functional brain connectivity within the left central executive network in our cohort with CM.
*Conclusions:* CM patients demonstrate an abnormal pattern of functional connectivity in the DFN, RCEN and SN, corresponding to brain regions involved with higher cortical pain and visual processing. This pattern of connectivity is altered by BoTN-A administration. The functional activity differences between CM and EM have been described in subcortical and brainstem areas in the past. However, to the best of our knowledge, our study demonstrated cortical connectivity changes after transforming CM to EM for the first time. This novel finding may have significant application in the clinical approach for management of CM in future. Furthermore, the absence of a left executive network in CM patients, which did not change after BoTN-A treatment, was unexpected and may provide a mechanistic explanation for cognitive abnormalities seen in this disorder. To confirm these findings, further research with larger number of patients are needed, in conjunction with placebo control.

**Title:** Association between migraine-related disability and co-morbid depressions among migraineurs having follow up at two neurology referral clinics in Addis Ababa, Ethiopia

**Authors: *B. A. AYELE**, Y. MAMUSHET
Dept. of Nuerology, Addis Ababa University, Col. of Hlth. Sceinces, Addis Ababa, Ethiopia

**Abstract: Background**: Migraine headache is one of commonest neurologic disorder to cause great disability among its sufferers, migraine not only cause pain, but also cause significant disability, economic loss, low productivity and reduced quality of life of individuals. According to recently published population based study in Ethiopia, the prevalence of Migraine headache in both urban and rural population is estimated to be 16.7%. **Objectives**: The aim of this study is to assess the association between migraine-related disability and co-morbid depression among migraineurs **Methods:** Cross sectional, descriptive survey was conducted among migraine patients age ≥ 13 who attended clinics during study period were included. Correlation between variables where determined using spearman correlation coefficient .The study was conducted between June 1- October 30, 2016. **Results:** During five months of study periods total of seventy migraine patients were seen at both neurology referral clinics. Fifty-three (74.3%) of our study participants are female with commonest age group being 20-30 years. Twenty (28.6%) of the participants completed secondary education. Seventy (70%) of participants has migraine without aura subtype, while the mean headache frequency and headache intensity was found to be 23.4± 14.9 and 7.4 ± 1.2 respectively. More than Forty-one (41.4%) of participants fulfilled Major depressive disorder (MDD) criteria. Out of depressive symptoms participants were asked, 10% admitted they have suicidal thoughts in the past two weeks. The mean Migraine disability assessment score and Patient health questioner score in our study is 46.7±30 and 9.2±4.4 respectively. More than two third (74.3%) of our study participants has severe disability. The correlation between migraine -related disability and depression was found positive, with statistically significant P-value 0.007 and correlation coefficient (r= 0.318). **Conclusion**: Based on this study we can conclude, there is positive correlation between migraine-related disability and co-morbid depression among migraineurs having followed up at both neurology referral clinics. In addition there is high prevalence of depression and severe disability among these study participants, indicating high disease burden. So we recommend having wider population based study in order to understand this association more deeply and to understand the wider social and economic impact of this most disabling neurologic disorder, yet ignored.

**Title:** RNA-Seq investigations of human post-mortem trigeminal ganglia: A transcriptomic perspective on migraine genetics

**Authors: *M. J. IADAROLA**[1], M. R. SAPIO[1], D. M. LAPAGLIA[1], J. THIERRY-MIEG[2], D. THIERRY-MIEG[2], S. J. RAITHEL[1], P. D. BURBELO[3], C. E. RAMSDEN[4], A. J. MANNES[1]
[1]Clin. Center, NIH, Dept. of Perioperative Med., Bethesda, MD; [2]Natl. Library of Med., Bethesda, MD; [3]Natl. Inst. of Dent. and Craniofacial Res., Bethesda, MD; [4]Natl. Inst. of Aging, Baltimore, MD

**Abstract: Background:** The trigeminal ganglion contains neurons that relay sensations of pain, touch, pressure, and many other somatosensory modalities from the body to the central nervous system. The ganglion is also a reservoir for latent herpes virus 1 infection. To gain a better understanding of molecular factors contributing to migraine and headache, transcriptome analyses were performed on postmortem human trigeminal ganglia.
**Methods:** RNA-Seq measurements of gene expression were conducted on small subregions of 16 human trigeminal ganglia. The samples were also characterized for transcripts derived from viral and bacterial genomes. Herpes simplex virus 1 (HSV-1) antibodies in blood were measured using the luciferase immunoprecipitation assay.
**Results:** Molecular heterogeneity across the samples was prominent and could be explained by sampling of anatomically distinct sub-regions of the excised ganglia consistent with neurally-enriched and non-neural, i.e. Schwann cell, enriched regions. The levels of HSV-1 transcripts detected in trigeminal ganglia correlated with blood levels of HSV-1 antibodies. Multiple migraine susceptibility genes are strongly expressed in neurally-enriched trigeminal samples and a separate group in blood vessels. Further profiling across species and in single cell DRG datasets suggested cell-specific expression of specific genes.
**Conclusions:** These data provide a comprehensive human trigeminal transcriptome and a framework for evaluation of inhomogeneous post-mortem tissues through extensive quality

control and refined downstream analyses for RNA-Seq methodologies. Expression profiling of migraine susceptibility genes identified by genetic association appears to emphasize the blood vessel component of the trigeminovascular system. Other genes displayed enriched expression in the trigeminal compared to dorsal root ganglion and in depth transcriptomic analyses of the *KCNK18* gene underlying familial migraine shows selective neural expression within two specific populations of ganglionic neurons. These data suggest that expression profiling of migraine-associated genes can extend and amplify the underlying neurobiology obtained from genetic association studies.

**Title:** Conditioned place aversion prolongs craniofacial cutaneous allodynia induced by acute nitroglycerin (NTG) administration: Novel animal model of chronic migraine

**Authors: *S. S. KOKANE**[1], A. NGO[1], R. BROWN[1], J. GULLACE[1], T. DUONG[1], E. KALAFCHI[1], F. TAO[2], Q. LIN[3]
[1]Psychology, The Univ. of Texas At Arlington, Arlington, TX; [2]Biomed. Sci., Texas A&M Univ. Col. of Dent., Dallas, TX; [3]Psychology, The Univ. of Texas at Arlington, Arlington, TX

**Abstract:** Several clinical and preclinical studies have demonstrated induction of a migraine-like headache upon acute administration of nitric oxide donor NTG. Cutaneous mechanical and thermal allodynia in the cranial receptive field of the ophthalmic branch of the trigeminal nerve has been observed as a result of NTG administration. However, the effects of NTG are acute and last for a few hours after administration. Repeated administration of NTG has been shown to induce chronic migraine-like symptoms which remain as long as the NTG continues to be administered. Upon withdrawal from NTG administration, these effects are reversible.In the present study, we have used conditioned place aversion paradigm to prolong the migraine-like effects induced by a single administration of NTG to last for more than 10 consecutive days.

After conditioning, C57BL/6 mice were administered with a single, 10 mg/kg dose of NTG intraperitoneally. Following single NTG administration, these animals were merely exposed to the pain-paired environment every day for 30 minutes for up to 12 days. Von Frey filaments were used to test cutaneous allodynia in the craniofacial region after exposure.We observed that craniofacial cutaneous allodynia induced by NTG administration persisted for all 12 days so long as the animals were exposed to the pain-paired environment. Upon cessation of exposure to the pain-paired environment, cutaneous allodynia was gradually extinguished. However, a single exposure to the pain-paired environment was sufficient to reinstate the craniofacial cutaneous allodynia. In another group of animals, topiramate was administered after NTG administration and exposure to the pain-paired environment. Topiramate prevented the development of craniofacial cutaneous allodynia. Topiramate is a clinically approved drug prescribed to migraine patients and was used to verify the development of migraine in the animal model.Taken together these results demonstrated that NTG administration coupled with exposure to the pain-paired environment led to prolongation of the craniofacial cutaneous allodynia induced by NTG for as long as the animal was exposed to the pain-paired environment. The development and prolongation of cutaneous allodynia was deferred in animals that were treated with topiramate. These results indicate that the negative affective component associated with headache pain persists for much longer and could possibly underlie the development towards chronicity in migraine patients.

**Authors: Y. ZHANG**[1], M. E. MARTENSON[2], A. P. LASSETER[3], *M. M. HEINRICHER[4]
[1]Dept Neurol Surgery, [2]Dept. Neurol Surgery, [3]Neurosci. Grad. Program, Oregon Hlth. & Sci. Univ., Portland, OR; [4]Dept Neurol Surgery, Mail Stop L-472, Oregon Hlth. and Sci. Univ. Dept. of Neurol., Portland, OR

**Abstract:** Despite the high prevalence of migraine in the general population, our knowledge of the underlying mechanisms remains incomplete. A variety of theories have focused on peripheral neural or neurovascular mechanisms. More recently, the importance of sensitization of *central* trigeminal pathways has been recognized. None of these theories has so far provided a complete explanation for migraine headache pain. We have suggested that pain-facilitating neurons in the rostral ventromedial medulla (RVM) contribute to pain in migraine headache, amplifying abnormal afferent transmission. In addition, we recently reported that a subset of pain-facilitating "ON-cells" and pain-inhibiting "OFF-cells" in the RVM respond to light stimulation. This light-evoked response could be relevant to photophobia in migraine. Moreover, a shift in the balance of activity between these two classes of cells can lead to enhanced or diminished nociception. The objective of this study was to test the hypothesis that the photoresponsiveness of RVM ON- and OFF-cells is altered in a rat model of migraine headache induced by systemically administered nitroglycerine (NTG). We recorded RVM ON- and OFF-cells in lightly anesthetized Sprague-Dawley (albino) and Long-Evans (pigmented) rats. We analyzed both initial (30 min post-NTG) and latent (90 min post NTG) effects of NTG (1 mg/kg) on the responses of these cells to white light of different intensities (30 to 16k lux). In the initial phase, NTG produced a significant enhancement of light-evoked responses in both ON- and OFF-cells, and an increase in ongoing activity of ON-cells. Ongoing firing of OFF-cells was not changed significantly. During the latent phase, the ongoing activities of both ON- and OFF-cells were comparable to baseline, while the stimulus-response curves of both populations were shifted to the left. By contrast, NEUTRAL-cells, RVM neurons without a known role in pain-modulation, did not respond to light before or after NTG. Saline administration had no effect on basal activity or light-evoked responses. These data suggest that dysfunction of intrinsic pain-modulating systems could act in concert with activation of sensory pathways to produce pain and photophobia during migraine headache.

**Abstract:** Craniofacial painful syndromes include a number of conditions that constitute a major public health problem. Only migraine ranks among the top three neurological disorders in Europe and the US. An increasingly popular approach to treat some of these conditions is the electrical neuromodulation of a cephalic peripheral nerve, such as the greater occipital nerve (GON), which has proved its therapeutic effectiveness particularly for chronic migraine. Only recently have rodent models been developed in an attempt to better understand the neurobiological bases of such therapies. Relevant data, however, are still scanty, and this is particularly so concerning the anatomy of the GON. With the aim of providing a thorough anatomical analysis of this nerve, we have recently started a comprehensive descriptive and morphometric study of the GON in young adult rats that includes the following: 1, A macroscopic anatomical study through microdissection; 2, a global retrograde labeling of the neurons in the cervical ganglia C2 and C3 that send their peripheral branches through the GON; 3, a characterization of these neurons by means of specific retrograde tracers, immunocytochemistry of the ganglia, and stereology; 4, an ultrastructural morphometric evaluation of the GON; and 5, a qualitative and quantitative analysis of the distribution in the cervical and medullary dorsal horn of the primary afferents transganglionically labeled from the GON. Our preliminary results show that, 1, the GON shows diverse patterns of peripheral branching; 2, neurons innervating the skin through the GON are located mainly in C2 and to a lesser extent in C3 ganglia; 3, quite likely, many peripheral axons originating in these ganglia divide before the GON reaches the subcutaneous tissue; and 4, there is a degree of topographical overlap between the central projections of C2 and C3 neurons and trigeminal primary afferents in upper spinal dorsal horn.

**Title:** Targeted deletion of TRESK $K^+$ channel preferentially enhances cephalic pain in mice

**Authors: *Z. GUO**, C. QIU, Y.-Q. CAO
Washington Univ. Pain Center, Dept. of Anesthesiol., Washington Univ. Sch. of Med., Saint Louis, MO

**Abstract:** TRESK (TWIK-related spinal cord $K^+$ channel, encoded by KCNK18) channel belongs to the two-pore-domain $K^+$ channel family and is abundantly expressed in all primary afferent neurons (PANs) in trigeminal ganglion (TG) and dorsal root ganglion (DRG). It is well established that TRESK is one of the major background $K^+$ channels in DRG neurons. Changes of TRESK activity in adult DRG neurons alter neuronal excitability and the transmission of extracephalic (body) pain. However, TRESK channel mutations in humans cause migraine headache but not extracephalic pain. This calls for a new model system to study the effects of TRESK mutations on the generation of cephalic pain, especially headache.
The first and best-studied TRESK mutation results in truncation of the TRESK protein. Mutant TRESK subunits do not form functional channels per se. When expressed in wild-type TG neurons, mutant TRESK reduces the endogenous TRESK current by 70%, exerting a strong dominant-negative effect. This suggests that targeted deletion of TRESK provides a good model to study the effects of mutation-induced de novo reduction of TRESK activity in humans.
In this study, we characterized the physiological properties of PANs and nociceptive responses of wild-type and TRESK knockout (KO) mice. Despite the ubiquitous loss of TRESK currents in all KO PANs, total background current was reduced in TG neurons but not DRG neurons from KO mice. Consequently, the excitability of small-diameter TG neurons that do not bind to isolectin B4 was significantly increased in TRESK KO mice; whereas the excitability of wild-type and KO DRG neurons were comparable. Moreover, the percentage of capsaicin-responsive neurons was significantly increased in TG but not DRG of TRESK KO mice. Quantitative PCR showed that the relative TRPV1 mRNA level was higher in KO TG tissues. We further investigated whether *de novo* loss of TRESK alter the responses to noxious stimuli at cephalic (cheek) and extracephalic (hindpaw) regions. Compared with wild-type mice, TRESK KO mice exhibited stronger responses to capsaicin, heat and cold stimuli on the cheek. Conversely, wild-type and KO mice responded similarly to capsaicin, heat, cold and mechanical stimuli to the hindpaw. In a mouse model of headache, dural application of inflammatory mediators elicited more robust head-directed nocifensive behavior in TRESK KO mice.
Taken together, our results indicate that *de novo* loss of TRESK in mice selectively increases the intrinsic excitability and capsaicin-responsiveness of TG neurons. Consequently, TRESK KO mice recapitulate the pathophysiology of TRESK mutations in humans, exhibiting enhanced cephalic pain but normal extracephalic pain.

**Abstract:** Dry eye disease (DED), caused by insufficient production or quality of tears, leads to persistent corneal irritation and pain, and altered properties of corneal afferent neurons. Alterations in corneal nerve morphology, including reduced nerve fiber density in the sub-basal nerve plexus, have been reported in individuals with DED and may be correlated with the occurrence of corneal hypoesthesia; however, other studies have observed an increase in corneal sensitivity in DED. Currently, little is known regarding the progression of DED with respect to nerve damage and the subsequent changes in corneal sensitivity. The aim of this study was to examine corneal nerve morphology and to correlate this with changes in corneal sensitivity following lacrimal gland excision (LGE)-induced dry eye in female and male mice. To produce a graded severity of dry eye, unilateral excision of the extraorbital lacrimal gland (single LGE), or excision of both the intraorbital and extraorbital lacrimal glands (double LGE) were performed. Tears were evaluated using phenol red threads, and fluorescein was used to examine the severity of corneal damage. Eye closure (squinting) was quantified as a measure of ongoing irritation. Nav1.8Cre-tdTomato mice were used to observe the morphology of small diameter afferent neurons in whole mount corneas 1-4 weeks post surgery. Terminal density was imaged from corneal whole mounts using a confocal microscope and analyzed with FIJI. Trigeminal ganglion ATF3 expression was quantified using immunohistochemistry in 12µm cryostat sections. 0.1% capsaicin was applied to the cornea and nocifensive swipes were recorded. Single and double LGE caused a significant reduction in tears, damage to the corneal epithelium, and an increase in eye closure with graded severity. Overall, greater corneal damage and eye closure was observed in female single LGE and double LGE as compared to male mice. Nerve terminal density was lower in both male and female double LGE mice compared to sham and single LGE treatment

groups. ATF3 expression was significantly increased in both male and female mice after double LGE 2-weeks post surgery. At this same time point capsaicin application elicited a greater nocifensive swiping response in female mice after single LGE when compared to sham and double LGE. No difference in eye swiping behavior was observed in male mice. These results indicate sex-specific differences in corneal epithelial cell damage, nerve morphology, and corneal sensitivity after LGE and are consistent with epidemiological reports of a higher incidence of DED in women.

**Abstract:** D-serine is an endogenous ligand for the glycine site of the *N*-methyl-D-aspartate receptors (NMDARs) and has been reported to play an important role in the processing of nociceptive transmission in the spinal cord dorsal horn. However, the cellular mechanisms underlying the action of D-serine in this process have not been investigated. Here we examine the possible role of neuronal nitric oxide synthase (nNOS) in the D-serine-induced potentiation of NMDAR function using animal models of NMDA-induced nociception and neuropathic pain following chronic constriction injury (CCI) of the sciatic nerve. Intrathecal administration of D-serine facilitates NMDA-induced nociception and increases in both total nitric oxide (NO) levels and PKC-dependent (Ser896) phosphorylation of the NMDAR GluN1 subunit (pGluN1), which were attenuated by pretreatment with the selective nNOS inhibitor, 7-nitroindazole. In CCI mice, intrathecal administration of the serine racemase inhibitor, LSOS or the D-serine degrading enzyme, DAAO suppressed NO production and nNOS activation, which was evidenced by a

significant increase in both the membrane expression of nNOS and the PSD95-PDZ domain binding form. Intrathecal administration of the inhibitor of PSD95-nNOS protein-protein interactions, IC87201 suppressed NO production, mechanical allodynia (MA), and PKC-dependent pGluN1 expression. Furthermore, intrathecal administration of 7-nitroindazole, the soluble guanylyl cyclase (sGC) inhibitor, ODQ or the PKC inhibitor, chelerythrine attenuated CCI-induced MA and pGluN1 expression. By contrast, D-serine and nNOS/sGC signaling had no effect on CCI-induced thermal hyperalgesia or GluN1 expression. Collectively spinal D-serine increases nNOS activity in CCI mice and modulates NO-induced increase in PKC-dependent pGluN1 expression, and ultimately contributes to the induction of MA following peripheral nerve injury.

**Abstract:** Voltage-gated sodium channels ($Na_Vs$) are critical for the upstroke of the action potential in peripheral sensory neurons. They are therefore crucial for peripheral somatosensation including pain sensing. Indeed, loss and gain of function mutations in a range of peripherally restricted isoforms (including $Na_V1.7$, 1.8 and 1.9) have been linked to painful and painless neuropathies. However, a recent study identified a mutation in the isoform $Na_V1.6$ in a patient with trigeminal neuralgia (Tanaka *et al*, Mol Med 2016;3(22)). Evidence from animal studies including oxaliplatin-induced pain and ciguatoxin-induced pain (Deuis et al. Neuro-oncology 2014;16(10):1324-1332; Inserra et al. Sci Rep. 2017;7:42810). In order to study $Na_V1.6$ in detail, selective pharmacological probes are required. Animal venoms are a rich source of biologically active peptides many of which selectively target ion channels such as $Na_Vs$. This work utilises *in vitro* and *ex vivo* electrophysiology along with animal behavioural studies in order to assess the function of $Na_V1.6$ in peripheral sensory neurons. Here we report that synthetically produced β-scorpion toxin peptide Cn2 is a potent and selective probe for $Na_V1.6$ *in vitro*. Cn2 causes

significant shift in voltage-dependence of activation cells that overexpress $Na_V1.6$. Functional contribution of $Na_V1.6$ to action potential generation in peripheral nerve terminals was assessed using skin-saphenous nerve recordings. There is little effect on C-fibre firing in response to $Na_V1.6$ activation by Cn2. Two distinct responses to Cn2 emerge in A-fibres. One group responds to threshold mechanical stimulus by firing high frequency, continuous, repetitive bursts of action potentials. The other group responds to mechanical stimulus with both increased firing frequency and number of action potentials per stimulus. Variation in response correlates with conduction velocity. This is in line with previous findings outlining a function for $Na_V1.6$ in mechanosensation. Furthermore, intra-plantar injection of $Na_V1.6$ selective agonists *in vivo* causes both spontaneous pain behaviours and mechanical but not thermal allodynia. Taken together, we find activation of A-fibres drives spontaneous and mechanically-induced pain behaviours. This works highlights the use of toxins in elucidating pain pathways moreover the importance of non-peripherally restricted $Na_V$ isoforms in pain generation. Furthermore, it adds to the growing body of evidence supporting a clear role for A-fibres in pain.

**Abstract:** Neurofibromatosis type 1 (NF1) is a rare autosomal dominant disease linked to mutations of the *Nf1* gene. NF1 patients commonly experience severe ongoing pain. Studies on mice with *Nf1* haploinsufficiency have been instructive in identifying sensitization of ion channels as a possible cause underlying the heightened pain suffered by NF1 patients. Data on pain predisposition in $Nf1^{+/-}$ mice have led to uncertain conclusions about the role of *Nf1* in pain. We used the clustered regularly interspaced short palindromic repeats/(CRISPR)-associated 9 (CRISPR/Cas9) genome editing system to create and characterize a novel rat model of NF1-related pain. Targeted intrathecal delivery of guide RNA/Cas9 nuclease plasmid in combination with a cationic polymer was used to generate allele-specific C-terminal truncation of neurofibromin, the protein encoded by the *Nf1* gene. Rats with truncation of neurofibromin,

showed increases in voltage-gated calcium (specifically N-type or CaV2.2) and voltage-gated sodium (particularly tetrodotoxin-sensitive) currents in sensory neurons. These gains-of-function were sufficient to underlie increased nociceptor excitability as well as behavioral hyperalgesia. The cytosolic regulatory protein collapsin response mediator protein 2 (CRMP2) regulates activity of these channels, and also binds to the targeted C-terminus of neurofibromin in a tripartite complex, suggesting a possible mechanism underlying NF1 pain. Prevention of CRMP2 phosphorylation with (*S*)-lacosamide resulted in normalization of channel current densities, excitability, as well as of hyperalgesia following CRISPR/Cas9 truncation of neurofibromin. These studies reveal the protein partners that drive NF1 pain and suggest that CRMP2 as a key target for therapeutic intervention.

**Abstract:** D-serine is considered to be an endogenous NMDA receptor ligand. The NMDA receptors play key roles in synaptic plasticity including not only learning and memory but also in persistent pain. D-serine is synthesized by glial or neuronal enzyme serine racemase (SR), and is degraded by an enzyme, D-amino acid oxidase (DAO). We previously showed that peripheral nerve injury-induced neuropathic pain is associated with an increased spinal content of D-serine (Kato et al, 2017). However, it still remains to elucidate how D-serine and its related enzymes are involved in neuropathic pain. To realize the contribution of D-serine and SR to synaptic transmission in the spinal dorsal horn, we generated SR knockout (KO) mice. Immunohistochemical staining revealed that SR was expressed in the superficial dorsal horn (SDH) in wild-type (WT) mice, while there was little SR expression in SR-KO mice. Additionally, liquid chromatography-mass spectrometry showed that the D-serine content in the SDH of SR KO mice was less than 10% of that of WT mice. Tight-seal whole-cell recordings

were made from neurons in the SDH in lumbar spinal slices. Non-NMDA and NMDA receptor-mediated excitatory postsynaptic currents (non-NMDA-EPSCs and NMDA-EPSCs) were pharmacologically isolated. The analysis showed the following: 1) The NMDA/non-NMDA ratio was significantly smaller in SR KO mice than in WT mice. 2) The time constant of decay time course of NMDA-EPSCs was significantly longer in SR KO mice than in WT mice. 3) The synaptic charge transferred during NMDA-EPSC was significantly larger in SR KO mice than in WT mice. Real-time quantitative RT-PCR analysis revealed that the expression level of NMDA receptor 2B subunit in the SDH was significantly larger in SR KO mice than in WT mice. Further, we analyzed the effects of loose sciatic nerve ligation (Bennett model), spinal nerve ligation (Chung model), and formalin injection. Behavioral observations showed the following results: 1) Mechanical allodynia in the Chung model and Bennett model was significantly augmented in SR KO mice compared to WT mice. 2) The second phase of the formalin-induced licking response was also augmented in the KO mice. Additionally, characterization of NMDA-EPSCs in SR-KO mice subjected to nerve ligation is currently under experiment. The present results suggest that SR-KO mice have a different NMDA receptor subunit composition compared to WT mice. Balance of function between SR and DAO regulates D-serine content, which may lead to alterations in NMDA receptor subunit composition. This might partly explain the differences in synaptic transmission and nociceptive behaviors between the SR-KO and WT mice.

**Abstract:** Understanding of cellular and molecular mechanisms that induce and maintain chronic pain is central to the development of new therapeutics. G-protein-coupled Receptor

Kinase 2 (GRK2) and Exchange protein directly activated by cAMP (Epac) play an active role in the pathogenesis of pain. Previous work by our group showed that GRK2 deficiency in nociceptors promotes the transition to chronic pain via a biased cAMP-induced Epac1-to-Rap1 signaling. In this study using RNA sequencing, we compared the transcriptome of the dorsal root ganglia (DRG) of WT mice that develop transient pain and of GRK2-deficient mice showing persistent pain in response to prostaglandin E2 (PGE2). On average, more than 50 million reads were identified in each sample and the sequencing results were analyzed by the EdgeR and Cufflinks software. Analysis of differentially expressed mRNAs associated with PGE2 treatment identified Peptidase inhibitor 16 (Pi16) as the most significantly upregulated transcript in GRK2-deficient mice. Pi16 is a poorly characterized member of the CAP (Cysteine-rich secretory proteins, Antigen 5, and Pathogenesis-related 1) superfamily of proteins. The role of pi16 in pain is unknown. The aim of this study was to determine a possible contribution of Pi16 to chronic pain. We show that Pi16 levels increase specifically in the ipsilateral lumbar DRGs and sciatic nerve in the spared nerve injury model of neuropathic pain. Pi16 knockout mice are protected against mechanical allodynia and spontaneous pain in this model. Interestingly, Pi16 is a non-neuronal protein secreted by fibroblasts in the epineurium and perineurium. Our present data supports a key role of fibroblasts in the pathogenesis of pain through secretion of Pi16. We propose that fibroblast-derived Pi16 may represent an important novel non-neuronal target for the treatment of chronic pain. Understanding how this fibroblast-derived protein regulates neuropathic pain will advance our insight into the cellular and molecular mechanisms underlying chronic pain.

**Abstract:** Neuropathic pain is a common disorder typically caused by disease of or damage to the peripheral nervous system. Spontaneous pain is a major feature of neuropathic pain disorders and is thought to be generated by the ectopic activity of peripheral somatosensory neurons. Unfortunately, it is not known which subtypes of peripheral sensory neurons become spontaneously active after nerve injury or what changes in gene expression cause their hyperexcitability. Here, we present functional and transcriptional data exploring the changes that take place in injured somatosensory neurons and contribute to their hyperexcitability. We used the sciatic nerve transection and spared nerve injury animal models of neuropathic pain. Sciatic nerve injury leads to pain behaviors such as heat and mechanical hyperalgesia, and mechanical allodynia, which are also present in patients with neuropathic pain. At various time points after nerve injury, we dissected and cultured the injured and naive lumbar L3-L5 dorsal root ganglia (DRG) neurons in vitro and then performed a range of functional and transcriptional analyses on these cultured neurons. We observed a higher incidence of spontaneous activity in the ipsilateral injured DRG neurons as compared to the naive control DRG neurons using both patch clamp electrophysiology and calcium imaging methods. Additionally, the injured DRGs were less excitable to a variety of electrical stimuli. We also observed a lower current density of voltage gated potassium currents in the ipsilateral DRG neurons, which would be consistent with their hyperexcitability. Finally, we performed a single cell transcriptional analysis on injured vs naive DRG neurons and found a number of differences in gene expression that are associated with injury as well as consistent with injury-induced hyperexcitability. We believe that a combined functional and transcriptional analysis may help identify changes that take place in defined subpopulations of somatosensory neurons in neuropathic pain and potentially identify new drug targets for the treatment thereof.

**Abstract:** Peripheral sensory neurons innervating the skin, muscle and viscera relay crucial information about thermal, mechanical, and chemical stimuli to the central nervous system. Small fiber neuropathy (SFN) is a chronic polyneuropathy, characterized by slow, length-dependent, bilateral degeneration of multiple nerve fibers. In SFN, small diameter axons and terminals of sensory Aδ and C sensory fibers selectively 'die back'. Recently, the disorder has been linked to gain-of-function mutations in voltage-gated sodium channels: $Na_v1.7$, $Na_v1.8$, and $Na_v1.9$, raising questions as to whether hyperexcitability causes or increases susceptibility to peripheral degeneration and neuropathy. We utilize CRISPR/Cas9 to introduce human SFN-linked $Na_v1.7$ mutations into mice as well as human induced pluripotent stem cells (hiPSC). We are then interrogating mutant mouse primary DRG neurons and human sensory neurons derived from the mutant hiPSC for altered excitability and defects in neurite length and innervation pattern, as well as other signs of cellular stress, to better understand whether the hyperexcitability caused by these mutations is causally linked to dying back sensory neuropathy.

**Title:** Slow changes in neuronal excitability in the spinal superficial dorsal horn evoked by the activation of unmyelinated primary afferents

**Authors: *K. KANEKO**, T. SAOTOME, Y. NUMATA, T. TERASHIMA, S. YAMAGUCHI, Y. HORI
Dept. of Physiol. and Biol. Information, Dokkyo Med. Univ., Tochigi, Japan

**Abstract:** Synaptic response in the spinal dorsal horn evoked by the stimulation of myelinated primary afferent fibers (Aβ and Aδ fibers) are well characterized. We investigated how the activation of unmyelinated primary afferent fibers (C fibers) affects synaptic activity and neuronal excitability in the spinal dorsal horn by means of voltage-sensitive dye imaging. Under halothane anesthesia, three-week-old male ICR mice were subjected to partial ligation of the sciatic nerve (Seltzer model). Transverse slices of 500 μm thickness with the dorsal root attached at the lumber enlargement level were obtained seven days after the nerve ligation. The slices were stained with the voltage-sensitive dye Di-4-ANEPPS. Di-4-ANEPPS fluorescence was measured using a MiCAM2 optical imaging system (Brain Vision Inc., Japan). A decrease or

increase in the fluorescence of the dye indicates membrane hyper polarization or depolarization, respectively. We analyzed fluorescence changes in the superficial dorsal horn (SDH) in response to electrical stimulation of the dorsal root at C-fiber strength. Mechanical allodynia was observed in the nerve-ligated mice. The stimulation of the dorsal root evoked fluorescence changes in the SDH that lasted more than one second. In the presence of the $GABA_A$ receptor antagonist bicuculline (Bic), the glycine receptor antagonist strychnine (Str), the NMDA receptor antagonist APV, and the non-NMDA receptor antagonist CNQX, a small but significant response remained. The remaining response was further reduced by the application of the NK-1 receptor antagonist CP99994. The CP99994-sensitive component was significantly smaller in mice that had been subjected to neonatal capsaicin applications. Thus, this long-lasting depolarizing response is mediated by Substance P (SP), which is released upon electrical stimulation of unmyelinated primary afferent fibers. After the SP-mediated response was blocked by CP99994, small but distinct fluorescence changes were still evoked by dorsal root stimulation. The magnitude of the CP99994-resistant component was larger in nerve-ligated mice than in control mice. Additionally, peripheral nerve injury is known to downregulate the expression of Na+/K+ ATPase. Thus, the observed long-lasting CP99994-resistant fluorescence changes might be attributed to the change in extracellular potassium concentrations elicited by the dorsal root stimulation. Finally, the voltage-sensitive dye imaging system could provide useful tools to observe slow changes in neuronal activity. In addition, we are currently investigating the effect of the glial cell inhibitor fluorocitrate on the CP99994-resistant component.

**Abstract:** Peripheral nerves convey to the brain versatile information about the body's environment and are responsible for somatosensory sensations, including pain. Healthy peripheral nerves conduct action potentials without interruption from their sites of origin (peripheral nerve endings), to dorsal spinal cord where synaptic communication first takes place. It is assumed that in the spinal cord, and subsequently in the central nervous system, the

peripheral somatosensory signals are integrated and analyzed. Surprisingly, cell bodies of sensory neurons express multiple receptors for classical neurotransmitters such as glutamate and GABA. Yet, the role of these somatic receptors and the source(s) of neurotransmitters that activate them is only beginning to emerge. Our recent data suggest that dorsal root ganglion (DRG) neuron cell bodies contain fully functional GABAergic communication system that can modulate nociceptive transmission (1). Here we aimed to establish the sensory modalities of DRG neurons that can release GABA. To this end, we performed immunohistochemical investigation of the vesicular GABA transporter (VGAT) expression within DRG of adult male Wistar rats. VGAT expression was found in subpopulations of DRG neurons of all sizes but was twice as frequent in larger- diameter neurons as compared with small ones (30% of large neurons vs. 15-20% of small and medium). VGAT immunofluorescence was found in 27.5% of TRPV1-positive, 16.67% of IB4-positive, 50% of Nf200-positive and in 78.62% of TrkC-positive neurons. There was a strong colocalization of VGAT with the synaptic vesicle marker, SV2. VGAT immunofluorescence was absent in satellite glia (as confirmed with the glial marker S100b). We then tested if VGAT in DRG localizes to the releasable vesicles. We incubated live cultured DRG neurons with the C-terminal VGAT antibody (VGAT-C) that binds to the luminal part of the transporter and, thus, can only bind to VGAT during the vesicle fusion event. Depolarization of DRG cultures resulted in robust uptake of VGAT-C, but not an N-terminal VGAT antibody; the uptake was significantly reduced by exclusion of $Ca^{2+}$ from the extracellular solution. These results describe functional GABA release machinery in a subset of DRG neurons that is likely to contribute to the modulation of nociceptive transmission. **Abstract:** Chemotherapy-induced peripheral neuropathy (CIPN) is a common complication of cancer treatments. Oxaliplatin is a first line drug for colorectal cancer that often produces neuropathic pain, including severe cold allodynia, often limiting the dose or duration of drug. Treatment with the specific α9α10 nicotinic acetylcholine receptor (nAChR) antagonist, α-conotoxin RgIA4, attenuates the development of oxaliplatin-induced cold allodynia. Here, we show that coadministration of RgIA4 with oxaliplatin not only relieves cold allodoynia during treatment, but also prevents this symptom for at least 3 weeks beyond cessation of treatment, suggesting a possible disease modifying effect. The parent compound RgIA is a bicyclic peptide with two disulfide bridges. It is a competitive antagonist of acetylcholine, binding at the α9(-)α10(+) nAChR subunit interface. Previous structural studies demonstrated that residues in the first cysteine loop of RgIA are essential for activity. Here, we demonstrate that residues in the second cysteine loop and at the C-terminus allow for the fine tuning of potency and binding kinetics. Modification of the identified residues remedy the discrepancy in potency between rat and human α9α10 nAChRs, closing a ~300-fold affinity gap. Solution NMR, molecular modeling studies, and two-electrode voltage clamping assays provide mechanistic insight into the mode of action at α9α10 nAChRs.

**Abstract:** Recent evidence in rodent models of peripheral neuropathy suggests sex differences may exist in immune cell phenotype and function underlying neuropathic pain. BIRT377 (BIRT) is a small molecule inhibitor of lymphocyte function-associated antigen 1 (LFA-1). LFA-1 is an adhesion molecule expressed on several immune cell types (e.g. T cells and monocytes) important for migration into areas of tissue damage. Allodynia, which is clinically observed as pathological sensitivity to light touch, can be induced in rodents following sciatic nerve damage using the well-characterized model, chronic constriction injury (CCI). Recent reports revealed that immune T cell actions in female rodents, but not in males, play a greater role in generating allodynia. Therefore, we hypothesized that the pain therapeutic effect of BIRT in females occurs via its actions on T cells while BIRT efficacy in males is T cell-independent. Following baseline (BL) hindpaw response thresholds to light touch stimulation (von Frey fiber test), all male and female mice (C57BL/6; ~3.5 months; N= 6/gp) underwent either sham or CCI (sciatic loose ligation of three 4-0 vs. 5-0 chromic gut sutures) surgery with response thresholds reassessed every 3-5 days for 56 days. In a separate group of aged-matched male and female C57BL/6 mice (N=6/gp) following BL and post-CCI (using three 5-0 chromic gut sutures) hindpaw assessment to Day 10, intravenous BIRT (i.v., tail vein; 2.5µg in 50µL) or equivolume vehicle was injected with daily response threshold reassessments through Day 24. This experiment was repeated in a third group of mice (C57BL/6, N=6/gp) but was terminated at maximal i.v. BIRT reversal efficacy followed by tissue collection for mRNA analysis. Lastly, T cells collected from naïve male and female mice (C57BL/6 aged-matched), cultured for 5 days +/- BIRT, were analyzed using flow cytometry to identify T cell-subsets expressing cytokines indicative of pain-related inflammatory (interleukin [IL]-17, RORɣ) or pain-suppressive anti-inflammatory (IL-10, transforming growth factor [TGF]β) function. Results reveal male and female mice develop allodynia similarly at onset, degree and duration, and similarly respond to i.v. BIRT with allodynic reversal lasting ~5 days. Sex differences in naïve T cell responses to BIRT revealed decreased IL-17 and RORɣ and increased IL-10 and TGFβ measured only in female-derived T cells, while no alterations were observed in male-derived cells. RNA analysis is ongoing. These data indicate female T cells are a key target underlying pain therapeutic effects of BIRT while in males, efficacy occurs through T cell-independent mechanisms.

**Abstract:** Introduction: Brain nicotinic acetylcholine receptors (nAChRs) are ligand-gated ion channels composed of a number of subunits (α2-10 and β2-4). Recently, it is reported that nicotinic acetylcholinergic mechanisms play important roles in regulating process of pain pathways. Thus, we investigated mRNA expression of several nAChRs subunits in the brain tissues using a rat model of chronic constriction injury (CCI) to clarify the new role of nAChRs. Materials and Methods: Wistar male rats (8 weeks old) were used, and their left sciatic nerve was exposed at the mid-thigh level through a gluteal muscle-splitting incision under anesthesia. Three loosely constrictive chromic gut ligatures were applied to produce CCI rat model. Sham rats were only exposed left sciatic nerve. Sensitivity to mechanical stimulation was measured by von Frey test using up-and-down method until 3 weeks. For gene expression analysis, rats were sacrificed 3 weeks later, and brain tissues from four regions (frontal cortex, thalamus, hippocampus, and amygdala) were dissected bilaterally on an ice-cold stage. The total RNA fraction of each tissue was extracted and treated with reverse transcriptase to keep as cDNA. The mRNA expression levels of the nAChR subunits genes; α3 (*chrna3*), α4 (*chrna4*), α7 (*chrna7*), β2 (*chrnb2*), and β4 (*chrnb4*), were calculated by real time PCR method with Taqman probe after GAPDH normalization. The calibrator cDNA of a matched brain region was randomly selected from 6 naive rats. The comparative CT method provides a relative quantification ratio according to the calibrator, allowing statistical comparison of gene expression among samples. Values from CCI and sham groups represented averages of triplicate measurements for each sample (n = 6, each). Results: The hind paw withdrawal thresholds in left side of CCI treated rats to von Frey stimulation were significantly reduced than those of others. *Chrnb2* mRNA expression in right thalamus was significantly increased than in the left in CCI groups, but was not significantly different in sham groups. However, there was no c*hrnb2* expressional difference between right and left sides in the frontal cortices of CCI rats. No other subunits showed significant laterality. Conclusion: The *chrnb2* expression in the thalamus may be involved in pain pathways.

**Title:** Epigenetic regulation by sigma-1 receptor in dorsal root ganglion: Link to neuropathic pain

**Authors: *H.-E. WU**[1], T.-C. SU[1], D. HUNG[1], T.-P. SU[2]
[2]Cell. Pathobiology Section Integrative Neurosci. Br., [1]IRP/NIDA/NIH, Baltimore, MD

**Abstract:** Primary sensory neurons at the dorsal root ganglions (DRGs) causes neuropathic pains, when undergoing pathophysiologic changes that lead to neuronal hyperexcitability, and are important target for treating neuropathic pains. The ER chaperone sigma-1 receptor (Sig-1R) has been known to play a role in neuropathic pains and has been shown to exist in DRGs notably at the nuclear envelope. However, the molecular event that may link Sig-1R to the modulation of neuropathic pain at the DRG is largely unknown. Recently it was reported that inhibition of histone methylation could reduce neuropathic pain by restoring potassium channel function in the DRG. Thus, we examined in the present study if the Sig-1R may play a role in the epigenetic regulation in DRGs with a specific focus on the Sig-1R effect on enzymes that affect the histone methylation and acetylation. The protein levels of those enzymes and their resultant activities as seen in the modification of respective substrates were compared in DRGs taken from wild type and Sig-1R knockout mice. Immunoblotting in Sig-1R knockout DRGs, when compared to those seen from wild type samples, showed a decreased expression of the enhancer of zeste homolog 2 methyltransferase (EZH2), euchromatic histone-lysine N-methyltransferase-2 (G9a), and histone deacetylase 4 (HDAC4), whereas exhibited an increased expression of the mixed-lineage leukemia 1 methyltransferase (MLL1). Correspondingly, the resultant level of the substrate for EZH2 and G9a, i.e., H3K27me3 and H3K9me2 respectively, was reduced while that (H3K4me3) for MLL1 was increased. However, the level of the substrate for HDAC4 acetyl H3 did not differ. In addition, we found a co-immunoprecipitation between Sig-1R and EZH2 in HEK293T cells. Taken together, our results suggest that the endogenous Sig-1R may participate in the genesis of neuropathic pain through the epigenetic modification of histone in the DRG. **Title:** Search of BEGAIN binding protein in the brain

**Authors: *T. KATANO**, S. ITO
Kansai Med. Univ., Hirakata, Japan

**Abstract:** We had been identified many proteins in the spinal dorsal horn related to chronic pain. Recently, we reported about brain-enriched guanlylate kinase-associated protein (BEGAIN) as a new responsible protein to neuropathic pain after spared nerve injury (SNI) in the spinal dorsal horn using knock-in mouse of Tyr1472 to Phe of GluN2B (eNeuro 3(5), e0110-16, 2016). Neuronal plasticity observed in chronic pain and memory in the spinal cord and / or the brain is regulated by many synaptic molecules, some of which are shared in their plasticity. In our previous report, BEGAIN also expresses in the cerebral cortex and hippocampus higher than in the spinal dorsal horn, and modifies the activity of NMDA receptors. However, it is not clear how BEGAIN acts on NMDA receptor function as a synaptic molecule. In the present study, to clarify the molecular functions of BEGAIN, we searched the BEGAIN binding proteins from synaptic fraction in the cerebral cortex. An approximately 80-kDa protein (p80) was purified as BEGAIN-binding protein by using a BEGAIN immobilized column. P80 had been identified as an increased protein in the spinal dorsal horn after SNI in our previous research as well as BEGAIN. Analysis of the molecular function of BEGAIN through interaction with p80 is in progress.

**Title:** Amygdala NMDA receptor involvement in mediating sensory-discriminative and affective-motivational pain responses after chronic constriction nerve injury

**Authors: T. ZHANG**, H. XU, W. CHEN, W. HUANG, *C.-W. CHOU
Anesthesiol., The First Affiliated Hospital, Sun Yat-Sen Univers, Guangdong, China

**Abstract:** Many studies and intervention on neuropathic pain have focused on the spinal cord level, but the efficacy of treating neuropathic pain is to date unsatisfactory. As many patients suffering from neuropathic pain usually have affective- motivational pain responses, the aim of this study is to investigate the relationship between the affective-motivational dimension of pain and the changes in the supraspinal region.Amygdala is a center of affective modulation in the central nervous system and it has emerged as an important brain region for pain modulation.NMDA (N-m ethyl-D-aspartate) receptor has been proven to be involved in the initiation and maintenance of neuropathic pain in the spinal cord level,but little is known about its role in amygdala. Therefore,here we hypothesize that the NMDA receptors in amygdala might be associated with the affective-motivational pain responses in neuropathic pain condition. To test this hypothesis, a rat model of chronic constriction injury (CCI) was used to induce neuropathic pain and a paradigm that reflecting the motivational-affective aspect of pain was established in this study(Place avoidance testing). After CCI, rats showed mechanical allodynia on postoperative day 14 and the time spent in light side of the chamber was also reduced significantly. Stereotaxic injection of NR1/NR2A antagonist (TCN 201)into amygdala (CeA) alleviated mechanical allodynia and the time spent in light side of the chamber was increased when compared with vehicle group.While injection of NR2B antagonist (Co 101244 hydrochloride) only altered the time spent in light side of the chamber, but did not alleviate mechanical allodynia. It suggests that different subtypes of NMDA receptors in amygdala may involve in different dimensions of pain process after injury.

**Abstract:** Chemotherapy-induced peripheral neuropathy (CIPN) is the most common dose-limiting toxicity for several anti-cancer agents. However, the mechanism behind CIPN is yet to be determined. The dorsal root ganglia (DRG) are the most susceptible target for neuroinflammation caused by the upregulation of cytokines and chemokines following chemotherapy. In this study, we first studied the potential effect of monocyte chemoattractant protein-1 (MCP-1), and its receptor CCR2 signaling within rat dorsal root ganglion (DRG) on single dose oxaliplatin-induced mechanical allodynia. After a single injection of 3mg/kg oxaliplatin, mechanical allodynia increased from the first day after oxaliplatin injection and persisted until day 15. Immunohistochemistry staining (IHC) showed that MCP-1 signaling tended to increase as early as 4hrs after oxaliplatin treatment, followed by a significant upregulation in MCP-1/CCR2 signaling on day 5, but both signals were normalized when tested on day15. These results suggested that with single dose oxaliplatin, MCP-1/CCR2 signaling contributed to the induction and severity of mechanical allodynia but not in the maintenance of this pain. In the same experiment, co-treatment with intrathecal anti-MCP-1 prevented oxaliplatin-induced mechanical allodynia but it was not able to reverse the pain when given 1 week after chemotherapy. Minocycline is a semi-synthetic tetracycline antibiotic with anti-inflammatory properties that has been used to attenuate neuropathic pain in several published studies. Here we found that rats treated with 2mg/kg oxaliplatin, to a accumulative dose of 8mg/kg, demonstrated less allodynia throughout the experiment (day 1, 7,and 14) if they were co-treated with minocycline. IHC staining on day 7 showed a marked decrease in MCP-1 level in rats co-treated with minocycline. This is the first study to demonstrate MCP-1/CCR2 signaling in two different models of oxliplatin related CIPN, and it further shows that blocking of this signal can attenuate oxaliplatin-induced mechanical allodynia.

**Title:** Injured dorsal root ganglion neuron-derived FLRT3 induces neuropathic pain via Unc5b

**Authors: *M. YAMADA**[1], Y. FUJITA[2], T. YAMASHITA[2]
[1]Dept. of Mol. Neurosci., Osaka Univ., Suita-shi, Osaka, Japan; [2]Dept. of Mol. Neurosci., Osaka Univ., Suita, Osaka, Japan

**Abstract:** Neuropathic pain is a type of chronic pain, frequently occurs after nerve injury, and induces hypersensitivity or allodynia resulting in aberrant neuronal excitability in the spinal cord dorsal horn. Our previous study revealed that Netrin-4 secreted from dorsal horn interneurons binds to Unc5B, and enhances the excitatory synaptic transmission, leading neuropathic pain. In addition to Netrin-4, Unc5B has been reported to bind several molecules including Fibronectin type III domain Leucine-rich repeat transmembrane protein 3 (FLRT3). FLRT3 is known as a modulator of neurite outgrowth, axon pathfinding and cell adhesion. Interestingly, FLRT3 is upregulated following axotomy of the sensory neurons, although the function of FLRT3 after peripheral nerve injury remains unknown. Here, we investigated whether spinal FLRT3 is involved in neuropathic pain. In the spinal cord dorsal horn, FLRT3 protein was increased at 7 and 14 days after sciatic nerve ligation, and its immunoreactivity was distributed in lamina II, particularly in the lesion of IB4-loss. The expression of FLRT3 mRNA was upregulated in the dorsal root ganglion (DRG), but not in the spinal cord after injury, suggesting that spinal FLRT3 was derived from DRG. In DRG, FLRT3 signal was observed in cell plasma of ATF3-positive injured sensory neurons. Intrathecal administration of FLRT3 protein to naïve rats induced mechanical allodynia and phosphorylated GluN2B in the spinal cord. In addition, DRG-specific FLRT3 overexpression also developed mechanical allodynia in rats by using adeno associated virus vector. Conversely, administration of an antibody, which inhibits FLRT3-Unc5B interaction, attenuated mechanical allodynia after partial sciatic nerve ligation. Our findings suggest that FLRT3, which is derived from injured DRG neuron, increases the excitability of the dorsal horn and induces mechanical allodynia via Unc5B receptor.

**Title:** Endogenous IL-10 is not required for spinal non-viral IL-10 transgene expression to treat neuropathic pain resulting in anti-inflammatory factors in DRG and spinal cord

**Authors: *A. G. VANDERWALL**[1,2], S. NOOR[1], J. E. SANCHEZ[1], M. S. SUN[1], X. O. YANG[3], L. L. JANTZIE[4], N. MELLIOS[1], E. D. MILLIGAN[1,2]
[1]Dept. of Neurosciences, [2]Dept. of Anesthesiol. and Critical Care, [3]Dept. of Mol. Genet. and Microbiology, [4]Dept. of Pediatrics, Univ. of New Mexico, Albuquerque, NM

**Abstract:** **Background:** Anti-inflammatory cytokine interleukin-10 (IL-10) reverses neuropathic pain in animal models by inhibiting actions of proinflammatory cytokines (e.g. IL-1β and tumor necrosis factor α [TNFα]). D-mannose (DM) is a mannose receptor (MR; CD206) agonist that improves therapeutic efficacy of non-viral IL-10 gene therapy (pDNA-IL-10; naked IL-10 plasmid). MR is a scavenger receptor but activation may increase IL-10 signaling. However, we previously presented DM+pDNA-IL-10 is efficacious in IL-10 deficient (IL-10 KO) mice following nerve damage (Vanderwall *et al.*, SfN 2016). Therefore, we examined whether enduring DM+IL-10 gene therapy induces local anti-inflammatory factors that act to diminish pain-generating proinflammatory factors.
**Methods:** IL-10 KO mice underwent unilateral sciatic Chronic Constriction Injury (CCI) vs. Sham surgery. Light touch sensitivity (allodynia) was assessed before and after surgery to Day 5, at which time intrathecal (i.t.) DM+pDNA-IL-10 vs. various control treatments was given followed by repeated assessment for allodynia through Day 17. Thereafter, tissues were collected (bilateral lumbar [L3-5] dorsal root ganglia [DRG] and cauda equina [CE]) for qRT-PCR mRNA analyses. Astrocytes in lumbar spinal cord (LSC) from previously behaviorally verified mice (citation above) were analyzed by GFAP immunoreactivity.
**Results:** While sham mice remained stably non-allodynic, CCI/DM+pDNA-IL-10 mice showed complete bilateral behavioral reversal throughout the timecourse compared to CCI-treated i.t. gene therapy controls. However, CCI mice given DM without pDNA-IL-10 revealed transient reversal from allodynia. Significant IL-10 mRNA was detected in CCI/DM+pDNA-IL-10 mice in both CE and ipsilateral (ipsi) DRG. Curiously, Sham/DM+pDNA-IL-10 mice did not reveal elevated IL-10 mRNA levels. While IL-1β (*il1b*) levels did not differ between groups, decreased TNFα (*tnf*) occurred in ipsi DRG from CCI/DM+pDNA-IL-10 mice compared to allodynic controls. The anti-inflammatory cytokine TGF-β1 (*tgfb1*) increased. Lastly, MR (*mrc1*) is expressed in ipsi DRG under all conditions. LSC dorsal horn astrocyte activation was decreased in CCI/DM+pDNA-IL-10 mice compared to allodynic controls. Ongoing studies will investigate changes post-gene therapy in contralateral DRG & LSC mRNA and LSC dorsal horn microglia.
**Conclusions:** IL-10 transgene is identified only under pathological conditions in pain-relevant tissues following a safe and unique non-viral DM+pDNA-IL-10 therapy with consequent anti-inflammatory changes in the DRG & LSC. Targeting DRG by DM+IL-10 gene therapy may ameliorate pathological spinal processes.

**Abstract:** Dorsal root ganglia (DRGs) are the first gateway to the somatosensory system containing the cell bodies of primary sensory neurons and other numerous non-neuronal cells such as satellite glial cells (SGCs), macrophages and few T cells. Anatomical and functional evidence suggests that primary sensory neurons rely on interplays with these non-neuronal cells for maintenance of homeostasis and proper somatosensory functions. Conversely, dysfunctions of primary sensory neurons and non-neuronal cells in DRGs associated with tissue or nerve injury can result in somatosensory disorders, including chronic pain. Although high-throughput single-cell RNA sequencing (RNA-seq) have emerged as powerful tools to study the biology of cells in the brain, this approach has not been used yet to provide a comprehensive pictures of neuronal and non-neuronal cells in the DRGs. We have now established the use of Drop-seq, a high-throughput microfluidic technique that combining nucleic acid barcoding and RNA-seq, to analyze the transcriptome of thousands of individual DRG cells. We have identified and visualized 13 clusters of cells in DRGs according to their transcriptional profiling and expression of distinct marker genes, such as Tac1 for peptidergic nociceptors, Il31ra and MrgprA3 for pruriceptors, and Kcnj10 (i.e. Kir4.1) for SGCs. We are currently exploring new candidates in neuronal-glial signaling in the setting of chronic pain. This work provide the first comprehensive cellular census of DRG tissue and most importantly the identification of new neuronal and non-neuronal molecular signatures that may result in alternative therapeutic targets for the prevention and resolution of chronic pain, debilitating condition that affect more than 100 million Americans and for which there are few treatment options.

**Title:** Characterization of peripheral neuron enhancer profiles in a model of neuropathic pain

**Authors: *F. DENK**, D. LOPES, S. B. MCMAHON
King's Col. London, London, United Kingdom

**Abstract:** Chronic neuropathic pain is frequently intractable to treatment and has a devastating impact on many lives. Its mechanisms are not fully understood, but there is evidence to suggest that hyperexcitability of peripheral nerves plays a major role. We hypothesize that some of this long-lasting hyperexcitability might be caused by changes to neuronal enhancer profiles. Enhancers are regions of the genome that regulate gene expression. Their location is cell-type specific and largely fixed once development is complete, though there have been reports of stimulus-dependent alterations in adult immune cells (e.g. Ostuni et al. 2013, Kaikkonen et al. 2013, Denk et al. 2016). In neurons, many enhancers are known to be induced by activity (Kim et al. 2010), and the same gene can be regulated by different enhancer combinations in a stimulus-specific manner (Joo et al. 2016). It is therefore conceivable that neuropathic injury alters the enhancer function of peripheral neurons to more permanently affect their transcriptional profile and ultimately their excitability.
This study used an animal model of chronic neuropathic pain. Male mice underwent partial sciatic nerve ligation or sham surgery and were sacrificed eight days or 28 days later. Dorsal root ganglia (DRG) were extracted, and nociceptors purified with the help of magnetically activated cell sorting. Cell-type specific transcriptional changes were assessed by RNA sequencing (n = 4). Enhancers were examined using chromatin immunoprecipitation and sequencing (ChIP-seq, n = 4) to probe for known associated histone modifications (H3k4me1, H3k27ac).
Contrary to transcriptional studies on mixed tissue, nociceptor-specific changes eight days after nerve injury did not center on immune-related genes, but exposed a signature primarily related to the consequences of axotomy.
Basic enhancer profiles as measured by H3K4me1 did not appear to be substantially altered by the pain state, either at 8 or 28 days.
In summary, our data so far suggest that peripheral neurons are distinct from immune cells, in that they do not display stimulus-induced remodeling of H3K4me1 enhancer marks. In depth

analysis of H3k27ac profiles, and hence conclusions about the effects of nerve injury on enhancer activity, are still outstanding.

**Abstract:** Chemotherapy-induced painful peripheral neuropathy (CIPN) is the most common toxicity associated with widely used chemotherapeutics. CIPN is the major cause of dose reduction or discontinuation of otherwise life-saving treatment. Unfortunately, CIPN can persist in cancer-survivors which adversely affects their quality of life. Moreover, available treatments have limited efficacy which warrants a better understanding of the biochemical changes that occur in response to chemotherapeutics. We have determined that the chemotherapeutic, bortezomib, alters the metabolism of sensory neurons where the production of energy becomes predominately reliant on glycolysis and to a lesser extent on oxidative phosphorylation. This metabolic phenotype is known as aerobic glycolysis. Thus, we propose to test the hypothesis that bortezomib induces aerobic glycolysis in sensory neurons which leads to the development of CIPN. Using molecular, biochemical and metabolic assays we characterized the metabolic changes that occur in sensory neurons in response to bortezomib. Moreover, we determined the mechanisms through which bortezomib initiates the biochemical changes that alter the metabolism of sensory neurons. Lastly, we have determine that targeting the molecules that maintain aerobic glycolysis alleviate CIPN. These data suggest that the development of therapeutic strategies that target aerobic glycolysis might prevent the development and maintenance of CIPN.

**Abstract:** Neuropathic pain (NP) is one of the most severe kinds of pain and many patients suffer with this condition. However available therapies are largely ineffective and inadequate in treating patients. NP is reported to be caused by peripheral nerve injury which induces hyper-excitability of the neurons in the sensory ganglion. Despite the absence of synaptic contacts in adult sensory ganglia, somata of sensory neurons can be transiently depolarized and cross-excited by activation of neighboring neurons within the same ganglion. Our previous research had shown that neurotransmitters are released within the peripheral sensory ganglia, which are responsible for causing pain. Further we have shown that inhibition of the release of these neurotransmitters reduced pain behavior in animal NP models. Our present research is focused on exploring the role of glial cells of trigeminal ganglion (TG) in NP. We are checking the release of cytokines from the primary culture of satellite glial cells (SGC) or Schwann cells of TG. We also aim to explore the neuron-glial interaction due to release of such cytokines. In the present study, we analyzed the cytokine up-regulation in TG cells in an animal model of orofacial NP. This model was created by infraorbital nerve constriction (IONC) surgery in Sprague-Dawley male rat. On the 7th day of IONC surgery, TGs were dissected and snap frozen for the fluorescent immunohistochemistry. SGC's were identified by their expression of glutamine synthetase (GS). Glial fibrillary acidic protein (GFAP), a marker of activation of SGC's was also analyzed. Co-expression of GS and GFAP on the constricted side of TG indicated increased SGC activity after the IONC surgery. We observed an increased expression of IL-2 in neuronal somata of TG. This expression of IL-2 was higher on the constricted side as compared to the non constricted side. We hypothesize that in the NP condition, there is an increased production of IL-2 by SGC's which is released extracellular. Because of the close proximity of neuron-SGC and various other mechanisms, IL-2 is taken up or endocytosed by the

neurons which is seen to be expressed in our immunohistochemistry section within the somata of the neurons. Our future work focuses to explore such possibilities and mechanisms.

**Abstract:** Neuropathic pain can be triggered, in part, by activity of diverse primary afferent pathways, including C and A delta nociceptors. To what extent these afferents contribute to neuropathic pain is not clear. We developed a method of selective activation of A delta or C fibers based on diode laser (DLss), the selectivity of which is documented in several small scale volunteer and clinical studies as well as in rodents and pigs. Because of this capacity, DLss can be used as a biomarker of A delta or C fiber status. DLss also allows for differentiation of C polymodal vs. C mechano-insensitive thermonociceptive fiber activation.
Here we examined the means of optimizing DLss protocols for large-scale clinical study requirements.
Safety: Because DLss does not require overheating of the epidermis for heat to reach dermal fibers, no adverse effects have been reported in over 100 volunteers and patients.
Training: Two days of intensive training were sufficient for 3 independent groups of experienced QST researchers that never used DLss before to become competent in the methods.
Protocol: Subjects were prepared as to insure reproducibility: tested areas were shaved, each site was marked with grid with cell sizes of 10 mm X 10 mm, 3 columns and 10 rows and baseline skin temperature was maintained with accuracy +/-0.5 oC. Stimulation began from 0 mA current, and the current was increased in 100 mA (about 0.1 W) increments until the stimulation was felt as painful. Pain threshold was obtained by applying:
a) method of levels, which consisted of a series of ascending and descending stimuli with 5 up and 5 down changes until the last painful sensation was given a pain rating 3 out 10 on the numeric rating scale and
b) method of limits, which consisted of a series of ascending stimuli with fixed step of 100 mA

with up to 10 changes until the last painful sensation was given a pain rating of 3 out 10.
Both methods were applied for each subject three times to compare their accuracy and to define the duration of each test. The stimulation protocol for activation for C nociceptors included the 5 mm in diameter area of stimulation, and duration of each stimulus was 2 sec; for A-delta nociceptors, spot diameter was 1 mm and stimulus duration was 60 ms. Each subject was tested before and after test or control treatment for each type of fiber.
Reproducibility: we found that both protocols provide excellent reproducibility in the frame of baseline physiological variability with a variability of measurements from 5% to 8%.
Robustness: Each test took between 10 min to 15 min to define each fiber type pain threshold.

**Title:** Alternative therapeutic approach to attenuate orthodontic pain -$CO_2$ laser therapy

**Authors: *T. TSUCHIYA**[1], N. HASEGAWA[1], N. SUDA[1], K. ADACHI[2]
[1]Orthodontology, [2]Parmacology, Meikai Univ. Sch. of Dent., Sakado, Japan

**Abstract:** The analgesic effect of laser irradiation is applied to many orofacial diseases and the efficacy of laser application on orthodontic force-induced pain has been investigated in both clinically and laboratory. However, the detail of laser action is not fully understood and the analgesic effect of laser irradiation is inconsistently reported. The aims of this study were 1) to determine whether the laser irradiation attenuate orthodontic pain by using jaw-opening reflex (JOR) model and 2) to evaluate the optimal irradiation protocol to obtain maximal analgesic effect on orthodontic pain. General anesthetized rats were applied continuous orthodontic force by Ni-Ti coil spring to only the right maxillary first molar. On the following day, rats were generally anesthetized and pair of electrodes was inserted bilateral anterior digastric muscle to record EMG activity and the maxillary first molar gingiva to electric stimulation. Passing current (200 μs) was applied to the right then the left maxillary first molar region to determine JOR threshold. After measuring JOR threshold, $CO_2$ laser irradiation (15, 30 or 600 s) was applied the right side maxillary first molar region then JOR threshold was determined again for subsequent 90 min with 30 min interval (D1 group). $CO_2$ laser irradiation (30 s) was also applied to the right maxillary first molar region immediately after orthodontic force application in other animals, and JOR excitability was evaluated on next day (D0 group). To confirm effect of laser irradiation on JOR excitability, another set of animals received only laser irradiation (30, 600 s, without

orthodontic treatment) to the right maxillary first molar region before JOR excitability evaluation (control group). Laser irradiation did not alter JOR threshold between right and left stimulations in the control group. Since JOR threshold was variable across animals, the right side threshold was standardized with that of left side in each animal. Application of orthodontic force in the D1 group significantly ($P < 0.05$) decreased right side JOR threshold (71.5 ± 5.7 %) compared with that on the left side. Laser irradiation (30 and 600 s) in D1 group significantly ($P < 0.05$) increased right side JOR threshold (30 s:97.5 ± 13.6 % @ 30 min, 93.3 ± 7.5 % @ 60 min, 111.1 ± 11.3 % @ 90 min;600 s: 92.5 ± 4.2 % @ 30 min, 91.1 ± 2.1 % @ 60 min). Interestingly, in D0 group, right side JOR threshold was also significantly ($P < 0.05$) increased (111.6 ± 7.4 %). Taken together, $CO_2$ laser irradiation is applicable for attenuating orthodontic pain and the analgesic effect of $CO_2$ laser irradiation is not transient.

**Title:** Results of fiber specific quantitative sensory test (QST) explains pain sensory deficits in patients with spontaneous peripheral neuropathic pain

**Authors: *M. I. NEMENOV**[1,2], M. KLUKINOV[2], D. C. YEOMANS[3], M. SCHMELZ[4]
[1]Lasmed LLC, Mountain View, CA; [2]Anesthesia, Stanford Univ., Palo Alto, CA; [3]Stanford Univ., Stanford, CA; [4]Heidelberg Univ., Mannheim, Germany

**Abstract:** Patients with painful peripheral neuropathies (PPN) have spontaneous pain but typically have reduced heat pain sensitivity, which is currently explained by significant denervation of epidermal cutaneous nociceptor fibers. However, we have showed that loss of pain sensitivity in PPN patients is actually fiber specific, with increased pain thresholds for Adelta and normal thresholds for C fiber mediated pain (1). These novel findings can't be completely explained by denervation. Besides, we found that mechano-insensitive C fibers (CMi), but not C polymodal (CMH) fibers are sensitized to heat in PPN patients (2) despite higher activation thresholds of normal CMi fibers for both electricity or heat when compared to those of CMH nociceptors. Thus, PPN associated loss of pain sensitivity could be explained by denervation of CMH and A delta fibers while responses of sensitized CMi fibers were relatively unaffected. Here we hypothesize that relatively low pain thresholds in PPN patients when assessed using diode laser C fiber specific stimulation (C-fiber DLss) as opposed to typical heat

stimuli are the result of the capacity of DLss to activate CMi fibers below pain threshold. Therefore, the heat pain deficit that has been measured in PPN patients with spontaneous pain may be related to the method of stimulation rather than overall loss of heat pain sensitivity. 12 healthy subjects without history of peripheral neuropathy were tested. Laser pulses of 1 sec, 5 mm diameter @980 nm (LassM-10M, LasMed, CA) were used for stimulation. Activation of CMi fibers was confirmed by recording of perfusion (PeriCAM, Perimed, Sweden). Baseline and laser evoked skin temperature was monitored by thermal camera (SC 6000, Flir, USA). The presence of post stimulus sensitization was assessed using neurological pins (Neurotips, Owen Mumford, USA). Laser-induced CMi activation (neurogenic flare) was recorded below pain threshold in ten subjects. No difference was observed in mechanical sensitivity between irradiated and surrounding skin. *We documented, for the first time, that neurogenic flare response, and therefore activation of CMi nociceptors can occur below the temperature threshold for pain in healthy subjects.* In parallel studies in pigs and rats, C-fiber DLss also induced neurogenic flare below pain thresholds. *The ability to activate CMi fibers with DLss should allow better assessment of PPN in patients and animal models.* 1. **Abstract:** Painful peripheral neuropathy (PPN) has a variety of causes, including diabetes, HIV, herpes zoster, chemotherapy and postsurgery. Most therapeutics target purported pain mechanisms in CNS with fewer than 1/3$^{rd}$ of patients achieving no more than 50% relief but while most having debilitating side effects. Here we directly compare a new laser non-contact

and 8% capsaicin patch (Acorda Theraputics) treatments. Capsaicin and heat are both TRPV1 agonists. Capsaicin depletes epidermal sensory endings of C fibers that presumably express TRPV1 as sources of PPN but the half-life of ~ 24 hours and can lead to prolonged inflammatory pain with continued treatment. This limits the use of high dose capsaicin patches even for FDA approved treatment of some types of PPN. We have previously shown that pulses of Diode Laser (DL) induced-heat, presumably an agonist of TRPV1 channels, can selectively activate mechano-insensitive C fibers that are abnormally spontaneously active in patients with painful versus painless neuropathy (1). In this SBIR Phase I feasibility study, we assessed the innervation density in pig skin biopsies seven days after 1 hour 8% capsaicin patch treatment (Acorda) and four dosages of laser irradiations that induced peak temperature up to 55$^{o}$C. Pigs were habituated for 2-3 days and trained to perform pain mechanical (neurological pins (Neurotips, Owen Mumford, USA) and diode laser C fiber selective behavioral tests (DLss, LasMed, CA) (1,2). The behavioral tests were conducted one day before and 6 days after the treatment in one pig and showed a significant increase of response latency to C fiber laser stimulation in the infrared-treated versus untreated areas ($p<0.02$) and in the same area before and after treatment ($p<0.04$). The PGP9.5 quantification demonstrated a significant depletion of cutaneous epidermal innervation with 10 pulses comparable to depletion produced by 8% capsaicin patch. Examination of alternating sections stained for H&E reveal no obvious damage from capsaicin treatment and DL treatment with 10 and 20 pulses, but some minor damage from 40 pulses. Therefore, the impact of a one-hour capsaicin treatment efficacy could be achieved in less than 2 minutes for DL treatment. 1. Moeller-Bertram T, Schilling JM, Bačkonja MM, Nemenov MI. **Abstract:** The translation of basic research findings to the development of safe and effective strategies for preventing and treating chronic pain remains a daunting health care challenge. Given the myriad shortcomings of typical rodent models, we have previously developed a peripheral neuritis trauma (PNT) model of chronic pain induced by a proximal sciatic nerve irritation in pigs which have a body size, metabolism, skin structure, and cutaneous innervation more relevant to that of humans. Three sutures pre-soaked in complete Freund's adjuvant (CFA), closely-spaced and loosely tied around the proximal sciatic nerve in pigs produces sustained pain behavior symptoms consistent with painful neuritis and/or neuropathic pain (NP) in humans. Here, we used multi-molecular immunolabeling and microscopic analyses to evaluate pig skin biopsies from various sciatic nerve injury models and demonstrate cutaneous innervation and epidermal keratinocyte pathologies similar to those reported in several human chronic NP afflictions. As seen previously in several human neuropathic pain afflictions such as postherpetic neuralgia, complex regional pain syndrome,and painful diabetic neuropathy, a reduction of small caliber innervation, including intraepidermal nerve fibers (IENF), was coupled with an increase in algesic mediators and a decrease in analgesic mediators among epidermal keratinocytes, which directly influence the level of excitability of remaining sensory endings within and near the epidermis. Of particular interest, small caliber innervation that expresses the neuropeptide CGRP, implicated in inflammatory pain, was preferentially spared especially in association with capillaries and precapillary arterioles in the upper dermis. Expression of the neurosignaling properties NaV1.6, CGRP, and endothelin-1 receptor A (ETRA), which are implicated in algesia, were increased on keratinocytes, whereas ETRB, implicated in analgesia, was decreased. The decrease in innervation occurred within the first week. Alterations in keratinocyte neurosignaling properties, induced by the proximal nerve injury, occurred during the second week and was recapitulated through at least 4 weeks, by which time all of the originally impacted keratinocytes should have been replaced. This model not only provides a relevant model for translational research, but also provides insights into potential novel therapeutic strategies.

**Title:** Cannabinoid CB2 receptors on epidermal keratinocytes and langerhans cells as potential targets for blocking paclitaxel-induced neuropathic pain

**Authors: X. LIN**[1], L. DENG[1], K. MACKIE[1], J. ROMERO[3], C. J. HILLARD[4], P. J. ALBRECHT[5], F. L. RICE[5], *A. G. HOHMANN[2]
[1]Psychological and Brain Sci., [2]Indiana Univ., Bloomington, IN; [3]Sch. of Pharm., Univ. Francisco De Vitoria, Pozuelo De Alarcon - Madrid, Spain; [4]Med. Col. Wisconsin, Milwaukee, WI; [5]Integrated Tissue Dynamics LLC, Rensselaer, NY

**Abstract:** Cannabinoid CB2 receptors are a promising therapeutic target because their activation suppresses pathological pain without unwanted psychotropic effects caused by activating CB1 receptors in the CNS. However, the cell types that contain CB2 receptors and mediate these analgesic effects are poorly understood due to questionable specificity of existing CB2 antibodies. Previously, we showed that the cannabilactone CB2 agonist AM1710 suppressed development and maintenance of paclitaxel-induced mechanical and cold allodynia without producing tolerance or physical dependence (Deng et al. (2015) Biological Psychiatry 77: 475-487). Moreover, anti-allodynic effects of AM1710 were absent in CB2 knockout (KO) mice but fully preserved in CB1 KO mice, confirming mediation by CB2. Here we show that the anti-allodynic efficacy of systemic AM1710 in the paclitaxel model is specifically blocked by SR144528, a CB2 receptor antagonist with limited CNS penetration. These observations suggest that CB2 receptors outside the CNS underlie the CB2-mediated suppression of chemotherapy-induced neuropathic pain induced by the CB2 agonist. We, therefore, developed mice with a CB2-promoter driven expression of green fluorescent protein (GFP) to identify CB2-expressing cell types in glabrous paw skin. Mice received repeated injections of paclitaxel (4 mg/kg i.p. on day 0, 2, 4 and 6) or its cremophor-based vehicle and were perfused during the maintenance stage of neuropathic pain when allodynia was maximal (i.e. day 15 following initiation of paclitaxel dosing). A separate group of mice were killed 1 h following an acute challenge with paclitaxel (4 mg/kg i.p.) and tissue was processed concurrently. GFP was differentially expressed on epidermal keratinocytes in stratified patterns that shifted and increased in intensity, especially after repeated paclitaxel injections. GFP was intensely expressed on dendritic cells, with the Langerhans subtype, invading the epidermis already after the acute and increasing after the repeated injections. As reported previously (Ibrahim et al. (2005) PNAS 102: 3093-3098) our studies confirm the expression of CB2 receptors on keratinocytes and revealed a novel expression on dendritic and Langerhans cells as potential targets for treating paclitaxel-induced neuropathic pain.

**Abstract:** EphB receptor tyrosine kinases were first found to play important roles during development, but recently have been implicated in synaptic plasticity in mature nervous system and pain processing. We have previously reported that ephrinB-EphB receptor signaling contributes to neuropathic pain by regulating neural excitability and synaptic plasticity in the dorsal horn neruons. How EphB receptors influence the excitability of dorsal root ganglion (DRG) neurons, however, remains elusive. We investigated roles of activity of ephrinB-EphB receptor signaling in neural excitability and its underlying mechanisms in acutely dissociated-, primary cultured-, or excised intact-DRG neurons from Sprague-Dawley rats. The results showed that EphB1 and EphB2 receptors are expressed in the large- and medium-sized as well as the small DRG neurons, but not in the satellite glial cells. Bath application of EphB receptor activator ephrinB2-Fc caused NMDA receptor-independent $Ca^{2+}$ influx and amplified NMDA induced-$Ca^{2+}$ influx in primary cultured DRG neurons. Blocking Src kinase by Src kinase inhibitor PP2 reversed ephrinB2-Fc-induced increase of NMDA-dependent $Ca^{2+}$ influx and phosphorylation of NR2B subunit. The mRNA and protein expressions of EphB1 and EphB2 receptors are greatly upregulated in DRG neurons following peripheral nerve injury. Intracellular concentration of $Ca^{2+}$ was significantly increased in the nerve injured-DRG neurons. In addition, the nerve injured-DRG neurons exhibited increased $Ca^{2+}$ response to NMDA that was reversed by EphB receptor blocker EphB2-Fc. Blocking EphB receptor activation also reversed nerve injury-induced upregulation of phosphorylation of NR2B receptor and other neurochemical markers. These findings demonstrate that EphB receptors can facilitate calcium influx of DRG neurons directly and via modulation of NMDA receptor and thus provide underlying mechanisms for its contribution to neuropathic pain.

**Title:** Overexpressing Tet1 in primary sensory neurons attenuated nerve injury-induced nociceptive hypersensitivity

**Authors:** ***Z. PAN**[1], Q. WU[2], G. WEI[3], S. WU[3], L. LIANG[3], A. BEKKER[3], Y.-X. TAO[3]
[1]Dept. of Anesthesiol. in New Jersey Med. School, Rutgers,, The State Univ. of New Jersey, Newark, NJ; [2]Dept. of Anesthesiol., Newark, NJ; [3]Dept. of Anesthesiology, New Jersey Med. School, Rutgers, The State Univ. of New Jersey, Newark, NJ

**Abstract:** DNMT3a-mediated DNA methylation contributes to the nerve injury-induced neuropathic pain genesis through the epigenetic silencing of mu opioid receptor (*Oprm1*) and *Kcna2* genes in the primary sensory neurons of dorsal root ganglion (DRG). Tet (ten eleven translocation) family of oxygenases catalyse the oxidation of 5-methylcytosine (5mC) to 5-hydroxymethylcytosine (5hmC), resulting in DNA demethylation and promotion of the gene transcription in biological processes. The present study investigated whether overexpressing Tet1 in the DRG affected nerve injury-induced pain hypersensitivity. As expected, DRG microinjection of herpes simplex viruses (HSV) expressing full-length Tet1 (HSV-Tet1) into the ipsilateral L5 DRG significantly increased the level of TET1 in the injected DRG. This increase attenuated the SNL-induced elevation of 5mC level and correspondingly rescued the SNL-induced decrease of 5hmc in promoter regions of *Oprm1* and *Kcna2 genes*, resulting in the reverse in the SNL-induced downregulation of MOR and KV 1.2 in the ipsilateral DRG. Behavioral observations revealed that microinjection of HSV-Tet1 into the ipsilateral L5 DRG alleviated mechanical allodynia, thermal hyperalgesia and cold allodynia in the development and maintenance of neuropathic pain without affecting locomotor function and basal responses to mechanical, thermal and cold stimuli. Moreover, microinjection of HSV-Tet1 into the ipsilateral L5 DRG improved morphine analgesia and prevented the morphine analgesic tolerance under neuropathic pain conditions. These results suggest that TE1 overexpression in DRG has the potential function in treatment of neuropathic pain through blocking nerve injury-induced DNA methylation in *Oprm1* and *Kcna2* genes in the DRG.

**Abstract:** Chemotherapy-induced neuropathic pain (CINP) is one of the major dose-limiting toxicities of cytostatic pharmacotherapy. It can affect up to 80% of patients and lead to reduction or discontinuation of the cancer treatment. Epigenetic modulation by DNA methylation, which in mammals occurs at cytosine residues catalyzed by DNA methyltransferase (DNMTs), plays an important role in the dynamic regulation of gene expression. DNA methylation triggered by chemotherapy has largely unexplored therapeutic consequence. Our study found that after administration of paclitaxel, K2p1.1 (KCNK1), one of the two-pore potassium channels, was decreased significantly in mouse DRG neurons, whereas DNMT3a (DNA methyltransferase 3a), but not DNMT1 and DNMT3b, was increased significantly in mouse DRG. DRG K2p1.1 decrease led to the elevations in rest membrane potential and neuronal hyperexcitability of DRG neurons. Blocking the increased DNMT3a in the DRG rescued the decrease of K2p1.1 in DRG and alleviated mechanical allodynia and thermal hyperalgesia in paclitaxel-treated mice. DNMT3a was co-localized with K2p1.1 in DRG neuron. Our results suggest that DNMT3a-triggered K2p1.1 down-regulation in DRG may be required for the development of CINP.

**Title:** MicroRNA 143 contributes to neuropathic pain through DNMT3a-triggered epigenetic silencing of MOR in DRG

**Authors:** ***S. WU**, B. XU, K. MO, L. LIANG, A. BEKKER, Y.-X. TAO
Anesthesiol., Rutgers, The State Univ. of New Jersey, Newark, NJ

**Abstract:** Dysregulation of microRNAs (miRNAs) in dorsal root ganglion (DRG) and spinal cord has been found following peripheral nerve injury. However, how miRNAs contribute to neuropathic pain remains elusive. The present study showed that the level of miR-143 was significantly decreased in the ipsilateral L5 DRG after spinal nerve ligation (SNL) at day 3 and 7 post-SNL in the rats. Blocking this decrease through pre-microinjection of miR-143 mimics into the ipsilateral L5 DRG prevented the SNL-induced pain hypersensitivities. In contrast, mimicking this decrease through microinjection of miR-143 inhibitors into L4/5DRG led to neuropathic pain-like symtoms in naive rats. Mechanismtically, miR-143 suppressed the expression of DNA methyltransferase 3A (Dnmt3a) post-transcriptionally in the DRG. Downregulating miR-143 significantly increased the expression of Dnmt3a, resulting in the suppression of the expression of mu opioid receptor (MOR), a downstream target of Dnmt3a, in the DRG. DRG overexpression of miR-143 blocked the SNL-induced increase in Dnmt3a and rescued the SNL-induced decrease in MOR in the ipsilateral DRG. These findings suggest that miR-143 reduction in the DRG contributes to neuropathic pain through Dnmt3a-triggered epigenetic silencing of MOR in the ipsilateral DRG.

**Abstract:** The alterations in gene transcription in the dorsal root ganglion (DRG) following nerve trauma contribute to the genesis of neuropathic pain. Transcription factors gate gene expression. We report here that peripheral nerve trauma caused by chronic constriction injury (CCI) increased the abundance of the transcription factor C/EBPβ (CCAAT/enhancer-binding protein-β) in the DRG. Blocking this increase mitigated the development and maintenance of CCI-induced mechanical, thermal, and cold pain hypersensitivities, without affecting basal responses to acute pain and locomotor activity. Mimicking this increase produced mechanical, thermal, and cold pain hypersensitivities. Mechanistically, C/EBPβ participated in CCI-induced decreases in the abundance of mRNAs and proteins of the voltage-gated potassium channel subunit Kv1.2 and mu opioid receptor through C/EBPβ-triggered activation of euchromatic histone-lysine N-methyltransferase 2 gene in the ipsilateral DRG. C/EBPβ is likely an endogenous initiator of neuropathic pain and may serve as a potential target for the prevention and treatment of this disorder.

**Abstract:** Neuropathic pain is a serious clinical disease. The dorsal root ganglion (DRG) is a major target to explore the peripheral mechanisms of neuropathic pain. Alternative splicing contributes to multiple physiological and pathological events including nociceptive processing. NrCAM, a neuronal cell adhesion molecule of the L1 family of immunoglobulins, has been indicated in neural development and disorders such as drug addiction and autism. However, it is unknown if Nrcam alternative splicing is involved in neuropathic pain. Using a mouse model of the fourth spinal nerve ligation (SNL)-induced neuropathic pain, we compared the junction reads of RNA-sequencing data obtained from both SNL and sham DRG by MISO (Mixture of Isoforms probablistic model for RNA-Seq). This bioinformatics approaches identified that SNL led to decreased exon skipping of Nrcam gene exon 10 in DRG. The expression of Nrcam RNA with exon 10, but not the total mRNA of Nrcam, was significantly increased in the ipsilateral DRG by reverse transcription PCR validation. Suppression of exon 10 inclusion via the specific antisense oligonucleotides targeting the splicing sites markedly reduced the SNL-induced pain hypersensitivity. Our findings suggests that Nrcam pre-mRNA alternative splicing may be a potential analgesic target for neuropathic pain.

**Abstract:** Clinical genetic studies have shown that loss-of-function of the $Na_v1.7$ voltage-gated sodium ion channel (*SCN9A*) leads to complete inability to perceive pain (**C**ongenital **I**ndifference to **P**ain - **CIP**), whereas $Na_v1.7$ gain-of-function alleles cause or contribute to chronic spontaneous pain. Mechanistically, $Na_v1.7$ governs the excitability of peripheral nociceptive sensory neurons and the transmission of noxious nociceptive signals into the spinal cord, possibly by facilitating action potential propagation across fine neuronal branch points. Mounting evidence indicates that $Na_v1.7$ plays a major role in transducing pain in acquired clinical neuropathic pain syndromes. To further our knowledge on the role of this channel in pain processing, we developed the first viable global $Na_v1.7$ knockout mouse (Gingras et al, 2014). These mice were anatomically normal, reached adulthood, and had phenotype wholly analogous to human congenital indifference to pain (**CIP**). Although the model had proven useful in various aspects of $Na_v1.7$ antagonist research, but the difficulties around breeding large number of animals due to the hand feeding requirements left a few unrequited questions, particularly regarding the role of $Na_v1.7$ in chronic pain. We report the generation of a humanized chimeric rat model designed to overcome identified species differences that would allow for unique chemical matter testing. Surprisingly, upon thorough characterization, it was observed that the animals had a protein translation deficit, which resulted in a surrogate $Na_v1.7$ KO-like phenotype. Here we show the full characterization of the animals at the molecular, protein and behavioral level in direct comparison to the report mouse global KO phenotype and highlight its novel experimental applications.

**Title:** Paclitaxel alters enzymes involved in the biosynthesis of nicotinamide adenine dinucleotide ($NAD^+$) in the dorsal root ganglia and dorsal horn of the rat: reversal by nicotinamide riboside

**Authors: *D. L. HAMMOND**[1], R. Y. WALDER[2], G. OURTIES[3], S. R. WHITE[4], M. V. HAMITY[4]
[1]Anesthesia Res. 3000 ML, Univ. Iowa, Iowa City, IA; [2]Pathology, Univ. of Iowa Hosp. and Clinics, Iowa City, IA; [3]Univ. d'Auvergne, Clermont-Ferrand, France; [4]Dept. of Anesthesia, Univ. of Iowa, Iowa City, IA

**Abstract:** Nicotinamide riboside (NR) is a form of vitamin B3 and a precursor of nicotinamide adenine dinucleotide ($NAD^{+)}$. Daily gavage with NR prevents the cold and tactile hypersensitivity and suppresses place escape avoidance behaviors in rats treated with paclitaxel. This study assessed the effects of paclitaxel on enzymes involved in *de novo* and salvage pathways for synthesis of $NAD^+$, and further tested whether NR could prevent these changes. Female Sprague Dawley rats received a cumulative dose of 19.8 mg/kg paclitaxel or Kolliphor:ethanol:saline (KES) vehicle i.v. and were killed six or 14 days later. Another cohort of rats was gavaged daily with 200 mg/kg NR or vehicle daily for one week before, during and continuing for 14 days after i.v. administration of paclitaxel or KES vehicle at which time the rats were killed. This dose of NR increases blood levels of $NAD^+$ by 50%. Levels of transcript for nicotinamide riboside kinases (*Nmrk*) 1 and 2, sirtuins (*Sirt*) 1 and 3, sterile alpha and TIR motif containing 1 (*Sarm-1*), nicotinamide mononucleotide adenylyl transferases (*Nmnat*) 1-3, and nicotinamide adenine phosphoribosyl transferase (*Nampt*) were determined in the L4 and L5 dorsal root ganglia (DRG) and spinal cord dorsal horn. All transcripts were determined in the same sample by RT-qPCR and normalized to hypoxanthine phosphoribosyltransferase 1 (*Hprt-1*) as a reference gene. In the dorsal horn, *Sirt-1* levels were decreased by 50% both six and 14 days after paclitaxel. No other transcripts were altered by paclitaxel. Treatment with NR prevented the decrease in *Sirt-1*. The reduction in *Sirt*-1, an $NAD^+$ consumer, in the dorsal horn may reflect a reduction in $NAD^+$ levels. In the DRG, *Nmnat*-1 and *Nmnat*-2 levels increased two-fold within 14 days of paclitaxel. Pretreatment with NR prevented these increases. Levels of transcript for *Nmrk*-1 and *Nampt* trended higher after paclitaxel. Of note, NR by itself increased transcripts for *Sarm-1*, *Nampt*, *Nmnat-2* and *Nmrk-1* by two-fold in the DRG. Levels of *Nmrk-2* in the DRG and dorsal horn were too low to quantitate. In comparison, sciatic nerve transection in male rats decreased *Sirt-3* and *Nmrk-1*, and did not alter *Sarm-1* or *Nampt* in the L4 and L5 DRG. Whether

corresponding changes in protein expression occur in the DRG and dorsal horn after paclitaxel and NR treatment remains to be determined. However, these results suggest that sensory neurons or glia in the DRG may be able to utilize NR to maintain levels of $NAD^+$ as a possible mechanism for relief of neuropathy induced by paclitaxel, but not nerve-injury.

**Title:** The nicotinamide adenine dinucleotide ($NAD^+$) precursor nicotinamide riboside (NR) relieves paclitaxel-induced peripheral neuropathy in tumor bearing rats and does not facilitate tumor growth or interfere with the effects of paclitaxel

**Authors: *M. V. HAMITY**[1], S. WHITE[1], K. GIBSON-CORLEY[2], D. HAMMOND[1]
[1]Anesthesia, [2]Pathology, Univ. of Iowa, Iowa City, IA

**Abstract:** Chemotherapy-induced peripheral neuropathy (CIPN) is a common disabling and dose-limiting adverse effect of many chemotherapeutic drugs, for which an effective treatment remains elusive. We recently reported NR, a naturally occurring vitamin B3 precursor of $NAD^+$, can prevent and relieve established CIPN induced by paclitaxel in tumor-naïve rats. However, studies in tumor-naïve rats do not fully model the clinical situation in that factors secreted by tumors not only alter the microenvironment, but can also cause systemic inflammation. It is also critical that drugs that alleviate CIPN do so without interfering with the chemotherapy. In the case of NR, there are additional concerns that an increase in $NAD^+$ levels could promote tumorigenesis. This study re-examined the effects of NR in tumor-bearing rats and determined whether NR treatment facilitates tumorigenesis or interferes with the chemotherapeutic effect of paclitaxel. Mammary gland tumors were induced in female rats by injection of 50 mg/kg i.p. NMU (N-methyl-N-nitrosourea) at 3 weeks of age. Rats were examined twice a week, and volume and number of tumors were recorded for up to 12 weeks after NMU injection. Upon the

appearance of a palpable tumor ~ 6 weeks later, NMU- treated rats were injected with a cumulative dose of 19.8 mg/kg i.v. paclitaxel over five days. NR (200 mg/kg) or vehicle was administered daily by gavage concomitant with the paclitaxel treatment and continuing for four weeks. Mechanical and cold sensitivity were assessed 14 and 21 days after paclitaxel to establish if NR treatment ameliorates CIPN in tumor-bearing rats. To evaluate if NR treatment promotes tumorigenesis, another set of rats was dosed daily with NR or vehicle starting 6 weeks after NMU treatment. To evaluate if NR interferes with chemotherapy effects, measurements of tumor number and size were also made in the rats treated with paclitaxel for a period of four weeks. The results indicate that NR diminished paclitaxel-induced mechanical hypersensitivity and cold sensitivity in tumor-bearing rats as it did in tumor-naïve rats. Importantly, daily gavage with NR did not facilitate tumor growth (size or number) compared to vehicle-treated rats. Paclitaxel reduced tumor size to an equivalent extent in NR and vehicle-treated rats, and rebound tumor growth after paclitaxel effects waned also did not differ between NR- and vehicle-treated rats. This study is one of the first to test the effects of a novel therapeutic in a tumor-bearing rodent model of CIPN induced by a clinically relevant dose of paclitaxel. These findings provide additional support for a clinical trial of NR for the relief of taxane-induced peripheral neuropathy.

**Title:** Role of Adenosine monophosphate-activated kinase in mechanical allodynia mediated by reactive oxygen species

**Authors: *K. M. HANKERD**, J. WANG, J.-H. LA, J. M. CHUNG
Dept. of Neurosci. and Cell Biol., Univ. of Texas Med. Br., Galveston, TX

**Abstract:** Production of excess reactive oxygen species (ROS) has been shown to mediate pathologic mechanical pain in several pain models, including the intradermal capsaicin injection model. However, it has not yet been elucidated which signaling molecules downstream of excessive ROS mediate and perpetuate pain. Adenosine monophosphate-activated kinase (AMPK) is a redox-sensitive protein kinase whose pharmacological activators were shown to reduce neuropathic mechanical pain. We thus hypothesized that AMPK would play a role in

ROS-mediated pathologic mechanical pain. C57BL/6N mice developed secondary mechanical allodynia and hyperalgesia after intradermal capsaicin injection. The ROS scavenger phenyl-N-tert-butylnitrone (PBN) selectively alleviated mechanical allodynia but not hyperalgesia. Similarly, activators of AMPK, metformin and A769662, inhibited only mechanical allodynia. Directly increasing ROS levels in the cerebrospinal fluid by intrathecal ROS donor injection produced mechanical allodynia and hyperalgesia. Metformin and A769662 also selectively attenuated mechanical allodynia in this intrathecal ROS donor injection model. AMPK activator treatment prior to intradermal capsaicin or intrathecal ROS donor injection significantly hampered the development of mechanical allodynia. These results suggest that decreased AMPK activity due to excess ROS contributes to ROS-mediated mechanical allodynia.

**Title:** Peripheral nerve activity maintains neuropathic mechanical allodynia but not hyperalgesia

**Authors: *J.-H. LA**, J. WANG, H. SHIM, J. CHUNG
Dept. of Neurosci. and Cell Biol., Univ. of Texas Med. Br., Galveston, TX

**Abstract:** Peripheral neuropathic injury often causes chronic mechanical allodynia (pain from an innocuous touch) and hyperalgesia (increased pain from a normally painful mechanical stimulus). Sensitization of nociceptive system has been suggested to be accountable for the chronic neuropathic pain symptoms. However, it remains unclear how the nociceptive system sensitization is persistently maintained. We hypothesized that it is maintained by ongoing peripheral nerve activities originating at the symptomatic area. To test this hypothesis, we injured L5 spinal nerve by tight ligation (L5 SNL) in the mouse and examined effects of local anesthesia on mechanical allodynia and hyperalgesia at two symptomatic areas in the hind paw plantar skin. Mechanical allodynia and hyperalgesia were measured as % occurrence of paw withdrawals from low- and high-intensity von Frey filament stimulations. L5 SNL-induced mechanical allodynia was robust at the base of 3$^{rd}$ and 4$^{th}$ toes (Site 1) but less pronounced at the center of the paw (Site 2). When a local anesthetic (bupivacaine 0.75%, 3 μl) was injected at Site 1, mechanical allodynia, but not hyperalgesia, at Site 2 was alleviated. Selective silencing of either TRPV1/A1-expressing nociceptors or TLR5-expressing Aβ-fibers at Site 1 did not affect mechanical allodynia and hyperalgesia at Site 2. These results suggest that nociceptive system

sensitization for chronic neuropathic mechanical allodynia is dynamically maintained by ongoing peripheral activities arising from the symptomatic areas, whereas that for chronic neuropathic mechanical hyperalgesia persists without being dependent on such peripheral inputs. Peripheral activities of TRPV1/A1-expressing nociceptors and TLR5-expressing Aβ-fibers do not appear to contribute to the dynamic maintenance of sensitization for chronic neuropathic mechanical allodynia.

**Title:** Decrease in excitatory synaptic response of spinal dorsal horn GABAergic neurons during burst inputs

**Authors: *C. BAE**, J.-H. LA, H. SHIM, S.-J. TANG, J. M. CHUNG
Dept. of Neurosci. and Cell Biol., Univ. of Texas Med. Br. At Galveston, Galveston, TX

**Abstract:** Decreased function of inhibitory interneurons (disinhibition) in the spinal cord has been suggested as an important mechanism for mechanical allodynia. To maintain mechanical allodynia, abnormal ongoing afferent input was shown to be necessary. Thus, we hypothesize that disinhibition is dynamically dependent on abnormal ongoing afferent input. To test this hypothesis, we examined the excitatory postsynaptic potential (EPSP) in spinal GABAergic neurons (GABAn) in the mouse spinal cord slices before, during, and after burst synaptic input simulating abnormal ongoing afferent inputs. Stimulation parameters for the burst input were adopted from studies inducing long-term potentiation of excitatory synaptic transmission in the spinal dorsal horn *in vivo*. GABAn were identified by green fluorescent protein (GFP) expression driven by GAD67 promoter. Synaptic inputs evoking excitatory postsynaptic currents with consistent onset latency and no failure at the burst stimulation frequency were selected for EPSP recordings. As results, lamina II GABAn (GFP-positive) showed a gradual decrease in EPSP amplitude during the burst input. After cessation of the burst input, GABAn EPSP amplitude returned to the baseline level. Unlike GABAn, unidentified (GFP-negative) lamina II neurons showed an increase in EPSP amplitude during the burst input, and this increase was maintained

long-term even after cessation of the burst input. Demonstrating that GABAn excitability to synaptic inputs decreases only while burst input is ongoing, these results suggest that disinhibition is dynamically dependent on abnormal ongoing afferent input.

**Title:** Nerve injury induces distinct changes in central terminals among nociceptor and mechanoreceptor subpopulations

**Authors: *L. K. CRAWFORD**[1], S. JEON[2], D. CHANG[3], D. D. GINTY[5], M. J. CATERINA[4]
[1]Dept of Mol. and Comparative Pathobiology, [2]Biol. Chem., [3]Biochem., Cellular, and Mol. Biol., [4]Neurosurg., Johns Hopkins Sch. of Med., Baltimore, MD; [5]Dept Neurosci, Harvard Med. Sch., Boston, MA

**Abstract:** Neuropathic pain affects a wide variety of patients, yet, due to our incomplete understanding of its underlying pathophysiology, current therapies for this condition are inadequate. In addition to pain neurons, or nociceptors, there is growing evidence that touch neurons known as low-threshold mechanoreceptors (LTMRs) also play an important role in painful pathologic conditions. Mechanical allodynia occurs when light touch, which would typically activate LTMRs in healthy skin, instead elicits a painful response. However, the role of LTMRs in mechanical allodynia is poorly understood. With the advent of genetic tools that enable targeted labeling of specific LTMR subtypes we can now examine how LTMRs might change in the pathologic setting and more closely evaluate differential roles for LTMR subtypes in allodynia. Inducible Cre mouse lines were crossed to reporter mouse lines to generate offspring with genetically labeled Adelta LTMRs and rapidly adapting Abeta LTMRs. The SNI model of neuropathic pain was used to generate mechanical allodynia in these mice, and the hypersensitive phenotype was quantified in behavioral tests. Spinal cord tissue from the level of nerve injury was examined to characterize central terminals of nociceptor and LTMR

subpopulations of sensory neurons. Preliminary results suggest that there may be differential loss of labeled axon terminals across sensory neuron subpopulations. Following nerve injury we often observed a regional decrease in IB4, a marker of non-peptidergic nociceptors, presumably due to a loss of axon terminals as a result of nerve injury. However, this response was not uniform across sensory neuron populations. By comparing patterns of axon terminals identified by markers of nociceptors or by lineage-specific genetic labeling, we found distinct changes across nociceptor and LTMR subtypes, suggesting distinct regulation of sensory neuron subtypes in a model of neuropathic pain. These data demonstrate that nociceptors and LTMRs do not show uniform responses to nerve injury and underscore the mechanistic clarity that more precise evaluation of neuronal subtypes can provide.

**Abstract:** Satellite glial cells (SGCs) are the main type of glial cells in sensory ganglia and are a potential gene-therapy target for chronic pain. Recombinant adeno-associated viral (AAV)-mediated therapeutic gene transfer is an effective and safe tool for treating chronic pain. However, AAV with various ubiquitous cell-potent promoters leads to gene transfer predominantly to neurons while glial cells are refractory to AAV transduction in the peripheral nervous system (PNS). The present study evaluated whether *in vivo* SGC transduction in the dorsal root ganglia (DRG) could be enhanced by SGC-specific GFAP promoter and by using AAVshH10 and AAVshH19 that are engineered capsid variants with glia-prone transduction. Titer-matched AAV6 (as control), AAVshH10, and AAVshH19 variants, all encoding the enhanced green fluorescent protein (EGFP) reporter driven by the ubiquitous cell-potent CMV promoter, as well as AAV6-EGFP driven by a GFAP promoter (AAV6-GFAP-EGFP) were injected into DRGs of adult rats. Neurotropism of gene transfer was determined and compared

by immunohistochemistry. Results showed that injection of AAV6-GFAP-EGFP induces efficient EGFP expression selectively in SGCs, whereas injection of either AAVshH10-CMV-EGFP or AAVshH19-CMV-EGFP into DRGs resulted in a similar *in vivo* transduction profile to AAV6-CMV-EGFP, all showing efficient transduction of sensory neurons without significant transduction of glial cell populations. Co-injection of AAV6-CMV-mCherry and AAV6-GFAP-EGFP induces transgene expression in neurons and SGCs separately. This report, together with our prior studies, demonstrate that the GFAP promoter rather than capsid tropism determines selective gene expression in SGCs following intraganglionic AAV delivery in adult rats. A dual AAV system, one with GFAP promoter and the other with CMV promoter, can efficiently express transgenes selectively in neurons vs. SGCs.

**Title:** Effects of peripheral nerve injury on the kinetics of electrically evoked GABA receptor-mediated currents in GABAergic and non-GABAergic neurons of the spinal dorsal horn

**Authors: T. AJIMA**, E. KATO, S. TANAKA, Y. HORI, *T. FUKUSHIMA
Dokkyo Med. Univ., Mibu, Japan

**Abstract:** In the spinal dorsal horn (SDH), several different types of neurons, including GABAergic inhibitory neurons and glutamatergic excitatory neurons, play important roles in modulating the synaptic transmission of sensory information, such as pain sensations. GABA is an inhibitory neurotransmitter that is crucially involved in the modulation of nociceptive transmission in the SDH. In this study, we characterized the GABA receptor-mediated currents recorded from the SDH neurons and investigated the effects of peripheral nerve injury on these currents. Experiments were performed on glutamate decarboxylase 67-green fluorescent protein (GFP) knock-in mice at the age of six to eight weeks. Spinal cord slices from the lumbar enlargement were prepared, and tight-seal whole-cell recordings were made from GFP-positive and GFP-negative neurons located in the SDH. Postsynaptic currents were evoked by internuncial electrical stimulation. GABA receptor-mediated inhibitory postsynaptic currents (GABA IPSCs) were pharmacologically isolated in the presence of the glycine receptor blocker strychnine, the NMDA receptor blocker CNQX, and the NMDA receptor blocker APV. The recordings were made at the holding potential of 0 mV. Partial sciatic nerve ligation (PNL) was performed according to the methods described by Seltzer et al. (1990). In sham-operated control mice, the peak amplitude of the GABA IPSCs recorded from the GFP-negative neurons was

larger than that from the GFP-positive neurons. However, the time decay of the GABA IPSCs was slower in the GFP-positive neurons than in the GFP-negative neurons. The PNL did not affect the amplitude of the GABA IPSCs but increased the rate of their decay over time in the GFP-negative neurons. In contrast, in the GFP-positive neurons, the PNL decreased the amplitude and slowed the time decay of the GABA IPSCs. The amount of charge transferred during the GABA IPSCs was decreased by the PNL in the GFP-negative neurons. It is presumed in the literature that the GFP-negative neurons in the SDH are predominantly glutamatergic excitatory neurons. If this assumption is true, our results indicate that the PNL decreases GABAergic inhibitory synaptic inputs to excitatory neurons in the SDH. The PNL-induced disinhibition of excitatory neurons may be involved in the mechanisms for peripheral nerve injury-induced mechanical allodynia. In order to elucidate the molecular adjustment that underlies our observed changes in the characteristics of GABA IPSCs, we are currently pursuing real-time quantative RT-PCR analysis to clarify how the PNL affects $GABA_A$ receptor subunit composition.

**Title:** Localized sympathectomy reduces regeneration and associated mechanical pain in the spinal nerve ligation model

**Authors: *W. XIE**, J. A. STRONG, J.-M. ZHANG
Anesthesiol., Univ. Cincinnati Coll Med., Cincinnati, OH

**Abstract:** It is known that the sympathetic nervous system plays an important role in regulating pain and inflammatory responses. Our previous studies have demonstrated that mechanical hypersensitivity evoked by either spinal nerve ligation (SNL), localized inflammation of the DRG (LID; a low back pain model) or injecting the hindpaw with Complete Freund's Adjuvant (CFA; an inflammatory pain model), was greatly reduced by localized sympathectomy achieved by cutting the grey rami to the L4 and L5 sensory ganglia. Also, we recently found that in the SNL model the injured spinal nerve underwent functional regeneration and target reinnervation. The actively regenerating nerve was closely associated with spontaneous afferent activity and pain, which were both reduced by inhibiting nerve regeneration. In this study, we examined

whether inhibiting nerve regeneration is one of the mechanisms underlying pain relief by localized sympathectomy in the SNL model. The L5 spinal nerve was ligated and cut with or without concurrently cutting the grey rami to the L5 and L4 sensory ganglia on the same side. The regenerated nerve emerging from the nerve stump proximal to the ligature was observed in vivo, and was found to be thinner and paler in the rats with localized sympathectomy at all examined time points (POD 14, 28 and 42). *In vivo* fiber recording (from filaments teased from the L5 dorsal root and disconnected centrally) showed localized sympathectomy greatly reduced spontaneous activity, which was previously shown to originate in newly regenerated nerve. Functional regeneration and distal target reinnervation were also inhibited by localized sympathectomy: by day 42, the majority of receptive fields responses conducting through regenerated nerve could be detected only in the thigh and upper leg, unlike in the SNL model without sympathectomy, in which receptive fields in the knee, lower leg, and paw could be progressively detected starting from day 28. Previous studies suggest that macrophage infiltration around the axotomized sensory neuronal cell bodies plays a critical role in promoting nerve regeneration. We found that localized sympathectomy significantly reduced the macrophage accumulation in L5 dorsal root ganglion induced by axotomy. This results indicate that sympathetic nerve activity is important for peripheral nerve regeneration and reinnervation. Sympathetic nerves may be involved in promoting recruitment of macrophage to axotomized DRG neuron to stimulate nerve regeneration. Sympathetic blockade may relieve chronic pain partially via inhibiting nerve regeneration.

**Title:** Collagens modulate sensitization signaling and CGRP expression of nociceptive neurons

**Authors: *K. MÖLLER**[1], C. LOOS[2], J. ISENSEE[1], J. HASENAUER[2], T. HUCHO[1]
[1]Univ. Hosp. of Cologne, Koeln, Germany; [2]Helmholtz Zentrum München - German Res. Ctr. for Envrn. Hlth., München, Germany

**Abstract:** Painful tissue alterations such as wounds, tumors or arthritis are accompanied by changes in the extracellular matrix (ECM). Even though ECM has been extensively studied for its impact on neurite outgrowth and regeneration, knowledge about its influence on pain sensitization signaling in nociceptive neurons is sparse. Thus, we aimed to identify ECM components which alter sensitization signaling in nociceptive neurons, and to analyze their subgroup specificity, cellular mechanism and downstream targets.
We analyzed about 1 million cultured primary sensory neurons from male rat dorsal root ganglia for an influence of 17 ECM proteins on basal and NGF-, 5-HT-, and OncostatinM-induced phosphorylation of endogenous PKA subunits and/or Erk1/2 at 7 time points (510 conditions), using immunocytochemistry and a novel High-Content-Screening (HCS) microscopy approach. Based on single-cell data of candidates, a mechanistic computational model was established and analyzed for mechanistic changes using ordinary differential equation constrained mixture modelling (ODE-MM). Further subgroup and mechanistic analysis was pursued via HCS microscopy.
We identified the class of collagens to modulate NGF-induced pErk1/2 but not pRII-PKA kinetics. In contrast, none of the other ECM proteins altered basal and induced Erk1/2 and RII-PKA phosphorylation. Neuronal subgroup comparability was validated by HCS based subgroup analysis and ODE-MM. Collagens did not modulate GDNF-induced pErk1/2 kinetics and thus growth factor signaling of another neuronal subgroup. Mechanistic analysis excluded changes in basal TrkA and Erk expression, ligand affinity and dephosphorylation, and identified NGF-mediated effects on the TrkA receptor level to be the reason for differential pErk1/2 signaling. Furthermore, we could show that collagens induce long-lasting elevations of pErk1/2 levels and downstream CGRP expression.
Collagen content and composition is strongly modified in painful tissue alterations such as wounds, tumors or arthritis. Our results suggest that collagens augment nociceptor sensitivity long-lastingly in such pathologies. The observed elevated CGRP expression proposes a further increased pain signaling by para- and autocrine CGRP activity.

**Title:** GSK-3 and microRNA-29 regulating blood nerve barrier tightness in neuropathy

**Authors: *H. L. RITTNER**[1], J. T. CHEN[1], S. YANG[2], S. SAUER[1], L. HU[2], A. BRACK[1]
[1]Universitätklinikum Würzburg, Wuerzburg, Germany; [2]Dept Anesthesiol. and Pain Med., Tongji Hosp. of Tongji Med. College, Huazhong Univ. of Sci. and Technology, 430030 Wuhan, China, Wuhan, China

**Abstract:** Background: In peripheral nerves, the blood-nerve barrier (BNB) consisting of the perineurium surrounding nerve fascicles and the endothelium of endoneurial blood vessels protects neurons against nerve damage. Perineurial cells or endoneurial cells are connected by adherens junctions and sealed by tight junction proteins (TJP) like claudins or occludin. BNB tightness after controlled opening for drug delivery e.g. by claudin-1 specific peptides is governed by glycogen kinase synthase 3 (GSK-3) reulating the beta-catenin pathway. In pathological states like neuropathy, the BNB is opened leading to diffusion of possible toxic metabolites and immune cell invasion. Here, we explored mechanisms controlling BNB tightness in neuropathy.
Methods: Animal experiments were approved by local authorities. Neuropathy was induced in male Wistar rats via chronic constriction injury of the sciatic nerve. Thermal and mechanical nociceptive thresholds as well as tight junction protein expression and selected micro-RNAs were analyzed in CCI and after treatment with glycogen-3 synthase kinase inhibitors.
Results: Chronic constriction injury resulted in a downregulation of claudin-1 and ZO-1 mRNA and protein in the sciatic nerve compared to sham animals. Also, microRNA-29 was downregulated starting after 1 d and persistent for up to 14 d in the peripheral nerve. In silico, microRNA-29 bound to the 3'UTR of GSK-3beta. In the early phase of inflammation phosphorylation of GSK-3beta was enhanced. Short-term treatment with a GSK-3 inhibitor prevented TJP downregulation and the development of allodynia. However, no significant long-term reversal of allodynia and thermal hypersensitivity or prevention of TJP downregulation was observed.
Conclusion: GSK-3beta is only involved in early BNB regulation possibly via to downregulation of microRNA-29.

**Abstract:** Nerve injury and neuropathies result in pain, loss of sensation, weakness, and systemic complications. Direct gene delivery to peripheral nerve has the potential to enable a host of novel therapies for these conditions. However, current gene delivery methods face numerous practical and translational hurdles, including heavy reliance on viral infection, stochasticity, and cellular damage. Additionally, delivery of targeted therapies to nerves is especially challenging because of the unique morphology of the neurons contained within, where cell bodies on the motor and sensory neurons reside within the central nervous system (CNS) and yet their axons can extend for over 1 meter into the body to either innervate muscle or sensory end organs. We developed a novel, facile, and powerful nanochannel-based technique for non-viral cargo delivery into nerves in a highly deterministic and benign manner. Cleanroom-based methods were used to fabricate millimeter-sized chip platforms for nanochannel-mediated gene delivery into the sciatic nerve (SN) of adult mice. Nanochannels are used to controllably nanoporate the cell membranes on the nerve tissue and electrophoretically deliver a wide variety of genes. We specifically delivered reprogramming angiogenic genes as potential strategy for the treatment of peripheral neuropathies. Delivery efficiency and retrograde transport from the SN to the CNS was assessed via immunofluorescence microscopy and qRT-PCR at the SN, dorsal root ganglion (DRG) and spinal cord (SC) levels. Tissue sections collected shortly after transfection revealed successful cargo delivery following the implementation of a short-lived (<100 ms) pulsed electric field across the nanostructured platform. Immunofluorescence analysis and qRT-PCR confirmed tissue transfection and strong pro-endothelial gene activity at the SN, DRG and SC levels. No appreciable behavioral changes (e.g., paw clenching, gait perturbations) were noted in mice that underwent the procedure. We were able to efficiently transfect peripheral nerve tissue using our nanostructured platform via non-viral approaches. This study supports the feasibility of gene delivery to targeted individual peripheral nerves to enhance regeneration following a focal injury to that nerve. Moreover, the retrograde delivery to the CNS expands the potential applicability of our method to the treatment of focal and regional CNS insults. Ongoing studies are currently focused on monitoring induced tissue plasticity following delivery of reprogramming factors, as well as developing pro-angiogenic reprogramming-based cell therapies for injury-induced neuropathies.

**Abstract:** Understanding the peripheral mechanisms underlying mechanical allodynia in neuropathic pain has proven challenging. The development of novel genetic lines in order to manipulate particular neurons within peripheral pain and somatosensitive circuits has facilitated the study of the underlying mechanisms in neuropathic pain. Previous work has shown that VGluT1 is primarily expressed in Aβ mechanoreceptors and proprioceptors offering a tool for the study of this population of neurons in mechanical pain, especially mechanical allodynia. In order to further study the role of Aβ mechanoreceptors in pain, we are currently using electrophysiology and microscopy to characterize a population of primary afferents expressing channelrhodopsin under the vesicular glutamate transporter type 1 Cre-recombinase driver (VGluT1:ChR2). In cultured dorsal root ganglion (DRG) neurons we find that VGluT1:ChR2 cells are enriched in large-diameter neurons. VGluT1:ChR2 neurons show narrow spike waveforms and lower spike thresholds consistent with Aβ mechanoreceptors. Importantly, activation of these neurons by optical stimuli lead to responses consistent with those elicited by direct current injection and the majority of neurons responded faithfully to optical stimuli up to 10 Hz. Immunohistochemistry performed on hairy and glabrous skin preparations revealed that VGluT1:ChR2 afferent endings terminated onto structures consistent with a mixed population of slowly and rapidly adapting mechanoreceptors including merkel cell-neurite complexes and lanceolate endings. The majority of VGlut1:ChR2 afferents terminated along the dermal-epidermal border and did not overlap with peptidergic nociceptor endings. Interestingly, a subset of terminals did however penetrate into the epidermis more consistent with free nerve endings. Taken together, this data suggests that the VGluT1:ChR2 subpopulation of DRG is enriched in low-threshold mechanoreceptors and validates the use of this model in studying the role of these cell-types in the expression of mechanical allodynia.

**Abstract:** Background: We demonstrated previously that angiotensin IV (Ang IV) and LVV-hemorphin 7 (LVV-H7) act through the blockade of insulin-regulated aminopeptidase (IRAP) to decrease oxytocin degradation, thereby causing antihyperalgesia at the spinal level in rats. We determined that intrathecal oxytocin can induce significant antihyperalgesia in male rats with inflammation but not in female rats. Thus, we speculate that Ang IV, LVV-H7, and oxytocin can induce antiallodynia, which could be of great therapeutic potential. Because the anti-hyperalgesia by these peptides was with sex difference, their possible antiallodynia was examined in male and female mice for comparison. We investigated whether Ang IV, LVV-H7, and oxytocin produce antiallodynia at the spinal level in mice and whether this antiallodynia differs between the sexes.Methods: Partial sciatic nerve ligation (PSNL) surgery was performed on adult male and female C57BL/6 mice from the same litter (25-30 g). The effects of intrathecal injections of Ang IV (25.8 nmole), LVV-H7 (27.2 nmole), and oxytocin (0.125 nmole or 1.25 nmole) were assessed through the von Frey test 3 days after PSNL.Results: Intrathecal injection of Ang IV, LVV-H7, and oxytocin all produced a potent antiallodynia in male mice. However, these antiallodynia effects were either extremely weak or absent in female mice at the same dose.Conclusions: Intrathecal Ang IV, LVV-H7, and oxytocin can all cause significant antiallodynia in male mice. The Ang IV-, LVV-H7-, and oxytocin-induced antiallodynia effects differed between the sexes at the spinal level in mice.

**Title:** Percutaneous electrical nerve stimulation elevates agmatine in spinal cords of nerve-injured rats

**Authors: *S. J. ERB**[1], C. PETERSON[2], R. H. SPELTZ[3], K. F. KITTO[3], K. A. SLUKA[6], G. L. WILCOX[4], C. A. FAIRBANKS[5]
[1]Pharmaceutics, [2]Exptl. and Clin. Pharmacol., [3]Neurosci., [4]Neuroscience, Pharmacology, Dermatol., [5]Pharmaceutics, Pharmacology, Neurosci., Univ. of Minnesota Twin Cities, Minneapolis, MN; [6]Physical Therapy & Rehab Sci., Univ. of Iowa, Iowa City, IA

**Abstract: Background:** Decarboxylated L-arginine (agmatine) prevents or reduces the development of opioid tolerance and self-administration, as well as manifestations of neuropathic pain in rodents. Since agmatine is endogenously expressed, we hypothesized that its release in response to percutaneous nerve stimulation (electroacupuncture, EA) may contribute to alleviation of neuropathic pain. We report that endogenous agmatine levels in two rat strains is correlated with the degree of nerve injury-induced hyperalgesia, that agmatine levels in spinal dialysate are elevated during EA, and that spinal agmatine levels are diminished following nerve injury. These observations are consistent with the hypothesis that agmatine is an anti-hyperalgesic modulator released into spinal microdialysate during and following EA stimulation.
**Methods:** Male Sprague Dawley and Long Evans rats were subjected to nerve injury. Development of tactile hypersensitivity was monitored by von Frey monofilament stimulation. Spinal cord extracts were derivatized for agmatine analysis via fluorescence HPLC. Nerve-injured Sprague Dawley rats were also implanted with transverse spinal cord microdialysis fibers (AN69 Hospal), where dialysate was perfused at 5 µL/min and collected in 15-min bins. Baseline samples were collected under isoflurane for 1 hr before and during a 30-min electro-acupuncture stimulation (4 Hz, Zusanli acupoint (ST36)). Control subjects were anesthetized, but not stimulated. Samples were collected for 3 hrs following stimulation and anesthesia. Again, mechanical allodynia was assessed using von Frey monofilaments and spinal cord extracts

derivatized for agmatine analysis via fluorescence HPLC and LC-MS/MS. **Results:** The magnitude of nerve injury-induced tactile hypersensitivity was significantly lower in Long Evans compared to Sprague Dawley rats. The tissue concentration of spinal agmatine was substantially higher in Long Evans compared to Sprague Dawley rats. In nerve-injured Sprague Dawley rats subjected to percutaneous EA, we observed an elevation in agmatine concentration in spinal microdialysate, relative to unstimulated controls. **Conclusion**: These observations support a role for agmatine in alleviation of nerve injury-induced neuropathic pain.

**Title:** A real-time rodent neural interface for deciphering acute pain signals

**Authors: *S. HU**[1], Q. ZHANG[2], J. WANG[3], Z. CHEN[4]
[1]Col. of Biomed. Engin. and Instrument Sci., Zhejiang Univ., Hangzhou, China; [2]Anesthesiol., New York Univ., New York, NY; [3]Anesthesiol., [4]Psychiatry, New York Univ. Sch. of Med., New York, NY

**Abstract:** In recent years, brain machine interfaces (BMI) have attracted accumulating interest with goals to map, assist, augment or repair the cognitive or sensory-motor functions of human and animal brains. Pain is a common experience in our daily lives. However, the neural mechanisms of pain are still poorly understood. To improve our understanding of neural mechanisms of nociceptive pain, we developed a novel rodent neural interface aimed at detecting acute pain signals based on simultaneously recorded ensemble spike activity from multiple brain areas. Specifically, a custom tetrode microdrive was used to simultaneously record neuronal ensemble activity from the rat primary somatosensory cortex (S1) and anterior cingulate cortex (ACC). Three sequential change-point detection algorithms were used to detect pain onset based on online-sorted neuronal ensemble spikes. One is a model-free method called CUSUM

algorithm, and the other two are model-based methods, including PLDS (Poisson Linear Dynamical System) and TLDS (Transformed Linear Dynamical System). The model parameters of PLDS and TLDS were identified by the expectation-maximization (EM) methods, and the latent state was inferred using recursive filtering methods to identify a change in common sensory input that drives the population spike activity. The system has two parallel workflows based on multithread: one for online system identification, and the other for real-time filtering based on the pre-identified system parameters. We implemented two models independently for S1 and ACC recordings. The ultimate change-point detection was determined by integrating information from two parallel decision systems. The detection accuracy was measured by the sensitivity and specificity. Our preliminary results showed that all three methods had low false negative rates (FNR <5%). PLDS and TLDS yielded a similar performance in false positive rate (FPR), whereas the model-free method had very poor FPR. In terms of detection timing, PLDS achieved earlier detection than TLDS in the majority of trials (82%), and they had similar timing in 12% of trials. In summary, we have developed the first rodent neural interface that is capable of detecting acute pain onset signals in real time.

**Title:** Interaction of VGF-derived peptides in microglial signaling

**Authors: *J. L. COOK**[1], K. KITTO[1], M. S. RIEDL[3], C. N. HONDA[2], C. A. FAIRBANKS[4], L. VULCHANOVA[5]
[2]Dept Neurosci., [1]Univ. of Minnesota, Minneapolis, MN; [3]Dept Neurosci., [4]Depts Pharmaceut, Pharmacol & Neurosci, Univ. Minnesota, Minneapolis, MN; [5]Neurosci., Univ. of Minnesota Dept. of Neurosci., Minneapolis, MN

**Abstract:** VGF is a neuropeptide precursor whose expression is rapidly and robustly increased in dorsal root ganglion and dorsal horn neurons following peripheral nerve injury. We have demonstrated that the VGF-derived peptide TLQP-21 contributes to both the development and maintenance of hypersensitivity after peripheral nerve injury and inflammation, and that intrathecal administration of TLQP-21 results in thermal hyperalgesia. TLQP-21 signals through

the C3aR1 receptor, and we have demonstrated that TLQP-21 elicits $Ca^{2+}$ transients in microglia in spinal cord slices and primary glial cultures. The c-terminus of VGF includes a number of peptides, and TLQP-21 is cleaved from a larger peptide with another bioactive peptide AQEE-30. It is likely that the two peptides are exerting their effects in parallel, and therefore we used behavioral and calcium imaging assays to determine if they interact functionally. When AQEE-30 and TLQP-21 were co-administered intrathecally, maximal thermal hyperalgesia was achieved at lower doses than administration of each peptide alone. In primary microglial cultures, TLQP-21 evoked calcium transients in a concentration-dependent manner, whereas AQEE-30 failed to elicit responses. However, TLQP-21 evoked transients were potentiated in the presence of equimolar concentrations of AQEE-30. To explore the potential downstream effectors of TLQP-21-evoked microglial activation, a semi-quantitative cytokine array was performed on supernatant collected from cells stimulated with control media or TLQP-21. A number of pro-inflammatory and chemotactic immune factors that are implicated in neuropathic pain were significantly increased in TLQP-21-treated media and further work will examine whether a combination of TLQP-21 and AQEE-30 changes the profile of downstream microglial signaling. In the context of increased VGF expression after nerve injury and the microglial effects of TLQP-21, the interaction of TLQP-21 and AQEE-30 could be important in neuroimmune signaling under conditions of neuropathic pain.

**Title:** Enduring pathological effects of prenatal alcohol exposure on touch hypersensitivity following peripheral nerve damage via neuroimmune mechanisms in adult rat offspring

**Authors:** ***J. SANCHEZ**[1], J. E. SANCHEZ[1], M. V. NYSUS[2], J. P. NORENBURG[2], D. D. SAVAGE[1], E. D. MILLIGAN[1]

**Abstract:** Allodynia (hypersensitivity to light mechanical touch) is a clinical neuropathic pain condition shown to be mediated by activated spinal glia (astrocytes and microglia) and is associated with sciatic nerve chronic constriction injury (CCI) induced by loose ligation of 4 chromic gut sutures. We recently demonstrated that young prenatal alcohol exposed (PAE) rats develop potentiated allodynia following CCI with elevated spinal glial activation (Noor et al., 2017). The goal of the current study was to determine whether following PAE if (1) the pain effects are enduring, (2) a minor CCI injury (1-suture model) produces allodynia, and (3) blocking the activation of lymphocyte function-associated antigen-1 (LFA-1), an adhesion molecule expressed on trafficking immune cells and microglia, could suppress allodynia.
PAE and Saccharin control rat offspring (as described by Savage et al., 2010) were used for all experiments. For goals 1 and 2, middle-aged male (1 yr) or young male (4 mo) and female (4 mo) rats were assessed for hindpaw responses to light mechanical touch (von Frey fiber test) prior to and after either a standard (4-suture) or a minor (1-suture) CCI or sham surgery. For goal 3, young male & female rat hindpaw responses were assessed prior to & after CCI or sham surgery and after spinal (intrathecal) BIRT-377 (an LFA-1 antagonist) or vehicle injection until peak drug efficacy. Tissue from middle-aged and young males were prepared for immunohistochemical (IHC) detection of GFAP for astrocyte activation, Iba1 for microglia & peripheral macrophages, and the microglial specific marker, transmembrane protein 119 (TMEM119). A separate group of young females was given intravenous BIRT-377 or vehicle and reassessed for 4 days.
Results show standard CCI potentiated allodynia in middle-aged PAE rats while minor CCI generated unilateral allodynia similarly to standard CCI injury in non-PAE rats. Potentiated allodynia coincided with exaggerated expression of all glial activation markers whereas minor injury induced increased astrocyte GFAP expression. No changes in expression of microglial activation was observed despite ongoing allodynia. Young males given spinal BIRT-377 reversed from allodynia while females did not. Spinal cords from these behaviorally verified rats revealed astrocyte reactivity was greatest in young PAE allodynic males while microglial reactivity was elevated under all CCI conditions. PAE females revealed full allodynic reversal following intravenous BIRT-377. These results indicate PAE creates enduring pathological susceptibility to neuropathy with potentially distinct spinal neuroimmune mechanisms underlying sex differences.

**Title:** Neuroglia activated by TREZ compression injury on trigeminal neuralgia animal model

**Authors: *D. LUO**, Y. YU
Dept. of Anatomy, Histology and Embryology, Fujian Med. University/School of Basic Med., Fujian, China

**Abstract:** Objects: Trigeminal root entry zone (TREZ) is a segment of trigeminal nerve adjacent to the pons, and it is a transitional zone between central nervous system (CNS) and peripheral nervous system (PNS). TREZ compressed by microvascular is the major cause of the primary trigeminal neuralgia (TN) in patients, but the pathogenesis of TN is still unclear. To study the pathomorphological changes of neuroglia cells under TN in the TREZ, a novel animal model of TN by chronic compression of the trigeminal nerve root (CCT) from inferior orbital fissure in the male SD rats was established.
Methods: Paraformaldehyde-fixed TREZ were processed into 30-um thick serial longitudinal sections on post-operation day 7, 14, 21 and 28 in CCT animal model group and sham operation group, respectively. GFAP, IBA-1, P75NTR and MBP as different glial markers were detected in the TREZ after operation by use of immunofluorescent staining.
Results: Immunofluorescent staining showed, GFAP immunoreactivity was very strong in the TREZ and formed the dome boundary of CNS-PNS glial barrier. A great number of the glia cells were activated after CCT operation. The interface of dome boundary stained by GFAP was highly irregular after trigeminal nerve root compression, and it extended distally from CNS to PNS compartment. Both IBA-1 immunoreactive microglia and P75NTR immunoreactivities in CCT group increased on day 7, and gradually decreased from day 14 after operation, which were higher than those in sham operation group ( $p < 0.05$). MBP immunoreactivities were also activated in CCT group after operation, and the arrangement of oligodendroglia in CNS compartment of TREZ was disordered.
Conclusion: Trigeminal nerve root compression activated most of the neuroglia cells in the TREZ of TN animal model, and the CNS-PNS boundary of myelin sheath formed by myelinating glia was also changed after mechanical injury. TREZ was fragile to chronic compression, and the neuroglia cells activation may participated in the pathogenesis of TN.

**Abstract:** A growing body of evidence indicates that prenatal alcohol exposure (PAE) may predispose individuals to secondary medical disabilities later in life. Animal models of PAE reveal neuroimmune sequelae such as elevated brain glial (astrocyte and microglial) activation with corresponding increases in proinflammatory cytokines. Our recent work demonstrates that young adult PAE rats display enhanced pathological sensitivity to light mechanical touch (allodynia) following adult-onset sciatic nerve injury (Noor *et al.*, 2016*),* which is mediated by increased spinal cord glial and cytokine actions that hyper-excite pain neurons. Corresponding elevations in spinal leukocyte activation and sciatic nerve proinflammatory cytokines also occur, suggesting that PAE-augmented immune responses extend beyond spinal glial cells to include alterations in peripheral immune cells. Therefore, we examined whether PAE-induced peripheral immune cell activation persists later in adulthood. Here, we have generated an overall peripheral immune cell profile in middle aged (~30 yrs human equivalent) male PAE rats using *ex vivo* flow

cytometry from the immune organs of the spleen, thymus, and medial iliac lymph node using the same moderate PAE paradigm reported previously (Savage *et al.,* 2010). Additionally, immune cell composition was characterized from peritoneal exudate cells (PECs) and peripheral blood. Functional responses of splenocytes and PECs to immune stimulation were further examined. While no significant change in the overall T and B cell numbers compared to non-PAE controls was observed, data suggest basal increases in natural killer cells numbers is present in the lymph node. Moreover, the proportions of CD11b/c+ leukocytes increase both in the spleen and lymph node, indicating basal activation in the absence of immune challenge. Interestingly, peripheral leukocytes (splenocytes and PECs) from PAE rats reveal exaggerated expression of pro-inflammatory cytokines such as tumor necrosis factor-alpha (TNFα) and interleukin (IL)-1β following *in vitro* immune stimulation. These data indicate that peripheral immune cells are primed in PAE rats to produce aberrant immune responses and may underlie a susceptibility to developing autoimmune disease and inflammatory conditions following immune challenge in adulthood. Together, these results provide novel insight into the vulnerability that PAE produces in predisposing individuals to lifelong neuropathological conditions. Ongoing studies are investigating possible sex differences in PAE neuroimmune responses in adult PAE rats following peripheral nerve injury.

**Title:** The hippocampal extracellular matrix regulates pain and memory dysfunction after peripheral injury

**Authors: *M. TAJERIAN**[1], V. HUNG[3], H. NGUYEN[1], T.-T. HUANG[1], D. CLARK[2]
[2]Anesthesiol., [1]Stanford University/ VAPAHCS, Palo Alto, CA; [3]VAPAHCS, Palo Alto, CA

**Abstract: Background:** Chronic pain is a heavy individual and societal burden, presenting with co-morbid psychiatric disorders (mood alterations and cognitive impairment) that parallel signs of brain neuroplasticity. Hippocampal involvement has been studied due to its role in cognition/memory and in modulating the overall pain experience. The functional, anatomical, and biochemical changes in patients and preclinical models suggest a pivotal role for hippocampal plasticity in the maintenance of chronic pain and implies a level of flexibility in the

extracellular environment in which cells function; a line of investigation not pursued to date. **Hypothesis**: Changes in the hippocampal extracellular matrix (ECM) support maladaptive cellular and behavioral plasticity after peripheral injury. **Methods**: We used a C57bl/6 male mouse model of chronic pain due to tibia fracture. Seven weeks post-injury, animals were tested for mechanical sensitivity and memory function. Slice electrophysiology was carried out in the hippocampal pyramidal layer. Adeno-associated virus-labeled hippocampal neurons were analyzed for dendritic complexity. Hippocampi were decellularized and used for scanning electron microscopy and atomic force microscopy. ECM components were measured using western blotting and ELISA. Immunohistochemistry was used to measure the abundance of stable inhibitory interneurons in the hippocampus. **Results:** We report deficits in working and location memory that are associated with increased hippocampal LTP, decreased dendritic complexity, altered ECM microarchitecture and decreased ECM rigidity. Furthermore, we observed biochemical changes in the ECM, including a decrease in aggrecan, an increase in matrix metalloprotease 8, and an increase in tissue inhibitor of matrix metalloprotease 2. We also report a reduction in specialized ECM nets around inhibitory interneurons, potentially accounting for the increased LTP. The reported anatomical, physiological, and biochemical changes in the hippocampal ECM reflect a local imbalance between plasticity-inhibiting and plasticity-promoting cues to help the organism adapt to a new environment that includes the multitude of co-morbidities that accompany injury and chronic pain. However, this prolonged imbalance can reach a pathological state thereby participating in the chronification of the overall pain experience and its resistance to traditional therapies. **Conclusions**: Targeting ECM plasticity in the chronic pain brain goes beyond examining nociceptive pathways themselves, and addresses structural factors supporting both pain and its related consequences.

**Abstract:** Regulator of G protein signaling 4 (RGS4) is a G-Protein Coupled Receptor (GPCR) modulator expressed in several CNS regions associated with pain transmission and perception. RGS4 controls the duration and direction of GPCR signaling by associating with activated Galpha ($Galpha_i$ and $Galpha_q$) subunits. Our previous studies used a neuropathic pain model to demonstrate that RGS4 is a positive modulator of the antiallodynic actions of monoamine-targeting antidepressants. Here, using the murine Complete Freud's adjuvant (CFA) and Spared Nerve Injury (SNI) models of chronic pain, we demonstrate a key role of RGS4 in the maintenance of sensitized behaviors. RGS4 Wild-type (RGS4WT) mice show prolonged mechanical and cold allodynia in response to peripheral inflammation or nerve injury, whereas mice lacking the Rgs4 gene (RGS4 Knock-out, RGS4KO) recover from mechanical and cold allodynia. This phenotype is observed both in female and male mice. RGS4 acts in a modality specific-manner as prevention of RGS4 affects mechanical and cold allodynia whereas it does not affect thermal hyperalgesia. Consistent with the behavioral studies, qPCR analysis highlights that RGS4 is uniquely regulated by long term peripheral inflammation or nerve injury in the spinal cord, the periaqueductal gray and the thalamus. Using viral mediated gene transfer for conditional knockdown of RGS4 in specific brain regions of adult floxed RGS4 mice, we also show that prevention of RGS4 action in the ventral posteromedial thalamic nucleus (VPm) results in the same phenotype to that observed in constitutive RGS4KO mice. Prevention of RGS4 action in a subset of nociceptive neurons expressing Vallinoid type-1 receptors (TRPV1) has a small but significant effect on recovery from CFA-induced allodynia. Finally, we applied RNA sequencing methodology in order to further understand the impact of RGS4 in gene regulation induced by peripheral inflammation in the thalamus. This analysis reveals different intracellular adaptations in the RGS4WT thalamus compared to RGS4KO groups in response to long term peripheral inflammation. Our data provide new information on the mechanisms underlying the maintenance of long-term pain states and point to RGS4 as a target for pain management.

**Abstract:** Pain continues to be a significant clinical problem due to its high prevalence, marked negative impact on quality of life and limited treatment options. The most common treatments such as opioid analgesics and non-steroidal anti-inflammatory drugs are frequently ineffective or have serious side effects. Development of more effective, well-tolerated pain treatments will come from a more complete understanding of the neural networks that mediate pain. This will then allow for the identification of the many key synaptic and molecular mechanisms that underlie this form of pain. Here we use a combination of chemogenetics, immunohistochemistry, electrophysiology and behavior to identify the neural network that mediates mechanical allodynia, a prevalent condition in which light touch or movement becomes painful with injury or disease. Our studies identify several critical neuronal populations that participate in the dorsal horn network for mechanical allodynia. Interestingly, the data also reveal the existence of distinct pathways depending on the type of injury. This latter finding has important implications not only for understanding at a basic level how the nervous system transmits mechanical allodynia, but it also reinforces that notion that etiology must be considered when implementing and developing treatment strategies.

**Abstract:** Pain evoked by innocuous mechanical stimuli or mechanical allodynia is a debilitating symptom suffered by millions of chronic pain patients. It exists in two forms, dynamic and static, which 1) are evoked by skin touch and skin pressure, respectively, 2) produce distinct perceptions, and 3) exhibit differential morphine sensitivity. However, neural circuits differentially transmitting these forms of allodynia remain unknown. Here we report that spinal neurons marked by developmental VGLUT3 expression form a morphine-resistant circuit required selectively to transmit dynamic mechanical pain. In contrast, static allodynia is likely mediated via both morphine-sensitive and morphine-resistant pathways that are preserved in VGLUT3 lineage neuron-ablated mice, but eliminated in somatostatin lineage neuron-ablated mice. The studies reveal for the first time separate spinal substrates transmitting dynamic versus static mechanical pain. Furthermore, acute silencing of VGLUT3 lineage neurons can attenuate pre-exisitng dynamic allodynia. The studies reveal for the first time separate spinal substrates transmitting dynamic versus static allodynia, and identify new cellular targets for treating these forms of neuropathic pain.

**Title:** Functional roles of the spinoparabrachial pathway in nociception

**Authors: *J. DENG**[1,2], D. MU[1,2], Y. SUN[1]
[1]Inst. of Neurosci., Shanghai City, China; [2]Grad. Sch., Univ. of Chinese Acad. of Sci., Shanghai, China

**Abstract:** Somatosensory signals information isare conveyed to the brain through by projection neurons in the dorsal spinal cord. The parabrachial nucleus (PBN), one of the major targets of the spinal cordprojection neurons, has been reported to be involved in pain sensation. However, the functional role of spinoparabrachial pathway in pain sensation is still unknown. Here, we investigated the anatomical and functional property of the spinoparabrachial pathway with a combination of viral tracing, slice electrophysiological and optogenetic techniques. We found that neurons in the spinal cord send projections to dorsal lateral PBN bilaterally. Use ofing the retrograde FuGB-Cre virus, we demonstrated that left PBN-projecting neurons in the spinal cord also send projections to right PBN and other brain areas, such as thalamus and periaqueductal grey. Moreover, neurons in PBN receive AMPA receptors-mediated excitatory input from the spinal dorsal horn. Optogenetic activation of the ipsilateral rather than contralateral spinoparabrachial projection induces pain related licking and flinching behaviors. While the emotion related behaviors, vocalization and conditional place avoidance (CPA), were only observed when the contralateral spinoparabrachial pathway was activated. Our study demonstrates the different roles of ipsi- and contralateral spinoparabrachial pathway in pain processing.

**Title:** Neuropathic pain creates an enduring deficit in medial prefrontal cortex-dependent behavioral performance that is resistant to gabapentin treatment but reversed by metformin

**Authors: *S. SHIERS**, G. PRADHAN, G. MEJIA, S. KROENER, T. PRICE
Cognition and Neurosci., Univ. of Texas At Dallas, Richardson, TX

**Abstract:** Chronic pain patients suffer from cognitive impairments reflected by deficits in working memory, emotion based decision-making, and cognitive flexibility even while taking commonly prescribed analgesics. These deficits are linked to problems in the medial prefrontal cortex (mPFC) in patients leading to the hypothesis that pain-related maladaptive plasticity occurs in this region disrupting healthy cortical activity. We sought to model this mPFC dysfunction in mice to examine molecular mechanisms of maladaptive plasticity and to assess the effect of therapeutics. Male mice with spared nerve injury (SNI) or sham surgery were given a single dose of intrathecal clonidine or 7-day treatment with systemic gabapentin or metformin. We assessed possible impairment in cognitive flexibility using an attentional set shifting task. SNI resulted in a profound impairment in cognitive flexibility which was not reversed by short-term pain relief using clonidine (10ug). Long-term treatment with gabapentin (100 mg/kg twice daily for 7 days) completely reversed mechanical hypersensitivity but had no positive effect on attentional set shifting. In stark contrast, metformin (200 mg/kg once daily for 7 days) completely reversed SNI-induced deficits in attentional set shifting. To examine molecular mechanisms of mPFC dysfunction we used immunohistochemistry to investigate changes in parvalbumin (an inhibitory interneuron marker), glial fibrillary acidic protein (GFAP; an astrocyte marker) and axon initial segment length (Ankyrin-G) in several mPFC subregions. While no changes in astrocytes or axon initial segment length have yet to be observed, there was significant loss of parvalbumin in the infralimbic cortex, a mPFC subregion involved in cognitive flexibility. Future analysis will examine whether gabapentin and metformin affect parvalbumin immunoreactivity. Our results highlight persistent changes in mPFC function in neuropathic pain and suggest that disease-modifying treatments are needed to positively influence this pathology.

**Title:** Long-term changes in sensory input to dorsal horn interneurons after neonatal tissue injury

**Authors: *J. LI**[1], M. L. BACCEI[2]
[1]Univ. Cincinnati, Cincinnati, OH; [2]Anesthesiol, Univ. of Cincinnati Dept. of Anesthesiol., Cincinnati, OH

**Abstract:** Recent work indicates that tissue damage during early life disrupts the balance between primary afferent-evoked excitation and inhibition of lamina I projection neurons in the adult spinal cord and facilitates spike timing-dependent LTP (t-LTP) at sensory synapses. However, whether this shift reflects cell type-specific alterations at synapses onto ascending projection neurons or are indicative of global changes in synaptic signaling across the mature superficial dorsal horn (SDH) remains unknown. To address this issue, the present study investigated the effects of neonatal surgical incision on primary afferent synaptic input to GABAergic and presumed glutamatergic interneurons in the adult mouse SDH using in vitro patch clamp recordings from spinal cord slices. Hindpaw incision at postnatal day (P) 3 strengthened primary afferent drive to mature Gad67-GFP neurons compared to naïve littermate controls, which included an increased prevalence of low-threshold sensory input. Afferent-evoked polysynaptic inhibition of these same neurons was reduced, resulting in a significant elevation in the excitation:inhibition (E:I) ratio. Paired presynaptic and postsynaptic stimulation at intervals that exclusively produced t-LTP in projection neurons evoked LTD in GABAergic neurons. There was a trend towards increased t-LTP in these neurons after P3 incision, although this did not reach statistical significance. Similar changes in the E:I ratio were observed in adjacent non-GFP neurons after neonatal incision, suggesting that early injury persistently shapes sensory input to excitatory interneurons in the SDH. Meanwhile, P21 incision failed to alter the E:I ratio in either population of interneurons during adulthood. Collectively, the results suggest that tissue damage during a critical period of early life evokes widespread changes in the processing of sensory information by interneurons within the spinal nociceptive circuit.

**Abstract:** Patients suffering chronic pain often development long-lasting affective disorders. Accordingly, many preclinical studies have reported that prolonged experimental pain leads to depressive-like, anxiety-like behavior and cognitive deficit in rodents. Locus coeruleus (LC) is the major source of noradrenaline in the CNS and although its role in the descending inhibition of acute pain is well established, it has been reported a contribution to the facilitation of chronic pain. In addition, basolateral amygdala (BLA) has been focused as the locus of pain aversive memory formation and affective anxiety-like states via noradrenergic LC in long-term neuropathic pain. In the present study, we evaluated the time-dependent changes in the descending and ascending pathways of LC during the development of neuropathic pain model. Also, we evaluated the role of LC-BLA pathway on sensory, cognitive and anxiety-like aspect in long-term neuropathic pain. Sprague-Dawley and Long Evans-Tg(TH-CRE)3.1.Desis male rats were used. CCI was used as neuropathic pain model: 2 (short-term), 7 (middle-term) and 30 (long-term) days after surgery. A combination of behavioral, pharmacology and chemogenetics techniques were used for testing pain threshold, cognitive and anxio-depressive-like behaviors. In short-term neuropathy the LC is involved in descending pain pathway contributing to endogenous analgesia. In long-term neuropathy there is a LC functional sensitization that may involve the LC-BLA ascending pathway, implicated in pain-related anxiety-like, depression-like and cognitive disorders. **Title:** Microglial activation mapping in sensory and affective brain regions following peripheral nerve injury

**Authors: *M. J. LACAGNINA**, T. J. FABISIAK, P. M. GRACE
Dept. of Critical Care & Resp. Care Res., Univ. of Texas MD Anderson Cancer Ctr., Houston, TX

**Abstract:** Neuropathic pain is a debilitating condition in which an injury or dysfunction of the nervous system results in persistent pain, and its manifestation includes both sensory and affective dimensions. Microglia are the resident immune cells of the central nervous system, and their activation as a consequence of peripheral nerve fiber injury can amplify nociceptive signaling through a variety of mechanisms (including the release of cytokines, chemokines, or other neuroimmune mediators), thereby contributing to the development and maintenance of chronic pain. Investigations regarding the contribution of microglia to persistent pain have largely been restricted to the spinal cord. However, the landscape of microglial activation in supraspinal brain regions has not yet been systemically mapped, and existing reports are limited by the number of brain regions analyzed or the number of timepoints assessed post-injury. To address this issue, we used a rodent model of peripheral nerve injury and quantified microglial activation at several timepoints and across multiple brain regions that encode sensory and affective components of pain. Adult male Sprague Dawley rats received unilateral chronic constriction injury (CCI) of the sciatic nerve, and the spinal cord and brain tissues were collected either prior to surgery or at 7 and 28 days following injury. Microglial activation was assessed by performing densitometry analysis of fixed tissue stained for CD11b. We observed transient upregulation of CD11b expression in structures primarily associated with encoding the sensory aspects of pain. In contrast, CD11b expression was persistently elevated in nuclei thought to mediate affective pain components. These results provide evidence in male rats that an injury in peripheral tissues can produce central microglial activation in distributed brain regions associated with pain processing, and this glial reactivity is both time-sensitive and brain region-specific. Moreover, the pattern and time course of CD11b expression suggests that microglia

may be persistently dysregulated in networks encoding negative affect, which warrants further investigation.

**Title:** Involvement of $GABAB_B$ receptor within the CSF-contacting nucleus in neuropathic pain of rats

**Authors: *L.-C. ZHANG**[1], S.-S. CHEN[2], S.-Y. SONG[2]
[1]Jiangsu Province Key Lab. of Anesthesiol., Xuzhou Med. Univ., Jiangsu, China; [2]Xuzhou Med. Univ., Xuzhou, China

**Abstract:** A special nucleus in the brain parenchyma, the cerebrospinal fluid contacting nucleus (CSF contacting nucleus), is just recognized in the central nervous system. The outstanding feature of this nucleus is that the neural somas locate in the parenchyma, and their processes stretch into CSF , which has the unique structural features participating in both neuro- neural and neuro- humoral crosstalk. It has been proved that CSF contacting nucleus play an role in the modulation of pain, but the molecular mechanism and exact pathway of that remains obscure. The aim of this study is to observe the expression of $GABA_B$ receptors in CSF-contacting nucleus and further to investigate its role in neuropathic pain. The study provide evidence of morphology and substance for revealing that the CSF-contacting nucleus is involved in the pain regulation. 1.$GABA_B$ receptors were observed in the CSF-contacting nucleus of normal and CCI neuropathic pain rats. Results :there was a basic expression of $GABA_B$ receptors in the CSF-contacting nucleus of normal rats. Compared to normal group, The proportion of $GABA_BR$ in CSF-contacting nucleus was significantly increased in neuropathic pain rats.There was no difference between left and right side of the CSF-contacting nucleus in neuropathic pain rats. 2.To observed the correlation between expression of $GABA_B$ receptors in the CSF-contacting nucleus of neuropathic pain and pain behavior at different time. The results indicated that the expression levels of $GABA_B$ receptors notably upregulated on day 3, and the elevation was maintained till day 14, with the peak on day 7. Further analysis of the correlation between the expression of $GABA_B$ receptors with pain behavior, there was a significant negative correlation between them. 3.Effects of i.c.v injection of baclofen ($GABA_B$ receptors agonist )on CCI-induced pain behavior in rats without CSF-contacting nuclues.The results are that after the

injection of baclfen into the LV on day 7 after the CCI, CCI-associated neuropathic pain was attenuated. However, this antinociception was of baclofen was inhibited by CGP55845, such that the TWL of CCI rats treated with CGP55845 and baclofen was lower than that of CCI rats treated with baclofen alone. No significant difference was detected in TWL between the CCI and CCI+saline groups. It suggested that $GABA_B$ receptors in CSF-contacting nucleus was significantly increased in neuropathic pain rats and the expression of GABAB receptors had a significant negative correlation with neuropathic pain behavior. GABAB receptors within CSF-contacting nucleus might play a functional role in modulating neuropathic pain.

Dept. of Neurosci., Univ. of Minnesota, Minneapolis, MN

**Abstract:** Brain derived neurotrophic factor (BDNF) signals via its cognate receptor Tropomyosin receptor kinase B (TrkB), which undergoes autophosphorylation upon binding of BDNF. This BDNF/TrkB signaling contributes to neuroplastic mechanisms of central sensitization under conditions of chronic pain. While BDNF is required for the development and maintenance of nerve injury-induced hypersensitivity in male rodents, it is dispensable for the maintenance of neuropathic pain in female mice, and the mechanism of this difference remains unknown. We hypothesized that comparison of TrkB activation in male and female mice will provide insight into this disparity. We utilized immunofluorescence directed against phosphorylation at the Tyr816 site of TrkB to examine the distribution of phosphorylated/activated TrkB (pTrkB) following nerve injury (spared nerve injury model, SNI) in male and female ICR mice. The observed pattern of labeling under normal conditions was consistent with previously reported expression of TrkB on dorsal horn primary afferent terminals, spinal neurons, and microglia. Selectivity of labeling was confirmed by the observation that it was substantially reduced following incubation of the tissue with Lambda

protein phosphatase. Preliminary immunofluorescent analysis following nerve injury shows that pTrkB is upregulated in dorsal horn of male and female mice 3 days post-SNI, and is at control levels by day 28 post-SNI. These initial observations suggest that BDNF signaling is increased in both sexes during the period of development of hypersensitivity. By comprehensive quantification of the time course and cellular identify of pTrkB immunofluorescence in control and SNI male verse female mice we hope to generate mechanistic insight into BDNF induced spinal neuroplasticity and sex differences in neuropathic pain.

**Abstract:** Chronic pain after traumatic brain injury (TBI) is very common, but the mechanisms linking TBI to pain and the pain-related interactions of TBI with peripheral injuries are poorly understood. In the current work we pursue the hypothesis that epigenetic changes induced by TBI support chronic pain sensitization. We used the rat lateral fluid percussion model to induce mild and moderate TBI. Some animals received hindpaw incisions as well. Mechanical allodynia was measured for up to eight weeks post-injury. Inhibitors of histone acetyltransferase (HAT) and histone deacetylase (HDAC) were used to probe epigenetic mechanisms. We followed serum markers including glial fibrillary acidic protein (GFAP), neuron-specific enolase 2 (ENO2) myelin basic protein (MBP) and S100β to gauge TBI injury severity. Our results showed that both mild and moderate TBI caused mechanical allodynia in the hindpaws of the rats lasting 3 or more weeks. Hindpaws contralateral to TBI showed more rapid and profound changes. The inhibition of HAT using curcumin 50 mg/kg s.c reduced mechanical sensitization while the HDAC inhibitor suberoylanilide hydroxamic acid 50mg/kg i.p. prolonged sensitization in the mild injury model rats. These agents did not systematically change serum markers in ways suggesting regulation of the degree of brain injury constituted a complete explanation for the

observations. Immunohistochemical analyses of spinal cord tissue localized changes in the level of acetylation of the H3K9 histone mark to dorsal horn neurons. Taken together, these findings demonstrate that TBI induces persistent pain sensitization, and changes in spinal neuronal histone proteins may play an important role.

**Title:** Involvement of IFN-gamma of trigeminal spinal sub nucleus caudal neurons in neuropathic pain in ruts with infraorbital nerve injury

**Authors: *S. YUKA**[1,2], A. OKADA-OGAWA[2], M. SHINODA[3], Y. IMAMURA[2], K. IWATA[3]
[1]Physiol., Nihon Univ. Sch. of Dent. Dent. Hospit, Tokyo, Japan; [2]Oral Diagnos. Sci., [3]Physiol., Nihon Univ. Sch. of Dent., Tokyo, Japan

**Abstract:** It is well known that the trigeminal nerve injury such as tooth extraction or orthodontic surgery causes severe pain (neuropathic pain) in the orofacial regions. The orofacial neuropathic pain caused by trigeminal nerve injury is difficult to diagnose and treat because of the complexity of its neuronal mechanism. It is very important to evaluate the neuronal mechanisms underlying orofacial neuropathic pain, in order to develop the appropriate approaches to treat neuropathic pain patients. For this purpose, we developed the neuropathic pain model with infraorbital nerve injury in rats. Recently, it has been reported that the peripheral nerve injury causes an upregulation of cytokine Interferon-gamma (IFN-gamma). Intrathecal administration of the IFN-gamma induced mechanical allodynia, contributing to the development of neuropathic pain. We hypothesized that IFN-gamma play a crucial role of a glia-neuronal interaction in the trigeminal spinal subnucleus caudalis (Vc), involving in the development of orofacial neuropathic pain in the whisker pad skin. We introduced a neuropathic pain model with infraorbital nerve injury following tight ligation of half of the infraorbital nerve (IONI). Mechanical nocifensive behavior, phosphorylated extracellular signal-regulated kinase (pERK), phosphorylated GluR1 (pGluR1), Iba1 (a marker of microglia) and IFN-gammaR immunohistochemistry were precisely analyzed in the IONI rats and the sham rats. Head-withdrawal threshold to mechanical stimulation of the whisker pad skin innervated by infraorbital nerve decreased at day 4 after nerve injury in IONI rat but not in sham rat. The pERK, pGluR1 and Iba1 expression significantly increased in Vc at day 4 after IONI. The decrements of head withdrawal threshold to mechanical stimulation were reversed during

intrathecal (i.t.) administration of MAPK/ERK kinase 1/2 inhibitor, PD98059 and inhibitor of microglia, minocycline. On the otherhands, i.t. administration of IFN-gamma induced decrements of head withdrawal threshold to mechanical stimulation in sham rats. The present findings have demonstrated that mechanical allodynia and hyperalgesia occur in the whisker pad area following the infraorbital nerve injury. It also suggest that GluR1 phosphorylation of Vc neurons and activation of microglia in Vc area are involved in the neuropathic pain, and IFN-gamma might play a important role of the glia-neuronal interaction.

**Title:** Involvement of the HMGB1-TLR4 signaling in the development of central post-stroke pain

**Authors: *S. TOKUYAMA**, W. MATSUURA, S. HARADA
Kobe Gakuin Univ., Kobe, Japan

**Abstract:** Central post-stroke pain (CPSP) is known as a sequelae occurring after cerebral stroke. The treatment of CPSP remains incomplete due to its resistance to both pharmacological and non-pharmacological therapies in approximately half of CPSP patients. Since cure of central post-stroke pain has been difficult, establishment of a novel treatment method is desired. High-mobility group box 1 (HMGB1) and the receptor for advanced glycation end products (RAGE, one of the receptors of HMGB1) have recently been shown to be critical in the modulation of nociceptive transduction following peripheral neuropathy. We have been suggested that spinal HMGB1 might be involved in the induction of CPSP. The aim of this study is to determine that HMGB1-toll like receptor 4 (TLR4), one of receptor of HMGB1, interaction in spinal glial cell is directly involved in induction of CPSP.
Male ddY mice were subjected to 30 min of bilateral carotid artery occlusion (BCAO). The development of hind paw mechanical hyperalgesia was measured using the von Frey test.
The expression of HMGB1 protein in the spinal cord was significantly increased on day 3 after BCAO. In addition, spinal microglia and astrocyte were clearly activated by BCAO. HMGB1

was colocalized with neurons, activated microglia and astrocyte after BCAO. On day 3 after BCAO, although TLR4 expression was no change compared with sham mice, intrathecal injection of LPS-RS (5 or 10 μg/mice, TLR4 antagonist) significantly blocked the mechanical allodynia on day 3 after BCAO using the von Frey test. We also confirmed that TLR4 was colocalized with HMGB1 and microglia in the spinal cord. Furthermore, BCAO-induced spinal microglia activation was suppressed by intravenous anti-HMGB1 antibody and intrathecal LPS-RS administration.
We concluded that ischemic-stress evokes HMGB1 release from spinal neurons and glia cells, and subsequent activation of spinal microglia by HMGB1 maintains the ischemic stress-induced pain. Additionally, microglial HMGB1-TLR4 interaction is directly involved in the pathogenesis of CPSP. Our findings are helpful for better understanding of the pathological mechanism in CPSP.

Sch. of Med., Suita, Japan; [4]Dept. of Plastic and Reconstructive Surgery, Univ. of Fukui Hosp., Eiheiji, Japan

**Abstract:** (Background) Nicotinic acetylcholine receptors (nAChRs) are widely expressed in the spinal cord and modulate nociceptive transmission. Activation of cholinergic pathways by the nicotinic agonists has been shown to elicit antinociceptive effects. The contribution of spinal nAChRs in inhibiting the trigeminal neuropathic pain remained unclear. Chronic constriction injury to the infraorbital nerve (ION-CCI) has proven a useful model for trigeminal neuropathic pain. The present study evaluated the possible role of spinal nAChRs in ION-CCI rat model. (Material and Methods) Male Sprague Dawley rats underwent unilateral CCI to the right ION. Two nylon (5-0) ligatures were tied around the ION. Series of von Frey filaments were used to determine pain hypersensitivity to mechanical stimulation on day 14 after surgery. A polyethylene (PE-10) catheter was implanted for upper cervical spinal injection of drugs. The rats were allowed to recover for 7 days. The potential anti-allodynic effects from intrathecal

administration of a nAChR agonist nicotine, an alpha4beta2 nAChR agonist RJR2403, and an alpha7 nAChR agonist PNU 282987 were examined. In addition, the role of nAChR, alpha4beta2 nAChR, and alpha7 nAChR in these effects was assessed by determine whether the anti-allodynic effects were prevented by intrathecal administration of a nAChR antagonist mecamylamine, an alpha4beta2 nAChR antagonist dihydro-beta-erythroidine, or an alpha7 nAChR antagonist methyllycaconitine. The time course data for the dose-response effects were analyzed by two-way analysis of variance and Tukey-Kramer multiple-comparison test. (Results) Intrathecal administration of nicotine, RJR2403, and PNU 282987 increased mechanical thresholds ($P$ <0.05). Mecamylamine significantly reduced the anti-allodynic effect of nicotine. Dihydro-beta-erythroidine significantly reduced the anti-allodynic effect of RJR2403. Methyllycaconitine significantly reduced the anti-allodynic effect of PNU 282987. (Conclusions) The results indicated that spinal nAChRs, alpha4beta2 nAChRs, and alpha7 nAChRs may play an important role in a rat model of trigeminal neuropathic pain.

**Title:** Activated spinal astrocytes sensitize the nociceptive transmission through the release of L-lactate

**Authors: K. MIYAMOTO**, K.-I. ISHIKURA, K. KUME, *M. OHSAWA
Nagoya City Univ., Aichi, Japan

**Abstract:** Neuropathic pain induces the functional changes of the central nervous systems. Among them, the morphological changes of the astrocytes by activation are important and play roles in the expression and maintenance of neuropathic pain. We previously revealed that intrathecal (i.t.) administration of L-lactate induced mechanical hyperalgesia, which was attenuated by i.t. treatment with α-cyano-4-hydroxycinnamate (4-CIN), a monocarboxylic acid transporter that transports L-lactate into astrocytes and neurons. In this study, we investigated the mechanisms of this L-lactate-induced mechanical hyperalgesia. L-lactate-induced lowering of mechanical withdrawal threshold was attenuated by i.t. treatment with isosafrole that inhibits lactate dehydrogenase 1 (LDH1) and LDH5 which convert L-lactate to pyruvate. I.t. administration of L-lactate increased the expressions of c-Fos (a marker for neuronal activity) in

the spinal cord dorsal horn, which was attenuated by i.t. treatment with 4-CIN. Lowered mechanical withdrawal threshold on seven days after the partial sciatic nerve ligation was attenuated by i.t. treatment with 4-CIN and isosafrole. Then, we microinjected an adeno-associated virus (AAV) vector expressing hM3Dq designer receptor exclusively activated by a designer drug (DREADD) under the control of the glial fibrillary acidic protein (GFAP) promotor into the L4 dorsal horn of spinal cord. Intraperitoneal (i.p.) administration of clozapine N-oxide (CNO), which is the designered ligand of hM3Dq, induced hyperalgesia in ipsilateral, but not contralateral side of AAV microinjection. This CNO-induced mechanical hyperalgesia was continued until 8 hours after administration, which was attenuated by i.t. treatment with 4-CIN. These results suggest that L-lactate released from reactive astrocytes in neuropathic pain is one of the key mediators to induce hyperalgesia through the direct sensitization of nociceptive transmission in the spinal cord.

**Abstract:** Herb-Herb pharmacological interactions are present when the active compounds of the herbs alter their pharmacodynamic or pharmacokinetic process. The interactions could be synergistic, additive, or antagonistic, and the modified effect could be therapeutic or toxic. Thus, the analysis of the results of herb-herb combinations is important for demonstrating the possible therapeutic utility of the combination treatment and to identify their potential use. The aim of the present study was to determine whether *Syzygium aromaticum* (L.) Merr. & L.M. Perry (Mirtaceae), is able to increase the antinociceptive effects of *Rosmarinus officinalis* L. (Lamiaceae). The peripheral antinociceptive effect was assayed in the formalin test in the rat. Rats received local pretreatment with saline, *Syzygium aromaticum* oil or *Rosmarinus officinalis* ethanolic extract followed by 50 µl of either 1% formalin. *Syzygium aromaticum* ($ED_{50}$=31.12±1.6 mg/kg) and *Rosmarinus officinalis* ($ED_{50}$=11.09±0.5 mg/kg) each showed a dose-dependent anti-nociceptive effect. The pharmacological interaction was investigated by an

isobologhaphic study using the $ED_{50}$ of each component in a fixed 1:1 ratio. The isobolographic analysis showed a synergistic interaction between *Syzygium aromaticum* and *Rosmarinus officinalis*, the experimental value Zexp= 5.6± 0.5 was lower than the theoretical value Zadd=21.1±1.1. These results provide evidence that this medicinal combination herb-herb are effective in this model of pain.

**Title:** Circuit-specific adaptations in mesoaccumbal circuitry modulate distinct features of chronic pain

**Authors: *W. REN**[1], M. V. CENTENO[1], X. WEI[1], I. WICKERSHAM[2], M. MARTINA[1], A. V. APKARIAN[1], D. J. SURMEIER[1]
[1]Dept. of Physiol., Northwestern Univ., Chicago, IL; [2]McGovern Inst. for Brain Res., MIT, Cambridge, MA

**Abstract:** The mesolimbic circuitry - including the ventral tegmental area (VTA) and nucleus accumbens (NAc) - shape chronic pain. We found that nociceptive signaling suppresses the activity of VTA dopamine neurons projecting to the medial shell of the NAc (msNAc), triggering cell-specific adaptations there and augmented chronic pain (tactile allodynia). However, recent work by other groups has shown that neurons in the neighboring core of the NAc (cNAc) manifest a very different set of adaptations in chronic pain models, suggesting that the dopaminergic innervation of this region by the VTA was responding differently to chronic nociceptive signaling. In support of this conclusion, anatomical studies have shown that msNAc and cNAc are innervated by distinct populations of VTA neuron.
To test the hypothesis that the circuitry of the msNAc and cNAc respond differently to chronic nociceptive signaling, cNAc spiny projection neurons (SPNs) and VTA dopaminergic neurons were studied in ex vivo brain slices from the spared nerve injury (SNI) rodent model of persistent neuropathic pain. Indeed, the intrinsic excitability of indirect pathway SPNs (iSPNs) in the cNAc

was lower and the strength of synaptic connections with prefrontal cortex was augmented in tissue from SNI mice - in sharp contrast with the adaptations in the msNAc. Using a non-toxic rabies virus carrying a Cre-recombinase expression construct, it was found that the VTA dopaminergic neurons innervating cNAc and msNAc were largely distinct, in agreement with previous studies. Moreover, the intrinsic excitability of these two VTA populations change in opposing ways following SNI - falling in cells innervating msNAc and rising in cells innervating cNAc - mirroring the changes in cNAc and msNAc. To test the hypothesis that these changes were causally linked to the pain state, chemogenetic approaches were used. Normalizing the excitability of the VTA-cNAc circuit diminished SNI-induced social recognition deficits, without affecting allodynia, contrasting it with our previous work showing chemogenetic correction of msNAc excitability alleviated allodynia. Thus, there are parallel VTA-NAc circuits that are causally linked to distinct features of the chronic pain state. The differential modulation of these circuits by SNI appears to stem from the circuitry controlling the VTA. Studies are underway to dissect this circuitry.

**Title:** Effect of isoflurane on selectively activated afferent pathways in neocortex

**Authors: *C. MURPHY**, B. KRAUSE, S. GRADY, M. I. BANKS
Dept. of Anesthesiol., Univ. of Wisconsin, Madison, WI

**Abstract:** The mechanisms underlying loss of consciousness (LOC) under anesthesia remain unknown; current studies suggest that anesthetic-induced LOC is mediated by the corticothalamic network. While some studies have proposed that anesthetics gate ascending information via thalamocortical (TC) projections, recent evidence suggests that feedback corticocortical (CC) projections may be preferentially affected by anesthetics. For example, current sinks triggered by stimulation of layer 1 afferents to primary auditory cortex are suppressed by isoflurane to a greater extent than layer 4 TC afferents. However, layer 1 contains axons originating from both TC and CC projections. We compared the effect of isoflurane on layer 1 versus layer 4 TC pathways to determine whether isoflurane-sensitive afferents in layer 1 might originate in the thalamus. We separately measured the effect of isoflurane on layer 1

currents following specific activation of CC feedback connections. Posterior parietal cortex (PPC) and secondary visual cortex (V2) both integrate information from higher order thalamus along with primary sensory and higher order cortical areas. Because activity in these areas is specifically linked to awareness, we investigated the effect of isoflurane on the properties of monosynaptic current sinks following stimulation of TC and CC afferents to PPC and V2, respectively. Channelrhodopsin was expressed in either posterior thalamus (Po) or cingulate cortex (Cg). Axon terminals in layers 1 and 4 of PPC or layer 1 of V2 were activated. Isoflurane was delivered to slices via artificial cerebral spinal fluid, and current source densities (CSD) were recorded using 16channel electrode arrays oriented orthogonally to the cortical laminae. Monosynaptic current sinks in respective layers were compared between control and drug conditions for each pathway. Consistent with previous findings, isoflurane only modestly suppressed the magnitude of monosynaptic current sinks following stimulus of TC afferents in layer 4. Interestingly, layer 1 TC current sinks were blocked to the same extent as layer 4 sinks, suggesting the most isoflurane-sensitive layer 1 fibers are not of thalamic origin. We also observed a concentration-dependent block by isoflurane of layer 1 CC feedback pathways to V2 following optogenetic stimulation.

**Abstract:** The processing of external stimuli requires the transmission of sensory information across brain regions. However, the nature and efficiency of synaptic transmission across neuronal circuits in the intact brain, in the context of information transformation, remain unclear.

Here, we take advantage of the well-known anatomical and functional organization of the rodent whisker thalamocortical pathway to perform simultaneous in vivo recording in the topographically aligned neurons from the ventroposteromedial nucleus of the thalamus (VPm) and layer 4 of primary somatosensory cortex (S1) to understand how thalamic neurons drive their downstream cortical targets. Using weak stimulation of the rodent whisker, we first inferred the functional connectivity between pairs of simultaneously recorded thalamocortical (TC) neurons using a cross-correlation technique. We then quantified synaptic efficacy, defined as the probability of eliciting a cortical spike in a short time window following a thalamic spike, for putatively connected pairs of neurons to investigate the effect of thalamic firing mode (e.g. burst vs tonic) on the synaptic efficacy of TC network. Preliminary analysis suggests a complicated relationship between thalamic firing mode and synaptic efficacy at the TC synapse. Additionally, it is well established that a single neuron in cortex receives inputs from multiple thalamic neurons and that synchronous activation of this population of thalamic inputs could maximally drive cortical neurons. Here, we are evaluating the effect of sensory stimulation on thalamic synchrony within and across barreloids as well as the implications of thalamic population activity for downstream cortical targets using a 32-channel probe in VPm combined with single unit recordings from S1. Preliminary analysis suggests that punctate whisker stimuli evoked synchronized response within and across thalamic barreloids, and this could potentially affect cortical integration of information downstream. Finally, applying white noise stimuli to a single whisker, we assessed stimulus feature selectivity in pairs of putatively connected and non-connected neurons, using traditional reverse correlation analysis. Preliminary results show that the feature selectivity between putatively connected neurons is not identical, instead suggesting that the cortical neuron is pooling its selectivity from the distinct selectivity of its thalamic inputs. Taken together, this work utilizes the simultaneous multi-site recording framework to provide a step towards establishing the relationship between sensory percepts and the neural circuits that underlie them.

**Title:** Thalamic state modulation of somatosensory encoding in the thalamocortical circuit

**Authors: *C. J. WHITMIRE**, Y. LIEW, A. PALA, G. B. STANLEY
Biomed. Engin., Georgia Inst. of Technol., Atlanta, GA

**Abstract:** While traditionally labelled as a relay nucleus, it is now widely accepted that the thalamus plays an important role in transforming sensory information traveling from the sensory periphery to primary sensory cortex. Furthermore, the distinct burst/tonic firing modes of the thalamus may represent different information processing states such that the regulation of thalamic firing modes could function as one mechanism for controlling how information is conveyed to downstream cortical targets. Yet how this gating mechanism impacts precise feature selectivity in the thalamocortical circuit remains unknown. Using in-vivo single unit recordings in the rat vibrissa thalamus (VPm), feature selectivity was assessed using white noise single-whisker stimulation while simultaneously manipulating the firing mode of the thalamic neurons using optogenetic hyperpolarization. In response to a white-noise stimulus delivered to the whisker, individual thalamic neurons displayed reliable responses containing a similar number of spikes irrespective of their level of hyperpolarization. However, the sensory evoked firing of the thalamic neurons shifted from tonic to bursting when optogenetically hyperpolarized. Furthermore, this shift in firing mode led to a loss of the feature selectivity as assessed using traditional reverse correlation techniques. Because the output of the thalamic neurons, or the spiking activity, is fundamentally different as a function of firing mode, the state-dependent thalamic input to cortex may induce significant shifts in cortical feature selectivity and encoding. To measure the impact of this state-dependent change in thalamic feature selectivity on neocortical feature selectivity and encoding, single unit cortical activity was recorded along a cortical column in primary somatosensory cortex (S1) using a 32-channel linear probe while optogenetically manipulating thalamic state. Consistent with the thalamic findings, cortical units with recoverable linear filters showed a reduction in the amplitude of their kernels with thalamic hyperpolarization. Furthermore, fast spiking cortical units were significantly more likely to exhibit sensory feature selectivity than regular spiking units suggesting differential processing of the incoming sensory information by different cell types. These results could have broad implications for a more comprehensive coding strategy whereby ongoing sensory stimulation as well as a host of endogenous and exogenous influences dynamically alters the state of the thalamus to fundamentally shape the functional encoding of the thalamocortical pathway.

**Abstract:** The thalamus is a central junction that processes both sensory and motor signals. Although many neurological disorders are linked to thalamic dysfunction, basic information about ongoing thalamic processing is still unknown. Specifically, it is unclear how ongoing changes in membrane polarization, firing modes, and overall firing rate alter the transmission of information to and from cortical regions. Thalamic neurons have complex firing modes (i.e., tonic and burst) and receive neuromodulatory inputs that shape ongoing activity. Although ongoing thalamic activity has been shown to dynamically alter ongoing cortical activity, it is unclear how distinct thalamic firing modes (i.e., state) change sensory percepts. Here, we utilized a genetically encoded voltage indicator, ArcLight, to measure large scale cortical sensory evoked response while measuring different thalamic states using thalamic single unit extracellular recordings. Specifically, we modulated the thalamic state through optogenetic hyperpolarization of the primary whisker thalamic nucleus (VPM) with viral delivery of halorhodopsin (eNph3.0). We found that by briefly shifting the thalamus to a more hyperpolarized state, we increased both the thalamic and cortical sensory evoked response. Furthermore, we found that by titrating the levels of thalamic hyperpolarization, we could control the spatial and temporal primary somatosensory cortical responses. Through *in vivo* extracellular single cell and *in vitro* intracellular whole cell recordings, we predict that thalamic hyperpolarization enables synchronized sensory evoked calcium bursting events. These busting events produce a larger

downstream cortical spatial response that theoretically should increase the detectability of sensory stimuli, at a cost of discriminability. Based on these results, we demonstrate the importance of thalamic state on controlling the flow of sensory information across cortex as a possible mechanism to control the perception of sensory information.

**Abstract:** When investigating tightly interconnected neural circuits such as the thalamocortical loop, isolating the function of individual components in the network is a powerful approach to understanding complex function. In contrast to irreversible lesioning techniques or slow pharmacological manipulations, optogenetics offers cell-type specific actuation at fast timescales. While widely used for such circuit dissection, optogenetic stimulation is nearly always designed before an experiment and presented in “open-loop”. The effectiveness of this approach is limited by changes in ongoing neural activity, variability in opsin expression, *etc*. A more robust approach is to “close the loop” around the activity of interest and update stimulation in real-time to compensate for such variability. We have developed a closed-loop control strategy where optical stimulation is updated in real-time to elicit a desired pattern of neural firing. We applied this technique to the stimulation of neurons in the somatosensory thalamus of fentanyl-anesthetized rats expressing channelrhodopsin (ChR2). Single-unit spiking isolated from extracellular recordings was smoothed into an online estimate of firing rate. A proportional-

integral controller operated on the error between the instantaneous firing rate and a desired pattern of firing to modulate the intensity of optical stimulation: blue light delivered to thalamus via an optic fiber. Simultaneous recordings in S1 provided insight into the downstream effects of thalamic control. Using a principled design strategy, we have found that this simple-to-implement control scheme is effective not only at holding firing rate of thalamic neurons steady (e.g., Newman *et al.* 2015) but also at eliciting time-varying trajectories in firing rate. We demonstrate the ability to track sinusoidal firing rates as well as to elicit patterns of rate modulation observed in the thalamus of the awake rat. Importantly, we find that the control strategy is more robust across neurons and results in less variability in response to optical stimulation than the *de facto* standard open-loop stimulation. Finally, we show that the thalamic responses to pulsatile inputs of the type used most often with ChR2 produce large, widespread responses in LFP recorded in cortex which may be due to highly synchronized thalamic inputs. In contrast, more continuously-modulated light inputs have subtle downstream effects in cortex, possibly indicating a less synchronous engagement of thalamus using our methodology. Taken together, our results represent an exciting maturation of closed-loop optogenetic control for circuit dissection.

**Abstract:** Sensory information about the external world reaches the cerebral cortex through the thalamus. Thalamic nuclei relay visual, auditory, somatosensory, and cognitive information to relevant cortical areas for further processing. Primary thalamic nuclei transmit information from the periphery to primary sensory cortices, whereas ‘higher-order’ thalamic nuclei are bi-directionally connected to multiple cortical areas, including primary sensory cortex, and are suggested to be involved in attention, perception, and cognition. Here, our overall goal is to

obtain a better understanding of how higher-order thalamic nuclei contribute to sensory processing. The higher-order somatosensory thalamus in mice, the posteromedial (POm) thalamic nucleus, integrates signals from and provides input to primary somatosensory cortex (S1), secondary somatosensory cortex (S2), motor cortex (M1), and other associational cortices. Previous research has suggested POm contains less information regarding sensory stimuli applied to the whiskers than primary whisker thalamus (VPM) and may instead predominately relay signals related to whisker motion. In electrophysiological recordings from awake, freely whisking mice, we observe that the activity of most POm neurons is modulated based the whisking state of the animal, suggesting a possible role for POm in encoding whisker motion. We additionally find, however, that whisking does not typically happen in isolation but usually co-occurs with other behavioral states, including changes in arousal and locomotion. Currently, we are examining whether whisking-related POm activity actually represents whisking or in fact reflects arousal.

**Title:** A sensorimotor pathway via higher order thalamus

**Authors: *C. MO**[1], S. SHERMAN[2]
[2]Neurobio., [1]Univ. of Chicago, Chicago, IL

**Abstract:** According to traditional wiring of a sensory pathway, once information reaches cortex, further processing occurs only within cortico-cortical connections. However, we now find that projections from primary to higher order sensory cortex have a parallel route through thalamus: cortico-thalamo-cortical pathways. These transthalamic pathways may play a significant role in ongoing cortical processing because they are glutamatergic driver projections, which are well-suited to the fast, efficient transfer of information. Transthalamic pathways have been found in visual, somatosensory and auditory pathways, but it is unknown if they exist beyond purely sensory systems. Given evidence of a direct, driver pathway from primary somatosensory cortex (S1) to primary motor cortex (M1) in the mouse, we hypothesized a parallel transthalamic pathway from S1 to M1 via the posterior medial nucleus (POm) in

thalamus.
Since transthalamic projections originate from layer 5 of cortex, we injected AAV-EF1a-DIO-ChR2-eYFP into S1 of Rbp4-Cre mice to express ChR2-eYFP in S1 layer 5 cells. Three weeks later, we injected the retrograde tracer Fluororuby into M1 of the same mouse, and after an additional 5 days, we could histologically verify M1-projecting cell bodies amidst S1 layer 5 terminals in POm. In another group of animals with the same injections, we performed whole cell patch recordings of Fluororuby-labeled cell bodies (which project to M1) and confirmed connectivity from S1 layer 5 by focal laser stimulation of ChR2-expressing terminals. Ten of 36 (28%) labeled cells and 17 of 27 (63%) unlabeled cells responded to activation within the zone of fluorescent overlap. Responses corresponded with driver properties: ionotropic receptor-dependent, large, monosynaptic EPSCs and paired-pulse depression to a 10Hz train. These were seen both when activated by laser at pre-synaptic terminals or their axons and with electrical stimulation of the axons. Preliminary data for experiments of the POm to M1 projection using ChR2 activation also shows driver properties. These data generalize the concept of transthalamic sensory cortices to a sensory-motor example.

**Title:** Diverse coding of higher-order thalamocortical projections during sensory perception

**Authors: R. CHEREAU**, S. PAGÈS, T. BAWA, *A. HOLTMAAT
Neurosci., Univ. of Geneva, Geneva, Switzerland

**Abstract:** The cortex plays a critical role in the integration of multisensory information in order to produce a relevant behavioral response. Emerging models suggest that the underlying mechanisms include not only corticocortical feedback but also thalamocortical feedback that shape the activity of a large array of cortical areas. The thalamus is a major relay for information streams between deep brain structures and the cortex. It is composed of nuclei that primarily transmit incoming sensory inputs to the cortex (first-order nuclei) and others that primarily receive input from the cortex and send information back to a larger array of cortical areas

(higher-order nuclei). How the output of higher-order nuclei affects cortical activity during sensory perception and learning remains poorly understood. Previous work from our lab showed that the posteromedial (POm) area of the thalamus, which is the higher-order nucleus for the somatosensory system, mediates sensory-evoked synaptic long-term potentiation of pyramidal neurons in the barrel cortex.
Here, we investigated the role of the POm in a reward-based sensory discrimination task. We used calcium imaging to track the activity of individual POm axonal boutons in layer 1 (L1) of the somatosensory cortex over days during the acquisition of a whisker-mediated texture discrimination task. We correlated the activity of the boutons with the performance of the mouse during this task. We observed diverse responses, correlating with the various sensory stimuli, as well as with the various behavioral outcomes of the task. We found the activity of a sub-population of POm boutons to be predictive of the discrimination of the different textures after the mice had become experts in the task. This study indicates that POm conveys sensory discriminatory information to the barrel cortex, which thereby may play a role in sensory perception and learning.

**Abstract:** The ventral posterolateral (VPL) nucleus of the thalamus serves as a relay center for the somatosensory system, receiving various forms of tactile and proprioception information from the periphery. The incoming sensory information is then shaped by neighboring GABAergic neurons of the reticular nucleus which have been observed to form both reciprocal (closed-loop) connections with VPL relay cells as well as disynaptic (open-loop) connections, an organization presumably designed for the propagation of oscillatory activity and lateral

inhibition of neighboring relay cells. In addition, recent immunogold work suggests that local interneurons represent about 3.7% of the neuronal population in the VPL of rats and mice. Although such a sparse population might seem negligible, interneuronal processes can contain richly branched arborizations with hundreds of terminals. Thus, it remains a possibility that local interneurons provide a significant source of inhibition to VPL network activity. The synaptic dynamics and physiological significance of these reticular neurons and local interneurons within the VPL remain to be elucidated. Here, we systematically investigated the electrophysiological and morphological characteristics of the VPL inhibitory influences in wistar han rats and GAD67-eGFP mice of age postnatal 14-18 days. We obtained whole cell single- and multi-patch clamp recordings of reticular neurons and local interneurons in acute slices and stained and morphologically reconstructed the neurons. We also investigated the properties of short term plasticity between connected pairs of VPL relay cells and inhibitory neurons. The data gathered from inhibitory interactions within the VPL is being integrated into an *in silico* model of the rat somatosensory cortex (Markram et al. 2015) to reconstruct and simulate this thalamocortical pathway. Thus, we explored how inhibition from the reticular nucleus and local interneurons within the VPL contribute to the excitatory tone of salient stimuli and the consequent impact on sensory perception.

**Title:** Impact of the superior colliculus on cortical processing of somatosensory (whisker) input

**Authors: *S. GHARAEI**, E. ARABZADEH, G. J. STUART
Eccels Inst. of Neuroscience,John Curtin Sch. of Med. Res., Australian Natl. Univ., Canberra, Australia

**Abstract:** Superior colliculus (SC) is an evolutionary ancient midbrain structure, which is highly conserved across species. Functionally, SC is thought to be important for detecting salient or novel sensory stimuli and eliciting an appropriate behavioral response. It is well established that SC receives direct input from the primary sensory cortices. What is not known is whether (and if so how) the SC modulates information processing in primary sensory cortex. To address this question, we combined optogenetic activation of SC with recordings in primary vibrissal

somatosensory cortex (vS1) of adult C57BL6/J mice. Adeno-associated virus was injected into SC to induce ChR2 expression (n=28). Two to four weeks after injection, we performed whole-cell and extracellular recordings under urethane anesthesia from vS1 while activating SC via an optic fiber. Using multi-electrode arrays in SC, we identified whisker responsive neurons located mainly in the intermediate layers of SC and confirmed their reliable activation with blue light. Consistent with the idea that SC can have an impact on cortical processing, photo-activation of ChR2 in SC led to light-evoked responses in vS1 neurons. These responses were manifested in the local field potential, as well as depolarization of the membrane potential and increased spiking activity. Furthermore, we found that photo-activation of SC led to a leftward shift in the input-output relationship of cortical neurons resulting in an enhanced capacity to detect low intensity stimuli. Given the absence of a direct anatomical projection from SC to vS1, we investigated two potential pathways for this functional modulation: (i) a projection from SC to facial nucleus, which is responsible for whisker movements though the facial nerve and (ii) an indirect thalamic pathway from SC to vS1 through the rostral sector of the posterior nucleus of the thalamus (Pom). Monitoring the whiskers under high-speed camera revealed whisker protractions after photo-activation of SC (latency = 20 ms). These movements were abolished after cutting the facial nerve, however, this procedure had no impact on vS1 responses following photo-activation of SC. Consistent with the idea that SC modulates vS1 via Pom, multi-electrode array recording indicated that photo-activation of SC led to increased firing of Pom neurons. Taken together, our results suggest that the SC, which plays a key role in attentional network, modulates sensory processing in primary somatosensory cortex via an indirect pathway through the thalamus.

**Abstract:** The dynamical regime of cortical neuronal networks is not static. Rather, it shifts between different states with different collective population dynamics, often driven by changes in cholinergic neuromodulation. Such changes in cortical state are associated with changes in how neurons respond to sensory input, i.e. coding is state-dependent. These facts raise some basic questions. Which cortical states are optimal for which types of coding? In general, does state-dependent coding imply tradeoffs, improving one type of coding at the cost of degrading another type of coding? In principle, such tradeoffs could be avoided if cortical state is spatially inhomogeneous. Little is known about such spatial variability of cortical state compared to well-studied temporal changes in state. Here we hypothesize that if one part of the network is in one state, another part of the network could be simultaneously in a different state. In this way, each part could be well-suited to different types of coding, thus avoiding compromised function at the level of the whole network.We tested this hypothesis in the context of somatosensory detection in anesthetized rats and visual detection in awake mice. Cholinergic changes in cortical state were imposed by microdialysis in the rats and by optogenetic stimulation of nucleus basalis in the mice. In the rats, dual microdialysis probes were used to infuse different spatial patterns of acetylcholine or neostigmine. In the transgenic mice (expressing ChR2-EYFP under the choline acetyltransferase promoter), an optic fiber was inserted into basal forebrain. First, using microelectrode array recordings we demonstrated that changes in cortical state could be quite spatially inhomogeneous. Changes in state at one location were often quite different than changes in state at a nearby location (~200 microns away). Second, we demonstrated that changes in state are associated with dramatic changes in the efficacy of sensory detection for single neurons or small groups of neurons (multi-unit activity at a single electrode). However, when considering larger, spatially-distributed populations of neurons, sensory detection can be maintained. Our findings suggest that spatial inhomogeneity of cortical state can be important and beneficial for sensory coding.

**Title:** Basal forebrain activation changes the vibrotactile responses of neurons in the hindpaw representation of rat SI cortex

**Authors: *B. VARDAR**, B. GÜÇLÜ
Inst. of Biomed. Engin., Bogazici Univ., Istanbul, Turkey

**Abstract:** Current understanding of attentional mechanisms in the cortex lacks detailed information within the tactile modality. We had previously measured the differential effects of cholinergic inputs, which are assumed to be involved in attentional modulation, on the vibrotactile responses of cortical neurons in the rat SI cortex via microinjection of acetylcholine and atropine. It was found that responses were mostly modulated by muscarinic receptors in deeper layers. In the current study, we electrically stimulated the basal forebrain (BF), which is the main source of cholinergic projections to the cortex. We recorded single-unit spike activity in the hindpaw representation of rat SI cortex from 16 neurons of 5 anesthetized Wistar albino rats. The vibrotactile responses were measured with and without BF stimulation (0.5-ms bipolar pulses at 100 Hz; duration: 0.5 s; amplitude: 50 µA). If present, BF stimulation just preceded the vibrotactile stimuli applied on the glabrous skin of the hindpaw (bursts of 5-, 40-, and 250-Hz sinusoidal displacements; duration: 0.5 s; zero-to-peak amplitude: 50 µm upon 0.5-mm static indentation). Each condition was repeated for 10 trials. Average firing rates were calculated for different time periods with respect to the vibrotactile stimulus ($R_b$: background; $R_o$: during the initial 100-ms of stimulus duration, $R_d$*: during the last 400-ms of stimulus duration). To quantify the changes in entrainment, vector strengths (VS) were also calculated for the entire vibrotactile stimulus duration. The short and long-term (after 30 min.) effects of BF activation were analyzed for different vibrotactile frequencies and cortical layers by using repeated measures ANOVA. Preliminary data show that BF activation produces both short and long-term increases in $R_b$ ($p=0.049$ and $p=0.036$, respectively), while there was only a long-term effect on $R_d$* ($p=0.004$). On the other hand, no significant effects of BF activation were found on $R_o$ ($p=0.838$ for short-term, $p=0.732$ for long-term) and VS ($p=0.622$ for short-term, $p=0.856$ for long-term). These results suggest that BF activation causes hyperactivity in the SI cortex, but the relative effects of vibrotactile inputs seem to be reduced in the pilot data. This may be due to stronger cholinergic connections onto inhibitory neurons and warrants more studies. In contrast to the microinjection of cholinergic agents, BF activation had long-term effects, probably reflecting the fact that BF projections are wide and diffuse, and they can alter the global activity pattern in the brain. We are currently collecting more data to model the local network dynamics in the hindpaw representation.

**Abstract:** Single cell RNA sequencing technologies have generated the first catalogs of transcriptionally defined neuronal subtypes of the brain. However, the biologically informative cellular processes that contribute to neuronal subtype specification and heterogeneity remain unclear. By comparing the gene expression profiles of individual layer 6 corticothalamic neurons (L6CThN) in somatosensory cortex, we demonstrate that the variance in gene expression across individual neurons is associated with long-range axonal target, sublaminar position within the cortex and neuronal activity state. These three basis vectors of identity contributed to both subtype identity and heterogeneity within each subtype, suggesting that changes in one of these basic defining features would influence not only gene expression but also the relative transcriptional definitions of each subtype. We tested this hypothesis by analyzing the transcriptomes of 1023 single L6CThNs collected at baseline and one and seven days following manipulation of the sensory inputs to barrel cortex. Analysis of the L6CThN population revealed that altering the activity of L6CThNs increased the heterogeneity within each transcriptional subtype and enhanced the distinction between the transcriptional subtypes of L6CThN. Pseudotemporal analysis of the molecular responses to altered sensory inputs showed that subtype specific biases in the choice of transcriptional state following manipulation of neuronal activity contributed to the increase in subtype differences and revealed distinct cellular mechanisms preferentially engaged along each response. Our results demonstrate that, in contrast to bulk analysis, single cell RNA sequencing approaches enable the assignment of canonical functional features to transcriptionally defined subtypes, generating a more comprehensive definition of neuronal cell types. Together, they reveal that neuronal activity state, axonal projection pattern and sublaminar position within the cortex are significant sources of transcriptional variation contributing to the identity of individual neurons.

**Abstract:** Layers 2 and 3 of the mouse somatosensory neocortex are critical in distributing incoming whisker sensations to neighboring cortical areas. Initially processed by the barrels of layer 4, these sensations are unilaterally transmitted to layers 2 and 3. Here, the signals are further processed and then relayed by supragranular projecting neurons to the contralateral primary somatosensory cortex (S1), ipsilateral primary motor cortex (M1) and ipsilateral secondary somatosensory cortex (S2). Although specific morphologies have been associated with the supragranular neuron's circuit networks, the number of functional classes of neurons remains unidentified. Specifically, it remains unknown whether neurons that project to the same cortical areas exhibit similar or different intrinsic properties. A morphological approach was adopted to analyze supragranular projecting neurons associated with M1, S1, and S2 circuits. The principal objective sought to determine if specific morphological groups are associated with each of the three projection sites (S1, M1, S2). Individual neurons in brain sections from CD-1 mice were labeled using Diolistics in conjunction with prior in vivo retrograde bead labeling. This allowed for the identification of the projecting neurons, which were then reconstructed from confocal images. Morphological measurements were made in Neurolucida and then analyzed using principal component analysis followed by a cluster analysis, revealing distinct groups of neurons. Our results suggest that layers 2 and 3 neurons projecting to different cortical locations exhibit distinct morphological characteristics.

**Title:** Diversity of VIP neurons: Insights into electrophysiological types and the influence of neuromodulation

**Authors: *A. PRÖNNEKE**, M. MÖCK, M. WITTE, J. F. STAIGER
Inst. for Neuroanatomy, Univ. Med. Ctr. Göttingen, Goettingen, Germany

**Abstract:** As an essential component of cortical circuitry VIP neurons are highly diverse in their electrophysiological profile. Whole-cell patch clamp recordings of individual VIP neurons across all layers of the mouse barrel cortex revealed at least 5 different electrophysiological types. We identified these by a novel unsupervised classification method based on firing pattern adaptation and frequency spectrum. One of these types, bursting VIP neurons, was exclusively located in upper layer II/III. Further experiments on bursting VIP neurons showed that their typical burst firing depended on membrane potential because in a more depolarized state their firing mode changed to tonic. We identified noradrenalin, acetylcholine (ACh), and serotonin (5HT) as neuromodulators depolarizing all layer II/III VIP neurons. Whereas cholinergic depolarization was mediated by non-α7 nicotinic receptors, serotonergic modulation was more complex. Our experiments revealed that only 50% of all VIP neurons displayed $5HT_{3a}$ receptor functionality despite their classification as $5HT_{3a}$ receptor expressing interneurons. Interestingly, all VIP neurons in layer II/III were depolarized by metabotropic $5HT_2$ receptors. In this manner, brain states caused by neuromodulators can be differentially integrated by the population of VIP neurons. Whereas bursting neurons change their firing behavior during neuromodulation, all other VIP neurons become more excitable without changes to their firing pattern. Additionally, ACh and 5HT can be differentiated because only 50% of all VIP neurons react with a strong and transient depolarization to 5HT, whereas all VIP neurons in layer II/III of the mouse barrel cortex are recruited by cholinergic input.

**Title:** Coupling of tactile LFP signals between mouse cortex and olfactory bulb

**Authors: *A. PARABUCKI**, I. LAMPL
Neurobio., Weizmann Inst. of Sci., Rehovot, Israel

**Abstract:** Broad-band field potentials are important and powerful tools when investigating and interpreting brain function. The reasons to believe so are ranging from the evidence of coupling local neuronal activity with FPs to ability to overcome physical impairments through brain machine interfaces. Thus, it is not a surprise that in the last decade the recording of local field potentials (LFP) has gained increasing popularity in basic and applied electrophysiology. However, there is an uncertainty over LFP regarding its locality and its possible contamination by volume conductance coming from the distant generators.
Using standard LFP recording techniques, we revealed prominent whisker evoked LFP signal in the olfactory bulb (OB) of anesthetized mice, highly correlated with the activity in the barrel cortex (BC). To test whether the LFP response observed in the OB upon whisker stimulation depends on the BC, we employed optogenetic and pharmacological tools. First, light activation of BC in Thy1-ChR2 mouse line induced a strong LFP response in the OB. Next, light-silencing of BC using ChR2-GAD-Cre mice attenuated whisker evoked LFP responses in both BC and OB. However, the lack of unit responses urged to investigate the origins of the whisker-evoked LFP in OB. Therefore, we have recorded from different brain structures and found that whisker LFP responses in the ventro-lateral orbitofrontal cortex (vlOrb) exhibited near zero latency when compared to the OB. Next, we performed multichannel recording of the LFPs in the OB followed by inverse current source density (iCSD) analysis. iCSD analysis could not identify sinks and sources of the current in the OB, strongly suggesting that the observed signal does not emerge by synaptic inputs within the OB. Finally, we tested this hypothesis by recording whisker-evoked LFP response following complete separation of the OB from the rest of the brain. As expected for the case of volume conductance, cutting all the connections between OB and the rest of the brain did not attenuate the LFP response to whisker stimulation.
In conclusion, LFP signal in the OB, dependent on barrel cortex activation and highly correlated with its local activity, represented a pure volume conductance signal that was sourced back to the activity in the vlOrb, located a few millimeters away. Therefore, our findings, demonstrating a

pure case of volume conductance, add on to the rising concern regarding interpretation of LFP data and consequently urge for careful experimental approach when dealing with LFPs.

**Title:** Organization of the whisker receptive field map in L2 of somatosensory cortex in awake behaving mice

**Authors: *H. WANG**, A. M. LEMESSURIER, D. E. FELDMAN
Helen Wills Neurosci. Inst., Univ. of California, Berkeley, Berkeley, CA

**Abstract:** Layer (L) 2/3 of primary sensory cortex provides the major output to higher cortical areas; therefore sensory coding in L2/3 is critical to understanding cortical information processing and perception. In mouse primary somatosensory cortex (S1), whisker receptive fields and maps have been well characterized under anesthesia, but not in awake mice, where active whisking precludes calibrated deflections of multiple whiskers. We developed a head-fixed whisker discrimination task suitable for mapping receptive fields in awake, whisker-attentive mice. Mice expressing GCaMP6s in L2/3 neurons had all whiskers intact, with 9 whiskers inserted into a 3 x 3 piezo array, and mice were trained to lick to occasional all-whisker stimuli (S+) but not to single-whisker stimuli (S-). Using 2-photon $Ca^{2+}$ imaging, we measured whisker-evoked $Ca^{2+}$ transients in L2 neurons during S- trials (12 imaging fields in 5 animals, total 1352 cells). 19% of neurons showed significant whisker-evoked responses, consistent with known sparse coding in L2/3 (Peron et al., 2015). Of responsive neurons, ~70% were narrowly tuned with a single best whisker evoking statistically greatest responses; other showed broader tuning with statistically equivalent responses driven by 2-5 whiskers. Cells were localized to specific anatomical barrel columns by post hoc cytochrome oxidase staining. Only 45% of responsive neurons within a barrel column were tuned to the columnar whisker; the remainders were tuned to one of the neighboring whiskers. Differently tuned neurons were spatially intermixed in a salt-and-pepper organization, but with average subcolumnar somatotopy aligned to the neighboring columns. As a result, the ensemble of neurons co-tuned for a single whisker was scattered over multiple anatomical columns in L2. Similar results were observed with pyramidal cell-specific expression of GCaMP6s. Thus, L2 neurons show substantial local tuning

heterogeneity in awake mice, superimposed on an orderly cross-columnar and subcolumnar whisker map. We are currently studying the effect of attention on whisker representation in L2.

**Title:** Tactile enrichment refines whisker map subcolumnar structure and population coding in L2/3 of S1

**Authors: *A. M. LEMESSURIER**[1], D. E. FELDMAN[2]
[1]Helen Wills Neurosci. Inst., UC Berkeley, Oakland, CA; [2]Molec & Cell Biology; Helen Wills Neurosci Inst., UC Berkeley, Berkeley, CA

**Abstract:** Sensory experience can powerfully alter whisker map topography in developing and adult somatosensory cortex (S1). To understand how natural tactile experience influences map development, we studied the effects of tactile enrichment on micro-scale organization of the whisker map in L2/3 and L4 of S1. Mice were raised with tactile enrichment (EN) or normal housing (NH) beginning at weaning (P21). GCaMP6s was expressed virally in L2/3 or L4 excitatory cells, using Drd3-Cre (L2/3) or Scnn1a-Cre (L4) mice. At P50 ± 10 days, we measured whisker responses and 9-whisker receptive fields from S1 neurons using 2-photon imaging through a chronic cranial window. After imaging was complete, cells were localized relative to anatomical (CO-stained) column boundaries. Within a single anatomical column, L2/3 cells were heterogeneously tuned to different whiskers in a spatially intermixed, salt-and-pepper fashion. Enrichment increased somatotopic precision in L2/3: 84% of cells within 100 um of a column center were tuned to the columnar whisker (CW) in EN, while only 57% were CW-tuned in NH. In both groups, this dropped to 20% at a radius of 350 um from the column center. CW-evoked response magnitude (mean $\Delta F/F$) was also elevated in column centers in EN mice. In L4 in both groups, the spread of neurons tuned to one whisker was narrower than in L2/3, suggesting a more focused whisker representation. EN mice showed substantially reduced spontaneous activity in both L2/3 and L4, and stronger CW-evoked responses in L2/3. To study the effects of enrichment on the spatial and temporal aspects of population coding, we compared pairwise noise correlations and signal correlations of whisker responses for neurons within each column. While signal correlations - which reflect overall tuning similarity - were increased for within-column pairs in EN compared to NH, noise correlations - which reflect trial-to-trial

response fluctuations - were decreased by 10% in EN relative to NH. In both groups, noise correlations decreased with distance between neurons, but this fall-off was spatially sharper in EN mice. These findings demonstrate a strong impact of juvenile sensory experience on sensory responsiveness and subcolumnar map topography, and suggest that enrichment may sharpen local excitatory subnetworks in L2/3 to promote more homogeneous whisker tuning and reduced firing correlations within single columns.

**Title:** Selectivity for multi-whisker stimuli by single neurons in mouse somatosensory cortex

**Authors: *K. J. LABOY-JUAREZ**[1], S. AHN[2], D. E. FELDMAN[3]
[1]Univ. of California Berkeley, Berkeley, CA; [2]Mol. Cell Biol., Univ. of California, Berkeley, Berkeley, CA; [3]Molec & Cell Biology; Helen Wills Neurosci Inst., UC Berkeley, Berkeley, CA

**Abstract:** Active whisker sensation generates complex multi-whisker patterns of deflection, but coding of multi-whisker stimuli remains poorly understood in whisker somatosensory cortex (S1). We characterized multi-whisker tuning and integration in mouse S1 by extensively mapping neural responses to 2-whisker combinations and sequences, an important subset of multi-whisker stimuli. Recordings were made in the D1 column with silicon probes in anesthetized mice. 52% of S1 single units were significantly tuned for specific 2-whisker sequences at specific inter-whisker-deflection-intervals (Δt, range: ±50 ms). This spatiotemporal tuning was strongest in L2/3 and L5, suggesting that multi-whisker tuning is enhanced by intracortical processing. Multi-whisker responses were generally sublinear, with prominent sublinear suppression of non-preferred stimuli, and more linear responses to preferred stimuli. As a result, multi-whisker tuning was significantly sharper than predicted by linear summation. The strongest spatiotemporal tuning was observed in neurons whose single best whisker was a non-columnar (non-D1) whisker. 2-whisker sequence responses were strongly affected by Δt. The mean Δt tuning curve showed a significant preference for positive Δt's (columnar whisker leading surround whisker) and strong inhibition at nearly simultaneous deflections. 80% of the variance in Δt tuning could be described by three principal components, representing order

tuning (whether surround or columnar whisker was deflected first) and suppression during simultaneous whisker deflections (Δt=0). Order tuning strongly sharpened spatial selectivity for specific 2-whisker sequences. These findings show that multi-whisker patterns are represented in single S1 columns due to a combination of linear and non-linear computations in single neurons.

**Title:** A subset of 'super-responding' neurons dominates output signaling in layer 5A of mouse barrel cortex

**Authors: *A. BIRKNER**, Z. VARGA, V. D. J. BONFARDIN, M. TOHMI, B. SAKMANN, A. KONNERTH
Inst. of Neuroscience, TU Munich, Muenchen, Germany

**Abstract:** Electrical recordings from different cortical regions of the mammalian brain indicate that the level of activity in layer 5 (L5) is often stronger than that in other cortical layers. However, it is difficult to verify this assumption directly because methods of functional imaging with single-cell resolution, like two-photon calcium imaging, were mostly restricted to the upper cortical layers. Here we implemented a recently developed method of deep-two photon imaging involving the use of the red-shifted calcium indicator Cal-590 (Tischbirek et al., PNAS 2015, Birkner et al., Cell Calcium 2016) for the analysis of L5 in the mouse barrel cortex. When recording from the upper sheet of L5, at a depth of 770-820 µm, we observed that the majority of neurons responded only weakly to whisker stimulation (1 s, 10 Hz). Instead, whisker stimulation evoked in a small subset of neurons (< 5%) large amplitude somatic calcium transients. These ‘super-responding’ neurons were activated extremely reliably by repeated stimulation of the whisker corresponding to the investigated barrel region (= principal whisker), mostly without any failure. Instead, surround whiskers evoked only rarely small calcium transients in these neurons. By using two-photon imaging-guided cell-attached recordings, we determined that each of the large calcium transients of the ‘super-responders’ reflects the activity of 10-20 action potentials. Next we wondered about the dendritic activity underlying ‘super-responsiveness’. For this analysis, we performed a two-step imaging experiment in which we first identified in L5

‘super-responsive’ neurons by using the red indicator Cal-590 AM for population staining, and then electroporated such neurons with the green calcium indicator OGB-1. The morphological inspection of the apical dendrites demonstrated that all tested ‘super-responders’ (10/10) belonged to the class of ‘thin’-tufted L5 pyramidal neurons. Two-photon calcium dendrite imaging revealed whisker stimulation-evoked presumed calcium spikes that extended over all branches of the tuft. The synaptic origin of these dendritic spikes was demonstrated by locally blocking in L1 synaptic excitation by a mix of CNQX/APV. Tuft dendritic spikes were reliably evoked by stimulation of the principle whisker and less effectively when stimulating one of the surround whiskers. They were only rarely encountered during spontaneous activity. In conclusion, our results reveal an unexpected sparseness of the activity in the upper L5, the presence of a small subset of thin-tufted ‘super-responding’ neurons and a key role of L1 tuft dendritic spikes for their output activity.

**Title:** Fast-spiking interneurons of barrel cortex show increased activity on detected trials in a vibrissae deflection detection task

**Authors: *H. SHIN**, J. BOTROS, S. R. JONES, C. I. MOORE
Brown University, Neurosci., Providence, RI

**Abstract:** Fast-spiking interneurons of sensory neocortex are widely regarded as contributing to perceptual success through controlling local excitatory output. Their precise role (e.g. suppression, enhancement or synchronization) is, however, a topic of intense debate. To address this question, we recorded extracellularly from 4 mice trained to perform a vibrissae deflection detection task, using the 16-tetrode flexDrive. We analyzed 84 sessions from well-trained mice showing lawful psychometric behavior. In 191 single units with fast-spiking waveform (FS), we observed at the population level enhanced sensory evoked activity on detected trials compared to non-detected trials (matched in the magnitude of the sensory drive). We also observed enhanced

evoked activity in 195 regular-spiking units (RS), in agreement with prior studies. We hypothesize that this concurrent increase of excitatory and inhibitory activity is possible due to the synchronization of FS firing, a signature of which is FS-gamma (i.e. FS synchrony repeating in ~25ms intervals). Therefore, we assessed when FS synchronization occurred with regard to the stimulus onset. Optogenetic trains of FS stimulation initiating before sensory input and continuing after it (peristimulus) have been shown to enhance tactile detection under some conditions. Prior hypotheses have posited a role for prestimulus FS-gamma, that can align a pre-established "window of opportunity" to coincide with initial excitatory sensory input arriving from lemniscal thalamus. In apparent conflict with this prediction, we found decreased FS activity prestimulus on detected trials, and lower power in the gamma band (30~80 Hz) in the local field potentials (LFP) in this time period. We hypothesize that the beneficial effect of FS-gamma is largely realized by sensory evoked feedforward FS activity, as opposed to optimal alignment of prestimulus gamma. Ongoing optogenetic experiments have replicated prior peristimulus findings, and are now being applied to dissect the causal role of prestimulus versus poststimulus FS-gamma.

**Title:** Phase dependent differences in excitatory and inhibitory modulation of somatosensory cortex during active touch

**Authors: *S. SUNIL**, J. B. SCHROEDER, J. T. RITT
Biomed. Engin., Boston Univ., Boston, MA

**Abstract:** Active sensing incorporates a closed-loop behavioral selection of information during sensory acquisition. To understand the role of primary somatosensory cortex (SI) in coordinating active sensing motions, we developed a real time feedback system that delivers optogenetic stimulation to SI in actively exploring mice, time locked to whisker motions. Water-restricted mice, trained to alternately traverse a linear track for water rewards, were implanted with custom hyperdrives over left SI for neural recording and stimulation, and with bilateral facial electromyography (EMG) electrodes in the whisker pad, to estimate whisker motions in real time. Online processing identified protractions and retractions during active whisker motions as animals traversed the track. Stimulation of excitatory neurons (thy1-ChR2 mice) lead to an

increase in regularity of whisking, whether locked to protractions or retractions. In addition, stimulation timed to protractions sped up the following whisk, with weak effects for retractions. Simultaneous neural recordings from SI showed pulse-induced increases in neural activity when stimulation was timed to protractions, but not when timed to retractions. Stimulation of inhibitory interneurons (PV-ChR2 mice) showed a similar dependence on motion of SI responsiveness, where stimulation locked to protractions resulted in a decrease in neural activity, while stimulation locked to retractions had a muted effect. These results suggest a cyclic modulation of excitation and inhibition in SI with each whisk, that may reflect that incoming sensory information is naturally acquired when whiskers are moving forward. However, the interwhisk interval following inhibitory stimulation appeared to depend more strongly than excitation on the stimulated phase of protraction. Inhibitory stimulation earlier in protractions appeared to speed up the following whisk, while inhibitory stimulation later in protractions appeared to slow down the following whisk. Overall, downstream areas may show preferential tuning to the timing of SI activity relative to self-motion, with differential timing precision across cell classes and/or layers. We relate these findings to "window of opportunity" models for active sensory processing. Moreover, these findings suggest that SI is likely to play a role in guiding sensory motions, in addition to encoding incoming sensory information.

**Abstract:** Somatostatin (SST)-expressing interneurons are a major subgroup of GABAergic interneurons in the barrel cortex. In thalamic recipient layers, SST interneurons receive only weak thalamic input but connect strongly to the local excitatory neurons. SST interneurons might thus be a source of feedback inhibition. The dynamics of this feedback inhibition is unknown and the evidence that SST interneurons are driven by the somatosensory input is lacking. In fact, prior studies suggest that SST interneurons might be primarily modulated by cholinergic input and other types of interneurons as a result of behavioral arousal. We thus measured the dynamics

of SST interneurons in mice performing an active, whisker-mediated object detection task. Whisker movements were tracked with millisecond (ms)-timescale resolution. SST interneurons were recorded in vivo using channelrhodopsin-guided juxtacellular and whole-cell recordings, in barrel columns corresponding to the whiskers with which the mouse solved the behavioral task.In the absence of whisker movement and touch, the baseline spike rate of SST interneurons was 3.3 ± 4.6 spikes / s (mean ± s.d.). After the onset of exploratory whisker movement, we observed either a modest increase (62% of neurons) or a decrease (38%) in spike rate (average during whisker movement, 4.8 ± 6.9 spikes / s). The reduction of spike rate in some SST neurons could be caused by fast-spiking (FS) interneurons, which are strongly driven by whisker movement. Indeed, reducing the spike rate of FS interneurons increased the spike rate of some SST interneurons. Touch between whisker and object elicited phasic spikes (0.7 ± 0.7 spikes/touch) in SST interneurons across all cortical layers (2-6). The latency of touch-evoked spikes in the SST interneurons is 12.8 ± 4.6 ms (median, 12.0 ms), longer than for excitatory neurons (8.9 ± 4.4 ms, median, 7.8 ms), fast-spiking interneurons (5.2 ± 2.7 ms, median, 4.2 ms), or the latency for touch-evoked thalamic input (4 ms). Touch induced a delayed (8-10 ms) membrane potential depolarization in the SST interneurons, which matches the spike latency of local excitatory neurons. This suggests that the SST neurons are excited by local excitatory neurons. We conclude that SST interneurons are a major source of millisecond-timescale feedback inhibition in the cortical circuits.

**Title:** Spatio-temporal coding in the rat primary and secondary somatosensory cortices

**Authors: *M. A. GOLDIN**, E. R. HARRELL, L. ESTEBANEZ, D. E. SHULZ
Ctr. Natl. Recherche Scientifique (CNRS), Unite Neurosciences Information Complexite (UNIC), Gif Sur Yvette, France

**Abstract:** The rodent vibrissal system plays a key role in the identification of objects in the environment. Such tactile recognition is likely to depend on the spatiotemporal dynamics of multi-whisker contacts with an object. However, the coding of these multiple contacts in the whisker somatosensory cortices is not well understood. To characterize the multi-whisker representations in the two largest somatosensory cortical regions, we applied with a 24 whisker piezoelectric stimulator three different types of stimuli to the caudal 24 macrovibrissae of anesthetized (Isofluorane) rats while recording the activity of multiple single neurons in either primary or secondary whisker somatosensory cortex (wSI or wSII). First, we applied identical Gaussian white noise deflections to all whiskers and analyzed the neuronal responses with reverse correlation techniques. We found that both cortices have a predominant low dimensional filter space, with wSII neurons filtering the stimulus in extended temporal windows compared with wSI. Second, in a stimulation context where each whisker receives its own, uncorrelated Gaussian stimulus, we found that the reverse correlation analysis was not suitable for wSII responses. However, using the region-specific temporal filters for whisker movements across time found in the correlated context, it became feasible to study both wSI and wSII responses in the uncorrelated condition. Our new method reduces the dimensionality of the spike triggered ensemble 50 times by transforming it to the meaningful stimulus coordinates of the respective sensory areas . This powerful approach allowed identifying for the first time, spatio-temporal receptive fields at a whisker-pad scale during continuous, simultaneous multi-whisker stimulation for an extended time window of 200ms. An analysis of the dynamics of the responses in wSI and wSII in the two dense stimulation contexts revealed that these regions contain specialized whisker representations. In wSI, the population encodes fine features of whisker movements on precise spatial and temporal scales. In wSII, many whiskers contribute equally to the firing of a single neuron, and these contributions occur over longer time scales than what is found in wSI. The predicted outcome of these coding principles were then tested and validated in a sparse noise stimulation context where each whisker was deflected independently but not simultaneously. In conclusion, the whisker system encodes both fine scale tactile features and broader tactile scene statistics at different timescales and these complementary representations are organized into distinct and specialized cortical regions.

**Title:** Visualizing learning-induced cortical plasticity in the barrel cortex with intrinsic signal optical imaging

**Authors: *A. M. POSLUSZNY**[1], R. ZAKRZEWSKA[1], M. KOSSUT[1,2]
[1]Nencki Inst. of Exptl. Biol. PAS, Warszawa, Poland; [2]Dept. of Psychology, Univ. of Social Sci. and Humanities (SWPS), Warszawa, Poland

**Abstract:** Intrinsic signal optical imaging (ISOI) was found to be a good tool for visualizing cortical plasticity in the models of vibrissae deprivation (Polley et al., 1999; Drew & Feldman, 2009). We investigate changes in the barrel cortex after fear learning in which stimulation of vibrissae is paired with a tail shock. Previously, we mapped changes in cortical representation of vibrissae involved in behavioral training with 2-deoxyglucose (2-DG) and found enlargement of functional cortical representation of the row of vibrissae stimulated during training. We wanted to replicate the 2-DG results with ISOI. The aim of the experiments was to find a protocol of vibrissae stimulation for the ISOI from the barrel cortex, which could provide constant signal in temporally separated recordings and enable visualization of plastic changes after learning. Two subsequent ISOI were performed with 6 days interval. Training consisted of 3 daily sessions of 40 trials of manual stimulation of row B vibrissae on one side of the snout (three 3-s smooth strokes with a fine brush) coupled with a mild tail shock. 24 hours after the last conditioning session the second ISOI was performed. Two protocols of vibrissae stimulation during ISOI were tested. In the first protocol 5-ms deflections of B1 vibrissa were applied for 1s with frequency of 5Hz. In the second protocol 5-ms deflections of B1 vibrissa were applied for 6s with frequency of 10Hz. Additionally, after second ISOI a 2-DG mapping was performed in order to confirm plasticity in the somatosensory cortex. Using 2-DG method a comparison was performed between left (stimulated during learning) and right (not stimulated) vibrissae representation. The repeated ISOI in which the first protocol (1s/ 5Hz) of vibrissae stimulation was applied, revealed no change of the B1 vibrissa representation after learning, a result that is inconsistent with 2-DG maps. ISOI using the second vibrissae stimulation protocol (6s/ 10Hz) showed expansion of cortical representation of vibrissa stimulated during learning, which was confirmed by 2-DG results. Our results indicate that different paradigms used for induction of experience-dependent plasticity in the barrel cortex require specific protocol for visualizing plastic changes by ISOI. This discrepancy could result from the effect described before, that the activation area seen in images produced by ISOI can be larger than or closer to the area of cellular cortical representation of stimulated whisker depending on the frequency of the stimulation or the number of the stimulation trials (Sheth et al., 1998; Polley et al., 1999).

**Title:** Cortical control of sensory gating in the rodent whisker system

**Authors: S. CHAKRABARTI**[1,2], *C. SCHWARZ[2]
[1]Werner Reichardt Ctr. For Integrative Neurosci., Tuebingen, Germany; [2]Univ. Tuebingen, Tuebingen, Germany

**Abstract:** Sensory gating, in which the neural responses to a sensory stimulus are reduced during motion, has been documented across several species and modalities. In the rodent whisker system, it has been repeatedly shown that cortical and thalamic responses to whisker stimulation are reduced during active whisking. Previous studies have further suggested that such gating is present in the brainstem and the abundance of cortical projections to the brainstem trigeminal sensory nuclei strongly suggest a cortical role in such gating. However, no study has demonstrated sensory gating in the brainstem or the dependence of such gating on cortical projections. In the present study we address these issues using awake behaving rats in an active whisking behavioral task. First, we show that sensory gating in which neural responses during whisking are reduced in amplitude, indeed occurs in the neurons in the trigeminal principal nucleus (Pr5). Second, we demonstrate using aspiration lesions of S1 and S2 cortex that such gating is abolished implicating the corticofugal fibers in a causal role. Third, we show that the initiation of whisking results in an increase in neural activity which is strongly reduced following cortical lesions. This increase in activity does not precede whisking onset, arguing against it being a pure motor signal. Finally we recorded from neurons in the trigeminal interpolaris nucleus (Sp5i) which is known to send inhibitory projections to the Pr5 and is therefore a likely candidate mediating the cortical evoked gating of Pr5 neurons. However, we did not find increased activity during whisking consistent with an intra-trigeminal inhibitory circuit nor did we detect whisking evoked activity as in Pr5. We therefore question whether Sp5i mediates the sensory gating of Pr5. Taken together our data point to a cortical origin of the sensory gating phenomenon in which corticofugal projections to Pr5 mediate tactile gating in the brainstem.

**Title:** Bidirectional rate coding through the core descending intracortical microcircuit

**Authors: *S. PLUTA**, H. ADESNIK
Univ. of California Berkeley, Berkeley, CA

**Abstract:** Neurons encode sensory stimuli through both increases and decreases in firing rates. This is particularly true of layer 5 (L5) cortical projection neurons that often exhibit high spontaneous firing rates in the absence of any external stimulus. The neural circuits that account for these bidirectional changes, however, are largely unknown. Prior *in vitro* work in somatosensory cortex demonstrated that descending input from L2/3 generates heterogeneous balances of excitation and inhibition in L5 pyramidal cells that potentially mediate both increases and decreases in touch evoked activity. To test this hypothesis, we optogenetically manipulated L2/3 activity in awake, actively sensing animals while simultaneously recording activity in L5. Optogenetic activation of L2/3 increased the firing rate only of L5 units facilitated by active touch, while it simultaneously decreased the firing rate of all L5 units suppressed by touch. Similarly, optogenetic deactivation of L2/3 reduced the activity of units displaying touched evoked increases in firing rate, while it simultaneously diminished the suppression of units displaying touch evoked decreases. Additionally, L2/3 deactivation significantly reduced the spatial selectivity of L5 projection neurons, both within single units and across the population. Surprisingly, the spatial selectivity of putative fast-spiking interneurons in L5 was unchanged, despite L2/3 deactivation significantly altering the firing rate of a minority of units. In conclusion, these data demonstrate that the core descending pathway of the intracortical microcircuit enhances the representation of touch by bidirectionally distributing the firing rates of cortical projection neurons.

**Title:** Whisker activation evokes network desynchronization and formation of functional small-world subnetworks in the primary and secondary somatosensory cortex of the rat

**Authors: M. KHATEB**, J. SCHILLER, *Y. SCHILLER
Technion Med. Sch., Haifa, Israel

**Abstract:** Neural synchrony is crucial for sensory and conscious processing, perceptual integration, attention selection, working memory and more. In this study, we investigated the effect of whisker activation on neuronal synchrony in the SI and SII somatosensory cortexs. To monitor neuronal synchrony we calculated the pairwise correlations during spontaneous activity and whisker activation in anesthetized and head restrained rats, and defined functional connections between neuronal pairs in case their firing was significantly correlated. Our results demonstrated a significant decorrelation of neuronal pairs in both S1 and S2 cortex during evoked activity. In S1, the average connectivity per unit (percent of units significantly correlated with the reference unit) decreased from 39.5 ± 5 % in the spontaneous pre-stimulus state to 25±4 % during whisker activation (p-value<0.01). A similar reduction was also observed in the S2 cortex, where connectivity per unit dropped from 26.5 ±5% during the spontaneous pre-stimulus state to 11.8 ±4 % during whisker activation (p-value<0.01). This decrease was observed in all recorded putative cortical layers of S1 and S2 (layers 2-5). At the end of whisker activation networks gradually increased their inter-neuronal synchronization, with an average time needed to return to the pre-stimulus connectivity values of 1.23 ± 0.17 seconds.
Interestingly, loss of functional connections (as measured by the existence of significant correlations) during whisker activation was not random, but rather followed specific spatial and functional principles: 1) Connections with spatially distant units where preferentially lost, while maintaining connections with nearby units. In so doing whisker activation transformed the S1 and S2 networks to a more "small-world-network" configuration. 2) Preferential maintenance of correlative connections with units that had similar texture selectivity. In addition we show that hubs (defined as the 10 % of units with the largest number of correlated connectivity) were most likely stimulus non selective units in both S1 and S2.
To conclude, Our data demonstrate stimulus evoked activity results in decorrelation/desynchronization of the cortical networks of primary and secondary

somatosensory cortex, and transformation of these networks to a more small-world network configuration. These findings suggest that during evoked activation the cortical network is segregated into smaller functional networks that may process different aspects of the sensory input.

**Title:** Functional impact of subtypes of somatostatin-expressing interneurons in cortical circuits

**Authors: *A. S. NAKA**[1], J. VEIT[1], H. ADESNIK[2]
[1]UC Berkeley, Berkeley, CA; [2]Univ. of California, Berkeley, Berkeley, CA

**Abstract:** Inhibitory neurons of the cortex are anatomically and molecular diverse. This implies that distinct subclasses might differentially contribute to specific aspects of neural computations. Dendrite-targeting somatostatin (SST) expressing interneurons exhibit an extreme level of morphological and molecular heterogeneity, and can be broken into multiple subtypes with distinct patterns of local connectivity. Emerging evidence suggests that different subtypes of SST cells are differentially coupled to sensory inputs and behavioral contingencies, yet how different sub-classes of SST cells functionally influence cortical dynamics and computation is essentially unknown. We optogenetically manipulated the activity of different subtypes of SST cells while measuring synaptic inhibition and spiking activity across the different cortical layers in primary sensory cortex. Our results suggest that SST subtypes are specialized to modulate different components of the cortical microcircuit and may thereby play distinct roles in cortical computation.

**Title:** Neuronal and non-neuronal factors mediate behavioral-state dependent development of functional hyperemia in the somatosensory cortex of juvenile mice

**Authors: *K. W. GHERES**[1], Q. ZHANG[2], P. J. DREW[3]
[1]Huck Inst. of the Life Sci., Pennsylvania State Univ. Univ. Park, University Park, PA; [2]Ctr. for Neural Engineering, Dept. of Engin. Sci. and Mechanics, The Pennsylvania State Univ., University Park, PA; [3]Dept. Engin. Sci. and Mechanics, Pennsylvania State Univ., University Park, PA

**Abstract:** In the adult somatosensory cortex, behavior-driven increases in neural activity evoke large, spatially restricted changes in blood volume due to arterial and venous dilations (1, 2). However, as rodent studies have shown neurovascular coupling can be inverted in the juvenile brain (3), we sought to understand how the behavior-evoked hemodynamic response matures during the postnatal period in mice. Using two-photon microscopy, intrinsic optical signal (IOS) imaging, and electrophysiology, we investigated how functional hyperemia is effected by neuronal and non-neuronal mechanisms during the postnatal period in the awake mouse. Stimulation of the vibrissae in the awake mouse caused biphasic (initial dilation followed by a constriction) hemodynamic responses over barrel cortex that developed into adult-like responses within two weeks of eye-opening (P30). In contrast, locomotion evoked decreases in cerebral blood volume in juveniles, rather than the increases in blood volume seen in adults, and only become adult-like four weeks after eye opening. Further analysis suggests these changes are due to decreases in venous blood volume that occur at the onset of locomotion. Electrophysiological recordings show increases in local field potentials as well as multi-unit spiking in response to locomotion during this period, suggesting a decoupling of the neurovascular relationship. This work suggests that age and behavioral-state dependent changes in the neurovascular relationship need to be considered for proper interpretation of hemodynamic signals in the developing brain.

**Abstract:** Recently, we developed new soft-cranial window for rodents with the soft, flexible, transparent, and biocompatible silicone-based polydimethylsiloxane (PDMS) (Heo et al. 2016). This soft-cranial window allows not only an easy access into tissues with electrodes or needles but also long-term monitoring for a large cortical area. But, this soft-window installation may affect the physiology of brain tissue because full craniotomy is a necessary step for it. Here, we investigated the effects of soft-cranial window installation on sensory-evoked cerebral hemodynamics at different post-op periods. C57bl/6 mice were used in this study. At 2 weeks and 6 weeks post soft-cranial window installation, we optically recorded cerebral blood volume (CBV) changes during a single whisker stimulation (C2 area) for either 4 seconds or 16 seconds and electrophysiologically recorded local field potential (LFP) for 0.1ms of the same stimulation. The animals at 6 weeks post soft-cranial window installation exhibited different CBV response patterns compared to that of the animals 2 weeks post-op. The animals at 6 weeks post-op showed more focalized CBV changes during a single whisker stimulation than the animals at 2 weeks post-op. Furthermore, the maximum CBV changes at the response center at 6 weeks post-op were larger than the CBV changes at 2 weeks post-op. LFP recording during a single whisker

stimulation also showed a similar pattern. The animals at 6 weeks post-op showed larger dendritic summation of neuronal membrane potential changes than the animals at 2 weeks post-op. In immunohistochemical studies, we found that the heightened expression level of GFAP of reactive astrocyte and activated microglia from the animals at 2 weeks post soft-cranial window compared to that of animals at 6 weeks post-op and normal control animals. Also, the animals at 2 weeks post-op exhibited higher brain-blood barrier (BBB) permeability than the animals at 6 weeks post-op and normal animals. This suggests that the soft-cranial window installation procedure with full craniotomy affects overall physiological conditions of brain tissue and may cause traumatic injury for a short term. Further investigation is necessary to understand the exact mechanism for the decreased hemodynamics alongside with decreased neuronal activation at initial periods after the soft cranial window installation.

**Title:** Decoding the cortical representation of auditory motion using EEG

**Authors: *A. BEDNAR**[1], E. C. LALOR[2]
[1]Trinity Col. Dublin, Dublin, Ireland; [2]Dept. of Biomed. Engin. and Dept. of Neurosci., Univ. of Rochester, Rochester, NY

**Abstract:** It is of increasing practical interest to be able to decode the spatial characteristics of an auditory scene from electrophysiological signals. This has potential applications in cognitively controlled hearing aids and for the evaluation of virtual acoustic environments. However, the cortical representation of auditory space is not well characterized - particularly as it relates to auditory motion - and the possibility of decoding cortical signals using non-invasive neuroimaging techniques remains unclear.
In previous work (Bednar et al 2017) we showed that we can classify evoked electroencephalographic (EEG) responses to discrete static sound stimuli as a function of their location in space. In the present study, we extend this work with the aim of decoding the trajectory of continuous, moving auditory stimuli.
Subjects listened to white noise over headphones, which had been spectro-temporally modified to be perceived as randomly moving on a semi-circular trajectory in the horizontal plane. Participants were asked to respond to infrequent tremolo targets which were embedded in the

stimuli. While subjects listened to the stimuli, we recorded their EEG using a 128-channel acquisition system. The data were analyzed by 1) deriving a linear mapping, known as a temporal response function (TRF), between the stimulus and a training set of EEG data, and 2) using the TRF to reconstruct an estimate of the time-varying sound source azimuth from a test set of EEG data.
Preliminary results show that we can decode sound trajectory with a reconstruction accuracy significantly above chance level. We find that reconstruction accuracy is highest when the sound trajectory is estimated using alpha-filtered EEG (8-12hz). Moreover, the subsequent analysis of the reconstruction model parameters reveals strong alpha-power lateralization at the occipital regions of the scalp.

**Abstract:** The ability to localize sound effectively is critical, not only for determining the directional origin of the sound, but also for segregating overlapping sound sources in complex environments. Much of our ability to localize sound in the vertical plane come from head related transfer functions derived from the filtering functions due to the shape of the pinna, while horizontal localization depends on auditory centers in the brain specialized for calculating intensity and timing differences between the two ears. In order to study sound localization, a group of St. Olaf undergraduate students, faculty, and staff developed a free-field stimulus presentation device known as the SoLoArc (Westerberg et al., 2015). The SoLoArc can systematically present auditory and visual stimuli in a 180 degree free-field environment in both the horizontal and vertical planes. A current challenge for psychophysical studies of free field sound localization is in how the participant indicates where they think the sound is coming from. Finger-pointing and head-pointing can be inaccurate and require movement of the participant, thereby altering the acoustic cues that they are using to localize the sound. For that reason, we

developed an automated system to capture participant responses as they indicate the source location on the SoLoArc. A potentiometer coupled to a servo motor is used to point a laser at the arc. The voltage derived from the potentiometer is converted into angular location, allowing the participant to indicate source localization without any movement of the head or body. Preliminary results indicate that this system accurately reports participant's perception of auditory stimuli in space allowing for more accurate estimates of source localization in both azimuth and elevation than finger pointing devices.

**Title:** Auditory recalibration in Virtual Reality

**Authors: *M. GONZALEZ-FRANCO**[1,2], C. C. BERGER[3,1], D. FLORENCIO[1], Z. ZHANG[1,4]
[1]Microsoft Res., Redmond, WA; [2]EVENT Lab., Univ. de Barcelona, Barcelona, Spain; [3]Karolinska Institutet, Stockholm, Sweden; [4]Univ. of Washington, Seattle, WA

**Abstract:** Inside Virtual Reality (VR), different modalities can be presented dynamically in synchronous or asynchronous ways to retrain and recalibrate the senses. This allows for scenarios in which subjects can develop further sensorial expertise or acuity. Generally, auditory perception has good temporal resolution, and humans are naturally good at distance estimation through audition. However, the spatial acuity of audition is poor compared to vision, and being able to discretize sounds in space is necessary to segregate distinct auditory sources in one's environment and enable selective attention. Research has revealed that repeated exposure to spatially and temporally aligned audiovisual stimuli, can lead to cross-modal plasticity and improved performance on source localization in the auditory domain. In Virtual Reality, auditory stimuli are often presented through a simulated spatialization that is calculated using head tracking devices. This is enabled by Head Related Transform Functions (HRTF), which can be generalized or calibrated on a per user basis. Although personalized HRTFs are known to improve one's accuracy for the direction of sounds, these calibrations are arduous. Therefore, HRTFs present a challenge for the adoption of the technology. Here, we hypothesized that personalized calibration of HRTFs might not be necessary if a recalibration of the participants' auditory capabilities is possible via cross-modal plasticity mechanisms. **Methods** Participants (n=16) undergo an auditory calibration inside a VR headset equipped with a generic HRTF. The calibration lasts for 60 seconds in which an audio sound bounces around the scene 10 meters in

front of the participant. In the cross-modal condition a sphere is attached to the sound. The control condition does not provide visual clues. In order to account for adaptation and plasticity effects, we ask participants to perform an audio localization task (25 trials) before and after the exposure. At each trial, the participant indicates the direction the audio is coming from by pointing with a virtual cylinder attached to their head and pressing a button. All the trials are randomly located in a 1D line perpendicular to the sight of the participant also 10 meter in front. The sounds come from 5 predefined locations 2.5 meters apart and all locations are presented at least 5 times without sequential duplicates. **Results** Looking at the actual pre- and post- exposure performance, we find that participants in the cross modal condition exhibited an improvement (Wilcoxon paired test, mean improvement=0.18, $p<0.1$). While participants in the control condition did not show improvement (mean improvement=-0.09, $p=0.6$).

**Title:** Neuronal discharging to ipsilateral acoustic stimuli in central nucleus of inferior colliculus from the activation of contralateral cochlear via bone-conduction

**Authors:** *J. WEI, ***J. WEI**, C. XIAO, Z. XIAO
Dept. of Physiol., Southern Med. Univ., Guangzhou, China

**Abstract:** Binaural integration remains unclear. The mechanism underlying binaural integration have been extensively explored in central nucleus of inferior colliculus (ICC). ICC neurons receive inputs from contralateral ICC and bilateral lower nuclei, are driven by contralateral and/or ipsilateral sound stimuli. Most of them are activated by contralateral stimuli and facilitated or suppressed by ipsilateral stimuli, that is, EE and EI neurons. However, it is unknown whether or not the EE and EI responses of ICC neurons are uploading from the lower

nuclei. In other words, what is the response of ICC neurons to contralateral or ipsilateral sound stimuli, respectively. Here, we adopted in vivo cell-attached recording to compare the response characteristic to contralateral or ipsilateral sound stimuli in normal hearing, middle ear blocked and cochlear damaged mice with enclosed sound delivery system. Furthermore, we performed in vivo whole-cell recordings to investigate the synaptic activity to ipsilateral sound stimuli in contralateral cochlear damaged mice with or without lidocaine in contralateral ICC. Data showed that responses to ipsilateral stimuli in normal was consistent with those in ipsilateral cochlear damaged mice and in contralateral middle ear blocked mice. It demonstrates that the responses to ipsilateral stimuli were formed by the activation of contralateral cochlear via bone-conduction rather than contralateral cochlear via air-conduction or ipsilateral cochlear. Moreover, no spike was evoked by contralateral acoustic stimuli in ICC of contralateral cochlear damaged mice, but stronger inhibitory postsynaptic currents (IPSCs) and weaker excitatory postsynaptic currents (EPSCs) to ipsilateral stimuli were recorded. After the ICC on the same side of the damaged cochlear was silenced with lidocaine, the EPSCs to ipsilateral stimuli faded away, the IPSCs decreased about 10-20%. The results suggests that ICC neurons only process contralateral auditory information, their discharging to ipsilateral stimuli is from the activation of contralateral cochlear via bone-conduction, they integrate subthreshold excitation from contralateral ICC and inhibition from contralateral ICC and directly ipsilateral lower nuclei when responding to ipsilateral stimuli.

**Title:** Stimulus dependent versus cell specific computational strategies in localization of two simultaneous sounds

**Authors: *S. M. WILLETT**[1], V. C. CARUSO[2], S. T. TOKDAR[1], J. M. GROH[1]
[2]Ctr. For Cognitive Neurosci., [1]Duke Univ., Durham, NC

**Abstract:** Coding of multiple simultaneous sounds is a known problem for broadly tuned neural representations of auditory space. Previous reports suggested neurons in monkey inferior colliculus (IC) implement time-division multiplexing, or alternation between firing rates corresponding to each stimulus (Caruso et. al., BioRxiv, 2017; Willett et. al., Soc Neuro Abstr 2016). These studies found a variety of fluctuating and stable response patterns across the set of

tested conditions. Here, we investigated whether the same neurons tested with different stimuli tended to demonstrate the same vs. different types of response patterns.
Single unit activity was recorded in the IC of a rhesus macaque performing single- and dual-sound localization tasks involving one or two saccades to the location of each stimulus. Spike counts on dual sound trials were modeled in relation to the Poisson distributions of spike counts observed on single sound trials. Responses were classified as deriving from (a) a mixture of the two single-sound Poissons, (b) an intermediate Poisson distribution with a rate between those of the two single sounds, or a Poisson distribution that (c) matched or (d) was outside the range of the single-sound Poissons. We then determined whether the winning model was consistent for all conditions an individual neuron was tested with.
The results were heterogeneous. Roughly 45% of cells appear to use a cell specific computation, with the majority of winning models being consistent across the tested conditions. Another 37% of cells exhibited distinctly different behavior across different stimulus conditions. Together, these results indicate that IC neurons can either play a consistent type of role in the population response to dual sounds or they can be flexible and respond differently to different combinations of stimuli.

**Title:** How many sound locations can humans distinguish at a time? Implications for neural processing of auditory space

**Authors: L. FARRELL**[1], *J. M. GROH[2]
[1]Duke Inst. for Brain Sci., [2]Duke Univ., Durham, NC

**Abstract:** • How the brain encodes multiple sounds is unclear, particularly given recent evidence that sound azimuth is encoded in the level of activity in a neural ensemble rather than via an auditory space map of circumscribed receptive fields. One possibility is that the brain takes advantage of frequency differences to sort different sound sources to different regions of tonotopic maps (Willett et al. Soc Neuro Abstr 2016). Alternatively, the brain may use time division multiplexing to encode multiple sounds via fluctuating activity rates corresponding to individual sounds across time (Caruso et al., biorxiv, 2017).
• Insight into which possibility or possibilities may apply and how they operate can be gained

from knowing how many sounds humans are capable of distinguishing at one time. In this study, 8 different bandpass filtered noise stimuli (with different center frequencies) were combined and presented simultaneously from between 1 and 8 different locations. For example, all 8 bandpass filtered stimuli were combined and played from 1 speaker, all were separately played from 8 speakers, or any combination in between. Human participants were asked to report how many different locations they heard on each trial.
• We found that the reported number of locations scaled with actual number up to about 4 sounds. However, participants tended to underestimate the actual number and were accurate only for 1-2 locations. Since the frequency information was held constant, we interpret these results chiefly under the time division multiplexing theory. We conclude that the time division multiplexing component of multiple stimulus encoding may operate on a duty cycle that permits representation of a maximum of four sound locations at a time.

**Title:** Interaural time difference sensitivity in turtles

**Authors: *K. L. WILLIS**[1,2], C. E. CARR[2]
[1]Biol., Univ. of Oklahoma, Norman, OK; [2]Biol., Univ. of Maryland, College Park, MD

**Abstract:** The hearing range of turtles is only about 50-1000 Hz. Hearing limited to low frequencies can constrain sound localization abilities, particularly in Red eared slider turtles, which have a small head, isolated middle ears, and an amphibious lifestyle. To determine if the turtle's nucleus laminaris NL were sensitive to interaural time differences (ITD), we investigated the physiological responses of the brain stem auditory nuclei, nucleus magnocellularis (NM) and NL. We recorded extracellular single and multi-unit responses in NM and NL to dichotic sound in an isolated head preparation. NM and NL neurons responded to frequencies from 100-600 Hz with thresholds from 60-80 dB SPL. NM neurons phase locked reliably with vector strengths of 0.82 ± 0.07 (n = 123). NL vector strengths were comparable to NM (0.70 ±0.17, n = 113). NM projected bilaterally to NL, which was sensitive to ITD. Measures of characteristic delay revealed best ITDs around ± 200μs. Turtle NL neurons typically had characteristic phases close

to 0 (0.12 (± 0.23, n=45), consistent with binaural excitation. Thus turtles encode ITDs consistent with their physiological range.

**Title:** The responses of neurons in central nucleus of inferior colliculus to binaural acoustic stimulation is either from ipsilateral or contralateral rather than binaural integration

**Authors: *Y. LIU**, J. WEI, Z. XIAO
Dept. of Physiol., Southern Med. Univ., Guangzhou, China

**Abstract:** Animals have two ears. They are thought to process binaural auditory information. Neurons in central nucleus of inferior colliculus (ICC) receive inputs from contralateral ICC and bilateral lower nuclei. Most of them are activated by contralateral stimuli and facilitated or suppressed by ipsilateral stimuli, called, EE and EI neurons. The synaptic mechanism underlying EE and EI neurons is thought to be the integration of binaural excitation and inhibition. However, it is lack of consolidated evidences.
Using in vivo whole cell recording in this study, we compared the synaptic excitation and inhibition of ICC to binaural stimulation with that to contralateral or ipsilateral stimulation by an intensity-intensity scan, in which the sound intensity for contralateral and ipsilateral stimuli were randomly delivered from 70 to 10 dB referred to no stimulus for contralateral or ipsilateral. When no sound was delivered in a unilateral, the responses presented to the contralateral or ipsilateral sound stimuli, otherwise to interaural level difference (ILD). At some intensity for an ipsilateral stimulus the postsynaptic excitatory (EPSCs)/inhibitory currents (IPSCs) were dependent on the contralateral sound intensity until to a point, to which the response was stronger than that to the ipsilateral intensity, beyond this point the binaural response was consistent with the ipsilateral response. So does that for an contralateral stimulus. In other words, the response to ILD was level-dependent on ipsilateral or contralateral stimulus, that is, the

response to binaural stimulus was selected either to ipsilateral or to contralateral stimulus. To confirm this selectivity, we used dichotic paired tone stimulation with a interaural time difference (ITD: 0, 1, 2, 3, 5, 10, 20, 40, 80, 160 ms) and directly assessed if the response to a unilateral stimulus is integrated with the another. When the acoustic stimuli were presented simultaneously to both ears (0 ms ITD), the binaural response was consistent with the contralateral or ipsilateral. When the ipsilateral acoustic stimulus was presented before or after the contralateral acoustic stimuli, the EPSCs/IPSCs to contralateral stimulus was separated from that to ipsilateral stimulus. Our findings suggest that the responses of ICC neurons to binaural acoustic stimulation is either from ipsilateral or contralateral acoustic stimulus rather than binaural integration.

**Title:** Pressure difference receiving ears influence ITD coding in American alligators

**Authors: *L. KETTLER**, C. E. CARR
Univ. of Maryland - Dept. of Biol., College Park, MD

**Abstract:** The difference between the timing of sounds at both ears (interaural time difference, ITD) is a key feature for sound source localization. However, ITD coding strategies may vary across taxa, head sizes, and frequencies. Two of the proposed mechanisms are a place code of neurons with different best ITDs within an iso-frequency band (Jeffress-model), and a population code that utilizes the slope of the rate-ITD curves of the entire neuron population over the physiological range, even while best ITDs lie outside the physiological range. A place code is less accurate with increasing noise, when head sizes are small, and for low frequencies where the peaks of ITD tuning curves become very broad. Thus, a rate-code may provide more robust encoding of ITD at low frequencies. In archosaurs, the detection of ITD is assumed to be consistent with a Jeffress-model-like place code, which consists of coincidence detectors and delay lines. An anatomical structure that resembles the Jeffress model has been found in the nucleus laminaris (NL) of archosaurs, including alligators and birds. However, an additional factor, namely pressure difference receiving ears, may influence ITD detection in archosaurs. Alligators, like most birds, are sensitive to ITDs at low frequencies, where coupled ears allow transmission of sounds through the dorsal and ventral sinuses that connect both middle ears and

create pressure difference receiving ears. Internal coupling increases the range of interaural time differences, and thus compensates for small head sizes. Thus, a place code might be efficient despite a low frequency hearing range. We performed in vivo electrophysiological experiments with American alligators to investigate the roles of evolutionary history and anatomical constraints on optimal ITD coding. Like in chicken and owls, best ITDs were broadly distributed in alligators but often outside the physiological range. Unlike in mammals, the slopes of the tuning curves did not uniformly cross 0μs. Models of the physiological range that included pressure difference receivers predicted that the range of ITD was increased with decreasing frequency, and aligned with the limit of best ITDs given by the period of the stimulus tone (pi-limit). The increase in ITD range with frequency, thus, circumvented the constraint of best ITDs lying outside the physiological range. Alligators and other archosaurs, therefore, may share a place code of ITD detection that co-evolved with internal coupling of ears. Since mammalian ears are not coupled, small early mammals may not have been able to compensate for their narrow ITD range, and may have evolved a population coding strategy.

**Title:** Excitatory inputs in cortical layer IV reinforced by ipsilateral acoustic stimuli through the inhibition from contralateral auditory cortex to ipsilateral layer VI

**Authors: *X. HAITING**[1], X. ZHANG[2], Z. XIAO[3]
[1]Southern Med. Univ., Dept. of Physiol., Guangdong, China; [2]Dept. of Physiol., Southern Med. Univ., Guangdong, China; [3]Southern Med. Univ., Guangzhou, China

**Abstract:** Binaural information processing is still unclear. The auditory cortex is the advanced central of auditory system, and should have significant function in binaural integration. However, our understanding of binaural integration in auditory cortex mainly remains in that cortical neurons are activated by contralateral stimuli and facilitated or suppressed by ipsilateral stimuli, that is, EE or EI neurons. It is unknown whether the EE and EI neurons distribute in layer specificity in auditory cortex, and what are their functions. With cell-attached recording and enclosed sound delivery, we found that the EE neurons mainly exist in the layer IV of auditory cortex while the EI neurons mainly exist in the layer VI. This presentation might upload from the subcortical nucleus. Whole-cell recording could separate the excitatory and inhibitory

inputs from the subcortical nucleus. Data showed that the excitation responding to bilateral acoustic stimuli was bigger or smaller than that to contralateral acoustic stimuli, while the inhibition responding to bilateral acoustic stimuli was always smaller than that to contralateral acoustic stimuli in layer IV. In layer VI, both excitation and inhibition responding to bilateral stimuli were smaller than those to contralateral stimuli. However, the inhibitions responding to bilateral stimuli in layer IV were not different from those in layer VI. When normalized the excitation to inhibition (E/I) for bilateral stimuli, the ratio for the layer IV neurons (1.44±0.48) was higher than that for the layer VI neurons (0.83±0.11). These results suggest that the binaural integration does exist in auditory cortex rather than uploading from the subcortex. A recent study reports that there is an inhibition from contralateral auditory cortex via layer II/III to ipsilateral layer V and VI in slice. When the contralateral auditory cortex was damaged or inhibited with lidocaine, the binaural integration in the layer IV and VI disappeared with the cell-attached and whole-cell recordings. When the ipsilateral layer VI was damaged or inhibited with lidocaine, the EE phenomenon, i.e., the enhancement of excitation relative to inhibition disappeared. Therefore, present study reveals a circuit underlying the binaural integration in auditory cortex, that is, the excitatory inputs in cortical layer IV is reinforced by ipsilateral acoustic timuli through the inhibition from contralateral auditory cortex to ipsilateral layer VI.

**Title:** Response types of the superior olivary nucleus of the barn owl

**Authors: *A. KRAEMER**[1], C. CARR[2]
[2]Biol., [1]Univ. of Maryland, College Park, MD

**Abstract:** Inhibition is important for auditory processing. In chickens, the superior olivary nucleus (SO) provides inhibitory feedback to first order nuclei, and has been hypothesized to improve ITD coding (Fukui et al., 2010; Burger et al., 2011; Tabor et al., 2012). Few studies have characterized SO response types in barn owls. Moiseff & Konishi (1983) recorded from the owl SO in vivo, and found the majority of units were only excited by the ipsilateral ear. All units recorded from the SO were ILD insensitive, although the authors noted their search criteria might have increased the percentage of monaural response types (Moiseff & Konishi 1983). The SO is morphologically heterogeneous, however, and projects to multiple targets. Some SO

neurons send inhibitory projections to two or more ipsilateral brainstem nuclei, while projections to the contralateral SON may originate from a separate population of neurons (Burger et al., 2005). Other SO neurons project to the inferior colliculus (Takahashi et al., 1988). Given the heterogeneity of SO cell types and projections, it seems likely to contain multiple response types. In order to examine auditory responses in SO, and to study the effects of descending inhibition provided to the first order auditory nuclei, we characterized barn owl SO responses in vivo. Electrolytic lesions confirmed recording locations. We measured tuning curves, tested for phase locking, and analyzed peristimulus time histograms, latency, regularity and PSTHs in addition to measuring rate-level function responses to noise stimuli. We also analyzed binaural measures of sensitivity to interaural level difference and interaural time difference, to categorize each response type. SO response types analyzed include primary-like, chopper, and onset, which are also found in the nucleus angularis (Koppl & Carr 2003). A majority of recorded SO single units were broadly tuned off-responses, similar to mammalian SPON units (Kulesza et al., 2003) and more responsive to noise than tones. We conclude that the SO displays similar response types and heterogeneity in response types to nucleus angularis, but more SO units preferred broad band stimuli, and many were binaural. These broadly tuned responses may serve to regulate the overall firing rate of other auditory brainstem nuclei and/or the contralateral SON.

**Title:** Perceptual Classification of Sounds: Why three auditory cortical fields are better than one

**Authors: *H. L. READ**[1,2,3], A. OSMAN[2], C. M. LEE[5], M. A. ESCABI[1,2,4]
[2]Biomed. Engin., [3]Behavioral Neurosci., [4]Electrical Engin., [1]Univ. of Connecticut, Storrs, CT; [5]Mol. and Integrative Physiol., Univ. of Illinois, Champaign, IL

**Abstract:** Auditory cortex is essential for mammals, including rodents, to behaviorally detect temporal cues in sound but it remains unclear what different cortical fields contribute to temporal cue discrimination (Threlkeld et al, 2008; Lomber & Malhotra, 2008). Previously, we found temporally precise spiking patterns change proportionally with temporal shape cues in the sound envelope for spike outputs from primary (A1) and non-primary Ventral and Suprarhinal (VAF, SRAF) auditory fields of the rat (Lee et al., 2016). Here, we extend these findings and report that the response peak delay as well as total response duration mirror changes in sound shape

parameters in all three cortical fields. We tested how each cortical field might contribute to behavioral discrimination between paired sounds or classification of nine different sound shapes using neural discrimination indices or a Naïve Bayesian classifiers applied to neural population recordings. Remarkably, we find discrimination and classification performances are reduced when the temporal precision of cortical neuron responses are degraded. This suggests that auditory cortical neurons do not classify these sound cues based on a spike rate alone. Accordingly, temporally precise spiking and not spike rate output provides the best signal for classification of sound shape in all three cortical fields. Moreover, we find sound burst durations need to be about two-fold greater than the reference sound duration for effective neural discrimination much like observed behaviorally (Kelly et al., 2006). An interesting new twist we discover is that there is not a single optimal time scale for best performance as time scales for temporally precise output and optimal discrimination increase in rank order with A1 < VAF < cSRAF. When we tested the scenario where neural population responses are drawn cumulatively from all three cortical fields, we find a more robust signal for classifying many sound shapes than observed with population outputs from any one field alone. Together these results support the concept that heterogeneous and complementary neural response time scales from these three auditory cortical fields provide a mechanism for animals to discriminate and classify a large number of sound shapes with a high degree of accuracy.

**Title:** Dynamic neuron to neuron correlation statistics can contribute to sound category identification

**Authors: *M. SADEGHI**[1], I. STEVENSON[2], M. ESCABI[1]
[1]Electrical and Computer Engin., [2]Psychological Sci., Univ. of Connecticut, Storrs, CT

**Abstract:** Real-world sounds including, natural or man-made, background or vocalized, vary dynamically in time and frequency and exhibit unique high-order statistical regularities in their spectrograms. Humans can detect and use such high-order statistical structure to perceive and ultimately identify sounds (McDermott & Simoncelli 2011). Numerous studies have also demonstrated that neurons in the central auditory pathway, including the auditory midbrain and cortex, respond to high-order sound statistics selectively and in an information theoretic optimal

manner. Yet how and if neural response statistics contribute directly to sound recognition phenomenon is largely unknown. Here we used an auditory cochlear model to test whether dynamic neuron-to-neuron correlation statistics can contribute to sound category identification phenomenon. Using the time-frequency outputs of a cochlear model, we measured the dynamic spectral-temporal correlation structure of sounds to test the hypothesis that non-stationary high-order statistics obtained from computational auditory cochlear model can contribute to sound recognition phenomenon. Specifically, we measured the model neuron-to-neuron correlation statistics between frequency organized cochlear channels at times-scales comparable to perceptual and cortical integration times (100-400 msec). Using a database of sounds from 10 natural and man-made categories, we applied dimensionality reduction to the dynamic correlations and constructed a high-dimensional statistical likelihood functions. A Naïve Bayes classifier was used to identify sounds in a ten-alternative forced choice task. The dynamic correlation statistics from the cochlear model outputs achieve robust sound category identification approaching 80% accuracy (10% chance level). When tested independently, both spectral and temporal correlations of the cochlear outputs appear to contribute equally since separately they achieve a similar level of performance. Finally, the classifier performance improves with increasing sound duration and plateaus at ~ 6 seconds mirroring human data performance for texture identification (McDermott & Simoncelli 2012). **Abstract:** Barlow and others have suggested that organisms and the neural networks that underlie sensoryperception are optimized to capture statistical regularities in sensory signals. Accordingly, high-order statistical regularities in natural sounds are critical for perceptually discriminating and categorizing sounds (McDermott and Simoncelli, 2011; Geffen et al., 2011). Though neural responses in the central auditory system vary with modulation and correlation

sound statistics (Attias and Schreiner 1998; Escabi and Schreiner, 2002; Woolley et al 2005; Rodriguez et al., 2012) it remains unclear whether sensitivity to high-order statistics could be used to discriminate sound category and how this might be instantiated. Here we characterize single neuron activity of central auditory neurons in the inferior colliculus of awake rabbits in response to an ensemble of sound textures including water, fire, birdsong chorus, snake sounds, and speech babble. Using texture synthesis (McDermott and Simoncelli 2011), we synthetically manipulate each sound by selectively adding or removing high-order statistics or by combining statistics from different sound to create chimeric sound mixtures. We find that correlated spiking between pairs of neurons or multi-unit recording sites is strongly modulated with the sound category and the synthetically manipulated statistics. Using neurometric and ideal observer analyses we demonstrate that the neuron-to-neuron response correlation statistics can be used to discriminate sounds. Systematic removal of the high-order sound statistics decreases the neural-based sound classification performance. Conversely, systematic increase in the number of neurons used or the sound duration increases neural-based sound classification performance. This study indicates that neuron-to-neuron correlation statistics in the inferior colliculus have the capacity to capture statistical regularities in sounds that are critical for sound categorization. These findings are significant as they support the concept that statistical regularities are major drivers of sensory systems in general. Moreover, our findings support the concept that mammalian systems have the capacity to optimize sensory categorization through correlated activity in neuron populations. **Title:** A freely-moving operant system for auditory discrimination in common marmosets

**Authors: *M. J. METKE**
UC San Diego, San Diego, CA

**Abstract:** Here we demonstrate a novel operant conditioning system developed for testing free-moving marmoset monkeys (Callithrix jacchus) that complements more traditional head-fixed approaches in nonhuman primates. The operant chamber is an acrylic and wire mesh box with three response ports arrayed horizontally across one wall. Each port consists of an IR LED proximity sensor for detecting subject responses, a tube for delivering juice rewards, and an LED for assisting training.

We have applied this novel system to examine periodicity discrimination in marmosets. The representation of periodic stimuli in primate auditory cortex relies on two distinct mechanisms: a stimulus-synchronized temporal code for slower stimuli and a non-synchronous rate code for frequencies beyond the maximal neuronal firing rate. Previous studies have suggested that largely separate neuronal populations utilise these distinct encoding schemes. However, these have been limited in their reliance on single-unit electrophysiology and head-restrained subjects. Marmosets were trained in a two-forced choice task in which they were presented two pure-tone stimuli with sound pips of varying frequency. Subjects were rewarded for correctly identifying whether or not the stimuli frequencies matched. Manipulating the frequency of the stimulus we create ROC curves to demonstrate the perceptual sensitivity to frequency.
In combination with implanted microelectrode arrays we can simultaneously record single and multi-unit activity throughout all fields of auditory cortex while monkeys perform the task. These data allow us to determine how each region of auditory cortex encode complex periodic stimuli. Further, manipulating the tonal makeup of the sound pips allows us to parse the contribution of each of the regions to the cortical representation of the stimulus. This work lays the foundation for future studies using optogenetics to manipulate auditory cortex during a task to modulate behavioral responses.

**Title:** A comparison of marmoset frontal cortex neuron responses to acoustic stimuli in multiple behavioral contexts

**Authors: *V. JOVANOVIC**[1], C. T. MILLER[2]
[2]Psychology, [1]UCSD, San Diego, CA

**Abstract:** Primate vocal communication is characterized by the production and perception of vocalizations within the context of active social behaviors. Within this complex system, what is communicated by a vocalization is heavily dependent on the immediate social context in which it occurs. However, much of what is known about the neural basis of primate communication comes from traditional studies involving subjects that are either passively listening or trained to respond to vocalizations with a conditioned behavioral response. Because of the active nature of communication, each of these more conventional approaches divorces the signal from the core

context in which it naturally occurs. Here we sought to test this critical issue by recording the responses of frontal cortex neurons in marmosets across multiple behavioral contexts. Specifically, we presented the same vocalizations (phee calls, twitters) and a variety of white noise stimuli to marmosets while they were head-fixed and freely-moving using identical stimulus presentation protocol. During each of these test sessions, we also recorded the same neurons while subjects engaged in their natural antiphonal calling behavior, which involves the reciprocal exchange of phee calls. Preliminary analyses revealed that (1) white noise elicited the most consistent and robust responses across all test stimuli, (2) only half of neurons responsive to an acoustic stimulus in the head-fixed condition exhibited a similar response to the same stimulus in the freely-moving condition and (3) phee calls elicited the weakest responses of all stimuli in all conditions. These findings suggest that neural responses under head-fixed, passively listening conditions may not be predictive of more natural contexts. We are currently examining a broader set of stimuli in order to test the hypothesis that distinct neural processes may underlie vocal signal processing during natural, active communication and these other behavioral contexts.

**Title:** Association between marmoset vocal variability and social context in naturalistic social environments

**Authors: *J. TSUNADA**, S. ELIADES
Dept. of Otorhinolaryngology, Univ. of Pennsylvania Sch. of Med., Philadelphia, PA

**Abstract:** Vocal communication plays a key role in maintaining group cohesion and social bonds for group-living primates. Successful vocal communication requires signalers to inform receivers about the social context of the produced vocal signals (e.g., vocal signals are directed toward specific receivers). Marmoset monkeys (*Callithrix jacchus*) exhibit many human-like social behaviors, including interactive vocal communication. It is unclear, however, the degree to which the natural variability of marmoset vocalizations is deliberate and informative versus a result of random fluctuation. Previous experiments using isolated pairs of marmosets have shown that marmosets produced acoustically different phee calls during vocal interaction than during spontaneous calling. However, vocal communication in naturalistic social environments involves

many types of vocalizations and many group members. Therefore, it remains unknown if marmosets produce acoustically different calls depending on details of the social context, and whether such vocal acoustics influence the responsiveness of others. We recorded vocalizations from an entire group of marmosets housed in a colony environment and measured their vocal interactions in order to determine which animals responded to other's vocalizations and in what order. We particularly focused on the marmoset trill call, frequently produced in the housing environment, and found that acoustical properties (e.g., duration) of a produced vocalization influenced the probability of evoking a vocal response. Furthermore, such response probabilities differed between different producer-responder pairs, suggesting an association between the acoustic properties of produced vocalizations and their intended receivers. Additionally, we further tested whether marmosets are sensitive to vocal acoustic variability by playback of computer-controlled vocal sounds in the housing environment. We found that playback of vocalizations evoked responsive vocal production from different individuals within colony. Together, these results further elaborate our understanding of the complex social mechanisms used by marmosets during vocal communication that can potentially be exploited to understand the neural basis of social behaviors.

**Title:** Auditory cortical activity predicts feedback-dependent vocal control in marmoset monkeys

**Authors: *S. ELIADES**[1], J. TSUNADA[2]
[1]Otorhinolaryngology: Head and Neck Surgery, [2]Dept. of Otorhinolaryngology, Univ. of Pennsylvania Sch. of Med., Philadelphia, PA

**Abstract:** Human speech is a sensory-motor process involving auditory self-monitoring to control vocal production and ensure accurate communication. Monitoring auditory feedback during vocal production allows one to quickly adjust speech to compensate for perceived changes in vocal output. Many animal species share similar feedback-dependent vocal control, however, the underlying neural mechanisms are unknown. Previous studies have demonstrated both a suppression of auditory cortex neurons during vocal production, and a sensitivity of such neurons to externally-perturbed auditory feedback. The role of this neural activity in vocal control is not known. We therefore investigated the responses of auditory cortical neurons in

marmoset monkeys during vocal self-monitoring and feedback-dependent vocal control. Recent work has shown that, when presented with real-time frequency-shifted auditory feedback, marmosets will compensate for altered feedback by rapidly changing the acoustics of their ongoing vocalizations. We used implanted electrode arrays to record neural activities during self-initiated vocal production while simultaneously altering vocal feedback and observing the resulting vocal compensation. We found that neural activities in auditory cortical neurons were sensitive to altered feedback during vocalization, consistent with previous results. We further found that auditory cortical responses predicted subsequent changes in vocal production. These results demonstrate the function of auditory cortex in self-monitoring during vocal production, and suggest a role for the auditory cortex in feedback-coding and vocal motor control.

**Title:** Behavioral significance and auditory cortical representation of harmonic vocalizations

**Authors: *N. L. SO**[1,3], S. M. N. WOOLLEY[2,3]
[2]Columbia Univ. Dept. of Psychology, [1]Columbia Univ., New York, NY; [3]Zuckerman Inst., New York, NY

**Abstract:** Vocal communication relies on the brain’s ability to detect and process vocal sounds in the environment. Auditory systems that are optimized for vocalization processing must robustly encode acoustic features that distinguish vocalizations from other sound categories. One acoustic hallmark of speech and other animal vocalizations is harmonic structure. Sounds that are harmonic contain energy concentrated at integer multiples of a fundamental frequency, and higher harmonicity correlates with greater pitch salience. Our studies address two main questions. First, how does variation in harmonic structure alter the behavioral significance of vocal sounds? Second, where does selectivity for harmonic structure arise in the auditory processing pathway? We use zebra finches (*Taeniopygia guttata*) to address these questions. These songbirds use harmonic calls and songs for social communication and have well-defined, experimentally accessible auditory systems.
Zebra finches exchange distance calls, a highly harmonic class of vocalizations, to maintain contact with each other when visually separated. Using a behavioral paradigm in which we present distance calls and assess birds’ vocal responses to these stimuli, we found that behavioral

responsiveness is sensitive to the degree of harmonic structure in stimulus calls; birds respond less to spectrally degraded versions of calls compared to natural versions of the same calls. To test whether the responses of auditory cortex (AC) neurons are similarly sensitive to harmonic structure, we recorded the responses of single AC neurons to natural and spectrally degraded distance calls, in awake, restrained zebra finches while they listen to the calls. We recorded single unit responses from: 1) the intermediate region (Field L2), which receives information from the thalamus; 2) the superficial regions (Field L1/CM), which receive input from the intermediate region; and 3) the deep region (Field L3), which receives input from both intermediate and superficial regions. Preliminary results suggest that neuronal responses in the intermediate and superficial regions do not differ with variations in calls' harmonic structure. In contrast, deep region neurons respond more to calls with high harmonic structure than to spectrally degraded versions of those calls. Together, results suggest that harmonic structure contributes to the behavioral salience of vocal communication sounds, and that neural selectivity for this feature arises in the deep region of primary AC.

**Abstract:** A central challenge in auditory neuroscience is to understand how observed patterns of neural activity in the auditory system relate to behavior. For example, neurons in primary (A1) as well as higher auditory cortical areas exhibit highly nonlinear and surprisingly specific tuning properties, but our understanding of these responses is only at a descriptive level, and the critical question of how these responses might support behavior remains unresolved. Here, we show that nonlinear A1 responses encode essential features for the classification of ethologically-relevant sounds such as conspecific vocalizations (calls). In vocal animals, increasing neural resources are committed for the processing of calls as one ascends the auditory processing hierarchy.

Therefore, the categorization of call types is a reasonable computational goal for the auditory cortex in these animals. We asked, using a theoretical information-maximization approach, how this goal can be best accomplished. We used marmoset vocalizations as our experimental model. First, we transformed the vocalizations into spectrotemporal patterns of auditory nerve activity (cochleagrams) using a highly realistic model of the auditory nerve. Based on an earlier model for visual classification, we then randomly generated a large number of features, or spectrotemporal snippets, from these cochleagrams. We used a greedy-search algorithm to choose the most informative and least redundant feature set for call categorization. We found that call categorization could be accomplished with high accuracy using just a small number of features. Highly informative features tended to be of intermediate size and complexity. Most interestingly, the responses of model feature-selective neurons predicted nonlinear neural responses in marmoset A1 in astonishing detail. These results demonstrate that the auditory cortex uses a mid-level feature based strategy for the recognition of complex sounds. These results further suggest that the tuning properties of neurons in higher auditory cortical stages are likely the result of goal-directed optimization.

[1]Dept. of Otolaryngology, [2]Bioengineering, [3]Univ. of Pittsburgh, Pittsburgh, PA

**Abstract:** Humans and vocal animals use vocalizations to communicate and interact with members of their species. Real-world environments add noises, echoes and other sounds to the intended message, degrading its acoustic content. However, we can maintain stable sound perception independent of listening conditions. We aim to determine the neural mechanisms by which stable sound perception can be achieved. To address this question in the context of natural behaviors, we use Guinea pig (GP) vocalizations as an experimental model. Previous studies in GPs have shown that at the level of the inferior colliculus and thalamus, few neurons show selective responses for individual vocalization categories. In primary and secondary cortical

areas, more neurons become selective for particular vocalization categories. It is not known, however, at which stage of the auditory hierarchy this selectivity arises, and how it is preserved or changed in the presence of real-world distortions. Here, we first tested if GPs can perceive vocalizations presented in a wide range of noisy environments using pupillometry as a behavioral readout. This allowed us to determine the GP's threshold for detecting a vocalization in noise. We then recorded single-unit activity in the medial geniculate body (MGB) and auditory cortex (A1) of awake GPs passively listening to vocalizations in different listening conditions. We discovered that neurons in MGB and thalamorecipient A1 layers (A1 L4) have low selectivity for vocalization categories and are more susceptible to acoustic distortions. In contrast, superficial layers of A1 (A1 L2/3) were highly selective for vocalizations and more invariant to distortion. These data demonstrate that both vocalization selectivity and invariance to listening conditions co-emerge in A1 L2/3. These results suggest that a dense representation of complex sounds in A1 L4 is transformed into an invariant and sparse representation in A1 L2/3.

**Title:** Aural contrast in midbrain responses to speech: Effects of noise and hearing loss

**Authors: *L. H. CARNEY**
Univ. of Rochester, Rochester, NY

**Abstract:** Responses to complex sounds in the auditory midbrain provide a representation, rich in contrast, that projects to the thalamus and cortex. Midbrain representations differ substantially from the stimulus spectrum. For example, voiced speech sounds are characterized by strong fluctuations at the fundamental frequency (F0), with the largest amplitude fluctuations in frequency channels near spectral peaks. However, auditory-nerve (AN) responses to voiced speech have the largest F0 fluctuations between spectral peaks and reduced F0 fluctuations near spectral peaks, where responses are dominated by a single harmonic close to best frequency. At conversational speech levels, the low-threshold, high-spontaneous-rate AN fibers, which provide the major input to the ascending auditory pathways, have saturated average discharge rates. However, the contrast in fluctuation amplitudes across AN frequency channels is ultimately represented in both rate and temporal responses in the midbrain, where average rates are sensitive to fluctuation amplitude. For unvoiced sounds, midbrain responses are driven by

fluctuations associated with spectral slopes and by temporal characteristics of the stimuli, such as transients. Aural contrast refers to the patterns of midbrain activity that encode the location of spectral peaks, slopes and transients which are important cues to the identity of speech sounds. Computational models for populations of AN fibers and midbrain neurons are used to illustrate and examine the contrasts associated with phonetic features. Aural contrast depends upon the gradual saturation of the inner hair cells (IHCs) over the range of levels in speech sounds and on cochlear amplification, which influences the operating point on the IHC nonlinearity. Background noise and sensorineural hearing loss affect this operating point and reduce aural contrast. Linear amplification does not restore the contrast cues. The representation of speech sounds at the level of the midbrain suggests novel contrast-based signal-processing strategies to improve aural contrast.

**Title:** The emergence of neural representations of auditory objects and the influence of acoustic features

**Authors: *M. OGG**[1,2], C. NEUFELD[3], T. A. CARLSON[4], L. R. SLEVC[2,1]
[1]Neurosci. and Cognitive Sci. Program, [2]Psychology, [3]Linguistics, Univ. of Maryland, College Park, MD; [4]Univ. of Sydney, Sydney, Australia

**Abstract:** Auditory objects correspond to sound sources in the listener's environment that allow one to orient themselves or respond to potential threats. A critical constraint on these percepts is that they require time to develop. Concurrently, auditory objects must be processed quickly, to allow for a rapid response. Therefore, a listener's auditory system must quickly transform acoustic information into mental representations of objects, which, in turn, support complex cognitive tasks. Relatively little is known about what acoustic features are extracted and used to construct auditory object representations early in perception. To better understand this process, we decoded natural sound tokens (speech, musical notes from different instruments, and everyday items) from the neural responses of human listeners recorded using MEG. We modeled pairwise decoding accuracy as a function of differences between stimuli along various acoustic dimensions (including aperiodicity, pitch, and spectral centroid) and representations (spectrotemporal modulation spectra and cochleograms) during the first 500 milliseconds following sound onset. We found that decoding accuracy peaked at 150 milliseconds, capturing the rapid emergence of the neural representation of auditory objects. Decoding results at 150 milliseconds were supported by differences in spectrotemporal modulation and aperiodicity between individual stimuli. Decoding after 150 milliseconds, however, came to rely on more frequency dependant features such as pitch and differences in spectral envelope in addition to aperiodicity. These results point to a set of acoustic cues that support the emergence of auditory object representations early in auditory perception.

**Title:** Cortical responses in human superior temporal gyrus that differentiate intonation contours in speech are a response to pitch, not fundamental frequency

**Authors: *C. TANG**[1], L. S. HAMILTON[1], E. F. CHANG[2]
[1]Univ. of California, San Francisco, San Francisco, CA; [2]Neurosurg., UCSF, San Francisco, CA

**Abstract:** Speech intonation is an important component of prosody in all spoken languages. It conveys sentence-level linguistic meaning, such as sentence type (statement vs. question) or focus (which word was emphasized). In our previous work using electrocorticography (ECoG),

we showed that specific neural populations in the human superior temporal gyrus (STG) respond differentially to speech stimuli with distinct intonation contours, realized through digital manipulation of the fundamental frequency (f0). Because those stimuli were synthesized to control for intensity and duration of syllables, the only acoustic difference across intonation conditions was f0 over time. Although the f0 of a sound generally determines its perceived pitch, sounds with acoustic energy at the fundamental removed, called 'missing fundamental' stimuli, can also produce a pitch percept. To determine whether STG responses that differentiated intonation contours in speech are a response to pitch or to f0, we created a set of non-speech stimuli that preserved each intonational pitch contour but did not contain f0 and played them to participants while we recorded cortical activity using ECoG. To test whether neural responses to pitch contours in the missing f0 stimuli were similar to neural responses to f0 contours in speech, we used linear discriminant analysis to fit a model predicting the intonation contour from neural responses to speech. We then tested this model on the missing f0 data to see whether the model could discriminate between responses to the missing f0 stimuli. We found that in almost all electrodes (47/49 electrodes from 3 participants), neural activity patterns to the different intonation contours were the same between speech and missing f0 stimuli. This result indicates that the cortical activity in neural populations that differentiate intonation contours in speech can be explained as a response to the perceptual attribute of 'pitch', rather than energy at the fundamental frequency.

**Title:** Context dependence of ultrasonic vocalizations of mice

**Authors: *S. AGARWALLA**[1], S. BANDYOPADHYAY[2]
[1]ELECTRONICS AND ELECTRICAL COMMUNICATION ENGINEERING, INDIAN INSTITUTE OF TECHNOLOGY, KHARAGPUR, India; [2]IIT Kharagpur, Kharagpur, India

**Abstract:** Social cues are known to modulate communication related behavior in a range of species including humans. In mice, ultrasonic vocalisations (USVs) are considered to be of communicative significance. Recordings of vocalizations of male mice (WT, C57BL6J) were made under four different contexts. The contexts are: (i) the male mouse alone, (ii) the male mouse with a female present in view but separated by a mesh, (iii) the male mouse alone in the same cage were it was exposed to a female mouse and (iv) male and female together without any mesh in between. The USV vocalizations were parsed as syllables and bouts of syllables. The sequence of USV syllables were obtained and analyzed based on distributions of syllables and transitions of various steps. Structure in vocalization sequences was studied using information theoretic approaches. Based on significant differences in each context it is concluded that different structures or patterns are present in vocalization based on context. Predictability of the sequences also varied depending on context. The current study hence provides not only further evidence that structures exist in vocalization sequences of mice but also suggests that the structures in vocalization change in a context dependent manner.

**Title:** Adaptive spectral changes in pulses of echolocating bats during group flight with multiple conspecifics

**Authors: *K. HASE**[1], Y. KADOYA[1], Y. MAITANI[1], T. MIYAMOTO[1], K. I. KOBAYASI[1,2], S. HIRYU[1,2,3]
[1]Grad. Sch. of Life and Med. Sci., [2]Fac. of Life and Med. Sci., Doshisha Univ., Kyotanabe, Japan; [3]JST PRESTO, Kawaguchi, Japan

**Abstract:** Because echolocating bats actively emit ultrasounds to scan surrounding environments, acoustic interferences occur when multiple conspecifics occupy same spaces. Although many studies tried to understand their solution to extract their own faint echoes from

backgrounds, little is known about whether and how echolocating bats adaptively alter acoustic characteristics of their emitted pulses because it is difficult to separately measure echolocation pulses of group flying bats. In the present research, we successfully recorded echolocation behavior of group flying Eastern bent-winged bats (*Miniopterus fuliginosus*) which emit downward frequency-modulated (FM) echolocation pulses. The bats were flown singly (Single flight 1), within groups of four bats (Group flight), and then flown singly again (Single flight 2). Echolocation pulses emitted by each individual of the groups were captured with individually mounted on-board microphones. This allowed us to investigate pulses emitted by each animal during group flight without the Doppler effect and atmospheric attenuation. As a result, the bats significantly expanded inter-individual differences in mean terminal frequency (TF) of the emitted pulses from 0.7 ± 0.6 kHz in single flight 1 and 0.6 ± 0.5 kHz in single flight 2 to 1.2 ± 0.7 kHz in group flight (Tukey's HSD test, $P < 0.05$). To understand how changes in acoustic characteristics of FM echolocation pulses reduce interferences, we calculated cross-correlation between an FM signal that mimicked echolocation pulses of *Miniopterus fuliginosus* and an acoustic characteristic (TF, initial frequency, and duration) of which was gradually changed from -10% to 10%. The cross-correlation vales were decreased the most when TF of the signal was manipulated. The half width at half maximum of the values was obtained when TF was changed by only 2%, corresponding to about 1 kHz (mean TF was about 48 kHz). Moreover, cross-correlation values between bats in same groups were significantly decreased in group flight in comparison with single flight 1 and 2 (Tukey's HSD test, $P < 0.05$). These results suggest that echolocating bats reduce similarities between their echoes and interfering sounds in the presence of multiple conspecifics, and changes in TF contribute the most to decrease the similarities.

**Title:** Motor cortex suppresses auditory cortical responses to self-generated sounds

**Authors: *D. M. SCHNEIDER**[1], R. D. MOONEY[2]
[1]Dept. of Neurobio., Duke Univ., Durham, NC; [2]Duke Univ. Hosp., Durham, NC

**Abstract:** One often wants to ignore the sounds of their own movements, such as the sound of their own footsteps, to focus on environmental cues. Filtering out self-generated sounds requires that the brain forms an internal model that selectively suppresses neural responses to sounds that are reliable consequences of certain movements. Consistent with such a predictive mechanism, indirect and population-level recordings suggest that auditory cortical responses to self-generated sounds are selectively attenuated. Moreover, correlative studies suggest that this predictive suppression may be mediated by motor cortical inputs to the auditory cortex. Although motor cortical inputs are capable of generically suppressing auditory cortical activity during a wide variety of movements, whether these inputs selectively suppress auditory cortical responses to self-generated sounds, and the synaptic mechanisms through which this predictive suppression may arise, remain unknown.
To address these questions, we developed an acoustic virtual reality (aVR) platform to study how the mouse cortex learns to predict the sounds associated with a movement. Following several days of aVR experience during which locomotion triggered a series of tones with fixed pitch, auditory cortical excitatory neurons became largely unresponsive to predictable self-generated sounds, yet they retained their responsiveness to locomotion-triggered sounds at other frequencies. Mice exhibited a perceptual blind-spot for tones matching the self-generated pitch when they were locomoting, but not for other sound frequencies and not when they were resting. In contrast to excitatory neurons, auditory cortical inhibitory neurons responsive to the training tone displayed enhanced movement-related activity after several days of aVR experience. Notably, long-range excitatory projections from the motor cortex are an important source of movement-related recruitment of auditory cortical inhibitory neurons. One possibility is that aVR experience selectively strengthens motor cortical drive onto auditory cortical neurons that are responsive to the locomotion-associated pitch. Consistent with this idea, we found that aVR experience strengthened connections between the motor cortex and auditory cortical interneurons that were responsive to the self-generated pitch, resulting in the selective motor-related recruitment of a tuned-subset of inhibitory neurons. These findings are consistent with a framework in which motor-related signals, and their interaction with local auditory cortical circuitry, can predictively suppress neuronal responses to self-generated sounds.

**Title:** Dopamine modulates the peripheral auditory system of a vocal fish

**Authors: *J. PERELMUTER**[1], J. A. SISNEROS[2], P. M. FORLANO[3]
[1]Psychology: Behavioral & Cognitive Neurosci., The Grad. Center, City Univ. of New York (, Brooklyn, NY; [2]Psychology, Univ. Washington, Seattle, WA; [3]Dept. of Biol., City Univ. of New York, Brooklyn Col., Brooklyn, NY

**Abstract:** Dopamine appears to be a conserved neuromodulator in the peripheral auditory system of vertebrates, having been identified in the ears of both mammals and fish. In rodents, it is hypothesized that dopamine protects the cochlea from noise trauma, however other functions remain unexplored. The plainfin midshipman (*Porichthys notatus*) is a seasonally breeding marine fish that coordinates its summer mating behavior through acoustic communication. In time for the breeding season, females undergo a steroid-dependent increase in peripheral hearing sensitivity which enhances their ability to find a mate. This coincides with a reduction of dopaminergic innervation in the saccule, the principal end-organ of hearing in midshipman fish. We hypothesized that the reduction of dopamine provides a release of inhibition which contributes to this increase in sensitivity. We recorded auditory evoked potentials from populations of saccular hair cells after the application of dopamine, dopamine receptor agonists and antagonists in summer reproductive females. Exogenous dopamine increased auditory thresholds (reducing sensitivity), confirming an inhibitory effect. A D2 receptor agonist produced a similar inhibitory effect; however, a D1 receptor agonist had no effect on sensitivity. Co-application of dopamine and a D2 receptor antagonist abolished the effect of dopamine. Exogenous dopamine also produced an inhibitory effect in females in the winter, when they do not reproduce and hearing sensitivity is naturally reduced. This suggests that dopamine receptor expression is relatively stable across seasons and that dopamine fiber plasticity alone may account for release of inhibition. Our results point to a novel biological function for dopamine, adaptive regulation of peripheral auditory sensitivity, and raises the possibility that this function could be conserved across vertebrates.

**Authors: *T. BANNO**[1,2], W. SUZUKI[2,3], N. MIYAKAWA[2,4], T. TANI[3], N. ICHINOHE[2,3]
[1]Dept. of Otorhinolaryngology:Head and Neck Surgery, Univ. of Pennsylvania Sch. of Med., Philadelphia, PA; [2]Natl. Ctr. of Neurol. and Psychiatry, Natl. Inst. of Neurosci., Tokyo, Japan; [3]RIKEN BSI, Saitama, Japan; [4]Natl. Inst. for Quantum and Radiological Sci. and Technol., Chiba, Japan

**Abstract:** Human speech and animal vocalizations are characterized by slow modulations in the sound envelope (ENV) and rapid fluctuations in temporal fine structures (TFS). Previous psychophysical studies demonstrated the ENV and TFS convey information of different aspect of speech; the ENV cues are critical for speech intelligibility, whereas the TFS cues are important for segregating the speech sound from the background noise. Although both of the acoustic cues are crucial for vocal communications, it has not been fully elucidated how the auditory system process this information. To address this issue, we used marmosets as a model for human speech perception and conducted electrophysiological recordings from the primary auditory cortex (A1) of anesthetized animals while presenting acoustic stimuli consisting of various combinations of amplitude (AM) and frequency modulations (FM). The fundamental frequency and the depth of the modulations were matched to the marmoset vocalizations so that the stimuli sounded similar to their calls when the AM and FM were equated to the temporal parameters of the vocalizations. We found the spike timing of the A1 neurons precisely followed the modulation frequency of the stimuli if the AM and/or FM were slower than ~10 Hz, suggesting the neurons temporally encode the slow rhythms in both the ENV and TFS of the sounds. A greater number of spikes were observed in the sounds with the slow AM and FM combinations, but the firing rate showed more obvious tunings for FM than AM as a population. The information carried by the firing rate was further examined by mutual information analysis, and we confirmed the general tendency that the A1 neurons encoded a higher amount of FM information. Interestingly, the neurons could have a high amount of information either for AM or FM but not for both, implying the A1 neurons were optimized for encoding the animal vocalization sounds. These results suggest the A1 neurons process information about ENV and TFS cues differently by the temporal and rate codings in a way that they efficiently encode the temporal structures in the conspecific vocalizations.

**Title:** Direct effects of social vocalizations on serotonin in the auditory midbrain

**Authors: *K. HOOD**, L. M. HURLEY
Biol., Indiana Univ., Bloomington, IN

**Abstract:** Neuromodulatory systems like the serotonergic system can represent salient features of behavioral context within sensory systems, tuning sensory neurons to relevant behavioral events. During sexual interactions, female house mice (*Mus musculus*) produce broadband vocalizations (BBVs) that correspond to rejection behaviors, while males produce ultrasonic vocalizations (USVs) that correspond to increased investigatory and sexual behaviors. High BBV production by a female in the first phase of a sexual interaction is inversely correlated with male mounting success. Serotonin in the inferior colliculus (IC), an auditory midbrain nucleus, parallels these events. Serotonin increases in males interacting with females, but is also inversely correlated to female rejection behaviors, including BBV production, indicating that serotonin reflects both the presence and behavior of the female partner. Despite this correlation, whether female vocalizations directly influence serotonergic dynamics in the auditory system is unknown. To address this issue, we used slow-scan voltammetry to measure serotonin in the IC of males whose access to a female partner was limited by a perforated barrier. In this condition, males produce 'courtship' USVs, but females do not vocalize. We compared changes in male IC serotonin in response to 1) limited access to a female or 2) limited access to a female and BBV playback. Compared to baseline levels, males with limited access to a female in preliminary trials did not show a change in IC serotonin. When males were presented with limited access to a female and BBV playback, however, serotonin levels declined. This preliminary finding favorably compares to behavioral studies using the same paradigm and stimuli, in which BBV playbacks also change male sexual behavior by decreasing USV production. Both male courtship behavior and serotonin in the auditory system may therefore be directly influenced by female vocalizations.

**Title:** Mechanisms of movement-related changes to auditory detection thresholds

**Authors: *J. SUNDARARAJAN**, D. M. SCHNEIDER, R. D. MOONEY
Duke Univ., Durham, NC

**Abstract:** Sensory stimuli can arise from our own movements as well as from the environment. For example, when walking along a leaf-covered path, our brain must distinguish the sounds generated by our footsteps from those of a stalking predator. How the brain makes this distinction is not clear. With respect to audition, studies in humans and other animals have demonstrated that self-generated vocalizations as well as other movements suppress auditory cortical responses to acoustic stimuli relative to responses to the same stimuli measured at rest. An influential but largely untested idea is that this cortical suppression works to minimize responses to predictable acoustic consequences of movements, while enhancing sensitivity to novel stimuli. How this cortical suppression influences auditory perception and whether this suppression functions predictively, as widely theorized, remain unknown. To explore these issues, we used operant methods to train head-fixed mice to lick in response to tone pips of varying intensities while at rest or running on a quiet treadmill. Using this approach, we observed that: 1) the overall threshold for auditory detection is elevated during movement compared to rest, 2) inactivating the auditory cortex elevates tone detection thresholds, indicating that the auditory cortex is a component of an auditory detection circuit in the mouse, 3) optogenetic activation of motor cortical terminals in the auditory cortex of resting mice increases detection thresholds in a manner similar to movement, and 4) movement-related elevation of auditory threshold is specific to predicted sounds following experience with predictable movement-related auditory feedback. These findings support a model in which motor cortical inputs to the auditory cortex function as part of a mechanism for selectively suppressing predictable acoustic consequences of movement while enhancing sensitivity to novel stimuli.

**Title:** Serial reversal learning in humans and gerbils: Data and network model

**Authors: *A. L. SCHULZ**[1], M. L. WOLDEIT[1], A. BRECHMANN[2], C. JARVERS[3], T. BROSCH[3], M. LOMMERZHEIM[1], H. NEUMANN[3], F. W. OHL[1]
[1]Systems Physiol. of Learning, [2]Special Lab. Non-Invasive Brain Imaging, Leibniz Inst. for Neurobio., Magdeburg, Germany; [3]Fac. of Engineering, Computer Sci. and Psychology, Inst. of Neural Information Processing, Ulm University, Germany

**Abstract:** Cognitive flexibility allows adjusting behavior in response to dynamic environmental contingencies and is one of the most important aspects of adaptive goal-directed behavior. An established experimental method for measuring this flexibility is the serial reversal task. In this task the behavioral contingencies between two stimuli and two corresponding trained behaviors are changed after subjects reached a certain performance. Subjects reach their performance level faster after multiple reversals indicating that subjects do not relearn contingencies every time anew but apply previously acquired patterns. However, this capability is sensitive to several parameters such as stimulus types, reinforcement and schedule. Rewarding reinforcement is used in almost all studies. In this study we employed a comparable multiple reversal task for human subjects and Mongolian gerbils employing auditory discrimination of upward and downward frequency-modulated tones. Human subjects were trained in a two-way alternative force choice task with positive and negative feedback and gerbils in a Go/Nogo discrimination task in a shuttle box with electrical foot shock as negative reinforcement. We found, that humans and gerbils alike reached a specific performance threshold faster after the second contingency reversal compared to the initial learning phase and first reversal. With multiple reversals the gerbils tended to generalize the two different stimuli and developed a shock minimization strategy rather than shock avoidance. Based on these results we propose a hierarchically organized network architecture capturing the shorter time period after a contingency reversal for until previous discrimination performance was reestablished (Jarvers et al. 2016). The network consists of multiple reinforcement learning subsystems which acquire behavioral strategies and a dynamic control network subsystem controlling the strategy selection. The model architecture is conceptually similar to other multiple-expert architectures (Jacobs et al. 1991, Graybiel 1998). However, in our model the dynamic control subsystem requires no additionally external cue but learns from the trace reinforcement only. In conclusion, we show that animal as well as human

subjects reached their performance level faster in an auditory serial reversal task after the second reversal, even gerbils received only negative feedback. Based on the behavioral data we propose a hierarchically organized network model resembling expert model architectures. Unlike previous modeling approaches we suggest that each expert subsystem selects strategies based on the trace of the past reinforcements.

**Title:** Neural discrimination of novel acoustic signals improves with repeated stimulus presentation

**Authors: *E. SOYMAN**, D. S. VICARIO
Rutgers Univ., Piscataway, NJ

**Abstract:** Organisms encounter numerous novel sensory signals throughout life. Thus, the sensory representations in the adult brain undergo dynamic changes to adapt to the complexity of the external world. One such dynamic encoding mechanism is the process of stimulus-specific adaptation (SSA), in which initially robust auditory responses to novel sounds gradually decrease as a function of stimulus repetition. The current study investigated the effects of SSA on neural recognition and discrimination of novel auditory signals in the songbird auditory forebrain. Songbirds use complex, learned acoustic signals for social communication with many parallels to human speech. Furthermore, the neural responses in an auditory structure in the songbird brain, Caudal Medial Nidopallium (NCM), undergo a long-term form of stimulus-specific adaptation, providing an excellent substrate to probe the neural underpinnings of adaptive sensory representations. Electrophysiological activity in NCM in response to novel songs was recorded bilaterally in awake, restrained zebra finches. A Euclidean distance-based metric was used to compute the dissimilarity between the spike trains in response to different stimuli at corresponding stimulus presentations. Strikingly, the temporal profiles of neural responses to different signals became more and more dissimilar from each other with stimulus repetition, despite decreases in overall firing rates with SSA. To test whether this increasing contrast among different stimuli improved decoding of stimuli from neural responses, a Bayesian decoding procedure was used. As predicted, the accuracy of neural recognition of stimulus identities

improved with stimulus repetition. Furthermore, the neural decoding process reached a specified confidence level for the correct stimulus at earlier points in the stimulus duration profile with repeated stimulus presentation. The improvements in neural decoding performance were also reflected in mutual information estimations. Mutual information, estimated for the first and the second half of the experiment separately, was compared to test the effect of stimulus repetition on the informativeness of neural responses. In line with above findings, mutual information estimations in the second half of the experiment were greater than those in the first half. Taken together, these findings demonstrate that SSA may represent a dynamic encoding process, which not only makes neural representations sparser - using fewer spikes - but also increases the contrast between complex signals for rapid stimulus recognition and discrimination.

**Title:** Corticostriatal plasticity underlying a sensory-motor association in an auditory discrimination task

**Authors: *S. GHOSH**[1], F. CARNEVALE[2], A. M. ZADOR[3]
[1]Watson Sch. of Biol. Sci., [2]Cold Spring Harbor Lab., Cold Spring Harbor, NY; [3]Cold Spring Harbor Lab., Cold Spg Hbr, NY

**Abstract:** Perceptual decision-making often involves pairing sensory discrimination with appropriate motor actions. The brain circuits involved in such decision-making, and how these circuits change during learning of such associations remain largely unexplained. Previous studies in rats trained on an auditory discriminatory task (the ‘tonecloud’ task) have established a critical role for the connections between auditory cortex and auditory striatum in task performance (Zador and Znamenskiy, 2013). Moreover, learning the tonecloud task results in a specific pattern of plasticity in this pathway, which is determined by the frequency tuning of the neurons projecting to the recording area and the corresponding motor response, e.g., ‘turn left’ or ‘turn right’ (Xiong et al., 2015). We are now investigating the striatal substrates of this plasticity and its effects on striatal circuitry.
The striatum is primarily composed of inhibitory medium spiny neurons (MSNs) that express either D1 or D2 type dopamine receptors and constitute the ‘Direct’ or ‘Indirect’ pathway, respectively. Stimulating D1 neurons facilitate contralateral movements whereas activating D2

neurons inhibits movement. Thus, the balance between these two seemingly antagonistic pathways is considered critical in movement control (Kreitzer and Malenka, 2008). We hypothesize that learning the tonecloud task induces changes in strength of corticostriatal synapses onto a given MSN depending both on its frequency tuning and the pathway it belongs to.
To test our hypothesis, we have adapted the tonecloud task to train mice. This allows us to use genetic markers to assess the learning induced changes in synaptic strength in the D1 vs. D2-MSNs. We have established that the corticostriatal projections in the mice are arranged in a tonotopic manner, as seen in rats. Moreover, training mice on the tonecloud task induces a specific pattern of plasticity that reflects the tone-response association. Also, mice trained on opposite training contingencies faithfully show opposite plasticity patterns. We are now using whole cell patch-clamp method on acute slices prepared from brains of trained transgenic animals (D1/A2A-CRE x Ai14) to measure the synaptic strength of the cortical afferents onto D1 or D2-MSNs. These experiments will help elucidate how the two major striatal pathways are recruited during such task-learning and thereby further our understanding of the role of striatal plasticity underlying arbitrary sensory-motor associations.

**Title:** Encoding of modulation frequencies and depths by surface and micro electrodes for a cochlear nucleus auditory prosthesis

**Authors: *M. HAN**[1], D. B. MCCREERY[2]
[1]Biomed. Engin. Dept., Univ. of Connecticut, Storrs, CT; [2]Neural Engin. Program, Huntington Med. Res. Inst., Pasadena, CA

**Abstract:** For persons with deafness who cannot benefit from cochlear implants, some hearing can be restored by an array of stimulating electrodes implanted on the surface of their cochlear nucleus (CN). However, these Auditory Brainstem Implants (ABIs) usually do not restore hearing comparable to that provided by cochlear implants. A clinical trial of a hybrid ABI

containing macroelectrodes on the surface of the CN and microelectrodes that penetrated into the nucleus showed that the surface electrodes best conveyed the loudness of the electrically-encoded sound but poorly conveyed its pitch, while the penetrating microelectrodes best conveyed the encoded sound's pitch, but with only limited range of loudness. In this study, we have chronically implanted arrays of penetrating silicon-based microelectrode arrays into cats' cochlear nucleus. These are three-dimensional, four-shanked devices with five to eight microelectrode sites on each shank. This allows access to the tonotopic organization of the ventral cochlear nucleus while also minimizing the number of shanks penetrating into the brain. The silicon shanks were fabricated using the Bosh-process deep reactive ion etching technique followed by mechanical shaping of the probes' tip region, yielding a mechanically sturdy shank and a sharpened tip to reduce insertion force into the cochlear nucleus (Han, 2012). The cochlear nucleus device also included macroelectrodes that reside on the surface of the nucleus. The neuronal activity induced by modulated electrical stimuli applied though both types of electrodes was recorded by another array of silicon microelectrodes implanted in the central nucleus of the cats' inferior colliculus. Results showed that the temporal modulation of the neuronal activity induced by the modulated stimuli applied in (penetrating) or on the surface of the CN was very similar across a range of modulation frequencies and modulation depths, especially for transient modulation simulating the periodicity of speech. This concordance should greatly facilitate development of an ABI using surface electrodes and penetrating microelectrodes in an integrated manner, in order to convey both the loudness and pitch of sound.

**Title:** Robust discrimination of sounds embedded in noise by adapting cortical gain

**Authors: *C. F. ANGELONI**, K. C. WOOD, M. N. GEFFEN
Univ. of Pennsylvania, Philadelphia, PA

**Abstract:** Natural acoustic environments are variable; to function in them it is necessary to reliably differentiate important sounds from one another despite the presence of a noisy background. Recent work demonstrated that neurons in auditory cortex modulate their response gain in an adaptive manner to account for changes in the spectrotemporal statistics of acoustic stimuli (Rabinowitz et al., *Neuron*, 2011; Natan et al., *Cereb. Cortex*, 2016). In the current study, we model how such changes in neural gain facilitate robust discrimination of stimuli embedded in different types of noise. Using a linear-nonlinear probabilistic model of neural activity, we simulated neural responses to sounds embedded in noise backgrounds of different contrast levels. Then, using techniques from signal detection theory, we estimate behavioral detection and discrimination from the predicted neural responses and how behavioral performance changes depending on the gain of the neuron and the loudness of the embedded signals relative to the mean noise level (ie. their signal to noise ratio, SNR). We find that detection of a signal embedded in noise is always facilitated by high gain, but does not change appreciably as the neuron adapts to a new noise context. However, discrimination in different noise contrasts depends on the gain state of the neuron when differentiating between targets embedded at different SNR levels. Namely, target stimuli with high SNR are readily discriminable in high contrast noise, but not low contrast, while target stimuli with low SNR are more discriminable in low contrast than high contrast. In this framework, we also observe differences in the time course of discrimination performance, such that during high to low contrast adaptation, discriminability decreased earlier and faster for higher SNR targets, while the opposite effect is seen in low to high contrast. These findings provide a predictive framework in which we can model detection and discrimination tasks in the presence of a noise background, the subsequent neural responses to target stimuli as a function of gain adaptation, and how those neural responses predict behavioral performance.

**Title:** Sound symbolism - Related brain area relative to language processing

**Authors: *S. ITAGAKI**, S. MURAI, K. I. KOBAYASI
Doshisha Univ., Kyotanabe, Kyoto, Japan

**Abstract:** Sound symbolism is an idea that sounds itself has certain impression. In most of the previous psychology and linguistics researches, stimuli were presented visually with alphabets, and subjects directly answered the impression of the sound. Our previous study confirmed that sound symbolism does occur even when the sound stimulus was presented aurally. The purpose of this study is to elucidate neural substrate for sound symbolism. In the experiment, we focused on sound symbolism in visual size. Subjects were all right-handed Japanese native speakers, and they did not have knowledge about sound symbolism and this experiment. They were required to answer visual size difference between standard and target stimulus. Visual stimuli were a gray circle on black background LCD screen, and had 1 type of standard and 2 types of target. Target size was either smaller or bigger than the standard by ±40%. Sound stimuli were voice sounds ( /bo/ and /pi/ ) and noise and click sound (control). Voice sounds were assumed to have impression of “bigger” and “smaller” respectively, according to previous researches. The subject performed the task under functional magnetic resonance imaging (fMRI) scanning. Congruent trials were defined as those where circle sizes were correlated with the impression of accompanying sounds, and incongruent trials were with opposite stimulus contingency. Additionally, we defined that sound symbolism does occur if reaction time of incongruent conditions is longer than that of congruent conditions. As a result, reaction times in incongruent condition were longer than congruent condition. According to analysis of MR signal, left triangular part of inferior frontal gyrus and left supramarginal gyrus are more activated in incongruent conditions than congruent conditions, and are a part of Broca’s area and Wernicke's area, respectively. The activation could reflect the functional interaction between the sound symbolism and language. The fMRI imaging results also shows that the location and amount of activity differ between subjects, suggesting the neural substrate of the sound symbolism could vary between individuals. We will discuss relationships between the functional brain differences and individual behavioral differences.

**Title:** Mapping out cortical contributions to auditory timing: A causal transcranial magnetic stimulation study of interval and beat-based timing perception

**Authors: *J. M. ROSS**[1], *J. M. ROSS[1], J. R. IVERSEN[2], R. BALASUBRAMANIAM[1]
[1]Cognitive and Information Sciences, SSHA, Univ. of California, Merced, Merced, CA; [2]Inst. for Neural Computation, UC San Diego, La Jolla, CA

**Abstract:** It has been suggested that networks involved with movement planning play an essential role in timing perception, but specific contributions of premotor, supplementary motor and parietal cortices are unknown. The Action Simulation for Auditory Prediction (ASAP) hypothesis proposes that the dorsal auditory stream is involved in bidirectional interchange between musical beat-based timing prediction in motor planning regions and auditory perception via parietal projections (Patel & Iversen, 2014). Regions that are not part of the dorsal auditory stream have also been implicated for duration-based interval timing perception and auditory-motor synchronization, including supplementary motor cortex and ventral premotor cortex. We used a transcranial magnetic stimulation protocol, continuous theta burst stimulation (cTBS), that is known to down-regulate cortical activity for up to 60 minutes following stimulation, to test for causal contributions to interval timing perception and predictive beat-based timing perception. cTBS target areas included dorsal premotor cortex (dPMC) and posterior parietal cortex (PPC), which are part of the dorsal auditory stream, and supplementary motor area (SMA) and ventral premotor cortex (vPMC). Our data support causal involvement of movement planning networks for timing perception, functionally distinct mechanisms for interval timing perception and beat-based timing perception, and contribute a nuanced understanding of cortical network dynamics for interval and beat-based timing perception.

**Title:** Experimental design for investigating the acoustic preference in rats

**Authors: *K. OKAMOTO**[1], K. FUJIMOTO[1], Y. KOMURA[2], R. KAJIWARA[1]
[1]Meiji Univ., Kanagawa, Japan; [2]Kyoto Univ., Kyoto, Japan

**Abstract:** For investigating whether rats have acoustic preference or not, many kinds of maze assay are commonly used and the preference level was assessed by tracking the locomotor activity of the animal in the maze. The aim of this study is to design the behavioral task for

extracting the acoustic preference in rats, and to construct apparatus which enables us to control the instrument for carrying out the task. In our system, modified M-shaped-maze (70cmX40cmX45cm) for alternative selection task was placed in a sound-attenuated box. The center lane with an infrared sensor (Panasonic, FX-501), which can trigger the acoustic stimulation from right and/or left lane, was used for the conditioning experiment. At the left and right side of the chamber, a light emitting diode (LED) and a drinking port as well as a speaker for presenting the sound were fixed. The LED was located 22cm above the floor and centered on the panel. The drinking port was fixed 20cm above the floor and also centered on the panel. Sucrose solution was delivered to the rat from the drinking port, which was connected to a plastic bottle through the solenoid valve (Takasago, JTV-2). The LED was also mounted on the panel at the end of center lane. To analyze the activity of the rat, three ceiling mounted digital video camera (logicool,C270) were utilized. The whole system was controlled by original software developed in our laboratory on the LabVIEW platform. The software running on the Windows10 machine communicated with all the equipment via the USB ports. The NI-DAQ Device (National Instruments co.) was also used as an interface controlling the LEDs, solenoid valves, and passing sensor. The video tracking system enabled behavior to be studied in a reliable and consistent way, and over longer time periods than if they are manually recorded. The system received three video signals simultaneously in parallel for the data analysis. To recognize the position of the rat, we defined all connecting pixels that were brighter than a threshold value as the animal, and all other pixels as the background. In addition, the software enabled multiple zones to be defined for each experiment. We divided the chamber into five zones. Also, the software changed the volume of sounds according to each zone where rat stayed in and measure the time spent in right and left zones in the chamber. As for the acoustic stimuli delivered to rats, we used white noise, famous classical music, and arranged-music which are considered to be audible for rats by using CUBASE software. By using such an experimental apparatus, we assessed rats' preferences for two contrasting pieces of acoustic stimuli.

**Title:** The cost of control in perceptual decision-making

**Authors: *J. R. CASTIÑEIRAS**, J. L. PARDO-VÁZQUEZ, M. VALENTE, A. RENART
Champalimaud Fndn., Lisbon, Portugal

**Abstract:** We consider the optimal strategy in a classic perceptual decision paradigm: the binary categorization of a noisy sensory stream. Reinforcement Learning (RL) can specify the best course of action (optimal policy) that an agent should follow, given certain contingencies, to maximize long-term reward. However, agents in RL are conceived as a *tabula rasa* without any existing behaviors or response tendencies that may interfere with the optimal policy. In the field of optimal control theory, on the other hand, optimal control laws can steer the existing dynamics of an agent in a way that is compatible with her current goals, but considering the cost of control in the optimization problem. We have generalized ideas from Optimal Control (Todorov, PNAS, 2009) to describe situations where an agent is uncertain about the state of the environment ('partial observability'), and applied this theory to construct a normative model of perceptual decision-making in control-limited agents. The goal of these agents is to maximize long-term reward subject to a control cost that penalizes deviations from a default tendency to make random choices at a particular rate. As in previous studies that did not consider the cost of control, the agent needs to perform Bayesian inference on upcoming observations to update her beliefs about the environment. However, we show that the cost of control changes how these beliefs about the sensory world are linked to action. Using latent-variable inference, we solve for the joint probability that the agent will make a particular choice, at a particular time, with a certain belief (decision confidence) and derive testable predictions specifying the phenomenology of how accuracy, reaction-time and decision-confidence depend on each other for different control costs. When control is cheap, one recovers the standard RL solution to the task (Rao, Front. Comp. Neuro., 2010; Drugowitsch et al., J. Neurosci., 2012) which relies on a hard, time-varying bound on belief. However, we identify a novel, high-control-cost regime, in which agents develop stochastic policies, and show that this stochasticity smooths the relationship between pre-choice beliefs and decision confidence. As a result, varying the cost of control, one recovers behavioral phenotypes that interpolate between the predictions of Signal Detection Theory and Sequential Sampling Theory.

**Title:** Contribution and interaction of auditory and posterior parietal cortex during an auditory delayed response task in head-fixed mice

**Authors: *R. STEINFELD**, A. TACÃO-MONTEIRO, A. RENART
Champalimaud Res., Champalimaud Fndn., Lisboa, Portugal

**Abstract:** The ability to internally manipulate or maintain information during brief periods of time is critical for goal-directed behaviour, for instance, in order to associate actions and their delayed consequences, or to plan future actions. Internally generated activity carrying information about recent sensory input during a delay period is thought to be important for this function. We have developed a delayed-response auditory frequency discrimination task for head-fixed mice to study the contribution of different cortical areas to this behaviour. Animals are presented with either of two pure frequency sounds indicating at which of two constantly available spouts water will be available. The mice are required to delay their response until presentation of a visual go cue, presented 400-700ms after sound offset. Premature licking will abort the trial. Performances typically average above 80% across a session. The mice behaviour is almost exclusively explained by the identity of the sound cue on each trial, although, using generalized linear models, it is possible to show that mice have a small tendency (< 5% of variance in the model output explained by the previous-trial predictor) to repeat their previous choice regardless of outcome. Performance is robust against presentation of loud, white noise sound distractors during the delay period. Optogenetic silencing (bilateral hSyn-Jaws activation by LED implants) during different epochs of the task revealed involvement of auditory cortex (ACx) during the sound cue presentation (10-15% reduction in performance; 5% increase in abort rate; stimulation during delay did produce similar effects on abort rate, but did not alter performance). We are currently studying the contribution and interaction between the ACx and the posterior parietal cortex (PPC) during performance of this task. Preliminary experiments

show that it is possible to simultaneously record large populations of neurons (50-80 simultaneous units in each area) with two 64-channel silicon probes in ACx and PPC. We will describe the activity of these two reciprocally connected cortical networks across layers in awake mice during a delayed response task.

**Title:** Effect of stimulus intensity versus stimulus identity in perceptual decision-making

**Authors: *A. RENART**, M. VALENTE, J. CASTIÑEIRAS, J. PARDO-VAZQUEZ
Champalimaud Res., Champalimaud Fndn., Lisboa, Portugal

**Abstract:** In most binary-choice perceptual decision-making experiments, subjects need to categorize the value of an unobserved latent variable on the basis of noisy observations. The difficulty of the task can either be controlled manipulating, at fixed intensity, stimulus identity (the distance between the latent variable and decision threshold), or by varying the overall intensity (energy) of the stimulus. To characterize the role of stimulus intensity and stimulus identity, we have developed a binary choice sound lateralization task for rats. The stimulus (delivered through custom-made detachable ultrasonic headphones) is a white-noise burst to each ear. The task of the animal is to report (reaction time - RT - configuration) the lateralization (sign of the inter-aural level difference - ILD: difference in dB SPL of each speaker) of the stimulus by poking in the corresponding lateral port, and the overall stimulus intensity (absolute binaural level - ABL: mean dB SPL of the two stimuli) is fixed at 20, 40 or 60 dB SPL in blocks of 80 trials. After taking rats to psychophysical threshold for ILD discrimination, accuracy in this task is a measure of perceptual sensitivity, in the sense that non-sensory factors don’t contribute

significantly to performance. Manipulations of motivation (either directly by increasing reward magnitude, or indirectly by restricting stimuli to the ILDs closest to the decision threshold) do not lead to increases in performance. Furthermore, generalized-linear modeling shows that the outcome of previous trials plays no role in explaining the outcome of a current trial. There is a speed-accuracy tradeoff as a function of ILD in the task. As expected, animals take longer to decide when the stimulus is close to the decision threshold. Accuracy (psychometric curve slope, or discriminability) does not change for the three ABLs we tested but, surprisingly, animals take longer to decide when intensity is lower. Thus, whereas increasing difficulty through either manipulating intensity or identity both lead to longer RTs, rats can use the extra time to achieve the same level of performance when the stimulus is fainter, but not when it is more close to decision threshold. Remarkably, this differential effect of identity and intensity is also observed at the level of the shape of the RT distributions: lowering ABL leads to a re-scaling of time by the same factor for each of the different ILDs, whereas changing ILD does not lead to temporal-rescaling. We hypothesize that this phenomenology results from the fact that intensity and identity in our task limit performance mainly through external and internal sources of noise respectively.

Kingdom; [3]Ctr. For Functional Connectomics, Korea Inst. of Sci. and Technol., Seoul, Korea, Republic of

**Abstract:** Voluntary behavior is based on the models animals have of what their bodies can do, their environment, the consequences of their actions, and how these relate to their current goals. These models are learned, and give rise to richer behaviors the more flexible and abstract they become. A key factor for this is to be able to break free from the 'immediacy of the present', which in principle permits associations only between spatially and temporally contiguous events. The ability to create overlap between the representations of spatially and temporally distal events, such as causes and effects, or intentions and actions, endows animals with the possibility of establishing more complex associations and plan ahead. The medial Prefrontal Cortex (mPFC) has traditionally been implicated in combining sensory information and contextual rules to generate and maintain active representations used to orchestrate behavior. Here we present a novel head-fixed spatial memory-guided behavioral task developed to explore how populations of neurons in the mouse mPFC guide behavior based on a transient environmental input that is no longer immediately available. In the task, head-fixed mice running on a treadmill with a long belt have to make a binary decision (stop or not stop) upon reaching an area (decision area - DA) with a different texture. The decision is made based on the identity (5 or 12 kHz) of a transient auditory cue, presented a variable distance before the DA. Through behavioral manipulations and data-analysis of the mice speed trajectories in the treadmill, we confirmed that (a) correct performance is dependent on the existence of an actual DA (and thus reflects a decision made at the DA on the basis of information no longer present in the environment, as opposed to being the result of a stereotyped movement trajectory specified at sound onset), (b) performance is flexible, in the sense of being equally good at several randomly presented delay distances, and (c) appears to be based on a representation of the no-longer-present sound, rather than on the speed of the mouse when he reaches the DA. These together point to the existence of an active control mechanism involved in guiding behavior during the delay period, in opposition to an automatic habitual type of strategy. Preliminary recordings using 64 channels silicone probes reveal the existence of stimuli and context responding neurons with varied temporal spiking profiles across the trials.

**Title:** Representations of amplitude modulations in auditory onsets, ramp tones, and speech in the human superior temporal gyrus

**Authors: *Y. OGANIAN**[1], E. F. CHANG[2]
[1]Neurolog. Surgery, Univ. of California, San Francisco, San Francisco, CA; [2]Neurosurg., UCSF, San Francisco, CA

**Abstract:** Making sense of complex auditory inputs requires temporally precise parsing of single events out of the auditory stream. Auditory event onsets are typically marked by an increase in amplitude, and previous animal and human studies identified the dynamics of amplitude rise at onset as a central feature encoded throughout the subcortical auditory pathway. Amplitude modulations, however, also mark changes within ongoing sounds, e.g. in the speech envelope. Yet, it is unknown how the human auditory cortex differentiates between amplitude rises in silence and within an ongoing sound, and whether onset encoding can account for tracking of the speech amplitude envelope. To address this, we designed tone stimuli containing amplitude ramps (.75 sec duration), rising from silence (*RfS* condition), or from an amplitude baseline (*RfB* condition, base amplitude -12dB re peak amplitude). The sound intensity of ramps increased linearly to peak amplitude and returned to silence/baseline, with a parametric modulation of the rate of amplitude change. Crucially, fast-rising ramps in the RfB condition are perceived as onsets, whereas slow-rising ramps are perceived as modulations of the ongoing sound. We recorded local field potentials using intracranial multi-electrode arrays placed over the temporal lobes of five patients undergoing evaluation for epilepsy neurosurgery, as they passively listened to the tones. In both conditions, ramps elicited transient responses in the high gamma frequency range (HG, 70-150 Hz) in posterior (p) and middle (m) superior temporal gyrus (STG), with larger HG amplitudes for fast-rising ramps. We observed a striking double dissociation of response types: pSTG encoded the rate of amplitude change in the *RfS* condition only, whereas mSTG encoded the rate of amplitude change in the *RfB* condition only. Crucially, an analysis of HG responses to continuous speech showed that the rate of amplitude envelope modulation in continuous speech was also represented in mSTG, but not in pSTG. Our results reveal functionally and spatially distinct representations of sound onsets in silence and in background along STG. Moreover, our data suggest that speech amplitude tracking in mSTG may rely on the same neural mechanisms as the encoding of onsets in background.

**Abstract:** In dyslexia, the double deficit hypothesis suggests that children who struggle to acquire reading exhibit deficits in phoneme processing, rapid automatized naming, or both. Recent work in rodent models suggests that these two deficits may be caused by different dyslexia susceptibility genes and may manifest in unique patterns of brain activation. In children who struggle to learn to read, poor reliability in the brain's response to sound has been verified in at least three independent studies, although not all children with dyslexia exhibit this feature. In the current study, we designed two tasks to differentiate between individuals with dyslexia who have increased neural variability to sound versus those who have difficulty processing rapid auditory stimuli. One task consisted of a ten-step consonant continuum between the sounds /b/ and /d/, with participants pressing one of two buttons to categorize each stimulus. The second task presented three sets of sounds at 4 different speeds, with participants making sense/nonsense judgements; sentences, strings of consonant-vowel-consonant sounds, and amplitude modulated white noise. Adults with and without dyslexia were assessed and then tested on both tasks twice; once in an initial behavioral session and again while magnetoencephalography (MEG) data were acquired. Tasks were administered twice both to measure consistency of the task as well as to validate performance while in the scanner. We present preliminary behavioral and brain data from these participants on the proportion of individuals with dyslexia exhibiting each of the two deficits described above, and the respective neural correlates.

**Abstract:** In animal behavioral experiments, we are constrained by the degree to which subjects can report what they know. Factors such as motivation and arousal weigh on behavioral decisions and may impinge on the ability to self-report underlying knowledge. This becomes particularly challenging when tracking behavioral performance and neural dynamics during learning. Is there evidence that animals know more at earlier stages of task learning than their performances suggests? To address this question, we trained awake, head-fixed mice on an auditory stimulus recognition task in which mice lick for a water reward in response to one tone (target, 8 kHz) and withhold licking to avoid a short time-out in response to a different tone (foil, 5 kHz). In every session, we introduced probe trials ("knowledge context", by removing the licktube for 20-40 trials) during predominantly active training ("testing context", presence of licktube, 200-300 trials). Surprisingly, in the knowledge context, mice correctly licked to the reward-linked tone and withheld from licking to the other tone much earlier in training (1700-2000 trials to expert, n=6) than in the testing context (3000-8000 trials to expert, n=6). Importantly, the individual learning trajectories in the knowledge context were far more stereotyped across animals than in the testing context. Thus, the striking differences in learning speed across animals does not arise from differences in baseline learning rates, but rather, due to other factors including internal state and behavioral strategies.
To understand how the two coexisting learning trajectories might arise, we implemented a neurally-inspired behavioral model subject to reward-prediction error (RPE) learning (Bathelier et al., 2013). The learning model consists of a decision unit that linearly sums feed-forward inhibition and excitatory drive from two sensory units, the target and foil tones, whose weights update based on positive and negative reward expectation error. A scaling parameter applied to feed-forward inhibition recapitulated the two context-dependent learning trajectories while scaling of excitatory drive, decision noise, or RPE learning rate parameters were insufficient. Our model therefore points to inhibition as a gate for latent knowledge suggesting that contextual factors may influence behavioral performance during learning via inhibitory networks (Kuchibhotla et al., 2017). Overall, behavioral dissociation between performance in knowledge versus testing contexts suggests that learning trajectories of individual animals may depend on a combination of RPE-based learning and contextual modulations.

**Title:** Feature selective attention shifts noise correlations based on both target and distractor tuning in A1

**Authors: *J. D. DOWNER**[1], K. N. O'CONNOR[2], M. L. SUTTER[3]
[2]Ctr. for Neurosci., [1]UC Davis, Davis, CA; [3]Univ. of California Davis, Davis, CA

**Abstract:** Feature selective attention (FSA) is a critical component of real-world listening. FSA mediates competition between simultaneous, mixed sound features to prioritize the processing of relevant features over irrelevant features. Though much recent work highlights the impact of task engagement on neural activity in primary auditory cortex (A1), how A1 supports FSA remains an open question. To study the effects of FSA on population-based neural coding, we measured noise correlations ($r_{noise}$) within small groups of A1 neurons while rhesus macaques performed a FSA task. Previously, most studies have shown that attention globally reduces $r_{noise}$ in sensory cortex, though recent evidence has shown that attention can shift $r_{noise}$ up or down depending on population tuning to the attended feature. We found that the effect of FSA on $r_{noise}$ depended not only on the population tuning to the relevant (attended) feature, but also on the tuning to the irrelevant (distractor) feature. These results suggest an efficient mechanism by which FSA reshapes high-dimensional population response distributions to simultaneously enhance the representation of relevant features while suppressing the representation of irrelevant features.

**Title:** Improved attentional decoding at a cocktail party for audiovisual speech

**Authors: *A. E. O'SULLIVAN**[1,2], E. C. LALOR[2,1,4,3]
[1]Neural Engin., Trinity Col. Dublin, Dublin, Ireland; [2]Biomed. Engin., [3]Neurosci., Univ. of Rochester, Rochester, NY; [4]Trinity Col. Inst. of Neurosci., Dublin, Ireland

**Abstract:** The brain's ability to selectively isolate and enhance a single speech stream from multiple competing sources allows us to successfully communicate in everyday life. In recent years, a great deal of progress has been made towards understanding this complex process. This has, for the most part, been provided through the use of 'decoders' which transform the recorded neural activity into an estimate of the heard acoustic envelope (Mesgarani and Chang 2012, Ding and Simon 2012). Crucially, these methods allow us to examine the neural dynamics of attention using natural, continuous speech. However, research on this topic to date has been constrained somewhat by the fact that it focuses purely on auditory speech. And we know from our everyday experience that listeners will often look at the talker's face in an effort to aid comprehension - especially in a noisy environment. Indeed, recent work on audiovisual speech has quantified this benefit and shown it is present for speech in quiet (Crosse et al., 2015), and even more so in the presence of background noise (Crosse et al., 2016). Importantly however, listeners will also often switch their attention to a different audio source (eavesdropping), while continuing to look at the face of their conversational partner. Understanding how attention operates under both of these conditions is central to advancing our knowledge on the interactions between top-down attentional selection and the bottom-up visual influence on speech processing. Here, we present subjects with congruent audiovisual (AV) speech in the presence of a competing audio (A) stream. Subjects are required to attend to one speech stream (condition 1: attend A; condition 2: attend AV) while ignoring the other. Our results show that we can better decode attentional selection to AV speech than A speech, and that this improvement is mainly driven by additional contributions from occipital regions. Furthermore, in decoding A speech in the presence of distracting AV speech, we find that the activity in these occipital regions is heavily down weighted. Combining indices of both audio and visual speech processing provides a more robust attention decoder which can successfully operate under both of these conditions. We also examine the underlying temporal dynamics of the interaction between visual speech and audio speech processing, and the extent to which this is influenced by attention. This work may lead to important neuroscientific insights on the interaction between attention and multisensory integration and aid progress towards the goal of an attentionally steered hearing aid.

**Title:** Dissociation of stimulus and outcome expectations in perceptual decision making

**Authors: *A. FUNAMIZU**[1], F. MARBACH[1,2], A. M. ZADOR[1]
[1]Cold Spring Harbor Lab., Cold Spring Harbor, NY; [2]Watson Sch. of Biol. Sci., Cold Spring Harbor, NY

**Abstract:** In perceptual decision making, humans and animals use the prior knowledge of stimulus probability and reward outcome to optimize their behavior. Although a series of studies have shown the neural substrate of outcome expectation in cortico-basal ganglia circuit, the neural substrate of stimulus expectation is unclear. To dissociate the two neural circuits, we are training head-fixed mice on an auditory frequency discrimination task (based on Marbach and Zador, bioRxiv 2016), in which either (i) the stimulus probability or (ii) the reward size for category A and category B trials changes in blocks, and analyze the choice behavior with a belief-updating reinforcement learning model.
We found that both the stimulus probability and reward amount biased mice toward choices associated with high-probability stimuli or large reward, respectively. In the stimulus probability task, a belief updating model, which recursively updated the probability of stimulus category, predicted the biased behavior better than a reinforcement learning model, which updated the expected outcome of each category. In contrast, in the reward amount task, the reinforcement learning model predicted the behavior better than the belief updating model. This suggests that mice updated their stimulus expectation in the stimulus probability task, while they updated their outcome expectation in the reward amount task. We expect that our paradigm combined with two-photon calcium imaging will help dissociate the neural circuits for stimulus and outcome expectations in the auditory cortex.

**Title:** Cortical processing of spectrally degraded speech revealed by intracranial electrophysiology

**Authors: *M. STEINSCHNEIDER**[1], K. V. NOURSKI[2], A. E. RHONE[3], H. KAWASAKI[4], M. A. HOWARD, III[5]
[1]Neurol., Albert Einstein Col. of Med., Bronx, NY; [2]The Univ. of Iowa, Iowa City, IA; [3]NEUROSURGERY, Univ. of Iowa, Iowa City, IA; [4]Dept Neurosurg., Univ. Iowa Hosp Clin., Iowa City, IA; [5]Univ. of Iowa Hosp. and Clinics, Iowa City, IA

**Abstract:** There is considerable variability in speech perception outcomes following cochlear implantation. Auditory cortical function and plasticity are hypothesized to account for much of this variability. Understanding the cortical processing of spectrally degraded speech can help define the roles of different auditory cortical areas in speech perception and contribute to improvements in CI design. A noise vocoder serves as an acoustic model of CI sound processing, allowing for investigation of responses to spectrally degraded speech in normal-hearing listeners. This study investigated electrocorticographic (ECoG) responses within auditory cortex elicited by noise-vocoded speech stimuli and related these responses to behavioral performance in a 2-alternative forced choice (2AFC) identification task. Subjects were neurosurgical patients undergoing chronic invasive monitoring for medically refractory epilepsy. Stimuli were utterances /aba/ and /ada/, spoken by a male talker. The stimuli were spectrally degraded using a noise vocoder (1-4 bands). ECoG data were recorded during performance of the 2AFC task and were obtained simultaneously from Heschl's gyrus (HG) and superior temporal gyrus (STG) using multicontact depth and subdural grid electrodes, respectively. Event-related band power was examined within the high gamma (70-150 Hz) frequency range. All subjects performed at chance-level identification accuracy with speech degraded to 1 or 2 spectral bands, and performed at or near ceiling with non-degraded stimuli. Subjects exhibited a wide variability in accuracy at 3- and 4-band conditions. High gamma responses in posteromedial HG (auditory

core cortex) were similar in magnitude for vocoded and natural stimuli and did not reflect behavioral performance. In contrast, intelligible stimuli elicited larger and broader patterns of high gamma activity on lateral STG. Responses from non-core cortex on anterolateral HG were generally weaker and often exhibited selectivity for natural stimuli. Findings highlight differences in representation of spectrally degraded speech across core and non-core cortical areas. These findings support earlier non-invasive results that demonstrate the relationship between robust non-core auditory responses and speech intelligibility. By modeling the patterns of cortical activity elicited by CI stimulation, intracranial data offer the opportunity to clarify cortical processing of degraded speech and, in future studies, the improvements that occur in CI users with rehabilitation and experience.

**Abstract:** Even young normal hearing listeners show great variance in their ability to understand speech with interfering background noise. The main aim of this study was to investigate the neural correlates of individual differences in speech-in-noise recognition. Cortical models of speech processing involves left-hemisphere inferior frontal gyrus (IFG). However, it is unclear how the IFG activity contributes to the behavioral variance in speech-in-noise performance. We tested primary auditory cortex and IFG activity in twenty-four normal hearing listeners during a 4-AFC monosyllabic word-in-noise understanding task using cortical surface-constrained EEG source analysis. Our results showed better encoding of speech-acoustic features in high performers as reflected in stronger and earlier responses in the auditory cortex than those of low performers. High performance was also related to strong left IFG activity, while low performance was linked with extended right IFG activity. This finding demonstrates that both auditory and bilateral prefrontal cortices are recruited during speech processing while differential lateralization of IFG activity is correlated with behavioral performance. Prolonged IFG activity may also indicate exertion of more listening effort by low performers in noise.

**Title:** A new behavioral paradigm for investigating auditory perception of untrained animals: Application of novel object recognition procedure to hearing research

**Authors: *Y. TAMAI**[1], T. NOGUCHI[2], S. HIRYU[3], K. I. KOBAYASI[2]
[1]Grad. Sch. of Life and Med. Sci., Doshisha Univ., Kyoto, Japan; [2]Doshisha Univ., Kyotanabe, Japan; [3]Doshisha Univ., Kyotanabe, Jordan

**Abstract:** Novel object recognition procedure (NOR) is widely used in rodent research because the method depends on animal's natural innate preference for novelty and does not require any training. The purpose of our study was to develop a new version of NOR which can investigate auditory modality. Mongolian gerbils (*Meriones unguiculatus*), one of the most common model animals in auditory physiology, were used to demonstrate the novel sound-object recognition procedure. Six kinds of noise burst trains were used as sound stimuli. Durations of each noise bursts were 125, 250, 500, 275, 375 and 1500 ms, and duty-cycle of each train was 50 %. These sounds were classified into two groups: familiar sounds (noise bursts of 250 and 500 ms) or novel sounds (noise bursts of 125, 275, 375 and 1500 ms). Before behavioral experiment, all subjects were habituated with an empty experimental box. After the habituation, each animal was familiarized with two different objects (rectangular and four-sided pyramidal object) placed inside the experimental box. Repetitive noise bursts (familiar sounds) were presented from both objects. One was noise bursts of 250 ms, the other was that of 500 ms. Animals behavior were recorded by video camera. The contact duration with each object was quantified as exploration. After subjects were familiarized with both objects and sounds, familiar sound (repetitive noise burst of 250 ms) was changed to novel sound (repetitive noise bursts of 125, 275 or 375 ms). As results, the exploration time significantly increased when we changed the duration of repetitive noise burst from 250 to both 125 and 375 ms but it did not when we changed that from 250 to 275 ms. In subsequent experiments, ibotenic acid (10 µg/1 µl), a neurotoxin for selectively destroying cell bodies, was injected into auditory cortex. Subject with the lesion did not show tendency to spend more time exploring novel sound-object (repetitive noise bursts of 375 ms or 1500 ms). However, changing one object to new object (i.e., different shape object) encourage subject to explore the new object. These results suggest that novel sound-object recognition

procedure is suitable behavioral experimental paradigm which can investigate auditory modality including the function of auditory cortex.

**Title:** Real-time tracking of the selective auditory attention from M/EEG via Bayesian filtering

**Authors: *S. MIRAN**[1], S. AKRAM[3], J. Z. SIMON[2], T. ZHANG[3], B. BABADI[1]
[1]Dept. of Electrical and Computer Engin., [2]Dept. of Biol. and Inst. for Systems Res., Univ. of Maryland, College Park, MD; [3]Starkey Hearing Technologies, Berkeley, CA

**Abstract:** The ability to rapidly switch attention across multiple speakers in a competing-speaker environment is one of the hallmarks of human auditory processing. The neural mechanisms underlying this phenomenon, a dynamic generalization of the classic cocktail party problem, are for the most part unknown. In the past few years, there have been successful attempts at decoding the attentional state of a listener in a competing-speaker environment using non-invasive neuroimaging data including magnetoencephalography (MEG) and electroencephalography (EEG). To this end, most existing approaches compute correlation-based measures by either regressing the features of each speech stream to the M/EEG channels (the decoding approach) or vice versa (the encoding approach). In the latter case, the regression coefficients for each speech stream are referred to as a Temporal Response Function (TRF). These procedures operate in an offline fashion, i.e., require the entire duration of the experiment and multiple trials to provide robust results. Therefore, they cannot be used in emerging applications such as smart hearing aid devices, where a single trial must be used in real-time to decode the attention state.
Recent results using MEG suggest that the prominent negative peak observed in the TRF with latency ~100 ms, the M100 component, is modulated by attentional state. Therefore, real-time tracking of the M100 component of each TRF in a multiple-speaker environment can yield a robust neural correlate of the selective auditory attention. In this study, we employ this finding in a Bayesian filtering framework in order to construct real-time algorithms for tracking the auditory attention from M/EEG data. We utilize a dynamic TRF estimation procedure to track the M100 component of each TRF. We account for the underlying dynamics of selective attention as well as the TRF components by state-space models. In order to infer the model parameters in real-time, we apply an Expectation-Maximization (EM) procedure together with a fixed-lag adaptive filter. We evaluate the performance of our proposed algorithm on

experimentally recorded M/EEG data. Our results reveal that the proposed real-time algorithm using single trial data performs nearly as accurately as existing offline techniques requiring multiple trials, while providing a significant degree of adaptivity and decrease in computational costs.

**Title:** Machine-learning classification of speech-evoked electroencephalographic signals reveals speech intelligibility

**Authors: *Y. NA**[1], S. KIM[2], I. CHOI[2], J. WOO[1]
[1]Dept. of Biomed. Engin., Univ. of Ulsan, Ulsan, Korea, Republic of; [2]Dept. of Communication Sci. and Disorders, Univ. of Iowa, Iowa City, IA

**Abstract:** An important issue of hearing science is individual differences in the central processing for speech understanding. Although previous studies uncovered general cortical pathway for speech perception that involves the interplay between temporal, parietal and frontal lobes, how to quantify differential cortical processing among individual listeners is unclear. Here, we propose to use a machine learning-based classifier of speech-evoked electroencephalographic (EEG) signals to quantify fidelity of cortical speech processing. We hypothesize that important time-varying characteristics of acoustic and semantic features are extracted more accurately in listeners with better speech understanding and more strongly reflected in their cortical neural representation, which results in more accurate classification of time-sensitive EEG signals. To prove this concept, we compared the accuracy of EEG-signal classifier when it classified natural sentence-evoked potentials and vocoded sentence-evoked potentials. Given that a vocoder degrades speech intelligibility, we expected worse accuracy of EEG-signal classification when it is applied to the vocoded-sentence driven cortical signals. We recorded 64-channel EEG signals from seven young normal hearing adults in response to ten natural sentences and their corresponding vocoded sentences in a passive listening condition. We used an eight frequency-band vocoder with continuous interleaved sampling strategy that mimics cochlear implant signal processing. Each sentence was repeated hundred times. One hundred random draws of ten trials (epochs) were used to compute event-related spectral perturbations

(ERSPs). We divided ERSPs into five frequency ranges and four different time windows (40, 50, 100, and 200 ms), which produced 105-550 features (i.e. time-frequency bins) per epoch. We reduced the feature dimensionality using minimal redundancy maximal criterion. An artificial neural network with one hidden layer was trained with 80% of ERSPs. The other 20% of ERSPs were used for the cross-validation of classification accuracy. Results confirmed our main hypothesis; classification accuracy was higher for natural sentence-driven EEG responses than vocoded sound-driven ones at frontal, central, and parietal electrodes in six out of seven subjects. This result demonstrates that a machine learning-based EEG classification can quantify the fidelity of speech comprehension. Now we are investigating whether this classification method is sensitive enough to reveal individual differences in normal hearing and hearing-impaired listeners' speech understanding.

**Title:** Differential phoneme confusion patterns linked with performance in a speech-in-noise task

**Authors: *A. T. SCHWALJE**[1], S. KIM[2], I. CHOI[2]
[1]Otolaryngology, Univ. of Iowa Hosp. and Clinics, Coralville, IA; [2]Dept. of Communication Sci. and Disorders, Univ. of Iowa, Iowa City, IA

**Abstract:** There is significant variability in the performance of normal hearing listeners in complex listening situations such as speech in noise. The purpose of this study is to investigate phoneme-level effects on behavioral word confusions, along with neural correlates of these confusions, on high and low performers in a speech in noise task. Recently, a method of analyzing EEG signals that are time-locked to individual phoneme onsets (phoneme-related-potential, PRP) was described, and differences in PRPs were seen for different manners of articulation of consonants. In the current study, thirty normal hearing adult subjects completed a 4 AFC consonant-vowel-consonant word-in-noise recognition task while 64-channel scalp EEG recordings were obtained. Preliminary analysis of behavioral phoneme confusions based on manner of articulation of consonants revealed significant differences between high and low performers, with low performers having significantly more plosive-to-affricate and fricative-to-fricative confusions in the low SNR condition, and more fricative-to-affricate and fricative-to-fricative confusions in the high SNR condition. A computational model of peripheral speech-acoustics encoding, phonological neighborhood density, and cortical surface-constrained EEG source analysis were used to predict the behavioral phoneme confusions.

**Title:** Perceptual manifestations of auditory modulation during speech planning

**Authors: Y. MERRIKHI**[1], R. EBRAHIMPOUR[1], *A. DALIRI[2]
[1]school of cognitive sciences, Inst. For Res. In Fundamental Sci. (IPM), Tehran, Iran, Islamic Republic of; [2]Dept. of Speech and Hearing Sci., Arizona State Univ. - Tempe Campus, Tempe, AZ

**Abstract:** Previous studies have shown that auditory system's response to auditory stimuli is modulated (suppressed) during speech movement production in comparison to its response to identical stimuli during rest. In addition, in a series of electrophysiological studies, we have shown that the auditory system's response to stimuli is already suppressed during speech movement planning, well before movement production. Here, we examined the perceptual consequences of the suppression of auditory system during planning using a psychophysical paradigm. The study consisted of three conditions: Speaking, Listening, and Reading. In all three conditions, each trial started with a presentation of a plus sign in white characters. During the presentation of the plus sign, a standard auditory stimulus was delivered (75 dB SPL). Then, a target word in white color was presented. During the presentation of the word, a comparison auditory stimulus with varying intensity was delivered (70-80 dB SPL). Next, the color of the word changed from white to green. In the speaking condition, participants were instructed to produce the target words aloud, immediately after the word changed to green color. In the listening condition, participants listened to a self-produced version of the word, which was played immediately after the word changed to green color. In the reading condition, participants were instructed to silently read the target word. After the completion of the trial, participants were asked whether the comparison stimulus was louder or softer than the standard stimulus.Proportion of correct responses were calculated for each comparison level, condition, and participant. Psychometric functions were fitted to individual data in each condition. Using the fitted psychometric functions, we calculated point of subjective equality (PSE) at 50% correct response, and just-noticeable difference (JND) at 75% correct response. Our results showed that PSE and JND were higher in the speaking condition as compared to those in the listening and the silent reading conditions. These results suggested that one consequence of the suppression of auditory system during planning is an increase in the perceptual threshold when comparing the loudness of two auditory stimuli. Overall, consistent with previous

electrophysiological results, we provided behavioral evidence for modulation of auditory system during speech planning.

**Title:** Auditory processing of mate choice cues in the female songbird

**Authors: *K. S. LAWLEY**, J. DUNNING, J. F. PRATHER
Dept. of Zoology and Physiol., Univ. of Wyoming, Laramie, WY

**Abstract:** Decision making consists of evaluating sensory signals and using that information to direct motor responses. The first step in this process is identifying and evaluating sensory signals, however, it remains unknown how the brain assigns value to some stimuli but not others. In many songbird species, including the Bengalese finches (*Lonchura striata domestica*) studied here, females recognize individual males by their songs and evaluate the features and quality of those songs to choose one mate from many suitors. A key experimental advantage is that song is a unimodal stimulus that is so effective in driving female preference that females will perform behavioral indicators of mate choice (i.e. copulation solicitation displays and calls) in response to song even if no male is physically present. Studies of female responses to song have implicated auditory cortical regions such as the caudal mesopallium (CM) in the expression of mate preferences. Here we electrolytically lesioned CM bilaterally to investigate: 1) whether CM plays a role in preference for conspecific over heterospecific songs, and 2) whether CM plays a role in higher-resolution preference for one conspecific song over others. Preliminary results confirm a previous report from another species that CM is important for species discrimination. Specifically, using calls as a measure of female preference, we have found that lesioning CM causes female birds to call more to heterospecific songs. Ongoing experiments are also investigating the degree to which lesioning CM alters preference among conspecific songs. This and future studies will determine the role of CM and other areas of the auditory lobule in song preference and mate choice.

**Title:** Interaction between top-down and bottom-up predictions in auditory decision-making

**Authors: *L. SURIYA-ARUNROJ**[1,2], Y. E. COHEN[1,2,3], J. I. GOLD[1]
[1]Dept. of Neurosci., [2]Dept. of Otorhinolaryngology-Head and Neck Surgery, Perelman Sch. of Med., [3]Dept. of Bioengineering, Univ. of Pennsylvania, Philadelphia, PA

**Abstract:** Auditory perception and decision-making are mediated by bottom-up and top-down processes. Although a perceptual decision is based primarily on incoming sensory stimuli (bottom-up processing), it can be biased by different cognitive and task-relevant pieces of information. For example, prior knowledge and attention can facilitate and modulate this decision process by prioritizing relevant stimuli or features of stimuli (top-down processing). In contrast, changes in stimulus salience, such as regularity violation, can also bias perceptual decision-making through bottom-up attention. However, the effects that top-down and bottom-up processing have on auditory decision-making are not well understood. Here, we investigate how top-down and bottom-up predictions influence auditory decision-making.
Human subjects listened to sequences of high-frequency (2000 Hz) and low-frequency (500 Hz) tone bursts (tone duration: 300 ms with a 10-ms $\cos^2$ ramp; inter-burst interval: 100 ms) embedded in background, broadband noise and played through headphones. Subjects reported whether the last tone in each sequence (i.e., the "test tone") was "low-frequency" or "high-frequency" by pressing the left or right button, respectively, on a gamepad. We titrated difficulty by varying the amplitude of the test tone relative to the noise masker. Top-down processing was manipulated by presenting a visual pre-cue that indicated the prior probability that the test tone would be high or low frequency for the given block of trials (corresponding to ratios of low- versus high-frequency tones of 5:1, 1:1, 1:5). Bottom-up processing was manipulated by varying the sequence of tone bursts presented just before the test tone ("pre-tones"), in terms of: 1) the ratio of high- and low-frequency pre-tones, which was either highly regular (all high or all low) or irregular (randomized); and 2) the number of pre-tones, which were selected from an approximately exponential distribution (range: 2-10) to minimize the ability to predict the timing of the test tone.
Preliminary results indicate that both the top-down and bottom-up manipulations caused choices biases. These biases were largest when stimulus discriminability was lowest, consistent with principles of signal detection theory. These biases also tended to be larger in response to the

bottom-up manipulations. Further analyses of choice and response times will help identify the computations used to incorporate these two sources of information into perceptual decisions.

**Abstract:** Speech unfolds in time, and words and sentences are built around sequential strings of phonemes. As a result, spoken language relies not only on the ability to segregate and recognize individual phonemic elements in ongoing speech, but also in understanding that ordered combinations of such discrete elements form auditory objects. The generation of these auditory objects, known as words, is essential for language since once we create a sound-to-meaning association, oral communication relies on recalling these “word memories” when a complex sound input is processed. Such memories may be stored in association cortices and retrieved when a sound input matches an acoustic memory template generated in auditory cortex.
To explore the neural mechanisms by which the auditory system encodes human words, we train ferrets to discriminate tri-syllabic consonant-vowel words. Ferrets are an excellent animal model to study speech representation because their hearing is similar to humans, their auditory cortex is complex enough to encode all phoneme classes (Mesgarani et al., 2008) and they can be trained to differentiate and recognize syllable sequences (Bizley et al., 2015; Duque et al., 2016). Several ferrets were trained on a conditioned avoidance GO/NO-GO task to lick a spout for water upon presentation of distractor words (e.g. FA-BE-ti) but to refrain from licking the spout after a target word (e.g. FA-BE-LO) was presented, in order to avoid a mild shock. Once the animals learned the task, a head-post was implanted to enable single unit electrophysiological recordings in primary auditory cortex (A1), higher order auditory cortical areas (dPEG) and frontal cortex (FC) while the animals were performing the behavioral task.

Preliminary neurophysiological data indicate that, unlike the stimulus-dependent responses in A1, responses in dPEG reveal differences between target and distractor words based on associated behavioral meaning. This study suggests that neurons in higher order auditory cortical areas can encode specific syllable sequences. These results will help us understand the neural basis for the representation of complex sound sequences, and yield deeper insight into neural mechanisms underlying initial stages in human speech processing.

**Title:** Perceptual alternation in auditory streaming as an evidence accumulation process

**Authors: *J. M. RINZEL**[1], A. NGUYEN[2], R. CURTU[2]
[1]Ctr. Neural Sci., New York Univ. Ctr. for Neural Sci., New York, NY; [2]Dept. of Math, The Univ. of Iowa, Iowa City, IA

**Abstract:** Subjects report when listening to brief pure tones, alternating high (A) and low (B), in sequences ABA_ABA_.... spontaneous switching between two percepts: “integration” (Int), a single, coherent stream, the galloping pattern and “segregation” (Seg), two simultaneous distinct streams: A_A_ and B___B___. This triplet stimulus is considered a paradigm for auditory perceptual grouping, stream formation, and for the cocktail party problem. The initial percept is typically Int while Seg ‘builds up’ with a time course of seconds. It’s said that Int is the default while evidence accumulates for the switch into Seg and thereafter, during long presentations, irregular alternations occur between Int and Seg. The psychometric build-up function (from trial-averaging) depends on the difference in A-tone and B-tone frequency, DF, is typically monotonic, and percept durations are gamma/lognormal distributed. Recordings from primary auditory cortex (area A1) of monkeys listening to triplet sequences have been used to construct neurometric functions from a signal-detection model (Micheyl etal, 2005) that resemble psychometric functions. However, that model predicts neither realistic mean percept durations nor percept durations that are gamma-like distributed (Pressnitzer & Hupe, 2006). We developed an accumulation model in the form of a multi-layer feedforward network with neural-like components. The model accepts A1 neuronal responses (including variability) as input. Each B-tone is classified as Int or Seg by binary units (each samples a subset of A1 neuron spike counts).

A noisy accumulator increments its activity based on the classifier output, representing growing evidence against the current percept. A switch and reset occur when a threshold is reached. The model generates build-up functions as well as percept durations with statistics that match data from our behavioral experiments (15 subjects, 30 sec trials) for DF=3,5,7 st (Fig. 1)
Fig. 1: Time course of accumulator model (**A)** yields build up function (**B**) and percept durations **(C)** that match experiment

**Abstract:** The detection of sound is essential for communication and survival in natural environments. Auditory task performance enhances the neural representation of behaviorally meaningful sound throughout primary and higher-order auditory cortices. However, it remains unclear how auditory cortex contributes to decision-making. For neurons in primary auditory cortex (A1) layer 2/3, heterogeneous stimulus selectivity and complex intracortical connectivity suggest that task-related information coding may differ across neural subpopulations. To study the neural correlates of decision-making in distinct neuronal subpopulations, we used in vivo 2-photon imaging in A1 layer 2/3 of mice performing tone detection and discriminations tasks. During tone detection, we found that neural responses to target tones were enhanced during correct detections, and the enhancement was independent of neuronal selectivity for tone frequency. Preliminary analysis from tone discrimination experiments suggest similar neural response enhancements. Using a linear neural decoder, we found that neurons tuned away from the target, with moderate noise correlations, and positive attentional gain, were the best predictors of behavioral choice. Population activity during behavioral tasks showed neuronal avalanches, suggestive of critical dynamics. Investigation of neural network activity using Granger causality and avalanche analyses suggest that separate clusters of neural networks within A1 may exhibit unique spatiotemporal activity patterns that depend on behavioral choice. Thus, we find that sensory-based decision-making may depend on inhibitory control of small neural populations in sensory cortex that are driven by the sum of sensory input, attentional gain, and the cost of behavioral choice.

**Abstract:** Understanding speech in noisy environments can be quite challenging, especially so for hearing impaired listeners. Performance on speech in noise word recognition task cannot be predicted directly from an audiogram alone, and speech degradation has been recently shown to recruit inferior frontal gyrus (IFG) in addition to auditory cortical areas along the superior temporal gyrus (STG). Recent human non-invasive neuroimaging work suggests that STG activity represents stimulus-driven low-level perceptual processing while IFG is recruited for top-down feedback processing to resolve perceptual ambiguity resulting from stimulus degradation.
Using a speech in noise word recognition task based on the California Consonant Test (CCT), we collected intracranial electrocorticography (ECoG) data in normal hearing subjects (n = 5). Subjects were implanted with intracranial subdural and depth electrodes for clinical seizure monitoring. Subjects were tested using a 4AFC word recognition task in which subjects listened to CVC monosyllabic words presented in multitalker babble at +3 and -3 dB SNR. The answer choices were drawn from a set of matching rhyme or cohort answer choices.
We examined the role of gamma and high gamma band responses in Heschl's Gyrus (HG), STG, and IFG during the task. Additionally, we analyzed the functional connectivity within auditory cortex as well as between auditory cortex and IFG. These results reveal the role of IFG as well as the functional architecture of both auditory and frontal cortices during speech perception in difficult hearing situations.

**Title:** Brain sources of the human MMN identified from intracranial recordings

**Authors: *A. O. BLENKMANN**[1], H. N. PHILLIPS[2], T. BEKINSCHTEIN[2], J. ROWE[2], P. G. LARSSON[3], J. IVANOVIC[3], C. MURAVCHIK[4], T. ENDESTAD[1], S. KOCHEN[5], A.-K. SOLBAKK[1]
[1]Univ. of Oslo, Oslo, Norway; [2]Univ. of Cambridge, Cambridge, United Kingdom; [3]Oslo Univ. Hosp., Oslo, Norway; [4]Univ. of La Plata, La Plata, Argentina; [5]Conicet, Capital Federal, Argentina

**Abstract:** In order to investigate the brain sources of the Mismatch Negativity (MMN) we recorded intracranial EEG in 20 candidates for epilepsy surgery while they listened to one out of two auditory tasks:1- Local-global paradigm (1) consisting of sequences of 5 complex binaural tones. Every sequence has a local pattern making the last tone predictable (STD) or not (DVT) based on the previous 4 tones (pat. 1-6).2- A modification of the local-global task (2), where tone sequences were either monaural or interaural (pat. 7-20).
Electrodes were localized using iElectrodes toolbox (3), from MRI and CT images in the MNI normalized space.
A total of 1249 channel recordings were analyzed. Channels with epileptic activity or noise were discarded. Bipolar montage was used to improve SNR. STD and DVT trials were segmented time-locked to stimuli, filtered (1-40Hz), and bad trials were rejected.
Channels with significant activations on STD or DVT trials compared to a surrogate null distribution were selected. The MMN was obtained subtracting STD from DVT. Non-parametric permutation-based and cluster-based statistics were used to determine significant activations ($p<0.05$) corrected for multiple comparisons.
We found the most consistent activations bilaterally in superior and middle temporal gyrus, precentral gyrus, postcentral gyrus and supramarginal gyrus, in right middle frontal gyrus, and left inferior frontal gyrus.
The earliest activations were observed at least in 2 independent conditions in the temporal lobe at 65/55ms, the frontal lobe at 95/100ms, and the parietal lobe at 80/65ms (for left/right hemispheres).
These results support that MMN sources, evoked by two different tasks and found in multiple patients, are consistently distributed in a fronto-temporo-parietal network. 1. T. **Abstract:** Multiple lines of evidence indicate that auditory striatum, by processing inputs from auditory cortex, guides decision-making in rodents performing an auditory discrimination task. However, the activity of auditory striatal neurons during this behavior has not been directly characterized. In particular, the roles of different striatal cell types are unkown. We used a genetically encoded calcium indicator (GCaMP6s) together with a chronically implanted lens and head-mounted microscope to image the activity of specific auditory striatal cell types in freely moving mice. The mice were trained on an auditory 2-alternative forced choice task (cloud-of-tones task). In this task, in each trial, mice initially held a fixed position while listening to a sound stimulus which consisted of a stream of tones. They then were required to move to a lickport located at the left or right, depending on whether the majority of tones were in a low or high frequency band. We found that in trained mice performing this task, D2-dopamine-receptor expressing medium spiny neurons (D2-MSNs) show an increased response to sound stimuli associated with a subsequent contralateral movement. This pattern (contralateral favored) parallels previous findings on movement-associated activity in motor striatum, suggesting that an increase in auditory striatal D2-MSN activity contributes to a subsequent contralateral action.

**Abstract:** The contingency of sensory feedback to one's actions is essential for the sense of agency, and experimental violation of this contingency is a standard paradigm in the neuroscience of self-awareness and schizophrenia. However, neural responses to this violation have arbitrarily been interpreted either as activation of the system generating forward prediction (agency-error account) or decreased suppression of processing of predictable input (prediction-error account). In this functional magnetic resonance imaging (fMRI) study, the regions responsive to auditory contingency errors were examined if they showed responses to an isolated auditory stimulus and to passive-contingency delay, which the prediction-error account expects. These responses were observed only in the auditory association cortex in the right superior temporal gyrus. Several multimodal and motor-association cortices did not show these responses, suggesting their relevance to the agency-error account. Thus we formulated the coexistence and dissociation of two accounts in neural contingency-error responses.

**Title:** Duration dependent changes in visual plasticity via monocular deprivation

**Authors: *S. MIN**, A. BALDWIN, A. REYNAUD, R. HESS

**Abstract:** Background: Short-term monocular deprivation has been recently shown to temporary increase the sensitivity of the patched eye. Many studies have patched subjects for an arbitrary period of 2.5 hours, but for no principled reason. This project explores the duration-dependence of this deprivation-induced plasticity phenomenon.
Methods: Three monocular deprivation durations were tested in nine subjects: 1-, 2-, 3- hours. Three of the nine subjects were patched for 5-hours. Monocular deprivation was achieved by the use of a translucent eyepatch. A session included two rounds of baseline testing of interocular eye balance, patching, and post-patching tests, which are the abridged versions of the baseline testing. Each post-patching test occurred at 0, 3, 6, 12, 24, 48, 60 and 96 minutes after patching in order to track the effects over time. Every subject performed two sessions per condition.
Results: 1-hour patching produced small but significant shifts in eye dominance. Larger shifts occurred from 2-hours patching, but 3-hours patching produced comparable effects to those measured after 2 hours of patching.
Discussions: These results show a saturation of the patching effect beyond 2-hours patching. Hence, we believe that 2-hours patching duration is the optimal duration for eye dominance changes induced by monocular deprivation.

**Abstract:** Proper interocular balance is necessary for normal binocular summation and stereovision. The weights of monocular inputs are dynamic and have an interdependent relationship yielding a single unified visual percept. Previous adult human psychophysical experiments using short term monocular deprivation (STMD) showed surprisingly a strengthening of the deprived eye (DE) post-deprivation, relative to the non-deprived eye (NDE).

We have been studying the neural mechanisms responsible for STMD-invoked monocular gain in adult macaque V1. We have previously shown, using optical imaging, a shift in interocular balance towards the deprived eye in the activities of the V1 ocular dominance columns (ODCs). Recording with multi-electrodes, we have also found a range of V1 single cell responses, often consistent with these STMD-induced shifts. We now have observed that the strengthening of the DE input post-deprivation is more appreciable in cells where its non-dominant eye has been deprived. Often both DE and NDE inputs are enhanced in the post-deprivation period, but the change in gain is greater in the DE relative to the NDE. These trends are more pronounced in the supragranular layers of V1. Preliminary current source density (CSD) analysis has also revealed marked STMD-induced shifts in the supragranular layers. Little or no such shifts are observed in the granular (input) layers of V1. Initial imaging and single-unit studies in macaque V2 have revealed STMD-induced interocular balance shifts post-deprivation similar to those observed in V1. These studies are aimed at dissecting the contributions of different elements of the visual cortical circuit, their role in establishing proper binocular vision and in the STMD-induced shifts of interocular balance.

**Title:** Role of matrix metalloproteinase-9 (MMP-9) in the response to chronic monocular deprivation and the reactivation of plasticity by light reintroduction following dark exposure

**Authors: *S. MURASE**, C. L. LANTZ, E. M. QUINLAN
Biol., Univ. of Maryland at Col. Park Dept. of Biol., College Park, MD

**Abstract:** The plasticity of ocular preference revealed by monocular deprivation is typically confined to a postnatal critical period. However, we previously proposed that dark exposure can reactivate robust synaptic plasticity in the adult primary visual cortex (V1; He 2007; Montey 2011). We recently reported that it is light reintroduction (LRx) after dark exposure (DE), which induces degradation of extracellular targets by matrix metalloproteinase-9 (MMP-9) that is responsible for the reactivation of structural and functional plasticity in adults (Murase et al., submitted). Although the visual system of MMP-$9^{-/-}$ mice develops normally, the functional and structural plasticity reactivated by LRx in WT adults (>P90) is absent. Moreover, structural and functional plasticity is rescued in MMP-$9^{-/-}$ mouse by exogenous hyaluronidase, an enzyme with

known targets in the ECM. Here we examine the role of MMP-9 in the induction and recovery from amblyopia induced by chronic monocular deprivation (cMD). cMD induces a significant decrease in the strength and selectivity of responses of neurons in the deprived visual cortex, and a decrease in the density of dendritic spines on basolateral dendrites of layer 4 neurons in deprived V1b (68±5.8% of non-deprived V1b, n=20 neurons, p=0.0014, t-test; Montey 2011). However, dendritic spine densities are unchanged in MMP-$9^{-/-}$ visual cortex following cMD (105.7±9.95% of non-deprived V1b, n=19, p=0.72, t-test). Similarly, the robust decrease in the contralateral bias index (CBI, (C-I)/(C+I)) of visually evoked potentials observed in WT mice in response to cMD (control: 0.35±0.054, n=7 subjects; cMD: -0.15±0.14, n=4 subjects, p=0.003, t-test) is absent in MMP-$9^{-/-}$ mice (control: 0.22±0.050, n=7, cMD: 0.25±0.046, n=5, p=0.72, t-test). Thus the visual cortex of $MMP9^{-/-}$ mice is highly resistant to this form of activity-dependent plasticity. Interestingly, immunoblot analysis reveals that DE followed by LRx significantly increases MMP-9 expression and activity in both the deprived and non-deprived V1 of cMD WT mice (MMP-9 level (% of control) deprived: *133.04±9.1%; non-deprived: *131.37±8.9%; $F_{(3,29)=}5.56$, p=0.004; cleavage of beta-dystroglycan (to track MMP-9 activity) deprived: *216.5±37.8%; non-deprived: *194.2±20.3%, $F_{(3,29)=}6.27$, p=0.002, one-way ANOVA, Tukey-Kramer post hoc, *p<0.05). Thus MMP-9 is involved in the response to, and recovery from, cMD. Thus, V1 retains the ability to up-regulate MMP-9 activity in response to LRx following cMD, suggesting that degradation of extracellular targets including ECM at synapses serving the deprived eye may contribute to the LRx-induced recovery.

**Abstract:** Reduced synaptic plasticity and excitatory synapse density contribute to age-related cognitive decline. A parallel reduction in circulating sex hormones, particularly Estrogen (E2), in both sexes is thought to exacerbate the age-related changes in cortical structure and function.
